**Package:** matlab.mixin

Horizontal concatenation for heterogeneous arrays

## Syntax

`C = horzcat(A1,A2,...)`

## Description

`C = horzcat(A1,A2,...)` concatenates the `matlab.mixin.Heterogeneous` objects `A1`, `A2`, and so on, to form the array `C`. All input arrays must have the same number of rows.

The class of object arrays `A1,A2,...` must be derived from the same root class of a `matlab.mixin.Heterogeneous` hierarchy.

MATLAB calls:

`C = horzcat(A1,A2,...)`

for the expressions:

`C = [A1,A2,...]`

`C = [A1 A2 ...]`

when `A1` is an array of `matlab.mixin.Heterogeneous` objects.

If all input arguments are of the same specific class, the class of the resulting array is unchanged. If all input arguments are of different subclasses of a common superclass that is derived from `matlab.mixin.Heterogeneous`, then the result is a heterogeneous array. The array's class is that of the most specific superclass shared by all input arguments.

If all input arguments are not members of the same heterogeneous hierarchy, MATLAB calls the `convertObjects` method, if defined by the dominant root class (the first argument or the left-most element in the concatenation if no other class is dominant).

The `horzcat` method is sealed in the class `matlab.mixin.Heterogeneous` and, therefore, you cannot override it in subclasses.

## Input Arguments

### A1

Object array of class `matlab.mixin.Heterogeneous`

### A2

Object array of class `matlab.mixin.Heterogeneous`

## Output Arguments

### C

Array resulting from the specified concatenation. The class of this array is that of the most specific superclass shared by the input arguments.

## Attributes

Sealed true

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

## See Also

`matlab.mixin.Heterogeneous` | `horzcat`

## vertcat

**Class:** matlab.mixin.Heterogeneous

**Package:** matlab.mixin

Vertical concatenation for heterogeneous arrays

## Syntax

`C = vertcat(A1,A2,...)`

## Description

`C = vertcat(A1,A2,...)` concatenates the `matlab.mixin.Heterogeneous` objects `A1`, `A2`, and so on, to form the array `C`. All input arrays must have the same number of columns.

The class of object arrays `A1`, `A2`, ... must be derived from the same root class of a `matlab.mixin.Heterogeneous` hierarchy.

MATLAB calls:

`C = vertcat(A1,A2,...)`

for the expression:

`C = [A1;A2;...]`

when `A1` and `A2`, and so on are arrays of `matlab.mixin.Heterogeneous` objects.

If all input arguments are of the same specific class, the class of the resulting array is unchanged. If all input arguments are of different subclasses of a common superclass that is derived from `matlab.mixin.Heterogeneous`, then the result is a heterogeneous array. The array's class is that of the most specific superclass shared by all input arguments.

If all input arguments are not members of the same heterogeneous hierarchy, MATLAB calls the `convertObjects` method, if defined by the dominant root class (the first argument or the left-most element in the concatenation if no other class is dominant).

The `horzcat` method is sealed in the class `matlab.mixin.Heterogeneous` and, therefore, you cannot override it in subclasses.

## Input Arguments

### A1

Object array of class `matlab.mixin.Heterogeneous`

### A2

Object array of class `matlab.mixin.Heterogeneous`

## Output Arguments

### c

Array resulting from the specified vertical concatenation. The class of this array is that of the most specific superclass shared by the input arguments.

## Attributes

Sealed true

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

## See Also

`matlab.mixin.Heterogeneous` | `vertcat`

## hex2dec

Convert hexadecimal number string to decimal number

### Syntax

```
d = hex2dec('hex_value')
```

### Description

`d = hex2dec('hex_value')` converts *hex\_value* to its floating-point integer representation. The argument *hex\_value* is a hexadecimal integer stored in a MATLAB string or cell array of strings. If the value of *hex\_value* is greater than hexadecimal 10,000,000,000,000, `hex2dec` might not return an exact conversion.

If *hex\_value* is a cell array of strings, each row is interpreted as a hexadecimal string.

### Examples

```
hex2dec('3ff')
```

```
ans =
```

```
1023
```

For a character array *S*,

```
S =
```

```
0FF
```

```
2DE
```

```
123
```

```
hex2dec(S)
```

```
ans =
```

```
255
```

```
734
```

```
291
```

## **See Also**

`dec2hex` | `format` | `hex2num` | `sprintf`

## hex2num

Convert hexadecimal number string to double-precision number

### Syntax

```
n = hex2num(S)
```

### Description

`n = hex2num(S)`, where `S` is a 16 character string or cell array of strings representing a hexadecimal number, returns the IEEE double-precision floating-point number `n` that it represents. Fewer than 16 characters are padded on the right with zeros. If `S` is a cell array of strings, each row is interpreted as a double-precision number.

NaNs, infinities and denorms are handled correctly.

### Examples

```
hex2num('400921fb54442d18')
```

returns `Pi`.

```
hex2num('bff')
```

returns

```
ans =
```

```
-1
```

### See Also

`num2hex` | `hex2dec` | `sprintf` | `format`

**Introduced before R2006a**

# hgexport

Export figure

## Syntax

```
hgexport(h,filename)
hgexport(h,'-clipboard')
```

## Description

`hgexport(h,filename)` writes figure `h` to the file `filename`.

`hgexport(h,'-clipboard')` writes figure `h` to the Microsoft Windows clipboard.

The format in which the figure is exported is determined by which renderer you use. The Painters renderer generates a metafile. The OpenGL renderer generate a bitmap.

## Alternatives

Use the **File > Export Setup** dialog. Use **Edit > Copy Figure** to copy the figure's content to the system clipboard. For details, see "Customize Figure Interactively Before Saving" and "Copy Figure to Clipboard from Edit Menu".

## See Also

`print`

**Introduced before R2006a**

## hggroup

Create group object

### Syntax

```
h = hggroup
h = hggroup(..., 'PropertyName', propertyvalue, ...)
```

### Properties

For a list of properties, see Group Properties.

### Description

`h = hggroup` creates a group object as a child of the current axes and returns its handle, `h`.

`h = hggroup(..., 'PropertyName', propertyvalue, ...)` creates a group object with the property values specified in the argument list.

A group object can be the parent of any axes, as well as other group objects. Use group objects to form a group of child objects that can be treated as a single object.

### Examples

Plot random data and parented the lines to the group object.

```
hg = hggroup;
plot(randn(5), randn(5), 'Parent', hg)
```

### Instance Diagram for This Example

The following diagram shows the object hierarchy created by this example.

## More About

- “Create Object Groups”

## See Also

hgtransform

**Introduced before R2006a**

## Group Properties

Control group appearance and behavior

Group object properties control the behavior of group objects. By changing property values, you can modify certain aspects of the group object.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = hggroup;
c = h.Children;
h.Visible = 'off';
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Visibility

#### **Visible** — Visibility of group

'on' (default) | 'off'

Visibility of group, specified as one of these values:

- 'on' — Display all objects in the group.
- 'off' — Hide all objects in the group. You still can access the properties of invisible group objects. Setting the `Visible` property for the group object does not change the `Visible` property for objects in the group.

#### **EraseMode** — (removed) Technique to draw and erase objects

'normal' (default) | 'none' | 'xor' | 'background'

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- 'normal' — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces

the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.

- 'none' — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, 'none', it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- 'xor' — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- 'background' — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is 'none'. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to 'normal'. This means graphics objects created with `EraseMode` set to 'none', 'xor', or 'background' can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### Type — Type of graphics object

'hgroup'

This property is read only.

Type of graphics object, returned as 'hgroup'. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

### Tag — Tag to associate with group

'' (default) | string

Tag to associate with the group, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

## **UserData** — Data to associate with group

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the group object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

## **DisplayName** — Text used by legend

'' (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the group.

Example: 'Text Description'

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where N is the number assigned to the group object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

## **Annotation** — Legend icon display style

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the group from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - `'on'` — Include the group object in the legend as one entry (default).
  - `'off'` — Do not include the group object in the legend.
  - `'children'` — Include only children of the group object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## Parent/Child

### **Parent — Parent of group**

axes object | group object | transform object

Parent of group, specified as an axes, group, or transform object.

### **Children — Children of group**

empty `GraphicsPlaceholder` array | array of graphics objects

Children of group, returned as an array of graphics objects. Use this property to view a list of the children or to reorder the children by setting the property to a permutation of itself.

You cannot add or remove children using the `Children` property of the group. To add a child to this list, set the `Parent` property of the child graphics object to the group object.

### **HandleVisibility — Visibility of object handle**

`'on'` (default) | `'off'` | `'callback'`

Visibility of group object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The group object handle is always visible.
- `'off'` — The group object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The group object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the group at the command-line, but allows callback functions to access it.

If the group object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### **ButtonDownFcn** — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the group. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The group object — You can access properties of the group object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **UIContextMenu — Context menu**

uicontextmenu object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the group. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

### **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the group when in plot edit mode, then MATLAB sets its `Selected` property to 'on'. If the `SelectionHighlight` property also is set to 'on', then MATLAB displays selection handles around the group.
- 'off' — Not selected.

### **SelectionHighlight — Display of selection handles when selected**

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the `Selected` property is set to 'on'.
- 'off' — Never display selection handles, even when the `Selected` property is set to 'on'.

## Callback Execution Control

### **PickableParts** — Children that can capture mouse clicks

'visible' (default) | 'none'

Children that can capture mouse clicks, specified as one of these values:

- 'visible' — Any child object can capture a mouse click, depending on the `PickableParts` property value of the child.
- 'none' — No child objects can capture mouse clicks, regardless of the `PickableParts` property value of the child.

### **HitTest** — Response to mouse clicks captured by children

'on' (default) | 'off'

Response to mouse clicks captured by children, specified one of these values:

- 'on' — Trigger the `ButtonDownFcn` callback of group. If you have defined the `UIContextMenu` property, then invoke the context menu.
- 'off' — Do not trigger the callbacks of the group. Instead, trigger the callbacks for the nearest ancestor of the group that has a `HitTest` property set to 'on' and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

A group cannot capture mouse clicks. However, if you click a child of the group and if the child has a `HitTest` property set to 'off', then the child passes the click to the group.

### **Interruptible** — Callback interruption

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the

**BusyAction** property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the **ButtonDownFcn** callback of the group is the running callback, then the **Interruptible** property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The **BusyAction** property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The **Interruptible** property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the **BusyAction** property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the group tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the group. Setting the `CreateFcn` property on an existing group has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during group creation. MATLAB executes the callback after creating the group and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The group object — You can access properties of the group object from within the callback function. You also can access the group object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

**DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the group. MATLAB executes the callback before destroying the group so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The group object — You can access properties of the group object from within the callback function. You also can access the group object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

**BeingDeleted — Deletion status of group**

'off' (default) | 'on'

This property is read only.

Deletion status of group, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the group begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the group no longer exists.

Check the value of the `BeingDeleted` property to verify that the group is not about to be deleted before querying or modifying it.

# hgload

Load graphics object hierarchy from file

## Syntax

```
h = hgload('filename')
[h,old_prop_values] = hgload(...,property_structure)
```

## Description

---

**Note:** `hgload` is not recommended. Use `openfig` instead.

---

`h = hgload('filename')` loads graphics object hierarchy from the FIG-file specified by `filename` and returns handles to the top-level objects. If `filename` contains no extension, then MATLAB adds the `.fig` extension.

`[h,old_prop_values] = hgload(...,property_structure)` overrides the properties on the top-level objects stored in the FIG-file with the values in `property_structure`, and returns their previous values in `old_prop_values`.

`property_structure` must be a structure having field names that correspond to property names and values that are the new property values.

`old_prop_values` is a cell array equal in length to `h`, containing the old values of the overridden properties for each object. Each cell contains a structure having field names that are property names, each of which contains the original value of each property that has been changed. Any property specified in `property_structure` that is not a property of a top-level object in the FIG-file is not included in `old_prop_values`.

Nonserializable objects (such as the default toolbars and the default menus) are not saved because they are created when the figure is created. This allows revisions of the default menus and toolbars to occur without affecting existing FIG-files.

## **Alternatives**

Use the **File > Open** on the figure window menu to access figure files with the **Open** dialog.

## **See Also**

hgsave | open

**Introduced before R2006a**

# hgsave

Save graphics object hierarchy to file

## Syntax

```
hgsave('filename')
hgsave(h,'filename')
hgsave(...,'-v6')
hgsave(...,'-v7.3')
```

## Description

---

**Note:** `hgsave` is not recommended. Use `savefig` instead.

---

`hgsave('filename')` saves the current figure to a file named `filename`.

`hgsave(h,'filename')` saves the objects identified by the array of handles `h` to a file named `filename`. If you do not specify an extension for `filename`, then the extension `.fig` is appended. If `h` is a vector, none of the handles in `h` may be ancestors or descendents of any other handles in `h`.

`hgsave(...,'-v6')` saves the FIG-file in a format that can be loaded by versions prior to MATLAB 7.

`hgsave(...,'-v7.3')` saves the FIG-file in a format that can be loaded only by MATLAB versions 7.3 and above. This format, based on HDF5 files, is intended for saving FIG-files larger than 2 GB.

## Backward Compatibility

When creating a figure you want to save and use in a MATLAB version prior to MATLAB 7, use the `'v6'` option with the plotting function and the `'-v6'` option for `hgsave`. Check the reference page for the plotting function you are using for more information.

In MATLAB release R2014b or later, you cannot open a save FIG-file in earlier versions of MATLAB. Use `savefig` to save figures that are compatible with earlier versions of MATLAB.

## Alternatives

Use the **File > Export Setup** dialog. Use **Edit > Copy Figure** to copy the figure's content to the system clipboard. For details, see “Customize Figure Interactively Before Saving” and “Copy Figure to Clipboard from Edit Menu”.

## See Also

`hgload` | `open` | `save` | `savefig`

**Introduced before R2006a**

# hgsetget

Abstract class used to derive handle class with set and get methods

---

**Note:** hgsetget will be removed in a future release. Use matlab.mixin.SetGet instead.

---

## Syntax

```
classdef myclass < hgsetget
```

## Description

classdef *myclass* < hgsetget makes *myclass* a subclass of the hgsetget class, which is a subclass of the handle class.

Use the hgsetget class to derive classes that inherit set and get methods that behave like Handle Graphics set and get functions.

## Methods

When you derive a class from the hgsetget class, your class inherits the following methods.

| Method  | Purpose                                                                                                                                        |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------|
| set     | Assigns values to the specified properties or returns a cell array of possible values for writable properties.                                 |
| get     | Returns value of specified property or a struct with all property values.                                                                      |
| setdisp | Called when set is called with no output arguments and a handle array, but no property name. Override this method to change what set displays. |

| Method  | Purpose                                                                                                                                                                |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| getdisp | Called when <code>get</code> is called with no output arguments and handle array, but no property name. Override this method to change what <code>get</code> displays. |

## More About

- “Implement Set/Get Interface for Properties”

# hgtransform

Create transform graphics object

## Syntax

```
h = hgtransform
h = hgtransform('PropertyName',propertyvalue,...)
```

## Properties

For a list of properties, see Transform Properties.

## Description

`h = hgtransform` creates a transform object and returns its handle.

`h = hgtransform('PropertyName',propertyvalue,...)` creates a transform object with the property value settings specified in the argument list. For a description of the properties, see Transform Properties.

Transform objects can contain other objects, which lets you treat the transform object and its children as a single entity with respect to visibility, size, orientation, etc. You can group objects by parenting them to a single transform object (i.e., setting the object's `Parent` property to the transform object's handle):

```
h = hgtransform;
surface('Parent',h,...)
```

The primary advantage of parenting objects to an transform object is that you can perform *transforms* (for example, translation, scaling, rotation, etc.) on the child objects in unison.

The parent of a transform object is either an axes object or another transform object.

Although you cannot see a transform object, setting its `Visible` property to `off` makes all its children invisible as well.

## Exceptions and Limitations

- A transform object can be the parent of any number of axes child objects belonging to the same axes, except for light objects.
- Transform objects can never be the parent of axes objects and therefore can contain objects only from a single axes.
- Transform objects can be the parent of other transform objects within the same axes.
- You cannot transform image objects because images are not true 3-D objects. Texture mapping the image data to a surface CData enables you to produce the effect of transforming an image in 3-D space.
- Transforms do not affect text objects unless the text object uses data units. If a text object has a position specified in data units, then the transform moves the lower left corner of the text. The transform does not affect the font size or orientation. To change the font size and orientation, use text properties.

---

**Note** Many plotting functions clear the axes (remove axes children) before drawing the graph. Clearing the axes also deletes any transform objects in the axes.

---

## Examples

### Transforming a Group of Objects

This example shows how to create a 3-D star with a group of surface objects parented to a single transform object. The transform object then rotates the object about the z-axis while scaling its size.

Create an axes and adjust the view. Set the axes limits to prevent auto limit selection during scaling.

```
ax = axes('XLim', [-1.5 1.5], 'YLim', [-1.5 1.5], 'ZLim', [-1.5 1.5]);
view(3)
grid on
```

Create the objects you want to parent to the transform object.

```
[x,y,z] = cylinder([.2 0]);
h(1) = surface(x,y,z, 'FaceColor', 'red');
h(2) = surface(x,y,-z, 'FaceColor', 'green');
h(3) = surface(z,x,y, 'FaceColor', 'blue');
h(4) = surface(-z,x,y, 'FaceColor', 'cyan');
h(5) = surface(y,z,x, 'FaceColor', 'magenta');
h(6) = surface(y,-z,x, 'FaceColor', 'yellow');
```

Create a transform object and parent the surface objects to it. Initialize the rotation and scaling matrix to the identity matrix (eye).

```
t = hgtransform('Parent',ax);
set(h,'Parent',t)
```

```
Rz = eye(4);
Sxy = Rz;
```

Form the  $z$ -axis rotation matrix and the scaling matrix. Rotate group and scale by using the increasing values of  $r$ .

```
for r = 1:.1:2*pi
 % Z-axis rotation matrix
 Rz = makehgtform('zrotate',r);
 % Scaling matrix
 Sxy = makehgtform('scale',r/4);
 % Concatenate the transforms and
 % set the transform Matrix property
 set(t,'Matrix',Rz*Sxy)
 drawnow
end
pause(1)
```

Reset to the original orientation and size using the identity matrix.

```
set(t, 'Matrix', eye(4))
```

### Transforming Objects Independently

This example creates two transform objects to illustrate how to transform each independently within the same axes. A translation transformation moves one transform object away from the origin.

Create and set up the axes object that will be the parent of both transform objects. Set the limits to accommodate the translated object.

```
ax = axes('XLim',[-3 1], 'YLim',[-3 1], 'ZLim',[-1 1]);
view(3)
grid on
```

Create the surface objects to group.

```
[x,y,z] = cylinder([.3 0]);
h(1) = surface(x,y,z, 'FaceColor', 'red');
h(2) = surface(x,y,-z, 'FaceColor', 'green');
h(3) = surface(z,x,y, 'FaceColor', 'blue');
h(4) = surface(-z,x,y, 'FaceColor', 'cyan');
h(5) = surface(y,z,x, 'FaceColor', 'magenta');
h(6) = surface(y,-z,x, 'FaceColor', 'yellow');
```

Create the transform objects and parent them to the same axes. Then, parent the surfaces to transform t1. Copy the surface objects and parent the copies to transform t2. This figure should not change.

```
t1 = hgtransform('Parent',ax);
t2 = hgtransform('Parent',ax);

set(h,'Parent',t1)
h2 = copyobj(h,t2);
```

Translate the second transform object away from the first transform object and display the result.

```
Txy = makehgtform('translate',[-1.5 -1.5 0]);
set(t2,'Matrix',Txy)
drawnow
```

Rotate both transform objects in opposite directions.

```
% Rotate 10 times (2pi radians = 1 rotation)
for r = 1:.1:20*pi
 % Form z-axis rotation matrix
 Rz = makehgtform('zrotate',r);
 % Set transforms for both transform objects
 set(t1,'Matrix',Rz)
 set(t2,'Matrix',Txy*inv(Rz))
 drawnow
end
```

# Transform Properties

Control transform appearance and behavior

Transform properties control the behavior of transform objects. By changing property values, you can modify certain aspects of the transform object.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = hgtransform;
c = h.Children;
h.Matrix = makehgtform('scale',0.5);
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Transform Matrix

### Matrix — Transform matrix

4-by-4 matrix

Transform matrix applied to the transform object and its children, specified as a 4-by-4 matrix. For more information about defining this matrix, see “Transforms Supported by `hgtransform`”.

Data Types: `double`

## Visibility

### Visible — Visibility of transform

'on' (default) | 'off'

Visibility of transform, specified as one of these values:

- 'on' — Display all objects in the transform.
- 'off' — Hide all objects in the transform. You still can access the properties of invisible transform objects. Setting the `Visible` property for the transform object does not change the `Visible` property for objects in the transform.

### EraseMode — (removed) Technique to draw and erase objects

'normal' (default) | 'none' | 'xor' | 'background'

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, `'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

**Type — Type of graphics object**  
'hgtransform'

This property is read only.

Type of graphics object, returned as 'hgtransform'. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

### **Tag — Tag to associate with transform**

' ' (default) | string

Tag to associate with the transform, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

### **UserData — Data to associate with transform**

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the transform object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: 1:100

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | table | cell

### **DisplayName — Text used by legend**

' ' (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the transform.

Example: 'Text Description'

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property

does not contain any text, then the legend generates a string. The string has the form 'dataN', where N is the number assigned to the transform object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

## **Annotation — Legend icon display style**

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the transform from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - 'on' — Include the transform object in the legend as one entry (default).
  - 'off' — Do not include the transform object in the legend.
  - 'children' — Include only children of the transform object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## **Parent/Child**

### **Parent — Parent of transform**

axes object | group object | transform object

Parent of transform, specified as an axes, group, or transform object.

### **Children — Children of transform**

empty `GraphicsPlaceholder` array | array of graphics objects

Children of transform, returned as an array of graphics objects. Use this property to view a list of the children or to reorder the children by setting the property to a permutation of itself.

You cannot add or remove children using the `Children` property of the transform. To add a child to this list, set the `Parent` property of the child graphics object to the transform object.

### **HandleVisibility — Visibility of object handle**

'on' (default) | 'off' | 'callback'

Visibility of transform object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The transform object handle is always visible.
- 'off' — The transform object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The transform object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the transform at the command-line, but allows callback functions to access it.

If the transform object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their `HandleVisibility` property setting.

## **Interactive Control**

### **ButtonDownFcn — Mouse-click callback**

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the transform. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The transform object — You can access properties of the transform object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

## **UIContextMenu — Context menu**

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the transform. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

## **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the transform when in plot edit mode, then MATLAB sets its `Selected` property to 'on'. If the `SelectionHighlight` property also is set to 'on', then MATLAB displays selection handles around the transform.
- 'off' — Not selected.

**SelectionHighlight** — Display of selection handles when selected

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the `Selected` property is set to 'on'.
- 'off' — Never display selection handles, even when the `Selected` property is set to 'on'.

**Callback Execution Control****PickableParts** — Children that can capture mouse clicks

'visible' (default) | 'none'

Children that can capture mouse clicks, specified as one of these values:

- 'visible' — Any child object can capture a mouse click, depending on the `PickableParts` property value of the child.
- 'none' — No child objects can capture mouse clicks, regardless of the `PickableParts` property value of the child.

**HitTest** — Response to mouse clicks captured by children

'on' (default) | 'off'

Response to mouse clicks captured by children, specified one of these values:

- 'on' — Trigger the `ButtonDownFcn` callback of transform. If you have defined the `UIContextMenu` property, then invoke the context menu.
- 'off' — Do not trigger the callbacks of the transform. Instead, trigger the callbacks for the nearest ancestor of the transform that has a `HitTest` property set to 'on' and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

A transform cannot capture mouse clicks. However, if you click a child of the transform and if the child has a `HitTest` property set to 'off', then the child passes the click to the transform.

**Interruptible** — Callback interruption

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the transform is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The **Interruptible** property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the **BusyAction** property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the **ButtonDownFcn** callback of the transform tries to interrupt a running callback that cannot be interrupted, then the **BusyAction** property determines if it is discarded or put in the queue. Specify the **BusyAction** property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

### CreateFcn — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the transform. Setting the **CreateFcn** property on an existing transform has no effect. You must define a default value for this property, or define this property using a **Name, Value** pair during transform creation. MATLAB executes the callback after creating the transform and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The transform object — You can access properties of the transform object from within the callback function. You also can access the transform object through the **CallbackObject** property of the root, which can be queried using the **gcbo** function.

- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### **DeleteFcn** — Deletion callback

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the transform. MATLAB executes the callback before destroying the transform so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The transform object — You can access properties of the transform object from within the callback function. You also can access the transform object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### **BeingDeleted** — Deletion status of transform

'off' (default) | 'on'

This property is read only.

Deletion status of transform, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the transform begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the transform no longer exists.

Check the value of the `BeingDeleted` property to verify that the transform is not about to be deleted before querying or modifying it.

## hidden

Remove hidden lines from mesh plot

### Syntax

```
hidden on
hidden off
hidden
```

### Description

Hidden line removal draws only those lines that are not obscured by other objects in a 3-D view. The `hidden` function only applies to surface plot objects that have a uniform `FaceColor`.

`hidden on` turns on hidden line removal for the current mesh plot so lines in the back of a mesh are hidden by those in front. This is the default behavior.

`hidden off` turns off hidden line removal for the current mesh plot.

`hidden` toggles the hidden line removal state.

### Examples

#### Show Obscured Lines

Create a mesh plot of the `peaks` function.

```
figure
mesh(peaks)
```

By default, MATLAB® hides obscured lines from the view. Show the obscured parts of the mesh by setting the hidden line removal to off.

```
hidden off
```

## More About

### Algorithms

When a surface graphics object has a uniform `FaceColor` matching the `Color` property of the axes, `hidden off` sets the `FaceColor` of the surface object to `'none'`.

`hidden on` sets the `FaceColor` property of such surface objects to match the axes `Color` property (or to match that of the figure, if axes `Color` is `'none'`).

## hilb

Hilbert matrix

### Syntax

```
H = hilb(n)
```

### Description

H = hilb(n) returns the Hilbert matrix of order n.

### Definitions

The Hilbert matrix is a notable example of a poorly conditioned matrix [1]. The elements of the Hilbert matrices are  $H(i,j) = 1/(i + j - 1)$ .

### Examples

Even the fourth-order Hilbert matrix shows signs of poor conditioning.

```
cond(hilb(4)) =
 1.5514e+04
```

### References

# hist

Histogram plot (not recommended; use `histogram`)

## Compatibility

`hist` is not recommended. Use `histogram` instead.

For more information, including suggestions on updating code, see “Replace Discouraged Instances of `hist` and `histc`”.

## Syntax

```
hist(x)
hist(x,nbins)
hist(x,xbins)

hist(ax, ___)

counts = hist(___)
[counts,centers] = hist(___)
```

## Description

`hist(x)` creates a histogram bar chart of the elements in vector `x`. The elements in `x` are sorted into 10 equally spaced bins along the `x`-axis between the minimum and maximum values of `x`. `hist` displays bins as rectangles, such that the height of each rectangle indicates the number of elements in the bin.

If the input is a multi-column array, `hist` creates histograms for each column of `x` and overlays them onto a single plot.

If the input is of data type `categorical`, each bin is a category of `x`.

`hist(x,nbins)` sorts `x` into the number of bins specified by the scalar `nbins`.

`hist(x,xbins)` sorts `x` into bins with intervals or categories determined by the vector `xbins`.

- If `xbins` is a vector of evenly spaced values, then `hist` uses the values as the bin centers.
- If `xbins` is a vector of unevenly spaced values, then `hist` uses the midpoints between consecutive values as the bin edges.
- If `x` is of data type `categorical`, then `xbins` must be a categorical vector or cell array of strings that specifies categories. `hist` plots bars only for those categories.

The length of the vector `xbins` is equal to the number of bins.

`hist(ax, ___)` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option `ax` can precede any of the input argument combinations in the previous syntaxes.

`counts = hist(___)` returns a row vector, `counts`, containing the number of elements in each bin.

`[counts,centers] = hist(___)` returns an additional row vector, `centers`, indicating the location of each bin center on the `x`-axis.

## Examples

### Histogram of Vector

```
x = [0 2 9 2 5 8 7 3 1 9 4 3 5 8 10 0 1 2 9 5 10];
hist(x)
```

`hist` sorts the values in `x` among 10 equally spaced bins between the minimum and maximum values in the vector, which are 0 and 10 in this example.

### **Histogram of Multiple Columns**

Generate three columns of 1,000 random numbers and plot the three column overlaid histogram.

```
x = randn(1000,3);
hist(x)
```

The values in `x` are sorted among 10 equally spaced bins between the minimum and maximum values. `hist` sorts and bins the columns of `x` separately and plots each column with a different color.

### Specify Number of Histogram Bins

Plot a histogram of 1,000 random numbers sorted into 50 equally spaced bins.

```
x = randn(1000,1);
nbins = 50;
hist(x,nbins)
```

### Specify Histogram Bin Intervals

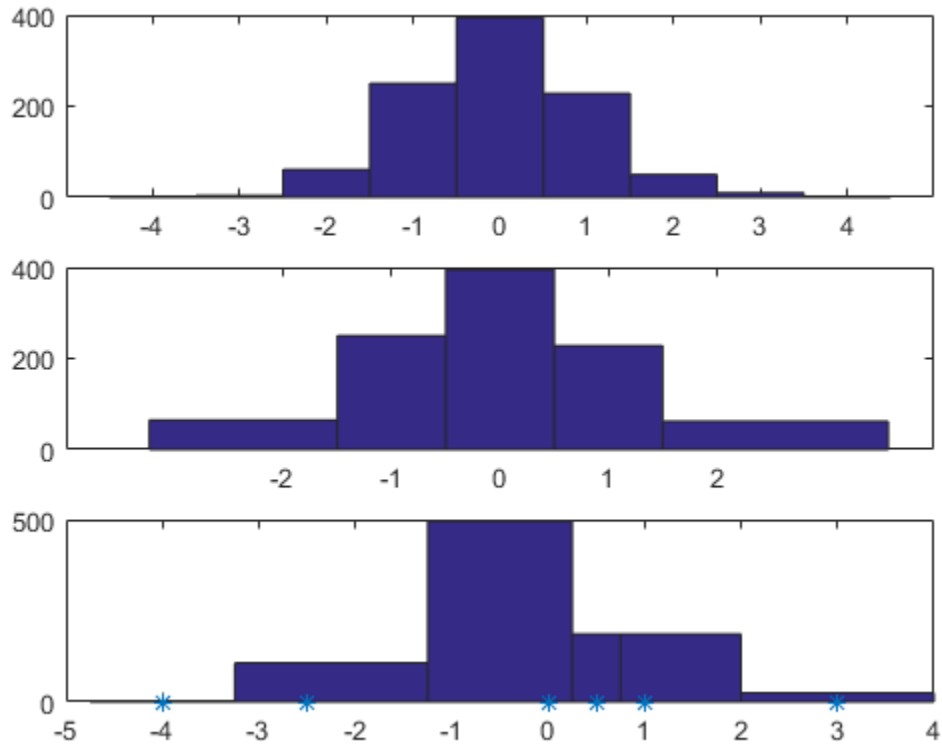

Plot three histograms of the same data using different bin intervals:

- In the upper subplot, specify the bin centers using a vector of evenly spaced values that span the values in  $x$ .
- In the middle subplot, specify the bin centers using a vector of evenly spaced values that do not span the values in  $x$ . The first and last bins extend to cover the minimum and maximum values in  $x$ .
- In the lower subplot, specify the bin intervals using a vector of unevenly spaced values. The `hist` function uses the midpoints between consecutive values as the bin edges and indicates the specified values by markers along the  $x$ -axis.

```
x = randn(1000,1);
subplot(3,1,1)
xbins1 = -4:4;
hist(x,xbins1)

subplot(3,1,2)
xbins2 = -2:2;
hist(x,xbins2)

subplot(3,1,3)
xbins3 = [-4 -2.5 0 0.5 1 3];
hist(x,xbins3)
```

### Specify Histogram Axes

Create a figure with two subplots. In the upper subplot, plot a histogram of 1,000 random numbers sorted into 50 equally spaced bins. In the lower subplot, plot a histogram of the same data and use bins with centers at -3, 0, and 3.

```
x = randn(1000,1);
ax1 = subplot(2,1,1);
hist(ax1,x,50)
```

```
ax2 = subplot(2,1,2);
xbins = [-3 0 3];
hist(ax2,x,xbins)
```

**Use hist to Calculate Only**

Generate 1,000 random numbers. Count how many numbers are in each of 10 equally spaced bins. Return the bin counts and bin centers.

```
x = randn(1000,1);
[counts,centers] = hist(x)
```

counts =

4    27    88    190    270    243    123    38    13    4

```
centers =
```

```
Columns 1 through 7
```

```
-2.8915 -2.2105 -1.5294 -0.8484 -0.1673 0.5137 1.1947
```

```
Columns 8 through 10
```

```
1.8758 2.5568 3.2379
```

Use `bar` to plot the histogram.

```
bar(centers,counts)
```

## Specify Histogram Colors

Generate 1,000 random numbers and create a histogram.

```
data = randn(1000,1);
hist(data)
```

Get the handle to the patch object that creates the histogram plot.

```
h = findobj(gca, 'Type', 'patch');
```

Set the face color of the bars plotted to an RGB triplet value of [0 0.5 0.5]. Set the edge color to white.

```
h.FaceColor = [0 0.5 0.5];
h.EdgeColor = 'w';
```

## Input Arguments

**x** — Input array

vector or matrix

Input vector or matrix.

- If **x** is a vector, then `hist` creates one histogram.
- If **x** is a matrix, then `hist` creates a separate histogram for each column and plots the histograms using different colors.

If the input array contains NaNs or undefined categorical values, `hist` does not include these values in the bin counts.

If the input array contains the infinite values `-Inf` or `Inf`, then `hist` sorts `-Inf` into the first bin and `Inf` into the last bin. If you do not specify the bin intervals, then `hist` calculates the bin intervals using only the finite values in the input array.

**Data Types:** `single` | `double` | `logical` | `categorical`

**`nbins` — Number of bins**

10 (default) | scalar

Number of bins. Input `x` must be numeric, not categorical.

**Data Types:** `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**`xbins` — Bin locations or categories**

vector

Bin locations or categories, specified as a vector.

If `x` is numeric or logical, then `xbins` must be of type `single` or `double`.

- If the elements in `xbins` are equally spaced, then these elements are the bin centers.
- If the elements in `xbins` are not equally spaced, then these elements are indicated by markers along the `x`-axis, but are not the actual bin centers. Instead, `hist` calculates the bin edges as the midpoints between consecutive elements in vector `xbins`. To specify the bin edges directly, use `histc`.
- `xbins` must contain only finite values. The first and last bins extend to cover the minimum and maximum values in `x`.

If `x` is categorical, then `xbins` must be a categorical vector or cell array of strings that specifies categories. `hist` plots bars only for those categories specified by `xbins`.

**`ax` — Axes object**

axes object

Axes object. Use `ax` to plot the histogram in a specific axes instead of the current axes (`gca`).

## Output Arguments

### **counts** — Counts of the number of elements in each bin

row vector

Counts of the number of elements in each bin, returned as a row vector.

### **centers** — Bin centers or categories

vector

Bin centers or categories, returned as a vector. If used with the syntax `[counts,centers] = hist(x,xbins)`, then the `centers` output has the same elements as the `xbins` input.

- If `x` is numeric or logical, then `centers` is a numeric row vector.
- If `x` is categorical, then `centers` is a cell array of strings.

**Introduced before R2006a**

# histc

Histogram bin counts (not recommended; use `histcounts`)

## Compatibility

`histc` is not recommended. Use `histcounts` instead.

For more information, including suggestions on updating code, see “Replace Discouraged Instances of `hist` and `histc`”.

## Syntax

```
bincounts = histc(x,binranges)
bincounts = histc(x,binranges,dim)
[bincounts,ind]= histc(___)
```

## Description

`bincounts = histc(x,binranges)` counts the number of values in `x` that are within each specified bin range. The input, `binranges`, determines the endpoints for each bin. The output, `bincounts`, contains the number of elements from `x` in each bin.

- If `x` is a vector, then `histc` returns `bincounts` as a vector of histogram bin counts.
- If `x` is a matrix, then `histc` operates along each column of `x` and returns `bincounts` as a matrix of histogram bin counts for each column.

To plot the histogram, use `bar(binranges,bincounts,'histc')`.

`bincounts = histc(x,binranges,dim)` operates along the dimension `dim`.

`[bincounts,ind]= histc( ___ )` returns `ind`, an array the same size as `x` indicating the bin number that each entry in `x` sorts into. Use this syntax with any of the previous input argument combinations.

## Examples

### Create Histogram Plot

Initialize the random number generator to make the output of `randn` repeatable.

```
rng(0, 'twister')
```

Define `x` as 100 normally distributed random numbers. Define bin ranges between -4 and 4. Determine the number of values in `x` that are within each specified bin range. Return the number of elements in each bin in `bincounts`.

```
x = randn(100,1);
binranges = -4:4;
[bincounts] = histc(x,binranges)
```

```
bincounts =
```

```
 0
 2
 17
 28
 32
 16
 3
 2
 0
```

To plot the histogram, use the `bar` function.

```
figure
bar(binranges,bincounts, 'histc')
```

### Return Bin Numbers for Histogram

Defined `ages` as a vector of ages. Sort `ages` into bins with varying ranges between 0 and 75.

```
ages = [3,12,24,15,5,74,23,54,31,23,64,75];
binranges = [0,10,25,50,75];
```

```
[bincounts,ind] = histc(ages,binranges)
```

```
bincounts =
```

```
 2 5 1 3 1
```

```
ind =
 1 2 2 2 1 4 2 4 3 2 4 5
```

`bincounts` contains the number of values in each bin. `ind` indicates the bin numbers.

## Input Arguments

### **x** — Values to be sorted

vector | matrix

Values to be sorted, specified as a vector or a matrix. The bin counts do not include values in `x` that are NaN or that lie outside the specified bin ranges. If `x` contains complex values, then `histc` ignores the imaginary parts and uses only the real parts.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **binranges** — Bin ranges

vector | matrix

Bin ranges, specified as a vector of monotonically nondecreasing values or a matrix of monotonically nondecreasing values running down each successive column. The values in `binranges` determine the left and right endpoints for each bin. If `binranges` contains complex values, then `histc` ignores the imaginary parts and uses only the real parts.

If `binranges` is a matrix, then `histc` determines the bin ranges by using values running down successive columns. Each bin includes the left endpoint, but does not include the right endpoint. The last bin consists of the scalar value equal to last value in `binranges`.

For example, if `binranges` equals the vector `[0,5,10,13]`, then `histc` creates four bins. The first bin includes values greater than or equal to 0 and strictly less than 5. The second bin includes values greater than or equal to 5 and less than 10, and so on. The last bin contains the scalar value 13.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**dim** — Dimension along which to operate

scalar

Dimension along which to operate, specified as a scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

## Output Arguments

**bincounts** — Number of elements in each bin

vector | matrix

Number of elements in each bin, returned as a vector or a matrix. The last entry in `bincounts` is the number of values in `x` that equal the last entry in `binranges`.

**ind** — Bin index numbers

vector | matrix

Bin index numbers, returned as a vector or a matrix that is the same size as `x`.

## More About

### Tips

- If values in `x` lie outside the specified bin ranges, then `histc` does not include these values in the bin counts. Start and end the `binranges` vector with `-inf` and `inf` to ensure that all values in `x` are included in the bin counts.

Introduced before R2006a

## histcounts

Histogram bin counts

### Syntax

```
[N,edges] = histcounts(X)
[N,edges] = histcounts(X,nbins)
[N,edges] = histcounts(X,edges)
[N,edges,bin] = histcounts(___)

N = histcounts(C)
N = histcounts(C,Categories)
[N,Categories] = histcounts(___)

[___] = histcounts(___ ,Name,Value)
```

### Description

`[N,edges] = histcounts(X)` partitions the  $X$  values into bins, and returns the count in each bin, as well as the bin edges. The `histcounts` function uses an automatic binning algorithm that returns bins with a uniform width, chosen to cover the range of elements in  $X$  and reveal the underlying shape of the distribution.

`[N,edges] = histcounts(X,nbins)` uses a number of bins specified by the scalar, `nbins`.

`[N,edges] = histcounts(X,edges)` sorts  $X$  into bins with the bin edges specified by the vector, `edges`. The value  $X(i)$  is in the  $k$ th bin if `edges(k) ≤ X(i) < edges(k+1)`. The last bin also includes the right bin edge, so that it contains  $X(i)$  if `edges(end-1) ≤ X(i) ≤ edges(end)`.

`[N,edges,bin] = histcounts( ___ )` also returns an index array, `bin`, using any of the previous syntaxes. `bin` is an array of the same size as  $X$  whose elements are the bin indices for the corresponding elements in  $X$ . The number of elements in the  $k$ th bin is `nnz(bin==k)`, which is the same as  $N(k)$ .

`N = histcounts(C)`, where `C` is a categorical array, returns a vector, `N`, that indicates the number of elements in `C` whose value is equal to each of `C`'s categories. `N` has one element for each category in `C`.

`N = histcounts(C,Categories)` counts only the elements in `C` whose value is equal to the subset of categories specified by `Categories`.

`[N,Categories] = histcounts( ___ )` also returns the categories that correspond to each count in `N` using either of the previous syntaxes for categorical arrays.

`[ ___ ] = histcounts( ___ ,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments using any of the input or output argument combinations in previous syntaxes. For example, you can specify `'BinWidth'` and a scalar to adjust the width of the bins for numeric data. For categorical data, you can specify `'Normalization'` and either `'count'`, `'countdensity'`, `'probability'`, `'pdf'`, `'cumcount'`, or `'cdf'`.

## Examples

### Bin Counts and Bin Edges

Distribute 100 random values into bins. `histcounts` automatically chooses an appropriate bin width to reveal the underlying distribution of the data.

```
X = randn(100,1);
[N,edges] = histcounts(X)
```

`N =`

```
 2 17 28 32 16 3 2
```

`edges =`

```
 -3 -2 -1 0 1 2 3 4
```

### Specify Number of Bins

Distribute 10 numbers into 6 equally spaced bins.

```
X = [2 3 5 7 11 13 17 19 23 29];
```

```
[N,edges] = histcounts(X,6)
```

```
N =
```

```
 2 2 2 2 1 1
```

```
edges =
```

```
 0 4.9000 9.8000 14.7000 19.6000 24.5000 29.4000
```

## Specify Bin Edges

Distribute 1,000 random numbers into bins. Define the bin edges with a vector, where the first element is the left edge of the first bin, and the last element is the right edge of the last bin.

```
X = randn(1000,1);
edges = [-5 -4 -2 -1 -0.5 0 0.5 1 2 4 5];
N = histcounts(X,edges)
```

```
N =
```

```
 0 24 149 142 195 200 154 111 25 0
```

## Normalized Bin Counts

Distribute all of the prime numbers less than 100 into bins. Specify 'Normalization' as 'probability' to normalize the bin counts so that `sum(N)` is 1. That is, each bin count represents the probability that an observation falls within that bin.

```
X = primes(100);
[N,edges] = histcounts(X, 'Normalization', 'probability')
```

```
N =
```

```
 0.4000 0.2800 0.2800 0.0400
```

```
edges =
```

```
0 30 60 90 120
```

### Determine Bin Placement

Distribute 100 random integers between -5 and 5 into bins, and specify 'BinMethod' as 'integers' to use unit-width bins centered on integers. Specify a third output for histcounts to return a vector representing the bin indices of the data.

```
X = randi([-5,5],100,1);
[N,edges,bin] = histcounts(X,'BinMethod','integers');
```

Find the bin count for the third bin by counting the occurrences of the number 3 in the bin index vector, bin. The result is the same as N(3).

```
count = nnz(bin==3)
```

```
count =
```

```
8
```

### Categorical Bin Counts

Create a categorical vector that represents votes. The categories in the vector are 'yes', 'no', or 'undecided'.

```
A = [0 0 1 1 1 0 0 0 0 NaN NaN 1 0 0 0 1 0 1 0 1 0 0 0 1 1 1 1];
C = categorical(A,[1 0 NaN],{'yes','no','undecided'})
```

```
C =
```

```
Columns 1 through 9
```

```
no no yes yes yes no no no no
```

```
Columns 10 through 16
```

```
undecided undecided yes no no no yes
```

```
Columns 17 through 25
```

```
no yes no yes no no no yes yes
```

```
Columns 26 through 27
```

```
yes yes
```

Determine the number of elements that fall into each category.

```
[N,Categories] = histcounts(C)
```

```
N =
```

```
11 14 2
```

```
Categories =
```

```
'yes' 'no' 'undecided'
```

## Input Arguments

### **X** — Data to distribute among bins

vector | matrix | multidimensional array

Data to distribute among bins, specified as a vector, matrix, or multidimensional array. If *X* is not a vector, then `histcounts` treats it as a single column vector, `X(:)`.

`histcounts` ignores all NaN values. Similarly, `histcounts` ignores `Inf` and `-Inf` values unless the bin edges explicitly specify `Inf` or `-Inf` as a bin edge.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **C** — Categorical data

categorical array

Categorical data, specified as a categorical array. `histcounts` ignores undefined categorical values.

Data Types: `categorical`

### **nbins** — Number of bins

positive integer

Number of bins, specified as a positive integer. If you do not specify `nbins`, then `histcounts` automatically calculates how many bins to use based on the values in `X`.

Example: `[N,edges] = histcounts(X,15)` uses 15 bins.

### **edges** — Bin edges

vector

Bin edges, specified as a vector. `edges(1)` is the left edge of the first bin, and `edges(end)` is the right edge of the last bin.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **Categories** — Categories included in count

all categories (default) | cell vector of strings | categorical vector

Categories included in count, specified as a cell vector of strings or categorical vector. By default, `histcounts` uses a bin for each category in categorical array `C`. Use `Categories` to specify a unique subset of the categories instead.

Example: `h = histcounts(C,{'Large','Small'})` counts only the categorical data in the categories 'Large' and 'Small'.

Data Types: `cell` | `categorical`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `[N,edges] = histcounts(X,'Normalization','probability')` normalizes the bin counts in `N`, such that `sum(N)` is 1.

### **'BinLimits'** — Bin limits

two-element vector

Bin limits, specified as a two-element vector, `[bmin,bmax]`. This option bins only the values in `X` that fall between `bmin` and `bmax` inclusive; that is, `X(X>=bmin & X<=bmax)`.

This option does not apply to categorical data.

Example: `[N,edges] = histcounts(X,'BinLimits',[1,10])` bins only the values in X that are between 1 and 10 inclusive.

**'BinMethod' – Binning algorithm**

'auto' (default) | 'scott' | 'fd' | 'integers' | 'sturges' | 'sqrt'

Binning algorithm, specified as one of the values in this table.

| Value      | Description                                                                                                                                                                                                                                                                                                                                                   |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'auto'     | The default 'auto' algorithm chooses a bin width to cover the data range and reveal the shape of the underlying distribution.                                                                                                                                                                                                                                 |
| 'scott'    | Scott's rule is optimal if the data is close to being normally distributed, but is also appropriate for most other distributions. It uses a bin width of $3.5 * \text{std}(X(:)) * \text{numel}(X)^{-1/3}$ .                                                                                                                                                  |
| 'fd'       | The Freedman-Diaconis rule is less sensitive to outliers in the data, and may be more suitable for data with heavy-tailed distributions. It uses a bin width of $2 * \text{IQR}(X(:)) * \text{numel}(X)^{-1/3}$ , where IQR is the interquartile range of X.                                                                                                  |
| 'integers' | The integer rule is useful with integer data, as it creates a bin for each integer. It uses a bin width of 1 and places bin edges halfway between integers. To prevent from accidentally creating too many bins, a limit of 65536 bins ( $2^{16}$ ) can be created with this rule. If the data range is greater than 65536, then wider bins are used instead. |
| 'sturges'  | Sturges' rule is a simple rule that is popular due to its simplicity. It chooses the number of bins to be $\text{ceil}(1 + \log_2(\text{numel}(X)))$ .                                                                                                                                                                                                        |
| 'sqrt'     | The Square Root rule is another simple rule widely used in other software                                                                                                                                                                                                                                                                                     |

| Value | Description                                                                       |
|-------|-----------------------------------------------------------------------------------|
|       | packages. It chooses the number of bins to be <code>ceil(sqrt(numel(X)))</code> . |

This option does not apply to categorical data.

Example: `[N,edges] = histcounts(X,'BinMethod','integers')` uses bins centered on integers.

### 'BinWidth' – Width of bins

scalar

Width of bins, specified as a scalar. If you specify `BinWidth`, then `histcounts` can use a maximum of 65,536 bins (or  $2^{16}$ ). If the specified bin width requires more bins, then `histcounts` uses a larger bin width corresponding to the maximum number of bins.

This option does not apply to categorical data.

Example: `[N,edges] = histcounts(X,'BinWidth',5)` uses bins with a width of 5.

### 'Normalization' – Type of normalization

'count' (default) | 'probability' | 'countdensity' | 'pdf' | 'cumcount' | 'cdf'

Type of normalization, specified as one of the values in this table.

| Value         | Description                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'count'       | Default normalization scheme. Each <code>N</code> value is equal to the number of observations in the bin, and <code>sum(N)</code> is equal to <code>numel(X)</code> .<br><br>For categorical data, each <code>N</code> value is the number of elements in each category, and <code>sum(N)</code> is equal to <code>numel(C)</code> or <code>sum(ismember(C(:),Categories))</code> . |
| 'probability' | Each <code>N</code> value is equal to the relative number of observations in the bin, (number of observations in bin / total number of observations), such that <code>sum(N)</code> is 1.                                                                                                                                                                                            |

| Value          | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | For categorical data, each N value is, (number of elements in category / total number of elements in all categories), such that $\text{sum}(N)$ is 1.                                                                                                                                                                                                                                            |
| 'countdensity' | Each N value is equal to the number of observations in the bin divided by the bin width.<br><br>For categorical data, this is the same as 'count'.                                                                                                                                                                                                                                               |

| 'cumcount'     | Each N value is equal to the cumulative number of observations in the bin and all previous bins. $N(\text{end})$ is equal to $\text{numel}(X)$ .<br><br>For categorical data, each N value is equal to the cumulative number of elements in each category and all previous categories. $N(\text{end})$ is equal to $\text{numel}(C)$ or $\text{sum}(\text{ismember}(C(:), \text{Categories}))$ . |
| 'cdf'          | Cumulative density function estimate. Each N value is equal to the cumulative relative number of observations in the bin and all previous bins. $N(\text{end})$ is equal to 1.<br><br>For categorical data, each N value is equal to the cumulative relative number of observations in each category and all previous categories. $N(\text{end})$ is equal to 1.                                 |

Example: `[N,edges] = histcounts(X,'Normalization','pdf')` bins the data using the probability density function estimate.

## Output Arguments

### **N** — Bin counts

row vector

Bin counts, returned as a row vector.

### **edges** — Bin edges

vector

Bin edges, returned as a vector. `edges(1)` is the left edge of the first bin, and `edges(end)` is the right edge of the last bin.

### **bin** — Bin indices

array

Bin indices, returned as an array of the same size as `X`. Each element in `bin` describes which numbered bin contains the corresponding element in `X`.

A value of 0 in `bin` indicates an element which does not belong to any of the bins (for example, a NaN value).

### **Categories** — Categories included in count

cell vector of strings

Categories included in count, returned as a cell vector of strings. `Categories` contains the categories in `C` that correspond to each count in `N`.

## More About

### Tips

- The behavior of `histcounts` is similar to that of the `discretize` function. Use `histcounts` to find the number of elements in each bin. On the other hand, use `discretize` to find which bin each element belongs to (without counting).
- “Replace Discouraged Instances of `hist` and `histe`”

**Introduced in R2014b**

# histcounts2

Bivariate histogram bin counts

## Syntax

```
[N,Xedges,Yedges] = histcounts2(X,Y)
[N,Xedges,Yedges] = histcounts2(X,Y,nbins)
[N,Xedges,Yedges] = histcounts2(X,Y,Xedges,Yedges)
[N,Xedges,Yedges] = histcounts2(___,Name,Value)
[N,Xedges,Yedges,binX,binY] = histcounts2(___)
```

## Description

`[N,Xedges,Yedges] = histcounts2(X,Y)` partitions the values in `X` and `Y` into 2-D bins, and returns the bin counts, as well as the bin edges in each dimension. The `histcounts2` function uses an automatic binning algorithm that returns uniform bins chosen to cover the range of values in `X` and `Y` and reveal the underlying shape of the distribution.

`[N,Xedges,Yedges] = histcounts2(X,Y,nbins)` specifies the number of bins to use in each dimension.

`[N,Xedges,Yedges] = histcounts2(X,Y,Xedges,Yedges)` partitions `X` and `Y` into bins with the bin edges specified by `Xedges` and `Yedges`.

`N(i,j)` counts the value `[X(k),Y(k)]` if `Xedges(i) ≤ X(k) < Xedges(i+1)` and `Yedges(j) ≤ Y(k) < Yedges(j+1)`. The last bins in each dimension also include the last (outer) edge. For example, `[X(k),Y(k)]` falls into the `i`th bin in the last row if `Xedges(end-1) ≤ X(k) ≤ Xedges(end)` and `Yedges(i) ≤ Y(k) < Yedges(i+1)`.

`[N,Xedges,Yedges] = histcounts2( ___,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments using any of the input arguments in previous syntaxes. For example, you can specify `'BinWidth'` and a two-element vector to adjust the width of the bins in each dimension.

`[N,Xedges,Yedges,binX,binY] = histcounts2( ___ )` also returns index arrays `binX` and `binY`, using any of the previous syntaxes. `binX` and `binY` are arrays of the same size as `X` and `Y` whose elements are the bin indices for the corresponding elements

in X and Y. The number of elements in the (i, j)th bin is equal to `nnz(binX==i & binY==j)`, which is the same as `N(i, j)` if `Normalization` is 'count'.

## Examples

### Bin Counts and Bin Edges

Distribute 100 pairs of random numbers into bins. `histcounts2` automatically chooses an appropriate bin width to reveal the underlying distribution of the data.

```
x = randn(100,1);
y = randn(100,1);
[N,Xedges,Yedges] = histcounts2(x,y)
```

N =

```
 0 0 0 2 0 0
 1 2 10 4 0 0
 1 4 9 9 5 0
 1 4 10 11 5 1
 1 4 6 3 1 1
 0 0 1 2 0 0
 0 0 1 0 1 0
```

Xedges =

```
 -3 -2 -1 0 1 2 3 4
```

Yedges =

```
 -3 -2 -1 0 1 2 3
```

### Specify Number of Bins in Each Dimension

Distribute 10 pairs of numbers into 12 bins. Specify 3 bins in the x-dimension, and 4 bins in the y-dimension.

```
x = [1 1 2 3 2 2 1 1 2 3];
y = [5 6 3 8 9 1 2 7 5 1];
```

```
nbins = [3 4];
[N,Xedges,Yedges] = histcounts2(x,y,nbins)
```

N =

```
 1 0 2 1
 1 1 1 1
 1 0 0 1
```

Xedges =

```
 0.6000 1.4000 2.2000 3.0000
```

Yedges =

```
 0 2.3000 4.6000 6.9000 9.2000
```

### Specify Bin Edges

Distribute 1,000 pairs of random numbers into bins. Define the bin edges with two vectors: one each for the x and y dimensions. The first element in each vector specifies the first edge of the first bin, and the last element is the last edge of the last bin.

```
x = randn(1000,1);
y = randn(1000,1);
Xedges = -5:5;
Yedges = [-5 -4 -2 -1 -0.5 0 0.5 1 2 4 5];
N = histcounts2(x,y,Xedges,Yedges)
```

N =

```
 0 0 0 0 0 0 0 0 0 0
 0 0 0 0 1 1 1 0 0 0
 0 0 5 5 3 5 1 2 0 0
 0 2 19 23 29 25 26 20 5 0
 0 10 36 51 59 71 54 46 10 0
 0 7 43 46 79 64 60 46 9 0
 0 3 12 18 21 23 19 9 6 0
 0 0 5 3 2 8 2 2 0 0
 0 0 0 1 1 1 0 0 0 0
```

```
0 0 0 0 0 0 0 0 0 0
```

### Normalized Bin Counts

Distribute 1,000 pairs of random numbers into bins. Specify `Normalization` as `'probability'` to normalize the bin counts such that `sum(N(:))` is 1. That is, each bin count represents the probability that an observation falls within that bin.

```
x = randn(1000,1);
y = randn(1000,1);
[N,Xedges,Yedges] = histcounts2(x,y,6,'Normalization','probability')
```

N =

```
0 0 0.0020 0.0020 0 0
0 0.0110 0.0320 0.0260 0.0070 0.0010
0.0010 0.0260 0.1410 0.1750 0.0430 0.0060
0 0.0360 0.1620 0.1940 0.0370 0.0040
0 0.0040 0.0300 0.0370 0.0100 0.0010
0 0.0030 0.0040 0.0040 0.0010 0
```

Xedges =

```
-4.0000 -2.7000 -1.4000 -0.1000 1.2000 2.5000 3.8000
```

Yedges =

```
-4.0000 -2.7000 -1.4000 -0.1000 1.2000 2.5000 3.8000
```

### Determine Bin Placement

Distribute 1,000 random integer pairs between -10 and 10 into bins, and specify `BinMethod` as `'integers'` to use unit-width bins centered on integers. Specify five outputs for `histcounts2` to return vectors representing the bin placement of the data.

```
x = randi([-10,10],1000,1);
y = randi([-10,10],1000,1);
[N,Xedges,Yedges,binX,binY] = histcounts2(x,y,'BinMethod','integers');
```

Determine which bin the value `(x(3),y(3))` falls into.

```
[x(3),y(3)]

ans =

 -8 10

bin = [binX(3) binY(3)]

bin =

 3 21
```

## Input Arguments

### **X, Y — Data to distribute among bins (as separate arguments)**

vectors | matrices | multidimensional arrays

Data to distribute among bins, specified as separate arguments of vectors, matrices, or multidimensional arrays. X and Y must have the same size.

Corresponding elements in X and Y specify the *x* and *y* coordinates of 2-D data points, [X(k), Y(k)]. The data types of X and Y can be different.

histcounts2 ignores all NaN values. Similarly, histcounts2 ignores Inf and -Inf values unless the bin edges explicitly specify Inf or -Inf as a bin edge.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **nbins — Number of bins in each dimension**

scalar | vector

Number of bins in each dimension, specified as a positive scalar integer or two-element vector of positive integers. If you do not specify nbins, then histcounts2 automatically calculates how many bins to use based on the values in X and Y:

- If nbins is a scalar, then histcounts2 uses that many bins in each dimension.
- If nbins is a vector, then nbins(1) specifies the number of bins in the *x*-dimension and nbins(2) specifies the number of bins in the *y*-dimension.

Example: `[N,Xedges,Yedges] = histcounts2(X,Y,[15 20])` uses 15 bins in the x-dimension and 20 bins in the y-dimension.

**Xedges — Bin edges in x-dimension**

vector

Bin edges in x-dimension, specified as a vector. `Xedges(1)` is the first edge of the first bin in the x-dimension, and `Xedges(end)` is the outer edge of the last bin.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**Yedges — Bin edges in y-dimension**

vector

Bin edges in y-dimension, specified as a vector. `Yedges(1)` is the first edge of the first bin in the y-dimension, and `Yedges(end)` is the outer edge of the last bin.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `[N,Xedges,Yedges] = histcounts2(X,Y,'Normalization','probability')` normalizes the bin counts in `N`, such that `sum(N)` is 1.

**'BinMethod' — Binning algorithm**`'auto'` (default) | `'scott'` | `'fd'` | `'integers'`

Binning algorithm, specified as one of the values in this table.

| Value               | Description                                                                                                                                |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'auto'</code> | The default <code>'auto'</code> algorithm chooses a bin width to cover the data range and reveal the shape of the underlying distribution. |

| Value      | Description                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'scott'    | Scott's rule is optimal if the data is close to being jointly normally distributed. This rule is appropriate for most other distributions, as well. It uses a bin size of $[3.5 \cdot \text{std}(X(:)) \cdot \text{numel}(X)^{-1/4}, 3.5 \cdot \text{std}(Y(:)) \cdot \text{numel}(Y)^{-1/4}]$ .                                                                                                                               |
| 'fd'       | The Freedman-Diaconis rule is less sensitive to outliers in the data, and might be more suitable for data with heavy-tailed distributions. It uses a bin size of $[2 \cdot \text{IQR}(X(:)) \cdot \text{numel}(X)^{-1/4}, 2 \cdot \text{IQR}(Y(:)) \cdot \text{numel}(Y)^{-1/4}]$ , where IQR is the interquartile range.                                                                                                      |
| 'integers' | The integer rule is useful with integer data, as it creates bins centered on pairs of integers. It uses a bin width of 1 for each dimension and places bin edges halfway between integers.<br><br>To avoid accidentally creating too many bins, you can use this rule to create a limit of 1024 bins ( $2^{10}$ ). If the data range for either dimension is greater than 1024, then the integer rule uses wider bins instead. |

Example: `[N,Xedges,Yedges] = histcounts2(X,Y,'BinMethod','integers')` uses 2-D bins centered on each pair of integers.

### 'BinWidth' — Width of bins in each dimension

vector

Width of bins in each dimension, specified as a two-element vector of positive integers, `[xWidth yWidth]`.

If you specify `BinWidth`, then `histcounts2` can use a maximum of 1024 bins ( $2^{10}$ ) along each dimension. If the specified bin width requires more bins, then `histcounts2` uses a larger bin width corresponding to the maximum number of bins.

Example: `[N,Xedges,Yedges] = histcounts2(X,Y,'BinWidth',[5 10])` uses bins with size 5 in the x-dimension and size 10 in the y-dimension.

**'XBinLimits' — Bin limits in x-dimension**

two-element vector

Bin limits in *x*-dimension, specified as a two-element vector, `[xbmin,xbmax]`. The vector indicates the first and last bin edges in the *x*-dimension.

This option only bins data that falls within the bin limits inclusively, `X>=xbmin & X<=xbmax`.

**'YBinLimits' — Bin limits in y-dimension**

two-element vector

Bin limits in *y*-dimension, specified as a two-element vector, `[ybmin,ybmax]`. The vector indicates the first and last bin edges in the *y*-dimension.

This option only bins data that falls within the bin limits inclusively, `Y>=ybmin & Y<=ybmax`.

**'Normalization' — Type of normalization**

'count' (default) | 'probability' | 'countdensity' | 'pdf' | 'cumcount' | 'cdf'

Type of normalization, specified as one of the values in the table.

| Value          | Description                                                                                                                                                                             |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'count'        | Default normalization scheme. Each N value is equal to the number of observations in each bin, and <code>sum(N(:))</code> is equal to <code>numel(X)</code> and <code>numel(Y)</code> . |
| 'probability'  | Each N value is equal to the relative number of observations, (Number of observations in bin / Total number of observations), such that <code>sum(N(:))</code> is 1.                    |
| 'countdensity' | Each N value is (Number of observations in bin) / (Area of bin). The sum of the bin volumes, (N value * Area of bin), is equal to <code>numel(X)</code> and <code>numel(Y)</code> .     |

| Value      | Description                                                                                                                                                                                                     |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'pdf'      | Probability density function estimate. Each N value is, (Number of observations in the bin) / (Total number of observations * Area of bin). The sum of the bin volumes, (N value * Area of bin), is equal to 1. |
| 'cumcount' | Each N value is the cumulative number of observations in each bin and all previous bins in both the x and y dimensions. N(end,end) is equal to numel(X) and numel(Y).                                           |
| 'cdf'      | Cumulative density function estimate. Each N value is equal to the cumulative relative number of observations in each bin and all previous bins in both the x and y dimensions. N(end,end) is equal to 1.       |

Example: `[N,Xedges,Yedges] = histcounts2(X,Y,'Normalization','pdf')`  
bins the data using the probability density function estimate for X and Y.

## Output Arguments

### **N** — Bin counts

array

Bin counts, returned as a numeric array.

The bin inclusion scheme for the different numbered bins in N, as well as their relative orientation to the x-axis and y-axis, is

For example, the  $(1, 1)$  bin includes values that fall on the first edge in each dimension, and the last bin in the bottom right includes values that fall on any of its edges.

**Xedges — Bin edges in x-dimension**

vector

Bin edges in  $x$ -dimension, returned as a vector. `Xedges(1)` is the first bin edge in the  $x$ -dimension and `Xedges(end)` is the last bin edge.

**Yedges — Bin edges in y-dimension**

vector

Bin edges in  $y$ -dimension, returned as a vector. `Yedges(1)` is the first bin edge in the  $y$ -dimension and `Yedges(end)` is the last bin edge.

**binX — Bin index in x-dimension**

array

Bin index in  $x$ -dimension, returned as a numeric array of the same size as `X`. Corresponding elements in `binX` and `binY` describe which numbered bin contains the corresponding values in `X` and `Y`. A value of 0 in `binX` or `binY` indicates an element that does not belong to any of the bins (such as a NaN value).

For example, `binX(1)` and `binY(1)` describe the bin placement for the value `[X(1), Y(1)]`.

**binY — Bin index in y-dimension**

array

Bin index in  $y$ -dimension, returned as a numeric array of the same size as  $Y$ . Corresponding elements in `binX` and `binY` describe which numbered bin contains the corresponding values in  $X$  and  $Y$ . A value of `0` in `binX` or `binY` indicates an element that does not belong to any of the bins (such as a NaN value).

For example, `binX(1)` and `binY(1)` describe the bin placement for the value `[X(1),Y(1)]`.

histogram(X,nbins)
histogram(X,edges)
```

```
histogram(C)
histogram(C,Categories)
```

```
histogram(____,Name,Value)
histogram(ax, ____)
h = histogram(____)
```

## Description

`histogram(X)` creates a histogram plot of `X`. The `histogram` function uses an automatic binning algorithm that returns bins with a uniform width, chosen to cover the range of elements in `X` and reveal the underlying shape of the distribution. `histogram` displays the bins as rectangles such that the height of each rectangle indicates the number of elements in the bin.

`histogram(X,nbins)` uses a number of bins specified by the scalar, `nbins`.

`histogram(X,edges)` sorts `X` into bins with the bin edges specified by the vector, `edges`. Each bin includes the left edge, but does not include the right edge, except for the last bin which includes both edges.

`histogram(C)`, where `C` is a categorical array, plots a histogram with a bar for each category in `C`.

`histogram(C,Categories)` plots only the subset of categories specified by `Categories`.

`histogram(___,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments using any of the previous syntaxes. For example, you can specify `'BinWidth'` and a scalar to adjust the width of the bins, or `'Normalization'` with a valid option (`'count'`, `'probability'`, `'countdensity'`, `'pdf'`, `'cumcount'`, or `'cdf'`) to use a different type of normalization.

`histogram(ax,___)` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option `ax` can precede any of the input argument combinations in the previous syntaxes.

`h = histogram(___)` returns a `Histogram` object. Use this to inspect and adjust the properties of the histogram.

## Examples

### Histogram of Vector

Generate 10,000 random numbers and create a histogram. The `histogram` function automatically chooses an appropriate number of bins to cover the range of values in `x` and show the shape of the underlying distribution.

```
x = randn(10000,1);
h = histogram(x)
```

`h =`

Histogram with properties:

```

 Data: [10000x1 double]
 Values: [1x37 double]
 NumBins: 37
 BinEdges: [1x38 double]
 BinWidth: 0.2000
 BinLimits: [-3.8000 3.6000]
 Normalization: 'count'
 FaceColor: 'auto'
 EdgeColor: [0 0 0]
```

Use `GET` to show all properties

When you specify an output argument to the `histogram` function, it returns a histogram object. You can use this object to inspect the properties of the histogram, such as the number of bins or the width of the bins.

Find the number of histogram bins.

```
nbins = h.NumBins
```

```
nbins =
```

```
37
```

## Specify Number of Histogram Bins

Plot a histogram of 1,000 random numbers sorted into 25 equally spaced bins.

```
x = randn(1000,1);
nbins = 25;
h = histogram(x,nbins)
```

h =

Histogram with properties:

```
 Data: [1000x1 double]
 Values: [1x25 double]
 NumBins: 25
 BinEdges: [1x26 double]
 BinWidth: 0.2800
 BinLimits: [-3.4000 3.6000]
Normalization: 'count'
 FaceColor: 'auto'
 EdgeColor: [0 0 0]
```

Use GET to show all properties

Find the bin counts.

```
counts = h.Values
```

```
counts =
```

```
Columns 1 through 13
```

```
1 3 0 6 14 19 31 54 74 80 92 122 104
```

```
Columns 14 through 25
```

```
115 88 80 38 32 21 9 5 5 5 0 2
```

## Change Number of Histogram Bins

Generate 1,000 random numbers and create a histogram.

```
X = randn(1000,1);
h = histogram(X)
```

h =

Histogram with properties:

```
 Data: [1000x1 double]
 Values: [1x23 double]
 NumBins: 23
 BinEdges: [1x24 double]
 BinWidth: 0.3000
 BinLimits: [-3.3000 3.6000]
Normalization: 'count'
 FaceColor: 'auto'
 EdgeColor: [0 0 0]
```

Use GET to show all properties

Use the `morebins` function to coarsely adjust the number of bins.

```
Nbins = morebins(h);
Nbins = morebins(h)
```

```
Nbins =
```

```
29
```

Adjust the bins at a fine grain level by explicitly setting the number of bins.

```
h.NumBins = 31;
```

### Specify Bin Edges of Histogram

Generate 1,000 random numbers and create a histogram. Specify the bin edges as a vector with wide bins on the edges of the histogram to capture the outliers that do not satisfy  $|x| < 2$ . The first vector element is the left edge of the first bin, and the last vector element is the right edge of the last bin.

```
x = randn(1000,1);
edges = [-10 -2:0.25:2 10];
h = histogram(x,edges);
```

Specify the `Normalization` property as `'countdensity'` to flatten out the bins containing the outliers. Now, the *area* of each bin (rather than the height) represents the frequency of observations in that interval.

```
h.Normalization = 'countdensity';
```

### Plot Categorical Histogram

Create a categorical vector that represents votes. The categories in the vector are 'yes', 'no', or 'undecided'.

```
A = [0 0 1 1 1 0 0 0 0 NaN NaN 1 0 0 0 1 0 1 0 1 0 0 0 1 1 1 1];
C = categorical(A,[1 0 NaN],{'yes','no','undecided'})
```

C =

Columns 1 through 9

no no yes yes yes no no no

Columns 10 through 16

undecided      undecided      yes      no      no      no      yes

Columns 17 through 25

no      yes      no      yes      no      no      no      yes      yes

Columns 26 through 27

yes      yes

Plot a categorical histogram of the votes, using a relative bar width of 0.5.

```
h = histogram(C, 'BarWidth', 0.5)
```

h =

Histogram with properties:

```

 Data: [1x27 categorical]
 Values: [11 14 2]
 Categories: {'yes' 'no' 'undecided'}
 Normalization: 'count'
 DisplayStyle: 'bar'
 FaceColor: 'auto'
 EdgeColor: [0 0 0]
```

Use GET to show all properties

### Histogram with Specified Normalization

Generate 1,000 random numbers and create a histogram using the 'probability' normalization.

```
x = randn(1000,1);
h = histogram(x, 'Normalization', 'probability')
```

h =

Histogram with properties:

Data: [1000x1 double]

```

 Values: [1x23 double]
 NumBins: 23
 BinEdges: [1x24 double]
 BinWidth: 0.3000
 BinLimits: [-3.3000 3.6000]
 Normalization: 'probability'
 FaceColor: 'auto'
 EdgeColor: [0 0 0]

```

Use GET to show all properties

Compute the sum of the bar heights. With this normalization, the height of each bar is equal to the probability of selecting an observation within that bin interval, and the height of all of the bars sums to 1.

```
S = sum(h.Values)
```

```
S =
```

```
1
```

## Plot Multiple Histograms

Generate two vectors of random numbers and plot a histogram for each vector in the same figure.

```
x = randn(2000,1);
y = 1 + randn(5000,1);
h1 = histogram(x);
hold on
h2 = histogram(y);
```

Since the sample size and bin width of the histograms are different, it is difficult to compare them. Normalize the histograms so that all of the bar heights add to 1, and use a uniform bin width.

```
h1.Normalization = 'probability';
h1.BinWidth = 0.25;
h2.Normalization = 'probability';
h2.BinWidth = 0.25;
```

### Adjust Histogram Properties

Generate 1,000 random numbers and create a histogram. Return the histogram object to adjust the properties of the histogram without recreating the entire plot.

```
x = randn(1000,1);
h = histogram(x)
```

```
h =
```

```
 Histogram with properties:
```

```
 Data: [1000x1 double]
```

```

 Values: [1x23 double]
 NumBins: 23
 BinEdges: [1x24 double]
 BinWidth: 0.3000
 BinLimits: [-3.3000 3.6000]
 Normalization: 'count'
 FaceColor: 'auto'
 EdgeColor: [0 0 0]

```

Use GET to show all properties

Specify exactly how many bins to use.

```
h.NumBins = 15;
```

Specify the edges of the bins with a vector. The first value in the vector is the left edge of the first bin. The last value is the right edge of the last bin.

```
h.BinEdges = [-3:3];
```

Change the color of the histogram bars.

```
h.FaceColor = [0 0.5 0.5];
h.EdgeColor = 'r';
```

## Determine Underlying Probability Distribution

Generate 5,000 normally distributed random numbers with a mean of 5 and a standard deviation of 2. Plot a histogram with `Normalization` set to `'pdf'` to produce an estimation of the probability density function.

```
x = 2*randn(5000,1) + 5;
histogram(x, 'Normalization', 'pdf')
```

In this example, the underlying distribution for the normally distributed data is known. You can, however, use the 'pdf' histogram plot to determine the underlying probability distribution of the data by comparing it against a known probability density function.

The probability density function for a normal distribution with mean  $\mu$ , standard deviation  $\sigma$ , and variance  $\sigma^2$  is

$$f(x, \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left[-\frac{(x - \mu)^2}{2\sigma^2}\right].$$

Overlay a plot of the probability density function for a normal distribution with a mean of 5 and a standard deviation of 2.

```
hold on
y = -5:0.1:15;
mu = 5;
sigma = 2;
f = exp(-(y-mu).^2./(2*sigma^2))./(sigma*sqrt(2*pi));
plot(y,f,'LineWidth',1.5)
```

- “Plot Categorical Data”

## Input Arguments

**X** — Data to distribute among bins

vector | matrix | multidimensional array

Data to distribute among bins, specified as a vector, matrix, or multidimensional array. If `X` is not a vector, then `histogram` treats it as a single column vector, `X(:)`, and plots a single histogram.

`histogram` ignores all NaN values. Similarly, `histogram` ignores `Inf` and `-Inf` values, unless the bin edges explicitly specify `Inf` or `-Inf` as a bin edge.

---

**Note:** If `X` contains integers of type `int64` or `uint64` that are larger than `flintmax`, then it is recommended that you explicitly specify the histogram bin edges. `histogram` automatically bins the input data using double precision, which lacks integer precision for numbers greater than `flintmax`.

---

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **C** — Categorical data

categorical array

Categorical data, specified as a categorical array. `histogram` ignores undefined categorical values.

Data Types: `categorical`

### **nbins** — Number of bins

positive integer

Number of bins, specified as a positive integer. If you do not specify `nbins`, then `histogram` automatically calculates how many bins to use based on the values in `X`.

Example: `histogram(X, 15)` creates a histogram with 15 bins.

### **edges** — Bin edges

vector

Bin edges, specified as a vector. `edges(1)` is the left edge of the first bin, and `edges(end)` is the right edge of the last bin.

The value `X(i)` is in the `k`th bin if `edges(k) ≤ X(i) < edges(k+1)`. The last bin also includes the right bin edge, so that it contains `X(i)` if `edges(end-1) ≤ X(i) ≤ edges(end)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

## **Categories** — Categories included in histogram

all categories (default) | cell vector of strings | categorical vector

---

**Note:** This option only applies to histograms of categorical data.

---

Categories included in histogram, specified as a cell vector of strings or categorical vector. By default, `histogram` plots a bar for each category in categorical array `C`. Use `Categories` to specify a unique subset of the categories instead.

Example: `h = histogram(C, {'Large', 'Small'})` plots only the categorical data in the categories 'Large' and 'Small'.

Example: `h.Categories` queries the categories that are plotted in histogram object `h`.

Data Types: `cell` | `categorical`

## **ax** — Axes object

axes object

Axes object. If you do not specify an axes, then the `histogram` function uses the current axes (`gca`).

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `histogram(X, 'BinWidth', 5)`

The histogram properties listed here are only a subset. For a complete list, see [Histogram Properties](#).

## **'BarWidth'** — Relative width of categorical bars

0.9 (default) | scalar in range [0, 1]

---

**Note:** This option only applies to histograms of categorical data.

---

Relative width of categorical bars, specified as a scalar value in the range `[0,1]`. Use this property to control the separation of categorical bars within the histogram. The default value is `0.9`, which means that the bar width is 90% of the space from the previous bar to the next bar, with 5% of that space on each side.

If you set this property to `1`, then adjacent bars touch.

Example: `0.5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**'BinLimits' — Bin limits**

two-element vector

Bin limits, specified as a two-element vector, `[bmin,bmax]`. This option plots a histogram using the values in the input array, `X`, that fall between `bmin` and `bmax` inclusive. That is, `X(X>=bmin & X<=bmax)`.

This option does not apply to histograms of categorical data.

Example: `histogram(X, 'BinLimits', [1,10])` plots a histogram using only the values in `X` that are between `1` and `10` inclusive.

**'BinLimitsMode' — Selection mode for bin limits**

`'auto'` (default) | `'manual'`

Selection mode for bin limits, specified as `'auto'` or `'manual'`. The default value is `'auto'`, so that the bin limits automatically adjust to the data.

If you explicitly specify either `BinLimits` or `BinEdges`, then `BinLimitsMode` is automatically set to `'manual'`. In that case, specify `BinLimitsMode` as `'auto'` to rescale the bin limits to the data.

This option does not apply to histograms of categorical data.

**'BinMethod' — Binning algorithm**

`'auto'` (default) | `'scott'` | `'fd'` | `'integers'` | `'sturges'` | `'sqrt'`

Binning algorithm, specified as one of the values in this table.

| Value               | Description                                                                           |
|---------------------|---------------------------------------------------------------------------------------|
| <code>'auto'</code> | The default <code>'auto'</code> algorithm chooses a bin width to cover the data range |

| Value      | Description                                                                                                                                                                                                                                                                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | and reveal the shape of the underlying distribution.                                                                                                                                                                                                                                                                                                                  |
| 'scott'    | Scott's rule is optimal if the data is close to being normally distributed. This rule is appropriate for most other distributions, as well. It uses a bin width of $3.5 * \text{std}(X(:)) * \text{numel}(X)^{-1/3}$ .                                                                                                                                                |
| 'fd'       | The Freedman-Diaconis rule is less sensitive to outliers in the data, and might be more suitable for data with heavy-tailed distributions. It uses a bin width of $2 * \text{IQR}(X(:)) * \text{numel}(X)^{-1/3}$ , where IQR is the interquartile range of X.                                                                                                        |
| 'integers' | The integer rule is useful with integer data, as it creates a bin for each integer. It uses a bin width of 1 and places bin edges halfway between integers. To avoid accidentally creating too many bins, you can use this rule to create a limit of 65536 bins ( $2^{16}$ ). If the data range is greater than 65536, then the integer rule uses wider bins instead. |
| 'sturges'  | Sturges' rule is popular due to its simplicity. It chooses the number of bins to be $\text{ceil}(1 + \log_2(\text{numel}(X)))$ .                                                                                                                                                                                                                                      |
| 'sqrt'     | The Square Root rule is widely used in other software packages. It chooses the number of bins to be $\text{ceil}(\text{sqrt}(\text{numel}(X)))$ .                                                                                                                                                                                                                     |

This option does not apply to histograms of categorical data.

---

**Note:** If you set the BinLimits, NumBins, BinEdges, or BinWidth property, then the BinMethod property is set to 'manual'.

---

Example: `histogram(X, 'BinMethod', 'integers')` creates a histogram with the bins centered on integers.

### **'BinWidth' — Width of bins**

scalar

Width of bins, specified as a scalar. When you specify `BinWidth`, then `histogram` can use a maximum of 65,536 bins (or  $2^{16}$ ). If instead the specified bin width requires more bins, then `histogram` uses a larger bin width corresponding to the maximum number of bins.

This option does not apply to histograms of categorical data.

Example: `histogram(X, 'BinWidth', 5)` uses bins with a width of 5.

### **'DisplayStyle' — Histogram display style**

'bar' (default) | 'stairs'

Histogram display style, specified as either 'bar' or 'stairs'. Specify 'stairs' to display a staircase plot, which displays the outline of the histogram without filling the interior.

The default value of 'bar' displays a histogram bar plot.

Example: `histogram(X, 'DisplayStyle', 'stairs')` plots the outline of the histogram.

### **'EdgeAlpha' — Transparency of histogram bar edges**

1 (default) | scalar value between 0 and 1 inclusive

Transparency of histogram bar edges, specified as a scalar value between 0 and 1 inclusive. A value of 1 means fully opaque and 0 means completely transparent (invisible).

Example: `histogram(X, 'EdgeAlpha', 0.5)` creates a histogram plot with semi-transparent bar edges.

### **'EdgeColor' — Histogram edge color**

[0 0 0] or black (default) | 'none' | 'auto' | RGB triplet or color string

Histogram edge color, specified as one of these values:

- 'none' — Edges are not drawn.

- 'auto' — Color of each edge is chosen automatically.
- RGB triplet or a color string — Edges use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: `histogram(X, 'EdgeColor', 'r')` creates a histogram plot with red bar edges.

#### 'FaceAlpha' — Transparency of histogram bars

0.6 (default) | scalar value between 0 and 1 inclusive

Transparency of histogram bars, specified as a scalar value between 0 and 1 inclusive. `histogram` uses the same transparency for all the bars of the histogram. A value of 1 means fully opaque and 0 means completely transparent (invisible).

Example: `histogram(X, 'FaceAlpha', 1)` creates a histogram plot with fully opaque bars.

#### 'FaceColor' — Histogram bar color

'auto' (default) | 'none' | RGB triplet or color string

Histogram bar color, specified as one of these values:

- 'none' — Bars are not filled.
- 'auto' — Histogram bar color is chosen automatically (default).

- RGB triplet or a color string — Bars are filled with the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

If you specify `DisplayStyle` as 'stairs', then `histogram` does not use the `FaceColor` property.

Example: `histogram(X, 'FaceColor', 'g')` creates a histogram plot with green bars.

### 'LineStyle' — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                       |
|--------|------------------|--------------------------------------------------------------------------------------|
| '-'    | Solid line       |  |
| '--'   | Dashed line      |  |
| ':'    | Dotted line      |  |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                              |

**'LineWidth' — Width of bar outlines**

0.5 (default) | positive value

Width of bar outlines, specified as a positive value in point units. One point equals 1/72 inch.

Example: 1.5

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**'Normalization' — Type of normalization**

'count' (default) | 'probability' | 'countdensity' | 'pdf' | 'cumcount' | 'cdf'

Type of normalization, specified as one of the values in this table.

| Value          | Description                                                                                                                                                                                                                                                                                                                                          |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'count'        | <p>Default normalization scheme. The height of each bar is the number of observations in each bin. The sum of the bar heights is <code>numel(X)</code>.</p> <p>For categorical histograms, the sum of the bar heights is either <code>numel(X)</code> or <code>sum(ismember(X(:),Categories))</code>.</p>                                            |
| 'probability'  | <p>The height of each bar is the relative number of observations, (number of observations in bin / total number of observations). The sum of the bar heights is 1.</p> <p>For categorical histograms, the height of each bar is, (number of elements in category / total number of elements in all categories). The sum of the bar heights is 1.</p> |
| 'countdensity' | <p>The height of each bar is, (number of observations in bin / width of bin). The area (height * width) of each bar is the number of observations in the bin. The sum of the bar areas is <code>numel(X)</code>.</p>                                                                                                                                 |

| Value      | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | For categorical histograms, this is the same as 'count'.                                                                                                                                                                                                                                                                                                                                                                 |
| 'pdf'      | <p>Probability density function estimate. The height of each bar is, (number of observations in the bin) / (total number of observations * width of bin). The area of each bar is the relative number of observations. The sum of the bar areas is 1.</p> <p>For categorical histograms, this is the same as 'probability'.</p>                                                                                          |
| 'cumcount' | <p>The height of each bar is the cumulative number of observations in each bin and all previous bins. The height of the last bar is <code>numel(X)</code>.</p> <p>For categorical histograms, the height of each bar is equal to the cumulative number of elements in each category and all previous categories. The height of the last bar is <code>numel(X)</code> or <code>sum(ismember(X(:),Categories))</code>.</p> |
| 'cdf'      | <p>Cumulative density function estimate. The height of each bar is equal to the cumulative relative number of observations in the bin and all previous bins. The height of the last bar is 1.</p> <p>For categorical data, the height of each bar is equal to the cumulative relative number of observations in each category and all previous categories. The height of the last bar is 1.</p>                          |

Example: `histogram(X, 'Normalization', 'pdf')` plots an estimate of the probability density function for X.

## 'Orientation' — Orientation of bars

'vertical' (default) | 'horizontal'

Orientation of bars, specified as 'vertical' or 'horizontal'.

Example: `histogram(X, 'Orientation', 'horizontal')` creates a histogram plot with horizontal bars.

## Output Arguments

### **h** — Histogram

object

Histogram, returned as an object. For more information, see [Using histogram Objects](#).

## More About

### Tips

- Histogram plots created using `histogram` have a context menu in plot edit mode that enables interactive manipulations in the figure window. For example, you can use the context menu to interactively change the number of bins, align multiple histograms, or change the display order.

# Using histogram Objects

Histogram bar plot for numeric data

## Description

Histograms are a type of bar plot for numeric data that group the data into bins. After you create a histogram object, you can modify aspects of the histogram by changing its property values. This is particularly useful for quickly modifying the properties of the bins or changing the display.

## Examples

### Adjust Properties of Histogram Object

This example creates a histogram object, and then shows how to adjust the properties of the histogram to affect the output display.

Create a histogram for all of the prime numbers less than 10,000,000. Specify an output argument to return the histogram object, h.

```
x = primes(1e7);
h = histogram(x)
```

h =

Histogram with properties:

```
 Data: [1x664579 double]
 Values: [1x100 double]
 NumBins: 100
 BinEdges: [1x101 double]
 BinWidth: 100000
 BinLimits: [0 10000000]
Normalization: 'count'
 FaceColor: 'auto'
 EdgeColor: [0 0 0]
```

Use GET to show all properties

Change the normalization of the histogram by setting the `Normalization` property to `'probability'`.

```
h.Normalization = 'probability';
```

Use horizontal bars for the histogram.

```
h.Orientation = 'horizontal';
```

Zoom in to a specific range of bins. When you set `BinLimits`, the `BinLimitsMode` automatically changes to 'manual'.

```
h.BinLimits = [1e6,2e6];
```

Zoom back out to the original bin scaling by switching `BinLimitsMode` back to `'auto'`.

```
h.BinLimitsMode = 'auto';
```

Change the number of bins in the histogram.

```
h.NumBins = 200;
```

Create a vertical stair histogram.

```
h.Orientation = 'vertical';
h.DisplayStyle = 'stairs';
```

## Saving and Loading Histogram Objects

Use the `savefig` function to save a histogram figure.

```
y = histogram(randn(10));
savefig('histogram.fig');
clear all
close all
```

Use `openfig` to load the histogram figure back into MATLAB. `openfig` also returns a handle to the figure, `h`.

```
h = openfig('histogram.fig');
```

Use the `findobj` function to locate the correct object handle from the figure handle. This allows you to continue manipulating the original histogram object used to generate the figure.

```
y = findobj(h, 'type', 'histogram')
```

```
y =
```

```
 Histogram with properties:
```

```
 Data: [10x10 double]
 Values: [2 17 28 32 16 3 2]
 NumBins: 7
```

```
BinEdges: [-3 -2 -1 0 1 2 3 4]
BinWidth: 1
BinLimits: [-3 4]
Normalization: 'count'
FaceColor: 'auto'
EdgeColor: [0 0 0]
```

Use GET to show all properties

## Properties

## More About

- Histogram Properties

**Introduced in R2014b**

# Histogram Properties

Control histogram appearance and behavior

Histogram properties control the appearance and behavior of the histogram. By changing property values, you can modify aspects of the histogram. Use dot notation to refer to a particular object and property:

```
h = histogram(randn(10,1));
c = h.BinWidth;
h.BinWidth = 2;
```

## Bins

### **BarWidth** — Relative width of categorical bars

0.9 (default) | scalar in range [0,1]

---

**Note:** This option only applies to histograms of categorical data.

---

Relative width of categorical bars, specified as a scalar value in the range [0,1]. Use this property to control the separation of categorical bars within the histogram. The default value is **0.9**, which means that the bar width is 90% of the space from the previous bar to the next bar, with 5% of that space on each side.

If you set this property to 1, then adjacent bars touch.

Example: 0.5

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **BinEdges** — Edges of bins

numeric vector

Edges of bins, specified as a numeric vector. The first vector element specifies the left edge of the first bin. The last element specifies the right edge of the last bin. If you do not specify the bin edges, then `histogram` automatically determines the location of the bin edges.

This option does not apply to histograms of categorical data.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**BinLimits — Bin limits**

two-element vector

Bin limits, specified as a two-element vector, `[bmin,bmax]`. This option plots a histogram using the values in the input array, `X`, that fall between `bmin` and `bmax` inclusive. That is, `X(X>=bmin & X<=bmax)`.

This option does not apply to histograms of categorical data.

Example: `histogram(X, 'BinLimits', [1,10])` plots a histogram using only the values in `X` that are between 1 and 10 inclusive.

**BinLimitsMode — Selection mode for bin limits**

'auto' (default) | 'manual'

Selection mode for bin limits, specified as 'auto' or 'manual'. The default value is 'auto', so that the bin limits automatically adjust to the data.

If you explicitly specify either `BinLimits` or `BinEdges`, then `BinLimitsMode` is automatically set to 'manual'. In that case, specify `BinLimitsMode` as 'auto' to rescale the bin limits to the data.

This option does not apply to histograms of categorical data.

**BinMethod — Binning algorithm**

'auto' (default) | 'scott' | 'fd' | 'integers' | 'sturges' | 'sqrt'

Binning algorithm, specified as one of the values in this table.

| Value   | Description                                                                                                                                                                                                                    |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'auto'  | The default 'auto' algorithm chooses a bin width to cover the data range and reveal the shape of the underlying distribution.                                                                                                  |
| 'scott' | Scott's rule is optimal if the data is close to being normally distributed. This rule is appropriate for most other distributions, as well. It uses a bin width of $3.5 \cdot \text{std}(X(:)) \cdot \text{numel}(X)^{-1/3}$ . |

| Value      | Description                                                                                                                                                                                                                                                                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'fd'       | The Freedman-Diaconis rule is less sensitive to outliers in the data, and might be more suitable for data with heavy-tailed distributions. It uses a bin width of $2 * \text{IQR}(X(:)) * \text{numel}(X)^{-1/3}$ , where IQR is the interquartile range of X.                                                                                                        |
| 'integers' | The integer rule is useful with integer data, as it creates a bin for each integer. It uses a bin width of 1 and places bin edges halfway between integers. To avoid accidentally creating too many bins, you can use this rule to create a limit of 65536 bins ( $2^{16}$ ). If the data range is greater than 65536, then the integer rule uses wider bins instead. |
| 'sturges'  | Sturges' rule is popular due to its simplicity. It chooses the number of bins to be $\text{ceil}(1 + \log_2(\text{numel}(X)))$ .                                                                                                                                                                                                                                      |
| 'sqrt'     | The Square Root rule is widely used in other software packages. It chooses the number of bins to be $\text{ceil}(\text{sqrt}(\text{numel}(X)))$ .                                                                                                                                                                                                                     |

This option does not apply to histograms of categorical data.

---

**Note:** If you set the `BinLimits`, `NumBins`, `BinEdges`, or `BinWidth` property, then the `BinMethod` property is set to `'manual'`.

---

Example: `histogram(X, 'BinMethod', 'integers')` creates a histogram with the bins centered on integers.

### **BinWidth** — Width of bins

scalar

Width of bins, specified as a scalar. When you specify `BinWidth`, then `histogram` can use a maximum of 65,536 bins (or  $2^{16}$ ). If instead the specified bin width requires more

bins, then `histogram` uses a larger bin width corresponding to the maximum number of bins.

This option does not apply to histograms of categorical data.

Example: `histogram(X, 'BinWidth', 5)` uses bins with a width of 5.

### **Categories** — Categories included in histogram

all categories (default) | cell vector of strings | categorical vector

---

**Note:** This option only applies to histograms of categorical data.

---

Categories included in histogram, specified as a cell vector of strings or categorical vector. By default, `histogram` plots a bar for each category in categorical array `C`. Use `Categories` to specify a unique subset of the categories instead.

Example: `h = histogram(C, {'Large', 'Small'})` plots only the categorical data in the categories 'Large' and 'Small'.

Example: `h.Categories` queries the categories that are plotted in histogram object `h`.

Data Types: `cell` | `categorical`

### **EdgeAlpha** — Transparency of histogram bar edges

1 (default) | scalar value between 0 and 1 inclusive

Transparency of histogram bar edges, specified as a scalar value between 0 and 1 inclusive. A value of 1 means fully opaque and 0 means completely transparent (invisible).

Example: `histogram(X, 'EdgeAlpha', 0.5)` creates a histogram plot with semi-transparent bar edges.

### **EdgeColor** — Histogram edge color

[0 0 0] or black (default) | 'none' | 'auto' | RGB triplet or color string

Histogram edge color, specified as one of these values:

- 'none' — Edges are not drawn.
- 'auto' — The color of each edge is chosen automatically.
- RGB triplet or a color string — Edges use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: `histogram(X, 'EdgeColor', 'r')` creates a histogram plot with red bar edges.

### FaceAlpha — Transparency of histogram bars

0.6 (default) | scalar value between 0 and 1 inclusive

Transparency of histogram bars, specified as a scalar value between 0 and 1 inclusive. `histogram` uses the same transparency for all the bars of the histogram. A value of 1 means fully opaque and 0 means completely transparent (invisible).

Example: `histogram(X, 'FaceAlpha', 1)` creates a histogram plot with fully opaque bars.

### FaceColor — Histogram bar color

'auto' (default) | 'none' | RGB triplet or color string

Histogram bar color, specified as one of these values:

- 'none' — Bars are not filled.
- 'auto' — The histogram bar color is chosen automatically (default).
- RGB triplet or a color string — Bars are filled with the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

If you specify `DisplayStyle` as 'stairs', then `histogram` does not utilize the `FaceColor` property.

Example: `histogram(X, 'FaceColor', 'g')` creates a histogram plot with green bars.

**LineStyle — Line style**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                       |
|--------|------------------|--------------------------------------------------------------------------------------|
| '-'    | Solid line       |  |
| '--'   | Dashed line      |  |
| ':'    | Dotted line      |  |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                              |

**LineWidth — Width of bar outlines**

0.5 (default) | positive value

Width of bar outlines, specified as a positive value in point units. One point equals 1/72 inch.

Example: 1.5

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Normalization — Type of normalization**

'count' (default) | 'probability' | 'countdensity' | 'pdf' | 'cumcount' | 'cdf'

Type of normalization, specified as one of the values in this table.

| Value          | Description                                                                                                                                                                                                                                                                                                                                          |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'count'        | <p>Default normalization scheme. The height of each bar is the number of observations in each bin. The sum of the bar heights is <code>numel(X)</code>.</p> <p>For categorical histograms, the sum of the bar heights is either <code>numel(X)</code> or <code>sum(ismember(X(:),Categories))</code>.</p>                                            |
| 'probability'  | <p>The height of each bar is the relative number of observations, (number of observations in bin / total number of observations). The sum of the bar heights is 1.</p> <p>For categorical histograms, the height of each bar is, (number of elements in category / total number of elements in all categories). The sum of the bar heights is 1.</p> |
| 'countdensity' | <p>The height of each bar is, (number of observations in bin / width of bin). The area (height * width) of each bar is the number of observations in the bin. The sum of the bar areas is <code>numel(X)</code>.</p>                                                                                                                                 |

| Value      | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | For categorical histograms, this is the same as 'count'.                                                                                                                                                                                                                                                                                                                                                                 |
| 'pdf'      | <p>Probability density function estimate. The height of each bar is, (number of observations in the bin) / (total number of observations * width of bin). The area of each bar is the relative number of observations. The sum of the bar areas is 1.</p> <p>For categorical histograms, this is the same as 'probability'.</p>                                                                                          |
| 'cumcount' | <p>The height of each bar is the cumulative number of observations in each bin and all previous bins. The height of the last bar is <code>numel(X)</code>.</p> <p>For categorical histograms, the height of each bar is equal to the cumulative number of elements in each category and all previous categories. The height of the last bar is <code>numel(X)</code> or <code>sum(ismember(X(:),Categories))</code>.</p> |
| 'cdf'      | <p>Cumulative density function estimate. The height of each bar is equal to the cumulative relative number of observations in the bin and all previous bins. The height of the last bar is 1.</p> <p>For categorical data, the height of each bar is equal to the cumulative relative number of observations in each category and all previous categories. The height of the last bar is 1.</p>                          |

Example: `histogram(X, 'Normalization', 'pdf')` plots an estimate of the probability density function for X.

**NumBins — Number of bins**

positive integer

Number of bins, specified as a positive integer. If you do not specify `NumBins`, then `histogram` automatically calculates how many bins to use based on the values in `Data`.

This option does not apply to histograms of categorical data.

**Data****Data — Data to distribute among bins**

vector | matrix | multidimensional array | categorical array

Data to distribute among bins, specified as a vector, matrix, multidimensional array, or categorical array. If `Data` is not a vector, then `histogram` treats it as a single column vector, `Data(:)`, and plots a single histogram.

`histogram` ignores all NaN and undefined categorical values. Similarly, `histogram` ignores Inf and -Inf values unless the bin edges explicitly specify Inf or -Inf as a bin edge.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | categorical

**Values — Bin values**

numeric vector

This property is read only.

Bin values, returned as a numeric vector. If `Normalization` is 'count' (the default), then the *k*th element in `Values` specifies how many elements of `Data` fall in the *k*th bin interval (bin counts). The last bin includes values that are on *either* bin edge, but all other bins only include values that fall on the left edge.

Depending on the value of `Normalization`, the `Values` property can instead contain a normalized variant of the bin counts.

**Histogram Type****DisplayStyle — Histogram display style**

'bar' (default) | 'stairs'

Histogram display style, specified as either `'bar'` or `'stairs'`. Specify `'stairs'` to display a staircase plot, which displays the outline of the histogram without filling the interior.

The default value of `'bar'` displays a histogram bar plot.

Example: `histogram(X, 'DisplayStyle', 'stairs')` plots the outline of the histogram.

### **Orientation — Orientation of bars**

`'vertical'` (default) | `'horizontal'`

Orientation of bars, specified as `'vertical'` or `'horizontal'`.

Example: `histogram(X, 'Orientation', 'horizontal')` creates a histogram plot with horizontal bars.

## **Visibility**

### **Visible — State of visibility**

`'on'` (default) | `'off'`

State of visibility, specified as one of these values:

- `'on'` — Display the histogram.
- `'off'` — Hide the histogram without deleting it. You still can access the properties of an invisible histogram object.

## **Identifiers**

### **Type — Type of graphics object**

`'histogram'` | `'categoricalhistogram'`

This property is read only.

Type of graphics object, returned as either `'histogram'` or `'categoricalhistogram'`. Use this property to find all objects of a given type within a plotting hierarchy, such as searching for the type using `findobj`.

### **Tag — Tag to associate with histogram**

`''` (default) | string

Tag to associate with the histogram, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

Data Types: char

### **UserData** — Data to associate with histogram

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the histogram object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: 1:100

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | table | cell

### **DisplayName** — Text used by legend

'' (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the histogram.

Example: 'Text Description'

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where N is the number assigned to the histogram object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

## **Annotation — Legend icon display style**

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the histogram from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - 'on' — Include the histogram object in the legend as one entry (default).
  - 'off' — Do not include the histogram object in the legend.
  - 'children' — Include only children of the histogram object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## **Parent/Child**

### **Parent — Parent of histogram**

axes object | group object | transform object

Parent of histogram, specified as an axes, group, or transform object.

### **Children — Children of histogram**

empty `GraphicsPlaceholder` array

The histogram has no children. You cannot set this property.

### **HandleVisibility — Visibility of object handle**

'on' (default) | 'off' | 'callback'

Visibility of histogram object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The histogram object handle is always visible.
- `'off'` — The histogram object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The histogram object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the histogram at the command-line, but allows callback functions to access it.

If the histogram object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### **ButtonDownFcn** — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the histogram. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The histogram object — You can access properties of the histogram object from within the callback function.

- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

## **UIContextMenu — Context menu**

uicontextmenu object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the histogram. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

## **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the histogram when in plot edit mode, then MATLAB sets its `Selected` property to 'on'. If the `SelectionHighlight` property also is set to 'on', then MATLAB displays selection handles around the histogram.
- 'off' — Not selected.

## **SelectionHighlight — Display of selection handles when selected**

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the `Selected` property is set to 'on'.

- `'off'` — Never display selection handles, even when the `Selected` property is set to `'on'`.

## Callback Execution Control

### **PickableParts** — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks only when visible. The `Visible` property must be set to `'on'`. The `HitTest` property determines if the histogram responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the histogram passes the click to the object below it in the current view of the figure window. The `HitTest` property of the histogram has no effect.

### **HitTest** — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the `ButtonDownFcn` callback of the histogram. If you have defined the `UIContextMenu` property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the histogram that has a `HitTest` property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the histogram object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **Interruptible** — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The **Interruptible** property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the **BusyAction** property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the histogram is the running callback, then the **Interruptible** property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The **BusyAction** property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The **Interruptible** property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the

**BusyAction** property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the **ButtonDownFcn** callback of the histogram tries to interrupt a running callback that cannot be interrupted, then the **BusyAction** property determines if it is discarded or put in the queue. Specify the **BusyAction** property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the histogram. Setting the **CreateFcn** property on an existing histogram has no effect. You must define a default value for this property, or define this property using a **Name, Value** pair during histogram creation. MATLAB executes the callback after creating the histogram and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The histogram object — You can access properties of the histogram object from within the callback function. You also can access the histogram object through the **CallbackObject** property of the root, which can be queried using the **gcb0** function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### **DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the histogram. MATLAB executes the callback before destroying the histogram so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The histogram object — You can access properties of the histogram object from within the callback function. You also can access the histogram object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### **BeingDeleted — Deletion status of histogram**

'off' (default) | 'on'

This property is read only.

Deletion status of histogram, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the histogram begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the histogram no longer exists.

Check the value of the `BeingDeleted` property to verify that the histogram is not about to be deleted before querying or modifying it.

# histogram2

Bivariate histogram plot

## Syntax

```
histogram2(X,Y)
histogram2(X,Y,nbins)
histogram2(X,Y,Xedges,Yedges)
histogram2(____,Name,Value)
histogram2(ax, ____)
h = histogram2(____)
```

## Description

`histogram2(X,Y)` creates a bivariate histogram plot of `X` and `Y`. The `histogram2` function uses an automatic binning algorithm that returns bins with a uniform area, chosen to cover the range of elements in `X` and `Y` and reveal the underlying shape of the distribution. `histogram2` displays the bins as 3-D rectangular bars such that the height of each bar indicates the number of elements in the bin.

`histogram2(X,Y,nbins)` specifies the number of bins to use in each dimension of the histogram.

`histogram2(X,Y,Xedges,Yedges)` specifies the edges of the bins in each dimension using the vectors `Xedges` and `Yedges`.

`histogram2( ____,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments using any of the previous syntaxes. For example, you can specify `'BinWidth'` and a two-element vector to adjust the width of the bins in each dimension, or `'Normalization'` with a valid option (`'count'`, `'probability'`, `'countdensity'`, `'pdf'`, `'cumcount'`, or `'cdf'`) to use a different type of normalization.

`histogram2(ax, ____)` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option `ax` can precede any of the input argument combinations in the previous syntaxes.

`h = histogram2( ___ )` returns a `Histogram2` object. Use this to inspect and adjust properties of the bivariate histogram.

## Examples

### Histogram of Vectors

Generate 10,000 pairs of random numbers and create a bivariate histogram. The `histogram2` function automatically chooses an appropriate number of bins to cover the range of values in `x` and `y` and show the shape of the underlying distribution.

```
x = randn(10000,1);
y = randn(10000,1);
h = histogram2(x,y)
xlabel('x')
ylabel('y')
```

`h =`

Histogram2 with properties:

```
 Data: [10000x2 double]
 Values: [25x28 double]
 NumBins: [25 28]
 XBinEdges: [1x26 double]
 YBinEdges: [1x29 double]
 BinWidth: [0.3000 0.3000]
Normalization: 'count'
 FaceColor: 'auto'
 EdgeColor: [0.1500 0.1500 0.1500]
```

Use `GET` to show all properties

When you specify an output argument to the `histogram2` function, it returns a `histogram2` object. You can use this object to inspect the properties of the histogram, such as the number of bins or the width of the bins.

Find the number of histogram bins in each dimension.

```
nXnY = h.NumBins
```

```
nXnY =
```

```
 25 28
```

### Specify Number of Histogram Bins

Plot a bivariate histogram of 1,000 pairs of random numbers sorted into 25 equally spaced bins, using 5 bins in each dimension.

```
x = randn(1000,1);
y = randn(1000,1);
nbins = 5;
h = histogram2(x,y,nbins)
```

h =

Histogram2 with properties:

```
 Data: [1000x2 double]
 Values: [5x5 double]
 NumBins: [5 5]
 XBinEdges: [-4 -2.4000 -0.8000 0.8000 2.4000 4]
 YBinEdges: [-4 -2.4000 -0.8000 0.8000 2.4000 4]
 BinWidth: [1.6000 1.6000]
Normalization: 'count'
 FaceColor: 'auto'
 EdgeColor: [0.1500 0.1500 0.1500]
```

Use GET to show all properties

Find the resulting bin counts.

```
counts = h.Values
```

```
counts =
```

```
0 2 3 1 0
2 40 124 47 4
1 119 341 109 10
1 32 117 33 1
0 4 8 1 0
```

## Adjust Number of Histogram Bins

Generate 1,000 pairs of random numbers and create a bivariate histogram.

```
x = randn(1000,1);
y = randn(1000,1);
h = histogram2(x,y)
```

h =

Histogram2 with properties:

```
 Data: [1000x2 double]
 Values: [15x15 double]
 NumBins: [15 15]
 XBinEdges: [1x16 double]
 YBinEdges: [1x16 double]
 BinWidth: [0.5000 0.5000]
Normalization: 'count'
 FaceColor: 'auto'
 EdgeColor: [0.1500 0.1500 0.1500]
```

Use GET to show all properties

Use the `morebins` function to coarsely adjust the number of bins in the  $x$  dimension.

```
nbins = morebins(h, 'x');
nbins = morebins(h, 'x')
```

```
nbins =
 19 15
```

Use the `fewerbins` function to adjust the number of bins in the `y` dimension.

```
nbins = fewerbins(h, 'y');
nbins = fewerbins(h, 'y')
```

```
nbins =
```

```
19 11
```

Adjust the number of bins at a fine grain level by explicitly setting the number of bins.

```
h.NumBins = [20 10];
```

### Color Histogram Bars by Height

Create a bivariate histogram using 1,000 normally distributed random numbers with 12 bins in each dimension. Specify `FaceColor` as `'flat'` to color the histogram bars by height.

```
h = histogram2(randn(1000,1),randn(1000,1),[12 12], 'FaceColor', 'flat');
colorbar
```

### Tiled Histogram View

Generate random data and plot a bivariate tiled histogram. Display the empty bins by specifying `ShowEmptyBins` as `'on'`.

```
x = 2*randn(1000,1)+2;
y = 5*randn(1000,1)+3;
h = histogram2(x,y,'DisplayStyle','tile','ShowEmptyBins','on');
```

### Specify Bin Edges of Histogram

Generate 1,000 pairs of random numbers and create a bivariate histogram. Specify the bin edges using two vectors, with infinitely wide bins on the boundary of the histogram to capture all outliers that do not satisfy  $|x| < 2$ .

```
x = randn(1000,1);
y = randn(1000,1);
Xedges = [-Inf -2:0.4:2 Inf];
Yedges = [-Inf -2:0.4:2 Inf];
h = histogram2(x,y,Xedges,Yedges)
```

h =

Histogram2 with properties:

```
 Data: [1000x2 double]
 Values: [12x12 double]
 NumBins: [12 12]
 XBinEdges: [1x13 double]
 YBinEdges: [1x13 double]
 BinWidth: 'nonuniform'
Normalization: 'count'
 FaceColor: 'auto'
 EdgeColor: [0.1500 0.1500 0.1500]
```

Use GET to show all properties

When the bin edges are infinite, `histogram2` displays each outlier bin (along the boundary of the histogram) as being double the width of the bin next to it.

Specify the `Normalization` property as `'countdensity'` to remove the bins containing the outliers. Now the *volume* of each bin represents the frequency of observations in that interval.

```
h.Normalization = 'countdensity';
```

### Normalized Histogram

Generate 1,000 pairs of random numbers and create a bivariate histogram using the 'probability' normalization.

```
x = randn(1000,1);
y = randn(1000,1);
h = histogram2(x,y,'Normalization','probability')
```

h =

Histogram2 with properties:

```

 Data: [1000x2 double]
 Values: [15x15 double]
 NumBins: [15 15]
 XBinEdges: [1x16 double]
 YBinEdges: [1x16 double]
 BinWidth: [0.5000 0.5000]
 Normalization: 'probability'
 FaceColor: 'auto'
 EdgeColor: [0.1500 0.1500 0.1500]

```

Use GET to show all properties

Compute the total sum of the bar heights. With this normalization, the height of each bar is equal to the probability of selecting an observation within that bin interval, and the heights of all of the bars sum to 1.

```
S = sum(h.Values(:))
```

```
S =
```

```
1.0000
```

## Adjust Histogram Properties

Generate 1,000 pairs of random numbers and create a bivariate histogram. Return the histogram object to adjust the properties of the histogram without recreating the entire plot.

```
x = randn(1000,1);
y = randn(1000,1);
h = histogram2(x,y)
```

```
h =
```

```
Histogram2 with properties:
```

```
 Data: [1000x2 double]
 Values: [15x15 double]
 NumBins: [15 15]
 XBinEdges: [1x16 double]
 YBinEdges: [1x16 double]
 BinWidth: [0.5000 0.5000]
Normalization: 'count'
 FaceColor: 'auto'
 EdgeColor: [0.1500 0.1500 0.1500]
```

```
Use GET to show all properties
```

Color the histogram bars by height.

```
h.FaceColor = 'flat';
```

Change the number of bins in each direction.

```
h.NumBins = [10 25];
```

Display the histogram as a tile plot.

```
h.DisplayStyle = 'tile';
view(2)
```

### Color Analysis with 2-D Histogram

Note: This example uses the `rgb2lab` function from Image Processing Toolbox™.

The  $L^*a^*b^*$  color space is an effective way to separate the color information, represented by the  $a^*$  and  $b^*$  values, from the brightness information, represented by the  $L^*$  values. In the  $a^* - b^*$  plane:

- When  $b^*$  is close to zero, then the colors range from green (for large negative values of  $a^*$ ) to red (for large positive values of  $a^*$ ).
- When  $a^*$  is close to zero, then the colors range from blue (for large negative values of  $b^*$ ) to yellow (for large positive values of  $b^*$ ).
- Colors far from the  $a^* - b^*$  origin are highly saturated.

- Colors close to the  $a^* - b^*$  origin are unsaturated.
- Colors exactly on the  $a^* - b^*$  origin ( $a^* = b^* = 0$ ) are neutral gray.

By plotting a 2-D histogram of  $a^*$  and  $b^*$ , it is possible to visualize the distribution of colors in an image.

Load the image `peppers.png`, which is a color photo of several types of peppers and other vegetables

```
rgb = imread('peppers.png');
imshow(rgb)
```

Use `rgb2lab` to convert the image into the L\*a\*b\* color space. Plot a bivariate histogram of `a` and `b` to visualize the color distribution.

```
Lab = rgb2lab(rgb);
a = Lab(:,:,2);
b = Lab(:,:,3);
h = histogram2(a,b,'DisplayStyle','tile','ShowEmptyBins','on', ...
 'XBinLimits',[-90 90],'YBinLimits',[-90 90]);
axis equal
colorbar
xlabel('a*')
ylabel('b*')
```

The histogram indicates that the image is dominated by one color component, which is the purple-pink background color. Because of this dominance, the rest of the color components are being squeezed towards the blue end of the color scale, and are not very visible.

To view the less dominant color components, rescale the histogram by setting the `CLim` property of the axes to have a range between 0 and 500. The result is that the histogram bins whose count is 500 or greater all saturate and display as yellow.

```
ax = gca;
ax.CLim = [0 500];
```

With the scaled histogram, it is easier to see some of the less dominant color components:

- 1 The color components on the left are from the red peppers.
- 2 The color components on the right are from the green peppers.
- 3 The color components near the top are from the yellow peppers.

## Input Arguments

### **X, Y — Data to distribute among bins (as separate arguments)**

vectors | matrices | multidimensional arrays

Data to distribute among bins, specified as separate arguments of vectors, matrices, or multidimensional arrays. *X* and *Y* must be the same size. If *X* and *Y* are not vectors, then `histogram2` treats them as single column vectors, `X(:)` and `Y(:)`, and plots a single histogram.

Corresponding elements in *X* and *Y* specify the *x* and *y* coordinates of 2-D data points, `[X(k), Y(k)]`. The data types of *X* and *Y* can be different.

`histogram2` ignores all NaN values. Similarly, `histogram2` ignores `Inf` and `-Inf` values, unless the bin edges explicitly specify `Inf` or `-Inf` as a bin edge.

---

**Note:** If *X* or *Y* contain integers of type `int64` or `uint64` that are larger than `flintmax`, then it is recommended that you explicitly specify the histogram bin edges. `histogram2` automatically bins the input data using double precision, which lacks integer precision for numbers greater than `flintmax`.

---

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **nbins — Number of bins in each dimension**

scalar | vector

Number of bins in each dimension, specified as a positive scalar integer or two-element vector of positive integers. If you do not specify `nbins`, then `histogram2` automatically calculates how many bins to use based on the values in *X* and *Y*.

- If `nbins` is a scalar, then `histogram2` uses that many bins in each dimension.
- If `nbins` is a vector, then `nbins(1)` specifies the number of bins in the *x*-dimension and `nbins(2)` specifies the number of bins in the *y*-dimension.

Example: `histogram2(X,Y,20)` uses 20 bins in each dimension.

Example: `histogram2(X,Y,[10 20])` uses 10 bins in the x-dimension and 20 bins in the y-dimension.

### **Xedges — Bin edges in x-dimension**

vector

Bin edges in x-dimension, specified as a vector. `Xedges(1)` is the first edge of the first bin in the x-dimension, and `Xedges(end)` is the outer edge of the last bin.

The value `[X(k),Y(k)]` is in the `(i,j)`th bin if `Xedges(i) ≤ X(k) < Xedges(i+1)` **and** `Yedges(j) ≤ Y(k) < Yedges(j+1)`. The last bins in each dimension also include the last (outer) edge. For example, `[X(k),Y(k)]` falls into the `i`th bin in the last row if `Xedges(end-1) ≤ X(k) ≤ Xedges(end)` **and** `Yedges(i) ≤ Y(k) < Yedges(i+1)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **Yedges — Bin edges in y-dimension**

vector

Bin edges in y-dimension, specified as a vector. `Yedges(1)` is the first edge of the first bin in the y-dimension, and `Yedges(end)` is the outer edge of the last bin.

The value `[X(k),Y(k)]` is in the `(i,j)`th bin if `Xedges(i) ≤ X(k) < Xedges(i+1)` **and** `Yedges(j) ≤ Y(k) < Yedges(j+1)`. The last bins in each dimension also include the last (outer) edge. For example, `[X(k),Y(k)]` falls into the `i`th bin in the last row if `Xedges(end-1) ≤ X(k) ≤ Xedges(end)` **and** `Yedges(i) ≤ Y(k) < Yedges(i+1)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **ax — Axes object**

object

Axes object. If you do not specify an axes, then the `histogram2` function uses the current axes (`gca`).

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: `histogram2(X,Y,'BinWidth',[5 10])`

The properties listed here are only a subset. For a complete list, see Histogram2 Properties.

**'BinMethod' — Binning algorithm**

'auto' (default) | 'scott' | 'fd' | 'integers'

Binning algorithm, specified as one of the values in this table.

| Value      | Description                                                                                                                                                                                                                                                                                                                              |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'auto'     | The default 'auto' algorithm chooses a bin width to cover the data range and reveal the shape of the underlying distribution.                                                                                                                                                                                                            |
| 'scott'    | Scott's rule is optimal if the data is close to being jointly normally distributed. This rule is appropriate for most other distributions, as well. It uses a bin size of $[3.5 \cdot \text{std}(X(:)) \cdot \text{numel}(X)^{-1/4}, 3.5 \cdot \text{std}(Y(:)) \cdot \text{numel}(Y)^{-1/4}]$ .                                         |
| 'fd'       | The Freedman-Diaconis rule is less sensitive to outliers in the data, and might be more suitable for data with heavy-tailed distributions. It uses a bin size of $[2 \cdot \text{IQR}(X(:)) \cdot \text{numel}(X)^{-1/4}, 2 \cdot \text{IQR}(Y(:)) \cdot \text{numel}(Y)^{-1/4}]$ , where IQR is the interquartile range.                |
| 'integers' | The integer rule is useful with integer data, as it creates bins centered on pairs of integers. It uses a bin width of 1 for each dimension and places bin edges halfway between integers.<br><br>To avoid accidentally creating too many bins, you can use this rule to create a limit of 1024 bins ( $2^{10}$ ). If the data range for |

| Value | Description                                                                           |
|-------|---------------------------------------------------------------------------------------|
|       | either dimension is greater than 1024, then the integer rule uses wider bins instead. |

---

**Note:** If you set the `NumBins`, `XBinEdges`, `YBinEdges`, `BinWidth`, or `BinLimits` property, then the `BinMethod` property is set to `'manual'`.

---

Example: `histogram2(X,Y, 'BinMethod', 'integers')` creates a bivariate histogram with the bins centered on pairs of integers.

**'BinWidth' — Width of bins in each dimension**

vector

Width of bins in each dimension, specified as a two-element vector of positive integers, `[xWidth yWidth]`.

If you specify `BinWidth`, then `histogram2` can use a maximum of 1024 bins ( $2^{10}$ ) along each dimension. If instead the specified bin width requires more bins, then `histogram2` uses a larger bin width corresponding to the maximum number of bins.

Example: `histogram2(X,Y, 'BinWidth', [5 10])` uses bins with size 5 in the x-dimension and size 10 in the y-dimension.

**'DisplayStyle' — Histogram display style**

`'bar3'` (default) | `'tile'`

Histogram display style, specified as either `'bar3'` or `'tile'`. Specify `'tile'` to display the histogram as a rectangular array of tiles with colors indicating the bin values.

The default value of `'bar3'` displays the histogram using 3-D bars.

Example: `histogram2(X,Y, 'DisplayStyle', 'tile')` plots the histogram as a rectangular array of tiles.

**'EdgeAlpha' — Transparency of histogram bar edges**

1 (default) | scalar value between 0 and 1 inclusive

Transparency of histogram bar edges, specified as a scalar value between 0 and 1 inclusive. A value of 1 means fully opaque and 0 means completely transparent (invisible).

Example: `histogram2(X,Y, 'EdgeAlpha', 0.5)` creates a bivariate histogram plot with semi-transparent bar edges.

**'EdgeColor' — Histogram edge color**

[0.15 0.15 0.15] (default) | 'none' | 'auto' | RGB triplet or color string

Histogram edge color, specified as one of these values:

- 'none' — Edges are not drawn.
- 'auto' — Color of each edge is chosen automatically.
- RGB triplet or a color string — Edges use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: `histogram2(X,Y, 'EdgeColor', 'r')` creates a 3-D histogram plot with red bar edges.

**'FaceAlpha' — Transparency of histogram bars**

1 (default) | scalar value between 0 and 1 inclusive

Transparency of histogram bars, specified as a scalar value between 0 and 1 inclusive. `histogram2` uses the same transparency for all the bars of the histogram. A value of 1 means fully opaque and 0 means completely transparent (invisible).

Example: `histogram2(X,Y, 'FaceAlpha',0.5)` creates a bivariate histogram plot with semi-transparent bars.

**'FaceColor' — Histogram bar color**

'auto' (default) | 'flat' | 'none' | RGB triplet or color string

Histogram bar color, specified as one of these values:

- 'none' — Bars are not filled.
- 'flat' — Bar colors vary with height. Bars with different height have different colors. The colors are selected from the figure or axes colormap.
- 'auto' — Bar color is chosen automatically (default).
- RGB triplet or a color string — Bars are filled with the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

If you specify `DisplayStyle` as 'stairs', then `histogram2` does not use the `FaceColor` property.

Example: `histogram2(X,Y, 'FaceColor', 'g')` creates a 3-D histogram plot with green bars.

**'FaceLighting' — Lighting effect on histogram bars**

'lit' (default) | 'flat' | 'none'

Lighting effect on histogram bars, specified as one of the values in this table.

| Value  | Description                                                                                                                                                                                                                                                 |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'lit'  | Histogram bars display a pseudo-lighting effect, where the sides of the bars use darker colors relative to the tops. The bars are unaffected by other light sources in the axes.<br><br>This is the default value when <code>DisplayStyle</code> is 'bar3'. |
| 'flat' | Histogram bars are not lit automatically. In the presence of other light objects, the lighting effect is uniform across the bar faces.                                                                                                                      |
| 'none' | Histogram bars are not lit automatically, and lights do not affect the histogram bars.<br><br><code>FaceLighting</code> can only be 'none' when <code>DisplayStyle</code> is 'tile'.                                                                        |

Example: `histogram2(X,Y, 'FaceLighting', 'none')` turns off the lighting of the histogram bars.

**'LineStyle' — Line style**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                       |
|--------|------------------|--------------------------------------------------------------------------------------|
| '-'    | Solid line       |  |
| '--'   | Dashed line      |  |
| ':'    | Dotted line      |  |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                              |

**'LineWidth' — Width of bar outlines**

0.5 (default) | positive value

Width of bar outlines, specified as a positive value in point units. One point equals 1/72 inch.

Example: 1.5

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**'Normalization' — Type of normalization**

'count' (default) | 'probability' | 'countdensity' | 'pdf' | 'cumcount' | 'cdf'

Type of normalization, specified as one of the values in the table.

| Value          | Description                                                                                                                                                                                                                                           |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'count'        | Default normalization scheme. The height of each bar is the number of observations in each bin. The sum of the bar heights is equal to <code>numel(X)</code> and <code>numel(Y)</code> .                                                              |
| 'probability'  | The height of each bar is the relative number of observations, (Number of observations in bin / Total number of observations). The sum of the bar heights is 1.                                                                                       |
| 'countdensity' | The height of each bar is (Number of observations in bin) / (Area of bin). The volume (Height * Area) of each bar is the number of observations in the bin. The sum of the bar volumes is equal to <code>numel(X)</code> and <code>numel(Y)</code> .  |
| 'pdf'          | Probability density function estimate. The height of each bar is, (Number of observations in the bin) / (Total number of observations * Area of bin). The volume of each bar is the relative number of observations. The sum of the bar volumes is 1. |

| Value      | Description                                                                                                                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'cumcount' | The height of each bar is the cumulative number of observations in each bin and all previous bins in both the $x$ and $y$ dimensions. The height of the last bar is equal to <code>numel(X)</code> and <code>numel(Y)</code> . |
| 'cdf'      | Cumulative density function estimate. The height of each bar is equal to the cumulative relative number of observations in each bin and all previous bins in both the $x$ and $y$ dimensions. The height of the last bar is 1. |

Example: `histogram2(X,Y,'Normalization','pdf')` plots an estimate of the probability density function for  $X$  and  $Y$ .

**'ShowEmptyBins' — Toggle display of empty bins**

'off' (default) | 'on'

Toggle display of empty bins, specified as either 'off' or 'on'. The default value is 'off'.

Example: `histogram2(X,Y,'ShowEmptyBins','on')` turns on the display of empty bins.

**'XBinLimits' — Bin limits in  $x$ -dimension**

vector

Bin limits in  $x$ -dimension, specified as a two-element vector, [`xbmin`,`xbmax`]. The vector indicates the first and last bin edges in the  $x$ -dimension.

`histogram2` only plots data that falls within the bin limits inclusively, `Data(Data(:,1)>=xbmin & Data(:,1)<=xbmax)`.

**'XBinLimitsMode' — Selection mode for bin limits in  $x$ -dimension**

'auto' (default) | 'manual'

Selection mode for bin limits in  $x$ -dimension, specified as 'auto' or 'manual'. The default value is 'auto', so that the bin limits automatically adjust to the data along the  $x$ -axis.

If you explicitly specify either `XBinLimits` or `XBinEdges`, then `XBinLimitsMode` is set automatically to `'manual'`. In that case, specify `XBinLimitsMode` as `'auto'` to rescale the bin limits to the data.

**'YBinLimits' — Bin limits in y-dimension**

vector

Bin limits in *y*-dimension, specified as a two-element vector, `[ybmin, ybmax]`. The vector indicates the first and last bin edges in the *y*-dimension.

`histogram2` only plots data that falls within the bin limits inclusively, `Data(Data(:,2)>=ybmin & Data(:,2)<=ybmax)`.

**'YBinLimitsMode' — Selection mode for bin limits in y-dimension**

`'auto'` (default) | `'manual'`

Selection mode for bin limits in *y*-dimension, specified as `'auto'` or `'manual'`. The default value is `'auto'`, so that the bin limits automatically adjust to the data along the *y*-axis.

If you explicitly specify either `YBinLimits` or `YBinEdges`, then `YBinLimitsMode` is set automatically to `'manual'`. In that case, specify `YBinLimitsMode` as `'auto'` to rescale the bin limits to the data.

## Output Arguments

**h — Bivariate histogram**

object

Bivariate histogram, returned as an object. For more information, see [Using Histogram2 Objects](#).

## More About

**Tips**

- Histogram plots created using `histogram2` have a context menu in plot edit mode that enables interactive manipulations in the figure window. For example, you can

use the context menu to interactively change the number of bins, align multiple histograms, or change the display order.

- Using Histogram2 Objects

# Using histogram2 Objects

Histogram bar plot for bivariate data

## Description

Bivariate histograms are a type of bar plot for numeric data that group the data into 2-D bins. After you create a `histogram2` object, you can modify aspects of the histogram by changing its property values. This is particularly useful for quickly modifying the properties of the bins or changing the display.

## Examples

### Adjust Properties of Histogram2 Object

This example creates a `histogram2` object, and then shows how to adjust the properties of the histogram to affect the output display.

Generate 1,000 random numbers in each dimension and create a bivariate histogram.

```
x = randn(1000,1);
y = randn(1000,1);
h = histogram2(x,y)
```

h =

Histogram2 with properties:

```
 Data: [1000x2 double]
 Values: [15x15 double]
 NumBins: [15 15]
 XBinEdges: [1x16 double]
 YBinEdges: [1x16 double]
 BinWidth: [0.5000 0.5000]
 Normalization: 'count'
 FaceColor: 'auto'
 EdgeColor: [0.1500 0.1500 0.1500]
```

Use GET to show all properties

Change the normalization of the histogram by setting the `Normalization` property to `'probability'`.

```
h.Normalization = 'probability';
```

Change the bin limits in each dimension so that  $-5 \leq x \leq 5$  and  $-2 \leq y \leq 2$ . When you set `XBinLimits` or `YBinLimits`, the `XBinLimitsMode` or `YBinLimitsMode` property automatically changes to 'manual'.

```
h.XBinLimits = [-5 5];
h.YBinLimits = [-2 2];
```

Show the empty bins.

```
h.ShowEmptyBins = 'on';
```

Change the display style to show tiles. Switch to a 2-D view.

```
h.DisplayStyle = 'tile';
view(2)
```

### **Saving and Loading Histogram2 Objects**

Use the `savefig` function to save a histogram2 figure.

```
y = histogram2(randn(100,1),randn(100,1));
savefig('histogram2.fig');
clear all
close all
```

Use `openfig` to load the histogram figure back into MATLAB. `openfig` also returns a handle to the figure, `h`.

```
h = openfig('histogram2.fig');
```

Use the `findobj` function to locate the correct object handle from the figure handle. This allows you to continue manipulating the original histogram object used to generate the figure.

```
y = findobj(h, 'type', 'histogram2')
```

```
y =
```

```
 Histogram2 with properties:
```

```
 Data: [100x2 double]
 Values: [7x6 double]
 NumBins: [7 6]
```

```
XBinEdges: [-3 -2 -1 0 1 2 3 4]
YBinEdges: [-3 -2 -1 0 1 2 3]
BinWidth: [1 1]
Normalization: 'count'
FaceColor: 'auto'
EdgeColor: [0.1500 0.1500 0.1500]
```

Use GET to show all properties

## Properties

Histogram2 Properties

# Histogram2 Properties

Control histogram2 appearance and behavior

Histogram2 properties control the appearance and behavior of the histogram. By changing property values, you can modify aspects of the histogram. Use dot notation to refer to a particular object and property:

```
h = histogram2(randn(10,1),randn(10,1));
c = h.NumBins;
h.NumBins = [4 7];
```

## Bins

### BinMethod — Binning algorithm

'auto' (default) | 'scott' | 'fd' | 'integers'

Binning algorithm, specified as one of the values in this table.

| Value      | Description                                                                                                                                                                                                                                                                                                               |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'auto'     | The default 'auto' algorithm chooses a bin width to cover the data range and reveal the shape of the underlying distribution.                                                                                                                                                                                             |
| 'scott'    | Scott's rule is optimal if the data is close to being jointly normally distributed. This rule is appropriate for most other distributions, as well. It uses a bin size of $[3.5 \cdot \text{std}(X(:)) \cdot \text{numel}(X)^{-1/4}, 3.5 \cdot \text{std}(Y(:)) \cdot \text{numel}(Y)^{-1/4}]$ .                          |
| 'fd'       | The Freedman-Diaconis rule is less sensitive to outliers in the data, and might be more suitable for data with heavy-tailed distributions. It uses a bin size of $[2 \cdot \text{IQR}(X(:)) \cdot \text{numel}(X)^{-1/4}, 2 \cdot \text{IQR}(Y(:)) \cdot \text{numel}(Y)^{-1/4}]$ , where IQR is the interquartile range. |
| 'integers' | The integer rule is useful with integer data, as it creates a bin for each pair of integers                                                                                                                                                                                                                               |

| Value | Description                                                                                                                                                                                                                                                                                                                      |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | X and Y. It uses a bin width of 1 for each dimension and places bin edges halfway between integers. To avoid accidentally creating too many bins, you can use this rule to create a limit of 1024 bins ( $2^{10}$ ). If the data range for either dimension is greater than 1024, then the integer rule uses wider bins instead. |

---

**Note:** If you set the `NumBins`, `XBinEdges`, `YBinEdges`, `BinWidth`, or `BinLimits` property, then the `BinMethod` property is set to `'manual'`.

---

Example: `histogram2(X,Y, 'BinMethod', 'integers')` creates a bivariate histogram with the bins centered on integers.

### **BinWidth — Width of bins in each dimension**

vector

Width of bins in each dimension, specified as a two-element vector. The first element in the vector gives the width of the bins in the *x*-dimension, and the second element gives the width of the bins in the *y*-dimension.

When you specify `BinWidth`, then `histogram2` can use a maximum of 1024 bins ( $2^{10}$ ) along each dimension. If instead the specified bin width requires more bins, then `histogram2` uses a larger bin width corresponding to the maximum number of bins.

Example: `histogram2(X,Y, 'BinWidth', [5 10])` uses bins with size 5 in the *x*-dimension and size 10 in the *y*-dimension.

### **EdgeAlpha — Transparency of histogram bar edges**

1 (default) | scalar value between 0 and 1 inclusive

Transparency of histogram bar edges, specified as a scalar value between 0 and 1 inclusive. A value of 1 means fully opaque and 0 means completely transparent (invisible).

Example: `histogram2(X,Y, 'EdgeAlpha', 0.5)` creates a bivariate histogram plot with semi-transparent bar edges.

**EdgeColor — Histogram edge color**

[0.15 0.15 0.15] (default) | 'none' | 'auto' | RGB triplet or color string

Histogram edge color, specified as one of these values:

- 'none' — Edges are not drawn.
- 'auto' — Color of each edge is chosen automatically.
- RGB triplet or a color string — Edges use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: `histogram2(X,Y,'EdgeColor','r')` creates a histogram plot with red bar edges.

**FaceAlpha — Transparency of histogram bars**

1.0 (default) | scalar value between 0 and 1 inclusive

Transparency of histogram bars, specified as a scalar value between 0 and 1 inclusive. `histogram2` uses the same transparency for all the bars of the histogram. A value of 1 means fully opaque and 0 means completely transparent (invisible).

Example: `histogram2(X,Y,'FaceAlpha',0.5)` creates a bivariate histogram plot with semi-transparent bars.

**FaceColor — Histogram bar color**

'auto' (default) | 'flat' | 'none' | RGB triplet or color string

Histogram bar color, specified as one of these values:

- 'none' — Bars are not filled.
- 'flat' — Bar colors vary with height. Bars with different height have different colors. The colors are selected from the figure or axes colormap.
- 'auto' — Bar color is chosen automatically (default).
- RGB triplet or a color string — Bars are filled with the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

If you specify `DisplayStyle` as 'stairs', then `histogram2` does not use the `FaceColor` property.

Example: `histogram2(X,Y,'FaceColor','g')` creates a histogram plot with green bars.

**FaceLighting — Lighting effect on histogram bars**

'lit' (default) | 'flat' | 'none'

Lighting effect on histogram bars, specified as one of the values in the table.

| Value  | Description                                                                                                                                                                                                                                                        |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'lit'  | <p>Histogram bars display a pseudo-lighting effect, where the sides of the bars use darker colors relative to the tops. The bars are unaffected by other light sources in the axes.</p> <p>This is the default value when <code>DisplayStyle</code> is 'bar3'.</p> |
| 'flat' | <p>Histogram bars are not lit automatically. In the presence of other light objects, the lighting effect is uniform across the bar faces.</p>                                                                                                                      |
| 'none' | <p>Histogram bars are not lit automatically, and lights do not affect the histogram bars.</p> <p><code>FaceLighting</code> can only be 'none' when <code>DisplayStyle</code> is 'tile'.</p>                                                                        |

Example: `histogram2(X,Y, 'FaceLighting', 'none')` turns off the lighting of the histogram bars.

### LineStyle – Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                       |
|--------|------------------|--------------------------------------------------------------------------------------|
| '-'    | Solid line       |  |
| '--'   | Dashed line      |  |
| ':'    | Dotted line      |  |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                              |

**LineWidth — Width of bar outlines**

0.5 (default) | positive value

Width of bar outlines, specified as a positive value in point units. One point equals 1/72 inch.

Example: 1.5

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Normalization — Type of normalization**

'count' (default) | 'probability' | 'countdensity' | 'pdf' | 'cumcount' | 'cdf'

Type of normalization, specified as one of the values in the table.

| Value          | Description                                                                                                                                                                                                                                           |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'count'        | Default normalization scheme. The height of each bar is the number of observations in each bin. The sum of the bar heights is equal to <code>numel(X)</code> and <code>numel(Y)</code> .                                                              |
| 'probability'  | The height of each bar is the relative number of observations, (Number of observations in bin / Total number of observations). The sum of the bar heights is 1.                                                                                       |
| 'countdensity' | The height of each bar is (Number of observations in bin) / (Area of bin). The volume (Height * Area) of each bar is the number of observations in the bin. The sum of the bar volumes is equal to <code>numel(X)</code> and <code>numel(Y)</code> .  |
| 'pdf'          | Probability density function estimate. The height of each bar is, (Number of observations in the bin) / (Total number of observations * Area of bin). The volume of each bar is the relative number of observations. The sum of the bar volumes is 1. |

| Value      | Description                                                                                                                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'cumcount' | The height of each bar is the cumulative number of observations in each bin and all previous bins in both the $x$ and $y$ dimensions. The height of the last bar is equal to <code>numel(X)</code> and <code>numel(Y)</code> . |
| 'cdf'      | Cumulative density function estimate. The height of each bar is equal to the cumulative relative number of observations in each bin and all previous bins in both the $x$ and $y$ dimensions. The height of the last bar is 1. |

Example: `histogram2(X,Y,'Normalization','pdf')` plots an estimate of the probability density function for  $X$  and  $Y$ .

### **NumBins** — Number of bins in each dimension

vector

Number of bins in each dimension, specified as a two-element vector of positive integers, `[nX nY]`. If you do not specify `NumBins`, then `histogram2` automatically calculates how many bins to use based on the values in  $X$  and  $Y$ .

Example: `histogram2(X,Y,[10 20])`

Example: `h.NumBins = [10 20]`

### **ShowEmptyBins** — Toggle display of empty bins

'off' (default) | 'on'

Toggle display of empty bins, specified as either 'off' or 'on'. The default value is 'off'.

Example: `histogram2(X,Y,'ShowEmptyBins','on')` turns on the display of empty bins.

### **XBinEdges** — Bin edges in $x$ -dimension

vector

Bin edges in  $x$ -dimension, specified as a vector. `Xedges(1)` is the first edge of the first bin in the  $x$ -dimension, and `Xedges(end)` is the outer edge of the last bin.

The value  $[X(k), Y(k)]$  is in the  $(i, j)$ th bin if  $Xedges(i) \leq X(k) < Xedges(i+1)$  **and**  $Yedges(j) \leq Y(k) < Yedges(j+1)$ . The last bins in each dimension also include the last (outer) edge. For example,  $[X(k), Y(k)]$  falls into the  $i$ th bin in the last row if  $Xedges(end-1) \leq X(k) \leq Xedges(end)$  **and**  $Yedges(i) \leq Y(k) < Yedges(i+1)$ .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **XBinLimits** — Bin limits in x-dimension

vector

Bin limits in x-dimension, specified as a two-element vector,  $[xbmin, xbmax]$ . The vector indicates the first and last bin edges in the x-dimension.

`histogram2` only plots data that falls within the bin limits inclusively, `Data(Data(:,1)>=xbmin & Data(:,1)<=xbmax)`.

### **XBinLimitsMode** — Selection mode for bin limits in x-dimension

'auto' (default) | 'manual'

Selection mode for bin limits in x-dimension, specified as 'auto' or 'manual'. The default value is 'auto', so that the bin limits automatically adjust to the data along the x-axis.

If you explicitly specify either `XBinLimits` or `XBinEdges`, then `XBinLimitsMode` is set automatically to 'manual'. In that case, specify `XBinLimitsMode` as 'auto' to rescale the bin limits to the data.

### **YBinEdges** — Bin edges in y-dimension

vector

Bin edges in y-dimension, specified as a vector. `Yedges(1)` is the first edge of the first bin in the y-dimension, and `Yedges(end)` is the outer edge of the last bin.

The value  $[X(k), Y(k)]$  is in the  $(i, j)$ th bin if  $Xedges(i) \leq X(k) < Xedges(i+1)$  **and**  $Yedges(j) \leq Y(k) < Yedges(j+1)$ . The last bins in each dimension also include the last (outer) edge. For example,  $[X(k), Y(k)]$  falls into the  $i$ th bin in the last row if  $Xedges(end-1) \leq X(k) \leq Xedges(end)$  **and**  $Yedges(i) \leq Y(k) < Yedges(i+1)$ .

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **YBinLimits** — Bin limits in y-dimension

vector

Bin limits in y-dimension, specified as a two-element vector, `[ybmin,ybmax]`. The vector indicates the first and last bin edges in the y-dimension.

`histogram2` only plots data that falls within the bin limits inclusively, `Data(Data(:,2)>=ybmin & Data(:,2)<=ybmax)`.

### **YBinLimitsMode — Selection mode for bin limits in y-dimension**

'auto' (default) | 'manual'

Selection mode for bin limits in y-dimension, specified as 'auto' or 'manual'. The default value is 'auto', so that the bin limits automatically adjust to the data along the y-axis.

If you explicitly specify either `YBinLimits` or `YBinEdges`, then `YBinLimitsMode` is set automatically to 'manual'. In that case, specify `YBinLimitsMode` as 'auto' to rescale the bin limits to the data.

## **Data**

### **Data — Data to distribute among bins**

matrix

Data to distribute among bins, specified as a matrix of size m-by-2. The X and Y inputs to `histogram2` correspond to the columns in `Data`, that is, `Data(:,1)` is `X(:)` and `Data(:,2)` is `Y(:)`.

`histogram2` ignores all NaN values. Similarly, `histogram2` ignores Inf and -Inf values, unless the bin edges explicitly specify Inf or -Inf as a bin edge.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **Values — Bin values**

matrix

This property is read only.

Bin values, returned as a numeric matrix. If `Normalization` is 'count', then the  $(i, j)$ th entry in `Values` specifies the bin count for the bin whose x edges are `[Xedges(i), Xedges(i+1)]` and whose y edges are `[Yedges(j), Yedges(j+1)]`.

Depending on the value of `Normalization`, the `Values` property instead can contain a normalized variant of the bin counts.

The bin inclusion scheme for the different numbered bins in `Values`, as well as their relative orientation to the  $x$ -axis and  $y$ -axis, is

For example, the  $(1,1)$  bin includes values that fall on the first edge in each dimension, and the last bin in the bottom right includes values that fall on any of its edges.

## Histogram Type

### DisplayStyle — Histogram display style

'bar3' (default) | 'tile'

Histogram display style, specified as either 'bar3' or 'tile'. Specify 'tile' to display the histogram as a rectangular array of tiles with colors indicating the bin values.

The default value of 'bar3' displays the histogram using 3-D bars.

Example: `histogram2(X,Y,'DisplayStyle','tile')` plots the histogram as a rectangular array of tiles.

## Visibility

### Visible — State of visibility

'on' (default) | 'off'

State of visibility, specified as one of these values:

- 'on' — Display the histogram2.
- 'off' — Hide the histogram2 without deleting it. You still can access the properties of an invisible histogram2 object.

## Identifiers

### Type — Type of graphics object

'histogram2' (default)

This property is read only.

Type of graphics object, returned as 'histogram2'. Use this property to find all objects of a given type within a plotting hierarchy, such as searching for the type using `findobj`.

### Tag — Tag to associate with histogram2

'' (default) | string

Tag to associate with the histogram2, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

Data Types: char

### UserData — Data to associate with histogram2

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the histogram2 object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: 1:100

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | table | cell

### DisplayName — Text used by legend

'' (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the histogram2.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where N is the number assigned to the `histogram2` object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

### **Annotation — Legend icon display style**

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the `histogram2` from a legend.

- 1** Query the `Annotation` property to get the `Annotation` object.
- 2** Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3** Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - `'on'` — Include the `histogram2` object in the legend as one entry (default).
  - `'off'` — Do not include the `histogram2` object in the legend.
  - `'children'` — Include only children of the `histogram2` object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## Parent/Child

### Parent — Parent of histogram2

axes object | group object | transform object

Parent of histogram2, specified as an axes, group, or transform object.

### Children — Children of histogram2

empty GraphicsPlaceholder array

The histogram2 has no children. You cannot set this property.

### HandleVisibility — Visibility of object handle

'on' (default) | 'off' | 'callback'

Visibility of histogram2 object handle in the Children property of the parent, specified as one of these values:

- 'on' — The histogram2 object handle is always visible.
- 'off' — The histogram2 object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The histogram2 object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the histogram2 at the command-line, but allows callback functions to access it.

If the histogram2 object is not listed in the Children property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their HandleVisibility property setting.

## Interactive Control

### ButtonDownFcn — Mouse-click callback

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the histogram2. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The histogram2 object — You can access properties of the histogram2 object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

## **UIContextMenu** — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the histogram2. Create the context menu using the uicontextmenu function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

## **Selected** — Selection state

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the histogram2 when in plot edit mode, then MATLAB sets its **Selected** property to 'on'. If the **SelectionHighlight** property also is set to 'on', then MATLAB displays selection handles around the histogram2.
- 'off' — Not selected.

### **SelectionHighlight** — Display of selection handles when selected

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the **Selected** property is set to 'on'.
- 'off' — Never display selection handles, even when the **Selected** property is set to 'on'.

## **Callback Execution Control**

### **PickableParts** — Ability to capture mouse clicks

'visible' (default) | 'none'

Ability to capture mouse clicks, specified as one of these values:

- 'visible' — Can capture mouse clicks only when visible. The **Visible** property must be set to 'on'. The **HitTest** property determines if the histogram2 responds to the click or if an ancestor does.
- 'none' — Cannot capture mouse clicks. Clicking the histogram2 passes the click to the object below it in the current view of the figure window. The **HitTest** property of the histogram2 has no effect.

### **HitTest** — Response to captured mouse clicks

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the **ButtonDownFcn** callback of the histogram2. If you have defined the **UIContextMenu** property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the histogram2 that has a **HitTest** property set to 'on' and a **PickableParts** property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the `histogram2` object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the `histogram2` is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the `histogram2` tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the `histogram2`. Setting the `CreateFcn` property on an existing `histogram2` has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during

histogram2 creation. MATLAB executes the callback after creating the histogram2 and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The histogram2 object — You can access properties of the histogram2 object from within the callback function. You also can access the histogram2 object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **DeleteFcn — Deletion callback**

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the histogram2. MATLAB executes the callback before destroying the histogram2 so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The histogram2 object — You can access properties of the histogram2 object from within the callback function. You also can access the histogram2 object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **BeingDeleted** — Deletion status of histogram2

'off' (default) | 'on'

This property is read only.

Deletion status of histogram2, returned as 'on' or 'off'. MATLAB sets the **BeingDeleted** property to 'on' when the delete function of the histogram2 begins execution (see the **DeleteFcn** property). The **BeingDeleted** property remains set to 'on' until the histogram2 no longer exists.

Check the value of the **BeingDeleted** property to verify that the histogram2 is not about to be deleted before querying or modifying it.

- Using histogram2 Objects

**Introduced in R2015b**

## **hms**

Hour, minute, and second numbers of duration

### **Syntax**

```
[h,m,s] = hms(t)
```

### **Description**

`[h,m,s] = hms(t)` returns the hour, minute, and second values of the datetime values in `t` as separate numeric arrays. The `h` and `m` outputs contain integer values, and the `s` output can contain a fractional part. `h`, `m`, and `s` are the same size as `t`.

Calling `hms` is equivalent to calling the `hour`, `minute`, and `second` functions.

### **Examples**

#### **Find Hour, Minute, and Second Numbers of datetime Array**

```
t1 = datetime('now','Format','HH:mm:ss.SSS');
t = t1 + minutes(0:45:135)
```

```
[h,m,s] = hms(t)
```

```
t =
```

```
 18:11:45.814 18:56:45.814 19:41:45.814 20:26:45.814
```

```
h =
```

```
 18 18 19 20
```

```
m =
```

```
 11 56 41 26

s =
 45.8140 45.8140 45.8140 45.8140
```

`hms` returns the hour, minute, and second numbers in separate arrays.

## Input Arguments

### **t** — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

## Output Arguments

### **h** — Hour numbers

numeric array

Hour numbers, returned as a numeric array of integer values from 0 to 23. The `h` output is of type `double` and is the same size as `t`.

### **m** — Minute numbers

numeric array

Minute numbers, returned as a numeric array of integer values from 0 to 59. The `m` output is of type `double` and is the same size as `t`.

### **s** — Second numbers

numeric array

Second numbers, returned as a numeric array of values from 0 to less than 60, and can include a fractional part. For `datetime` values whose time zone is `UTCLeapSeconds`, the `s` output can contain a value between 60 and 61 for times that fall during a leap second occurrence. The `s` output is of type `double` and is the same size as `t`.

**Introduced in R2014b**

# hold

Retain current plot when adding new plots

## Syntax

```
hold on
hold off
hold all
hold
```

```
hold(ax, 'on')
hold(ax, 'off')
hold(ax)
```

## Description

`hold on` retains plots in the current axes so that new plots added to the axes do not delete existing plots. New plots use the next colors and line styles based on the `ColorOrder` and `LineStyleOrder` properties of the axes. MATLAB adjusts axes limits, tick marks, and tick labels to display the full range of data.

`hold off` sets the hold state to off so that new plots added to the axes clear existing plots and reset all axes properties. The next plot added to the axes uses the first color and line style based on the `ColorOrder` and `LineStyleOrder` properties of the axes. This is the default behavior.

`hold all` is the same as `hold on`.

---

**Note:** This syntax will be removed in a future release. Use `hold on` instead.

---

`hold` toggles the hold state between on and off.

`hold(ax, 'on')` sets the hold state to on for the axes specified by `ax` instead of the current axes.

`hold(ax, 'off')` sets the hold state to off for the specified axes.

`hold(ax)` toggles the hold state for the specified axes.

## Examples

### Add Line Plot to Existing Graph

Create a line plot. Then, use `hold on` to add a second line plot without deleting the existing plot. The new plot uses the next color and line style based on the `ColorOrder` and `LineStyleOrder` properties of the axes.

```
x = linspace(-pi,pi);
y1 = sin(x);
y2 = cos(x);

plot(x,y1)
hold on
plot(x,y2)
```

Reset the hold state to off so that new plots delete existing plots. New plots start from the beginning of the color order and line style order.

```
hold off
y3 = sin(2*x);
plot(x,y3)
```

## Specify Hold State for Specific Axes

Create a figure with two subplots and add a line plot to each subplot.

```
ax1 = subplot(2,1,1);
x = linspace(0,2*pi);
y1 = sin(x);
plot(x,y1)
```

```
ax2 = subplot(2,1,2);
y2 = cos(x);
plot(x,y2)
```

Add a second line plot to the upper subplot.

```
hold(ax1, 'on')
y3 = sin(2*x);
plot(ax1,x,y3)
```

Reset the hold state to off for the upper subplot so that new plots replace the existing plots, which is the default behavior.

```
hold(ax1, 'off')
y4 = sin(4*x);
plot(ax1,x,y4)
```

## Input Arguments

**ax** — Axes object

axes object

Axes object. Use `ax` to set the hold state for a specific axes, instead of the current axes.

## More About

### Tips

- Use the `ishold` function to test the hold state.
- The `hold` function toggles the `NextPlot` property of the axes between `'add'` and `'replace'`.
- If an axes does not exist, then the `hold` command creates one.

**Introduced before R2006a**

# home

Send cursor home

## Syntax

home

## Description

`home` moves the cursor to the upper-left corner of the window. When using the MATLAB desktop, `home` also scrolls the visible text in the window up and out of view. You can use the scroll bar to see what was previously on the screen.

## Examples

Execute a MATLAB command that displays something in the Command Window and then run the `home` function. `home` moves the cursor to the upper-left corner of the screen and clears the screen.

```
magic(5)
```

```
ans =
```

```
 17 24 1 8 15
 23 5 7 14 16
 4 6 13 20 22
 10 12 19 21 3
 11 18 25 2 9
```

```
home
```

`clc`

Introduced before R2006a

## horzcat

Concatenate arrays horizontally

### Syntax

`C = horzcat(A1, ..., AN)`

### Description

`C = horzcat(A1, ..., AN)` horizontally concatenates arrays `A1, ..., AN`. All arrays in the argument list must have the same number of rows.

- If the inputs are multidimensional arrays, `horzcat` concatenates along the second dimension. The first and remaining dimensions must match.
- If the inputs are tables, `horzcat` concatenates by matching row names when present, or by matching position for tables that do not have row names. All the table inputs must have unique variable names and the row names for all tables that have them must be identical, except for order.

`horzcat` assigns values for the `Description` and `UserData` properties in `C` using the first nonempty value for the corresponding property in the tables `A1, ..., AN`.

MATLAB calls `C = horzcat(A1, A2, ...)` for the syntax `C = [A1 A2 ...]` when any of the inputs are an object.

### Tips

You can concatenate categorical arrays with cell arrays of strings. For more information, see “Combine Categorical Arrays”.

If all the input arrays are ordinal categorical arrays, they must have the same sets of categories including their order. For more information, see “Ordinal Categorical Arrays”.

You can concatenate datetime arrays with cell arrays of strings.

You can concatenate duration arrays and calendar duration arrays. The result is a calendar duration array.

You can concatenate duration or calendar duration arrays with numeric arrays. Prior to concatenation, MATLAB converts the numeric array to an array of equivalent days using the `days` function.

For information on combining unlike integer types, integers with nonintegers, or cell arrays with non-cell arrays, see “Valid Combinations of Unlike Classes”.

## Examples

### Horizontally Concatenate Two Matrices

Create a 3-by-5 matrix, **A**.

```
A = magic(5);
A(4:5,:) = []
```

A =

```
 17 24 1 8 15
 23 5 7 14 16
 4 6 13 20 22
```

Create a 3-by-3 matrix, **B**.

```
B = magic(3)*100
```

B =

```
 800 100 600
 300 500 700
 400 900 200
```

Horizontally concatenate **A** and **B**.

```
C = horzcat(A,B)
```

C =

```
17 24 1 8 15 800 100 600
23 5 7 14 16 300 500 700
 4 6 13 20 22 400 900 200
```

## Horizontally Concatenate Two Tables

Create a table, A, with three rows and two variables.

```
A = table([5;6;5],['M'; 'M'; 'M'],...
 'VariableNames',{ 'Age' 'Gender'},...
 'RowNames',{ 'Thomas' 'Gordon' 'Percy'})
```

A =

```
 Age Gender
----- -
Thomas 5 M
Gordon 6 M
Percy 5 M
```

Create a table, B, with three rows and three variables.

```
B = table([45;41;40],[45;32;34],{ 'NY'; 'CA'; 'MA'},...
 'VariableNames',{ 'Height' 'Weight' 'Birthplace'},...
 'RowNames',{ 'Percy' 'Gordon' 'Thomas'})
```

B =

```
 Height Weight Birthplace
----- -
Percy 45 45 'NY'
Gordon 41 32 'CA'
Thomas 40 34 'MA'
```

Horizontally concatenate A and B.

```
C = horzcat(A,B)
```

C =

```
 Age Gender Height Weight Birthplace
----- -
Thomas 5 M 40 34 'MA'
Gordon 6 M 41 32 'CA'
Percy 5 M 45 45 'NY'
```

The order of rows in `C` matches the order in `A`.

## More About

`vertcat` | `cat` | `strcat` | `char` | special character

**Introduced before R2006a**

## horzcat (tscollection)

Horizontal concatenation for `tscollection` objects

### Syntax

```
tsc = horzcat(tsc1,tsc2,...)
```

### Description

`tsc = horzcat(tsc1,tsc2,...)` performs horizontal concatenation for `tscollection` objects:

```
tsc = [tsc1 tsc2 ...]
```

This operation combines multiple `tscollection` objects, which must have the same time vectors, into one `tscollection` containing `timeseries` objects from all concatenated collections.

### See Also

`tscollection` | `vertcat` (`tscollection`)

Introduced before R2006a

# hour

Hour number

## Syntax

```
h = hour(t)
```

## Description

`h = hour(t)` returns the hour numbers of the datetime values in `t`. The `h` output is a double array the same size as `t` and contains integer values from 0 to 23.

The `hour` function returns the hour numbers of datetime values. To assign hour values to a datetime array, `t`, use `t.Hour` and modify the `Hour` property.

## Examples

### Find Hour Number of Datetime Values

```
t = datetime('today'):hours(8):datetime('tomorrow');
t.Format = 'MMM dd, HH:mm'
```

```
t =
```

```
 Aug 24, 00:00 Aug 24, 08:00 Aug 24, 16:00 Aug 25, 00:00
```

```
h = hour(t)
```

```
h =
```

```
 0 8 16 0
```

## Input Arguments

**t** — **Input date and time**  
datetime array

Input date and time, specified as a `datetime` array.

## See Also

`hms` | `minute` | `second` | `timeofday`

**Introduced in R2014b**

# hours

Duration in hours

## Syntax

```
H = hours(X)
```

## Description

`H = hours(X)` returns an array of hours equivalent to the values in `X`.

- If `X` is a numeric array, then `H` is a **duration** array in units of hours.
- If `X` is a **duration** array, then `H` is a **double** array with each element equal to the number of hours in the corresponding element of `X`.

The `hours` function converts between **duration** and **double** values. To display a duration in units of hours, set its `Format` property to `'h'`.

## Examples

### Create Duration Array of Hours

```
X = magic(4);
H = hours(X)
```

```
H =
```

```
16 hrs 2 hrs 3 hrs 13 hrs
 5 hrs 11 hrs 10 hrs 8 hrs
 9 hrs 7 hrs 6 hrs 12 hrs
 4 hrs 14 hrs 15 hrs 1 hr
```

### Convert Durations to Numeric Array of Hours

Create a **duration** array.

```
X = hours(2:10:38) + minutes(30)
```

```
X =
```

```
 2.5 hrs 12.5 hrs 22.5 hrs 32.5 hrs
```

Convert each duration in X to a number of hours.

```
H = hours(X)
```

```
H =
```

```
 2.5000 12.5000 22.5000 32.5000
```

View the data type of H

```
whos H
```

| Name | Size | Bytes | Class  | Attributes |
|------|------|-------|--------|------------|

## hsv2rgb

Convert HSV colormap to RGB colormap

### Syntax

```
M = hsv2rgb(H)
rgb_image = hsv2rgb(hsv_image)
```

### Description

`M = hsv2rgb(H)` converts a hue-saturation-value (HSV) colormap to a red-green-blue (RGB) colormap. `H` is an  $m$ -by-3 matrix, where  $m$  is the number of colors in the colormap. The columns of `H` represent hue, saturation, and value, respectively. `M` is an  $m$ -by-3 matrix. Its columns are intensities of red, green, and blue, respectively.

`rgb_image = hsv2rgb(hsv_image)` converts the HSV image to the equivalent RGB image. HSV is an  $m$ -by- $n$ -by-3 image array whose three planes contain the hue, saturation, and value components for the image. RGB is returned as an  $m$ -by- $n$ -by-3 image array whose three planes contain the red, green, and blue components for the image.

### More About

#### Tips

As `H(:, 1)` varies from 0 to 1, the resulting color varies from red through yellow, green, cyan, blue, and magenta, and returns to red. When `H(:, 2)` is 0, the colors are unsaturated (i.e., shades of gray). When `H(:, 2)` is 1, the colors are fully saturated (i.e., they contain no white component). As `H(:, 3)` varies from 0 to 1, the brightness increases.

The MATLAB `hsv` colormap uses `hsv2rgb([huesaturationvalue])` where `hue` is a linear ramp from 0 to 1, and `saturation` and `value` are all 1's.

## hypot

Square root of sum of squares

### Syntax

```
c = hypot(a,b)
```

### Description

`c = hypot(a,b)` returns the element-wise result of the following equation, computed to avoid underflow and overflow:

```
c = sqrt(abs(a).^2 + abs(b).^2)
```

Inputs `a` and `b` must follow these rules:

- Both `a` and `b` must be single- or double-precision, floating-point arrays.
- The sizes of the `a` and `b` arrays must either be equal, or one a scalar and the other nonscalar. In the latter case, `hypot` expands the scalar input to match the size of the nonscalar input.
- If `a` or `b` is an empty array (0-by-N or N-by-0), the other must be the same size or a scalar. The result `C` is an empty array having the same size as the empty input(s).

`hypot` returns the following in output `C`, depending upon the types of inputs:

- If the inputs to `hypot` are complex (`w+xi` and `y+zi`), then the statement `c = hypot(w+xi,y+zi)` returns the *positive real* result

```
c = sqrt(abs(w).^2+abs(x).^2+abs(y).^2+abs(z).^2)
```
- If `a` or `b` is  $\pm\text{Inf}$ , `hypot` returns `Inf`.
- If neither `a` nor `b` is `Inf`, but one or both inputs is `NaN`, `hypot` returns `NaN`.
- If all inputs are finite, the result is finite. The one exception is when both inputs are very near the value of the MATLAB constant `realmax`. The reason for this is that the equation `c = hypot(realmax,realmax)` is theoretically  $\sqrt{2} * \text{realmax}$ , which overflows to `Inf`.

## Examples

### Example 1

To illustrate the difference between using the `hypot` function and coding the basic `hypot` equation in M-code, create an anonymous function that performs the same function as `hypot`, but without the consideration to underflow and overflow that `hypot` offers:

```
myhypot = @(a,b) sqrt(abs(a).^2+abs(b).^2);
```

Find the upper limit at which your coded function returns a useful value. You can see that this test function reaches its maximum at about `1e154`, returning an infinite result at that point:

```
myhypot(1e153,1e153)
ans =
 1.4142e+153
```

```
myhypot(1e154,1e154)
ans =
 Inf
```

Do the same using the `hypot` function, and observe that `hypot` operates on values up to about `1e308`, which is approximately equal to the value for `realmax` on your computer (the largest double-precision floating-point number you can represent on a particular computer):

```
hypot(1e308,1e308)
ans =
 1.4142e+308
```

```
hypot(1e309,1e309)
ans =
 Inf
```

### Example 2

`hypot(a,a)` theoretically returns `sqrt(2)*abs(a)`, as shown in this example:

```
x = 1.271161e308;
y = x * sqrt(2)
```

```
y =
 1.7977e+308
```

```
y = hypot(x,x)
y =
 1.7977e+308
```

# i

Imaginary unit

## Syntax

```
1i
z = a + bi
z = x + 1i*y
```

## Description

`1i` returns the basic imaginary unit. `i` is equivalent to `sqrt(-1)`.

You can use `i` to enter complex numbers. You also can use the character `j` as the imaginary unit. To create a complex number without using `i` and `j`, use the `complex` function.

`z = a + bi` returns a complex numerical constant, `z`.

`z = x + 1i*y` returns a complex array, `z`.

## Examples

### Complex Scalar

Create a complex scalar and use the character, `i`, without a multiplication sign as a suffix in forming a complex numerical constant.

```
z = 1+2i
z =
 1.0000 + 2.0000i
```

### Complex Vector

Create a complex vector from two 4-by-1 vectors of real numbers.

```
x = [1:4]';
y = [8:-2:2]';

z = x+1i*y
z =

 1.0000 + 8.0000i
 2.0000 + 6.0000i
 3.0000 + 4.0000i
 4.0000 + 2.0000i
```

z is a 4-by-1 complex vector.

## Complex Exponential

Create a complex scalar representing a complex vector with radius, *r*, and angle from the origin, *theta*.

```
r = 4;
theta = pi/4;

z = r*exp(1i*theta)
z =

 2.8284 + 2.8284i
```

## Input Arguments

### **a** — Real component of complex scalar

scalar

Real component of a complex scalar, specified as a scalar.

Data Types: `single` | `double`

### **b** — Imaginary component of complex scalar

scalar

Imaginary component of a complex scalar, specified as a scalar.

If **b** is `double`, you can use the character, `i`, without a multiplication sign as a suffix in forming the complex numerical constant.

Example: `7i`

If **b** is `single`, you must use a multiplication sign when forming the complex numerical constant.

Example: `single(7)*i`

Data Types: `single` | `double`

### **x — Real component of complex array**

scalar | vector | matrix | multidimensional array

Real component of a complex array, specified as a scalar, vector, matrix, or multidimensional array.

The size of **x** must match the size of **y**, unless one is a scalar. If either **x** or **y** is a scalar, MATLAB expands the scalar to match the size of the other input.

`single` can combine with `double`.

Data Types: `single` | `double`

### **y — Imaginary component of complex array**

scalar | vector | matrix | multidimensional array

Imaginary component of a complex array, specified as a scalar, vector, matrix, or multidimensional array.

The size of **x** must match the size of **y**, unless one is a scalar. If either **x** or **y** is a scalar, MATLAB expands the scalar to match the size of the other input.

`single` can combine with `double`.

Data Types: `single` | `double`

## **Output Arguments**

### **z — Complex array**

scalar | vector | matrix | multidimensional array

Complex array, returned as a scalar, vector, matrix, or multidimensional array.

The size of **z** is the same as the input arguments.

`z` is `single` if at least one input argument is `single`. Otherwise, `z` is `double`.

## More About

### Tips

- For speed and improved robustness in complex arithmetic, use `1i` and `1j` instead of `i` and `j`.
- Since `i` is a function, it can be overridden and used as a variable. However, it is best to avoid using `i` and `j` for variable names if you intend to use them in complex arithmetic.
- Use the `complex` function to create a complex output in the following cases:
  - When the names `i` and `j` might be used for other variables (and do not equal `sqrt(-1)`)
  - When the inputs are not `double` or `single`
  - When the imaginary component is all zeros

# ichol

Incomplete Cholesky factorization

## Syntax

```
L = ichol(A)
L = ichol(A,opts)
```

## Description

`L = ichol(A)` performs the incomplete Cholesky factorization of `A` with zero-fill.

`L = ichol(A,opts)` performs the incomplete Cholesky factorization of `A` with options specified by `opts`.

By default, `ichol` references the lower triangle of `A` and produces lower triangular factors.

## Input Arguments

### A

Sparse matrix

### opts

Structure with up to five fields:

The default value is 'nofill'.                                                                                                                                                                                                                                                                                                                           |
| droptol    | Drop tolerance when type is 'ict'                                      | Nonnegative scalar used as a drop tolerance when performing ICT. Elements which are smaller in magnitude than a local drop tolerance are dropped from the resulting factor except for the diagonal element which is never dropped. The local drop tolerance at step $j$ of the factorization is $\text{norm}(A(j:\text{end}, j), 1) * \text{droptol}$ . 'droptol' is ignored if 'type' is 'nofill'. The default value is 0. |
| michol     | Indicates whether to perform modified incomplete Cholesky              | Indicates whether or not <i>modified incomplete Cholesky</i> (MIC) is performed. The field may be 'on' or 'off'. When performing MIC, the diagonal is compensated for dropped elements to enforce the relationship $A * e = L * L' * e$ where $e = \text{ones}(\text{size}(A, 2), 1)$ . The default value is 'off'.                                                                                                         |
| diagcomp   | Perform compensated incomplete Cholesky with the specified coefficient | Real nonnegative scalar used as a global diagonal shift $\alpha$ in forming the incomplete Cholesky factor. That is, instead of performing incomplete Cholesky on $A$ , the factorization of $A + \alpha * \text{diag}(\text{diag}(A))$ is formed. The default value is 0.                                                                                                                                                  |

| Field Name | Summary                                              | Description                                                                                                                                                                                                                                                                                                                     |
|------------|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| shape      | Determines which triangle is referenced and returned | Valid values are 'upper' and 'lower'. If 'upper' is specified, only the upper triangle of A is referenced and R is constructed such that A is approximated by R'*R. If 'lower' is specified, only the lower triangle of A is referenced and L is constructed such that A is approximated by L*L'. The default value is 'lower'. |

## Examples

### Incomplete Cholesky Factorization

This example generates an incomplete Cholesky factorization.

Start with a symmetric positive definite matrix, A:

```
N = 100;
A = delsq(numgrid('S',N));
```

A is the two-dimensional, five-point discrete negative Laplacian on a 100-by-100 square grid with Dirichlet boundary conditions. The size of A is  $98 \times 98 = 9604$  (not 10000 as the borders of the grid are used to impose the Dirichlet conditions).

The no-fill incomplete Cholesky factorization is a factorization which contains only nonzeros in the same position as A contains nonzeros. This factorization is extremely cheap to compute. Although the product  $L \cdot L'$  is typically very different from A, the product  $L \cdot L'$  will match A on its pattern up to round-off.

```
L = ichol(A);
norm(A-L*L', 'fro') ./ norm(A, 'fro')
```

```
ans =
```

```
0.0916
```

```
norm(A-(L*L')).*spones(A),'fro')./norm(A,'fro')
```

```
ans =
```

```
4.9606e-17
```

`ichol` may also be used to generate incomplete Cholesky factorizations with threshold dropping. As the drop tolerance decreases, the factor tends to get more dense and the product  $L*L'$  tends to be a better approximation of  $A$ . The following plots show the relative error of the incomplete factorization plotted against the drop tolerance as well as the ratio of the density of the incomplete factors to the density of the complete Cholesky factor.

```
n = size(A,1);
ntols = 20;
droptol = logspace(-8,0,ntols);
nrm = zeros(1,ntols);
nz = zeros(1,ntols);
nzComplete = nnz(chol(A,'lower'));
for k = 1:ntols
 L = ichol(A,struct('type','ict','droptol',droptol(k)));
 nz(k) = nnz(L);
 nrm(k) = norm(A-L*L','fro')./norm(A,'fro');
end
figure
loglog(droptol,nrm,'LineWidth',2)
title('Drop tolerance vs norm(A-L*L','fro')./norm(A,'fro')')
figure
semilogx(droptol,nz./nzComplete,'LineWidth',2)
title('Drop tolerance vs fill ratio ichol/chol')
```

The relative error is typically on the same order as the drop tolerance, although this is not guaranteed.

### Using ichol as a Preconditioner

This example shows how to use an incomplete Cholesky factorization as a preconditioner to improve convergence.

Create a symmetric positive definite matrix, A.

```
N = 100;
A = delsq(numgrid('S',N));
```

Create an incomplete Cholesky factorization as a preconditioner for `pcg`. Use a constant vector as the right hand side. As a baseline, execute `pcg` without a preconditioner.

```
b = ones(size(A,1),1);
tol = 1e-6;
maxit = 100;
[x0,f10,rr0,it0,rv0] = pcg(A,b,tol,maxit);
```

Note that `f10 = 1` indicating that `pcg` did not drive the relative residual to the requested tolerance in the maximum allowed iterations. Try the no-fill incomplete Cholesky factorization as a preconditioner.

```
L1 = ichol(A);
[x1,f11,rr1,it1,rv1] = pcg(A,b,tol,maxit,L1,L1');
```

`f11 = 0`, indicating that `pcg` converged to the requested tolerance and did so in 59 iterations (the value of `it1`). Since this matrix is a discretized Laplacian, however, using modified incomplete Cholesky can create a better preconditioner. A modified incomplete Cholesky factorization constructs an approximate factorization that preserves the action of the operator on the constant vector. That is, `norm(A*e-L*(L'*e))` will be approximately zero for `e = ones(size(A,2),1)` even though `norm(A-L*L', 'fro') / norm(A, 'fro')` is not close to zero. It is not necessary to specify type for this syntax since `nofill` is the default, but it is good practice.

```
opts.type = 'nofill';
opts.michol = 'on';
L2 = ichol(A,opts);
e = ones(size(A,2),1);
norm(A*e-L2*(L2'*e))
[x2,f12,rr2,it2,rv2] = pcg(A,b,tol,maxit,L2,L2');
```

```
ans =
 3.7983e-14
```

`pcg` converges (`f12 = 0`) but in only 38 iterations. Plotting all three convergence histories shows the convergence.

```
semilogy(0:maxit,rv0./norm(b), 'b. ');
hold on
semilogy(0:it1,rv1./norm(b), 'r. ');
semilogy(0:it2,rv2./norm(b), 'k. ');
```

```
legend('No Preconditioner', 'IC(0)', 'MIC(0)');
```

The plot shows that the modified incomplete Cholesky preconditioner creates a much faster convergence.

You can also try incomplete Cholesky factorizations with threshold dropping. The following plot shows convergence of `pcg` with preconditioners constructed with various drop tolerances.

```
L3 = ichol(A, struct('type', 'ict', 'droptol', 1e-1));
[x3, fl3, rr3, it3, rv3] = pcg(A, b, tol, maxit, L3, L3');
L4 = ichol(A, struct('type', 'ict', 'droptol', 1e-2));
[x4, fl4, rr4, it4, rv4] = pcg(A, b, tol, maxit, L4, L4');
```

```

L5 = ichol(A, struct('type','ict','droptol',1e-3));
[x5,f15,rr5,it5,rv5] = pcg(A,b,tol,maxit,L5,L5');

figure
semilogy(0:maxit,rv0./norm(b),'b-','linewidth',2);
hold on
semilogy(0:it3,rv3./norm(b),'b-.','linewidth',2);
semilogy(0:it4,rv4./norm(b),'b--','linewidth',2);
semilogy(0:it5,rv5./norm(b),'b:','linewidth',2);
legend('No Preconditioner','ICT(1e-1)','ICT(1e-2)', ...
 'ICT(1e-3)','Location','SouthEast');

```

Note the incomplete Cholesky preconditioner constructed with drop tolerance  $1e-2$  is denoted as `ICT(1e-2)`.

As with the zero-fill incomplete Cholesky, the threshold dropping factorization can benefit from modification (i.e. `opts.michol = 'on'`) since the matrix arises from an elliptic partial differential equation. As with `MIC(0)`, the modified threshold based dropping incomplete Cholesky will preserve the action of the preconditioner on constant vectors, that is `norm(A*e-L*(L'*e))` will be approximately zero.

### Using the `diagcomp` Option

This example illustrates the use of the `diagcomp` option of `ichol`.

Incomplete Cholesky factorizations of positive definite matrices do not always exist. The following code constructs a random symmetric positive definite matrix and attempts to solve a linear system using `pcg`.

```
S = rng('default');
A = sprandsym(1000,1e-2,1e-4,1);
rng(S);
b = full(sum(A,2));
[x0,f10,rr0,it0,rv0] = pcg(A,b,1e-6,100);
```

Since convergence is not attained, try to construct an incomplete Cholesky preconditioner.

```
L = ichol(A,struct('type','ict','droptol',1e-3));
```

```
Error using ichol
Encountered nonpositive pivot.
```

If `ichol` breaks down as above, you can use the `diagcomp` option to construct a shifted incomplete Cholesky factorization. That is, instead of constructing `L` such that `L*L'` approximates `A`, `ichol` with diagonal compensation constructs `L` such that `L*L'` approximates `M = A + alpha*diag(diag(A))` without explicitly forming `M`. As incomplete factorizations always exist for diagonally dominant matrices, `alpha` can be found to make `M` diagonally dominant.

```
alpha = max(sum(abs(A),2)./diag(A))-2
```

```
alpha =
 62.9341
```

```
L1 = ichol(A, struct('type','ict','droptol',1e-3,'diagcomp',alpha));
[x1,f11,rr1,it1,rv1] = pcg(A,b,1e-6,100,L1,L1');
```

Here, `pcg` still fails to converge to the desired tolerance within the desired number of iterations, but as the plot below shows, convergence is better for `pcg` with this preconditioner than with no preconditioner. Choosing a smaller `alpha` may help. With some experimentation, we can settle on an appropriate value for `alpha`.

```
alpha = .1;
L2 = ichol(A, struct('type','ict','droptol',1e-3,'diagcomp',alpha));
[x2,f12,rr2,it2,rv2] = pcg(A,b,1e-6,100,L2,L2');
```

Now, `pcg` converges and a plot can show the convergence histories with each preconditioner.

```
semilogy(0:100,rv0./norm(b),'b. ');
hold on;
semilogy(0:100,rv1./norm(b),'r. ');
semilogy(0:it2,rv2./norm(b),'k. ');
legend('No Preconditioner','\alpha \approx 63','\alpha = .1');
xlabel('Iteration Number');
ylabel('Relative Residual');
```

## More About

### Tips

- The factor given by this routine may be useful as a preconditioner for a system of linear equations being solved by iterative methods such as `pcg` or `minres`.
- `ichol` works only for sparse square matrices

# idivide

Integer division with rounding option

## Syntax

```
C = idivide(A, B, opt)
C = idivide(A, B)
C = idivide(A, B, 'fix')
C = idivide(A, B, 'round')
C = idivide(A, B, 'floor')
C = idivide(A, B, 'ceil')
```

## Description

`C = idivide(A, B, opt)` is the same as `A./B` for integer classes except that fractional quotients are rounded to integers using the optional rounding mode specified by `opt`. The default rounding mode is `'fix'`. Inputs `A` and `B` must be real and must have the same dimensions unless one is a scalar. The arguments `A` and `B` must belong to the same integer class. Alternatively, one of the arguments can be a scalar double, while the other can be any integer type except `int64` or `uint64`. The result `C` belongs to the integer class of the input arguments.

`C = idivide(A, B)` is the same as `A./B` except that fractional quotients are rounded toward zero to the nearest integers.

`C = idivide(A, B, 'fix')` is the same as the syntax shown immediately above.

`C = idivide(A, B, 'round')` is the same as `A./B` for integer classes. Fractional quotients are rounded to the nearest integers.

`C = idivide(A, B, 'floor')` is the same as `A./B` except that fractional quotients are rounded toward negative infinity to the nearest integers.

`C = idivide(A, B, 'ceil')` is the same as `A./B` except that the fractional quotients are rounded toward infinity to the nearest integers.

## Examples

```
a = int32([-2 2]);
b = int32(3);

idivide(a,b) % Returns [0 0]
idivide(a,b,'floor') % Returns [-1 0]
idivide(a,b,'ceil') % Returns [0 1]
idivide(a,b,'round') % Returns [-1 1]
```

## if, elseif, else

Execute statements if condition is true

### Syntax

```
if expression
 statements
elseif expression
 statements
else
 statements
end
```

### Description

`if expression, statements, end` evaluates an expression, and executes a group of statements when the expression is true. An expression is true when its result is nonempty and contains only nonzero elements (logical or real numeric). Otherwise, the expression is false.

The `elseif` and `else` blocks are optional. The statements execute only if previous expressions in the `if...end` block are false. An `if` block can include multiple `elseif` blocks.

### Examples

#### Use if, elseif, and else for Conditional Assignment

Create a matrix of 1s.

```
nrows = 4;
ncols = 6;
A = ones(nrows,ncols);
```

Loop through the matrix and assign each element a new value. Assign 2 on the main diagonal, -1 on the adjacent diagonals, and 0 everywhere else.

```
for c = 1:ncols
```

```

for r = 1:nrows
 if r == c
 A(r,c) = 2;
 elseif abs(r-c) == 1
 A(r,c) = -1;
 else
 A(r,c) = 0;
 end
end
end
A

```

A =

```

 2 -1 0 0 0 0
 -1 2 -1 0 0 0
 0 -1 2 -1 0 0
 0 0 -1 2 -1 0

```

### Compare Arrays

Expressions that include relational operators on arrays, such as  $A > 0$ , are true only when every element in the result is nonzero.

Test if any results are true using the `any` function.

```

limit = 0.75;
A = rand(10,1)

```

A =

```

0.8147
0.9058
0.1270
0.9134
0.6324
0.0975
0.2785
0.5469
0.9575

```

```
0.9649
```

```
if any(A > limit)
 disp('There is at least one value above the limit.')
else
 disp('All values are below the limit.')
end
```

```
There is at least one value above the limit.
```

### **Test Arrays for Equality**

Compare arrays using `isequal` rather than the `==` operator to test for equality, because `==` results in an error when the arrays are different sizes.

Create two arrays.

```
A = ones(2,3);
B = rand(3,4,5);
```

If `size(A)` and `size(B)` are the same, concatenate the arrays; otherwise, display a warning and return an empty array.

```
if isequal(size(A),size(B))
 C = [A; B];
else
 disp('A and B are not the same size.')
 C = [];
end
```

```
A and B are not the same size.
```

### **Determine if Strings Match**

Use `strcmp` to compare strings. Using `==` to test for equality results in an error when the strings are different sizes.

```
reply = input('Would you like to see an echo? (y/n): ','s');
if strcmp(reply,'y')
 disp(reply)
end
```

### **Evaluate Multiple Conditions in Expression**

Determine if a value falls within a specified range.

```
x = 10;
minVal = 2;
maxVal = 6;

if (x >= minVal) && (x <= maxVal)
 disp('Value within specified range.')
elseif (x > maxVal)
 disp('Value exceeds maximum value.')
else
 disp('Value is below minimum value.')
end
```

```
Value exceeds maximum value.
```

## More About

### Expression

An expression can include relational operators (such as `<` or `==`) and logical operators (such as `&&`, `||`, or `~`). Use the logical operators **and** and **or** to create compound expressions. MATLAB evaluates compound expressions from left to right, adhering to operator precedence rules.

Within the conditional expression of an `if...end` block, logical operators `&` and `|` behave as short-circuit operators. This behavior is the same as `&&` and `||`, respectively. Since `&&` and `||` consistently short-circuit in conditional expressions and statements, it is good practice to use `&&` and `||` instead of `&` and `|` within the expression. For example,

```
x = 42;
if exist('myfunction.m','file') && (myfunction(x) >= pi)
 disp('Expressions are true')
end
```

The first part of the expression evaluates to false. Therefore, MATLAB does not need to evaluate the second part of the expression, which would result in an undefined function error.

### Tips

- You can nest any number of `if` statements. Each `if` statement requires an `end` keyword.

- Avoid adding a space after `else` within the `elseif` keyword (`else if`). The space creates a nested `if` statement that requires its own `end` keyword.

# iff

Inverse fast Fourier transform

## Syntax

```
y = iff(X)
y = iff(X,n)
y = iff(X,[],dim)
y = iff(X,n,dim)
y = iff(..., 'symmetric')
y = iff(..., 'nonsymmetric')
```

## Description

`y = iff(X)` returns the inverse discrete Fourier transform (DFT) of vector `X`, computed with a fast Fourier transform (FFT) algorithm. If `X` is a matrix, `iff` returns the inverse DFT of each column of the matrix.

`iff` tests `X` to see whether vectors in `X` along the active dimension are *conjugate symmetric*. If so, the computation is faster and the output is real. An `N`-element vector `x` is conjugate symmetric if  $x(i) = \text{conj}(x(\text{mod}(N-i+1,N)+1))$  for each element of `x`.

If `X` is a multidimensional array, `iff` operates on the first non-singleton dimension.

`y = iff(X,n)` returns the `n`-point inverse DFT of vector `X`.

`y = iff(X,[],dim)` and `y = iff(X,n,dim)` return the inverse DFT of `X` across the dimension `dim`.

`y = iff(..., 'symmetric')` causes `iff` to treat `X` as conjugate symmetric along the active dimension. This option is useful when `X` is not exactly conjugate symmetric, merely because of round-off error.

`y = iff(..., 'nonsymmetric')` is the same as calling `iff(...)` without the argument `'nonsymmetric'`.

For any `X`, `iff(fft(X))` equals `X` to within roundoff error.

## Data Type Support

`ifft` supports inputs of data types `double` and `single`. If you call `ifft` with the syntax `y = ifft(X, ...)`, the output `y` has the same data type as the input `X`.

## More About

### Algorithms

The algorithm for `ifft(X)` is the same as the algorithm for `fft(X)`, except for a sign change and a scale factor of `n = length(X)`. As for `fft`, the execution time for `ifft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `ifft` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

## ifft2

2-D inverse fast Fourier transform

### Syntax

```
Y = ifft2(X)
Y = ifft2(X,m,n)
y = ifft2(..., 'symmetric')
y = ifft2(..., 'nonsymmetric')
```

### Description

`Y = ifft2(X)` returns the two-dimensional inverse discrete Fourier transform (DFT) of `X`, computed with a fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`ifft2` tests `X` to see whether it is *conjugate symmetric*. If so, the computation is faster and the output is real. An `M`-by-`N` matrix `X` is conjugate symmetric if  $X(i,j) = \text{conj}(X(\text{mod}(M-i+1, M) + 1, \text{mod}(N-j+1, N) + 1))$  for each element of `X`.

`Y = ifft2(X,m,n)` returns the `m`-by-`n` inverse fast Fourier transform of matrix `X`.

`y = ifft2(..., 'symmetric')` causes `ifft2` to treat `X` as conjugate symmetric. This option is useful when `X` is not exactly conjugate symmetric, merely because of round-off error.

`y = ifft2(..., 'nonsymmetric')` is the same as calling `ifft2(...)` without the argument `'nonsymmetric'`.

For any `X`, `ifft2(fft2(X))` equals `X` to within roundoff error.

### Data Type Support

`ifft2` supports inputs of data types `double` and `single`. If you call `ifft2` with the syntax `y = ifft2(X, ...)`, the output `y` has the same data type as the input `X`.

## More About

### Algorithms

The algorithm for `ifft2(X)` is the same as the algorithm for `fft2(X)`, except for a sign change and scale factors of `[m,n] = size(X)`. The execution time for `ifft2` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `ifft2` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

# ifftn

N-D inverse fast Fourier transform

## Syntax

```
Y = ifftn(X)
Y = ifftn(X,siz)
y = ifftn(..., 'symmetric')
y = ifftn(..., 'nonsymmetric')
```

## Description

`Y = ifftn(X)` returns the n-dimensional inverse discrete Fourier transform (DFT) of `X`, computed with a multidimensional fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`ifftn` tests `X` to see whether it is *conjugate symmetric*. If so, the computation is faster and the output is real. An `N1-by-N2-by- ... Nk` array `X` is conjugate symmetric if

$$X(i_1, i_2, \dots, i_k) = \text{conj}(X(\text{mod}(N_1 - i_1 + 1, N_1) + 1, \text{mod}(N_2 - i_2 + 1, N_2) + 1, \dots, \text{mod}(N_k - i_k + 1, N_k) + 1))$$

for each element of `X`.

`Y = ifftn(X, siz)` pads `X` with zeros, or truncates `X`, to create a multidimensional array of size `siz` before performing the inverse transform. The size of the result `Y` is `siz`.

`y = ifftn(..., 'symmetric')` causes `ifftn` to treat `X` as conjugate symmetric. This option is useful when `X` is not exactly conjugate symmetric, merely because of round-off error.

`y = ifftn(..., 'nonsymmetric')` is the same as calling `ifftn(...)` without the argument `'nonsymmetric'`.

## Data Type Support

`ifftn` supports inputs of data types `double` and `single`. If you call `ifftn` with the syntax `y = ifftn(X, ...)`, the output `y` has the same data type as the input `X`.

## More About

### Tips

For any  $X$ , `ifftn(fftn(X))` equals  $X$  within roundoff error.

### Algorithms

`ifftn(X)` is equivalent to

```
Y = X;
for p = 1:length(size(X))
 Y = ifft(Y,[],p);
end
```

This computes in-place the one-dimensional inverse DFT along each dimension of  $X$ .

The execution time for `ifftn` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `ifftn` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

---

**Introduced before R2006a**

# ifftshift

Inverse FFT shift

## Syntax

```
ifftshift(X)
ifftshift(X,dim)
```

## Description

`ifftshift(X)` swaps the left and right halves of the vector `X`. For matrices, `ifftshift(X)` swaps the first quadrant with the third and the second quadrant with the fourth. If `X` is a multidimensional array, `ifftshift(X)` swaps “half-spaces” of `X` along each dimension.

`ifftshift(X,dim)` applies the `ifftshift` operation along the dimension `dim`.

---

**Note:** `ifftshift` undoes the results of `fftshift`. If the matrix `X` contains an odd number of elements, `ifftshift(fftshift(X))` must be done to obtain the original `X`. Simply performing `fftshift(X)` twice will not produce `X`.

## ilu

Incomplete LU factorization

### Syntax

```
ilu(A,setup)
[L,U] = ilu(A,setup)
[L,U,P] = ilu(A,setup)
```

### Description

`ilu` produces a unit lower triangular matrix, an upper triangular matrix, and a permutation matrix.

`ilu(A,setup)` computes the incomplete LU factorization of **A**. **setup** is an input structure with up to five setup options. The fields must be named exactly as shown in the table below. You can include any number of these fields in the structure and define them in any order. Any additional fields are ignored.

| Field Name           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>type</code>    | Type of factorization. Values for <code>type</code> include: <ul style="list-style-type: none"><li>'<code>nofill</code>' (default)—Performs ILU factorization with 0 level of fill in, known as ILU(0). With <code>type</code> set to '<code>nofill</code>', only the <code>milu</code> setup option is used; all other fields are ignored.</li><li>'<code>crout</code>'—Performs the Crout version of ILU factorization, known as ILUC. With <code>type</code> set to '<code>crout</code>', only the <code>droptol</code> and <code>milu</code> setup options are used; all other fields are ignored.</li><li>'<code>ilutp</code>'—Performs ILU factorization with threshold and pivoting.</li></ul> If <code>type</code> is not specified, the ILU factorization with 0 level of fill in is performed. Pivoting is only performed with <code>type</code> set to ' <code>ilutp</code> '. |
| <code>droptol</code> | Drop tolerance of the incomplete LU factorization. <code>droptol</code> is a non-negative scalar. The default value is 0, which produces the complete LU factorization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Field Name    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Entries from the newly-formed column of the factors are subtracted from the diagonal of the upper triangular factor, <math>U</math>, preserving column sums. That is, <math>e' * A = e' * L * U</math>.</li> <li>• <b>'off'</b> (default)—No modified incomplete LU factorization is produced.</li> </ul> |
| <b>udiag</b>  | <p>If <b>udiag</b> is 1, any zeros on the diagonal of the upper triangular factor are replaced by the local drop tolerance. The default is 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>thresh</b> | <p>Pivot threshold between 0 (forces diagonal pivoting) and 1, the default, which always chooses the maximum magnitude entry in the column to be the pivot.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

`ilu(A, setup)` returns  $L+U$ -`speye(size(A))`, where  $L$  is a unit lower triangular matrix and  $U$  is an upper triangular matrix.

`[L,U] = ilu(A, setup)` returns a unit lower triangular matrix in  $L$  and an upper triangular matrix in  $U$ .

`[L,U,P] = ilu(A, setup)` returns a unit lower triangular matrix in  $L$ , an upper triangular matrix in  $U$ , and a permutation matrix in  $P$ .

## Limitations

`ilu` works on sparse square matrices only.

## Examples

Start with a sparse matrix and compute the LU factorization.

```
A = gallery('neumann', 1600) + speye(1600);
setup.type = 'crout';
setup.milu = 'row';
setup.droptol = 0.1;
[L,U] = ilu(A,setup);
e = ones(size(A,2),1);
norm(A*e-L*U*e)
```

```
ans =
```

```
1.4251e-014
```

This shows that  $A$  and  $L*U$ , where  $L$  and  $U$  are given by the modified Crout ILU, have the same row-sum.

Start with a sparse matrix and compute the LU factorization.

```
A = gallery('neumann', 1600) + speye(1600);
setup.type = 'nofill';
nnz(A)
ans =
```

```
7840
```

```
nnz(lu(A))
ans =
```

```
126478
```

```
nnz(ilu(A,setup))
ans =
```

```
7840
```

This shows that A has 7840 nonzeros, the complete LU factorization has 126478 nonzeros, and the incomplete LU factorization, with 0 level of fill-in, has 7840 nonzeros, the same amount as A.

## More About

### Tips

These incomplete factorizations may be useful as preconditioners for a system of linear equations being solved by iterative methods such as BICG (BiConjugate Gradients), GMRES (Generalized Minimum Residual Method).

# im2double

Convert image to double precision

## Syntax

```
I2 = im2double(I)
I2 = im2double(I, 'indexed')
```

## Description

`I2 = im2double(I)` converts the intensity image `I` to double precision, rescaling the data if necessary. `I` can be a grayscale intensity image, a truecolor image, or a binary image.

If the input image is of class `double`, then the output image is identical.

`I2 = im2double(I, 'indexed')` converts the indexed image `I` to double precision, offsetting the data if necessary.

## Examples

### Convert Image to Double Precision

```
I = imread('peppers.png');
whos I
```

| Name | Size      | Bytes  | Class | Attributes |
|------|-----------|--------|-------|------------|
| I    | 384x512x3 | 589824 | uint8 |            |

```
I2 = im2double(I);
whos I2
```

| Name | Size      | Bytes   | Class  | Attributes |
|------|-----------|---------|--------|------------|
| I2   | 384x512x3 | 4718592 | double |            |

## Convert Image to Double Precision on GPU

Convert an array to class `double` on the GPU. This example requires the Parallel Computing Toolbox.

```
I1 = gpuArray(reshape(uint8(linspace(1,255,25)),[5 5]));
I2 = im2double(I1);
```

## Input Arguments

### I — Input image

scalar | vector | matrix | multidimensional array

Input image, specified as a scalar, vector, matrix, or multidimensional array.

- If I is an intensity or truecolor image, it can be `uint8`, `uint16`, `double`, `logical`, `single`, or `int16`.
- If I is an indexed image, it can be `uint8`, `uint16`, `double` or `logical`.
- If I is a binary image, it must be `logical`.

If the Parallel Computing Toolbox is installed, I can be a `gpuArray` and `im2double` converts I on a GPU.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

## More About

### Tips

- `im2double` supports the generation of efficient, production-quality C/C++ code if you have MATLAB Coder™ installed.

### See Also

`double` | `gpuArray` | `im2int16` | `im2single` | `im2uint16` | `im2uint8`

## **im2frame**

Convert image to movie frame

### **Syntax**

```
f = im2frame(X,map)
```

```
f = im2frame(X)
```

### **Description**

`f = im2frame(X,map)` converts the indexed image, `X`, and the associated colormap, `map`, into a movie frame `f`.

- If you specify `X` as an `m`-by-`n` array of integers, then `im2frame` uses the associated colormap, `map`, where `map` is a three-column array of values in the range `[0,1]`. Each row of `map` is a three-element RGB triplet that specifies the red, green, and blue components of a single color of the colormap.
- If you specify `X` as an `m`-by-`n`-by-3 truecolor image, then `map` is optional and has no effect.

`f = im2frame(X)` converts the indexed image, `X`, into a movie frame `f` using the current colormap if `X` contains an indexed image.

For more information on image types, see “Image Types”.

### **Class Support**

`X` must be of class `uint8` or `double`.

### **Examples**

#### **Convert Image Sequence to Movie**

Use `im2frame` to convert a sequence of images into a movie.

```
F(1) = im2frame(X1,map);
F(2) = im2frame(X2,map);
...
F(n) = im2frame(Xn,map);
movie(F)
```

## im2java

Convert image to Java image

### Syntax

```
jimage = im2java(I)
jimage = im2java(X,MAP)
jimage = im2java(RGB)
```

### Description

To work with a MATLAB image in the Java environment, you must convert the image from its MATLAB representation into an instance of the Java image class, `java.awt.Image`.

`jimage = im2java(I)` converts the intensity image `I` to an instance of the Java image class, `java.awt.Image`.

`jimage = im2java(X,MAP)` converts the indexed image `X`, with colormap `MAP`, to an instance of the Java image class, `java.awt.Image`.

`jimage = im2java(RGB)` converts the RGB image `RGB` to an instance of the Java image class, `java.awt.Image`.

### Class Support

The input image can be of class `uint8`, `uint16`, or `double`.

---

**Note** Java requires `uint8` data to create an instance of the Java image class, `java.awt.Image`. If the input image is of class `uint8`, `jimage` contains the same `uint8` data. If the input image is of class `double` or `uint16`, `im2java` makes an equivalent image of class `uint8`, rescaling or offsetting the data as necessary, and then converts this `uint8` representation to an instance of the Java image class, `java.awt.Image`.

---

## Examples

This example reads an image into the MATLAB workspace and then uses `im2java` to convert it into an instance of the Java image class.

```
I = imread('ngc6543a.jpg');
javaImage = im2java(I);
frame = javax.swing.JFrame;
icon = javax.swing.ImageIcon(javaImage);
label = javax.swing.JLabel(icon);
frame.getContentPane.add(label);
frame.pack
frame.show
```

**Introduced before R2006a**

## imag

Imaginary part of complex number

### Syntax

```
Y = imag(Z)
```

### Description

`Y = imag(Z)` returns the imaginary part of the elements of array `Z`.

### Examples

```
imag(2+3i)
```

```
ans =
```

```
 3
```

### See Also

`conj` | `i` | `j` | `real`

Introduced before R2006a

# image

Display image from array

## Syntax

```
image(C)
image(x,y,C)
image('CData',C)
image('XData',x,'YData',y,'CData',C)

image(____,Name,Value)

im = image(____)
```

## Description

`image(C)` displays the data in array `C` as an image. Each element of `C` specifies the color for 1 pixel of the image. The resulting image is an `m`-by-`n` grid of pixels where `m` is the number of columns and `n` is the number of rows in `C`. The row and column indices of the elements determine the centers of the corresponding pixels.

`image(x,y,C)` specifies the image location. Use `x` and `y` to specify the locations of the corners corresponding to `C(1,1)` and `C(m,n)`. To specify both corners, set `x` and `y` as two-element vectors. To specify the first corner and let `image` determine the other, set `x` and `y` as scalar values. The image is stretched and oriented as applicable.

`image('CData',C)` adds the image to the current axes without replacing existing plots. This syntax is the low-level version of `image(C)`. For more information, see “High-Level Versus Low-Level Version of Image” on page 1-4297.

`image('XData',x,'YData',y,'CData',C)` specifies the image location. This syntax is the low-level version of `image(x,y,C)`.

`image( ____,Name,Value)` specifies image properties using one or more name-value pair arguments. You can specify image properties with any of the input argument combinations in the previous syntaxes.

`im = image( ____ )` returns the image object created. Use `im` to set properties of the image after it is created. You can specify this output with any of the input argument

combinations in the previous syntaxes. For a list of image properties and descriptions, see Image Properties.

## Examples

### Display Image of Matrix Data

Create matrix **C**. Display an image of the data in **C**. Add a colorbar to the graph to show the current colormap.

```
C = [0 2 4 6; 8 10 12 14; 16 18 20 22];
image(C)
colorbar
```

By default, the `CDataMapping` property for the image is set to `'direct'` so `image` interprets values in `C` as indices into the colormap. For example, the bottom right pixel corresponding to the last element in `C`, 22, uses the 22nd color of the colormap.

Scale the values to the full range of the current colormap by setting the `CDataMapping` property to `'scaled'` when creating the image.

```
image(C, 'CDataMapping', 'scaled')
colorbar
```

Alternatively, you can use the `imagesc` function to scale the values instead of using `image(C, 'CDataMapping', 'scaled')`. For example, use `imagesc(C)`.

### Control Image Placement

Place the image so that it lies between 5 and 8 on the  $x$ -axis and between 3 and 6 on the  $y$ -axis.

```
x = [5 8];
y = [3 6];
C = [0 2 4 6; 8 10 12 14; 16 18 20 22];
image(x,y,C)
```

Notice that the pixel corresponding to  $C(1,1)$  is centered over the point  $(5,3)$ . The pixel corresponding to  $C(3,4)$  is centered over the point  $(8,6)$ . `image` positions and orients the rest of the image between those two points.

## Display Image of 3-D Array of True Colors

Create  $C$  as a 3-D array of true colors. Use only red colors by setting the last two pages of the array to zeros.

```
C = zeros(3,3,3);
C(:,:,1) = [.1 .2 .3; .4 .5 .6; .7 .8 .9]
```

```
C(:,:,1) =
```

```
 0.1000 0.2000 0.3000
 0.4000 0.5000 0.6000
 0.7000 0.8000 0.9000
```

```
C(:,:,2) =
```

```
 0 0 0
 0 0 0
 0 0 0
```

```
C(:,:,3) =
```

```
 0 0 0
 0 0 0
 0 0 0
```

Display an image of the data in  $C$ .

```
image(C)
```

### Modify Image After Creation

Plot a line, and then create an image on top of the line. Return the image object.

```
plot(1:3)
hold on
C = [1 2 3; 4 5 6; 7 8 9];
im = image(C);
```

Make the image semitransparent so that the line shows through the image.

```
im.AlphaData = 0.5;
```

### Read and Display JPEG Image File

Read a JPEG image file.

```
C = imread('ngc6543a.jpg');
```

`imread` returns a 650-by-600-by-3 array, `C`.

Display the image.

```
image(C)
```

### Add Image to Axes in 3-D View

Create a surface plot. Then, add an image under the surface. `image` displays the image in the  $xy$ -plane.

```
Z = 10 + peaks;
surf(Z)
hold on
image(Z, 'CDataMapping', 'scaled')
```

## Input Arguments

### **C** — Image color data

vector or matrix | 3-D array of RGB triplets

Image color data, specified in one of these forms:

- Vector or matrix — This format defines indexed image data. Each element of **C** defines a color for 1 pixel of the image. For example, **C** = [1 2 3; 4 5 6; 7 8 9];. The elements of **C** map to colors in the colormap of the associated axes. The **CDataMapping** property controls the mapping method.

- 3-D array of RGB triplets — This format defines true color image data using RGB triplet values. Each RGB triplet defines a color for 1 pixel of the image. An RGB triplet is a three-element vector that specifies the intensities of the red, green, and blue components of the color. The first page of the 3-D array contains the red components, the second page contains the green components, and the third page contains the blue components. Since the image uses true colors instead of colormap colors, the `CDataMapping` property has no effect.
  - If `C` is of type `double`, then an RGB triplet value of `[0 0 0]` corresponds to black and `[1 1 1]` corresponds to white.
  - If `C` is an integer type, then the image uses the full range of data to determine the color. For example, if `C` is of type `uint8`, then `[0 0 0]` corresponds to black and `[255 255 255]` corresponds to white. If `CData` is of type `int8`, then `[-128 -128 -128]` corresponds to black and `[127 127 127]` corresponds to white.
  - If `C` is of type `logical`, then `[0 0 0]` corresponds to black and `[1 1 1]` corresponds to white.

This illustration shows the relative dimensions of `C` for the two color models.

The behavior of NaN elements is not defined.

To use the low-level version of the `image` function instead, set the `CData` property as a name-value pair. For example, `image('CData',C)`.

## Converting Between Data Types

To convert indexed image data from an integer type to type `double`, add 1. For example, if `X8` is indexed image data of type `uint8`, convert it to type `double` using:

```
X64 = double(X8) + 1;
```

To convert indexed image data from type `double` to an integer type, subtract 1 and use `round` to ensure that all the values are integers. For example, if `X64` is indexed image data of type `double`, convert it to `uint8` using:

```
X8 = uint8(round(X64 - 1));
```

To convert true color image data from an integer type to type `double`, rescale the data. For example, if `RGB8` is true color image data of type `uint8`, convert it to `double` using:

```
RGB64 = double(RGB8)/255;
```

To convert true color image data from type `double` to an integer type, rescale the data and use `round` to ensure that all the values are integers. For example, if `RGB64` is image data of type `double`, convert it to `uint8` using:

```
RGB8 = uint8(round(RGB64*255));
```

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **x** — Placement along x-axis

[1 `size(C,2)`] (default) | two-element vector | scalar

Placement along the *x*-axis, specified in one of these forms:

- Two-element vector — Use the first element as the location for the center of `C(1,1)` and the second element as the location for the center of `C(m,n)`, where `[m,n] = size(C)`. If `C` is a 3-D array, then `m` and `n` are the first two dimensions. Evenly distribute the centers of the remaining elements of `C` between those two points.

The width of each pixel is determined by the expression:

$$(x(2)-x(1))/(size(C,2)-1)$$

If  $x(1) > x(2)$ , then the image is flipped left-right.

- Scalar — Center  $C(1,1)$  at this location and each following element one unit apart.

To use the low-level version of the `image` function instead, set the `XData` property as a name-value pair. For example, `image('XData',x,'YData',y,'CData',C)`.

You cannot interactively pan or zoom outside the x-axis limits or y-axis limits of an image, unless the limits are already set outside the bounds of the image. If the limits are already outside the bounds, there is no such restriction. If other objects (such as a line) occupy the axes and extend beyond the bounds of the image, you can pan or zoom to the bounds of the other objects, but no further.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **y** — Placement along y-axis

`[1 size(C,1)]` (default) | two-element vector | scalar

Placement along y-axis, specified in one of these forms:

- Two-element vector — Use the first element as the location for the center of  $C(1,1)$  and the second element as the location for the center of  $C(m,n)$ , where  $[m,n] = size(C)$ . If  $C$  is a 3-D array, then  $m$  and  $n$  are the first two dimensions. Evenly distribute the centers of the remaining elements of  $C$  between those two points.

The height of each pixel is determined by the expression:

$$(y(2)-y(1))/(size(C,1)-1)$$

If  $y(1) > y(2)$ , then the image is flipped up-down.

- Scalar — Center  $C(1,1)$  at this location and each following element one unit apart.

To use the low-level version of the `image` function instead, set the `YData` property as a name-value pair. For example, `image('XData',x,'YData',y,'CData',C)`.

You cannot interactively pan or zoom outside the x-axis limits or y-axis limits of an image, unless the limits are already set outside the bounds of the image. If the limits are already outside the bounds, there is no such restriction. If other objects (such as a line) occupy the axes and extend beyond the bounds of the image, you can pan or zoom to the bounds of the other objects, but no further.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `image([1 2 3], 'AlphaData', 0.5)` displays a semitransparent image.

The properties listed here are a subset of image properties. For a complete list, see Image Properties.

### 'CDataMapping' — Color data mapping method

'direct' (default) | 'scaled'

Color data mapping method, specified as 'direct' or 'scaled'. Use this property to control the mapping of color data values in `CData` into the colormap. `CData` must be a vector or a matrix defining indexed colors. This property has no effect if `CData` is a 3-D array defining true colors.

The methods have these effects:

- 'direct' — Interpret the values as indices into the current colormap. Values with a decimal portion are fixed to the nearest lower integer.
  - If the values are of type `double` or `single`, then values of 1 or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap.
  - If the values are of type `uint8`, `uint16`, `uint32`, `uint64`, `int8`, `int16`, `int32`, or `int64`, then values of 0 or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap (or up to the range limits of the type).
  - If the values are of type `logical`, then values of 0 map to the first color in the colormap and values of 1 map to the second color in the colormap.
- 'scaled' — Scale the values to range between the minimum and maximum color limits. The `CLim` property of the axes contains the color limits.

**'AlphaData' — Transparency data**

1 (default) | scalar | array the same size as CData

Transparency data, specified in one of these forms:

- Scalar — Use a consistent transparency across the entire image.
- Array the same size as CData — Use a different transparency value for each image element.

The AlphaDataMapping property controls how MATLAB interprets the alpha data transparency values.

Example: 0.5

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**'AlphaDataMapping' — Interpretation of AlphaData values**

'none' (default) | 'scaled' | 'direct'

Interpretation of AlphaData values, specified as one of these values:

- 'none' — Interpret the values as transparency values. A value of 1 or greater is completely opaque, a value of 0 or less is completely transparent, and a value between 0 and 1 is semitransparent.
- 'scaled' — Map the values into the figure's alphamap. The minimum and maximum alpha limits of the axes determine the alpha data values that map to the first and last elements in the alphamap, respectively. For example, if the alpha limits are [3 5], then alpha data values less than or equal to 3 map to the first element in the alphamap. Alpha data values greater than or equal to 5 map to the last element in the alphamap. The ALim property of the axes contains the alpha limits. The Alphamap property of the figure contains the alphamap.
- 'direct' — Interpret the values as indices into the figure's alphamap. Values with a decimal portion are fixed to the nearest lower integer:
  - If the values are of type double or single, then values of 1 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap map to the last element in the alphamap.
  - If the values are of type integer, then values of 0 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap map to the last element in the alphamap (or up to the range limits of the type). The

integer types are `uint8`, `uint16`, `uint32`, `uint64`, `int8`, `int16`, `int32`, and `int64`.

- If the values are of type `logical`, then values of 0 map to the first element in the `alphamap` and values of 1 map to the second element in the `alphamap`.

## Output Arguments

**im** — Image object

scalar

Image object, returned as a scalar. Use `im` to set properties of the image after it is created. For a list, see Image Properties.

## More About

### High-Level Versus Low-Level Version of Image

The `image` function has two versions, the high-level version and the low-level version. If you use `image` with `'CData'` as an input argument, then you are using the low-level version. Otherwise, you are using the high-level version.

The high-level version of `image` calls `newplot` before plotting and sets these axes properties:

- Layer to `'top'`. The image is shown in front of any tick marks or grid lines.
- YDir to `'reverse'`. Values along the *y*-axis increase from top to bottom. To decrease the values from top to bottom, set YDir to `'normal'`. This setting reverses both the *y*-axis and the image.
- View to `[0 90]`.

The low-level version of the `image` function does not call `newplot` and does not set these axes properties.

### Tips

- To read image data into MATLAB from graphics files in various standard formats, such as TIFF, use `imread`. To write MATLAB image data to graphics files, use

`imwrite`. The `imread` and `imwrite` functions support a variety of graphics file formats and compression schemes.

# Image Properties

Control image appearance and behavior

Image properties control the appearance and behavior of image objects. By changing property values, you can modify certain aspects of the image.

Starting in R2014b, you can use dot notation to query and set properties.

```
im = image(rand(20));
C = im.CData;
im.CDataMapping = 'scaled';
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Image Data

### CData — Image color data

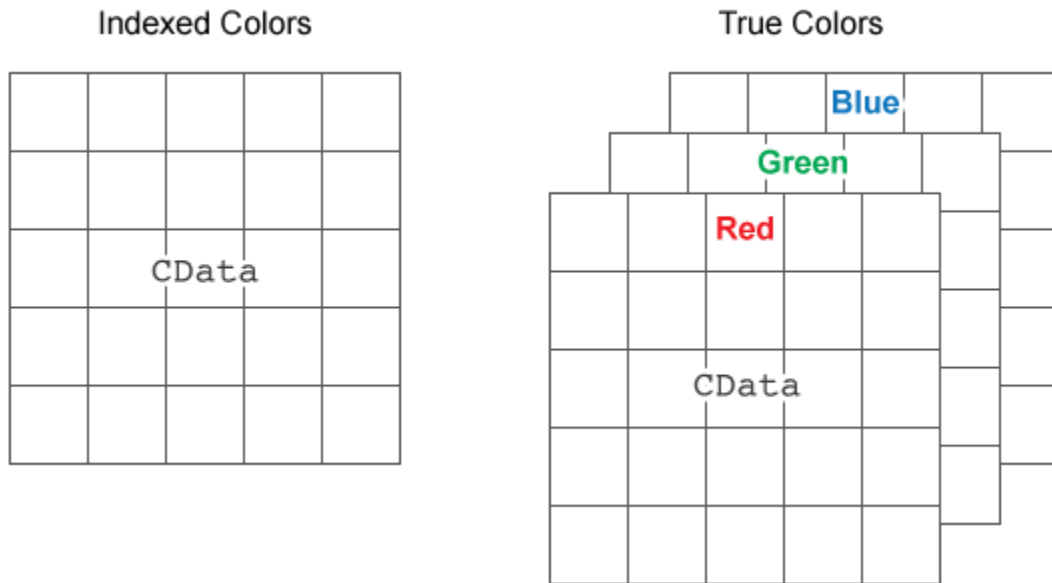

64-by-64 array (default) | vector or matrix | 3-D array of RGB triplets

Image color data, specified in one of these forms:

- Vector or matrix — This format defines indexed image data. Each element defines a color for one pixel of the image. The elements map to colors in the colormap. The `CDataMapping` property controls the mapping method.
- 3-D array of RGB triplets — This format defines true color image data using RGB triplet values. Each RGB triplet defines a color for one pixel of the image. An RGB triplet is a three-element vector that specifies the intensities of the red, green, and blue components of the color. The first page of the 3-D array contains the red components, the second page contains the green components, and the third page contains the blue components. Since the image uses true colors instead of colormap colors, the `CDataMapping` property has no effect.
  - If `CData` is of type `double`, then an RGB triplet value of `[0 0 0]` corresponds to black and `[1 1 1]` corresponds to white.
  - If `CData` is an integer type, then the image uses the full range of data to determine the color. For example, if `CData` is of type `uint8`, then `[0 0 0]` corresponds to black and `[255 255 255]` corresponds to white. If `CData` is of type `int8`, then `[-128 -128 -128]` corresponds to black and `[127 127 127]` corresponds to white.

- If `CData` is of type `logical`, then `[0 0 0]` corresponds to black and `[1 1 1]` corresponds to white.

This illustration shows the relative dimensions of `CData` for the two color models.

The behavior of NaN elements is not defined.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**CDataMapping — Color data mapping method**

`'direct'` (default) | `'scaled'`

Color data mapping method, specified as `'direct'` or `'scaled'`. Use this property to control the mapping of color data values in `CData` into the `colormap`. `CData` must be a vector or a matrix defining indexed colors. This property has no effect if `CData` is a 3-D array defining true colors.

The methods have these effects:

- `'direct'` — Interpret the values as indices into the current `colormap`. Values with a decimal portion are fixed to the nearest lower integer.

- If the values are of type `double` or `single`, then values of 1 or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap.
- If the values are of type `uint8`, `uint16`, `uint32`, `uint64`, `int8`, `int16`, `int32`, or `int64`, then values of 0 or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap (or up to the range limits of the type).
- If the values are of type `logical`, then values of 0 map to the first color in the colormap and values of 1 map to the second color in the colormap.
- `'scaled'` — Scale the values to range between the minimum and maximum color limits. The `CLim` property of the axes contains the color limits.

## Image Position

### XData — Placement along x-axis

[1 size(CData,2)] (default) | two-element vector | scalar

Placement along the *x*-axis, specified in one of these forms:

- Two-element vector — Use the first element as the location for the center of `CData(1,1)` and the second element as the location for the center of `CData(m,n)`, where `[m,n] = size(CData)`. Evenly distribute the centers of the remaining `CData` elements between those two points.

The width of each pixel is determined by the expression:

$$(XData(2) - XData(1)) / (\text{size}(CData,2) - 1)$$

If `XData(1) > XData(2)`, then the image is flipped left-right.

- Scalar — Center `CData(1,1)` at this location and each following element one unit apart.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### YData — Placement along y-axis

[1 size(CData,1)] (default) | two-element vector | scalar

Placement along *y*-axis, specified in one of these forms:

- Two-element vector — Use the first element as the location for the center of `CData(1,1)` and the second element as the location for the center of `CData(m,n)`, where `[m,n] = size(CData)`. Evenly distribute the centers of the remaining `CData` elements between those two points.

The height of each pixel is determined by the expression:

```
(YData(2) - YData(1)) / (size(CData,1) - 1)
```

If `YData(1) > YData(2)`, then the image is flipped up-down.

- Scalar — Center `CData(1,1)` at this location and each following element one unit apart.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

## Image Transparency

### **AlphaData** — Transparency data

1 (default) | scalar | array the same size as `CData`

Transparency data, specified in one of these forms:

- Scalar — Use a consistent transparency across the entire image.
- Array the same size as `CData` — Use a different transparency value for each image element.

The `AlphaDataMapping` property controls how MATLAB interprets the alpha data transparency values.

Example: `0.5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **AlphaDataMapping** — Interpretation of `AlphaData` values

'none' (default) | 'scaled' | 'direct'

Interpretation of `AlphaData` values, specified as one of these values:

- 'none' — Interpret the values as transparency values. A value of 1 or greater is completely opaque, a value of 0 or less is completely transparent, and a value between 0 and 1 is semitransparent.

- **'scaled'** — Map the values into the figure's alphamap. The minimum and maximum alpha limits of the axes determine the alpha data values that map to the first and last elements in the alphamap, respectively. For example, if the alpha limits are [3 5], then alpha data values less than or equal to 3 map to the first element in the alphamap. Alpha data values greater than or equal to 5 map to the last element in the alphamap. The `ALim` property of the axes contains the alpha limits. The `Alphamap` property of the figure contains the alphamap.
- **'direct'** — Interpret the values as indices into the figure's alphamap. Values with a decimal portion are fixed to the nearest lower integer:
  - If the values are of type `double` or `single`, then values of 1 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap map to the last element in the alphamap.
  - If the values are of type `integer`, then values of 0 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap map to the last element in the alphamap (or up to the range limits of the type). The integer types are `uint8`, `uint16`, `uint32`, `uint64`, `int8`, `int16`, `int32`, and `int64`.
  - If the values are of type `logical`, then values of 0 map to the first element in the alphamap and values of 1 map to the second element in the alphamap.

## Visibility

### Visible — State of visibility

'on' (default) | 'off'

State of visibility, specified as one of these values:

- **'on'** — Display the image.
- **'off'** — Hide the image without deleting it. You still can access the properties of an invisible image object.

### Clipping — Clipping of image object to axes limits

'on' (default) | 'off'

Clipping of the image object to the axes limits, specified as one of these values:

- **'on'** — Do not display parts of the image object that are outside the axes limits.
- **'off'** — Display the entire image object, even if parts of it appear outside the axes limits. Parts of the image object might appear outside the axes limits if you create a

plot, set `hold` on, freeze the axis scaling, and then create the image object so that it is larger than the original plot.

The `Clipping` property of the axes that contains the image object must be set to `'on'`, otherwise this property has no effect. For more information about the clipping behavior, see the `Clipping` property of the axes.

## Identifiers

### Type — Type of graphics object

`'image'`

This property is read only.

Type of graphics object, returned as the string `'image'`.

### Tag — Tag to associate with image

`''` (default) | string

Tag to associate with the image, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

### UserData — Data to associate with image

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the image object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

## Parent/Child

### Parent — Parent of image

axes object | group object | transform object

Parent of image, specified as an axes, group, or transform object.

### **Children — Children of image**

empty `GraphicsPlaceholder` array

The image has no children. You cannot set this property.

### **HandleVisibility — Visibility of object handle**

'on' (default) | 'off' | 'callback'

Visibility of image object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The image object handle is always visible.
- 'off' — The image object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The image object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the image at the command-line, but allows callback functions to access it.

If the image object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their `HandleVisibility` property setting.

## **Interactive Control**

### **ButtonDownFcn — Mouse-click callback**

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle

- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the image. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The image object — You can access properties of the image object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

## **UIContextMenu — Context menu**

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the image. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

## **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the image when in plot edit mode, then MATLAB sets its **Selected** property to 'on'. If the **SelectionHighlight** property also is set to 'on', then MATLAB displays selection handles around the image.
- 'off' — Not selected.

### **SelectionHighlight** — Display of selection handles when selected

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the **Selected** property is set to 'on'.
- 'off' — Never display selection handles, even when the **Selected** property is set to 'on'.

## **Callback Execution Control**

### **PickableParts** — Ability to capture mouse clicks

'visible' (default) | 'none'

Ability to capture mouse clicks, specified as one of these values:

- 'visible' — Can capture mouse clicks only when visible. The **Visible** property must be set to 'on'. The **HitTest** property determines if the image responds to the click or if an ancestor does.
- 'none' — Cannot capture mouse clicks. Clicking the image passes the click to the object below it in the current view of the figure window. The **HitTest** property of the image has no effect.

### **HitTest** — Response to captured mouse clicks

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the **ButtonDownFcn** callback of the image. If you have defined the **UIContextMenu** property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the image that has a **HitTest** property set to 'on' and a **PickableParts** property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the image object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the image is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the image tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the image. Setting the `CreateFcn` property on an existing image has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during image creation. MATLAB executes the callback after creating the image and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The image object — You can access properties of the image object from within the callback function. You also can access the image object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the image. MATLAB executes the callback before destroying the image so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The image object — You can access properties of the image object from within the callback function. You also can access the image object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: {@myCallback, arg3}

### **BeingDeleted** — Deletion status of image

'off' (default) | 'on'

This property is read only.

Deletion status of image, returned as 'on' or 'off'. MATLAB sets the **BeingDeleted** property to 'on' when the delete function of the image begins execution (see the **DeleteFcn** property). The **BeingDeleted** property remains set to 'on' until the image no longer exists.

Check the value of the **BeingDeleted** property to verify that the image is not about to be deleted before querying or modifying it.

### **See Also**

image | imagesc

### **More About**

- “Access Property Values”
- “Graphics Object Properties”

## imagesc

Display image with scaled colors

### Syntax

```
imagesc(C)
imagesc(x,y,C)
imagesc(____,clims)
imagesc('CData',C)
imagesc('XData',x,'YData',y,'CData',C)

imagesc(____,Name,Value)

im = imagesc(____)
```

### Description

`imagesc(C)` displays the data in array `C` as an image that uses the full range of colors in the colormap. Each element of `C` specifies the color for 1 pixel of the image. The resulting image is an  $m$ -by- $n$  grid of pixels where  $m$  is the number of columns and  $n$  is the number of rows in `C`. The row and column indices of the elements determine the centers of the corresponding pixels.

`imagesc(x,y,C)` specifies the image location. Use `x` and `y` to specify the locations of the corners corresponding to `C(1,1)` and `C(m,n)`. To specify both corners, set `x` and `y` as two-element vectors. To specify the first corner and let `imagesc` determine the other, set `x` and `y` as scalar values. The image is stretched and oriented as applicable.

`imagesc( ____,clims)` specifies the data values that map to the first and last elements of the colormap. Specify `clims` as a two-element vector of the form `[cmin cmax]`, where values less than or equal to `cmin` map to the first color in the colormap and values greater than or equal to `cmax` map to the last color in the colormap.

`imagesc('CData',C)` adds the image to the current axes without replacing existing plots. This syntax is the low-level version of `imagesc(C)`. For more information, see “High-Level Versus Low-Level Version” on page 1-4323.

`imagesc('XData',x,'YData',y,'CData',C)` specifies the image location. This syntax is the low-level version of `imagesc(x,y,C)`.

`imagesc( ____,Name,Value)` specifies image properties using one or more name-value pair arguments. You can specify image properties with any of the input argument combinations in the previous syntaxes. For a list of image properties and descriptions, see [Image Properties](#).

`im = imagesc( ____)` returns the image object created. Use `im` to set properties of the image after it is created. You can specify this output with any of the input argument combinations in the previous syntaxes.

## Examples

### Display Image of Matrix Data

Create matrix `C`. Display an image of the data in `C`. Add a colorbar to the graph to show the current colormap. By default, `imagesc` scales the color limits so that image uses the full range of the colormap, where the smallest value in `C` maps to the first color in the colormap and the largest value maps to the last color.

```
C = [0 2 4 6; 8 10 12 14; 16 18 20 22];
imagesc(C)
colorbar
```

## Control Image Placement

Place the image so that it lies between 5 and 8 on the  $x$ -axis and between 3 and 6 on the  $y$ -axis.

```
x = [5 8];
y = [3 6];
C = [0 2 4 6; 8 10 12 14; 16 18 20 22];
imagesc(x,y,C)
```

Notice that the pixel corresponding to  $C(1,1)$  is centered over the point (5,3). The pixel corresponding to  $C(3,4)$  is centered over the point (8,6). `imagesc` positions and orients the rest of the image between those two points.

### Control Scaling of Data Values into Colormap

Create  $C$  as an array of data values. Create an image of  $C$  and set the color limits so that values of 4 or less map to the first color in the colormap and values of 18 or more map to the last color in the colormap. Display a colorbar to show how the data values map into the colormap.

```
C = [0 2 4 6; 8 10 12 14; 16 18 20 22];
clims = [4 18];
```

```
imagesc(C,clims)
colorbar
```

## Modify Image After Creation

Create an image and return the image object, `im`. Then, make the image semitransparent by setting the `AlphaData` property of the image object.

```
C = [1 2 3; 4 5 6; 7 8 9];
im = imagesc(C);
```

```
im.AlphaData = .5;
```

## Add Image to Axes in 3-D View

Create a surface plot. Then, add an image under the surface. `imagesc` displays the image in the xy-plane.

```
Z = 10 + peaks;
surf(Z)
hold on
imagesc(Z)
```

## Input Arguments

### **C** — Image color data

vector or matrix

Image color data, specified as a vector or a matrix. Each element of **C** defines a color for 1 pixel of the image. The elements of **C** map to colors in the colormap of the associated axes. The smallest value in **C** maps to the first color in the colormap and the largest value maps to the last color. The behavior of NaN elements is not defined.

To use the low-level version of the `imagesc` function instead, set the `CData` property as a name-value pair. For example, `imagesc('CData',C)`.

## Converting Between Data Types

To convert the image data from an integer type to type `double`, add 1. For example, if `X8` is indexed image data of type `uint8`, convert it to type `double` using:

```
X64 = double(X8) + 1;
```

To convert the image data from type `double` to an integer type, subtract 1 and use `round` to ensure that all the values are integers. For example, if `X64` is indexed image data of type `double`, convert it to `uint8` using:

```
X8 = uint8(round(X64 - 1));
```

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **x** — Placement along x-axis

[1 `size(C,2)`] (default) | two-element vector | scalar

Placement along the *x*-axis, specified in one of these forms:

- Two-element vector — Use the first element as the location for the center of `C(1,1)` and the second element as the location for the center of `C(m,n)`, where `[m,n] = size(C)`. If `C` is a 3-D array, then `m` and `n` are the first two dimensions. Evenly distribute the centers of the remaining elements of `C` between those two points.

The width of each pixel is determined by the expression:

```
(x(2) - x(1)) / (size(C,2) - 1)
```

If `x(1) > x(2)`, then the image is flipped left-right.

- Scalar — Center `C(1,1)` at this location and each following element one unit apart.

To use the low-level version of the `imagesc` function instead, set the `XData` property as a name-value pair. For example, `imagesc('XData',x,'YData',y,'CData',C)`.

You cannot interactively pan or zoom outside the *x*-axis limits or *y*-axis limits of an image, unless the limits are already set outside the bounds of the image. If the limits are already outside the bounds, there is no such restriction. If other objects (such as a line) occupy the axes and extend beyond the bounds of the image, you can pan or zoom to the bounds of the other objects, but no further.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **y** — Placement along y-axis

[1 `size(C,1)`] (default) | two-element vector | scalar

Placement along *y*-axis, specified in one of these forms:

- Two-element vector — Use the first element as the location for the center of  $C(1,1)$  and the second element as the location for the center of  $C(m,n)$ , where  $[m,n] = \text{size}(C)$ . If  $C$  is a 3-D array, then  $m$  and  $n$  are the first two dimensions. Evenly distribute the centers of the remaining elements of  $C$  between those two points.

The height of each pixel is determined by the expression:

$$(y(2) - y(1)) / (\text{size}(C,1) - 1)$$

If  $y(1) > y(2)$ , then the image is flipped up-down.

- Scalar — Center  $C(1,1)$  at this location and each following element one unit apart.

To use the low-level version of the `imagesc` function instead, set the `YData` property as a name-value pair. For example, `imagesc('XData',x,'YData',y,'CData',C)`.

You cannot interactively pan or zoom outside the x-axis limits or y-axis limits of an image, unless the limits are already set outside the bounds of the image. If the limits are already outside the bounds, there is no such restriction. If other objects (such as a line) occupy the axes and extend beyond the bounds of the image, you can pan or zoom to the bounds of the other objects, but no further.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **clims** — Color limits

two-element vector of form [`cmin` `cmax`]

Color limits, specified as a two-element vector of the form [`cmin` `cmax`], where `cmax` is greater than `cmin`. Values in  $C$  that are less than or equal to `cmin` map to the first color in the colormap. Values greater than or equal to `cmax` map to the last color in the colormap. Values between `cmin` and `cmax` linearly map to the colormap.

If you specify the color limits, then the `imagesc` function sets the `CLim` property of the axes to the values specified. If you do not specify the color limits, then `imagesc` sets the `CLim` property of the axes to the minimum and maximum values in  $C$ .

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `imagesc([1 2 3], 'AlphaData', 0.5)` displays a semitransparent image.

The properties listed here are a subset of image properties. For a complete list, see [Image Properties](#).

### 'AlphaData' — Transparency data

1 (default) | scalar | array the same size as `CData`

Transparency data, specified in one of these forms:

- Scalar — Use a consistent transparency across the entire image.
- Array the same size as `CData` — Use a different transparency value for each image element.

The `AlphaDataMapping` property controls how MATLAB interprets the alpha data transparency values.

Example: 0.5

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### 'AlphaDataMapping' — Interpretation of AlphaData values

'none' (default) | 'scaled' | 'direct'

Interpretation of `AlphaData` values, specified as one of these values:

- 'none' — Interpret the values as transparency values. A value of 1 or greater is completely opaque, a value of 0 or less is completely transparent, and a value between 0 and 1 is semitransparent.
- 'scaled' — Map the values into the figure's `alphamap`. The minimum and maximum alpha limits of the axes determine the alpha data values that map to the first and last elements in the `alphamap`, respectively. For example, if the alpha limits are `[3 5]`, then alpha data values less than or equal to 3 map to the first element in

the alphamap. Alpha data values greater than or equal to 5 map to the last element in the alphamap. The `ALim` property of the axes contains the alpha limits. The `Alphamap` property of the figure contains the alphamap.

- `'direct'` — Interpret the values as indices into the figure's alphamap. Values with a decimal portion are fixed to the nearest lower integer:
  - If the values are of type `double` or `single`, then values of 1 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap map to the last element in the alphamap.
  - If the values are of type integer, then values of 0 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap map to the last element in the alphamap (or up to the range limits of the type). The integer types are `uint8`, `uint16`, `uint32`, `uint64`, `int8`, `int16`, `int32`, and `int64`.
  - If the values are of type `logical`, then values of 0 map to the first element in the alphamap and values of 1 map to the second element in the alphamap.

## Output Arguments

**`im`** — Image object

scalar

Image object, returned as a scalar. Use `im` to set properties of the image after it is created. For a list, see Image Properties.

## More About

### High-Level Versus Low-Level Version

The `imagesc` function has two versions, the high-level version and the low-level version. If you use `imagesc` with `'CData'` as an input argument, then you are using the low-level version. Otherwise, you are using the high-level version.

The high-level version of `imagesc` calls `newplot` before plotting and sets these axes properties:

- Layer to `'top'`. The image is shown in front of any tick marks or grid lines.

- `YDir` to `'reverse'`. Values along the  $y$ -axis increase from top to bottom. To decrease the values from top to bottom, set `YDir` to `'normal'`. This setting reverses both the  $y$ -axis and the image.
- `View` to `[0 90]`.

The low-level version of the `imagesc` function does not call `newplot` and does not set these axes properties.

For both versions, the `imagesc` function sets:

- The `CData` property of the image object to the values in `C`.
- The `CDataMapping` property of the image object to `'scaled'`.
- The `CLim` property of the axes to the minimum and maximum values in `C`, unless you specify the `clims` input argument.

## Tips

- To read image data into MATLAB from graphics files in various standard formats, such as TIFF, use `imread`. To write MATLAB image data to graphics files, use `imwrite`. The `imread` and `imwrite` functions support various graphics file formats and compression schemes.
- To view or set the color limits of the axes, you can use the `caxis` function.

**Introduced before R2006a**

# imapprox

Approximate indexed image by reducing number of colors

## Syntax

```
[Y,newmap] = imapprox(X,map,n)
[Y,newmap] = imapprox(X,map,tol)
Y = imapprox(X,map,newmap)
Y = imapprox(...,dither_option)
```

## Description

`[Y,newmap] = imapprox(X,map,n)` approximates the colors in the indexed image `X` and associated colormap `map` by using minimum variance quantization. `imapprox` returns the indexed image `Y` with colormap `newmap`, which has at most `n` colors.

`[Y,newmap] = imapprox(X,map,tol)` approximates the colors in `X` and `map` through uniform quantization. `newmap` contains at most  $(\text{floor}(1/\text{tol})+1)^3$  colors. `tol` must be between 0 and 1.0.

`Y = imapprox(X,map,newmap)` approximates the colors in `map` by using colormap mapping to find the colors in `newmap` that best match the colors in `map`.

`Y = imapprox(...,dither_option)` enables or disables dithering. `dither_option` is a string that can have one of these values.

| Value               | Description                                                                                           |
|---------------------|-------------------------------------------------------------------------------------------------------|
| {'dither'}(default) | Dithers, if necessary, to achieve better color resolution at the expense of spatial resolution.       |
| 'nodither'          | Maps each color in the original image to the closest color in the new map. No dithering is performed. |

## Class Support

The input image *X* can be of class `uint8`, `uint16`, or `double`. The output image *Y* is of class `uint8` if the length of `newmap` is less than or equal to 256. If the length of `newmap` is greater than 256, *Y* is of class `double`.

## Examples

Load an indexed image of a mandrill's face. Display image *X* using its associated colormap, `map`, which has 220 colors.

```
load mandrill
figure('color','k')
image(X)
colormap(map)
size(map) % See that the color map has 220 entries

ans =
 220 3

axis off % Remove axis ticks and numbers
axis image % Set aspect ratio to obtain square pixels
```

Reduce the number of colors in the indexed image from 220 to only 16 colors by producing a new image, `Y`, and its associated colormap, `newmap`:

```
figure('color','k')
[Y, newmap] = imapprox(X, map, 16);
size(newmap) % See that the new color map has 16 entries

ans =
 16 3

image(Y)
colormap(newmap)
axis off % Remove axis ticks and numbers
axis image % Set aspect ratio to obtain square pixels
```

## More About

### Algorithms

`imapprox` uses `rgb2ind` to create a new colormap that uses fewer colors.

# imfinfo

Information about graphics file

## Syntax

```
info = imfinfo(filename)
info = imfinfo(filename,fmt)
info = imfinfo(URL)
```

## Description

`info = imfinfo(filename)` returns a structure whose fields contain information about an image in a graphics file, `filename`.

The format of the file is inferred from its contents.

- If `filename` is a TIFF, HDF, ICO, GIF, or CUR file containing more than one image, then `info` is a structure array with one element for each image in the file. For example, `info(3)` would contain information about the third image in the file.

`info = imfinfo(filename,fmt)` additionally looks for a file named `filename.fmt`, if MATLAB cannot find a file named `filename`.

`info = imfinfo(URL)` returns information about the image at the specified internet resource, `URL`.

## Examples

### Return Information About Graphics File

Find information about the example image, `ngc6543a.jpg`.

```
info = imfinfo('ngc6543a.jpg')
info =
```

```
 Filename: 'matlabroot\toolbox\matlab\demos\ngc6543a.jpg'
 FileModDate: '01-Oct-1996 16:19:44'
 FileSize: 27387
 Format: 'jpg'
 FormatVersion: ''
 Width: 600
 Height: 650
 BitDepth: 24
 ColorType: 'truecolor'
 FormatSignature: ''
 NumberOfSamples: 3
 CodingMethod: 'Huffman'
 CodingProcess: 'Sequential'
 Comment: {'CREATOR: XV Version 3.00b Rev: 6/15/94 Quality = 75, Smoothing
 '}
```

## Input Arguments

### **filename** — Name of graphics file

string

Name of graphics file, specified as a string.

Example: 'myImage.jpg'

Example: 'C:\myFolder\myImage.jpg'

Data Types: char

### **fmt** — Image format

string

Image format, specified as a string. The possible values for **fmt** are contained in the MATLAB file format registry. To view of list of these formats, run the **imformats** command.

Example: 'gif'

Data Types: char

### **URL** — Image location

string

Image location, specified as a string. URL must include the protocol type (e.g., **http://**).

Data Types: char

## Output Arguments

### **info** — Information about graphics file

structure array

Information about the graphics file, returned as a structure array. The set of fields in `info` depends on the individual file and its format. This table lists the nine fields that always appear, and describes their values.

| Field Name                 | Description                                                                                                                                                                                                 | Value            |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| <code>Filename</code>      | Name of the file or the internet URL specified. If the file is not in the current folder, the string contains the full path name of the file.                                                               | string           |
| <code>FileModDate</code>   | Date when the file was last modified.                                                                                                                                                                       | string           |
| <code>FileSize</code>      | Size of the file, in bytes.                                                                                                                                                                                 | integer          |
| <code>Format</code>        | File format, as specified by <i>fmt</i> . For formats with more than one possible extension (for example, JPEG and TIFF files), <code>imfinfo</code> returns the first variant in the file format registry. | string           |
| <code>FormatVersion</code> | File format version.                                                                                                                                                                                        | string or number |
| <code>Width</code>         | Image width, in pixels.                                                                                                                                                                                     | integer          |
| <code>Height</code>        | Image height, in pixels.                                                                                                                                                                                    | integer          |
| <code>BitDepth</code>      | Number of bits per pixel.                                                                                                                                                                                   | integer          |
| <code>ColorType</code>     | Image type. <code>ColorType</code> includes, but is not limited to, 'truecolor' for a truecolor (RGB) image, 'grayscale' for a grayscale intensity image, or 'indexed' for an indexed image.                | string           |

Additional fields returned by some file formats:

- **JPEG and TIFF only** — If `filename` contains Exchangeable Image File Format (EXIF) tags, then `info` might also contain 'DigitalCamera' or 'GPSInfo' (global positioning system information) fields.

- **GIF only** — `imfinfo` returns the value of the `'DelayTime'` field in hundredths of seconds.
- **JPEG2000 only** — The `info` structure contains an `m-by-3` cell array, `'ChannelDefinition'`. The first column of `'ChannelDefinition'` reports a channel position as it exists in the file. The second column reports the type of channel, and the third column reports the channel mapping.

## See Also

`imformats` | `imread` | `imwrite`

**Introduced before R2006a**

# imformats

Manage image file format registry

## Syntax

```
imformats
```

```
formatStruct = imformats(fmt)
```

```
registry = imformats
```

```
registry = imformats(formatStruct)
```

```
registry = imformats('add',formatStruct)
```

```
registry = imformats('remove',fmt)
```

```
registry = imformats('update',fmt,formatStruct)
```

```
registry = imformats('factory')
```

## Description

`imformats` displays a table of information listing all the values in the MATLAB file format registry. This registry determines which file formats the `imfinfo`, `imread`, and `imwrite` functions support.

`formatStruct = imformats(fmt)` searches the known formats in the MATLAB file format registry for the format associated with the file name extension specified by `fmt`. If found, `formatStruct` is a structure containing the characteristics and function names associated with the format. Otherwise, `formatStruct` is an empty structure.

`registry = imformats` returns a structure array, `registry`, containing all the values in the MATLAB file format registry.

`registry = imformats(formatStruct)` sets the MATLAB file format registry for the current MATLAB session to the values in `formatStruct`. The output structure, `registry`, contains the new registry settings. Use this syntax to replace image file format support.

Incorrect use of `imformats` to specify values in the MATLAB file format registry can result in the inability to load any image files. To return the file format registry to a working state, use `imformats` with the `'factory'` input.

`registry = imformats('add',formatStruct)` adds the values in `formatStruct` to the file format registry. Use this syntax to add image file format support.

`registry = imformats('remove',fmt)` removes the format with the extension specified by `fmt` from the file format registry. Use this syntax to remove image file format support.

`registry = imformats('update',fmt,formatStruct)` changes the format registry values for the format with extension `fmt` to have the values specified by `formatStruct`.

`registry = imformats('factory')` resets the MATLAB file format registry to the default format registry values. This removes any user-specified settings.

## Examples

### Determine if File Format Exists in Registry

Determine if the file format associated with the `.bmp` file extension is in the image file format registry.

```
formatStruct = imformats('bmp')
```

```
formatStruct =

 ext: {'bmp'}
 isa: @isbmp
 info: @imbmpinfo
 read: @readbmp
 write: @writebmp
 alpha: 0
 description: 'Windows Bitmap'
```

`formatStruct` is a non-empty structure, so the BMP file format is in the registry.

### Add, Update, or Remove File Format from Registry

Add a hypothetical file format, `ABC`, to the image file format registry. Update, and then remove the format.

Create a structure with seven fields, defining values for the new format.

```
formatStruct = struct('ext','abc','isa',@isabc,...
 'info',@abcinfo,'read',@readabc,'write','',...
 'alpha',0,'description','My ABC Format')
```

```
formatStruct =
 ext: 'abc'
 isa: @isabc
 info: @abcinfo
 read: @readabc
 write: ''
 alpha: 0
 description: 'My ABC Format'
```

`formatStruct` is a 1-by-1 structure with seven fields. In this example, the `write` field is empty.

Add the new format to the file format registry.

```
registry = imformats('add',formatStruct);
```

Redefine the format associated with the extension, `abc`, by adding a value for the `write` field. Then, update the registry value for the format.

```
formatStruct2 = struct('ext','abc','isa',@isabc,...
 'info',@abcinfo,'read',@readabc,'write',@writeabc,...
 'alpha',0,'description','My ABC Format');
```

```
registry = imformats('update','abc',formatStruct2);
```

Remove the format with the extension, `abc`, from the file format registry.

```
registry = imformats('remove','abc');
```

## Input Arguments

**formatStruct** — File format registry values

structure array

File format registry values, specified as a structure array with the following 7 fields.

| Field                    | Description                                                            | Value                                                    |
|--------------------------|------------------------------------------------------------------------|----------------------------------------------------------|
| <code>ext</code>         | File name extensions that are valid for this format.                   | Cell array of strings                                    |
| <code>isa</code>         | Name of the function that determines if a file is of a certain format. | String or function handle                                |
| <code>info</code>        | Name of the function that reads information about a file.              | String or function handle                                |
| <code>read</code>        | Name of the function that reads image data in a file.                  | String or function handle                                |
| <code>write</code>       | Name of the function that writes MATLAB data to a file.                | String or function handle                                |
| <code>alpha</code>       | Presence or absence of an alpha channel.                               | 1 if the format has an alpha channel; otherwise it is 0. |
| <code>description</code> | Text description of the file format.                                   | String                                                   |

The values for the `isa`, `info`, `read`, and `write` fields must be either functions on the MATLAB search path or function handles.

Data Types: `struct`

### **fmt** — File format extension

string

File format extension, specified as a string.

Example: `'jpg'`

Data Types: `char`

## **Output Arguments**

### **registry** — File format registry

structure array

File format registry, returned as a structure array with the following fields.

| Field                    | Description                                                            | Value                                                    |
|--------------------------|------------------------------------------------------------------------|----------------------------------------------------------|
| <code>ext</code>         | File name extensions that are valid for this format.                   | Cell array of strings                                    |
| <code>isa</code>         | Name of the function that determines if a file is of a certain format. | String or function handle                                |
| <code>info</code>        | Name of the function that reads information about a file.              | String or function handle                                |
| <code>read</code>        | Name of the function that reads image data in a file.                  | String or function handle                                |
| <code>write</code>       | Name of the function that writes MATLAB data to a file.                | String or function handle                                |
| <code>alpha</code>       | Presence or absence of an alpha channel.                               | 1 if the format has an alpha channel; otherwise it is 0. |
| <code>description</code> | Text description of the file format.                                   | String                                                   |

---

**Note:** Use the `imread`, `imwrite`, and `imfinfo` functions to read, write, or get information about an image file when the file format is in the format registry. Do not directly invoke the functions returned in the fields of the `registry` structure array.

---

## More About

### Tips

- Changes to the format registry do not persist between MATLAB sessions. To have a format always available when you start MATLAB, add the appropriate `imformats` command to the MATLAB startup file, `startup.m`, located in `$MATLAB/toolbox/local` on UNIX systems, or `$MATLAB\toolbox\local` on Windows systems.
- “What Is the MATLAB Search Path?”

### See Also

**Introduced before R2006a**

# import

Add package or class to current import list

## Syntax

```
import PackageName.ClassName
import PackageName.FunctionName
import PackageName.*
```

```
import
L = import
```

## Description

`import PackageName.ClassName` adds the class name to the current import list. Use the `import` function in your code to refer to a class without specifying the entire package name.

The import list scope is defined as follows:

- Script invoked from the MATLAB command prompt — Scope is the base MATLAB workspace.
- Function, including nested and local function — Scope is the function and the function does not share the import list of the parent function. If the import list is needed in a MATLAB function or script and in any local functions, you must call the `import` function for each function.

The import list of a function is persistent across calls to that function and is cleared only when the function is cleared. For more information, see the `clear` function.

To clear the current import list, type `clear import` at the MATLAB command prompt. Do not call `clear import` within a function.

`import PackageName.FunctionName` adds the specified package-based function. Use this syntax to shorten the name of a specific function in a package without importing every function in the package, which might cause unexpected name conflicts.

`import PackageName.*` adds the specified package name. `PackageName` must be followed by `.*`.

Avoid using this syntax, as importing packages brings an unspecified set of names into the local scope, which might conflict with names in the MATLAB workspace. One possible use for this syntax is to import a partial package name. Then when you call a function, you use a shorter package name which does not conflict with simple function names. For example, the `matlab.io.hdf4.sd` package has a `close` function, which can conflict with the MATLAB `close` function.

`import` displays the current import list in the scope.

`L = import` returns the current import list.

## Examples

### Shorten Calls to Java Class Methods

```
import java.util.Currency java.lang.String
```

Create a `java.lang.String` object. There is no need to type the package name, `java.lang`.

```
s = String('hello')
```

```
s =
```

```
hello
```

List the `Currency` class methods, without typing the package name.

```
methods Currency
```

```
Methods for class Currency:
```

|                                     |                             |                        |
|-------------------------------------|-----------------------------|------------------------|
| <code>equals</code>                 | <code>getDisplayname</code> | <code>notify</code>    |
| <code>getAvailableCurrencies</code> | <code>getInstance</code>    | <code>notifyAll</code> |
| <code>getClass</code>               | <code>getNumericCode</code> | <code>toString</code>  |
| <code>getCurrencyCode</code>        | <code>getSymbol</code>      | <code>wait</code>      |

```
getDefaultFractionDigits hashCode
```

### Shorten HDF4 Scientific Data Set Package Name

Use partial package names on your import list to simplify calls to `matlab.io.hdf4.sd` package functions and avoid conflicts with the MATLAB `close` function.

```
import matlab.io.hdf4.*
```

Display the full path to the example file `sd.hdf` on your system using the shortened package name `sd`.

```
sdID = sd.start('sd.hdf');
filename = sd.getFilename(sdID)
```

```
filename =
```

```
C:\Program Files\MATLAB\R2015a\toolbox\matlab\imagesci\sd.hdf
```

Call the `close` function with the `sd` package name.

```
sd.close(sdID)
```

There is no name conflict with the MATLAB `close` function when you import the partial package name.

```
which close
```

```
C:\Program Files\MATLAB\R2015a\toolbox\matlab\graphics\close.p
```

If you use the `matlab.io.hdf4.sd.*` syntax to import the entire package name, when you call `close`, MATLAB always chooses the package function. You cannot use `close` to remove a figure.

### Import Single Package Function

Import the `matlab.io.hdf4.sd` package function, `readChunk` in a function, `myfunc`. You can call the function using the simple `readChunk` name, but only within the scope of `myfunc`.

```
function data = myfunc(ID,n,m)
import matlab.io.hdf4.sd.readChunk
data = readChunk(ID,[n m]);
```

end

## Import Package in Both Script and Function

Open the `sd.hdf` example file and access the temperature data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID, 'temperature');
sdsID = sd.select(sdID, idx);
```

Call the `myfunc` function from the previous example to read the data. `myfunc` must have its own `import` statement in order to use a shorted package name.

```
dataChunk = myfunc(sdsID, 0, 1);
```

Close the file.

```
sd.endAccess(sdsID);
sd.close(sdID);
```

## Display Current Import List

```
import
```

```
ans =
```

```
 'java.util.Currency'
 'java.lang.String'
 'matlab.io.hdf4.*'
 'matlab.io.hdf4.sd.readChunk'
```

- “Use import in MATLAB Functions”
- “Package Function and Class Method Name Conflict”

## Input Arguments

### PackageName — Name of package

character array

Name of the package, specified as a character array.

Example: `matlab.io.hdf4`

**ClassName — Name of class**

character array

Name of the class, specified as a character array.

Example: Currency

**FunctionName — Name of package function**

character array

Name of the package function, specified as a character array.

Example: readChunk

## Output Arguments

**L — Import list**

cell array of character arrays

Import list returned as a cell array of character arrays.

## Limitations

- `import` cannot load a Java JAR package created by the MATLAB Compiler SDK™ product.

## More About

- “Importing Classes”

## See Also

`clear` | `importdata` | `load`

Introduced before R2006a

# importdata

Load data from file

## Syntax

```
A = importdata(filename)
A = importdata('-pastespecial')
A = importdata(____,delimiterIn)
A = importdata(____,delimiterIn,headerlinesIn)
[A,delimiterOut,headerlinesOut] = importdata(____)
```

## Description

`A = importdata(filename)` loads data into array `A`.

`A = importdata('-pastespecial')` loads data from the system clipboard rather than from a file.

`A = importdata( ____,delimiterIn)` interprets `delimiterIn` as the column separator in ASCII file, `filename`, or the clipboard data. You can use `delimiterIn` with any of the input arguments in the above syntaxes.

`A = importdata( ____,delimiterIn,headerlinesIn)` loads data from ASCII file, `filename`, or the clipboard, reading numeric data starting from line `headerlinesIn+1`.

`[A,delimiterOut,headerlinesOut] = importdata( ____ )` additionally returns the detected delimiter character for the input ASCII file in `delimiterOut` and the detected number of header lines in `headerlinesOut`, using any of the input arguments in the previous syntaxes.

## Examples

### Import and Display an Image

Import and display the sample image, `ngc6543a.jpg`.

```
A = importdata('ngc6543a.jpg');
image(A)
```

The output, A, is class uint8 because the helper function, `imread`, returns empty results for `colormap` and `alpha`.

### Import a Text File and Specify Delimiter and Column Header

Using a text editor, create a space-delimited ASCII file with column headers called `myfile01.txt`.

| Day1  | Day2  | Day3  | Day4  | Day5  | Day6  | Day7  |
|-------|-------|-------|-------|-------|-------|-------|
| 95.01 | 76.21 | 61.54 | 40.57 | 5.79  | 20.28 | 1.53  |
| 23.11 | 45.65 | 79.19 | 93.55 | 35.29 | 19.87 | 74.68 |

```
60.68 1.85 92.18 91.69 81.32 60.38 44.51
48.60 82.14 73.82 41.03 0.99 27.22 93.18
89.13 44.47 17.63 89.36 13.89 19.88 46.60
```

Import the file, specifying the space delimiter and the single column header.

```
filename = 'myfile01.txt';
delimiterIn = ' ';
headerlinesIn = 1;
A = importdata(filename,delimiterIn,headerlinesIn);
```

View columns 3 and 5.

```
for k = [3, 5]
 disp(A.colheaders{1, k})
 disp(A.data(:, k))
 disp(' ')
end
```

Day3

```
61.5400
79.1900
92.1800
73.8200
17.6300
```

Day5

```
5.7900
35.2900
81.3200
0.9900
13.8900
```

## Import a Text File and Return Detected Delimiter

Using a text editor, create a comma-delimited ASCII file called `myfile02.txt`.

```
1,2,3
4,5,6
7,8,9
```

Import the file, and display the output data and detected delimiter character.

```
filename = 'myfile02.txt';
[A,delimiterOut]=importdata(filename)
```

```
A =
 1 2 3
 4 5 6
 7 8 9
```

```
delimiterOut =
```

```
,
```

### Import Data from Clipboard

Copy the following lines to the clipboard. Select the text, right-click, and then select **Copy**.

```
1,2,3
4,5,6
7,8,9
```

Import the clipboard data into MATLAB by typing the following.

```
A = importdata('-pastespecial')
```

```
A =
 1 2 3
 4 5 6
 7 8 9
```

## Input Arguments

**filename** — Name and extension of file to import

string

Name and extension of the file to import, specified as a string. If `importdata` recognizes the file extension, it calls the MATLAB helper function designed to import the associated file format (such as `load` for MAT-files or `xlsread` for spreadsheets). Otherwise, `importdata` interprets the file as a delimited ASCII file.

For ASCII files and spreadsheets, `importdata` expects to find numeric data in a rectangular form (that is, like a matrix). Text headers can appear above or to the left of the numeric data, as follows:

- Column headers or file description text at the top of the file, above the numeric data.
- Row headers to the left of the numeric data.

Example: 'myFile.jpg'

Data Types: char

### **delimiterIn** — Column separator character

string

Column separator character, specified as a string. The default character is interpreted from the file. Use '\t' for tab.

Example: ','

Example: '\t'

Data Types: char

### **headerLinesIn** — Number of text header lines in ASCII file

nonnegative scalar integer

Number of text header lines in the ASCII file, specified as a nonnegative scalar integer. If you do not specify `headerLinesIn`, the `importdata` function detects this value in the file.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## Output Arguments

### **A** — Data from the file

matrix | multidimensional array | scalar structure array

Data from the file, returned as a matrix, multidimensional array, or scalar structure array, depending on the characteristics of the file. Based on the file format of the input file, `importdata` calls a helper function to read the data. When the helper function returns more than one nonempty output, `importdata` combines the outputs into a `struct` array.

This table lists the file formats associated with helper functions that can return more than one output, and the possible fields in the structure array, `A`.

| File Format                  | Possible Fields                              | Class                                                                                                                                                                                                                                                           |
|------------------------------|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MAT-files                    | One field for each variable                  | Associated with each variable.                                                                                                                                                                                                                                  |
| ASCII files and Spreadsheets | data<br>textdata<br>colheaders<br>rowheaders | For ASCII files, <b>data</b> contains a <b>double</b> array. Other fields contain <b>cell</b> arrays of strings. <b>textdata</b> includes row and column headers.<br>For spreadsheets, each field contains a <b>struct</b> , with one field for each worksheet. |
| Images                       | cdata<br>colormap<br>alpha                   | See <b>imread</b> .                                                                                                                                                                                                                                             |
| Audio files                  | data<br>fs                                   | See <b>audioread</b> .                                                                                                                                                                                                                                          |

The MATLAB helper functions for most other supported file formats return one output. For more information about the class of each output, see the functions listed in “Supported File Formats for Import and Export”.

If the ASCII file or spreadsheet contains either column or row headers, but not both, **importdata** returns a **colheaders** or **rowheaders** field in the output structure, where:

- **colheaders** contains only the last line of column header text. **importdata** stores all text in the **textdata** field.
- **rowheaders** is created only when the file or worksheet contains a single column of row headers.

**delimiterOut** — Detected column separator in the input ASCII file

string

Detected column separator in the input ASCII file, returned as a string.

**headerlinesOut** — Detected number of text header lines in the input ASCII file

integer

Detected number of text header lines in the input ASCII file, returned as an integer.

## More About

### Tips

- To import ASCII files with nonnumeric characters outside of column or row headers, including columns of character data or formatted dates or times, use `textscan` instead of `importdata`.
- “Supported File Formats for Import and Export”
- “Ways to Import Text Files”
- “Ways to Import Spreadsheets”
- “Import or Export a Sequence of Files”

**Introduced before R2006a**

# Import Tool

Import data from file

## Description

The **Import Tool** lets you preview and import data from spreadsheet files, delimited text files, and fixed-width text files. You can interactively select the data to import and reuse the script or function that the tool generates to import other similar files.

## Open the Import Tool App

- MATLAB Toolstrip: On the **Home** tab, in the **Variable** section, click **Import Data**.
- MATLAB command prompt: Enter `uiimport(filename)`, where *filename* is a string specifying the name of a text or spreadsheet file.

## Examples

### Select Range to Import

Import ranges of data from a tab-delimited text file and replace nonnumeric values in the file.

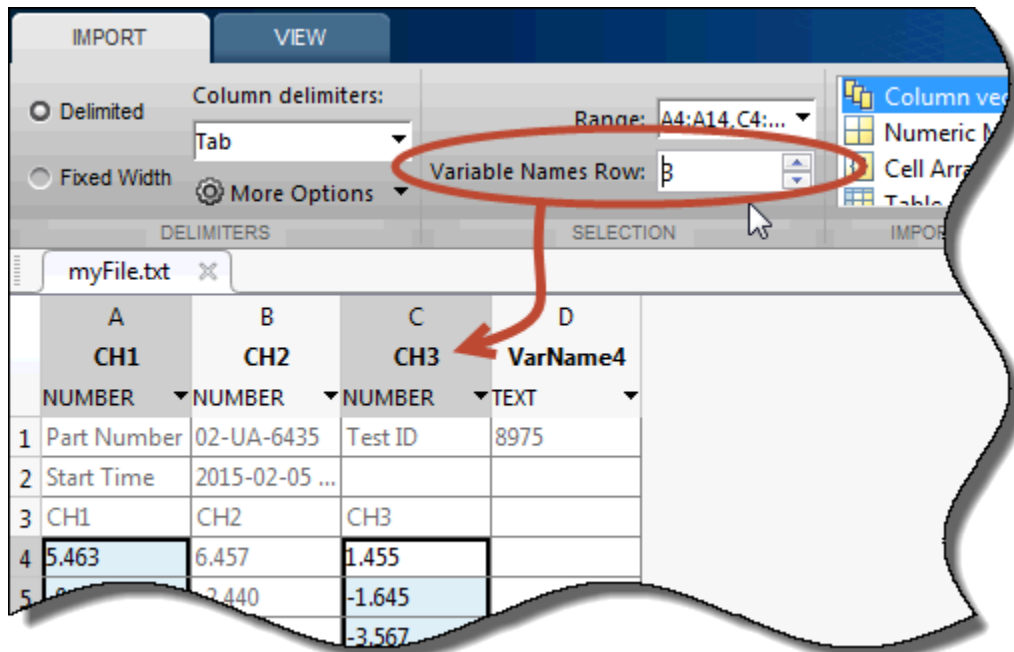

Drag the cursor to select the cells to import. Press **Ctrl** to select noncontiguous ranges.

The screenshot shows the 'Import Tool' interface with the 'VIEW' tab selected. The 'Column delimiters' are set to 'Tab'. The 'Range' is 'A4:A14,C4:...' and the 'Variable Names Row' is '1'. The 'Imported Data' section shows a list of data types: Column vectors, Numeric Matrix, Cell Array, and Table. A 'Replace' checkbox is also visible.

The data table is displayed below the interface:

|    | A           | B              | C       | D        |
|----|-------------|----------------|---------|----------|
|    | PartNumber  | UA6435         | TestID  | VarName4 |
|    | NUMBER      | NUMBER         | NUMBER  | TEXT     |
| 1  | Part Number | 02-UA-6435     | Test ID | 8975     |
| 2  | Start Time  | 2015-02-05 ... |         |          |
| 3  | CH1         | CH2            | CH3     |          |
| 4  | 5.463       | 6.457          | 1.455   |          |
| 5  | -0.134      | -2.440         | -1.645  |          |
| 6  | -1.454      | -0.475         | -3.567  |          |
| 7  | 9.576       | 5.464          | 6.544   |          |
| 8  | 8.465       | 8.131          | ERROR   |          |
| 9  | 1.323       | 4.567          | 5.312   |          |
| 10 | 0.126       | -3.450         | -8.453  |          |
| 11 | 4.567       | 9.450          | 7.451   |          |
| 12 | -2.949      | -5.459         | -5.134  |          |
| 13 | 2.634       | 7.451          | ERROR   |          |
| 14 | 8.157       | 1.572          | 7.541   |          |
| 15 | Overload    | False          |         |          |
| 16 | Tag         |                |         |          |

Modify the **Variable Names Row** field to indicate the row you want the Import Tool to use for the variable names.

By default, NaN replaces unimportable values in numeric cells. However, you can change this value to any other numeric value. Specify how to treat unimportable values on the **Import** tab, in the **Unimportable Cells** section.

# 1 Alphabetical List

| 12 | -2.949      | -5.459         | -5.134   |                    |
| 13 | 2.634       | 7.451          | ERROR    |                    |
| 14 | 8.157       | 1.572          | 7.541    |                    |
| 15 | Overload    | False          |          |                    |
| 16 | Tag         |                |          |                    |

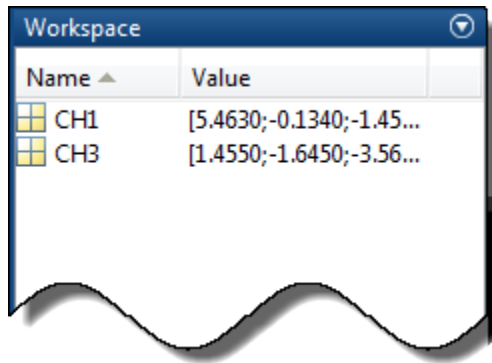

Alternatively, exclude any row that contains an unimportable cell from being imported.

Exclude rows with unimportable cells

UNIMPORTABLE CELLS

Click **Import Selection** . The new column vectors appear in your workspace.

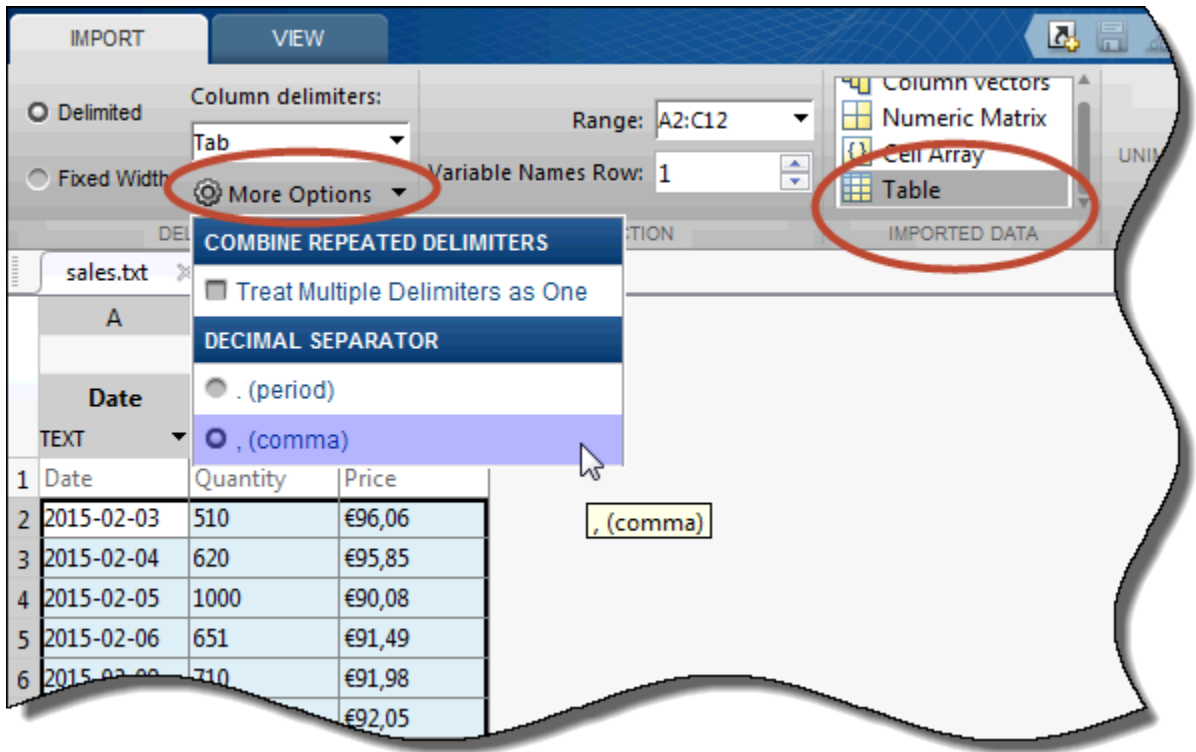

| Name ▲ | Value                    |
|--------|--------------------------|
| CH1    | [5.4630;-0.1340;-1.45... |
| CH3    | [1.4550;-1.6450;-3.56... |

### Specify Decimal Separator and Date Format

Import dates and numbers from a text file into a table. Specify the decimal separator for numeric values in the file and a custom format for dates.

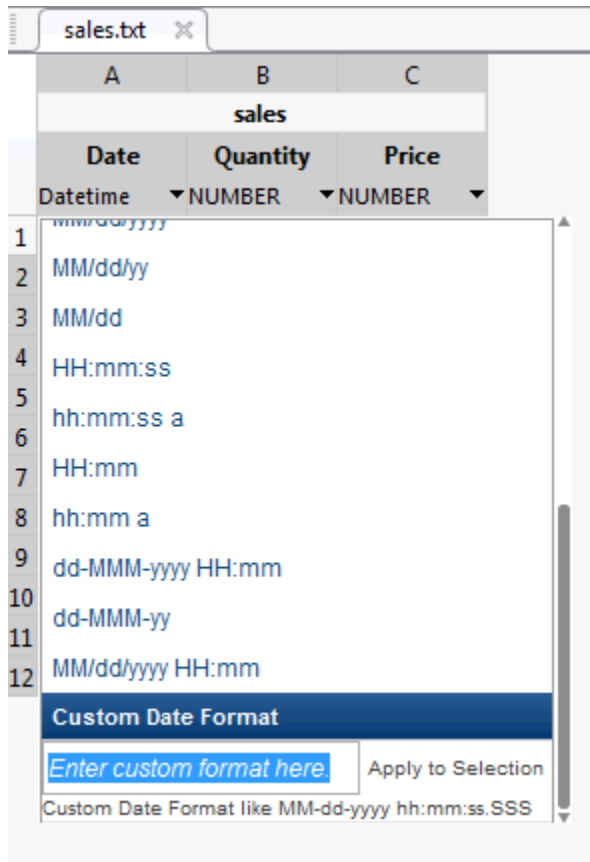

In the **Imported Data** section, select **Table** to import the file data into a **table** variable. In this example, the third column of data contains monetary amounts where the decimal separator is a comma. In the **Delimiters** section, select **More Options**. Then, under **Decimal Separator**, select **, (comma)**.

The Import Tool appropriately converts the monetary values.

|    | A          | B        | C      |
|----|------------|----------|--------|
|    | sales      |          |        |
|    | Date       | Quantity | Price  |
|    | TEXT       | NUMBER   | NUMBER |
| 1  | Date       | Quantity | Price  |
| 2  | 2015-02-03 | 510      | €96,06 |
| 3  | 2015-02-04 | 620      | €95,85 |
| 4  | 2015-02-05 | 1000     | €90,08 |
| 5  | 2015-02-06 | 651      | 91.49  |
| 6  | 2015-02-09 | 710      | €91,98 |
| 7  | 2015-02-10 | 702      | €92,05 |
| 8  | 2015-02-11 | 698      | €93,01 |
| 9  | 2015-02-12 | 695      | €93,64 |
| 10 |            |          | €93,52 |
| 11 |            |          | €93,52 |

Specify that a column contains date or time data by changing the data type for the column to **DATE/TIME**. Click **more date formats...** Scroll down the list to enter a custom date format.

Click **Import Selection**  to import the table.

[csvread](#) | [dlmread](#) | [importdata](#) | [readtable](#) | [textscan](#) | [xlsread](#)

# imread

Read image from graphics file

## Syntax

```
A = imread(filename)
A = imread(filename,fmt)
A = imread(____,idx)
A = imread(____,Name,Value)
[A,map] = imread(____)
[A,map,transparency] = imread(____)
```

## Description

`A = imread(filename)` reads the image from the file specified by `filename`, inferring the format of the file from its contents. If `filename` is a multi-image file, then `imread` reads the first image in the file.

`A = imread(filename,fmt)` additionally specifies the format of the file with the standard file extension indicated by `fmt`. If `imread` cannot find a file with the name specified by `filename`, it looks for a file named *filename.fmt*.

`A = imread( ____,idx)` reads the specified image or images from a multi-image file. This syntax applies only to GIF, CUR, ICO, and HDF4 files. You must specify a `filename` input, and you can optionally specify `fmt`.

`A = imread( ____,Name,Value)` specifies format-specific options using one or more name-value pair arguments, in addition to any of the input arguments in the previous syntaxes.

`[A,map] = imread( ____ )` reads the indexed image in `filename` into `A` and reads its associated colormap into `map`. Colormap values in the image file are automatically rescaled into the range `[0,1]`.

`[A,map,transparency] = imread( ____ )` additionally returns the image transparency. This syntax applies only to PNG, CUR, and ICO files. For PNG files,

transparency is the alpha channel, if one is present. For CUR and ICO files, it is the AND (opacity) mask.

## Examples

### Read and Display Image

Read a sample image.

```
A = imread('ngc6543a.jpg');
```

`imread` returns a 650-by-600-by-3 array, `A`.

Display the image.

```
image(A)
```

## Convert Indexed Image to RGB

Read an image and convert it to an RGB image.

Read the first image in the sample indexed image file, `corn.tif`.

```
[X,map] = imread('corn.tif');
```

`X` is a 415-by-312 array of type `uint8`.

Verify that the colormap, `map`, is not empty, and convert the data in `X` to RGB.

```
if ~isempty(map)
 Im = ind2rgb(X,map);
```

```
end
```

View the size and class of `X`.

```
whos Im
```

| Name | Size      | Bytes   | Class  | Attributes |
|------|-----------|---------|--------|------------|
| Im   | 415x312x3 | 3107520 | double |            |

`X` is now a 415-by-312-by-3 array of type `double`.

### Read Specific Image in Multipage TIFF File

Read the third image in the sample file, `corn.tif`.

```
[X,map] = imread('corn.tif',3);
```

### Return Alpha Channel of PNG Image

Return the alpha channel of the sample image, `peppers.png`.

```
[X,map,alpha] = imread('peppers.png');
alpha
```

```
alpha =
```

```
 []
```

No alpha channel is present, so `alpha` is empty.

### Read Specified Region of TIFF Image

Read a specific region of pixels of the sample image, `corn.tif`.

Specify the `'PixelRegion'` parameter with a cell array of vectors indicating the boundaries of the region to read. The first vector specifies the range of rows to read, and the second vector specifies the range of columns to read.

```
A = imread('corn.tif','PixelRegion',{[1,2],[2,5]});
```

`imread` reads the image data in rows 1-2 and columns 2-5 from `corn.tif` and returns the 2-by-4 array, `A`.

## Input Arguments

### **filename** — File name

string

File name, specified as a string. If the file is not in the current folder or in a folder on the MATLAB path, specify the full path name.

`filename` also can be an internet URL specifying an image location. The URL must include the protocol type (for example, `http://`).

For information on the bit depths, compression schemes, and color spaces supported for each file type, see “Algorithms” on page 1-4369.

Example: `'myFile.jpg'`

Example: `'http://www.mathworks.com/myImage.gif'`

Data Types: char

### **fmt** — Image format

string

Image format, specified as a string indicating the standard file extension. Call `imformats` to see a list of supported formats and their file extensions.

Example: `'png'`

Data Types: char

### **idx** — Image to read

integer scalar | vector of integers

Image to read, specified as an integer scalar or, for GIF files, a vector of integers. For example, if `idx` is 3, then `imread` returns the third image in the file. For a GIF file, if `idx` is `1:5`, then `imread` returns only the first five frames. The `idx` argument is supported only for multi-image GIF, CUR, ICO, and HDF4 files.

When reading multiple frames from the same GIF file, specify `idx` as a vector of frames or use the `'Frames'`, `'all'` name-value pair argument. Because of the way that GIF

files are structured, these syntaxes provide faster performance compared to calling `imread` in a loop.

For HDF4 files, `idx` corresponds to the reference number of the image to read. Reference numbers do not necessarily correspond to the order of the images in the file. You can use `imfinfo` to match image order with reference number.

Example: 3

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: 'Index', 5 reads the fifth image of a TIFF file.

## GIF Files

### 'Frames' — Frame to read

1 (default) | positive integer | vector of integers | 'all'

Frames to read, specified as the comma-separated pair consisting of 'Frames' and a positive integer, a vector of integers, or the string 'all'. For example, if you specify the value 3, `imread` reads the third frame in the file. If you specify 'all', then `imread` reads all frames and returns them in the order in which they appear in the file.

Example: 'frames', 5

## JPEG 2000 Files

### 'PixelRegion' — Subimage to read

cell array in the form {rows, cols}

Subimage to read, specified as the comma-separated pair consisting of 'PixelRegion' and a cell array of the form {rows, cols}. The `rows` input specifies the range of rows to read. The `cols` input specifies the range of columns to read. Both `rows` and `cols` must be two-element vectors containing 1-based indices. For example, 'PixelRegion', {[1 2], [3 4]} reads the subimage bounded by rows 1 and 2 and columns 3 and 4 in the

image data. If the `'ReductionLevel'` value is greater than 0, then `rows` and `cols` are coordinates of the subimage.

Example: `'PixelRegion',[1 100],[4 500]}`

### **'ReductionLevel' — Reduction of image resolution**

0 (default) | nonnegative integer

Reduction of the image resolution, specified as the comma-separated pair consisting of `'ReductionLevel'` and a nonnegative integer. For reduction level  $L$ , the image resolution is reduced by a factor of  $2^L$ . The reduction level is limited by the total number of decomposition levels as specified by the `'WaveletDecompositionLevels'` field in the output of the `imfinfo` function.

Example: `'ReductionLevel',5`

Data Types: `single` | `double`

### **'V79Compatible' — Compatibility with MATLAB 7.9 (R2009b) and earlier**

false (default) | true

Compatibility with MATLAB 7.9 (R2009b) and earlier, specified as the comma-separated pair consisting of `'V79Compatible'` and either `true` or `false`. If you specify `true`, then the returned grayscale or RGB image is consistent with previous versions of `imread` (MATLAB 7.9 (R2009b) and earlier).

Example: `'V79Compatible',true`

Data Types: `logical`

## **PNG Files**

### **'BackgroundColor' — Background color**

'none' | integer | 3-element vector of integers

Background color, specified as `'none'`, an integer, or a three-element vector of integers. If `BackgroundColor` is `'none'`, then `imread` does not perform any compositing. Otherwise, `imread` blends transparent pixels with the background color.

- If the input image is indexed, then the value of `BackgroundColor` must be an integer in the range `[1, P]`, where `P` is the colormap length.
- If the input image is grayscale, then the value of `BackgroundColor` must be an integer in the range `[0, 1]`.

- If the input image is RGB, then the value of `BackgroundColor` must be a three-element vector with values in the range `[0, 1]`.

The default value for `BackgroundColor` depends on the presence of the `transparency` output argument and the image type:

- If you request the `transparency` output argument, then the default value of `BackgroundColor` is `'none'`.
- If you do not request the `transparency` output and the PNG file contains a background color chunk, then that color is the default value for `BackgroundColor`.
- If you do not request the `transparency` output and the file does not contain a background color chunk, then the default value for `BackgroundColor` is 1 for indexed images, 0 for grayscale images, and `[0 0 0]` for truecolor (RGB) images.

## TIFF Files

### 'Index' — Image to read

1 (default) | positive integer

Image to read, specified as the comma-separated pair consisting of `'Index'` and a positive integer. For example, if the value of `Index` is 3, then `imread` reads the third image in the file.

Data Types: `single` | `double`

### 'Info' — Information about image

structure array

Information about the image, specified as the comma-separated pair consisting of `'Info'` and a structure array returned by the `imfinfo` function. Use the `Info` name-value pair argument to help `imread` locate the images in a multi-image TIFF file more quickly.

Data Types: `struct`

### 'PixelRegion' — Region boundary

cell array

Region boundary, specified as the comma-separated pair consisting of `'PixelRegion'` and a cell array of the form `{rows, cols}`. The `rows` input specifies the range of rows

to read. The `cols` input specifies the range of columns to read. `rows` and `cols` must be either two-element or three-element vectors of 1-based indices. A two-element vector specifies the first and last rows or columns to read. For example, `'PixelRegion', {[1 2], [3 4]}` reads the region bounded by rows 1 and 2 and columns 3 and 4 in the image data.

A three-element vector must be in the form `[start increment stop]`, where `start` is the first row or column to read, `increment` is an incremental value, and `stop` is the last row or column to read. This syntax allows image downsampling. For example, `'PixelRegion', {[1 2 10], [4 3 12]}` reads the region bounded by rows 1 and 10 and columns 4 and 12, and samples data from every 2 pixels in the vertical direction, and every 3 pixels in the horizontal direction.

Example: `'PixelRegion', {[1 100], [4 500]}`

Data Types: `cell`

## Output Arguments

### **A** — Image data

array

Image data, returned as an array.

- If the file contains a grayscale image, then `A` is an `m-by-n` array.
- If the file contains an indexed image, then `A` is an `m-by-n` array of index values corresponding to the color at that index in `map`.
- If the file contains a truecolor image, then `A` is an `m-by-n-by-3` array.
- If the file is a TIFF file containing color images that use the CMYK color space, then `A` is an `m-by-n-by-4` array.

The class of `A` depends on the image format and the bit depth of the image data. For more information, see “Algorithms” on page 1-4369

### **map** — Colormap

`m-by-3` matrix

Colormap associated with the indexed image data in `A`, returned as an `m-by-3` matrix of class `double`.

## transparency — Transparency information

matrix

Transparency information, returned as a matrix. For PNG files, transparency is the alpha channel, if present. If no alpha channel is present, or if you specify the 'BackgroundColor' name-value pair argument, then transparency is []. For CUR and ICO files, transparency is the AND mask. For cursor files, this mask sometimes contains the only useful data.

## More About

### Bit Depth

Bit depth is the number of bits used to represent each image pixel.

Bit depth is calculated by multiplying the bits-per-sample with the samples-per-pixel. Thus, a format that uses 8 bits for each color component (or sample) and three samples per pixel has a bit depth of 24. Sometimes the sample size associated with a bit depth can be ambiguous. For example, does a 48-bit bit depth represent six 8-bit samples, four 12-bit samples, or three 16-bit samples? See “Algorithms” on page 1-4369 for sample size information to avoid this ambiguity.

### Algorithms

For most image file formats, `imread` uses 8 or fewer bits per color plane to store image pixels. This table lists the class of the returned image array, `A`, for the bit depths used by the file formats.

| Bit Depth in File           | Class of Array Returned by <code>imread</code>                                                          |
|-----------------------------|---------------------------------------------------------------------------------------------------------|
| 1 bit per pixel             | logical                                                                                                 |
| 2 to 8 bits per color plane | uint8                                                                                                   |
| 9 to 16 bits per pixel      | uint16 (BMP, JPEG, PNG, and TIFF)<br><br>For the 16-bit BMP packed format (5-6-5), MATLAB returns uint8 |

The following sections provide information about the support for specific formats, listed in alphabetical order by format name.

|                                                    |                                                                    |                                                  |

## BMP — Windows Bitmap

This table lists supported bit depths and the data type of the output image data array.

| Supported Bit Depths | No Compression | RLE Compression | Output Class | Notes                            |
|----------------------|----------------|-----------------|--------------|----------------------------------|
| 1 bit                | ✓              | —               | logical      |                                  |
| 4 bit                | ✓              | ✓               | uint8        |                                  |
| 8 bit                | ✓              | ✓               | uint8        |                                  |
| 16 bit               | ✓              | —               | uint8        | 1 sample/pixel                   |
| 24 bit               | ✓              | —               | uint8        | 3 samples/pixel                  |
| 32 bit               | ✓              | —               | uint8        | 3 samples/pixel (1 byte padding) |

## CUR — Cursor File

This table lists supported bit depths and the data type of the output image data array.

| Supported Bit Depths | No Compression | Compression | Output Class |
|----------------------|----------------|-------------|--------------|
| 1 bit                | ✓              | —           | logical      |

| Supported Bit Depths | No Compression | Compression | Output Class |
|----------------------|----------------|-------------|--------------|
| 4 bit                | ✓              | –           | uint8        |
| 8 bit                | ✓              | –           | uint8        |

**Note** By default, Microsoft Windows cursors are 32-by-32 pixels. Since MATLAB pointers must be 16-by-16, you might need to scale your image. If you have Image Processing Toolbox™, you can use the `imresize` function.

## GIF — Graphics Interchange Format

This table lists supported bit depths and the data type of the output image data array.

| Supported Bit Depths | No Compression | Compression | Output Class |
|----------------------|----------------|-------------|--------------|
| 1 bit                | ✓              | –           | logical      |
| 2 bit to 8 bit       | ✓              | –           | uint8        |

## HDF4 — Hierarchical Data Format

This table lists supported bit depths and the data type of the output image data array.

| Supported Bit Depths | Raster Image with colormap | Raster image without colormap | Output Class | Notes           |
|----------------------|----------------------------|-------------------------------|--------------|-----------------|
| 8 bit                | ✓                          | ✓                             | uint8        |                 |
| 24 bit               | –                          | ✓                             | uint8        | 3 samples/pixel |

## ICO — Icon File

See “CUR — Cursor File” on page 1-4370

## JPEG — Joint Photographic Experts Group

`imread` reads any baseline JPEG image, as well as JPEG images with some commonly used extensions. For information on JPEG 2000 file support, see JPEG 2000.

| Supported Bits per Sample | Lossy Compression | Lossless Compression | Output Class | Notes            |
|---------------------------|-------------------|----------------------|--------------|------------------|
| 8 bit                     | ✓                 | ✓                    | uint8        | Grayscale or RGB |
| 12 bit                    | ✓                 | ✓                    | uint16       | Grayscale or RGB |
| 16 bit                    | –                 | ✓                    | uint16       | Grayscale        |

## JPEG 2000 — Joint Photographic Experts Group 2000

For information about JPEG files, see JPEG.

---

**Note:** Indexed JPEG 2000 images are not supported. Only JP2 compatible color spaces are supported for JP2/JPX files. By default, all image channels are returned in the order they are stored in the file.

---

| Supported Bits per Sample | Lossy Compression | Lossless Compression | Output Class    | Notes            |
|---------------------------|-------------------|----------------------|-----------------|------------------|
| 1 bit                     | ✓                 | ✓                    | logical         | Grayscale only   |
| 2 bit to 8 bit            | ✓                 | ✓                    | uint8 or int8   | Grayscale or RGB |
| 9 bit to 16 bit           | ✓                 | ✓                    | uint16 or int16 | Grayscale or RGB |

## PBM — Portable Bitmap

This table lists supported bit depths and the data type of the output image data array.

| Supported Bit Depths | Raw Binary | ASCII (Plain) Encoded | Output Class |
|----------------------|------------|-----------------------|--------------|
| 1 bit                | ✓          | ✓                     | logical      |

## PCX — Windows Paintbrush

This table lists supported bit depths and the data type of the output image data array.

| Supported Bit Depths | Output Class | Notes          |
|----------------------|--------------|----------------|
| 1 bit                | logical      | Grayscale only |

| Supported Bit Depths | Output Class | Notes                            |
|----------------------|--------------|----------------------------------|
| 8 bit                | uint8        | Grayscale or indexed             |
| 24 bit               | uint8        | RGB<br>Three 8-bit samples/pixel |

## PGM — Portable Graymap

This table lists supported bit depths and the data type of the output image data array.

| Supported Bit Depths | Raw Binary | ASCII (Plain Encoded) | Output Class                                     | Notes             |
|----------------------|------------|-----------------------|--------------------------------------------------|-------------------|
| 8 bit                | ✓          | —                     | uint8                                            |                   |
| 16 bit               | ✓          | —                     | uint16                                           |                   |
| Arbitrary            | —          | ✓                     | 1-bit to 8-bit: uint8<br>9-bit to 16-bit: uint16 | Values are scaled |

## PNG — Portable Network Graphics

This table lists supported bit depths and the data type of the output image data array.

| Supported Bit Depths | Output Class | Notes                              |
|----------------------|--------------|------------------------------------|
| 1 bit                | logical      | Grayscale                          |
| 2 bit                | uint8        | Grayscale                          |
| 4 bit                | uint8        | Grayscale                          |
| 8 bit                | uint8        | Grayscale or Indexed               |
| 16 bit               | uint16       | Grayscale or Indexed               |
| 24 bit               | uint8        | RGB<br>Three 8-bit samples/pixel.  |
| 48 bit               | uint16       | RGB<br>Three 16-bit samples/pixel. |

## PPM — Portable Pixmap

This table lists supported bit depths and the data type of the output image data array.

| Supported Bit Depths | Raw Binary | ASCII (Plain) Encoded | Output Class |
|----------------------|------------|-----------------------|--------------|
| Up to 16 bit         | ✓          | –                     | uint8        |
| Arbitrary            | –          | ✓                     |              |

## RAS — Sun Raster

This table lists supported bit depths and the data type of the output image data array.

| Supported Bit Depths | Output Class | Notes                                      |
|----------------------|--------------|--------------------------------------------|
| 1 bit                | logical      | Bitmap                                     |
| 8 bit                | uint8        | Indexed                                    |
| 24 bit               | uint8        | RGB<br>Three 8-bit samples/pixel           |
| 32 bit               | uint8        | RGB with Alpha<br>Four 8-bit samples/pixel |

## TIFF — Tagged Image File Format

`imread` reads most images supported by the TIFF specification or LibTIFF. The `imread` function supports these TIFF capabilities:

- Any number of samples per pixel
- CCITT group 3 and 4 FAX, Packbits, JPEG, LZW, Deflate, ThunderScan compression, and uncompressed images
- Logical, grayscale, indexed color, truecolor and hyperspectral images
- RGB, CMYK, CIELAB, ICCLAB color spaces. If the color image uses the CMYK color space, `A` is an `m-by-n-by-4` array. To determine which color space is used, use `imfinfo` to get information about the graphics file and look at the value of the `PhotometricInterpretation` field. If a file contains CIELAB color data, `imread` converts it to ICCLAB before bringing it into the MATLAB workspace. This conversion is necessary because 8-bit or 16-bit TIFF CIELAB-encoded values use a mixture of signed and unsigned data types that cannot be represented as a single MATLAB array.
- Data organized into tiles or scanlines

`imread` reads and converts TIFF images as follows:

- YCbCr images are converted into the RGB colorspace.
- All grayscale images are read as if black = 0, white = largest value.
- 1-bit images are returned as class `logical`.
- CIELab images are converted into ICCLab colorspace.

For copyright information, open the `libtiffcopyright.txt` file.

## XWD — X Window Dump

This table lists the supported bit depths, compression, and output classes for XWD files.

| Supported Bit Depths | ZPimages | XYBitmaps | XYPimages | Output Class |
|----------------------|----------|-----------|-----------|--------------|
| 1 bit                | ✓        | –         | ✓         | logical      |
| 8 bit                | ✓        | –         | –         | uint8        |

- “Importing Images”

Introduced before R2006a

# imshow

Display image

## Syntax

```
imshow(I)
imshow(X, map)
imshow(filename)
imshow(I, [low high])
imshow(___, Name, Value)

himage = imshow(___)
```

## Description

`imshow(I)` displays image `I` in a Handle Graphics figure, where `I` is a grayscale, RGB (truecolor), or binary image. For binary images, `imshow` displays pixels with the value 0 (zero) as black and 1 as white. `imshow` optimizes figure, axes, and image object properties for image display.

`imshow(X, map)` displays the indexed image `X` with the colormap `map`. A colormap matrix can have any number of rows, but it must have exactly 3 columns. Each row is interpreted as a color, with the first element specifying the intensity of red light, the second green, and the third blue. Color intensity can be specified on the interval 0.0 to 1.0.

`imshow(filename)` displays the image stored in the graphics file specified by `filename`.

`imshow(I, [low high])` displays grayscale image `I`, specifying the display range as a two-element vector, `[low high]`. For more information, see the `DisplayRange` parameter.

`imshow(___, Name, Value)` displays an image, using name-value pairs to control aspects of the operation.

`himage = imshow( ___ )` returns the handle to the image object created by `imshow`.

## Examples

### Display Grayscale Image

Display a grayscale image by reading an RGB image into the workspace and converting it to a grayscale image.

Read RGB image into the workspace.

```
RGB = imread('peppers.png');
```

Convert the image to grayscale.

```
I = rgb2gray(RGB);
```

Display the grayscale image.

```
imshow(I)
```

### Display Image from File

Display an image stored in a file.

```
imshow('peppers.png');
```

### Display Indexed Image

Read a sample indexed image, `corn.tif`, into the workspace, and then display it.

```
[X,map] = imread('corn.tif');
imshow(X,map)
```

## Input Arguments

**I** — Input image

scalar | vector | matrix | m-by-n-by-3 array

Input image, specified as a scalar, vector, or matrix representing a grayscale, RGB, or binary image. Multi-plane image inputs must be RGB images of size *m*-by-*n*-by-3. An RGB image can be `uint8`, `uint16`, `single`, or `double`. A grayscale image can be any numeric data type. A binary image is of class `logical`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **X** — Indexed image

2-D array of real numeric values

Indexed image, specified as a 2-D array of real numeric values. The values in *X* are indices into the colormap specified by `map`.

Data Types: `single` | `double` | `uint8` | `logical`

### **map** — Colormap

*m*-by-3 array

Colormap, specified as an *m*-by-3 array of type `single` or `double` in the range [0 1], or an *m*-by-3 array of type `uint8`. Each row specifies an RGB color value.

Data Types: `single` | `double` | `uint8`

### **filename** — File name

string

File name, specified as a string. The image must be readable by `imread`. The `imshow` function displays the image, but does not store the image data in the MATLAB workspace. If the file contains multiple images, `imshow` displays the first image in the file.

Example: `imshow('peppers.png')`

Data Types: `char`

### **[low high]** — Grayscale image display range

two-element vector

Grayscale image display range, specified as a two-element vector. For more information, see the `'DisplayRange'` name-value pair argument.

Example: `[50 250]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `imshow('board.tif', 'Border', 'tight')`

### 'Border' — Figure window border space

'loose' (default) | 'tight'

Figure window border space, specified as the comma-separated pair consisting of 'Border' and either 'tight' or 'loose'. When set to 'loose', the figure window includes space around the image in the figure. When set to 'tight', the figure window does not include any space around the image in the figure.

If the image is very small or if the figure contains other objects besides an image and its axes, `imshow` might use a border regardless of how this parameter is set.

Example: `imshow('board.tif', 'Border', 'tight')`

Data Types: char

### 'Colormap' — Colormap

m-by-3 matrix

Colormap, specified as the comma-separated pair consisting of 'Colormap' and an m-by-3 matrix. `imshow` uses this to set the figure's `colormap` property. Use this parameter to view grayscale images in false color. If you specify an empty colormap (`[]`), then `imshow` ignores this parameter.

Example: `newmap = copper; imshow('board.tif', 'Colormap', newmap)`

Data Types: double

### 'DisplayRange' — Grayscale image display range

two-element vector

Grayscale image display range, specified as the comma-separated pair consisting of 'DisplayRange' and a two-element vector of the form `[low high]`. The `imshow` function displays the value `low` (and any value less than `low`) as black, and it displays the value `high` (and any value greater than `high`) as white. Values between `low` and

high are displayed as intermediate shades of gray, using the default number of gray levels.

For `uint8`, `'DisplayRange'` defaults to `[0 255]`. For all other data types it defaults to `[min(I(:)) max(I(:))]`. If you specify an empty matrix (`[]`), `imshow` uses the default.

---

**Note:** Including the parameter name is optional, except when the image is specified by a file name. The syntax `imshow(I,[low high])` is equivalent to `imshow(I,'DisplayRange',[low high])`. If you call `imshow` with a file name, then you must specify the `'DisplayRange'` parameter.

---

Example: `h = imshow(I,'DisplayRange',[0 80]);`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **'InitialMagnification' — Initial magnification of image display**

100 (default) | numeric scalar | `'fit'`

Initial magnification of image display, specified as the comma-separated pair consisting of `'InitialMagnification'` and a numeric scalar or the string, `'fit'`. If set to 100, then `imshow` displays the image at 100% magnification (one screen pixel for each image pixel). If set to `'fit'`, then `imshow` scales the entire image to fit in the window.

Initially, `imshow` always displays the entire image. If the magnification value is so large that the image is too big to display on the screen, `imshow` warns and displays the image at the largest magnification that fits on the screen.

If the image is displayed in a figure with its `'WindowStyle'` property set to `'docked'`, then `imshow` warns and displays the image at the largest magnification that fits in the figure.

Note: If you specify the axes position (using `subplot` or `axes`), `imshow` ignores any initial magnification you might have specified and defaults to the `'fit'` behavior.

When you use `imshow` with the `'Reduce'` parameter, the initial magnification must be `'fit'`.

Example: `h = imshow(I,'InitialMagnification','fit');`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char`

**'Parent' — Parent axes of image object**

handle

Parent axes of image object, specified as the comma-separated pair consisting of 'Parent' and a handle. Use the 'Parent' name-value argument to build a UI that gives you control of the figure and axes properties.

Data Types: `function_handle`

**'Reduce' — Indicator for subsampling**

`true` | `false` | `1` | `0`

Indicator for subsampling image, specified as the comma-separated pair consisting of 'Reduce' and either `true`, `false`, `1`, or `0`. This argument is valid only when you use it with the name of a TIFF file. Use the `Reduce` argument to display overviews of very large images.

Data Types: `logical`

**'Xdata' — X-axis limits of nondefault coordinate system**

two-element vector

X-axis limits of nondefault coordinate system, specified as the comma-separated pair consisting of 'Xdata' and a two-element vector. This argument establishes a nondefault spatial coordinate system by specifying the image `XData`. The value can have more than two elements, but `imshow` uses only the first and last elements.

Example: `'Xdata', [100 200]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**'YData' — Y-axis limits of nondefault coordinate system**

two-element vector

Y-axis limits of nondefault coordinate system, specified as the comma-separated pair consisting of 'Ydata' and a two-element vector. The value can have more than two elements, but `imshow` uses only the first and last elements.

Example: `'YData', [100 200]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

**himage** — Image object  
handle

Image object, specified as a handle.

## More About

### Tips

- If you have Image Processing Toolbox, you can use the Image Viewer app as an integrated environment for displaying images and performing common image processing tasks.
- If you have Image Processing Toolbox, you can use the `iptsetpref` function to set toolbox preferences that modify the behavior of `imshow`.
- The `imshow` function is not supported when you start MATLAB with the `-nojvm` option.

### See Also

`image` | `imagesc` | `imfinfo` | `imread` | `imwrite` | `iptsetpref`

## **imwrite**

Write image to graphics file

### **Syntax**

```
imwrite(A,filename)
imwrite(A,map,filename)

imwrite(____,fmt)

imwrite(____,Name,Value)
```

### **Description**

`imwrite(A,filename)` writes image data `A` to the file specified by `filename`, inferring the file format from the extension. `imwrite` creates the new file in your current folder. The bit depth of the output image depends on the data type of `A` and the file format. For most formats:

- If `A` is of data type `uint8`, then `imwrite` outputs 8-bit values.
- If `A` is of data type `uint16` and the output file format supports 16-bit data (JPEG, PNG, and TIFF), then `imwrite` outputs 16-bit values. If the output file format does not support 16-bit data, then `imwrite` returns an error.
- If `A` is a grayscale or RGB color image of data type `double` or `single`, then `imwrite` assumes that the dynamic range is `[0,1]` and automatically scales the data by 255 before writing it to the file as 8-bit values. If the data in `A` is `single`, convert `A` to `double` before writing to a GIF or TIFF file.
- If `A` is of data type `logical`, then `imwrite` assumes that the data is a binary image and writes it to the file with a bit depth of 1, if the format allows it. BMP, PNG, or TIFF formats accept binary images as input arrays.

If `A` contains indexed image data, you should additionally specify the `map` input argument.

`imwrite(A,map,filename)` writes the indexed image in `A` and its associated colormap, `map`, to the file specified by `filename`.

- If **A** is an indexed image of data type `double` or `single`, then `imwrite` converts the indices to zero-based indices by subtracting 1 from each element, and then writes the data as `uint8`. If the data in **A** is `single`, convert **A** to `double` before writing to a GIF or TIFF file.

`imwrite( ____, fmt )` writes the image in the format specified by `fmt`, regardless of the file extension in `filename`. You can specify `fmt` after the input arguments in any of the previous syntaxes.

`imwrite( ____, Name, Value )` specifies additional parameters for output GIF, HDF, JPEG, PBM, PGM, PNG, PPM, and TIFF files, using one or more name-value pair arguments. You can specify `Name`, `Value` after the input arguments in any of the previous syntaxes.

## Examples

### Write Grayscale Image to PNG

Write a 50-by-50 array of grayscale values to a PNG file in the current folder.

```
A = rand(50);
imwrite(A, 'myGray.png')
```

### Write Indexed Image Data to PNG

Write an indexed image array and its associated colormap to a PNG file.

Load sample image data from the file, `clown.mat`.

```
load clown.mat
```

The image array `X` and its associated colormap, `map`, are loaded into the MATLAB workspace.

Write the data to a new PNG file.

```
imwrite(X, map, 'myclown.png')
```

`imwrite` creates the file, `myclown.png`, in your current folder.

View the new file by opening it outside of MATLAB.

### Write Indexed Image with MATLAB Colormap

Write image data to a new PNG file with the built-in MATLAB colormap, `copper`.

Load sample image data from the file `clown.mat`.

```
load clown.mat
```

The image array `X` and its associated colormap, `map`, are loaded into the MATLAB workspace. `map` is a matrix of 81 RGB vectors.

Define a copper-tone colormap with 81 RGB vectors. Then, write the image data to a PNG file using the new colormap.

```
newmap = copper(81);
imwrite(X,newmap,'copperclown.png');
```

`imwrite` creates the file, `copperclown.png`, in your current folder.

View the new file by opening it outside of MATLAB.

### Write Truecolor Image to JPEG

Create and write truecolor image data to a JPEG file.

Create a 49-by-49-by-3 array of random RGB values.

```
A = rand(49,49);
A(:,:,2) = rand(49,49);
A(:,:,3) = rand(49,49);
```

Write the image data to a JPEG file, specifying the output format using the string, 'jpg'. Add a comment to the file using the 'Comment' name-value pair argument.

```
imwrite(A,'newImage.jpg','jpg','Comment','My JPEG file')
```

View information about the new file.

```
imfinfo('newImage.jpg')
```

ans =

```
Filename: 'S:\newImage.jpg'
FileModDate: '25-Jan-2013 16:18:41'
FileSize: 2339
Format: 'jpg'
```

```
FormatVersion: ''
 Width: 49
 Height: 49
 BitDepth: 24
 ColorType: 'truecolor'
FormatSignature: ''
NumberOfSamples: 3
 CodingMethod: 'Huffman'
 CodingProcess: 'Sequential'
 Comment: {'My JPEG file'}
```

## Write Multiple Images to TIFF File

Write multiple images to a single multipage TIFF file.

Create two sets of random image data, `im1` and `im2`.

```
im1 = rand(50,40,3);
im2 = rand(50,50,3);
```

Write the first image to a new TIFF file. Then, append the second image to the same file.

```
imwrite(im1, 'myMultipageFile.tif')
imwrite(im2, 'myMultipageFile.tif', 'WriteMode', 'append')
```

## Write Animated GIF

Animate a series of plots and write the result to a GIF file.

Define the x-axis limits for the plot and specify the output file name.

```
x = 0:0.01:1;
figure
filename = 'testAnimated.gif';
```

Call `frame2im` to get image data from a single movie frame. Because three-dimensional data is not supported for GIF files, call `rgb2ind` to convert the RGB data in the image data, `im`, to an indexed image, `A`, with a colormap, `map`. Call `imwrite` with the name-value pair argument, `'WriteMode', 'append'`, to append multiple images to the first image.

```
for n = 1:0.5:5
 y = x.^n;
 plot(x,y)
 drawnow
 frame = getframe(1);
```

```

im = frame2im(frame);
[A,map] = rgb2ind(im,256);
if n == 1;
 imwrite(A,map,filename,'gif','LoopCount',Inf,'DelayTime',1);
else
 imwrite(A,map,filename,'gif','WriteMode','append','DelayTime',1);
end
end

```

`imwrite` writes the GIF file to your current folder. Name-value pair `'LoopCount', Inf` causes the animation to continuously loop. `'DelayTime', 1` specifies a 1-second delay between the display of each image in the animation.

## Input Arguments

### **A** — Image data to write

matrix

Image data to write, specified as a full (nonsparse) matrix.

- For grayscale images, **A** can be  $m$ -by- $n$ .
- For indexed images, **A** can be  $m$ -by- $n$ . Specify the associated colormap in the `map` input argument.
- For truecolor images, **A** must be  $m$ -by- $n$ -by-3. `imwrite` does not support writing RGB images to GIF files.

For TIFF files, **A** can be an  $m$ -by- $n$ -by-4 array containing color data that uses the CMYK color space.

For multiframe GIF files, **A** can be an  $m$ -by- $n$ -by-1-by- $p$  array containing grayscale or indexed images, where  $p$  is the number of frames to write. RGB images are not supported in this case.

Data Types: `double` | `single` | `uint8` | `uint16` | `logical`

### **filename** — Name of output file

string

Name of the output file including the file extension, specified as a string. For a list of the image types that `imwrite` can write, see the description for the `fmt` input argument.

Example: `'myFile.gif'`

Data Types: char

**map — Colormap of indexed image**

m-by-3 array

Colormap associated with indexed image data in **A**, specified as an m-by-3 array. **map** must be a valid MATLAB colormap. See **colormap** for a list of built-in MATLAB colormaps. Most image file formats do not support colormaps with more than 256 entries.

Example: `[0,0,0;0.5,0.5,0.5;1,1,1]`

Example: `jet(60)`

Data Types: double

**fmt — Format of output file**

string

Format of the output file, specified as one of the following strings.

This table also summarizes the types of images that **imwrite** can write. The MATLAB file format registry determines which file formats are supported. See **imformats** for more information about this registry.

For certain formats, **imwrite** can accept additional name-value pair arguments. To view these arguments, click the linked format names below.

| Value of <b>fmt</b> | Format of Output File                   | Description                                                                                     |
|---------------------|-----------------------------------------|-------------------------------------------------------------------------------------------------|
| 'bmp'               | Windows Bitmap (BMP)                    | 1-bit, 8-bit, and 24-bit uncompressed images                                                    |
| 'gif'               | Graphics Interchange Format (GIF)       | 8-bit images                                                                                    |
| 'hdf'               | Hierarchical Data Format (HDF4)         | 8-bit raster image data sets with or without associated colormap, 24-bit raster image data sets |
| 'jpg' or 'jpeg'     | Joint Photographic Experts Group (JPEG) | 8-bit, 12-bit, and 16-bit Baseline JPEG images                                                  |

| Value of <code>fmt</code> | Format of Output File                             | Description                                                                                                                                                                                                                                               |
|---------------------------|---------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                           |                                                   | <b>Note:</b> <code>imwrite</code> converts indexed images to RGB before writing data to JPEG files, because the JPEG format does not support indexed images.                                                                                              |
| 'j2k' or 'jpx'            | JPEG 2000 — Joint Photographic Experts Group 2000 | 1-bit, 8-bit, and 16-bit JPEG 2000 images                                                                                                                                                                                                                 |
| 'pbm'                     | Portable Bitmap (PBM)                             | Any 1-bit PBM image, ASCII (plain) or raw (binary) encoding                                                                                                                                                                                               |
| 'pcx'                     | Windows Paintbrush (PCX)                          | 8-bit images                                                                                                                                                                                                                                              |
| 'pgm'                     | Portable Graymap (PGM)                            | Any standard PGM image; ASCII (plain) encoded with arbitrary color depth; raw (binary) encoded with up to 16 bits per gray value                                                                                                                          |
| 'png'                     | Portable Network Graphics (PNG)                   | 1-bit, 2-bit, 4-bit, 8-bit, and 16-bit grayscale images; 8-bit and 16-bit grayscale images with alpha channels; 1-bit, 2-bit, 4-bit, and 8-bit indexed images; 24-bit and 48-bit truecolor images; 24-bit and 48-bit truecolor images with alpha channels |
| 'pnm'                     | Portable Anymap (PNM)                             | Any of the PPM/PGM/PBM formats, chosen automatically                                                                                                                                                                                                      |
| 'ppm'                     | Portable Pixmap (PPM)                             | Any standard PPM image: ASCII (plain) encoded with arbitrary color depth or raw (binary) encoded with up to 16 bits per color component                                                                                                                   |
| 'ras'                     | Sun™ Raster (RAS)                                 | Any RAS image, including 1-bit bitmap, 8-bit indexed, 24-bit truecolor, and 32-bit truecolor with alpha                                                                                                                                                   |

| Value of <code>fmt</code> | Format of Output File           | Description                                                                                                                                                                                                                                                                                                                |
|---------------------------|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'tif' or 'tiff'           | Tagged Image File Format (TIFF) | Baseline TIFF images, including: <ul style="list-style-type: none"> <li>• 1-bit, 8-bit, 16-bit, 24-bit, and 48-bit uncompressed images and images with packbits, LZW, or Deflate compression</li> <li>• 1-bit images with CCITT 1D, Group 3, and Group 4 compression</li> <li>• CIELAB, ICCLAB, and CMYK images</li> </ul> |
| 'xwd'                     | X Windows Dump (XWD)            | 8-bit ZPixmap                                                                                                                                                                                                                                                                                                              |

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `imwrite(A, 'myFile.png', 'BitDepth', 8)` writes the data in `A` using 8 bits to represent each pixel.

## GIF — Graphics Interchange Format

### 'BackgroundColor' — Color to use as background color

scalar integer

Color to use as background color for the indexed image, specified as the comma-separated pair consisting of 'BackgroundColor' and a scalar integer corresponding to the colormap index.

The background color is used for some disposal methods in animated GIFs.

- If image data `A` is `uint8` or `logical`, then the colormap index is zero-based.
- If image data `A` is `double`, then the colormap index is one-based.

The default background color corresponds to the first color in the colormap.

Example: 'BackgroundColor', 15

**'Comment' — Comment to add to image**

string | cell array of strings

Comment to add to the image, specified as the comma-separated pair consisting of 'Comment' and a string or a 1-by-n cell array of strings. For a cell array of strings, `imwrite` adds a carriage return after each string.

Example: 'Comment', {'Sample #314', 'January 5, 2013'}

Data Types: char | cell

**'DelayTime' — Delay before displaying next image**

0.5 (default) | scalar value in the range [0,655]

Delay before displaying next image, in seconds, specified as the comma-separated pair consisting of 'DelayTime' and a scalar value in the range [0,655]. A value of 0 displays images as fast as your hardware allows.

Example: 'DelayTime', 60

**'DisposalMethod' — Disposal method of animated GIF**

'doNotSpecify' (default) | 'leaveInPlace' | 'restoreBG' | 'restorePrevious'

Disposal method of an animated GIF, specified as the comma-separated pair consisting of 'DisposalMethod' and one of the following strings.

| Value of DisposalMethod  | Result                                                                    |
|--------------------------|---------------------------------------------------------------------------|
| 'doNotSpecify' (default) | Replace one full-size, nontransparent frame with another.                 |
| 'leaveInPlace'           | Any pixels not covered up by the next frame continue to display.          |
| 'restoreBG'              | The background color or background tile shows through transparent pixels. |
| 'restorePrevious'        | Restore to the state of a previous, undisposed frame.                     |

Example: 'DisposalMethod', 'restoreBG'

**'Location' — Offset of screen relative to image**

[0,0] (default) | two-element vector

Offset of the screen relative to the image, measured from the top left corner of each, specified as the comma-separated pair consisting of 'Location' and a two-element vector. The first vector element specifies the offset from the top, and the second element specifies the offset from the left, in pixels.

Example: 'Location', [10, 15]

Data Types: double

### 'LoopCount' — Number of times to repeat animation

Inf (default) | integer in the range [0, 65535]

Number of times to repeat the animation, specified as the comma-separated pair consisting of 'LoopCount' and either an integer in the range [0, 65535], or the value Inf. If you specify 0, the animation plays once. If you specify the value 1, the animation plays twice, and so on. A LoopCount value of Inf causes the animation to continuously loop.

To enable animation within Microsoft PowerPoint®, specify a value for 'LoopCount' within the range [1, 65535]. Some Microsoft applications interpret the value 0 to mean do not loop at all.

Example: 'LoopCount', 3

### 'ScreenSize' — Height and width of frame

height and width of input image (default) | two-element vector

Height and width of the frame, specified as the comma-separated pair consisting of 'ScreenSize' and a two-element vector. When you use the ScreenSize argument with 'Location', it provides a way to write frames to the image that are smaller than the whole frame. 'DisposalMethod' determines the fill value for pixels outside the frame.

Example: 'ScreenSize', [1000 1060]

Data Types: double

### 'TransparentColor' — Color to use as transparent color

scalar integer

Color to use as transparent color for the image, specified as the comma-separated pair consisting of 'TransparentColor' and a scalar integer corresponding to the colormap index.

- If image data A is `uint8` or `logical`, then indexing begins at 0.
- If image data A is `double`, then indexing begins at 1.

Example: `'TransparentColor',20`

#### **'WriteMode' — Writing mode**

`'overwrite'` (default) | `'append'`

Writing mode, specified as the comma-separated pair consisting of `'WriteMode'` and either `'overwrite'` or `'append'`. In `overwrite` mode, `imwrite` overwrites an existing file, `filename`. In `append` mode, `imwrite` adds a single frame to the existing file.

Example: `'WriteMode','append'`

### **HDF4 — Hierarchical Data Format**

#### **'Compression' — Compression scheme**

`'none'` (default) | `'jpeg'` | `'rle'`

Compression scheme, specified as the comma-separated pair consisting of `'Compression'` and one of the following strings.

| Value of Compression          | Result                                                            |
|-------------------------------|-------------------------------------------------------------------|
| <code>'none'</code> (default) | No compression                                                    |
| <code>'jpeg'</code>           | JPEG compression. Valid only for grayscale and RGB images.        |
| <code>'rle'</code>            | Run-length encoding. Valid only for grayscale and indexed images. |

Example: `'Compression','jpeg'`

#### **'Quality' — Quality of JPEG-compressed file**

75 (default) | scalar in the range [0,100]

Quality of the JPEG-compressed file, specified as the comma-separated pair consisting of `'Quality'` and a scalar in the range [0,100], where 0 is lower quality and higher compression, and 100 is higher quality and lower compression. This parameter applies only if `'Compression'` is `'jpeg'`.

Example: `'Quality',25`

## **'WriteMode' — Writing mode**

'overwrite' (default) | 'append'

Writing mode, specified as the comma-separated pair consisting of 'WriteMode' and either 'overwrite' or 'append'. In `overwrite` mode, `imwrite` overwrites an existing file, `filename`. In `append` mode, `imwrite` adds a single frame to the existing file.

Example: 'WriteMode', 'append'

## **JPEG — Joint Photographic Experts Group**

### **'BitDepth' — Number of bits per pixel**

8 (default) | scalar

Number of bits per pixel, specified as the comma-separated pair consisting of 'BitDepth' and a scalar.

- For grayscale images, the `BitDepth` value can be 8, 12, or 16. The default value is 8. For 16-bit images, the 'Mode' name-value pair argument must be 'lossless'.
- For color images, the `BitDepth` value is the number of bits per plane, and can be 8 or 12. The default is 8 bits per plane.

Example: 'BitDepth', 12

### **'Comment' — Comment to add to image**

string | character array | n-by-1 cell array of strings

Comment to add to the image, specified as the comma-separated pair consisting of 'Comment' and a single string, a character array, or an n-by-1 cell array of strings. `imwrite` writes each row of input as a comment in the JPEG file.

Example: 'Comment', {'First line'; 'second line'; 'third line'}

Data Types: char | cell

### **'Mode' — Type of compression**

'lossy' (default) | 'lossless'

Type of compression, specified as the comma-separated pair consisting of 'Mode' and one of the following strings:

- 'lossy'
- 'lossless'

Example: 'Mode', 'lossless'

### 'Quality' — Quality of output file

75 (default) | scalar in the range [0,100]

Quality of the output file, specified as the comma-separated pair consisting of 'Quality' and a scalar in the range [0,100], where 0 is lower quality and higher compression, and 100 is higher quality and lower compression. A Quality value of 100 does not write a lossless JPEG image. Instead, use the 'Mode', 'lossless' name-value pair argument.

Example: 'Quality', 100

## JPEG 2000— Joint Photographic Experts Group 2000

### 'Comment' — Comment to add to image

string | character array | cell array of strings

Comment to add to the image, specified as the comma-separated pair consisting of 'Comment' and a single string, a character array, or a cell array of strings. `imwrite` writes each row of input as a comment in the JPEG 2000 file.

Example: 'Comment', {'First line'; 'second line'; 'third line'}

Example: 'Comment', {'First line', 'second line', 'third line'}

Data Types: cell | char

### 'CompressionRatio' — Target compression ratio

1 (default) | scalar

Target compression ratio, specified as the comma-separated pair consisting of 'CompressionRatio' and a real scalar greater than or equal to 1. The compression ratio is the ratio of the input image size to the output compressed size. For example, a value of 2.0 implies that the output image size is half of the input image size or less. A higher value implies a smaller file size and reduced image quality. The compression ratio does not take into account the header size.

Specifying `CompressionRatio` is valid only when 'Mode' is 'lossy'.

Example: 'CompressionRatio', 3

### 'Mode' — Type of compression

'lossy' (default) | 'lossless'

Type of compression, specified as the comma-separated pair consisting of 'Mode' and one of the following strings:

- 'lossy'
- 'lossless'

Example: 'Mode', 'lossless'

**'ProgressionOrder' — Order of packets in code stream**

'LRCP' (default) | 'RLCP' | 'RPCL' | 'PCRL' | 'CPRL'

Order of packets in the code stream, specified as the comma-separated pair consisting of 'ProgressionOrder' and one of the following strings:

- 'LRCP'
- 'RLCP'
- 'RPCL'
- 'PCRL'
- 'CPRL'

The characters in the text strings represent the following: L = layer, R = resolution, C = component and P = position.

Example: 'ProgressionOrder', 'RLCP'

**'QualityLayers' — Number of quality layers**

1 (default) | integer in the range [1,20]

Number of quality layers, specified as the comma-separated pair consisting of 'QualityLayers' and an integer in the range [1,20].

Example: 'QualityLayers', 8

**'ReductionLevels' — Number of reduction levels**

4 (default) | integer in the range [1,8]

Number of reduction levels, or wavelet decomposition levels, specified as the comma-separated pair consisting of 'ReductionLevels' and an integer in the range [1,8].

Example: 'ReductionLevels', 6

**'TileSize' — Tile height and width**

image size (default) | two-element vector

Tile height and width, specified as the comma-separated pair consisting of `'TileSize'` and a two-element vector. The minimum size you can specify is `[128 128]`.

Example: `'TileSize',[130 130]`

## **PBM-, PGM-, and PPM — Portable Bitmap, Graymap, Pixmap**

### **'Encoding' — Encoding**

`'rawbits'` (default) | `'ASCII'`

Encoding, specified as the comma-separated pair consisting of `'Encoding'` and either `'rawbits'` for binary encoding, or `'ASCII'` for plain encoding.

Example: `'Encoding','ASCII'`

### **'MaxValue' — Maximum gray or color value**

scalar

Maximum gray or color value, specified as the comma-separated pair consisting of `'MaxValue'` and a scalar.

Available only for PGM and PPM files. For PBM files, this value is always 1.

If the image array is `uint16`, then the default value for `MaxValue` is 65535. Otherwise, the default value is 255.

Example: `'MaxValue',510`

## **PNG — Portable Network Graphics**

In addition to the following name-value pair arguments, you can use any parameter name that satisfies the PNG specification for keywords. That is, the name uses only printable characters, contains 80 or fewer characters, and does not contain leading or trailing spaces. The value corresponding to these user-specified names must be a string that contains no control characters other than linefeed.

### **'Alpha' — Transparency of each pixel**

matrix of values in the range `[0,1]`

Transparency of each pixel, specified as the comma-separated pair consisting of `'Alpha'` and a matrix of values in the range `[0,1]`. The row and column dimensions of the `Alpha` matrix must be the same as those of the image data array. You can specify `Alpha` only for grayscale (`m-by-n`) and truecolor (`m-by-n-by-3`) image data.

---

**Note:** You cannot specify both 'Alpha' and 'Transparency' at the same time.

---

Data Types: double | uint8 | uint16

**'Author' — Author information**

string

Author information, specified as the comma-separated pair consisting of 'Author' and a string.

Example: "Author', 'Ann Smith'

Data Types: char

**'Background' — Background color when compositing transparent pixels**

scalar in the range [0, 1] | integer in the range [1, P] | 3-element vector in the range [0, 1]

Background color when compositing transparent pixels, specified as the comma-separated pair consisting of 'Background' and a value dependent on the image data, as follows.

| Image Type       | Form of Background Value                                                                                                                                                       |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Grayscale images | Scalar in the range [0, 1].                                                                                                                                                    |
| Indexed images   | Integer in the range [1, P], where P is the colormap length. For example, 'Background', 50 sets the background color to the color specified by the 50th index in the colormap. |
| Truecolor images | Three-element vector of RGB intensities in the range [0, 1]. For example, 'Background', [0 1 1] sets the background color to cyan.                                             |

Data Types: double

**'BitDepth' — Number of bits per pixel**

scalar

Number of bits per pixel, specified as the comma-separated pair consisting of 'BitDepth' and a scalar. Depending on the output image, the scalar can be one of the following values.

| Image Type                             | Allowed Values for BitDepth |
|----------------------------------------|-----------------------------|
| Grayscale images                       | 1, 2, 4, 8, or 16           |
| Grayscale images with an alpha channel | 8 or 16                     |
| Indexed images                         | 1, 2, 4, or 8               |
| Truecolor images                       | 8 or 16                     |

- If the image is of class `double` or `uint8`, then the default bit depth is 8 bits per pixel.
- If the image is `uint16`, then the default is 16 bits per pixel.
- If the image is `logical`, then the default is 1 bit per pixel.

Example: 'BitDepth',4

### 'Chromaticities' — Reference white point and primary chromaticities

8-element vector

Reference white point and primary chromaticities, specified as the comma-separated pair consisting of 'Chromaticities' and an 8-element vector, [wx wy rx ry gx gy bx by]. The elements wx and wy are the chromaticity coordinates of the white point, and the elements rx, ry, gx, gy, bx, and by are the chromaticity coordinates of the three primary colors.

If you specify `Chromaticities`, you should also specify the `Gamma` name-value pair argument.

Example: 'Chromaticities',  
[0.312,0.329,0.002,0.002,0.001,0.001,0.115,0.312]

Data Types: `double`

### 'Comment' — Comment to add to image

string

Comment to add to the image, specified as the comma-separated pair consisting of 'Comment' and a string.

## **'Copyright' — Copyright notice**

string

Copyright notice, specified as the comma-separated pair consisting of 'Copyright' and a string.

## **'CreationTime' — Time of original image creation**

string

Time of original image creation, specified as a string.

## **'Description' — Description of image**

string

Description of the image, specified as the comma-separated pair consisting of 'Description' and a string.

## **'Disclaimer' — Legal disclaimer**

string

Legal disclaimer, specified as the comma-separated pair consisting of 'Disclaimer' and a string.

## **'Gamma' — File gamma**

scalar

File gamma, specified as the comma-separated pair consisting of 'Gamma' and a scalar.

Example: 'Gamma', 2.2

## **'ImageModTime' — Time of last image modification**

serial date number | date string

Time of the last image modification, specified as the comma-separated pair consisting of 'ImageModTime' and a MATLAB serial date number or a date string that can be converted to a date vector using the `datevec` function. Values should be in Coordinated Universal Time (UTC).

The default `ImageModTime` value is the time when you call `imwrite`.

Example: 'ImageModTime', '17-Jan-2013 11:23:10'

Data Types: double | char

**'InterlaceType' — Interlacing scheme**`'none'` (default) | `'adam7'`

Interlacing scheme, specified as the comma-separated pair consisting of `'InterlaceType'` and either `'none'` for no interlacing, or `'adam7'` to use the Adam7 algorithm.

Example: `'InterlaceType','adam7'`

**'ResolutionUnit' — Unit for image resolution**`'unknown'` (default) | `'meter'`

Unit for image resolution, specified as the comma-separated pair consisting of `'ResolutionUnit'` and either `'unknown'` or `'meter'`. If you specify `ResolutionUnit`, you must include at least one of the `XResolution` and `YResolution` name-value pair arguments. When the value of `ResolutionUnit` is `'meter'`, the `XResolution` and `YResolution` values are interpreted in pixels per meter.

Example: `'ResolutionUnit','meter','XResolution',1000`

**'SignificantBits' — Number of bits to regard as significant**`[]` (default) | scalar | vector

Number of bits in the data array to regard as significant, specified as the comma-separated pair consisting of `'SignificantBits'` and a scalar or a vector in the range `[1,BitDepth]`. Depending on the output image type, the value must be in the following form.

| Image Type                               | Form of SignificantBits Value |
|------------------------------------------|-------------------------------|
| Grayscale image without an alpha channel | Scalar                        |
| Grayscale image with an alpha channel    | 2-element vector              |
| Indexed image                            | 3-element vector              |
| Truecolor image without an alpha channel | 3-element vector              |
| Truecolor image with an alpha channel    | 4-element vector              |

Example: `'SignificantBits',[2,3]`

**'Software' — Software used to create the image**

string

Software used to create the image, specified as the comma-separated pair consisting of 'Software' and a string.

**'Source' — Device used to create the image**

string

Device used to create the image, specified as the comma-separated pair consisting of 'Source' and a string.

**'Transparency' — Pixels to consider transparent**

[ ] (default) | scalar in the range [0,1] | vector

Pixels to consider transparent when no alpha channel is used, specified as the comma-separated pair consisting of 'Transparency' and a scalar or a vector. Depending on the output image, the value must be in the following form.

| Image Type       | Form of Transparency Value                                                                                                                                                                                     |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Grayscale images | Scalar in the range [0,1], indicating the grayscale color to be considered transparent.                                                                                                                        |
| Indexed images   | Q-element vector of values in the range [0,1], where Q is no larger than the colormap length and each value indicates the transparency associated with the corresponding colormap entry. In most cases, Q = 1. |
| Truecolor images | 3-element vector of RGB intensities in the range [0,1], indicating the truecolor color to consider transparent.                                                                                                |

---

**Note:** You cannot specify both 'Transparency' and 'Alpha' at the same time.

---

Example: 'Transparency', [1 1 1]

Data Types: double

**'Warning' — Warning of nature of content**

string

Warning of nature of content, specified as the comma-separated pair consisting of 'Warning' and a string.

### **'XResolution' — Image resolution in horizontal direction**

scalar

Image resolution in the horizontal direction, in pixels/unit, specified as the comma-separated pair consisting of 'XResolution' and a scalar. Define the unit by specifying the `ResolutionUnit` name-value pair argument.

If you do not also specify `YResolution`, then the `XResolution` value applies to both the horizontal and vertical directions.

Example: 'XResolution',900

### **'YResolution' — Image resolution in vertical direction**

scalar

Image resolution in the vertical direction, in pixels/unit, specified as the comma-separated pair consisting of 'XResolution' and a scalar. Define the unit by specifying the `ResolutionUnit` name-value pair argument.

If you do not also specify `XResolution`, then the `YResolution` value applies to both the horizontal and vertical directions.

Example: 'YResolution',900

## **RAS — Sun Raster Graphic**

### **'Alpha' — Transparency of each pixel**

[ ] (default) | matrix

Transparency of each pixel, specified as the comma-separated pair consisting of 'Alpha' and a matrix with row and column dimensions the same as those of the image data array.

Valid only for truecolor (m-by-n-by-3) image data.

Data Types: double | single | uint8 | uint16

### **'Type' — Image type**

'standard' (default) | 'rgb' | 'rle'

Image type, specified as the comma-separated pair consisting of 'Type' and one of the following strings.

| Value of Type        | Description                                          |
|----------------------|------------------------------------------------------|
| 'standard' (default) | Uncompressed, B-G-R color order for truecolor images |
| 'rgb'                | Uncompressed, R-G-B color order for truecolor images |
| 'rle'                | Run-length encoding of 1-bit and 8-bit images        |

Example: 'Type', 'rgb'

## **TIFF — Tagged Image File Format**

### **'ColorSpace' — Color space representing color data**

'rgb' (default) | 'cielab' | 'icclab'

Color space representing the color data, specified as the comma-separated pair consisting of 'ColorSpace' and one of the following strings:

- 'rgb'
- 'cielab'
- 'icclab'

Valid only when the image data array, *A*, is truecolor (m-by-n-by-3). To use the CMYK color space in a TIFF file, do not use the 'ColorSpace' name-value pair argument. Instead, specify an m-by-n-by-4 image data array.

`imwrite` can write color image data that uses the  $L^*a^*b^*$  color space to TIFF files. The 1976 CIE  $L^*a^*b^*$  specification defines numeric values that represent luminance ( $L^*$ ) and chrominance ( $a^*$  and  $b^*$ ) information. To store  $L^*a^*b^*$  color data in a TIFF file, the values must be encoded to fit into either 8-bit or 16-bit storage. `imwrite` can store  $L^*a^*b^*$  color data in a TIFF file using the following encodings:

- CIELAB encodings — 8-bit and 16-bit encodings defined by the TIFF specification
- ICCLAB encodings — 8-bit and 16-bit encodings defined by the International Color Consortium

The output class and encoding used by `imwrite` depends on the class of the input image data array and the `ColorSpace` value, as shown in the following table. (The 8-bit and 16-bit CIELAB encodings cannot be input arrays because they use a mixture of signed and unsigned values and cannot be represented as a single MATLAB array.)

| Input Class and Encoding                                                                                                                                                                                                 | Value of <code>ColorSpace</code> | Output Class and Encoding |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|---------------------------|
| 8-bit ICCLAB<br><br>Values are integers in the range [0 255]. $L^*$ values are multiplied by 255/100. 128 is added to both the $a^*$ and $b^*$ values.                                                                   | 'icclab'                         | 8-bit ICCLAB              |
|                                                                                                                                                                                                                          | 'cielab'                         | 8-bit CIELAB              |
| 16-bit ICCLAB<br><br>Values are integers in the range [0, 65280]. $L^*$ values are multiplied by 65280/100. 32768 is added to both the $a^*$ and $b^*$ values, which are represented as integers in the range [0,65535]. | 'icclab'                         | 16-bit ICCLAB             |
|                                                                                                                                                                                                                          | 'cielab'                         | 16-bit CIELAB             |
| Double-precision 1976 CIE $L^*a^*b^*$ values<br><br>$L^*$ is in the dynamic range [0, 100]. $a^*$ and $b^*$ can take any value. Setting $a^*$ and $b^*$ to 0 (zero) produces a neutral color (gray).                     | 'icclab'                         | 8-bit ICCLAB              |
|                                                                                                                                                                                                                          | 'cielab'                         | 8-bit CIELAB              |

Example: `'ColorSpace', 'cielab'`

#### 'Compression' — Compression scheme

`'packbits' | 'none' | 'lzw' | 'deflate' | 'jpeg' | 'ccitt' | 'fax3' | 'fax4'`

Compression scheme, specified as the comma-separated pair consisting of 'Compression' and one of the following strings:

- 'packbits' (default for nonbinary images)
- 'none'
- 'lzw'
- 'deflate'
- 'jpeg'
- 'ccitt' (binary images only, and the default for such images)
- 'fax3' (binary images only)
- 'fax4' (binary images only)

'jpeg' is a lossy compression scheme; other compression modes are lossless. Also, if you specify 'jpeg' compression, you must specify the 'RowsPerStrip' parameter and the value must be a multiple of 8.

Example: 'Compression', 'none'

## 'Description' — Image description

string

Image description, specified by the comma-separated pair consisting of 'Description' and a string. This is the text that `imfinfo` returns in the `ImageDescription` field for the output image.

Example: 'Description', 'Sample 2A301'

## 'Resolution' — X- and Y-resolution

72 (default) | scalar | two-element vector

X- and Y-resolution, specified as the comma-separated pair consisting of 'Resolution' and a scalar indicating both resolution, or a two-element vector containing the X-Resolution and Y-Resolution.

Example: 'Resolution', 80

Example: 'Resolution', [320, 72]

Data Types: double

## 'RowsPerStrip' — Number of rows to include in each strip

scalar

Number of rows to include in each strip, specified as the comma-separated pair consisting of `'RowsPerStrip'` and a scalar. The default value is such that each strip is about 8 kilobytes.

You must specify `RowsPerStrip` if you specify `'jpeg'` compression. The value must be a multiple of 8.

Example: `'RowsPerStrip',16`

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **'WriteMode' — Writing mode**

`'overwrite'` (default) | `'append'`

Writing mode, specified as the comma-separated pair consisting of `'WriteMode'` and either `'overwrite'` or `'append'`. In `overwrite` mode, `imwrite` overwrites an existing file. In `append` mode, `imwrite` adds a page to the existing file.

Example: `'WriteMode','append'`

## incenters

**Class:** TriRep

(Not recommended) Incenters of specified simplices

---

**Note:** `incenters(TriRep)` is not recommended. Use `incenter(triangulation)` instead.

`TriRep` is not recommended. Use `triangulation` instead.

---

## Syntax

`IC = inceters(TR,SI)`  
`[IC RIC] = inceters(TR, SI)`

## Description

`IC = inceters(TR,SI)` returns the coordinates of the incenter of each specified simplex `SI`.

`[IC RIC] = inceters(TR, SI)` returns the inceters and the corresponding radius of the inscribed circle/sphere.

## Input Arguments

|    |                                                                                                                                                                                                                                                                                                                               |
|----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TR | Triangulation representation.                                                                                                                                                                                                                                                                                                 |
| SI | Column vector of simplex indices that index into the triangulation matrix <code>TR.Triangulation</code> . If <code>SI</code> is not specified the incenter information for the entire triangulation is returned, where the incenter associated with simplex <code>i</code> is the <code>i</code> 'th row of <code>IC</code> . |

## Output Arguments

- IC**             $m$ -by- $n$  matrix, where  $m = \text{length}(\text{SI})$ , the number of specified simplices, and  $n$  is the dimension of the space where the triangulation resides. Each row  $\text{IC}(i, :)$  represents the coordinates of the incenter of simplex  $\text{SI}(i)$ .
- RIC**            Vector of length  $\text{length}(\text{SI})$ , the number of specified simplices.

## Definitions

A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

## Examples

### Example 1

Load a 3-D triangulation:

```
load tetmesh
```

Use `TriRep` to compute the incenters of the first five tetrahedra.

```
trep = TriRep(tet, X)
ic = incenters(trep, [1:5]')
```

### Example 2

Query a 2-D triangulation created with `DelaunayTri`.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
dt = DelaunayTri(x,y);
```

Compute incenters of the triangles:

```
ic = incenters(dt);
```

Plot the triangles and incenters:

```
triplot(dt);
axis equal;
axis([-0.2 1.2 -0.2 1.2]);
hold on;
plot(ic(:,1),ic(:,2),'*r');
hold off;
```

## inOutStatus

**Class:** DelaunayTri

(Not recommended) Status of triangles in 2-D constrained Delaunay triangulation

---

**Note:** `inOutStatus(DelaunayTri)` is not recommended. Use `isInterior(delaunayTriangulation)` instead.

`DelaunayTri` is not recommended. Use `delaunayTriangulation` instead.

---

## Syntax

`IN = inOutStatus(DT)`

## Description

`IN = inOutStatus(DT)` returns the in/out status of the triangles in a 2-D constrained Delaunay triangulation of a geometric domain. Given a Delaunay triangulation that has a set of constrained edges that define a bounded geometric domain. The *i*'th triangle in the triangulation is classified as inside the domain if `IN(i) = 1` and outside otherwise.

---

**Note:** `inOutStatus` is only relevant for 2-D constrained Delaunay triangulations where the imposed edge constraints bound a closed geometric domain.

---

## Input Arguments

`DT`                      Delaunay triangulation.

## Output Arguments

**IN** Logical array of length equal to the number of triangles in the triangulation. The constrained edges in the triangulation define the boundaries of a valid geometric domain.

## Examples

Create a geometric domain that consists of a square with a square hole:

```
outerprofile = [-5 -5; -3 -5; -1 -5; 1 -5; 3 -5; ...
 5 -5; 5 -3; 5 -1; 5 1; 5 3;...
 5 5; 3 5; 1 5; -1 5; -3 5; ...
 -5 5; -5 3; -5 1; -5 -1; -5 -3;];
innerprofile = outerprofile.*0.5;
profile = [outerprofile; innerprofile];
outercons = [(1:19)' (2:20)'; 20 1];
innercons = [(21:39)' (22:40)'; 40 21];
edgeconstraints = [outercons; innercons];
Create a constrained Delaunay triangulation of the domain:
```

```
dt = DelaunayTri(profile, edgeconstraints)
subplot(1,2,1);
triplot(dt);
hold on;
plot(dt.X(outercons',1), dt.X(outercons',2), ...
 '-r', 'LineWidth', 2);
plot(dt.X(innercons',1), dt.X(innercons',2), ...
 '-r', 'LineWidth', 2);
axis equal;
% Plot showing interior and exterior
% triangles with respect to the domain.
hold off;
subplot(1,2,2);
inside = inOutStatus(dt);
triplot(dt(inside, :), dt.X(:,1), dt.X(:,2));
hold on;
plot(dt.X(outercons',1), dt.X(outercons',2), ...
 '-r', 'LineWidth', 2);
plot(dt.X(innercons',1), dt.X(innercons',2), ...
 '-r', 'LineWidth', 2);
axis equal;
```

```
% Plot showing interior triangles only
hold off;
```

## ind2rgb

Convert indexed image to RGB image

### Syntax

```
RGB = ind2rgb(X,map)
```

### Description

`RGB = ind2rgb(X,map)` converts the indexed image, `X`, and the corresponding colormap, `map`, to the truecolor image, `RGB`. The indexed image, `X`, is an `m`-by-`n` array of integers. The colormap, `map`, is a three-column array of values in the range `[0,1]`. Each row of `map` is a three-element RGB triplet that specifies the red, green, and blue components of a single color of the colormap.

- If you specify `X` as an array of class `uint8` or `uint16`, then the value 0 corresponds to the first color in the colormap.
- If you specify `X` as an array of class `single` or `double`, then the value 1 corresponds to the first color in the colormap.

The truecolor image output, `RGB`, is an `m`-by-`n`-by-3 array. For more information on image types, see “Image Types”.

### Class Support

`X` can be of class `uint8`, `uint16`, `single`, or `double`. `RGB` is an `m`-by-`n`-by-3 array of class `double`.

# ind2sub

Subscripts from linear index

## Syntax

```
[I,J] = ind2sub(siz,IND)
[I1,I2,I3,...,In] = ind2sub(siz,IND)
```

## Description

The `ind2sub` command determines the equivalent subscript values corresponding to a single index into an array.

`[I,J] = ind2sub(siz,IND)` returns the matrices `I` and `J` containing the equivalent row and column subscripts corresponding to each linear index in the matrix `IND` for a matrix of size `siz`. `siz` is a vector with `ndim(A)` elements (in this case, 2), where `siz(1)` is the number of rows and `siz(2)` is the number of columns.

---

**Note** For matrices, `[I,J] = ind2sub(size(A),find(A>5))` returns the same values as `[I,J] = find(A>5)`.

---

`[I1,I2,I3,...,In] = ind2sub(siz,IND)` returns `n` subscript arrays `I1,I2,...,In` containing the equivalent multidimensional array subscripts equivalent to `IND` for an array of size `siz`. `siz` is an `n`-element vector that specifies the size of each array dimension.

The `IND` input can be `single`, `double`, or any integer type. The outputs are always of class `double`.

## Examples

### Example 1 — Two-Dimensional Matrices

The mapping from linear indexes to subscript equivalents for a 3-by-3 matrix is

This code determines the row and column subscripts in a 3-by-3 matrix, of elements with linear indices 3, 4, 5, 6.

```
IND = [3 4 5 6]
s = [3,3];
[I,J] = ind2sub(s,IND)
```

```
I =
 3 1 2 3
J =
 1 2 2 2
```

### Example 2 – Three-Dimensional Matrices

The mapping from linear indexes to subscript equivalents for a 2-by-2-by-2 array is

This code determines the subscript equivalents in a 2-by-2-by-2 array, of elements whose linear indices 3, 4, 5, 6 are specified in the IND matrix.

```
IND = [3 4;5 6];
s = [2,2,2];
[I,J,K] = ind2sub(s,IND)
```

```
I =
 1 2
 1 2
```

```
J =
 2 2
 1 1
```

```
K =
 1 1
 2 2
```

### Example 3 — Effects of Returning Fewer Outputs

When calling `ind2sub` for an N-dimensional matrix, you would typically supply N output arguments in the call: one for each dimension of the matrix. This example shows what happens when you return three, two, and one output when calling `ind2sub` on a 3-dimensional matrix.

The matrix is 2-by-2-by-2 and the linear indices are 1 through 8:

```
dims = [2 2 2];
indices = [1 2 3 4 5 6 7 8];
```

The 3-output call to `ind2sub` returns the expected subscripts for the 2-by-2-by-2 matrix:

```
[rowsub colsub pagsub] = ind2sub(dims, indices)
rowsub =
 1 2 1 2 1 2 1 2
colsub =
 1 1 2 2 1 1 2 2
pagsub =
 1 1 1 1 2 2 2 2
```

If you specify only two outputs (row and column), `ind2sub` still returns a subscript for each specified index, but drops the third dimension from the matrix, returning subscripts for a 2-dimensional, 2-by-4 matrix instead:

```
[rowsub colsub] = ind2sub(dims, indices)
rowsub =
 1 2 1 2 1 2 1 2
colsub =
 1 1 2 2 3 3 4 4
```

If you specify one output (row), `ind2sub` drops both the second and third dimensions from the matrix, and returns subscripts for a 1-dimensional, 1-by-8 matrix instead:

```
[rowsub] = ind2sub(dims, indices)
rowsub =
 1 2 3 4 5 6 7 8
```

# Inf

Infinity

## Syntax

Inf

`I = Inf(n)`

`I = Inf(sz1,...,szN)`

`I = Inf(sz)`

`I = Inf(classname)`

`I = Inf(n,classname)`

`I = Inf(sz1,...,szN,classname)`

`I = Inf(sz,classname)`

`I = Inf('like',p)`

`I = Inf(n,'like',p)`

`I = Inf(sz1,...,szN,'like',p)`

`I = Inf(sz,'like',p)`

## Description

Inf returns the IEEE arithmetic representation for positive infinity. Infinity values result from operations like division by zero and overflow, which lead to results too large to represent as conventional floating-point values.

`I = Inf(n)` is an n-by-n matrix of Inf values.

`I = Inf(sz1,...,szN)` is a sz1-by-...-by-szN array of Inf values where `sz1,...,szN` indicates the size of each dimension. For example, `Inf(3,4)` returns a 3-by-4 array of Inf values.

`I = Inf(sz)` is an array of Inf values where the size vector, `sz`, defines `size(I)`. For example, `Inf([3,4])` returns a 3-by-4 array of Inf values.

---

**Note** The size inputs `sz1, . . . , szN`, as well as the elements of the size vector `sz`, should be nonnegative integers. Negative integers are treated as 0.

---

`I = Inf(classname)` returns an `Inf` value where the string, `classname`, specifies the data type. `classname` can be either `'single'` or `'double'`.

`I = Inf(n,classname)` returns an `n`-by-`n` array of `Inf` values of data type `classname`.

`I = Inf(sz1, . . . , szN,classname)` returns a `sz1`-by-`...`-by-`szN` array of `Inf` values of data type `classname`.

`I = Inf(sz,classname)` returns an array of `Inf` values where the size vector, `sz`, defines `size(I)` and `classname` defines `class(I)`.

`I = Inf('like',p)` returns an array of `Infs` of the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`I = Inf(n, 'like', p)` returns an `n`-by-`n` array of `Inf` values like `p`.

`I = Inf(sz1, . . . , szN, 'like', p)` returns a `sz1`-by-`...`-by-`szN` array of `Inf` values like `p`.

`I = Inf(sz, 'like', p)` returns an array of `Inf` values like `p` where the size vector, `sz`, defines `size(I)`.

## Examples

`1/0`, `1.e1000`, `2^2000`, and `exp(1000)` all produce `Inf`.

`log(0)` produces `-Inf`.

`Inf-Inf` and `Inf/Inf` both produce `NaN` (Not-a-Number).

## inferiorto

Specify inferior class relationship

### Syntax

```
inferiorto('class1', 'class2', ...)
```

### Description

`inferiorto('class1', 'class2', ...)` establishes that the class invoking this function in its constructor has lower precedence than the classes in the argument list. MATLAB uses this precedence to determine which method or function MATLAB calls in any given situation.

Use this function only from a constructor that calls the `class` function to create objects (classes defined before MATLAB 7.6).

### Examples

Specify class precedence.

Suppose `a` is an object of class `class_a`, `b` is an object of class `class_b`, and `c` is an object of class `class_c`. Suppose the constructor method of `class_c` contains the statement:

```
inferiorto('class_a')
```

This function call establishes `class_a` as taking precedence over `class_c` for function dispatching. Therefore, either of the following two statements:

```
e = fun(a,c);
e = fun(c,a);
```

Invoke `class_a`/fun.

If you call a function with two objects having an unspecified relationship, the two objects have equal precedence. In this case, MATLAB calls the method of the left-most object. So `fun(b, c)` calls `class_b`/fun, while `fun(c, b)` calls `class_c`/fun.

# inline

Construct inline object

## Compatibility

`inline` will be removed in a future release. Use “Anonymous Functions” instead.

## Syntax

```
inline(expr)
inline(expr, arg1, arg2, ...)
inline(expr, n)
```

## Description

`inline(expr)` constructs an inline function object from the MATLAB expression contained in the string `expr`. The input argument to the inline function is automatically determined by searching `expr` for an isolated lower case alphabetic character, other than `i` or `j`, that is not part of a word formed from several alphabetic characters. If no such character exists, `x` is used. If the character is not unique, the one closest to `x` is used. If two characters are found, the one later in the alphabet is chosen.

`inline(expr, arg1, arg2, ...)` constructs an inline function whose input arguments are specified by the strings `arg1`, `arg2`, ... . Multicharacter symbol names may be used.

`inline(expr, n)` where `n` is a scalar, constructs an inline function whose input arguments are `x`, `P1`, `P2`, ... .

## Examples

### Example 1

This example creates a simple inline function to square a number.

```
g = inline('t^2')
g =
```

```
 Inline function:
 g(t) = t^2
```

You can convert the result to a string using the `char` function.

```
char(g)
ans =
t^2
```

## Example 2

This example creates an inline function to represent the formula  $f = 3\sin(2x^2)$ . The resulting inline function can be evaluated with the `argnames` and `formula` functions.

```
f = inline('3*sin(2*x.^2)')
f =
 Inline function:
 f(x) = 3*sin(2*x.^2)

argnames(f)
ans =
 'x'

formula(f)
ans =
3*sin(2*x.^2)
```

## Example 3

This call to `inline` defines the function `f` to be dependent on two variables, `alpha` and `x`:

```
f = inline('sin(alpha*x)')
f =
```

```
Inline function:
f(alpha,x) = sin(alpha*x)
```

If `inline` does not return the desired function variables or if the function variables are in the wrong order, you can specify the desired variables explicitly with the `inline` argument list.

```
g = inline('sin(alpha*x)', 'x', 'alpha')
```

```
g =
```

```
Inline function:
g(x,alpha) = sin(alpha*x)
```

## More About

### Tips

Three commands related to `inline` allow you to examine an inline function object and determine how it was created.

`char(fun)` converts the inline function into a character array. This is identical to `formula(fun)`.

`argnames(fun)` returns the names of the input arguments of the inline object `fun` as a cell array of strings.

`formula(fun)` returns the formula for the inline object `fun`.

A fourth command `vectorize(fun)` inserts a `.` before any `^`, `*` or `/` in the formula for `fun`. The result is a vectorized version of the inline function.

**Introduced before R2006a**

## inmem

Names of functions, MEX-files, classes in memory

### Syntax

```
M = inmem
[M,X] = inmem
[M,X,C] = inmem
[...] = inmem('-completenames')
```

### Description

`M = inmem` returns a cell array of strings containing the names of the functions that are currently loaded.

`[M,X] = inmem` returns an additional cell array `X` containing the names of the MEX-files that are currently loaded.

`[M,X,C] = inmem` also returns a cell array `C` containing the names of the classes that are currently loaded.

`[...] = inmem('-completenames')` returns not only the names of the currently loaded function and MEX-files, but the path and filename extension for each as well. No additional information is returned for loaded classes.

### Examples

#### Functions in Memory

List the functions that remain in memory after calling the `magic` function.

```
clear all
magic(10);
```

```
M = inmem
```

```
M =
```

```
'workspacefunc'
'magic'
```

The function list includes `magic` and additional functions that are in memory in your current session.

### **MEX-Files in Memory**

Call a sample MEX-function named `arrayProduct`, and then verify that the MEX-function is in memory. You must have a supported C compiler installed on your system to run this example.

```
clear all
sampleFolder = fullfile(matlabroot, 'extern', 'examples', 'mex');
addpath(sampleFolder)
mex arrayProduct.c

s = 5;
A = [1.5, 2, 9];
B = arrayProduct(s,A);

[M,X] = inmem('-completenames');
X

X =
 'matlabroot\extern\examples\mex\arrayProduct.mexw64'
```

### **See Also**

`clear`

**Introduced before R2006a**

## innerjoin

Inner join between two tables

### Syntax

```
C = innerjoin(A,B)
C = innerjoin(A,B,Name,Value)
[C,ia,ib] = innerjoin(__)
```

### Description

`C = innerjoin(A,B)` creates the table, `C`, as the inner join between the tables `A` and `B` by matching up rows using all the variables with the same name as key variables.

The inner join retains only the rows that match between `A` and `B` with respect to the key variables. `C` contains all nonkey variables from `A` and `B`.

`C = innerjoin(A,B,Name,Value)` performs the inner-join operation with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the variables to use as key variables.

`[C,ia,ib] = innerjoin( __ )` also returns index vectors, `ia` and `ib` indicating the correspondence between rows in `C` and those in `A` and `B` respectively. You can use this syntax with any of the input arguments in the previous syntaxes.

### Examples

#### Inner-Join Operation of Tables with One Variable in Common

Create a table, `A`.

```
A = table([5;12;23;2;6],...
 {'cereal';'pizza';'salmon';'cookies';'pizza'},...
 'VariableNames',{ 'Age', 'FavoriteFood' })
```

`A =`

```
 Age FavoriteFood
```

```

5 'cereal'
12 'pizza'
23 'salmon'
2 'cookies'
6 'pizza'

```

Create a table, B, with one variable in common with A.

```

B = table({'cereal';'cookies';'pizza';'salmon';'cake'},...
 [110;160;140;367;243],...
 {'A-';'D';'B';'B';'C-'},...
 'VariableNames',{'FavoriteFood','Calories','NutritionGrade'})

```

B =

| FavoriteFood | Calories | NutritionGrade |
|--------------|----------|----------------|
| 'cereal'     | 110      | 'A-'           |
| 'cookies'    | 160      | 'D'            |
| 'pizza'      | 140      | 'B'            |
| 'salmon'     | 367      | 'B'            |
| 'cake'       | 243      | 'C-'           |

Use the `innerjoin` function to create a new table, C, with data from tables A and B.

```
C = innerjoin(A,B)
```

C =

| Age | FavoriteFood | Calories | NutritionGrade |
|-----|--------------|----------|----------------|
| 5   | 'cereal'     | 110      | 'A-'           |
| 2   | 'cookies'    | 160      | 'D'            |
| 12  | 'pizza'      | 140      | 'B'            |
| 6   | 'pizza'      | 140      | 'B'            |
| 23  | 'salmon'     | 367      | 'B'            |

Table C is sorted by the key variable, FavoriteFood.

### Inner-Join Operation of Tables and Indices to Values

Create a table, A.

```
A = table({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...
 'VariableNames',{ 'Key1' 'Var1'})
```

A =

| Key1 | Var1 |
|------|------|
| 'a'  | 1    |
| 'b'  | 2    |
| 'c'  | 3    |
| 'e'  | 11   |
| 'h'  | 17   |

Create a table, **B**, with common values in the variable **Key1** between tables **A** and **B**, but also containing rows with values of **Key1** not present in **A**.

```
B = table({'a' 'b' 'd' 'e'},[4 5 6 7]',...
 'VariableNames',{ 'Key1' 'Var2'})
```

B =

| Key1 | Var2 |
|------|------|
| 'a'  | 4    |
| 'b'  | 5    |
| 'd'  | 6    |
| 'e'  | 7    |

Use the `innerjoin` function to create a new table, **C**, with data from tables **A** and **B**. Retain only rows whose values in the variable **Key1** match.

Also, return index vectors, **ia** and **ib** indicating the correspondence between rows in **C** and rows in **A** and **B** respectively.

```
[C,ia,ib] = innerjoin(A,B)
```

C =

| Key1 | Var1 | Var2 |
|------|------|------|
| 'a'  | 1    | 4    |
| 'b'  | 2    | 5    |
| 'e'  | 11   | 7    |

```
ia =
```

```
1
2
4
```

```
ib =
```

```
1
2
4
```

Table C is sorted by the values in the key variable, Key1, and contains the horizontal concatenation of A(ia, :) and B(ib, 'Var2') .

### Inner-Join Operation of Tables Using Left and Right Keys

Create a table, A.

```
A = table([10;4;2;3;7],[5;4;9;6;1],[10;3;8;8;4])
```

```
A =
```

| Var1 | Var2 | Var3 |
|------|------|------|
| ———  | ———  | ———  |
| 10   | 5    | 10   |
| 4    | 4    | 3    |
| 2    | 9    | 8    |
| 3    | 6    | 8    |
| 7    | 1    | 4    |

Create a table, B, with common values in the second variable as the first variable of table A.

```
B = table([6;1;1;6;8],[2;3;4;5;6])
```

```
B =
```

| Var1 | Var2 |
|------|------|
| ———  | ———  |

```
6 2
1 3
1 4
6 5
8 6
```

Use the `innerjoin` function to create a new table, **C**, with data from tables **A** and **B**. Use the first variable of **A** and the second variable of **B** as key variables.

```
[C,ia,ib] = innerjoin(A,B,'LeftKeys',1,'RightKeys',2)
```

C =

| Var1_A | Var2 | Var3 | Var1_B |
|--------|------|------|--------|
| 2      | 9    | 8    | 6      |
| 3      | 6    | 8    | 1      |
| 4      | 4    | 3    | 1      |

ia =

```
3
4
2
```

ib =

```
1
2
3
```

Table **C** retains only the rows that match between **A** and **B** with respect to the key variables.

Table **C** contains the horizontal concatenation of `A(ia,:)` and `B(ib,'Var1')`.

## Input Arguments

**A, B** — Input tables  
tables

Input tables, specified as tables.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: 'Keys', 2 uses the second variable in A and the second variable in B as key variables.

### 'Keys' — Variables to use as keys

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys, specified as the comma-separated pair consisting of 'Keys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You cannot use the 'Keys' name-value pair argument with the 'LeftKeys' and 'RightKeys' name-value pair arguments.

Example: 'Keys', [1 3] uses the first and third variables in A and B as a key variables.

### 'LeftKeys' — Variables to use as keys in A

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in A, specified as the comma-separated pair consisting of 'LeftKeys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the 'LeftKeys' name-value pair argument in conjunction with the 'RightKeys' name-value pair argument. 'LeftKeys' and 'RightKeys' both must specify the same number of key variables. `innerjoin` pairs key values based on their order.

Example: 'LeftKeys', 1 uses only the first variable in A as a key variable.

### 'RightKeys' — Variables to use as keys in B

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in **B**, specified as the comma-separated pair consisting of `'RightKeys'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the `'RightKeys'` name-value pair argument in conjunction with the `'LeftKeys'` name-value pair argument. `'LeftKeys'` and `'RightKeys'` both must specify the same number of key variables. `innerjoin` pairs key values based on their order.

Example: `'RightKeys',3` uses only the third variable in **B** as a key variable.

### **'LeftVariables' — Variables from A to include in C**

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from **A** to include in **C**, specified as the comma-separated pair consisting of `'LeftVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use `'LeftVariables'` to include or exclude key variables, as well as nonkey variables from the output, **C**.

By default, `innerjoin` includes all variables from **A**.

### **'RightVariables' — Variables from B to include in C**

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from **B** to include in **C**, specified as the comma-separated pair consisting of `'RightVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use `'RightVariables'` to include or exclude key variables, as well as nonkey variables from the output, **C**.

By default, `innerjoin` includes all the variables from **B** except the key variables.

## Output Arguments

### **C — Inner join from A and B**

table

Inner join from A and B, returned as a table. The output table, C, contains one row for each pair of rows in tables A and B that share the same combination of values in the key variables. If A and B contain variables with the same name, `innerjoin` adds a unique suffix to the corresponding variable names in C.

In general, if there are  $m$  rows in table A and  $n$  rows in table B that all contain the same combination of values in the key variables, table C contains  $m*n$  rows for that combination.

C is sorted by the values in the key variables and contains the horizontal concatenation of `A(ia, LeftVars)` and `B(ib, RightVars)`. By default, `LeftVars` consists of all the variables of A, and `RightVars` consists of all the nonkey variables from B. Otherwise, `LeftVars` consists of the variables specified by the 'LeftVariables' name-value pair argument, and `RightVars` is the variables specified by the 'RightVariables' name-value pair argument.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the output table, C. For more information, see [Table Properties](#).

### **ia** — Index to A

column vector

Index to A, returned as a column vector. Each element of `ia` identifies the row in table A that corresponds to that row in the output table, C.

### **ib** — Index to B

column vector

Index to B, returned as a column vector. Each element of `ib` identifies the row in table B that corresponds to that row in the output table, C.

## More About

### Key Variable

Variable used to match and combine data between the input tables, A and B.

### See Also

`join` | `outerjoin`

**Introduced in R2013b**

# inpolygon

Points located inside or on edge of polygonal region

## Syntax

```
in = inpolygon(xq,yq,xv,yv)
[in,on] = inpolygon(xq,yq,xv,yv)
```

## Description

`in = inpolygon(xq,yq,xv,yv)` returns `in` indicating if the query points specified by `xq` and `yq` are inside or on the edge of the polygon area defined by `xv` and `yv`.

`[in,on] = inpolygon(xq,yq,xv,yv)` also returns `on` indicating if the query points are on the edge of the polygon area.

## Examples

### Points Inside Convex Polygon

Define a pentagon and a set of points. Then, determine which points lie inside (or on the edge) of the pentagon.

Define the x and y coordinates of polygon vertices to create a pentagon.

```
L = linspace(0,2.*pi,6);
xv = cos(L)';
yv = sin(L)';
```

Define x and y coordinates of 250 random query points. Initialize the random-number generator to make the output of `randn` repeatable.

```
rng default
xq = randn(250,1);
```

```
yq = randn(250,1);
```

Determine whether each point lies inside or on the edge of the polygon area. Also determine whether any of the points lie on the edge of the polygon area.

```
[in,on] = inpolygon(xq,yq,xv,yv);
```

Determine the number of points lying inside or on the edge of the polygon area.

```
numel(xq(in))
```

```
ans =
```

```
80
```

Determine the number of points lying on the edge of the polygon area.

```
numel(xq(on))
```

```
ans =
```

```
0
```

Since there are no points lying on the edge of the polygon area, all 80 points identified by `xq(in)`, `yq(in)` are strictly inside the polygon area.

Determine the number of points lying outside the polygon area (not inside or on the edge).

```
numel(xq(~in))
```

```
ans =
```

```
170
```

Plot the polygon and the query points. Display the points inside the polygon with a red plus. Display the points outside the polygon with a blue circle.

```
figure
plot(xv,yv) % polygon
axis equal

hold on
plot(xq(in),yq(in),'r+') % points inside
plot(xq(~in),yq(~in),'bo') % points outside
hold off
```

### Points Inside Multiply Connected Polygon

Find the points inside a square with a square hole.

Define a square region with a square hole. Specify the vertices of the outer loop in a counterclockwise direction, and specify the vertices for the inner loop in a clockwise direction. Use NaN to separate the coordinates for the outer and inner loops.

```
xv = [1 4 4 1 1 NaN 2 2 3 3 2];
yv = [1 1 4 4 1 NaN 2 3 3 2 2];
```

Define x and y coordinates of 500 random points. Initialize the random-number generator to make the output of `randn` repeatable.

```
rng default
xq = rand(500,1)*5;
yq = rand(500,1)*5;
```

Determine whether each point lies inside or on the edge of the polygon area.

```
in = inpolygon(xq,yq,xv,yv);
```

Plot the polygon and the query points. Display the points inside the polygon with a red plus. Display the points outside the polygon with a blue circle.

```
figure

plot(xv,yv,'LineWidth',2) % polygon
axis equal

hold on
plot(xq(in),yq(in),'r+') % points inside
plot(xq(~in),yq(~in),'bo') % points outside
hold off
```

Query points in the square hole are outside the polygon.

### Points Inside Self-Intersecting Polygon

Define the x and y coordinates for a pentagon.

```
xv = [0.5;0.2;1.0;0;0.8;0.5];
yv = [1.0;0.1;0.7;0.7;0.1;1];
```

Define the x and y coordinates of 12 query points.

```
xq = [0.1;0.5;0.9;0.2;0.4;0.5;0.5;0.9;0.6;0.8;0.7;0.2];
yq = [0.4;0.6;0.9;0.7;0.3;0.8;0.2;0.4;0.4;0.6;0.2;0.6];
```

Determine whether each point lies inside or on the edge of the polygon area. Also determine whether any of the points lie on the edge of the polygon area.

```
[in,on] = inpolygon(xq,yq,xv,yv);
```

Determine the number of points lying inside or on the edge of the polygon area.

```
numel(xq(in))
```

```
ans =
```

```
8
```

Determine the number of points lying on the edge of the polygon area.

```
numel(xq(on))
```

```
ans =
```

```
2
```

Determine the number of points lying outside the polygon area (not inside or on the edge).

```
numel(xq(~in))
```

```
ans =
```

```
4
```

Plot the polygon and the points. Display the points strictly inside the polygon with a red plus. Display the points on the edge with a black asterisk. Display the points outside the polygon with a blue circle.

```
figure
```

```
plot(xv,yv) % polygon
```

```
hold on
```

```

plot(xq(in&-on),yq(in&-on),'r+') % points strictly inside
plot(xq(on),yq(on),'k*') % points on edge
plot(xq(~in),yq(~in),'bo') % points outside
hold off

```

Six points lie inside the polygon. Two points lie on the edge of the polygon. Four points lie outside the polygon.

## Input Arguments

**xq** — x-coordinates of query points

scalar | vector | matrix | multidimensional array

x-coordinates of query points, specified as a scalar, vector, matrix, or multidimensional array.

The size of `xq` must match the size of `yq`.

Data Types: `double` | `single`

### **yq — y-coordinates of query points**

scalar | vector | matrix | multidimensional array

y-coordinates of query points, specified as a scalar, vector, matrix, or multidimensional array.

The size of `yq` must match the size of `xq`.

Data Types: `double` | `single`

### **xv — x-coordinates of polygon vertices**

vector

x-coordinates of polygon vertices, specified as a vector.

The size of `xv` must match the size of `yv`.

To specify vertices of multiply connected or disjoint polygons, separate the coordinates for distinct loops with `NaN`. Additionally for multiply connected polygons, you must orient the vertices for external and internal loops in opposite directions.

The polygon cannot be self-intersecting and multiply connected due to the ambiguity associated with self-intersections and loop orientations.

Data Types: `double` | `single`

### **yv — y-coordinates of polygon vertices**

vector

y-coordinates of polygon vertices, specified as a vector.

The size of `yv` must match the size of `xv`.

To specify vertices of multiply connected or disjoint polygons, separate the coordinates for distinct loops with `NaN`. Additionally for multiply connected polygons, you must orient the vertices for external and internal loops in opposite directions.

The polygon cannot be self-intersecting and multiply connected due to the ambiguity associated with self-intersections and loop orientations.

Data Types: `double` | `single`

## Output Arguments

### **in** — Indicator for points inside or on edge of polygon area

logical array

Indicator for the points inside or on the edge of the polygon area, returned as a logical array. `in` is the same size as `xq` and `yq`.

- A logical 1 (`true`) indicates that the corresponding query point is inside the polygonal region or on the edge of the polygon boundary.
- A logical 0 (`false`) indicates that the corresponding query point is outside the polygonal region.

Therefore, you can use `in` to index into `xq` and `yq` to identify query points of interest.

|                               |                                                        |
|-------------------------------|--------------------------------------------------------|
| <code>xq(in), yq(in)</code>   | Query points inside or on the edge of the polygon area |
| <code>xq(~in), yq(~in)</code> | Query points outside the polygonal region              |

### **on** — Indicator for points on edge of polygon area

logical array

Indicator for the points on the edge of the polygon area, returned as a logical array. `on` is the same size as `xq` and `yq`.

- A logical 1 (`true`) indicates that the corresponding query point is on the polygon boundary.
- A logical 0 (`false`) indicates that the corresponding query point is inside or outside the polygon boundary.

Therefore, you can use `on` and `in` to index into `xq` and `yq` identify query points of interest.

|                             |                                      |
|-----------------------------|--------------------------------------|
| <code>xq(on), yq(on)</code> | Query points on the polygon boundary |
|-----------------------------|--------------------------------------|

xq(~on), yq(~on)

Query points inside or outside the polygon boundary

xq(in&~on), yq(in&~on)

Query points strictly inside the polygonal region

# input

Request user input

## Syntax

```
x = input(prompt)
str = input(prompt, 's')
```

## Description

`x = input(prompt)` displays the text in `prompt` and waits for the user to input a value and press the **Return** key. The user can enter expressions, like `pi/4` or `rand(3)`, and can use variables in the workspace.

- If the user presses the **Return** key without entering anything, then `input` returns an empty matrix.
- If the user enters an invalid expression at the prompt, then MATLAB displays the relevant error message, and then redisplay the prompt.

`str = input(prompt, 's')` returns the entered text as a string, without evaluating the input as an expression.

## Examples

### Request Numeric Input or Expression

Request a numeric input, and then multiply the input by 10.

```
prompt = 'What is the original value? ';
x = input(prompt)
y = x*10
```

At the prompt, enter a numeric value or array, such as 42.

```
x =
```

```
42
y =
420
```

The `input` function also accepts expressions. For example, rerun the code.

```
prompt = 'What is the original value? ';
x = input(prompt)
y = x*10
```

At the prompt, enter `magic(3)`.

```
x =
 8 1 6
 3 5 7
 4 9 2

y =
 80 10 60
 30 50 70
 40 90 20
```

The expression does not need to return a numeric result. For example:

```
prompt = 'What color is the sun? ';
s = input(prompt)
```

At the prompt, type `upper('yellow')`.

```
s =
YELLOW
```

## Request Unprocessed Text Input

Request a simple text response that requires no evaluation.

```
prompt = 'Do you want more? Y/N [Y]: ';
str = input(prompt, 's');
if isempty(str)
 str = 'Y';
end
```

The `input` function returns the text exactly as typed. If the input is empty, this code assigns a default value, 'Y', to the output string, `str`.

## Input Arguments

**prompt** — Text displayed to the user

string

Text displayed to the user, specified as a string.

To create a prompt that spans several lines, use '\n' to indicate each new line. To include a backslash ('\') in the prompt, use '\\ '.

## Output Arguments

**x** — Result calculated from input

array

Result calculated from input, returned as an array. The type and dimensions of the array depend upon the response to the prompt.

**str** — Exact text of input

string

Exact text of the input, returned as a string.

# inputdlg

Create dialog box that gathers user input

## Syntax

```
answer = inputdlg(prompt)
answer = inputdlg(prompt,dlg_title)
answer = inputdlg(prompt,dlg_title,num_lines)
answer = inputdlg(prompt,dlg_title,num_lines,defAns)
answer = inputdlg(prompt,dlg_title,num_lines,defAns,options)
```

## Description

`answer = inputdlg(prompt)` creates a modal dialog box and returns user input for multiple prompts in the cell array. `prompt` is a cell array containing prompt strings.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in Figure Properties.

---

`answer = inputdlg(prompt,dlg_title)` `dlg_title` specifies a title for the dialog box.

`answer = inputdlg(prompt,dlg_title,num_lines)` `num_lines` specifies the number of lines for each user-entered value. `num_lines` can be a scalar, column vector, or a  $m \times 2$  array.

- If `num_lines` is a scalar, it applies to all prompts.
- If `num_lines` is a column vector, each element specifies the number of lines of input for a prompt.
- If `num_lines` is an array, it must be size  $m$ -by-2, where  $m$  is the number of prompts on the dialog box. Each row refers to a prompt. The first column specifies the number of lines of input for a prompt. The second column specifies the width of the field in characters.

`answer = inputdlg(prompt,dlg_title,num_lines,defAns)` `defAns` specifies the default value to display for each prompt. `defAns` must contain the same number of elements as `prompt` and all elements must be strings.

`answer = inputdlg(prompt,dlg_title,num_lines,defAns,options)` If `options` is the string 'on', the dialog is made resizable in the horizontal direction. If `options` is a structure, the fields shown in the following table are recognized:

| Field       | Description                                                                                               |
|-------------|-----------------------------------------------------------------------------------------------------------|
| Resize      | Can be 'on' or 'off' (default). If 'on', the window is resizable horizontally.                            |
| WindowStyle | Can be either 'normal' or 'modal' (default).                                                              |
| Interpreter | Can be either 'none' (default) or 'tex'. If the value is 'tex', the prompt string are rendered using TeX. |

If the user clicks the **Cancel** button to close an `inputdlg` box, the dialog returns an empty cell array:

```
answer =
 {}
```

## Examples

### Example 1

Create a dialog box to input an integer and colormap name. Allow one line for each value.

```
prompt = {'Enter matrix size:', 'Enter colormap name:'};
dlg_title = 'Input';
num_lines = 1;
defaultans = {'20', 'hsv'};
answer = inputdlg(prompt,dlg_title,num_lines,defaultans);
```

## Example 2

Create a dialog box named to accept comma-separated numbers. MATLAB stores accepts the input as a string, so convert the string to numbers using `str2num`.

```
x = inputdlg('Enter space-separated numbers:',...
 'Sample', [1 50]);
data = str2num(x{:});
```

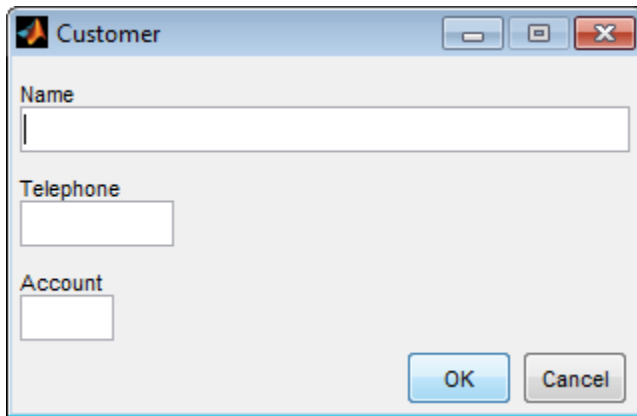

## Example 3

Create a dialog box to display input fields of different widths.

```
x = inputdlg({'Name', 'Telephone', 'Account'},...
 'Customer', [1 50; 1 12; 1 7]);
```

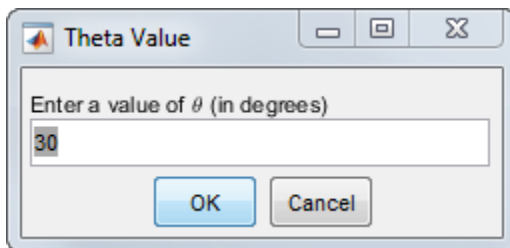

## Example 4

Create a dialog box, specifying a value in the options structure. In this case, the options structure specifies TeX to be the string interpreter.

```
prompt={'Enter a value of \theta (in degrees)'};
name = 'Theta Value';
defaultans = {'30'};
options.Interpreter = 'tex';
answer = inputdlg(prompt,name,[1 40],defaultans,options);
```

## More About

### Tips

`inputdlg` uses the `uiwait` function to suspend execution until the user responds.

The returned variable `answer` is a cell array containing strings, one string per text entry field, starting from the top of the dialog box.

To convert a member of the cell array to a number, use `str2num`. To do this, you can add the following code to the end of any of the examples below:

```
% Use curly bracket for subscript
[val status] = str2num(answer{1});
if ~status
 % Handle empty value returned
 % for unsuccessful conversion
 % ...
end
% val is a scalar or matrix converted from the first input
Users can enter scalar or vector values into inputdlg fields; str2num converts space- and comma-delimited strings into row vectors, and semicolon-delimited strings into column vectors. For example, if answer{1} contains '1 2 3;4 -5 6+7i', the conversion produces:
```

```
val = str2num(answer{1})
val =
 1.0000 2.0000 3.0000
 4.0000 -5.0000 6.0000 + 7.0000i
```

# inputname

Variable name of function input

## Syntax

```
s = inputname(argNumber)
```

## Description

`s = inputname(argNumber)` returns the workspace variable name, `s`, corresponding to the argument number `argNumber`.

You cannot call `inputname` from the MATLAB command prompt or in a script you call from the command prompt.

## Examples

### Display Variable Name of Function Input

Create the following function in a file, `myfun.m`, in your current working folder.

```
function myfun(a,b)
s = inputname(1);
disp(['First calling variable is ' s '.'])
end
```

Call the function at the command prompt using the variables `x` and `y`.

```
x = 5;
y = 3;
myfun(x,y)
```

```
First calling variable is "x".
```

Call the function using values instead of variables. The `inputname` function returns an empty `char` array because its input does not have a name.

```
myfun(5,3)
```

```
First calling variable is ''.
```

## Display All Calling Variable Names

Create the following function in a file, `myfun2.m`, in your current working folder.

```
function myfun2(a,b,c)
for m = 1:nargin
 disp(['Calling variable ' num2str(m) ' is '' inputname(m) ''.'])
end
```

Call the function at the command prompt.

```
x = {'hello', 'goodbye'};
y = struct('a',42, 'b',78);
z = rand(4);
```

```
myfun2(x,y,z)
```

```
Calling variable 1 is 'x'.
Calling variable 2 is 'y'.
Calling variable 3 is 'z'.
```

Call the function using a field of `y`. Because the input argument contains dot indexing, the `inputname` function returns an empty `char` array for the second variable name and all subsequent variable names.

```
myfun2(x,y.a,z)
```

```
Calling variable 1 is 'x'.
Calling variable 2 is ''.
Calling variable 3 is ''.
```

Call the function using the second cell of `x`. Because the input argument contains cell indexing, the `inputname` function returns an empty `char` array for the first variable name and all subsequent variable names.

```
myfun2(x{2},y,z)
```

```
Calling variable 1 is ''.
Calling variable 2 is ''.
```

Calling variable 3 is ''.

## Input Arguments

### **argNumber** — Number of function input argument

scalar, real, positive integer value

Number of function input argument, specified as a scalar, real, positive integer value. If **argNumber** exceeds the number of input arguments passed into the function, MATLAB throws an error.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

### **s** — Workspace variable name

string

Workspace variable name, returned as a string. If the input argument has no name, the `inputname` function returns an empty character array (''). For example, an input argument has no name if it is a number, an expression, or an indexing expression instead of a variable.

If an input argument to the function that calls `inputname` contains cell or dot indexing, `inputname` returns an empty character array for that variable and subsequent variables. Extracting elements from a cell array or a field from a structure yields a comma-separated list. A comma-separated list causes the location of any input that follows to be dynamic. Therefore, `inputname` returns '' for the argument that produced the list and the arguments that follow.

## More About

### Tips

- `inputname` is a convenient way to communicate the name of an input variable to a function. For example, a function checks the data types of inputs and, if it finds an incorrect type, displays the name of the variable from your workspace.

- Avoid using `inputname` in the critical path of code or to obtain variable names to be used with commands such as `eval`, `evalin`, and `assignin`. This use of `inputname` can lead to code that is difficult to maintain.
- `inputname` returns an error if it is called inside an overloaded `subsref`, `subsasgn`, `subsindex`, or `numel` method.

**Introduced before R2006a**

# inputParser class

Parse function inputs

## Description

The `inputParser` object allows you to manage inputs to a function by creating an input scheme. To check the input, you can define validation functions for required arguments, optional arguments, and name-value pair arguments. Optionally, you can set properties to adjust the parsing behavior, such as handling case sensitivity, structure array inputs, and inputs that are not in the input scheme.

After calling the `parse` method to parse the inputs, the `inputParser` saves names and values of inputs that match the input scheme (stored in `Results`), names of inputs that are not passed to the function and, therefore, are assigned default values (stored in `UsingDefaults`), and names and values of inputs that do not match the input scheme (stored in `Unmatched`).

## Construction

`p = inputParser` creates `inputParser` object `p`.

## Properties

### CaseSensitive

Scalar logical value that indicates whether to match case when checking argument names.

Possible values:

|                        |                                                   |
|------------------------|---------------------------------------------------|
| <code>false</code> (0) | Names are not sensitive to case: 'a' matches 'A'. |
| <code>true</code> (1)  | Names are case sensitive: 'a' does not match 'A'. |

**Default:** `false`

## **FunctionName**

String that specifies the name of the function to include in error messages. By specifying the `FunctionName`, the `parse` method of the `inputParser` will throw error messages as if it were that function. This allows the error to be attributed to the correct function and allows easy access to function documentation through the error message.

**Default:** The default value is an empty string, `''`.

## **KeepUnmatched**

Scalar logical value that indicates how to handle parameter name and value inputs that are not in the input scheme.

Possible values:

|                        |                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>false</code> (0) | Throw an error whenever inputs are not in the scheme.                                                                                                           |
| <code>true</code> (1)  | Store the parameter names and values of unmatched inputs in the <code>Unmatched</code> property of the <code>inputParser</code> object, and suppress the error. |

**Default:** `false`

## **PartialMatching**

Scalar logical value that indicates whether partial matching of parameter names will be accepted. Partial parameter matching is supported by the `addParameter` method. If the value of `StructExpand` is `true`, then `PartialMatching` is not supported for structure field names corresponding to input parameter names.

Possible values:

|                        |                                                                                                                                                                                                     |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>true</code> (1)  | Inputs that are leading substrings of parameter names will be accepted and the value matched to that parameter. If there are multiple possible matches to the input string, MATLAB throws an error. |
| <code>false</code> (0) | Input names are required to match a parameter name exactly (with respect to the <code>CaseSensitive</code> property.)                                                                               |

**Default:** `true`

## StructExpand

Scalar logical value that specifies whether to interpret a structure array as a single input or as a set of parameter name and value pairs.

|           |                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------|
| true (1)  | Expand structures into separate inputs. Each field name corresponds to an input parameter name. |
| false (0) | Regard a structure array as a single input argument.                                            |

**Default:** true

## Read Only Properties

### Parameters

Cell array of strings that contains the names of arguments currently defined in the input scheme.

Each method that adds an input argument to the scheme (`addRequired`, `addOptional`, `addParameter`) updates the `Parameters` property.

### Results

Structure containing names and values of inputs that match the function input scheme, populated by the `parse` method.

Each field of the `Results` structure corresponds to the name of an input.

### Unmatched

Structure array containing the names and values of inputs that do not match the function input scheme, populated by the `parse` method.

If `KeepUnmatched` is `false` (default) or all inputs match the scheme, then `Unmatched` is a 1-by-1 structure with no fields. Otherwise, each field of the structure corresponds to the name of an input that did not match the scheme.

### UsingDefaults

Cell array containing the names of inputs not passed explicitly to the function and assigned default values, populated by the `parse` method.

## Methods

|                            |                                                                                |
|----------------------------|--------------------------------------------------------------------------------|
| <code>addOptional</code>   | Add optional positional argument to input parser scheme                        |
| <code>addParameter</code>  | Add optional parameter name-value pair argument to input parser scheme         |
| <code>addParamValue</code> | (Not recommended) Add parameter name and value argument to Input Parser scheme |
| <code>addRequired</code>   | Add required positional argument to input parser scheme                        |
| <code>parse</code>         | Parse function inputs                                                          |

You can define your scheme by calling `addRequired`, `addOptional`, and `addParameter` in any order, but when you call your function that uses the input parser, you should pass in required inputs first, followed by any optional positional inputs, and, finally, any name-value pairs.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

The `copy` method creates another scheme with the same properties as an existing `inputParser` object:

```
pNew = copy(pOld);
```

## Examples

### Input Validation

Check the validity of required and optional function inputs.

Create a custom function with required and optional inputs in the file `findArea.m`.

```

function a = findArea(width,varargin)
 p = inputParser;
 defaultHeight = 1;
 defaultUnits = 'inches';
 defaultShape = 'rectangle';
 expectedShapes = {'square','rectangle','parallelogram'};

 addRequired(p,'width',@isnumeric);
 addOptional(p,'height',defaultHeight,@isnumeric);
 addParameter(p,'units',defaultUnits);
 addParameter(p,'shape',defaultShape,...
 @(x) any(validatestring(x,expectedShapes)));

 parse(p,width,varargin{:});
 a = p.Results.width .* p.Results.height;

```

The input parser checks whether `width` and `height` are numeric, and whether the `shape` matches a string in cell array `expectedShapes`. `@` indicates a function handle, and the syntax `@(x)` creates an anonymous function with input `x`.

Call the function with inputs that do not match the scheme. For example, specify a nonnumeric value for the `width` input:

```
findArea('text')
```

```

Error using findArea (line 14)
The value of 'width' is invalid. It must satisfy the function: isnumeric.

```

Specify an unsupported value for `shape`:

```
findArea(4,'shape','circle')
```

```

Error using findArea (line 14)
The value of 'shape' is invalid. Expected input to match one of these strings:
square, rectangle, parallelogram
The input, 'circle', did not match any of the valid strings.

```

### Extra Parameter Value Inputs

Store parameter name and value inputs that are not in the input scheme instead of throwing an error.

```

default = 0;
value = 1;

```

```
p = inputParser;
p.KeepUnmatched = true;
addOptional(p, 'expectedInputName', default)
parse(p, 'extraInput', value);
```

View the unmatched parameter name and value:

```
p.Unmatched
```

```
ans =
```

```
 extraInput: 1
```

## Case Sensitivity

Enforce case sensitivity when checking function inputs.

```
p = inputParser;
p.CaseSensitive = true;
defaultValue = 0;
addParameter(p, 'InputName', defaultValue)
```

```
parse(p, 'inputname', 10)
```

'inputname' is not a recognized parameter. For a list of valid name-value pair arguments, see the documentation for this function.

## Structure Array Inputs

Parse structure array inputs with the `StructExpand` property set to `true` (default) or `false`.

Expand a structure array input into parameter name and value pairs using the default `true` value of the `StructExpand` property.

```
s.input1 = 10;
s.input2 = 20;
default = 0;
```

```
p = inputParser;
addParameter(p, 'input1', default)
addParameter(p, 'input2', default)
parse(p, s)
```

```
p.Results
```

```
ans =
```

```
input1: 10
input2: 20
```

Explicitly specifying a parameter name and value pair overrides values in the structure.

```
parse(p,s,'input2',300)
p.Results
```

```
ans =
```

```
input1: 10
input2: 300
```

Accept a structure array input as a single argument by setting the `StructExpand` property to `false`.

```
s2.first = 1;
s2.random = rand(3,4,2);
s2.mytext = 'some text';
```

```
p = inputParser;
p.StructExpand = false;
addRequired(p,'structInput')
parse(p,s2)
```

```
results = p.Results
fieldList = fieldnames(p.Results.structInput)
```

```
results =
```

```
structInput: [1x1 struct]
```

```
fieldList =
```

```
'first'
```

```
'random'
'mytext'
```

## Parse Inputs Using `validateattributes`

Create a function that parses information about people and, if parsing passes, adds the information to a cell array.

Create a function, `addPerson`, that sets up an `inputParser` scheme using `validateAttributes`. The function should accept the list of people, modify the list if necessary and return the list. Use a persistent `inputParser` to avoid construction of a new object with every function call. If this is the first call to the function, add a titles row to the cell array.

```
function mList = addPerson(mList,varargin)

persistent p
if isempty(p)
 p = inputParser;
 p.FunctionName = 'addPerson';
 addRequired(p,'name',@(x)validateattributes(x',{'char'},...
 {'nonempty'}))
 addRequired(p,'id',@(x)validateattributes(x',{'numeric'},...
 {'nonempty','integer','positive'}))
 addOptional(p,'birthyear',9999,@(x)validateattributes(x,...
 {'numeric'},{'nonempty'}))
 addParameter(p,'nickname','- ',@(x)validateattributes(x,...
 {'char'},{'nonempty'}))
 addParameter(p,'favColor','- ',@(x)validateattributes(x,...
 {'char'},{'nonempty'}))
end

parse(p,varargin{:})

if isempty(mList)
 mList = fieldnames(p.Results)';
end
mList = [mList; struct2cell(p.Results)'];

end
```

Create an empty list, and add a person to it.

```
pList = {};
pList = addPerson(pList,78,'Joe');
```

```
Error using addPerson
The value of 'name' is invalid. Expected input to be one of these types:
```

```
char
```

```
Instead its type was double.
Error in addPerson (line 17)
parse(p,mList,name,id,varargin{:});
```

The parsing failed because the function received the inputs in the incorrect order and tried to assign `name` a value of `78`. This entry was not added to `pList`.

Add several more people to the list.

```
pList = addPerson(pList, 'Joe', 78);
pList = addPerson(pList, 'Mary', 3, 1942, 'favColor', 'red');
pList = addPerson(pList, 'James', 182, 1970, 'nickname', 'Jimmy')

pList =
 'birthyear' 'favColor' 'id' 'name' 'nickname'
 [9999] '-' [78] 'Joe' '-'
 [1942] 'red' [3] 'Mary' '-'
 [1970] '-' [182] 'James' 'Jimmy'
```

## More About

- “Input Parser Validation Functions”

**Introduced in R2007a**

# inspect

Open Property Inspector

## Syntax

```
inspect
inspect(h)
inspect([h1,h2,...])
inspect -close
```

## Description

`inspect` opens the Property Inspector. Use the Property Inspector to display and modify properties of an object. Select an object in a figure window or the Layout Editor. To select an object in a figure window, plot edit mode must be on. If you do not select an object, then the Property Inspector is blank.

`inspect(h)` displays the properties for the object, `h`, where `h` can be most handle objects. For example, specify `h` as a MATLAB graphics object or a Simulink object.

`inspect([h1,h2,...])` displays properties that objects `h1` and `h2` have in common. If there are no such properties, `inspect` displays a blank window. You can inspect and edit any number of objects, for example, objects returned by the `bar` function.

`inspect -close` closes the Property Inspector.

The Property Inspector has the following behaviors:

- Only one Property Inspector window is active at any given time; when you inspect a new object, its properties replace those of the object last inspected.
- When the Property Inspector is open and plot edit mode is on, clicking any object in the figure window displays the properties of that object (or set of objects) in the Property Inspector.
- When you select and inspect two or more objects of different types, the Property Inspector only shows the properties that all objects have in common.

- To change the value of any property, click on the property name shown at the left side of the window, and then enter the new value in the field at the right.

The Property Inspector provides two different views:

- List view — properties are ordered alphabetically (default); this is the only view available for annotation objects.
- Group view — properties are grouped under classified headings (MATLAB graphics objects only)

To view alphabetically, click the “AZ” Icon  in the Property Inspector toolbar. To see properties in groups, click

the “++” icon . When properties are grouped, the “-” and “+” icons are enabled; click  to expand all categories and click  to collapse all categories. You can also expand and collapse individual categories by clicking on the “+” next to the category name. Some properties expand and collapse

---

**Notes** To see a complete description of any property, right-click on its name or value and select **What's This**; a help window opens that displays the reference page entry for it.

The Property Inspector displays most, but not all, properties of MATLAB graphics objects. For example, the **Parent** and **Children** properties are not shown.

`inspect h` displays a Property Inspector window that enables modification of the string 'h', not the object h.

If you modify properties at the MATLAB command line, you must refresh the Property Inspector window to see the change reflected there. Refresh the Property Inspector by reinvoking `inspect` on the object.

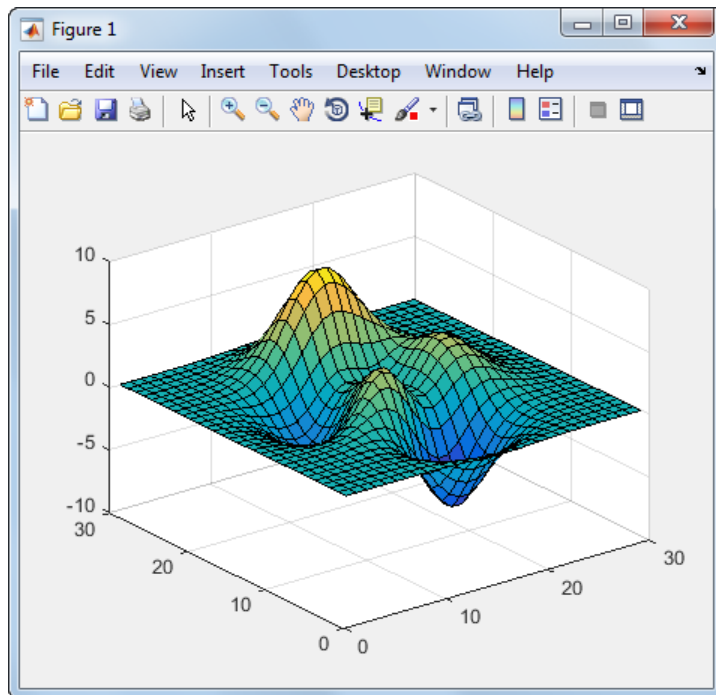

---

## Examples

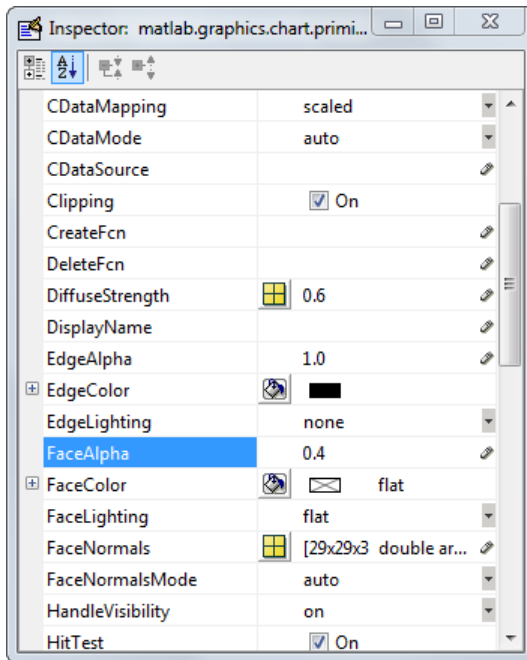

### Example 1

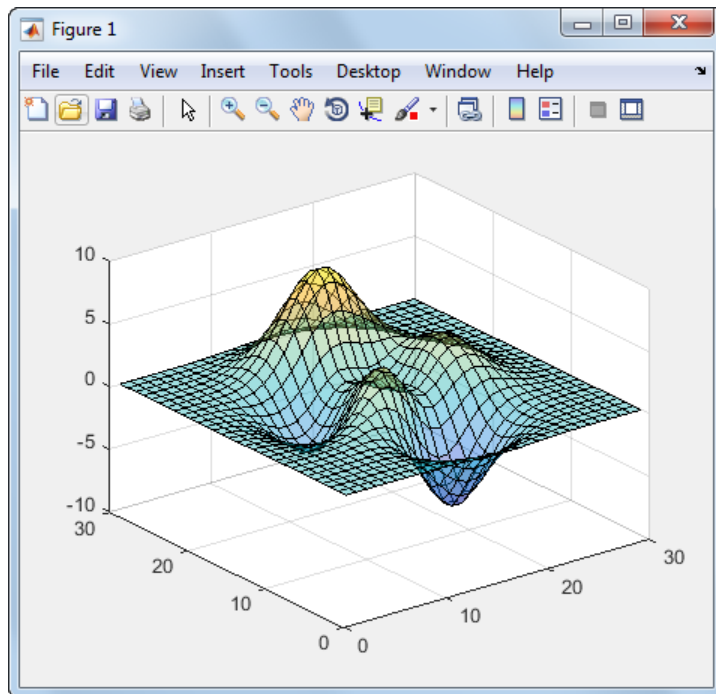

Create a surface mesh plot and view its properties with the Property Inspector.

```
Z = peaks(30);
f = surf(Z);
inspect(f);
```

In the Property Inspector, change the `FaceAlpha` property from `1.0` to `0.4`. Setting this value in the Property Inspector is equivalent to the command, `f.FaceAlpha = 0.4`, which changes the transparency of the surface faces to 40%.

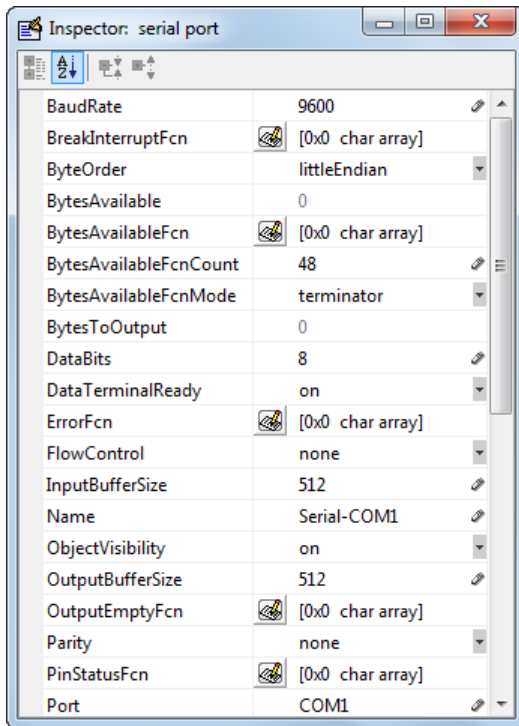

## Example 2

Create a serial port object for COM1 on a Windows platform and use the Property Inspector to peruse its properties:

```
s = serial('COM1');
inspect(s);
```

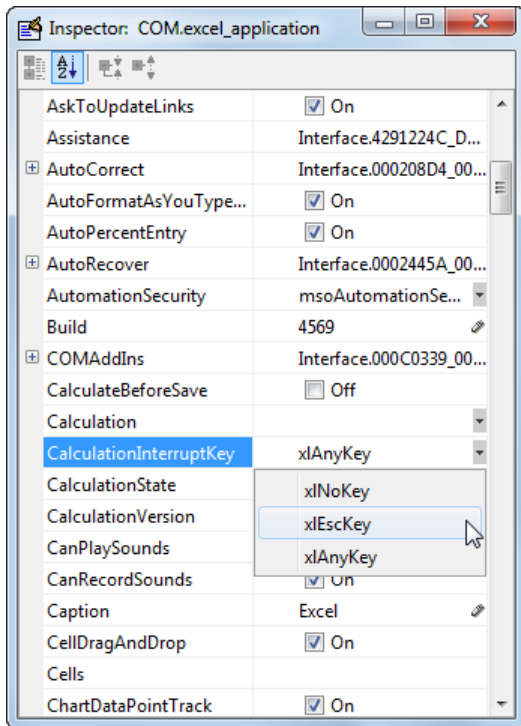

Because COM objects do not define property groupings, the Property Inspector enables only the alphabetical list view of COM object properties.

### Example 3

Create a COM Excel server and open a Property Inspector window with `inspect`.

```
h = actxserver('excel.application');
inspect(h);
```

Scroll down until you see the `CalculationInterruptKey` property, which by default is `xlAnyKey`. Click on the down-arrow in the right margin of the Property Inspector, and then select `xlEscKey` from the drop-down menu.

Check this property in the MATLAB Command Window using `get` to confirm that the property value changed.

```
get(h, 'CalculationInterruptKey')
```

```
ans =
xlEscKey
```

# instrcallback

Event information when event occurs

## Syntax

```
instrcallback(obj,event)
```

## Description

`instrcallback(obj,event)` displays a message that contains the event type, `event`, the time the event occurred, and the name of the serial port object, `obj`, that caused the event to occur.

For error events, the error message is also displayed. For pin status events, the pin that changed value and its value are also displayed.

## Examples

The following example creates the serial port object, `s`, on a Windows platform. It configures `s` to execute `instrcallback` when an output-empty event occurs. The event occurs after the `*IDN?` command is written to the instrument.

```
s = serial('COM1');
set(s,'OutputEmptyFcn',@instrcallback)
fopen(s)
fprintf(s,'*IDN?','async')
```

```
OutputEmpty event occurred at 08:37:49 for the object:
Serial-COM1.
```

Read the identification information from the input buffer and end the serial port session.

```
idn = fscanf(s);
fclose(s)
delete(s)
clear s
```

## **More About**

### **Tips**

Use `instrcallback` as a template to create callback functions that suit your specific application needs.

**Introduced before R2006a**

# instrfind

Read serial port objects from memory to MATLAB workspace

## Syntax

```
out = instrfind
out = instrfind('PropertyName',PropertyValue,...)
out = instrfind(S)
out = instrfind(obj,'PropertyName',PropertyValue,...)
```

## Description

`out = instrfind` returns all valid serial port objects as an array to `out`.

`out = instrfind('PropertyName',PropertyValue,...)` returns an array of serial port objects whose property names and property values match those specified.

`out = instrfind(S)` returns an array of serial port objects whose property names and property values match those defined in the structure `S`. The field names of `S` are the property names, while the field values are the associated property values.

`out = instrfind(obj,'PropertyName',PropertyValue,...)` restricts the search for matching property name/property value pairs to the serial port objects listed in `obj`.

## Examples

Suppose you create the following two serial port objects on a Windows platform.

```
s1 = serial('COM1');
s2 = serial('COM2');
set(s2,'BaudRate',4800)
fopen([s1 s2])
```

You can use `instrfind` to return serial port objects based on property values.

```
out1 = instrfind('Port','COM1');
```

```
out2 = instrfind({'Port','BaudRate'},{'COM2',4800});
```

You can also use `instrfind` to return cleared serial port objects to the MATLAB workspace.

```
clear s1 s2
newobjs = instrfind
```

```
Instrument Object Array
Index: Type: Status: Name:
1 serial open Serial-COM1
2 serial open Serial-COM2
```

To close both `s1` and `s2`

```
fclose(newobjs)
```

## More About

### Tips

Refer to “Displaying Property Names and Property Values” for a list of serial port object properties that you can use with `instrfind`.

You must specify property values using the same format as the `get` function returns. For example, if `get` returns the `Name` property value as `MyObject`, `instrfind` will not find an object with a `Name` property value of `myobject`. However, this is not the case for properties that have a finite set of string values. For example, `instrfind` will find an object with a `Parity` property value of `Even` or `even`.

You can use property name/property value string pairs, structures, and cell array pairs in the same call to `instrfind`.

### See Also

`clear` | `get`

**Introduced before R2006a**

# instrfindall

Find visible and hidden serial port objects

## Syntax

```
out = instrfindall
out = instrfindall('P1',V1,...)
out = instrfindall(s)
out = instrfindall(objs,'P1',V1,...)
```

## Description

`out = instrfindall` finds all serial port objects, regardless of the value of the object's `ObjectVisibility` property. The object or objects are returned to `out`.

`out = instrfindall('P1',V1,...)` returns an array, `out`, of serial port objects whose property names and corresponding property values match those specified as arguments.

`out = instrfindall(s)` returns an array, `out`, of serial port objects whose property names and corresponding property values match those specified in the structure `S`, where the field names correspond to property names and the field values correspond to the current value of the respective property.

`out = instrfindall(objs,'P1',V1,...)` restricts the search for objects with matching property name/value pairs to the serial port objects listed in `objs`.

Note that you can use string property name/property value pairs, structures, and cell array property name/property value pairs in the same call to `instrfindall`.

## Examples

Suppose you create the following serial port objects on a Windows platform:

```
s1 = serial('COM1');
s2 = serial('COM2');
```

```
set(s2, 'ObjectVisibility', 'off')
```

Because object `s2` has its `ObjectVisibility` set to `'off'`, it is not visible to commands like `instrfind`:

```
instrfind
```

```
Serial Port Object : Serial-COM1
```

However, `instrfindall` finds all objects regardless of the value of `ObjectVisibility`:

```
instrfindall
```

```
Instrument Object Array
Index: Type: Status: Name:
1 serial closed Serial-COM1
2 serial closed Serial-COM2
```

The following statements use `instrfindall` to return objects with specific property settings, which are passed as cell arrays:

```
props = {'PrimaryAddress', 'SecondaryAddress'};
vals = {2,0};
obj = instrfindall(props,vals);
```

You can use `instrfindall` as an argument when you want to apply the command to all objects, visible and invisible. For example, the following statement makes all objects visible:

```
set(instrfindall, 'ObjectVisibility', 'on')
```

## More About

### Tips

`instrfindall` differs from `instrfind` in that it finds objects whose `ObjectVisibility` property is set to `off`.

Property values are case sensitive. You must specify property values using the same format as that returned by the `get` function. For example, if `get` returns the `Name` property value as `'MyObject'`, `instrfindall` will not find an object with a `Name` property value of `'myobject'`. However, this is not the case for properties that have a

finite set of string values. For example, `instrfindall` will find an object with a `Parity` property value of `'Even'` or `'even'`.

**See Also**

`get` | `instrfind` | `ObjectVisibility`

## **int2str**

Convert integer to string

### **Syntax**

```
str = int2str(N)
```

### **Description**

`str = int2str(N)` converts an integer to a string with integer format. The input `N` can be a single integer or a vector or matrix of integers. Noninteger inputs are rounded before conversion.

### **Examples**

`int2str(2+3)` is the string '5'.

One way to label a plot is

```
title(['case number ' int2str(n)])
```

For matrix or vector inputs, `int2str` returns a string matrix:

```
int2str(eye(3))
```

```
ans =
```

```
1 0 0
0 1 0
0 0 1
```

### **See Also**

`fprintf` | `num2str` | `sprintf` | `cast`

**Introduced before R2006a**

## int8

Convert to 8-bit signed integer

### Syntax

```
intArray = int8(array)
```

### Description

`intArray = int8(array)` converts the elements of an array into signed 8-bit (1-byte) integers of class `int8`.

### Input Arguments

#### **array**

Array of any numeric class, such as `single` or `double`. If `array` is already of class `int8`, the `int8` function has no effect.

### Output Arguments

#### **intArray**

Array of class `int8`. Values range from  $-2^7$  to  $2^7 - 1$ .

The `int8` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
int8(2^7) % 2^7 = 128
```

returns

```
ans =
 127
```

## Examples

Convert a double array to `int8`:

```
mydata = int8(magic(10));
```

## Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = int8(zeros(100)); % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'int8'); % Preferred
```

## See Also

**Introduced before R2006a**

# int16

Convert to 16-bit signed integer

## Syntax

```
intArray = int16(array)
```

## Description

`intArray = int16(array)` converts the elements of an array into signed 16-bit (2-byte) integers of class `int16`.

## Input Arguments

### **array**

Array of any numeric class, such as `single` or `double`. If `array` is already of class `int16`, the `int16` function has no effect.

## Output Arguments

### **intArray**

Array of class `int16`. Values range from  $-2^{15}$  to  $2^{15} - 1$ .

The `int16` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
int16(2^15) % 2^15 = 32768
```

returns

```
ans =
 32767
```

## Examples

Convert a double array to `int16`:

```
mydata = int16(magic(100));
```

## Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = int16(zeros(100)); % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'int16'); % Preferred
```

## See Also

`intmax` | `intmin`

**Introduced before R2006a**

## int32

Convert to 32-bit signed integer

### Syntax

```
intArray = int32(array)
```

### Description

`intArray = int32(array)` converts the elements of an array into signed 32-bit (4-byte) integers of class `int32`.

### Input Arguments

#### **array**

Array of any numeric class, such as `single` or `double`. If `array` is already of class `int32`, the `int32` function has no effect.

### Output Arguments

#### **intArray**

Array of class `int32`. Values range from  $-2^{31}$  to  $2^{31} - 1$ .

The `int32` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
int32(2^31) % 2^31 = 2147483648
```

returns

```
ans =
 2147483647
```

## Examples

Convert a double array to `int32`:

```
mydata = int32(magic(1000));
```

## Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = int32(zeros(100)); % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'int32'); % Preferred
```

## See Also

`double` | `single` | `int8` | `int16` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` |  
`intmax` | `intmin`

**Introduced before R2006a**

# int64

Convert to 64-bit signed integer

## Syntax

```
intArray = int64(array)
```

## Description

`intArray = int64(array)` converts the elements of an array into signed 64-bit (8-byte) integers of class `int64`.

## Input Arguments

### **array**

Array of any numeric class, such as `single` or `double`. If `array` is already of class `int64`, the `int64` function has no effect.

## Output Arguments

### **intArray**

Array of class `int64`. Values range from  $-2^{63}$  to  $2^{63} - 1$ .

The `int64` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
int64(2^63) % 2^63 = 9223372036854775808
```

returns

```
ans =
 9223372036854775807
```

## Examples

Convert a literal value to `int64`:

```
x = int64(9007199254740993);
```

## Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = int64(zeros(100)); % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'int64'); % Preferred
```

## More About

### Tips

Double-precision floating-point numbers have only 52 bits in the mantissa. Therefore, `double` values cannot represent all integers greater than  $2^{53}$  correctly. Before performing arithmetic operations on values larger than  $2^{53}$  in magnitude, convert the values to 64-bit integers. For example,

```
x = int64(2^53+1); % Floating-point arithmetic, loses precision
```

is not as accurate as the 64-bit integer arithmetic operation:

```
x = int64(2^53) + 1; % Preferred
```

### See Also

`double` | `single` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `uint64` | `intmax` | `intmin`

**Introduced before R2006a**

# integral

Numerical integration

## Syntax

```
q = integral(fun,xmin,xmax)
q = integral(fun,xmin,xmax,Name,Value)
```

## Description

`q = integral(fun,xmin,xmax)` numerically integrates function `fun` from `xmin` to `xmax` using global adaptive quadrature and default error tolerances.

`q = integral(fun,xmin,xmax,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments. For example, specify `'WayPoints'` followed by a vector of real or complex numbers to indicate specific points for the integrator to use.

## Examples

### Improper Integral

Create the function  $f(x) = e^{-x^2}(\ln x)^2$ .

```
fun = @(x) exp(-x.^2).*log(x).^2;
```

Evaluate the integral from `x=0` to `x=Inf`.

```
q = integral(fun,0,Inf)
```

```
q =
```

```
 1.9475
```

### Parameterized Function

Create the function  $f(x) = 1/(x^3 - 2x - c)$  with one parameter, `c`.

```
fun = @(x,c) 1./(x.^3-2*x-c);
```

Evaluate the integral from  $x=0$  to  $x=2$  at  $c=5$ .

```
q = integral(@(x)fun(x,5),0,2)
```

```
q =
```

```
-0.4605
```

### Singularity at Lower Limit

Create the function  $f(x) = \ln(x)$ .

```
fun = @(x)log(x);
```

Evaluate the integral from  $x=0$  to  $x=1$  with the default error tolerances.

```
format long
```

```
q1 = integral(fun,0,1)
```

```
q1 =
```

```
-1.000000010959678
```

Evaluate the integral again, specifying 12 decimal places of accuracy.

```
q2 = integral(fun,0,1,'RelTol',0,'AbsTol',1e-12)
```

```
q2 =
```

```
-1.000000000000010
```

### Complex Contour Integration Using Waypoints

Create the function  $f(z) = 1/(2z - 1)$ .

```
fun = @(z) 1./(2*z-1);
```

Integrate in the complex plane over the triangular path from  $0$  to  $1+1i$  to  $1-1i$  to  $0$  by specifying waypoints.

```
q = integral(fun,0,0,'Waypoints',[1+1i,1-1i])
```

```
q =
```

```
0 - 3.1416i
```

### Vector-Valued Function

Create the vector-valued function  $f(x) = [\sin x, \sin 2x, \sin 3x, \sin 4x, \sin 5x]$  and integrate from  $x=0$  to  $x=1$ . Specify 'ArrayValued', true to evaluate the integral of an array-valued or vector-valued function.

```
fun = @(x)sin((1:5)*x);
q = integral(fun,0,1,'ArrayValued',true)

q =

 0.4597 0.7081 0.6633 0.4134 0.1433
```

### Improper Integral of Oscillatory Function

Create the function  $f(x) = x^5 e^{-x} \sin x$ .

```
fun = @(x)x.^5.*exp(-x).*sin(x);
```

Evaluate the integral from  $x=0$  to  $x=Inf$ , adjusting the absolute and relative tolerances.

```
format long
q = integral(fun,0,Inf,'RelTol',1e-8,'AbsTol',1e-13)

q =

-14.999999999998364
```

- “Integration to Find Arc Length”
- “Complex Line Integrals”

## Input Arguments

### fun — Integrand

function handle

Integrand, specified as a function handle, which defines the function to be integrated from  $x_{min}$  to  $x_{max}$ .

For scalar-valued problems, the function  $y = fun(x)$  must accept a vector argument,  $x$ , and return a vector result,  $y$ . This generally means that `fun` must use array operators

instead of matrix operators. For example, use `.*` (times) rather than `*` (mtimes). If you set the 'ArrayValued' option to `true`, then `fun` must accept a scalar and return an array of fixed size.

### **xmin** — Lower limit of *x*

real number | complex number

Lower limit of *x*, specified as a real (finite or infinite) scalar value or a complex (finite) scalar value. If either `xmin` or `xmax` are complex, then `integral` approximates the path integral from `xmin` to `xmax` over a straight line path.

Data Types: `double` | `single`

Complex Number Support: Yes

### **xmax** — Upper limit of *x*

real number | complex number

Upper limit of *x*, specified as a real number (finite or infinite) or a complex number (finite). If either `xmin` or `xmax` are complex, `integral` approximates the path integral from `xmin` to `xmax` over a straight line path.

Data Types: `double` | `single`

Complex Number Support: Yes

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'AbsTol', 1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

### **'AbsTol'** — Absolute error tolerance

nonnegative real number

Absolute error tolerance, specified as the comma-separated pair consisting of `'AbsTol'` and a nonnegative real number. `integral` uses the absolute error tolerance to limit an estimate of the absolute error,  $|q - Q|$ , where *q* is the computed value of the integral and *Q* is the (unknown) exact value. `integral` might provide more decimal places of precision if you decrease the absolute error tolerance. The default value is `1e-10`.

---

**Note:** `AbsTol` and `RelTol` work together. `integral` might satisfy the absolute error tolerance or the relative error tolerance, but not necessarily both. For more information on using these tolerances, see the “Tips” on page 1-4502 section.

---

Example: `'AbsTol', 1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

Data Types: `single` | `double`

### **'RelTol' — Relative error tolerance**

nonnegative real number

Relative error tolerance, specified as the comma-separated pair consisting of `'RelTol'` and a nonnegative real number. `integral` uses the relative error tolerance to limit an estimate of the relative error,  $|q - Q|/|Q|$ , where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. `integral` might provide more significant digits of precision if you decrease the relative error tolerance. The default value is `1e-6`.

---

**Note:** `RelTol` and `AbsTol` work together. `integral` might satisfy the relative error tolerance or the absolute error tolerance, but not necessarily both. For more information on using these tolerances, see the Tips section.

---

Example: `'RelTol', 1e-9` sets the relative error tolerance to approximately 9 significant digits.

Data Types: `single` | `double`

### **'ArrayValued' — Array-valued function flag**

`false` (default) | `true` | `0` | `1`

Array-valued function flag, specified as the comma-separated pair consisting of `'ArrayValued'` and either `false`, `true`, `0`, or `1`. Set this flag to `true` to indicate that `fun` is a function that accepts a scalar input and returns a vector, matrix, or N-D array output.

The default value of `'false'` indicates that `fun` is a function that accepts a vector input and returns a vector output.

Example: `'ArrayValued', true` indicates that the integrand is an array-valued function.

**'Waypoints' — Integration waypoints**

vector

Integration waypoints, specified as the comma-separated pair consisting of 'Waypoints' and a vector of real or complex numbers. Use waypoints to indicate any points in the integration interval that you would like the integrator to use. You can use waypoints to integrate efficiently across discontinuities of the integrand. Specify the locations of the discontinuities in the vector you supply.

You can specify waypoints when you want to perform complex contour integration. If `xmin`, `xmax`, or any entry of the waypoints vector is complex, the integration is performed over a sequence of straight line paths in the complex plane.

Example: 'Waypoints', [1+1i, 1-1i] specifies two complex waypoints along the interval of integration.

Data Types: single | double

Complex Number Support: Yes

## More About

### Tips

- Do not use waypoints to specify singularities. Instead, split the interval and add the results of separate integrations with the singularities at the endpoints.
- The `integral` function attempts to satisfy:

$$\text{abs}(q - Q) \leq \max(\text{AbsTol}, \text{RelTol} * \text{abs}(q))$$

where `q` is the computed value of the integral and `Q` is the (unknown) exact value.

The absolute and relative tolerances provide a way of trading off accuracy and computation time. Usually, the relative tolerance determines the accuracy of the integration. However if `abs(q)` is sufficiently small, the absolute tolerance determines the accuracy of the integration. You should generally specify both absolute and relative tolerances together.

- If you specify a complex value for `xmin`, `xmax`, or any waypoint, all of your limits and waypoints must be finite.
- If you are specifying single-precision limits of integration, or if `fun` returns single-precision results, you might need to specify larger absolute and relative error tolerances.

**Introduced in R2012a**

## integral2

Numerically evaluate double integral

### Syntax

```
q = integral2(fun,xmin,xmax,ymin,ymax)
q = integral2(fun,xmin,xmax,ymin,ymax,Name,Value)
```

### Description

`q = integral2(fun,xmin,xmax,ymin,ymax)` approximates the integral of the function  $z = \text{fun}(x,y)$  over the planar region  $x_{\min} \leq x \leq x_{\max}$  and  $y_{\min}(x) \leq y \leq y_{\max}(x)$ .

`q = integral2(fun,xmin,xmax,ymin,ymax,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments.

### Examples

#### Integrate Triangular Region with Singularity at the Boundary

The function

$$f(x,y) = \frac{1}{(\sqrt{x+y})(1+x+y)}$$

is undefined when  $x$  and  $y$  are zero. `integral2` performs best when singularities are on the integration boundary.

Create the anonymous function.

```
fun = @(x,y) 1./ (sqrt(x + y) .* (1 + x + y).^2)
```

Integrate over the triangular region bounded by  $0 \leq x \leq 1$  and  $0 \leq y \leq 1 - x$ .

```
ymax = @(x) 1 - x
q = integral2(fun,0,1,0,ymax)
```

```
q =
```

```
0.2854
```

### Evaluate Double Integral in Polar Coordinates

Define the function

$$f(\theta, r) = \frac{r}{\sqrt{r \cos \theta + r \sin \theta} (1 + r \cos \theta + r \sin \theta)^2}$$

```
fun = @(x,y) 1./ (sqrt(x + y) .* (1 + x + y).^2);
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;
```

Define a function for the upper limit of  $r$ .

```
rmax = @(theta) 1./(sin(theta) + cos(theta));
```

Integrate over the region bounded by  $0 \leq \theta \leq \pi/2$  and  $0 \leq r \leq r_{\max}$ .

```
q = integral2(polarfun,0,pi/2,0,rmax)
```

```
q =
```

```
0.2854
```

### Evaluate Double Integral of Parameterized Function with Specific Method and Error Tolerance

Create the anonymous parameterized function  $f(x,y) = ax^2 + by^2$  with parameters  $a=3$  and  $b=5$ .

```
a = 3; b = 5;
fun = @(x,y) a*x.^2 + b*y.^2;
```

Evaluate the integral over the region  $0 \leq x \leq 5$  and  $-5 \leq y \leq 0$ . Specify the 'iterated' method and approximately 10 significant digits of accuracy.

```
format long
q = integral2(fun,0,5,-5,0,'Method','iterated',...
'AbsTol',0,'RelTol',1e-10)
```

q =

1.6666666666666666e+03

- “Singularity on Interior of Integration Domain”

## Input Arguments

### **fun** — Integrand

function handle

Integrand, specified as a function handle, defines the function to be integrated over the planar region  $x_{\min} \leq x \leq x_{\max}$  and  $y_{\min}(x) \leq y \leq y_{\max}(x)$ . The function **fun** must accept two arrays of the same size and return an array of corresponding values. It must perform element-wise operations.

Data Types: `function_handle`

### **xmin** — Lower limit of *x*

real number

Lower limit of *x*, specified as a real scalar value that is either finite or infinite.

Data Types: `double` | `single`

### **xmax** — Upper limit of *x*

real number

Upper limit of *x*, specified as a real scalar value that is either finite or infinite.

Data Types: `double` | `single`

### **ymin** — Lower limit of *y*

real number | function handle

Lower limit of *y*, specified as a real scalar value that is either finite or infinite. You can specify **ymin** to be a function handle (a function of *x*) when integrating over a nonrectangular region.

Data Types: `double` | `function_handle` | `single`

### **ymax** — Upper limit of *y*

real number | function handle

Upper limit of  $y$ , specified as a real scalar value that is either finite or infinite. You also can specify `ymax` to be a function handle (a function of  $x$ ) when integrating over a nonrectangular region.

Data Types: `double` | `function_handle` | `single`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'AbsTol', 1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

### 'AbsTol' — Absolute error tolerance

nonnegative real number

Absolute error tolerance, specified as the comma-separated pair consisting of `'AbsTol'` and a nonnegative real number. `integral2` uses the absolute error tolerance to limit an estimate of the absolute error,  $|q - Q|$ , where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. `integral2` might provide more decimal places of precision if you decrease the absolute error tolerance. The default value is `1e-10`.

---

**Note:** `AbsTol` and `RelTol` work together. `integral2` might satisfy the absolute error tolerance or the relative error tolerance, but not necessarily both. For more information on using these tolerances, see the “Tips” on page 1-4509 section.

---

Example: `'AbsTol', 1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

Data Types: `double` | `single`

### 'RelTol' — Relative error tolerance

nonnegative real number

Relative error tolerance, specified as the comma-separated pair consisting of `'RelTol'` and a nonnegative real number. `integral2` uses the relative error tolerance to limit an estimate of the relative error,  $|q - Q|/|Q|$ , where  $q$  is the computed value of the integral

and  $Q$  is the (unknown) exact value. `integral2` might provide more significant digits of precision if you decrease the relative error tolerance. The default value is `1e-6`.

---

**Note:** `RelTol` and `AbsTol` work together. `integral2` might satisfy the relative error tolerance or the absolute error tolerance, but not necessarily both. For more information on using these tolerances, see the “Tips” on page 1-4509 section.

---

Example: `'RelTol', 1e-9` sets the relative error tolerance to approximately 9 significant digits.

Data Types: `double` | `single`

### 'Method' — Integration method

`'auto'` (default) | `'tiled'` | `'iterated'`

Integration method, specified as the comma-separated pair consisting of `'Method'` and one of the methods described below.

| Integration Method      | Description                                                                                                                                                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'auto'</code>     | For most cases, <code>integral2</code> uses the <code>'tiled'</code> method. It uses the <code>'iterated'</code> method when any of the integration limits are infinite. This is the default method.                                                                            |
| <code>'tiled'</code>    | <code>integral2</code> transforms the region of integration to a rectangular shape and subdivides it into smaller rectangular regions as needed. The integration limits must be finite.                                                                                         |
| <code>'iterated'</code> | <code>integral2</code> calls <code>integral</code> to perform an iterated integral. The outer integral is evaluated over $x_{\min} \leq x \leq x_{\max}$ . The inner integral is evaluated over $y_{\min}(x) \leq y \leq y_{\max}(x)$ . The integration limits can be infinite. |

Example: `'Method', 'tiled'` specifies the tiled integration method.

## Output Arguments

### `q` — Computed integral

numeric value

Computed integral of  $\text{fun}(x, y)$  over the specified region, returned as a numeric value.

## More About

### Tips

- The `integral2` function attempts to satisfy:

$$\text{abs}(q - Q) \leq \max(\text{AbsTol}, \text{RelTol} * \text{abs}(q))$$

where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value.

The absolute and relative tolerances provide a way of trading off accuracy and computation time. Usually, the relative tolerance determines the accuracy of the integration. However if `abs(q)` is sufficiently small, the absolute tolerance determines the accuracy of the integration. You should generally specify both absolute and relative tolerances together.

- The `'iterated'` method can be more effective when your function has discontinuities within the integration region. However, the best performance and accuracy occurs when you split the integral at the points of discontinuity and sum the results of multiple integrations.
- When integrating over nonrectangular regions, the best performance and accuracy occurs when `ymin`, `ymax`, (or both) are function handles. Avoid setting integrand function values to zero to integrate over a nonrectangular region. If you must do this, specify `'iterated'` method.
- Use the `'iterated'` method when `ymin`, `ymax`, (or both) are unbounded functions.
- When parameterizing anonymous functions, be aware that parameter values persist for the life of the function handle. For example, the function `fun = @(x,y) x + y + a` uses the value of `a` at the time `fun` was created. If you later decide to change the value of `a`, you must redefine the anonymous function with the new value.
- If you are specifying single-precision limits of integration, or if `fun` returns single-precision results, you might need to specify larger absolute and relative error tolerances.
- “Parameterizing Functions”
- “Create Function Handle”

integral | integral3 | trapz

**Introduced in R2012a**

# integral3

Numerically evaluate triple integral

## Syntax

```
q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax)
q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax,Name,Value)
```

## Description

`q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax)` approximates the integral of the function  $z = \text{fun}(x,y,z)$  over the region  $x_{\min} \leq x \leq x_{\max}$ ,  $y_{\min}(x) \leq y \leq y_{\max}(x)$  and  $z_{\min}(x,y) \leq z \leq z_{\max}(x,y)$ .

`q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments.

## Examples

### Triple Integral with Finite Limits

Define the anonymous function  $f(x,y,z) = y \sin x + z \cos x$ .

```
fun = @(x,y,z) y.*sin(x)+z.*cos(x)
```

Integrate over the region  $0 \leq x \leq \pi$ ,  $0 \leq y \leq 1$ , and  $-1 \leq z \leq 1$ .

```
q = integral3(fun,0,pi,0,1,-1,1)
```

```
q =
```

```
 2.0000
```

### Integral Over the Unit Sphere in Cartesian Coordinates

Define the anonymous function  $f(x,y,z) = x \cos y + x^2 \cos z$ .

```
fun = @(x,y,z) x.*cos(y) + x.^2.*cos(z)
```

Define the limits of integration.

```
xmin = -1;
xmax = 1;
ymin = @(x)-sqrt(1 - x.^2);
ymax = @(x) sqrt(1 - x.^2);
zmin = @(x,y)-sqrt(1 - x.^2 - y.^2);
zmax = @(x,y) sqrt(1 - x.^2 - y.^2);
```

Evaluate the definite integral with the 'tiled' method.

```
q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax,'Method','tiled')
q =
 0.7796
```

## Evaluate Improper Triple Integral of Parameterized Function

Define the anonymous parameterized function  $f(x,y,z) = 10/(x^2 + y^2 + z^2 + a)$ .

```
a = 2;
f = @(x,y,z) 10./(x.^2 + y.^2 + z.^2 + a);
```

Evaluate the triple integral over the region  $-\infty \leq x \leq 0$ ,  $-100 \leq y \leq 0$ , and  $-100 \leq z \leq 0$ .

```
format long
q1 = integral3(f,-Inf,0,-100,0,-100,0)
q1 =
 2.734244598320928e+03
```

Evaluate the integral again and specify accuracy to approximately 9 significant digits.

```
q2 = integral3(f,-Inf,0,-100,0,-100,0,'AbsTol',0,'RelTol',1e-9)
q2 =
 2.734244599944285e+03
```

## Input Arguments

**fun** — Integrand  
function handle

Integrand, specified as a function handle, defines the function to be integrated over the region  $x_{\min} \leq x \leq x_{\max}$ ,  $y_{\min}(x) \leq y \leq y_{\max}(x)$ , and  $z_{\min}(x, y) \leq z \leq z_{\max}(x, y)$ . The function `fun` must accept three arrays of the same size and return an array of corresponding values. It must perform element-wise operations.

Data Types: `function_handle`

**`xmin` — Lower limit of `x`**

real number

Lower limit of `x`, specified as a real scalar value that is either finite or infinite.

Example:

Data Types: `double` | `single`

**`xmax` — Upper limit of `x`**

real number

Upper limit of `x`, specified as a real scalar value that is either finite or infinite.

Data Types: `double` | `single`

**`ymin` — Lower limit of `y`**

real number | function handle

Lower limit of `y`, specified as a real scalar value that is either finite or infinite. You also can specify `ymin` to be a function handle (a function of `x`) when integrating over a nonrectangular region.

Example:

Data Types: `double` | `function_handle` | `single`

**`ymax` — Upper limit of `y`**

real number | function handle

Upper limit of `y`, specified as a real scalar value that is either finite or infinite. You also can specify `ymax` to be a function handle (a function of `x`) when integrating over a nonrectangular region.

Example:

Data Types: `double` | `function_handle` | `single`

**`zmin` — Lower limit of `z`**

real number | function handle

Lower limit of  $z$ , specified as a real scalar value that is either finite or infinite. You also can specify `zmin` to be a function handle (a function of  $x,y$ ) when integrating over a nonrectangular region.

Data Types: `double` | `function_handle` | `single`

**zmax — Upper limit of z**

real number | function handle

Upper limit of  $z$ , specified as a real scalar value that is either finite or infinite. You also can specify `zmax` to be a function handle (a function of  $x,y$ ) when integrating over a nonrectangular region.

Data Types: `double` | `function_handle` | `single`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, . . . , `NameN`, `ValueN`.

Example: `'AbsTol'`, `1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

**'AbsTol' — Absolute error tolerance**

nonnegative real number

Absolute error tolerance, specified as the comma-separated pair consisting of `'AbsTol'` and a nonnegative real number. `integral3` uses the absolute error tolerance to limit an estimate of the absolute error,  $|q - Q|$ , where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. `integral3` might provide more decimal places of precision if you decrease the absolute error tolerance. The default value is `1e-10`.

---

**Note:** `AbsTol` and `RelTol` work together. `integral3` might satisfy the absolute error tolerance or the relative error tolerance, but not necessarily both. For more information on using these tolerances, see the “Tips” on page 1-4516 section.

---

Example: `'AbsTol'`, `1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

Data Types: double | single

### 'RelTol' — Relative error tolerance

nonnegative real number

Relative error tolerance, specified as the comma-separated pair consisting of 'RelTol' and a nonnegative real number. `integral3` uses the relative error tolerance to limit an estimate of the relative error,  $|q - Q|/|Q|$ , where  $q$  is the computed value of the integral and  $Q$  is the (unknown) exact value. `integral3` might provide more significant digits of precision if you decrease the relative error tolerance. The default value is  $1e-6$ .

---

**Note:** RelTol and AbsTol work together. `integral3` might satisfy the relative error tolerance or the absolute error tolerance, but not necessarily both. For more information on using these tolerances, see the “Tips” on page 1-4516 section.

---

Example: 'RelTol',  $1e-9$  sets the relative error tolerance to approximately 9 significant digits.

Data Types: double | single

### 'Method' — Integration method

'auto' (default) | 'tiled' | 'iterated'

Integration method, specified as the comma-separated pair consisting of 'Method' and one of the methods described below.

| Integration Method | Description                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'auto'             | For most cases, <code>integral3</code> uses the 'tiled' method. It uses the 'iterated' method when any of the integration limits are infinite. This is the default method.                                                                                                                                                           |
| 'tiled'            | <code>integral3</code> calls <code>integral</code> to integrate over $x_{\min} \leq x \leq x_{\max}$ . It calls <code>integral2</code> with the 'tiled' method to evaluate the double integral over $y_{\min}(x) \leq y \leq y_{\max}(x)$ and $z_{\min}(x,y) \leq z \leq z_{\max}(x,y)$ .                                            |
| 'iterated'         | <code>integral3</code> calls <code>integral</code> to integrate over $x_{\min} \leq x \leq x_{\max}$ . It calls <code>integral2</code> with the 'iterated' method to evaluate the double integral over $y_{\min}(x) \leq y \leq y_{\max}(x)$ and $z_{\min}(x,y) \leq z \leq z_{\max}(x,y)$ . The integration limits can be infinite. |

Example: 'Method', 'tiled' specifies the tiled integration method.

## Output Arguments

### **q** — Computed integral

numeric value

Computed integral of `fun(x,y,z)` over the specified region, returned as a numeric value.

## More About

### Tips

- The `integral3` function attempts to satisfy:

$$\text{abs}(q - Q) \leq \max(\text{AbsTol}, \text{RelTol} * \text{abs}(q))$$

where `q` is the computed value of the integral and `Q` is the (unknown) exact value.

The absolute and relative tolerances provide a way of trading off accuracy and computation time. Usually, the relative tolerance determines the accuracy of the integration. However if `abs(q)` is sufficiently small, the absolute tolerance determines the accuracy of the integration. You should generally specify both absolute and relative tolerances together.

- The 'iterated' method can be more effective when your function has discontinuities within the integration region. However, the best performance and accuracy occurs when you split the integral at the points of discontinuity and sum the results of multiple integrations.
- When integrating over nonrectangular regions, the best performance and accuracy occurs when any or all of the limits: `ymin`, `ymax`, `zmin`, `zmax` are function handles. Avoid setting integrand function values to zero to integrate over a nonrectangular region. If you must do this, specify 'iterated' method.
- Use the 'iterated' method when any or all of the limits: `ymin(x)`, `ymax(x)`, `zmin(x,y)`, `zmax(x,y)` are unbounded functions.
- When parameterizing anonymous functions, be aware that parameter values persist for the life of the function handle. For example, the function `fun = @(x,y,z) x + y + z + a` uses the value of `a` at the time `fun` was created. If you later decide to change the value of `a`, you must redefine the anonymous function with the new value.

- If you are specifying single-precision limits of integration, or if `fun` returns single-precision results, you may need to specify larger absolute and relative error tolerances.

## interfaces

List custom interfaces exposed by COM server object

### Syntax

```
customlist = interfaces(h)
```

### Description

`customlist = interfaces(h)` returns cell array of strings `customlist` listing all custom interfaces implemented by the component in a specific COM server object. The server is designated by input argument `h`, the handle returned by the `actxcontrol` or `actxserver` function when creating that server.

The `interfaces` function only lists the custom interfaces exposed by the object; it does not return interfaces. Use the `invoke` function to return a handle to a specific custom interface.

COM functions are available on Microsoft Windows systems only.

# interp1

1-D data interpolation (table lookup)

## Compatibility

If you pass nonuniformly spaced points and specify the 'v5cubic' method, `interp1` issues a warning. In addition, note the status of the following syntaxes:

- The behavior of `interp1(..., 'cubic')` will change in a future release.
- `pp = interp1(..., 'pp')` is not recommended.

## Syntax

```
vq = interp1(x,v,xq)
vq = interp1(x,v,xq,method)
vq = interp1(x,v,xq,method,extrapolation)

vq = interp1(v,xq)
vq = interp1(v,xq,method)
vq = interp1(v,xq,method,extrapolation)

pp = interp1(x,v,method,'pp')
```

## Description

`vq = interp1(x,v,xq)` returns interpolated values of a 1-D function at specific query points using linear interpolation. Vector `x` contains the sample points, and `v` contains the corresponding values,  $v(x)$ . Vector `xq` contains the coordinates of the query points.

If you have multiple sets of data that are sampled at the same point coordinates, then you can pass `v` as an array. Each column of array `v` contains a different set of 1-D sample values.

`vq = interp1(x,v,xq,method)` specifies a string for choosing an alternative interpolation method: 'nearest', 'next', 'previous', 'linear', 'spline', 'pchip', or 'cubic'. The default method is 'linear'.

`vq = interp1(x,v,xq,method,extrapolation)` specifies a strategy for evaluating points that lie outside the domain of `x`. Set `extrapolation` to the string, `'extrap'`, when you want to use the `method` algorithm for extrapolation. Alternatively, you can specify a scalar value, in which case, `interp1` returns that value for all points outside the domain of `x`.

`vq = interp1(v,xq)` returns interpolated values and assumes a default set of sample point coordinates. The default points are the sequence of numbers from 1 to `n`, where `n` depends on the shape of `v`:

- When `v` is a vector, the default points are `1:length(v)`.
- When `v` is an array, the default points are `1:size(v,1)`.

Use this syntax when you are not concerned about the absolute distances between points.

`vq = interp1(v,xq,method)` specifies any of the alternative interpolation methods and uses the default sample points.

`vq = interp1(v,xq,method,extrapolation)` specifies an extrapolation strategy and uses the default sample points.

`pp = interp1(x,v,method,'pp')` returns the piece-wise polynomial form of  $v(x)$  using the `method` algorithm.

## Examples

### Interpolation of Coarsely Sampled Sine Function

Define the sample points, `x`, and corresponding sample values, `v`.

```
x = 0:pi/4:2*pi;
v = sin(x);
```

Define the query points to be a finer sampling over the range of `x`.

```
xq = 0:pi/16:2*pi;
```

Interpolate the function at the query points and plot the result.

```
figure
```

```
vq1 = interp1(x,v,xq);
plot(x,v,'o',xq,vq1,':');
xlim([0 2*pi]);
title('(Default) Linear Interpolation');
```

Now evaluate  $v$  at the same points using the 'spline' method.

```
figure
vq2 = interp1(x,v,xq,'spline');
plot(x,v,'o',xq,vq2,':');
xlim([0 2*pi]);
title('Spline Interpolation');
```

### Interpolation Without Specifying Points

Define a set of function values.

```
v = [0 1.41 2 1.41 0 -1.41 -2 -1.41 0];
```

Define a set of query points that fall between the default points, 1:9. In this case, the default points are 1:9 because v contains 9 values.

```
xq = 1.5:8.5;
```

Evaluate v at xq.

```
vq = interp1(v,xq);
```

Plot the result.

```
figure
plot((1:9),v,'o',xq,vq,'*');
legend('v','vq');
```

### Interpolation of Complex Values

Define a set of sample points.

```
x = 1:10;
```

Define the values of the function,  $v(x) = 5x + x^2i$ , at the sample points.

```
v = (5*x)+(x.^2*1i);
```

Define the query points to be a finer sampling over the range of x.

```
xq = 1:0.25:10;
```

Interpolate v at the query points.

```
vq = interp1(x,v,xq);
```

Plot the real part of the result in red and the imaginary part in blue.

```
figure
plot(x,real(v), '*r', xq,real(vq), '-r');
hold on
plot(x,imag(v), '*b', xq,imag(vq), '-b');
```

### Extrapolation Using Two Different Methods

Define the sample points,  $x$ , and corresponding sample values,  $v$ .

```
x = [1 2 3 4 5];
v = [12 16 31 10 6];
```

Specify the query points,  $xq$ , that extend beyond the domain of  $x$ .

```
xq = [0 0.5 1.5 5.5 6];
```

Evaluate  $v$  at  $xq$  using the 'pchip' method.

```
vq1 = interp1(x,v,xq,'pchip')
```

```
vq1 =
 19.3684 13.6316 13.2105 7.4800 12.5600
```

Next, evaluate  $v$  at  $xq$  using the 'linear' method.

```
vq2 = interp1(x,v,xq,'linear')
```

```
vq2 =
 NaN NaN 14 NaN NaN
```

Now, use the 'linear' method with the 'extrap' option.

```
vq3 = interp1(x,v,xq,'linear','extrap')
```

```
vq3 =
 8 10 14 4 2
```

'pchip' extrapolates by default, but 'linear' does not.

## Designate Constant Value for All Queries Outside the Domain of $x$

Define the sample points,  $x$ , and corresponding sample values,  $v$ .

```
x = [-3 -2 -1 0 1 2 3];
v = 3*x.^2;
```

Specify the query points,  $xq$ , that extend beyond the domain of  $x$ .

```
xq = [-4 -2.5 -0.5 0.5 2.5 4];
```

Now evaluate  $v$  at  $xq$  using the 'pchip' method and assign any values outside the domain of  $x$  to the value, 27.

```
vq = interp1(x,v,xq,'pchip',27)
```

```
vq =
 27.0000 18.6563 0.9375 0.9375 18.6563 27.0000
```

### Interpolate Multiple Sets of Data in One Pass

Define the sample points.

```
x = (-5:5)';
```

Sample three different parabolic functions at the points defined in  $x$ .

```
v1 = x.^2;
v2 = 2*x.^2 + 2;
v3 = 3*x.^2 + 4;
```

Create matrix  $v$ , whose columns are the vectors,  $v1$ ,  $v2$ , and  $v3$ .

```
v = [v1 v2 v3];
```

Define a set of query points,  $xq$ , to be a finer sampling over the range of  $x$ .

```
xq = -5:0.1:5;
```

Evaluate all three functions at  $xq$  and plot the results.

```
vq = interp1(x,v,xq,'pchip');
figure
plot(x,v,'o',xq,vq);

h = gca;
h.XTick = -5:5;
```

The circles in the plot represent  $v$ , and the solid lines represent  $vq$ .

## Input Arguments

### $x$ — Sample points

vector

Sample points, specified as a row or column vector of real numbers. The values in  $x$  must be distinct. The length of  $x$  must conform to one of the following requirements:

- If  $v$  is a vector, then `length(x)` must equal `length(v)`.
- If  $v$  is an array, then `length(x)` must equal `size(v,1)`.

Example: [1 2 3 4 5 6 7 8 9 10]

Example: 1:10

Example: [3 7 11 15 19 23 27 31]'

Data Types: single | double | duration | datetime

### **v** — Sample values

vector | matrix | array

Sample values, specified as a vector, matrix, or array of real or complex numbers. If **v** is a matrix or an array, then each column contains a separate set of 1-D values.

Example: rand(1,10)

Example: rand(10,1)

Example: rand(10,3)

Data Types: single | double | duration | datetime

Complex Number Support: Yes

### **xq** — Query points

scalar | vector | matrix | array

Query points, specified as a scalar, vector, matrix, or array of real numbers.

Example: 5

Example: 1:0.05:10

Example: (1:0.05:10)'

Example: [0 1 2 7.5 10]

Data Types: single | double | duration | datetime

### **method** — Interpolation method

'linear' (default) | 'nearest' | 'next' | 'previous' | 'spline' | 'pchip' | 'cubic'

Interpolation method, specified as a string from the table below.

| method string | Description                                       | Continuity | Comments                      |
|---------------|---------------------------------------------------|------------|-------------------------------|
| 'linear'      | Linear interpolation. The interpolated value at a | $C^0$      | • Requires at least 2 points. |

| method string | Description                                                                                                                                                                                    | Continuity    | Comments                                                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
|               | query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. This is the default interpolation method.                                  |               | <ul style="list-style-type: none"> <li>Requires more memory and computation time than nearest neighbor.</li> </ul>                                  |
| 'nearest'     | Nearest neighbor interpolation. The interpolated value at a query point is the value at the nearest sample grid point.                                                                         | Discontinuous | <ul style="list-style-type: none"> <li>Requires at least 2 points.</li> <li>Modest memory requirements</li> <li>Fastest computation time</li> </ul> |
| 'next'        | Next neighbor interpolation. The interpolated value at a query point is the value at the next sample grid point.                                                                               | Discontinuous | <ul style="list-style-type: none"> <li>Requires at least 2 points.</li> <li>Same memory requirements and computation time as 'nearest'.</li> </ul>  |
| 'previous'    | Previous neighbor interpolation. The interpolated value at a query point is the value at the previous sample grid point.                                                                       | Discontinuous | <ul style="list-style-type: none"> <li>Requires at least 2 points.</li> <li>Same memory requirements and computation time as 'nearest'.</li> </ul>  |
| 'pchip'       | Shape-preserving piecewise cubic interpolation. The interpolated value at a query point is based on a shape-preserving piecewise cubic interpolation of the values at neighboring grid points. | $C^1$         | <ul style="list-style-type: none"> <li>Requires at least 4 points.</li> <li>Requires more memory and computation time than linear.</li> </ul>       |
| 'cubic'       | Same as 'pchip'.                                                                                                                                                                               | $C^1$         | This method currently returns the same result as 'pchip'. In a future release, this method will perform cubic convolution.                          |

| method string | Description                                                                                                                                                                                            | Continuity | Comments                                                                                                                                       |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 'v5cubic'     | Cubic convolution used in MATLAB 5.                                                                                                                                                                    | $C^1$      | Points must be uniformly spaced. 'cubic' will replace 'v5cubic' in a future release.                                                           |
| 'spline'      | Spline interpolation using not-a-knot end conditions. The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. | $C^2$      | <ul style="list-style-type: none"> <li>Requires at least 4 points.</li> <li>Requires more memory and computation time than 'pchip'.</li> </ul> |

### extrapolation — Extrapolation strategy

'extrap' | scalar value

Extrapolation strategy, specified as the string, 'extrap', or a real scalar value.

- Specify 'extrap' when you want `interp1` to evaluate points outside the domain using the same method it uses for interpolation.
- Specify a scalar value when you want `interp1` to return a specific constant value for points outside the domain.

The default behavior depends on the input arguments:

- If you specify the 'pchip' or 'spline' interpolation methods, then the default behavior is 'extrap'.
- All other interpolation methods return NaN by default for query points outside the domain.

Example: 'extrap'

Example: 5

Data Types: char | single | double

## Output Arguments

### **vq** — Interpolated values

scalar | vector | matrix | array

Interpolated values, returned as a scalar, vector, matrix, or array. The size of **vq** depends on the shape of **v** and **xq**.

| Shape of <b>v</b>   | Shape of <b>xq</b>  | Size of <b>Vq</b>                                                    | Example                                                                                                            |
|---------------------|---------------------|----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Vector              | Vector              | <code>size(xq)</code>                                                | If <code>size(v) = [1 100]</code> and <code>size(xq) = [1 500]</code> , then <code>size(vq) = [1 500]</code> .     |
| Vector              | Matrix or N-D Array | <code>size(xq)</code>                                                | If <code>size(v) = [1 100]</code> and <code>size(xq) = [50 30]</code> , then <code>size(vq) = [50 30]</code> .     |
| Matrix or N-D Array | Vector              | <code>[length(xq) size(v,2), ..., size(v,n)]</code>                  | If <code>size(v) = [100 3]</code> and <code>size(xq) = [1 500]</code> , then <code>size(vq) = [500 3]</code> .     |
| Matrix or N-D Array | Matrix or N-D Array | <code>[size(xq,1), ..., size(xq,m) size(v,2), ..., size(v,m)]</code> | If <code>size(v) = [4 5 6]</code> and <code>size(xq) = [2 3 7]</code> , then <code>size(vq) = [2 3 7 5 6]</code> . |

### **pp** — Piecewise polynomial

structure

Piecewise polynomial, returned as a structure that you can pass to the `ppval` function for evaluation.

## See Also

`griddedInterpolant` | `interp2` | `interp3` | `interpn`

Introduced before R2006a

# interp1q

Quick 1-D linear interpolation

---

**Note:** `interp1q` is not recommended. Use `interp1` instead.

---

## Syntax

```
yi = interp1q(x,Y,xi)
```

## Description

`yi = interp1q(x,Y,xi)` returns the value of the 1-D function `Y` at the points of column vector `xi` using linear interpolation. The vector `x` specifies the coordinates of the underlying interval. The length of output `yi` is equal to the length of `xi`.

`interp1q` is quicker than `interp1` on non-uniformly spaced data because it does no input checking.

For `interp1q` to work properly,

- `x` must be a monotonically increasing column vector.
- `Y` must be a column vector or matrix with `length(x)` rows.
- `xi` must be a column vector

`interp1q` returns NaN for any values of `xi` that lie outside the coordinates in `x`. If `Y` is a matrix, then the interpolation is performed for each column of `Y`, in which case `yi` is `length(xi)-by-size(Y,2)`.

## Examples

### Linear Interpolation Using `interp1q`

Generate a coarse sine curve and interpolate over a finer abscissa.

```
x = (0:10)';
y = sin(x);
xi = (0:.25:10)';
yi = interp1q(x,y,xi);
plot(x,y, 'o',xi,yi)
```

## See Also

[interp1](#) | [interp2](#) | [interp3](#) | [interp](#)

# interp2

Interpolation for 2-D gridded data in meshgrid format

## Compatibility

In a future release, `interp2` will not accept mixed combinations of row and column vectors for the sample and query grids. For more information, and recommendations for updating your code, see “Functionality being removed or changed”.

## Syntax

```
Vq = interp2(X,Y,V,Xq,Yq)
```

```
Vq = interp2(V,Xq,Yq)
```

```
Vq = interp2(V)
```

```
Vq = interp2(V,k)
```

```
Vq = interp2(____,method)
```

```
Vq = interp2(____,method,extrapval)
```

## Description

`Vq = interp2(X,Y,V,Xq,Yq)` returns interpolated values of a function of two variables at specific query points using linear interpolation. The results always pass through the original sampling of the function. `X` and `Y` contain the coordinates of the sample points. `V` contains the corresponding function values at each sample point. `Xq` and `Yq` contain the coordinates of the query points.

`Vq = interp2(V,Xq,Yq)` assumes a default grid of sample points. The default grid points cover the rectangular region, `X=1:n` and `Y=1:m`, where `[m,n] = size(V)`. Use this syntax to when you want to conserve memory and are not concerned about the absolute distances between points.

`Vq = interp2(V)` returns the interpolated values on a refined grid formed by dividing the interval between sample values once in each dimension.

`Vq = interp2(V,k)` returns the interpolated values on a refined grid formed by repeatedly dividing the intervals `k` times in each dimension.

`Vq = interp2( ____,method)` specifies an optional, trailing input argument that you can pass with any of the previous syntaxes. The `method` argument can be any of the following strings that specify alternative interpolation methods: `'linear'`, `'nearest'`, `'cubic'`, or `'spline'`. The default method is `'linear'`.

`Vq = interp2( ____,method,extrapval)` also specifies `extrapval`, a scalar value that is assigned to all queries that lie outside the domain of the sample points.

If you omit the `extrapval` argument for queries outside the domain of the sample points, then based on the `method` argument `interp2` returns one of the following:

- The extrapolated values for the `'spline'` method
- NaN values for interpolation methods other than `'spline'`

## Examples

### Interpolate Over a Grid Using Default Method

Coarsely sample the `peaks` function.

```
[X,Y] = meshgrid(-3:3);
V = peaks(X,Y);
```

Plot the coarse sampling.

```
figure
surf(X,Y,V)
title('Original Sampling');
```

Create the query grid with spacing of 0.25.

```
[Xq,Yq] = meshgrid(-3:0.25:3);
```

Interpolate at the query points.

```
Vq = interp2(X,Y,V,Xq,Yq);
```

Plot the result.

```
figure
surf(Xq,Yq,Vq);
title('Linear Interpolation Using Finer Grid');
```

### Interpolate Over a Grid Using Cubic Method

Coarsely sample the peaks function.

```
[X,Y] = meshgrid(-3:3);
V = peaks(7);
```

Plot the coarse sampling.

```
figure
surf(X,Y,V)
title('Original Sampling');
```

Create the query grid with spacing of 0.25.

```
[Xq,Yq] = meshgrid(-3:0.25:3);
```

Interpolate at the query points, and specify cubic interpolation.

```
Vq = interp2(X,Y,V,Xq,Yq,'cubic');
```

Plot the result.

```
figure
surf(Xq,Yq,Vq);
title('Cubic Interpolation Over Finer Grid');
```

### Refine Grayscale Image

Load some image data into the workspace.

```
load clown
```

Isolate a small region of the image and cast it to single.

```
V = single(X(1:124,75:225));
```

Display the image.

```
figure
imagesc(V);
```

```
colormap gray
axis image
axis off
title('Original Image');
```

Insert interpolated values by repeatedly dividing the intervals between points of the refined grid five times in each dimension.

```
Vq = interp2(V,5);
```

Display the result.

```
figure
```

```
imagesc(Vq);
colormap gray
axis image
axis off
title('Linear Interpolation');
```

**Linear Interpolation**

**Evaluate Outside the Domain of X and Y**

Coarsely sample a function over the range, [-2, 2] in both dimensions.

```
[X,Y] = meshgrid(-2:0.75:2);
R = sqrt(X.^2 + Y.^2)+ eps;
V = sin(R)./(R);
```

Plot the coarse sampling.

```
figure
surf(X,Y,V)
xlim([-4 4])
ylim([-4 4])
title('Original Sampling')
```

Create the query grid that extends beyond the domain of X and Y.

```
[Xq,Yq] = meshgrid(-3:0.2:3);
```

Perform cubic interpolation within the domain of X and Y, and assign all queries that fall outside to zero.

```
Vq = interp2(X,Y,V,Xq,Yq,'cubic',0);
```

Plot the result.

```
figure
surf(Xq,Yq,Vq)
title('Cubic Interpolation with Vq=0 Outside Domain of X and Y');
```

## Input Arguments

**X, Y** — Sample grid points  
matrices | vectors

Sample grid points, specified as real matrices or vectors.

- If  $X$  and  $Y$  are matrices, then they contain the coordinates of a full grid (in `meshgrid` format). Use the `meshgrid` function to create the  $X$  and  $Y$  matrices together. Both matrices must be the same size.
- If  $X$  and  $Y$  are vectors, then they are treated as a grid vectors. The values in both vectors must be strictly monotonic and increasing.

Example: `[X,Y] = meshgrid(1:30,-10:10)`

Data Types: `single` | `double`

### **V — Sample values**

matrix

Sample values, specified as a real or complex matrix. The size requirements for  $V$  depend on the size of  $X$  and  $Y$ .

- If  $X$  and  $Y$  are matrices representing a full grid (in `meshgrid` format), then  $V$  must be the same size as  $X$  and  $Y$ .
- If  $X$  and  $Y$  are grid vectors, then  $V$  must be a matrix containing `length(Y)` rows and `length(X)` columns.

Example: `rand(10,10)`

Data Types: `single` | `double`

Complex Number Support: Yes

### **Xq, Yq — Query points**

scalars | vectors | matrices | arrays

Query points, specified as a real scalars, vectors, matrices, or arrays.

- If  $Xq$  and  $Yq$  are scalars, then they are the coordinates of a single query point.
- If  $Xq$  and  $Yq$  are vectors of different orientations, then  $Xq$  and  $Yq$  are treated as grid vectors.
- If  $Xq$  and  $Yq$  are vectors of the same size and orientation, then  $Xq$  and  $Yq$  are treated as scattered points in 2-D space.
- If  $Xq$  and  $Yq$  are matrices, then they represent either a full grid of query points (in `meshgrid` format) or scattered points.

- If  $Xq$  and  $Yq$  are N-D arrays, then they represent scattered points in 2-D space.

Example: `[Xq,Yq] = meshgrid((1:0.1:10),(-5:0.1:0))`

Data Types: `single` | `double`

### **k** — Refinement factor

1 (default) | real, nonnegative, integer scalar

Refinement factor, specified as a real, nonnegative, integer scalar. This value specifies the number of times to repeatedly divide the intervals of the refined grid in each dimension. This results in  $2^k - 1$  interpolated points between sample values.

If  $k$  is 0, then  $Vq$  is the same as  $V$ .

`interp2(V,1)` is the same as `interp2(V)`.

The following illustration shows the placement of interpolated values (in red) among nine sample values (in black) for  $k=2$ .

Example: `interp2(V,2)`

Data Types: `single` | `double`

### **method** — Interpolation method

'linear' (default) | 'nearest' | 'cubic' | 'spline'

Interpolation method, specified as a string from this table.

| Method    | Description                                                                                                                                                                                                                    | Continuity    | Comments                                                                                                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'linear'  | The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. This is the default interpolation method.                                      | $C^0$         | <ul style="list-style-type: none"> <li>Requires at least two grid points in each dimension</li> <li>Requires more memory than 'nearest'</li> </ul>                                                                                                                                            |
| 'nearest' | The interpolated value at a query point is the value at the nearest sample grid point.                                                                                                                                         | Discontinuous | <ul style="list-style-type: none"> <li>Requires two grid points in each dimension.</li> <li>Fastest computation with modest memory requirements</li> </ul>                                                                                                                                    |
| 'cubic'   | The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic convolution.                            | $C^1$         | <ul style="list-style-type: none"> <li>Grid must have uniform spacing in each dimension, but the spacing does not have to be the same for all dimensions</li> <li>Requires at least four points in each dimension</li> <li>Requires more memory and computation time than 'linear'</li> </ul> |
| 'spline'  | The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic spline using not-a-knot end conditions. | $C^2$         | <ul style="list-style-type: none"> <li>Requires four points in each dimension</li> <li>Requires more memory and computation time than 'cubic'</li> </ul>                                                                                                                                      |

### extrapval — Function value outside domain of X and Y

scalar

Function value outside domain of X and Y, specified as a real or complex scalar. `interp2` returns this constant value for all points outside the domain of X and Y.

Example: 5

Example: 5+1i

Data Types: single | double

Complex Number Support: Yes

## Output Arguments

### Vq — Interpolated values

scalar | vector | matrix

Interpolated values, returned as a real or complex scalar, vector, or matrix. The size and shape of Vq depends on the syntax you use and, in some cases, the size and value of the input arguments.

| Syntaxes                                                                                                      | Special Conditions                                  | Size of Vq                                                                                | Example                                                                |
|---------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|-------------------------------------------------------------------------------------------|------------------------------------------------------------------------|
| interp2(X,Y,V,Xq,Yq)<br>interp2(V,Xq,Yq)<br>and variations of these syntaxes that include method or extrapval | Xq, Yq are scalars                                  | Scalar                                                                                    | size(Vq) = [1 1] when you pass Xq and Yq as scalars.                   |
| Same as above                                                                                                 | Xq, Yq are vectors of the same size and orientation | Vector of same size and orientation as Xq and Yq                                          | If size(Xq) = [100 1] and size(Yq) = [100 1], then size(Vq) = [100 1]. |
| Same as above                                                                                                 | Xq, Yq are vectors of mixed orientation             | Matrix in which the number of rows is length(Yq), and the number of columns is length(Xq) | If size(Xq) = [1 100] and size(Yq) = [50 1], then size(Vq) = [50 100]. |
| Same as above                                                                                                 | Xq, Yq are matrices or arrays of the same size      | Matrix or array of the same size as Xq and Yq                                             | If size(Xq) = [50 25] and size(Yq) = [50 25], then size(Vq) = [50 25]. |

## More About

### Strictly Monotonic

A set of values that are always increasing or decreasing, without reversals. For example, the sequence,  $a = [2 \ 4 \ 6 \ 8]$  is strictly monotonic and increasing. The sequence,  $b = [2 \ 4 \ 4 \ 6 \ 8]$  is not strictly monotonic because there is no change in value between  $b(2)$  and  $b(3)$ . The sequence,  $c = [2 \ 4 \ 6 \ 8 \ 6]$  contains a reversal between  $c(4)$  and  $c(5)$ , so it is not monotonic at all.

### Full Grid (in meshgrid Format)

For `interp2`, the full grid is a pair of matrices whose elements represent a grid of points over a rectangular region. One matrix contains the  $x$ -coordinates, and the other matrix contains the  $y$ -coordinates. The values in the  $x$ -matrix are strictly monotonic and increasing along the rows. The values along its columns are constant. The values in the  $y$ -matrix are strictly monotonic and increasing along the columns. The values along its rows are constant. Use the `meshgrid` function to create a full grid that you can pass to `interp2`.

For example, the following code creates a full grid for the region,  $-1 \leq x \leq 3$  and  $1 \leq y \leq 4$ :

```
[X,Y] = meshgrid(-1:3,(1:4))
```

X =

```
-1 0 1 2 3
-1 0 1 2 3
-1 0 1 2 3
```

```
 -1 0 1 2 3
Y =
 1 1 1 1 1
 2 2 2 2 2
 3 3 3 3 3
 4 4 4 4 4
```

## Grid Vectors

For `interp2`, grid vectors consist of a pair of mixed-orientation vectors that define the  $x$ - and  $y$ -coordinates in a grid. One vector is a row vector, and the other is a column vector.

For example, the following code creates the grid vectors that specify the region,  $-1 \leq x \leq 3$  and  $1 \leq y \leq 4$ :

```
x = -1:3;
y = (1:4)';
```

## Scattered Points

For `interp2`, scattered points consist of a pair of arrays that define a collection of points scattered in 2-D space. One array contains the  $x$ -coordinates, and the other contains the  $y$ -coordinates.

For example, the following code specifies the points, (2,7), (5,3), (4,1), and (10,9):

```
x = [2 5; 4 10];
y = [7 3; 1 9];
```

**Introduced before R2006a**

# interp3

Interpolation for 3-D gridded data in meshgrid format

## Compatibility

In a future release, `interp3` will not accept mixed combinations of row and column vectors for the sample and query grids. For more information, and recommendations for updating your code, see “Functionality being removed or changed”.

## Syntax

```
Vq = interp3(X,Y,Z,V,Xq,Yq,Zq)
```

```
Vq = interp3(V,Xq,Yq,Zq)
```

```
Vq = interp3(V)
```

```
Vq = interp3(V,k)
```

```
Vq = interp3(____,method)
```

```
Vq = interp3(____,method,extrapval)
```

## Description

`Vq = interp3(X,Y,Z,V,Xq,Yq,Zq)` returns interpolated values of a function of three variables at specific query points using linear interpolation. The results always pass through the original sampling of the function. `X`, `Y`, and `Z` contain the coordinates of the sample points. `V` contains the corresponding function values at each sample point. `Xq`, `Yq`, and `Zq` contain the coordinates of the query points.

`Vq = interp3(V,Xq,Yq,Zq)` assumes a default grid of sample points. The default grid points cover the region, `X=1:n`, `Y=1:m`, `Z=1:p`, where `[m,n,p] = size(V)`. Use this syntax when you want to conserve memory and are not concerned about the absolute distances between points.

`Vq = interp3(V)` returns the interpolated values on a refined grid formed by dividing the interval between sample values once in each dimension.

`Vq = interp3(V,k)` returns the interpolated values on a refined grid formed by repeatedly dividing the intervals `k` times in each dimension.

`Vq = interp3( ____,method)` specifies an optional, trailing input argument that you can pass with any of the previous syntaxes. The `method` argument can be any of the following strings that specify alternative interpolation methods: `'linear'`, `'nearest'`, `'cubic'`, or `'spline'`. The default method is `'linear'`.

`Vq = interp3( ____,method,extrapval)` also specifies `extrapval`, a scalar value that is assigned to all queries that lie outside the domain of the sample points.

If you omit the `extrapval` argument for queries outside the domain of the sample points, then based on the `method` argument `interp3` returns one of the following:

- The extrapolated values for the `'spline'` method
- NaN values for interpolation methods other than `'spline'`

## Examples

### Interpolate Using Default Method

Load the points and values of the flow function, sampled at 10 points in each dimension.

```
[X,Y,Z,V] = flow(10);
```

The `flow` function returns the grid in the arrays, `X`, `Y`, `Z`. The grid covers the region,  $0.1 \leq X \leq 10$ ,  $-3 \leq Y \leq 3$ ,  $-3 \leq Z \leq 3$ , and the spacing is  $\Delta X = 0.5$ ,  $\Delta Y = 0.7$ , and  $\Delta Z = 0.7$ .

Now, plot slices through the volume of the sample at: `X=6`, `X=9`, `Y=2`, and `Z=0`.

```
figure
slice(X,Y,Z,V,[6 9],2,0);
shading flat
```

Create a query grid with spacing of 0.25.

```
[Xq,Yq,Zq] = meshgrid(.1:.25:10, -3:.25:3, -3:.25:3);
```

Interpolate at the points in the query grid and plot the results using the same slice planes.

```
Vq = interp3(X,Y,Z,V,Xq,Yq,Zq);
figure
slice(Xq,Yq,Zq,Vq,[6 9],2,0);
shading flat
```

### Interpolate Using Cubic Method

Load the points and values of the flow function, sampled at 10 points in each dimension.

```
[X,Y,Z,V] = flow(10);
```

The `flow` function returns the grid in the arrays, `X`, `Y`, `Z`. The grid covers the region,  $0.1 \leq X \leq 10$ ,  $-3 \leq Y \leq 3$ ,  $-3 \leq Z \leq 3$ , and the spacing is  $\Delta X = 0.5$ ,  $\Delta Y = 0.7$ , and  $\Delta Z = 0.7$ .

Plot slices through the volume of the sample at: `X=6`, `X=9`, `Y=2`, and `Z =0`.

`figure`

```
slice(X,Y,Z,V,[6 9],2,0);
shading flat
```

Create a query grid with spacing of 0.25.

```
[Xq,Yq,Zq] = meshgrid(.1:.25:10,-3:.25:3,-3:.25:3);
```

Interpolate at the points in the query grid using the 'cubic' interpolation method. Then plot the results.

```
Vq = interp3(X,Y,Z,V,Xq,Yq,Zq,'cubic');
figure
slice(Xq,Yq,Zq,Vq,[6 9],2,0);
```

shading flat

### Evaluate Outside the Domain of X, Y, and Z

Create the grid vectors,  $x$ ,  $y$ , and  $z$ . These vectors define the points associated with values in  $V$ .

```
x = 1:100;
y = (1:50)';
z = 1:30;
```

Define the sample values to be a 50-by-100-by-30 random number array,  $V$ . Use the `gallery` function to create the array.

```
V = gallery('uniformdata',50,100,30,0);
```

Evaluate  $V$  at three points outside the domain of  $x$ ,  $y$ , and  $z$ . Specify `extrapval = -1`.

```
xq = [0 0 0];
yq = [0 0 51];
zq = [0 101 102];
vq = interp3(x,y,z,V,xq,yq,zq,'linear',-1)
```

```
vq =
```

```
 -1 -1 -1
```

All three points evaluate to  $-1$  because they are outside the domain of  $x$ ,  $y$ , and  $z$ .

## Input Arguments

### **X, Y, Z** — Sample grid points

arrays | vectors

Sample grid points, specified as real arrays or vectors.

- If  $X$ ,  $Y$ , and  $Z$  are arrays, then they contain the coordinates of a full grid (in `meshgrid` format). Use the `meshgrid` function to create the  $X$ ,  $Y$ , and  $Z$  arrays together. These arrays must be the same size.
- If  $X$ ,  $Y$ , and  $Z$  are vectors, then they are treated as a grid vectors. The values in these vectors must be strictly monotonic and increasing.

Example: `[X,Y,Z] = meshgrid(1:30,-10:10,1:5)`

Data Types: `single` | `double`

### **V** — Sample values

array

Sample values, specified as a real or complex array. The size requirements for  $V$  depend on the size of  $X$ ,  $Y$ , and  $Z$ .

- If  $X$ ,  $Y$ , and  $Z$  are arrays representing a full grid (in `meshgrid` format), then the size of  $V$  matches the size of  $X$ ,  $Y$ , or  $Z$ .

- If  $X$ ,  $Y$ , and  $Z$  are grid vectors, then `size(V) = [length(Y) length(X) length(Z)]`.

Example: `rand(10,10,10)`

Data Types: `single` | `double`

Complex Number Support: Yes

### **Xq, Yq, Zq — Query points**

scalars | vectors | arrays

Query points, specified as a real scalars, vectors, or arrays.

- If  $Xq$ ,  $Yq$ , and  $Zq$  are scalars, then they are the coordinates of a single query point in  $R^3$ .
- If  $Xq$ ,  $Yq$ , and  $Zq$  are vectors of different orientations, then  $Xq$ ,  $Yq$ , and  $Zq$  are treated as grid vectors in  $R^3$ .
- If  $Xq$ ,  $Yq$ , and  $Zq$  are vectors of the same size and orientation, then  $Xq$ ,  $Yq$ , and  $Zq$  are treated as scattered points in  $R^3$ .
- If  $Xq$ ,  $Yq$ , and  $Zq$  are arrays of the same size, then they represent either a full grid of query points (in `meshgrid` format) or scattered points in  $R^3$ .

Example: `[Xq,Yq,Zq] = meshgrid((1:0.1:10),(-5:0.1:0),3:5)`

Data Types: `single` | `double`

### **k — Refinement factor**

1 (default) | real, nonnegative, integer scalar

Refinement factor, specified as a real, nonnegative, integer scalar. This value specifies the number of times to repeatedly divide the intervals of the refined grid in each dimension. This results in  $2^k - 1$  interpolated points between sample values.

If  $k$  is 0, then  $Vq$  is the same as  $V$ .

`interp3(V,1)` is the same as `interp3(V)`.

The following illustration depicts  $k=2$  in one plane of  $R^3$ . There are 72 interpolated values in red and 9 sample values in black.

Example: `interp3(V,2)`

Data Types: `single` | `double`

**method – Interpolation method**

`'linear'` (default) | `'nearest'` | `'cubic'` | `'spline'`

Interpolation method, specified as a string from this table.

| Method                 | Description                                                                                                                                                                               | Continuity    | Comments                                                                                                                                                        |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'linear'</code>  | The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. This is the default interpolation method. | $C^0$         | <ul style="list-style-type: none"> <li>Requires at least two grid points in each dimension</li> <li>Requires more memory than <code>'nearest'</code></li> </ul> |
| <code>'nearest'</code> | The interpolated value at a query point is the value at the nearest sample grid point.                                                                                                    | Discontinuous | <ul style="list-style-type: none"> <li>Requires two grid points in each dimension</li> <li>Fastest computation with modest memory requirements</li> </ul>       |

**extrapval** — Function value outside domain of X, Y, and Z

scalar

Function value outside domain of X, Y, and Z, specified as a real or complex scalar. `interp3` returns this constant value for all points outside the domain of X, Y, and Z.

Example: 5

Example: 5+1i

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

**Vq** — Interpolated values

scalar | vector | array

Interpolated values, returned as a real or complex scalar, vector, or array. The size and shape of Vq depends on the syntax you use and, in some cases, the size and value of the input arguments.

| Syntaxes                                                                                                                 | Special Conditions                                                       | Size of Vq                                                                          | Example                                                                                                           |

## More About

### Strictly Monotonic

A set of values that are always increasing or decreasing, without reversals. For example, the sequence,  $a = [2\ 4\ 6\ 8]$  is strictly monotonic and increasing. The sequence,  $b$

= [2 4 4 6 8] is not strictly monotonic because there is no change in value between  $b(2)$  and  $b(3)$ . The sequence,  $c = [2 4 6 8 6]$  contains a reversal between  $c(4)$  and  $c(5)$ , so it is not monotonic at all.

### **Full Grid (in meshgrid Format)**

For `interp3`, a full grid consists of three arrays whose elements represent a grid of points that define a region in  $R^3$ . The first array contains the  $x$ -coordinates, the second array contains the  $y$ -coordinates, and the third array contains the  $z$ -coordinates. The values in each array vary along a single dimension and are constant along the other dimensions.

The values in the  $x$ -array are strictly monotonic, increasing, and vary along the second dimension. The values in the  $y$ -array are strictly monotonic, increasing, and vary along the first dimension. The values in the  $z$ -array are strictly monotonic, increasing, and vary along the third dimension. Use the `meshgrid` function to create a full grid that you can pass to `interp3`.

### **Grid Vectors**

For `interp3`, grid vectors consist of three vectors of mixed-orientation that define the points on a grid in  $R^3$ .

For example, the following code creates the grid vectors for the region,  $1 \leq x \leq 3$ ,  $4 \leq y \leq 5$ , and  $6 \leq z \leq 8$ :

```
x = 1:3;
y = (4:5)';
z = 6:8;
```

### **Scattered Points**

For `interp3`, scattered points consist of three arrays or vectors,  $Xq$ ,  $Yq$ , and  $Zq$ , that define a collection of points scattered in  $R^3$ . The  $i$ th array contains the coordinates in the  $i$ th dimension.

For example, the following code specifies the points, (1, 19, 10), (6, 40, 1), (15, 33, 22), and (0, 61, 13).

```
Xq = [1 6; 15 0];
Yq = [19 40; 33 61];
Zq = [10 1; 22 13];
```

## interpft

1-D interpolation using FFT method

### Syntax

```
y = interpft(x,n)
y = interpft(x,n,dim)
```

### Description

`y = interpft(x,n)` returns the vector `y` that contains the value of the periodic function `x` resampled to `n` equally spaced points.

If `length(x) = m`, and `x` has sample interval `dx`, then the new sample interval for `y` is `dy = dx*m/n`. Note that `n` cannot be smaller than `m`.

If `X` is a matrix, `interpft` operates on the columns of `X`, returning a matrix `Y` with the same number of columns as `X`, but with `n` rows.

`y = interpft(x,n,dim)` operates along the specified dimension.

### Examples

Interpolate a triangle-like signal using an interpolation factor of 5. First, set up signal to be interpolated:

```
y = [0 .5 1 1.5 2 1.5 1 .5 0 -.5 -1 -1.5 -2 -1.5 -1 -.5 0];
N = length(y);
```

Perform the interpolation:

```
L = 5;
M = N*L;
x = 0:L:L*N-1;
xi = 0:M-1;
yi = interpft(y,M);
```

```
plot(x,y,'o',xi,yi,'*')
legend('Original data','Interpolated data')
```

## More About

### Algorithms

The `interpft` command uses the FFT method. The original vector `x` is transformed to the Fourier domain using `fft` and then transformed back with more points.

### See Also

`interp1`

**Introduced before R2006a**

## interp

Interpolation for 1-D, 2-D, 3-D, and N-D gridded data in ndgrid format

### Compatibility

In a future release, `interp` will not accept mixed combinations of row and column vectors for the sample and query grids. For more information, and recommendations for updating your code, see “Functionality being removed or changed”.

### Syntax

```
Vq = interp(X1,X2,...,Xn,V,Xq1,Xq2,...,Xqn)
```

```
Vq = interp(V,Xq1,Xq2,...,Xqn)
```

```
Vq = interp(V)
```

```
Vq = interp(V,k)
```

```
Vq = interp(____,method)
```

```
Vq = interp(____,method,extrapval)
```

### Description

`Vq = interp(X1,X2,...,Xn,V,Xq1,Xq2,...,Xqn)` returns interpolated values of a function of  $n$  variables at specific query points using linear interpolation. The results always pass through the original sampling of the function.  $X1, X2, \dots, Xn$  contain the coordinates of the sample points.  $V$  contains the corresponding function values at each sample point.  $Xq1, Xq2, \dots, Xqn$  contain the coordinates of the query points.

`Vq = interp(V,Xq1,Xq2,...,Xqn)` assumes a default grid of sample points. The default grid consists of the points,  $1, 2, 3, \dots, n_i$  in each dimension. The value of  $n_i$  is the length of the  $i$ th dimension in  $V$ . Use this syntax to when you want to conserve memory and are not concerned about the absolute distances between points.

`Vq = interp(V)` returns the interpolated values on a refined grid formed by dividing the interval between sample values once in each dimension.

`Vq = interpn(V,k)` returns the interpolated values on a refined grid formed by repeatedly dividing the intervals `k` times in each dimension.

`Vq = interpn( ____,method)` specifies an optional, trailing input argument that you can pass with any of the previous syntaxes. The `method` argument can be any of the following strings that specify alternative interpolation methods: `'linear'`, `'nearest'`, `'pchip'`, `'cubic'`, or `'spline'`. The default method is `'linear'`.

`Vq = interpn( ____,method,extrapval)` also specifies `extrapval`, a scalar value that is assigned to all queries that lie outside the domain of the sample points.

If you omit the `extrapval` argument for queries outside the domain of the sample points, then based on the `method` argument `interp` returns one of the following:

- The extrapolated values for the `'spline'` method
- NaN values for interpolation methods other than `'spline'`

## Examples

### 1-D Interpolation

Define the sample points and values.

```
x = [1 2 3 4 5];
v = [12 16 31 10 6];
```

Define the query points, `xq`, and interpolate.

```
xq = (1:0.1:5);
vq = interpn(x,v,xq,'cubic');
```

Plot the result.

```
figure
plot(x,v,'o',xq,vq,'-');
legend('Samples','Cubic Interpolation');
```

## 2-D Interpolation

Create a set of grid points and corresponding sample values.

```
[X1,X2] = ndgrid((-5:1:5));
R = sqrt(X1.^2 + X2.^2)+ eps;
V = sin(R)./(R);
```

Interpolate over a finer grid using `ntimes=1`.

```
Vq = interpn(V, 'cubic');
mesh(Vq);
```

### Evaluate Outside Domain of 3-D Function

Create the grid vectors, `x1`, `x2`, and `x3`. These vectors define the points associated with the values in `V`.

```
x1 = 1:100;
x2 = (1:50)';
x3 = 1:30;
```

Define the sample values to be a 100-by-50-by-30 random number array, `V`. Use the `gallery` function to create the array.

```
V = gallery('uniformdata',100,50,30,0);
```

Evaluate  $V$  at three points outside the domain of  $x_1$ ,  $x_2$ , and  $x_3$ . Specify `extrapval = -1`.

```
xq1 = [0 0 0];
xq2 = [0 0 51];
xq3 = [0 101 102];
vq = interpn(x1,x2,x3,V,xq1,xq2,xq3,'linear',-1)
```

```
vq =
 -1 -1 -1
```

All three points evaluate to  $-1$  because they are outside the domain of  $x_1$ ,  $x_2$ , and  $x_3$ .

## 4-D Interpolation

Define an anonymous function that represents  $f = te^{-x^2-y^2-z^2}$ .

```
f = @(x,y,z,t) t.*exp(-x.^2 - y.^2 - z.^2);
```

Create a grid of points in  $R^4$ . Then, pass the points through the function to create the sample values,  $V$ .

```
[x,y,z,t] = ndgrid(-1:0.2:1,-1:0.2:1,-1:0.2:1,0:2:10);
V = f(x,y,z,t);
```

Now, create the query grid.

```
[xq,yq,zq,tq] = ...
ndgrid(-1:0.05:1,-1:0.08:1,-1:0.05:1,0:0.5:10);
```

Interpolate  $V$  at the query points.

```
Vq = interpn(x,y,z,t,V,xq,yq,zq,tq);
```

Create a movie to show the results.

```
figure('renderer','zbuffer');
nframes = size(tq, 4);
for j = 1:nframes
 slice(yq(:,:,j),xq(:,:,j),zq(:,:,j),...)
```

```
 Vq(:,:,j),0,0,0);
 caxis([0 10]);
 M(j) = getframe;
end
movie(M);
```

## Input Arguments

**$X_1, X_2, \dots, X_n$**  — Sample grid points  
arrays | vectors

Sample grid points, specified as real arrays or vectors.

- If  $X_1, X_2, \dots, X_n$  are arrays, then they contain the coordinates of a full grid (in `ndgrid` format). Use the `ndgrid` function to create the  $X_1, X_2, \dots, X_n$  arrays together. These arrays must be the same size.
- If  $X_1, X_2, \dots, X_n$  are vectors, then they are treated as grid vectors. The values in these vectors must be strictly monotonic and increasing.

Example: `[X1,X2,X3] = ndgrid(1:30,-10:10,1:5)`

Data Types: `single` | `double`

### **V — Sample values**

array

Sample values, specified as a real or complex array. The size requirements for  $V$  depend on the size of  $X_1, X_2, \dots, X_n$ .

- If  $X_1, X_2, \dots, X_n$  are arrays representing a full grid (in `ndgrid` format), then the size of  $V$  matches the size of any array,  $X_1, X_2, \dots, X_n$ .
- If  $X_1, X_2, \dots, X_n$  are grid vectors, then  $V$  is an array whose  $i$ th dimension is the same length as grid vector  $X_i$ , where  $i = 1, 2, \dots, n$ .

Example: `rand(10,5,3,2)`

Data Types: `single` | `double`

Complex Number Support: Yes

### **Xq1, Xq2, ..., Xqn — Query points**

scalars | vectors | arrays

Query points, specified as a real scalars, vectors, or arrays.

- If  $X_{q1}, X_{q2}, \dots, X_{qn}$  are scalars, then they are the coordinates of a single query point in  $R^n$ .
- If  $X_{q1}, X_{q2}, \dots, X_{qn}$  are vectors of different orientations, then  $X_{q1}, X_{q2}, \dots, X_{qn}$  are treated as grid vectors in  $R^n$ .
- If  $X_{q1}, X_{q2}, \dots, X_{qn}$  are vectors of the same size and orientation, then  $X_{q1}, X_{q2}, \dots, X_{qn}$  are treated as scattered points in  $R^n$ .
- If  $X_{q1}, X_{q2}, \dots, X_{qn}$  are arrays of the same size, then they represent either a full grid of query points (in `ndgrid` format) or scattered points in  $R^n$ .

Example: `[X1,X2,X3,X4] = ndgrid(1:10,1:5,7:9,10:11)`

Data Types: `single` | `double`

### **k** — Refinement factor

1 (default) | real, nonnegative, integer scalar

Refinement factor, specified as a real, nonnegative, integer scalar. This value specifies the number of times to repeatedly divide the intervals of the refined grid in each dimension. This results in  $2^k - 1$  interpolated points between sample values.

If  $k$  is 0, then  $V_q$  is the same as  $V$ .

`interpn(V,1)` is the same as `interpn(V)`.

The following illustration depicts  $k=2$  in  $R^2$ . There are 72 interpolated values in red and 9 sample values in black.

Example: `interpn(V,2)`

Data Types: `single` | `double`

### **method** — Interpolation method

'linear' (default) | 'nearest' | 'pchip' | 'cubic' | 'spline'

Interpolation method, specified as a string from this table.

| Method    | Description                                                                                                                                                                                                   | Continuity    | Comments                                                                                                                                                                                                                                                                                            |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'linear'  | The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. This is the default interpolation method.                     | $C^0$         | <ul style="list-style-type: none"> <li>• Requires at least two grid points in each dimension</li> <li>• Requires more memory than 'nearest'</li> </ul>                                                                                                                                              |
| 'nearest' | The interpolated value at a query point is the value at the nearest sample grid point.                                                                                                                        | Discontinuous | <ul style="list-style-type: none"> <li>• Requires two grid points in each dimension.</li> <li>• Fastest computation with modest memory requirements</li> </ul>                                                                                                                                      |
| 'pchip'   | Shape-preserving piecewise cubic interpolation (for 1-D only). The interpolated value at a query point is based on a shape-preserving piecewise cubic interpolation of the values at neighboring grid points. | $C^1$         | <ul style="list-style-type: none"> <li>• Requires at least four points</li> <li>• Requires more memory and computation time than 'linear'</li> </ul>                                                                                                                                                |
| 'cubic'   | The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic convolution.           | $C^1$         | <ul style="list-style-type: none"> <li>• Grid must have uniform spacing in each dimension, but the spacing does not have to be the same for all dimensions</li> <li>• Requires at least four points in each dimension</li> <li>• Requires more memory and computation time than 'linear'</li> </ul> |
| 'spline'  | The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic                        | $C^2$         | <ul style="list-style-type: none"> <li>• Requires four points in each dimension</li> <li>• Requires more memory and computation time than 'cubic'</li> </ul>                                                                                                                                        |

| Method | Description                             | Continuity | Comments |
|--------|-----------------------------------------|------------|----------|
|        | spline using not-a-knot end conditions. |            |          |

### **extrapval** — Function value outside domain of $X_1, X_2, \dots, X_n$

scalar

Function value outside domain of  $X_1, X_2, \dots, X_n$ , specified as a real or complex scalar. **interpn** returns this constant value for all points outside the domain of  $X_1, X_2, \dots, X_n$ .

Example: 5

Example:  $5+1i$

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Vq** — Interpolated values

scalar | vector | array

Interpolated values, returned as a real or complex scalar, vector, or array. The size and shape of **Vq** depends on the syntax you use and, in some cases, the size and value of the input arguments.

| Syntaxes                                                                                                                                                                         | Special Conditions                                                   | Size of <b>Vq</b>                                              | Example                                                                                                                     |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>interpn(X1, ..., Xn, V, X)</code><br><code>interpn(V, Xq1, ..., Xqn)</code><br>and variations of these syntaxes that include <code>method</code> or <code>extrapval</code> | $X_{q1}, \dots, X_{qn}$ are scalars                                  | Scalar                                                         | <code>size(Vq) = [1 1]</code> when you pass $X_{q1}, \dots, X_{qn}$ as scalars.                                             |

## More About

### Strictly Monotonic

A set of values that are always increasing or decreasing, without reversals. For example, the sequence,  $a = [2\ 4\ 6\ 8]$  is strictly monotonic and increasing. The sequence,  $b = [2\ 4\ 4\ 6\ 8]$  is not strictly monotonic because there is no change in value between  $b(2)$  and  $b(3)$ . The sequence,  $c = [2\ 4\ 6\ 8\ 6]$  contains a reversal between  $c(4)$  and  $c(5)$ , so it is not monotonic at all.

### Full Grid (in ndgrid Format)

For `interpn`, the full grid consists of  $n$  arrays,  $X_1, X_2, \dots, X_n$ , whose elements represent a grid of points in  $R^n$ . The  $i$ th array,  $X_i$ , contains strictly monotonic, increasing values that vary most rapidly along the  $i$ th dimension.

Use the `ndgrid` function to create a full grid that you can pass to `interpn`. For example, the following code creates a full grid in  $R^2$  for the region,  $1 \leq X_1 \leq 3$ ,  $1 \leq X_2 \leq 4$ .

```
[X1,X2] = ndgrid(-1:3,(1:4))
```

$X_1 =$

```
-1 -1 -1 -1
 0 0 0 0
 1 1 1 1
 2 2 2 2
 3 3 3 3
```

$X_2 =$

```
1 2 3 4
1 2 3 4
1 2 3 4
1 2 3 4
1 2 3 4
```

### Grid Vectors

For `interpn`, grid vectors consist of  $n$  vectors of mixed-orientation that define the points of a grid in  $R^n$ .

For example, the following code creates the grid vectors in  $R^3$  for the region,  $1 \leq x_1 \leq 3$ ,  $4 \leq x_2 \leq 5$ , and  $6 \leq x_3 \leq 8$ :

```
x1 = 1:3;
x2 = (4:5)';
x3 = 6:8;
```

**Scattered Points**

For `interpn`, scattered points consist of  $n$  arrays or vectors,  $Xq_1, Xq_2, \dots, Xq_n$ , that define a collection of points scattered in  $R^n$ . The  $i$ th array,  $X_i$ , contains the coordinates in the  $i$ th dimension.

For example, the following code specifies the points, (1, 19, 10), (6, 40, 1), (15, 33, 22), and (0, 61, 13) in  $R^3$ .

```
Xq1 = [1 6; 15 0];
Xq2 = [19 40; 33 61];
Xq3 = [10 1; 22 13];
```

# interpstreamspeed

Interpolate stream-line vertices from flow speed

## Syntax

```
interpstreamspeed(X,Y,Z,U,V,W,vertices)
interpstreamspeed(U,V,W,vertices)
interpstreamspeed(X,Y,Z,speed,vertices)
interpstreamspeed(speed,vertices)
interpstreamspeed(X,Y,U,V,vertices)
interpstreamspeed(U,V,vertices)
interpstreamspeed(X,Y,speed,vertices)
interpstreamspeed(speed,vertices)
interpstreamspeed(...,sf)
vertsout = interpstreamspeed(...)
```

## Description

`interpstreamspeed(X,Y,Z,U,V,W,vertices)` interpolates streamline vertices based on the magnitude of the vector data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`interpstreamspeed(U,V,W,vertices)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(U)`.

`interpstreamspeed(X,Y,Z,speed,vertices)` uses the 3-D array `speed` for the speed of the vector field.

`interpstreamspeed(speed,vertices)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p]=size(speed)`.

`interpstreamspeed(X,Y,U,V,vertices)` interpolates streamline vertices based on the magnitude of the vector data `U, V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`interpstreamspeed(U,V,vertices)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[M N]=size(U)`.

`interpstreamspeed(X,Y,speed,vertices)` uses the 2-D array `speed` for the speed of the vector field.

`interpstreamspeed(speed,vertices)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[M,N]= size(speed)`.

`interpstreamspeed(...,sf)` uses `sf` to scale the magnitude of the vector data and therefore controls the number of interpolated vertices. For example, if `sf` is 3, then `interpstreamspeed` creates only one-third of the vertices.

`vertsout = interpstreamspeed(...)` returns a cell array of vertex arrays.

## Examples

This example draws streamlines using the vertices returned by `interpstreamspeed`. Dot markers indicate the location of each vertex. This example enables you to visualize the relative speeds of the flow data. Streamlines having widely spaced vertices indicate faster flow; those with closely spaced vertices indicate slower flow.

```
load wind
```

```

[sx sy sz] = meshgrid(80,20:1:55,5);
verts = stream3(x,y,z,u,v,w,sx, sy, sz);
iverts = interpstreamspeed(x,y,z,u,v,w,verts,0.2);
sl = streamline(iverts);
set(sl,'Marker','.')
axis tight; view(2); daspect([1 1 1])

```

This example plots streamlines whose vertex spacing indicates the value of the gradient along the streamline.

```

figure
z = membrane(6,30);
[u v] = gradient(z);
pcolor(z)

```

```
hold on
[verts averts] = streamslice(u,v);
iverts = interpstreamspeed(u,v,verts,15);
sl = streamline(iverts);
set(sl,'Marker','.')
shading interp
axis tight
view(2)
daspect([1,1,1])
hold off
```

## intersect

Set intersection of two arrays

### Syntax

```
C = intersect(A,B)
C = intersect(A,B,'rows')
[C,ia,ib] = intersect(A,B)
[C,ia,ib] = intersect(A,B,'rows')

[C,ia,ib] = intersect(____,setOrder)

[C,ia,ib] = intersect(A,B,'legacy')
[C,ia,ib] = intersect(A,B,'rows','legacy')
```

### Description

`C = intersect(A,B)` returns the data common to both **A** and **B** with no repetitions.

- If **A** and **B** are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `intersect` returns the values common to both **A** and **B**. The values of **C** are in sorted order.
- If **A** and **B** are tables, then `intersect` returns the set of rows common to both tables. The rows of table **C** are in sorted order.

`C = intersect(A,B,'rows')` treats each row of **A** and each row of **B** as single entities and returns the rows common to both **A** and **B**. The rows of **C** are in sorted order.

The `'rows'` option does not support cell arrays, unless one of the inputs is either a categorical array or a datetime array.

`[C,ia,ib] = intersect(A,B)` also returns index vectors **ia** and **ib**.

- If **A** and **B** are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `C = A(ia)` and `C = B(ib)`.

- If A and B are tables, then `C = A(ia,:)` and `C = B(ib,:)`.

`[C,ia,ib] = intersect(A,B,'rows')` also returns index vectors `ia` and `ib`, such that `C = A(ia,:)` and `C = B(ib,:)`.

`[C,ia,ib] = intersect(___,setOrder)` returns `C` in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A`, and then `B`. If no value is specified, the default is `'sorted'`.

`[C,ia,ib] = intersect(A,B,'legacy')` and `[C,ia,ib] = intersect(A,B,'rows','legacy')` preserve the behavior of the `intersect` function from R2012b and prior releases.

The `'legacy'` option does not support categorical arrays, tables, datetime arrays, or duration arrays.

## Examples

### Intersection of Two Vectors

Define two vectors with values in common.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
```

Find the values common to both A and B.

```
C = intersect(A,B)
```

```
C =
```

```
 4 7
```

### Intersection of Two Tables

Define two tables with rows in common.

```
A = table([1:5]', ['A'; 'B'; 'C'; 'D'; 'E'], logical([0;1;0;1;0]))
B = table([1:2:10]', ['A'; 'C'; 'E'; 'G'; 'I'], logical(zeros(5,1)))
```

```
A =
```

| Var1 | Var2 | Var3  |
|------|------|-------|
| 1    | A    | false |
| 2    | B    | true  |
| 3    | C    | false |
| 4    | D    | true  |
| 5    | E    | false |

B =

| Var1 | Var2 | Var3  |
|------|------|-------|
| 1    | A    | false |
| 3    | C    | false |
| 5    | E    | false |
| 7    | G    | false |
| 9    | I    | false |

Find the rows common to both A and B.

C = intersect(A,B)

C =

| Var1 | Var2 | Var3  |
|------|------|-------|
| 1    | A    | false |
| 3    | C    | false |
| 5    | E    | false |

### Intersection of Two Vectors and Their Indices

Define two vectors with values in common.

A = [7 1 7 7 4]; B = [7 0 4 4 0];

Find the values common to both A and B, as well as the index vectors ia and ib, such that C = A(ia) and C = B(ib).

[C,ia,ib] = intersect(A,B)

C =

```

4 7

ia =

5
1

ib =

3
1

```

### Intersection of Two Tables and Their Indices

Define a table, A, of gender, age, and height for five people.

```

A = table(['M';'M';'F';'M';'F'],[27;52;31;46;35],[74;68;64;61;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty' 'Bob' 'Judy'})

```

A =

|       | Gender | Age | Height |
|-------|--------|-----|--------|
|       | -----  | --- | -----  |
| Ted   | M      | 27  | 74     |
| Fred  | M      | 52  | 68     |
| Betty | F      | 31  | 64     |
| Bob   | M      | 46  | 61     |
| Judy  | F      | 35  | 64     |

Define a table, B, with rows in common with A.

```

B = table(['F';'M';'F';'F'],[31;47;35;23],[64;68;62;58],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Meg' 'Joe' 'Beth' 'Amy'})

```

B =

|      | Gender | Age | Height |
|------|--------|-----|--------|
|      | -----  | --- | -----  |
| Meg  | F      | 31  | 64     |
| Joe  | M      | 47  | 68     |
| Beth | F      | 35  | 62     |

```
Amy F 23 58
```

Find the rows common to both A and B, as well as the index vectors `ia` and `ib`, such that `C = A(ia,:)` and `C = B(ib,:)`.

```
[C,ia,ib] = intersect(A,B)
```

```
C =
```

```
 Gender Age Height
 ----- --- -
Betty F 31 64
```

```
ia =
```

```
 3
```

```
ib =
```

```
 1
```

Two rows that have the same values, but different names, are considered equal. Therefore, we discover that Betty, `A(3,:)`, and Meg, `B(1,:)` have the same gender, age, and height.

## Intersection of Rows in Two Matrices

Define two matrices with rows in common.

```
A = [2 2 2; 0 0 1; 1 2 3; 1 1 1];
```

```
B = [1 2 3; 2 2 2; 2 2 0];
```

Find the rows common to both A and B as well as the index vectors `ia` and `ib`, such that `C = A(ia,:)` and `C = B(ib,:)`.

```
[C,ia,ib] = intersect(A,B,'rows')
```

```
C =
```

```
 1 2 3
 2 2 2
```

```
ia =

 3
 1
```

```
ib =

 1
 2
```

A and B do not need to have the same number of rows, but they must have the same number of columns.

### Intersection with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in C.

Specify `'stable'` if you want the values in C to have the same order as in A.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
[C,ia,ib] = intersect(A,B,'stable')
```

```
C =

 7 4
```

```
ia =

 1
 5
```

```
ib =

 1
 3
```

Alternatively, you can specify `'sorted'` order.

```
[C,ia,ib] = intersect(A,B,'sorted')
```

```
C =
```

```
 4 7

ia =

 5
 1

ib =

 3
 1
```

## Intersection of Vectors Containing NaNs

Define two vectors containing NaN.

```
A = [5 NaN NaN]; B = [5 NaN NaN];
```

Find the values common to both A and B.

```
C = intersect(A,B)
```

```
C =

 5
```

`intersect` treats NaN values as distinct.

## Cell Array of Strings with Trailing White Space

Create a cell array of strings, A.

```
A = {'dog', 'cat', 'fish', 'horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ', 'cat', 'fish ', 'horse'};
```

Find the strings common to both A and B.

```
[C,ia,ib] = intersect(A,B)
```

```
C =
```

```

 'cat' 'horse'

ia =

 2
 4

ib =

 2
 4

```

`intersect` treats trailing white space in cell arrays of strings as distinct characters.

### Intersection of Arrays of Different Classes and Shapes

Create a column vector character array.

```
A = ['A'; 'B'; 'C'], class(A)
```

```

A =

A
B
C

```

```
ans =
```

```
char
```

Create a 2-by-3 matrix containing elements of numeric type double.

```
B = [65 66 67; 68 69 70], class(B)
```

```

B =

 65 66 67
 68 69 70

```

```
ans =
```

```
double
```

Find the values common to both A and B.

```
[C,ia,ib] = intersect(A,B)
```

```
C =
```

```
A
```

```
B
```

```
C
```

```
ia =
```

```
1
```

```
2
```

```
3
```

```
ib =
```

```
1
```

```
3
```

```
5
```

`intersect` interprets **B** as a character array and returns a character array, **C**.

```
class(C)
```

```
ans =
```

```
char
```

## Intersection of Char and Cell Array of Strings

Create a character array containing animal names that have three letters.

```
A = ['dog'; 'cat'; 'fox'; 'pig'];
```

```
class(A)
```

```
ans =
```

```
char
```

Create a cell array of strings containing animal names of varying lengths.

```
B = {'cat', 'dog', 'fish', 'horse'};
class(B)
```

```
ans =
```

```
cell
```

Find the strings common to both A and B.

```
C = intersect(A,B)
```

```
C =
```

```
 'cat'
 'dog'
```

The result, C, is a cell array of strings.

```
class(C)
```

```
ans =
```

```
cell
```

### Preserve Legacy Behavior of intersect

Use the 'legacy' flag to preserve the behavior of `intersect` from R2012b and prior releases in your code.

Find the intersection of A and B with the current behavior.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
[C1,ia1,ib1] = intersect(A,B)
```

```
C1 =
```

```
 4 7
```

```
ia1 =
```

```
5
1
```

```
ib1 =
```

```
3
1
```

Find the unique elements of A and preserve the legacy behavior.

```
[C2,ia2,ib2] = intersect(A,B,'legacy')
```

```
C2 =
```

```
4 7
```

```
ia2 =
```

```
5 4
```

```
ib2 =
```

```
4 1
```

## Input Arguments

### A, B — Input arrays

numeric arrays | logical arrays | character arrays | categorical arrays | datetime arrays  
| duration arrays | cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, cell arrays of strings, or tables.

A and B must be of the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.

- Categorical arrays can combine with cell arrays of strings or single strings.
- Datetime arrays can combine with cell arrays of date strings or single date strings.

If **A** and **B** are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither **A** nor **B** are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names. In this case, the categories of **C** are the sorted union of the categories from **A** and **B**.

If you specify the `'rows'` option, **A** and **B** must have the same number of columns.

If **A** and **B** are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

If **A** and **B** are datetime arrays, they must be consistent with each other in whether they specify a time zone.

Furthermore, **A** and **B** can be objects with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

### **setOrder** — Order flag

`'sorted'` (default) | `'stable'`

Order flag, specified as `'sorted'` or `'stable'`, indicates the order of the values (or rows) in **C**.

| Order Flag            | Meaning                                                                                                                                                                                                      |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'sorted'</code> | The values (or rows) in <b>C</b> return in sorted order. For example:<br><code>C = intersect([7 0 5],[7 1 5],'sorted')</code><br>returns <code>C = [5 7]</code> .                                            |
| <code>'stable'</code> | The values (or rows) in <b>C</b> return in the same order as they appear in <b>A</b> and <b>B</b> . For example:<br><code>C = intersect([7 0 5],[7 1 5],'stable')</code><br>returns <code>C = [7 5]</code> . |

## Output Arguments

### **C** — Data common to A and B

vector | matrix | table

Data common to A and B, returned as a vector, matrix, or table. If the inputs A and B are tables, the order of the variables in the resulting table, C, is the same as the order of the variables in A.

The following describes the shape of C when the inputs are vectors or matrices and when the 'legacy' flag is not specified:

- If the 'rows' flag is not specified, then C is a column vector unless both A and B are row vectors.
- If the 'rows' flag is not specified and both A and B are row vectors, then C is a row vector.
- If the 'rows' flag is specified, then C is a matrix containing the rows in common from A and B.
- If A and B have no values (or rows) in common, then C is an empty matrix.

The class of the inputs A and B determines the class of C:

- If the class of A and B are the same, then C is the same class.
- If you combine a `char` or `nondouble` numeric class with `double`, then C is the same class as the `nondouble` input.
- If you combine a `logical` class with `double`, then C is `double`.
- If you combine a cell array of strings with `char`, then C is a cell array of strings.
- If you combine a categorical array with a cell array of strings or single string, then C is a categorical array.
- If you combine a `datetime` array with a cell array of date strings or single date string, then C is a `datetime` array.

### **ia** — Index to A

column vector

Index to A, returned as a column vector when the 'legacy' flag is not specified. `ia` identifies the values (or rows) in A that are common to B. If there is a repeated value (or row) in A, then `ia` contains the index to the first occurrence of the value (or row).

**ib** — Index to B

column vector

Index to B, returned as a column vector when the 'legacy' flag is not specified. **ib** identifies the values (or rows) in B that are common to A. If there is a repeated value (or row) in B, then **ib** contains the index to the first occurrence of the value (or row).

## More About

### Tips

- To find the intersection with respect to a subset of variables from a table, you can use column subscripting. For example, you can use `intersect(A(:,vars),B(:,vars))`, where *vars* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.
- “Combine Categorical Arrays”

Introduced before R2006a

## intmax

Largest value of specified integer type

### Syntax

```
v = intmax
v = intmax('classname')
```

### Description

`v = intmax` is the largest positive value that can be represented in the MATLAB software with a 32-bit integer. Any value larger than the value returned by `intmax` saturates to the `intmax` value when cast to a 32-bit integer.

`v = intmax('classname')` is the largest positive value in the integer class `classname`. Valid values for the string `classname` are

|         |          |          |          |
|---------|----------|----------|----------|
| 'int8'  | 'int16'  | 'int32'  | 'int64'  |
| 'uint8' | 'uint16' | 'uint32' | 'uint64' |

`intmax('int32')` is the same as `intmax` with no arguments.

### Examples

Find the maximum value for a 64-bit signed integer:

```
v = intmax('int64')
v =
 9223372036854775807
```

Convert this value to a 32-bit signed integer:

```
x = int32(v)
x =
 2147483647
```

Compare the result with the default value returned by `intmax`:

```
isequal(x, intmax)
ans =
 1
```

### **See Also**

`intmin` | `realmax` | `int8` | `uint8` | `isa` | `class` | `realmin`

**Introduced before R2006a**

## intmin

Smallest value of specified integer type

### Syntax

```
v = intmin
v = intmin('classname')
```

### Description

`v = intmin` is the smallest value that can be represented in the MATLAB software with a 32-bit integer. Any value smaller than the value returned by `intmin` saturates to the `intmin` value when cast to a 32-bit integer.

`v = intmin('classname')` is the smallest positive value in the integer class `classname`. Valid values for the string `classname` are

|         |          |          |          |
|---------|----------|----------|----------|
| 'int8'  | 'int16'  | 'int32'  | 'int64'  |
| 'uint8' | 'uint16' | 'uint32' | 'uint64' |

`intmin('int32')` is the same as `intmin` with no arguments.

### Examples

Find the minimum value for a 64-bit signed integer:

```
v = intmin('int64')
v =
```

```
-9223372036854775808
```

Convert this value to a 32-bit signed integer:

```
x = int32(v)
x =
```

```
-2147483648
```

Compare the result with the default value returned by `intmin`:

```
isequal(x, intmin)
ans =
```

```
1
```

**Introduced before R2006a**

## **inv**

Matrix inverse

### **Syntax**

`Y = inv(X)`

### **Description**

`Y = inv(X)` returns the inverse of the square matrix `X`. A warning message is printed if `X` is badly scaled or nearly singular.

In practice, it is seldom necessary to form the explicit inverse of a matrix. A frequent misuse of `inv` arises when solving the system of linear equations  $Ax = b$ . One way to solve this is with `x = inv(A)*b`. A better way, from both an execution time and numerical accuracy standpoint, is to use the matrix division operator `x = A\b`. This produces the solution using Gaussian elimination, without forming the inverse. See `mldivide (\)` for further information.

---

**Note:** MATLAB computes  $X^{(-1)}$  and `inv(X)` in the same manner, and both are subject to the same limitations.

---

### **Examples**

Here is an example demonstrating the difference between solving a linear system by inverting the matrix with `inv(A)*b` and solving it directly with `A\b`. A random matrix `A` of order 500 is constructed so that its condition number, `cond(A)`, is  $1.e10$ , and its norm, `norm(A)`, is 1. The exact solution `x` is a random vector of length 500 and the right-hand side is `b = A*x`. Thus the system of linear equations is badly conditioned, but consistent.

On a 300 MHz, laptop computer the statements

```
n = 500;
Q = orth(randn(n,n));
d = logspace(0,-10,n);
```

```

A = Q*diag(d)*Q';
x = randn(n,1);
b = A*x;
tic, y = inv(A)*b; toc
err = norm(y-x)
res = norm(A*y-b)

```

produce

```

elapsed_time =
 1.4320
err =
 7.3260e-006
res =
 4.7511e-007

```

while the statements

```

tic, z = A\b, toc
err = norm(z-x)
res = norm(A*z-b)

```

produce

```

elapsed_time =
 0.6410
err =
 7.1209e-006
res =
 4.4509e-015

```

It takes almost two and one half times as long to compute the solution with  $y = \text{inv}(A)*b$  as with  $z = A\b$ . Both produce computed solutions with about the same error,  $1.e-6$ , reflecting the condition number of the matrix. But the size of the residuals, obtained by plugging the computed solution back into the original equations, differs by several orders of magnitude. The direct solution produces residuals on the order of the machine accuracy, even though the system is badly conditioned.

The behavior of this example is typical. Using  $A\b$  instead of  $\text{inv}(A)*b$  is two to three times as fast and produces residuals on the order of machine accuracy, relative to the magnitude of the data.

# invhilb

Inverse of Hilbert matrix

## Syntax

```
H = invhilb(n)
```

## Description

`H = invhilb(n)` generates the exact inverse of the exact Hilbert matrix for  $n$  less than about 15. For larger  $n$ , `invhilb(n)` generates an approximation to the inverse Hilbert matrix.

## Limitations

The exact inverse of the exact Hilbert matrix is a matrix whose elements are large integers. These integers may be represented as floating-point numbers without roundoff error as long as the order of the matrix,  $n$ , is less than 15.

Comparing `invhilb(n)` with `inv(hilb(n))` involves the effects of two or three sets of roundoff errors:

- The errors caused by representing `hilb(n)`
- The errors in the matrix inversion process
- The errors, if any, in representing `invhilb(n)`

It turns out that the first of these, which involves representing fractions like  $1/3$  and  $1/5$  in floating-point, is the most significant.

## Examples

`invhilb(4)` is

```
 16 -120 240 -140
```

|       |       |       |       |
|-------|-------|-------|-------|
| - 120 | 1200  | -2700 | 1680  |
| 240   | -2700 | 6480  | -4200 |
| -140  | 1680  | -4200 | 2800  |

# invoke

Invoke method on COM object or interface, or display methods

## Syntax

```
S = invoke(h)
S = invoke(h, 'methodname')
S = invoke(h, 'methodname', arg1, arg2, ...)
S = invoke(h, 'custominterfacename')
```

## Description

`S = invoke(h)` returns structure array, `S`, containing a list of all methods supported by the object or interface, `h`, along with the prototypes for these methods. If `S` is empty, either there are no properties or methods in the object, or MATLAB cannot read the object type library. Refer to the COM vendor documentation.

`S = invoke(h, 'methodname')` invokes the method specified in the string `methodname`, and returns an output value, if any, in `S`. The data type of the return value depends on the invoked method, which is determined by the control or server.

`S = invoke(h, 'methodname', arg1, arg2, ...)` invokes the method specified in the string `methodname` with input arguments `arg1, arg2, ...`.

`S = invoke(h, 'custominterfacename')` returns an `Interface` object `S`, which is a handle to a custom interface implemented by the COM component. The `h` argument is a handle to the COM object. The `custominterfacename` argument is a string returned by the `interfaces` function.

If the method returns a COM interface, then the `invoke` function returns a new MATLAB COM object that represents the interface returned. For a description of how MATLAB converts COM types, see “Handle COM Data in MATLAB”.

COM functions are available on Microsoft Windows systems only.

## Examples

Invoke the `Redraw` method in the `mwsamp` control.

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.1',[0 0 200 200],f);
h.Radius = 100;
invoke(h,'Redraw')
```

Alternatively, call the method directly.

```
Redraw(h)
```

Display all `mwsamp` methods.

```
invoke(h)
```

```
ans =
 AboutBox = void AboutBox(handle)
 Beep = void Beep(handle)
 FireClickEvent = void FireClickEvent(handle)
 .
 .
```

## Getting a Custom Interface Example

Once you have created a COM server, you can query the server component to see if any custom interfaces are implemented. Use the `interfaces` function to return a list of all available custom interfaces:

```
h = actxserver('mytestenv.calculator');
customlist = interfaces(h)

customlist =
 ICalc1
 ICalc2
 ICalc3
```

To get a handle to the custom interface you want, use the `invoke` function.

```
c1 = invoke(h,'ICalc1')

c1 =
 Interface.Calc_1.0_Type_Library.ICalc_Interface
```

Use this handle with COM client functions to access the properties and methods of the object through the selected custom interface.

## ipermute

Inverse permute dimensions of N-D array

### Syntax

```
A = ipermute(B,order)
```

### Description

`A = ipermute(B,order)` is the inverse of `permute`. `ipermute` rearranges the dimensions of `B` so that `permute(A,order)` will produce `B`. `B` has the same values as `A` but the order of the subscripts needed to access any particular element are rearranged as specified by `order`. All the elements of `order` must be unique.

### Examples

Consider the 2-by-2-by-3 array `a`:

```
a = cat(3,eye(2),2*eye(2),3*eye(2))
```

```
a(:,:,1) = a(:,:,2) =
 1 0 2 0
 0 1 0 2
```

```
a(:,:,3) =
 3 0
 0 3
```

Permuting and inverse permuting `a` in the same fashion restores the array to its original form:

```
B = permute(a,[3 2 1]);
C = ipermute(B,[3 2 1]);
isequal(a,C)
ans =
```

```
1
```

## More About

### Tips

`permute` and `ipermute` are a generalization of transpose (`.'`) for multidimensional arrays.

`permute`

**Introduced before R2006a**

## is\*

Detect state

### Description

These functions detect the state of MATLAB entities:

|                    |                                                                   |
|--------------------|-------------------------------------------------------------------|
| isa                | Detect object of given MATLAB class or Java class                 |
| isappdata          | Determine if object has specific application-defined data         |
| isbetween          | Array elements occurring within date and time interval            |
| iscalendarduration | Determine if input is duration array                              |
| iscategorical      | Determine whether input is categorical array                      |
| iscategory         | Test for categorical array categories                             |
| iscell             | Determine if input is cell array                                  |
| iscellstr          | Determine if input is cell array of strings                       |
| ischar             | Determine if input is character array                             |
| iscolumn           | Determine whether input is column vector                          |
| iscom              | Determine if input is Component Object Model (COM) object         |
| isdatetime         | Determine if input is datetime array                              |
| isdir              | Determine if input is folder                                      |
| isdst              | Datetime values occurring during daylight saving time             |
| isduration         | Determine if input is duration array                              |
| isempty            | Determine if input is empty array                                 |
| isequal            | Determine if arrays are numerically equal                         |
| isequaln           | Determine if arrays are numerically equal, treating NaNs as equal |
| isevent            | Determine if input is Component Object Model (COM) object event   |
| isfield            | Determine if input is MATLAB structure array field                |
| isfinite           | Detect finite elements of array                                   |

|             |                                                                 |
|-------------|-----------------------------------------------------------------|
| isfloat     | Determine if input is floating-point array                      |
| ishandle    | Detect valid graphics object handles                            |
| ishold      | Determine if graphics hold state is on                          |
| isinf       | Detect infinite elements of array                               |
| isinteger   | Determine if input is integer array                             |
| isinterface | Determine if input is Component Object Model (COM) interface    |
| isjava      | Determine if input is Java object                               |
| iskeyword   | Determine if input is MATLAB keyword                            |
| isletter    | Detect elements that are alphabetic letters                     |
| islogical   | Determine if input is logical array                             |
| ismac       | Determine if running MATLAB for Macintosh OS X platform         |
| ismatrix    | Determine whether input is matrix                               |
| ismember    | Detect members of specific set                                  |
| ismethod    | Determine if input is object method                             |

| <code>isweekend</code>   | Datetime values occurring during weekend                    |

- a. UNIX is a registered trademark of The Open Group in the United States and other countries.

## See Also

`isa` | `exist`

## isa

Determine if input is object of specified class

### Syntax

```
tf = isa(obj,ClassName)
tf = isa(obj,classCategory)
```

### Description

`tf = isa(obj,ClassName)` returns `true` if `obj` is an instance of the class specified by `ClassName`, and `false` otherwise. `isa` also returns `true` if `obj` is an instance of a class that is derived from `ClassName`.

`obj` can be any MATLAB variable.

`ClassName` can be any of the following:

- Name of any MATLAB class or fundamental type
- Name of a Java, or .NET class

#### MATLAB Fundamental Types

|          |                         |
|----------|-------------------------|
| 'single' | Single-precision number |
| 'double' | Double-precision number |
| 'int8'   | Signed 8-bit integer    |
| 'int16'  | Signed 16-bit integer   |
| 'int32'  | Signed 32-bit integer   |
| 'int64'  | Signed 64-bit integer   |
| 'uint8'  | Unsigned 8-bit integer  |
| 'uint16' | Unsigned 16-bit integer |
| 'uint32' | Unsigned 32-bit integer |
| 'uint64' | Unsigned 64-bit integer |

|                   |                       |
|-------------------|-----------------------|
| 'logical'         | Logical true or false |
| 'char'            | Character or string   |
| 'struct'          | Structure array       |
| 'cell'            | Cell array            |
| 'function_handle' | function handle       |

`tf = isa(obj, classCategory)` returns `true` if `obj` is an instance of any of the classes in the specified `classCategory`, and `false` otherwise. `isa` also returns `true` if `obj` is an instance of a class that is derived from any of the classes in `classCategory`.

`classCategory` can be `'numeric'`, `'float'`, or `'integer'`, representing a category of numeric types:

### Categories of Numeric Types

|           |                                                                                                                                                                                                                                                         |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'numeric' | Integer or floating-point array ( <code>double</code> , <code>single</code> , <code>int8</code> , <code>uint8</code> , <code>int16</code> , <code>uint16</code> , <code>int32</code> , <code>uint32</code> , <code>int64</code> , <code>uint64</code> ) |
| 'float'   | Single- or double-precision floating-point array ( <code>double</code> , <code>single</code> )                                                                                                                                                          |
| 'integer' | Signed or unsigned integer array ( <code>int8</code> , <code>uint8</code> , <code>int16</code> , <code>uint16</code> , <code>int32</code> , <code>uint32</code> , <code>int64</code> , <code>uint64</code> )                                            |

To test for a sparse array, use `issparse`. To test for a complex array, use `~isreal`.

## Examples

These examples show the values returned by `isa` when passed different types:

Determine if the value returned by the `pi` function is of class `double`:

```
isa(pi, 'double')

ans =

 1
```

More generally, determine if the value returned by the `pi` function is a numeric value:

```
isa(pi, 'numeric')
```

```
ans =
```

```
1
```

`isa` also returns `true` for the `float` category because the class `double` is a floating-point type. However, `pi` does not return an integer type:

```
isa(pi, 'integer')
```

```
ans =
```

```
0
```

Determine if the 2-by-3 array returned by `true` is of type logical:

```
isa(true(2,3), 'logical')
```

```
ans =
```

```
1
```

Identify an instance of the MATLAB `containers.Map` class:

```
colorcodes = containers.Map({'Color', 'RGB'}, ...
 {'Yellow', uint8([255,255,0])});
isa(colorcodes, 'containers.Map')
```

```
ans =
```

```
1
```

The map key, `RGB`, references a `uint8` array:

```
isa(colorcodes('RGB'), 'integer')
```

```
ans =
```

```
1
```

Specifying a particular integer class provides more specific testing:

```
if strcmp(colorcodes('Color'), 'Yellow') && ...
 isa(colorcodes('RGB'), 'uint8')
```

```
 disp '''The Color is Yellow and the RGB numbers are uint8 values'''
end
'The Color is Yellow and the RGB numbers are uint8 values'
```

### **See Also**

class | is\* | isnumeric | isfloat | isinteger | exist

# isappdata

True if application-defined data exists

## Syntax

```
tf = isappdata(h,name)
```

## Description

`tf = isappdata(h,name)` returns `logical(1)` if application-defined data exists and these conditions are met:

- The application data has the specified `name` value.
- The application data is associated with the UI component, `h`.

Otherwise, `isappdata` returns `logical(0)`

## See Also

`getappdata` | `rmappdata` | `setappdata`

**Introduced before R2006a**

## isbanded

Determine if matrix is within specific bandwidth

### Syntax

```
tf = isbanded(A,lower,upper)
```

### Description

`tf = isbanded(A,lower,upper)` returns logical 1 (`true`) if matrix `A` is within the specified lower bandwidth, `lower`, and upper bandwidth, `upper`; otherwise, it returns logical 0 (`false`).

### Examples

#### Test Square Matrix

Create a 5-by-5 square matrix.

```
A = [2 3 0 0 0 ; 1 -2 -3 0 0; 0 -1 2 3 0 ; 0 0 1 -2 -3; 0 0 0 -1 2]
```

```
A =
```

```
 2 3 0 0 0
 1 -2 -3 0 0
 0 -1 2 3 0
 0 0 1 -2 -3
 0 0 0 -1 2
```

The result is a square matrix with nonzero diagonals above and below the main diagonal.

Specify both bandwidths, `lower` and `upper`, as 1 to test if `A` is tridiagonal.

```
isbanded(A,1,1)
```

```
ans =
```

```
 1
```

The result is logical 1 (**true**).

Test if **A** has nonzero elements below the main diagonal by specifying **lower** as 0.

```
isbanded(A,0,1)
```

```
ans =
```

```
 0
```

The result is logical 0 (**false**) because **A** has nonzero elements below the main diagonal.

### Test Nonsquare Matrix

Create a 3-by-5 matrix.

```
A = [1 0 0 0 0; 2 1 0 0 0; 3 2 1 0 0]
```

```
A =
```

```
 1 0 0 0 0
 2 1 0 0 0
 3 2 1 0 0
```

The result is a rectangular matrix.

Test if **A** has nonzero elements above the main diagonal.

```
isbanded(A,2,0)
```

```
ans =
```

```
 1
```

The result is logical 1 (**true**) because the elements above the main diagonal are all zero.

### Test Sparse Block Matrix

Create a 100-by-100 sparse block matrix.

```
B = kron(speye(25),ones(4));
```

Test if **B** has a lower and upper bandwidth of 1.

```
isbanded(B,1,1)
```

```
ans =
 0
```

The result is logical 0 (**false**) because the nonzero blocks centered on the main diagonal are larger than 2-by-2.

Test if **B** has a lower and upper bandwidth of 3.

```
isbanded(B,3,3)
ans =
 1
```

The result is logical 1 (**true**). The matrix, **B**, has an upper and lower bandwidth of 3 since the nonzero diagonal blocks are 4-by-4.

## Input Arguments

### **A** — Input array

numeric array

Input array, specified as a numeric array. **isbanded** returns logical 0 (**false**) if **A** has more than two dimensions.

Data Types: `single` | `double`

Complex Number Support: Yes

### **lower** — Lower bandwidth

nonnegative integer scalar

Lower bandwidth, specified as a nonnegative integer scalar. The lower bandwidth is the number of nonzero diagonals below the main diagonal. **isbanded** returns logical 0 (**false**) if there are nonzero elements below the boundary diagonal, `diag(A, -lower)`.

### **upper** — Upper bandwidth

nonnegative integer scalar

Upper bandwidth, specified as a nonnegative integer scalar. The upper bandwidth is the number of nonzero diagonals above the main diagonal. **isbanded** returns logical 0 (**false**) if there are nonzero elements above the boundary diagonal, `diag(A, upper)`.

## More About

### Tips

- Use the `bandwidth` function to find the upper and lower bandwidths of a given matrix.
- Use `isbanded` to test for several different matrix structures by specifying appropriate upper and lower bandwidths. The table below lists some common tests.

| Lower Bandwidth        | Upper Bandwidth        | Function Call                     | Tests for               |
|------------------------|------------------------|-----------------------------------|-------------------------|
| 0                      | 0                      | <code>isbanded(A,0,0)</code>      | Diagonal matrix         |
| 1                      | 1                      | <code>isbanded(A,1,1)</code>      | Tridiagonal matrix      |
| 0                      | <code>size(A,2)</code> | <code>isbanded(A,0,size(A,</code> | Upper triangular matrix |
| <code>size(A,1)</code> | 0                      | <code>isbanded(A,size(A,1)</code> | Lower triangular matrix |
| 1                      | <code>size(A,2)</code> | <code>isbanded(A,1,size(A,</code> | Upper Hessenberg matrix |
| <code>size(A,1)</code> | 1                      | <code>isbanded(A,size(A,1)</code> | Lower Hessenberg matrix |

Introduced in R2014a

## isbetween

Determine elements within date and time interval

### Syntax

```
tf = isbetween(t,tlower,tupper)
```

### Description

`tf = isbetween(t,tlower,tupper)` returns an array the same size as `t` containing logical 1 (true) where the corresponding element of `t` is a datetime that lies within the closed interval specified by the corresponding elements of `tlower` and `tupper`. The output `tf` indicates which elements of `t` satisfy:

```
tlower <= t <= tupper
```

### Examples

#### Determine if Dates Occur Within Interval

Define a lower bound and an upper bound for dates.

```
tlower = datetime(2014,05,16)
```

```
tlower =
```

```
 16-May-2014
```

```
tupper = '23-May-2014'
```

```
tupper =
```

```
 23-May-2014
```

`tlower` and `tupper` can be `datetime` arrays or strings. Here, `tlower` is a `datetime` array and `tupper` is a single string.

Create an array of `datetime` values and determine if each `datetime` lies within the interval bounded by `tlower` and `tupper`.

```
t = tlower + caldays(2:2:10)
```

```
t =
```

```
 18-May-2014 20-May-2014 22-May-2014 24-May-2014 26-May-2014
```

```
tf = isbetween(t,tlower,tupper)
```

```
tf =
```

```
 1 1 1 0 0
```

## Input Arguments

### **t** — Input date and time

`datetime` array | cell array of `datetime` strings | `datetime` string

Input date and time, specified as a `datetime` array, a cell array of `datetime` strings, or a single `datetime` string.

### **tlower** — Lower bound of date and time interval

`datetime` array | cell array of `datetime` strings | `datetime` string

Lower bound of date and time interval, specified as a `datetime` array, a cell array of `datetime` strings, or a single `datetime` string.

### **tupper** — Upper bound of date and time interval

`datetime` array | cell array of date strings | `datetime` string

Upper bound of date and time interval, specified as a `datetime` array, a cell array of `datetime` strings, or a single `datetime` string.

# iscalendarduration

Determine if input is calendar duration array

## Syntax

```
tf = iscalendarduration(t)
```

## Description

`tf = iscalendarduration(t)` returns logical 1 (true) if `t` is a `calendarDuration` array. Otherwise, it returns logical 0 (false).

## Examples

### Determine if Array Contains Calendar Duration Values

Determine if the output of an arithmetic calculation is a `calendarDuration` array.

Add two `calendarDuration` arrays.

```
d1 = calyears(1:4);
d2 = caldays(1:4);
d = d1 + d2
```

```
d =
```

```
 1y 1d 2y 2d 3y 3d 4y 4d
```

Determine if the output is a `calendarDuration` array.

```
tf = iscalendarduration(d)
```

```
tf =
```

1

## **Input Arguments**

### **t — Input array**

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. `t` can be any data type.

### **See Also**

`calendarDuration` | `isdatetime` | `isduration`

**Introduced in R2014b**

# iscategorical

Determine whether input is categorical array

## Syntax

```
tf = iscategorical(A)
```

## Description

`tf = iscategorical(A)` returns logical 1 (true) if `A` is a categorical array. Otherwise, `iscategorical` returns logical 0 (false).

## Examples

### Determine Whether Workspace Variable Is Categorical Array

Create a workspace variable, `A`.

```
A = categorical({'red' 'green' 'violet'; 'orange' 'red' 'yellow'})
```

```
A =
```

```
 red green violet
orange red yellow
```

Verify that the workspace variable, `A`, is a categorical array.

```
tf = iscategorical(A)
```

```
tf =
```

```
 1
```

A is a 2-by-3 categorical array.

## Input Arguments

### **A** — Input variable

workspace variable

Input variable, specified as a workspace variable. A can be any data type.

### See Also

`categorical` | `iscell` | `islogical` | `isnumeric` | `isobject` | `isstruct` | `istable`

**Introduced in R2013b**

# iscategory

Test for categorical array categories

## Syntax

```
tf = iscategory(A, catnames)
```

## Description

`tf = iscategory(A, catnames)` returns an array containing logical 1 (true) where the data in `catnames` is a category of `A`. Otherwise, `iscategory` returns logical 0 (false).

`tf` is the same size as `catnames`.

## Examples

### Test for Categories

Create an ordinal categorical array, `A`.

```
A = categorical({'shirt' 'pants'; 'pants' 'hat'; 'shirt' 'pants'})
```

`A =`

```
 shirt pants
 pants hat
 shirt pants
```

`A` is a 3-by-2 categorical array.

Test if the articles of clothing, `shirt`, `pants`, `socks`, and `shoes`, are categories of `A`.

```
catnames = {'shirt' 'pants' 'socks' 'shoes'};
tf = iscategory(A, catnames)
```

`tf =`

```
1 1 0 0
```

shirt and pants are categories of A, but socks, and shoes are not.

iscategory does not tell us anything about the category, hat, which we did not include in catnames.

## Test for Category with No Corresponding Data

Create a categorical array, A.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'},...
 {'boat' 'car' 'plane' 'train'})
```

```
A =
```

```
plane car train car plane
```

A is a 1-by-5 categorical array.

Test to see if boat is a category in A.

```
tf = iscategory(A, 'boat')
```

```
tf =
```

```
1
```

iscategory returns true, even though A does not contain any values from the category boat.

## Input Arguments

### A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

### catnames — Category names

string | cell array of strings | categorical array

Category names, specified as a string, cell array of strings, or categorical array.

**See Also**

addcats | categorical | categories | ismember | mergecats | removecats |  
renamecats | reordercats | setcats | unique

**Introduced in R2013b**

## iscell

Determine whether input is cell array

## Syntax

```
tf = iscell(A)
```

## Description

`tf = iscell(A)` returns logical 1 (true) if `A` is a cell array and logical 0 (false) otherwise.

## Examples

```
A{1,1} = [1 4 3; 0 5 8; 7 2 9];
A{1,2} = 'Anne Smith';
A{2,1} = 3+7i;
A{2,2} = -pi:pi/10:pi;
```

```
iscell(A)
```

```
ans =
```

```
1
```

## See Also

`cell` | `istable` | `iscellstr` | `isstruct` | `isnumeric` | `islogical` | `isobject` | `isa` | `is*`

**Introduced before R2006a**

# iscellstr

Determine whether input is cell array of strings

## Syntax

```
tf = iscellstr(A)
```

## Description

`tf = iscellstr(A)` returns logical 1 (**true**) if **A** is a cell array of strings (or an empty cell array), and logical 0 (**false**) otherwise. A cell array of strings is a cell array where every element is a character array.

## Examples

```
A{1,1} = 'Thomas Lee';
A{1,2} = 'Marketing';
A{2,1} = 'Allison Jones';
A{2,2} = 'Development';
```

```
iscellstr(A)
```

```
ans =
```

```
1
```

## See Also

`cellstr` | `istable` | `iscategorical` | `iscell` | `isstrprop` | `strings` | `char` | `isstruct` | `isa` | `is*`

Introduced before R2006a

## ischar

Determine whether item is character array

### Syntax

```
tf = ischar(A)
```

### Description

`tf = ischar(A)` returns logical 1 (true) if `A` is a character array and logical 0 (false) otherwise.

### Examples

Given the following cell array,

```
C{1,1} = magic(3); % double array
C{1,2} = 'John Doe'; % char array
C{1,3} = 2 + 4i % complex double
```

```
C =
```

```
 [3x3 double] 'John Doe' [2.0000+ 4.0000i]
```

`ischar` shows that only `C{1,2}` is a character array.

```
for k = 1:3
x(k) = ischar(C{1,k});
end
```

```
x
```

```
x =
```

```
 0 1 0
```

**See Also**

char | strings | isletter | isspace | isstrprop | iscellstr | isnumeric | isa | is\*

**Introduced before R2006a**

## iscolumn

Determine whether input is column vector

### Syntax

```
iscolumn(V)
```

### Description

`iscolumn(V)` returns logical 1 (**true**) if `size(V)` returns `[n 1]` with a nonnegative integer value `n`, and logical 0 (**false**) otherwise.

### Examples

Determine if a vector is a column. This example is a row so `iscolumn` returns 0:

```
V = rand(1,5);
iscolumn(V)
ans =
 0
```

Transpose the vector to make it a column. `iscolumn` returns 1:

```
V1 = V';
iscolumn(V1)
ans =
 1
```

### See Also

`ismatrix` | `isrow` | `isscalar` | `isvector`

## iscom

Determine whether input is COM or ActiveX object

## Syntax

```
tf = iscom(h)
```

## Description

`tf = iscom(h)` returns logical 1 (**true**) if handle `h` is a COM or Microsoft ActiveX object. Otherwise, returns logical 0 (**false**).

COM functions are available on Microsoft Windows systems only.

## Examples

Test an instance of a Microsoft Excel application.

```
h = actxserver('Excel.Application');
iscom(h)
```

MATLAB displays **true**, indicating object `h` is a COM object.

Test an Excel interface:

```
h = actxserver('Excel.Application');
% Create a workbooks object
w = get(h,'workbooks');
iscom(w)
```

MATLAB displays **false**, indicating object `w` is not a COM object.

## More About

- “MATLAB COM Integration”

**Introduced before R2006a**

# isdatetime

Determine if input is datetime array

## Syntax

```
tf = isdatetime(t)
```

## Description

`tf = isdatetime(t)` returns logical 1 (true) if `t` is a datetime array. Otherwise, it returns logical 0 (false).

## Examples

### Determine if Array Contains Datetime Values

Define an array.

```
A = [datetime('now');datetime('tomorrow');datetime(2016,1,15)]
```

```
A =
```

```
24-Aug-2015 18:00:58
25-Aug-2015 00:00:00
15-Jan-2016 00:00:00
```

Determine if the array is a `datetime` array.

```
tf = isdatetime(A)
```

```
tf =
```

```
1
```

## Input Arguments

### **t** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **t** can be any data type.

### See Also

`datetime` | `iscalendarduration` | `isduration`

**Introduced in R2014b**

## isdiag

Determine if matrix is diagonal

### Syntax

```
tf = isdiag(A)
```

### Description

`tf = isdiag(A)` returns logical 1 (`true`) if `A` is a diagonal matrix; otherwise, it returns logical 0 (`false`).

### Examples

#### Test Diagonal Matrix

Create a 4-by-4 identity matrix.

```
I = eye(4)
```

```
I =
```

```
 1 0 0 0
 0 1 0 0
 0 0 1 0
 0 0 0 1
```

Test to see if the matrix is diagonal.

```
isdiag(I)
```

```
ans =
```

```
 1
```

The result is logical 1 (`true`) because all of the nonzero elements in `I` are on the main diagonal.

## Test Banded Matrix

Create a matrix with nonzero elements on the main and first diagonals.

```
A = 3*eye(4) + diag([2 2 2],1)
```

```
A =
```

```
 3 2 0 0
 0 3 2 0
 0 0 3 2
 0 0 0 3
```

Test to see if the matrix is diagonal.

```
isdiag(A)
```

```
ans =
```

```
 0
```

The matrix is not diagonal since there are nonzero elements above the main diagonal.

Create a new matrix, `B`, from the main diagonal elements of `A`.

```
B = diag(diag(A));
```

Test to see if `B` is a diagonal matrix.

```
isdiag(B)
```

```
ans =
```

```
 1
```

The result is logical 1 (`true`) because there are no nonzero elements above or below the main diagonal of `B`.

## Input Arguments

**A** — Input array

numeric array

Input array, specified as a numeric array. `isdiag` returns logical 0 (`false`) if A has more than two dimensions.

Data Types: `single` | `double`

Complex Number Support: Yes

## More About

### Diagonal Matrix

A matrix is diagonal if all elements above and below the main diagonal are zero. Any number of the elements on the main diagonal can also be zero.

For example, the 4-by-4 identity matrix,

$$I_4 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

is a diagonal matrix. Diagonal matrices are typically, but not always, square.

### Tips

- Use the `diag` function to produce diagonal matrices for which `isdiag` returns logical 1 (`true`).
- The functions `isdiag`, `istriu`, and `istril` are special cases of the function `isbanded`, which can perform all of the same tests with suitably defined upper and lower bandwidths. For example, `isdiag(A) == isbanded(A,0,0)`.

### See Also

`bandwidth` | `diag` | `isbanded` | `istril` | `istriu` | `tril` | `triu`

Introduced in R2014a

## **isdir**

Determine whether input is folder

### **Syntax**

```
tf = isdir('A')
```

### **Description**

`tf = isdir('A')` returns logical 1 (**true**) if **A** is a folder. Otherwise, it returns logical 0 (**false**).

### **Examples**

Run:

```
tf=isdir('myfiles/results')
```

MATLAB returns

```
tf =
 1
```

indicating that `myfiles/results` is a folder.

### **See Also**

`dir` | `is*`

**Introduced before R2006a**

# isdst

Determine daylight saving time elements

## Syntax

```
tf = isdst(t)
```

## Description

`tf = isdst(t)` returns an array the same size as `t` containing logical 1 (`true`) where the corresponding element of `t` is a datetime that occurs during Daylight Saving Time, and logical 0 (`false`) otherwise. `isdst` returns `false` for all elements when the `TimeZone` property of `t` is empty (`''`).

## Examples

### Determine If Datetime Occurs During Daylight Saving Time

```
t = datetime(2014,3,7:11,'TimeZone','America/New_York')
```

```
t =
```

```
 07-Mar-2014 08-Mar-2014 09-Mar-2014 10-Mar-2014 11-Mar-2014
```

```
tf = isdst(t)
```

```
tf =
```

```
 0 0 0 1 1
```

March 10 and March 11, 2014 in the `America/New_York` time zone occur during daylight saving time.

## Input Arguments

**t** — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

## See Also

`datetime` Properties | `isweekend` | `tzoffset`

**Introduced in R2014b**

# isduration

Determine if input is duration array

## Syntax

```
tf = isduration(t)
```

## Description

`tf = isduration(t)` returns logical 1 (true) if `t` is a duration array. Otherwise, it returns logical 0 (false).

## Examples

### Determine if Array Contains Duration Values

Determine if the output of an arithmetic calculation is a duration array.

Subtract a `datetime` array from another.

```
t1 = datetime(2014,03,16:17);
t2 = datetime(2014,03,20);
dt = t2 - t1
```

```
dt =
```

```
 96:00:00 72:00:00
```

Determine if the output is a duration array.

```
tf = isduration(dt)
```

```
tf =
```

## Input Arguments

### **t** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **t** can be any data type.

### See Also

`duration` | `iscalendarduration` | `isdatetime`

**Introduced in R2014b**

# isEdge

**Class:** TriRep

(Not recommended) Test if vertices are joined by edge

---

**Note:** `isEdge(TriRep)` is not recommended. Use `isConnected(triangulation)` instead.

`TriRep` is not recommended. Use `triangulation` instead.

---

## Syntax

`TF = isEdge(TR, V1, V2)`

`TF = isEdge(TR, EDGE)`

## Description

`TF = isEdge(TR, V1, V2)` returns an array of 1/0 (true/false) flags, where each entry `TF(i)` is true if `V1(i), V2(i)` is an edge in the triangulation. `V1, V2` are column vectors representing the indices of the vertices in the mesh, that is, indices into the vertex coordinate arrays.

`TF = isEdge(TR, EDGE)` specifies the edge start and end indices in matrix format.

## Input Arguments

|        |                                                             |
|--------|-------------------------------------------------------------|
| TR     | Triangulation representation.                               |
| V1, V2 | Column vectors of mesh vertices.                            |
| EDGE   | Matrix of size n-by-2 where n is the number of query edges. |

## Output Arguments

TF            Array of 1/0 (true/false) flags, where each entry `TF(i)` is true if `V1(i)`, `V2(i)` is an edge in the triangulation.

## Examples

### Example 1

Load a 2-D triangulation and use `TriRep` to query the presence of an edge between pairs of points.

```
load trimesh2d
trep = TriRep(tri, x,y);
```

Test if vertices 3 and 117 are connected by an edge

```
isEdge(trep, 3, 117)
```

Test if vertices 3 and 164 are connected by an edge

```
isEdge(trep, 3, 164)
```

### Example 2

Direct query of a 3-D Delaunay triangulation created using `DelaunayTri`.

```
X = rand(10,3)
dt = DelaunayTri(X)
```

Test if vertices 2 and 7 are connected by an edge

```
isEdge(dt, 2, 7);
```

### See Also

triangulation | delaunayTriangulation

# isempty

Determine whether array is empty

## Syntax

```
TF = isempty(A)
```

## Description

`TF = isempty(A)` returns logical 1 (**true**) if **A** is an empty array and logical 0 (**false**) otherwise. An empty array has at least one dimension of size zero, for example, 0-by-0 or 0-by-5.

## Examples

```
B = rand(2,2,2);
B(:, :, :) = [];
```

```
isempty(B)
```

```
ans = 1
```

## See Also

`is*`

Introduced before R2006a

## **isempty (tscollection)**

Determine whether `tscollection` object is empty

### **Syntax**

```
isempty(tsc)
```

### **Description**

`isempty(tsc)` returns a logical value for `tscollection` object `tsc`, as follows:

- 1 — When `tsc` contains neither `timeseries` members nor a time vector
- 0 — When `tsc` contains either `timeseries` members or a time vector

### **See Also**

`timeseries` | `length (tscollection)` | `size (tscollection)` | `tscollection`

**Introduced before R2006a**

# isequal

Determine array equality

## Syntax

```
tf = isequal(A,B)
tf = isequal(A1,A2,...,An)
```

## Description

`tf = isequal(A,B)` returns logical 1 (**true**) if **A** and **B** are the same size and their contents are of equal value; otherwise, it returns logical 0 (**false**). The test compares both real and imaginary parts of numeric arrays. **isequal** ignores the data type of the values in determining whether they are equal. For cell arrays, categorical arrays, tables, or structures, the function returns logical 1 (**true**) only when all elements and properties are equal. Undefined categorical elements, NaN (Not a Number), or NaT (Not a Time) values are considered to be unequal to other elements, as well as themselves.

`tf = isequal(A1,A2,...,An)` returns logical 1 (**true**) if all the inputs are numerically equal.

## Examples

### Compare Two Numeric Matrices

Create two numeric matrices and compare them for equality.

```
A = zeros(3,3)+1e-20;
B = zeros(3,3);
tf = isequal(A,B)
```

```
tf =
```

```
0
```

The function returns logical 0 (`false`) because the matrices differ by a very small amount and are not *exactly* equal.

### **Compare Two Structures**

Create two structures and specify the fields in a different order.

```
A = struct('field1',0.005,'field2',2500);
B = struct('field2',2500,'field1',0.005);
```

Compare the structures for equality.

```
tf = isequaln(A,B)
```

```
tf =
```

```
 1
```

Even though the ordering of the fields in each structure is different, `isequal` treats them as the same because the values are equal.

### **Comparing Numeric Values with Special Nonnumeric Values**

Compare the logical value `true` to the double integer 1.

```
isequal(true,1)
```

```
ans =
```

```
 1
```

Notice that `isequal` does not consider data type when it tests for equality.

Similarly, compare 'A' to the ASCII-equivalent integer, 65.

```
isequal('A',65)
```

```
ans =
```

```
 1
```

The result is logical 1 (`true`) since `double('A')` equals 65.

### **Compare Vectors Containing NaN Values**

Create three vectors containing NaN values.

```
A1 = [1 NaN NaN];
A2 = [1 NaN NaN];
A3 = [1 NaN NaN];
```

Compare the vectors for equality.

```
tf = isequal(A1,A2,A3)
```

```
tf =

 0
```

The result is logical 0 (false) because `isequal` does not treat NaN values as equal to each other.

### Compare Two Datetime Values

Determine if midnight on January 13, 2013 in Anchorage, Alaska is equal to 11 AM on the same date in Cairo.

```
t1 = datetime(2013,1,13,0,0,0, 'TimeZone', 'America/Anchorage');
t2 = datetime(2013,1,13,11,0,0, 'TimeZone', 'Africa/Cairo');
tf = isequal(t1,t2)
```

```
tf =

 1
```

Add 8 months to the date, and compare the datetime values for equality.

```
t1 = datetime(2013,9,13,0,0,0, 'TimeZone', 'America/Anchorage');
t2 = datetime(2013,9,13,11,0,0, 'TimeZone', 'Africa/Cairo');
tf = isequal(t1,t2)
```

```
tf =

 0
```

The datetime values are no longer equal since Cairo does not observe daylight saving time.

## Input Arguments

### **A, B — Inputs to be compared**

numeric arrays | categorical arrays | cell arrays | tables | structures | ...

Inputs to be compared, specified as numeric arrays, categorical arrays, cell arrays, tables, or structures. Also, you can specify the inputs as logical arrays, character arrays, datetime arrays, duration arrays, calendarDuration arrays, or objects. The numeric types of A and B do not have to match.

You can compare a categorical array to a cell array of strings of the same size, or a single categorical element to a single string.

You can compare a datetime array to a cell array of date strings or a single date string.

If inputs A and B are *both*

- Structures -- Fields need not be in the same order as long as the contents are equal.
- Ordinal categorical arrays -- Must have the same sets of categories, including their order.
- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequal` compares the category names of each pair of elements.
- Datetime arrays -- `isequal` ignores time zone and display format when it compares points in time.
- Objects of different classes -- `isequal` returns logical 0 (`false`). This applies even when the objects have the same properties and their values match.

### **A1, A2, . . . , An — Series of inputs to be compared**

numeric arrays | categorical arrays | cell arrays | tables | structures | ...

Series of inputs to be compared, specified as numeric arrays, categorical arrays, cell arrays, tables, or structures. Also, you can specify the inputs as logical arrays, character arrays, datetime arrays, duration arrays, calendarDuration arrays, or objects. The numeric types of the inputs do not have to match.

You can compare categorical arrays to cell arrays of strings of the same size, or single categorical elements to single strings.

You can compare a datetime array to a cell array of date strings or a single date string.

If the inputs are *all*

- Structures -- Fields need not be in the same order as long as the contents are equal.
- Ordinal categorical arrays -- Must have the same sets of categories, including their order.
- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequal` compares the category names of each pair of elements.
- Datetime arrays -- `isequal` ignores time zone and display format when it compares points in time.
- Objects of different classes -- `isequal` returns logical 0 (`false`). This applies even when the objects have the same properties and their values match.

## More About

### Tips

- When comparing handle objects, use `==` to test whether objects have the same handle. Use `isequal` to determine if objects with different handles have equal property values.
- Use `isequaln` if you want to test for equality and treat NaN or NaT values as equal.
- The equality of two function handles depends on how they are constructed. For more information, see “Compare Function Handles”.

### See Also

`eq` | `is*` | `isa*` | `isequaln` | relational operators | `strcmp`

Introduced before R2006a

## **isenum**

Determine if variable is enumeration

### **Syntax**

```
tf = isenum(e)
```

### **Description**

`tf = isenum(e)` returns logical 1 (`true`) if `e` is an enumeration. Otherwise, it returns logical 0 (`false`). Empty enumeration objects return `true`.

If `e` is a heterogeneous array, `isenum` always returns `false`.

### **Examples**

#### **Test for Enumeration**

Determine if a variable is an enumeration.

The PPM class defines enumerations for three levels:

```
classdef PPM < int32
 enumeration
 High (1000)
 Medium (100)
 Low (10)
 end
end
```

Create a variable representing a level. Use `isenum` to determine if the variable is an enumeration:

```
currentLevel = PPM.High;
isenum(currentLevel)

ans =
```

1

## Input Arguments

### **e** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as any MATLAB variable.

## More About

- “How to Use Enumerations”

## See Also

islogical | isnumeric | isobject | isstruct

**Introduced in R2015a**

## isequaln

Determine array equality, treating NaN values as equal

### Syntax

```
tf = isequaln(A,B)
tf = isequaln(A1,A2,...,An)
```

### Description

`tf = isequaln(A,B)` returns logical 1 (**true**) if **A** and **B** are the same size and their contents are of equal value; otherwise, it returns logical 0 (**false**). The test compares both real and imaginary parts of numeric arrays. `isequaln` ignores the data type of the values in determining whether they are equal. For cell arrays, categorical arrays, tables, or structures, the function returns logical 1 (**true**) only when all elements and properties are equal. Undefined categorical elements, NaN (Not a Number), or NaT (Not a Time) values are considered to be equal to other such values.

`tf = isequaln(A1,A2,...,An)` returns logical 1 (**true**) if all the inputs are numerically equal.

### Examples

#### Compare Two Numeric Matrices

Create two numeric matrices and compare them for equality.

```
A = zeros(3,3)+1e-20;
B = zeros(3,3);
tf = isequaln(A,B)
```

```
tf =
 0
```

The function returns logical 0 (`false`) because the matrices differ by a very small amount and are not *exactly* equal.

### Compare Two Structures

Create two structures and specify the fields in a different order.

```
A = struct('field1',0.005,'field2',2500);
B = struct('field2',2500,'field1',0.005);
```

Compare the structures for equality.

```
tf = isequaln(A,B)
```

```
tf =
```

```
 1
```

Even though the ordering of the fields in each structure is different, `isequaln` treats them as the same because the values are equal.

### Comparing Numeric Values with Special Nonnumeric Values

Compare the logical value `true` to the double integer 1.

```
isequaln(true,1)
```

```
ans =
```

```
 1
```

Notice that `isequaln` does not consider data type when it tests for equality.

Similarly, compare 'A' to the ASCII-equivalent integer, 65.

```
isequaln('A',65)
```

```
ans =
```

```
 1
```

The result is logical 1 (`true`) since `double('A')` equals 65.

### Compare Vectors Containing NaN Values

Create three vectors containing NaN values.

```
A1 = [1 NaN NaN];
A2 = [1 NaN NaN];
A3 = [1 NaN NaN];
```

Compare the vectors for equality.

```
tf = isequaln(A1,A2,A3)
```

```
tf =
```

```
1
```

The result is logical 1 (**true**) because `isequaln` treats the NaN values as equal to each other.

## Input Arguments

### **A, B** — Inputs to be compared

numeric arrays | categorical arrays | cell arrays | tables | structures | ...

Inputs to be compared, specified as numeric arrays, categorical arrays, cell arrays, tables, or structures. Also, you can specify the inputs as logical arrays, character arrays, datetime arrays, duration arrays, calendarDuration arrays, or objects. The numeric types of **A** and **B** do not have to match.

You can compare a categorical array to a cell array of strings of the same size, or a single categorical element to a single string.

You can compare a datetime array to a cell array of date strings or a single date string.

If inputs **A** and **B** are *both*

- Structures -- Fields need not be in the same order as long as the contents are equal.
- Ordinal categorical arrays -- Must have the same sets of categories, including their order.
- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequaln` compares the category names of each pair of elements.
- Datetime arrays -- `isequal` ignores time zone and display format when it compares points in time.
- Objects of different classes -- `isequaln` returns logical 0 (**false**). This applies even when the objects have the same properties and their values match.

**A1 ,A2 , . . . ,An — Series of inputs to be compared**

numeric arrays | categorical arrays | cell arrays | tables | structures | ...

Series of inputs to be compared, specified as numeric arrays, categorical arrays, cell arrays, tables, or structures. Also, you can specify the inputs as logical arrays, character arrays, datetime arrays, duration arrays, calendarDuration arrays, or objects. The numeric types of the inputs do not have to match.

You can compare categorical arrays to cell arrays of strings of the same size, or single categorical elements to single strings.

You can compare a datetime array to a cell array of date strings or a single date string.

If the inputs are *all*

- Structures -- Fields need not be in the same order as long as the contents are equal.
- Ordinal categorical arrays -- Must have the same sets of categories, including their order.
- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequaln` compares the category names of each pair of elements.
- Datetime arrays -- `isequaln` ignores time zone and display format when it compares points in time.
- Objects of different classes -- `isequaln` returns logical 0 (`false`). This applies even when the objects have the same properties and their values match.

## More About

### Tips

- When comparing handle objects, use `==` to test whether objects have the same handle. Use `isequaln` to treat NaN values as equal and determine if objects with different handles have equal property values.
- Use `isequal` if you want to test for equality and treat NaN or NaT values as unequal.
- The equality of two function handles depends on how they are constructed. For more information, see “Compare Function Handles”.

`eq` | `is*` | `isa*` | `isequal` | relational operators | `strcmp`

**Introduced in R2012a**

# isequalwithequalnans

Test arrays for equality, treating NaNs as equal

---

**Note:** `isequalwithequalnans` is not recommended. Use `isequaln` instead.

---

## Syntax

```
tf = isequalwithequalnans(A, B, ...)
```

## Description

`tf = isequalwithequalnans(A, B, ...)` returns logical 1 (**true**) if the input arrays are the same type and size and hold the same contents, and logical 0 (**false**) otherwise. NaN (Not a Number) values are considered to be equal to each other. Numeric data types and structure field order do not have to match.

## Examples

Arrays containing NaNs are handled differently by `isequal` and `isequalwithequalnans`. `isequal` does not consider NaNs to be equal, while `isequalwithequalnans` does.

```
A = [32 8 -29 NaN 0 5.7];
B = A;
isequal(A, B)
ans =
 0
```

```
isequalwithequalnans(A, B)
ans =
 1
```

The position of NaN elements in the array does matter. If they are not in the same position in the arrays being compared, then `isequalwithequalnans` returns zero.

```
A = [2 4 6 NaN 8]; B = [2 4 NaN 6 8];
isequalwithequalnans(A, B)
ans =
 0
```

## More About

### Tips

`isequalwithequalnans` is the same as `isequal`, except `isequalwithequalnans` considers NaN (Not a Number) values to be equal, and `isequal` does not.

`isequalwithequalnans` recursively compares the contents of cell arrays and structures. If all the elements of a cell array or structure are numerically equal, `isequalwithequalnans` returns logical 1.

### See Also

`isequal` | `strcmp` | `isa` | `is*` | relational operators | `isequaln`

**Introduced before R2006a**

## isevent

Determine whether input is COM object event

### Syntax

```
tf = isevent(h, 'eventname')
```

### Description

`tf = isevent(h, 'eventname')` returns logical 1 (**true**) if `eventname` is an event recognized by COM object `h`. Otherwise, returns logical 0 (**false**). The `eventname` argument is not case-sensitive.

COM functions are available on Microsoft Windows systems only.

### Examples

This example tests events in a MATLAB sample control object.

- 1 Create an instance of the `mwsamp` control and test `Db1Click`.

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],f);
isevent(h,'Db1Click')
```

MATLAB displays **true**, indicating `Db1Click` is an event.

- 2 Try the same test on `Redraw`.

```
isevent(h,'Redraw')
```

MATLAB displays **false**, indicating `Redraw` is not an event; it is a method.

Test events in a Microsoft Excel workbook object.

- 1 Create a `Workbook` object `wb`

```
myApp = actxserver('Excel.Application');
```

```
wbs = myApp.Workbooks;
wb = Add(wbs);
```

## 2 Test Activate.

```
isevent(wb, 'Activate')
```

MATLAB displays `true`, indicating `Activate` is an event.

## 3 Test Save

```
isevent(wb, 'Save')
```

MATLAB displays `false`, indicating `Save` is not an event; it is a method.

## More About

- “Exploring Events”

## See Also

`events` (COM) | `eventlisteners` | `registerevent`

# isfield

Determine whether input is structure array field

## Syntax

```
tf = isfield(S, 'fieldname')
tf = isfield(S, C)
```

## Description

`tf = isfield(S, 'fieldname')` examines structure `S` to see if it includes the field specified by the quoted string `'fieldname'`. Output `tf` is set to logical 1 (`true`) if `S` contains the field, or logical 0 (`false`) if not. If `S` is not a structure array, `isfield` returns `false`.

`tf = isfield(S, C)` examines structure `S` for multiple fieldnames as specified in cell array of strings `C`, and returns an array of logical values to indicate which of these fields are part of the structure. Elements of output array `tf` are set to a logical 1 (`true`) if the corresponding element of `C` holds a fieldname that belongs to structure `S`. Otherwise, logical 0 (`false`) is returned in that element. In other words, if structure `S` contains the field specified in `C{m,n}`, `isfield` returns a logical 1 (`true`) in `tf(m,n)`.

---

**Note** `isfield` returns `false` if the `field` or `fieldnames` input is empty.

---

## Examples

### Example 1 — Single Fieldname Syntax

Given the following MATLAB structure,

```
patient.name = 'John Doe';
patient.billing = 127.00;
patient.test = [79 75 73; 180 178 177.5; 220 210 205];
```

`isfield` identifies `billing` as a field of that structure.

```
isfield(patient,'billing')
ans =
 1
```

## Example 2 — Multiple Fieldname Syntax

Check structure `S` for any of four possible fieldnames. Only the first is found, so the first element of the return value is set to `true`:

```
S = struct('one', 1, 'two', 2);

fields = isfield(S, {'two', 'pi', 'One', 3.14})
fields =
 1 0 0 0
```

## More About

- dynamic field names

## See Also

**Introduced before R2006a**

# isfinite

Array elements that are finite

## Syntax

```
TF = isfinite(A)
```

## Description

`TF = isfinite(A)` returns an array the same size as `A` containing logical 1 (**true**) where the elements of the array `A` are finite and logical 0 (**false**) where they are infinite or NaN. For a complex number `z`, `isfinite(z)` returns 1 if both the real and imaginary parts of `z` are finite, and 0 if either the real or the imaginary part is infinite or NaN.

For any real `A`, exactly one of the three quantities `isfinite(A)`, `isinf(A)`, and `isnan(A)` is equal to one.

## Examples

```
a = [-2 -1 0 1 2];
isfinite(1./a)
ans =
 1 1 0 1 1
isfinite(0./a)
ans =
 1 1 0 1 1
```

## See Also

`isinf` | `isnan` | `is*`

Introduced before R2006a

## isfloat

Determine if input is floating-point array

### Syntax

```
tf = isfloat(A)
```

### Description

`tf = isfloat(A)` returns `true` if `A` is a floating-point array and `false` otherwise. The floating-point types are `single` and `double`, and subclasses of `single` and `double`.

### Examples

These examples show the values `isfloat` returns when passed specific types:

```
% pi returns a floating-point value
isfloat(pi)
ans =
 1
% Complex numbers are floating-point values
isfloat(3+7i)
ans =
 1
% Single-precision numbers are floating-point values
isfloat(realmax('single'))
ans =
 1
% isfloat returns a logical value
isfloat(isfloat(pi))
ans =
 0
```

### See Also

`isa` | `isinteger` | `double` | `single` | `isnumeric`

**Introduced before R2006a**

# isglobal

(To be removed) Determine if input is global variable

---

**Note** `isglobal` has been removed. Avoid conditions in your code that check variable scope. If you need to convert your code quickly in the short term, replace `isglobal` with `~isempty(whos('global', 'variable'))`. However, you should refactor your code to avoid conditional checks on variable scope.

---

## Syntax

```
tf = isglobal(A)
```

## Description

`tf = isglobal(A)` returns logical 1 (**true**) if `A` has been declared to be a global variable in the context from which `isglobal` is called, and logical 0 (**false**) otherwise.

## More About

### Tips

`isglobal` is most commonly used in conjunction with conditional global declaration. An alternate approach is to use a pair of variables, one local and one declared global.

Instead of using

```
if condition
 global x
end

x = some_value

if isglobal(x)
```

```
 do_something
end
```

You can use

```
global gx
if condition
 gx = some_value
else
 x = some_value
end
```

```
if condition
 do_something
end
```

If no other workaround is possible, you can replace the command

```
isglobal(variable)
```

with

```
~isempty(whos('global','variable'))
```

## See Also

global | isvarname | isa | is\*

**Introduced before R2006a**

# isgraphics

True for valid graphics object handles

## Syntax

```
tf = isgraphics(H)
tf = isgraphics(H,type)
```

## Description

`tf = isgraphics(H)` returns `true` for elements of `H` that are valid graphics object and `false` where elements are not valid graphics objects.

`tf = isgraphics(H,type)` returns `true` for elements of `H` that are valid graphics objects of the type specified by the `type` argument. An object type is the string contained in the object's `Type` property.

## Examples

### Test for Valid Handles

Create a plot and return the handle array. Test array for valid handles

```
H = plot(rand(5));
isgraphics(H)
```

```
ans =
```

```
1
1
1
1
1
```

## Test for Handle Types

Create a plot and return the handle array. Concatenate with other graphics objects and test for handles that are of type line.

```
H = plot(rand(5));
a = [H;gca;gcf];
isgraphics(a,'line')
```

```
ans =
```

```
 1
 1
 1
 1
 1
 0
 0
```

## Input Arguments

**H** — Input variable or expression

graphics object array

Input variable or expression that evaluates to graphics object handles.

**type** — The object type

char

The object type, specified as a quoted string. An object's type is contained in its `Type` property.

## Output Arguments

**tf** — true or false

logical array

Logical array of 1s and 0s indicating the elements of the input array that are valid object handles or valid handles of a specific type if you specify a type argument.

## More About

- “Graphics Object Handles”

## See Also

### Functions

isa | ishghandle

**Introduced in R2014b**

## ishandle

Test for valid graphics or Java object handle

### Syntax

ishandle(H)

### Description

ishandle(H) returns an array whose elements are 1 where the elements of H are graphics or Java object handles, and 0 where they are not.

---

**Note:** Use the most specific function for your application instead of `ishandle`, as described in the following sections.

---

### MATLAB Handle Objects

Use the `isa` function to determine the class of MATLAB objects.

Use the `handle` class `isvalid` method to determine the validity of handle objects. See “Test Handle Validity” for information on testing for MATLAB handle objects.

### Graphics Object Handles

Use `isgraphics` for graphics objects.

### Java Object Handles

Use `isjava` for Java objects.

### See Also

`isa` | `isjava` | `isgraphics`

**Introduced before R2006a**

## ishermitian

Determine if matrix is Hermitian or skew-Hermitian

### Syntax

```
tf = ishermitian(A)
tf = ishermitian(A,skewOption)
```

### Description

`tf = ishermitian(A)` returns logical 1 (**true**) if square matrix **A** is Hermitian; otherwise, it returns logical 0 (**false**).

`tf = ishermitian(A,skewOption)` specifies the type of the test. Specify `skewOption` as 'skew' to determine if **A** is skew-Hermitian.

### Examples

#### Test if Symmetric Matrix Is Hermitian

Create a 3-by-3 matrix.

```
A = [1 0 1i; 0 1 0; 1i 0 1]
```

A =

```
1.0000 + 0.0000i 0.0000 + 0.0000i 0.0000 + 1.0000i
0.0000 + 0.0000i 1.0000 + 0.0000i 0.0000 + 0.0000i
0.0000 + 1.0000i 0.0000 + 0.0000i 1.0000 + 0.0000i
```

The matrix is symmetric with respect to its real-valued diagonal.

Test whether the matrix is Hermitian.

```
tf = ishermitian(A)
```

```
tf =
 0
```

The result is logical 0 (**false**) because **A** is not Hermitian. In this case, **A** is equal to its transpose, **A'**, but not its complex conjugate transpose, **A'**.

Change the element in **A(3,1)** to be **-1i**.

```
A(3,1) = -1i;
```

Determine if the modified matrix is Hermitian.

```
tf = ishermitian(A)

tf =
 1
```

The matrix, **A**, is now Hermitian because it is equal to its complex conjugate transpose, **A'**.

### Test if Matrix Is Skew-Hermitian

Create a 3-by-3 matrix.

```
A = [-1i -1 1-i;1 -1i -1;-1-i 1 -1i]

A =

 0.0000 - 1.0000i -1.0000 + 0.0000i 1.0000 - 1.0000i
 1.0000 + 0.0000i 0.0000 - 1.0000i -1.0000 + 0.0000i
 -1.0000 - 1.0000i 1.0000 + 0.0000i 0.0000 - 1.0000i
```

The matrix has pure imaginary numbers on the main diagonal.

Specify **skewOption** as **'skew'** to determine whether the matrix is skew-Hermitian.

```
tf = ishermitian(A,'skew')

tf =
 1
```

The matrix,  $A$ , is skew-Hermitian since it is equal to the negation of its complex conjugate transpose,  $-A'$ .

## Input Arguments

### **A** — Input matrix

numeric matrix

Input matrix, specified as a numeric matrix. If  $A$  is not square, then `ishermitian` returns logical 0 (`false`).

Data Types: `single` | `double`

Complex Number Support: Yes

### **skewOption** — Test type

'nonskew' (default) | 'skew'

Test type, specified as 'nonskew' (default) or 'skew'. Specify 'skew' to test whether  $A$  is skew-Hermitian. Specifying `ishermitian(A, 'nonskew')` is equivalent to `ishermitian(A)`.

Data Types: `char`

## More About

### Hermitian Matrix

- A square matrix,  $A$ , is Hermitian if it is equal to its complex conjugate transpose,  $A = A'$ .

In terms of the matrix elements, this means that

$$a_{i,j} = \bar{a}_{j,i}.$$

- The entries on the diagonal of a Hermitian matrix are always real. Since real matrices are unaffected by complex conjugation, a real matrix that is symmetric is also Hermitian. For example, the matrix

$$A = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 2 & 0 \\ 1 & 0 & 1 \end{bmatrix}$$

is both symmetric and Hermitian.

- The eigenvalues of a Hermitian matrix are real.

### Skew-Hermitian Matrix

- A square matrix,  $A$ , is skew-Hermitian if it is equal to the negation of its complex conjugate transpose,  $A = -A'$ .

In terms of the matrix elements, this means that

$$a_{i,j} = -\bar{a}_{j,i}.$$

- The entries on the diagonal of a skew-Hermitian matrix are always pure imaginary or zero. Since real matrices are unaffected by complex conjugation, a real matrix that is skew-symmetric is also skew-Hermitian. For example, the matrix

$$A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$$

is both skew-Hermitian and skew-symmetric.

- The eigenvalues of a skew-Hermitian matrix are purely imaginary or zero.

**Introduced in R2014a**

## ishghandle

True for graphics object handles

### Syntax

```
ishghandle(h)
```

### Description

`ishghandle(h)` returns an array that contains 1's where the elements of `h` are handles to existing graphic objects and 0's where they are not. Differs from `ishandle` in that Simulink objects handles return false.

### Examples

Create a plot and find the valid handles:

```
x = [1:10];
y = [1:10];
p = plot(x,y);
ishghandle(p)
```

```
ans =
```

```
1
```

### More About

- “Graphics Object Handles”

### See Also

`isa` | `isgraphics` | `gca`

# ishold

Current hold state

## Syntax

```
tf = ishold
```

## Description

`tf = ishold` returns 1 if `hold` is on, and 0 if it is off. When `hold` is on, the current plot and most axis properties are held so that subsequent graphing commands add to the existing graph.

A state of `hold` on implies that both figure and axes `NextPlot` properties are set to `add`.

## More About

- “Control Graph Display”

## See Also

`hold` | `newplot`

**Introduced before R2006a**

## isinf

Array elements that are infinite

### Syntax

```
TF = isinf(A)
```

### Description

`TF = isinf(A)` returns an array the same size as `A` containing logical 1 (**true**) where the elements of `A` are `+Inf` or `-Inf` and logical 0 (**false**) where they are not. For a complex number `z`, `isinf(z)` returns 1 if either the real or imaginary part of `z` is infinite, and 0 if both the real and imaginary parts are finite or NaN.

For any real `A`, exactly one of the three quantities `isfinite(A)`, `isinf(A)`, and `isnan(A)` is equal to one.

### Examples

```
a = [-2 -1 0 1 2];
```

```
isinf(1./a)
```

```
ans =
 0 0 1 0 0
```

```
isinf(0./a)
```

```
ans =
 0 0 0 0 0
```

### See Also

`isfinite` | `isnan` | `is*`

**Introduced before R2006a**

# isinteger

Determine if input is integer array

## Syntax

```
tf = isinteger(A)
```

## Description

`tf = isinteger(A)` returns `true` if the array `A` is an integer type and `false` otherwise.

An integer array is any of the following integer types and any subclasses of those types:

### MATLAB Integer Types

|                     |                               |
|---------------------|-------------------------------|
| <code>int8</code>   | 8-bit signed integer array    |
| <code>uint8</code>  | 8-bit unsigned integer array  |
| <code>int16</code>  | 16-bit signed integer array   |
| <code>uint16</code> | 16-bit unsigned integer array |
| <code>int32</code>  | 32-bit signed integer array   |
| <code>uint32</code> | 32-bit unsigned integer array |
| <code>int64</code>  | 64-bit signed integer array   |
| <code>uint64</code> | 64-bit unsigned integer array |

## Examples

These examples show the values `isinteger` returns when passed specific types:

```
% uint8 is one of the integer types
isinteger(uint8(1:255))
ans =
 1
```

```
% pi returns a double-precision value
isinteger(pi)
ans =
 0
% Constants are double-precision by default
isinteger(3)
ans =
 0
% isinteger returns a logical value
isinteger(isinteger(uint8(3)))
ans =
 0
```

## See Also

[isa](#) | [isnumeric](#) | [isfloat](#)

**Introduced before R2006a**

# isinterface

Determine whether input is COM interface

## Syntax

```
tf = isinterface(h)
```

## Description

`tf = isinterface(h)` returns logical 1 (**true**) if handle `h` is a COM interface. Otherwise, returns logical 0 (**false**).

COM functions are available on Microsoft Windows systems only.

## Examples

Test an instance of a Microsoft Excel application.

```
h = actxserver('Excel.Application');
isinterface(h)
```

MATLAB displays **false**, indicating object `h` is not an interface.

Test a `workbooks` object

```
w = get(h, 'workbooks');
isinterface(w)
```

MATLAB displays **true**, indicating object `w` is an interface.

## More About

- “Exploring Interfaces”

## See Also

`iscom` | `interfaces`

## **isjava**

Determine if input is Java object

### **Syntax**

```
tf = isjava(A)
```

### **Description**

`tf = isjava(A)` returns logical 1 (true) if object A is a Java object. Otherwise, it returns logical 0 (false).

### **Examples**

#### **Test If java.util.Date Is Java Object**

Create an instance of the Java Date class.

```
myDate = java.util.Date;
isjava(myDate)
```

```
ans =
```

```
 1
```

`myDate` is a Java object.

However, `myDate` is not a MATLAB object.

```
isobject(myDate)
```

```
ans =
```

```
 0
```

### **See Also**

`is*` | `isa` | `isobject` | `javaArray` | `javaMethod` | `javaObject`

**Introduced before R2006a**

## isKey

**Class:** containers.Map

**Package:** containers

Determine if `containers.Map` object contains key

## Syntax

```
tf = isKey(mapObj, keySet)
```

## Description

`tf = isKey(mapObj, keySet)` looks for the specified keys in `mapObj`, and returns logical `true` (1) for the keys that it finds, and logical `false` (0) for those it does not. `keySet` is a scalar key or a cell array of keys.

## Input Arguments

### **mapObj**

Object of class `containers.Map`.

### **keySet**

Scalar value, string, or cell array that specifies keys to find in `mapObj`.

## Output Arguments

### **tf**

Array of logical values. If `keySet` is a scalar or a string, `tf` is a scalar. Otherwise, `tf` has the same size and dimensions as `keySet`.

## Examples

### Find Keys in a Map

Construct a map that contains rainfall data for several months:

```
months = {'Jan', 'Feb', 'Mar', 'Apr'};
rainfall = [327.2, 368.2, 197.6, 178.4];
mapObj = containers.Map(months,rainfall);
```

Determine if keys Apr, May, and Jun are in the map:

```
keySet = {'Apr','May','Jun'};
tf = isKey(mapObj,keySet)
```

This code returns 1-by-3 vector `tf`:

```
tf =
 1 0 0
```

### Find a Single Key

Determine if `mapObj` from the previous example contains key `Feb`:

```
keySet = 'Feb';
tf = isKey(mapObj,keySet)
```

This code returns scalar `tf`:

```
tf =
 1
```

### See Also

[keys](#) | [values](#) | [containers.Map](#) | [remove](#)

## iskeyword

Determine whether input is MATLAB keyword

### Syntax

```
tf = iskeyword('str')
iskeyword str
iskeyword
```

### Description

`tf = iskeyword('str')` returns logical 1 (true) if the string `str` is a keyword in the MATLAB language and logical 0 (false) otherwise. MATLAB keywords cannot be used as variable names.

`iskeyword str` uses the MATLAB command format.

`iskeyword` returns a list of all MATLAB keywords.

### Examples

To test if the word `while` is a MATLAB keyword,

```
iskeyword while
ans =
 1
```

To obtain a list of all MATLAB keywords,

```
iskeyword
 'break'
 'case'
 'catch'
 'classdef'
 'continue'
 'else'
 'elseif'
```

```
'end'
'for'
'function'
'global'
'if'
'otherwise'
'parfor'
'persistent'
'return'
'spmd'
'switch'
'try'
'while'
```

## See Also

**Introduced before R2006a**

## isletter

Array elements that are alphabetic letters

## Syntax

```
tf = isletter('str')
```

## Description

`tf = isletter('str')` returns an array the same size as `str` containing logical `1` (`true`) where the elements of `str` are letters of the alphabet and logical `0` (`false`) where they are not.

## Examples

Find the letters in character array `s`.

```
s = 'A1,B2,C3';
```

```
isletter(s)
```

```
ans =
```

```
 1 0 0 1 0 0 1 0
```

## See Also

**Introduced before R2006a**

# islogical

Determine if input is logical array

## Syntax

```
tf = islogical(A)
```

## Description

`tf = islogical(A)` returns `true` if `A` is a logical array and `false` otherwise. `islogical` also returns `true` if `A` is an instance of a class that is derived from the logical class.

## Examples

These examples show the values `islogical` returns when passed specific types:

```
% Relational operators return logical values
```

```
islogical(5<7)
ans =
 1
```

```
% true and false return logical values
```

```
islogical(true) & islogical(false)
ans =
 1
```

```
% Constants are double-precision by default
```

```
islogical(1)
ans =
 0
```

```
% logical creates logical values
```

```
islogical(logical(1))
ans =
 1
```

## **More About**

- “Determine if Arrays Are Logical”

## **See Also**

`is*` | `isa` | `logical`

**Introduced before R2006a**

## ismac

Determine if version is for Mac OS X platform

## Syntax

```
tf = ismac
```

## Description

`tf = ismac` returns logical 1 (true) if the version of MATLAB software is for the Apple Mac OS X platform. Otherwise, it returns logical 0 (false).

## Examples

### Execute MATLAB Command Based on Platform

```
if ismac
 % Code to run on Mac platform
elseif isunix
 % Code to run on Linux platform
elseif ispc
 % Code to run on Windows platform
else
 disp('Cannot recognize platform')
end
```

## More About

### Tips

- The `isunix` function also determines if version is for Mac OS X platforms.

### See Also

`computer` | `is*` | `ispc` | `isstudent` | `isunix`

**Introduced in R2007a**

# ismatrix

Determine whether input is matrix

## Syntax

```
ismatrix(V)
```

## Description

`ismatrix(V)` returns logical 1 (**true**) if `size(V)` returns `[m n]` with nonnegative integer values `m` and `n`, and logical 0 (**false**) otherwise.

## Examples

Create three vectors:

```
V1 = rand(5,1);
V2 = rand(5,1);
V3 = rand(5,1);
```

Concatenate the vectors and check that the result is a matrix. `ismatrix` returns 1:

```
M = cat(2,V1,V2,V3);
ismatrix(M)
ans =
 1
```

## See Also

`iscolumn` | `isrow` | `isscalar` | `isvector`

# ismember

Array elements that are members of set array

## Syntax

```
Lia = ismember(A,B)
Lia = ismember(A,B,'rows')
[Lia,Locb] = ismember(A,B)
[Lia,Locb] = ismember(A,B,'rows')

[Lia,Locb] = ismember(____, 'legacy')
```

## Description

`Lia = ismember(A,B)` returns an array containing **1 (true)** where the data in **A** is found in **B**. Elsewhere, it returns **0 (false)**.

- If **A** and **B** are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `ismember` returns a logical value for each element of **A**. The output, **Lia**, is an array of the same size as **A**.
- If **A** and **B** are tables, then `ismember` returns a logical value for each row of **A**. The output, **Lia**, is a column vector with the same number of rows as **A**.

`Lia = ismember(A,B,'rows')` treats each row of **A** and each row of **B** as single entities and returns a column vector containing **1 (true)** where the rows of **A** are also rows of **B**. Elsewhere, it returns **0 (false)**.

**A** and **B** must have the same number of columns when you use the `'rows'` option. Furthermore, the `'rows'` option does not support cell arrays, unless one of the inputs is either a categorical array or a datetime array.

`[Lia,Locb] = ismember(A,B)` also returns an array, **Locb**.

- If **A** and **B** are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then **Locb** contains the lowest index in **B** for each value in **A** that is a member of **B**. The output array, **Locb**, contains **0** wherever **A** is not a member of **B**.

- If A and B are tables, then LOcb contains the lowest index in B for each row in A that is also a row in B. The output vector, LOcb, contains 0 whenever A is not a row of B.

[Lia,Locb] = ismember(A,B,'rows') also returns a column vector, Locb, containing the lowest index in B for each row in A that is also a row in B. The output vector, Locb, contains 0 wherever A is not a row of B.

[Lia,Locb] = ismember(\_\_\_\_,'legacy') preserves the behavior of the ismember function from R2012b and prior releases using any of the input arguments in previous syntaxes.

The 'legacy' option does not support categorical arrays, tables, datetime arrays, or duration arrays.

## Examples

### Values That Are Members of Set

Create two vectors with values in common.

```
A = [5 3 4 2];
B = [2 4 4 4 6 8];
```

Determine which elements of A are also in B.

```
Lia = ismember(A,B)
```

```
Lia =
 0 0 1 1
```

A(3) and A(4) are found in B.

### Table Rows Found in Another Table

Create two tables with rows in common.

```
A = table([1:5]', ['A';'B';'C';'D';'E'], logical([0;1;0;1;0]))
B = table([1:2:10]', ['A';'C';'E';'G';'I'], logical(zeros(5,1)))
```

A =

| Var1 | Var2 | Var3  |
|------|------|-------|
| 1    | A    | false |
| 2    | B    | true  |
| 3    | C    | false |
| 4    | D    | true  |
| 5    | E    | false |

B =

| Var1 | Var2 | Var3  |
|------|------|-------|
| 1    | A    | false |
| 3    | C    | false |
| 5    | E    | false |
| 7    | G    | false |
| 9    | I    | false |

Determine which rows of A are also in B.

```
Lia = ismember(A,B)
```

Lia =

```
1
0
1
0
1
```

A(1,:), A(3,:), and A(5,:) are found in B.

### Members of Set and Indices to Values

Create two vectors with values in common.

```
A = [5 3 4 2];
B = [2 4 4 4 6 8];
```

Determine which elements of **A** are also in **B** as well as their corresponding locations in **B**.

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =
```

```
 0 0 1 1
```

```
Locb =
```

```
 0 0 2 1
```

The lowest index to **A**(3) is **B**(2), and **A**(4) is found in **B**(1).

### Rows of Another Table and Their Location

Create a table, **A**, of gender, age, and height for five people.

```
A = table(['M';'M';'F';'M';'F'],[27;52;31;46;35],[74;68;64;61;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty' 'Bob' 'Judy'})
```

```
A =
```

|       | Gender | Age | Height |
|-------|--------|-----|--------|
| Ted   | M      | 27  | 74     |
| Fred  | M      | 52  | 68     |
| Betty | F      | 31  | 64     |
| Bob   | M      | 46  | 61     |
| Judy  | F      | 35  | 64     |

Create another table, **B**, with rows in common with **A**.

```
B = table(['M';'F';'F';'F'],[47;31;35;23],[68;64;62;58],...
```

```
'VariableNames',{ 'Gender' 'Age' 'Height'},...
'RowNames',{ 'Joe' 'Meg' 'Beth' 'Amy'})
```

B =

|      | Gender | Age | Height |
|------|--------|-----|--------|
|      | -----  | --- | -----  |
| Joe  | M      | 47  | 68     |
| Meg  | F      | 31  | 64     |
| Beth | F      | 35  | 62     |
| Amy  | F      | 23  | 58     |

Determine which rows of A are also in B, as well as their corresponding locations in B.

```
[Lia,Locb] = ismember(A,B)
```

Lia =

```
0
0
1
0
0
```

Locb =

```
0
0
2
0
0
```

Two rows that have the same values, but different names, are considered equal. The same data for Betty is found in B(2, :), which corresponds to Meg.

## Rows That Belong to a Set

Create two matrices with a row in common.

```
A = [1 3 5 6; 2 4 6 8];
B = [2 4 6 8; 1 3 5 7; 2 4 6 8];
```

Determine which rows of A are also in B as well as their corresponding locations in B.

```
[Lia, Locb] = ismember(A,B, 'rows')
```

```
Lia =
```

```
0
1
```

```
Locb =
```

```
0
1
```

The lowest index to A(2,:) is B(1,).

### Members of Set Containing NaN Values

Create two vectors containing NaN.

```
A = [5 NaN NaN];
B = [5 NaN NaN];
```

Determine which elements of A are also in B, as well as their corresponding locations in B.

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =
```

```
1 0 0
```

```
Locb =
```

```
1 0 0
```

`ismember` treats NaN values as distinct.

## Cell Array of Strings with Trailing White Space

Create a cell array of strings, A.

```
A = {'dog', 'cat', 'fish', 'horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ', 'cat', 'fish ', 'horse'};
```

Determine which strings of A are also in B.

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =
```

```
 0 1 0 1
```

```
Locb =
```

```
 0 2 0 4
```

`ismember` treats trailing white space in cell arrays of strings as distinct characters.

## Members of Char and Cell Array of Strings

Create a character array, A, and a cell array of strings, B.

```
A = ['cat'; 'dog'; 'fox'; 'pig'];
B = {'dog', 'cat', 'fish', 'horse'};
```

Determine which strings of A are also in B.

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =
```

```
 1
 1
 0
```

```
0
```

```
Locb =
```

```
2
```

```
1
```

```
0
```

```
0
```

### Preserve Legacy Behavior of ismember

Use the 'legacy' flag to preserve the behavior of `ismember` from R2012b and prior releases in your code.

Find the members of **B** with the current behavior.

```
A = [5 3 4 2];
B = [2 4 4 4 6 8];
[Lia1,Locb1] = ismember(A,B)
```

```
Lia1 =
```

```
0 0 1 1
```

```
Locb1 =
```

```
0 0 2 1
```

Find the members of **B**, and preserve the legacy behavior.

```
[Lia2,Locb2] = ismember(A,B,'legacy')
```

```
Lia2 =
```

```
0 0 1 1
```

```
Locb2 =
```

0 0 4 1

## Input Arguments

### A – Query array

numeric array | logical array | character array | categorical array | datetime arrays | duration arrays | cell array of strings | table

Query array, specified as a numeric array, logical array, character array, categorical array, datetime array, duration array, cell array of strings, or a table.

A must belong to the same class as B with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.
- Datetime arrays can combine with cell arrays of date strings or single date strings.

If A and B are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither A nor B are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names.

If you specify the `'rows'` option, A must have the same number of columns as B.

If A is a table, it must have the same variable names as B. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

If A and B are datetime arrays, they must be consistent with each other in whether they specify a time zone.

Furthermore, A can be an object with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)
- `eq`
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

**B — Set array**

numeric array | logical array | character array | categorical array | datetime arrays | duration arrays | cell array of strings | table

Set array, specified as a numeric array, logical array, character array, categorical array, datetime array, duration array, cell array of strings, or a table.

B must belong to the same class as A with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.
- Datetime arrays can combine with cell arrays of date strings or single date strings.

If A and B are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither A nor B are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names.

If you specify the `'rows'` option, B must have the same number of columns as A.

If B is a table, it must have the same variable names as A. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

If A and B are datetime arrays, they must be consistent with each other in whether they specify a time zone.

Furthermore, B can be an object with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)
- `eq`
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

## Output Arguments

**Lia — Logical index to A**

vector | matrix | N-D array

Logical index to **A**, returned as a vector, matrix or N-D array containing 1 (**true**) wherever the values (or rows) in **A** are members of **B**. Elsewhere, it returns 0 (**false**).

**Lia** is an array of the same size as **A**, unless you specify the 'rows' flag.

If the 'rows' flag is specified or if **A** is a table, **Lia** is a column vector with the same number of rows as **A**.

### **Locb — Locations in B**

vector | matrix | N-D array

Locations in **B**, returned as a vector, matrix, or N-D array. If the 'legacy' flag is not specified, **Locb** contains the lowest indices to the values (or rows) in **B** that are found in **A**. **Locb** contains 0 wherever **A** is not a member of **B**.

**Locb** is an array of the same size as **A** unless you specify the 'rows' flag.

If the 'rows' flag is specified or if **A** is a table, **Locb** is a column vector with the same number of rows as **A**.

## More About

### Tips

- To find the rows from table **A** that are found in **B** with respect to a subset of variables, you can use column subscripting. For example, you can use `ismember(A(:,vars),B(:,vars))`, where *vars* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

**Introduced before R2006a**

# ismembertol

Members of set within tolerance

## Syntax

```
LIA = ismembertol(A,B,tol)
LIA = ismembertol(A,B)
[LIA,LocB] = ismembertol(___)
[___] = ismembertol(___ ,Name,Value)
```

## Description

`LIA = ismembertol(A,B,tol)` returns an array containing logical 1 (**true**) where the elements of **A** are within tolerance of the elements in **B**. Otherwise, the array contains logical 0 (**false**). Two values, **u** and **v**, are within tolerance if

$$\text{abs}(u-v) \leq \text{tol} * \max(\text{abs}([A(:);B(:)]))$$

That is, `ismembertol` scales the `tol` input based on the magnitude of the data.

`ismembertol` is similar to `ismember`. Whereas `ismember` performs exact comparisons, `ismembertol` performs comparisons using a tolerance.

`LIA = ismembertol(A,B)` uses a default tolerance of  $1e-6$  for single-precision inputs and  $1e-12$  for double-precision inputs.

`[LIA,LocB] = ismembertol( ___ )` also returns an array, `LocB`, that contains the index location in **B** for each element in **A** that is a member of **B**. You can use any of the input arguments in previous syntaxes.

`[ ___ ] = ismembertol( ___ ,Name,Value)` uses additional options specified by one or more **Name-Value** pair arguments using any of the input or output argument combinations in previous syntaxes. For example, `ismembertol(A,B, 'ByRows', true)` compares the rows of **A** and **B** and returns a logical column vector.

## Examples

### Set Members in Presence of Numerical Error

Create a vector,  $x$ . Obtain a second vector,  $y$ , by transforming and untransforming  $x$ . This transformation introduces round-off differences to  $y$ .

```
x = (1:6)'*pi;
y = 10.^log10(x);
```

Verify that  $x$  and  $y$  are not identical by taking the difference.

```
x-y
```

```
ans =
```

```
1.0e-14 *
0.0444
0
0
0
0
-0.3553
```

Use `ismember` to find the elements of  $x$  that are in  $y$ . The `ismember` function performs exact comparisons and determines that some of the matrix elements in  $x$  are not members of  $y$ .

```
lia = ismember(x,y)
```

```
lia =
```

```
0
1
1
1
1
0
```

Use `ismembertol` to perform the comparison using a small tolerance. `ismembertol` treats elements that are within tolerance as equal and determines that all of the elements in `x` are members of `y`.

```
LIA = ismembertol(x,y)
```

```
LIA =
```

```

1
1
1
1
1
1
1
```

### Determine Set Members by Rows

By default, `ismembertol` looks for *elements* that are within tolerance, but it also can find *rows* of a matrix that are within tolerance.

Create a numeric matrix, `A`. Obtain a second matrix, `B`, by transforming and untransforming `A`. This transformation introduces round-off differences to `B`.

```
A = [0.05 0.11 0.18; 0.18 0.21 0.29; 0.34 0.36 0.41; ...
 0.46 0.52 0.76; 0.82 0.91 1.00];
B = log10(10.^A);
```

Use `ismember` to find the rows of `A` that are in `B`. `ismember` performs exact comparisons and thus determines that most of the rows in `A` are not members of `B`, even though some of the rows differ by only a small amount.

```
lia = ismember(A,B,'rows')
```

```
lia =
```

```

0
0
0
0
1
```

Use `ismembertol` to perform the row comparison using a small tolerance. `ismembertol` treats rows that are within tolerance as equal and thus determines that all of the rows in `A` are members of `B`.

```
LIA = ismembertol(A,B,'ByRows',true)
```

```
LIA =
```

```
1
1
1
1
1
```

## Average Similar Values in Vectors

Create two vectors of random numbers and determine which values in `A` are also members of `B`, using a tolerance. Specify `OutputAllIndices` as `true` to return all of the indices for the elements in `B` that are within tolerance of the corresponding elements in `A`.

```
rng(5)
A = rand(1,15);
B = rand(1,5);
[LIA,LocAllB] = ismembertol(A,B,0.2,'OutputAllIndices',true)
```

```
LIA =
```

```
Columns 1 through 13
```

```
1 0 1 0 1 1 1 1 1 1 0 1 1
```

```
Columns 14 through 15
```

```
1 0
```

```
LocAllB =
```

```
Columns 1 through 6
```

```

 [2x1 double] [0] [2x1 double] [0] [3x1 double] [2x1 double]
Columns 7 through 12
 [4] [3x1 double] [3x1 double] [2x1 double] [0] [2x1 double]
Columns 13 through 15
 [4x1 double] [2x1 double] [0]

```

Find the average value of the elements in **B** that are within tolerance of the value **A(13)**. The cell **LocAllB{13}** contains all the indices for elements in **B** that are within tolerance of **A(13)**.

```

A(13)
allB = B(LocAllB{13})
aveB = mean(allB)

ans =

 0.4413

allB =

 0.2741 0.4142 0.2961 0.5798

aveB =

 0.3911

```

### Specify Absolute Tolerance

By default, `ismembertol` uses a tolerance test of the form  $\text{abs}(u-v) \leq \text{tol} \cdot \text{DS}$ , where `DS` automatically scales based on the magnitude of the input data. You can specify a different `DS` value to use with the `DataScale` option. However, absolute tolerances (where `DS` is a scalar) do not scale based on the magnitude of the input data.

First, compare two small values that are a distance `eps` apart. Specify `tol` and `DS` to make the within tolerance equation  $\text{abs}(u-v) \leq 10^{-6}$ .

```
x = 0.1;
ismembertol(x, exp(log(x)), 10^-6, 'DataScale', 1)
```

```
ans =
 1
```

Next, increase the magnitude of the values. The round-off error in the calculation  $\exp(\log(x))$  is proportional to the magnitude of the values, specifically to  $\text{eps}(x)$ . Even though the two large values are a distance  $\text{eps}$  from one another,  $\text{eps}(x)$  is now much larger. Therefore,  $10^{-6}$  is no longer a suitable tolerance.

```
x = 10^10;
ismembertol(x, exp(log(x)), 10^-6, 'DataScale', 1)
```

```
ans =
 0
```

Correct this issue by using the default (scaled) value of `DS`.

```
Y = [0.1 10^10];
ismembertol(Y, exp(log(Y)))
```

```
ans =
 1 1
```

## Specify DataScale by Column

Create a set of random 2-D points, and then use `ismembertol` to group the points into vertical bands that have a similar (within-tolerance) x-coordinate to a small set of query points, `B`. Use these options with `ismembertol`:

- Specify `ByRows` as `true`, since the point coordinates are in the rows of `A` and `B`.
- Specify `OutputAllIndices` as `true` to return the indices for all points in `A` that have an x-coordinate within tolerance of the query points in `B`.

- Specify `DataScale` as `[1 Inf]` to use an absolute tolerance for the x-coordinate, while ignoring the y-coordinate.

```
A = rand(1000,2);
B = [(0:.2:1)',0.5*ones(6,1)];
[LIA,LocAllB] = ismembertol(B, A, 0.1, 'ByRows', true, ...
 'OutputAllIndices', true, 'DataScale', [1,Inf])
```

```
LIA =
```

```
1
1
1
1
1
1
1
```

```
LocAllB =
```

```
[94x1 double]
[223x1 double]
[195x1 double]
[212x1 double]
[187x1 double]
[89x1 double]
```

Plot the points in A that are within tolerance of each query point in B.

```
hold on
plot(B(:,1),B(:,2),'x')
for k = 1:length(LocAllB)
 plot(A(LocAllB{k},1), A(LocAllB{k},2),'.')
end
```

- “Group Scattered Data Using a Tolerance”

## Input Arguments

### **A** — Query array

scalar | vector | matrix

Query array, specified as a scalar, vector, or matrix. Inputs **A** and **B** must be full.

If you specify the **ByROWS** option, then **A** and **B** must have the same number of columns.

Data Types: single | double

**B — Query array**

scalar | vector | matrix

Query array, specified as a scalar, vector, or matrix. Inputs **A** and **B** must be full.

If you specify the **ByRows** option, then **A** and **B** must have the same number of columns.

Data Types: single | double

**tol — Comparison tolerance**

positive real scalar

Comparison tolerance, specified as a positive real scalar. `ismembertol` scales the `tol` input using the maximum absolute values in the input arrays **A** and **B**. Then `ismembertol` uses the resulting scaled comparison tolerance to determine which elements in **A** are also a member of **B**. If two elements are within tolerance of each other, then `ismembertol` considers them to be equal.

Two values,  $u$  and  $v$ , are within tolerance if  $\text{abs}(u - v) \leq \text{tol} * \max(\text{abs}([A(:); B(:)]))$ .

To specify an absolute tolerance, specify both `tol` and the `'DataScale'` Name-Value pair.

Example: `tol = 0.05`

Example: `tol = 1e-8`

Example: `tol = eps`

Data Types: single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `LIA = ismembertol(A,B,'ByRows',true)`

**'OutputAllIndices' — Output index type**

false (default) | true | 0 | 1

Output index type, specified as the comma-separated pair consisting of 'OutputAllIndices' and either `false` (default), `true`, `0`, or `1`. `ismembertol` interprets numeric `0` as `false` and numeric `1` as `true`.

When `OutputAllIndices` is `true`, the `ismembertol` function returns the second output, `LocB`, as a cell array. The cell array contains the indices for *all* elements in `B` that are within tolerance of the corresponding value in `A`. That is, each cell in `LocB` corresponds to a value in `A`, and the values in each cell correspond to locations in `B`.

Example: `[LIA,LocAllB] = ismembertol(A,B,tol,'OutputAllIndices',true)`

### 'ByRows' — Row comparison toggle

`false` (default) | `true` | `0` | `1`

Row comparison toggle, specified as the comma-separated pair consisting of 'ByRows' and either `false` (default), `true`, `0`, or `1`. `ismembertol` interprets numeric `0` as `false` and numeric `1` as `true`. Use this option to find rows in `A` and `B` that are within tolerance.

When `ByRows` is `true`:

- `ismembertol` compares the rows of `A` and `B` by considering each column separately. Thus, `A` and `B` must have the same number of columns.
- If the corresponding row in `A` is within tolerance of a row in `B`, then `LIA` contains logical `1` (`true`). Otherwise, it contains logical `0` (`false`).

Two rows, `u` and `v`, are within tolerance if `abs(u-v) <= tol*max(abs([A;B]))`.

Example: `LIA = ismembertol(A,B,tol,'ByRows',true)`

### 'DataScale' — Scale of data

scalar | vector

Scale of data, specified as the comma-separated pair consisting of 'DataScale' and either a scalar or vector. Specify `DataScale` as a numeric scalar, `DS`, to change the tolerance test to be, `abs(u-v) <= tol*DS`.

When used together with the `ByRows` option, the `DataScale` value also can be a vector. In this case, each element of the vector specifies `DS` for a corresponding column in `A`. If a value in the `DataScale` vector is `Inf`, then `ismembertol` ignores the corresponding column in `A`.

Example: `LIA = ismembertol(A,B,'DataScale',1)`

```
Example: [LIA,LocB] = ismembertol(A,B,'ByRows',true,'DataScale',
[eps(1) eps(10) eps(100)])
```

Data Types: single | double

## Output Arguments

### LIA — Logical index to A

vector | matrix

Logical index to A, returned as a vector or matrix containing logical 1 (`true`) wherever the elements (or rows) in A are members of B (within tolerance). Elsewhere, LIA contains logical 0 (`false`).

LIA is the same size as A, unless you specify the `ByRows` option. In that case, LIA is a column vector with the same number of rows as A.

### LocB — Locations in B

vector | matrix | cell array

Locations in B, returned as a vector, matrix, or cell array. `LocB` contains the indices to the elements (or rows) in B that are found in A (within tolerance). `LocB` contains 0 wherever an element in A is not a member of B.

If `OutputAllIndices` is `true`, then `ismembertol` returns `LocB` as a cell array. The cell array contains the indices for *all* elements in B that are within tolerance of the corresponding value in A. That is, each cell in `LocB` corresponds to a value in A, and the values in each cell correspond to locations in B.

`LocB` is the same size as A, unless you specify the `ByRows` option. In that case, `LocB` is a column vector with the same number of rows as A.

## See Also

`eps` | `ismember` | `unique` | `unique_tol`

Introduced in R2015a

## **ismethod**

Determine if method of object

### **Syntax**

```
tf = ismethod(obj, 'methodName')
```

### **Description**

`tf = ismethod(obj, 'methodName')` returns logical 1 (**true**) if the specified `methodName` is a public method of object `obj`. Otherwise, returns logical 0 (**false**).

### **Examples**

Determine if objects support equality testing:

```
if ismethod(obj1, 'eq') && ismethod(obj2, 'eq')
 tf = obj1 == obj2;
end
```

### **See Also**

`methods` | `class` | `isprop` | `isobject`

**Introduced before R2006a**

## ismethod (COM)

Determine whether input is COM object method

### Syntax

```
tf = ismethod(h, 'methodname')
```

### Description

`tf = ismethod(h, 'methodname')` returns logical 1 (`true`) if the specified `methodname` is a method you can call on COM object `h`. Otherwise, returns logical 0 (`false`).

COM functions are available on Microsoft Windows systems only.

### Examples

Test members of an instance of a Microsoft Excel application.

```
h = actxserver('Excel.Application');
ismethod(h, 'SaveWorkspace')
```

MATLAB returns `true`, `SaveWorkspace` is a method.

Try the same test on `UsableWidth`.

```
ismethod(h, 'UsableWidth')
```

MATLAB returns `false`, `UsableWidth` is not a method; it is a property.

### More About

- “Exploring Methods”

### See Also

`methods` | `isprop` | `methodsvi` | `isevent` | `isobject` | `class`

## ismissing

Find table elements with missing values

### Syntax

```
TF = ismissing(A)
TF = ismissing(A,id)
```

### Description

`TF = ismissing(A)` returns a logical array, `TF`, that indicates which elements in the table `A` contain a missing value. The size of `TF` is the same as the size of `A`.

Indicators for missing data depend on the data type:

- NaN for numeric arrays and `duration` arrays
- `<undefined>` for categorical arrays
- Empty string, `{ ' ' }`, for cell arrays of strings
- Blank string, `[ ' ' ]`, for character arrays
- NaT for `datetime` arrays

`ismissing` ignores other data types.

`TF = ismissing(A,id)` treats the values in `id` as missing value indicators. When you specify `id`, you must include the indicators listed in the previous syntax to have `ismissing` recognize them as missing value indicators.

### Examples

#### Missing Values in Table with Various Data Types

Create a table with variables of different data types and find the elements with missing values.

```
dblVar = [NaN;3;5;7;9;11];
singleVar = single([1;NaN;5;7;9;11]);
cellstrVar = {'one';'three';'';'seven';'nine';'eleven'};
charVar = ['A';'C';'E';' ';'I';'J'];
categoryVar = categorical({'red';'yellow';'blue';'violet';'';'ultraviolet'});
m = [1:2:10];
dateVar = [datetime(2015,m,15) NaN]';
```

```
A = table(dblVar,singleVar,cellstrVar,charVar,categoryVar,dateVar)
```

```
A =
```

| dblVar | singleVar | cellstrVar | charVar | categoryVar | dateVar     |
|--------|-----------|------------|---------|-------------|-------------|
| NaN    | 1         | 'one'      | A       | red         | 15-Jan-2015 |
| 3      | NaN       | 'three'    | C       | yellow      | 15-Mar-2015 |
| 5      | 5         | ' '        | E       | blue        | 15-May-2015 |
| 7      | 7         | 'seven'    |         | violet      | 15-Jul-2015 |
| 9      | 9         | 'nine'     | I       | <undefined> | 15-Sep-2015 |
| 11     | 11        | 'eleven'   | J       | ultraviolet | NaN         |

ismissing returns 1 where the corresponding element in A has a missing value.

```
TF = ismissing(A)
```

```
TF =
```

|   |   |   |   |   |   |
|---|---|---|---|---|---|
| 1 | 0 | 0 | 0 | 0 | 0 |
| 0 | 1 | 0 | 0 | 0 | 0 |
| 0 | 0 | 1 | 0 | 0 | 0 |
| 0 | 0 | 0 | 1 | 0 | 0 |
| 0 | 0 | 0 | 0 | 1 | 0 |
| 0 | 0 | 0 | 0 | 0 | 1 |

The size of TF is the same as the size of A.

### Specify Indicators for Missing Values in Table

Create a table where 'NA', '' -99, NaN, and Inf represent missing values. Then, find the elements with missing values.

```
dblVar = [NaN;3;Inf;7;9];
int8Var = int8([1;3;5;7;-99]);
cellstrVar = {'one';'three';'';'NA';'nine'};
```

```
charVar = ['A';'C';'E';' ';'I'];
A = table(dblVar,int8Var,cellstrVar,charVar)
A =
```

| dblVar | int8Var | cellstrVar | charVar |
|--------|---------|------------|---------|
| NaN    | 1       | 'one'      | A       |
| 3      | 3       | 'three'    | C       |
| Inf    | 5       | ' '        | E       |
| 7      | 7       | 'NA'       |         |
| 9      | -99     | 'nine'     | I       |

`ismissing` returns 1 where the corresponding element in `A` has a missing value.

```
id = {'NA' '' -99 NaN Inf};
TF = ismissing(A,id)
```

```
TF =

 1 0 0 0
 0 0 0 0
 1 0 1 0
 0 0 1 1
 0 1 0 0
```

`ismissing` recognizes data in each variable of table `A` as missing values. `ismissing` ignores trailing white space in character arrays. Therefore, since the empty string, `' '`, is specified as a missing value indicator, `ismissing` identifies as missing values the empty string in `A.cellstrVar`, and also the blank space in `A.charVar`.

## Input Arguments

### **A** — Input data

table

Input data, specified as a table.

### **id** — Missing value indicators

numeric vector | string | cell array containing numeric values and strings

Missing value indicators, specified as a numeric vector, string, or cell array containing numeric values and strings. Use strings to identify categories in categorical variables that you want to treat as missing values.

When you specify `id`, you must include `NaN`, the empty string, '`<undefined>`', or `NaN` to have `ismissing` recognize these values as missing value indicators.

When you specify the empty string as a missing value, `ismissing` treats empty strings in cell arrays of strings, and also blank strings in character arrays, as missing values.

Example: `TF = ismissing(A, -99)` recognizes only `-99` as a missing value.

Data Types: `double` | `char` | `cell`

## More About

### Tips

- To return only complete rows from `A`, use `A(~any(TF,2),:)`.
- To return only the variables from `A` with no missing values, use `A(:,~any(TF,1))`.
- Since integer variables cannot store `NaN`, use a special integer value (otherwise unused) to indicate missing integer data. For example, `-99`.

### Algorithms

`ismissing` treats leading and trailing white space differently for cell arrays of strings, character arrays, and categorical arrays.

- For cell arrays of strings, `ismissing` does not ignore white space. All strings must match exactly.
- For character arrays, `ismissing` ignores trailing white space. Therefore, when you specify the empty string, `' '`, as a missing value indicator, `ismissing` identifies as missing values the empty string in cell arrays of strings, `' '`, and the blank space in character arrays, `' '`.
- For categorical arrays, `ismissing` ignores leading and trailing white space.

**Introduced in R2013b**

# isnan

Array elements that are NaN

## Syntax

```
TF = isnan(A)
```

## Description

`TF = isnan(A)` returns an array the same size as `A` containing logical 1 (**true**) where the elements of `A` are NaNs and logical 0 (**false**) where they are not. For a complex number `z`, `isnan(z)` returns 1 if either the real or imaginary part of `z` is NaN, and 0 if both the real and imaginary parts are finite or `Inf`.

For any real `A`, exactly one of the three quantities `isfinite(A)`, `isinf(A)`, and `isnan(A)` is equal to one.

## Examples

```
A = [-2 -1 0 1 2];
```

```
isnan(1./A)
ans =
 0 0 0 0 0
```

```
isnan(0./A)
ans =
 0 0 1 0 0
```

## See Also

`isfinite` | `nan` | `isinf` | `is*`

Introduced before R2006a

## isnat

Determine NaT (Not-a-Time) elements

### Syntax

```
tf = isnat(A)
```

### Description

`tf = isnat(A)` returns an array the same size as the datetime array, `A`, containing logical 1 (`true`) where the elements of `A` are Not-a-Time (NaTs) and logical 0 (`false`) where they are not. NaT represents a datetime that is undefined.

### Examples

#### Determine If Array Elements are NaT

Create a datetime array from numeric values containing NaN.

```
d = datetime(2014,[1 2 NaN 4],1)
```

```
d =
```

```
 01-Jan-2014 01-Feb-2014 NaT 01-Apr-2014
```

Determine if any elements of `d` are NaT (Not-a-Time).

```
isnat(d)
```

```
ans =
```

```
 0 0 1 0
```

### Input Arguments

**A** — Input array

datetime array

Input array, specified as a datetime array.

**See Also**

isfinite | isinf

**Introduced in R2014b**

## isnumeric

Determine if input is numeric array

### Syntax

```
tf = isnumeric(A)
```

### Description

`tf = isnumeric(A)` returns `true` if `A` is a numeric array and `false` otherwise.

A numeric array is any of the following numeric types and any subclasses of those types:

#### MATLAB Numeric Types

|                     |                                       |
|---------------------|---------------------------------------|
| <code>single</code> | Single-precision floating-point array |
| <code>double</code> | Double-precision floating-point array |
| <code>int8</code>   | 8-bit signed integer array            |
| <code>uint8</code>  | 8-bit unsigned integer array          |
| <code>int16</code>  | 16-bit signed integer array           |
| <code>uint16</code> | 16-bit unsigned integer array         |
| <code>int32</code>  | 32-bit signed integer array           |
| <code>uint32</code> | 32-bit unsigned integer array         |
| <code>int64</code>  | 64-bit signed integer array           |
| <code>uint64</code> | 64-bit unsigned integer array         |

### Examples

These examples show the values `isnumeric` returns when passed specific types:

```
% pi returns a numeric value
isnumeric(pi)
```

```
ans =
 1
% Complex numbers are numeric
isnumeric(3+7i)
ans =
 1
% Integers are numeric
isnumeric(uint8(1:255))
ans =
 1
% isnumeric returns a logical value
isnumeric(isnumeric(pi))
ans =
 0
```

## See Also

isfloat | isnan | isreal | isinteger | isprime | isfinite | isinf | isa | is\*

**Introduced before R2006a**

## isobject

Determine if input is MATLAB object

### Syntax

```
tf = isobject(A)
```

### Description

`tf = isobject(A)` returns `true` if `A` is an object of a MATLAB class. Otherwise, it returns `false`.

Instances of MATLAB fundamental classes return `false`. Use `isa` to test for any of these types. See “Fundamental MATLAB Classes” for more on these classes.

### Examples

Define the following MATLAB class:

```
classdef button < handle
 properties
 UiHandle
 end
 methods
 function obj = button(pos)
 obj.UiHandle = uicontrol('Position',pos,...
 'Style','pushbutton');
 end
 end
end
```

Test for MATLAB objects.

```
h = button([20 20 60 60]);
isobject(h)

ans =
```

```
1
isobject(h.UiHandle)
ans =
1
```

Create an object that is a MATLAB numeric type:

```
a = pi;
isobject(a)
ans =
0
isa(a, 'double')
ans =
1
```

## isocaps

Compute isosurface end-cap geometry

### Syntax

```
fvc = isocaps(X,Y,Z,V,isovalue)
fvc = isocaps(V,isovalue)
fvc = isocaps(...,'enclose')
fvc = isocaps(...,'whichplane')
[f,v,c] = isocaps(...)
isocaps(...)
```

### Description

`fvc = isocaps(X,Y,Z,V,isovalue)` computes isosurface end-cap geometry for the volume data `V` at isosurface value `isovalue`. The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`.

The struct `fvc` contains the face, vertex, and color data for the end-caps and can be passed directly to the `patch` command.

`fvc = isocaps(V,isovalue)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)` where `[m,n,p] = size(V)`.

`fvc = isocaps(...,'enclose')` specifies whether the end-caps enclose data values above or below the value specified in `isovalue`. The string `enclose` can be either `above` (default) or `below`.

`fvc = isocaps(...,'whichplane')` specifies on which planes to draw the end-caps. Possible values for `whichplane` are `all` (default), `xmin`, `xmax`, `ymin`, `ymax`, `zmin`, or `zmax`.

`[f,v,c] = isocaps(...)` returns the face, vertex, and color data for the end-caps in three arrays instead of the struct `fvc`.

`isocaps(...)` without output arguments draws a patch with the computed faces, vertices, and colors.

## Examples

### Compute Isosurface End-Cap Geometry

This example uses a data set that is a collection of MRI slices of a human skull. It illustrates the use of `isocaps` to draw the end-caps on this cutaway volume.

The red isosurface shows the outline of the volume (skull) and the end-caps show what is inside of the volume.

The patch created from the end-cap data (`p2`) uses interpolated face coloring, which means the gray colormap and the light sources determine how it is colored. The isosurface patch (`p1`) used a flat red face color, which is affected by the lights, but does not use the colormap.

```
load mri
D = squeeze(D);
D(:,1:60,:) = [];
p1 = patch(isosurface(D, 5), 'FaceColor', 'red', ...
 'EdgeColor', 'none');
p2 = patch(isocaps(D, 5), 'FaceColor', 'interp', ...
 'EdgeColor', 'none');
view(3)
axis tight
daspect([1,1,.4])
colormap(gray(100))
camlight left
camlight
lighting gouraud
isonormals(D,p1)
```

# isocolors

Calculate isosurface and patch colors

## Syntax

```
nc = isocolors(X,Y,Z,C,vertices)
nc = isocolors(X,Y,Z,R,G,B,vertices)
nc = isocolors(C,vertices)
nc = isocolors(R,G,B,vertices)
nc = isocolors(...,PatchHandle)
isocolors(...,PatchHandle)
```

## Description

`nc = isocolors(X,Y,Z,C,vertices)` computes the colors of isosurface (patch object) `vertices` (`vertices`) using color values `C`. Arrays `X`, `Y`, `Z` define the coordinates for the color data in `C` and must be monotonic vectors that represent a Cartesian, axis-aligned grid (as if produced by `meshgrid`). The colors are returned in `nc`. `C` must be 3-D (index colors).

`nc = isocolors(X,Y,Z,R,G,B,vertices)` uses `R`, `G`, `B` as the red, green, and blue color arrays (true color).

`nc = isocolors(C,vertices)`, and `nc = isocolors(R,G,B,vertices)` assume `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(C)`.

`nc = isocolors(...,PatchHandle)` uses the vertices from the patch identified by `PatchHandle`.

`isocolors(...,PatchHandle)` sets the `FaceVertexCData` property of the patch specified by `PatchHandle` to the computed colors.

## Examples

### Indexed Color Data

This example displays an isosurface and colors it with random data using indexed color.

```
[x,y,z] = meshgrid(1:20,1:20,1:20);
data = sqrt(x.^2 + y.^2 + z.^2);
cdata = smooth3(rand(size(data)), 'box', 7);
p = patch(isosurface(x,y,z,data,10));
isonormals(x,y,z,data,p)
isocolors(x,y,z,cdata,p)
p.FaceColor = 'interp';
p.EdgeColor = 'none';
view(150,30)
daspect([1 1 1])
axis tight
camlight
lighting gouraud
```

### True Color Data

This example displays an isosurface and colors it with true color (RGB) data.

```
[x,y,z] = meshgrid(1:20,1:20,1:20);
data = sqrt(x.^2 + y.^2 + z.^2);
p = patch(isosurface(x,y,z,data,20));
isonormals(x,y,z,data,p)
[r,g,b] = meshgrid(20:-1:1,1:20,1:20);
isocolors(x,y,z,r/20,g/20,b/20,p)
p.FaceColor = 'interp';
p.EdgeColor = 'none';
view(150,30)
daspect([1 1 1])
```

camlight  
lighting gouraud

## Modified True Color Data

This example uses `isosurface` to calculate the true color data using the isosurface's (patch object's) vertices, but then returns the color data in a variable (`c`) in order to modify the values. It then explicitly sets the isosurface's `FaceVertexCData` to the new data (`1 - c`).

```
[x,y,z] = meshgrid(1:20,1:20,1:20);
data = sqrt(x.^2 + y.^2 + z.^2);
p = patch(isosurface(data,20));
isonormals(data,p)
```

```
[r,g,b] = meshgrid(20:-1:1,1:20,1:20);
c = isocolors(r/20,g/20,b/20,p);
p.FaceVertexCData = 1-c;
p.FaceColor = 'interp';
p.EdgeColor = 'none';
view(150,30)
daspect([1 1 1])
camlight
lighting gouraud
```

## More About

# isonormals

Compute normals of isosurface vertices

## Syntax

```
n = isonormals(X,Y,Z,V,vertices)
n = isonormals(V,vertices)
n = isonormals(V,p)
n = isonormals(X,Y,Z,V,p)
n = isonormals(..., 'negate')
isonormals(V,p)
isonormals(X,Y,Z,V,p)
```

## Description

`n = isonormals(X,Y,Z,V,vertices)` computes the normals of the isosurface vertices from the vertex list, `vertices`, using the gradient of the data `V`. The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`. The computed normals are returned in `n`.

`n = isonormals(V,vertices)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)` where `[m,n,p] = size(V)`.

`n = isonormals(V,p)` and `n = isonormals(X,Y,Z,V,p)` compute normals from the vertices of the patch identified by the handle `p`.

`n = isonormals(..., 'negate')` negates (reverses the direction of) the normals.

`isonormals(V,p)` and `isonormals(X,Y,Z,V,p)` set the `VertexNormals` property of the patch identified by the handle `p` to the computed normals rather than returning the values.

## Examples

### Isosurface Using Different Types of Surface Normals

Compare the effect of different surface normals on the visual appearance of lit isosurfaces. In one case, the triangles used to draw the isosurface define the normals. In

the other, the `isonormals` function uses the volume data to calculate the vertex normals based on the gradient of the data points. The latter approach generally produces a smoother-appearing isosurface.

Define a 3-D array of volume data.

```
data = cat(3,[0 .2 0; 0 .3 0; 0 0 0],...
 [.1 .2 0; 0 1 0; .2 .7 0],...
 [0 .4 .2; .2 .4 0;.1 .1 0]);
data = interp3(data,3,'cubic');
```

Draw an isosurface from the volume data and add lights. This isosurface uses triangle normals.

```
figure
subplot(1,2,1)
fv = isosurface(data,.5);
p1 = patch(fv,'FaceColor','red','EdgeColor','none');
view(3)
daspect([1,1,1])
axis tight
camlight
camlight(-80,-10)
lighting gouraud
title('Triangle Normals')
```

Draw the same lit isosurface using normals calculated from the volume data.

```
subplot(1,2,2)
fv = isosurface(data, .5);
p2 = patch(fv, 'FaceColor', 'red', 'EdgeColor', 'none');
isonormals(data, p2)
view(3)
daspect([1 1 1])
axis tight
camlight
camlight(-80, -10)
lighting gouraud
title('Data Normals')
```

**Triangle Normals**

**Data Normals**

These isosurfaces illustrate the difference between triangle and data normals.

**Introduced before R2006a**

# isordinal

Determine whether input is ordinal categorical array

## Syntax

```
tf = isordinal(A)
```

## Description

`tf = isordinal(A)` returns logical 1 (true) if `A` is an ordinal categorical array. Otherwise, `isordinal` returns logical 0 (false).

If a categorical array is ordinal, you can use relational operations for inequality comparisons, such as greater and less than, in addition to tests for equality.

## Examples

### Determine Whether Categorical Array Is Ordinal

Create a categorical array containing the sizes of 10 objects. Use the names `small`, `medium`, and `large` for the values 'S', 'M', and 'L'.

```
A = categorical({'M';'L';'S';'S';'M';'L';'M';'L';'M';'S'},...
 {'S','M','L'},{'small','medium','large'})
```

```
A =
```

```
medium
large
small
small
medium
large
medium
large
medium
small
```

Determine if the categories of **A** have a mathematical ordering.

```
isordinal(A)
```

```
ans =
```

```
0
```

**A** is not ordinal. You must use the `'Ordinal'`, `true` name-value pair argument in the function `categorical` to create an ordinal categorical array.

## Input Arguments

### **A** — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

## More About

### Tips

- To convert a categorical array, **A**, from nonordinal to ordinal, use `A = categorical(A, 'Ordinal', true)`.
- To convert a categorical array, **A**, from ordinal to nonordinal, use `A = categorical(A, 'Ordinal', false)`.
- “Ordinal Categorical Arrays”

# isosurface

Extract isosurface data from volume data

## Syntax

```
fv = isosurface(X,Y,Z,V,isovalue)
fv = isosurface(V,isovalue)
fvc = isosurface(...,colors)
fv = isosurface(...,'noshare')
fv = isosurface(...,'verbose')
[f,v] = isosurface(...)
[f,v,c] = isosurface(...)
isosurface(...)
```

## Description

`fv = isosurface(X,Y,Z,V,isovalue)` computes isosurface data from the volume data `V` at the isosurface value specified in `isovalue`. That is, the isosurface connects points that have the specified value much the way contour lines connect points of equal elevation.

The arrays `X`, `Y`, and `Z` represent a Cartesian, axis-aligned grid. `V` contains the corresponding values at these grid points. The coordinate arrays (`X`, `Y`, and `Z`) must be monotonic and conform to the format produced by `meshgrid`. `V` must be a 3D volume array of the same size as `X`, `Y`, and `Z`.

The struct `fv` contains the faces and vertices of the isosurface, which you can pass directly to the `patch` command.

`fv = isosurface(V,isovalue)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)` where `[m,n,p] = size(V)`.

`fvc = isosurface(...,colors)` interpolates the array `colors` onto the scalar field and returns the interpolated values in the `facevertexcdata` field of the `fvc` structure. The size of the `colors` array must be the same as `V`. The `colors` argument enables you to control the color mapping of the isosurface with data different from that

used to calculate the isosurface (e.g., temperature data superimposed on a wind current isosurface).

`fv = isosurface(..., 'noshare')` does not create shared vertices. This is faster, but produces a larger set of vertices.

`fv = isosurface(..., 'verbose')` prints progress messages to the command window as the computation progresses.

`[f,v] = isosurface(...)` or `[f,v,c] = isosurface(...)` returns the faces and vertices (and `faceVertexCData`) in separate arrays instead of a struct.

`isosurface(...)` with no output arguments, creates a patch in the current axes with the computed faces and vertices. If no current axes exists, a new axes is created with a 3-D view.

## Special Case Behavior — `isosurface` Called with No Output Arguments

If there is no current axes and you call `isosurface` without assigning output arguments, MATLAB creates a new axes, sets it to a 3-D view, and adds lighting to the isosurface graph.

## Examples

### Example 1

This example uses the flow data set, which represents the speed profile of a submerged jet within an infinite tank (type `help flow` for more information). The isosurface is drawn at the data value of -3. The statements that follow the `patch` command prepare the isosurface for lighting by

- Recalculating the isosurface normals based on the volume data (`isonormals`)
- Setting the face and edge color (`set`, `FaceColor`, `EdgeColor`)
- Specifying the view (`daspect`, `view`)
- Adding lights (`camlight`, `lighting`)

```
[x,y,z,v] = flow;
p = patch(isosurface(x,y,z,v,-3));
```

```
isonormals(x,y,z,v,p)
p.FaceColor = 'red';
p.EdgeColor = 'none';
daspect([1,1,1])
view(3); axis tight
camlight
lighting gouraud
```

## Example 2

Visualize the same flow data as above, but color-code the surface to indicate magnitude along the X-axis. Use a sixth argument to `isosurface`, which provides a means to overlay another data set by coloring the resulting isosurface. The `colors` variable is a

vector containing a scalar value for each vertex in the isosurface, to be portrayed with the current color map. In this case, it is one of the variables that define the surface, but it could be entirely independent. You can apply a different color scheme by changing the current figure color map.

```
[x,y,z,v] = flow;
[faces,verts,colors] = isosurface(x,y,z,v,-3,x);
patch('Vertices', verts, 'Faces', faces, ...
 'FaceVertexCData', colors, ...
 'FaceColor','interp', ...
 'edgecolor', 'interp');
view(30,-15);
axis vis3d;
colormap copper
```

## More About

### Tips

You can pass the `fv` structure created by `isosurface` directly to the `patch` command, but you cannot pass the individual faces and vertices arrays (`f`, `v`) to `patch` without specifying property names. For example,

```
patch(isosurface(X,Y,Z,V,isovalue))
```

or

```
[f,v] = isosurface(X,Y,Z,V,isovalue);
patch('Faces',f,'Vertices',v)
```

- “Connecting Equal Values with Isosurfaces”

Introduced before R2006a

## ispc

Determine if version is for Windows (PC) platform

## Syntax

```
tf = ispc
```

## Description

`tf = ispc` returns logical 1 (**true**) if the version of MATLAB software is for the Microsoft Windows platform. Otherwise, it returns logical 0 (**false**).

## Examples

### Execute MATLAB Command Based on Platform

```
if ismac
 % Code to run on Mac plaform
elseif isunix
 % Code to run on Linux plaform
elseif ispc
 % Code to run on Windows platform
else
 disp('Cannot recognize platform')
end
```

## See Also

`computer` | `is*` | `ismac` | `isstudent` | `isunix`

**Introduced before R2006a**

# ispref

Test for existence of preference

## Syntax

```
ispref('group','pref')
ispref('group')
ispref('group',{'pref1','pref2',... 'prefn'})
```

## Description

`ispref('group','pref')` returns 1 if the preference specified by `group` and `pref` exists, and 0 otherwise.

`ispref('group')` returns 1 if the `GROUP` exists, and 0 otherwise.

`ispref('group',{'pref1','pref2',... 'prefn'})` returns a logical array the same length as the cell array of preference names, containing 1 where each preference exists, and 0 elsewhere.

## Examples

```
addpref('mytoolbox','version','1.0')
ispref('mytoolbox','version')
```

```
ans =
 1.0
```

## See Also

`addpref` | `rmpref` | `getpref` | `setpref` | `uigetpref` | `uisetpref`

Introduced before R2006a

## isprime

Determine which array elements are prime

### Syntax

```
TF = isprime(X)
```

### Description

`TF = isprime(X)` returns a logical array the same size as `X`. The value at `TF(i)` is true when `X(i)` is a prime number. Otherwise, the value is false.

### Examples

#### Determine if Double Integer Values Are Prime

```
tf = isprime([2 3 0 6 10])
```

```
tf =
```

```
 1 1 0 0 0
```

2 and 3 are prime, but 0, 6, and 10 are not.

#### Determine if Unsigned Integer Values Are Prime

```
x = uint16([333 71 99]);
```

```
tf = isprime(x)
```

```
tf =
```

```
 0 1 0
```

71 is prime, but 333 and 99 are not.

## Input Arguments

### **X** — Input values

scalar, vector, or array of real, nonnegative integer values

Input values, specified as a scalar, vector, or array of real, nonnegative integer values.

Example: 17

Example: [1 2 3 4]

Example: int16([127 255 4095])

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **See Also**

is\* | primes

**Introduced before R2006a**

## isprop

Determine if property of object

### Syntax

```
tf = isprop(obj, 'PropertyName')
```

### Description

`tf = isprop(obj, 'PropertyName')` returns `true` if the specified `PropertyName` is a property of object `obj`. Otherwise, `isprop` returns logical `false`.

If `obj` is an array, `isprop` returns a logical array the same size as `obj`. Each `true` element of `tf` corresponds to an element of `obj` that has the property, `PropertyName`.

---

**Note:** If `obj` is an empty object or an array of empty objects, `isprop` returns an empty logical array, even if `PropertyName` is a property of `obj`.

---

While `isprop` returns `true` if the class of an object defines a property of that name, classes can control access to property values by defining property attributes. Property access can be defined as:

- Readable and writable
- Read only
- Write only
- Accessible only to certain class methods

Therefore, `isprop` might indicate that a property exists, but you might not be able to access that property. For more information, see “Get Information About Properties”.

### Examples

This example uses `isprop` to determine if `XDataSource` is a property of object `h` before attempting to set the property value:

```
h = plot(1:10);
if isprop(h,'XDataSource')
 set(h,'XDataSource','x')
else
 error(['XDataSource not a property of class ',class(h)])
end
```

Since `XDataSource` is a property of `h`, its value is set to `'x'`.

## See Also

`properties` | `ismethod`

**Introduced before R2006a**

## isprop (COM)

Determine whether input is COM object property

### Syntax

```
tf = isprop(h, 'propertyname')
```

### Description

`tf = isprop(h, 'propertyname')` returns logical 1 (**true**) if the specified `name` is a property of COM object `h`. Otherwise, returns logical 0 (**false**).

COM functions are available on Microsoft Windows systems only.

### Examples

Test a property of an instance of a Microsoft Excel application.

```
h = actxserver('Excel.Application');
isprop(h, 'UsableWidth')
```

MATLAB returns **true**, `UsableWidth` is a property.

Try the same test on `SaveWorkspace`.

```
isprop(h, 'SaveWorkspace')
```

MATLAB returns **false**. `SaveWorkspace` is not a property; it is a method.

# isprotected

Determine whether categories of categorical array are protected

## Syntax

```
tf = isprotected(A)
```

## Description

`tf = isprotected(A)` returns logical 1 (**true**) if the categories of **A** are protected. Otherwise, `isprotected` returns logical 0 (**false**).

- **true** — When you assign new values to **B**, the values must belong to one of the existing categories. Therefore, you only can combine arrays that have the same categories. To add new categories to **B**, you must use the `addcats` function.
- **false** — When you assign new values to **B**, the categories update automatically. Therefore, you can combine (nonordinal) categorical arrays that have different categories. The categories can update to include the categories from both arrays.

## Examples

### Determine Whether Categories Are Protected

Create a categorical array containing the sizes of 10 objects. Use the names `small`, `medium`, and `large` for the values `'S'`, `'M'`, and `'L'`.

```
valueset = {'S','M','L'};
catnames = {'small','medium','large'};
```

```
A = categorical({'M';'L';'S';'S';'M';'L';'M';'L';'M';'S'},...
 valueset,catnames,'Ordinal',true)
```

```
A =
```

```
 medium
 large
```

```
small
small
medium
large
medium
large
medium
small
```

A is a 10-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
'small'
'medium'
'large'
```

Determine whether the categories of A are protected.

```
tf = isprotected(A)
```

```
tf =
```

```
1
```

Since A is an ordinal categorical array, the categories are protected. If you try to add a new value that does not belong to one of the existing categories, for example `A(11) = 'xlarge'`, then MATLAB returns an error.

First, use `addcats` to add a new category for `xlarge`.

```
A = addcats(A, 'xlarge', 'After', 'large');
```

Since A is protected, you can now add a value for `xlarge` since it has an existing category.

```
A(11) = 'xlarge'
```

```
A =
```

```
medium
```

```
large
small
small
medium
large
medium
large
medium
small
xlarge
```

A is now a 11-by-1 categorical array with four categories, such that `small < medium < large < xlarge`.

- “Work with Protected Categorical Arrays”

## Input Arguments

### **A** — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

The categories of ordinal categorical arrays are always protected.

### See Also

`categorical` | `categories`

**Introduced in R2013b**

## isreal

Determine whether array is real

### Syntax

```
tf = isreal(A)
```

### Description

`tf = isreal(A)` returns logical 1 (true) when `A` does not have an imaginary part. Otherwise, it returns logical 0 (false).

If `A` has a stored imaginary part with value 0, then `isreal(A)` returns logical 0 (false).

### Examples

#### Determine Whether Matrix Contains All Real Values

Define a 3-by-4 matrix, `A`.

```
A = [7 3+4i 2 5i;...
 2i 1+3i 12 345;...
 52 108 78 3];
```

Determine whether the array is real.

```
tf = isreal(A)
```

```
tf =
```

```
0
```

Since `A` contains complex elements, `isreal` returns false.

#### Define Complex Number with Zero-Valued Imaginary Part

Use the `complex` function to create a scalar, `A`, with zero-valued imaginary part.

```
A = complex(12)
```

```
A =
```

```
12.0000 + 0.0000i
```

Determine whether A is real.

```
tf = isreal(A)
```

```
tf =
```

```
0
```

A is not real because it has an imaginary part, even though the value of the imaginary part is 0.

Determine whether A contains any elements with zero-valued imaginary part.

```
~any(imag(A))
```

```
ans =
```

```
1
```

A contains elements with zero-valued imaginary part.

### Computation Resulting in Zero-Valued Imaginary Part

Define two complex scalars, x and y.

```
x=3+4i;
```

```
y=5-4i;
```

Determine whether the addition of two complex scalars, x and y, is real.

```
A = x+y
```

```
A =
```

```
8
```

MATLAB drops the zero imaginary part.

```
isreal(A)
```

```
ans =

 1
```

A is real since it does not have an imaginary part.

## Find Real Elements in Cell Array

Create a cell array.

```
C{1,1} = pi; % double
C{2,1} = 'John Doe'; % char array
C{3,1} = 2 + 4i; % complex double
C{4,1} = ispc; % logical
C{5,1} = magic(3); % double array
C{6,1} = complex(5,0) % complex double
```

```
C =

 [3.1416]
 'John Doe'
 [2.0000 + 4.0000i]
 [1]
 [3x3 double]
 [5.0000 + 0.0000i]
```

C is a 1-by-6 cell array.

Loop over the elements of a cell array to distinguish between real and complex elements.

```
for k = 1:6
 x(k,1) = isreal(C{k,1});
end
```

```
x
```

```
x =

 1
 1
 0
 1
 1
 0
```

All but `C{3,1}` and `C{6,1}` are real arrays.

## Input Arguments

### A — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

- For numeric data types, if A does not have an imaginary part, `isreal` returns `true`; if A does have an imaginary part `isreal` returns `false`.
- For logical and char data types, `isreal` always returns `true`.
- For table, cell, struct, datetime, function\_handle, and object data types, `isreal` always returns `false`.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16  
| uint32 | uint64 | logical | char | struct | table | cell | datetime |  
function\_handle

Complex Number Support: Yes

## More About

### Tips

- `isreal(complex(A))` always returns `false`, even when the imaginary part is all zeros.
- `~isreal(x)` detects arrays that have an imaginary part, even if it is all zeros.
- “Complex Numbers”

`complex` | `isa` | `isfinite` | `isinf` | `isnan` | `isnumeric` | `isprime`

Introduced before R2006a

## **isrow**

Determine whether input is row vector

### **Syntax**

```
isrow(V)
```

### **Description**

`isrow(V)` returns logical 1 (**true**) if `size(V)` returns `[1 n]` with a nonnegative integer value `n`, and logical 0 (**false**) otherwise.

### **Examples**

Determine if a vector is a row. This example is a column so `isrow` returns 0:

```
V = rand(5,1);
isrow(V)
ans =
 0
```

Transpose the vector to make it a row. `isrow` returns 1:

```
V1 = V';
isrow(V1)
ans =
 1
```

### **See Also**

`iscolumn` | `ismatrix` | `isscalar` | `isvector`

# isscalar

Determine whether input is scalar

## Syntax

```
isscalar(A)
```

## Description

`isscalar(A)` returns logical 1 (true) if `size(A)` returns [1 1], and logical 0 (false) otherwise.

## Examples

Test matrix A and one element of the matrix:

```
A = rand(5);
```

```
isscalar(A)
ans =
 0
```

```
isscalar(A(3,2))
ans =
 1
```

## See Also

`isvector` | `isrow` | `ismatrix` | `iscolumn` | `islogical` | `ischar` | `isa` | `is*`

**Introduced before R2006a**

## issorted

Determine whether set elements are in sorted order

### Syntax

```
TF = issorted(A)
TF = issorted(A, 'rows')
```

### Description

`TF = issorted(A)` returns logical 1 (**true**) if the elements of `A` are in sorted order, and logical 0 (**false**) otherwise. Input `A` can be a vector or an N-by-1 or 1-by-N cell array of strings. `A` is considered to be sorted if `A` and the output of `sort(A)` are equal.

`TF = issorted(A, 'rows')` returns logical 1 (**true**) if the rows of two-dimensional matrix `A` are in sorted order, and logical 0 (**false**) otherwise. Matrix `A` is considered to be sorted if `A` and the output of `sortrows(A)` are equal.

---

**Note** Only the `issorted(A)` syntax supports `A` as a cell array of strings.

The `issorted(A, 'rows')` syntax supports `A` as a categorical array, but not as a cell array of strings.

---

### Examples

#### Example 1 — Using `issorted` on a vector

```
A = [5 12 33 39 78 90 95 107 128 131];

issorted(A)
ans =
 1
```

## Example 2 — Using issorted on a matrix

```
A = magic(5)
A =
 17 24 1 8 15
 23 5 7 14 16
 4 6 13 20 22
 10 12 19 21 3
 11 18 25 2 9
```

```
issorted(A, 'rows')
ans =
 0
```

```
B = sortrows(A)
B =
 4 6 13 20 22
 10 12 19 21 3
 11 18 25 2 9
 17 24 1 8 15
 23 5 7 14 16
```

```
issorted(B)
ans =
 1
```

## Example 3 — Using issorted on a cell array

```
x = {'one'; 'two'; 'three'; 'four'; 'five'};
issorted(x)
ans =
 0
```

```
y = sort(x)
y =
 'five'
 'four'
 'one'
 'three'
 'two'
```

```
issorted(y)
```

## More About

### Tips

For character arrays, `issorted` uses ASCII, rather than alphabetical, order.

You cannot use `issorted` on arrays of greater than two dimensions.

### See Also

`sort` | `sortrows` | `unique` | `ismember` | `intersect` | `union` | `setdiff` | `setxor` | `is*`

**Introduced before R2006a**

# isspace

Array elements that are space characters

## Syntax

```
tf = isspace('str')
```

## Description

`tf = isspace('str')` returns an array the same size as `'str'` containing logical 1 (`true`) where the elements of `str` are Unicode-represented whitespace characters, and logical 0 (`false`) where they are not.

Whitespace characters for which `isspace` returns `true` include tab, line feed, vertical tab, form feed, carriage return, and space, in addition to a number of other Unicode characters. To see all characters for which `isspace` returns `true`, enter the following command, and then look up the returned decimal codes in a Unicode reference:

```
find(isspace(char(1):char(intmax('uint16'))))
```

## Examples

```
isspace(' Find spa ces ')
Columns 1 through 13
 1 1 0 0 0 0 0 1 0 0 0 0 1 0 0
Columns 14 through 15
 0 1
```

## See Also

Introduced before R2006a

## **issparse**

Determine whether input is sparse

### **Syntax**

TF = issparse(S)

### **Description**

TF = issparse(S) returns logical 1 (**true**) if the storage class of S is sparse and logical 0 (**false**) otherwise.

### **See Also**

is\* | sparse | full

**Introduced before R2006a**

## isstr

Determine whether input is character array

---

**Note:** `isstr` is not recommended. Use `ischar` instead.

---

### See Also

`ischar` | `isa` | `is*`

**Introduced before R2006a**

## isstrprop

Determine whether string is of specified category

### Syntax

```
tf = isstrprop('str', 'category')
```

### Description

`tf = isstrprop('str', 'category')` returns a logical array the same size as `str` containing logical 1 (true) where the elements of `str` belong to the specified *category*, and logical 0 (false) where they do not.

The `str` input can be a character array, cell array, or any MATLAB numeric type. If `str` is a cell array, then the return value is a cell array of the same shape as `str`.

The *category* input can be any of the strings shown in the left column below:

| Category | Description                                                                                                                                                                                                                                                                                                                                                                        |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| alpha    | True for those elements of <code>str</code> that are alphabetic                                                                                                                                                                                                                                                                                                                    |
| alphanum | True for those elements of <code>str</code> that are alphanumeric                                                                                                                                                                                                                                                                                                                  |
| cntrl    | True for those elements of <code>str</code> that are control characters (for example, <code>char(0:20)</code> )                                                                                                                                                                                                                                                                    |
| digit    | True for those elements of <code>str</code> that are numeric digits                                                                                                                                                                                                                                                                                                                |
| graphic  | True for those elements of <code>str</code> that are graphic characters. These are all values that represent any characters except for the following:<br><br>unassigned, space, line separator,<br>paragraph separator, control characters,<br>Unicode format control characters,<br>private user-defined characters,<br>Unicode surrogate characters,<br>Unicode other characters |
| lower    | True for those elements of <code>str</code> that are lowercase letters                                                                                                                                                                                                                                                                                                             |

| Category | Description                                                                                                                                                                                                                                     |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| print    | True for those elements of <code>str</code> that are graphic characters, plus <code>char(32)</code>                                                                                                                                             |
| punct    | True for those elements of <code>str</code> that are punctuation characters                                                                                                                                                                     |
| wspace   | True for those elements of <code>str</code> that are white-space characters. This range includes the ANSI <sup>®</sup> C definition of white space, { ' ', '\t', '\n', '\r', '\v', '\f' }, in addition to a number of other Unicode characters. |
| upper    | True for those elements of <code>str</code> that are uppercase letters                                                                                                                                                                          |
| xdigit   | True for those elements of <code>str</code> that are valid hexadecimal digits                                                                                                                                                                   |

## Examples

Test for alphabetic characters in a string:

```
A = isstrprop('abc123def', 'alpha')
A =
 1 1 1 0 0 0 1 1 1
```

Test for numeric digits in a string:

```
A = isstrprop('abc123def', 'digit')
A =
 0 0 0 1 1 1 0 0 0
```

Test for hexadecimal digits in a string:

```
A = isstrprop('abcd1234efgh', 'xdigit')
A =
 1 1 1 1 1 1 1 1 1 0 0
```

Test for numeric digits in a character array:

```
A = isstrprop(char([97 98 99 49 50 51 101 102 103]), ...
 'digit')
A =
 0 0 0 1 1 1 0 0 0
```

Test for alphabetic characters in a two-dimensional cell array:

```
A = isstrprop({'abc123def'; '456ghi789'}, 'alpha')
```

```
A =
 [1x9 logical]
 [1x9 logical]
```

```
A{:,:}
ans =
 1 1 1 0 0 0 1 1 1
 0 0 0 1 1 1 0 0 0
```

Test for white-space characters in a string:

```
A = isstrprop(sprintf('a bc\n'), 'wspace')
A =
 0 1 0 0 1
```

## More About

### Tips

Numbers of type `double` are converted to `int32` according to MATLAB rules of double-to-integer conversion. Numbers of type `int64` and `uint64` bigger than `int32(inf)` saturate to `int32(inf)`.

MATLAB classifies the elements of the `str` input according to the Unicode definition of the specified category. If the numeric value of an element in the input array falls within the range that defines a Unicode character category, then this element is classified as being of that category. The set of Unicode character codes includes the set of ASCII character codes, but also covers a large number of languages beyond the scope of the ASCII set. The classification of characters is dependent on the global location of the platform on which MATLAB is installed.

Whitespace characters for which the `wspace` option returns `true` include tab, line feed, vertical tab, form feed, carriage return, and space, in addition to a number of other Unicode characters. To see all characters for which the `wspace` option returns `true`, enter the following command, and then look up the returned decimal codes in a Unicode reference:

```
find(isstrprop(char(1):char(intmax('uint16')), 'wspace'))
```

### See Also

**Introduced before R2006a**

## **isstruct**

Determine whether input is structure array

### **Syntax**

```
tf = isstruct(A)
```

### **Description**

`tf = isstruct(A)` returns logical 1 (true) if `A` is a MATLAB structure and logical 0 (false) otherwise.

### **Examples**

```
patient.name = 'John Doe';
patient.billing = 127.00;
patient.test = [79 75 73; 180 178 177.5; 220 210 205];
```

```
isstruct(patient)
```

```
ans =
```

```
1
```

### **More About**

# isstudent

Determine if version is Student Version

## Syntax

```
tf = isstudent
```

## Description

`tf = isstudent` returns logical 1 (**true**) if the version of MATLAB software is the Student Version, and returns logical 0 (**false**) for commercial versions.

## See Also

`ver` | `version` | `license` | `ispc` | `isunix` | `is*`

**Introduced before R2006a**

## issymmetric

Determine if matrix is symmetric or skew-symmetric

### Syntax

```
tf = issymmetric(A)
tf = issymmetric(A,skewOption)
```

### Description

`tf = issymmetric(A)` returns logical 1 (**true**) if square matrix **A** is symmetric; otherwise, it returns logical 0 (**false**).

`tf = issymmetric(A,skewOption)` specifies the type of the test. Specify `skewOption` as 'skew' to determine if **A** is skew-symmetric.

### Examples

#### Test if Hermitian Matrix Is Symmetric

Create a 3-by-3 matrix.

```
A = [1 0 1i; 0 1 0; -1i 0 1]
```

A =

```
1.0000 + 0.0000i 0.0000 + 0.0000i 0.0000 + 1.0000i
0.0000 + 0.0000i 1.0000 + 0.0000i 0.0000 + 0.0000i
0.0000 - 1.0000i 0.0000 + 0.0000i 1.0000 + 0.0000i
```

The matrix is Hermitian and has a real-valued diagonal.

Test whether the matrix is symmetric.

```
tf = issymmetric(A)
```

```
tf =
 0
```

The result is logical 0 (**false**) because **A** is not symmetric. In this case, **A** is equal to its complex conjugate transpose, **A'**, but not its nonconjugate transpose, **A.'**

Change the element in **A(3,1)** to be **1i**.

```
A(3,1) = 1i;
```

Determine whether the modified matrix is symmetric.

```
tf = issymmetric(A)
```

```
tf =
 1
```

The matrix, **A**, is now symmetric because it is equal to its nonconjugate transpose, **A.'**

### Test if Matrix Is Skew-Symmetric

Create a 4-by-4 matrix.

```
A = [0 1 -2 5; -1 0 3 -4; 2 -3 0 6; -5 4 -6 0]
```

```
A =
 0 1 -2 5
 -1 0 3 -4
 2 -3 0 6
 -5 4 -6 0
```

The matrix is real and has a diagonal of zeros.

Specify **skewOption** as **'skew'** to determine whether the matrix is skew-symmetric.

```
tf = issymmetric(A, 'skew')
```

```
tf =
 1
```

The matrix,  $A$ , is skew-symmetric since it is equal to the negation of its nonconjugate transpose,  $-A.'.$

## Input Arguments

### **A** — Input matrix

numeric matrix

Input matrix, specified as a numeric matrix. If  $A$  is not square, then `issymmetric` returns logical 0 (`false`).

Data Types: `single` | `double`

Complex Number Support: Yes

### **skewOption** — Test type

'nonskew' (default) | 'skew'

Test type, specified as 'nonskew' (default) or 'skew'. Specify 'skew' to test whether  $A$  is skew-symmetric. Specifying `issymmetric(A, 'nonskew')` is equivalent to `issymmetric(A)`.

Data Types: `char`

## More About

### **Symmetric Matrix**

- A square matrix,  $A$ , is symmetric if it is equal to its nonconjugate transpose,  $A = A.'.$

In terms of the matrix elements, this means that

$$a_{i,j} = a_{j,i}.$$

- Since real matrices are unaffected by complex conjugation, a real matrix that is symmetric is also Hermitian. For example, the matrix

$$A = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 2 & 0 \\ 1 & 0 & 1 \end{bmatrix}$$

is both symmetric and Hermitian.

### Skew-Symmetric Matrix

- A square matrix,  $A$ , is skew-symmetric if it is equal to the negation of its nonconjugate transpose,  $A = -A'$ .

In terms of the matrix elements, this means that

$$a_{i,j} = -a_{j,i}.$$

- Since real matrices are unaffected by complex conjugation, a real matrix that is skew-symmetric is also skew-Hermitian. For example, the matrix

$$A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$$

is both skew-symmetric and skew-Hermitian.

## isTiled

**Class:** Tiff

Determine if tiled image

## Syntax

```
tf = isTiled(tiffobj)
```

## Description

`tf = isTiled(tiffobj)` returns `true` if the image has a tiled organization and `false` if the image has a stripped organization.

## Examples

### Determine if Image Has Tiled Organization

Open a Tiff object and check if the image in the TIFF file has a tiled or stripped organization.

```
t = Tiff('example.tif', 'r');
tf = isTiled(t)
```

```
tf =
```

```
1
```

The image has a tiled organization.

Close the Tiff object.

```
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## References

This method corresponds to the `TIFFIsTiled` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

## istable

Determine whether input is table

### Syntax

```
tf = istable(T)
```

### Description

`tf = istable(T)` returns logical 1 (`true`) if `T` is a table. Otherwise, it returns logical 0 (`false`) otherwise.

### Examples

#### Determine if Workspace Variable Is Table

Create a workspace variable, `T`.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
 {'NY';'CA';'MA'},[true;false;false])
```

`T =`

| Var1 | Var2 | Var3 | Var4 |       |
|------|------|------|------|-------|
| M    | 45   | 45   | 'NY' | true  |
| F    | 41   | 32   | 'CA' | false |
| M    | 40   | 34   | 'MA' | false |

Verify that the workspace variable, `T`, is a table.

```
istable(T)
```

```
ans =
```

```
1
```

T is a table.

### Determine if Subset of Table Is Table

Create a table, T.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
 {'NY';'CA';'MA'},[true;false;false])
```

T =

| Var1 | Var2 | Var3 | Var4 |       |
|------|------|------|------|-------|
| M    | 45   | 45   | 'NY' | true  |
| F    | 41   | 32   | 'CA' | false |
| M    | 40   | 34   | 'MA' | false |

Determine if the subset of table T that contains only the second and fourth variables is a table.

```
istable(T{:[2 4]})
```

ans =

```
0
```

Conversely, accessing data with curly braces, T{:[2 4]}, returns a matrix and not a table.

## Input Arguments

### T — Input variable

workspace variable

Input variable, specified as a workspace variable. T can be any data type.

### See Also

iscell | islogical | isnumeric | isobject | isstruct | table

Introduced in R2013b

## **istril**

Determine if matrix is lower triangular

### **Syntax**

```
tf = istril(A)
```

### **Description**

`tf = istril(A)` returns logical 1 (true) if `A` is a lower triangular matrix; otherwise, it returns logical 0 (false).

### **Examples**

#### **Test Lower Triangular Matrix**

Create a 5-by-5 matrix.

```
D = tril(magic(5))
```

```
D =
```

```
 17 0 0 0 0
 23 5 0 0 0
 4 6 13 0 0
 10 12 19 21 0
 11 18 25 2 9
```

Test `D` to see if it is lower triangular.

```
istril(D)
```

```
ans =
```

```
 1
```

The result is logical 1 (`true`) because all elements above the main diagonal are zero.

### Test Matrix of Zeros

Create a 5-by-5 matrix of zeros.

```
Z = zeros(5);
```

Test Z to see if it is lower triangular.

```
istril(Z)
```

```
ans =
```

```
1
```

The result is logical 1 (`true`) because a lower triangular matrix can have any number of zeros on its main diagonal.

## Input Arguments

### A — Input array

numeric array

Input array, specified as a numeric array. `istril` returns logical 0 (`false`) if A has more than two dimensions.

Data Types: `single` | `double`

Complex Number Support: Yes

## More About

### Lower Triangular Matrix

A matrix is lower triangular if all elements above the main diagonal are zero. Any number of the elements on the main diagonal can also be zero.

For example, the matrix

$$A = \begin{pmatrix} 1 & 0 & 0 & 0 \\ -1 & 1 & 0 & 0 \\ -2 & -2 & 1 & 0 \\ -3 & -3 & -3 & 1 \end{pmatrix}$$

is lower triangular. A diagonal matrix is both upper and lower triangular.

**Tips**

- Use the `tril` function to produce lower triangular matrices for which `istril` returns logical 1 (true).
- The functions `isdiag`, `istriu`, and `istril` are special cases of the function `isbanded`, which can perform all of the same tests with suitably defined upper and lower bandwidths. For example, `istril(A) == isbanded(A, size(A,1), 0)`.

**See Also**

`bandwidth` | `diag` | `isbanded` | `isdiag` | `istriu` | `tril` | `triu`

**Introduced in R2014a**

## istriu

Determine if matrix is upper triangular

### Syntax

```
tf = istriu(A)
```

### Description

`tf = istriu(A)` returns logical 1 (true) if `A` is an upper triangular matrix; otherwise, it returns logical 0 (false).

### Examples

#### Test Upper Triangular Matrix

Create a 5-by-5 matrix.

```
A = triu(magic(5))
```

A =

```
 17 24 1 8 15
 0 5 7 14 16
 0 0 13 20 22
 0 0 0 21 3
 0 0 0 0 9
```

Test `A` to see if it is upper triangular.

```
istriu(A)
```

ans =

```
 1
```

The result is logical 1 (`true`) because all elements below the main diagonal are zero.

## Test Matrix of Zeros

Create a 5-by-5 matrix of zeros.

```
Z = zeros(5);
```

Test Z to see if it is upper triangular.

```
istriu(Z)
```

```
ans =
```

```
1
```

The result is logical 1 (`true`) because an upper triangular matrix can have any number of zeros on the main diagonal.

## Input Arguments

### A — Input array

numeric array

Input array, specified as a numeric array. `istriu` returns logical 0 (`false`) if A has more than two dimensions.

Data Types: `single` | `double`

Complex Number Support: Yes

## More About

### Upper Triangular Matrix

A matrix is upper triangular if all elements below the main diagonal are zero. Any number of the elements on the main diagonal can also be zero.

For example, the matrix

$$A = \begin{pmatrix} 1 & -1 & -1 & -1 \\ 0 & 1 & -2 & -2 \\ 0 & 0 & 1 & -3 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

is upper triangular. A diagonal matrix is both upper and lower triangular.

### Tips

- Use the `triu` function to produce upper triangular matrices for which `istriu` returns logical 1 (true).
- The functions `isdiag`, `istriu`, and `istril` are special cases of the function `isbanded`, which can perform all of the same tests with suitably defined upper and lower bandwidths. For example, `istriu(A) == isbanded(A,0,size(A,2))`.

### See Also

`bandwidth` | `diag` | `isbanded` | `isdiag` | `istril` | `tril` | `triu`

**Introduced in R2014a**

## isundefined

Find undefined elements in categorical array

### Syntax

```
TF = isundefined(A)
```

### Description

`TF = isundefined(A)` returns a logical array, `TF`, that indicates which elements in the categorical array, `A`, contain undefined values. `isundefined` returns logical 1 (`true`) for undefined elements; otherwise it returns logical 0 (`false`). The size of `TF` is the same as the size of `A`.

Any elements in `A` without a corresponding category are undefined. Undefined values are similar to NaN in numeric arrays.

### Examples

#### Categorical Array with Undefined Values

Create a categorical array, `A`, from numeric values where 1, 2, and 3 represent red, green, and blue respectively.

```
A = categorical([4 1; 2 3; 2 1; 3 4; 1 1],1:3,{'red','green','blue'})
```

```
A =
```

```
<undefined> red
green blue
green red
blue <undefined>
red red
```

`A` is a 5-by-2 categorical array with three categories: red, green, and blue. Array elements corresponding to the numeric value 4 in the input array to the `categorical`

function do not have a corresponding category. Therefore, they are undefined in the output categorical array, **A**.

Find undefined elements in **A**.

```
TF = isundefined(A)
```

```
TF =
```

```
 1 0
 0 0
 0 0
 0 1
 0 0
```

**A**(1,1) and **A**(4,2) are undefined.

## Input Arguments

### **A** — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

## See Also

`ismember`

**Introduced in R2013b**

## **isunix**

Determine if version is for Linux or Mac platforms

### **Syntax**

```
tf = isunix
```

### **Description**

`tf = isunix` returns logical 1 (**true**) if the version of MATLAB is for Linux or Apple Mac OS X platforms. Otherwise, it returns logical 0 (**false**).

### **Examples**

#### **Execute MATLAB Command Based on Platform**

```
if ismac
 % Code to run on Mac platform
elseif isunix
 % Code to run on Linux platform
elseif ispc
 % Code to run on Windows platform
else
 disp('Cannot recognize platform')
end
```

#### **See Also**

`computer` | `is*` | `ismac` | `ispc` | `isstudent`

**Introduced before R2006a**

## isvalid (serial)

Determine whether serial port objects are valid

### Syntax

```
out = isvalid(obj)
```

### Description

`out = isvalid(obj)` returns the logical array `out`, which contains a `0` where the elements of the serial port object, `obj` are invalid serial port objects and a `1` where the elements of `obj` are valid serial port objects.

### Examples

Suppose you create the following two serial port objects.

```
s1 = serial('COM1');
s2 = serial('COM1');
```

`s2` becomes invalid after it is deleted.

```
delete(s2)
```

`isvalid` verifies that `s1` is valid and `s2` is invalid.

```
sarray = [s1 s2];
isvalid(sarray)
```

```
ans =
 1 0
```

## More About

### Tips

`obj` becomes invalid after it is removed from memory with the `delete` function. Because you cannot connect an invalid serial port object to the device, you should remove it from the workspace with the `clear` command.

### See Also

`clear` | `delete`

**Introduced before R2006a**

## isvarname

Determine whether input is valid variable name

### Syntax

```
tf = isvarname('str')
isvarname str
```

### Description

`tf = isvarname('str')` returns logical 1 (true) if the string `str` is a valid MATLAB variable name and logical 0 (false) otherwise. A valid variable name is a character string of letters, digits, and underscores, totaling not more than `namelengthmax` characters and beginning with a letter.

MATLAB keywords are not valid variable names. Type the command `iskeyword` with no input arguments to see a list of MATLAB keywords.

`isvarname str` uses the MATLAB command format.

### Examples

This variable name is valid:

```
isvarname foo
ans =
 1
```

This one is not because it starts with a number:

```
isvarname 8th_column
ans =
 0
```

If you are building strings from various pieces, place the construction in parentheses.

```
d = date;
```

```
isvarname(['Monday_', d(1:2)])
ans =
 1
```

## More About

- “Variable Names”

## See Also

**Introduced before R2006a**

## isvector

Determine whether input is vector

### Syntax

```
isvector(A)
```

### Description

`isvector(A)` returns logical 1 (**true**) if `size(A)` returns `[1 n]` or `[n 1]` with a nonnegative integer value `n`, and logical 0 (**false**) otherwise.

### Examples

Test matrix A and its row and column vectors:

```
A = rand(5);
```

```
isvector(A)
ans =
 0
```

```
isvector(A(3, :))
ans =
 1
```

```
isvector(A(:, 2))
ans =
 1
```

### See Also

`iscolumn` | `isrow` | `ismatrix` | `isscalar` | `isempty` | `isnumeric` | `islogical` | `ischar` | `isa` | `is*`

**Introduced before R2006a**

## isweekend

Determine weekend elements

### Syntax

```
tf = isweekend(t)
```

### Description

`tf = isweekend(t)` returns an array the same size as `t` containing logical 1 (`true`) where the corresponding element of `t` is a datetime that occurs on a weekend day, and logical 0 (`false`) otherwise. Weekend days are Saturday and Sunday.

### Examples

#### Determine If Date Occurs During Weekend

```
t = datetime(2014,5,2:5, 'Format', 'eee dd-MMM-yyyy')
```

```
t =
```

```
 Fri 02-May-2014 Sat 03-May-2014 Sun 04-May-2014 Mon 05-May-2014
```

```
tf = isweekend(t)
```

```
tf =
```

```
 0 1 1 0
```

May 3 and May 4, 2014 are days that fall on a weekend.

## Input Arguments

**t** — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

## See Also

`day` | `isdst`

**Introduced in R2014b**

## i

Imaginary unit

### Syntax

```
1j
z = a + bj
z = x + 1j*y
```

### Description

1j returns the basic imaginary unit. j is equivalent to `sqrt(-1)`.

You can use j to enter complex numbers. You also can use the character i as the imaginary unit. To create a complex number without using i and j, use the `complex` function.

`z = a + bj` returns a complex numerical constant, z.

`z = x + 1j*y` returns a complex array, z.

### Examples

#### Complex Scalar

Create a complex scalar and use the character, j, without a multiplication sign as a suffix in forming a complex numerical constant.

```
z = 1+2j
```

```
z =
```

```
1.0000 + 2.0000i
```

#### Complex Vector

Create a complex vector from two 4-by-1 vectors of real numbers.

```
x = [1:4]';
y = [8:-2:2]';

z = x+1j*y
z =

 1.0000 + 8.0000i
 2.0000 + 6.0000i
 3.0000 + 4.0000i
 4.0000 + 2.0000i
```

z is a 4-by-1 complex vector.

### Complex Exponential

Create a complex scalar representing a complex vector with radius, *r*, and angle from the origin, *theta*.

```
r = 4;
theta = pi/4;

z = r*exp(1j*theta)
z =

 2.8284 + 2.8284i
```

## Input Arguments

### **a** — Real component of complex scalar

scalar

Real component of a complex scalar, specified as a scalar.

Data Types: `single` | `double`

### **b** — Imaginary component of complex scalar

scalar

Imaginary component of a complex scalar, specified as a scalar.

If **b** is `double`, you can use the character, `j`, without a multiplication sign as a suffix in forming the complex numerical constant.

Example: `7j`

If **b** is `single`, you must use a multiplication sign when forming the complex numerical constant.

Example: `single(7)*j`

Data Types: `single` | `double`

### **x — Real component of complex array**

scalar | vector | matrix | multidimensional array

Real component of a complex array, specified as a scalar, vector, matrix, or multidimensional array.

The size of **x** must match the size of **y**, unless one is a scalar. If either **x** or **y** is a scalar, MATLAB expands the scalar to match the size of the other input.

`single` can combine with `double`.

Data Types: `single` | `double`

### **y — Imaginary component of complex array**

scalar | vector | matrix | multidimensional array

Imaginary component of a complex array, specified as a scalar, vector, matrix, or multidimensional array.

The size of **x** must match the size of **y**, unless one is a scalar. If either **x** or **y** is a scalar, MATLAB expands the scalar to match the size of the other input.

`single` can combine with `double`.

Data Types: `single` | `double`

## Output Arguments

### **z — Complex array**

scalar | vector | matrix | multidimensional array

Complex array, returned as a scalar, vector, matrix, or multidimensional array.

The size of **z** is the same as the input arguments.

`z` is `single` if at least one input argument is `single`. Otherwise, `z` is `double`.

## More About

### Tips

- For speed and improved robustness in complex arithmetic, use `1i` and `1j` instead of `i` and `j`.
- Since `j` is a function, it can be overridden and used as a variable. However, it is best to avoid using `i` and `j` for variable names if you intend to use them in complex arithmetic.
- Use the `complex` function to create a complex output in the following cases:
  - When the names `i` and `j` might be used for other variables (and do not equal `sqrt(-1)`)
  - When the inputs are not `double` or `single`
  - When the imaginary component is all zeros
- “Complex Numbers”

`complex` | `conj` | `i` | `imag` | `real`

Introduced before R2006a

# javaaddpath

Add entries to dynamic Java class path

## Syntax

```
javaaddpath(dpath)
javaaddpath(dpath, '-end')
```

## Description

`javaaddpath(dpath)` adds one or more folders or Java Archive (JAR) files to the beginning of the current dynamic class path. Use the dynamic path when developing and debugging your own Java classes.

`javaaddpath(dpath, '-end')` adds files or folders to the end of the path.

## Examples

### Add Folder to Dynamic Class Path

Display the current dynamic path.

```
javaclasspath('-dynamic')
```

```
DYNAMIC JAVA PATH
```

```
<empty>
```

The output reflects your configuration.

Add the current folder.

```
javaaddpath(pwd)
```

Display the dynamic path.

```
p = javaclasspath
```

```
p =
 'c:\work\Java'
```

The output reflects your current folder.

### Append URL to Dynamic Class Path

```
javaaddpath('http://www.example.com','-end')
p = javaclasspath

p =
 'c:\work\Java'
 'http://www.example.com'
```

## Input Arguments

### **dpath** — Folder or JAR file

string | cell array of strings

Folder or JAR file, specified as a string or cell array of strings, to add to the dynamic path. When you add a folder to the path, MATLAB includes all files in that folder as part of the path.

Data Types: char | cell

## Limitations

- MATLAB does not support JAR files generated by the MATLAB Compiler SDK product.

## More About

### Tips

- MATLAB provides the dynamic path as a convenience for when you develop your own Java classes. Although the dynamic path offers flexibility in changing the path, Java classes on the dynamic path might load more slowly than classes on the static path. Also, classes on the dynamic path might not behave the same as classes on the static path. If your class does not behave as expected, use the static path.

After you develop and debug a Java class, add the class to the static path.

- This command clears the definitions of all Java classes defined by files on the dynamic class path.
- To add folders to the static path, which MATLAB loads at startup, create a `javaclasspath.txt` file, as described in “Static Path”.
- “Bring Java Classes into MATLAB Workspace”

`clear` | `javaclasspath` | `javarmpath`

**Introduced before R2006a**

# javaArray

Construct Java array object

## Syntax

```
ObjArr = javaArray(PackageName.ClassName,x1,...,xN)
```

## Description

ObjArr = javaArray(PackageName.ClassName,x1,...,xN) constructs an empty Java array object for objects of the specified PackageName.ClassName class.

## Examples

### Create 4-By-5 Array

Create 4-by-5 array of java.lang.Double type.

```
x1 = 4;
x2 = 5;
dblArray = javaArray('java.lang.Double',x1,x2);
```

Fill in values.

```
for m = 1:x1
 for n = 1:x2
 dblArray(m,n) = java.lang.Double((m*10) + n);
 end
end
```

Display results.

```
dblArray
```

```
dblArray =
```

```
java.lang.Double[][]:
 [11] [12] [13] [14] [15]
```

[21]   [22]   [23]   [24]   [25]  
[31]   [32]   [33]   [34]   [35]  
[41]   [42]   [43]   [44]   [45]

## Input Arguments

**PackageName.ClassName** — Name of Java class

string

Name of Java class, including package name, specified as a string.

Data Types: char

**x1, ..., xN** — Dimensions of the array

integer

Dimensions of the array, specified as integer. If any argument is zero, `javaArray` creates a zero-length Java array with the specified number of dimensions. A zero-length Java array is not the same as an empty MATLAB array, which is converted to a Java `null` when passed to a Java method.

Data Types: double

## Output Arguments

**ObjArr** — Java array

Java array

Java array with dimensions `x1, ..., xN`.

## More About

### Java Array Object

A Java array object is an object with Java dimensionality.

### Tips

- The array created by `javaArray` is equivalent to the array created by the following Java code:

```
A = new PackageName.ClassName[x1]...[xN];
```

- To create an array of primitive Java types, create an array of the equivalent MATLAB type, shown in the Conversion of MATLAB Types to Java Types table. See “Conversion of MATLAB Argument Data”.
- “Java Arrays”

**Introduced before R2006a**

# javachk

Error message based on Java feature support

## Syntax

```
MSG = javachk(feature)
javachk(feature,component)
```

## Description

MSG = javachk(feature) returns a generic error message if the specified Java feature is not available in the current MATLAB session.

javachk(feature,component) also names the specified component in the error message.

## Examples

### Generate Error

```
if isempty(javachk('jvm'))
 scalar = java.lang.Double(5);
end
% Check that JVM is available & JavaFigures are supported
error(javachk('jvm'))
error(javachk('awt'))
```

### Generate Error in User-Defined Script

If you write a script, myFile, that displays a Java Frame and want it to error gracefully if a frame cannot be displayed, do the following:

```
error(javachk('awt','myFile'))
myFrame = java.awt.Frame;
myFrame.setVisible(1)
```

If the script cannot display a frame, it displays this error:

myFile is not supported on this platform.

## Input Arguments

### **feature** — Java feature

'awt' | 'desktop' | 'jvm' | 'swing'

Java feature, specified as one of these values:

'awt'	UI components in the Java Abstract Window Toolkit (AWT) are available.
'desktop'	MATLAB interactive desktop is running.
'jvm'	Java Virtual Machine software (JVM™) is running.
'swing'	Swing components (Java lightweight UI components in the Java Foundation Classes) are available.

### **component** — Identifier

string

Identifier, specified as a string, to display in the error message.

Data Types: char

## Output Arguments

### **MSG** — Error message

structure

Error message, returned as a structure with these fields:

If it is available, javachk returns an error structure with empty `message` and `identifier` fields.

### **message** — Message

string | empty

Message, specified as a string.

**identifier** — Identifier

string | empty

Identifier, specified as a string.

**See Also**

error | usejava

**Introduced before R2006a**

# javaclasspath

Return Java class path or specify dynamic path

## Syntax

```
javaclasspath
javaclasspath(' -dynamic')
javaclasspath(' -static')

dpath = javaclasspath
spath = javaclasspath(' -static')
jpath = javaclasspath(' -all')

javaclasspath(dpath)
javaclasspath(dpath1,dpath2)

javaclasspath(statusmsg)
```

## Description

javaclasspath displays the static and dynamic segments of the Java class path.

javaclasspath(' -dynamic' ) displays the dynamic path.

javaclasspath(' -static' ) displays the static path.

dpath = javaclasspath returns the dynamic path, dpath.

spath = javaclasspath(' -static' ) returns the static path, spath.

jpath = javaclasspath(' -all' ) returns the entire path, jpath. The returned cell array contains first the static segment of the path, and then the dynamic segment.

javaclasspath(dpath) changes the dynamic path to dpath. Use this syntax to reload Java classes you are actively developing and debugging.

javaclasspath(dpath1,dpath2) changes the dynamic path to the concatenation of paths dpath1,dpath2.

`javaclasspath(statusmsg)` enables or disables the display of status messages.

## Examples

### Modify Path Using Cell Array

Create a cell array with two path values.

```
dpath = {'http://domain.com', 'http://some.domain.com/jarfile.jar'};
```

Set message flag to display class-loading messages.

```
javaclasspath('-v1')
```

Modify path.

```
javaclasspath(dpath)
```

```
Loading following class path(s) from local file system:
```

```
* http://domain.com
```

```
* http://some.domain.com/jarfile.jar
```

Display updated dynamic path.

```
javaclasspath('-dynamic')
```

```
DYNAMIC JAVA PATH
```

```
http://domain.com
```

```
http://some.domain.com/jarfile.jar
```

MATLAB adds folders from `dpath` to the existing path.

### Capture Contents of Dynamic Path

Create a cell array, `p`, with the entries of the dynamic path.

```
javaclasspath('-v0') %Suppress display of class-loading messages
```

```
p = javaclasspath
```

```
p =
```

```
 {}
```

If there are no entries on the dynamic path, MATLAB creates an empty cell array.

## Input Arguments

### **dpath** — Path entries

string | cell array of strings

Path entries, specified as a string or cell array of strings, to specify for the dynamic path. Converts relative paths to absolute paths.

Example: `javaclasspath('http://domain.com')`

Data Types: char | cell

### **dpath1, dpath2** — Path entries

string | cell array of strings

Path entries, specified as a string or cell array of strings, concatenated, to specify for the dynamic path.

Data Types: char | cell

### **statusmsg** — Message flag

'-v0' (default) | '-v1'

Message flag, specified as one of these values:

- |       |                                                                                    |
|-------|------------------------------------------------------------------------------------|
| '-v0' | Does not display status messages while loading the Java path from the file system. |
| '-v1' | Displays status messages.                                                          |

Controls status message display from the `javaclasspath`, `javaaddpath`, and `javarmpath` functions.

## Output Arguments

### **dpath** — Dynamic path entries

cell array of strings

Dynamic path entries for the current path, returned as a cell array of strings. If no path entries are defined, `dpath` is an empty cell array.

## **spath** — Static path entries

cell array of strings

Static path entries for the current path, returned as a cell array of strings. If no path entries are defined, **spath** is an empty cell array.

## **jpath** — All path entries

cell array of strings

All path entries, returned as a cell array of strings. If no path entries are defined, **jpath** is an empty cell array.

## More About

### Static Path

The static path is a segment of the Java path which is loaded at the start of each MATLAB session from the MATLAB built-in Java path and the file `javaclasspath.txt`.

The static Java path offers better Java class-loading performance than the dynamic Java path. However, to modify the static Java path, edit the file `javaclasspath.txt` and restart MATLAB. For more information, see “Static Path”.

### Dynamic Path

The dynamic path is a segment of the Java class path.

MATLAB provides the dynamic path as a convenience for when you develop your own Java classes. You can load the dynamic path any time during a MATLAB session using the `javaclasspath` function. Although the dynamic path offers flexibility in changing the path, Java classes on the dynamic path might load more slowly than classes on the static path. Also, classes on the dynamic path might not behave the same as classes on the static path. If your class does not behave as expected, use the static path.

After you develop and debug a Java class, add the class to the static path.

You can define the dynamic path (using `javaclasspath`), modify the path (using `javaaddpath` and `javarmppath`), and refresh the Java class definitions for all classes on the dynamic path (using `clear java`) without restarting MATLAB. For more information, see “Dynamic Path”.

**Tips**

- MATLAB searches the static path before the dynamic path.
- Java classes on the static path should not have dependencies on classes on the dynamic path. Such dependencies produce run-time errors.
- This command clears the definitions of all Java classes defined by files on the dynamic class path.
- MATLAB displays a warning if you add an entry to the dynamic path that is already specified on the static path.
- “Java Class Path”

## **matlab.exception.JavaException class**

**Package:** matlab.exception

Capture error information for Java exception

### **Description**

Process information from a `matlab.exception.JavaException` object to handle Java errors thrown from Java methods called from MATLAB. This class is derived from `MException`.

### **Construction**

`e = matlab.exception.JavaException(msgID, errMsg, excObj)` constructs instance `e` of `matlab.exception.JavaException` class.

### **Input Arguments**

**msgID**

message identifier

**errMsg**

error message string

**excObj**

`java.lang.Throwable` object that caused the exception

### **Output Arguments**

**e**

Instance of `matlab.exception.JavaException` class

## Properties

### ExceptionObject

Java exception object that caused the error.

## Tips

- You do not typically construct a `matlab.exception.JavaException` object explicitly. MATLAB automatically constructs a `JavaException` object whenever Java throws an exception. The `JavaException` object wraps the original Java exception.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Examples

```
try
 java.lang.Class.forName('foo');
catch e
 e.message
 if(isa(e, 'matlab.exception.JavaException'))
 ex = e.ExceptionObject;
 assert(isJava(ex));
 ex.printStackTrace;
 end
end
```

## More About

- “Capture Information About Exceptions”
- “Throw an Exception”

**Introduced in R2012b**

# javaMethod

Call Java method

## Syntax

```
javaMethod(MethodName,JavaObj,x1,...,xN)
javaMethod(StaticMethodName,ClassName,x1,...,xN)
```

## Description

`javaMethod(MethodName,JavaObj,x1,...,xN)` calls the method in the class of the Java object array with the signature matching the arguments `x1,...,xN`.

`javaMethod(StaticMethodName,ClassName,x1,...,xN)` calls the static method in class `ClassName`.

## Examples

### Call Method on Java Object

Create a `java.util.Date` object, `myDate`, and change the month to 3.

```
myDate = java.util.Date;
javaMethod('setMonth',myDate,3)
```

### Call Static Method

Call `java.lang.Double` static method, `isNaN`, to test variable `num`.

```
num = 2.2;
if javaMethod('isNaN','java.lang.Double',num)
 disp('This is not a number')
end
```

Since `num` contains a number, no message is displayed.

## Call Method Specified at Runtime

This example, searching for a text pattern in a string, uses variables for the pattern and for the search method. These variables could be set at runtime from user input.

Choose method, `startsWith`, and identify pattern, `str`.

```
fnc = 'startsWith';
str = java.lang.String('Four score');
```

Identify text to search.

```
gAddress = java.lang.String('Four score and seven years ago');
```

Search `gAddress`.

```
javaMethod(fnc,gAddress,str)
```

```
ans =
 1
```

`gAddress` starts with the words `Four score`.

## Input Arguments

### **MethodName** — Name of nonstatic Java method

string

Name of nonstatic Java method, specified as a string.

Data Types: char

### **JavaObj** — Array

Java object

Array, specified as a Java object of the class containing the method.

### **x1, ..., xN** — Java method input arguments

any type

Java method input arguments, 1 through N (if any), required by `MethodName` or `StaticMethodName`, specified by any type. The argument type is specified by the method argument list.

**StaticMethodName — Name of static Java method**

string

Name of static Java method, specified as a string.

Data Types: char

**ClassName — Name of Java class**

string

Name of Java class, specified as a string, containing `StaticMethodName`.

Data Types: char

## More About

### Tips

- In most cases, use either MATLAB or Java syntax to call methods on Java objects:

```
% MATLAB syntax
method(object, arg1, ..., argn)

/* Java syntax */
object.method(arg1, ..., argn)
```

- Use `javaMethod` to call methods having names that exceed the maximum length of a MATLAB identifier. (Call the `nameLengthMax` function to obtain the maximum identifier length.)

This is the only way you can call such a method in MATLAB. For example, if you have the following function:

```
javaMethod('DataDefinitionAndDataManipulationTransactions', T)
```

- Use `javaMethod` when you want to specify the method name as a variable, to be invoked at runtime. When calling a static method, you also can use a variable in place of the class name argument. For example, see “Call Method Specified at Runtime” on page 1-4834.

- “Calling Syntax”

# javaMethodEDT

Call Java method from Event Dispatch Thread (EDT)

## Syntax

```
javaMethodEDT(MethodName,JavaObj,x1,...,xN)
javaMethodEDT(StaticMethodName,ClassName,x1,...,xN)
```

## Description

`javaMethodEDT(MethodName,JavaObj,x1,...,xN)` calls the method in the class of the Java object array with the signature matching the arguments `x1,...,xN` from the Event Dispatch Thread (EDT)

`javaMethodEDT(StaticMethodName,ClassName,x1,...,xN)` calls the static method in class `ClassName`.

## Examples

### Call Method from EDT

Create a `java.util.Vector` object, `v`, and add a `string` element.

```
v = java.util.Vector;
javaMethodEDT('add',v,'string');
```

## Input Arguments

### MethodName — Name of nonstatic Java method

`string`

Name of nonstatic Java method, specified as a string.

Data Types: `char`

**JavaObj — Array**

Java object

Array, specified as a Java object of the class containing the method.

**x1, . . . , xN — Java method input arguments**

any type

Java method input arguments, 1 through N (if any), required by `MethodName` or `StaticMethodName`, specified by any type. The argument type is specified by the method argument list.

**StaticMethodName — Name of static Java method**

string

Name of static Java method, specified as a string.

Data Types: char

**ClassName — Name of Java class**

string

Name of Java class, specified as a string, containing `StaticMethodName`.

Data Types: char

## More About

### EDT

The EDT is the Event Dispatch Thread, used in Java.

### See Also

`import` | `isjava` | `javaMethod` | `javaObjectEDT` | `methods`

**Introduced in R2009a**

# javaObject

Call Java constructor

## Syntax

```
JavaObj = javaObject(ClassName, x1, . . . , xN)
```

## Description

JavaObj = javaObject(ClassName, x1, . . . , xN) returns Java object array, JavaObj, created by the Java constructor for the class with the argument list matching x1, . . . , xN.

## Examples

### Create Java Object

Create a Java object, strObj, of class java.lang.String.

```
strObj = javaObject('java.lang.String', 'hello');
```

## Input Arguments

### ClassName — Name of Java class

string

Name of Java class, specified as a string.

Data Types: char

### x1, . . . , xN — Java constructor input arguments

any type

Java constructor input arguments, 1 through N (if any), required by ClassName, specified by any type. The argument type is specified by the class constructor argument list.

## **More About**

- “Using the javaObjectEDT Function”

## **See Also**

`import` | `javaArray` | `javaMethod` | `javaObjectEDT` | `methods`

**Introduced before R2006a**

# javaObjectEDT

Call Java constructor on Event Dispatch Thread (EDT)

## Syntax

```
JavaObj = javaObjectEDT(ClassName, x1, ..., xN)
```

## Description

JavaObj = javaObjectEDT(ClassName, x1, ..., xN) returns Java object array, JavaObj, created from the EDT by the Java constructor for the class with the signature matching the arguments x1, ..., xN.

## Examples

### Construct Java Object Array from the EDT

```
f = javaObjectEDT('javax.swing.JFrame', 'New Title');
```

### Call Method on Java Object

Create a JOptionPane on the EDT.

```
optPane = javaObjectEDT('javax.swing.JOptionPane');
```

Call the createDialog method on the EDT.

```
dlg = optPane.createDialog([], 'Sample Dialog');
```

## Input Arguments

### ClassName — Name of Java class

string

Name of Java class, specified as a string.

Data Types: char

**x1, ..., xN — Java constructor input arguments**

any type

Java constructor input arguments, 1 through N (if any), required by `ClassName`, specified by any type. The argument type is specified by the class constructor argument list.

## More About

### EDT

The EDT is the Event Dispatch Thread, used in Java.

### Tips

- MATLAB calls methods on `JavaObj` from the EDT.
- Static methods on the specified class or Java object run on the MATLAB thread unless called using the `javaMethodEDT` function.

### See Also

`import` | `javaMethodEDT` | `javaObject` | `methods`

**Introduced in R2009a**

# javarmpath

Remove entries from dynamic Java class path

## Syntax

```
javarmpath(dpath1, ..., dpathN)
```

## Description

`javarmpath(dpath1, ..., dpathN)` removes one or more files or folders from the current dynamic class path.

## Examples

### Remove Folder from Dynamic Path

In order to preserve the state of the dynamic path on your system, this example first adds folders to the path, then removes one of these folders.

Create a variable that points to the MATLAB examples folder.

```
expath = fullfile(matlabroot, 'extern', 'examples')
```

```
expath =
```

```
C:\Program Files\MATLAB\R2012b\extern\examples
```

The path reflects the folder to your MATLAB installation.

Add two folders to the path.

```
javaclasspath({...
 expath, ...
 'http://www.example.com'})
javaclasspath('-dynamic')
```

```
DYNAMIC JAVA PATH
```

```
C:\Program Files\MATLAB\R2012b\extern\examples
http://www.example.com
```

The output displays these new folders on your existing path.

Remove one folder.

```
javarmpath(expath)
javaclasspath('-dynamic')
```

```
DYNAMIC JAVA PATH
```

```
http://www.example.com
```

The path no longer contains the examples folder.

## Input Arguments

**dpath1, ..., dpathN — Folders or JAR files**

string

Folders or JAR files, specified as strings, to remove from path.

Data Types: char

## More About

### Tips

- This command clears the definitions of all Java classes defined by files on the dynamic class path.
- “Bring Java Classes into MATLAB Workspace”

## See Also

### Functions

clear | javaaddpath | javaclasspath

**Introduced before R2006a**

# join

Merge two tables by matching up rows using key variables

## Syntax

```
C = join(A,B)
C = join(A,B,Name,Value)
[C,ib] = join(___)
```

## Description

`C = join(A,B)` merges tables `A` and `B` by matching up rows using all the variables with the same name as key variables. The key values must be common to both `A` and `B`, except for order.

`join` retains all the variables from `A` and appends the corresponding contents from the nonkey variables of `B`.

`C = join(A,B,Name,Value)` joins the tables with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the variables to use as key variables.

`[C,ib] = join( ___ )` also returns an index vector, `ib`, such that each element of `ib` identifies the row in `B` that corresponds to that row in the output table, `C`. You can use this syntax with any of the input arguments of the previous syntaxes.

## Examples

### Append Values from One Table to Another

Create a table, `A`.

```
A = table({'John','Jane','Jim','Jerry','Jill'},[1;2;1;2;1],...
 'VariableNames',{'Employee' 'Department'})
```

`A =`

Employee	Department
'John'	1
'Jane'	2
'Jim'	1
'Jerry'	2
'Jill'	1

Create a table, B, with a variable in common with A.

```
B = table([1 2]', {'Mary' 'Mike'}', ...
 'VariableNames', {'Department' 'Manager'})
```

B =

Department	Manager
1	'Mary'
2	'Mike'

Create a new table, C, containing data from tables A and B. Use the `join` function to repeat and append `Manager` data from table B to the data from table A based on the key variable, `Department`.

```
C = join(A,B)
```

C =

Employee	Department	Manager
'John'	1	'Mary'
'Jane'	2	'Mike'
'Jim'	1	'Mary'
'Jerry'	2	'Mike'
'Jill'	1	'Mary'

## Merge Tables with One Variable in Common

Create a table, A.

```
A = table([5;12;23;2;6], ...
```

```
{'cereal';'pizza';'salmon';'cookies';'pizza'},...
'VariableNames',{ 'Age', 'FavoriteFood' },...
'RowNames',{ 'Amy', 'Bobby', 'Holly', 'Harry', 'Sally'}}
```

A =

	Age	FavoriteFood
Amy	5	'cereal'
Bobby	12	'pizza'
Holly	23	'salmon'
Harry	2	'cookies'
Sally	6	'pizza'

Create a table, B, with one variable in common with A.

```
B = table({'cereal';'cookies';'pizza';'salmon';'cake'},...
[110;160;140;367;243],...
{'B';'D';'B-';'A';'C-'},...
'VariableNames',{ 'FavoriteFood', 'Calories', 'NutritionGrade'})
```

B =

FavoriteFood	Calories	NutritionGrade
'cereal'	110	'B'
'cookies'	160	'D'
'pizza'	140	'B-'
'salmon'	367	'A'
'cake'	243	'C-'

Create a new table, C, with data from tables A and B. Use FavoriteFood as a key variable to the join function.

```
C = join(A,B)
```

C =

	Age	FavoriteFood	Calories	NutritionGrade
Amy	5	'cereal'	110	'B'
Bobby	12	'pizza'	140	'B-'

Holly	23	'salmon'	367	'A'
Harry	2	'cookies'	160	'D'
Sally	6	'pizza'	140	'B-'

Table C does not include information from the last row of table B about 'cake' since there is no corresponding entry in table A.

## Merge Tables by Specifying One Key Variable

Create a table, A.

```
A = table([10;4;2;3;7],[5;4;9;6;1],[10;3;8;8;4])
```

A =

Var1	Var2	Var3
10	5	10
4	4	3
2	9	8
3	6	8
7	1	4

Create a table, B, giving Var2 the same contents as Var2 from table A.

```
B = table([6;1;1;6;8],[5;4;9;6;1])
```

B =

Var1	Var2
6	5
1	4
1	9
6	6
8	1

Create a new table, C, containing data from tables A and B. Use Var1 in table A and Var2 in table B as key variables to the `join` function.

```
C = join(A,B, 'Keys', 'Var2')
```

C =

Var1_A	Var2	Var3	Var1_B
10	5	10	6
4	4	3	1
2	9	8	1
3	6	8	6
7	1	4	8

`join` adds a unique suffix to the nonkey variable `Var1` to distinguish the data from tables A and B.

### Keep One Copy of Nonkey Variables

Create a new table with data from tables A and B. If any nonkey variables have the same name in both tables, keep only the copy from table A.

Create a table, A.

```
A = table([10;4;2;3;7],[5;4;9;6;1])
```

A =

Var1	Var2
10	5
4	4
2	9
3	6
7	1

Create a table, B, giving `Var2` the same contents as `Var2` from table A.

```
B = table([6;1;1;6;8],[5;4;9;6;1],[10;3;8;8;4])
```

B =

Var1	Var2	Var3
6	5	10
1	4	3

```

1 9 8
6 6 8
8 1 4

```

Create a new table, **C**, with data from tables **A** and **B**. Use **Var2** as a key variable to the `join` function and keep only the copy of **Var1** from table **A**.

```
C = join(A,B, 'Keys', 'Var2', 'KeepOneCopy', 'Var1')
```

C =

```

Var1 Var2 Var3

10 5 10
4 4 3
2 9 8
3 6 8
7 1 4

```

**C** does not contain the **Var1** data from table **B**.

### Merge Tables Using Row Names as Keys

Create a table, **A**.

```
A = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
 'VariableNames',{ 'Gender' 'Age'},...
 'RowNames',{ 'Smith' 'Johnson' 'Williams' 'Jones' 'Brown'})
```

A =

```

 Gender Age

Smith M 38
Johnson M 43
Williams F 38
Jones F 40
Brown F 49

```

Create a table, **B**, such that there is a one-to-one correspondence between the rows of **A** and the rows of **B**.

```
B = table([64;69;67;71;64],...
```

```
[119;163;133;176;131],...
[122 80; 109 77; 117 75; 124 93; 125 83],...
'VariableNames',{ 'Height' 'Weight' 'BloodPressure'},...
'RowNames',{ 'Brown' 'Johnson' 'Jones' 'Smith' 'Williams'}}
```

B =

	Height	Weight	BloodPressure	
	_____	_____	_____	
Brown	64	119	122	80
Johnson	69	163	109	77
Jones	67	133	117	75
Smith	71	176	124	93
Williams	64	131	125	83

Create a new table, C, with data from tables A and B. Use the row names as keys to the `join` function.

```
C = join(A,B, 'Keys', 'RowNames')
```

C =

	Gender	Age	Height	Weight	BloodPressure	
	_____	_____	_____	_____	_____	
Smith	M	38	71	176	124	93
Johnson	M	43	69	163	109	77
Williams	F	38	64	131	125	83
Jones	F	40	67	133	117	75
Brown	F	49	64	119	122	80

The rows of C are in the same order as A.

### Merge Tables Using Left and Right Keys

Create a table, A.

```
A = table([10;4;2;3;7],[5;4;9;6;1],[10;3;8;8;4])
```

A =

Var1	Var2	Var3
_____	_____	_____

```
10 5 10
 4 4 3
 2 9 8
 3 6 8
 7 1 4
```

Create a table, **B**, giving **Var2** the same contents as **Var1** from table **A**, except for order.

```
B = table([6;1;1;6;8],[2;3;4;7;10])
```

B =

```
 Var1 Var2
 ---- ----
 6 2
 1 3
 1 4
 6 7
 8 10
```

Create a new table, **C**, containing data from tables **A** and **B**. Use **Var1** from table **A** with **Var2** from table **B** as key variables to the `join` function.

```
[C,ib] = join(A,B, 'LeftKeys',1, 'RightKeys',2)
```

C =

```
 Var1_A Var2 Var3 Var1_B
 ---- ---- ---- ----
 10 5 10 8
 4 4 3 1
 2 9 8 6
 3 6 8 1
 7 1 4 6
```

ib =

```
5
3
1
2
4
```

C is the horizontal concatenation of A and B (`ib, 2`).

## Input Arguments

### A, B — Input tables

tables

Input tables, specified as tables. For all key variables, each row of A must match exactly one row in B.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Keys', 2` uses the second variable in A and the second variable in B as key variables.

### 'Keys' — Variables to use as keys

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector | `'RowNames'`

Variables to use as keys, specified as the comma-separated pair consisting of `'Keys'` and a positive integer, vector of positive integers, variable name, cell array of variable names, logical vector, or `'RowNames'`.

If you specify the string `'RowNames'`, then `join` uses the row names of A and row names of B as keys. In this case, there must be a row in B for every row in A.

You cannot use the `'Keys'` name-value pair argument with the `'LeftKeys'` and `'RightKeys'` name-value pair arguments.

Example: `'Keys', [1 3]` uses the first and third variables from A and B as a key variables.

### 'LeftKeys' — Variables to use as keys in A

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in A, specified as the comma-separated pair consisting of 'LeftKeys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the 'LeftKeys' name-value pair argument in conjunction with the 'RightKeys' name-value pair argument. 'LeftKeys' and 'RightKeys' both must specify the same number of key variables. `join` pairs key values based on their order.

Example: 'LeftKeys', 1 uses only the first variable in A as a key variable.

**'RightKeys' — Variables to use as keys in B**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in B, specified as the comma-separated pair consisting of 'RightKeys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the 'RightKeys' name-value pair argument in conjunction with the 'LeftKeys' name-value pair argument. 'LeftKeys' and 'RightKeys' both must specify the same number of key variables. `join` pairs values in A and B based on their order.

Example: 'RightKeys', 3 uses only the third variable in B as a key variable.

**'LeftVariables' — Variables from A to include in C**

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from A to include in C, specified as the comma-separated pair consisting of 'LeftVariables' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use 'LeftVariables' to include or exclude key variables, as well as nonkey variables from the output, C.

By default, `join` includes all variables from A.

**'RightVariables' — Variables from B to include in C**

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from **B** to include in **C**, specified as the comma-separated pair consisting of `'RightVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use `'RightVariables'` to include or exclude key variables, as well as nonkey variables from the output, **C**.

By default, `join` includes all the variables from **B** except the key variables.

### **'KeepOneCopy'** — Variables for which `join` retains only the copy from **A**

variable name | cell array containing one or more variable names

Variables for which `join` retains only the copy from **A**, specified as the comma-separated pair consisting of `'KeepOneCopy'` and a variable name or a cell array containing one or more variable names.

Key variables appear once in **C**, but if nonkey variables with identical names occur in **A** and **B**, then `join` retains both copies in **C** by default. You must use the `'KeepOneCopy'` name-value pair to retain only the copy from **A**.

Example: `'KeepOneCopy', Var2` keeps only the copy from **A** of the nonkey variable `Var2`.

## Output Arguments

### **C** — Merged data from **A** and **B**

table

Merged data from **A** and **B**, returned as a table. The table, **C**, contains one row for each row in **A**, appearing in the same order. If **A** and **B** contain nonkey variables with the same name, `join` adds a unique suffix to the corresponding variable names in **C**, unless you specify the `'KeepOneCopy'` name-value pair argument.

`join` creates **C** by horizontally concatenating `A(:, LeftVars)` and `B(ib, RightVars)`. By default, `LeftVars` is all the variables of **A**, and `RightVars` is all the nonkey variables from **B**. Otherwise, `LeftVars` consists of the variables specified by the `'LeftVariables'` name-value pair argument, and `RightVars` consists of the variables specified by the `'RightVariables'` name-value pair argument.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the output table, **C**. For more information, see [Table Properties](#).

## **ib** — Index to B

column vector

Index to B, returned as a column vector. Each element of **ib** identifies the row in B that corresponds to that row in the output table, C.

## **More About**

### **Key Variable**

Variable used to match and combine data between the input tables, A and B.

### **Key Value**

Entry in a key variable of A.

### **Algorithms**

The `join` function first finds one or more key variables. Then, `join` uses the key variables to find the row in input table B that matches each row in input table A, and combines those rows to create a row in output table C.

- If there is a one-to-one mapping between key values in A and B, then `join` sorts the data in B and appends it to table A.
- If there is a many-to-one mapping between key values in A and B, then `join` sorts and repeats the data in B before appending it to table A.
- If there is data in a key variable of B that does not map to a key value in A, then `join` does not include that data in the output table, C.

**Introduced in R2013b**

# juliandate

Convert MATLAB datetime to Julian date

## Syntax

```
d = juliandate(t)
d = juliandate(t,dateType)
```

## Description

`d = juliandate(t)` returns a **double** array containing “Julian date” on page 1-4858 equivalent to the datetime values in `t`. If `t` has a time zone, then `juliandate` computes `d` with respect to UTC. `juliandate` ignores leap seconds unless the time zone of `t` is `UTCLeapSeconds`.

`d = juliandate(t,dateType)` returns the type of Julian dates specified by `dateType`. For example, you can convert datetime values to modified Julian dates.

## Examples

### Convert Datetime Array to Julian Dates

Create a datetime array. Then, convert the dates to Julian dates.

```
t = datetime('today') + calmonths(1:3)

t =
 24-Sep-2015 24-Oct-2015 24-Nov-2015

d = juliandate(t)

d =
```

```
1.0e+06 *
2.4573 2.4573 2.4574
```

## Input Arguments

### **t** — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

### **dateType** — Type of Julian date values

'`juliandate`' (default) | '`modifiedjuliandate`'

Type of Julian date values, specified as either '`juliandate`' or '`modifiedjuliandate`'.

- If `dateType` is '`juliandate`', then `juliandate` converts the `datetime` values in `t` to the equivalent Julian dates. A Julian date is the number of days and fractional days since noon on November 24, 4712 BCE in the proleptic Gregorian calendar, or January 1, 4713 BCE in the proleptic Julian calendar.
- If `dateType` is '`modifiedjuliandate`', then `juliandate` converts the `datetime` values in `t` to the equivalent modified Julian dates. A modified Julian date is the number of days and fractional days since November 17, 1858 00:00:00.

## More About

### Julian date

A Julian date is the number of days and fractional days since noon on November 24, 4712 BCE in the proleptic Gregorian calendar, or January 1, 4713 BCE in the proleptic Julian calendar.

# keyboard

Input from keyboard

## Syntax

keyboard

## Description

`keyboard`, when placed in a program `.m` file, stops execution of the file and gives control to the keyboard. The special status is indicated by a **K** appearing before the prompt. You can examine or change variables; all MATLAB commands are valid. This keyboard mode is useful for debugging your functions.

To terminate the keyboard mode, type `dbcont`, and then press **Enter**. To terminate keyboard mode and exit the function, type `dbquit`, and press **Enter**.

## See Also

`dbstop` | `input` | `quit` | `pause` | `dbcont`

**Introduced before R2006a**

## keys

**Class:** `containers.Map`

**Package:** `containers`

Identify keys of `containers.Map` object

## Syntax

```
keySet = keys(mapObj)
```

## Description

`keySet = keys(mapObj)` returns cell array `keySet`, which contains all of the keys in `mapObj`.

## Input Arguments

**mapObj**

Object of class `containers.Map`.

## Output Arguments

**keySet**

1-by-n cell array, where n is the number of keys in `mapObj`.

## Examples

### Get the Keys in a Map

Create a map, and view the keys in the map:

```
myKeys = {'a', 'b', 'c'};
myValues = [1,2,3];
mapObj = containers.Map(myKeys,myValues);

keySet = keys(mapObj)
```

This code returns 1-by-3 cell array `keySet`:

```
keySet =
 'a' 'b' 'c'
```

### See Also

`isKey` | `values` | `containers.Map` | `remove`

# kron

Kronecker tensor product

## Syntax

`K = kron(A,B)`

## Description

`K = kron(A,B)` returns the Kronecker tensor product of matrices `A` and `B`. If `A` is an  $m$ -by- $n$  matrix and `B` is a  $p$ -by- $q$  matrix, then `kron(A,B)` is an  $m*p$ -by- $n*q$  matrix formed by taking all possible products between the elements of `A` and the matrix `B`.

## Examples

### Block Diagonal Matrix

Create a block diagonal matrix.

Create a 4-by-4 identity matrix and a 2-by-2 matrix that you want to be repeated along the diagonal.

```
A = eye(4);
B = [1 -1; -1 1];
```

Use `kron` to find the Kronecker tensor product.

```
K = kron(A,B)
```

```
K =
```

```
 1 -1 0 0 0 0 0 0
 -1 1 0 0 0 0 0 0
 0 0 1 -1 0 0 0 0
 0 0 -1 1 0 0 0 0
 0 0 0 0 1 -1 0 0
```

```

0 0 0 0 -1 1 0 0
0 0 0 0 0 0 1 -1
0 0 0 0 0 0 -1 1

```

The result is an 8-by-8 block diagonal matrix.

### Repeat Matrix Elements

Expand the size of a matrix by repeating elements.

Create a 2-by-2 matrix of ones and a 2-by-3 matrix whose elements you want to repeat.

```

A = [1 2 3; 4 5 6];
B = ones(2);

```

Calculate the Kronecker tensor product using `kron`.

```

K = kron(A,B)

```

K =

```

1 1 2 2 3 3
1 1 2 2 3 3
4 4 5 5 6 6
4 4 5 5 6 6

```

The result is a 4-by-6 block matrix.

### Sparse Laplacian Operator Matrix

This example visualizes a sparse Laplacian operator matrix.

The matrix representation of the discrete Laplacian operator on a two-dimensional,  $n$ -by- $n$  grid is a  $n*n$ -by- $n*n$  sparse matrix. There are at most five nonzero elements in each row or column. You can generate the matrix as the Kronecker product of one-dimensional difference operators. In this example  $n = 5$ .

```

n = 5;
I = speye(n,n);
E = sparse(2:n,1:n-1,1,n,n);
D = E+E' - 2*I;
A = kron(D,I)+kron(I,D);

```

Visualize the sparsity pattern with `spy`.

```
spy(A, 'k')
```

## Input Arguments

### **A, B** — Input matrices

scalars | vectors | matrices

Input matrices, specified as scalars, vectors, or matrices. If either A or B is sparse, then kron multiplies only nonzero elements and the result is also sparse.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

Complex Number Support: Yes

## More About

### Kronecker Tensor Product

If  $A$  is an  $m$ -by- $n$  matrix and  $B$  is a  $p$ -by- $q$  matrix, then the Kronecker tensor product of  $A$  and  $B$  is a large matrix formed by multiplying  $B$  by each element of  $A$

$$A \otimes B = \begin{bmatrix} a_{11}B & a_{12}B & \cdots & a_{1n}B \\ a_{21}B & a_{22}B & \cdots & a_{2n}B \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1}B & a_{m2}B & \cdots & a_{mn}B \end{bmatrix}.$$

For example, two simple 2-by-2 matrices produce

$$A = \begin{bmatrix} 1 & -2 \\ -1 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 4 & -3 \\ 2 & 3 \end{bmatrix}$$

$$A \otimes B = \begin{bmatrix} 1 \cdot 4 & 1 \cdot -3 & -2 \cdot 4 & -2 \cdot -3 \\ 1 \cdot 2 & 1 \cdot 3 & -2 \cdot 2 & -2 \cdot 3 \\ -1 \cdot 4 & -1 \cdot -3 & 0 \cdot 4 & 0 \cdot -3 \\ -1 \cdot 2 & -1 \cdot 3 & 0 \cdot 2 & 0 \cdot 3 \end{bmatrix} = \begin{bmatrix} 4 & -3 & -8 & 6 \\ 2 & 3 & -4 & -6 \\ -4 & 3 & 0 & 0 \\ -2 & -3 & 0 & 0 \end{bmatrix}.$$

## Using KeyValueStore Objects

Store key-value pairs for use with mapreduce

### Description

The `mapreduce` function automatically creates a `KeyValueStore` object during execution and uses it to store key-value pairs added by the map and reduce functions. Although you never need to explicitly create a `KeyValueStore` object to use `mapreduce`, you do need to use the `add` and `addmulti` object functions to interact with this object in the map and reduce functions.

### Examples

#### Add Key-Value Pair to KeyValueStore in Map Function

The following map function uses the `add` function to add key-value pairs one at a time to an intermediate `KeyValueStore` object (named `intermKVStore`).

```
function MeanDistMapFun(data, info, intermKVStore)
 distances = data.Distance(~isnan(data.Distance));
 sumLenKey = 'sumAndLength';
 sumLenValue = [sum(distances), length(distances)];
 add(intermKVStore, sumLenKey, sumLenValue);
end
```

#### Add Multiple Key-Value Pairs to KeyValueStore in Map Function

The following map function uses `addmulti` to add several key-value pairs to an intermediate `KeyValueStore` object (named `intermKVStore`). Note that this map function collects multiple keys in the `intermKeys` variable, and multiple values in the `intermVals` variable. This prepares a single call to `addmulti` to add all of the key-value pairs at once. It is a best practice to use a single call to `addmulti` rather than using `add` in a loop.

```
function meanArrivalDelayByDayMapper(data, ~, intermKVStore)
% Mapper function for the MeanByGroupMapReduceExample.

% Copyright 2014 The MathWorks, Inc.
```

```

% Data is an n-by-2 table: first column is the DayOfWeek and the second
% is the ArrDelay. Remove missing values first.
delays = data.ArrDelay;
day = data.DayOfWeek;
notNaN = ~isnan(delays);
day = day(notNaN);
delays = delays(notNaN);

% find the unique days in this chunk
[intermKeys,-,idx] = unique(day, 'stable');

% group delays by idx and apply @grpstatsfun function to each group
intermVals = accumarray(idx,delays,size(interKeys),@countsum);
addmulti(interKVStore,intermKeys,intermVals);

function out = countsum(x)
n = length(x); % count
s = sum(x); % mean
out = {[n, s]};

```

## Object Functions

add	Add single key-value pair to KeyValueStore
addmulti	Add multiple key-value pairs to KeyValueStore

## Create Object

The `mapreduce` function automatically creates `KeyValueStore` objects during execution.

### More About

- “Getting Started with MapReduce”

**Introduced in R2014b**

## lastDirectory

**Class:** Tiff

Determine if current IFD is last in file

### Syntax

```
tf = lastDirectory(tiffobj)
```

### Description

`tf = lastDirectory(tiffobj)` returns `true` if the current image file directory (IFD) is the last IFD in the TIFF file; otherwise, `false`. If the file contains only one image, the current IFD is the last.

### Examples

#### Determine if Current Directory is the Last Directory

Open a Tiff object and determine if the current directory is the last directory in the file.

```
t = Tiff('example.tif', 'r');
tf = lastDirectory(t)
```

```
tf =
```

```
0
```

The current directory is not the last directory in the file.

Close the Tiff object.

```
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## References

This method corresponds to the `TIFFLastDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

`Tiff.setDirectory`

# Chart Line Properties

Control chart line appearance and behavior

Chart line properties control the appearance and behavior of a chart line object. By changing property values, you can modify certain aspects of the line.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = plot(1:10);
c = h.Color;
h.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Line

### LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	
'--'	Dashed line	
':'	Dotted line	
'-.'	Dash-dotted line	
'none'	No line	No line

### LineWidth — Line width

0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

**Color — Line color**

[0 0 0] (default) | RGB triplet | color string | 'none'

Line color, specified as an RGB triplet, a color string, or 'none'. The default RGB triplet value of [0 0 0] corresponds to black. If you specify the **Color** as 'none', then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

**LineJoin — Style of line corners**

'round' (default) | 'miter' | 'chamfer'

Style of line corners, specified as 'round', 'miter', or 'chamfer'. This table illustrates the appearance of the different values.

The appearance of the 'round' option might look different if the `Renderer` property of the figure is set to 'opengl' instead of 'painters'.

### **AlignVertexCenters** — Sharp vertical and horizontal lines

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a `GraphicsSmoothing` property set to 'on' and a `Renderer` property set to 'opengl', then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- 'off' — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- 'on' — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

---

**Note:** You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

---

## **Markers**

### **Marker** — Marker symbol

'none' (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the chart line object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

### MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

### MarkerEdgeColor — Marker outline color

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the **Color** property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

Example:  $[0.5 \ 0.5 \ 0.5]$

Example: 'blue'

**MarkerFaceColor** — Marker fill color

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the Color property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]

Long Name	Short Name	RGB Triplet
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.3 0.2 0.1]

Example: 'green'

## Data

### XData — x values

vector

$x$  values, specified as a vector.

- For 2-D line plots, if you do not specify the  $x$  values, then MATLAB uses the indices of **YData** as the  $x$  values for the plot. **XData** and **YData** must have equal lengths.
- For 3-D line plots, if you do not specify the  $x$  values, then MATLAB uses the indices of **ZData** as the  $x$  values for the plot. **XData**, **YData**, and **ZData** must have equal lengths.

Example: [1:10]

### YData — y values

vector

$y$  values, specified as a vector. For 2-D line plots, **XData** and **YData** must have equal lengths. For 3-D line plots, **XData**, **YData**, and **ZData** must have equal lengths.

Example: [1:10]

### ZData — z values

vector

z values for the 3-D line plot, specified as a vector. `XData`, `YData`, and `ZData` must have equal lengths.

Example: `[1:10]`

### **XDataSource — Variable linked to XData**

' ' (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: `'x'`

### **YDataSource — Variable linked to YData**

' ' (default) | string containing MATLAB workspace variable name

Variable linked to `YData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `YData`.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, then MATLAB does not update the `YData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: `'y'`

### **ZDataSource — Variable linked to ZData**

' ' (default) | string containing MATLAB workspace variable name

Variable linked to `ZData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `ZData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `ZData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: `'z'`

### **XDataMode — Selection mode for XData**

`'auto'` (default) | `'manual'`

Selection mode for `XData`, specified as one of these values:

- `'auto'` — Use the indices of the values in `YData` (or `ZData` for 3-D plots).
- `'manual'` — Use manually specified values. To specify the values, set the `XData` property or specify the input argument `X` to the plotting function.

## **Visibility**

### **Visible — State of visibility**

`'on'` (default) | `'off'`

State of visibility, specified as one of these values:

- `'on'` — Display the chart line.
- `'off'` — Hide the chart line without deleting it. You still can access the properties of an invisible chart line object.

### **Clipping — Clipping of chart line object to axes limits**

`'on'` (default) | `'off'`

Clipping of the chart line object to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the chart line object that are outside the axes limits.

- 'off' — Display the entire chart line object, even if parts of it appear outside the axes limits. Parts of the chart line object might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the chart line object so that it is larger than the original plot.

The `Clipping` property of the axes that contains the chart line object must be set to 'on', otherwise this property has no effect. For more information about the clipping behavior, see the `Clipping` property of the axes.

### **EraseMode — (removed) Technique to draw and erase objects**

'normal' (default) | 'none' | 'xor' | 'background'

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- 'normal' — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- 'none' — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, 'none', it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- 'xor' — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- 'background' — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is 'none'. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to 'normal'. This means graphics objects created with `EraseMode` set to 'none', 'xor', or 'background' can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain

greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### Type — Type of graphics object

'line'

This property is read only.

Type of graphics object, returned as 'line'. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

### Tag — User-specified tag

'' (default) | string

Tag to associate with the chart line, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

### UserData — Data to associate with chart line

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the chart line object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: 1:100

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | table | cell

### DisplayName — Text used by legend

'' (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the chart line.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where N is the number assigned to the chart line object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

### **Annotation — Legend icon display style**

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the chart line from a legend.

- 1** Query the `Annotation` property to get the `Annotation` object.
- 2** Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3** Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - `'on'` — Include the chart line object in the legend as one entry (default).
  - `'off'` — Do not include the chart line object in the legend.
  - `'children'` — Include only children of the chart line object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## Parent/Child

### Parent — Parent of chart line

axes object | group object | transform object

Parent of chart line, specified as an axes, group, or transform object.

### Children — Children of chart line

empty GraphicsPlaceholder array

The chart line has no children. You cannot set this property.

### HandleVisibility — Visibility of object handle

'on' (default) | 'off' | 'callback'

Visibility of chart line object handle in the Children property of the parent, specified as one of these values:

- 'on' — The chart line object handle is always visible.
- 'off' — The chart line object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The chart line object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the chart line at the command-line, but allows callback functions to access it.

If the chart line object is not listed in the Children property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### ButtonDownFcn — Mouse-click callback

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the chart line. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The chart line object — You can access properties of the chart line object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

## **UIContextMenu — Context menu**

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the chart line. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

## **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the chart line when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the `SelectionHighlight` property also is set to `'on'`, then MATLAB displays selection handles around the chart line.
- `'off'` — Not selected.

### **SelectionHighlight — Display of selection handles when selected**

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the `Selected` property is set to `'on'`.
- `'off'` — Never display selection handles, even when the `Selected` property is set to `'on'`.

## **Callback Execution Control**

### **PickableParts — Ability to capture mouse clicks**

`'visible'` (default) | `'all'` | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The `Visible` property must be set to `'on'` and you must click a part of the chart line that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The `HitTest` property determines if the chart line responds to the click or if an ancestor does.
- `'all'` — Can capture mouse clicks regardless of visibility. The `Visible` property can be set to `'on'` or `'off'` and you can click a part of the chart line that has no color. The `HitTest` property determines if the chart line responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the chart line passes the click through it to the object below it in the current view of the figure window. The `HitTest` property has no effect.

### **HitTest — Response to captured mouse clicks**

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the `ButtonDownFcn` callback of the chart line. If you have defined the `UIContextMenu` property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the chart line that has a `HitTest` property set to 'on' and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the chart line object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the chart line is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
- If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.

- If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

**BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the chart line tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

**CreateFcn — Creation callback**

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle

- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the chart line. Setting the `CreateFcn` property on an existing chart line has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during chart line creation. MATLAB executes the callback after creating the chart line and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The chart line object — You can access properties of the chart line object from within the callback function. You also can access the chart line object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the chart line. MATLAB executes the callback before destroying the chart line so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The chart line object — You can access properties of the chart line object from within the callback function. You also can access the chart line object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **BeingDeleted — Deletion status of chart line**

'off' (default) | 'on'

This property is read only.

Deletion status of chart line, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the chart line begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the chart line no longer exists.

Check the value of the `BeingDeleted` property to verify that the chart line is not about to be deleted before querying or modifying it.

## lasterr

Last error message

---

**Note:** `lasterr` will be removed in a future version. You can obtain information about any error that has been generated by catching an `MException`. See “Capture Information About Exceptions” in the Programming Fundamentals documentation.

---

## Syntax

```
msgstr = lasterr
[msgstr, msgid] = lasterr
lasterr('new_msgstr')
lasterr('new_msgstr', 'new_msgid')
[msgstr, msgid] = lasterr('new_msgstr', 'new_msgid')
```

## Description

`msgstr = lasterr` returns the last error message generated by the MATLAB software.

`[msgstr, msgid] = lasterr` returns the last error in `msgstr` and its message identifier in `msgid`. If the error was not defined with an identifier, `lasterr` returns an empty string for `msgid`. See “Message Identifiers” in the MATLAB Programming Fundamentals documentation for more information on the `msgid` argument and how to use it.

`lasterr('new_msgstr')` sets the last error message to a new string, `new_msgstr`, so that subsequent invocations of `lasterr` return the new error message string. You can also set the last error to an empty string with `lasterr('')`.

`lasterr('new_msgstr', 'new_msgid')` sets the last error message and its identifier to new strings `new_msgstr` and `new_msgid`, respectively. Subsequent invocations of `lasterr` return the new error message and message identifier.

`[msgstr, msgid] = lasterr('new_msgstr', 'new_msgid')` returns the last error message and its identifier, also changing these values so that subsequent

invocations of `lasterr` return the message and identifier strings specified by `new_msgstr` and `new_msgid` respectively.

## Examples

### Example 1

Here is a function that examines the `lasterr` string and displays its own message based on the error that last occurred. This example deals with two cases, each of which is an error that can result from a matrix multiply:

```
function matrix_multiply(A, B)
try
 A * B
catch
 errmsg = lasterr;
 if(strfind(errmsg, 'Inner matrix dimensions'))
 disp('** Wrong dimensions for matrix multiply')
 else
 if(strfind(errmsg, 'not defined for variables of class'))
 disp('** Both arguments must be double matrices')
 end
 end
end
end
```

If you call this function with matrices that are incompatible for matrix multiplication (e.g., the column dimension of **A** is not equal to the row dimension of **B**), MATLAB catches the error and uses `lasterr` to determine its source:

```
A = [1 2 3; 6 7 2; 0 -1 5];
B = [9 5 6; 0 4 9];

matrix_multiply(A, B)
** Wrong dimensions for matrix multiply
```

### Example 2

Specify a message identifier and error message string with `error`:

```
error('MyToolbox:angleTooLarge', ...
 'The angle specified must be less than 90 degrees.');
```

In your error handling code, use `lasterr` to determine the message identifier and error message string for the failing operation:

```
[errmsg, msgid] = lasterr
errmsg =
 The angle specified must be less than 90 degrees.
msgid =
 MyToolbox:angleTooLarge
```

## **See Also**

error | lasterror | rethrow | warning | lastwarn

**Introduced before R2006a**

# lasterror

Last error message and related information

---

**Note:** `lasterror` will be removed in a future version. You can obtain information about any error that has been generated by catching an `MException`. See “Capture Information About Exceptions” in the Programming Fundamentals documentation.

---

## Syntax

```
s = lasterror
s = lasterror(err)
s = lasterror('reset')
```

## Description

`s = lasterror` returns a structure `s` containing information about the most recent error issued by the MATLAB software. The return structure contains the following fields:

Fieldname	Description
<code>message</code>	Character array containing the text of the error message.
<code>identifier</code>	Character array containing the message identifier of the error message. If the last error issued by MATLAB had no message identifier, then the <code>identifier</code> field is an empty character array.
<code>stack</code>	Structure providing information on the location of the error. The structure has fields <code>file</code> , <code>name</code> , and <code>line</code> , and is the same as the structure returned by the <code>dbstack</code> function. If <code>lasterror</code> returns no stack information, <code>stack</code> is a 0-by-1 structure having the same three fields.

---

**Note** The `lasterror` return structure might contain additional fields in future versions of MATLAB.

---

The fields of the structure returned in `stack` are

Fieldname	Description
<code>file</code>	Name of the file in which the function generating the error appears. This field is the empty string if there is no file.
<code>name</code>	Name of the function in which the error occurred. If this is the primary function in the file, and the function name differs from the file name, <code>name</code> is set to the file name.
<code>line</code>	Line number of the file at which the error occurred.

See “Message Identifiers” in the MATLAB Programming Fundamentals documentation for more information on the syntax and usage of message identifiers.

`s = lasterror(err)` sets the last error information to the error message and identifier specified in the structure `err`. Subsequent invocations of `lasterror` return this new error information. The optional return structure `s` contains information on the previous error.

`s = lasterror('reset')` sets the last error information to the default state. In this state, the `message` and `identifier` fields of the return structure are empty strings, and the `stack` field is a 0-by-1 structure.

## Examples

### Example 1

Save the following MATLAB code in a file called `average.m`:

```
function y = average(x)
% AVERAGE Mean of vector elements.
% AVERAGE(X), where X is a vector, is the mean of vector elements.
% Nonvector input results in an error.
check_inputs(x)
y = sum(x)/length(x); % The actual computation

function check_inputs(x)
[m,n] = size(x);
if ~(m == 1 || (n == 1) || (m == 1 && n == 1))
 error('AVG:NotAVector', 'Input must be a vector.')
end
```

Now run the function. Because this function requires vector input, passing a scalar value to it forces an error. The error occurs in subroutine `check_inputs`:

```
average(200)
Error using average>check_inputs (line 11)
Input must be a vector.
```

```
Error in average (line 5)
check_inputs(x)
```

Get the three fields from `lasterror`:

```
err = lasterror
err =
 message: [1x61 char]
 identifier: 'AVG:NotAVector'
 stack: [2x1 struct]
```

Display the text of the error message:

```
msg = err.message
msg =
 Error using average>check_inputs (line 11)
 Input must be a vector.
```

Display the fields containing the `stack` information. `err.stack` is a 2-by-1 structure because it provides information on the failing subroutine `check_inputs` and also the outer, primary function `average`:

```
st1 = err.stack(1,1)
st1 =
 file: 'd:\matlab_test\average.m'
 name: 'check_inputs'
 line: 11

st2 = err.stack(2,1)
st2 =
 file: 'd:\matlab_test\average.m'
 name: 'average'
 line: 5
```

---

**Note** As a rule, the name of your primary function should be the same as the name of the file that contains that function. If these names differ, MATLAB uses the file name in the `name` field of the `stack` structure.

---

## Example 2

`lasterror` is often used in conjunction with the `MException.rethrow` function in `try`, `catch` statements. For example,

```
try
 do_something
catch
 do_cleanup
 rethrow(lasterror)
end
```

## More About

### Tips

MathWorks is gradually transitioning MATLAB error handling to an object-oriented scheme that is based on the `MException` class. Although support for `lasterror` is expected to continue, using the static `MException.last` method of `MException` is preferable.

---

**Warning** `lasterror` and `MException.last` are not guaranteed to always return identical results. For example, `MException.last` updates its error status only on uncaught errors, where `lasterror` can update its error status on any error, whether it is caught or not.

---

**Introduced before R2006a**

# lastwarn

Last warning message

## Syntax

```
msgstr = lastwarn
[msgstr, msgid] = lastwarn
lastwarn('new_msgstr')
lastwarn('new_msgstr', 'new_msgid')
[msgstr, msgid] = lastwarn('new_msgstr', 'new_msgid')
```

## Description

`msgstr = lastwarn` returns the last warning message generated by MATLAB, regardless of its display state.

`[msgstr, msgid] = lastwarn` returns the last warning in `msgstr` and its message identifier in `msgid`. If the warning was not defined with an identifier, `lastwarn` returns an empty string for `msgid`.

`lastwarn('new_msgstr')` sets the last warning message to a new string, `new_msgstr`, so that subsequent invocations of `lastwarn` return the new warning message string. You can also set the last warning to an empty string with `lastwarn('')`.

`lastwarn('new_msgstr', 'new_msgid')` sets the last warning message and its identifier to new strings `new_msgstr` and `new_msgid`, respectively. Subsequent invocations of `lastwarn` return the new warning message and message identifier.

`[msgstr, msgid] = lastwarn('new_msgstr', 'new_msgid')` returns the last warning message and its identifier, also changing these values so that subsequent invocations of `lastwarn` return the message and identifier strings specified by `new_msgstr` and `new_msgid`, respectively.

## Examples

Write a short function that generates a warning message. At the start of the function, enable any warnings that have a message identifier called `TestEnv:InvalidInput`:

```
function myfun(p1)
warning on TestEnv:InvalidInput;

exceedMax = find(p1 > 5000);
if any(exceedMax)
 warning('TestEnv:InvalidInput', ...
 '%d values in the "%s" array exceed the maximum.', ...
 length(exceedMax), inputname(1))
end
```

Pass an invalid value to the function:

```
dataIn = magic(10) - 2;

myfun(dataIn)
Warning: 2 values in the "dataIn" array exceed the maximum.
> In myfun at 4
```

Use `lastwarn` to determine the message identifier and error message string for the operation:

```
[warnmsg, msgid] = lastwarn
warnmsg =
 2 values in the "dataIn" array exceed the maximum.
msgid =
 TestEnv:InvalidInput
```

## More About

### Tips

`lastwarn` does not return warnings that are reported during the parsing of MATLAB commands. (Warning messages that include the failing file name and line number are parse-time warnings.)

### See Also

`warning` | `error`

## lcm

Least common multiple

### Syntax

```
L = lcm(A,B)
```

### Description

`L = lcm(A,B)` returns the least common multiples of the elements of `A` and `B`.

### Examples

#### Least Common Multiples of Double Array and a Scalar

```
A = [5 17; 10 60];
B = 45;
L = lcm(A,B)
```

```
L =
```

```
 45 765
 90 180
```

#### Least Common Multiples of Unsigned Integers

```
A = uint16([255 511 15]);
B = uint16([15 127 1023]);
L = lcm(A,B)
```

```
L =
```

```
 255 64897 5115
```

### Input Arguments

#### **A, B** — Input values

scalars, vectors, or arrays of real, positive integer values

Input values, specified as scalars, vectors, or arrays of real, positive integer values. A and B can be any numeric type, and they can be of different types within certain limitations:

- If A or B is of type `single`, then the other can be of type `single` or `double`.
- If A or B belongs to an integer class, then the other must belong to the same class or it must be a `double` scalar value.

A and B must be the same size or one must be a scalar.

Example: `[20 3 13],[10 6 7]`

Example: `int16([100 30 200]),int16([20 15 9])`

Example: `int16([100 30 200]),20`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

## Output Arguments

### **L** — Least common multiple

real, positive integer values

Least common multiple, returned as an array of real positive integer values. L is the same size as A and B, and it has the same type as A and B. If A and B are of different types, then L is returned as the nondouble type.

## ldl

Block LDL' factorization for Hermitian indefinite matrices

### Syntax

```
L = ldl(A)
[L,D] = ldl(A)
[L,D,P] = ldl(A)
[L,D,p] = ldl(A, 'vector')
[U,D,P] = ldl(A, 'upper')
[U,D,p] = ldl(A, 'upper', 'vector')
[L,D,P,S] = ldl(A)
[L,D,P,S] = LDL(A, THRESH)
[U,D,p,S] = LDL(A, THRESH, 'upper', 'vector')
```

### Description

`L = ldl(A)` returns only the permuted lower triangular matrix  $L$  as in the two-output form. The permutation information is lost, as is the block diagonal factor  $D$ . By default, `ldl` references only the diagonal and lower triangle of  $A$ , and assumes that the upper triangle is the complex conjugate transpose of the lower triangle. Therefore `[L,D,P] = ldl(TRIL(A))` and `[L,D,P] = ldl(A)` both return the exact same factors. Note, this syntax is not valid for sparse  $A$ .

`[L,D] = ldl(A)` stores a block diagonal matrix  $D$  and a permuted lower triangular matrix in  $L$  such that  $A = L*D*L'$ . The block diagonal matrix  $D$  has 1-by-1 and 2-by-2 blocks on its diagonal. Note, this syntax is not valid for sparse  $A$ .

`[L,D,P] = ldl(A)` returns unit lower triangular matrix  $L$ , block diagonal  $D$ , and permutation matrix  $P$  such that  $P'*A*P = L*D*L'$ . This is equivalent to `[L,D,P] = ldl(A, 'matrix')`.

`[L,D,p] = ldl(A, 'vector')` returns the permutation information as a vector,  $p$ , instead of a matrix. The  $p$  output is a row vector such that  $A(p,p) = L*D*L'$ .

`[U,D,P] = ldl(A, 'upper')` references only the diagonal and upper triangle of  $A$  and assumes that the lower triangle is the complex conjugate transpose of the upper triangle.

This syntax returns a unit upper triangular matrix  $U$  such that  $P' * A * P = U' * D * U$  (assuming that  $A$  is Hermitian, and not just upper triangular). Similarly,  $[L, D, P] = \text{ldl}(A, 'lower')$  gives the default behavior.

$[U, D, p] = \text{ldl}(A, 'upper', 'vector')$  returns the permutation information as a vector,  $p$ , as does  $[L, D, p] = \text{ldl}(A, 'lower', 'vector')$ .  $A$  must be a full matrix.

$[L, D, P, S] = \text{ldl}(A)$  returns unit lower triangular matrix  $L$ , block diagonal  $D$ , permutation matrix  $P$ , and scaling matrix  $S$  such that  $P' * S * A * S * P = L * D * L'$ . This syntax is only available for real sparse matrices, and only the lower triangle of  $A$  is referenced. `ldl` uses MA57 for sparse real symmetric  $A$ .

$[L, D, P, S] = \text{LDL}(A, \text{THRESH})$  uses `THRESH` as the pivot tolerance in MA57. `THRESH` must be a double scalar lying in the interval  $[0, 0.5]$ . The default value for `THRESH` is `0.01`. Using smaller values of `THRESH` may give faster factorization times and fewer entries, but may also result in a less stable factorization. This syntax is available only for real sparse matrices.

$[U, D, p, S] = \text{LDL}(A, \text{THRESH}, 'upper', 'vector')$  sets the pivot tolerance and returns upper triangular  $U$  and permutation vector  $p$  as described above.

## Examples

These examples illustrate the use of the various forms of the `ldl` function, including the one-, two-, and three-output form, and the use of the `vector` and `upper` options. The topics covered are:

- “Example 1 — Two-Output Form of `ldl`” on page 1-4902
- “Example 2 — Three Output Form of `ldl`” on page 1-4902
- “Example 3 — The Structure of  $D$ ” on page 1-4903
- “Example 4 — Using the `'vector'` Option” on page 1-4903
- “Example 5 — Using the `'upper'` Option” on page 1-4903
- “Example 6 — `linsolve` and the Hermitian indefinite solver” on page 1-4904

Before running any of these examples, you will need to generate the following positive definite and indefinite Hermitian matrices:

```
A = full(delsq(numgrid('L', 10)));
```

```
B = gallery('uniformdata',10,0);
M = [eye(10) B; B' zeros(10)];
```

The structure of  $M$  here is very common in optimization and fluid-flow problems, and  $M$  is in fact indefinite. Note that the positive definite matrix  $A$  must be full, as `ldl` does not accept sparse arguments.

## Example 1 — Two-Output Form of `ldl`

The two-output form of `ldl` returns  $L$  and  $D$  such that  $A - (L^*D^*L')$  is small,  $L$  is permuted unit lower triangular, and  $D$  is a block 2-by-2 diagonal. Note also that, because  $A$  is positive definite, the diagonal of  $D$  is all positive:

```
[LA,DA] = ldl(A);
fprintf(1, ...
'The factorization error ||A - LA*DA*LA'|| is %g\n', ...
norm(A - LA*DA*LA'));
neginds = find(diag(DA) < 0)
```

Given  $a$  and  $b$ , solve  $Ax=b$  using  $LA$ ,  $DA$ :

```
bA = sum(A,2);
x = LA' \ (DA \ (LA \ bA));
fprintf(...
'The absolute error norm ||x - ones(size(bA))|| is %g\n', ...
norm(x - ones(size(bA))));
```

## Example 2 — Three Output Form of `ldl`

The three output form returns the permutation matrix as well, so that  $L$  is in fact unit lower triangular:

```
[Lm, Dm, Pm] = ldl(M);
fprintf(1, ...
'The error norm ||Pm'*M*Pm - Lm*Dm*Lm'|| is %g\n', ...
norm(Pm'*M*Pm - Lm*Dm*Lm'));
fprintf(1, ...
'The difference between Lm and tril(Lm) is %g\n', ...
norm(Lm - tril(Lm)));
```

Given  $b$ , solve  $Mx=b$  using  $Lm$ ,  $Dm$ , and  $Pm$ :

```
bM = sum(M,2);
```

```
x = Pm*(Lm\'(Dm\'(Lm\'(Pm'*bM))));
fprintf(...
'The absolute error norm ||x - ones(size(b))|| is %g\n', ...
norm(x - ones(size(bM))));
```

### Example 3 — The Structure of D

D is a block diagonal matrix with 1-by-1 blocks and 2-by-2 blocks. That makes it a special case of a tridiagonal matrix. When the input matrix is positive definite, D is almost always diagonal (depending on how definite the matrix is). When the matrix is indefinite however, D may be diagonal or it may express the block structure. For example, with A as above, DA is diagonal. But if you shift A just a bit, you end up with an indefinite matrix, and then you can compute a D that has the block structure.

```
figure; spy(DA); title('Structure of D from ldl(A)');
[Las, Das] = ldl(A - 4*eye(size(A)));
figure; spy(Das);
title('Structure of D from ldl(A - 4*eye(size(A)))');
```

### Example 4 — Using the 'vector' Option

Like the lu function, ldl accepts an argument that determines whether the function returns a permutation vector or permutation matrix. ldl returns the latter by default. When you select 'vector', the function executes faster and uses less memory. For this reason, specifying the 'vector' option is recommended. Another thing to note is that indexing is typically faster than multiplying for this kind of operation:

```
[Lm, Dm, pm] = ldl(M, 'vector');
fprintf(1, 'The error norm ||M(pm,pm) - Lm*Dm*Lm\'|| is %g\n', ...
norm(M(pm,pm) - Lm*Dm*Lm'));

% Solve a system with this kind of factorization.
clear x;
x(pm,:) = Lm\'(Dm\'(Lm\'(bM(pm,:))));
fprintf('The absolute error norm ||x - ones(size(b))|| is %g\n', ...
norm(x - ones(size(bM))));
```

### Example 5 — Using the 'upper' Option

Like the chol function, ldl accepts an argument that determines which triangle of the input matrix is referenced, and also whether ldl returns a lower (L) or upper (L') triangular factor. For dense matrices, there are no real savings with using the upper triangular version instead of the lower triangular version:

```
Ml = tril(M);
[Lm1, Dm1, Pm1] = ld1(Ml, 'lower'); % 'lower' is default behavior.
fprintf(1, ...
'The difference between Lm1 and Lm is %g\n', norm(Lm1 - Lm));
[Umu, Dmu, pmu] = ld1(triu(M), 'upper', 'vector');
fprintf(1, ...
'The difference between Umu and Lm'' is %g\n', norm(Umu - Lm'));

% Solve a system using this factorization.
clear x;
x(pmu,:) = Umu\Dmu\((Umu'\(bM(pmu,:))));
fprintf(...
'The absolute error norm ||x - ones(size(b))|| is %g\n', ...
norm(x - ones(size(bM))));
```

When specifying both the 'upper' and 'vector' options, 'upper' must precede 'vector' in the argument list.

## Example 6 — linsolve and the Hermitian indefinite solver

When using the `linsolve` function, you may experience better performance by exploiting the knowledge that a system has a symmetric matrix. The matrices used in the examples above are a bit small to see this so, for this example, generate a larger matrix. The matrix here is symmetric positive definite, and below we will see that with each bit of knowledge about the matrix, there is a corresponding speedup. That is, the symmetric solver is faster than the general solver while the symmetric positive definite solver is faster than the symmetric solver:

```
Abig = full(delsq(numgrid('L', 30)));
bbig = sum(Abig, 2);
LSopts.POSDEF = false;
LSopts.SYM = false;
tic; linsolve(Abig, bbig, LSopts); toc;
LSopts.SYM = true;
tic; linsolve(Abig, bbig, LSopts); toc;
LSopts.POSDEF = true;
tic; linsolve(Abig, bbig, LSopts); toc;
```

## More About

### Algorithms

`ld1` uses the MA57 routines in the Harwell Subroutine Library (HSL) for real sparse matrices.

## **ldivide, .\**

Left array division

### **Syntax**

```
x = B.\A
x = ldivide(B,A)
```

### **Description**

`x = B.\A` divides each element of `A` by the corresponding element of `B`.

- If `A` and `B` are arrays, then they must be the same size.
- If either `A` or `B` is a scalar, then MATLAB expands the scalar value into an appropriately sized array.

`x = ldivide(B,A)` is an alternative way to divide `A` by `B`, but is rarely used. It enables operator overloading for classes.

### **Examples**

#### **Divide Two Numeric Arrays**

```
A = ones(2, 3);
B = [1 2 3; 4 5 6];
x = B.\A
```

```
x =
```

```
 1.0000 0.5000 0.3333
 0.2500 0.2000 0.1667
```

#### **Divide a Scalar by a Numeric Array**

```
C = 2;
D = [1 2 3; 4 5 6];
x = D.\C
```

```
x =

 2.0000 1.0000 0.6667
 0.5000 0.4000 0.3333
```

## Input Arguments

### A — Numerator

scalar | vector | matrix | multidimensional array

Numerator, specified as a scalar, vector, matrix or multidimensional array. If **B** is an integer data type, then **A** must be the same integer type or a scalar double.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | duration

Complex Number Support: Yes

### B — Denominator

scalar | vector | matrix | multidimensional array

Denominator, specified as a scalar, vector, matrix or multidimensional array. If **A** is an integer data type, then **B** must be the same integer type or a scalar double.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | duration

Complex Number Support: Yes

## Output Arguments

### x — Solution

scalar | vector | matrix | multidimensional array

Solution, returned as a scalar, vector, matrix or multidimensional array. If either **A** or **B** are integer data types, then **x** is that same integer data type.

## More About

### Tips

- MATLAB does not support complex integer division.

- “Array vs. Matrix Operations”
- “Operator Precedence”

**See Also**

`mldivide` | `mrdivide` | `rdivide`

**Introduced before R2006a**

## le, <=

Determine less than or equal to

### Syntax

```
A <= B
le(A,B)
```

### Description

A <= B returns a logical array with elements set to logical 1 (true) where A is less than or equal to B; otherwise, it returns logical 0 (false).

The test compares only the real part of numeric arrays. `le` returns logical 0 (false) where A or B have NaN or undefined categorical elements.

`le(A,B)` is an alternate way to execute `A <= B`, but is rarely used. It enables operator overloading for classes.

### Examples

#### Test Vector Elements

Find which vector elements are less than or equal to a given value.

Create a numeric vector.

```
A = [1 12 18 7 9 11 2 15];
```

Test the vector for elements that are less than or equal to 12.

```
A <= 12
```

```
ans =
```

```
 1 1 0 1 1 1 1 0
```

The result is a vector with values of logical 1 (true) where the elements of A satisfy the expression.

Use the vector of logical values as an index to view the values in A that are less than or equal to 12.

```
A(A <= 12)
```

```
ans =
```

```
 1 12 7 9 11 2
```

The result is a subset of the elements in A.

## Replace Elements of Matrix

Create a matrix.

```
A = magic(4)
```

```
A =
```

```
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

Replace all values less than or equal to 9 with the value 10.

```
A(A <= 9) = 10
```

```
A =
```

```
 16 10 10 13
 10 11 10 10
 10 10 10 12
 10 14 15 10
```

The result is a new matrix whose smallest element is 10.

## Compare Values in Categorical Array

Create an ordinal categorical array.

```
A = categorical({'large' 'medium' 'small'; 'medium' ...
```

```
'small' 'large'}},{'small' 'medium' 'large'},'Ordinal',1)
```

```
A =
```

```
 large medium small
 medium small large
```

The array has three categories: 'small', 'medium', and 'large'.

Find all values less than or equal to the category 'medium'.

```
A <= 'medium'
```

```
ans =
```

```
 0 1 1
 1 1 0
```

A value of logical 1 (`true`) indicates a value less than or equal to the category 'medium'.

Compare the rows of A.

```
A(1,:) <= A(2,:)
```

```
ans =
```

```
 0 0 1
```

The function returns logical 1 (`true`) where the first row has a category value less than or equal to the second row.

### Test Complex Numbers

Create a vector of complex numbers.

```
A = [1+i 2-2i 1+3i 1-2i 5-i];
```

Find the values that are less than or equal to 3.

```
A(A <= 3)
```

```
ans =
```

```
1.0000 + 1.0000i 2.0000 - 2.0000i 1.0000 + 3.0000i 1.0000 - 2.0000i
```

`le` compares only the real part of the elements in A.

Use `abs` to find which elements are within a radius of 3 from the origin.

```
A(abs(A) <= 3)
```

```
ans =
```

```
1.0000 + 1.0000i 2.0000 - 2.0000i 1.0000 - 2.0000i
```

The result has one less element. The element `1.0000 + 3.0000i` is not within a radius of 3 from the origin.

## Test Duration Values

Create a `duration` array.

```
d = hours(21:25) + minutes(75)
```

```
d =
```

```
22.25 hrs 23.25 hrs 24.25 hrs 25.25 hrs 26.25 hrs
```

Test the array for elements that are less than or equal to one standard day.

```
d <= 1
```

```
ans =
```

```
1 1 0 0 0
```

## Input Arguments

### A — Left array

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Left array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

### **B — Right array**

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Right array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

## **More About**

### **Tips**

- Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the `<=` operator reflects. For more information, see “Avoiding Common Problems with Floating-Point Arithmetic”.
- “Ordinal Categorical Arrays”

```

## Description

`legend(s1,...,sN)` creates a legend in the current axes using the specified strings to label each set of data. The legend shows an icon of the associated object next to each string.

`legend(s1,...,sN,'Location',Value)` specifies the legend location. Set `Value` to a location string such as `'northoutside'`. For a list of strings, see the `Location` property.

`legend( ____, 'Orientation', Value)` specifies the legend orientation. This option can be used with either of the input argument combinations in the previous syntaxes. Set `Value` as either `'vertical'` or `'horizontal'`. For more information, see the `Orientation` property.

`legend(str)` creates a legend in the current axes and uses the entries in `str` to label each set of data. Specify `str` as either a cell array of strings or a matrix of strings.

`legend(str, Name, Value)` specifies legend properties. Use this syntax if you want to specify `Name, Value` pairs other than `Location` and `Orientation` when creating a legend. For example, `'FontSize', 12` sets the font size to 12 points.

`legend(entries, ____)` displays legend entries for the objects in the graph specified by the vector `entries`. Use this syntax if you want to display legend entries for only some of the objects in the graph. The option, `entries`, can precede any of the input argument combinations in the previous syntaxes.

`legend('boxon')` displays the box around the legend.

`legend('boxoff')` removes the box around the legend.

`legend('hide')` hides the legend associated with the current axes. Hiding the legend does not delete it.

`legend('show')` makes the legend in the current axes visible. If a legend does not exist, then MATLAB creates one using the default strings.

`legend('toggle')` toggles the legend visibility. If a legend does not exist, then MATLAB creates one using the default strings.

`legend('off')` deletes the legend from the current axes.

`legend(ax, ____)` uses the axes specified by `ax` instead of the current axes (`gca`). The option, `ax`, can precede any of the previous input argument combinations.

`h = legend( ____)` returns the legend object. Use `h` to query and set properties of the legend after it is created.

---

**Note:** Starting in R2014b, the `legend` function returns a legend object. In previous releases it returns an axes object.

---

`[h,icons,plots,s] = legend(____)` additionally returns the objects used to create the legend icons, the objects plotted in the graph, and an array of text strings.

## Examples

### Add Legend to Graph

Create a graph of sine and cosine. Add a legend to the graph indicating the two functions.

```
x = -pi:pi/20:pi;
y1 = sin(x);
y2 = cos(x);

figure
plot(x,y1,'-ro',x,y2,'-.b')
legend('sin(x)', 'cos(x)')
```

### Specify Legend Location

Create a graph of sine and cosine. Add a legend to the top left corner of the graph by specifying the 'Location' property as 'northwest'.

```
x = -pi:pi/20:pi;
y1 = sin(x);
y2 = cos(x);

figure
plot(x,y1,'-ro',x,y2,'-.b')
legend('sin(x)', 'cos(x)', 'Location', 'northwest')
```

### Add Horizontal Legend Above Graph

Create a graph of sine and cosine. Add a horizontal legend above the axes.

```
x = -pi:pi/20:pi;
y1 = sin(x);
y2 = cos(x);
```

```
figure
plot(x,y1,'-ro',x,y2,'-.b')
legend('sin(x)', 'cos(x)', 'Location', 'northoutside', 'Orientation', 'horizontal')
```

### Change Legend Font Size

Define the data, `x`, `ydata`, and `ycos`.

```
rng default % initialize random number generator
x = linspace(0,4*pi,100);
ydata = cos(x) + 0.5*randn(1,100);
ycos = cos(x);
```

Plot `ydata` and `ycos`. Add a legend to the graph using a small, bold font. To specify Name, Value pairs when creating a legend, you must specify the legend description strings as a cell array by using curly braces, `{}`.

```
figure
```

```
plot(x,ydata,'*',x,ycos)
legend({'Collected Data','y = cos(x)'}, 'FontSize',8,'FontWeight','bold')
```

### Display Subset of Lines in Legend

Plot five lines and return the chart line objects from the plot function.

```
x = linspace(0,3*pi);
y1 = sin(x);
p1 = plot(x,y1);

y2 = sin(x - pi/4);
hold on
p2 = plot(x,y2);
```

```
y3 = sin(x - pi/2);
p3 = plot(x,y3);

y4 = sin(x - 3*pi/4);
p4 = plot(x,y4);

y5 = sin(x - pi);
p5 = plot(x,y5);
hold off
```

Add a legend for the first and last lines, p1 and p5.

```
legend([p1,p5], 'sin(x)', 'sin(x-\pi)')
```

### Specify Legend Location and Remove Border

Create a plot of sine and cosine. Add a legend to the bottom left of the axes.

```
x = linspace(0,2*pi,50);
ysin = sin(x);
ycos = cos(x);
```

```
figure
stem(x,ysin)
hold all
plot(x,ycos)
hold off
```

```
legend('sin(x)', 'cos(x)', 'Location', 'southwest')
```

Remove the legend border.

```
legend('boxoff')
```

### Specify Custom Legend Size and Location

Define the data.

```
theta = linspace(0,2*pi,100);
x1 = sin(theta);
y1 = cos(theta);

x2 = 2*sin(theta);
y2 = 2*cos(theta);
```

Create a scatter plot of two circles. Use `axis equal` to set equal scaling along both the  $x$ -axis and  $y$ -axis.

```
figure
scatter(x1,y1)
hold on
scatter(x2,y2,'*g')
hold off
axis equal
```

Add a legend to the center of the graph using the `Position` property. To set the `Position` property when creating a legend, you must define the legend strings as a cell array by using curly braces, `{}`.

```
legend({'radius = 1','radius = 2'},'Position',[0.39,0.45,0.25,0.1])
```

### Delete Legend

Create a plot of sine and cosine and add a legend.

```
x = linspace(0,2*pi,50);
ysin = sin(x);
ycos = cos(x);
```

```
figure
plot(x,ysin,x,ycos)
legend('sine','cosine')
```

Delete the legend.

```
legend('off')
```

### Specify Axes for Legend

Create a figure with two subplots and return the two axes handles, `ax1` and `ax2`. Plot random data in each subplot.

```
rng default % initialize random number generator
y1 = rand(3);
y2 = rand(5);

figure
ax1 = subplot(2,1,1); % upper subplot
plot(y1)

ax2 = subplot(2,1,2); % lower subplot
```

```
plot(y2)
```

Add a legend to the upper subplot by passing its axes handle to `legend`.

```
legend(ax1, 'Line 1', 'Line 2', 'Line 3')
```

- “Exclude Objects from Graph Legend”
- “Specify Legend Descriptions During Line Creation”

## Input Arguments

**s1, ..., sN** — Description for each object

comma-separated list of strings

Description for each object, specified as a comma-separated list of strings.

MATLAB sets the `String` property of the legend to the specified strings. MATLAB also sets the `DisplayName` properties of the objects to the specified strings.

If you do not specify legend strings, then `legend` uses the `DisplayName` properties of the objects instead. If an object does not have a `DisplayName` property, or if you have not defined a value for this property, then `legend` uses a string of the form `'data1'`, `'data2'`, and so on.

Example: `'Sine Function'`, `'Cosine Function'`

## **str** — Description for each object

cell array of strings | matrix of strings

Description for each object, specified as a cell array of strings or a matrix of strings. If `str` is a matrix, then the `legend` function uses each row of the matrix to label a set of data.

MATLAB sets the `String` property of the legend to the specified strings. MATLAB also sets the `DisplayName` properties of the objects to the specified strings.

If you do not specify legend strings, then `legend` uses the `DisplayName` properties of the objects instead. If an object does not have a `DisplayName` property, or if you have not defined a value for this property, then `legend` uses a string of the form `'data1'`, `'data2'`, and so on.

Example: `{'Sine Function','Cosine Function'}`

## **entries** — List of graphics objects to include in legend

vector

List of graphics objects to include in the legend, specified as a vector. Specifying objects is useful if you do not want to add a description for every object in the graph.

These are the graphics objects that can be included in the legend:

- `Animated line` objects
- `Area` objects
- `Bar series` objects
- `Chart line` objects
- `Chart surface` objects
- `Contour` objects
- `Errorbar series` objects
- `Group` objects

- Histogram objects
- Patch objects
- Primitive line objects
- Primitive surface objects
- Quiver series objects
- Scatter series objects
- Stair objects
- Stem series objects
- Transform objects

### **ax — Axes object**

axes object

Axes object. If you do not specify an axes, then the `legend` function adds a legend to the current axes.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

The properties listed here are only a subset. For a complete list see Legend Properties.

Example: `'FontSize', 12, 'TextColor', 'blue'`

### **'Location' — Location with respect to axes**

supported location string

Location with respect to the axes, specified as one of the location strings listed in this table.

<b>Supported String</b>	<b>Resulting Location</b>
'north'	Inside top of axes
'south'	Inside bottom of axes
'east'	Inside right of axes
'west'	Inside left of axes

Supported String	Resulting Location
'northeast'	Inside top-right of axes (default for 2-D axes)
'northwest'	Inside top-left of axes
'southeast'	Inside bottom-right of axes
'southwest'	Inside bottom-left of axes
'northoutside'	Above the axes
'southoutside'	Below the axes
'eastoutside'	To the right of the axes
'westoutside'	To the left of the axes
'northeastoutside'	Outside top-right corner of the axes (default for 3-D axes)
'northwestoutside'	Outside top-left corner of the axes
'southeastoutside'	Outside bottom-right corner of the axes
'southwestoutside'	Outside bottom-left corner of the axes
'best'	Inside axes where least conflict with data in plot
'bestoutside'	To the right of the axes
'none'	Determined by <b>Position</b> property

To display the legend in a location that is not listed in the table, use the **Position** property to specify a custom location. If you set the **Position** property, then MATLAB automatically sets the **Location** property to 'none'.

Example: 'northoutside'

**'Orientation' — Orientation**

'vertical' (default) | 'horizontal'

Orientation, specified as one of these values:

- 'vertical' — Stacks the legend entries vertically. This is the default.
- 'horizontal' — Lists the legend entries side-by-side.

Example: 'horizontal'

**'Box' — Box outline**`'on' (default) | 'off'`

Box outline, specified as one of these values:

- `'on'` — Displays the box around the legend. This is the default.
- `'off'` — Removes the box around the legend.

Example: `'off'`

**'String' — Legend entry descriptions**`cell array of strings`

Legend entry descriptions, specified as a cell array of strings. If you specify strings as input to `legend`, then MATLAB sets the `String` property to the specified strings and uses these strings in the legend display. If you do not specify strings, then MATLAB uses the `DisplayName` properties of the objects, or a string of the form `'data1'`, `'data2'`, and so on. The `String` property reflects the entries in the legend.

Example: `{'Sine', 'Cosine', 'Tangent'}`

**'Interpreter' — Interpretation of text characters**`'tex' (default) | 'latex' | 'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup.
- `'latex'` — Interpret text strings using LaTeX markup.
- `'none'` — Display literal characters.

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers with the `Interpreter` property set to `'tex'`. Modifiers remain in effect until the end of the string. Superscripts and subscripts are an exception because they only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
<code>^{} </code>	Superscript	'text <sup>{superscript}</sup> '
<code>_{} </code>	Subscript	'text <sub>{subscript}</sub> '
<code>\bf</code>	Bold font	'\bf text'
<code>\it</code>	Italic font	'\it text'
<code>\sl</code>	Oblique font (usually the same as italic font)	'\sl text'
<code>\rm</code>	Normal font	'\rm text'
<code>\fontname{specifier}</code>	Font name — Set <code>specifier</code> as the name of a font family. You can use this in combination with other modifiers.	'\fontname{Courier} text'
<code>\fontsize{specifier}</code>	Font size — Set <code>specifier</code> as a numeric scalar value in point units to change the font size.	'\fontsize{15} text'
<code>\color{specifier}</code>	Font color — Set <code>specifier</code> as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue.	'\color{magenta} text'
<code>\color[rgb]{specifier}</code>	Custom font color — Set <code>specifier</code> as a three-element RGB triplet.	'\color[rgb]{0,0.5,0.5} text'

This table lists the supported special characters with the `Interpreter` property set to 'tex'.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
<code>\alpha</code>	α	<code>\upsilon</code>	υ	<code>\sim</code>	~
<code>\angle</code>	∠	<code>\phi</code>	Φ	<code>\leq</code>	≤
<code>\ast</code>	*	<code>\chi</code>	χ	<code>\infty</code>	∞

<code>\vee</code>	∨	<code>\langle</code>	⟨	<code>\copyright</code>	©

## LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at <http://www.latex-project.org/>.

### 'TextColor' — Text color

[0,0,0] or 'black' (default) | RGB triplet | supported color string

Text color, specified as an RGB triplet or a supported color string. The default color is black with an RGB triplet value of [0,0,0].

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]

Long Name	Short Name	RGB Triplet
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0,0,1]

Example: 'blue'

### 'FontSize' — Font size

9 (default) | scalar value greater than zero

Font size, specified as a scalar value greater than zero in point units. The default value is 9 points. If you change the axes font size, then MATLAB automatically sets the legend font size to 90% of the axes font size. If you manually set the legend font size, then changing the axes font size does not affect the legend.

Example: 12

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

## Output Arguments

### **h** — Legend object

legend object

Legend object. Use **h** to modify the legend after it has been created.

### **icons** — Objects used to create legend icons and descriptions

text, patch, and line objects

Objects used to create the legend icons and descriptions, returned as text, patch, and line object.

### **plots** — Objects plotted in graph

vector of objects

Objects plotted in the graph, returned as a vector of objects.

## **s** — Text strings used in legend

cell array

Text strings used in the legend, returned as a cell array.

## **More About**

### **Tips**

- An axes can have only one legend.
- To use legend keywords, such as 'Location' or 'off' as legend descriptions, you must pass the string in a cell array to `legend`. For example, `l = legend({'Location'})` displays a legend with the entry `Location`.
- To label more than 20 objects in the legend, you must specify a string for each object. Otherwise, `legend` depicts only the first 20 objects in the graph.
- `legend` associates strings with objects in the same order that the objects are listed in the axes `Children` property.

### **Properties**

Legend Properties

**Introduced before R2006a**

# Legend Properties

Control legend appearance and behavior

Legend properties control the appearance and behavior of a legend object. By changing property values, you can modify certain aspects of the legend. Use dot notation to refer to a particular object and property:

```
h = legend('show');
c = h.TextColor;
h.TextColor = 'red';
```

## Appearance

### TextColor — Text color

[0,0,0] or 'black' (default) | RGB triplet | supported color string

Text color, specified as an RGB triplet or a supported color string. The default color is black with an RGB triplet value of [0,0,0].

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0,0,1]

Example: 'blue'

**Color — Background color**

[1,1,1] or 'white' (default) | RGB triplet | supported color string

Background color, specified as an RGB triplet or a supported color string. The default color is white with an RGB triplet value of [1,1,1].

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0,0,1]

Example: 'b'

**Box — Box outline**

'on' (default) | 'off'

Box outline, specified as one of these values:

- 'on' — Displays the box around the legend. This is the default.
- 'off' — Removes the box around the legend.

Example: 'off'

**EdgeColor — Box outline color**

[0.15 0.15 0.15] (default) | RGB triplet | supported color string

Box outline color, specified as an RGB triplet or a supported color string. The default color is dark gray with an RGB triplet value of `[0.15,0.15,0.15]`.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: `[0,1,0]`

Example: `'g'`

### **LineWidth — Width of box outline**

0.5 (default) | positive value

Width of box outline, specified as a positive value in point units. One point equals 1/72 inches.

Example: 1.5

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **Location and Size**

### **Location — Location with respect to axes**

supported location string

Location with respect to the axes, specified as one of the location strings listed in this table.

Supported String	Resulting Location
'north'	Inside top of axes
'south'	Inside bottom of axes
'east'	Inside right of axes
'west'	Inside left of axes
'northeast'	Inside top-right of axes (default for 2-D axes)
'northwest'	Inside top-left of axes
'southeast'	Inside bottom-right of axes
'southwest'	Inside bottom-left of axes
'northoutside'	Above the axes
'southoutside'	Below the axes
'eastoutside'	To the right of the axes
'westoutside'	To the left of the axes
'northeastoutside'	Outside top-right corner of the axes (default for 3-D axes)
'northwestoutside'	Outside top-left corner of the axes
'southeastoutside'	Outside bottom-right corner of the axes
'southwestoutside'	Outside bottom-left corner of the axes
'best'	Inside axes where least conflict with data in plot
'bestoutside'	To the right of the axes
'none'	Determined by <b>Position</b> property

To display the legend in a location that is not listed in the table, use the **Position** property to specify a custom location. If you set the **Position** property, then MATLAB automatically sets the **Location** property to 'none'.

Example: 'northoutside'

**Orientation — Orientation**`'vertical'` (default) | `'horizontal'`

Orientation, specified as one of these values:

- `'vertical'` — Stacks the legend entries vertically. This is the default.
- `'horizontal'` — Lists the legend entries side-by-side.

Example: `'horizontal'`

**Position — Custom location and size**

four-element vector

Custom location and size, specified as a four-element vector of the form `[left, bottom, width, height]`. The first two values, `left` and `bottom`, specify the distance from the lower-left corner of the figure to the lower-left corner of the legend. The last two values, `width` and `height`, specify the dimensions of the legend. The `Units` property determines the position units.

If you specify the `Position` property, then MATLAB automatically changes the legend's `Location` property to `'none'`.

Example: `[0.1,0.1,0.3,0.7]`

**Units — Position units**`'normalized'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'points'` | `'pixels'`

Position units, specified as one of the values in this table.

Units	Description
<code>'normalized'</code> (default)	Normalized with respect to the container, which is usually the figure. The lower left corner of the figure maps to (0,0) and the upper right corner maps to (1,1).
<code>'inches'</code>	Inches.
<code>'centimeters'</code>	Centimeters.
<code>'characters'</code>	Based on the default system font character size.

Units	Description
	<ul style="list-style-type: none"> <li>• Character width = width of letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>
'points'	Points. One point equals 1/72 inch.
'pixels'	Pixels.  Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems: <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> On Linux systems, the size of a pixel is determined by your system resolution.

All units are measured from the lower-left corner of the container window.

This property affects the **Position** property. If you change the units, then it is good practice to return it to its default value after completing your computation to prevent affecting other functions that assume **Units** is the default value.

If you specify the **Position** and **Units** properties as **Name, Value** pairs when creating the legend, then the order of specification matters. If you want to define the position with particular units, then you must set the **Units** property before the **Position** property.

## Text

### String – Legend entry descriptions

cell array of strings

Legend entry descriptions, specified as a cell array of strings. If you specify strings as input to **legend**, then MATLAB sets the **String** property to the specified strings and uses these strings in the legend display. If you do not specify strings, then MATLAB uses the **DisplayName** properties of the objects, or a string of the form 'data1', 'data2', and so on. The **String** property reflects the entries in the legend.

Example: {'Sine', 'Cosine', 'Tangent'}

### Interpreter — Interpretation of text characters

'tex' (default) | 'latex' | 'none'

Interpretation of text characters, specified as one of these values:

- 'tex' — Interpret text strings using a subset of TeX markup.
- 'latex' — Interpret text strings using LaTeX markup.
- 'none' — Display literal characters.

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers with the **Interpreter** property set to 'tex'. Modifiers remain in effect until the end of the string. Superscripts and subscripts are an exception because they only modify the next character or the text within the curly braces {}.

Modifier	Description	Example of String
<code>^{ }</code>	Superscript	'text <sup>{superscript}</sup> '
<code>_{ }</code>	Subscript	'text <sub>{subscript}</sub> '
<code>\bf</code>	Bold font	'\bf text'
<code>\it</code>	Italic font	'\it text'
<code>\sl</code>	Oblique font (usually the same as italic font)	'\sl text'
<code>\rm</code>	Normal font	'\rm text'
<code>\fontname{specifier}</code>	Font name — Set <b>specifier</b> as the name of a font family. You can use this in combination with other modifiers.	'\fontname{Courier} text'

Modifier	Description	Example of String
<code>\fontsize{specifier}</code>	Font size — Set specifier as a numeric scalar value in point units to change the font size.	<code>'\fontsize{15} text'</code>
<code>\color{specifier}</code>	Font color — Set specifier as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue.	<code>'\color{magenta} text'</code>
<code>\color[rgb]{specifier}</code>	Custom font color — Set specifier as a three-element RGB triplet.	<code>'\color[rgb]{0,0.5,0.5} text'</code>

This table lists the supported special characters with the `Interpreter` property set to `'tex'`.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
<code>\alpha</code>	$\alpha$	<code>\upsilon</code>	$\upsilon$	<code>\sim</code>	$\sim$
<code>\angle</code>	$\angle$	<code>\phi</code>	$\Phi$	<code>\leq</code>	$\leq$
<code>\ast</code>	$*$	<code>\chi</code>	$\chi$	<code>\infty</code>	$\infty$
<code>\beta</code>	$\beta$	<code>\psi</code>	$\psi$	<code>\clubsuit</code>	$\clubsuit$
<code>\gamma</code>	$\gamma$	<code>\omega</code>	$\omega$	<code>\diamondsuit</code>	$\diamondsuit$
<code>\delta</code>	$\delta$	<code>\Gamma</code>	$\Gamma$	<code>\heartsuit</code>	$\heartsuit$
<code>\epsilon</code>	$\epsilon$	<code>\Delta</code>	$\Delta$	<code>\spadesuit</code>	$\spadesuit$
<code>\zeta</code>	$\zeta$	<code>\Theta</code>	$\Theta$	<code>\leftrightarrow</code>	$\leftrightarrow$
<code>\eta</code>	$\eta$	<code>\Lambda</code>	$\Lambda$	<code>\leftarrow</code>	$\leftarrow$
<code>\theta</code>	$\Theta$	<code>\Xi</code>	$\Xi$	<code>\Leftarrow</code>	$\Leftarrow$
<code>\vartheta</code>	$\vartheta$	<code>\Pi</code>	$\Pi$	<code>\uparrow</code>	$\uparrow$

<code>\rceil</code>	$\rceil$	<code>\rangle</code>	$\rangle$	<code>\mid</code>	$\mid$
<code>\vee</code>	$\vee$	<code>\langle</code>	$\langle$	<code>\copyright</code>	$\copyright$

## LaTeX Markup

To use LaTeX markup, set the **Interpreter** property to 'latex'. The displayed text uses the default LaTeX font style. The **FontName**, **FontWeight**, and **FontAngle** properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at <http://www.latex-project.org/>.

## Font Style

### FontAngle — Character slant

'normal' (default) | 'italic'

Character slant, specified as 'normal' or 'italic'. Not all fonts have both font styles. Therefore, the italic font might look the same as the normal font.

---

**Note:** The 'oblique' value has been removed. Use 'italic' instead.

---

### FontName — Font name

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. The 'FixedWidth' value relies on the root FixedWidthFontName property. Setting the root FixedWidthFontName property causes an immediate update of the display to use the new font.

Example: 'Cambria'

### FontSize — Font size

9 (default) | scalar value greater than zero

Font size, specified as a scalar value greater than zero in point units. The default value is 9 points. If you change the axes font size, then MATLAB automatically sets the legend font size to 90% of the axes font size. If you manually set the legend font size, then changing the axes font size does not affect the legend.

Example: 12

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**FontWeight — Thickness of text characters**`'normal'` (default) | `'bold'`

Thickness of the text characters, specified as one of these values:

- `'normal'` — Default weight as defined by the particular font
- `'bold'` — Thicker character outlines than normal

MATLAB uses the `FontWeight` property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight still can result in the normal font weight.

---

**Note:** The `'light'` and `'demi'` font weight values have been removed. Use `'normal'` instead.

---

**Visibility****Visible — State of visibility**`'on'` (default) | `'off'`

State of visibility, specified as one of these values:

- `'on'` — Display the legend.
- `'off'` — Hide the legend without deleting it. You still can access the properties of an invisible legend object.

**Identifiers****Type — Type of graphics object**`'legend'` (default)

This property is read only.

Type of graphics object, returned as `'legend'`. Use this property to find all objects of a given type within a plotting hierarchy.

**Tag — Tag to associate with legend**`'legend'` (default) | string

Tag to associate with the legend, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

Data Types: char

## **UserData** — Data to associate with legend

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the legend object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: 1:100

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | table | cell

## **Parent/Child**

### **Parent** — Parent of legend

figure object | uipanel object | uitab object

Parent of the legend, specified as a figure object, uipanel object, or a uitab object.

The legend must have the same parent as the associated axes. If you change the parent of the associated axes, then the legend automatically updates to use the same parent.

### **Children** — Children of legend

empty `GraphicsPlaceholder` array

The legend has no children. You cannot set this property.

### **HandleVisibility** — Visibility of object handle

'on' (default) | 'off' | 'callback'

Visibility of legend object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The legend object handle is always visible.
- 'off' — The legend object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The legend object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the legend at the command-line, but allows callback functions to access it.

If the legend object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### **ButtonDownFcn** — Callback that executes when you click the legend

@bdowncb (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the legend. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The legend object — You can access properties of the legend object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **UIContextMenu — Context menu**

`uicontextmenu` handle (default)

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the legend. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

### **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the legend when in plot edit mode, then MATLAB sets its `Selected` property to 'on'. If the `SelectionHighlight` property also is set to 'on', then MATLAB displays selection handles around the legend.
- 'off' — Not selected.

### **SelectionHighlight — Display of selection handles when selected**

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the `Selected` property is set to 'on'.
- 'off' — Never display selection handles, even when the `Selected` property is set to 'on'.

## Callback Execution Control

### **PickableParts** — Ability to capture mouse clicks

'visible' (default) | 'none'

Ability to capture mouse clicks, specified as one of these values:

- 'visible' — Can capture mouse clicks when visible. The `Visible` property must be set to 'on' and you must click a part of the legend that has a defined color. You cannot click a part that has an associated color property set to 'none'. The `HitTest` property determines if the legend responds to the click or if an ancestor does.
- 'none' — Cannot capture mouse clicks. Clicking the legend passes the click to the object below it in the current view of the figure window. The `HitTest` property of the legend has no effect.

### **HitTest** — Response to captured mouse clicks

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the `ButtonDownFcn` callback of the legend. If you have defined the `UIContextMenu` property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the legend that has a `HitTest` property set to 'on' and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the legend object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **Interruptible** — Callback interruption

'off' (default) | 'on'

Callback interruption, specified as 'off' or 'on'. The `Interruptible` property determines if a running callback can be interrupted.

If the `ButtonDownFcn` callback of the legend is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- 'off' — The running callback cannot be interrupted. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.
- 'on' — The running callback can be interrupted. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

Example: 'off'

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The **Interruptible** property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the **BusyAction** property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the **ButtonDownFcn** callback of the legend tries to interrupt a running callback that cannot be interrupted, then the **BusyAction** property determines if it is discarded or put in the queue. Specify the **BusyAction** property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the legend. Setting the **CreateFcn** property on an existing legend has no effect. You must define a default value for this property, or define this property using a **Name, Value** pair during legend creation. MATLAB executes the callback after creating the legend and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The legend object — You can access properties of the legend object from within the callback function. You also can access the legend object through the **CallbackObject** property of the root, which can be queried using the **gcbo** function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the legend. MATLAB executes the callback before destroying the legend so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The legend object — You can access properties of the legend object from within the callback function. You also can access the legend object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **BeingDeleted — Deletion status of legend**

'off' (default) | 'on'

This property is read only.

Deletion status of legend, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the legend begins execution (see the

DeleteFcn property). The `BeingDeleted` property remains set to 'on' until the legend no longer exists.

Check the value of the `BeingDeleted` property to verify that the legend is not about to be deleted before querying or modifying it.

# legendre

Associated Legendre functions

## Syntax

```
P = legendre(n,X)
S = legendre(n,X,'sch')
N = legendre(n,X,'norm')
```

## Description

`P = legendre(n,X)` computes the associated Legendre functions of degree  $n$  and order  $m = 0, 1, \dots, n$ , evaluated for each element of  $X$ . Argument  $n$  must be a scalar integer, and  $X$  must contain real values in the domain  $-1 \leq x \leq 1$ .

If  $X$  is a vector, then  $P$  is an  $(n+1)$ -by- $q$  matrix, where  $q = \text{length}(X)$ . Each element  $P(m+1, i)$  corresponds to the associated Legendre function of degree  $n$  and order  $m$  evaluated at  $X(i)$ .

In general, the returned array  $P$  has one more dimension than  $X$ , and each element  $P(m+1, i, j, k, \dots)$  contains the associated Legendre function of degree  $n$  and order  $m$  evaluated at  $X(i, j, k, \dots)$ . Note that the first row of  $P$  is the Legendre polynomial evaluated at  $X$ , i.e., the case where  $m = 0$ .

`S = legendre(n,X,'sch')` computes the “Schmidt Seminormalized Associated Legendre Functions” on page 1-4962.

`N = legendre(n,X,'norm')` computes the “Fully Normalized Associated Legendre Functions” on page 1-4962.

## Examples

### Example 1

The statement `legendre(2,0:0.1:0.2)` returns the matrix

	<b>x = 0</b>	<b>x = 0.1</b>	<b>x = 0.2</b>
m = 0	-0.5000	-0.4850	-0.4400
m = 1	0	-0.2985	-0.5879
m = 2	3.0000	2.9700	2.8800

## Example 2

Given,

```
X = rand(2,4,5);
n = 2;
P = legendre(n,X)
```

then

```
size(P)
ans =
 3 2 4 5
```

and

```
P(:,1,2,3)
ans =
 -0.2475
 -1.1225
 2.4950
```

is the same as

```
legendre(n,X(1,2,3))
ans =
 -0.2475
 -1.1225
 2.49501
```

## More About

### Associated Legendre Functions

The Legendre functions are defined by

$$P_n^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_n(x),$$

where

$$P_n(x)$$

is the Legendre polynomial of degree  $n$ :

$$P_n(x) = \frac{1}{2^n n!} \left[ \frac{d^n}{dx^n} (x^2 - 1)^n \right]$$

### Schmidt Seminormalized Associated Legendre Functions

The Schmidt seminormalized associated Legendre functions are related to the nonnormalized associated Legendre functions  $P_n^m(x)$  by

$$P_n(x) \text{ for } m = 0,$$

$$S_n^m(x) = (-1)^m \sqrt{\frac{2(n-m)!}{(n+m)!}} P_n^m(x) \text{ for } m > 0.$$

### Fully Normalized Associated Legendre Functions

The fully normalized associated Legendre functions are normalized such that

$$\int_{-1}^1 \left( N_n^m(x) \right)^2 dx = 1$$

and are related to the unnormalized associated Legendre functions  $P_n^m(x)$  by

$$N_n^m = (-1)^m \sqrt{\frac{(n + \frac{1}{2})(n-m)!}{2(n+m)!}} P_n^m(x)$$

## Algorithms

legendre uses a three-term backward recursion relationship in  $m$ . This recursion is on a version of the Schmidt seminormalized associated Legendre functions  $Q_n^m(x)$ , which are complex spherical harmonics. These functions are related to the standard Abramowitz and Stegun [1] functions  $P_n^m(x)$  by

$$P_n^m(x) = \sqrt{\frac{(n+m)!}{(n-m)!}} Q_n^m(x)$$

They are related to the Schmidt form given previously by

$$\begin{aligned} m = 0: & \quad S_n^m(x) = Q_n^0(x) \\ m > 0: & \quad S_n^m(x) = (-1)^m \sqrt{2} Q_n^m(x) \end{aligned}$$

# length

Length of largest array dimension

## Syntax

```
L = length(X)
```

## Description

`L = length(X)` returns the length of the largest array dimension in `X`. For vectors, the length is simply the number of elements. For arrays with more dimensions, the length is `max(size(X))`. The length of an empty array is zero.

## Examples

### Number of Vector Elements

Find the length of a uniformly spaced vector in the interval `[5,10]`.

```
v = 5:10
```

```
v =
```

```
 5 6 7 8 9 10
```

```
L = length(v)
```

```
L =
```

```
 6
```

### Length of Rectangular Matrix

Find the length of a 3-by-7 matrix of zeros.

```
X = zeros(3,7);
```

```
L = length(X)
```

```
L =
 7
```

### Length of Structure Fields

Create a structure with fields for `Day` and `Month`. Use the `structfun` function to apply `length` to each field.

```
S = struct('Day',[1 13 14 26], 'Month',{'Jan','Feb', 'Mar'})
```

```
S =
```

```
 Day: [1 13 14 26]
 Month: {'Jan' 'Feb' 'Mar'}
```

```
L = structfun(@(field) length(field),S)
```

```
L =
```

```
 4
 3
```

## Input Arguments

### X — Input array

numeric array | character array | logical array | structure | cell array | categorical array | datetime array | duration array | calendarDuration array

Input array, specified as a numeric array, character array, logical array, structure, cell array, categorical array, datetime array, duration array, or calendarDuration array.

`length` does not operate on tables. To examine the dimensions of a table, use the `height`, `width`, or `size` functions.

Complex Number Support: Yes

### See Also

`ndims` | `numel` | `size`

Introduced before R2006a

## length

**Class:** `containers.Map`

**Package:** `containers`

Length of `containers.Map` object

## Syntax

```
mapLength = length(mapObj)
```

## Description

`mapLength = length(mapObj)` returns the number of key-value pairs in `mapObj`.

## Input Arguments

**mapObj**

Object of class `containers.Map`.

## Output Arguments

**mapLength**

Scalar numeric value that indicates the number of key-value pairs in `mapObj`. This number is equivalent to `size(mapObj, 1)` and to `mapObj.Count`.

## Examples

### Determine the Length of a Map

Create a map, and determine the number of key-value pairs:

```
myKeys = {'a', 'b', 'c'};
myValues = [1,2,3];
mapObj = containers.Map(myKeys,myValues);
```

```
mapLength = length(mapObj)
```

This code returns

```
mapLength =
 3
```

## See Also

isKey | keys | values | containers.Map | size

## **length (serial)**

Length of serial port object array

### **Syntax**

`length(obj)`

### **Description**

`length(obj)` returns the length of the serial port object, `obj`. It is equivalent to the command `max(size(obj))`.

### **See Also**

`size`

**Introduced before R2006a**

## length (tscollection)

Length of time vector

### Syntax

```
length(tsc)
```

### Description

`length(tsc)` returns an integer that represents the length of the time vector for the `tscollection` object `tsc`.

### See Also

```
tscollection | isempty (tscollection) | size (tscollection)
```

**Introduced before R2006a**

## libfunctions

Return information on functions in shared library

### Syntax

```
libfunctions libname
```

```
m = libfunctions(libname)
m = libfunctions(libname, '-full')
```

### Description

`libfunctions libname` displays names of functions defined in library, `libname`. If you called `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

`m = libfunctions(libname)` returns names of functions in cell array `m`.

`m = libfunctions(libname, '-full')` returns function signatures.

### Examples

#### Display Functions in `shrlibsampl` Library

Add path to `examples` folder.

```
addpath(fullfile(matlabroot, 'extern', 'examples', 'shrlib'))
```

Display functions in library.

```
if not(libisloaded('shrlibsampl'))
 loadlibrary('shrlibsampl')
end
libfunctions('shrlibsampl')
```

Functions in library shrlibsample:

addDoubleRef	exportedDoubleValue	printExportedDoubleValue
addMixedTypes	getListOfStrings	readEnum
addStructByRef	multDoubleArray	stringToUpper
addStructFields	multDoubleRef	
allocateStruct	multiplyShort	
deallocateStruct	print2darray	

Clean up.

```
unloadlibrary shrlibsample
```

## Input Arguments

**libname** — Name of shared library

string

Name of shared library, specified as a string. Do not include the path or file extension in libname.

If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

Data Types: char

## Output Arguments

**m** — Function names

cell array

Functions names, returned as a cell array.

## Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

**See Also**

`calllib` | `libfunctionsview` | `loadlibrary`

**Introduced before R2006a**

# libfunctionsview

Display shared library function signatures in window

## Syntax

```
libfunctionsview libname
```

## Description

`libfunctionsview libname` displays information about functions in library, `libname`, in a new window.

## Input Arguments

### **libname** — Name of shared library

string

Name of shared library, specified as a string. Do not include the path or file extension in `libname`.

If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

Data Types: char

## Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

## Examples

### Display Function Signatures for Library `libmx`

```
if not(libisloaded('libmx'))
```

```
hfile = fullfile(matlabroot, 'extern', 'include', 'matrix.h');
loadlibrary('libmx', hfile)
end
libfunctionsview libmx
```

MATLAB creates a new window displaying function signatures.

## See Also

[libfunctions](#) | [calllib](#)

**Introduced before R2006a**

# libisloaded

Determine if shared library is loaded

## Syntax

```
tf = libisloaded(libname)
```

## Description

`tf = libisloaded(libname)` returns logical 1 (`true`) if the shared library, `libname`, is loaded. Otherwise, it returns logical 0 (`false`).

## Examples

### Load Functions in Library

Load example library, `shrlibsampl`, if it is not already loaded.

```
if ~libisloaded('shrlibsampl')
 loadlibrary('shrlibsampl')
end
```

## Input Arguments

### **libname** — Name of shared library

string

Name of shared library, specified as a string. Do not include the path or file extension in `libname`.

If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

Data Types: char

**See Also**

loadlibrary | unloadlibrary

**Introduced before R2006a**

# libpointer

Pointer object for use with shared library

## Syntax

```
p = libpointer
p = libpointer(DataType)
p = libpointer(DataType,Value)
```

## Description

`p = libpointer` creates NULL pointer `p` of type `voidPtr`.

`p = libpointer(DataType)` creates NULL pointer of specified `DataType`.

`p = libpointer(DataType,Value)` creates pointer initialized to a copy of `Value`.

## Examples

### Create NULL Pointer for string Argument

```
p = libpointer('string');
```

- “Multilevel Pointers”

## Input Arguments

### **DataType** — Type of pointer

string

Type of pointer, specified as a string, of any MATLAB numeric type, structure defined in the library, or enumeration defined in the library. For a list of valid MATLAB numeric types, refer to these tables in “C and MATLAB Equivalent Types”.

- MATLAB Primitive Types

- MATLAB Extended Types

Example: 'int16Ptr'

Data Types: char

### **Value — Value for pointer object**

any valid value

Value, specified as any valid value for given type.

## **Limitations**

- Use with libraries that are loaded using the `loadlibrary` function.

## **More About**

### **Tips**

- This is an advanced feature for experienced C programmers. MATLAB automatically converts data passed to and from external library functions to the data type expected by the external function. Use a `lib.pointer` object instead of automatic conversion in the following situations.
  - You want to modify the data in the input arguments.
  - You are passing large amounts of data, and you want to control when MATLAB makes copies of the data.
  - The library stores and uses the pointer for a period of time so you want the MATLAB function to control the lifetime of the `lib.pointer` object.
- “Pointer Arguments”

### **See Also**

`lib.pointer` | `calllib` | `libstruct`

**Introduced before R2006a**

# lib.pointer class

**Package:** lib

Pointer object compatible with C pointer

## Description

MATLAB automatically converts arguments that are passed by reference to a function in an external library. Use a pointer object instead of automatic conversion in the following situations.

- The function modifies data in an input argument.
- You are passing large amounts of data, and you want to control when MATLAB makes copies of the data.
- The library stores and uses the pointer for a period of time so you want the MATLAB function to control the lifetime of the `lib.pointer` object.

## Construction

To create a `lib.pointer` object, use the MATLAB `libpointer` function.

A library function can return a `lib.pointer` object. Use the `setdatatype` method to manually convert the argument to use in MATLAB.

## Properties

### Data Type

Type of pointer, specified as a string, of any MATLAB numeric type, structure defined in the library, or enumeration defined in the library. For a list of valid MATLAB numeric types, refer to these tables in “C and MATLAB Equivalent Types”.

- MATLAB Primitive Types
- MATLAB Extended Types

## Value

Value, specified as any valid value for given type.

## Methods

<code>disp</code>	Display <code>lib.pointer</code> type
<code>isNull</code>	Points to <code>NULL</code> pointer
<code>plus</code>	+ (plus) operator for pointer arithmetic
<code>reshape</code>	Reshape <code>lib.pointer</code> array
<code>setdatatype</code>	Initialize type and size of <code>lib.pointer</code> object

## Definitions

A passed-by-reference argument in the function signature has type names ending with `Ptr` or `PtrPtr`.

## Examples

### Create Pointer

Create a pointer, `pv`, of type `int16`, initialized to 485.

```
pv = libpointer('int16Ptr',485);
```

Display the properties of `pv`.

```
get(pv)
```

```
Value: 485
DataType: 'int16Ptr'
```

### See Also

`libpointer`

## **More About**

- “Pointer Arguments”

**Introduced before R2006a**

## disp

**Class:** lib.pointer

**Package:** lib

Display lib.pointer type

## Syntax

```
disp(h)
```

## Description

disp(h) displays type for lib.pointer object, h.

## Input Arguments

**h** — lib.pointer object.  
handle

lib.pointer object, specified as a handle.

## Examples

### Display lib.pointer Type

Create a double pointer set to 15.

```
xp = libpointer('doublePtr',15);
```

Display pointer data type.

```
disp(xp)
```

```
libpointer
```

# isNull

**Class:** lib.pointer

**Package:** lib

Points to NULL pointer

## Syntax

```
tf = isNull(h)
```

## Description

`tf = isNull(h)` returns true if `h` is a `lib.pointer` object.

## Input Arguments

**h** — **lib.pointer** object.  
handle

lib.pointer object, specified as a handle.

## Examples

### Create Null lib.pointer Object

```
nullp = libpointer('doublePtr', []);
isNull(nullp)
```

## plus

**Class:** lib.pointer

**Package:** lib

+ (plus) operator for pointer arithmetic

## Syntax

```
hout = plus(h,offset)
```

```
hout = h + offset
```

## Description

`hout = plus(h,offset)` returns pointer `hout`. Pointer `hout` is valid only as long as the original pointer, `h`, exists.

`hout = h + offset` is an alternative syntax.

## Input Arguments

**h** — **lib.pointer object.**

handle

lib.pointer object, specified as a handle.

**offset** — **Scalar increment**

uint64

Scalar increment, specified as `uint64`, from `h`.

## Related Examples

- “Iterate Through an Array”

# reshape

**Class:** lib.pointer

**Package:** lib

Reshape lib.pointer array

## Syntax

reshape(h, xdim, ydim)

## Description

reshape(h, xdim, ydim) creates an xdim-by-ydim matrix from lib.pointer object h.

## Input Arguments

**h** — **lib.pointer object.**  
handle

lib.pointer object, specified as a handle.

**xdim** — **Size of x dimension**  
double

Size of x dimension, specified as double.

**ydim** — **Size of y dimension**  
double

Size of y dimension, specified as double.

## setdatatype

**Class:** lib.pointer

**Package:** lib

Initialize type and size of lib.pointer object

### Syntax

```
setdatatype(h,type,size)
```

### Description

setdatatype(h,type,size) sets data type, type, of size, to lib.pointer, h.

### Input Arguments

**h** — **lib.pointer** object.

handle

lib.pointer object, specified as a handle.

**type** — **Data type**

string

Data type, specified as a string.

**size** — **Size**

double

Size, specified as double.

### Examples

#### Set Size and Type of lib.pointer Output Variable

Load the shrllibsample library.

```
if ~libisloaded('shrlibsample')
 addpath(fullfile(matlabroot,'extern','examples','shrlib'))
 loadlibrary('shrlibsample')
end
```

The `multDoubleRef` function takes a scalar value specified as `doubleptr`. Create variable `xp` as a `lib.pointer` object, and call the function.

```
xp = libpointer('doublePtr',99);
[xobj,xval] = calllib('shrlibsample','multDoubleRef',xp);
```

To use the variable `xobj`, set its size and data type.

```
setdatatype(xobj,'doublePtr',1,1)
xobj.Value
```

```
ans =
```

```
495
```

## libstruct

Convert MATLAB structure to C-style structure for use with shared library

### Syntax

```
S = libstruct(structtype)
S = libstruct(structtype,mlstruct)
```

### Description

`S = libstruct(structtype)` creates NULL pointer to MATLAB libstruct object S.

`S = libstruct(structtype,mlstruct)` creates pointer initialized to mlstruct.

### Examples

#### Call Function with `c_struct` Input Argument

Call the `addStructFields` function by creating a variable of type `c_struct`.

Load the `shrlibsample` library in the `matlabroot\extern\examples\shrlib` folder, which contains the `c_struct` type.

```
if ~libisloaded('shrlibsample')
 addpath(fullfile(matlabroot,'extern','examples','shrlib'))
 loadlibrary('shrlibsample')
end
```

Display function signatures for `shrlibsample` and search the list for the `addStructFields` entry.

```
libfunctionsview shrlibsample

double addStructFields(c_struct)
```

The input argument is a pointer to a `c_struct` data type.

Create a MATLAB structure, `sm`.

```
sm.p1 = 476; sm.p2 = -299; sm.p3 = 1000;
```

Construct a `libstruct` object `sc` from the `c_struct` type.

```
sc = libstruct('c_struct',sm)
```

The fields of `sc` contain the values of the MATLAB structure, `sm`.

Call the `addStructFields` function.

```
calllib('shrlibsample', 'addStructFields', sc)
```

```
ans =
 1177
```

To clean up, first clear the `libstruct` object, and then unload the library.

```
clear sc
unloadlibrary shrlibsample
```

- “Shared Library shrlibsample”

## Input Arguments

### **structtype** — C structure

structure

C structure defined in shared library.

### **m1struct** — MATLAB structure

structure

MATLAB structure used to initialize the fields in `S`.

Data Types: `struct`

## Output Arguments

### **S** — Pointer

MATLAB `libstruct` object

Pointer, returned as MATLAB `libstruct` object.

## Limitations

- Use with libraries that are loaded using the `loadlibrary` function.
- You can only use the `libstruct` function on scalar structures.
- When converting a MATLAB structure to a `libstruct` object, the structure must adhere to the requirements listed in “Structure Argument Requirements”.

## More About

### Tips

- If a function in the shared library has a structure argument, use `libstruct` to create the argument. The `libstruct` function creates a C-style structure that you pass to functions in the library. You handle this structure in MATLAB as you would a true MATLAB structure.
- “Structure Arguments”

**Introduced before R2006a**

# license

Get license number or perform licensing task

## Syntax

```
license
license('inuse')

S = license('inuse')
S = license('inuse',feature)

status = license('test',feature)
license('test',feature,toggle)

[status,errmsg] = license('checkout',feature)
```

## Description

`license` returns the license number for this MATLAB product. The return value also can be `'demo'` for a demonstration version of MATLAB, `'student'`, for a student version of MATLAB, or `'unknown'`, if the license number cannot be determined.

`license('inuse')` displays a list of licenses checked out in the current MATLAB session. The product list is alphabetical by license feature name. These names are the same as the valid values for the `feature` input.

`S = license('inuse')` returns an array of structures indicating checked-out licenses and the user name of each person who has a license checked out.

`S = license('inuse',feature)` checks if the product specified by `feature` is checked out in the current MATLAB session. If the product is checked out, then `license` returns the product name and the user name of the person who has it checked out. Otherwise, the fields of `S` are empty.

`status = license('test',feature)` tests if a license exists for the product specified by `feature`.

`license('test',feature,toggle)` enables or disables testing of the product specified by `feature`, depending on the value of `toggle`.

`[status,errmsg] = license('checkout',feature)` checks out a license for the specified product. If you specify the optional second output argument, `errmsg`, then `license` returns the text of any error message encountered if the checkout is unsuccessful.

## Examples

### Display Licenses in Use

Display a list of licenses currently being used.

```
license('inuse')
```

```
image_toolbox
map_toolbox
matlab
```

`license` displays a list of products in alphabetical order by the license feature name.

### Get Licenses in Use and User Names

Get a list of licenses in use with information about each user.

```
S = license('inuse');
```

`license` returns a structure array.

View the first element of `S`.

```
S(1)
```

```
ans =
```

```
 feature: 'image_toolbox'
 user: 'juser'
```

### Determine If License Is in Use

Determine if the license for MATLAB is in use.

```
S = license('inuse','MATLAB')

S =

 feature: 'matlab'
 user: 'jsmith'
```

If the license is in use, then **S** is a structure array with nonempty fields.

### Determine If License Exists

Determine if a license exists for Mapping Toolbox™.

```
status = license('test','map_toolbox')

status =

 1
```

`license` returns 1 if a license exists.

### Check Out License

Check out a license for Control System Toolbox.

```
[status,errmsg] = license('checkout','control_toolbox')

status =

 1

errmsg =

 ''
```

The `status` output is 1 and the `errmsg` output is empty if the checkout is successful.

## Input Arguments

**feature** — License feature name  
string

License feature name, specified as a string. The INCREMENT lines in a license file indicate the valid strings. To locate your license file, see [Where are the license files for MATLAB located?](#)

As an example, this table lists the `feature` value for a few commonly used products.

<b>feature Value</b>	<b>MathWorks Product</b>
'MATLAB'	MATLAB
'SIMULINK'	Simulink
'Control_Toolbox'	Control System Toolbox™
'Curve_Fitting_Toolbox'	Curve Fitting Toolbox™
'Signal_Blocks'	DSP System Toolbox™
'Image_Toolbox'	Image Processing Toolbox
'Optimization_Toolbox'	Optimization Toolbox™
'Distrib_Computing_Toolbox'	Parallel Computing Toolbox
'Signal_Toolbox'	Signal Processing Toolbox
'Stateflow'	Stateflow®
'Statistics_Toolbox'	Statistics and Machine Learning Toolbox
'Symbolic_Toolbox'	Symbolic Math Toolbox™

Values of `feature` are not case-sensitive.

**toggle — Ability to test product license**

'enable' | 'disable'

Ability to test the existence of a product license, specified as either 'enable' or 'disable'.

- If `toggle` is 'enable', then the syntax, `license('test',feature)` returns 1 when the product license exists and 0 when the product license does not exist.
- If `toggle` is 'disable', then the syntax, `license('test',feature)` always returns 0 (product license does not exist) for the specified product.

---

**Note** Disabling a test for a particular product can affect other tests for the existence of the license, not just tests performed by the `license` command.

---

## Output Arguments

### **S** — Checked out products

array of structures

Checked out products, returned as an array of structures, where each structure represents a checked-out license. The structures contain two fields:

- **feature** — license feature name
- **user** — user name of the person who has the license checked out

If the fields are empty, then the product is not currently checked out.

### **status** — Test or checkout status

1 | 0

Test or checkout status, returned as 1 or 0.

- When testing for the existence of a license, 1 indicates that the license exists, and 0 indicates that the license does not exist.

The existence of a license does not necessarily mean that the license can be checked out or that the product is installed. **status** is 1 even if the license has expired or if a system administrator has excluded you from using the product.

- When checking out a license, 1 indicates that the checkout is successful, and 0 indicates that the `license` function could not check out a license.

### **errmsg** — Error message

string

Error message for unsuccessful license checkout, returned as a string. If the checkout is successful, then **errmsg** is empty.

# light

Create light object

## Syntax

```
light('PropertyName',propertyvalue,...)
handle = light(...)
```

## Properties

For a list of properties, see [Light Properties](#).

## Description

`light` creates a light object in the current axes. Lights affect only patch and surface objects.

`light('PropertyName',propertyvalue,...)` creates a light object using the specified values for the named properties. For a description of the properties, see [Light Properties](#). The MATLAB software parents the light to the current axes unless you specify another axes with the `Parent` property.

`handle = light(...)` returns the handle of the light object created.

## Examples

Light the `peaks` surface plot with a local light source oriented along the direction defined by the vector `[-1 0 0]`, that is, looking from 0 along the positive x-axis.

```
surf(peaks,'FaceLighting','gouraud','FaceColor','interp',...
 'AmbientStrength',0.5)
light('Position',[-1 0 0],'Style','local')
```

## Tutorials

For more information about lighting, see “Lighting Overview”.

## More About

### Tips

You cannot see a light object *per se*, but you can see the effects of the light source on patch and surface objects. You can also specify an axes-wide ambient light color that illuminates these objects. However, ambient light is visible only when at least one light object is present and visible in the axes.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see `set` and `get` for examples of how to specify these data types).

See also the Patch Properties and Primitive Surface Properties `AmbientStrength`, `DiffuseStrength`, `SpecularStrength`, `SpecularExponent`, `SpecularColorReflectance`, and `VertexNormals` properties. Also see the `lighting` and `material` commands.

### See Also

`lighting` | `patch` | `material` | `surface`

**Introduced before R2006a**

# Light Properties

Control light appearance and behavior

Light properties control the appearance and behavior of light objects. By changing property values, you can modify certain aspects of the light.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = light;
c = h.Color;
h.Style = 'local';
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Color, Position, and Style

### Color — Color of light

[1 1 1] (default) | RGB triplet | color string

Color of light emanating from the light object, specified as an RGB triplet or a color string. The default RGB triplet of [1 1 1] corresponds to white.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'green'

## **Position — Location of light source**

[1 0 1] (default) | three-element vector of the form [x y z]

Location of light source, specified as a three-element vector of the form [x y z]. Define the vector elements in data units from the axes origin to the (x, y, z) coordinate. The actual location of the light depends on the value of the **Style** property.

Example: [-40 -4 140]

## **Style — Type of light source**

'infinite' (default) | 'local'

Type of light source, specified as one of these values:

- 'infinite' — Place the light at infinity. Use the **Position** property to specify the direction from which the light shines in parallel rays.
- 'local' — Place the light at the location specified by the **Position** property. The light is a point source that radiates from the location in all directions.

## **Visibility**

### **Visible — Visibility of light from light source**

'on' (default) | 'off'

Visibility of light from light source, specified as 'on' or 'off'.

## **Identifiers**

### **Type — Type of graphics object**

'light'

This property is read only.

Type of graphics object, returned as the string 'light'. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

### **Tag — Tag to associate with light**

'' (default) | string

Tag to associate with the light, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

### **UserData** — Data to associate with light

[ ] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the light object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

## **Parent/Child**

### **Parent** — Parent of light

axes object | group object | transform object

Parent of light, specified as an axes, group, or transform object.

### **Children** — Children of light

empty `GraphicsPlaceholder` array

The light has no children. You cannot set this property.

### **HandleVisibility** — Visibility of object handle

'on' (default) | 'off' | 'callback'

Visibility of light object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The light object handle is always visible.
- 'off' — The light object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.

- `'callback'` — The light object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the light at the command-line, but allows callback functions to access it.

If the light object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles regardless of their `HandleVisibility` property setting.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the light. Setting the `CreateFcn` property on an existing light has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during light creation. MATLAB executes the callback after creating the light and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The light object — You can access properties of the light object from within the callback function. You also can access the light object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### **DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the light. MATLAB executes the callback before destroying the light so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The light object — You can access properties of the light object from within the callback function. You also can access the light object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### **BeingDeleted — Deletion status of light**

'off' (default) | 'on'

This property is read only.

Deletion status of light, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the light begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the light no longer exists.

Check the value of the `BeingDeleted` property to verify that the light is not about to be deleted before querying or modifying it.

## Unused Properties

### **ButtonDownFcn** — (unused) Mouse-click callback

' ' (default) | function handle | cell array | string

Light objects do not use this property.

### **UIContextMenu** — (unused) Context menu

uicontextmenu object

Light objects do not use this property.

### **Selected** — (unused) Selection state

'off' (default) | 'on'

Light objects do not use this property.

### **SelectionHighlight** — (unused) Display of selection handles when selected

'on' (default) | 'off'

Light objects do not use this property.

## lightangle

Create or position light object in spherical coordinates

### Syntax

```
lightangle(az,e1)
light_handle = lightangle(az,e1)
lightangle(light_handle,az,e1)
[az,e1] = lightangle(light_handle)
```

### Description

`lightangle(az,e1)` creates a light at the position specified by azimuth and elevation. `az` is the azimuthal (horizontal) rotation and `e1` is the vertical elevation (both in degrees). The interpretation of azimuth and elevation is the same as that of the `view` command.

`light_handle = lightangle(az,e1)` creates a light and returns the handle of the light in `light_handle`.

`lightangle(light_handle,az,e1)` sets the position of the light specified by `light_handle`.

`[az,e1] = lightangle(light_handle)` returns the azimuth and elevation of the light specified by `light_handle`.

### Examples

```
surf(peaks)
axis vis3d
h = light;
for az = -50:10:50
 lightangle(h,az,30)
 pause(.2)
end
```

## More About

### Tips

By default, when a light is created, its style is `infinite`. If the light handle passed in to `lightangle` refers to a local light, the distance between the light and the camera target is preserved as the position is changed.

- “Lighting Overview”

# lighting

Specify lighting algorithm

## Syntax

```
lighting flat
lighting gouraud
lighting none
```

## Description

`lighting` selects the algorithm used to calculate the effects of `light` objects on all `surface` and `patch` objects in the current axes. In order for the `lighting` command to have any effects, however, you must create a lighting object by using the `light` function.

`lighting flat` produces uniform lighting across each of the faces of the object. Select this method to view faceted objects.

`lighting gouraud` calculates the vertex normals and interpolates linearly across the faces. Select this method to view curved surfaces.

`lighting none` turns off lighting.

## More About

### Tips

The `surf`, `mesh`, `pcolor`, `fill`, `fill3`, `surface`, and `patch` functions create graphics objects that are affected by light sources. The `lighting` command sets the `FaceLighting` and `EdgeLighting` properties of surfaces and patches appropriately for the graphics object.

- “Lighting Overview”

## **lin2mu**

Convert linear audio signal to mu-law

### **Syntax**

```
mu = lin2mu(y)
```

### **Description**

`mu = lin2mu(y)` converts linear audio signal amplitudes in the range  $-1 \leq Y \leq 1$  to mu-law encoded “flints” in the range  $0 \leq u \leq 255$ .

### **See Also**

`mu2lin`

**Introduced before R2006a**

# line

Create line object

## Syntax

```
line
line(X,Y)
line(X,Y,Z)
line(X,Y,Z,'PropertyName',propertyvalue,...)
line('XData',x,'YData',y,'ZData',z,...)
h = line(...)
```

## Properties

For a list of properties, see [Primitive Line Properties](#).

## Description

`line` creates a line object in the current axes with default values  $x = [0 \ 1]$  and  $y = [0 \ 1]$ . You can specify the color, width, line style, and marker type, as well as other characteristics.

The `line` function has two forms:

- Automatic color and line style cycling. When you specify multiple line coordinate data as a column array using the informal syntax (i.e., the first three arguments are interpreted as the coordinates),

```
line(X,Y,Z)
```

MATLAB cycles through the axes `ColorOrder` and `LineStyleOrder` property values the way the `plot` function does. However, unlike `plot`, `line` does not call the `newplot` function.

- Purely low-level behavior. When you call `line` with only property name/property value pairs,

```
line('XData',x,'YData',y,'ZData',z)
```

MATLAB draws a line object in the current axes using the default line color (see the `colordef` function for information on color defaults). Note that you cannot specify matrix coordinate data with the low-level form of the `line` function.

`line(X,Y)` adds the line defined in vectors `X` and `Y` to the current axes. If `X` and `Y` are matrices of the same size, `line` draws one line per column.

`line(X,Y,Z)` creates lines in three-dimensional coordinates.

`line(X,Y,Z,'PropertyName',propertyvalue,...)` creates a line using the values for the property name/property value pairs specified and default values for all other properties. For a description of the properties, see Primitive Line Properties.

`line('XData',x,'YData',y,'ZData',z,...)` creates a line in the current axes using the property values defined as arguments. This is the low-level form of the `line` function, which does not accept matrix coordinate data as the other informal forms described above.

`h = line(...)` returns a column vector of primitive line handles corresponding to each line object the function creates.

## Examples

This example uses the `line` function to add a shadow to plotted data. First, plot some data and save the line's handle:

```
t = 0:pi/20:2*pi;
hline1 = plot(t,sin(t),'k');
ax = gca;
```

Next, add a shadow by offsetting the  $x$ -coordinates. Make the shadow line light gray and wider than the default `LineWidth`:

```
hline2 = line(t+.06,sin(t),...
 'LineWidth',4,...
 'Color',[.8 .8 .8],...
 'Parent',ax);
```

Finally, pull the first line to the front:

```
set(gca, 'Children', [hline1 hline2])
```

## Drawing Lines Interactively

You can use the `ginput` function to select points from a figure. For example:

```
[x,y] = ginput(5);
line(x,y)
```

### Drawing with mouse motion

You can use the axes `CurrentPoint` property and the figure `WindowButtonDownFcn` and `WindowButtonMotionFcn` properties to select a point with a mouse click and draw a line to another point by dragging the mouse, like a simple drawing program. The following example illustrates a few useful techniques for doing this type of interactive drawing.

Click to view in editor — This example enables you to click and drag the cursor to draw lines.

Click to run example — Click the left mouse button in the axes and move the cursor, left-click to define the line end point, right-click to end drawing mode.

## Input Argument Dimensions — Informal Form

This statement reuses the one-column matrix specified for `ZData` to produce two lines, each having four points.

```
line(rand(4,2),rand(4,2),rand(4,1))
```

If all the data has the same number of columns and one row each, MATLAB transposes the matrices to produce data for plotting. For example,

```
line(rand(1,4),rand(1,4),rand(1,4))
```

is changed to

```
line(rand(4,1),rand(4,1),rand(4,1))
```

This also applies to the case when just one or two matrices have one row. For example, the statement

```
line(rand(2,4),rand(2,4),rand(1,4))
```

is equivalent to

```
line(rand(4,2),rand(4,2),rand(4,1))
```

## More About

### Tips

In its informal form, the `line` function interprets the first three arguments (two for 2-D) as the X, Y, and Z coordinate data, allowing you to omit the property names. You must specify all other properties as name/value pairs. For example,

```
line(X,Y,Z,'Color','r','LineWidth',4)
```

The low-level form of the `line` function can have arguments that are only property name/property value pairs. For example,

```
line('XData',x,'YData',y,'ZData',z,...
 'Color','r','LineWidth',4)
```

Line properties control various aspects of the line object. You can also set and query property values after creating the line using dot notation or the `set` and `get` functions

Unlike high-level functions such as `plot`, `line` does not respect the settings of the figure and axes `NextPlot` properties. It simply adds line objects to the current axes. However, axes properties that are under automatic control, such as the axis limits, can change to accommodate the line within the current axes.

### Connecting the dots

The coordinate data is interpreted as vectors of corresponding x, y, and z values:

```
X = [x(1) x(2) x(3)...x(n)]
Y = [y(1) y(2) y(3)...y(n)]
Z = [z(1) z(2) z(3)...z(n)]
```

where a point is determined by the corresponding vector elements:

```
p1(x(i),y(i),z(i))
```

For example, to draw a line from the point located at  $x = .3$  and  $y = .4$  and  $z = 1$  to the point located at  $x = .7$  and  $y = .9$  and  $z = 1$ , use the following data:

```
axis([0 1 0 1])
line([.3 .7],[.4 .9],[1 1],'Marker','.', 'LineStyle','-')
```

### Properties

[Primitive Line Properties](#)

**Introduced before R2006a**

## LineStyle (Line Specification)

Line specification string syntax

### Description

Plotting functions accept *string specifiers* as arguments and modify the graph generated accordingly. Three components can be specified in the *string specifiers* along with the plotting command. They are:

- Line style
- Marker symbol
- Color

For example:

```
plot(x,y, '-.or')
```

plots *y* versus *x* using a dash-dot line (-.), places circular markers (o) at the data points, and colors both line and marker red (r). Specify the components (in any order) as a quoted string after the data arguments. Note that linespecs are single strings, not property-value pairs.

### Plotting Data Points with No Line

If you specify a marker, but not a line style, only the markers are plotted. For example:

```
plot(x,y, 'd')
```

### Line Style Specifiers

You indicate the line styles, marker types, and colors you want to display using *string specifiers*, detailed in the following tables:

Specifier	LineStyle
'-'	Solid line (default)
'--'	Dashed line

Specifier	LineStyle
'.'	Dotted line
'-.'	Dash-dot line

## Marker Specifiers

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)

**Note:** The point (.) marker type does not change size when the specified value is less than 5.

## Color Specifiers

Specifier	Color
r	Red
g	Green
b	Blue

Specifier	Color
c	Cyan
m	Magenta
y	Yellow
k	Black
w	White

## Related Properties

This page also describes how to specify the properties of lines used for plotting. MATLAB graphics give you control over these visual characteristics:

- `LineWidth` — Specifies the width (in points) of the line.
- `MarkerEdgeColor` — Specifies the color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).
- `MarkerFaceColor` — Specifies the color of the face of filled markers.
- `MarkerSize` — Specifies the size of the marker in points (must be greater than 0).

In addition, you can specify the `LineStyle`, `Color`, and `Marker` properties instead of using the symbol string. This is useful if you want to specify a color that is not in the list by using RGB triplet values. See [Chart Line Properties](#) for details on these properties and [ColorSpec](#) for more information on color.

## Examples

Plot the sine function over three different ranges using different line styles, colors, and markers.

```
figure
t = 0:pi/20:2*pi;
plot(t,sin(t),'-r*')
hold on
plot(t,sin(t-pi/2),'--mo')
plot(t,sin(t-pi),':bs')
hold off
```

Create a plot illustrating how to set line properties:

```
figure
plot(t,sin(2*t),'-mo',...
 'LineWidth',2,...
 'MarkerEdgeColor','k',...
 'MarkerFaceColor',[.49 1 .63],...
 'MarkerSize',10)
```

[axes](#) | [line](#) | [plot](#) | [patch](#) | [set](#) | [surface](#) | [ColorSpec](#)

# linkaxes

Synchronize limits of specified 2-D axes

## Syntax

```
linkaxes(axes_handles)
linkaxes(axes_handles, 'option')
```

## Description

Use `linkaxes` to synchronize the individual axis limits across several figures or subplots within a figure. Calling `linkaxes` makes all input axes have identical limits. Linking axes is best when you want to zoom or pan in one subplot and display the same range of data in another subplot.

---

**Note:** Use `linkaxes` for axes that remain in 2-D views.

---

`linkaxes(axes_handles)` links the  $x$ - and  $y$ -axis limits of the axes specified in the vector `axes_handles`. You can link any number of existing plots or subplots. The `axes_handles` input should be a vector of the handles for each plot or subplot. Entering an array of values results in an error message.

`linkaxes(axes_handles, 'option')` links the axes' `axes_handles` according to the specified option. The `option` argument can be one of the following strings:

<code>x</code>	Link $x$ -axis only.
<code>y</code>	Link $y$ -axis only.
<code>xy</code>	Link $x$ -axis and $y$ -axis.
<code>off</code>	Remove linking.

See the `linkprop` function for more advanced capabilities that allow you to link object properties on any graphics object.

## Examples

### Create Subplots and Link Their Axes

Create three subplots and link their  $x$ -axes and  $y$ -axes so that they are always in sync.

First, create a figure with three subplots. Plot data in each subplot.

```
figure
ax1 = subplot(2,2,1);
x1 = linspace(0,6);
y1 = sin(x1);
plot(x1,y1)

ax2 = subplot(2,2,2);
x2 = linspace(0,10);
y2 = sin(2*x2);
plot(x2,y2)

ax3 = subplot(2,2,[3,4]);
x3 = linspace(0,16);
y3 = sin(6*x3);
plot(x3,y3)
```

Now link the axes for the three subplots using the `linkaxes` function. Pass the string `'xy'` as an input argument to the function to link both the  $x$ -axes and  $y$ -axes. The `linkaxes` function uses the limits from the first axes passed to it.

```
linkaxes([ax1,ax2,ax3], 'xy')
```

Panning or zooming into one of the subplots displays the same range of data in the other two subplots. To remove the linking, use `linkaxes([ax1, ax2, ax3]), 'off'`.

### Use Specific Subplot to Determine Limits for All Subplots

Load the `count.dat` data set which returns a three-column array named `count`. Create a new figure with three subplots and return the axes handles. In each subplot, create a bar graph.

```
load count.dat

figure
ax1 = subplot(3,1,1);
bar(count(:,1), 'g');
```

```
ax2 = subplot(3,1,2);
bar(count(:,2), 'b');

ax3 = subplot(3,1,3);
bar(count(:,3), 'm');
```

Link the  $x$ -axes and  $y$ -axes limits using `linkaxes` with the argument `'xy'`. Base the limits on the third subplot by passing its axes handle, `ax3`, as the first input to `linkaxes`.

```
linkaxes([ax3,ax2,ax1], 'xy');
```

If you zoom in on one subplot, then the other two subplots behave in the same manner. To enable interactive zooming, use `ZOOM on`. To disable zooming, use `ZOOM off`.

### Link x-Axes And Change Axis Limits

Load the `count.dat` data set which returns a three-column array named `count`. Create a new figure with two subplots and return the axes handles. In each subplot, create a bar graph.

```
load count.dat
figure
ax1 = subplot(2,1,1);
bar(count(:,1), 'g');
```

```
ax2 = subplot(2,1,2);
bar(count(:,2), 'b');
```

Link the x-axes for the two subplots.

```
linkaxes([ax1,ax2], 'x');
```

Set the  $x$ -axis limits for the second subplot. Setting the limits overrides the limits initially set by `linkaxes`. Changing the  $x$ -axis limits effects both subplots.

```
ax2.XLim = [4.5,9.5];
```

If you pan either subplot, then both subplots pan uniformly in the  $x$ -direction, but only one subplot moves in the  $y$ -direction. To enable interactive panning, use `pan on`. To disable panning, use `pan off`.

## More About

### Tips

The first axes you supply to `linkaxes` determines the  $x$ - and  $y$ -limits for all linked axes. This can cause plots to partly or entirely disappear if their limits or scaling are very different. To override this behavior, after calling `linkaxes`, specify the limits of the axes that you want to control with the `set` command, as the third example illustrates.

---

**Note:** `linkaxes` is not designed to be transitive across multiple invocations. If you have three axes, `ax1`, `ax2`, and `ax3` and want to link them together, call `linkaxes` with `[ax1, ax2, ax3]` as the first argument. Linking `ax1` to `ax2`, then `ax2` to `ax3`, "unbinds" the `ax1-ax2` linkage.

---

## See Also

`linkdata` | `linkprop` | `pan` | `zoom`

Introduced before R2006a

# linkdata

Automatically update graphs when variables change

## Syntax

```
linkdata on
linkdata off
linkdata
linkdata(figure_handle,...)
linkobj = linkdata(figure_handle)
```

## Description

`linkdata on` turns on data linking for the current figure.

`linkdata off` turns data linking off.

`linkdata` by itself toggles the state of data linking.

`linkdata(figure_handle,...)` applies the function to the specified figure handle.

`linkobj = linkdata(figure_handle)` returns a *linkdata object* for the specified figure. The object has one read-only property, **Enable**, the string 'on' or 'off', depending on the linked state of the figure.

Data linking connects graphs in figure windows to variables in the base or a function's workspace via their **XDataSource**, **YDataSource**, and **ZDataSource** properties. When you turn on data linking for a figure, MATLAB compares variables in the current (base or function caller) workspace with the **XData**, **YData**, and **ZData** properties of graphs in the affected figure to try to match them. When a match is found, the appropriate **XDataSource**, **YDataSource** and/or **ZDataSource** for the graph are set to strings that name the matching variables.

Any subsequent changes to linked variables are reflected in graphs that use them as data sources and in the Variables editor, if the linked variables are displayed there.

Conversely, any changes to plotted data values made at the command line, in the Variables editor, or with the Brush tool (such as deleting or replacing data points), are immediately reflected in the workspace variables linked to the data points.

When a figure containing graphs is linked and any variable identified as `XDataSource`, `YDataSource`, and/or `ZDataSource` changes its values in the workspace, all graphs displaying it in that and other linked figures automatically update. This operation is equivalent to automatically calling the `refreshdata` function on the corresponding figure when a variable changes.

Linked figure windows identify themselves by the appearance of the Linked Plot information bar at the top of the window. When `linkdata` is `off` for a figure, the Linked Plot information bar is removed. If `linkdata` cannot unambiguously identify data sources for a graph in a linked figure, it reports this via the Linked Plot information bar, which gives the user an opportunity to identify data sources. The information bar displays a warning icon and a message, **No graphics have data sources** and also prompts **fix it**. Clicking **fix it** opens the Specify Data Source Properties dialog box for identifying variable names and ranges of data sources used in the graph.

## Examples

### Example 1

Create two variables, plot them as area charts, and link the plot to them:

```
x = 1:20;
y = rand(20,3);
area(x,y)
linkdata on
```

Change values for linked variable  $y$  in the workspace:

```
y(10,:) = 0;
```

The area graph immediately updates.

## Example 2

Delete a figure if it is not linked, based on a returned `linkdata` object:

```
fig = figure;
ld = linkdata(fig)

ld =
 graphics.linkdata

if strcmp(ld.Enable, 'off')
 delete(fig)
end
```

## Example 3

If a plotting function can display a complex variable, then you can link such plots. To do so, you need to describe the data sources as expressions to separate the real and imaginary parts of the variable. For example,

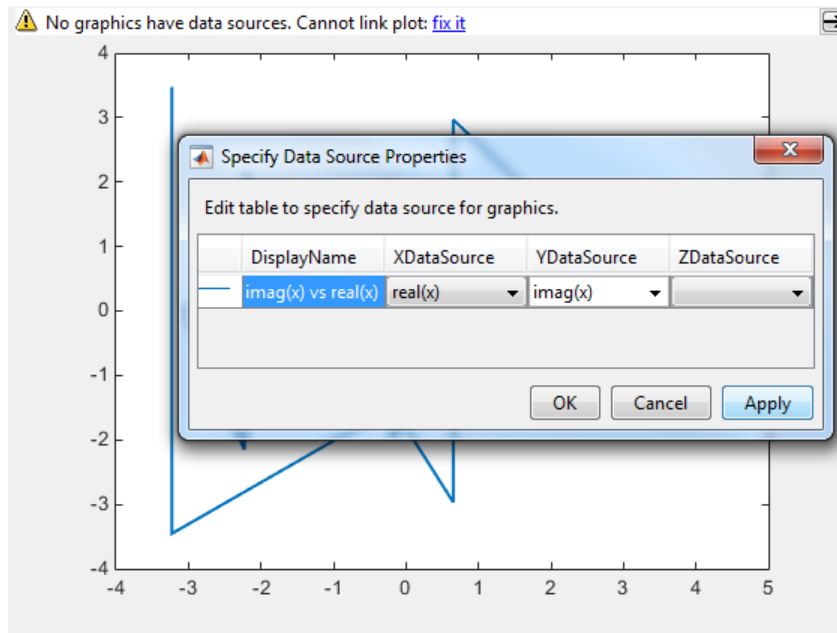

```
x = eig(randn(20,20));
whos
```

Name	Size	Bytes	Class	Attributes
x	20x1	320	double	complex

yields a complex vector. You can use `plot` to display the real portion as  $x$  and the imaginary portion as  $y$ , then link the graph to the variable:

```
plot(x)
linkdata
```

However, `linkdata` cannot unambiguously identify the graph's data sources, and you must tell it by typing `real(x)` and `imag(x)` into the Specify Data Source Properties dialog box that displays when you click **fix it** in the Linked Plot information bar.

To avoid having to type the data source names in the dialog box, you can specify them when you plot:

```
plot(x, 'XDataSource', 'real(x)', 'YDataSource', 'imag(x)')
```

If you subsequently change values of  $x$  programmatically or manually, the plot updates accordingly.

---

**Note:** Although you can use data brushing on linked plots of complex data, your brush marks only appear in the plot you are brushing, not in other plots or in the Variables editor. This is because function calls, such as `real(x)` and `imag(x)`, that you specify as data sources are not interpreted when brushing graphed data.

---

## More About

### Tips

- “Types of Variables You Can Link” on page 1-5036
- “Restoring Links that Break” on page 1-5036
- “Linking Rapidly Changing Data” on page 1-5036
- “Linking Brushed Graphs” on page 1-5037

## Types of Variables You Can Link

You can use `linkdata` to connect a graph with scalar, vector and matrix numeric variables of any class (including `complex`, if the graphing function can plot it) — essentially any data for which `isnumeric` equals `true`. See “Example 3” on page 1-5034 for instructions on linking complex variables. You can also link plots to numeric fields within structures. You can specify MATLAB expressions as data sources, for example, `sqrt(y)+1`.

## Restoring Links that Break

Refreshing data on a linked plot fails if the strings in the `XDataSource`, `YDataSource`, or `ZDataSource` properties, when evaluated, are incompatible with what is in the current workspace, such that the corresponding `XData`, `YData`, or `ZData` are unable to respond. The visual appearance of the object in the graph is not affected by such failures, so graphic objects show no indication of broken links. Instead, a warning icon and the message **Failing links** appear on the Linked Plot information bar along with an **Edit** button that opens the Specify Data Sources dialog box.

## Linking Rapidly Changing Data

`linkdata` buffers updates to data and dispatches them to plots at roughly half-second intervals. This makes data linking not suitable for smoothly animating changes in data

values unless they are updated in loops that are forced to execute two times per second or less.

One consequence of buffering link updates is that `linkdata` might not detect changes in data streams it monitors. If you are running a function that uses `assignin` or `evalin` to update workspace variables, `linkdata` can sometimes fail to process updates that change values but not the size and class of workspace variables. Such failures only happen when the function itself updates the plot.

## Linking Brushed Graphs

If you link data sources to graphs that have been brushed, their brushing marks can change or vanish. This is because the workspace variables in those graphs now dictate which, if any, observations are brushed, superseding any brushing annotations that were applied to their graphical data (`YData`, etc.). For more details, see “How Data Linking Affects Data Brushing” on page 1-819 in the `brush` reference page.

- “Making Graphs Responsive with Data Linking”

## See Also

`brush` | `linkaxes` | `linkprop` | `refreshdata`

# linkprop

Keep same value for corresponding properties of graphics objects

## Syntax

```
hlink = linkprop(obj_handles, 'PropertyName')
```

```
hlink = linkprop(obj_handles, {'PropertyName1', 'PropertyName2', ...})
```

## Description

Use `linkprop` to maintain the same values for the corresponding properties of different graphics objects.

---

**Note:** Use `linkprop` only with Handle Graphics objects.

---

`hlink = linkprop(obj_handles, 'PropertyName')` maintains the same value for the property *PropertyName* on all objects whose handles appear in `obj_handles`. `linkprop` returns the link object in `hlink`. See “About Link Objects” on page 1-5039 for more information.

`hlink = linkprop(obj_handles, {'PropertyName1', 'PropertyName2', ...})` maintains the same respective values for all properties passed as a cell array on all objects whose handles appear in `obj_handles`.

MATLAB updates the linked properties of all linked objects immediately when `linkprop` is called. The first object in the list `obj_handles` determines the property values for the other objects.

A set of graphics objects can have only one link object connecting their properties at any given time. Calling `linkprop` creates a new link object. This new link object replaces any existing link object that is associated with the objects specified in `obj_handles`. However, you can manage which properties and which objects are linked by calling methods on that object:

- To add an object to the list of linked objects, use the `addtarget` method.

- To link new properties of currently-linked objects, use the `addprop` method.
- To stop linking an object, use the `removetarget` method.
- To stop properties from linking, use the `removeprop` method.

## About Link Objects

The link object that `linkprop` returns stores the mechanism that links the properties of different graphics objects. Therefore, the link object must exist within the context where you want property linking to occur (such as in the base workspace if users are to interact with the objects from the command line or figure tools).

The following list describes ways to maintain a reference to the link object.

- Return the link object as an output argument from a function and keep it in the base workspace while interacting with the linked objects.
- Make the `hlink` variable global.
- Store the `hlink` variable in an object's `UserData` property or in application data.

## Updating a Link Object

If you want to change either the graphics objects or the properties that are linked, you need to use the link object methods designed for that purpose. These methods are functions that operate only on link objects. To use them, you must first create a link object using `linkprop`.

Method	Purpose
<code>addtarget</code>	Add specified graphics object to the link object's targets.
<code>removetarget</code>	Remove specified graphics object from the link object's targets.
<code>addprop</code>	Add specified property to the linked properties.
<code>removeprop</code>	Remove specified property from the linked properties.

## Method Syntax

```
ddtarget(hlink,obj_handles)
```

```
removetarget(hlink,obj_handles)
addprop(hlink,'PropertyName')
removeprop(hlink,'PropertyName')
```

## Method Arguments

- `hlink` — Link object returned by `linkprop`
- `obj_handles` — One or more graphic object handles
- `PropertyName` — Name of a property common to all target objects

## Examples

### Link Axes So They Rotate Simultaneously

Link properties of two axes so that rotating one axes automatically rotates the other.

Create a figure with two axes and store the axes handles. Add plots to both axes.

```
figure
ax1 = subplot(2,1,1);
[X1,Y1,Z1] = peaks;
surf(X1,Y1,Z1)

ax2 = subplot(2,1,2);
[X2,Y2,Z2] = peaks(10);
surf(X2,Y2,Z2)
```

Link the `CameraPosition` and `CameraUpVector` properties of the axes and return the link object handle. Then, enable interactive rotation and use the mouse to rotate either axes. Rotating one axes automatically rotates the other in the same manner.

```
hlink = linkprop([ax1,ax2],{'CameraPosition','CameraUpVector'});
rotate3d on
```

To disable interactive rotation, use `rotate3d off`.

Link an additional property by passing the link object handle and the property name to `addprop`.

```
addprop(hlink, 'PlotBoxAspectRatio')
```

Introduced before R2006a

## **linsolve**

Solve linear system of equations

### **Syntax**

```
X = linsolve(A,B)
X = linsolve(A,B,opts)
```

### **Description**

`X = linsolve(A,B)` solves the linear system  $A \cdot X = B$  using LU factorization with partial pivoting when  $A$  is square and QR factorization with column pivoting otherwise. The number of rows of  $A$  must equal the number of rows of  $B$ . If  $A$  is  $m$ -by- $n$  and  $B$  is  $m$ -by- $k$ , then  $X$  is  $n$ -by- $k$ . `linsolve` returns a warning if  $A$  is square and ill conditioned or if it is not square and rank deficient.

`[X, R] = linsolve(A,B)` suppresses these warnings and returns  $R$ , which is the reciprocal of the condition number of  $A$  if  $A$  is square, or the rank of  $A$  if  $A$  is not square.

`X = linsolve(A,B,opts)` solves the linear system  $A \cdot X = B$  or  $A' \cdot X = B$ , using the solver that is most appropriate given the properties of the matrix  $A$ , which you specify in `opts`. For example, if  $A$  is upper triangular, you can set `opts.UT = true` to make `linsolve` use a solver designed for upper triangular matrices. If  $A$  has the properties in `opts`, `linsolve` is faster than `mldivide`, because `linsolve` does not perform any tests to verify that  $A$  has the specified properties.

---

**Notes** If  $A$  does not have the properties that you specify in `opts`, `linsolve` returns incorrect results and does not return an error message. If you are not sure whether  $A$  has the specified properties, use `mldivide` instead.

For small problems, there is no speed benefit in using `linsolve` on triangular matrices as opposed to using the `mldivide` function.

---

The `TRANSA` field of the `opts` structure specifies the form of the linear system you want to solve:

- If you set `opts.TRANSA = false`, `linsolve(A,B,opts)` solves  $A*X = B$ .
- If you set `opts.TRANSA = true`, `linsolve(A,B,opts)` solves  $A'*X = B$ .

The following table lists all the field of `opts` and their corresponding matrix properties. The values of the fields of `opts` must be logical and the default value for all fields is false.

Field Name	Matrix Property
LT	Lower triangular
UT	Upper triangular
UHESS	Upper Hessenberg
SYM	Real symmetric or complex Hermitian
POSDEF	Positive definite
RECT	General rectangular
TRANSA	Conjugate transpose — specifies whether the function solves $A*X = B$ or $A'*X = B$

The following table lists all combinations of field values in `opts` that are valid for `linsolve`. A true/false entry indicates that `linsolve` accepts either true or false.

LT	UT	UHESS	SYM	POSDEF	RECT	TRANSA
true	false	false	false	false	true/false	true/false
false	true	false	false	false	true/false	true/false
false	false	true	false	false	false	true/false
false	false	false	true	true/false	false	true/false
false	false	false	false	false	true/false	true/false

## Examples

The following code solves the system  $A'x = b$  for an upper triangular matrix  $A$  using both `mldivide` and `linsolve`.

```
A = triu(rand(5,3)); x = [1 1 1 0 0]'; b = A'*x;
y1 = (A')\b
```

```
opts.UT = true; opts.TRANSA = true;
y2 = linsolve(A,b,opts)
```

```
y1 =
```

```
1.0000
1.0000
1.0000
0
0
```

```
y2 =
```

```
1.0000
1.0000
1.0000
0
0
```

---

**Note** If you are working with matrices having different properties, it is useful to create an options structure for each type of matrix, such as `opts_sym`. This way you do not need to change the fields whenever you solve a system with a different type of matrix **A**.

---

**Introduced before R2006a**

# linspace

Generate linearly spaced vector

## Syntax

```
y = linspace(x1,x2)
y = linspace(x1,x2,n)
```

## Description

`y = linspace(x1,x2)` returns a row vector of 100 evenly spaced points between `x1` and `x2`.

`y = linspace(x1,x2,n)` generates `n` points. The spacing between the points is  $(x2 - x1) / (n - 1)$ .

`linspace` is similar to the colon operator, “:”, but gives direct control over the number of points and always includes the endpoints. “lin” in the name “`linspace`” refers to generating linearly spaced values as opposed to the sibling function `logspace`, which generates logarithmically spaced values.

## Examples

### Vector of Evenly Spaced Numbers

Create a vector of 100 evenly spaced points in the interval `[-5,5]`.

```
y = linspace(-5,5);
```

### Vector with Specified Number of Values

Create a vector of 7 evenly spaced points in the interval `[-5,5]`.

```
y1 = linspace(-5,5,7)
```

```
y1 =
```

```
-5.0000 -3.3333 -1.6667 0 1.6667 3.3333 5.0000
```

### Vector of Evenly Spaced Complex Numbers

Create a vector of complex numbers with 8 evenly spaced points between  $1+2i$  and  $10+10i$ .

```
y = linspace(1+2i,10+10i,8)
```

```
y =
```

```
Columns 1 through 5
```

```
1.0000 + 2.0000i 2.2857 + 3.1429i 3.5714 + 4.2857i 4.8571 + 5.4286i 6.1429 + 6.5714i
```

```
Columns 6 through 8
```

```
7.4286 + 7.7143i 8.7143 + 8.8571i 10.0000 +10.0000i
```

## Input Arguments

### **x1, x2** — Point interval

pair of numeric scalars

Point interval, specified as a pair of numeric scalars. **x1** and **x2** define the interval over which `linspace` generates points. **x1** and **x2** can be real or complex, and **x2** can be either larger or smaller than **x1**. If **x2** is smaller than **x1**, then the vector contains descending values.

Data Types: `single` | `double` | `datetime` | `duration`

Complex Number Support: Yes

### **n** — Number of points

100 (default) | real numeric scalar

Number of points, specified as a real numeric scalar.

- If **n** is 1, `linspace` returns **x2**.
- If **n** is zero or negative, `linspace` returns an empty 1-by-0 matrix.
- If **n** is not an integer, `linspace` rounds down and returns `floor(n)` points.

## RandStream.list

Random number generator algorithms

### Class

RandStream

### Syntax

RandStream.list

### Description

RandStream.list lists all the generator algorithms that can be used when creating a random number stream with RandStream or RandStream.create. The available generator algorithms and their properties are given in the following table.

Keyword	Generator	Multiple Stream and Substream Support	Approximate Period In Full Precision
mt19937ar	Mersenne twister (used by default stream at MATLAB startup)	No	$2^{19937} - 1$
dsfmt19937	SIMD-oriented fast Mersenne twister	No	$2^{19937} - 1$
mcg16807	Multiplicative congruential generator	No	$2^{31} - 2$
mlfg6331_64	Multiplicative lagged Fibonacci generator	Yes	$2^{124}$
mrg32k3a	Combined multiple recursive generator	Yes	$2^{127}$

Keyword	Generator	Multiple Stream and Substream Support	Approximate Period In Full Precision
shr3cong	Shift-register generator summed with linear congruential generator	No	$2^{64}$
swb2712	Modified subtract with borrow generator	No	$2^{1492}$

See “Choosing a Random Number Generator” for details about these generator algorithms. See <http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/emt.html> for a full description of the Mersenne twister algorithm.

- “Creating and Controlling a Random Number Stream”

# listdlg

Create list-selection dialog box

## Syntax

```
[Selection,ok] = listdlg(Name,Value,...)
```

## Description

`[Selection,ok] = listdlg(Name,Value,...)` creates a modal dialog that allows the user to select one or more items from a list. The function returns two output arguments containing information about the items the user selected. The first output, **Selection**, contains the indices of the selected rows in the list. **Selection** is an empty array when no selection is made. The second output, **ok**, is 0 when no selection is made, or 1 when a selection is made.

The input arguments, **Name**, **Value**, are pairs of arguments that specify certain aspects of the dialog box. The pair, `'ListString',S` is required, but you can optionally specify any number of other pairs. This table lists all possible **Name**, **Value** input arguments:

Name	Value
<code>'ListString'</code> (required)	Cell array of strings that specify the list items.
<code>'SelectionMode'</code>	String indicating whether one or many items can be selected: <code>'single'</code> or <code>'multiple'</code> (the default).
<code>'ListSize'</code>	List box size in pixels, specified as a two-element vector <code>[width height]</code> . Default is <code>[160 300]</code> .
<code>'InitialValue'</code>	Vector of indices of the list box items that are initially selected. Default is 1, the first item.
<code>'Name'</code>	String for the dialog box's title. Default is an empty string.
<code>'PromptString'</code>	String matrix or cell array of strings that appears as text above the list box. Default is an empty cell array.

Name	Value
'OKString'	String for the OK button. Default is 'OK'.
'CancelString'	String for the Cancel button. Default is 'Cancel'.

Double-clicking on an item or pressing **Return** when multiple items are selected has the same effect as clicking the **OK** button. The dialog box has a **Select all** button (when in multiple selection mode) that enables you to select all list items.

## Examples

This example displays a dialog box that enables the user to select a file from the current directory.

The `listdlg` function returns two output arguments. The first output, `s`, is the index to the selected row in the list. The second output, `v`, is 0 when no selection is made, or 1 when a selection is made.

```
d = dir;
str = {d.name};
[s,v] = listdlg('PromptString','Select a file:',...
 'SelectionMode','single',...
 'ListString',str)
```

## More About

### Modal Dialog

A window that blocks interaction with other windows until the user closes the blocking window. For more information, see the figure `WindowState` property description.

### See Also

`uigetfile` | `uigetdir` | `questdlg` | `uicontrol`

**Introduced before R2006a**

## listfonts

List available system fonts

### Syntax

```
c = listfonts
c = listfonts(h)
```

### Description

`c = listfonts` returns sorted list of available system fonts.

`c = listfonts(h)` returns sorted list of available system fonts and includes the `FontName` property of the object with handle `h`.

### Examples

#### Example 1

This example returns a list of available system fonts similar in format to the one shown.

```
list = listfonts

list =
 'Agency FB'
 'Algerian'
 'Arial'
 ...
 'ZapfChancery'
 'ZapfDingbats'
 'ZWAdobeF'
```

#### Example 2

This example returns a list of available system fonts with the value of the `FontName` property, for the object with handle `h`, included and sorted in the list.

```
h = uicontrol('Style','text','String',...
 'My Font','FontName','MyFont');
list = listfonts(h)

list =
 'Agency FB'
 'Algerian'
 'Arial'
 ...
 'MyFont'
 ...
 'ZapfChancery'
 'ZapfDingbats'
 'ZWAdobeF'
```

## More About

### Tips

Calling `listfonts` returns a list of all fonts on your system, possibly including fonts that you cannot use with MATLAB. Consider using the `uifont` function to preview fonts to that MATLAB can render in figure windows. Like `uifont`, the **Custom Fonts** pane of MATLAB Preferences also previews available fonts and only shows those that MATLAB can render.

### See Also

`uifont`

# load

Load variables from file into workspace

## Syntax

```
load(filename)
load(filename,variables)
load(filename,'-ascii')
load(filename,'-mat')
load(filename,'-mat',variables)
```

```
S = load(___)
```

```
load filename
```

## Description

`load(filename)` loads data from `filename`.

- If `filename` is a MAT-file, then `load(filename)` loads variables in the MAT-File into the MATLAB workspace.
- If `filename` is an ASCII file, then `load(filename)` creates a double-precision array containing data from the file.

`load(filename,variables)` loads the specified variables from the MAT-file, `filename`.

`load(filename,'-ascii')` treats `filename` as an ASCII file, regardless of the file extension.

`load(filename,'-mat')` treats `filename` as a MAT-file, regardless of the file extension.

`load(filename,'-mat',variables)` loads the specified variables from `filename`.

`S = load( ___ )` loads data into `S`, using any of the input arguments in the previous syntax group.

- If `filename` is a MAT-file, then `S` is a structure array.
- If `filename` is an ASCII file, then `S` is a double-precision array containing data from the file.

`load filename` is the command form of the syntax. Command form requires fewer special characters. You do not need to type parentheses or enclose input strings in single quotes. Separate inputs with spaces instead of commas.

For example, to load a file named `durer.mat`, these statements are equivalent:

```
load durer.mat % command form
load('durer.mat') % function form
```

You can include any of the inputs described in previous syntaxes. For example, to load the variable named `X`:

```
load durer.mat X % command form
load('durer.mat','X') % function form
```

Do not use command form when any of the inputs, such as `filename`, are variables.

## Examples

### Load All Variables from MAT-File

Load all variables from the example MAT-file, `gong.mat`. Check the contents of the workspace before and after the load operation.

```
disp('Contents of workspace before loading file:')
whos
```

```
disp('Contents of gong.mat:')
whos('-file','gong.mat')
```

```
load('gong.mat')
disp('Contents of workspace after loading file:')
whos
```

You also can use command syntax to load the variables. Clear the previously loaded variables and repeat the `load` operation.

```
clear y Fs
```

```
load gong.mat
```

### Load Specific Variable From MAT-File

Load only variable `y` from example file `handel.mat`. If the workspace already contains variable `y`, the `load` operation overwrites it with data from the file.

```
load('handel.mat','y')
```

You also can use command syntax to load the variable, `y`.

```
load handel.mat y
```

### Use Regular Expressions to Load Specific Variables

View the contents of the example file, `accidents.mat`.

```
whos -file accidents.mat
```

Name	Size	Bytes	Class	Attributes
<code>datasources</code>	3x1	2724	cell	
<code>hwycols</code>	1x1	8	double	
<code>hwydata</code>	51x17	6936	double	
<code>hwyheaders</code>	1x17	2758	cell	
<code>hwyidx</code>	51x1	408	double	
<code>hwyrows</code>	1x1	8	double	
<code>statelabel</code>	51x1	6596	cell	
<code>ushwydata</code>	1x17	136	double	
<code>uslabel</code>	1x1	138	cell	

Use function syntax to load all variables with names not beginning with `'hwy'`, from the file.

```
load('accidents.mat', '-regexp', '^(?!hwy)...')
```

Alternatively, use command syntax to load the same variables.

```
load accidents.mat -regexp '^(?!hwy)...'
```

### Load List of Variables into Structure Array

The file, `durer.mat`, contains variables `X`, `caption`, and `map`. Create a cell array of variable names to load.

```
filename = 'durer.mat';
```

```

myVars = {'X', 'caption'};
S = load(filename, myVars{:})

S =

 X: [648x509 double]
 caption: [2x28 char]

```

Only the variables `X` and `caption` are loaded into the structure array, `S`.

### Load ASCII File

Create an ASCII file from several 4-column matrices, and load the data back into a double-precision array.

```

a = magic(4);
b = ones(2, 4) * -5.7;
c = [8 6 4 2];
save -ascii mydata.dat a b c
clear a b c

```

```
load mydata.dat -ascii
```

`load` creates an array of type `double` named `mydata`.

View information about `mydata`.

```
whos mydata
```

Name	Size	Bytes	Class	Attributes
mydata	7x4	224	double	

## Input Arguments

### **filename** — Name of file

`matlab.mat` (default) | string

Name of file, specified as a string. If you do not specify `filename`, the `load` function searches for a file named `matlab.mat`.

`filename` can include a file extension and a full or partial path. If `filename` has no extension (that is, no text after a period), `load` looks for a file named `filename.mat`. If

`filename` has an extension other than `.mat`, the `load` function treats the file as ASCII data.

When using the command form of `load`, it is unnecessary to enclose input strings in single quotes. However, if `filename` contains a space, you must enclose the argument in single quotes. For example, `load 'filename withspace.mat'`.

ASCII files must contain a rectangular table of numbers, with an equal number of elements in each row. The file delimiter (the character between elements in each row) can be a blank, comma, semicolon, or tab character. The file can contain MATLAB comments (lines that begin with a percent sign, `%`).

Example: `'myFile.mat'`

Data Types: `char`

**variables** — Names of variables to load

string

Names of variables to load, specified as one or more strings. When using the command form of `load`, you do not need to enclose input strings in single quotes. `variables` can be in one of the following forms.

Form of <code>variables</code> Input	Variables to Load
<code>var1, ..., varN</code>	Load the listed variables, specified as individual strings. Use the <code>'*'</code> wildcard to match patterns. For example, <code>load('filename.mat', 'A*')</code> or <code>load filename.mat A*</code> loads all variables in the file whose names start with A.
<code>'-regex', expr1, ..., exprN</code>	Load only the variables or fields whose names match the regular expressions, specified as strings. For example, <code>load('filename.mat', '-regex', '^Mon', '^Tues')</code> or <code>load filename.mat -regex ^Mon ^Tues</code> loads only the variables in the file whose names begin with Mon or Tues.

Data Types: `char`

## Output Arguments

### S — Loaded variables or data

structure array | m-by-n array

Loaded variables, returned as a structure array, if `filename` is a MAT-File.

Loaded data, returned as an m-by-n array of type `double`, if `filename` is an ASCII file. `m` is equal to the number of lines in the file, and `n` is equal to the number of values on a line.

## More About

### Algorithms

If you do not specify an output for the `load` function, MATLAB creates a variable named after the loaded file (minus any file extension). For example, the command

```
load mydata.dat
```

reads data into a variable called `mydata`.

To create the variable name, `load` precedes any leading underscores or digits in `filename` with an X and replaces any other nonalphabetic characters with underscores. For example, the command

```
load 10-May-data.dat
```

creates a variable called `X10_May_data`.

**Introduced before R2006a**

## load (COM)

Initialize control object from file

### Syntax

```
load(h, 'filename')
```

### Description

`load(h, 'filename')` initializes the COM object associated with the interface represented by the MATLAB COM object `h` from file specified in the string `filename`. The file must have been created previously by serializing an instance of the same control.

COM functions are available on Microsoft Windows systems only.

---

**Note** The COM `load` function is only supported for controls at this time.

---

### Examples

Create an `mwsamp` control and save its original state to the file `mwsample`.

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl1.2',[0 0 200 200],f);
save(h,'mwsample')
```

Alter the figure by changing its label and the radius of the circle.

```
h.Label = 'Circle';
h.Radius = 50;
Redraw(h)
```

Restore the control to its original state using the `load` function.

```
load(h,'mwsample')
get(h)
```

```
ans =
 Label: 'Label'
```

Radius: 20

**See Also**

save (COM) | delete (COM) | actxcontrol | actxserver | release

**Introduced before R2006a**

## load (serial)

Load serial port objects and variables into MATLAB workspace

### Syntax

```
load filename
load filename obj1 obj2 ...
out = load('filename','obj1','obj2',...)
```

### Description

`load filename` returns all variables from the file specified by `filename` into the MATLAB workspace.

`load filename obj1 obj2 ...` returns the serial port objects specified by `obj1 obj2 ...` from the file `filename` into the MATLAB workspace.

`out = load('filename','obj1','obj2',...)` returns the specified serial port objects from the file `filename` as a structure to `out` instead of directly loading them into the workspace. The field names in `out` match the names of the loaded serial port objects.

### Examples

---

**Note:** This example is based on a Windows platform.

---

Suppose that you create the serial port objects `s1` and `s2`, configure a few properties for `s1`, and connect both objects to their instruments:

```
s1 = serial('COM1');
s2 = serial('COM2');
set(s1,'Parity','mark','DataBits',7);
fopen(s1);
fopen(s2);
```

Save `s1` and `s2` to the file `MyObject.mat`, and then load the objects back into the workspace:

```
save MyObject s1 s2;
load MyObject s1;
load MyObject s2;

get(s1, {'Parity', 'DataBits'})

ans =
 'mark' [7]

get(s2, {'Parity', 'DataBits'})

ans =
 'none' [8]
```

## More About

### Tips

Values for read-only properties are restored to their default values upon loading. For example, the `Status` property is restored to `closed`. To determine if a property is read-only, examine its reference pages.

### See Also

`save` | `Status`

**Introduced before R2006a**

# loadlibrary

Load C/C++ shared library into MATLAB

## Syntax

```
loadlibrary(libname,hfile)
loadlibrary(libname)
loadlibrary(libname,hfile,Name,Value)
loadlibrary(libname,@protofile)
[notfound,warnings] = loadlibrary(___)
```

## Description

`loadlibrary(libname,hfile)` loads functions from shared library, `libname`, defined in header file, `hfile`, into MATLAB.

`loadlibrary(libname)` loads the library if the name of the header file is the same as the name of the library file.

`loadlibrary(libname,hfile,Name,Value)` loads the library with one or more `Name,Value` arguments.

`loadlibrary(libname,@protofile)` uses a prototype file, `protofile`, in place of a header file.

`[notfound,warnings] = loadlibrary( ___ )` returns warning information, and can include any of the input arguments in previous syntaxes.

## Examples

### Display Functions in `shr1libsample` Library

Add path to `examples` folder.

```
addpath(fullfile(matlabroot,'extern','examples','shr1lib'))
```

Display functions in library.

```
if not(libisloaded('shrlibsample'))
 loadlibrary('shrlibsample')
end
libfunctions('shrlibsample')
```

Functions in library shrlibsample:

addDoubleRef	exportedDoubleValue	printExportedDoubleValue
addMixedTypes	getListOfStrings	readEnum
addStructByRef	multDoubleArray	stringToUpper
addStructFields	multDoubleRef	
allocateStruct	multiplyShort	
deallocateStruct	print2darray	

Clean up.

```
unloadlibrary shrlibsample
```

## Load Library Using Multiple Header Files

Suppose that you have a library, `mylib`, with the header file, `mylib.h`. The header file contains the statement, `#include header2.h`. To use functions defined in `header2.h`, call `loadlibrary` with the `addheader` option.

```
loadlibrary('mylib','mylib.h','addheader','header2')
```

## Call `stringToUpper` Function Using Alias Name

```
if libisloaded('shrlibsample')
 unloadlibrary('shrlibsample')
else
 addpath(fullfile(matlabroot,'extern','examples','shrlib'))
end
```

Create an alias name `lib` for library `shrlibsample`.

```
loadlibrary('shrlibsample','shrlibsample.h','alias','lib')
```

Call function `stringToUpper` using the alias name.

```
str = 'This was a Mixed Case string';
```

```
calllib('lib', 'stringToUpper', str)
```

```
ans =
```

```
THIS WAS A MIXED CASE STRING
```

Clean up.

```
unloadlibrary lib
```

### Search Alternative Paths for Header Files

Add path to folder containing `shrlibsample` and its header file, `shrlibsample.h`.

```
addpath(fullfile(matlabroot, 'extern', 'examples', 'shrlib'))
```

The `shrlibsample.h` header file includes the header file, `shrhhelp.h`. If `shrhhelp.h` is in a different folder, for example, `c:\work`, use the `'includepath'` option to tell MATLAB where to find the file.

```
loadlibrary('shrlibsample', 'shrlibsample.h', 'includepath', 'c:\work')
```

Clean up.

```
unloadlibrary shrlibsample
```

### Create Alias Name for MATLAB `mxGetNumberOfDimensions` Function

This example shows how to replace the `mxGetNumberOfDimensions` function name in the MATLAB Matrix Library API with a shorter alias name, `mxGetDims`. To define the alias name, create a prototype file then load the library using the prototype file as the header file.

Use a folder for which you have write-access.

```
cd('c:\work')
```

Create a prototype file, `mxproto.m`.

```
hfile = fullfile(matlabroot, 'extern', 'include', 'matrix.h');
[notfound, warnings] = loadlibrary('libmx', hfile, 'mfilename', 'mxproto')
```

MATLAB creates the prototype file in the current folder. Ignore the warning message, Type `'longdouble'` was not found.

Add the alias name to the prototype file. Open the file in MATLAB Editor.

```
edit mxproto.m
```

Search for the function `mxGetNumberOfDimensions`.

The following command assigns the alias `mxGetDims`.

```
fcns.alias{fcnNum}='mxGetDims';
```

Add the command to the line before the command to increment `fcnNum`. The new function prototype, with the new command shown in bold, looks like the following:

```
fcns.name{fcnNum}='mxGetNumberOfDimensions';
fcns.calltype{fcnNum}='cdecl';
fcns.LHS{fcnNum}='int32';
fcns.RHS{fcnNum}={'MATLAB array'};
fcns.alias{fcnNum}='mxGetDims'; % Alias defined
fcnNum=fcnNum+1; % Increment fcnNum
```

Reload `libmx` using the prototype file.

```
unloadlibrary libmx
loadlibrary('libmx',@mxproto)
```

Call the function by its alias name.

```
y = rand(4,7,2);
calllib('libmx','mxGetDims',y)
```

```
ans =
 3
```

Clean up.

```
unloadlibrary shrllibsample
```

## Input Arguments

**libname** — Name of shared library

string

Name of shared library, specified as a string. The name is case-sensitive and must match the file on your system.

On Microsoft Windows systems, `libname` refers to the name of a shared library (`.dll`) file. On Linux systems, it refers to the name of a shared object (`.so`) file. On Apple Mac systems, it refers to a dynamic shared library (`.dylib`). If you do not include a file extension with the `libname` argument, `loadlibrary` attempts to find the library with either the appropriate platform MEX-file extension or the appropriate platform library extension. For a list of MEX-file extensions, use `mexext`.

MATLAB extracts the name portion of the `libname` string to identify the library in other shared library functions. For example, when you call the `calllib` function, do not include the path or file extension in the library argument name.

Data Types: `char`

### **hfile** — Name of C header file

string

Name of C header file, specified as a string. The name is case-sensitive and must match the file on your system. If you do not include a file extension in the file name, `loadlibrary` uses `.h` for the extension.

Data Types: `char`

### **protofile** — Name of prototype file

string

Name of prototype file, specified as a string. The name is case-sensitive and must match the file on your system. The string `@protofile` specifies a function handle to the prototype file. When using a prototype file, the only valid `Name, Value` pair argument is **alias**.

Data Types: `char`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

### **'addheader'** — Header file

string

Header file, specified as the comma-separated pair consisting of 'addheader' and a string. Specify the file name without a file extension.

Each file specified by `addheader` must have a corresponding `#include` statement in the base header file. To load only the functions defined in the header file that you want to use in MATLAB, use `addheader`.

MATLAB does not verify the existence of header files and ignores any that are not needed.

**'alias' — Alternative name for library**

string

Alternative name for library, specified as the comma-separated pair consisting of 'alias' and a string. Associates the specified name with the library. All subsequent calls to MATLAB functions that reference this library must use this alias until the library is unloaded.

**'includepath' — More search path for subordinate header files**

string

more search path for subordinate header files—header files within header files, specified as the comma-separated pair consisting of 'includepath' and a string.

**'mfilename' — Prototype file**

string

Prototype file, specified as the comma-separated pair consisting of 'mfilename' and a string. Generates a prototype file in the current folder. The prototype file name must be different from the library name. Use this file in place of a header file when loading the library.

**'thunkfilename' — Thunk file**

string

Thunk file, specified as the comma-separated pair consisting of 'thunkfilename' and a string. Overrides the default thunk file name.

## Output Arguments

**notfound — Names of functions**

cell array

Names of functions found in header files but missing from the library, returned as cell array.

Data Types: `cell`

### **warnings** — Warnings

character array

Warnings produced while processing the header file, returned as character array.

## Limitations

- You must have a supported C compiler and Perl must be available.
- Do not call `loadlibrary` if the library is already in memory. To test this condition, call `libisloaded`.
- `loadlibrary` does not support libraries generated by the MATLAB Compiler SDK product.
- The MATLAB Shared Library interface does not support library functions with function pointer inputs.
- For more information, see “Limitations to Shared Library Support”.

## More About

### Prototype File

A prototype file is a file of MATLAB commands which you can modify and use in place of a header file.

### Thunk File

A thunk file is a compatibility layer to a 64-bit library generated by MATLAB. The name of the thunk file is `BASENAME_thunk_COMPUTER.c` where *BASENAME* is either the name of the shared library or, if specified, the `mfilename` prototype name. *COMPUTER* is the string returned by the `computer` function.

MATLAB compiles this file and creates the file `BASENAME_thunk_COMPUTER.LIBEXT`, where *LIBEXT* is the platform-dependent default shared library extension, for example, `dll` on Windows.

## Tips

- If you have more than one library file of the same name, load the first using the library file name. Then load the additional libraries using the **alias** option.
- Use the **alias** option as an alternate name for a library. To load an alternate header file, use the `@protofile` argument.
- “When to Use Prototype Files”
- Supported and Compatible Compilers

**Introduced before R2006a**

# loadobj

Modify load process for object

## Syntax

```
b = loadobj(a)
```

## Description

`b = loadobj(a)` is called by the `load` function if the class of `a` defines a `loadobj` method. `load` returns `b` as the value loaded from a MAT-file.

Define a `loadobj` method when objects of the class require special processing when loaded from MAT-files. If you define a `saveobj` method, then define a `loadobj` method to restore the object to the desired state.

Define `loadobj` as a static method so it can accept as an argument whatever object or structure that you saved in the MAT-file.

When loading a subclass object, `load` calls only the subclass `loadobj` method. If a superclass defines a `loadobj` method, the subclass inherits this method. However, it is possible that the inherited method does not perform the necessary operations to load the subclass object. Consider overriding superclass `loadobj` methods.

If any superclass in a class hierarchy defines a `loadobj` method, then the subclass `loadobj` method must ensure that the subclass and superclass objects load properly. Ensure proper loading by calling the superclass `loadobj` (or other methods) from the subclass `loadobj` method.

## Input Arguments

**a**

The input argument, `a`, can be:

- The object as loaded from the MAT-file.

- A structure created by `load` (if `load` cannot resolve the object).
- A structure returned by the `saveobj` method that was saved instead of the object.

Implement your `loadobj` method to work with scalar objects or structures. When you have saved an object array, `load` calls `loadobj` on each element of the saved array.

**Introduced before R2006a**

# localfunctions

Function handles to all local functions in MATLAB file

## Syntax

```
fcns = localfunctions
```

## Description

`fcns = localfunctions` returns a cell array of function handles, `fcns`, to all local functions in the current file.

You cannot define local functions in the context of the command line, scripts, or anonymous functions, so when you call `localfunctions` from these contexts, you get an empty cell array. Within the cell array, `localfunctions` returns the function handles in an undefined order.

## Examples

### Create Handles to Local Functions in File

Create the following function in a file, `ellipseVals.m`, in your working folder. The function returns a cell array with handles to all the local functions.

```
function fh = ellipseVals
fh = localfunctions;
end

function f = computeFocus(a,b)
f = sqrt(a^2-b^2);
end

function e = computeEccentricity(a,b)
f = computeFocus(a,b);
e = f/a;
end
```

```
function ae = computeArea(a,b)
ae = pi*a*b;
end
```

At the command prompt, invoke the function to get a cell array of handles to the local functions.

```
fh = ellipseVals
```

```
fh =
```

```
 @computeFocus
 @computeEccentricity
 @computeArea
```

Call a local function using its handle to compute the area of an ellipse. The `computeArea` function handle is the third element in the cell array.

```
fh{3}(3,1)
```

```
ans =
```

```
 9.4248
```

# log

Natural logarithm

## Syntax

$Y = \log(X)$

## Description

$Y = \log(X)$  returns the natural logarithm  $\ln(x)$  of each element in array  $X$ .

The `log` function's domain includes negative and complex numbers, which can lead to unexpected results if used unintentionally. For negative and complex numbers  $z = u + i*w$ , the complex logarithm `log(z)` returns

$\log(\text{abs}(z)) + 1i*\text{atan2}(w,u)$

If you want negative and complex numbers to return error messages rather than return complex results, use `reallog` instead.

## Examples

### Natural Logarithm of Negative Number

Show that the natural logarithm of -1 is  $i\pi$ .

```
log(-1)
```

```
ans =
```

```
0.0000 + 3.1416i
```

## Input Arguments

### **X** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Y — Logarithm values**

scalar | vector | matrix | multidimensional array

Logarithm values, returned as a scalar, vector, matrix, or multidimensional array.

For positive real values of X in the interval (0, Inf), Y is in the interval (-Inf,Inf). For complex and negative real values of X, Y is complex. The data type of Y is the same as that of X.

### **See Also**

**Introduced before R2006a**

# log10

Common logarithm (base 10)

## Syntax

$Y = \log_{10}(X)$

## Description

$Y = \log_{10}(X)$  returns the common logarithm of each element in array  $X$ . The function accepts both real and complex inputs. For real values of  $X$  in the interval  $(0, \text{Inf})$ ,  $\log_{10}$  returns real values in the interval  $(-\text{Inf}, \text{Inf})$ . For complex and negative real values of  $X$ , the  $\log_{10}$  function returns complex values.

## Examples

### Calculate Scalar Common Logarithm Values

Examine several values of the base 10 logarithm function.

Calculate the common logarithm of 1.

```
log10(1)
```

```
ans =
```

```
0
```

The result is 0, which is the x-intercept of the  $\log_{10}$  function.

Calculate the common logarithm of 10.

```
log10(10)
```

```
ans =
```

```
1
```

The result is 1 since  $10^1 = 10$ .

Calculate the common logarithm of 100.

```
log10(100)
```

```
ans =
```

```
2
```

The result is 2 since  $10^2 = 100$ .

Calculate the common logarithm of 0.

```
log10(0)
```

```
ans =
```

```
-Inf
```

The result is -Inf since  $10^{(-Inf)} = 0$ .

### **Real-Valued Common Logarithm**

Create a vector of real numbers in the interval [0.5, 10].

```
X = (0.5:0.5:10)';
```

Calculate the common logarithm of X.

```
Y = log10(X)
```

```
Y =
```

```
-0.3010
0
0.1761
0.3010

```

### Complex-Valued Common Logarithm

Create two Cartesian grids for X and Y.

```
[X,Y] = meshgrid(0:0.5:1.5, -2:0.5:2);
```

Calculate the complex base 10 logarithm  $\log_{10}(X + iY)$  on the grid. Use `1i` for improved speed and robustness with complex arithmetic.

```
Z = log10(X + 1i*Y)
```

Z =

```

0.3010 + 0.6822i 0.3142 + 0.5758i 0.3495 + 0.4808i 0.3979 + 0.4027i

```

## Input Arguments

### X — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double`  
Complex Number Support: Yes

**See Also**

`exp` | `log` | `log1p` | `log2` | `loglog` | `logm` | `reallog` | `semilogx` | `semilogy`

**Introduced before R2006a**

# log1p

Compute  $\log(1+x)$  accurately for small values of  $x$

## Syntax

$y = \log1p(x)$

## Description

$y = \log1p(x)$  computes  $\log(1+x)$ , compensating for the roundoff in  $1+x$ .  $\log1p(x)$  is more accurate than  $\log(1+x)$  for small values of  $x$ . For small  $x$ ,  $\log1p(x)$  is approximately  $x$ , whereas  $\log(1+x)$  can be zero.

## See Also

`log` | `expm1`

**Introduced before R2006a**

## log2

Base 2 logarithm and dissect floating-point numbers into exponent and mantissa

### Syntax

```
Y = log2(X)
[F,E] = log2(X)
```

### Description

$Y = \log_2(X)$  computes the base 2 logarithm of the elements of  $X$ .

$[F,E] = \log_2(X)$  returns arrays  $F$  and  $E$ . Argument  $F$  is an array of real values, usually in the range  $0.5 \leq \text{abs}(F) < 1$ . For real  $X$ ,  $F$  satisfies the equation:  $X = F \cdot 2.^E$ . Argument  $E$  is an array of integers that, for real  $X$ , satisfy the equation:  $X = F \cdot 2.^E$ .

### Examples

For IEEE arithmetic, the statement  $[F,E] = \log_2(X)$  yields the values:

<b>X</b>	<b>F</b>	<b>E</b>
1	1/2	1
pi	pi/4	2
-3	-3/4	2
eps	1/2	-51
realmax	1-eps/2	1024
realmin	1/2	-1021

## More About

### Tips

This function corresponds to the ANSI C function `frexp()` and the IEEE floating-point standard function `logb()`. Any zeros in `X` produce `F = 0` and `E = 0`.

### See Also

`log` | `pow2`

**Introduced before R2006a**

## logical

Convert numeric values to logicals

### Syntax

```
L = logical(A)
```

### Description

`L = logical(A)` converts `A` into an array of logical values. Any nonzero element of `A` is converted to logical 1 (`true`) and zeros are converted to logical 0 (`false`). Complex values and NaNs cannot be converted to logical values and result in a conversion error.

### Examples

#### Pick Odd Elements from Numeric Matrix

Pick out the odd-numbered elements of a numeric matrix.

Create a numeric matrix.

```
A = [1 -3 2;5 4 7;-8 1 3];
```

Find the modulus, `mod(A,2)`, and convert it to a logical array for indexing.

```
L = logical(mod(A,2))
```

```
L =
```

```
 1 1 0
 1 0 1
 0 1 1
```

The array has logical 1 (`true`) values where `A` is odd.

Use `L` as a logical index to pick out the odd elements of `A`.

```
A(L)
```

```
ans =
```

```
 1
 5
 -3
 1
 7
 3
```

The result is a vector containing all odd elements of A.

Use the logical NOT operator, `~`, on L to find the even elements of A.

```
A(~L)
```

```
ans =
```

```
 -8
 4
 2
```

## Input Arguments

### A — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

## More About

### Tips

- Most arithmetic operations involving logical arrays return double values. For example, adding zero to a logical array returns a double array.
- Logical arrays also are created by the relational operators (`==`, `<`, `>`, `~`, etc.) and functions like `any`, `all`, `isnan`, `isinf`, and `isfinite`.
- “Using Logicals in Array Indexing”

- “Determine if Arrays Are Logical”

**See Also**

false | islogical | true

**Introduced before R2006a**

# loglog

Log-log scale plot

## Syntax

```
loglog(Y)
loglog(X1,Y1,...)
loglog(X1,Y1,LineStyle,...)
loglog(...,'PropertyName',PropertyValue,...)
h = loglog(...)
```

## Description

`loglog(Y)` plots the columns of `Y` versus their index if `Y` contains real numbers. If `Y` contains complex numbers, `loglog(Y)` and `loglog(real(Y),imag(Y))` are equivalent. `loglog` ignores the imaginary component in all other uses of this function.

`loglog(X1,Y1,...)` plots all  $Y_n$  versus  $X_n$  pairs. If only one of  $X_n$  or  $Y_n$  is a matrix, `loglog` plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

`loglog(X1,Y1,LineStyle,...)` plots all lines defined by the  $X_n, Y_n, LineSpec$  triples, where `LineStyle` determines line type, marker symbol, and color of the plotted lines. You can mix  $X_n, Y_n, LineSpec$  triples with  $X_n, Y_n$  pairs, for example,

```
loglog(X1,Y1,X2,Y2,LineStyle,X3,Y3)
```

`loglog(...,'PropertyName',PropertyValue,...)` sets line property values for all the charting lines created. For a list of properties, see [Chart Line Properties](#).

`h = loglog(...)` returns a column vector of chart line handles, one handle per line.

If you do not specify a color when plotting more than one line, **loglog** automatically cycles through the colors and line styles in the order specified by the current axes.

If you attempt to add a **loglog**, **semilogx**, or **semilogy** plot to a linear axis mode graph with **hold on**, the axis mode remains as it is and the new data plots as linear.

## Examples

### Logarithmic Scale for Both Axes

Create a plot using a logarithmic scale for both the x-axis and the y-axis. Set the `LineStyle` string so that **loglog** plots using a line with square markers. Display the grid.

```
x = logspace(-1,2);
y = exp(x);

figure
loglog(x,y, '-s')
grid on
```

## See Also

### Functions

LineStyle | plot | semilogx | semilogy

### Properties

Chart Line Properties

Introduced before R2006a

# logm

Matrix logarithm

## Syntax

```
L = logm(A)
[L,exitflag] = logm(A)
```

## Description

$L = \text{logm}(A)$  is the principal matrix logarithm of  $A$ , the inverse of  $\text{expm}(A)$ . The output,  $L$ , is the unique logarithm for which every eigenvalue has imaginary part lying strictly between  $-\pi$  and  $\pi$ . If  $A$  is singular or has any eigenvalues on the negative real axis, then the principal logarithm is undefined. In this case, **logm** computes a nonprincipal logarithm and returns a warning message.

`[L,exitflag] = logm(A)` returns a scalar `exitflag` that describes the exit condition of **logm**:

- If `exitflag = 0`, the algorithm was successfully completed.
- If `exitflag = 1`, too many matrix square roots had to be computed. However, the computed value of  $L$  might still be accurate.

## Examples

### Compare Matrix Logarithms

Calculate the matrix exponential of a matrix,  $A$ .

```
A = [1 1 0; 0 0 2; 0 0 -1];
Y = expm(A)
```

```
Y =
```

```
 2.7183 1.7183 1.0862
```

```

0 1.0000 1.2642
0 0 0.3679

```

Calculate the matrix logarithm of Y to reproduce the original matrix, A.

P = logm(Y)

P =

```

1.0000 1.0000 0.0000
0 0 2.0000
0 0 -1.0000

```

log(A) involves taking the logarithm of zero, so it produces inferior results.

Q = log(A)

Q =

```

0.0000 + 0.0000i 0.0000 + 0.0000i -Inf + 0.0000i
-Inf + 0.0000i -Inf + 0.0000i 0.6931 + 0.0000i
-Inf + 0.0000i -Inf + 0.0000i 0.0000 + 3.1416i

```

## Input Arguments

### A — Input matrix

square matrix

Input matrix, specified as a square matrix.

Data Types: `single` | `double`

Complex Number Support: Yes

## Limitations

- For most matrices:

$$\text{logm}(\text{expm}(A)) = A = \text{expm}(\text{logm}(A))$$

These identities can fail for some  $A$ . For example, if the computed eigenvalues of  $A$  include an exact zero, then  $\text{logm}(A)$  generates infinity. Or, if the elements of  $A$  are too large,  $\text{expm}(A)$  can overflow.

## More About

### Tips

- If  $A$  is real symmetric or complex Hermitian, then so is  $\text{logm}(A)$ .
- Some matrices, like  $A = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$ , do not have any logarithms, real or complex, so  $\text{logm}$  cannot be expected to produce one.

### Algorithms

The algorithm  $\text{logm}$  uses is described in [1] and [2].

# logspace

Generate logarithmically spaced vector

## Syntax

```
y = logspace(a,b)
y = logspace(a,b,n)
y = logspace(a,pi)
```

## Description

`y = logspace(a,b)` generates a row vector `y` of 50 logarithmically spaced points between decades  $10^a$  and  $10^b$ . The `logspace` function is especially useful for creating frequency vectors. The function is the logarithmic equivalent of `linspace` and the `:` operator.

`y = logspace(a,b,n)` generates `n` points between decades  $10^a$  and  $10^b$ .

`y = logspace(a,pi)` generates points between  $10^a$  and `pi`, which is useful in digital signal processing for creating logarithmically spaced frequencies in the interval  $[10^a, \pi]$ .

## Examples

### Vector of Logarithmically Spaced Numbers

Create a vector of 50 logarithmically spaced points in the interval  $[10^1, 10^5]$ .

```
y = logspace(1,5);
```

### Vector with Specified Number of Values

Create a vector of 7 logarithmically spaced points in the interval  $[10^1, 10^5]$ .

```
y1 = logspace(1,5,7)
```

```
y1 =
1.0e+05 *
0.0001 0.0005 0.0022 0.0100 0.0464 0.2154 1.0000
```

## Vector of Logarithmically Spaced Complex Numbers

Create a vector of complex numbers with 8 logarithmically spaced points between  $10^{(1+2i)}$  and  $10^{(5+5i)}$ .

```
y = logspace(1+2i,5+5i,8)
```

```
y =
1.0e+04 *
Columns 1 through 4
-0.0001 - 0.0010i 0.0029 - 0.0024i 0.0133 + 0.0040i 0.0147 + 0.0497i
Columns 5 through 8
-0.1242 + 0.1479i -0.7150 - 0.0822i -1.2137 - 2.3924i 4.9458 - 8.6913i
```

## Input Arguments

### **a** — First bound

numeric scalar

First bound, specified as a numeric scalar. The **a** argument defines a bound of the interval over which `logspace` generates points. **a** can be real or complex, and the other bound, **b**, can be either larger or smaller than **a**. If **b** is smaller than **a**, then the vector contains descending values.

Data Types: `single` | `double`

Complex Number Support: Yes

### **b** — Second bound

numeric scalar

Second bound, specified as a numeric scalar. The **b** argument defines a bound of the interval over which **logspace** generates points. **b** can be real or complex, and **b** can be either larger or smaller than the other bound, **a**. If **b** is smaller than **a**, then the vector contains descending values.

Data Types: `single` | `double`

Complex Number Support: Yes

### **n** — Number of points

50 (default) | real numeric scalar

Number of points, specified as a real numeric scalar.

- If **n** is 1, **logspace** returns  $10^b$ .
- If **n** is zero or negative, **logspace** returns an empty row vector.
- If **n** is not an integer, **logspace** rounds **n** down and returns `floor(n)` points.

### **See Also**

`colon` | `linspace`

**Introduced before R2006a**

## lookfor

Search for keyword in all help entries

### Alternatives

As an alternative to the `lookfor` function, use the Function Browser.

### Syntax

```
lookfor topic
lookfor topic -all
```

### Description

`lookfor topic` searches for the string `topic` in the first comment line (the H1 line) of the help text in all MATLAB program files found on the search path. For all files in which a match occurs, `lookfor` displays the H1 line.

`lookfor topic -all` searches the entire first comment block of a MATLAB program file looking for `topic`.

### Examples

For example:

```
lookfor inverse
```

finds at least a dozen matches, including H1 lines containing "inverse hyperbolic cosine," "two-dimensional inverse FFT," and "pseudoinverse." Contrast this with

```
which inverse
```

```
or
```

```
what inverse
```

These functions run more quickly, but probably fail to find anything because MATLAB does not have a function `inverse`.

In summary, `what` lists the functions in a given folder, `which` finds the folder containing a given function or file, and `lookfor` finds all functions in all folders that might have something to do with a given keyword.

Even more extensive than the `lookfor` function are the find features in the Current Folder browser. For example, you can look for all occurrences of a specified word in all the MATLAB program files in the current folder and its subfolders. For more information, see “Find Files and Folders”.

## lower

Convert string to lowercase

### Syntax

```
t = lower('str')
B = lower(A)
```

### Description

`t = lower('str')` returns the string formed by converting any uppercase characters in `str` to the corresponding lowercase characters and leaving all other characters unchanged.

`B = lower(A)` when `A` is a cell array of strings, returns a cell array the same size as `A` containing the result of applying `lower` to each string within `A`.

### Examples

`lower('MathWorks')` is `mathworks`.

### More About

#### Tips

Character sets supported:

- PC: Latin-1 for the Microsoft Windows operating system
- Other: ISO Latin-1 (ISO 8859-1)

#### See Also

`upper`

**Introduced before R2006a**

## ls

List folder contents

### Syntax

```
ls
ls name
list = ls(name)
```

### Description

`ls` lists the contents of the current folder.

`ls name` lists the files and folders in the current folder that match the specified name. You can use wildcards.

`list = ls(name)` returns the files and folders in the current folder that match the specified name to `list`.

### Input Arguments

#### **name**

A string value specifying a file or folder name.

### Output Arguments

#### **list**

- On UNIX platforms, `list` is a character row vector of names separated by tab and space characters.
- On Microsoft Windows platforms, `list` is an `m`-by-`n` character array of names—`m` is the number of names and `n` is the number of characters in the longest name. MATLAB pads names shorter than `n` characters with space characters.

## Examples

List all the files and folders in the current folder:

```
ls
```

List all the files and folders in the current folder that begin with the letter h:

```
ls h*
```

Return the list of all the files and folders in the current folder to `mylist`:

```
mylist = ls;
```

## Alternatives

- View files and folders in the Current Folder browser.

Open the Current Folder browser by issuing the `filebrowser` command.

## More About

### Tips

- On UNIX platforms, you can add any flags to `ls` that the operating system supports.

## lscov

Least-squares solution in presence of known covariance

### Syntax

```
x = lscov(A,B)
x = lscov(A,B,w)
x = lscov(A,B,V)
x = lscov(A,B,V,alg)
[x,stdx] = lscov(...)
[x,stdx,mse] = lscov(...)
[x,stdx,mse,S] = lscov(...)
```

### Description

`x = lscov(A,B)` returns the ordinary least squares solution to the linear system of equations  $A*x = B$ , i.e.,  $x$  is the  $n$ -by-1 vector that minimizes the sum of squared errors  $(B - A*x)'*(B - A*x)$ , where  $A$  is  $m$ -by- $n$ , and  $B$  is  $m$ -by-1.  $B$  can also be an  $m$ -by- $k$  matrix, and `LSCOV` returns one solution for each column of  $B$ . When  $\text{rank}(A) < n$ , `LSCOV` sets the maximum possible number of elements of  $x$  to zero to obtain a "basic solution".

`x = lscov(A,B,w)`, where  $w$  is a vector length  $m$  of real positive weights, returns the weighted least squares solution to the linear system  $A*x = B$ , that is,  $x$  minimizes  $(B - A*x)'*diag(w)*(B - A*x)$ .  $w$  typically contains either counts or inverse variances.

`x = lscov(A,B,V)`, where  $V$  is an  $m$ -by- $m$  real symmetric positive definite matrix, returns the generalized least squares solution to the linear system  $A*x = B$  with covariance matrix proportional to  $V$ , that is,  $x$  minimizes  $(B - A*x)'*inv(V)*(B - A*x)$ .

More generally,  $V$  can be positive semidefinite, and `LSCOV` returns  $x$  that minimizes  $e'*e$ , subject to  $A*x + T*e = B$ , where the minimization is over  $x$  and  $e$ , and  $T*T' = V$ . When  $V$  is semidefinite, this problem has a solution only if  $B$  is consistent with  $A$  and  $V$  (that is,  $B$  is in the column space of  $[A \ T]$ ), otherwise `LSCOV` returns an error.

By default, `lscov` computes the Cholesky decomposition of  $V$  and, in effect, inverts that factor to transform the problem into ordinary least squares. However, if `lscov` determines that  $V$  is semidefinite, it uses an orthogonal decomposition algorithm that avoids inverting  $V$ .

`x = lscov(A,B,V,alg)` specifies the algorithm used to compute  $x$  when  $V$  is a matrix. `alg` can have the following values:

- 'chol' uses the Cholesky decomposition of  $V$ .
- 'orth' uses orthogonal decompositions, and is more appropriate when  $V$  is ill-conditioned or singular, but is computationally more expensive.

`[x,stdx] = lscov(...)` returns the estimated standard errors of  $x$ . When  $A$  is rank deficient, `stdx` contains zeros in the elements corresponding to the necessarily zero elements of  $x$ .

`[x,stdx,mse] = lscov(...)` returns the mean squared error. If  $B$  is assumed to have covariance matrix  $\sigma^2V$  (or  $(\sigma^2)\times\text{diag}(1/M)$ ), then `mse` is an estimate of  $\sigma^2$ .

`[x,stdx,mse,S] = lscov(...)` returns the estimated covariance matrix of  $x$ . When  $A$  is rank deficient, `S` contains zeros in the rows and columns corresponding to the necessarily zero elements of  $x$ . `lscov` cannot return `S` if it is called with multiple right-hand sides, that is, if `size(B,2) > 1`.

The standard formulas for these quantities, when  $A$  and  $V$  are full rank, are

- $x = \text{inv}(A' \cdot \text{inv}(V) \cdot A) \cdot A' \cdot \text{inv}(V) \cdot B$
- $\text{mse} = B' \cdot (\text{inv}(V) - \text{inv}(V) \cdot A \cdot \text{inv}(A' \cdot \text{inv}(V) \cdot A) \cdot A' \cdot \text{inv}(V)) \cdot B ./ (m-n)$
- $S = \text{inv}(A' \cdot \text{inv}(V) \cdot A) \cdot \text{mse}$
- $\text{stdx} = \text{sqrt}(\text{diag}(S))$

However, `lscov` uses methods that are faster and more stable, and are applicable to rank deficient cases.

`lscov` assumes that the covariance matrix of  $B$  is known only up to a scale factor. `mse` is an estimate of that unknown scale factor, and `lscov` scales the outputs `S` and `stdx` appropriately. However, if  $V$  is known to be exactly the covariance matrix of  $B$ , then that scaling is unnecessary. To get the appropriate estimates in this case, you should rescale `S` and `stdx` by  $1/\text{mse}$  and  $\text{sqrt}(1/\text{mse})$ , respectively.

## Examples

### Example 1 — Computing Ordinary Least Squares

The MATLAB backslash operator (`\`) enables you to perform linear regression by computing ordinary least-squares (OLS) estimates of the regression coefficients. You can also use `lscov` to compute the same OLS estimates. By using `lscov`, you can also compute estimates of the standard errors for those coefficients, and an estimate of the standard deviation of the regression error term:

```
x1 = [.2 .5 .6 .8 1.0 1.1]';
x2 = [.1 .3 .4 .9 1.1 1.4]';
X = [ones(size(x1)) x1 x2];
y = [.17 .26 .28 .23 .27 .34]';
```

```
a = X\y
a =
 0.1203
 0.3284
 -0.1312
```

```
[b,se_b,mse] = lscov(X,y)
b =
 0.1203
 0.3284
 -0.1312
se_b =
 0.0643
 0.2267
 0.1488
mse =
 0.0015
```

### Example 2 — Computing Weighted Least Squares

Use `lscov` to compute a weighted least-squares (WLS) fit by providing a vector of relative observation weights. For example, you might want to downweight the influence of an unreliable observation on the fit:

```
w = [1 1 1 1 1 .1]';
[bw,sew_b,msew] = lscov(X,y,w)
```

```

bw =
 0.1046
 0.4614
 -0.2621
sew_b =
 0.0309
 0.1152
 0.0814
msew =
 3.4741e-004

```

### Example 3 — Computing General Least Squares

Use `lscov` to compute a general least-squares (GLS) fit by providing an observation covariance matrix. For example, your data may not be independent:

```
V = .2*ones(length(x1)) + .8*diag(ones(size(x1)));
```

```

[bg,sew_b,mseg] = lscov(X,y,V)
bg =
 0.1203
 0.3284
 -0.1312
sew_b =
 0.0672
 0.2267
 0.1488
mseg =
 0.0019

```

### Example 4 — Estimating the Coefficient Covariance Matrix

Compute an estimate of the coefficient covariance matrix for either OLS, WLS, or GLS fits. The coefficient standard errors are equal to the square roots of the values on the diagonal of this covariance matrix:

```

[b,se_b,mse,S] = lscov(X,y);

S
S =
 0.0041 -0.0130 0.0075
 -0.0130 0.0514 -0.0328
 0.0075 -0.0328 0.0221

```

```
[se_b sqrt(diag(S))]
ans =
 0.0643 0.0643
 0.2267 0.2267
 0.1488 0.1488
```

## More About

### Algorithms

The vector  $x$  minimizes the quantity  $(A*x-B)'*inv(V)*(A*x-B)$ . The classical linear algebra solution to this problem is

$$x = inv(A'*inv(V)*A)*A'*inv(V)*B$$

but the `lsqcov` function instead computes the QR decomposition of  $A$  and then modifies  $Q$  by  $V$ .

# lsqnonneg

Solve nonnegative least-squares constraints problem

## Equation

Solves nonnegative least-squares curve fitting problems of the form

$$\min_x \|C \cdot x - d\|_2^2, \text{ where } x \geq 0.$$

## Syntax

```
x = lsqnonneg(C,d)
x = lsqnonneg(C,d,options)
x = lsqnonneg(problem)
[x,resnorm] = lsqnonneg(...)
[x,resnorm,residual] = lsqnonneg(...)
[x,resnorm,residual,exitflag] = lsqnonneg(...)
[x,resnorm,residual,exitflag,output] = lsqnonneg(...)
[x,resnorm,residual,exitflag,output,lambda] = lsqnonneg(...)
```

## Description

`x = lsqnonneg(C,d)` returns the vector `x` that minimizes `norm(C*x-d)` subject to `x >= 0`. `C` and `d` must be real.

`x = lsqnonneg(C,d,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `lsqnonneg` uses these `options` structure fields:

<b>Display</b>	Level of display. 'off' displays no output; 'final' displays just the final output; 'notify' (default) displays output only if the function does not converge.
----------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------

**TolX** Termination tolerance on  $x$ , a positive scalar. The default is  $10 \cdot \text{eps} \cdot \text{norm}(C, 1) \cdot \text{length}(C)$ .

$x = \text{lsqnonneg}(\text{problem})$  finds the minimum for `problem`, where `problem` is a structure with the following fields:

**C** Matrix  
**d** Vector  
**solver** 'lsqnonneg'  
**options** Options structure created using `optimset`

$[x, \text{resnorm}] = \text{lsqnonneg}(\dots)$  returns the value of the squared 2-norm of the residual:  $\text{norm}(C \cdot x - d)^2$ .

$[x, \text{resnorm}, \text{residual}] = \text{lsqnonneg}(\dots)$  returns the residual,  $d - C \cdot x$ .

$[x, \text{resnorm}, \text{residual}, \text{exitflag}] = \text{lsqnonneg}(\dots)$  returns a value `exitflag` that describes the exit condition of `lsqnonneg`:

>0 Indicates that the function converged to a solution  $x$ .

0 Indicates that the iteration count was exceeded. Increasing the tolerance (`TolX` parameter in `options`) may lead to a solution.

$[x, \text{resnorm}, \text{residual}, \text{exitflag}, \text{output}] = \text{lsqnonneg}(\dots)$  returns a structure `output` that contains information about the operation in the following fields:

**algorithm** 'active-set'  
**iterations** The number of iterations taken  
**message** Exit message

$[x, \text{resnorm}, \text{residual}, \text{exitflag}, \text{output}, \text{lambda}] = \text{lsqnonneg}(\dots)$  returns the dual vector (Lagrange multipliers) `lambda`, where  $\text{lambda}(i) \leq 0$  when  $x(i)$  is (approximately) 0, and  $\text{lambda}(i)$  is (approximately) 0 when  $x(i) > 0$ .

## Examples

Compare the unconstrained least squares solution to the `lsqnonneg` solution for a 4-by-2 problem:

```

C = [
 0.0372 0.2869
 0.6861 0.7071
 0.6233 0.6245
 0.6344 0.6170];
d = [
 0.8587
 0.1781
 0.0747
 0.8405];
[C\d lsqnonneg(C,d)] =
 -2.5627 0
 3.1108 0.6929
[norm(C*(C\d)-d) norm(C*lsqnonneg(C,d)-d)] =
 0.6674 0.9118

```

The solution from `lsqnonneg` does not fit as well (has a larger residual), as the least squares solution. However, the nonnegative least squares solution has no negative components.

## More About

### Algorithms

`lsqnonneg` uses the algorithm described in [1]. The algorithm starts with a set of possible basis vectors and computes the associated dual vector `lambda`. It then selects the basis vector corresponding to the maximum value in `lambda` in order to swap out of the basis in exchange for another possible candidate. This continues until `lambda <= 0`.

`optimset`

Introduced before R2006a

# lsqr

LSQR method

## Syntax

```
x = lsqr(A,b)
lsqr(A,b,tol)
lsqr(A,b,tol,maxit)
lsqr(A,b,tol,maxit,M)
lsqr(A,b,tol,maxit,M1,M2)
lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter,resvec] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter,resvec,lsvec] = lsqr(A,b,tol,maxit,M1,M2,x0)
```

## Description

`x = lsqr(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$  if  $A$  is consistent, otherwise it attempts to solve the least squares solution  $x$  that minimizes  $\text{norm}(b-A*x)$ . The  $m$ -by- $n$  coefficient matrix  $A$  need not be square but it should be large and sparse. The column vector  $b$  must have length  $m$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x, 'notransp')` returns  $A*x$  and `afun(x, 'transp')` returns  $A' * x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `lsqr` converges, a message to that effect is displayed. If `lsqr` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x) / \text{norm}(b)$  and the iteration number at which the method stopped or failed.

`lsqr(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `lsqr` uses the default,  $1e-6$ .

`lsqr(A,b,tol,maxit)` specifies the maximum number of iterations.

`lsqr(A,b,tol,maxit,M)` and `lsqr(A,b,tol,maxit,M1,M2)` use n-by-n preconditioner `M` or `M = M1*M2` and effectively solve the system  $A \cdot \text{inv}(M) \cdot y = b$  for `y`, where  $y = M \cdot x$ . If `M` is `[]` then `lsqr` applies no preconditioner. `M` can be a function `mfun` such that `mfun(x, 'notransp')` returns  $M \setminus x$  and `mfun(x, 'transp')` returns  $M' \setminus x$ .

`lsqr(A,b,tol,maxit,M1,M2,x0)` specifies the n-by-1 initial guess. If `x0` is `[]`, then `lsqr` uses the default, an all zero vector.

`[x,flag] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a convergence flag.

Flag	Convergence
0	lsqr converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	lsqr iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	lsqr stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>lsqr</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if you specify the `flag` output.

`[x,flag,relres] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns an estimate of the relative residual  $\text{norm}(b-A \cdot x) / \text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a vector of the residual norm estimates at each iteration, including  $\text{norm}(b-A \cdot x_0)$ .

`[x,flag,relres,iter,resvec,lsvec] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a vector of estimates of the scaled normal equations residual at each iteration:  $\text{norm}(A \cdot \text{inv}(M)' \cdot (B-A \cdot X)) / \text{norm}(A \cdot \text{inv}(M), 'fro')$ . Note that the estimate of  $\text{norm}(A \cdot \text{inv}(M), 'fro')$  changes, and hopefully improves, at each iteration.

## Examples

### Example 1

```
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);

x = lsqr(A,b,tol,maxit,M1,M2);
```

displays the following message:

```
lsqr converged at iteration 11 to a solution with relative
residual 3.5e-009
```

### Example 2

This example replaces the matrix **A** in Example 1 with a handle to a matrix-vector product function **afun**. The example is contained in a function **run\_lsqr** that

- Calls **lsqr** with the function handle **@afun** as its first argument.
- Contains **afun** as a nested function, so that all variables in **run\_lsqr** are available to **afun**.

The following shows the code for **run\_lsqr**:

```
function x1 = run_lsqr
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = lsqr(@afun,b,tol,maxit,M1,M2);
```

```

function y = afun(x,transp_flag)
 if strcmp(transp_flag,'transp') % y = A'*x
 y = 4 * x;
 y(1:n-1) = y(1:n-1) - 2 * x(2:n);
 y(2:n) = y(2:n) - x(1:n-1);
 elseif strcmp(transp_flag,'notransp') % y = A*x
 y = 4 * x;
 y(2:n) = y(2:n) - 2 * x(1:n-1);
 y(1:n-1) = y(1:n-1) - x(2:n);
 end
end
end
end

```

When you enter

```
x1=run_lsqr;
```

MATLAB software displays the message

```
lsqr converged at iteration 11 to a solution with relative
residual 3.5e-009
```

Introduced before R2006a

## lt, <

Determine less than

## Syntax

```
A < B
lt(A,B)
```

## Description

`A < B` returns an array with elements set to logical 1 (`true`) where `A` is less than `B`; otherwise, it returns logical 0 (`false`).

The test compares only the real part of numeric arrays. `lt` returns logical 0 (`false`) where `A` or `B` have NaN or undefined categorical elements.

`lt(A,B)` is an alternate way to execute `A < B`, but is rarely used. It enables operator overloading for classes.

## Examples

### Test Vector Elements

Determine if vector elements are less than a given value.

Create a numeric vector.

```
A = [1 12 18 7 9 11 2 15];
```

Test the vector for elements that are less than 12.

```
A < 12
```

```
ans =
```

```
 1 0 0 1 1 1 1 0
```

The result is a vector with values of logical 1 (true) where the elements of A satisfy the expression.

Use the vector of logical values as an index to view the values in A that are less than 12.

```
A(A < 12)
```

```
ans =
```

```
 1 7 9 11 2
```

The result is a subset of the elements in A.

### Replace Elements of Matrix

Create a matrix.

```
A = magic(4)
```

```
A =
```

```
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

Replace all values less than 9 with the value 10.

```
A(A < 9) = 10
```

```
A =
```

```
 16 10 10 13
 10 11 10 10
 9 10 10 12
 10 14 15 10
```

The result is a new matrix whose smallest element is 9.

### Compare Values in Categorical Array

Create an ordinal categorical array.

```
A = categorical({'large' 'medium' 'small'; 'medium' ...
 'small' 'large'}, {'small' 'medium' 'large'}, 'Ordinal', 1)
```

A =

```
 large medium small
 medium small large
```

The array has three categories: 'small', 'medium', and 'large'.

Find all values less than the category 'medium'.

```
A < 'medium'
```

ans =

```
 0 0 1
 0 1 0
```

A value of logical 1 (true) indicates a value less than the category 'medium'.

Compare the rows of A.

```
A(1,:) < A(2,:)
```

ans =

```
 0 0 1
```

The function returns logical 1 (true) where the first row has a category value less than the second row.

## Test Complex Numbers

Create a vector of complex numbers.

```
A = [1+i 2-2i 1+3i 1-2i 5-i];
```

Find the values that are less than 3.

```
A(A < 3)
```

ans =

```
1.0000 + 1.0000i 2.0000 - 2.0000i 1.0000 + 3.0000i 1.0000 - 2.0000i
```

It compares only the real part of the elements in A.

Use `abs` to find which elements are within a radius of 3 from the origin.

```
A(abs(A) < 3)
```

```
ans =
```

```
1.0000 + 1.0000i 2.0000 - 2.0000i 1.0000 - 2.0000i
```

The result has one less element. The element  $1.0000 + 3.0000i$  is not within a radius of 3 from the origin.

### Compare Dates

Create a vector of dates.

```
A = datetime([2014,05,01;2014,05,31])
```

```
A =
```

```
01-May-2014
31-May-2014
```

Find the dates that occur before May 10, 2014.

```
A(A < '2014-05-10')
```

```
ans =
```

```
01-May-2014
```

## Input Arguments

### A — Left array

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Left array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

## **B — Right array**

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Right array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

# lu

LU matrix factorization

## Syntax

```

Y = lu(A)
[L,U] = lu(A)
[L,U,P] = lu(A)
[L,U,P,Q] = lu(A)
[L,U,P,Q,R] = lu(A)
[...] = lu(A, 'vector')
[...] = lu(A, thresh)
[...] = lu(A, thresh, 'vector')

```

## Description

The `lu` function expresses a matrix  $A$  as the product of two essentially triangular matrices, one of them a permutation of a lower triangular matrix and the other an upper triangular matrix. The factorization is often called the  $LU$ , or sometimes the  $LR$ , factorization.  $A$  can be rectangular.

`Y = lu(A)` returns matrix  $Y$  that, for sparse  $A$ , contains the strictly lower triangular  $L$ , i.e., without its unit diagonal, and the upper triangular  $U$  as submatrices. That is, if `[L,U,P] = lu(A)`, then  $Y = U + L - \text{eye}(\text{size}(A))$ . For nonsparse  $A$ ,  $Y$  is the output from the LAPACK `dgetrf` or `zgetrf` routine. The permutation matrix  $P$  is not returned.

`[L,U] = lu(A)` returns an upper triangular matrix in  $U$  and a permuted lower triangular matrix in  $L$  such that  $A = L*U$ . Return value  $L$  is a product of lower triangular and permutation matrices.

`[L,U,P] = lu(A)` returns an upper triangular matrix in  $U$ , a lower triangular matrix  $L$  with a unit diagonal, and a permutation matrix  $P$ , such that  $L*U = P*A$ . The statement `lu(A, 'matrix')` returns identical output values.

`[L,U,P,Q] = lu(A)` for sparse nonempty  $A$ , returns a unit lower triangular matrix  $L$ , an upper triangular matrix  $U$ , a row permutation matrix  $P$ , and a column reordering

matrix  $Q$ , so that  $P^*A^*Q = L^*U$ . If  $A$  is empty or not sparse, `lu` displays an error message. The statement `lu(A, 'matrix')` returns identical output values.

`[L,U,P,Q,R] = lu(A)` returns unit lower triangular matrix  $L$ , upper triangular matrix  $U$ , permutation matrices  $P$  and  $Q$ , and a diagonal scaling matrix  $R$  so that  $P^*(R\backslash A)^*Q = L^*U$  for sparse non-empty  $A$ . Typically, but not always, the row-scaling leads to a sparser and more stable factorization. The statement `lu(A, 'matrix')` returns identical output values.

`[...] = lu(A, 'vector')` returns the permutation information in two row vectors  $p$  and  $q$ . You can specify from 1 to 5 outputs. Output  $p$  is defined as  $A(p, :)=L^*U$ , output  $q$  is defined as  $A(:, q)=L^*U$ , and output  $R$  is defined as  $R(:, p)\backslash A(:, q)=L^*U$ .

`[...] = lu(A, thresh)` controls pivoting. This syntax applies to sparse matrices only. The `thresh` input is a one- or two-element vector of type `single` or `double` that defaults to `[0.1, 0.001]`. If  $A$  is a square matrix with a mostly symmetric structure and mostly nonzero diagonal, MATLAB uses a symmetric pivoting strategy. For this strategy, the diagonal where

$$A(i, j) \geq \text{thresh}(2) * \max(\text{abs}(A(j:m, j)))$$

is selected. If the diagonal entry fails this test, a pivot entry below the diagonal is selected, using `thresh(1)`. In this case,  $L$  has entries with absolute value  $1/\min(\text{thresh})$  or less.

If  $A$  is not as described above, MATLAB uses an asymmetric strategy. In this case, the sparsest row  $i$  where

$$A(i, j) \geq \text{thresh}(1) * \max(\text{abs}(A(j:m, j)))$$

is selected. A value of 1.0 results in conventional partial pivoting. Entries in  $L$  have an absolute value of  $1/\text{thresh}(1)$  or less. The second element of the `thresh` input vector is not used when MATLAB uses an asymmetric strategy.

Smaller values of `thresh(1)` and `thresh(2)` tend to lead to sparser LU factors, but the solution can become inaccurate. Larger values can lead to a more accurate solution (but not always), and usually an increase in the total work and memory usage. The statement `lu(A, thresh, 'matrix')` returns identical output values.

`[...] = lu(A, thresh, 'vector')` controls the pivoting strategy and also returns the permutation information in row vectors, as described above. The `thresh` input must precede `'vector'` in the input argument list.

---

**Note** In rare instances, incorrect factorization results in  $P^*A^*Q \neq L^*U$ . Increase `thresh`, to a maximum of 1.0 (regular partial pivoting), and try again.

---

## Arguments

A	Rectangular matrix to be factored.
thresh	Pivot threshold for sparse matrices. Valid values are in the interval $[0, 1]$ . If you specify the fourth output Q, the default is 0.1. Otherwise, the default is 1.0.
L	Factor of A. Depending on the form of the function, L is either a unit lower triangular matrix, or else the product of a unit lower triangular matrix with P'.
U	Upper triangular matrix that is a factor of A.
P	Row permutation matrix satisfying the equation $L^*U = P^*A$ , or $L^*U = P^*A^*Q$ . Used for numerical stability.
Q	Column permutation matrix satisfying the equation $P^*A^*Q = L^*U$ . Used to reduce fill-in in the sparse case.
R	Row-scaling matrix

## Examples

### Example 1

Start with

```
A = [1 2 3
 4 5 6
 7 8 0];
```

To see the LU factorization, call `lu` with two output arguments.

```
[L1,U] = lu(A)
```

```
L1 =
 0.1429 1.0000 0
```

$$\begin{matrix} 0.5714 & 0.5000 & 1.0000 \\ 1.0000 & 0 & 0 \end{matrix}$$

$$U = \begin{matrix} 7.0000 & 8.0000 & 0 \\ 0 & 0.8571 & 3.0000 \\ 0 & 0 & 4.5000 \end{matrix}$$

Notice that L1 is a permutation of a lower triangular matrix: if you switch rows 2 and 3, and then switch rows 1 and 2, the resulting matrix is lower triangular and has 1s on the diagonal. Notice also that U is upper triangular. To check that the factorization does its job, compute the product

$$L1*U$$

which returns the original A. The inverse of the example matrix,  $X = \text{inv}(A)$ , is actually computed from the inverses of the triangular factors

$$X = \text{inv}(U)*\text{inv}(L1)$$

Using three arguments on the left side to get the permutation matrix as well,

$$[L2,U,P] = \text{lu}(A)$$

returns a truly lower triangular L2, the same value of U, and the permutation matrix P.

$$L2 =$$

$$\begin{matrix} 1.0000 & 0 & 0 \\ 0.1429 & 1.0000 & 0 \\ 0.5714 & 0.5000 & 1.0000 \end{matrix}$$

$$U = \begin{matrix} 7.0000 & 8.0000 & 0 \\ 0 & 0.8571 & 3.0000 \\ 0 & 0 & 4.5000 \end{matrix}$$

$$P = \begin{matrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{matrix}$$

Note that  $L2 = P*L1$ .

$$P*L1$$

ans =

```

1.0000 0 0
0.1429 1.0000 0
0.5714 0.5000 1.0000

```

To verify that  $L2*U$  is a permuted version of  $A$ , compute  $L2*U$  and subtract it from  $P*A$ :

$P*A - L2*U$

ans =

```

0 0 0
0 0 0
0 0 0

```

In this case,  $\text{inv}(U) * \text{inv}(L)$  results in the permutation of  $\text{inv}(A)$  given by  $\text{inv}(P) * \text{inv}(A)$ .

The determinant of the example matrix is

$d = \det(A)$

$d = 27$

It is computed from the determinants of the triangular factors

$d = \det(L) * \det(U)$

The solution to  $Ax = b$  is obtained with matrix division

$x = A \backslash b$

The solution is actually computed by solving two triangular systems

$y = L \backslash b$

$x = U \backslash y$

## Example 2

The 1-norm of their difference is within roundoff error, indicating that  $L*U = P*B*Q$ .

Generate a 60-by-60 sparse adjacency matrix of the connectivity graph of the Buckminster-Fuller geodesic dome.

```
B = bucky;
```

Use the sparse matrix syntax with four outputs to get the row and column permutation matrices.

```
[L,U,P,Q] = lu(B);
```

Apply the permutation matrices to **B**, and subtract the product of the lower and upper triangular matrices.

```
Z = P*B*Q - L*U;
norm(Z,1)
```

```
ans =
 7.9936e-015
```

### Example 3

This example illustrates the benefits of using the 'vector' option. Note how much memory is saved by using the `lu(F, 'vector')` syntax.

```
F = gallery('uniformdata',[1000 1000],0);
g = sum(F,2);
[L,U,P] = lu(F);
[L,U,p] = lu(F,'vector');
whos P p
```

Name	Size	Bytes	Class	Attributes
P	1000x1000	8000000	double	
p	1x1000	8000	double	

The following two statements are equivalent. The first typically requires less time:

```
x = U \ (L \ (g(p,:)));
y = U \ (L \ (P*g));
```

## More About

### Tips

Most of the algorithms for computing LU factorization are variants of Gaussian elimination. The factorization is a key step in obtaining the inverse with `inv` and the

determinant with `det`. It is also the basis for the linear equation solution or matrix division obtained with `\` and `/`.

## Primitive Line Properties

Control primitive line appearance and behavior

Primitive line properties control the appearance and behavior of a primitive line object. By changing property values, you can modify certain aspects of the line.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = line;
s = h.LineStyle;
h.LineStyle = ':';
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Line

#### LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	
'--'	Dashed line	
':'	Dotted line	
'-.'	Dash-dotted line	
'none'	No line	No line

#### LineWidth — Line width

0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

**Color — Line color**

[0 0 0] (default) | RGB triplet | color string | 'none'

Line color, specified as an RGB triplet, a color string or 'none'. The default RGB triplet value of [0 0 0] corresponds to black. If you specify the color as 'none', then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

**LineJoin — Style of line corners**

'round' (default) | 'miter' | 'chamfer'

Style of line corners, specified as 'round', 'miter', or 'chamfer'. This table illustrates the appearance of the different values.

The appearance of the 'round' option might look different if the `Renderer` property of the figure is set to 'opengl' instead of 'painters'.

### **AlignVertexCenters** — Sharp vertical and horizontal lines

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a `GraphicsSmoothing` property set to 'on' and a `Renderer` property set to 'opengl', then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- 'off' — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- 'on' — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

---

**Note:** You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

---

## **Markers**

### **Marker** — Marker symbol

'none' (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the primitive line object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

### **MarkerSize** — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

### **MarkerEdgeColor** — Marker outline color

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the **Color** property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

Example:  $[0.5 \ 0.5 \ 0.5]$

Example: 'blue'

### **MarkerFaceColor** — Marker fill color

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the Color property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]

Long Name	Short Name	RGB Triplet
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.3 0.2 0.1]

Example: 'green'

## Data

### XData — x values

[0 1] (default) | vector

$x$  values, specified as a vector. XData and YData must have equal lengths.

Example: 1:10

### YData — y values

[0 1] (default) | vector

$y$  values, specified as a vector. XData and YData must have equal lengths.

Example: 1:10

### ZData — z values

empty matrix (default) | vector

$z$  values, specified as a vector. ZData must have the same length as XData and YData.

Example: 1:10

## Visibility

### Visible — State of visibility

'on' (default) | 'off'

State of visibility, specified as one of these values:

- 'on' — Display the primitive line.
- 'off' — Hide the primitive line without deleting it. You still can access the properties of an invisible primitive line object.

**Clipping — Clipping of primitive line object to axes limits**

'on' (default) | 'off'

Clipping of the primitive line object to the axes limits, specified as one of these values:

- 'on' — Do not display parts of the primitive line object that are outside the axes limits.
- 'off' — Display the entire primitive line object, even if parts of it appear outside the axes limits. Parts of the primitive line object might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the primitive line object so that it is larger than the original plot.

The `Clipping` property of the axes that contains the primitive line object must be set to 'on', otherwise this property has no effect. For more information about the clipping behavior, see the `Clipping` property of the axes.

**EraseMode — (removed) Technique to draw and erase objects**

'normal' (default) | 'none' | 'xor' | 'background'

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- 'normal' — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- 'none' — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, 'none', it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.

- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### Type — Type of graphics object

`'line'`

This property is read only.

Type of graphics object, returned as `'line'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

### Tag — Tag to associate with primitive line

`''` (default) | string

Tag to associate with the primitive line, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

### UserData — Data to associate with primitive line

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the primitive line object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | table | cell`

### **DisplayName** — Text used by legend

`''` (default) | `string`

Text used by the legend, specified as a string. The text appears next to an icon of the primitive line.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the primitive line object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

### **Annotation** — Legend icon display style

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the primitive line from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.

**3** Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:

- `'on'` — Include the primitive line object in the legend as one entry (default).
- `'off'` — Do not include the primitive line object in the legend.
- `'children'` — Include only children of the primitive line object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## Parent/Child

### Parent — Parent of primitive line

`axes object` | `group object` | `transform object`

Parent of primitive line, specified as an axes, group, or transform object.

### Children — Children of primitive line

empty `GraphicsPlaceholder` array

The primitive line has no children. You cannot set this property.

### HandleVisibility — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of primitive line object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The primitive line object handle is always visible.
- `'off'` — The primitive line object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The primitive line object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the primitive line at the command-line, but allows callback functions to access it.

If the primitive line object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle

properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### **ButtonDownFcn** — Mouse-click callback

`'` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the primitive line. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The primitive line object — You can access properties of the primitive line object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **UIContextMenu** — Context menu

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the primitive line. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then the context menu does not appear.

---

### **Selected** — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the primitive line when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the `SelectionHighlight` property also is set to `'on'`, then MATLAB displays selection handles around the primitive line.
- `'off'` — Not selected.

### **SelectionHighlight** — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the `Selected` property is set to `'on'`.
- `'off'` — Never display selection handles, even when the `Selected` property is set to `'on'`.

## **Callback Execution Control**

### **PickableParts** — Ability to capture mouse clicks

`'visible'` (default) | `'all'` | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The `Visible` property must be set to `'on'` and you must click a part of the primitive line that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The `HitTest` property determines if the primitive line responds to the click or if an ancestor does.

- 'all' — Can capture mouse clicks regardless of visibility. The `Visible` property can be set to 'on' or 'off' and you can click a part of the primitive line that has no color. The `HitTest` property determines if the primitive line responds to the click or if an ancestor does.
- 'none' — Cannot capture mouse clicks. Clicking the primitive line passes the click through it to the object below it in the current view of the figure window. The `HitTest` property has no effect.

### **HitTest — Response to captured mouse clicks**

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the `ButtonDownFcn` callback of the primitive line. If you have defined the `UIContextMenu` property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the primitive line that has a `HitTest` property set to 'on' and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the primitive line object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
-

If the `ButtonDownFcn` callback of the primitive line is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the primitive line tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.

- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the primitive line. Setting the **CreateFcn** property on an existing primitive line has no effect. You must define a default value for this property, or define this property using a **Name, Value** pair during primitive line creation. MATLAB executes the callback after creating the primitive line and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The primitive line object — You can access properties of the primitive line object from within the callback function. You also can access the primitive line object through the **CallbackObject** property of the root, which can be queried using the **gcbo** function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: @myCallback

Example: {@myCallback, arg3}

### **DeleteFcn** — Deletion callback

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the primitive line. MATLAB executes the callback before destroying the primitive line so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The primitive line object — You can access properties of the primitive line object from within the callback function. You also can access the primitive line object through the `CallbackObject` property of the root, which can be queried using the `gcb0` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **BeingDeleted** — Deletion status of primitive line

'off' (default) | 'on'

This property is read only.

Deletion status of primitive line, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the primitive line begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the primitive line no longer exists.

Check the value of the `BeingDeleted` property to verify that the primitive line is not about to be deleted before querying or modifying it.

# magic

Magic square

## Syntax

```
M = magic(n)
```

## Description

`M = magic(n)` returns an  $n$ -by- $n$  matrix constructed from the integers 1 through  $n^2$  with equal row and column sums. The order  $n$  must be a scalar greater than or equal to 3.

## Examples

The magic square of order 3 is

```
M = magic(3)
```

```
M =
```

```
 8 1 6
 3 5 7
 4 9 2
```

This is called a magic square because the sum of the elements in each column is the same.

```
sum(M) =
```

```
 15 15 15
```

And the sum of the elements in each row, obtained by transposing twice, is the same.

```
sum(M')' =
```

```
 15
```

```
15
15
```

This is also a special magic square because the diagonal elements have the same sum.

```
sum(diag(M)) =
```

```
15
```

The value of the characteristic sum for a magic square of order  $n$  is

```
sum(1:n^2)/n
```

which, when  $n = 3$ , is 15.

## Limitations

If you supply  $n$  less than 3, `magic` returns either a nonmagic square, or else the degenerate magic squares 1 and [ ].

## More About

### Tips

A magic square, scaled by its magic sum, is doubly stochastic.

### Algorithms

There are three different algorithms:

- $n$  odd
- $n$  even but not divisible by four
- $n$  divisible by four

To make this apparent, type

```
for n = 3:20
 A = magic(n);
 r(n) = rank(A);
end
```

For  $n$  odd, the rank of the magic square is  $n$ . For  $n$  divisible by 4, the rank is 3. For  $n$  even but not divisible by 4, the rank is  $n/2 + 2$ .

```
[(3:20)', r(3:20)']
```

```
ans =
```

3	3
4	3
5	5
6	5
7	7
8	3
9	9
10	7
11	11
12	3
13	13
14	9
15	15
16	3
17	17
18	11
19	19
20	3

Plotting `A` for  $n = 18, 19, 20$  shows the characteristic plot for each category.

# makehgtform

Create 4-by-4 transform matrix

## Syntax

```
M = makehgtform
M = makehgtform('translate',[tx ty tz])
M = makehgtform('scale',s)
M = makehgtform('scale',[sx,sy,sz])
M = makehgtform('xrotate',t)
M = makehgtform('yrotate',t)
M = makehgtform('zrotate',t)
M = makehgtform('axisrotate',[ax,ay,az],t)
```

## Description

Use `makehgtform` to create transform matrices for translation, scaling, and rotation of graphics objects. Apply the transform to graphics objects by assigning the transform to the `Matrix` property of a parent transform object.

`M = makehgtform` returns an identity transform.

`M = makehgtform('translate',[tx ty tz])` or `M = makehgtform('translate',tx,ty,tz)` returns a transform that translates along the *x*-axis by `tx`, along the *y*-axis by `ty`, and along the *z*-axis by `tz`.

`M = makehgtform('scale',s)` returns a transform that scales uniformly along the *x*-, *y*-, and *z*-axes.

`M = makehgtform('scale',[sx,sy,sz])` returns a transform that scales along the *x*-axis by `sx`, along the *y*-axis by `sy`, and along the *z*-axis by `sz`.

`M = makehgtform('xrotate',t)` returns a transform that rotates around the *x*-axis by `t` radians.

`M = makehgtform('yrotate',t)` returns a transform that rotates around the *y*-axis by `t` radians.

`M = makehgtform('zrotate',t)` returns a transform that rotates around the  $z$ -axis by  $t$  radians.

`M = makehgtform('axisrotate',[ax,ay,az],t)` Rotate around axis `[ax ay az]` by  $t$  radians.

Note that you can specify multiple operations in one call to `makehgtform` and the MATLAB software returns a transform matrix that is the result of concatenating all specified operations. For example,

```
m = makehgtform('xrotate',pi/2,'yrotate',pi/2);
```

is the same as

```
mx = makehgtform('xrotate',pi/2);
my = makehgtform('yrotate',pi/2);
m = mx*my;
```

# mapreduce

Programming technique for analyzing data sets that do not fit in memory

## Syntax

```
outds = mapreduce(ds,mapfun,reducefun)
outds = mapreduce(ds,mapfun,reducefun,mr)
outds = mapreduce(____,Name,Value)
```

## Description

`outds = mapreduce(ds,mapfun,reducefun)` applies map function `mapfun` to input datastore `ds`, and then passes the values associated with each unique key to reduce function `reducefun`. The output datastore is a `KeyValueDatastore` object that points to `.mat` files in the current folder.

`outds = mapreduce(ds,mapfun,reducefun,mr)` optionally specifies the run-time configuration settings for `mapreduce`. The `mr` input is the result of a call to the `mapreducer` function. Typically, this argument is used with Parallel Computing Toolbox, MATLAB Distributed Computing Server, or MATLAB Compiler. For more information, see “Speed Up and Deploy MapReduce Using Other Products”.

`outds = mapreduce( ____,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments using any of the previous syntaxes. For example, you can specify `'OutputFolder'` followed by a string specifying a path to the output folder.

## Examples

- “Using MapReduce to Fit a Logistic Regression Model”
- “Tall Skinny QR (TSQR) Matrix Factorization Using MapReduce”
- “Compute Maximum Average HSV of Images with MapReduce”

## Input Arguments

### **ds** — Input datastore

datastore object

Input datastore, specified as a datastore object. Use the `datastore` function to create a datastore object from your data set.

### **mapfun** — Function handle to map function

function handle

Function handle to map function. `mapfun` receives chunks from input datastore `ds`, and then uses the `add` and `addmulti` functions to add key-value pairs to an intermediate `KeyValueStore` object. The number of calls to the map function by `mapreduce` is equal to the number of chunks in the `datastore` (the number of chunks is determined by the `ReadSize` property of the datastore).

The inputs to the map function are `data`, `info`, and `intermKVStore`, which `mapreduce` automatically creates and passes to the map function:

- The `data` and `info` inputs are the result of a call to the `read` function of `datastore`, which `mapreduce` executes automatically before each call to the map function.
- `intermKVStore` is the name of the intermediate `KeyValueStore` object to which the map function needs to add key-value pairs. If none of the calls to the map function add key-value pairs to `intermKVStore`, then `mapreduce` does not call the reduce function and the output datastore is empty.

An example of a template for the map function is

```
function myMapper(data, info, intermKVStore)
%do a calculation with the data chunk
add(intermKVStore, key, value)
end
```

Example: @myMapper

Data Types: function\_handle

### **reducefun — Function handle to reduce function**

function handle

Function handle to reduce function. `mapreduce` calls `reducefun` once for each unique key added to the intermediate `KeyValueStore` by the map function. In each call, `mapreduce` passes the values associated with the active key to `reducefun` as a `ValueIterator` object. The `reducefun` function loops through the values for each key using the `hasnext` and `getnext` functions. Then, after performing some calculation(s), it writes key-value pairs to the final output.

The inputs to the reduce function are `intermKey`, `intermValIter`, and `outKVStore`, which `mapreduce` automatically creates and passes to the reduce function:

- `intermKey` is the active key from the intermediate `KeyValueStore` object. Each call to the reduce function by `mapreduce` specifies a new unique key from the keys in the intermediate `KeyValueStore` object.
- `intermValIter` is the `ValueIterator` associated with the active key, `intermKey`. This `ValueIterator` object contains all of the values associated with the active key. Scroll through the values using the `hasnext` and `getnext` functions.
- `outKVStore` is the name for the final `KeyValueStore` object to which the reduce function needs to add key-value pairs. `mapreduce` takes the output key-value pairs from `outKVStore` and returns them in the output datastore, `outds`, which is a `KeyValueDatastore` object by default. If none of the calls to the reduce function add final key-value pairs to `outKVStore`, then the output datastore is empty.

An example of a template for the reduce function is

```
function myReducer(interKey, interValIter, outKVStore)
while hasNext(interValIter)
 X = getNext(interValIter);
 %do a calculation with the current value, X
end
add(outKVStore, key, value)
end
```

Example: @myReducer

Data Types: function\_handle

**mr** — Execution environment

MapReducer object

Execution environment, specified as a MapReducer object. `mr` is the result of a call to the `mapreduce` function. The default `mr` argument is a call to `gcmr`, which uses the default global execution environment for `mapreduce` (in MATLAB the default is `mapreducer(0)`, which returns a `SerialMapReducer` object).

---

**Note:** This setting specifies the execution environment for `mapreduce` and is not necessary to run `mapreduce` on your local computer. For more information, see “Speed Up and Deploy MapReduce Using Other Products”.

---

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, . . . , `NameN`, `ValueN`.

Example: `outds = mapreduce(ds, @mapfun, @reducefun, 'Display', 'off', 'OutputFolder', 'C:\Users\username\Desktop')`

**'OutputType' — Type of datastore output**

'Binary' (default) | 'TabularText'

Type of datastore output, specified as 'Binary' or 'TabularText'. The default setting of 'Binary' returns a `KeyValueDatastore` output datastore that points to binary (.mat or .seq) files in the output folder. The 'TabularText' option returns a `TabularTextDatastore` output datastore that points to .txt files in the output folder.

The table provides the details for each of the output types.

'OutputType'	Type of datastore output	Datastore points to files of type	Values that the Reduce function can add	Keys that the Reduce function can add	Details
'Binary' (default)	<code>KeyValueDatastore</code>	.mat (or .seq when running	Any valid MATLAB object.	Strings, or numeric scalars that	N/A

'OutputType	Type of datastore output	Datastore points to files of type	Values that the Reduce function can add	Keys that the Reduce function can add	Details
		against Hadoop).		are not NaN, complex, logical, or sparse.	
'TabularText	TabularText	.txt	Strings, or numeric scalars that are not NaN, complex, logical, or sparse.	Strings, or numeric scalars that are not NaN, complex, logical, or sparse.	<ul style="list-style-type: none"> <li>• File is UTF-8 encoded.</li> <li>• Keys and values are tab (\t) separated.</li> <li>• The row delimiter is \r\n on Windows, and \n on Linux and Mac.</li> </ul>

**'OutputFolder' — Destination folder of mapreduce output**

pwd (default) | file path

Destination folder for mapreduce output, specified as a file path. The default output folder is the current folder, pwd. You can specify a different path with a fully qualified path or with a path relative to the current folder.

Example: `mapreduce(..., 'OutputFolder', 'MyOutputFolder\Results')` specifies a file path relative to the current folder for the output.

**'Display' — Toggle for command line progress output**

'on' (default) | 'off'

Toggle for command line progress output, specified as 'on' or 'off'. The default is 'on', so that `mapreduce` displays progress information in the command window during the map and reduce phases of execution.

## Output Arguments

### **outds** — Output datastore

KeyValueDatastore (default) | TabularTextDatastore

Output datastore, returned as a `KeyValueDatastore` or `TabularTextDatastore` object. By default, `outds` is a `KeyValueDatastore` object that points to `.mat` files in the current folder. Use the `Name`, `Value` pair arguments for `'OutputType'` and `'OutputFolder'` to return a `TabularTextDatastore` object or change the location of the output files, respectively.

`mapreduce` does not sort the key-value pairs in `outds`. Their order may differ when using other products with `mapreduce`.

To view the contents of `outds`, use the `preview`, `read`, or `readall` functions of `datastore`.

## More About

### Tips

- Debugging your `mapreduce` algorithms to examine how key-value pairs move through the different phases is always useful. To examine the movement of data, set breakpoints in your map and reduce functions. The breakpoints stop execution of `mapreduce`, allowing you to examine the current status of relevant variables, like the `KeyValueStore` or `ValueIterator`. For more information, see “Debug MapReduce Algorithms”.
- Some recommendations to optimize `mapreduce` performance on any platform are:
  - Minimize the number of calls to the map function. The easiest approach is to increase the value of the `ReadSize` property of the input datastore. The result is that `mapreduce` passes larger chunks of data to the map function, and the datastore depletes with fewer reads.
  - Decrease the amount of intermediate data sent between map and reduce functions. One approach is to use `unique` inside a map function to combine similar keys. See “Compute Mean by Group Using MapReduce” for an example of this technique.

`datastore` | `gcmr` | Using `KeyValueStore` Objects | `mapreducer` | Using `ValueIterator` Objects

**Introduced in R2014b**

# mapreducer

Define execution environment for mapreduce

## Syntax

```
mapreducer
mapreducer(0)
mapreducer(mr)
mr = mapreducer(___)
mr = mapreducer(___ , 'ObjectVisibility', 'Off')
```

## Description

`mapreducer` sets the global execution environment for `mapreduce` to be the default (`SerialMapReducer` in MATLAB).

`mapreducer` is the execution configuration function for `mapreduce`. Use this function to set, change, or store the execution environment to run `mapreduce` using Parallel Computing Toolbox, MATLAB Distributed Computing Server, or MATLAB Compiler.

`mapreducer(0)` sets the global execution environment for `mapreduce` to be the local MATLAB session.

`mapreducer(mr)` sets the global execution environment for `mapreduce` using a previously created `MapReducer` object, `mr`.

`mr = mapreducer( ___ )` also returns a `MapReducer` object using any of the previous syntaxes. Use `mr` as a fourth input argument to `mapreduce` when you want to explicitly specify the execution environment.

`mr = mapreducer( ___ , 'ObjectVisibility', 'Off')` toggles the visibility of the `MapReducer` object, `mr`, using any of the previous syntaxes. Use this syntax to create new `MapReducer` objects without affecting the global execution environment of `mapreduce`.

---

**Note:** In MATLAB, the `mapreduce` function automatically runs using a `SerialMapReducer`, and it is unnecessary to specify configuration settings using

`mapreducer`. However, if you have Parallel Computing Toolbox, MATLAB Distributed Computing Server, or MATLAB Compiler, then additional `mapreducer` configuration options are available for running in parallel or deployed environments. For more information, see the documentation in each product.

---

## Output Arguments

### **mr** — Execution environment for `mapreduce`

MapReducer object

Execution environment for `mapreduce`, returned as a MapReducer object.

If the `ObjectVisibility` property of `mr` is set to `'On'` (the default), then `mr` defines the default execution environment for `mapreduce`. You can pass `mr` to the `mapreduce` function to explicitly specify the execution environment, even if its `ObjectVisibility` property is set to `'Off'`.

Pass `mr` to the `mapreduce` function when using the following products:

- Parallel Computing Toolbox enables you to run `mapreduce` computations using a parallel pool.
- MATLAB Distributed Computing Server extends Parallel Computing Toolbox, enabling you to run `mapreduce` computations on a remote cluster. This includes support for Hadoop.
- MATLAB Compiler enables you to create standalone applications or deployable archives, which you can share with colleagues or deploy to production Hadoop systems.

## More About

### Tips

- If you have Parallel Computing Toolbox, see the `mapreducer` function reference page for additional information.
- If you have MATLAB Compiler, see the `mapreducer` function reference page for additional information.
- “Speed Up and Deploy MapReduce Using Other Products”

## **See Also**

gcmr | mapreduce

**Introduced in R2014b**

## containers.Map class

**Package:** containers

Map values to unique keys

### Description

A Map object is a data structure that allows you to retrieve values using a corresponding key. Keys can be real numbers or text strings and provide more flexibility for data access than array indices, which must be positive integers. Values can be scalar or nonscalar arrays.

### Construction

`mapObj = containers.Map` constructs an empty Map container `mapObj`.

`mapObj = containers.Map(keySet,valueSet)` constructs a Map that contains one or more values and a unique key for each value.

`mapObj = containers.Map(keySet,valueSet,'UniformValues',isUniform)` specifies whether all values must be uniform (either all scalars of the same data type, or all strings). Possible values for `isUniform` are logical `true` (1) or `false` (0).

`mapObj = containers.Map('KeyType',kType,'ValueType',vType)` constructs an empty Map object and sets the `KeyType` and `ValueType` properties. The order of the key type and value type argument pairs is not important, but both pairs are required.

### Input Arguments

#### **keySet**

1-by-n array that specifies n unique keys for the map.

All keys in a Map object are real numeric values or all keys are strings. If  $n > 1$  and the keys are strings, `keySet` must be a cell array. The number of keys in `keySet` must equal the number of values in `valueSet`.

**valueSet**

1-by-n array of any class that specifies n values for the map. The number of values in `valueSet` must equal the number of keys in `keySet`.

**'UniformValues'**

Parameter string to use with the `isUniform` argument.

**isUniform**

Logical value that specifies whether all values are uniform. If `isUniform` is `true` (1), all values must be scalars of the same data type, or all values must be strings. If `isUniform` is `false` (0), then `containers.Map` sets the `ValueType` to `'any'`.

**Default:** `true` for empty `Map` objects, otherwise determined by the data types of values in `valueSet`.

**'KeyType'**

Parameter string to use with the `kType` argument.

**kType**

String that specifies the data type for the keys. Possible values are `'char'`, `'double'`, `'single'`, `'int32'`, `'uint32'`, `'int64'`, or `'uint64'`.

**Default:** `'char'` for empty `Map` objects, otherwise determined by the data types of keys in `keySet`. If you specify keys of different numeric types, `kType` is `'double'`.

**'ValueType'**

Literal string parameter to use with the `vType` argument.

**vType**

String that specifies the data type for the values. Possible values are `'any'`, `'char'`, `'logical'`, `'double'`, `'single'`, `'int8'`, `'uint8'`, `'int16'`, `'uint16'`, `'int32'`, `'uint32'`, `'int64'`, or `'uint64'`.

**Default:** `'any'` when you create an empty `Map` object or when you specify values of different sizes or types, otherwise determined by the data type of `valueSet`.

## Properties

### Count

Unsigned 64-bit integer that represents the total number of key-value pairs contained in the `Map` object. Read only.

### KeyType

Character array that indicates the data type of all keys in the `Map` object. The default `KeyType` for empty `Map` objects is `'char'`. Otherwise, `KeyType` is determined from the data type of the `keySet` inputs. Read only.

### ValueType

Character array that indicates the data type of all values in the `Map` object. If you construct an empty `Map` object or specify values with different data types, then the value of `ValueType` is `'any'`. Otherwise, `ValueType` is determined from the data type of the `valueSet` inputs. Read only.

## Methods

<code>isKey</code>	Determine if <code>containers.Map</code> object contains key
<code>keys</code>	Identify keys of <code>containers.Map</code> object
<code>length</code>	Length of <code>containers.Map</code> object
<code>remove</code>	Remove key-value pairs from <code>containers.Map</code> object
<code>size</code>	Size of <code>containers.Map</code> object
<code>values</code>	Identify values in <code>containers.Map</code> object

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Construct a Map and View Properties

Construct a Map object that contains rainfall data for several months:

```
keySet = {'Jan', 'Feb', 'Mar', 'Apr'};
valueSet = [327.2, 368.2, 197.6, 178.4];
mapObj = containers.Map(keySet,valueSet)
```

This code returns a description of the map, including the property values:

```
mapObj =

 containers.Map handle
 Package: containers

 Properties:
 Count: 4
 KeyType: 'char'
 ValueType: 'double'

 Methods, Events, Superclasses
```

Get a specific property using dot notation, such as

```
mapObj.Count
```

which returns

```
ans =

 4
```

### Look Up Values in a Map

Use the map created in the previous example to find the rainfall data for February:

```
rainFeb = mapObj('Feb')
```

This code returns

```
rainFeb =

 368.2000
```

## Add a Single Value and Key to a Map

Add data for the month of May to the map created in the first example:

```
mapObj('May') = 100.0;
```

## Add Multiple Values and Keys by Concatenating Maps

Create a map that contains rainfall data for June, July, and August, and add the data to `mapObj` (from previous examples):

```
keySet = {'Jun', 'Jul', 'Aug'};
valueSet = [69.9, 32.3, 37.3];
newMap = containers.Map(keySet, valueSet);

mapObj = [mapObj; newMap];
```

Map objects only support vertical concatenation (that is, adding columns with a semicolon, `;`). When concatenating maps, the data type of all values must be consistent with the `ValueType` of the leftmost map. In this example, both maps have the a `ValueType` of `double`.

## Get the Keys or Values in a Map

Determine all the keys of `mapObj` (from previous examples) by calling the `keys` method:

```
allKeys = keys(mapObj)
```

This method returns the keys in alphabetical order:

```
allKeys =
 'Apr' 'Aug' 'Feb' 'Jan' 'Jul' 'Jun' 'Mar' 'May'
```

Get multiple values from the map by calling the `values` method. Like the `keys` method, you can request all values with the syntax `values(mapObj)`. Alternatively, request values for specific keys. For example, view the values for March, April, and May in `mapObj`:

```
springValues = values(mapObj, {'Mar', 'Apr', 'May'})
```

This method returns the values in a cell array, in the order corresponding to the specified keys:

```
springValues =
 [197.6000] [178.4000] [100]
```

## Remove Keys and Values

Remove the data for March and April from `mapObj` (from previous examples) by calling the `remove` method, and view the remaining keys:

```
remove(mapObj,{'Mar','Apr'});
keys(mapObj)
```

This code returns

```
ans =
 'Aug' 'Feb' 'Jan' 'Jul' 'Jun' 'May'
```

## Create a Map with Nonscalar Values

Map integer keys to nonscalar arrays, and view the value for one of the keys:

```
keySet = [5,10,15];
valueSet = {magic(5),magic(10),magic(15)};
mapObj = containers.Map(keySet,valueSet);
mapObj(5)
```

This code returns

```
ans =
 17 24 1 8 15
 23 5 7 14 16
 4 6 13 20 22
 10 12 19 21 3
 11 18 25 2 9
```

## Construct an Empty Map

Construct a map with no values, but set the `KeyType` and `ValueType` properties:

```
mapObj = containers.Map('KeyType','char','ValueType','int32')
```

This code returns

```
mapObj =
```

```
containers.Map handle
Package: containers
```

```
Properties:
 Count: 0
 KeyType: 'char'
 ValueType: 'int32'
```

Methods, Events, Superclasses

## Specify Whether Values Are Uniform

Construct a map with numeric values, and specify that the values do not have to be uniform:

```
keySet = {'a','b','c'};
valueSet = {1,2,3};
mapObj = containers.Map(keySet,valueSet,'UniformValues',false);
```

This map allows nonnumeric values, so

```
mapObj('d') = 'OK';
values(mapObj)
```

returns

```
ans =
 [1] [2] [3] 'OK'
```

## See Also

isKey | values | keys

## mat2cell

Convert array to cell array with potentially different sized cells

### Syntax

```
C = mat2cell(A,dim1Dist,...,dimNDist)
C = mat2cell(A,rowDist)
```

### Description

`C = mat2cell(A,dim1Dist,...,dimNDist)` divides array `A` into smaller arrays within cell array `C`. Vectors `dim1Dist,...,dimNDist` specify how to divide the rows, columns, and (when applicable) higher dimensions of `A`.

`C = mat2cell(A,rowDist)` divides array `A` into an `n`-by-1 cell array `C`, where `n == numel(rowDist)`.

### Input Arguments

#### **A**

Any type of array.

#### **dim1Dist,...,dimNDist**

Numeric vectors that describe how to divide each dimension of `A`. For example, this command

```
c = mat2cell(x, [10, 20, 30], [25, 25])
```

divides a 60-by-50 array into six arrays contained in a cell array.

For the  $k$ th dimension, `sum(dimkDist) == size(A, k)`.

If the  $k$ th dimension of  $A$  is zero, set the corresponding `dimkDist` to the empty array, `[]`. For example,

```
a = rand(3, 0, 4);
c = mat2cell(a, [1, 2], [], [2, 1, 1]);
```

### **rowDist**

Numeric vector that describes how to divide the rows of  $A$ . When you do not specify distributions for any other dimension, the `mat2cell` function creates an  $n$ -by-1 cell array  $C$ , where  $n == \text{numel}(\text{rowDist})$ .

## **Output Arguments**

### **c**

Cell array. The  $k$ th dimension of array  $C$  is given by `size(C, k) == numel(dimkDist)`. The  $k$ th dimension of the  $i$ th cell of  $C$  is given by `size(C{i}, k) == dimkDist(i)`.

## **Examples**

Divide the 5-by-4 matrix  $X$  into 2-by-3 and 2-by-2 matrices contained in a cell array.

```
X = reshape(1:20,5,4)'
```

```
C = mat2cell(X, [2 2], [3 2])
celldisp(C)
```

This code returns

```
X =
 1 2 3 4 5
 6 7 8 9 10
 11 12 13 14 15
 16 17 18 19 20

C =
 [2x3 double] [2x2 double]
 [2x3 double] [2x2 double]
```

```
C{1,1} =
 1 2 3
 6 7 8
```

```
C{2,1} =
 11 12 13
 16 17 18
```

```
C{1,2} =
 4 5
 9 10
```

```
C{2,2} =
 14 15
 19 20
```

Divide X (created in the previous example) into a 2-by-1 cell array.

```
C = mat2cell(X, [1 3])
celldisp(C)
```

This code returns

```
C =
 [1x5 double]
 [3x5 double]
```

```
C{1} =
 1 2 3 4 5
```

```
C{2} =
 6 7 8 9 10
 11 12 13 14 15
 16 17 18 19 20
```

## See Also

**Introduced before R2006a**

# mat2str

Convert matrix to string

## Syntax

```
str = mat2str(A)
str = mat2str(A,n)
str = mat2str(A, 'class')
str = mat2str(A, n, 'class')
```

## Description

`str = mat2str(A)` converts matrix `A` into a string. This string is suitable for input to the `eval` function such that `eval(str)` produces the original matrix to within 15 digits of precision.

`str = mat2str(A,n)` converts matrix `A` using `n` digits of precision.

`str = mat2str(A, 'class')` creates a string with the name of the class of `A` included. This option ensures that the result of evaluating `str` will also contain the class information.

`str = mat2str(A, n, 'class')` uses `n` digits of precision and includes the class information.

## Limitations

The `mat2str` function is intended to operate on scalar, vector, or rectangular array inputs only. An error will result if `A` is a multidimensional array.

## Examples

### Example 1

Consider the matrix

```
x = [3.85 2.91; 7.74 8.99]
x =
 3.8500 2.9100
 7.7400 8.9900
```

The statement

```
A = mat2str(x)
```

produces

```
A =
 [3.85 2.91;7.74 8.99]
```

where A is a string of 21 characters, including the square brackets, spaces, and a semicolon.

`eval(mat2str(x))` reproduces x.

## Example 2

Create a 1-by-6 matrix of signed 16-bit integers, and then use `mat2str` to convert the matrix to a 1-by-33 character array, A. Note that output string A includes the class name, `int16`:

```
x1 = int16([-300 407 213 418 32 -125]);
```

```
A = mat2str(x1, 'class')
```

```
A =
 int16([-300 407 213 418 32 -125])
```

```
class(A)
```

```
ans =
 char
```

Evaluating the string A gives you an output x2 that is the same as the original `int16` matrix:

```
x2 = eval(A);
```

```
if isnumeric(x2) && isa(x2, 'int16') && all(x2 == x1)
 disp 'Conversion back to int16 worked'
end
```

Conversion back to int16 worked

**Introduced before R2006a**

## material

Control reflectance properties of surfaces and patches

### Syntax

```
material shiny
material dull
material metal
material([ka kd ks])
material([ka kd ks n])
material([ka kd ks n sc])
material default
```

### Description

`material` sets the lighting characteristics of `surface` and `patch` objects.

`material shiny` sets the reflectance properties so that the object has a high specular reflectance relative to the diffuse and ambient light, and the color of the specular light depends only on the color of the light source.

`material dull` sets the reflectance properties so that the object reflects more diffuse light and has no specular highlights, but the color of the reflected light depends only on the light source.

`material metal` sets the reflectance properties so that the object has a very high specular reflectance, very low ambient and diffuse reflectance, and the color of the reflected light depends on both the color of the light source and the color of the object.

`material([ka kd ks])` sets the ambient/diffuse/specular strength of the objects.

`material([ka kd ks n])` sets the ambient/diffuse/specular strength and specular exponent of the objects.

`material([ka kd ks n sc])` sets the ambient/diffuse/specular strength, specular exponent, and specular color reflectance of the objects.

`material default` sets the ambient/diffuse/specular strength, specular exponent, and specular color reflectance of the objects to their defaults.

## More About

### Tips

The `material` command sets the `AmbientStrength`, `DiffuseStrength`, `SpecularStrength`, `SpecularExponent`, and `SpecularColorReflectance` properties of all `surface` and `patch` objects in the axes. There must be visible `light` objects in the axes for lighting to be enabled. Look at the `materal.m` file to see the actual values set (enter the command type `material`).

- “Lighting Overview”

`lighting` | `patch` | `light` | `surface`

Introduced before R2006a

## matfile

Access and change variables directly in MAT-files, without loading into memory

### Syntax

```
m = matfile(filename)
m = matfile(filename, 'Writable', isWritable)
```

### Description

`m = matfile(filename)` creates a MAT-file object, `m`, connected to the MAT-file named `filename`. The object allows you to access and change variables directly in a MAT-file, without having to load the variables into memory.

The partial loading and saving that the `matfile` function provides requires less memory than the `load` and `save` commands, which always operate on entire variables.

`m = matfile(filename, 'Writable', isWritable)` enables or disables write access to the file.

### Examples

#### Load Entire Variable

Load variable `topo` from the example file, `topography.mat`.

Open the example MAT-file, `topography.mat`.

```
filename = 'topography.mat';
m = matfile(filename);
```

Read the variable `topo` from the MAT-file.

```
topo = m.topo;
```

MATLAB loads the entire variable, `topo`, into the workspace.

### Save Entire Variable to Existing MAT-file

Generate a 20-by-20 example array, `x`, and save it to a MAT-file called `myFile.mat`.

```
x = magic(20);
save('myFile.mat', 'x');
```

Create a MAT-file object connected to the existing MAT-file named `myFile.mat`. Enable write access to the MAT-file by setting `Writable` to `true`.

```
m = matfile('myFile.mat', 'Writable', true);
```

Generate a 15-by-15 example array, `y`.

```
y = magic(15);
```

Save `y` to the MAT-file. Specify the variable in the MAT-file using dot notation similar to accessing fields of structure arrays.

```
m.y = y;
```

MATLAB adds a variable named `y` to the file.

Display all variables stored in the MAT-file, `myFile.mat`.

```
whos('-file', 'myFile.mat')
```

Name	Size	Bytes	Class	Attributes
x	20x20	3200	double	
y	15x15	1800	double	

### Load and Save Parts of Variables

Access specific elements of a MAT-file variable.

Open a new MAT-file, `myFile2.mat`.

```
m = matfile('myFile2.mat');
```

Save a 20-by-20 example array to part of a variable, `y`, in `myFile2.mat`. Specify the variable in the MAT-file using dot notation similar to accessing fields of structure arrays.

```
m.y(81:100,81:100) = magic(20);
```

MATLAB inserts the 20-by-20 array into the elements of `y` specified by the indices (81:100,81:100).

Read a subset of array `y` into a new workspace variable, `z`.

```
z = m.y(85:94,85:94);
```

MATLAB reads the 10-by-10 subarray specified by the indices (85:94,85:94) from the MAT-file into workspace variable `z`.

## Determine Size of Variables

Determine the size of a variable, and then calculate the average of each column.

Open the example MAT-file, `stocks.mat`.

```
filename = 'stocks.mat';
m = matfile(filename);
```

Determine the size of the variable, `stocks`, in `stocks.mat`.

```
[nrows,ncols] = size(m,'stocks');
```

Compute the average of each column of the variable `stocks`.

```
avgs = zeros(1,ncols);
for i = 1:ncols
 avgs(i) = mean(m.stocks(:,i));
end
```

## Enable Write Access to MAT-file

Enable write access to the MAT-file, `myFile.mat`, by setting `Writable` to `true` when you open the MAT-file.

```
filename = 'myFile.mat';
m = matfile(filename,'Writable',true);
```

Alternatively, set `Properties.Writable` in a separate step after you open the MAT-file.

```
m.Properties.Writable = true;
```

## Input Arguments

### **filename** — Name of MAT-file

string

Name of a MAT-file, specified as a string. If the file is not in the current folder, **filename** must include a full or a relative path. If **filename** does not include an extension, then **matfile** appends **.mat**.

If the file does not exist, then **matfile** creates a Version 7.3 MAT-file on the first assignment to a variable.

**matfile** only supports efficient partial loading and saving for MAT-files in Version 7.3 format. If you index into a variable in a Version 7 (the current default) or earlier MAT-file, MATLAB warns and temporarily loads the entire contents of the variable.

Example: 'myFile.mat'

Data Types: char

### **isWritable** — Write access to MAT-file

true | false

Write access to the MAT-file, specified as either **true** or **false**.

- **true** enables saving to the MAT-file. If the file is read only, MATLAB changes the system permissions with the **fileattrib** function.
- **false** disables saving to the MAT-file. MATLAB does not change the system permissions.

The default value is **true** for new files, and **false** for existing files.

Data Types: logical

## Output Arguments

### **m** — MAT-file object

matlab.io.MatFile object

MAT-file object connected to a MAT-file.

Access variables in the MAT-file with dot notation similar to accessing fields of structure arrays:

- To load part of variable `varName` from the MAT-file corresponding to `m`, call:

```
loadedData = m.varName(indices);
```

- To save part of variable `varName` to the MAT-file corresponding to `m`, call:

```
m.varName(indices) = dataToSave;
```

When accessing variables, specify indices for all dimensions. Indices can be a single value, an equally spaced range of increasing values, or a colon (`:`); for example:

```
m.varName(100:500,200:600)
m.varName(:,501:1000)
m.varName(1:2:1000,80)
```

## Limitations

- `matfile` does not support linear indexing. You must specify indices for all dimensions.
- `matfile` does not support indexing into:
  - Variables of tables
  - Cells of cell arrays
  - Fields of structure arrays
  - User-defined classes
  - Sparse arrays
- You cannot assign complex values to an indexed portion of a real array.
- You cannot evaluate function handles using the `m` output. For example, if your MAT-file contains function handle `myfunc`, the syntax `m.myfunc()` attempts to index into the function handle, and does not invoke the function.
- Efficient partial loading and saving requires Version 7.3 MAT-files. To create a Version 7.3 MAT-file, call the `save` function with the `'-v7.3'` option. For example, to convert an existing MAT-file named `durer.mat` to Version 7.3, call:

```
load('durer.mat');
```

```
save('mycopy_durer.mat', '-v7.3');
```

## More About

### Tips

- Using the `end` keyword as part of an index causes MATLAB to load the entire variable into memory. For very large variables, this load operation results in **Out of Memory** errors. Rather than using `end`, determine the extent of a variable, `myVar`, with the `size` method, such as:

```
sizeMyVar = size(m, 'myVar')
```

- “Load Parts of Variables from MAT-Files”
- “Save Parts of Variables to MAT-Files”
- MAT-File Versions

**Introduced in R2011b**

# matlab.codetools.requiredFilesAndProducts

List dependencies of MATLAB program files

## Syntax

```
fList = matlab.codetools.requiredFilesAndProducts(files)
[fList, pList] = matlab.codetools.requiredFilesAndProducts(files)
[fList, pList] =
matlab.codetools.requiredFilesAndProducts(___, 'toponly')
```

## Description

`fList = matlab.codetools.requiredFilesAndProducts(files)` returns a list of the MATLAB program files required to run the program files specified by `files`.

The `matlab.codetools.requiredFilesAndProducts` function is intended to provide you with information to pass on to consumers of your MATLAB program files.

`[fList, pList] = matlab.codetools.requiredFilesAndProducts(files)` also returns a list of the MathWorks products possibly required to run the program files specified by `files`.

If you use the `matlab.codetools.requiredFilesAndProducts` function on MATLAB code that you received, `pList` only includes the required toolboxes that are installed on your system. In this case, `pList` can be incomplete.

`[fList, pList] = matlab.codetools.requiredFilesAndProducts( ___, 'toponly' )` indicates that for a file or product to be included in the output, it must be used directly by at least one file specified in `files`. The 'toponly' input string is case insensitive.

## Examples

### Identify Required Files and Products for MATLAB Toolbox Function

Determine the required files and products for the `edge` function in the Image Processing Toolbox.

```
[fList,pList] = matlab.codetools.requiredFilesAndProducts('edge.m')
fList =
 {}

pList =
1x2 struct array with fields:
 Name
 Version
 ProductNumber
 Certain
```

There are no required MATLAB files, but there are two required products.

List the required products.

```
{pList.Name}'
ans =
 'MATLAB'
 'Image Processing Toolbox'
```

### Identify Required Files and Products for Your MATLAB Program Files

In your current working folder, create a function in the file `getRandomNumber.m`.

```
function a = getRandomNumber
 rng shuffle
 a = rand;
end
```

Now, at the command line, determine the required files and products for `getRandomNumber.m`.

```
[fList,pList] = matlab.codetools.requiredFilesAndProducts('getRandomNumber.m')
fList =
 'C:\work\getRandomNumber.m'
```

```
pList =

 Name: 'MATLAB'
 Version: '8.5'
ProductNumber: 1
 Certain: 1
```

The only file required to run the `getRandomNumber` function is the function file itself. The only required MathWorks product is MATLAB.

In your current working folder, create a function in the file `displayNumber.m`.

```
function displayNumber
 a = getRandomNumber;
 disp(['Your number is ' num2str(a)])
end
```

Now, at the command line, determine the required files and products for `displayNumber.m`.

```
[fList,pList] = matlab.codetools.requiredFilesAndProducts('displayNumber.m')
```

```
fList =

 'C:\work\displayNumber.m' 'C:\work\getRandomNumber.m'
```

```
pList =

 Name: 'MATLAB'
 Version: '8.5'
ProductNumber: 1
 Certain: 1
```

In addition to the function file itself, the `displayNumber` function requires the `getRandomNumber.m` file. The only required MathWorks product is MATLAB.

## Identify Top-Level Dependencies Only

In your current working folder, create a handle class in the file `ExampleHandle.m`.

```
classdef ExampleHandle < handle
 % class content
```

```
end
```

In your current working folder, create a class in the file `AnotherExampleHandle.m` that inherits from `ExampleHandle`.

```
classdef AnotherExampleHandle < ExampleHandle
 % class content
end
```

In your current working folder, create a function in the file `getHandles.m` that instantiates `AnotherExampleHandle` objects.

```
function [h1,h2] = getHandles()
 h1 = AnotherExampleHandle;
 h2 = AnotherExampleHandle;
end
```

Now, at the command line, determine the required files for `getHandles.m`.

```
[fList,~] = matlab.codetools.requiredFilesAndProducts('getHandles.m');
fList'

ans =

 'C:\work\AnotherExampleHandle.m'
 'C:\work\ExampleHandle.m'
 'C:\work\getHandles.m'
```

Determine the required files that are directly required for `getHandles.m`.

```
[fList,~] = matlab.codetools.requiredFilesAndProducts('getHandles.m','toponly')
fList =

 'C:\work\AnotherExampleHandle.m' 'C:\work\getHandles.m'
```

Although `AnotherExampleHandle.m` requires `ExampleHandle.m`, that file is not a direct requirement for `getHandles.m`.

## Input Arguments

### **files** — List of files for analysis

string or cell array of strings

List of files for analysis, specified as a string or cell array of strings. Each string is the name of a single MATLAB program file. For example, `files` is a list of MATLAB program files that you intend to provide to other users. The `matlab.codetools.requiredFilesAndProducts` function provides you with requirements information to pass along with your files.

To ensure an accurate dependency report, `files` and dependencies must be on the MATLAB path. `matlab.codetools.requiredFilesAndProducts` does not return information about dependent files not on the path.

Example: `'myFile.m'` or `'C:\Program Files\MATLAB\R2014a\my_work\myFile.m'`

Example: `{'myFile.m', 'myOtherFile.m'}`

Example: `cellstr(ls('*.*'))`

## Output Arguments

### **fList** — List of user-authored MATLAB program files

cell array of strings

List of user-authored MATLAB program files required by `files`, returned as a cell array of strings. Each string indicates the full path of the required file. `fList` does not include built-in MATLAB files, since these files are installed with the products listed in `pList`.

### **pList** — List of MathWorks products

structure or array of structures

List of MathWorks products possibly required by `files`, returned as a structure or array of structures. Each product is described by name (`Name` field), version (`Version` field), product number (`ProductNumber` field), and a certainty indicator (`Certain` field). The `Certain` field has a value of 1 if `matlab.codetools.requiredFilesAndProducts` determines the product is required by the specified program files, `files`, or a value of 0 if the product is possibly required.

The `matlab.codetools.requiredFilesAndProducts` function is intended to provide you with information to pass on to consumers of your MATLAB program files. The version numbers indicate the version of the products you have installed when you execute the function. `Version` is not an indicator of backward compatibility.

## More About

- “Identify Program Dependencies”

**Introduced in R2014a**

## matlab.engine.engineName

Return name of shared MATLAB session

### Syntax

```
name = matlab.engine.engineName
```

### Description

`name = matlab.engine.engineName` returns the name of the MATLAB session if the session is shared. Otherwise, `matlab.engine.engineName` returns the empty value `''`.

### Examples

#### Name of Shared MATLAB Session

Share the MATLAB session and return its name.

```
matlab.engine.shareEngine('Engine_1');
name = matlab.engine.engineName
```

```
name =
```

```
Engine_1
```

- “Connect Python to Running MATLAB Session”

#### See Also

`matlab.engine.isEngineShared` | `matlab.engine.shareEngine`

**Introduced in R2015b**

# matlab.engine.isEngineShared

Determine if MATLAB session is shared

## Syntax

```
tf = matlab.engine.isEngineShared
```

## Description

`tf = matlab.engine.isEngineShared` returns logical 1 (true) if a MATLAB session is shared. It returns logical 0 (false) if the session is not shared. By default, MATLAB sessions are not shared.

## Examples

### Test If MATLAB Session Is Shared

Determine if the current MATLAB session is shared for connections to other processes.

```
tf = matlab.engine.isEngineShared
```

```
tf =
```

```
0
```

By default, the session is not shared.

- “Connect Python to Running MATLAB Session”

## See Also

`matlab.engine.engineName` | `matlab.engine.shareEngine`

**Introduced in R2015b**

## matlab.engine.shareEngine

Convert running MATLAB session to shared session

### Syntax

```
matlab.engine.shareEngine
matlab.engine.shareEngine(name)
```

### Description

`matlab.engine.shareEngine` converts the current MATLAB session to a shared session with a default name. The default name is 'MATLAB\_<process\_ID>', where <process\_ID> is a number that indicates the process ID of the current MATLAB session.

`matlab.engine.shareEngine(name)` converts the current MATLAB session to a shared session and gives it the name specified by `name`.

If there is already a shared MATLAB session on your local machine that has the name specified by `name`, then `matlab.engine.shareEngine` converts the current session to a shared session with a default name.

### Examples

#### Share MATLAB Session

Convert the current MATLAB session to a shared session with a default name.

```
matlab.engine.shareEngine
matlab.engine.engineName
```

```
ans =
```

```
MATLAB_49593
```

`matlab.engine.shareEngine` gives the shared session the default name `MATLAB_49593`, where `49593` is the process ID of the MATLAB session. The process ID is different each time you start MATLAB.

### Name and Share Your MATLAB Session

Give a name to the current MATLAB session and share the session.

```
matlab.engine.shareEngine('Engine_1')
matlab.engine.engineName
```

```
ans =
```

```
Engine_1
```

- “Connect Python to Running MATLAB Session”

## Input Arguments

### **name** — Name of shared MATLAB session

character array

Name of the shared MATLAB session, specified as a character array. `name` must be a valid MATLAB variable name.

## More About

### Tips

You also can use a MATLAB startup option to start a shared session. To start a shared MATLAB session, type this command at the operating system prompt:

```
matlab -r 'matlab.engine.shareEngine'
```

### See Also

`matlab.engine.engineName` | `matlab.engine.isEngineShared`

Introduced in R2015b

## matlab.io.MatFile class

**Package:** matlab.io

Load and save parts of variables in MAT-files

### Description

The `matfile` function constructs a `matlab.io.MatFile` object that corresponds to a MAT-File, such as

```
matObj = matfile('myFile.mat')
```

Access variables in the MAT-file as properties of `matObj`, with dot notation similar to accessing fields of structs. The syntax for loading and saving part of variable `varName` in the MAT-file corresponding to `matObj` is:

```
loadedData = matObj.varName(indices); % Load into workspace
matObj.varName(indices) = dataToSave; % Save to file
```

When indexing, specify indices for all dimensions. Indices can be a single value, an equally spaced range of increasing values, or a colon (:), such as

```
matObj.varName(100:500, 200:600)
matObj.varName(:, 501:1000)
matObj.varName(1:2:1000, 80)
```

### Limitations

- Using the `end` keyword as part of an index causes MATLAB to load the entire variable into memory. For very large variables, this load operation results in **Out of Memory** errors. Rather than using `end`, determine the extent of a variable with the `size` method, such as:

```
sizeMyVar = size(matObj,'myVar')
```

- `matfile` does not support linear indexing. You must specify indices for all dimensions.
- `matfile` does not support indexing into:
  - Cells of cell arrays

- Fields of structs
- User-defined classes
- Sparse arrays
- You cannot assign complex values to an indexed portion of a real array.
- You cannot evaluate function handles using a `MatFile` object. For example, if your MAT-file contains function handle `myfunc`, the syntax `matObj.myfunc()` attempts to index into the function handle, and does not invoke the function.

## Construction

`matObj = matfile(filename)` constructs a `matlab.io.MatFile` object that can load or save parts of variables in MAT-file `filename`. MATLAB does not load any data from the file into memory when creating the object.

`matObj = matfile(filename, 'Writable', isWritable)` enables or disables write access to the file for object `matObj`. Possible values for `isWritable` are logical `true` (1) or `false` (0).

## Input Arguments

### **filename**

String enclosed in single quotation marks that specifies the name of a MAT-file.

`filename` can include a full or partial path, otherwise `matfile` searches for the file along the MATLAB search path. If `filename` does not include an extension, `matfile` appends `.mat`.

If the file does not exist, `matfile` creates a Version 7.3 MAT-file on the first assignment to a variable.

`matfile` only supports partial loading and saving for MAT-files in Version 7.3 format (described in MAT-File Versions). If you index into a variable in a Version 7 (the current default) or earlier MAT-file, MATLAB warns and temporarily loads the entire contents of the variable.

### **'Writable'**

Parameter to use with the `isWritable` argument.

### **isWritable**

Logical value that specifies whether to allow saving to the file. Possible values:

- true** (1) Enable saving. If the file is read only, change the system permissions with `fileattrib`.
- false** (0) Disable saving with `matfile`. MATLAB does not change the system permissions.

**Default:** `true` for new files, `false` for existing files

## **Properties**

### **Properties.Source**

String that contains the fully qualified path to the file. Read only.

### **Properties.Writable**

Logical value that specifies whether to allow saving to the file. Possible values:

- true** (1) Enable saving. If the file is read only, change the system permissions with `fileattrib`.
- false** (0) Disable saving with `matfile`. MATLAB does not change the system permissions.

**Default:** `true` for new files, `false` for existing files

## **Methods**

<code>size</code>	Array dimensions
<code>who</code>	Names of variables in MAT-file
<code>whos</code>	Names, sizes, and types of variables in MAT-file

You cannot access help for these methods using the `help` command. Find help on the methods from the command line using the `doc` command, such as `doc matlab.io.MatFile/size`.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

Create `myFile.mat` in a temporary folder and save data to part of variable `savedVar`:

```
filename = fullfile(tempdir,'myFile.mat');
matObj = matfile(filename);
matObj.savedVar(81:100,81:100) = magic(20);
```

Load part of the data into variable `loadVar`:

```
loadVar = matObj.savedVar(85:94,85:94);
```

Load or save an entire variable by omitting the indices. For example, load variable `topo` from `topography.mat`:

```
filename = 'topography.mat';
matObj = matfile(filename);
topo = matObj.topo;
```

Determine the dimensions of a variable, and process one part of the variable at a time. In this case, calculate and store the average of each column of variable `stocks` in the example file `stocks.mat`:

```
filename = 'stocks.mat';
matObj = matfile(filename);
[nrows, ncols] = size(matObj,'stocks');

avgs = zeros(1,ncols);
for idx = 1:ncols
 avgs(idx) = mean(matObj.stocks(:,idx));
end
```

By default, `matfile` only supports loading data from existing files. To enable saving, set `Writable` to `true` either during construction of the object,

```
filename = 'myFile.mat';
matObj = matfile(filename,'Writable',true);
```

or in a separate step, by setting `Properties.Writable`:

```
filename = 'myFile.mat';
matObj = matfile(filename);
matObj.Properties.Writable = true;
```

## **See Also**

`load` | `save` | `size` | `whos`

# matlab.io.fits.closeFile

Close FITS file

## Syntax

```
closeFile(fptr)
```

## Description

`closeFile(fptr)` closes an open FITS file.

This function corresponds to the `fits_close_file` (`ffclos`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits','READONLY');
fits.closeFile(fptr);
```

## See Also

[createFile](#) | [openFile](#)

## matlab.io.fits.createFile

Create FITS file

### Syntax

```
fptr = createFile(filename)
```

### Description

`fptr = createFile(filename)` creates a FITS file. An error will be returned if the specified file already exists, unless the filename is prefixed with an exclamation point (!). In that case CFITSIO will overwrite (delete) any existing file with the same name.

This function corresponds to the `fits_create_file` (`ffinit`) function in the CFITSIO library C API.

### Examples

Create a new FITS file, overwriting any existing file by the same name.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr, 'uint8', [256 512]);
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

### See Also

[closeFile](#) | [createImg](#) | [createTbl](#) | [openFile](#)

# matlab.io.fits.deleteFile

Delete FITS file

## Syntax

```
deleteFile(fptr)
```

## Description

`deleteFile(fptr)` closes and deletes an open FITS file. This can be useful if a FITS file cannot be properly closed.

This function corresponds to the `fits_delete_file` (`ffdel`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'tst0012.fits');
copyfile(srcFile, 'myfile.fits');
fileattrib('myfile.fits', '+w');
fptr = fits.openFile('myfile.fits', 'readwrite');
fits.deleteFile(fptr);
fptrs = fits.getOpenFiles()
```

## See Also

`closeFile` | `createFile`

## matlab.io.fits.fileName

Name of FITS file

### Syntax

```
name = fileName(fpPtr)
```

### Description

`name = fileName(fpPtr)` returns the name of the FITS file associated with the file handle.

This function corresponds to the `fits_file_name` (`ffflnm`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits','READONLY');
name = fits.fileName(fpPtr);
fits.closeFile(fpPtr);
```

### See Also

`createFile` | `openFile`

# matlab.io.fits.fileMode

I/O mode of FITS file

## Syntax

```
mode = fileMode(fptr)
```

## Description

`mode = fileMode(fptr)` returns the I/O mode of the opened FITS file. Possible values returned for `mode` are 'READONLY' or 'READWRITE'.

This function corresponds to the `fits_file_mode` (`ffflmd`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
mode = fits.fileMode(fptr);
fits.closeFile(fptr);
```

## See Also

[createFile](#) | [openFile](#)

## matlab.io.fits.openFile

Open FITS file

### Syntax

```
fptr = openFile(filename)
fptr = openFile(filename,mode)
```

### Description

`fptr = openFile(filename)` opens an existing FITS file in read-only mode and returns a file pointer, `fptr`, which references the primary array (first header data unit, or "HDU").

`fptr = openFile(filename,mode)` opens an existing FITS file according to the `mode`, which describes the type of access. `mode` may be either 'READONLY' or 'READWRITE'.

This function corresponds to the `fits_open_file` (`ffopen`) function in the CFITSIO library C API.

### Examples

Open a file in read-only mode and read image data from the primary array.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
imagedata = fits.readImg(fptr);
fits.closeFile(fptr);
```

Open a file in read-write mode and add a comment to the primary array.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fptr = fits.openFile('myfile.fits','readwrite');
fits.writeComment(fptr,'This is just a comment.');
```

```
fits.closeFile(fptr);
```

**See Also**

[closeFile](#) | [createFile](#)

## matlab.io.fits.createImg

Create FITS image

### Syntax

```
createImg(fptr,bitpix,naxes)
```

### Description

`createImg(fptr,bitpix,naxes)` creates a new primary image or image extension with a specified datatype `bitpix` and size `naxes`. If the FITS file is currently empty then a primary array is created, otherwise a new image extension is appended to the file.

The first two elements of `naxes` correspond to the NAXIS2 and NAXIS1 keywords, while any additional elements correspond to the NAXIS3, NAXIS4 ... NAXISn keywords.

The datatype `bitpix` may be given as either a CFITSIO name or as the corresponding MATLAB datatype.

'byte_img'	'uint8'
'short_img'	'int16'
'long_img'	'int32'
'longlong_img'	'int64'
'float_img'	'single'
'double_img'	'double'

This function corresponds to the `fits_create_img11` (`ffcrim11`) function in the CFITSIO library C API.

### Examples

Create two images in a new FITS file. There are 100 rows (NAXIS2 keyword) and 200 columns (NAXIS1 keyword) in the first image, and 256 rows (NAXIS2 keyword), 512 columns (NAXIS1 keyword), and 3 planes (NAXIS3 keyword) in the second image.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr, 'int16', [100 200]);
fits.createImg(fptr, 'byte_img', [256 512 3]);
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

## See Also

[createTbl](#) | [insertImg](#) | [readImg](#) | [setCompressionType](#) | [writeImg](#)

## matlab.io.fits.getImgSize

Size of image

### Syntax

```
imagesize = getImgSize(fpPtr)
```

### Description

`imagesize = getImgSize(fpPtr)` returns the number of rows and columns of an image. This function corresponds to the `fits_get_img_size` (`ffgisz`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*;
fpPtr = fits.openFile('tst0012.fits');
hdus = [1 3 4];
for j = hdus;
 htype = fits.movAbsHDU(fpPtr,j);
 sz = fits.getImgSize(fpPtr);
 fprintf('HDU %d: "%s", [' , j, htype);
 for k = 1:numel(sz)
 fprintf(' %d ', sz(k));
 end
 fprintf(']\n');
end
fits.closeFile(fpPtr);
```

### See Also

[createImg](#) | [getImgType](#)

# matlab.io.fits.getImgType

Data type of image

## Syntax

```
datatype = getImgType(fptr)
```

## Description

`datatype = getImgType(fptr)` gets the data type of an image. `datatype` can be one of the following strings:

```
'BYTE_IMG'
'SHORT_IMG'
'LONG_IMG'
'LONGLONG_IMG'
'FLOAT_IMG'
'DOUBLE_IMG'
```

This function corresponds to the `fits_get_img_type` (`ffgidt`) function in the CFITSIO library C API.

## Examples

```
fptr = fits.openFile('tst0012.fits');
hdus = [1 3 4];
for j = hdus;
 htype = fits.movAbsHDU(fptr,j);
 dtype = fits.getImgType(fptr);
 fprintf('HDU %d: "%s", "%s"\n', j, htype, dtype);
end
fits.closeFile(fptr);
```

**See Also**  
getImgSize

# matlab.io.fits.insertImg

Insert FITS image after current image

## Syntax

```
insertImage(fpPtr,bitpix,naxes)
```

## Description

`insertImage(fpPtr,bitpix,naxes)` inserts a new image extension immediately following the current HDU. If the file has just been created, a new primary array is inserted at the beginning of the file. Any following extensions in the file will be shifted down to make room for the new extension. If the current HDU is the last HDU in the file, then the new image extension will be appended to the end of the file.

This function corresponds to the `fits_insert_img11` (`ffiimg11`) function in the CFITSIO library C API.

## Examples

Create a 150x300 image between the 1st and 2nd images in a FITS file.

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.createImg(fpPtr,'byte_img',[100 200]);
fits.createImg(fpPtr,'byte_img',[200 400]);
fits.movAbsHDU(fpPtr,1);
fits.insertImg(fpPtr,'byte_img',[150 300]);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','mode','min');
```

## See Also

`createImg`

## matlab.io.fits.readImg

Read image data

### Syntax

```
imgdata = readImg(fptr)
imgdata = readImg(fptr,fpixel,lpixel)
imgdata = readImg(fptr,fpixel,lpixel,inc)
```

### Description

`imgdata = readImg(fptr)` reads the entire current image. The number of rows in `imgdata` will correspond to the value of the `NAXIS2` keyword, while the number of columns will correspond to the value of the `NAXIS1` keyword. Any further dimensions of `imgdata` will correspond to `NAXIS3`, `NAXIS4`, and so on.

`imgdata = readImg(fptr,fpixel,lpixel)` reads the subimage defined by pixel coordinates `fpixel` and `lpixel`. The `fpixel` argument is the coordinate of the first pixel and `lpixel` is the coordinate of the last pixel. `fpixel` and `lpixel` are one-based.

`imgdata = readImg(fptr,fpixel,lpixel,inc)` reads the subimage defined by `fpixel`, `lpixel`, and `inc`. The `inc` argument denotes the inter- element spacing along each extent.

This function corresponds to the `fits_read_subset (ffgsv)` function in the CFITSIO library C API.

### Examples

Read an entire image.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
data = fits.readImg(fptr);
fits.closeFile(fptr);
```

Read a 70x80 image subset.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
img = fits.readImg(fptr,[11 11],[80 90]);
fits.closeFile(fptr);
```

## See Also

[createImg](#) | [writeImg](#)

## matlab.io.fits.setBscale

Reset image scaling

### Syntax

```
setBscale(fptr,BSCALE,BZERO)
```

### Description

`setBscale(fptr,BSCALE,BZERO)` resets the scaling factors in the primary array or image extension according to the equation

$$\text{output} = (\text{FITS array}) * \text{BSCALE} + \text{BZERO}$$

The inverse formula is used when writing data values to the FITS file.

This only affects the automatic scaling performed when the data elements are read. It does not change the BSCALE and BZERO keyword values.

### Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.setBscale(fptr,2.0,0.5);
data = fits.readImg(fptr);
fits.closeFile(fptr);
```

### See Also

`readImg`

# matlab.io.fits.writelmng

Write to FITS image

## Syntax

```
writeImg(fptr,data)
writeImg(fptr,data,fpixel)
```

## Description

`writeImg(fptr,data)` writes an entire image to the FITS data array. The number of rows and columns in `data` must equal the values of the NAXIS2 and NAXIS1 keywords, respectively. Any further extents must correspond to the NAXIS3, NAXIS4 ... NAXISn keywords respectively.

`writeImg(fptr,data,fpixel)` writes a subset of an image to the FITS data array. `fpixel` gives the coordinate of the first pixel in the image region.

This function corresponds to the `fits_write_subset` (`ffpss`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'long_img',[256 512]);
data = reshape(1:256*512,[256 512]);
data = int32(data);
fits.writeImg(fptr,data);
fits.closeFile(fptr);
```

Create an 80x40 uint8 image and set all but the outermost pixels to 1.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'uint8',[80 40]);
```

```
data = ones(78,38);
fits.writeImg(fptr,data,[1 1]);
fits.closeFile(fptr);
```

## **See Also**

[createImg](#) | [readImg](#)

# matlab.io.fits.deleteKey

Delete key by name

## Syntax

```
deleteKey(fptr, keyname)
```

## Description

`deleteKey(fptr, keyname)` deletes a keyword by name.

This function corresponds to the `fits_delete_key` (`ffdrec`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'tst0012.fits');
copyfile(srcFile, 'myfile.fits');
fileattrib('myfile.fits', '+w');
fprintf('Before key deletion...\n');
fitsdisp('myfile.fits', 'index', 1);
fptr = fits.openFile('myfile.fits', 'readwrite');
fits.deleteKey(fptr, 'DATE');
fits.closeFile(fptr);
fprintf('\n\nAfter key deletion...\n');
fitsdisp('myfile.fits', 'index', 1);
```

## See Also

`deleteRecord` | `writeKey`

## matlab.io.fits.deleteRecord

Delete key by record number

### Syntax

```
deleteRecord(fpPtr, keynum)
```

### Description

`deleteRecord(fpPtr, keynum)` deletes a keyword by record number.

This function corresponds to the `fits_delete_record` (`ffdrec`) function in the CFITSIO library C API.

### Examples

Delete the 18th keyword ("ORIGIN") in a primary array.

```
import matlab.io.*
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'tst0012.fits');
copyfile(srcFile, 'myfile.fits');
fileattrib('myfile.fits', '+w');
fpPtr = fits.openFile('myfile.fits', 'readwrite');
card = fits.readRecord(fpPtr, 18);
fits.deleteRecord(fpPtr, 18);
fits.closeFile(fpPtr);
```

### See Also

`deleteKey` | `readRecord`

# matlab.io.fits.getHeaderSpace

Number of keywords in header

## Syntax

```
[nkeys,morekeys] = fits.getHeaderSpace(fpPtr)
```

## Description

`[nkeys,morekeys] = fits.getHeaderSpace(fpPtr)` returns the number of existing keywords (not counting the END keyword) and the amount of space currently available for more keywords. It returns `morekeys = -1` if the header has not yet been closed. Note that the CFITSIO library will dynamically add space if required when writing new keywords to a header so in practice there is no limit to the number of keywords that can be added to a header.

This function corresponds to the `fits_get_hdrspace` (`ffghsp`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
[nkeys,morekeys] = fits.getHeaderSpace(fpPtr);
fits.closeFile(fpPtr);
```

## matlab.io.fits.readCard

Header record of keyword

### Syntax

```
card = readCard(fpPtr, keyName)
```

### Description

`card = readCard(fpPtr, keyName)` returns the entire 80-character header record of the keyword, with any trailing blank characters stripped off.

This function corresponds to the `fits_read_card` (`ffgcrd`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fpPtr);
for j = 1:n
 fits.movAbsHDU(fpPtr, j);
 card = fits.readCard(fpPtr, 'NAXIS');
 fprintf('HDU %d: '%s'\n', j, card);
end
fits.closeFile(fpPtr);
```

# matlab.io.fits.readKey

Keyword

## Syntax

```
[value,comment] = readKey(fptr,keyname)
```

## Description

`[value,comment] = readKey(fptr,keyname)` returns the specified key and comment. `value` is returned as a string.

This function corresponds to the `fits_read_key_str` (`ffgkys`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
 fits.movAbsHDU(fptr,j);
 [key,comment] = fits.readKey(fptr,'NAXIS');
 fprintf('HDU %d: NAXIS %s, "%s"\n', j, key, comment);
end
fits.closeFile(fptr);
```

# matlab.io.fits.readKeyLongLong

Keyword as int64

## Syntax

```
[value,comment] = readKeyLongLong(fptr,keyname)
```

## Description

[value,comment] = readKeyLongLong(fptr,keyname) returns the specified key and comment. value is returned an int64 scalar value.

This function corresponds to the fits\_read\_key\_lnglng (ffgkyjj) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
 fits.movAbsHDU(fptr,j);
 [key,comment] = fits.readKeyLongLong(fptr,'NAXIS');
 fprintf('HDU %d: NAXIS %d, "%s"\n', j, key, comment);
end
fits.closeFile(fptr);
```

## See Also

readKey | readKeyCmplx | readKeyDb1

# matlab.io.fits.readKeyLongStr

Long string value

## Syntax

```
[value,comment] = readKeyLongStr(fptr,keyname)
```

## Description

`[value,comment] = readKeyLongStr(fptr,keyname)` returns the specified long string value and comment.

This function corresponds to the `fits_read_key_longstr` (`ffgkls`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
idata = repmat(char(97:106),1,10);
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.writeKey(fptr,'mykey',idata);
odata1 = fits.readKey(fptr,'mykey');
odata2 = fits.readKeyLongStr(fptr,'mykey');
fits.closeFile(fptr);
```

## See Also

`readKey`

## matlab.io.fits.readKeyUnit

Physical units string from keyword

### Syntax

```
units = readKeyUnit(fptr,keywordname)
```

### Description

`units = readKeyUnit(fptr,keywordname)` returns the physical units string from an existing keyword. If no units are defined, `units` is returned as an empty string.

This function corresponds to the `fits_read_key_unit` ( `ffgunt`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'long_img',[10 20]);
fits.writeKey(fptr,'VELOCITY',12.3,'orbital speed');
fits.writeKeyUnit(fptr,'VELOCITY','km/s');
units = fits.readKeyUnit(fptr,'VELOCITY');
fits.closeFile(fptr);
```

### See Also

[readKey](#) | [writeKeyUnit](#)

# matlab.io.fits.readRecord

Header record specified by number

## Syntax

```
card = readRecord(fptr, keynum)
```

## Description

`card = readRecord(fptr, keynum)` returns the entire 80-character header record identified by the numeric `keynum`. Trailing blanks are truncated.

This function corresponds to the `fits_read_record` (`ffgrec`) function in the CFITSIO library C API.

## Examples

Read the second record in each HDU.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getHdrSpace(fptr);
for j = 1:n
 card = fits.readRecord(fptr, j);
 fprintf('record %d: "%s"\n', j, card);
end
fits.closeFile(fptr);
```

## See Also

`deleteRecord` | `readCard` | `readKey`

## matlab.io.fits.writeComment

Write or append COMMENT keyword to CHU

### Syntax

```
writeComment(fptr,comment)
```

### Description

`writeComment(fptr,comment)` writes (appends) a COMMENT keyword to the CHU. The comment string will be continued over multiple keywords if it is longer than 70 characters.

This function corresponds to the `fits_write_comment` (`ffpcom`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.writeComment(fptr,'this is a comment');
fits.writeComment(fptr,'this is another comment');
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

### See Also

[writeDate](#) | [writeHistory](#)

# matlab.io.fits.writeDate

Write DATE keyword to CHU

## Syntax

```
writeDate(FPTR)
```

## Description

`writeDate(FPTR)` writes the DATE keyword to the CHU.

This function corresponds to the `fits_write_date` (`ffpdat`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr, 'byte_img', [100 200]);
fits.writeDate(fptr);
fits.closeFile(fptr);
fitsdisp('myfile.fits', 'mode', 'full');
```

## See Also

[writeComment](#) | [writeHistory](#)

## matlab.io.fits.writeKey

Update or add new keyword into current HDU

### Syntax

```
writeKey(fpPtr, keyName, value, comment)
writeKey(fpPtr, keyName, value, comment, decimals)
```

### Description

`writeKey(fpPtr, keyName, value, comment)` adds a new record in the current HDU, or updates it if it already exists. `comment` is optional.

`writeKey(fpPtr, keyName, value, comment, decimals)` adds a new floating point keyword in the current HDU, or updates it if it already exists. You must use this syntax to write a keyword with imaginary components. `decimals` is ignored otherwise.

If a character `value` exceeds 68 characters in length, the LONGWARN convention is automatically employed.

This function corresponds to the `fits_write_key` (`ffpky`) and `fits_update_key` (`ffuky`) family of functions in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.createImg(fpPtr, 'byte_img', [100 200]);
fits.writeKey(fpPtr, 'mykey1', 'a char value', 'with a comment');
fits.writeKey(fpPtr, 'mykey2', int32(1));
fits.writeKey(fpPtr, 'mykey3', 5+7*j, 'with another comment');
fits.writeKey(fpPtr, 'mykey4', 4/3, 'with yet another comment', 2);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits', 'mode', 'full');
```

### See Also

[deleteKey](#) | [readKey](#) | [readRecord](#)

# matlab.io.fits.writeKeyUnit

Write physical units string

## Syntax

```
writeKeyUnit(fptr, keyname, unit)
```

## Description

`writeKeyUnit(fptr, keyname, unit)` writes a physical units string into an existing keyword.

This function corresponds to the `fits_write_key_unit` (`ffpunit`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.createFile('myFitsFile.fits');
fits.createImg(fptr, 'long_img', [10 20]);
fits.writeKey(fptr, 'VELOCITY', 12.3, 'orbital speed');
fits.writeKeyUnit(fptr, 'VELOCITY', 'km/s');
fits.closeFile(fptr);
```

## See Also

`readKeyUnit`

## matlab.io.fits.writeHistory

Write or append HISTORY keyword to CHU

### Syntax

```
writeHistory(fptr,history)
```

### Description

`writeHistory(fptr,history)` writes (appends) a HISTORY keyword to the CHU. The history string is continued over multiple keywords if it is longer than 70 characters.

This function corresponds to the `fits_write_history` (`ffphis`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr, 'byte_img', [100 200]);
fits.writeHistory(fptr, 'this is a history keyword');
fits.closeFile(fptr);
fitsdisp('myfile.fits', 'mode', 'full');
```

### See Also

`writeComment` | `writeDate`

# matlab.io.fits.copyHDU

Copy current HDU from one file to another

## Syntax

```
copyHDU(infptr,outfptr)
```

## Description

`copyHDU(infptr,outfptr)` copies the current HDU from the FITS file associated with `infptr` and appends it to the end of the FITS file associated with `outfptr`.

This function corresponds to the `fits_copy_hdu` (`ffcopy`) function in the CFITSIO library C API.

## Examples

Copy the first, third, and fifth HDUs from one file to another.

```
import matlab.io.*
infptr = fits.openFile('tst0012.fits');
outfptr = fits.createFile('myfile.fits');
fits.copyHDU(infptr,outfptr);
fits.movAbsHDU(infptr,3);
fits.copyHDU(infptr,outfptr);
fits.movAbsHDU(infptr,5);
fits.copyHDU(infptr,outfptr);
fits.closeFile(infptr);
fits.closeFile(outfptr);
fitsdisp('tst0012.fits','mode','min','index',[1 3 5]);
fitsdisp('myfile.fits','mode','min');
```

## See Also

`deleteHDU`

## matlab.io.fits.deleteHDU

Delete current HDU in FITS file

### Syntax

```
HDU_TYPE = deleteHDU(fpnr)
```

### Description

`HDU_TYPE = deleteHDU(fpnr)` deletes the current HDU in the FITS file. Any following HDUs will be shifted forward in the file, filling the gap created by the deleted HDU. In the case of deleting the primary array (the first HDU in the file) then the current primary array will be replaced by a null primary array containing the minimum set of required keywords and no data. If there are more HDUs in the file following the HDU being deleted, then the current HDU will be redefined to point to the following HDU. If there are no following HDUs then the current HDU will be redefined to point to the previous HDU. `HDU_TYPE` returns the type of the new current HDU.

This function corresponds to the `fits_delete_hdu` (`ffdhdu`) function in the CFITSIO library C API.

### Examples

Delete the second HDU in a FITS file.

```
import matlab.io.*
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'tst0012.fits');
copyfile(srcFile, 'myfile.fits');
fileattrib('myfile.fits', '+w');
fitsdisp('myfile.fits', 'mode', 'min');
fpnr = fits.openFile('myfile.fits', 'readwrite');
fits.movAbsHDU(fpnr, 2);
new_current_hdu = fits.deleteHDU(fpnr);
fits.closeFile(fpnr);
fitsdisp('myfile.fits', 'mode', 'min');
```

## See Also

copyHDU

## matlab.io.fits.getHDUnum

Number of current HDU in FITS file

### Syntax

```
N = getHDUnum(fptr)
```

### Description

`N = getHDUnum(fptr)` returns the number of the current HDU in the FITS file. The primary array has HDU number 1.

This function corresponds to the `fits_get_hdu_num` (`ffghdn`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getHDUnum(fptr);
fits.closeFile(fptr);
```

### See Also

[getHDUtype](#) | [getNumHDUs](#)

# matlab.io.fits.getHDUtype

Type of current HDU

## Syntax

```
htype = getHDUtype(fptr)
```

## Description

`htype = getHDUtype(fptr)` returns the type of the current HDU in the FITS file. The possible values for `htype` are:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
```

This function corresponds to the `fits_get_hdu_type` (`ffghdt`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
 fits.getHDUtype(fptr);
end
fits.closeFile(fptr);
```

## See Also

`getHDUnum`

## matlab.io.fits.getNumHDUs

Total number of HDUs in FITS file

### Syntax

```
N = getNumHDUs(fpPtr)
```

### Description

`N = getNumHDUs(fpPtr)` returns the number of completely defined HDUs in a FITS file. If a new HDU has just been added to the FITS file, then that last HDU will only be counted if it has been closed, or if data has been written to the HDU. The current HDU remains unchanged by this routine.

This function corresponds to the `fits_get_num_hdus (ffthdu)` function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fpPtr);
fits.closeFile(fpPtr);
```

### See Also

getHDUenum

# matlab.io.fits.movAbsHDU

Move to absolute HDU number

## Syntax

```
htype = fits.movAbsHDU(fp_ptr,HDUNUM)
```

## Description

`htype = fits.movAbsHDU(fp_ptr,HDUNUM)` moves to a specified absolute HDU number (starting with 1 for the primary array) in the FITS file. The possible values for `htype` are:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
```

This function corresponds to the `fits_move_abs_hdu` function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fp_ptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fp_ptr);
for j = 1:n
 htype = fits.movAbsHDU(fp_ptr,j);
 fprintf('HDU %d: "%s"\n',j,htype);
end
fits.closeFile(fp_ptr);
```

## See Also

`getNumHDUs` | `movNamHDU` | `movRelHDU`

## matlab.io.fits.movNamHDU

Move to first HDU having specific type and keyword values

### Syntax

```
movNamHDU(fpPtr, hdutype, EXTNAME, EXTVER)
```

### Description

`movNamHDU(fpPtr, hdutype, EXTNAME, EXTVER)` moves to the first HDU which has the specified extension type and `EXTNAME` and `EXTVER` keyword values (or `HDUNAME` and `HDUVER` keywords).

The `hdutype` parameter may have a value of:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
'ANY_HDU'
```

If `hdutype` is `'ANY_HDU'`, only the `EXTNAME` and `EXTVER` values are used to locate the correct extension. If the input value of `EXTVER` is 0, then the `EXTVER` keyword is ignored and the first HDU with a matching `EXTNAME` (or `HDUNAME`) keyword will be found.

This function corresponds to the `fits_movnam_hdu` (`ffmnhd`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
fits.movNamHDU(fpPtr, 'IMAGE_HDU', 'quality', 1);
fits.closeFile(fpPtr);
```

## See Also

[movAbsHDU](#) | [movRe1HDU](#)

## matlab.io.fits.movRelHDU

Move relative number of HDUs from current HDU

### Syntax

```
hType = moveRelHDU(fptr,nmove)
```

### Description

`hType = moveRelHDU(fptr,nmove)` moves a relative number of HDUs forward or backward from the current HDU and returns the HDU type, `hType`, of the resulting HDU. The possible values for `hType` are:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
```

This function corresponds to the `fits_movrel_hdu` (`ffmrhd`) function in the CFITSIO library C API.

### Examples

Move through each HDU in succession, then move backwards twice by two HDUs.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
 hType = fits.movAbsHDU(fptr,j);
 fprintf('HDU %d: "%s"\n',j,hType);
end
hType = fits.movRelHDU(fptr,-2);
n = fits.getHDUnum(fptr);
fprintf('HDU %d: "%s"\n',n,hType);
hType = fits.movRelHDU(fptr,-2);
```

```
n = fits.getHDUnum(fptr);
fprintf('HDU %d: "%s"\n',n,htype);
fits.closeFile(fptr);
```

## See Also

movAbsHDU | movNamHDU

## matlab.io.fits.writeChecksum

Compute and write checksum for current HDU

### Syntax

```
writeChecksum(fptr)
```

### Description

`writeChecksum(fptr)` computes and writes the `DATASUM` and `CHECKSUM` keyword values for the current HDU into the current header. If the keywords already exist, their values are updated only if necessary (for example, if the file has been modified since the original keyword values were computed).

This function corresponds to the `fits_write_chksum (ffpcks)` function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr, 'long_img', [10 20]);
fits.writeChecksum(fptr)
fits.closeFile(fptr);
fitsdisp('myfile.fits', 'mode', 'full');
```

### See Also

`fitsdisp`

# matlab.io.fits.imgCompress

Compress HDU from one file into another

## Syntax

```
imgCompress(infptr,outfptr)
```

## Description

`imgCompress(infptr,outfptr)` initializes the output HDU, copies all the keywords, and loops through the input image, compressing the data and writing the compressed data to the output HDU.

This function corresponds to the `fits_img_compress` function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
infptr = fits.openFile('tst0012.fits');
outfptr = fits.createFile('myfile.fits');
fits.setCompressionType(outfptr,'rice');
fits.imgCompress(infptr,outfptr);
fits.closeFile(infptr);
fits.closeFile(outfptr);
```

## See Also

`setCompressionType`

## matlab.io.fits.isCompressedImg

Determine if current image is compressed

### Syntax

```
TF = isCompressedImg(fptr)
```

### Description

`TF = isCompressedImg(fptr)` returns true if the image in the current HDU is compressed.

This function corresponds to the `fits_is_compressed_image` function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
bool = fits.isCompressedImg(fptr);
fits.closeFile(fptr);
```

### See Also

`setCompressionType`

# matlab.io.fits.setCompressionType

Set image compression type

## Syntax

```
setCompressionType(fptr,comptype)
```

## Description

`setCompressionType(fptr,comptype)` specifies the image compression algorithm that should be used when writing a FITS image.

Supported values for `comptype` include:

```
'GZIP'
'GZIP2'
'RICE'
'PLIO'
'HCOMPRESS'
'NOCOMPRESS'
```

This function corresponds to the `fits_set_compression_type` function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.setCompressionType(fptr,'GZIP2');
fits.createImg(fptr,'long_img',[256 512]);
data = reshape(1:256*512,[256 512]);
data = int32(data);
fits.writeImg(fptr,data);
fits.closeFile(fptr);
```

```
fitsdisp('myfile.fits','mode','full');
```

### **See Also**

createImg | setTileDim

# matlab.io.fits.setHCompScale

Set scale parameter for HCOMPRESS algorithm

## Syntax

```
setHCompScale(fptr, scale)
```

## Description

`setHCompScale(fptr, scale)` sets the scale parameter to be used with the HCOMPRESS compression algorithm. Setting the scale parameter causes the algorithm to operate in lossy mode.

This function corresponds to the `fits_set_hcomp_scale` function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
data = 50*ones(256,512,'double') + 10 * rand([256 512]);
fptr = fits.createFile('myfile.fits');
fits.setCompressionType(fptr,'HCOMPRESS_1');
fits.setHCompScale(fptr,2.5);
fits.createImg(fptr,'double_img',[256 512]);
fits.writeImg(fptr,data);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

## See Also

`setCompressionType` | `setHCompSmooth`

# matlab.io.fits.setHCompSmooth

Set smoothing for images compressed with HCOMPRESS

## Syntax

```
setHCompSmooth(fptr,smooth)
```

## Description

`setHCompSmooth(fptr,smooth)` sets the smoothing to be used when compressing an image with the HCOMPRESS algorithm. Setting either the scale or smoothing parameter causes the algorithm to operate in lossy mode.

This function corresponds to the `fits_set_hcomp_smooth` function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
data = int32(50*ones(256,512,'double') + 10 * rand([256 512]));
fptr = fits.createFile('myfile.fits');
fits.setCompressionType(fptr,'HCOMPRESS');
fits.setHCompSmooth(fptr,1);
fits.createImg(fptr,'long_img',[256 512]);
fits.writeImg(fptr,data);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

## See Also

[setCompressionType](#) | [setHCompScale](#)

# matlab.io.fits.setTileDim

Set tile dimensions

## Syntax

```
fits.setTileDim(fptr,tiledims)
```

## Description

`fits.setTileDim(fptr,tiledims)` specifies the size of the image compression tiles to be used when creating a compressed image.

This function corresponds to the `fits_set_tile_dim` function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.setCompressionType(fptr,'RICE_1');
fits.setTileDim(fptr,[64 128]);
fits.createImg(fptr,'byte_img',[256 512]);
data = ones(256,512,'uint8');
fits.writeImg(fptr,data);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

## See Also

`setCompressionType`

## matlab.io.fits.createTbl

Create new ASCII or binary table extension

### Syntax

```
fptr = createTbl(fptr,tbltype,nrows,ttype,tform,tunit,extname)
```

### Description

`fptr = createTbl(fptr,tbltype,nrows,ttype,tform,tunit,extname)` creates a new ASCII or bintable table extension. `ttype` must be either `'binary'` or `'ascii'`. The `nrows` argument gives the initial number of rows to be created in the table and should normally be zero. `tunit` specifies the units for each column, but can be an empty cell array if no units are desired. `extname` specifies the extension name, but can be omitted.

`tform` specifies the format of the column. For binary tables, the values should be in the form of `'rt'`, where `'r'` is the repeat count and `'t'` is one of the following letters.

'A'	ASCII character
'B'	Byte or <code>uint8</code>
'C'	Complex (single precision)
'D'	Double precision
'E'	Single precision
'I'	<code>int16</code>
'J'	<code>int32</code>
'K'	<code>int64</code>
'L'	Logical
'M'	Complex (double precision)
'X'	Bit ( <code>int8</code> zeros and ones)

A column can also be specified as having variable-width if the `tform` value has the form `'1Pt'` or `'1Qt'`, where `'t'` specifies the data type as above.

For ASCII tables, the `tform` values take the form:

Iw	int16 column with width 'w'
Aw	ASCII column with width 'w'
Fww.dd	Fixed point
Eww.dd	Single precision with width 'ww' and precision 'dd'
Dww.dd	Double precision with width 'ww' and precision 'dd'

This function corresponds to the `fits_create_tbl` (`ffcrtb`) function in the CFITSIO library C API.

## Examples

Create a binary table. The first column contains strings of nine characters each. The second column contains four-element sequences of bits. The third column contains three-element sequences of `uint8` values. The fourth column contains double-precision scalars.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2','Col3','Col4'};
tform = {'9A','4X','3B','1D'};
tunit = {'m/s','kg','kg/m^3','candela'};
fits.createTbl(fptr,'binary',10,ttype,tform,tunit,'my-table');
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

Create a two-column table where the first column has a single double-precision value, but the second column has a variable-length double-precision value.

```
import matlab.io.*
fptr = fits.createFile('myfile2.fits');
ttype = {'Col1','Col2'};
tform = {'1D','1PD'};
fits.createTbl(fptr,'binary',0,ttype,tform);
fits.closeFile(fptr);
fitsdisp('myfile2.fits');
```

**See Also**

`createImg` | `insertATbl` | `insertBTbl` | `readCol` | `writeCol`

# matlab.io.fits.deleteCol

Delete column from table

## Syntax

```
deleteCol(fpPtr,colnum)
```

## Description

`deleteCol(fpPtr,colnum)` deletes the column from an ASCII or binary table.

This function corresponds to the `fits_delete_col` (`ffdcoll`) function in the CFITSIO library C API.

## Examples

Delete the second column in a binary table.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fprintf('Before: '); fitsdisp('myfile.fits','index',2,'mode','min');
fpPtr = fits.openFile('myfile.fits','readwrite');
fits.movAbsHDU(fpPtr,2);
fits.deleteCol(fpPtr,2);
fits.closeFile(fpPtr);
fprintf('After : '); fitsdisp('myfile.fits','index',2,'mode','min');
```

## See Also

`deleteRows`

## matlab.io.fits.deleteRows

Delete rows from table

### Syntax

```
deleteRows(fpPtr,firstrow,nrows)
```

### Description

`deleteRows(fpPtr,firstrow,nrows)` deletes rows from an ASCII or binary table.

This function corresponds to the `fits_delete_rows` (`ffdraw`) function in the CFITSIO library C API.

### Examples

Delete the second, third, and fourth rows in a binary table (second HDU).

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fprintf('Before: '); fitsdisp('myfile.fits','index',2,'mode','min');
fpPtr = fits.openFile('myfile.fits','readwrite');
fits.movAbsHDU(fpPtr,2);
fits.deleteRows(fpPtr,2,2);
fits.closeFile(fpPtr);
fprintf('After : '); fitsdisp('myfile.fits','index',2,'mode','min');
```

### See Also

`deleteCol` | `insertRows`

# matlab.io.fits.insertRows

Insert rows into table

## Syntax

```
insertRows(fpPtr,firstrow,nrows)
```

## Description

`insertRows(fpPtr,firstrow,nrows)` inserts rows into an ASCII or binary table. `firstrow` is a one-based number.

This function corresponds to the `fits_insert_rows` (`ffifrow`) function in the CFITSIO library C API.

## Examples

Insert five rows into an empty table.

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2'};
tform = {'3A','1D'};
tunit = {'m/s','candela'};
fits.createTbl(fpPtr,'binary',0,ttype,tform,tunit,'my-table');
fits.insertRows(fpPtr,1,5);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','index',2);
```

## See Also

## matlab.io.fits.getAColParms

ASCII table information

### Syntax

```
[ttype,tbcol,tunit,tform,scale,zero,nulstr,tdisp] =
getAColParms(fptr,colnum)
```

### Description

```
[ttype,tbcol,tunit,tform,scale,zero,nulstr,tdisp] =
getAColParms(fptr,colnum) gets information about an existing ASCII table column.
```

This function corresponds to the `fits_get_acolparms` (`fffacl`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,5);
[ttype,tbcol,tunit,tform,scale,zero,nulstr,tdisp] = fits.getAColParms(fptr,2);
fits.closeFile(fptr);
```

### See Also

`getBColParms`

# matlab.io.fits.getBColParms

Binary table information

## Syntax

```
[ttype,tunit,typechar,repeat,scale,zero,nulval,tdisp] =
getBColParms(fpPtr,colnum)
```

## Description

```
[ttype,tunit,typechar,repeat,scale,zero,nulval,tdisp] =
getBColParms(fpPtr,colnum) gets information about an existing binary table column.
```

This function corresponds to the `fits_get_bcolparms` (`ffgbcl`) function in the CFITSIO library C API.

## Examples

Get information about the second column in a binary table.

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fpPtr,2);
[ttype,tunit,typechar,repeat,scale,zero,nulval,tdisp]= fits.getBColParms(fpPtr,2);
fits.closeFile(fpPtr);
```

## See Also

`getAColParms`

# matlab.io.fits.getColName

Table column name

## Syntax

```
[colnum,colname] = getColNum(fpPtr,templt,casesen)
```

## Description

`[colnum,colname] = getColNum(fpPtr,templt,casesen)` gets the table column numbers and names of the columns whose names match an input template name. If `casesen` is true, then the column name match is case-sensitive. `casesen` defaults to false.

The input column name template may be either the exact name of the column to be searched for, or it may contain wildcard characters (\*, ?, or #), or it may contain the integer number of the desired column (with the first column = 1). The '\*' wildcard character matches any sequence of characters (including zero characters) and the '?' character matches any single character. The # wildcard matches any consecutive string of decimal digits (0-9).

## Examples

Return all the columns starting with the letter 'C'.

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fpPtr,2);
[nums,names] = fits.getColName(fpPtr,'C*');
fits.closeFile(fpPtr);
```

## See Also

[getAColParms](#) | [getBColParms](#)

# matlab.io.fits.getColType

Scaled column data type, repeat value, width

## Syntax

```
[dtype,repeat,width] = getColType(fptr,colnum)
```

## Description

`[dtype,repeat,width] = getColType(fptr,colnum)` returns the data type, vector repeat value, and the width in bytes of a column in an ASCII or binary table.

This function corresponds to the `fits_get_coltype11` (`ffgtc111`) function in the CFITSIO library C API.

## Examples

Get information about the 'FLUX' column in the second HDU.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[dtype,repeat,width] = fits.getColType(fptr,5);
fits.closeFile(fptr);
```

## See Also

`getEqColType`

## matlab.io.fits.getEqColType

Column data type, repeat value, width

### Syntax

```
[dtype,repeat,width] = getColType(fptr,colnum)
```

### Description

`[dtype,repeat,width] = getColType(fptr,colnum)` returns the scaled data type needed to store the scaled column data type, the vector repeat value, and the width in bytes of a column in an ASCII or binary table.

This function corresponds to the `fits_get_eqcoltype11` (`ffeqty11`) function in the CFITSIO library C API.

### Examples

Get information about the 'FLUX' column in the second HDU.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[dtype,repeat,width] = fits.getEqColType(fptr,5);
fits.closeFile(fptr);
```

### See Also

`getColType`

# matlab.io.fits.getNumCols

Number of columns in table

## Syntax

```
ncols = getNumCols(fptr)
```

## Description

`ncols = getNumCols(fptr)` gets the number of columns in the current FITS table. This function corresponds to the `fits_get_num_cols` (`ffgncl`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
ncols = fits.getNumCols(fptr);
nrows = fits.getNumRows(fptr);
fits.closeFile(fptr);
```

## See Also

`getNumRows`

## matlab.io.fits.getNumRows

Number of rows in table

### Syntax

```
nrows = getNumRows(fptr)
```

### Description

`nrows = getNumRows(fptr)` gets the number of rows in the current FITS table. This function corresponds to the `fits_get_num_rows11` (`ffgnrwl`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
ncols = fits.getNumCols(fptr);
nrows = fits.getNumRows(fptr);
fits.closeFile(fptr);
```

### See Also

`getNumCols`

# matlab.io.fits.insertCol

Insert column into table

## Syntax

```
insertCol(fptr,colnum,ttype,tform)
```

## Description

`insertCol(fptr,colnum,ttype,tform)` inserts a column into an ASCII or binary table.

This function corresponds to the `fits_insert_col` (`fficol`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2'};
tform = {'3A','1D'};
tunit = {'m/s','candela'};
fits.createTbl(fptr,'binary',0,ttype,tform,tunit,'my-table');
fits.insertCol(fptr,3,'Col3','3D');
fits.closeFile(fptr);
fitsdisp('myfile.fits','index',2);
```

## See Also

`insertRows`

## matlab.io.fits.insertATbl

Insert ASCII table after current HDU

### Syntax

```
insertATbl(fptr, rowlen, nrows, ttype, tbc01, tform, tunit, extname)
```

### Description

`insertATbl(fptr, rowlen, nrows, ttype, tbc01, tform, tunit, extname)` inserts a new ASCII table extension immediately following the current HDU. Any following extensions are shifted down to make room for the new extension. If there are no other following extensions, then the new table extension is simply appended to the end of the file. If the FITS file is currently empty then this routine creates a dummy primary array before appending the table to it. The new extension becomes the current HDU. If `rowlen` is 0, then CFITSIO calculates the default `rowlen` based on the `tbc01` and `ttype` values.

`tform` can take the following forms. In each case, 'w' and 'ww' represent the widths of the ASCII columns.

Iw	int16 column
Aw	ASCII column
Fww.dd	Fixed point with 'dd' digits after the decimal point
Eww.dd	Single precision with 'dd' digits of precision
Dww.dd	Double precision with 'dd' digits of precision

Binary tables are recommended instead of ASCII tables.

This function corresponds to the `fits_insert_atbl (ffitab)` function in the CFITSIO library C API.

## Examples

Create an ASCII table between two images.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'uint8',[20 30]);
fits.createImg(fptr,'int16',[30 40]);
fits.movRelHDU(fptr,-1);
ttype = {'Name','Short','Fix','Double'};
tbcol = [1 17 28 43];
tform = {'A15','I10','F14.2','D12.4'};
tunit = {'','m**2','cm','km/s'};
fits.insertATbl(fptr,0,0,ttype,tbcol,tform,tunit,'my-table');
fits.writeCol(fptr,1,1,char('abracadabra','hocus-pocus'));
fits.writeCol(fptr,2,1,int16([0; 1]));
fits.writeCol(fptr,3,1,[12.4; 4/3]);
fits.writeCol(fptr,4,1,[12.4; 4e8/3]);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','min');
```

## See Also

[createTbl](#) | [insertBTbl](#)

## matlab.io.fits.insertBTbl

Insert binary table after current HDU

### Syntax

```
insertBTbl(fpPtr,nrows,ttype,tform,tunit,extname,pcount)
```

### Description

`insertBTbl(fpPtr,nrows,ttype,tform,tunit,extname,pcount)` inserts a new binary table extension immediately following the current HDU. Any following extensions are shifted down to make room for the new extension. If there are no other following extensions then the new table extension is simply appended to the end of the file. If the FITS file is currently empty then this routine creates a dummy primary array before appending the table to it. The new extension becomes the CHDU. If there are following extensions in the file and if the table contains variable-length array columns then `pcount` must specify the expected final size of the data heap. Otherwise, `pcount` must be zero.

This function corresponds to the `fits_insert_btbl` (`ffibin`) function in the CFITSIO library C API.

### Examples

Create a table following the primary array. Then, insert a new table just before it.

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2'};
tform = {'9A','1D'};
tunit = {'m/s','candela'};
fits.createTbl(fpPtr,'binary',10,ttype,tform,tunit,'my-table');
fits.movRelHDU(fpPtr,-1);
fits.insertBTbl(fpPtr,5,ttype,tform,tunit,'my-new-table',0);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits');
```

## See Also

[createTbl](#) | [insertATbl](#)

## matlab.io.fits.readATblHdr

Read header information from current ASCII table

### Syntax

```
[rowlen,nrows,ttype,tbcol,tform,tunit,exname] = readATblHdr(fptr)
```

### Description

```
[rowlen,nrows,ttype,tbcol,tform,tunit,exname] = readATblHdr(fptr)
```

reads header information for the current ASCII table.

This function corresponds to the `fits_read_atblhdr11` (`ffghtb11`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,5);
[rowlen,nrows,ttype,tbcol,tform,tunit,exname] = fits.readATblHdr(fptr);
fits.closeFile(fptr);
```

### See Also

`readBTblHdr`

# matlab.io.fits.readBTblHdr

Read header information from current binary table

## Syntax

```
[nrows,ttype,tform,tunit,extname,pcount] = readBTblHdr(fptr)
```

## Description

`[nrows,ttype,tform,tunit,extname,pcount] = readBTblHdr(fptr)` reads header information for the current binary table.

This function corresponds to the `fits_read_btblhdr11` (`ffghbn11`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[nrows,ttype,tform,tunit,extname,pcount] = fits.readBTblHdr(fptr);
fits.closeFile(fptr);
```

## See Also

`readATblHdr`

## matlab.io.fits.readCol

Read rows of ASCII or binary table column

### Syntax

```
[coldata,nullval] = readCol(fpPtr,colnum)
[coldata,nullval] = readCol(fpPtr,colnum,firstrow,numrows)
```

### Description

`[coldata,nullval] = readCol(fpPtr,colnum)` reads an entire column from an ASCII or binary table column. `nullval` is a logical array specifying if a particular element of `coldata` should be treated as undefined. It is the same size as `coldata`.

`[coldata,nullval] = readCol(fpPtr,colnum,firstrow,numrows)` reads a subsection of rows from an ASCII or binary table column.

The MATLAB data type returned by `readCol` corresponds to the data type returned by `getEqColType`.

This function corresponds to the `fits_read_col` (`ffgcv`) function in the CFITSIO library C API.

### Examples

Read an entire column.

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fpPtr,2);
colnum = fits.getColName(fpPtr,'flux');
fluxdata = fits.readCol(fpPtr,colnum);
fits.closeFile(fpPtr);
```

Read the first five rows in a column.

```
import matlab.io.*
```

```
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
colnum = fits.getColName(fptr,'flux');
fluxdata = fits.readCol(fptr,colnum,1,5);
fits.closeFile(fptr);
```

## See Also

writeCol

## matlab.io.fits.setTscale

Reset image scaling

### Syntax

```
setTscale(fptr,colnum,tscale,tzero)
```

### Description

`setTscale(fptr,colnum,tscale,tzero)` resets the scaling factors for a table column according to the equation:

$$\text{output} = (\text{FITS array}) * \text{tscale} + \text{tzero}$$

The inverse formula is used when writing data values to the FITS file.

This only affects the automatic scaling performed when the data elements are read. It does not change the `tscale` and `tzero` keyword values.

### Examples

Turn off automatic scaling in a table column where the `tscale` and `tzero` keywords are present.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
scaled_data = fits.readCol(fptr,3);
fits.setTscale(fptr,3,1.0,0.0);
unscaled_data = fits.readCol(fptr,3);
fits.closeFile(fptr);
```

### See Also

`readImg`

# matlab.io.fits.writeCol

Write elements into ASCII or binary table column

## Syntax

```
writeCol(fpPtr,colnum,firstrow,coldata)
```

## Description

`writeCol(fpPtr,colnum,firstrow,coldata)` writes elements into an ASCII or binary table extension column.

When writing rows of data to a variable length field, `coldata` must be a cell array.

This function corresponds to the `fits_write_col` (`ffpcol`) function in the CFITSIO library C API.

## Examples

Write to a table with ASCII, `uint8`, double-precision, and variable-length double-precision columns.

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
ttype = {'Col1', 'Col2', 'Col3', 'Col4'};
tform = {'3A', '3B', '1D', '1PD'};
tunit = {'m/s', 'kg/m^3', 'candela', 'parsec'};
fits.createTbl(fpPtr, 'binary', 0, ttype, tform, tunit, 'my-table');
fits.writeCol(fpPtr, 1, 1, ['dog'; 'cat']);
fits.writeCol(fpPtr, 2, 1, [0 1 2; 3 4 5; 6 7 8; 9 10 11]);
fits.writeCol(fpPtr, 3, 1, [1; 2; 3; 4]);
fits.writeCol(fpPtr, 4, 1, {1; [1 2]; [1 2 3]; [1 2 3 4]});
fits.closeFile(fpPtr);
fitsdisp('myfile.fits', 'index', 2, 'mode', 'full');
```

Write to a table with logical, bit, double precision, and variable-length complex single-precision columns.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1', 'Col2', 'Col3', 'Col4'};
tform = {'2L', '3X', '1D', '1PC'};
tunit = {'', 'kg/m^3', 'candela', 'parsec'};
fits.createTbl(fptr, 'binary', 0, ttype, tform, tunit, 'my-table');
fits.writeCol(fptr, 1, 1, [false false; true false]);
fits.writeCol(fptr, 2, 1, int8([0 1 1; 1 1 1; 1 1 1; 1 0 1]));
fits.writeCol(fptr, 3, 1, [1; 2; 3; 4]);
data = cell(4, 1);
data{1} = single(1);
data{2} = single(1+2j);
data{3} = single([1j 2 3+j]);
data{4} = single([1 2+3j 3 4]);
fits.writeCol(fptr, 4, 1, data);
fits.closeFile(fptr);
fitsdisp('myfile.fits', 'index', 2, 'mode', 'full');
```

## See Also

[createTbl](#) | [readCol](#)

# matlab.io.fits.getConstantValue

Numeric value of named constant

## Syntax

```
N = getConstantValue(name)
```

## Description

`N = getConstantValue(name)` returns the numeric value corresponding to the named CFITSIO constant.

## Examples

```
import matlab.io.*
n = fits.getConstantValue('BYTE_IMG');
```

## matlab.io.fits.getVersion

Revision number of the CFITSIO library

### Syntax

```
V = getVersion()
```

### Description

`V = getVersion()` returns the revision number of the CFITSIO library. This function corresponds to the `fits_get_version` (`ffvers`) function in the CFITSIO library C API.

### Examples

```
import matlab.io.*
v = fits.getVersion();
```

# matlab.io.fits.getOpenFiles

List of open FITS files

## Syntax

```
fptrs = getOpenFiles()
```

## Description

`fptrs = getOpenFiles()` returns a list of file pointers of all open FITS files.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
clear fptr;
fptr = fits.getOpenFiles();
fits.closeFile(fptr);
```

## See Also

[closeFile](#) | [openFile](#)

## matlab.io.hdf4.sd

Interact directly with HDF4 multifile scientific data set (SD) interface

### Description

To use these MATLAB functions, you should be familiar with the HDF SD C API. In most cases, the syntax of the MATLAB function is similar to the syntax of the corresponding HDF library function. The functions are implemented as the package `matlab.io.hdf4.sd`. To use this package, prefix the function name with a package path, or use the `import` function to add the package to the current import list, prior to calling the function, for example,

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf', 'read');
```

### Access

<code>matlab.io.hdf4.sd.close</code>	Terminate access to SD interface
<code>matlab.io.hdf4.sd.endAccess</code>	Terminate access to data set
<code>matlab.io.hdf4.sd.getFilename</code>	Name of file
<code>matlab.io.hdf4.sd.select</code>	Identifier of data set with specified index
<code>matlab.io.hdf4.sd.setExternalFile</code>	Store data in external file
<code>matlab.io.hdf4.sd.start</code>	Open HDF file and initialize SD interface

### Read/Write

<code>matlab.io.hdf4.sd.create</code>	Create new data set
<code>matlab.io.hdf4.sd.readData</code>	Read subsample of data
<code>matlab.io.hdf4.sd.setFillMode</code>	Set current fill mode of file
<code>matlab.io.hdf4.sd.writeData</code>	Write to data set

## Inquiry

matlab.io.hdf4.sd.fileInfo	Number of data sets and global attributes in file
matlab.io.hdf4.sd.getCompInfo	Information about data set compression
matlab.io.hdf4.sd.getFillValue	Fill value for data set
matlab.io.hdf4.sd.getInfo	Information about data set
matlab.io.hdf4.sd.idToRef	Reference number corresponding to data set identifier
matlab.io.hdf4.sd.idType	Type of object
matlab.io.hdf4.sd.isCoordVar	Determine if data set is a coordinate variable
matlab.io.hdf4.sd.isRecord	Determine if data set is appendable
matlab.io.hdf4.sd.nameToIndex	Index value of named data set
matlab.io.hdf4.sd.nameToIndices	List of data sets with same name
matlab.io.hdf4.sd.refToIndex	Index of data set corresponding to reference number

## Dimensions

matlab.io.hdf4.sd.dimInfo	Information about dimension
matlab.io.hdf4.sd.getDimID	Dimension identifier
matlab.io.hdf4.sd.getDimScale	Scale data for dimension
matlab.io.hdf4.sd.setDimName	Associate name with dimension
matlab.io.hdf4.sd.setDimScale	Set scale values for dimension

## User-defined Attributes

matlab.io.hdf4.sd.attrInfo	Information about attribute
matlab.io.hdf4.sd.findAttr	Index of specified attribute

matlab.io.hdf4.sd.readAttr

Read attribute value

matlab.io.hdf4.sd.setAttr

Write attribute value

## Predefined Attributes

matlab.io.hdf4.sd.getCal

Data set calibration information

matlab.io.hdf4.sd.getDataStrs

Predefined attribute strings for data set

matlab.io.hdf4.sd.getDimStrs

Predefined attribute strings for dimension

matlab.io.hdf4.sd.getFillValue

Fill value for data set

matlab.io.hdf4.sd.getRange

Maximum and minimum range values

matlab.io.hdf4.sd.setCal

Set data set calibration information

matlab.io.hdf4.sd.setDataStrs

Set predefined attributes for data set

matlab.io.hdf4.sd.setDimStrs

Set label, unit, and format attribute strings

matlab.io.hdf4.sd.setFillValue

Set fill value for data set

matlab.io.hdf4.sd.setRange

Set maximum and minimum range value  
for data set

## Chunking/Tiling Operations

matlab.io.hdf4.sd.getChunkInfo

Chunk size for data set

matlab.io.hdf4.sd.readChunk

Read chunk from data set

matlab.io.hdf4.sd.setChunk

Set chunk size and compression method of  
data set

matlab.io.hdf4.sd.writeChunk

Write chunk to data set

## Compression

matlab.io.hdf4.sd.setCompress

Set compression method of data set

matlab.io.hdf4.sd.setNBitDataSet

Specify nonstandard bit length for data set  
values

# matlab.io.hdf4.sd.attrInfo

**Package:** matlab.io.hdf4.sd

Information about attribute

## Syntax

```
[name,datatype,nelts] = attrInfo(objID,idx)
```

## Description

`[name,datatype,nelts] = attrInfo(objID,idx)` returns the name, data type, and number of elements in the specified attribute. The attribute is specified by its zero-based index value. `objID` can be either an SD interface identifier, a data set identifier, or a dimension identifier.

This function corresponds to the `SAttrinfo` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.findAttr(sdID,'creation_date');
[name,datatype,nelts] = sd.attrInfo(sdID,idx);
data = sd.readAttr(sdID,idx);
sd.close(sdID);
```

## See Also

`sd.findAttr`

## matlab.io.hdf4.sd.close

**Package:** matlab.io.hdf4.sd

Terminate access to SD interface

### Syntax

```
sd.close(sdID)
```

### Description

`sd.close(sdID)` closes the file identified by `sdID`.

This function corresponds to the `SDend` function in the HDF C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID, 'temperature');
sdsID = sd.select(sdID, idx);
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

`sd.start`

# matlab.io.hdf4.sd.create

**Package:** matlab.io.hdf4.sd

Create new data set

## Syntax

```
sdsID = create(sdID,name,datatype,dims)
```

## Description

`sdsID = create(sdID,name,datatype,dims)` creates a data set with the given name `name`, data type `datatype`, and dimension sizes `dims`.

To create a data set with an unlimited dimension, the last value in `dims` should be set to 0.

This function corresponds to the `SDcreate` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `dims` parameter is reversed with respect to the C library API.

## Examples

Create a 3D data set with an unlimited dimension.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20 0]);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.endAccess`

## matlab.io.hdf4.sd.dimInfo

**Package:** matlab.io.hdf4.sd

Information about dimension

### Syntax

```
[name,dimlen,datatype,nattrs] = dimInfo(dimID)
```

### Description

`[name,dimlen,datatype,nattrs] = dimInfo(dimID)` returns the name, length, data type, and number of attributes of the specified dimension.

This function corresponds to the `SDdiminfo` function in the HDF library C API.

### Examples

Read a 2-by-3 portion of a data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'latitude');
sdsID = sd.select(sdID,idx);
dimID = sd.getDimID(sdsID,0);
[name,dimlen,datatype,nattrs] = sd.dimInfo(dimID);
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

`sd.getDimID`

# matlab.io.hdf4.sd.endAccess

**Package:** matlab.io.hdf4.sd

Terminate access to data set

## Syntax

```
sd.endAccess(sdsID)
```

## Description

`sd.endAccess(sdsID)` terminates access to the data set identified by `sdsID`. Failing to call this function after all operations on the specified data set are complete may result in loss of data.

This function corresponds to the `SDendaccess` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID, 'temperature');
sdsID = sd.select(sdID, idx);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.close` | `sd.select`

## matlab.io.hdf4.sd.fileInfo

**Package:** matlab.io.hdf4.sd

Number of data sets and global attributes in file

### Syntax

```
[ndatasets,ngatts] = fileInfo(sdID)
```

### Description

`[ndatasets,ngatts] = fileInfo(sdID)` returns the number of data sets `ndatasets` and the number of global attributes `ngatts` in the file identified by `sdID`.

`ndatasets` includes the number of coordinate variable data sets.

This function corresponds to the `SDfileinfo` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
[ndatasets,ngatts] = sd.fileInfo(sdID);
sd.close(sdID);
```

### See Also

# matlab.io.hdf4.sd.findAttr

**Package:** matlab.io.hdf4.sd

Index of specified attribute

## Syntax

```
idx = findAttr(objID,attrname)
```

## Description

`idx = findAttr(objID,attrname)` returns the index of the attribute specified by `attrname`. The `objID` input can be either an SD interface identifier, a data set identifier, or a dimension identifier.

The function corresponds to the `SDfindattr` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.findAttr(sdID,'creation_date');
data = sd.readAttr(sdID,idx);
sd.close(sdID);
```

## matlab.io.hdf4.sd.getCal

**Package:** matlab.io.hdf4.sd

Data set calibration information

### Syntax

```
[cal,calErr,offset,offsetErr,datatype] = getCal(sdsID)
```

### Description

[cal,calErr,offset,offsetErr,datatype] = getCal(sdsID) retrieves the calibration information associated with a data set.

This function corresponds to the SDgetcal function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
[cal,calErr,offset,offsetErr,dtype] = sd.getCal(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

sd.setCal

# matlab.io.hdf4.sd.getChunkInfo

**Package:** matlab.io.hdf4.sd

Chunk size for data set

## Syntax

```
chunkDims = getChunkInfo(sdsID)
```

## Description

`chunkDims = getChunkInfo(sdsID)` returns the chunk size for the data set specified by `sdsID`. If a data set is chunked, the dimensions of the chunks is returned in `chunkDims`. Otherwise `chunkDims` is `[]`.

This function corresponds to the `SDgetchunkinfo` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `chunkDims` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
cdims = sd.getChunkInfo(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.getCompInfo` | `sd.setChunk`

## matlab.io.hdf4.sd.getCompInfo

**Package:** matlab.io.hdf4.sd

Information about data set compression

### Syntax

```
[comptype,compparms] = getCompType(sdsID)
```

### Description

[comptype,compparms] = getCompType(sdsID) retrieves the compression type and compression information for a data set. `comptype` can be one of the following strings.

'none'	No compression
'rle'	Run-length encoding
'nbit'	NBIT compression
'skphuff'	Skipping Huffman compression
'deflate'	GZIP compression
'szip'	SZIP compression

If `comptype` is 'none' or 'rle', then `compparms` is [ ].

If `comptype` is 'nbit', then `compparms` is a 4-element array.

compparm(1)	sign_ext
compparm(2)	fill_one
compparm(3)	start_bit
compparm(4)	bit_len

If `comptype` is 'deflate', then `compparms` contains the deflation value, a number between 0 and 9.

If `comptype` is `'gzip'`, then `compparms` is a 5-element array. Consult the HDF Reference Manual for details on SZIP compression.

This function corresponds to the `SDgetcompinfo` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[100 50]);
sd.setCompress(sdsID,'deflate',5);
[comptype,compparm] = sd.getCompInfo(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

[sd.setCompress](#) | [sd.setNBitDataSet](#)

## matlab.io.hdf4.sd.getDataStrs

**Package:** matlab.io.hdf4.sd

Predefined attribute strings for data set

### Syntax

```
[label,unit,format,coordsys] = getDataStrs(sdsID)
[label,unit,format,coordsys] = getDataStrs(sdsID,maxlen)
```

### Description

[label,unit,format,coordsys] = `getDataStrs(sdsID)` returns the label, unit, format, and coordsys attributes for the data set identified by `sdsID`.

[label,unit,format,coordsys] = `getDataStrs(sdsID,maxlen)` returns the label, unit, format, and coordsys attributes for the data set identified by `sdsID`. The `maxlen` input is the maximum length of any of the attribute strings. It defaults to 1000 if not specified.

This function corresponds to the `SDgetdatastrs` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
[label,unit,fmt,coordsys] = sd.getDataStrs(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

`sd.setDataStrs`

# matlab.io.hdf4.sd.getDimID

**Package:** matlab.io.hdf4.sd

Dimension identifier

## Syntax

```
dimID = getDimID(sdsID,dimnumber)
```

## Description

`dimID = getDimID(sdsID,dimnumber)` returns the identifier of the dimension given its index.

---

**Note:** MATLAB uses Fortran-style indexing while the HDF library uses C-style indexing. The order of the dimension identifiers retrieved with `sd.getDimID` are reversed from what would be retrieved via the C API.

---

This function corresponds to the `SDgetdimid` function in the HDF library C API.

## Examples

Read an entire data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dimID0 = sd.getDimID(sdsID,0);
dimID1 = sd.getDimID(sdsID,1);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.setDimName`

# matlab.io.hdf4.sd.getDimScale

**Package:** matlab.io.hdf4.sd

Scale data for dimension

## Syntax

```
scale = getDimScale(dimID)
```

## Description

`scale = getDimScale(dimID)` returns the scale values of the dimension identified by `dimID`.

This function corresponds to the `SDgetdimscale` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',20);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'x');
sd.setDimScale(dimID,0:5:95);
sd.endAccess(sdsID);
sd.close(sdID);
sdID = sd.start('myfile.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dimID = sd.getDimID(sdsID,0);
scale = sd.getDimScale(dimID);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

**Package:** matlab.io.hdf4.sd

Predefined attribute strings for dimension

## Syntax

```
[label,unit,format] = getDimStrs(dimID)
```

## Description

`[label,unit,format] = getDimStrs(dimID)` returns the label, unit, and format attributes for the dimension identified by `dimID`.

This function corresponds to the `SDgetdimstrs` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',20);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'x');
sd.setDimStrs(dimID,'xdim','none','%d');
sd.endAccess(sdsID);
sd.close(sdID);
sdID = sd.start('myfile.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dimID = sd.getDimID(sdsID,0);
[label,unit,fmt] = sd.getDimStrs(dimID);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

# matlab.io.hdf4.sd.getFilename

**Package:** matlab.io.hdf4.sd

Name of file

## Syntax

```
filename = getFilename(sdID)
```

## Description

`filename = getFilename(sdID)` retrieves the name of a file previously opened with the `sd` package with identifier `sdID`.

This function corresponds to the `SDgetfilename` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
filename = sd.getFilename(sdID);
sd.close(sdID);
```

## See Also

# matlab.io.hdf4.sd.getFillValue

**Package:** matlab.io.hdf4.sd

Fill value for data set

## Syntax

```
fillvalue = getFillValue(sdsID)
```

## Description

`fillvalue = getFillValue(sdsID)` returns the fill value for a data set.

This function corresponds to the `SDgetfillvalue` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID, 'temperature');
sdsID = sd.select(sdID, idx);
fillvalue = sd.getFillValue(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.setFillValue`

## matlab.io.hdf4.sd.getInfo

**Package:** matlab.io.hdf4.sd

Information about data set

### Syntax

```
[name,dims,datatype,nattrs] = getInfo(sdsID)
```

### Description

`[name,dims,datatype,nattrs] = getInfo(sdsID)` returns the name, extents, and number of attributes of the data set identified by `sdsID`.

This function corresponds to the `SDgetinfo` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `dims` parameter is reversed with respect to the C library API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
[name,dims,datatype,nattrs] = sd.getInfo(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

# matlab.io.hdf4.sd.getRange

**Package:** matlab.io.hdf4.sd

Maximum and minimum range values

## Syntax

```
[maxval,minval] = getRange(sdsID)
```

## Description

[maxval,minval] = getRange(sdsID) retrieves the "valid\_range" two-element attribute value.

This function corresponds to the SDgetrange function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
[maxval,minval] = sd.getRange(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

sd.setRange

## matlab.io.hdf4.sd.idToRef

**Package:** matlab.io.hdf4.sd

Reference number corresponding to data set identifier

### Syntax

```
ref = idToRef(sdsID)
```

### Description

`ref = idToRef(sdsID)` returns the reference number corresponding to the data set.

This function corresponds to the `SDidtooref` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID, 'temperature');
sdsID = sd.select(sdID, idx);
ref = sd.idToRef(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

`sd.refToIndex`

# matlab.io.hdf4.sd.idType

**Package:** matlab.io.hdf4.sd

Type of object

## Syntax

```
objtype = idType(objID)
```

## Description

`objtype = idType(objID)` returns the type of object that `objID` represents. Possible values for `objtype` are:

'NOT_SDAPI_ID'	The object is not an HDF SD identifier.
'SD_ID'	The object is an SD identifier (file handle) .
'SDS_ID'	The object is a data set identifier.
'DIM_ID'	The object is a dimension identifier.

This function corresponds to the `SDidtype` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
objType = sd.idType(sdID);
sd.close(sdID);
```

## matlab.io.hdf4.sd.isCoordVar

**Package:** matlab.io.hdf4.sd

Determine if data set is a coordinate variable

### Syntax

```
TF = isCoordVar(sdsID)
```

### Description

TF = isCoordVar(sdsID) returns true if a data set is a coordinate variable and returns false otherwise.

This function corresponds to the SDiscoordvar function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
ndataset = sd.fileInfo(sdID);
for idx = 0:ndataset-1
 sdsID = sd.select(sdID,idx);
 sdsName = sd.getInfo(sdsID);
 fprintf('%s (index %d) ', sdsName, idx);
 if (sd.isCoordVar(sdsID))
 fprintf('is a coordinate variable.\n');
 else
 fprintf('is not a coordinate variable.\n');
 end
 sd.endAccess(sdsID);
end
sd.close(sdID);
```

### See Also

sd.isRecord

# matlab.io.hdf4.sd.isRecord

**Package:** matlab.io.hdf4.sd

Determine if data set is appendable

## Syntax

```
TF = isRecord(sdsID)
```

## Description

`TF = isRecord(sdsID)` determines if the data set specified by `sdsID` is appendable, meaning that the slowest changing dimension is unlimited.

This function corresponds to the `SDisrecord` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
ndataset = sd.fileInfo(sdID);
for idx = 0:ndataset-1
 sdsID = sd.select(sdID,idx);
 sdsName = sd.getInfo(sdsID);
 if sd.isRecord(sdsID)
 fprintf('%s is a record variable.\n',sdsName);
 else
 fprintf('%s is not a record variable.\n',sdsName);
 end
 sd.endAccess(sdsID);
end
sd.close(sdID);
```

## See Also

`sd.isCoordVar`

## matlab.io.hdf4.sd.nameToIndex

**Package:** matlab.io.hdf4.sd

Index value of named data set

### Syntax

```
idx = nameToIndex(sdID,sdsname)
```

### Description

`idx = nameToIndex(sdID,sdsname)` returns the index of the data set with the name specified by `sdsname`. If there is more than one data set with the same name, the routine returns the index of the first one.

This function corresponds to the `SDnametoindex` function in the HDF C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf','read');
idx = sd.nameToIndex(sdID,'temperature');
sd.close(sdID);
```

### See Also

`sd.select`

# matlab.io.hdf4.sd.nameToIndices

**Package:** matlab.io.hdf4.sd

List of data sets with same name

## Syntax

```
varstruct = nameToIndices(sdID,sdsname)
```

## Description

`varstruct = nameToIndices(sdID,sdsname)` returns a structure array for all data sets with the same name. Each element of `varstruct` has two fields.

'index'	Index of data set
'type'	Type of data set, either 'SDSVAR', 'COORDVAR', or 'UNKNOWN'

This function corresponds to the `SDnametoindices` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
varlist = sd.nameToIndices(sdID, 'latitude');
sd.close(sdID);
```

## See Also

`sd.isCoordVar` | `sd.setDimScale`

## matlab.io.hdf4.sd.readAttr

**Package:** matlab.io.hdf4.sd

Read attribute value

### Syntax

```
data = readAttr(objID,idx)
```

### Description

`data = readAttr(objID,idx)` reads the value of the attribute specified by index `idx`. The `objID` input can be an SD interface identifier, a data set identifier, or a dimension identifier. `idx` is a zero-based index.

This function corresponds to the `SDreadattr` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.findAttr(sdID,'creation_date');
data = sd.readAttr(sdID,idx);
sd.close(sdID);
```

### See Also

`sd.findAttr` | `sd.setAttr`

# matlab.io.hdf4.sd.readChunk

**Package:** matlab.io.hdf4.sd

Read chunk from data set

## Syntax

```
datachunk = readChunk(sdsID,origin)
```

## Description

`datachunk = readChunk(sdsID,origin)` reads an entire chunk of data from the data set identified by `sdsID`. The `origin` input specifies the location of the chunk in zero-based chunking coordinates, not in data set coordinates.

This function corresponds to the `SDreadchunk` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `origin` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dataChunk = sd.readChunk(sdsID,[0 1]);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.writeChunk` | `sd.writeData`

# matlab.io.hdf4.sd.readData

**Package:** matlab.io.hdf4.sd

Read subsample of data

## Syntax

```
data = readData(sdsID)
data = readData(sdsID,start,count)
data = readData(sdsID,start,count,stride)
```

## Description

`data = readData(sdsID)` reads all of the data for the data set identified by `sdsID`.

`data = readData(sdsID,start,count)` reads a contiguous hyperslab of data from the data set identified by `sdsID`. The `start` input specifies the starting position from where the hyperslab is read. `count` specifies the number of values to read along each data set dimension.

`data = readData(sdsID,start,count,stride)` reads a strided hyperslab of data from the data set identified by `sdsID`.

`start`, `count`, and `stride` use zero-based indexing.

This function corresponds to the `SDreaddata` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `start`, `count`, and `stride` parameters are reversed with respect to the C library API.

## Examples

Read an entire data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
```

```
sdsID = sd.select(sdID,idx);
data = sd.readData(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

Read a 2-by-3 portion of a data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
data = sd.readData(sdsID,[0 0],[2 3]);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.writeData`

## matlab.io.hdf4.sd.refToIndex

**Package:** matlab.io.hdf4.sd

Index of data set corresponding to reference number

### Syntax

```
idx = refToIndex(sdID,ref)
```

### Description

`idx = refToIndex(sdID,ref)` returns the index of the data set identified by its reference number `ref`. The `idx` output can then be passed to `sd.select`, to obtain a data set identifier.

This function corresponds to the `SDrefToIndex` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf','read');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
ref = sd.idToRef(sdsID);
idx2 = sd.refToIndex(sdID,ref);
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

`sd.idToRef` | `sd.select`

# matlab.io.hdf4.sd.select

**Package:** matlab.io.hdf4.sd

Identifier of data set with specified index

## Syntax

```
sdsID = select(sdID,IDX)
```

## Description

`sdsID = select(sdID,IDX)` returns the identifier of the data set specified by its index.

This function corresponds to the `SDselect` function in the HDF C library.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf','read');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.endAccess` | `sd.nameToIndex`

# matlab.io.hdf4.sd.setAttr

**Package:** matlab.io.hdf4.sd

Write attribute value

## Syntax

setAttr(objID,name,value)

## Description

setAttr(objID,name,value) attaches an attribute to the object specified by objID. If objID is the SD interface identifier, then a global attribute is created. If a data identifier is specified, then the attribute is attached to the data set. If a dimension identifier is specified, then the attribute is attached to the dimension.

This function corresponds to the SDsetattr function in the HDF library C API.

## Examples

Attach attributes to a file, a data set, and to a dimension.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sd.setAttr(sdID,'creation_date',datestr(now));
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setAttr(sdsID,'long_name','Temperature in sunlight.');
```

```
dimID0 = sd.getDimID(sdsID,0);
sd.setAttr(dimID0,'long_name','latitude');
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

# matlab.io.hdf4.sd.setCal

**Package:** matlab.io.hdf4.sd

Set data set calibration information

## Syntax

```
setCal(sdsID,cal,calErr,offset,offsetErr,datatype)
```

## Description

`setCal(sdsID,cal,calErr,offset,offsetErr,datatype)` sets the calibration information for a data set.

This function corresponds to the `SDsetcal` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setDataStrs(sdsID,'Temperature','degrees_kelvin','%.3f','spherical');
sd.setCal(sdsID,1,0,273,0,'double');
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.getCal`

# matlab.io.hdf4.sd.setChunk

**Package:** matlab.io.hdf4.sd

Set chunk size and compression method of data set

## Syntax

```
setChunk(sdsID, chunkSize, comptype, compparm)
```

## Description

`setChunk(sdsID, chunkSize, comptype, compparm)` makes the data set specified by `sdsID` a chunked data set with chunk size given by `chunkSize` and compression specified by `comptype` and `compparm`. The `comptype` input can be one of the following strings.

'none'	No compression
'skphuff'	Skipping Huffman compression
'deflate'	GZIP compression
'rle'	Run-length encoding

- If `comptype` is 'none' or 'rle', then `compparm` need not be specified.
- If `comptype` is 'skphuff', then `compparm` is the skipping size.
- If `comptype` is 'deflate', then `compparm` is the deflate level, which must be between 0 and 9.

This function corresponds to the `SDsetchunk` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `chunkSize` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdf4.*
```

```
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[200 100]);
sd.setChunk(sdsID,[20 10],'skphuff',16);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

# matlab.io.hdf4.sd.setCompress

**Package:** matlab.io.hdf4.sd

Set compression method of data set

## Syntax

```
setCompress(sdsID,comptype,compparm)
```

## Description

`setCompress(sdsID,comptype,compparm)` sets the compression scheme for the specified data set. The compression must be done before writing the data set. `comptype` can be one of the following strings.

'none'	No compression
'skphuff'	Skipping Huffman compression
'deflate'	GZIP compression
'rle'	Run-length encoding

- If `comptype` is 'none' or 'rle', then `compparm` need not be specified.
- If `comptype` is 'skphuff', then `compparm` is the skipping size.
- If `comptype` is 'deflate', then `compparm` is the deflate level, which must be between 0 and 9.

This function corresponds to the `SDsetcompress` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[200 100]);
sd.setCompress(sdsID,'deflate',5);
data = rand(200,100);
```

```
sd.writeData(sdsID,[0 0],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

**See Also**

`sd.setChunk`

## matlab.io.hdf4.sd.setDataStrs

**Package:** matlab.io.hdf4.sd

Set predefined attributes for data set

### Syntax

```
setDataStrs(sdsID, label, unit, format, coordsys)
```

### Description

`setDataStrs(sdsID, label, unit, format, coordsys)` sets the predefined attributes 'long\_name', 'units', 'format', and 'coordsys' for a data set.

This function corresponds to the `SDsetdatastrs` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf', 'create');
sdsID = sd.create(sdID, 'temperature', 'double', [10 20]);
sd.setDataStrs(sdsID, 'degrees_celsius', 'degrees_east', '', 'geo');
sd.endAccess(sdsID);
sd.close(sdID);
```

# matlab.io.hdf4.sd.setDimName

**Package:** matlab.io.hdf4.sd

Associate name with dimension

## Syntax

```
setDimName(dimID,dimname)
```

## Description

`setDimName(dimID,dimname)` sets the name of the dimension identified by `dimID` to `dimname`.

This function corresponds to the `SDsetdimname` function in the HDF library C API.

## Examples

Create a 2D data set with dimensions 'lat' and 'lon'.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'lat');
dimID = sd.getDimID(sdsID,1);
sd.setDimName(dimID,'lon');
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.dimInfo`

## matlab.io.hdf4.sd.setDimScale

**Package:** matlab.io.hdf4.sd

Set scale values for dimension

### Syntax

```
setDimScale(dimID,scaledata)
```

### Description

`setDimScale(dimID,scaledata)` sets the scale values for a dimension.

This function corresponds to the `SDsetdimscale` function in the HDF library C API.

### Examples

Create a 2D data set with dimensions 'lat' and 'lon'.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'lat');
sd.setDimScale(dimID,0:10:90);
dimID = sd.getDimID(sdsID,1);
sd.setDimName(dimID,'lon');
sd.setDimScale(dimID, -180:18:179);
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

`sd.getDimScale`

# matlab.io.hdf4.sd.setDimStrs

**Package:** matlab.io.hdf4.sd

Set label, unit, and format attribute strings

## Syntax

```
setDimStrs(dimID,label,unit,format)
```

## Description

`setDimStrs(dimID,label,unit,format)` sets the label, unit, and format attributes for the dimension identified by `dimID`.

This function corresponds to the `SDsetdimstrs` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'lat');
dimID = sd.getDimID(sdsID,1);
sd.setDimName(dimID,'lon');
sd.setDimStrs(dimID,'Degrees of Longitude','degrees_east','%.2f');
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.getDimStrs`

## matlab.io.hdf4.sd.setExternalFile

**Package:** matlab.io.hdf4.sd

Store data in external file

### Syntax

```
setExternalFile(sdsID,extfile,offset)
```

### Description

`setExternalFile(sdsID,extfile,offset)` moves data values (not metadata) into the external data file `extfile` starting at the byte offset, `offset`.

Data can only be moved once for any given data set. The external file should be kept with the main file.

This function corresponds to the `SDsetexternalfile` function in the HDF library C API.

### Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setExternalFile(sdsID,'myExternalFile.dat',0);
sd.writeData(sdsID,[0 0],rand(10,20));
sd.endAccess(sdsID);
sd.close(sdID);
```

### See Also

`sd.create` | `sd.writeData`

# matlab.io.hdf4.sd.setFillMode

**Package:** matlab.io.hdf4.sd

Set current fill mode of file

## Syntax

```
prevmode = setFillMode(sdID,fillmode)
```

## Description

`prevmode = setFillMode(sdID,fillmode)` returns the previous fill mode of a file and resets it to `fillmode`. This setting applies to all data sets contained in the file identified by `sdID`.

Possible values of `fillmode` are `'fill'`, and `'nofill'`. `'fill'` is the default mode and indicates that fill values will be written when the data set is created. `'nofill'` indicates that the fill values will not be written.

When a fixed-size data set is created, the first call to `sd.writeData` will fill the entire data set with the default or user-defined fill value if `fillmode` is `'fill'`. In data sets with an unlimited dimension, if a new write operation takes place along the unlimited dimension beyond the last location of the previous write operation, the array locations between these written areas will be initialized to the user-defined fill value, or the default fill value if a user-defined fill value has not been specified.

If it is certain that all data set values will be written before any read operation takes place, there is no need to write the fill values. Calling `sd.setFillMode` with `'nofill'` can improve performance in this case.

This function corresponds to the `SDsetfillmode` function in the HDF library C API.

## Examples

Write two partial records. Write the first in `'nofill'` mode, and the second with `'fill'` mode.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sd.setFillMode(sdID,'nofill');
sdsID = sd.create(sdID,'temperature','double',[10 10 0]);
sd.writeData(sdsID,[0 0 0], rand(5,5));
sd.setFillMode(sdID,'fill');
sd.setFillValue(sdsID,-999);
sd.writeData(sdsID,[0 0 1], rand(5,5));
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

[sd.setFillValue](#) | [sd.setFillValue](#)

# matlab.io.hdf4.sd.setFillValue

**Package:** matlab.io.hdf4.sd

Set fill value for data set

## Syntax

```
setFillValue(sdsID,fillValue)
```

## Description

`setFillValue(sdsID,fillValue)` sets the fill value for a data set. The fill value must have the same data type as the data set.

This function corresponds to the `SDsetfillvalue` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setFillValue(sdsID,-999);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.getFillValue`

## matlab.io.hdf4.sd.setNBitDataSet

**Package:** matlab.io.hdf4.sd

Specify nonstandard bit length for data set values

### Syntax

`setNBitDataSet(sdsID,startBit,bitlen,ext,fillone)`

### Description

`setNBitDataSet(sdsID,startBit,bitlen,ext,fillone)` specifies that the integer data set identified by `sdsID` contains data of a non-standard length defined by `startBit` and `bitlen`.

Any length between 1 and 32 bits can be specified. After `setNBitDataset` has been called for the data set array, any read or write operation will involve conversion between the new data length of the data set array and the data length of the read or write buffer.

Bit lengths of all data types are counted from the right of the bit field starting with 0. In a bit field containing the values 01111011, bits 2 and 7 are set to 0 and all the other bits are set to 1. The least significant bit is bit 0.

The `startBit` parameter specifies the left-most position of the variable-length bit field to be written. For example, in the bit field described in the preceding paragraph a `startBit` parameter set to 4 would correspond to the fourth bit value of 1 from the right.

The parameter `bitlen` specifies the number of bits of the variable-length bit field to be written. This number includes the starting bit and the count proceeds toward the right end of the bit field - toward the lower-bit numbers. For example, starting at bit 5 and writing 4 bits of the bit field described in the preceding paragraph would result in the bit field 1110 being written to the data set. This would correspond to a `startBit` value of 5 and a `bitlen` value of 4.

The parameter `ext` specifies whether to use the left-most bit of the variable-length bit field to sign-extend to the left-most bit of the data set data. For example, if 9-bit signed integer data is extracted from bits 17-25 and the bit in position 25 is 1, then when the

data is read back from disk, bits 26-31 will be set to 1. Otherwise bit 25 will be 0 and bits 26-31 will be set to 0. The `ext` parameter can be set to `true` (or 1) or `false` (or 0); specify `true` to sign-extend.

The parameter `fillone` specifies whether to fill the "background" bits with the value 1 or 0. This parameter is also set to either `true` (or 1) or `false` (or 0).

The "background" bits of a non-standard length data set are the bits that fall outside of the non-standard length bit field stored on disk. For example, if five bits of an unsigned 16-bit integer data set located in bits 5 to 9 are written to disk with the parameter `fillone` set to `true` (or 1), then when the data is reread into memory bits 0 to 4 and 10 to 15 would be set to 1. If the same 5-bit data was written with a `fillone` value of `false` (or 0), then bits 0 to 4 and 10 to 15 would be set to 0.

The operation on `fillone` is performed before the operation on `ext`. For example, using the `ext` example above, bits 0 to 16 and 26 to 31 will first be set to the background bit value, and then bits 26 to 31 will be set to 1 or 0 based on the value of the 25th bit.

This function corresponds to the `SDsetnbitdataset` in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','int32',[10 20]);
sd.setNBitDataSet(sdsID,6,4,0,0);
data = int32([1:200]);
data = reshape(data,10,20);
sd.writeData(sdsID,[0 0],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.setCompress`

# matlab.io.hdf4.sd.setRange

**Package:** matlab.io.hdf4.sd

Set maximum and minimum range value for data set

## Syntax

```
setRange(sdsID,maxval,minval)
```

## Description

`setRange(sdsID,maxval,minval)` sets the maximum and minimum range values of the data set identified by `sdsID`. These values form the "valid\_range" attribute for `sdsID`.

The actual maximum and minimum values of the data set are not computed. The "valid\_range" attribute is for informational purposes only.

This function corresponds to the `SDsetrange` function in the HDF library C interface.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setDataStrs(sdsID,'Temperature','degrees_celsius','% .2f',' ');
sd.setRange(sdsID,1000,-273.15);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

`sd.getRange`

# matlab.io.hdf4.sd.start

**Package:** matlab.io.hdf4.sd

Open HDF file and initialize SD interface

## Syntax

```
sdID = start(filename)
sdID = start(filename,access)
```

## Description

`sdID = start(filename)` opens the file `filename` in read-only mode. This routine must be called for each file before any other `sd` calls can be made on that file.

`sdID = start(filename,access)` opens the file `filename` with the access mode specified by `access`. This routine must be called before any other SD interface operations can be made on that file. `access` can be one of the following strings:

- 'read'
- 'write'
- 'create'

`access` defaults to 'read' if not supplied.

This function corresponds to the `SDstart` function in the HDF library C API.

## Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
sd.close(sdID);
```

## See Also

`sd.close`

# matlab.io.hdf4.sd.writeChunk

**Package:** matlab.io.hdf4.sd

Write chunk to data set

## Syntax

```
writeChunk(sdsID,origin,dataChunk)
```

## Description

`writeChunk(sdsID,origin,dataChunk)` writes an entire chunk of data to the data set identified by `sdsID`. The `origin` input specifies the location of the chunk in chunking coordinates, not in data set coordinates.

This function corresponds to the `SDwritechunk` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `origin` parameter is reversed with respect to the C library API.

## Examples

Write to a 2D chunked and compressed data set. The chunked layout constitutes a 10-by-5 grid.

```
import matlab.io.hdf4.*
sdsID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdsID,'temperature','double',[100 50]);
sd.setChunk(sdsID,[10 10],'deflate',5);
for j = 0:9
 for k = 0:4
 origin = [j k];
 data = (1:100) + k*1000 + j*10000;
 data = reshape(data,10,10);
 sd.writeChunk(sdsID,origin,data);
 end
end
```

```
sd.endAccess(sdsID);
sd.close(sdID);
```

**See Also**

[sd.readChunk](#) | [sd.writeData](#)

## matlab.io.hdf4.sd.writeData

**Package:** matlab.io.hdf4.sd

Write to data set

### Syntax

```
writeData(sdsID,data)
writeData(sdsID,start,data)
writeData(sdsID,start,stride,data)
```

### Description

`writeData(sdsID,data)` writes all the data to the data set identified by `sdsID`.

`writeData(sdsID,start,data)` writes a contiguous hyperslab to the data set. `start` specifies the zero-based starting index. The number of values along each dimension is inferred from the size of `data`.

`writeData(sdsID,start,stride,data)` writes a strided hyperslab of data to a grid datafield. The number of elements to write along each dimension is inferred either from the size of `data` or from the data set itself.

`start` and `stride` use zero-based indexing.

This function corresponds to the `SDreadchunk` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `start` and `stride` parameters are reversed with respect to the C library API.

### Examples

Write to a 2D data set.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
```

```
data = rand(10,20);
sd.writeData(sdsID,[0 0],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

Write to a 2D unlimited data set.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 0]);
data = rand(10,20);
sd.writeData(sdsID,[0 0],data);
data = rand(10,30);
sd.writeData(sdsID,[0 20],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

## See Also

# matlab.io.hdfEOS.gd

Low-level access to HDF-EOS grid data

## Description

To use these MATLAB functions, you must be familiar with the HDF-EOS library C interface. In most cases, the syntax of the MATLAB function is similar to the syntax of the corresponding HDF-EOS library function. The functions are implemented as the package `matlab.io.hdfEOS.gd`. To use this package, prefix the function name with a package path, or use the `import` function to add the package to the current import list, prior to calling the function, for example,

```
import matlab.io.hdfEOS.*
gfid = gd.open(filename,'read');
```

## Access

<code>matlab.io.hdfEOS.gd.attach</code>	Attach to existing grid
<code>matlab.io.hdfEOS.gd.close</code>	Close HDF-EOS grid file
<code>matlab.io.hdfEOS.gd.detach</code>	Detach from existing grid
<code>matlab.io.hdfEOS.gd.open</code>	Open grid file

## Definition

<code>matlab.io.hdfEOS.gd.create</code>	Create new grid structure
<code>matlab.io.hdfEOS.gd.defComp</code>	Set grid field compression
<code>matlab.io.hdfEOS.gd.defDim</code>	Define new dimension within grid
<code>matlab.io.hdfEOS.gd.defField</code>	Define new data field within grid
<code>matlab.io.hdfEOS.gd.defOrigin</code>	Define origin of pixels in grid
<code>matlab.io.hdfEOS.gd.defPixReg</code>	Define pixel registration within grid
<code>matlab.io.hdfEOS.gd.defProj</code>	Define grid projection
<code>matlab.io.hdfEOS.gd.writeBlkSomOffset</code>	Write Block SOM offset

## Basic I/O

matlab.io.hdfEOS.gd.getFillValue	Fill value for specified field
matlab.io.hdfEOS.gd.readAttr	Read grid attribute
matlab.io.hdfEOS.gd.readField	Read data from grid field
matlab.io.hdfEOS.gd.setFillValue	Set fill value for specified field
matlab.io.hdfEOS.gd.writeAttr	Write grid attribute
matlab.io.hdfEOS.gd.writeField	Write data to grid field

## Inquiry

matlab.io.hdfEOS.gd.compInfo	Compression information for field
matlab.io.hdfEOS.gd.dimInfo	Length of dimension
matlab.io.hdfEOS.gd.fieldInfo	Information about data field
matlab.io.hdfEOS.gd.gridInfo	Position and size of grid
matlab.io.hdfEOS.gd.inqAttrs	Names of grid attributes
matlab.io.hdfEOS.gd.inqDims	Information about dimensions defined in grid
matlab.io.hdfEOS.gd.inqFields	Information about data fields defined in grid
matlab.io.hdfEOS.gd.inqGrid	Names of grids in file
matlab.io.hdfEOS.gd.nEntries	Number of specified objects
matlab.io.hdfEOS.gd.originInfo	Origin code
matlab.io.hdfEOS.gd.pixRegInfo	Pixel registration code
matlab.io.hdfEOS.gd.projInfo	GCTP projection information about grid
matlab.io.hdfEOS.gd.readBlkSomOffset	Read Block SOM offset

## Subsetting

matlab.io.hdfeos.gd.defBoxRegion	Define region of interest by latitude and longitude
matlab.io.hdfeos.gd.defVrtRegion	Define vertical subset region
matlab.io.hdfeos.gd.extractRegion	Read region of interest from field
matlab.io.hdfeos.gd.getPixels	Pixel rows and columns for latitude/longitude pairs
matlab.io.hdfeos.gd.getPixValues	Read data values for specified pixels
matlab.io.hdfeos.gd.interpolate	Bilinear interpolation on a grid field
matlab.io.hdfeos.gd.regionInfo	Information about subsetted region

## Tiling

matlab.io.hdfeos.gd.defTile	Define tiling parameters
matlab.io.hdfeos.gd.readTile	Read single tile of data from field
matlab.io.hdfeos.gd.setTileComp	Set tiling and compression for field with fill value
matlab.io.hdfeos.gd.tileInfo	Tile size of grid field
matlab.io.hdfeos.gd.writeTile	Write tile to field

## Utility

matlab.io.hdfeos.gd.ij2ll	Convert row and column space to latitude and longitude
matlab.io.hdfeos.gd.ll2ij	Convert latitude and longitude to row and column space

matlab.io.hdfeos.gd.sphereCodeToName

Name corresponding to GCTP sphere code

matlab.io.hdfeos.gd.sphereNameToCode

Numeric GCTP code corresponding to  
sphere name

# matlab.io.hdfEOS.gd.attach

**Package:** matlab.io.hdfEOS.gd

Attach to existing grid

## Syntax

```
gridID = attach(gfID,gridName)
```

## Description

`gridID = attach(gfID,gridName)` attaches to the grid dataset identified by `gridName` in the file identified by `gfID`. The `gridID` output is the identifier for the grid dataset.

This function corresponds to the `GDattach` function in the HDF-EOS library C API.

## Examples

Attach to the grid named 'PolarGrid' in the file 'grid.hdf'.

```
import matlab.io.hdfEOS.*
gfID = gd.open('grid.hdf');
gridID = gd.attach(gfID,'PolarGrid');
gd.detach(gridID);
gd.close(gfID);
```

## See Also

`gd.detach` | `gd.inqGrid` | `gd.readField`

# matlab.io.hdfeos.gd.close

**Package:** matlab.io.hdfeos.gd

Close HDF-EOS grid file

## Syntax

```
close(gfID)
```

## Description

`close(gfID)` closes an HDF-EOS grid file identified by `gfID`.

This function corresponds to the `GDClose` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfeos.*
gfID = gd.open('grid.hdf');
gd.close(gfID);
```

## See Also

`gd.create` | `gd.open`

## matlab.io.hdfEOS.gd.compInfo

**Package:** matlab.io.hdfEOS.gd

Compression information for field

### Syntax

```
[compCode,parms] = compInfo(gridID,fieldname)
```

### Description

[compCode,parms] = compInfo(gridID,fieldname) returns the compression code and compression parameters for a given field. Refer to `gd.defComp` for a description of various compression schemes and parameters.

This function corresponds to the `GDcompinfo` function in the HDF-EOS library C API.

### Examples

Get compression information for the `ice_temp` field.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[compCode,compParms] = gd.compInfo(gridID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

### See Also

`gd.defComp`

---

# matlab.io.hdfEOS.gd.create

**Package:** matlab.io.hdfEOS.gd

Create new grid structure

## Syntax

```
gridID = create(gfID,gridName,xdim,ydim,upLeft,lowRight)
```

## Description

`gridID = create(gfID,gridName,xdim,ydim,upLeft,lowRight)` creates a new grid structure where `gfID` is the grid file identifier. `gridName` is the name of the new grid. `xdim` and `ydim` define the size of the grid. `upLeft` is a two-element vector containing the location of the upper left pixel, and `lowRight` is a two-element vector containing the location of the lower right pixel.

---

**Note:** `upLeft` and `lowRight` are in units of meters for all GCTP projections other than the geographic and bcea projections, which should have units of packed degrees.

---

---

**Note:** For certain projections, `upLeft` and `lowRight` can be given as [ ].

---

- Polar Stereographic projection of an entire hemisphere.
  - Goode Homolosine projection of the entire globe.
  - Lambert Azimuthal entire polar or equatorial projection.
- 

---

**Note:** MATLAB uses Fortran-style ordering, but the HDF-EOS library uses C-style ordering.

---

This function corresponds to the `GDcreate` function in the HDF-EOS library C API.

## Examples

Create a polar stereographic grid of the northern hemisphere.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
gd.detach(gridID);
gd.close(gfid);
```

Create a UTM grid bounded by 54 E to 60 E longitude and 20 N to 30 N latitude. Divide the grid into 120 bins along the x-axis and 200 bins along the y-axis.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
uplft = [210584.50041 3322395.95445];
lowrgt = [813931.10959 2214162.53278];
gridID = gd.create(gfid,'UTMGrid',120,200,uplft,lowrgt);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

# matlab.io.hdfeos.gd.defBoxRegion

**Package:** matlab.io.hdfeos.gd

Define region of interest by latitude and longitude

## Syntax

```
regionID = defBoxRegion(gridID,cornerLat,cornerLon)
```

## Description

`regionID = defBoxRegion(gridID,cornerLat,cornerLon)` defines a latitude-longitude box region as a subset region for a grid. `regionID` can be used to read all the entries of a data field within the region.

This function corresponds to the `GDdefboxregion` function in the HDF-EOS library C API.

## Examples

Define a region of interest between 20 and 50 degrees latitude and between -90 and -60 degrees longitude.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
cornerlat = [20 50];
cornerlon = [-90 -60];
regionID = gd.defBoxRegion(gridID,cornerlat,cornerlon);
data = gd.extractRegion(gridID,regionID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.extractRegion`

## matlab.io.hdfEOS.gd.defComp

**Package:** matlab.io.hdfEOS.gd

Set grid field compression

### Syntax

```
defComp(gridID,compscheme,compparm)
```

### Description

`defComp(gridID,compscheme,compparm)` sets the HDF field compression for subsequent field definitions. The compression scheme does not apply to one-dimensional fields. `compscheme` can be one of the following strings.

'rle'	Run-length encoding
'skphuff'	Skipping Huffman
'deflate'	Gzip deflate
'none'	No compression

When the compression scheme is 'deflate', `compparm` is the deflate compression level, an integer between 0 and 9. `compparm` can be omitted for the other compression schemes.

If a field is defined with compression, it must be written with a single call to `gd.writeField`. If this is not possible, you should consider using tiling.

This function corresponds to the `GDdefcomp` function in the HDF-EOS library C API.

### Examples

Create a grid with a polar stereographic `Pressure` field using run-length encoding, and then an `Opacity` field with deflate compression.

```
import matlab.io.hdfEOS.*
```

```
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
projparm = zeros(1,13);
projparm(6) = 90000000;
gd.defProj(gridID,'ps',[],'WGS 84',projparm);
dims = { 'XDim', 'YDim' };
gd.defComp(gridID,'rle');
gd.defField(gridID,'Pressure',dims,'float');
gd.defComp(gridID,'deflate',5);
gd.defField(gridID,'Opacity',dims,'float');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

[gd.defField](#) | [gd.defTile](#)

## matlab.io.hdfEOS.gd.defDim

**Package:** matlab.io.hdfEOS.gd

Define new dimension within grid

### Syntax

```
defDim(gridID,dimname,dimlen)
```

### Description

`defDim(gridID,dimname,dimlen)` defines a new dimension named `dimname` with length `dimlen` in the grid structure identified by `gridID`.

To specify an unlimited dimension, you can use either 0 or 'unlimited' for `dimlen`.

This function corresponds to the `GDdefdim` function in the HDF-EOS library C API.

### Examples

Define a dimension 'Band' with length of 15 and an unlimited dimension 'Time'.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
gd.defDim(gridID,'Band',15);
gd.defDim(gridID,'Time',0);
gd.detach(gridID);
gd.close(gfid);
```

### See Also

`gd.defField` | `gd.dimInfo`

# matlab.io.hdfeos.gd.defField

**Package:** matlab.io.hdfeos.gd

Define new data field within grid

## Syntax

```
defField(gridID,fieldname,dimlist,dtype)
defField(gridID,fieldname,dimlist,dtype,mergeCode)
```

## Description

`defField(gridID,fieldname,dimlist,dtype)` defines data fields for a grid specified by `gridID`. The `fieldname` input is the name of the new field. `dimlist` is a cell array of geolocation dimensions and should be listed in FORTRAN-style order, that is, the fastest varying dimension should be listed first. `dimlist` can also be a string if there is only one dimension. `dtype` is the data type of the field.

`defField(gridID,fieldname,dimlist,dtype,mergeCode)` defines a data field with a specific merge code. `mergeCode` can be either 'nomerge' or 'automerge'. The `mergeCode` input defaults to 'nomerge' if not provided.

This function corresponds to the `GDdeffield` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

## Examples

Define a single precision grid field 'Temperature' with dimensions 'XDim' and 'YDim'. Then define a single precision field 'Spectra' with dimensions 'XDim', 'YDim', and 'Bands'.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
xdim = 120; ydim = 200;
gridID = gd.create(gfid,'geo',xdim,ydim,[],[]);
```

```
gd.defProj(gridID, 'geo', [], [], []);
dimlist = { 'XDim', 'YDim' };
gd.defField(gridID, 'Temperature', dimlist, 'single');
gd.defDim(gridID, 'Bands', 3);
dimlist = { 'XDim', 'YDim', 'Bands' };
gd.defField(gridID, 'Spectra', dimlist, 'uint8');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

gd.create | gd.defDim

# matlab.io.hdfeos.gd.defOrigin

**Package:** matlab.io.hdfeos.gd

Define origin of pixels in grid

## Syntax

```
defOrigin(gridID,originCode)
```

## Description

`defOrigin(gridID,originCode)` defines the origin of pixels in a grid. `gridID` is the identifier of the grid, and `originCode` can be one of the following four strings.

'ul'	Upper-left
'ur'	Upper-right
'll'	Lower-left
'lr'	Lower-right

You can select any corner of the grid pixel as the origin. If this routine is not invoked, the grid defaults to using the upper-left corner for the origin.

This function corresponds to the `GDdeforigin` function in the HDF-EOS library C API.

## Examples

Create a polar stereographic grid with the origin of the grid pixel in the lower right corner.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
projparm = zeros(1,13);
projparm(6) = 90000000;
gd.defProj(gridID,'ps',[],'WGS 84',projparm);
```

```
gd.defOrigin(gridID, 'lr');
gd.detach(gridID);
gd.close(gfid);
```

## **See Also**

gd.defPixReg | gd.originInfo

# matlab.io.hdfeos.gd.defPixReg

**Package:** matlab.io.hdfeos.gd

Define pixel registration within grid

## Syntax

```
defPixReg(gridID,pixRegCode)
```

## Description

`defPixReg(gridID,pixRegCode)` defines whether the pixel center or pixel corner is used when requesting the location (longitude and latitude) of a given pixel. `pixRegCode` can be one of the following strings.

'center'	Center of pixel cell
'corner'	Corner of pixel cell

If this routine is not invoked, the pixel registration is 'center'.

This function corresponds to the GDdefpixreg function in the HDF-EOS library.

## Examples

Define a grid with pixel registration in the center.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
projparm = zeros(1,13);
projparm(6) = 90000000;
gd.defProj(gridID,'ps',[],'WGS 84',projparm);
gd.defPixReg(gridID,'corner');
gd.detach(gridID);
gd.close(gfid);
```

**See Also**

`gd.defOrigin` | `gd.pixRegInfo`

# matlab.io.hdfeos.gd.defProj

**Package:** matlab.io.hdfeos.gd

Define grid projection

## Syntax

```
defProj(gridID,projCode,zoneCode,sphereCode,projParm)
```

## Description

`defProj(gridID,projCode,zoneCode,sphereCode,projParm)` defines a GCTP projection on the grid specified by `gridID`. The `projCode` argument can be one of the following strings.

'geo'	Geographic
'utm'	Universal Transverse Mercator
'albers'	Albers Canonical Equal Area
'lamcc'	Lambert Conformal Conic
'ps'	Polar Stereographic
'polyc'	Polyconic
'tm'	Transverse Mercator
'lamaz'	Lambert Azimuthal Equal Area
'snsoid'	Sinusoidal
'hom'	Hotine Oblique Mercator
'som'	Space Oblique Mercator
'good'	Interrupted Goode Homolosine
'cea'	Cylindrical Equal Area
'bcea'	Behrmann Cylindrical Equal Area
'isinus'	Integerized Sinusoidal

If `projCode` is 'geo', then `zoneCode`, `sphereCode`, and `projParm` should be specified as []. Any other values for these parameters are ignored.

`zoneCode` is the Universal Transverse Mercator zone code. It should be specified as -1 for other projections.

`sphereCode` is the name of the GCTP spheroid or the corresponding numeric code.

`projParm` is a vector of up to 13 elements containing projection-specific parameters. For more details about `projCode`, `zoneCode`, `sphereCode`, and `projParm`, see Chapter 6 of HDF-EOS Library Users Guide for the ECS Project, Volume 1: Overview and Examples.

This function corresponds to the `GDdefproj` function in the HDF library C API.

## Examples

Create a UTM grid bounded by 54 E to 60 E longitude and 20 N to 30 N latitude (zone 40). Divide the grid into 120 bins along the x-axis and 200 bins along the y-axis.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf', 'create');
uplft = [210584.50041 3322395.95445];
lowrgt = [813931.10959 2214162.53278];
gridID = gd.create(gfid, 'UTMGrid', 120, 200, uplft, lowrgt);
gd.defProj(gridID, 'utm', 40, 'Clarke 1866', []);
gd.detach(gridID);
gd.close(gfid);
```

Add a polar stereographic projection of the northern hemisphere with true scale at 90 N, 0 longitude below the pole using the WGS 84 spheroid.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf', 'create');
gridID = gd.create(gfid, 'PolarGrid', 100, 100, [], []);
projparm = zeros(1, 13);
projparm(6) = 90000000;
gd.defProj(gridID, 'ps', [], 'WGS 84', projparm);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

# matlab.io.hdfeos.gd.defTile

**Package:** matlab.io.hdfeos.gd

Define tiling parameters

## Syntax

```
defTile(gridID,tileDims)
```

## Description

`defTile(gridID,tileDims)` defines tiling dimensions for subsequent field definitions. If `tileDims` is `[]`, then subsequently defined fields will have no tiling.

This function corresponds to the `GDdeftile` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tileDims` parameter is reversed with respect to the C library API.

## Examples

Define a field with tiling, then a subsequent field with no tiling.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'GeoGrid',120,200,[],[]);
gd.defDim(gridID,'Bands',3);
gd.defProj(gridID,'geo',[],[],[]);
gd.defTile(gridID,[30 50 1]);
dimlist = {'XDim','YDim','Bands'};
gd.defField(gridID,'Spectra',dimlist,'float');
gd.defTile(gridID,[]);
dimlist = {'XDim','YDim'};
gd.defField(gridID,'Temperature',dimlist,'int32');
gd.detach(gridID);
gd.close(gfid);
```

**See Also**

# matlab.io.hdfEOS.gd.defVrtRegion

**Package:** matlab.io.hdfEOS.gd

Define vertical subset region

## Syntax

```
out_RID = defVrtRegion(gridID,regionID,vobj,vRange)
```

## Description

`out_RID = defVrtRegion(gridID,regionID,vobj,vRange)` defines a vertical subset region and can be used on either a monotonic field or contiguous elements of a dimension.

`regionID` should be 'noprevious' if no prior subsetting has occurred. Otherwise it should be a value as returned from a previous subsetting routine.

`vobj` is the name of either the dimension or field to subset. If `vobj` is a dimension, it should be prefixed with 'DIM: '.

`vRange` is the minimum and maximum range for the vertical subset.

This function corresponds to the `GDdefvrtregion` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
range = [333 667];
regionID = gd.defVrtRegion(gridID,'noprevious','Height',range);
data = gd.extractRegion(gridID,regionID,'pressure');
gd.detach(gridID);
gd.close(gfid);
```

```
import matlab.io.hdfes.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid, 'PolarGrid');
range = [3 5];
regionID = gd.defVrtRegion(gridID, 'noprevious', 'DIM:Height', range);
data = gd.extractRegion(gridID, regionID, 'pressure');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.extractRegion`

# matlab.io.hdfEOS.gd.detach

**Package:** matlab.io.hdfEOS.gd

Detach from existing grid

## Syntax

```
detach(gridID)
```

## Description

detach(gridID) detaches from the grid identified by gridID.

This function corresponds to the GDdetach function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
gfID = gd.open('grid.hdf');
gridID = gd.attach(gfID, 'PolarGrid');
gd.detach(gridID);
gd.close(gfID);
```

## See Also

gd.attach

## matlab.io.hdfEOS.gd.dimInfo

**Package:** matlab.io.hdfEOS.gd

Length of dimension

### Syntax

```
dimlen = diminfo(gridID,dimname)
```

### Description

`dimlen = diminfo(gridID,dimname)` retrieves the length of the specified user-defined dimension.

Please note that the two extents used to create the grid are not considered user-defined dimensions. To retrieve the length of XDim and YDim, use `gd.gridInfo`. This function corresponds to the `GDdiminfo` function in the HDF-EOS library C API.

### Examples

Inquire about a 'Bands' dimension.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
dimlen = gd.dimInfo(gridID,'Height');
gd.detach(gridID);
gd.close(gfid);
```

### See Also

# matlab.io.hdfeos.gd.extractRegion

**Package:** matlab.io.hdfeos.gd

Read region of interest from field

## Syntax

```
data = extractRegion(gridID,regionID,fieldname)
```

## Description

`data = extractRegion(gridID,regionID,fieldname)` extract data from a subsetted region.

This routine corresponds to the `GDextractregion` function in the HDF-EOS library C API.

## Examples

Define and extract a region of interest between 20 and 50 degrees latitude and between -90 and -60 degrees longitude.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
cornerlat = [20 50];
cornerlon = [-90 -60];
regionID = gd.defBoxRegion(gridID,cornerlat,cornerlon);
data = gd.extractRegion(gridID,regionID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.defBoxRegion` | `gd.defVrtRegion`

# matlab.io.hdfEOS.gd.fieldInfo

**Package:** matlab.io.hdfEOS.gd

Information about data field

## Syntax

```
[dims,ntype,dimlist] = fieldInfo(gridID,fieldname)
```

## Description

`[dims,ntype,dimlist] = fieldInfo(gridID,fieldname)` returns information about a specific geolocation or data field in the grid. `dims` is a vector containing the dimension sizes of the field. `ntype` is a string containing the HDF number type of the field. `dimlist` is a cell array of strings containing the list of dimension names.

This function corresponds to the `GDfieldinfo` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
[dims,ntype,dimlist] = gd.fieldInfo(gridID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

# matlab.io.hdfEOS.gd.getFillValue

**Package:** matlab.io.hdfEOS.gd

Fill value for specified field

## Syntax

```
fillvalue = getFillValue(gridID,fieldname)
```

## Description

`fillvalue = getFillValue(gridID,fieldname)` retrieves the fill value for the specified field.

This function corresponds to the `GDgetfillvalue` function in the HDF-EOS library C API.

## Examples

Return the fill value for the 'ice\_temp' field in the 'PolarGrid' grid.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
fillvalue = gd.getFillValue(gridID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.setFillValue`

# matlab.io.hdfEOS.gd.getPixels

**Package:** matlab.io.hdfEOS.gd

Pixel rows and columns for latitude/longitude pairs

## Syntax

```
[row,col] = getPixels(gridID,lat,lon)
```

## Description

`[row,col] = getPixels(gridID,lat,lon)` converts latitude/longitude pairs into zero-based pixel row and column coordinates. The origin is the upper left-hand corner of the grid pixel. If the latitude/longitude pairs are outside the grid, then `row` and `col` are -1.

This function corresponds to the `GDgetpixels` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
cornerlat = [20 50];
cornerlon = [-90 -60];
[row,col] = gd.getPixels(gridID,cornerlat,cornerlon);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.getPixValues`

# matlab.io.hdfeos.gd.getPixValues

**Package:** matlab.io.hdfeos.gd

Read data values for specified pixels

## Syntax

```
data = getPixValues(gridID,rows,cols,fieldname)
```

## Description

`data = getPixValues(gridID,rows,cols,fieldname)` reads data values for the pixels specified by the zero-based `rows` and `cols` coordinates. All entries along the non-geographic dimensions, i.e. NOT `XDim` and `YDim`, are returned.

This function corresponds to the `GDgetpixvalues` function in the HDF-EOS library C API.

## Examples

Read the grid field's corner values.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
rows = [0 99 99 0];
cols = [0 0 99 99];
data = gd.getPixValues(gridID,rows,cols,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

## matlab.io.hdfEOS.gd.gridInfo

**Package:** matlab.io.hdfEOS.gd

Position and size of grid

### Syntax

```
[xDim,yDim,upLeft,lowRight] = gridInfo(gridID)
```

### Description

[xDim,yDim,upLeft,lowRight] = gridInfo(gridID) returns the size of a grid as well as the upper left and lower right corners of the grid.

---

**Note:** upLeft and lowRight are in units of meters for all GCTP projections other than the geographic and bcea projections, which will have units of packed degrees.

---

This function corresponds to the GDgridinfo function in the HDF-EOS library C API.

### Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[xdimsize,ydimsize,upleft,lowright] = gd.gridInfo(gridID);
gd.detach(gridID);
gd.close(gfid);
```

### See Also

# matlab.io.hdfEOS.gd.ij2ll

**Package:** matlab.io.hdfEOS.gd

Convert row and column space to latitude and longitude

## Syntax

```
[lat,lon] = ij2ll(gridID,row,col)
```

## Description

`[lat,lon] = ij2ll(gridID,row,col)` converts a grid's row and column coordinates to latitude and longitude in decimal degrees.

`row` and `col` are zero-based and defined such that `col` increases monotonically with the `XDim` dimension and `row` increases monotonically with the `YDim` dimension in the HDF-EOS library.

This routine corresponds to the `GDij2ll` function in the HDF-EOS C API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[xdim,ydim] = gd.gridInfo(gridID);
r = 0:(xdim-1);
c = 0:(ydim-1);
[Col,Row] = meshgrid(c,r);
[lat,lon] = gd.ij2ll(gridID,Row,Col);
gd.detach(gridID);
gd.close(gfid);
```

## matlab.io.hdfEOS.gd.inqAttrs

**Package:** matlab.io.hdfEOS.gd

Names of grid attributes

### Syntax

```
attrList = inqAttrs(gridID)
```

### Description

`attrList = inqAttrs(gridID)` returns the list of grid attribute names. `attrList` is a cell array.

This function corresponds to the `GDinqattrs` function in the HDF-EOS library C API.

### Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid, 'PolarGrid');
attrList = gd.inqAttrs(gridID);
gd.detach(gridID);
gd.close(gfid);
```

### See Also

# matlab.io.hdfEOS.gd.inqDims

**Package:** matlab.io.hdfEOS.gd

Information about dimensions defined in grid

## Syntax

```
[dimnames,dimlens] = inqDims(gridID)
```

## Description

[dimnames,dimlens] = inqDims(gridID) returns the names of the dimensions dimnames in a cell array and their respective lengths dimlens. This does not include the grid extent dimensions XDim and YDim.

This function corresponds to the GDinqdims function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the dimnames and dimlens parameters are reversed with respect to the C library API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
[dims,dimlens] = gd.inqDims(gridID);
gd.detach(gridID);
gd.close(gfid);
```

## matlab.io.hdfEOS.gd.inqFields

**Package:** matlab.io.hdfEOS.gd

Information about data fields defined in grid

### Syntax

```
[fldList,fldRank,fldType] = inqFields(gridID)
```

### Description

`[fldList,fldRank,fldType] = inqFields(gridID)` returns the list of fields `fldList` as a cell array. `fldRank` contains the rank of each data field. `fldType` is a cell array containing the data type of each data field.

This function corresponds to the `GDinqfields` function in the HDF-EOS library C API.

### Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[fldList,fldRank,fldType] = gd.inqFields(gridID);
gd.detach(gridID);
gd.close(gfid);
for j = 1:numel(fldRank)
 fprintf('%s: Rank %d, datatype %s\n', fldList{j},fldRank(j),fldType{j});
end
```

# matlab.io.hdfEOS.gd.interpolate

**Package:** matlab.io.hdfEOS.gd

Bilinear interpolation on a grid field

## Syntax

```
data = interpolate(gridID,lat,lon,fieldname)
```

## Description

`data = interpolate(gridID,lat,lon,fieldname)` performs bilinear interpolation on lat/lon pairs from the data in the grid field.

`data` contains the interpolated field values.

This function corresponds to the `GDinterpolate` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('example.hdf');
gridID = gd.attach(gfid,'MonthlyRain');
[lat,lon] = gd.ij2ll(gridID,[36 36],[14 15]);
data = gd.interpolate(gridID,lat,lon,'TbOceanRain');
gd.detach(gridID);
gd.close(gfid);
```

**Package:** matlab.io.hdfeos.gd

Convert latitude and longitude to row and column space

## Syntax

```
[row,col] = ll2ij(gridID,lat,lon)
```

## Description

`[row,col] = ll2ij(gridID,lat,lon)` converts latitude and longitude coordinates to a pre-defined grid's row and column coordinates.

`row` and `col` are zero-based and defined such that `col` increases monotonically with the `XDim` dimension and `row` increases monotonically with the `YDim` dimension in the HDF-EOS library.

This routine corresponds to the `GDll2ij` function in the HDF-EOS C API.

## Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
lat = [46 46 42 42];
lon = [-71 -67 -67 -71];
[row,col] = gd.ll2ij(gridID,lat,lon);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

## matlab.io.hdfEOS.gd.nEntries

**Package:** matlab.io.hdfEOS.gd

Number of specified objects

### Syntax

```
nentries = nEntries(gridID,entType)
```

### Description

`nentries = nEntries(gridID,entType)` returns the number of specified objects in a grid. `entType` can be either `'dims'` or `'fields'`.

This function corresponds to the `GDnentries` function in the HDF-EOS library C API.

### Examples

```
import matlab.io.hdfEOS.*
fid = gd.open('grid.hdf');
gridID = gd.attach(fid,'PolarGrid');
ndims = gd.nEntries(gridID,'dims');
nflDs = gd.nEntries(gridID,'fields');
gd.detach(gridID);
gd.close(fid);
fprintf('The number of dimensions is %d.\n', ndims);
fprintf('The number of fields is %d.\n', nflDs);
```

# matlab.io.hdfeos.gd.open

**Package:** matlab.io.hdfeos.gd

Open grid file

## Syntax

```
gfid = open(filename,access)
```

## Description

`gfid = open(filename,access)` opens or creates an HDF-EOS grid file identified by `filename` and returns a file ID. `access` can be one of the following string values:

'read'	Read-only
'rdwr'	Read-write
'create'	Creates a file, deleting it if it already exists

If `access` is not provided, it defaults to 'read'.

This function corresponds to the `GDopen` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gd.close(gfid);
```

# matlab.io.hdfEOS.gd.originInfo

**Package:** matlab.io.hdfEOS.gd

Origin code

## Syntax

```
originCode = originInfo(gridID)
```

## Description

`originCode = originInfo(gridID)` retrieves the origin code for the grid specified by `gridID`. The `originCode` output is one of the following four string values.

'ul'	Upper-left
'ur'	Upper-right
'll'	Lower-left
'lr'	Lower-right

This function corresponds to the `GDoriginInfo` routine in the HDF-EOS library.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
origin = gd.originInfo(gridID);
gd.detach(gridID);
gd.close(gfid);
```

GCTP projection information about grid

### Syntax

```
[projCode,zoneCode,sphereName,projParm] = projInfo(gridID)
```

### Description

[projCode,zoneCode,sphereName,projParm] = projInfo(gridID) returns the GCTP projection code, zone code, spheroid, and projection parameters for the grid identified by gridID.

zoneCode is -1 if projCode is anything other than 'UTM'.

This function corresponds to the GDprojinfo function in the HDF-EOS library C API.

For details about the GCTP projection code, zone code, spheroid code, and projection parameters, please consult the HDF-EOS User's Guide.

### Examples

```
import matlab.io.hdfEOS.*
fid = gd.open('grid.hdf');
gridID = gd.attach(fid,'PolarGrid');
[projCode,zoneCode,sphereCode,projParm] = gd.projInfo(gridID);
gd.detach(gridID);
gd.close(fid);
```

# matlab.io.hdfeos.gd.readAttr

**Package:** matlab.io.hdfeos.gd

Read grid attribute

## Syntax

```
data = readAttr(gridID,attrname)
```

## Description

`data = readAttr(gridID,attrname)` reads a grid attribute.

This function corresponds to the `GDreadattr` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
data = gd.readAttr(gridID,'creation_date');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.writeAttr`

# matlab.io.hdfEOS.gd.readBlkSomOffset

**Package:** matlab.io.hdfEOS.gd

Read Block SOM offset

## Syntax

```
offset = readBlkSomOffset(GID)
```

## Description

`offset = readBlkSomOffset(GID)` reads the block SOM offset values, in pixels, from a standard SOM (Space Oblique Mercator) projection. `offset` is a vector of offset values for SOM projection data. This routine can only be used with grids that use the SOM projection.

This function corresponds to the `GDbkSOMoffset` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
lowright = [30521379.68485 1152027.64253];
upleft = [-11119487.42844 8673539.24806];
gridID = gd.create(gfid,'SOM',120,60,upleft,lowright);
projparm(1) = 6378137;
projparm(2) = 0.006694348;
projparm(4) = 98096360; % 98.161 in DDDMMSSSS
projparm(5) = 87069061; % 87.112 in DDDMMSSSS
projparm(9) = 0.068585416*1440;
projparm(10) = 0.0;
projparm(12) = 6;
gd.defProj(gridID,'som',[],[],projparm);
gd.writeBlkSomOffset(gridID,[5 10 12 8 2]);
gd.detach(gridID);
```

```
gd.close(gfid);
gfid = gd.open('myfile.hdf');
gridID = gd.attach(gfid, 'SOM');
blk = gd.readBlkSomOffset(gridID);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.writeBlkSomOffset`

# matlab.io.hdfEOS.gd.readField

**Package:** matlab.io.hdfEOS.gd

Read data from grid field

## Syntax

```
data = readField(gridID,fieldname)
data = readField(gridID,fieldname,start,count)
data = readField(gridID,fieldname,start,count,stride)
[data,lat,lon] = readField(___)
```

## Description

`data = readField(gridID,fieldname)` reads the entire grid field identified by `fieldname` in the grid identified by `gridID`.

`data = readField(gridID,fieldname,start,count)` reads a contiguous hyperslab of data from the field. `start` specifies the zero-based starting index of the hyperslab. `count` specifies the number of values to read along each dimension.

`data = readField(gridID,fieldname,start,count,stride)` reads a strided hyperslab of data from the field. `stride` specifies the inter-element spacing along each dimension.

`[data,lat,lon] = readField( ___ )` reads the data and the associated geocoordinates from the grid field. This syntax is only allowed when the leading two dimensions of the grid are 'XDim' and 'YDim'.

This function corresponds to the `GDreadfield` function in the HDF-EOS library C API.

## Examples

Read the data, latitude, and longitude for the 'ice\_temp' field.

```
import matlab.io.hdfEOS.*
```

```
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid, 'PolarGrid');
[data,lat,lon] = gd.readField(gridID, 'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

Read only the first 4x4 hyperslab of data, latitude, and longitude for the 'ice\_temp' field.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid, 'PolarGrid');
[data2,lat2,lon2] = gd.readField(gridID, 'ice_temp', [0 0], [4 4]);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.writeField`

# matlab.io.hdfEOS.gd.readTile

**Package:** matlab.io.hdfEOS.gd

Read single tile of data from field

## Syntax

```
data = readTile(gridID,fieldname,tileCoords)
```

## Description

`data = readTile(gridID,fieldname,tileCoords)` reads a single of data from a field. If the data is to be read tile by tile, this routine is more efficient than `gd.readField`. In all other cases, use `gd.readField`. The `tileCoords` argument has the form `[rownum colnum]` and is defined in terms of the tile coordinates, not the data elements.

This function corresponds to the `GDreadtile` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tileCoords` parameter is reversed with respect to the C library API.

## Examples

Define a field with a 2-by-3 tiling scheme.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
for h = 0:9
 data = gd.readTile(gridID,'pressure',[0 0 h]);
end
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.tileInfo` | `gd.writeTile`

# matlab.io.hdfEOS.gd.regionInfo

**Package:** matlab.io.hdfEOS.gd

Information about subsetted region

## Syntax

```
[dims,upLeft,lowRight] = regionInfo(gridID,regionID,fieldname)
```

## Description

`[dims,upLeft,lowRight] = regionInfo(gridID,regionID,fieldname)` returns the dimensions and corner points for the specified field of a subsetted region identified by `regionID` in the grid identified by `gridID`.

This function corresponds to the `GDregioninfo` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
cornerlat = [20 50];
cornerlon = [-90 -60];
regionID = gd.defBoxRegion(gridID,cornerlat,cornerlon);
[dims,upleft,lowright] = gd.regionInfo(gridID,regionID,'ice_temp');
data = gd.extractRegion(gridID,regionID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.defBoxRegion` | `gd.defVrtRegion`

# matlab.io.hdfEOS.gd.setFillValue

**Package:** matlab.io.hdfEOS.gd

Set fill value for specified field

## Syntax

```
setFillValue(gridID,fieldname,fillvalue)
```

## Description

`setFillValue(gridID,fieldname,fillvalue)` sets the fill value for the specified field. The fill value should have the same data type as the field.

This function corresponds to the `GDsetfillvalue` function in the HDF-EOS library C API.

## Examples

Create a new double-precision field with a fill value of -1.

```
import matlab.io.hdfEOS.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','grid.hdf');
copyfile(srcFile,'myfile.hdf');
fileattrib('myfile.hdf','+w');
gfid = gd.open('myfile.hdf','rdwr');
gridID = gd.attach(gfid,'PolarGrid');
gd.defComp(gridID,'none');
gd.defField(gridID,'newfield',{'XDim','YDim},'double');
gd.setFillValue(gridID,'newfield',-1);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.getFillValue`

# matlab.io.hdfEOS.gd.setTileComp

**Package:** matlab.io.hdfEOS.gd

Set tiling and compression for field with fill value

## Syntax

```
setTileComp(gridID,fieldname,tilesize,compCode,compParm)
```

## Description

`setTileComp(gridID,fieldname,tilesize,compCode,compParm)` sets the tiling and compression for a field that had a fill value. This function must be applied after `gd.defField` and `gd.setFillValue`. The `compCode` argument can be one of the following strings.

'rle'	Run-length encoding
'skphuff'	Skipping Huffman
'deflate'	Deflate
'none'	No compression

`compParm` need only be specified when the compression scheme is 'deflate', and then must be an integer between 0 and 9.

This function corresponds to the `GDsettilecomp` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tilesize` parameter is reversed with respect to the C library API.

## Examples

Define a temperature field with a 2-by-2 tiling scheme, a fill value of -999, and deflate compression.

```
import matlab.io.hdfEOS.*
```

```
gfid = gd.open('myfile.hdf','create');
upleft = [210584.50041 3322395.95445];
lowright = [813931.10959 2214162.53278];
gridID = gd.create(gfid,'UTMGrid',120,200,upleft,lowright);
spherecode = 0; zonecode = 40;
projparm = zeros(1,13);
gd.defProj(gridID,'utm',zonecode,spherecode,projparm);
gd.defDim(gridID,'Time',10);
gd.defField(gridID,'Pollution',{'XDim','YDim','Time'],'float');
gd.setFillValue(gridID,'Pollution',single(7));
gd.setTileComp(gridID,'Pollution',[40 20 1],'deflate',5);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

# matlab.io.hdfeos.gd.sphereCodeToName

**Package:** matlab.io.hdfeos.gd

Name corresponding to GCTP sphere code

## Syntax

```
name = sphereCodeToName(code)
```

## Description

`name = sphereCodeToName(code)` returns the name for the spheroid corresponding to the spheroid code. The list of supported GCTP spheroids is as follows:

GCTP Spheroid Code	Spheroid Name
0	Clarke 1866
1	Clarke 1880
2	Bessel
3	International 1967
4	International 1909

`gd.defProj` | `gd.sphereCodeToName`

# matlab.io.hdfEOS.gd.tileInfo

**Package:** matlab.io.hdfEOS.gd

Tile size of grid field

## Syntax

```
tileDims = tileInfo(gridID,fieldname)
```

## Description

`tileDims = tileInfo(gridID,fieldname)` returns the tile dimensions of the field specified by `fieldname` in the grid specified by `gridID`. If the field is not tiled, then `tileDims` is `[]`.

This function corresponds to the `GDtileinfo` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tileDims` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
tileDims = gd.tileInfo(gridID,'pressure');
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.defTile`

# matlab.io.hdfEOS.gd.writeAttr

**Package:** matlab.io.hdfEOS.gd

Write grid attribute

## Syntax

```
writeAttr(gridID,attrname,data)
```

## Description

`writeAttr(gridID,attrname,data)` writes an attribute to a grid. If the attribute does not exist, it is created. If the attribute exists, it can be modified in place, but it cannot be recreated with a different data type or length.

This function corresponds to the `GDwriteattr` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','grid.hdf');
copyfile(srcFile,'myfile.hdf');
fileattrib('myfile.hdf','+w');
gfid = gd.open('myfile.hdf','rdwr');
gridID = gd.attach(gfid,'PolarGrid');
gd.writeAttr(gridID,'modification_date',datestr(now));
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.readAttr`

# matlab.io.hdfeos.gd.writeBlkSomOffset

**Package:** matlab.io.hdfeos.gd

Write Block SOM offset

## Syntax

```
writeBlkSomOffset(gridID,offset)
```

## Description

`writeBlkSomOffset(gridID,offset)` writes the block SOM offset values `n` pixels for a standard Solar Oblique Mercator (SOM) projection. `offset` is a vector of offset values for SOM projection data. This routine can only be used with grids that use the SOM projection. You must take care to use this function properly in conjunction with `gd.defProj`. The 12th element of the projection parameters must be set to the total number of blocks to be defined. `offset` starts by listing the offset to the second block, so the 12th element of the projection parameters is always one more than the length of `offset`.

All fields defined after writing the block SOM offset values will automatically include "SOMBlockDim" as the slowest varying dimension.

This function corresponds to the `GDb1kSOMoffset` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
lowright = [30521379.68485 1152027.64253];
upleft = [-11119487.42844 8673539.24806];
gridID = gd.create(gfid,'SOM',120,60,upleft,lowright);
projparm(1) = 6378137;
projparm(2) = 0.006694348;
projparm(4) = 98096360; % 98.161 in DDDMMSS
```

```
projparm(5) = 87069061; % 87.112 in DDDMMSS
projparm(9) = 0.068585416*1440;
projparm(10) = 0.0;
projparm(12) = 6;
gd.defProj(gridID, 'som', [], [], projparm);
gd.writeBlkSomOffset(gridID, [5 10 12 8 2]);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.readBlkSomOffset`

# matlab.io.hdfeos.gd.writeField

**Package:** matlab.io.hdfeos.gd

Write data to grid field

## Syntax

```
writeField(gridID,fieldname,data)
writeField(gridID,fieldname,start,data)
writeField(gridID,fieldname,start,stride,data)
```

## Description

`writeField(gridID,fieldname,data)` writes all the data to a grid field. The field is identified by `fieldname` and the grid is identified by `gridID`.

`writeField(gridID,fieldname,start,data)` writes a contiguous hyperslab to the grid field. `start` specifies the zero-based starting index.

`writeField(gridID,fieldname,start,stride,data)` writes a strided hyperslab of data to a grid data field. `stride` specifies the inter-element spacing along each dimension. The number of elements to write along each dimension is inferred from the size of `data`.

This function corresponds to the `GDwritefield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `start` and `stride` parameters are reversed with respect to the C library API.

## Examples

Write all the data to a grid field.

```
import matlab.io.hdfeos.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','grid.hdf');
copyfile(srcFile,'myfile.hdf');
fileattrib('myfile.hdf','+w');
```

```
gfid = gd.open('myfile.hdf','rdwr');
gridID = gd.attach(gfid,'PolarGrid');
data = zeros(100,100,'uint16');
gd.writeField(gridID,'ice_temp',data);
gd.detach(gridID);
gd.close(gfid);
```

## See Also

`gd.readField`

# matlab.io.hdfEOS.gd.writeTile

**Package:** matlab.io.hdfEOS.gd

Write tile to field

## Syntax

```
writeTile(gridID,fieldname,tileCoords,data)
```

## Description

`writeTile(gridID,fieldname,tileCoords,data)` writes a single tile of data to a field. If the field data can be arranged tile by tile, this routine is more efficient than `gd.writeField`. In all other cases, use `gd.writeField`. The `tileCoords` argument has the form `[rownum colnum]` and is defined in terms of the tile coordinates, not the data elements.

This function corresponds to the `GDwritetile` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tileCoords` parameter is reversed with respect to the C library API.

## Examples

Define a field with a 2-by-3 tiling scheme.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
xdim = 200; ydim = 180;
gridID = gd.create(gfid,'PolarGrid',xdim,ydim,[],[]);
zonecode = 40;
spherecode = 0;
projParm = zeros(1,13);
projParm(6) = 90000000;
gd.defProj(gridID,'ps',[],spherecode,projParm);
tileSize = [100 60];
gd.defTile(gridID,tileSize);
```

```
dimlist = {'XDim','YDim'};
gd.defField(gridID,'Pressure',dimlist,'int32');
for c = 0:2
 for r = 0:1
 data = (r+c)*ones(tileSize,'int32');
 gd.writeTile(gridID,'Pressure',[r c],data);
 end
end
gd.detach(gridID);
gd.close(gfid);
```

# matlab.io.hdfEOS.sw

Low-level access to HDF-EOS swath files

## Description

To use these MATLAB functions, you must be familiar with the HDF-EOS library C interface. In most cases, the syntax of the MATLAB function is similar to the syntax of the corresponding HDF-EOS library function. The functions are implemented as the package `matlab.io.hdfEOS.sw`. To use this package, prefix the function name with a package path, or use the `import` function to add the package to the current import list, prior to calling the function, for example,

```
import matlab.io.hdfEOS.*
fileId = sw.open(filename);
```

## Access

<code>matlab.io.hdfEOS.sw.attach</code>	Attach to swath data set
<code>matlab.io.hdfEOS.sw.close</code>	Close swath file
<code>matlab.io.hdfEOS.sw.create</code>	Create new swath structure
<code>matlab.io.hdfEOS.sw.detach</code>	Detach from swath
<code>matlab.io.hdfEOS.sw.open</code>	Open swath file

## Definition

<code>matlab.io.hdfEOS.sw.defComp</code>	Set grid field compression
<code>matlab.io.hdfEOS.sw.defDataField</code>	Define new data field within swath
<code>matlab.io.hdfEOS.sw.defDim</code>	Define new dimension within swath
<code>matlab.io.hdfEOS.sw.defDimMap</code>	Define mapping between geolocation and data dimensions
<code>matlab.io.hdfEOS.sw.defGeoField</code>	Define new data field within swath

## Basic I/O

matlab.io.hdfEOS.sw.getFillValue	Fill value for specified field
matlab.io.hdfEOS.sw.readAttr	Read swath attribute
matlab.io.hdfEOS.sw.readField	Read data from swath field
matlab.io.hdfEOS.sw.setFillValue	Set fill value for the specified field
matlab.io.hdfEOS.sw.writeAttr	Write swath attribute
matlab.io.hdfEOS.sw.writeField	Write data to swath field

## Inquiry

matlab.io.hdfEOS.sw.compInfo	Compression information for field
matlab.io.hdfEOS.sw.dimInfo	Size of dimension
matlab.io.hdfEOS.sw.fieldInfo	Information about swath field
matlab.io.hdfEOS.sw.geoMapInfo	Type of dimension mapping for named dimension
matlab.io.hdfEOS.sw.idxMapInfo	Indexed array of geolocation mapping
matlab.io.hdfEOS.sw.inqAttrs	Names of swath attributes
matlab.io.hdfEOS.sw.inqDataFields	Information about geolocation fields
matlab.io.hdfEOS.sw.inqDims	Information about dimensions defined in swath
matlab.io.hdfEOS.sw.inqGeoFields	Information about geolocation fields
matlab.io.hdfEOS.sw.inqIdxMaps	Information about swath indexed geolocation mapping
matlab.io.hdfEOS.sw.inqMaps	Information about swath geolocation relations
matlab.io.hdfEOS.sw.inqSwath	Names of swaths in file

matlab.io.hdfEOS.sw.mapInfo

Offset and increment of specific geolocation mapping

matlab.io.hdfEOS.sw.nEntries

Number of entries for specific type

## Subsetting

matlab.io.hdfEOS.sw.defBoxRegion

Define latitude-longitude region for swath

matlab.io.hdfEOS.sw.defTimePeriod

Define time period of interest

matlab.io.hdfEOS.sw.defVrtRegion

Subset on monotonic field or dimension

matlab.io.hdfEOS.sw.extractPeriod

Read data from subsetted time period

matlab.io.hdfEOS.sw.extractRegion

Read subsetted region

matlab.io.hdfEOS.sw.periodInfo

Information about subsetted period

matlab.io.hdfEOS.sw.regionInfo

Information about subsetted region

# matlab.io.hdfEOS.sw.attach

**Package:** matlab.io.hdfEOS.sw

Attach to swath data set

## Syntax

```
swathID = attach(swfid,swathname)
```

## Description

`swathID = attach(swfid,swathname)` attaches to the swath identified by `swathname` in the file identified by `swfid`. The `swathID` output is the identifier for the named swath.

This function corresponds to the `SWattach` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

`sw.detach`

# matlab.io.hdfEOS.sw.close

**Package:** matlab.io.hdfEOS.sw

Close swath file

## Syntax

```
close(swfID)
```

## Description

`close(swfID)` closes an HDF-EOS swath file identified by `swfID`.

This function corresponds to the `SWclose` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'ExampleSwath');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

## matlab.io.hdfEOS.sw.compInfo

**Package:** matlab.io.hdfEOS.sw

Compression information for field

### Syntax

```
[code,parms] = compInfo(swathID,fieldname)
```

### Description

[code,parms] = compInfo(swathID,fieldname) returns the compression code and compression parameters for a given field. Refer to `sw.defComp` for a description of various compression schemes and parameters.

This function corresponds to the `SWcompinfo` function in the HDF-EOS library C API.

### Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
[compCode,parms] = sw.compInfo(swathID,'Spectra');
sw.detach(swathID);
sw.close(swfid);
```

### See Also

`sw.defComp`

# matlab.io.hdfEOS.sw.create

**Package:** matlab.io.hdfEOS.sw

Create new swath structure

## Syntax

```
swathID = create(swfileID,swathname)
```

## Description

`swathID = create(swfileID,swathname)` creates a new swath structure where `swfileID` is the swath file identifier and `swathname` is the name of the new swath. The swath is created as a Vgroup with the HDF file with the name `swathname` and HDF Vgroup class 'SWATH'.

This function corresponds to the `SWcreate` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfileID = sw.open('myfile.hdf','create');
swathID = sw.create(swfileID,'ExampleSwath');
sw.detach(swathID);
sw.close(swfileID);
```

## See Also

`sw.detach`

## matlab.io.hdfEOS.sw.defBoxRegion

**Package:** matlab.io.hdfEOS.sw

Define latitude-longitude region for swath

### Syntax

```
regionID = defBoxRegion(swathID,lat,lon,mode)
```

### Description

`regionID = defBoxRegion(swathID,lat,lon,mode)` defines a latitude-longitude box region for a swath. `lat` and `lon` are two-element arrays containing the latitude and longitude in decimal degrees of the box corners. A cross track is determined to be within the box if a condition is met according to the value of `mode`:

'MIDPOINT'	The cross track midpoint is within the box.
'ENDPOINT'	Either endpoint is within the box.
'ANYPPOINT'	Any point of the cross track is within the box.

All elements of a cross track are within the region if the condition is met. The swath must have both Longitude and Latitude (or Colatitude) defined.

`regionID` is an identifier to be used by `sw.extractRegion` to read all the entries of a data field within the region.

This function corresponds to the `SWdefboxregion` and `SWregionindex` functions in the HDF-EOS library C API.

### Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
lat = [34 44];
```

```
lon = [16 24];
regionID = sw.defBoxRegion(swathID,lat,lon,'MIDPOINT');
data = sw.extractRegion(swathID,regionID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

sw.extractRegion

# matlab.io.hdfEOS.sw.defComp

**Package:** matlab.io.hdfEOS.sw

Set grid field compression

## Syntax

```
defComp(swathID,compscheme,compparm)
```

## Description

`defComp(swathID,compscheme,compparm)` sets the field compression for subsequent definitions. The compression scheme does not apply to one-dimensional fields. `compscheme` can be one of the following strings.

'rle'	Run-length encoding
'skphuff'	Skipping Huffman
'deflate'	Gzip compression
'none'	No compression

When the compression scheme is 'deflate', the `compparm` input is the deflate compression level, an integer between 0 and 9. `compparm` can be omitted for the other compression schemes.

Fields defined with compression must be written with a single call to `sw.writeField`.

This function corresponds to the `SWdefcomp` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'Track',4000);
```

```
sw.defDim(swathID, 'Xtrack', 2000);
sw.defDim(swathID, 'Bands', 3);
sw.defComp(swathID, 'rle');
dims = {'Xtrack', 'Track'};
sw.defDataField(swathID, 'Pressure', dims, 'float');
sw.defComp(swathID, 'deflate', 5);
sw.defDataField(swathID, 'Opacity', dims, 'float');
sw.defComp(swathID, 'skphuff');
dims = {'Xtrack', 'Track', 'Bands'};
sw.defDataField(swathID, 'Spectra', dims, 'float');
sw.defComp(swathID, 'none');
dims = {'Xtrack', 'Track'};
sw.defDataField(swathID, 'Temperature', dims, 'float');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

`sw.compInfo`

## matlab.io.hdfEOS.sw.defDataField

**Package:** matlab.io.hdfEOS.sw

Define new data field within swath

### Syntax

```
defDataField(swathID,fieldname,dimlist,dtype)
defDataField(swathID,fieldname,dimlist,dtype,mergeCode)
```

### Description

`defDataField(swathID,fieldname,dimlist,dtype)` defines a data field to be stored in the swath identified by `swathID`. The `dimlist` input can be a cell array of dimension names, or a single char if there is only one dimension. `dtype` is the data type of the field and can be one of the following strings.

- 'double'
- 'single'
- 'int32'
- 'uint32'
- 'int16'
- 'uint16'
- 'int8'
- 'uint8'
- 'char'

`dimlist` should be ordered such that the fastest varying dimension is listed first. This is opposite from the order in which the dimensions are listed in the C API.

`defDataField(swathID,fieldname,dimlist,dtype,mergeCode)` defines a data field that can be merged with other data fields according to the value of `mergeCode`. The `mergeCode` input can be one of two strings, 'automerge' and 'nomerge'. If `mergeCode` is 'automerge', then the HDF-EOS library will attempt to merge swath

fields into a single object. This should not be done if you wish to access the swath fields individually with the another interface. By default, `mergeCode` is 'nomerge'.

---

**Note:** To assure that the fields defined by `sw.defDataField` are properly established in the file, the swath should be detached and then reattached before writing to any fields.

---

This function corresponds to the `SWdefdatafield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
sw.defDim(swathID,'Bands',3);
sw.defDimMap(swathID,'GeoTrack','DataTrack',0,2);
sw.defDimMap(swathID,'GeoXtrack','DataXtrack',1,2);
dims = {'GeoXtrack','GeoTrack'};
sw.defGeoField(swathID,'Longitude',dims,'float');
sw.defGeoField(swathID,'Latitude',dims,'float');
dims = {'DataXtrack','DataTrack','Bands'};
sw.defDataField(swathID,'Spectra',dims,'float');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

`sw.defGeoField` | `sw.inqDataFields`

## matlab.io.hdfEOS.sw.defDim

**Package:** matlab.io.hdfEOS.sw

Define new dimension within swath

### Syntax

```
defDim(swathID,dimname,dimlen)
```

### Description

`defDim(swathID,dimname,dimlen)` defines a new dimension named `dimname` with length `dimlen` in the swath structure identified by `swathID`.

To specify an unlimited dimension, use either 0 or 'unlimited' for `dimlen`.

This function corresponds to the `SWdefdim` function in the HDF-EOS library.

### Examples

Define a dimension 'Band' with length of 15 and an unlimited dimension 'Time'.

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
sw.detach(swathID);
sw.close(swfid);
```

### See Also

`sw.dimInfo`

# matlab.io.hdfEOS.sw.defDimMap

**Package:** matlab.io.hdfEOS.sw

Define mapping between geolocation and data dimensions

## Syntax

```
defDimMap(swathID,geoDim,dataDim,offset,increment)
```

## Description

`defDimMap(swathID,geoDim,dataDim,offset,increment)` defines a monotonic mapping between the geolocation and data dimensions, which usually have differing lengths. `offset` gives the index of the data element corresponding to the first geolocation element, and `increment` gives the number of data elements to skip for each geolocation element. If the geolocation dimension begins "before" the data dimension, then `offset` is negative. Similarly, if the geolocation dimension has higher resolution than the data dimension, then `increment` is negative.

This function corresponds to the `SWdefdimmap` function in the HDF-EOS library.

## Examples

Create a dimension mapping such that the first element of the GeoTrack dimension corresponds to the first element of the DataTrack Dimension and such that the data dimension has twice the resolution as the geolocation dimension. Also create a dimension mapping such that the first element of the GeoXtrack dimension corresponds to the second element of the DataXtrack dimensions and such that the data dimension has twice the resolution as the geolocation dimension.

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
```

```
sw.defDim(swathID, 'DataXtrack',2000);
sw.defDimMap(swathID, 'GeoTrack', 'DataTrack',0,2);
sw.defDimMap(swathID, 'GeoXtrack', 'DataXtrack',1,2);
sw.detach(swathID);
sw.close(swfid);
```

## See Also

sw.defDim | sw.mapInfo

# matlab.io.hdfEOS.sw.defGeoField

**Package:** matlab.io.hdfEOS.sw

Define new data field within swath

## Syntax

```
defGeoField(swathID,fieldname,dimlist,dtype)
defGeoField(swathID,fieldname,dimlist,dtype,mergeCode)
```

## Description

`defGeoField(swathID,fieldname,dimlist,dtype)` defines a geolocation field to be stored in the swath identified by `swathID`. The `dimlist` argument can be a cell array of dimension names or a single char if there is only one dimension. `dtype` is the data type of the field

`dimlist` should be ordered such that the fastest varying dimension is listed first. This is opposite from the order in which the dimensions are listed in the C API.

`defGeoField(swathID,fieldname,dimlist,dtype,mergeCode)` defines a geolocation field that may be merged with other geolocation fields according to the value of `mergeCode`. The `mergeCode` argument can be one of two strings, 'automerge' and 'nomerge'. If `mergeCode` is 'automerge', then the HDF-EOS library will attempt to merge swath fields into a single object. This should not be done if you wish to access the swath fields individually with the another interface. By default, `mergeCode` is 'nomerge'.

This function corresponds to the `SWdefgeofield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdfEOS.*
```

```
swfid = sw.open('myfile.hdf', 'create');
swathID = sw.create(swfid, 'MySwath');
sw.defDim(swathID, 'GeoTrack', 2000);
sw.defDim(swathID, 'GeoXtrack', 1000);
sw.defDim(swathID, 'DataTrack', 4000);
sw.defDim(swathID, 'DataXtrack', 2000);
sw.defDimMap(swathID, 'GeoTrack', 'DataTrack', 0, 2);
sw.defDimMap(swathID, 'GeoXtrack', 'DataXtrack', 1, 2);
dims = {'GeoXtrack', 'GeoTrack'};
sw.defGeoField(swathID, 'Longitude', dims, 'float');
sw.defGeoField(swathID, 'Latitude', dims, 'float');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

sw.defDataField | sw.inqGeoFields

# matlab.io.hdfEOS.sw.defTimePeriod

**Package:** matlab.io.hdfEOS.sw

Define time period of interest

## Syntax

```
outpID = defTimePeriod(swathID,start,stop,mode)
```

## Description

`outpID = defTimePeriod(swathID,start,stop,mode)` defines a time period for a swath. `outpID` is a swath period ID that can be used to read all the entries of a data field within the time period. The swath structure must have the 'Time' field defined. A cross track is within a time period if a condition is met according to the value of `mode`:

'MIDPOINT'	The midpoint is within the time period.
'ENDPOINT'	Either endpoint is within the time period.

This function corresponds to the `SWdeftimeperiod` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
starttime = 25;
stoptime = 425;
periodID = sw.defTimePeriod(swathID,starttime,stoptime,'MIDPOINT');
data = sw.extractPeriod(swathID,periodID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

# matlab.io.hdfEOS.sw.defVrtRegion

**Package:** matlab.io.hdfEOS.sw

Subset on monotonic field or dimension

## Syntax

```
regionID_out = defVrtRegion(swathID,regionID,vertObj,range)
```

## Description

`regionID_out = defVrtRegion(swathID,regionID,vertObj,range)` subsets on a monotonic field or contiguous elements of a dimension. Whereas `defBoxRegion` and `defTimePeriod` subset along the 'Track' dimension, this routine allows the user to subset along any dimension. `regionID` specifies the subsetted region from a previous call. `vertObj` specifies the dimension by which to subset. `range` specifies the minimum and maximum values for `vertObj`.

If there is no current subsetted region, `regionID` should be 'noprevious'.

`vertObj` can be either a dimension or a field. If it is a dimension, then `range` should consist of dimension indices. If `vertObj` corresponds to a field, then `range` should consist of the minimum and maximum field values. `vertObj` must be one-dimensional in this case, and the its values must be monotonic.

This function corresponds to the `SWdefvrtregion` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
regionID = sw.defVrtRegion(swathID,'noprevious','Bands',[450 600]);
data = sw.extractRegion(swathID,regionID,'Spectra');
sw.detach(swathID);
```

```
sw.close(swfid);
```

## matlab.io.hdfEOS.sw.extractPeriod

**Package:** matlab.io.hdfEOS.sw

Read data from subsetted time period

### Syntax

```
data = extractPeriod(swathID,periodID,fieldname)
```

### Description

`data = extractPeriod(swathID,periodID,fieldname)` reads data for the given field for the time period specified by `periodID`.

This routine corresponds to the `SWextractperiod` function in the HDF-EOS library C API.

### Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
starttime = 25;
stoptime = 425;
periodID = sw.defTimePeriod(swathID,starttime,stoptime,'MIDPOINT');
data = sw.extractPeriod(swathID,periodID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

**Package:** matlab.io.hdfEOS.sw

Information about swath indexed geolocation mapping

### Syntax

```
[idxMap,idxSize] = inqIdxMaps(swathID)
```

### Description

`[idxMap,idxSize] = inqIdxMaps(swathID)` retrieves all indexed geolocation/data mappings defined in the swath. `idxMap` is a cell array with each element consisting of the names of the dimensions of a mapping, separated by a ' / '. `idxSize` contains the size of the index arrays corresponding to each mapping.

This function corresponds to the `SWinqidxmaps` routine in the HDF-EOS library.

### See Also

`sw.inqMaps`

# matlab.io.hdfEOS.sw.inqMaps

**Package:** matlab.io.hdfEOS.sw

Information about swath geolocation relations

## Syntax

```
[map,offset,increment] = inqMaps(swathID)
```

## Description

`[map,offset,increment] = inqMaps(swathID)` returns the dimension mapping list, the offset of each geolocation relation, and the increment of each geolocation relation. These mappings are not indexed. `map` is a cell array where each element contains the names of the dimensions for each mapping, separated by a slash. `offset` and `increment` contain the offset and increment of each geolocation relation.

This function corresponds to the `SWinqmaps` routine in the HDF-EOS library.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
[dimmap,offset,increment] = sw.inqMaps(swathID);
sw.detach(swathID);
sw.close(swfid);
```

# matlab.io.hdfEOS.sw.nEntries

**Package:** matlab.io.hdfEOS.sw

Number of entries for specific type

## Syntax

```
nEnts = nEntries(swathID,type)
```

## Description

`nEnts = nEntries(swathID,type)` returns the number of entries in a swath. Valid inputs for `type` include:

'dims'	or 'HDFE_NENTDIM'
'maps'	or 'HDFE_NENTMAP'
'imaps'	or 'HDFE_NENTIMAP'
'geofields'	or 'HDFE_NENTGFLD'
'datafields'	or 'HDFE_NENTFLD'

This function corresponds to the `SWnentries` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
ndims = sw.nEntries(swathID,'dims');
sw.detach(swathID);
sw.close(swfid);
```

# matlab.io.hdfEOS.sw.open

**Package:** matlab.io.hdfEOS.sw

Open swath file

## Syntax

```
swfID = open(filename)
swfID = open(filename,access)
```

## Description

`swfID = open(filename)` opens an HDF-EOS swath file for read-only access.

`swfID = open(filename,access)` opens or creates an HDF-EOS swath file identified by `filename` and returns a file ID. `access` can be one of the following string values.

'read' (default)	Read-only
'rdwr'	Read-write
'create'	Creates a file, deleting it if it already exists

This routine corresponds to the `SWopen` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
sw.close(swfid);
```

## See Also

`sw.close`

# matlab.io.hdfEOS.sw.periodInfo

**Package:** matlab.io.hdfEOS.sw

Information about subsetted period

## Syntax

```
[datatype,dims] = periodInfo(swathID,periodID,fieldname)
```

## Description

`[datatype,dims] = periodInfo(swathID,periodID,fieldname)` retrieves information about the period defined for the given field. `datatype` is the data type of the field. `dims` is the dimensions of the subsetted region.

This function corresponds to the `SWperiodinfo` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dims` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
starttime = 25;
stoptime = 425;
periodID = sw.defTimePeriod(swathID,starttime,stoptime,'MIDPOINT');
[ntype,dims] = sw.periodInfo(swathID,periodID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

`sw.defTimePeriod` | `sw.extractPeriod`

## matlab.io.hdfEOS.sw.readAttr

**Package:** matlab.io.hdfEOS.sw

Read swath attribute

### Syntax

```
data = readAttr(swathID,attrname)
```

### Description

`data = readAttr(swathID,attrname)` reads a swath attribute.

This function corresponds to the `SWreadAttr` function in the HDF-EOS library C API.

### Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
value = sw.readAttr(swathID,'creation_date');
sw.detach(swathID);
sw.close(swfid);
```

### See Also

`sw.writeAttr`

# matlab.io.hdfEOS.sw.readField

**Package:** matlab.io.hdfEOS.sw

Read data from swath field

## Syntax

```
data = readField(swathID,fieldname)
data = readField(swathID,fieldname,start,count)
data = readField(swathID,fieldname,start,count,stride)
```

## Description

`data = readField(swathID,fieldname)` reads an entire swath field.

`data = readField(swathID,fieldname,start,count)` reads a contiguous hyperslab of data from the swath field `fieldname`. The `start` input specifies the zero-based index of the first element to be read. `count` specifies the number of elements along each dimension to read.

`data = readField(swathID,fieldname,start,count,stride)` reads a strided hyperslab of data from the swath field `fieldname`. The `stride` input specifies the inter-element spacing along each dimension.

This function corresponds to the `SWreadfield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `start`, `count`, and `stride` parameters are reversed with respect to the C library API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
data = sw.readField(swathID,'Longitude');
sw.detach(swathID);
sw.close(swfid);
```

**See Also**

sw.writeField

# matlab.io.hdfEOS.sw.regionInfo

**Package:** matlab.io.hdfEOS.sw

Information about subsetted region

## Syntax

```
[datatype,extent] = regionInfo(swathID,regionID,fieldname)
```

## Description

`[datatype,extent] = regionInfo(swathID,regionID,fieldname)` returns the data type and extent of a subsetted region of a field. `regionID` is the identifier for the subsetted region.

This function corresponds to the `SWregioninfo` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `extent` parameter is reversed with respect to the C library API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
lat = [34 44];
lon = [16 24];
regionID = sw.defBoxRegion(swathID,lat,lon,'MIDPOINT');
[ntype,dims] = sw.regionInfo(swathID,regionID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

## See Also

sw.defBoxRegion | sw.defVrtRegion

# matlab.io.hdfEOS.sw.setFillValue

**Package:** matlab.io.hdfEOS.sw

Set fill value for the specified field

## Syntax

```
setFillValue(swathID,fieldname,fillvalue)
```

## Description

`setFillValue(swathID,fieldname,fillvalue)` sets the fill value for the specified field. The field must have more than two dimensions.

This function corresponds to the `SWsetfillvalue` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'Track',400);
sw.defDim(swathID,'Xtrack',200);
dims = {'Track','Xtrack'};
sw.defDataField(swathID,'Temperature',dims,'float');
sw.setFillValue(swathID,'Temperature',single(-999));
sw.detach(swathID);
sw.close(swfid);
```

## See Also

`sw.setFillValue`

# matlab.io.hdfEOS.sw.writeAttr

**Package:** matlab.io.hdfEOS.sw

Write swath attribute

## Syntax

```
writeAttr(swathID,attrname,data)
```

## Description

`writeAttr(swathID,attrname,data)` writes an attribute to a swath. If the attribute does not exist, it is created. If the attribute exists, it can be modified in place, but it cannot be recreated with a different data type or length.

This function corresponds to the `SWwriteattr` function in the HDF-EOS library C API.

## Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.writeAttr(swathID,'creation_date',datestr(now));
sw.detach(swathID);
sw.close(swfid);
```

## See Also

`sw.readAttr`

# matlab.io.hdfEOS.sw.writeField

**Package:** matlab.io.hdfEOS.sw

Write data to swath field

## Syntax

```
writeField(swathID,fieldname,data)
writeField(swathID,fieldname,start,data)
writeField(swathID,fieldname,start,stride,data)
```

## Description

`writeField(swathID,fieldname,data)` writes an entire swath data field.

`writeField(swathID,fieldname,start,data)` writes a contiguous hyperslab to a swath field. `start` specifies the index of the first element to write. The number of elements along each dimension is inferred from either the size of `data` or from the swath field itself.

`writeField(swathID,fieldname,start,stride,data)` writes a strided hyperslab to a swath field. `stride` specifies the inter-element spacing along each dimension.

This function corresponds to the `SWwritefield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `start` and `stride` parameters are reversed with respect to the C library API.

## Examples

Write data to a geolocation field 'Longitude'.

```
lon = [-50:49];
data = repmat(lon(:),1,100);
data = single(data);
import matlab.io.hdfEOS.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','swath.hdf');
```

```
copyfile(srcFile, 'myfile.hdf');
fileattrib('myfile.hdf', '+w');
swfid = sw.open('myfile.hdf', 'rdwr');
swathID = sw.attach(swfid, 'Example Swath');
sw.writeField(swathID, 'Longitude', data);
sw.detach(swathID);
sw.close(swfid);
```

## See Also

`sw.readField`

# matlab.io.saveVariablesToScript

Save workspace variables to MATLAB script

## Syntax

```
matlab.io.saveVariablesToScript(filename)
matlab.io.saveVariablesToScript(filename,varnames)
matlab.io.saveVariablesToScript(filename,Name,Value)
[r1,r2] = matlab.io.saveVariablesToScript(filename)
```

## Description

`matlab.io.saveVariablesToScript(filename)` saves variables in the current workspace to a MATLAB script named `filename.m`. The filename can include the `.m` suffix. If you do not include it, the function adds it when it creates the file.

Variables that MATLAB cannot generate code for are saved to a MAT-file named `filename.mat`.

If a file with the same name already exists, it is overwritten.

`matlab.io.saveVariablesToScript(filename,varnames)` saves only workspace variables specified by `varnames` to the MATLAB script.

`matlab.io.saveVariablesToScript(filename,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[r1,r2] = matlab.io.saveVariablesToScript(filename)` additionally returns two cell arrays:

- `r1` for variables that were saved to the MATLAB script
- `r2` for variables that were saved to a MAT-file

## Examples

### Save Workspace Variables to MATLAB Script

Save variables from a workspace to a MATLAB script, `test.m`.

```
matlab.io.saveVariablesToScript('test.m')
```

### Save Specific Workspace Variables to MATLAB Script

Create and save variable `myVar` from a workspace to a MATLAB script, `test.m`.

```
myVar = 55.3;
matlab.io.saveVariablesToScript('test.m','myVar')
```

### Append Specific Variables to Existing MATLAB Script

Create two variables, `a` and `b`, and save them to an existing MATLAB script `abfile.m`.

```
a = 72.3;
b = pi;
matlab.io.saveVariablesToScript('abfile.m',{'a','b'},...
'SaveMode','append')
```

### Update Specific Variables in Existing MATLAB Script

Update and save two variables, `y` and `z`, to an existing MATLAB script `yzfile.m`.

```
y = 15.7;
z = 3 * pi;
matlab.io.saveVariablesToScript('yzfile.m',{'y','z'},...
'SaveMode','update')
```

### Specify MATLAB Script Configuration for Saving Variable

Update and save variable `resistance` to an existing MATLAB script `designData.m` while specifying the configuration of the script file.

```
resistance = [10 20.5 11 13.7 15.1 7.7];
matlab.io.saveVariablesToScript('designData.m','resistance',...
'SaveMode','Update','MaximumArraySize',5,...
'MaximumNestingLevel',5,'MaximumTextWidth',30)
```

### Specify 2-D Slice for Saving 3-D Array in MATLAB Script

Specify a 2-D slice for the output of the 3-D array `my3Dtable`, such that the 2-D slice expands along the first and third dimensions. Save the 2-D slice in the MATLAB script `sliceData.m`.

```
level1 = [1 2; 3 4];
```

```
level2 = [5 6; 7 8];
my3Dtable(:, :, 1) = level1;
my3Dtable(:, :, 2) = level2;
matlab.io.saveVariablesToScript('sliceData.m','MultidimensionalFormat',[1,3])
```

The resulting MATLAB code is similar to the following:

```
level1 = ...
 [1 2;
 3 4];

level2 = ...
 [5 6;
 7 8];
my3Dtable = zeros(2, 2, 2);
my3Dtable(:,1,:) = ...
 [1 5;
 3 7];

my3Dtable(:,2,:) = ...
 [2 6;
 4 8];
```

## Save Variables Matching a Regular Expression

Save variables that match the expression `autoL*` to a MATLAB script `autoVariables.m`.

```
matlab.io.saveVariablesToScript('autoVariables.m','RegExp','autoL*')
```

## Save Variables to Version 7.3 MATLAB Script

Create two variables, `p` and `q`, and save them to a version 7.3 MATLAB script `version73.m`.

```
p = 49;
q = 35.5;
matlab.io.saveVariablesToScript('version73.m','p','q',...
'MATFileVersion','v7.3')
```

## Return Variables Saved to MATLAB Script

Save variables that were saved to a MATLAB script to the variable `r1`, and those that were saved to a MAT-file to the variable `r2`.

```
[r1,r2] = matlab.io.saveVariablesToScript('mydata.m')
```

```
r1 =
```

```
 'level1'
 'level2'
 'level3'
 'my3Dtable'
```

```
r2 =
```

```
Empty cell array: 0-by-1
```

## Input Arguments

### **filename** — Name of MATLAB script for saving variables

filename | variable

Name of MATLAB script for saving variables, specified as a string giving a file name or a variable containing the file name.

Example: `matlab.io.saveVariablesToScript('myVariables.m')`

### **varnames** — Name of variables to save

string | cell array

Name of variables to save, specified as a string or a cell array.

Example: `{'X','Y','Z'}`

Data Types: `char` | `cell`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `'MaximumArraySize',500,'MATFileVersion','v4'` specifies that the maximum number of array elements to save is 500 using MATLAB version 4 syntax.

**'MATFileVersion' — MATLAB version whose syntax to use**

'v7.3' (default) | 'v4' | 'v6' | 'v7'

MATLAB version whose syntax to use for saving MAT-files, specified as the comma-separated pair consisting of 'MATFileVersion' and one of the following version numbers:

- 'v4'
- 'v6'
- 'v7'
- 'v7.3'

Example: 'MATFileVersion','v6'

Data Types: char

**'MaximumArraySize' — Maximum array elements to save**

1000 (default) | integer

Maximum array elements to save, specified as the comma-separated pair consisting of 'MaximumArraySize' and an integer in the range of 1 to 10,000.

Example: 'MaximumArraySize',1050

**'MaximumNestingLevel' — Maximum number of object levels or array hierarchies to save**

20 (default) | integer

Maximum number of object levels or array hierarchies to save, specified as the comma-separated pair consisting of 'MaximumNestingLevel' and an integer in the range of 1 to 200.

Example: 'MaximumNestingLevel',67

**'MaximumTextWidth' — Text wrap width during save**

76 (default) | integer

Text wrap width during save, specified as the comma-separated pair consisting of 'MaximumTextWidth' and an integer in the range of 32 to 256.

Example: 'MaximumTextWidth',82

**'MultidimensionalFormat' — Dimensions of 2-D slices that represent n-D arrays of char, logic, or numeric data**

'rowvector' (default) | integer cell array

Dimensions of 2-D slices that represent n-D arrays of char, logic, or numeric data, specified as the comma-separated pair consisting of `'MultidimensionalFormat'` and one of these values:

- `'rowvector'` — Save multidimensional variables as a single row vector.
- `integer cell array` — Save a 2-D slice of multidimensional variables, where the dimensions satisfy all the following criteria:
  - Two positive integers represent dimensions.
  - The two integers are less than or equal to the dimensions of the n-D array.
  - The second integer is greater than the first.

Example: `'MultidimensionalFormat',[1,3]`

### **'RegExp' — Regular expression for matching**

string

Regular expression for matching, specified as the comma-separated pair consisting of `'RegExp'` and one or more expressions given as a string.

Example: `'RegExp','level*'`

Data Types: char

### **'SaveMode' — Mode to save MATLAB script**

`'create'` (default) | `'update'` | `'append'`

Mode to save MATLAB script, specified as the comma-separated pair consisting of `SaveMode` and one of these values:

- `'create'` — Save variables to a new MATLAB script.
- `'update'` — Only update variables that are already present in a MATLAB script.
- `'append'` — Update variables that are already present in a MATLAB script and append new variables to the end of the script.

Example: `'SaveMode','Update'`

## **Output Arguments**

**r1** — Variables that were saved to a MATLAB script

cell array

Variables that were saved to a MATLAB script, returned as a cell array of variable names.

## **r2 – Variables that were saved to a MAT-file**

cell array

Variables that were saved to a MAT-file, returned as a cell array of variable names.

## **Limitations**

- `matlab.io.saveVariablesToScript` does not save the following variables to a MATLAB script or a MAT-file.
  - Java objects
  - .NET objects
  - Python objects
- `matlab.io.saveVariablesToScript` saves the following variables only to a MAT-file.
  - MATLAB objects
  - Function handles
  - Anonymous functions

# matlab.lang.makeUniqueStrings

Construct unique strings from input strings

## Syntax

```
U = matlab.lang.makeUniqueStrings(S)
```

```
U = matlab.lang.makeUniqueStrings(S,excludedStrings)
```

```
U = matlab.lang.makeUniqueStrings(S,whichStringsIdx)
```

```
U = matlab.lang.makeUniqueStrings(S, __ , maxStringLength)
```

```
[U, modified] = matlab.lang.makeUniqueStrings(__)
```

## Description

`U = matlab.lang.makeUniqueStrings(S)` constructs unique strings, `U`, from input strings, `S`, by appending an underscore and a number to duplicate strings.

`U = matlab.lang.makeUniqueStrings(S,excludedStrings)` constructs strings that are unique within `U` and with respect to `excludedStrings`. The `makeUniqueStrings` function does not check `excludedStrings` for uniqueness.

`U = matlab.lang.makeUniqueStrings(S,whichStringsIdx)` specifies the subset of `S` to make unique within the entire set. `makeUniqueStrings` makes the strings in `S(whichStringsIdx)` unique among themselves and with respect to the remaining strings. `makeUniqueStrings` returns the remaining strings unmodified in `U`. Use this syntax when you have an array of strings, and need to check that only some elements of the array are unique.

`U = matlab.lang.makeUniqueStrings(S, __ , maxStringLength)` specifies the maximum length, `maxStringLength`, of strings in `U`. If `makeUniqueStrings` cannot make elements in `S` unique without exceeding `maxStringLength`, it returns an error. You can use this syntax with any of the input arguments of the previous syntaxes.

`[U, modified] = matlab.lang.makeUniqueStrings( __ )` returns a logical array, `modified`, indicating modified strings.

## Examples

### Construct Unique Strings

Create an array of strings and make each element unique.

```
S = {'John' 'Sue' 'Nick' 'John' 'Campion' 'John' 'Jason'};
U = matlab.lang.makeUniqueStrings(S)
```

```
U =
```

```
 'John' 'Sue' 'Nick' 'John_1' 'Campion' 'John_2' 'Jason'
```

The `makeUniqueStrings` function appends the duplicate strings in elements 3 and 5 with underscores and incrementing numbers.

### Construct Unique Strings and Specify Exclusions

Without specifying excluded strings, make the strings in `U` unique.

```
S = {'John' 'Sue' 'Nick' 'John' 'Campion' 'John' 'Jason'};
U = matlab.lang.makeUniqueStrings(S)
```

```
U =
```

```
 'John' 'Sue' 'Nick' 'John_1' 'Campion' 'John_2' 'Jason'
```

Specify that the string, `'Nick'`, should be excluded from the output.

```
U = matlab.lang.makeUniqueStrings(S, 'Nick')
```

```
U =
```

```
 'John' 'Sue' 'Nick_1' 'John_1' 'Campion' 'John_2' 'Jason'
```

`makeUniqueStrings` excludes `'Nick'` from `U` and instead modifies the first duplicate string, found in element 3, to be `'Nick_1'`.

Exclude workspace variables from the unique string array.

```
Sue = 42;
U = matlab.lang.makeUniqueStrings(S, who)
```

```
U =
```

```
 'John' 'Sue_1' 'Nick' 'John_1' 'Campion' 'John_2' 'Jason'
```

Since 'Sue' exists in the workspace, `makeUniqueStrings` makes this string unique by appending an underscore and number.

### Construct Unique Strings for Specified Array Elements

Create an array of strings and make only the first four elements unique.

```
S = {'quiz' 'quiz' 'quiz' 'exam' 'quiz' 'exam'};
U = matlab.lang.makeUniqueStrings(S, 1:4)
```

```
U =
```

```
 'quiz_1' 'quiz_2' 'quiz_3' 'exam_1' 'quiz' 'exam'
```

The first four elements in `U` are unique among themselves, and among the remaining strings in elements 5 and 6 ('quiz' and 'exam'). Alternatively, you can use a logical array instead of a range of linear indices to achieve the same results: `U = matlab.lang.makeUniqueStrings(S, [true true true true false false])` or `U = matlab.lang.makeUniqueStrings(S, logical([1 1 1 1 0 0]))`.

Append a duplicate 'quiz' onto the end of `S` and make the first four elements unique.

```
S{end+1} = 'quiz';
U = matlab.lang.makeUniqueStrings(S, 1:4)
```

```
S =
```

```
 'quiz' 'quiz' 'quiz' 'exam' 'quiz' 'exam' 'quiz'
```

```
U =
```

```
 'quiz_1' 'quiz_2' 'quiz_3' 'exam_1' 'quiz' 'exam' 'quiz'
```

The strings that `makeUniqueStrings` checks are still unique among themselves and among the remaining strings. Since `makeUniqueStrings` does not check any elements after element 4, duplicate strings remain.

## Construct Unique Strings with Maximum Length

Create an array from `S` where the first three elements are unique and the maximum length of each string is 5.

```
S = {'sampleData' 'sampleData' 'sampleData' 'sampleData'};
U = matlab.lang.makeUniqueStrings(S, 1:3, 5)
```

```
U =
```

```
 'sampl' 'sam_1' 'sam_2' 'sampleData'
```

The first element is truncated to 5 characters. The second and third elements are truncated to 3 characters to allow `makeUniqueStrings` to append an underscore and number, and still not exceed 5 characters.

## Determine Modified Strings

```
S = {'a%name', 'name_1', '2_name'};
[N, modified] = matlab.lang.makeValidName(S)
```

```
N =
```

```
 'a_name' 'name_1' 'x2_name'
```

```
modified =
```

```
 1 0 1
```

`makeValidName` did not modify the second element.

## Input Arguments

### **S** — Input strings

string or cell array of strings

Input strings, specified as a string or cell array of strings.

**excludedStrings — Strings to exclude**

string or cell array of strings

Strings to exclude from **U**, specified as a string or cell array of strings.

Example: 'dontDuplicateThisString', {'excludeS1', 'excludeS2'}, who

**whichStringsIdx — Subset of strings to make unique**

range of linear indices or logical array

Subset of strings, **S**, to make unique within the entire set, specified as a range of linear indices or as a logical array with the same size and shape as **S**. If there are duplicates in **S**, the `makeUniqueStrings` function only modifies those specified by `whichStringsIdx`.

If `whichStringsIdx` is a logical array, strings are checked for uniqueness when the array element in the same position has a value of `true`.

Example: `1:5, logical([1 0 1]), [true false true]`

**maxLength — Maximum length of output strings**

integer

Maximum length of output strings in **U**, specified as an integer. If `makeUniqueStrings` cannot make elements in **S** unique without exceeding `maxLength`, it returns an error.

## Output Arguments

**U — Unique strings**

string | cell array of strings

Unique strings, returned as a string or cell array of strings. The output has the same dimension as the input, **S**.

**modified — Indicator of modified strings**

logical scalar | logical array

Indicator of modified strings, returned as a logical scalar or array and having the same dimension as the input, **S**. A value of 1 (`true`) indicates that `makeUniqueStrings`

modified the input string in the corresponding location. A value of 0 (`false`) indicates that `makeUniqueStrings` did not need to modify the input string in the corresponding location.

## More About

### Tips

- To ensure strings are valid and unique, use `matlab.lang.makeValidName` before `matlab.lang.makeUniqueStrings`.

```
S = {'my.Name', 'my_Name', 'my_Name'};
validStrings = matlab.lang.makeValidName(S)
validUniqueStrings = matlab.lang.makeUniqueStrings(validStrings, ...
 {}, nameLengthmax)
```

```
validStrings =
```

```
 'my_Name' 'my_Name' 'my_Name'
```

```
validUniqueStrings =
```

```
 'my_Name' 'my_Name_1' 'my_Name_2'
```

### See Also

`matlab.lang.makeValidName` | `nameLengthmax` | `who`

**Introduced in R2014a**

# matlab.lang.makeValidName

Construct valid MATLAB identifiers from input strings

## Syntax

```
N = matlab.lang.makeValidName(S)
N = matlab.lang.makeValidName(S,Name,Value)
[N, modified] = matlab.lang.makeValidName(___)
```

## Description

`N = matlab.lang.makeValidName(S)` constructs valid MATLAB identifiers, `N`, from input strings, `S`. The `makeValidName` function does not guarantee the strings in `N` are unique.

A valid MATLAB identifier is a string of alphanumerics (`A–Z`, `a–z`, `0–9`) and underscores, such that the first character is a letter and the length of the string is less than or equal to `namelengthmax`.

`makeValidName` deletes any whitespace characters prior to replacing any characters that are not alphanumerics or underscores. If a whitespace character is followed by a lowercase letter, `makeValidName` converts the letter to the corresponding uppercase character.

`N = matlab.lang.makeValidName(S,Name,Value)` includes additional options specified by one or more `Name,Value` pair arguments.

`[N, modified] = matlab.lang.makeValidName( ___ )` returns a logical array, `modified`, indicating modified strings. You can use this syntax with any of the input arguments of the previous syntaxes.

## Examples

### Construct Valid MATLAB Identifiers

```
S = {'Item_#', 'Price/Unit', '1st order', 'Contact'};
N = matlab.lang.makeValidName(S)
```

```
N =
 'Item__' 'Price_Unit' 'x1stOrder' 'Contact'
```

In the first and second strings, `makeValidName` replaced the invalid characters (`#` and `/`), with underscores. In the third string, `makeValidName` appended a prefix because the string doesn't begin with a letter, deleted the empty space, and capitalized the character following the deleted space.

## Construct Valid MATLAB Identifiers Using Specified Replacement Style

Replace invalid characters with the corresponding hexadecimal representation.

```
S = {'Item_#', 'Price/Unit', '1st order', 'Contact'};
N = matlab.lang.makeValidName(S, 'ReplacementStyle', 'hex')
```

```
N =
 'Item_0x23' 'Price0x2FUnit' 'x1stOrder' 'Contact'
```

In the first and second strings, `makeValidName` replaced the invalid characters (`#` and `/`), with their hexadecimal representation. In the third string, `makeValidName` appended a prefix because the string doesn't begin with a letter, deleted the empty space, and capitalized the character following the deleted space.

Delete invalid characters.

```
N = matlab.lang.makeValidName(S, 'ReplacementStyle', 'delete')
```

```
N =
 'Item_' 'PriceUnit' 'x1stOrder' 'Contact'
```

`makeValidName` deleted the invalid characters (`#` and `/`). In the third string, `makeValidName` appended a prefix because the string doesn't begin with a letter, deleted the empty space, and capitalized the character following the deleted space.

## Construct Valid MATLAB Identifiers Using Specified Prefix

```
S = {'1stMeasurement', '2ndMeasurement', 'Control'};
```

```
N = matlab.lang.makeValidName(S, 'Prefix', 'm_')

N =

 'm_1stMeasurement' 'm_2ndMeasurement' 'Control'
```

Only the strings that do not start with a letter are prepended with a prefix.

### Determine Modified Strings

```
S = {'a%name', 'name_1', '2_name'};
[N, modified] = matlab.lang.makeValidName(S)
```

```
N =

 'a_name' 'name_1' 'x2_name'
```

```
modified =

 1 0 1
```

makeValidName did not modify the second element.

## Input Arguments

### S — Input strings

string or cell array of strings

Input strings, specified as a string or cell array of strings. If **S** is a cell array of strings, it must be a 1×N or N×1 cell array.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: 'ReplacementStyle', 'delete' deletes invalid characters.

**'ReplacementStyle' — Replacement style**

'underscore' (default) | 'delete' | 'hex'

Replacement style, specified as a string. The value controls how MATLAB replaces nonalphanumeric characters.

ReplacementStyle Value	Description
'underscore' (default)	Replaces all characters that are not alphanumeric or underscores with underscores. 'underscore' deletes whitespace characters and changes a lowercase letter following a whitespace to uppercase.
'hex'	Replaces each character that is not an alphanumeric or underscore with its corresponding hexadecimal representation. 'hex' deletes whitespace characters and changes a lowercase letter following a whitespace to uppercase.
'delete'	Deletes all characters that are not alphanumeric or underscores. 'delete' deletes whitespace characters and changes any lowercase letter following a whitespace to uppercase.

**'Prefix' — Character to prefix**

'x' (default) | string

Character to prefix to input strings that do not begin with a letter after `makeValidName` replaces nonalphanumeric characters, specified as a string. A valid prefix must start with a letter, contain only alphanumeric characters and underscores, and not be longer than the value of `namelengthmax`.

## Output Arguments

**N — Valid MATLAB identifiers**

string | cell array of strings

Valid MATLAB identifiers, returned as a string or cell array of strings. The output has the same number of dimensions as the input, `S`.

## modified — Indicator of modified strings

logical scalar | logical array

Indicator of modified strings, returned as a logical scalar or array and having the same number of dimensions as the input, **S**. A value of 1 (**true**) indicates that `makeValidName` modified the input string in the corresponding location. A value of 0 (**false**) indicates that `makeValidName` did not need to modify the input string in the corresponding location.

## More About

### Tips

- To ensure strings are valid and unique, use `matlab.lang.makeUniqueStrings` after `matlab.lang.makeValidName`.

```
S = {'my.Name', 'my_Name', 'my_Name'};
validStrings = matlab.lang.makeValidName(S)
validUniqueStrings = matlab.lang.makeUniqueStrings(validStrings, {}, ...
 namelengthmax)
```

```
validStrings =
```

```
 'my_Name' 'my_Name' 'my_Name'
```

```
validUniqueStrings =
```

```
 'my_Name' 'my_Name_1' 'my_Name_2'
```

- To customize an invalid character replacement, first use functions such as `strrep` or `regexprep` to convert to valid characters. For example, convert '@' characters in the string, **S**, to 'At' using `strrep(S, '@', 'At')`. Then, use `matlab.lang.makeValidName` to ensure that all characters in the strings are valid.

Introduced in R2014a

# matlabrc

Start up file for MATLAB program

## Description

At startup time, MATLAB automatically executes the file `matlabrc.m`. This function establishes the MATLAB path, sets the default figure size, and sets some uicontrol defaults.

On multiuser or networked systems, system administrators can put messages, definitions, or other code that applies to all users in their `matlabrc.m` file.

The file `matlabrc.m` invokes the `startup.m` file, if it exists on the search path MATLAB uses.

Individual users should use the `startup.m` file to customize MATLAB startup. The `matlabrc.m` file, located in the `matlabroot/toolbox/local` folder, is reserved for system administrators.

## Examples

### Turn off Figure Window Toolbar

If you do not want the toolbar to appear in the figure window, remove the comment marks from the following line in the `matlabrc.m` file. Alternatively, create a similar line in your own `startup.m` file.

```
% set(0,'defaultfiguretoolbar','none')
```

## More About

### Tips

You can also start MATLAB using options you define at the command prompt or in your Microsoft Windows shortcut for MATLAB.

## Algorithms

MATLAB invokes `matlabrc` at startup. `matlabrc.m` contains the statements

```
if exist('startup') == 2
 startup
end
```

that invokes `startup.m`, if it exists. Extend this process to create additional startup files, if necessary.

- Startup Options

## See Also

`matlabroot` | `quit` | `restoredefaultpath` | `startup`

# matlabroot

Root folder

## Syntax

```
matlabroot
mr = matlabroot
```

## Description

`matlabroot` returns the name of the folder where the MATLAB software is installed. Use `matlabroot` to create a path to MATLAB and toolbox folders that does not depend on a specific platform, MATLAB version, or installation location.

`mr = matlabroot` returns the name of the folder in which the MATLAB software is installed and assigns it to `mr`.

## Examples

Get the location where MATLAB is installed:

```
matlabroot
```

MATLAB returns:

```
C:\Program Files\MATLAB\R2009a
```

Produce a full path to the `toolbox/matlab/general` folder that is correct for the platform on which it is executed:

```
fullfile(matlabroot, 'toolbox', 'matlab', 'general')
```

Change the current folder to the MATLAB root folder:

```
cd(matlabroot)
```

To add the folder `myfiles` to the MATLAB search path, run

```
addpath([matlabroot ' /toolbox/local/myfiles'])
```

## More About

### Tips

### matlabroot as Folder Name

The term *matlabroot* also refers to the folder where MATLAB files are installed. For example, “save to *matlabroot*/toolbox/local” means save to the `toolbox/local` folder in the MATLAB root folder.

### Using \$matlabroot as a Literal

In some files, `$matlabroot` is literal. In those files, MATLAB interprets `$matlabroot` as the full path to the MATLAB root folder. For example, including the line:

```
$matlabroot/toolbox/local/myfile.jar
```

in `javaclasspath.txt`, adds `myfile.jar`, which is located in the `toolbox/local` folder, to the static Java class path.

Sometimes, particularly in older code examples, the term `$matlabroot` or `$MATLABROOT` is not meant to be interpreted literally but is used to represent the value returned by the `matlabroot` function.

### matlabroot on Macintosh Platforms

In R2008b (V7.7) and more recent versions, running `matlabroot` on Apple Macintosh platforms returns

```
/Applications/MATLAB_R2008b.app
```

In versions prior to R2008b (V7.7), such as R2008a (V7.6), running `matlabroot` on Macintosh platforms returns, for example

```
/Applications/MATLAB_R2008a
```

When you use GUIs on Macintosh platforms, you cannot directly view the contents of the MATLAB root folder. For more information, see “Navigating Within the MATLAB Root Folder on Macintosh Platforms”.

# matlabshared.supportpkg.checkForUpdate

List of support packages that can be updated

## Syntax

```
matlabshared.supportpkg.checkForUpdate
info = matlabshared.supportpkg.checkForUpdate
```

## Description

`matlabshared.supportpkg.checkForUpdate` displays information about support package updates in the MATLAB Command Window. If an update is available, use `supportPackageInstaller` to install the updates.

`info = matlabshared.supportpkg.checkForUpdate` returns a structured array of information about installed support packages.

## Examples

### Check for support package updates

```
matlabshared.supportpkg.checkForUpdate
```

```
No support packages need updates.
```

If one or more updates are available, the command line displays that information in the response.

### Get a structured array of support package updates

```
info = matlabshared.supportpkg.checkForUpdate
```

```
info =
```

```
 Name: 'Arduino'
 InstalledVersion: '3.0'
```

BaseProduct: 'Simulink'

## Output Arguments

### **info** — Return argument from function

structure created using `matlabshared.supportpkg.checkForUpdate`

Information about support package updates, returned as a structured array.

### **See Also**

`matlabshared.supportpkg.getInstalled` | `supportPackageInstaller` | `targetupdater`

# matlabshared.supportpkg.getInstalled

List of installed support packages

## Syntax

```
matlabshared.supportpkg.getInstalled
info = matlabshared.supportpkg.getInstalled
```

## Description

`matlabshared.supportpkg.getInstalled` displays information about installed support packages in the MATLAB Command Window.

`info = matlabshared.supportpkg.getInstalled` returns a structured array of information about installed support packages.

## Examples

### Get a list of installed support packages

```
matlabshared.supportpkg.getInstalled
```

```
Name Version Base Product

Arduino 3.0 Simulink
```

### Get a structured array of installed support packages

```
info = matlabshared.supportpkg.getInstalled
```

```
info =
```

```
 Name: 'Arduino'
 InstalledVersion: '3.0'
```

BaseProduct: 'Simulink'

## Output Arguments

### **info** — Return argument from function

structure created using `matlabshared.supportpkg.getInstalled`

Information about installed support packages, returned as a structured array.

### **See Also**

`matlabshared.supportpkg.checkForUpdate` | `supportPackageInstaller` | `targetupdater`

# matlab (Linux)

Start MATLAB program from Linux system prompt

## Syntax

```
matlab
matlab option1 ... optionN
```

## Description

`matlab` is a Bourne shell script that starts the MATLAB program from a Linux system prompt. Here the term `matlab` refers to this script and MATLAB refers to the program.

The `matlab` script:

- Determines the MATLAB root folder, the value returned by the `matlabroot` function.
- Processes command-line options, if any.
- Reads the MATLAB startup file, `.matlab7rc.sh`.
- Sets MATLAB environment variables.

`matlab option1 ... optionN` starts MATLAB with the specified startup options.

Alternatively, assign startup options in the MATLAB “.matlab7rc.sh Startup File” on page 1-5486. Modifying the `.matlab7rc.sh` file defines startup options every time you start MATLAB.

MATLAB uses the Java Virtual Machine (JVM) software to run the desktop and to display graphics. The `-nojvm` option allows you to start MATLAB without the JVM. Using this option minimizes memory usage and improves initial startup speed, but restricts functionality.

## Input Arguments

**option1 ... optionN** — One or more startup options  
strings

One or more startup options, specified as strings corresponding to valid startup options from the following tables.

## Mode Options

Option	Result
-desktop	Start MATLAB without a controlling terminal. Use this option when you start MATLAB from a window manager menu or desktop icon.
-nodesktop	<p>Run the JVM software without opening the MATLAB desktop. You can use development environment tools by calling them as functions.</p> <p>Use this option to run in batch processing mode.</p> <p>If you pipe to MATLAB using the &gt; constructor, the <b>nodesktop</b> option is used automatically.</p> <p>MATLAB provides a command window-only interface in the desktop environment. On the <b>Home</b> tab, click <b>Layout</b>. Then, under <b>Select Layout</b>, select <b>Command Window Only</b>.</p>
-nojvm	Start MATLAB without the JVM software. Features that require Java software (such as the desktop tools and graphics) are not supported.

## Display Options

Option	Result
-noFigureWindows	Disable the display of figure windows in MATLAB.
-nosplash	Do not display the splash screen during startup.
-nodisplay	Start the JVM software without starting the MATLAB desktop. This option does not display X commands. It overrides the <b>DISPLAY</b> environment variable.
-display xDisp	Send X commands to X Window Server display <b>xDisp</b> . This option overrides the <b>DISPLAY</b> environment variable.

## Execute MATLAB Script or Function

Option	Result
<code>-r <i>statement</i></code>	<p>Execute the specified MATLAB <i>statement</i>, specified as a string or as the name of a MATLAB script or function. If <i>statement</i> is MATLAB code, enclose the string with double quotation marks. If <i>statement</i> is the name of a MATLAB function or script, do not specify the file extension and do not use quotation marks. Any required file must be on the MATLAB search path or in the startup folder.</p> <p>Example: <code>-r "disp(['Current folder: ' pwd])"</code></p> <p>Example: <code>-r myscript</code></p>

## Specify MATLAB Version

Option	Result
<code>v=<i>variant</i></code>	<p>Start the version of MATLAB in the <code>bin/arch/<i>variant</i></code> folder instead of the <code>bin/arch</code> folder. <i>arch</i> is the system architecture, the value returned by the <code>computer('arch')</code> function. <i>variant</i> is a string representing a MATLAB version.</p>

## Debugging Options

Option	Result
<code>-logfile <i>filename</i></code>	<p>Copy Command Window output, including error reports, into <i>filename</i>, specified as a string.</p> <p>Example: <code>-logfile output.log</code></p>
<code>-n</code>	<p>Display, without starting MATLAB, final values of the environment variables and arguments passed to the MATLAB executable. This option also displays other diagnostic information for use when working with a Technical Support Representative.</p>

Option	Result
-e	Display, without starting MATLAB, all environment variables and their values to standard output. If the exit status is not 0 on return, then the variables and values might not be correct.
-D <i>debugger</i> <i>debugopts</i>	<p>Start MATLAB in debug mode. This option uses the debugger program name, <i>debugger</i>, specified as a string, for example, <code>gdb</code>, <code>lldb</code>, or <code>dbx</code>. You can specify the full path to the debugger. This option must be the first option in the <code>matlab</code> command.</p> <p>Debugger program command-line options, <i>debugopts</i>, specified as a string of valid options for <i>debugger</i>. See your debugger documentation for details. Do not use any other <code>matlab</code> command options when using <i>debugopts</i>.</p> <p>Do not add a space between <b>D</b> and <i>debugger</i>.</p> <p>Example: <code>-Dgdb</code></p>
-jdb <i>portnumber</i>	<p>Enable use of the Java debugger. The Java debugger uses the default <i>portnumber</i> value 4444 to communicate with MATLAB.</p> <p>The port number is optional. However, to use the Java debugger while running multiple MATLAB sessions, you must specify a port number. The <i>portnumber</i> value must be an integer in the range 0–65535. The integer cannot be reserved or currently in use by another application on your system.</p>
-debug	Display information for debugging X-based problems. Use this option only when working with a Technical Support Representative from MathWorks, Inc.

## Use Single Computational Thread

By default, MATLAB uses the multithreading capabilities of the computer on which it is running.

Option	Result
-singleCompThread	Limit MATLAB to a single computational thread.

## Disable Searching Custom Java Class Path

Option	Result
-nouserjavapath	Disable use of <code>javaclasspath.txt</code> and <code>javalibrarypath.txt</code> files. For more information, see “java.opts Files”.

## OpenGL Library Options

These options control the use of software OpenGL libraries when MATLAB detects a graphics driver with known issues. For more information, see “Graphics Features with OpenGL Requirements”.

Option	Result
-softwareopengl	Force MATLAB to start with software OpenGL libraries.
-nosoftwareopengl	Disable auto-selection of OpenGL software.

## Specify License File

Option	Result
-c <i>license</i>	Use the specified license file, <i>license</i> , specified as a string, a colon-separated list of license file names, or a <code>port@host</code> entry. For more information, see Understanding License Files in “License Management”.

## Help Options

Option	Result
-h	Display startup options without starting MATLAB.

Option	Result
-help	Same as -h option.

## Examples

### Start MATLAB Without Desktop

```
matlab -nojvm -nodisplay -nosplash
```

### Display Current Folder at Startup

```
matlab -r "disp(['Current folder: ' pwd])"
```

## Definitions

### .matlab7rc.sh Startup File

The `.matlab7rc.sh` shell script contains variable definitions used by the `matlab` script.

Use the `.matlab7rc.sh` file to redefine variables defined in the `matlab` script. `matlab` looks for the first occurrence of `.matlab7rc.sh` in the:

- Current folder
- Home folder (`$HOME`)
- `matlabroot/bin` folder

To edit the `.matlab7rc.sh` file, use the template located in the `matlabroot/bin` folder.

This table lists the variables. For more information, see the comments in the `.matlab7rc.sh` file.

Variable	Definition and Standard Assignment Behavior
ARCH	The machine architecture.  MATLAB checks for a valid architecture in this order:

Variable	Definition and Standard Assignment Behavior
	<ul style="list-style-type: none"> <li>• The value ARCH passed with the -arch or -arch/ext argument to the script.</li> <li>• The value of the environment variable MATLAB_ARCH.</li> </ul>
DISPLAY	<p>The host name of the X Window display MATLAB uses for output.</p> <p>The value of Xdisplay passed with the -display argument to the script is used; otherwise, the value in the environment is used. MATLAB ignores DISPLAY if the -nodisplay argument is passed.</p>
LD_LIBRARY_PATH	<p>Final Load library path.</p> <p>The final value is normally a colon-separated list of four sublists, each of which could be empty. The first sublist is defined in .matlab7rc.sh as LD_PATH_PREFIX. The second sublist is computed in the script and includes folders inside the MATLAB root folder and relevant Java folders. The third sublist contains any nonempty value of LD_LIBRARY_PATH from the environment possibly augmented in .matlab7rc.sh. The final sublist is defined in .matlab7rc.sh as LD_PATH_SUFFIX.</p>
MATLAB	<p>The MATLAB root folder.</p> <p>MATLAB uses the default computed by the script unless MATLABdefault is reset in .matlab7rc.sh.</p> <p>Currently MATLABdefault is not reset in the shipping .matlab7rc.sh.</p>
MATLABPATH	<p>The MATLAB search path.</p> <p>The final value is a colon-separated list with the MATLABPATH from the environment prepended to a list of computed defaults. At startup, you can add subfolders of userpath to the MATLAB search path. See userpath for details.</p>

Variable	Definition and Standard Assignment Behavior
SHELL	<p>The shell to use with the MATLAB “!” or <code>unix</code> commands. This value is taken from the environment, unless <code>SHELL</code> is reset in <code>.matlab7rc.sh</code>.</p> <p>The default <code>.matlab7rc.sh</code> file does not reset <code>SHELL</code>.</p>
MATLAB_SHELL	<p>The shell to use instead of <code>SHELL</code>. MATLAB checks for <code>MATLAB_SHELL</code> first and, if empty or not defined, checks <code>SHELL</code>. If <code>SHELL</code> is also empty or not defined, MATLAB uses the Bourne shell, <code>/bin/sh</code>.</p> <p>Use an absolute path for the value of <code>MATLAB_SHELL</code>, that is, <code>/bin/sh</code>, not simply <code>sh</code>.</p> <p>The default <code>.matlab7rc.sh</code> file does not reference or set <code>MATLAB_SHELL</code>.</p>
TOOLBOX	<p>The path of the toolbox folder.</p> <p>A nonempty value in the environment is used first. Otherwise, <code>matlabroot/toolbox</code>, computed by the script, is used unless <code>TOOLBOX</code> is reset in <code>.matlab7rc.sh</code>. Currently <code>TOOLBOX</code> is not reset in the shipping <code>.matlab7rc.sh</code>.</p>

The `matlab` script determines the path of the MATLAB root folder by looking up the folder tree from the `matlabroot/bin` folder (where the `matlab` script is located). MATLAB use the `MATLAB` variable to locate all files within the MATLAB folder tree.

You can change the definition of `MATLAB`. For example, change the definition if you want to run a different version of MATLAB. Or change the definition if your system uses certain types of automounting schemes and the path determined by the `matlab` script is not correct.

- “Startup Options”

## matlab (Mac)

Start MATLAB program from Mac Terminal

### Syntax

```
matlab
matlab option1 ... optionN
```

### Description

`matlab` is a Bourne shell script that starts the MATLAB program from a Mac system prompt. Here the term `matlab` refers to this script and MATLAB refers to the program.

The `matlab` script is located in the MATLAB application package, `/Applications/matlabroot/MATLAB_release.app/bin`, where *matlabroot* is the name of the folder in which you installed MATLAB and *release* is the MATLAB release number.

The `matlab` script:

- Determines the MATLAB root folder, the value returned by the `matlabroot` function.
- Processes command-line options, if any.
- Reads the MATLAB startup file, `.matlab7rc.sh`.
- Sets MATLAB environment variables.

`matlab option1 ... optionN` starts MATLAB with the specified startup options.

Alternatively, assign startup options in the MATLAB “.matlab7rc.sh Startup File” on page 1-5495. Modifying the `.matlab7rc.sh` file defines startup options every time you start MATLAB.

MATLAB uses the Java Virtual Machine (JVM) software to run the desktop and to display graphics. The `-nojvm` option allows you to start MATLAB without the JVM. Using this option minimizes memory usage and improves initial startup speed, but restricts functionality.

## Input Arguments

**option1 ... optionN** — One or more startup options

strings

One or more startup options, specified as strings corresponding to valid startup options from the following tables.

## Mode Options

Option	Result
-desktop	Start MATLAB without a controlling terminal. Use this option when you start MATLAB from a window manager menu or desktop icon.
-nodesktop	Run the JVM software without opening the MATLAB desktop. You can use development environment tools by calling them as functions.  Use this option to run in batch processing mode.  If you pipe to MATLAB using the > constructor, the <b>nodesktop</b> option is used automatically.  MATLAB provides a command window-only interface in the desktop environment. On the <b>Home</b> tab, click <b>Layout</b> . Then, under <b>Select Layout</b> , select <b>Command Window Only</b> .
-nojvm	Start MATLAB without the JVM software. Features that require Java software (such as the desktop tools and graphics) are not supported.

## Display Options

Option	Result
-noFigureWindows	Disable the display of figure windows in MATLAB.
-nosplash	Do not display the splash screen during startup.

Option	Result
-nodisplay	Start the JVM software without starting the MATLAB desktop.

## Execute MATLAB Script or Function

Option	Result
-r <i>statement</i>	<p>Execute the specified MATLAB <i>statement</i>, specified as a string or as the name of a MATLAB script or function. If <i>statement</i> is MATLAB code, enclose the string with double quotation marks. If <i>statement</i> is the name of a MATLAB function or script, do not specify the file extension and do not use quotation marks. Any required file must be on the MATLAB search path or in the startup folder.</p> <p>Example: -r "disp(['Current folder: ' pwd])"</p> <p>Example: -r myscript</p>

## Specify MATLAB Version

Option	Result
v= <i>variant</i>	Start the version of MATLAB in the bin/ <i>arch</i> / <i>variant</i> folder instead of the bin/ <i>arch</i> folder. <i>arch</i> is the system architecture, the value returned by the <code>computer('arch')</code> function. <i>variant</i> is a string representing a MATLAB version.

## Debugging Options

Option	Result
-logfile <i>filename</i>	<p>Copy Command Window output, including error reports, into <i>filename</i>, specified as a string.</p> <p>Example: -logfile output.log</p>

Option	Result
-n	Display, without starting MATLAB, final values of the environment variables and arguments passed to the MATLAB executable. This option also displays other diagnostic information for use when working with a Technical Support Representative.
-e	Display, without starting MATLAB, all environment variables and their values to standard output. If the exit status is not 0 on return, then the variables and values might not be correct.
-D <i>debugger debugopts</i>	<p>Start MATLAB in debug mode. This option uses the debugger program name, <i>debugger</i>, specified as a string, for example, <b>gdb</b>, <b>lldb</b>, or <b>dbx</b>. You can specify the full path to the debugger. This option must be the first option in the <b>matlab</b> command.</p> <p>Debugger program command-line options, <i>debugopts</i>, specified as a string of valid options for <i>debugger</i>. See your debugger documentation for details. Do not use any other <b>matlab</b> command options when using <i>debugopts</i>.</p> <p>Do not add a space between <b>D</b> and <i>debugger</i>.</p> <p>Example: <b>-Dlldb</b></p>
-jdb <i>portnumber</i>	<p>Enable use of the Java debugger. The Java debugger uses the default <i>portnumber</i> value 4444 to communicate with MATLAB.</p> <p>The port number is optional. However, to use the Java debugger while running multiple MATLAB sessions, you must specify a port number. The <i>portnumber</i> value must be an integer in the range 0–65535. The integer cannot be reserved or currently in use by another application on your system.</p>

## Use Single Computational Thread

By default, MATLAB uses the multithreading capabilities of the computer on which it is running.

Option	Result
<code>-singleCompThread</code>	Limit MATLAB to a single computational thread.

## Disable Searching Custom Java Class Path

Option	Result
<code>-nouserjavapath</code>	Disable use of <code>javaclasspath.txt</code> and <code>javalibrarypath.txt</code> files. For more information, see “java.opts Files”.

## Specify License File

Option	Result
<code>-c license</code>	Use the specified license file, <i>license</i> , specified as a string, a colon-separated list of license file names, or a <code>port@host</code> entry. For more information, see Understanding License Files in “License Management”.

## Help Options

Option	Result
<code>-h</code>	Display startup options without starting MATLAB.
<code>-help</code>	Same as <code>-h</code> option.

## Examples

### Start MATLAB R2015a from Applications Folder

Move to the `bin` folder within the application package for MATLAB installed in a folder named `MyMATLAB`.

```
cd /Applications/MyMATLAB/MATLAB_R2015a.app/bin
```

Preface the `matlab` command with `./` characters.

```
./matlab -nosplash
```

### Start MATLAB from Any Folder

Start MATLAB R2015a from any Terminal folder by specifying the full path name. Assume MATLAB is installed in a folder named `MyMATLAB`.

```
/Applications/MyMATLAB/MATLAB_R2015a.app/bin/matlab
```

### Start MATLAB Without Desktop

```
matlab -nojvm -nodisplay -nosplash
```

### Display Current Folder at Startup

```
matlab -r "disp(['Current folder: ' pwd])"
```

## Definitions

### `.matlab7rc.sh` Startup File

The `.matlab7rc.sh` shell script contains variable definitions used by the `matlab` script. To redefine variables defined in the `matlab` script, modify the `.matlab7rc.sh` file.

`matlab` looks for the first occurrence of `.matlab7rc.sh` in the:

- Current folder
- Home folder (`$HOME`)

- *matlabroot/bin* folder

To edit the `.matlab7rc.sh` file, use the template located in the *matlabroot/bin* folder.

The following table lists the variables. For more information, see the comments in the `.matlab7rc.sh` file.

<b>.matlab7rc.sh Variable</b>	<b>Definition and Standard Assignment Behavior</b>
ARCH	<p>The machine architecture.</p> <p>MATLAB checks for a valid architecture in this order:</p> <ul style="list-style-type: none"> <li>• The value ARCH passed with the <code>-arch</code> or <code>-arch/ext</code> argument to the script.</li> <li>• The value of the environment variable <code>MATLAB_ARCH</code>.</li> </ul>
DYLD_LIBRARY_PATH	<p>Final Load library path.</p> <p>The final value is normally a colon-separated list of four sublists, each of which could be empty. The first sublist is defined in <code>.matlab7rc.sh</code> as <code>LDPATH_PREFIX</code>. The second sublist is computed in the script and includes folders inside the MATLAB root folder and relevant Java folders. The third sublist contains any nonempty value of <code>DYLD_LIBRARY_PATH</code> from the environment possibly augmented in <code>.matlab7rc.sh</code>. The final sublist is defined in <code>.matlab7rc.sh</code> as <code>LDPATH_SUFFIX</code>.</p>
MATLAB	<p>The MATLAB root folder.</p> <p>MATLAB uses the default computed by the script unless <code>MATLABdefault</code> is reset in <code>.matlab7rc.sh</code>.</p> <p>Currently <code>MATLABdefault</code> is not reset in the shipping <code>.matlab7rc.sh</code>.</p>
MATLABPATH	<p>The MATLAB search path.</p> <p>The final value is a colon-separated list with the <code>MATLABPATH</code> from the environment prepended to a list of</p>

<code>.matlab7rc.sh</code> Variable	Definition and Standard Assignment Behavior
	computed defaults. At startup, you can add subfolders of <code>userpath</code> to the MATLAB search path. See <code>userpath</code> for details.
SHELL	The shell to use with the MATLAB “!” or <code>unix</code> commands. This value is taken from the environment, unless SHELL is reset in <code>.matlab7rc.sh</code> .  The default <code>.matlab7rc.sh</code> file does not reset SHELL.
MATLAB_SHELL	The shell to use instead of SHELL. MATLAB checks for MATLAB_SHELL first and, if empty or not defined, checks SHELL. If SHELL is also empty or not defined, MATLAB uses the Bourne shell, <code>/bin/sh</code> .  Use an absolute path for the value of MATLAB_SHELL, that is, <code>/bin/sh</code> , not simply <code>sh</code> .  The default <code>.matlab7rc.sh</code> file does not reference or set MATLAB_SHELL.
TOOLBOX	Path of the toolbox folder.  A nonempty value in the environment is used first. Otherwise, <code>matlabroot/toolbox</code> , computed by the script, is used unless TOOLBOX is reset in <code>.matlab7rc.sh</code> . Currently TOOLBOX is not reset in the shipping <code>.matlab7rc.sh</code> .

The `matlab` script determines the path of the MATLAB root folder by looking up the folder tree from the `matlabroot/bin` folder (where the `matlab` script is located). MATLAB use the MATLAB variable to locate all files within the MATLAB folder tree.

You can change the definition of MATLAB. For example, change the definition if you want to run a different version of MATLAB. Or change the definition if your system uses certain types of automounting schemes and the path determined by the `matlab` script is not correct.

## See Also

`matlab` (Windows) | `matlab` (Linux) | `matlabroot` | `unix`

## **Related Examples**

- “Start MATLAB on Mac Platforms”

## **More About**

- “Startup Options”

# matlab (Windows)

Start MATLAB program from Windows system prompt

## Syntax

```
matlab
matlab option1 ... optionN
```

## Description

`matlab` starts the MATLAB program from the Microsoft Windows system prompt. Here the term `matlab` refers to the command you type, and MATLAB refers to the program).

The `matlab` command:

- Determines the MATLAB root folder, the value returned by the `matlabroot` function.
- Determines the host machine architecture, 32-bit or 64-bit.
- Processes command-line options and passes other options to MATLAB.

`matlab option1 ... optionN` starts MATLAB with the specified startup options.

## Input Arguments

**option1 ... optionN** — One or more startup options

strings

One or more startup options, specified as strings corresponding to valid startup options from the following tables.

## Display Options

Option	Result
-noFigureWindows	Disable the display of figure windows in MATLAB.

Option	Result
-nosplash	Do not display the splash screen during startup.

## Execute MATLAB Script or Function

Option	Result
-r <i>statement</i>	<p>Execute the MATLAB <i>statement</i>, specified as a string or as the name of a MATLAB script or function. If <i>statement</i> is MATLAB code, enclose the string with double quotation marks. If <i>statement</i> is the name of a MATLAB function or script, do not specify the file extension and do not use quotation marks. Any required file must be on the MATLAB search path or in the startup folder.</p> <p>Example: -r "disp(['Current folder: ' pwd])"</p> <p>Example: -r myscript</p>

## Run 32-Bit MATLAB on 64-Bit Platforms

Option	Result
-win32	Run 32-bit MATLAB on 64-bit processors.

## Debugging Options

Option	Result
-logfile <i>filename</i>	<p>Copy Command Window output, including error log reports, in to <i>filename</i>, specified as a string.</p> <p>Example: -logfile output.log</p>
-jdb <i>portnumber</i>	<p>Enable use of the Java debugger. The Java debugger uses the default <i>portnumber</i> value 4444 to communicate with MATLAB.</p>

Option	Result
	The port number is optional. However, to use the Java debugger while running multiple MATLAB sessions, you must provide a port number. The <i>portnumber</i> value must be an integer in the range 0–65535. The integer cannot be reserved or currently in use by another application on your system.

## Use Single Computational Thread

By default, MATLAB uses the multithreading capabilities of the computer on which it is running.

Option	Result
<code>-singleCompThread</code>	Limit MATLAB to a single computational thread.

## Disable Searching Custom Java Class Path

Option	Result
<code>-nouserjavapath</code>	Disable use of <code>javaclasspath.txt</code> and <code>javalibrarypath.txt</code> files. For more information, see “java.opts Files”.

## OpenGL Library Options

These options control the use of software OpenGL libraries when MATLAB detects a graphics driver with known issues. For more information, see “Graphics Features with OpenGL Requirements”.

Option	Result
<code>-softwareopengl</code>	Force MATLAB to start with software OpenGL libraries.
<code>-nosoftwareopengl</code>	Disable auto-selection of OpenGL software.

## COM Automation Server Options

Option	Result
-automation	Start MATLAB as a Component Object Model (COM) Automation server. MATLAB does not display the splash screen and minimizes the window. Use for a single call to MATLAB.
-regserver	<p>Register MATLAB as a COM Automation server in the Windows registry. MATLAB displays a minimized command window; close this window.</p> <p>You must have administrator privileges to change the Windows registry. Based on your User Account Control (UAC) settings, you might need to right-click a Windows Command Processor and select <b>Run as administrator</b>. If that option is not available, contact your system administrator.</p> <p>MATLAB remains registered until you use the -unregserver option.</p> <p>Alternatively, you can register MATLAB from the MATLAB command prompt. Type:</p> <pre>!matlab -regserver</pre> <p>MATLAB displays a minimized command window. To continue working with MATLAB, Open this window and exit MATLAB.</p>
-unregserver	Remove MATLAB COM server entries from the registry.

## Wait for MATLAB to Terminate

By default, when you call the `matlab` command from a script, the command starts MATLAB and then immediately executes the next statements in the script. The `-wait` option pauses the script until MATLAB terminates.

Option	Result
-wait	Use in a startup script to process the results from MATLAB. Calling MATLAB with this option blocks the script from continuing until the results are generated.

## Shield Options

For 32-bit Windows platforms only.

Shield options provide the specified level of protection of the address space used by MATLAB during startup. These options attempt to provide the largest contiguous block of memory available after startup, which is useful for processing large data sets. These options load resources, such as DLLs, into locations without fragmenting the address space. For shield option values other than **none**, address space is protected up to or after the processing of `matlabrc`. Use higher levels of protection to secure larger initial blocks of contiguous memory. However, a higher level might not always provide a larger size block and might cause startup problems. Therefore, start with a lower level of protection, and if successful, try the next higher level. Use the MATLAB `memory` function after startup to see the size of the largest contiguous block of memory. This function helps you determine the actual effect of the setting you used. If your `matlabrc.m` or `startup.m` file requires significant memory, a higher level of protection might cause startup to fail. In that event try a lower level.

Enter one of the options shown in the following table.

Option	Description
-shield minimum	<p>Default setting. Protect the range 0x50000000–0x70000000 until startup processes <code>matlabrc</code>. This option ensures that there is at least approximately 500 MB of contiguous memory up to this point.</p> <p>Start with this option. If MATLAB fails to start successfully, use the <code>-shield none</code> option instead.</p> <p>If MATLAB starts successfully and you want to try to ensure an even larger contiguous block after startup, try using the <code>-shield medium</code> option.</p>

Option	Description
-shield medium	<p>Protect the same range as <code>-shield minimum</code> until after startup processes <code>matlabrc</code>. This option ensures that there is at least approximately 500 MB of contiguous memory.</p> <p>If MATLAB fails to start successfully with this option, use <code>-shield minimum</code> instead.</p> <p>If MATLAB starts successfully and you want to try to ensure an even larger contiguous block after startup, try using the <code>-shield maximum</code> option.</p>
-shield maximum	<p>Protect the maximum range, which can be up to approximately 1.5 GB, until startup processes <code>matlabrc</code>.</p> <p>If MATLAB fails to start successfully, use the <code>-shield medium</code> option instead.</p>
-shield none	<p>Disable address shielding. Use this option if MATLAB fails to start successfully with the <code>-shield minimum</code> option.</p>

## Specify License File

For more information, see Understanding License Files in “License Management”.

Option	Result
-c <i>license</i>	<p>Use the License File, <i>license</i>, specified as a string, a colon-separated list of license file names, or a <code>port@host</code> entry. If specifying multiple files, separate the names by semicolons and enclose the entire list in quotation marks. If the path to your license file contains a space, enclose the path name in quotation marks.</p> <p>Example: <code>-c "c:\TMW license \license_agreement.txt"</code></p>

## Help Options

Option	Result
-h	Display startup options without starting MATLAB.
-help	Same as -h option.
-?	Same as -h option.

## Examples

### Startup Without Splash Screen

```
matlab -nosplash
```

### Copy Command Window Output into output.log File

```
matlab -logfile output.log
```

### More About

- “Start MATLAB on Windows Platforms”
- “Startup Options”

## max

Largest elements in array

### Syntax

$M = \max(A)$

$M = \max(A, [], \text{dim})$

$[M, I] = \max(\_\_\_)$

$C = \max(A, B)$

$\_\_\_ = \max(\_\_\_, \text{nanflag})$

### Description

$M = \max(A)$  returns the largest elements of  $A$ .

- If  $A$  is a vector, then  $\max(A)$  returns the largest element of  $A$ .
- If  $A$  is a matrix, then  $\max(A)$  is a row vector containing the maximum value of each column.
- If  $A$  is a multidimensional array, then  $\max(A)$  operates along the first array dimension whose size does not equal 1, treating the elements as vectors. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same. If  $A$  is an empty array with first dimension 0, then  $\max(A)$  returns an empty array with the same size as  $A$ .

$M = \max(A, [], \text{dim})$  returns the largest elements along dimension  $\text{dim}$ . For example, if  $A$  is a matrix, then  $\max(A, [], 2)$  is a column vector containing the maximum value of each row.

$[M, I] = \max(\_\_\_)$  finds the indices of the maximum values of  $A$  and returns them in output vector  $I$ , using any of the input arguments in the previous syntaxes. If the maximum value occurs more than once, then  $\max$  returns the index corresponding to the first occurrence.

$C = \max(A, B)$  returns an array the same size as  $A$  and  $B$  with the largest elements taken from  $A$  or  $B$ . Either the dimensions of  $A$  and  $B$  are the same, or one can be a scalar.

`___ = max( ___, nanflag)` specifies whether to include or omit NaN values in the calculation for any of the previous syntaxes. For the single input case, to specify `nanflag` without specifying `dim`, use `max(A, [], nanflag)`. For example, `max(A, [], 'includenan')` includes all NaN values in `A` while `max(A, [], 'omitnan')` ignores them.

## Examples

### Largest Vector Element

Create a vector and compute its largest element.

```
A = [23 42 37 18 52];
M = max(A)
```

```
M =

 52
```

### Largest Complex Element

Create a complex vector and compute its largest element, that is, the element with the largest magnitude.

```
A = [-2+2i 4+i -1-3i];
max(A)
```

```
ans =

 4.0000 + 1.0000i
```

### Largest Element in Each Matrix Column

Create a matrix and compute the largest element in each column.

```
A = [2 8 4; 7 3 9]
```

```
A =
```

```
 2 8 4
 7 3 9
```

```
M = max(A)
```

```
M =
```

```
 7 8 9
```

## Largest Element in Each Matrix Row

Create a matrix and compute the largest element in each row.

```
A = [1.7 1.2 1.5; 1.3 1.6 1.99]
```

```
A =
```

```
 1.7000 1.2000 1.5000
 1.3000 1.6000 1.9900
```

```
M = max(A, [], 2)
```

```
M =
```

```
 1.7000
 1.9900
```

## Largest Element Indices

Create a matrix A and compute the largest elements in each column, as well as the row indices of A in which they appear.

```
A = [1 9 -2; 8 4 -5]
```

```
A =
```

```
 1 9 -2
 8 4 -5
```

```
[M, I] = max(A)
```

```
M =
```

```
 8 9 -2
```

```
I =
```

```
 2 1 1
```

### Largest Element Comparison

Create a matrix and return the largest value between each of its elements compared to a scalar.

```
A = [1 7 3; 6 2 9]
```

```
A =
```

```
 1 7 3
 6 2 9
```

```
B = 5;
```

```
C = max(A,B)
```

```
C =
```

```
 5 7 5
 6 5 9
```

### Largest Element in Matrix

Create a matrix A and use its column representation,  $A(:, :)$ , to find the value and index of the largest element.

```
A = [8 2 4; 7 3 9]
```

```
A =
```

```
 8 2 4
 7 3 9
```

```
A(:)
```

```
ans =
```

```
 8
 7
 2
 3
 4
 9
```

```
[M,I] = max(A(:))
```

```
M =
```

```
 9
```

```
I =
```

```
 6
```

I is the index of A(:) containing the largest element.

Now, use the `ind2sub` function to extract the row and column indices of A corresponding to the largest element.

```
[I_row, I_col] = ind2sub(size(A),I)
```

```
I_row =
```

```
 2
```

```
I_col =
```

---

3

If you need only the maximum value of `A` and not its index, then call the `max` function twice.

```
M = max(max(A))
```

```
M =
```

```
9
```

### Largest Element Involving NaN

Create a vector and compute its maximum, excluding NaN values.

```
A = [1.77 -0.005 3.98 -2.95 NaN 0.34 NaN 0.19];
M = max(A,[], 'omitnan')
```

```
M =
```

```
3.9800
```

`max(A)` will also produce this result since `'omitnan'` is the default option.

Use the `'includenan'` flag to return NaN.

```
M = max(A,[], 'includenan')
```

```
M =
```

```
NaN
```

## Input Arguments

### A — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

- If  $A$  is complex, then  $\max(A)$  returns the complex number with the largest magnitude. If magnitudes are equal, then  $\max(A)$  returns the value with the largest magnitude and the largest phase angle.
- If  $A$  is a scalar, then  $\max(A)$  returns  $A$ .
- If  $A$  is a 0-by-0 empty array, then  $\max(A)$  is as well.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `categorical` | `datetime` | `duration`  
Complex Number Support: Yes

**dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension  $dim$  indicates the dimension whose length reduces to 1. The `size(M, dim)` is 1, while the sizes of all other dimensions remain the same, unless `size(A, dim)` is 0. If `size(A, dim)` is 0, then  $\max(A, dim)$  returns an empty array with the same size as  $A$ .

Consider a two-dimensional input array,  $A$ :

- If  $dim = 1$ , then  $\max(A, [], 1)$  returns a row vector containing the largest element in each column.

$\max(A, [], 1)$

- If  $dim = 2$ , then  $\max(A, [], 2)$  returns a column vector containing the largest element in each row.

`max` returns `A` if `dim` is greater than `ndims(A)`.

### **B** — Additional input array

scalar | vector | matrix | multidimensional array

Additional input array, specified as a scalar, vector, matrix, or multidimensional array.

- The dimensions of `A` and `B` must match, or one can be a scalar.
- `A` and `B` can be the same data type or one can be `double` with the other `single`, `duration`, or any integer data type.
- If `A` and `B` are ordinal categorical arrays, they must have the same sets of categories with the same order.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `categorical` | `datetime` | `duration`

Complex Number Support: Yes

### **nanflag** — NaN condition

'omitnan' (default) | 'includenan'

NaN condition, specified as one of these values:

- 'omitnan' — Ignore all NaN values in the input.
- 'includenan' — Include the NaN values in the input for the calculation.

The `max` function does not support the `nanflag` option for `categorical` arrays. For `datetime` arrays, `NaT` is treated like NaN.

Data Types: `char`

## Output Arguments

### **M** — Maximum values

scalar | vector | matrix | multidimensional array

Maximum values, returned as a scalar, vector, matrix, or multidimensional array. `size(M, dim)` is 1, while the sizes of all other dimensions match the size of the corresponding dimension in `A`, unless `size(A, dim)` is 0. If `size(A, dim)` is 0, then `M` is an empty array with the same size as `A`.

### **I** — Index to maximum values of `A`

scalar | vector | matrix | multidimensional array

Index to maximum values of `A`, returned as a scalar, vector, matrix, or multidimensional array. `I` is the same size as `M`. If the largest element occurs more than once, then `I` contains the index to the first occurrence of the value.

### **C** — Maximum elements from `A` or `B`

scalar | vector | matrix | multidimensional array

Maximum elements from `A` or `B`, returned as a scalar, vector, matrix, or multidimensional array.

The size of `C` depends on the sizes of `A` and `B`:

- If `A` and `B` are arrays of the same size, then the size of `C` matches the size of `A` and `B`.
- If either `A` or `B` is a scalar, then the size of `C` matches the size of the nonscalar input array.
- If either `A` or `B` is an empty array with the other a scalar, then `C` is an empty array.

The data type of `C` depends on the data types of `A` and `B`:

- If `A` and `B` are the same data type, then `C` matches the data type of `A` and `B`.
- If either `A` or `B` is `single`, then `C` is `single`.
- If either `A` or `B` is an integer data type with the other a scalar `double`, then `C` assumes the integer data type.

# MaximizeCommandWindow

Open Automation server window

## Syntax

### IDL Method Signature

```
HRESULT MaximizeCommandWindow(void)
```

### Microsoft Visual Basic Client

```
MaximizeCommandWindow
```

### MATLAB Client

```
MaximizeCommandWindow(h)
```

## Description

`MaximizeCommandWindow(h)` displays the window for the server attached to handle `h`, and makes it the currently active window on the desktop.

`MaximizeCommandWindow` restores the window to the size it had at the time it was minimized, not to the maximum size on the desktop. If the server window was not previously in a minimized state, `MaximizeCommandWindow` does nothing.

## Examples

From a Visual Basic .NET client, modify the size of the command window in a MATLAB Automation server.

```
Dim Matlab As Object
Matlab = CreateObject("matlab.application")
```

Matlab.MinimizeCommandWindow

```
'Now return the server window to its former state on
'the desktop and make it the currently active window.
```

Matlab.MaximizeCommandWindow

## **See Also**

MinimizeCommandWindow

**Introduced before R2006a**

# maxNumCompThreads

Control maximum number of computational threads

---

**Note:** `maxNumCompThreads` will be removed in a future version. You can set the `-singleCompThread` option when starting MATLAB to limit MATLAB to a single computational thread. By default, MATLAB makes use of the multithreading capabilities of the computer on which it is running.

---

## Syntax

```
N = maxNumCompThreads
LASTN = maxNumCompThreads(N)
LASTN = maxNumCompThreads('automatic')
```

## Description

`N = maxNumCompThreads` returns the current maximum number of computational threads `N`.

`LASTN = maxNumCompThreads(N)` sets the maximum number of computational threads to `N`, and returns the previous maximum number of computational threads, `LASTN`.

`LASTN = maxNumCompThreads('automatic')` sets the maximum number of computational threads using what the MATLAB software determines to be the most desirable. It additionally returns the previous maximum number of computational threads, `LASTN`.

Currently, the maximum number of computational threads is equal to the number of computational cores on your machine.

---

**Note** Setting the maximum number of computational threads using `maxNumCompThreads` does not propagate to your next MATLAB session.

---

**Introduced in R2007b**

## mean

Average or mean value of array

### Syntax

```
M = mean(A)
M = mean(A,dim)
M = mean(____,outtype)
M = mean(____,nanflag)
```

### Description

`M = mean(A)` returns the mean of the elements of `A` along the first array dimension whose size does not equal 1.

- If `A` is a vector, then `mean(A)` returns the mean of the elements.
- If `A` is a matrix, then `mean(A)` returns a row vector containing the mean of each column.
- If `A` is a multidimensional array, then `mean(A)` operates along the first array dimension whose size does not equal 1, treating the elements as vectors. This dimension becomes 1 while the sizes of all other dimensions remain the same.

`M = mean(A,dim)` returns the mean along dimension `dim`. For example, if `A` is a matrix, then `mean(A,2)` is a column vector containing the mean of each row.

`M = mean( ____,outtype)` returns the mean with a specified data type, using any of the input arguments in the previous syntaxes. `outtype` can be `'default'`, `'double'`, or `'native'`.

`M = mean( ____,nanflag)` specifies whether to include or omit NaN values from the calculation for any of the previous syntaxes. `mean(A, 'includenan')` includes all NaN values in the calculation while `mean(A, 'omitnan')` ignores them.

## Examples

### Mean of Matrix Columns

Create a matrix and compute the mean of each column.

```
A = [0 1 1; 2 3 2; 1 3 2; 4 2 2]
```

```
A =
```

```
 0 1 1
 2 3 2
 1 3 2
 4 2 2
```

```
M = mean(A)
```

```
M =
```

```
 1.7500 2.2500 1.7500
```

### Mean of Matrix Rows

Create a matrix and compute the mean of each row.

```
A = [0 1 1; 2 3 2]
```

```
A =
```

```
 0 1 1
 2 3 2
```

```
M = mean(A,2)
```

```
M =
```

```
 0.6667
 2.3333
```

**Mean of 3-D Array**

Create a 4-by-2-by-3 array of integers between 1 and 10 and compute the mean values along the second dimension.

```
A = gallery('integerdata',10,[4,2,3],1);
M = mean(A,2)
```

```
M(:,:,1) =
```

```
 9.5000
 6.5000
 9.5000
 6.0000
```

```
M(:,:,2) =
```

```
 1.5000
 4.0000
 7.5000
 7.5000
```

```
M(:,:,3) =
```

```
 7.0000
 2.5000
 4.0000
 5.5000
```

**Mean of Single-Precision Array**

Create a single-precision vector of ones and compute its single-precision mean.

```
A = single(ones(1e8,1));
M = mean(A,'native')
```

```
M =
```

```
 1
```

The expected mean, 1, cannot be represented in single-precision due to saturation. Use the `double` output type to calculate the expected mean of `A`.

```
M = mean(A, 'double')
```

```
M =
 1
```

### Mean Excluding NaN

Create a vector and compute its mean, excluding NaN values.

```
A = [1 0 0 1 NaN 1 NaN 0];
M = mean(A, 'omitnan')
```

```
M =
 0.5000
```

If you do not specify `'omitnan'`, then `mean(A)` returns NaN.

## Input Arguments

### **A** — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

- If `A` is a scalar, then `mean(A)` returns `A`.
- If `A` is an empty 0-by-0 matrix, then `mean(A)` returns NaN.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `datetime` | `duration`

### **dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to 1. The `size(M, dim)` is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, `A`.

- If `dim = 1`, then `mean(A, 1)` returns a row vector containing the mean of the elements in each column.

- If `dim = 2`, then `mean(A, 2)` returns a column vector containing the mean of the elements in each row.

`mean` returns `A` when `dim` is greater than `ndims(A)` or when `size(A, dim)` is 1.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**outtype — Output data type**`'default'` (default) | `'double'` | `'native'`

Output data type, specified as `'default'`, `'double'`, or `'native'`. These options also specify the data type in which the operation is performed.

<b>outtype</b>	<b>Output data type</b>
<code>'default'</code>	double, unless the input data type is <code>single</code> , <code>duration</code> , or <code>datetime</code> , in which case, the output is <code>'native'</code>
<code>'double'</code>	double, unless the data type is <code>duration</code> or <code>datetime</code> , in which case, <code>'double'</code> is not supported
<code>'native'</code>	same data type as the input, unless <ul style="list-style-type: none"> <li>• Input data type is <code>logical</code>, in which case, the output is <code>double</code></li> <li>• Input data type is <code>char</code>, in which case, <code>'native'</code> is not supported</li> </ul>

Data Types: `char`

**nanflag — NaN condition**`'includenan'` (default) | `'omitnan'`

NaN condition, specified as one of these values:

- `'includenan'` — Include NaN values when computing the mean, resulting in NaN.
- `'omitnan'` — Ignore all NaN values in the input.

The `mean` function does not support the `nanflag` option for `datetime` or `duration` arrays.

Data Types: `char`

## More About

### Mean

For a random variable vector  $A$  made up of  $N$  scalar observations, the mean is defined as

$$\mu = \frac{1}{N} \sum_{i=1}^N A_i.$$

**See Also**

mean | median | mode | std | sum | var

**Introduced before R2006a**

# median

Median value of array

## Syntax

```
M = median(A)
M = median(A,dim)
M = median(___,nanflag)
```

## Description

`M = median(A)` returns the median value of `A`.

- If `A` is a vector, then `median(A)` returns the median value of `A`.
- If `A` is a nonempty matrix, then `median(A)` treats the columns of `A` as vectors and returns a row vector of median values.
- If `A` is an empty 0-by-0 matrix, `median(A)` returns `NaN`.
- If `A` is a multidimensional array, then `median(A)` treats the values along the first array dimension whose size does not equal 1 as vectors. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.

`median` computes natively in the numeric class of `A`, such that `class(M) = class(A)`.

`M = median(A,dim)` returns the median of elements along dimension `dim`. For example, if `A` is a matrix, then `median(A,2)` is a column vector containing the median value of each row.

`M = median( ___,nanflag)` optionally specifies whether to include or omit `NaN` values in the median calculation for any of the previous syntaxes. For example, `median(A, 'omitnan')` ignores all `NaN` values in `A`.

## Examples

### Median of Matrix Columns

Define a 4-by-3 matrix.

```
A = [0 1 1; 2 3 2; 1 3 2; 4 2 2]
```

```
A =
```

```
 0 1 1
 2 3 2
 1 3 2
 4 2 2
```

Find the median value of each column.

```
M = median(A)
```

```
M =
```

```
 1.5000 2.5000 2.0000
```

For each column, the median value is the mean of the middle two numbers in sorted order.

### Median of Matrix Rows

Define a 2-by-3 matrix.

```
A = [0 1 1; 2 3 2]
```

```
A =
```

```
 0 1 1
 2 3 2
```

Find the median value of each row.

```
M = median(A,2)
```

```
M =
```

```
 1
 2
```

For each row, the median value is the middle number in sorted order.

### Median of 3-D Array

Create a 1-by-3-by-4 array of integers between 1 and 10.

```
A = gallery('integerdata',10,[1,3,4],1)
```

```
A(:,:,1) =
```

```
 10 8 10
```

```
A(:,:,2) =
```

```
 6 9 5
```

```
A(:,:,3) =
```

```
 9 6 1
```

```
A(:,:,4) =
```

```
 4 9 5
```

Find the median values of this 3-D array along the second dimension.

```
M = median(A)
```

```
M(:,:,1) =
```

```
 10
```

```
M(:,:,2) =
```

```
 6
```

```
M(:,:,3) =
```

```
 6
```

```
M(:,:,4) =
```

```
 5
```

This operation produces a 1-by-1-by-4 array by computing the median of the three values along the second dimension. The size of the second dimension is reduced to 1.

Compute the median along the first dimension of A.

```
M = median(A,1);
isequal(A,M)
```

```
ans =
```

```
1
```

This command returns the same array as A because the size of the first dimension is 1.

### Median of 8-Bit Integer Array

Define a 1-by-4 vector of 8-bit integers.

```
A = int8(1:4)
```

```
A =
```

```
1 2 3 4
```

Compute the median value.

```
M = median(A),
class(M)
```

```
M =
```

```
3
```

```
ans =
```

```
int8
```

M is the mean of the middle two numbers in sorted order returned as an 8-bit integer.

### Median Excluding NaN

Create a vector and compute its median, excluding NaN values.

```
A = [1.77 -0.005 3.98 -2.95 NaN 0.34 NaN 0.19];
M = median(A, 'omitnan')
```

```
M =
```

0.2650

## Input Arguments

### **A** — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. **A** can be a numeric array, ordinal categorical array, datetime array, or duration array.

### **dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension **dim** indicates the dimension whose length reduces to 1. The `size(M, dim)` is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, **A**.

- If `dim = 1`, then `median(A, 1)` returns a row vector containing the median of the elements in each column.

`median(A, 1)`

- If `dim = 2`, then `median(A, 2)` returns a column vector containing the median of the elements in each row.

`median(A,2)`

`median` returns `A` when `dim` is greater than `ndims(A)`.

**nanflag — NaN condition**

`'includenan'` (default) | `'omitnan'`

NaN condition, specified as one of these values:

- `'includenan'` — the median of input containing NaN values is also NaN.
- `'omitnan'` — all NaN values appearing in the input are ignored. Note: the NaN flags are not set to 0.

The `nanflag` option does not support datetime arrays, duration arrays, or categorical arrays.

Data Types: `char`

## More About

### Algorithms

For ordinal categorical arrays, MATLAB interprets the median of an even number of elements as follows:

If the number of categories between the middle two values is ...	Then the median is ...
zero (values are from consecutive categories)	larger of the two middle values

<b>If the number of categories between the middle two values is ...</b>	<b>Then the median is ...</b>
an odd number	value from category occurring midway between the two middle values
an even number	value from larger of the two categories occurring midway between the two middle values

**Introduced before R2006a**

# memmapfile

Create memory map to a file

## Syntax

```
m = memmapfile(filename)
m = memmapfile(filename,Name,Value)
```

## Description

`m = memmapfile(filename)` maps an existing file, `filename`, to memory and returns the memory map, `m`.

Memory-mapping is a mechanism that maps a portion of a file, or an entire file, on disk to a range of memory addresses within the MATLAB address space. Then, MATLAB can access files on disk in the same way it accesses dynamic memory, accelerating file reading and writing. Memory-mapping allows you to work with data in a file as if it were a MATLAB array.

`m = memmapfile(filename,Name,Value)` specifies the properties of `m` using one or more name-value pair arguments. For example, you can specify the format of the data in the file.

## Examples

### Map Entire File of uint8 Data

At the command prompt, create a sample file in your current folder called `records.dat`, containing 10 `uint8` values.

```
myData = uint8(1:10)';
fileID = fopen('records.dat','w');
fwrite(fileID, myData,'uint8');
fclose(fileID);
```

Create a map for `records.dat`. When using `memmapfile`, the default data format is `uint8` so the file name is the only required input argument in this case.

```
m = memmapfile('records.dat')

m =

 Filename: 'd:\matlab\records.dat'
 Writable: false
 Offset: 0
 Format: 'uint8'
 Repeat: Inf
 Data: 10x1 uint8 array
```

MATLAB maps the entire `records.dat` file to memory, setting all properties of the memory map to their default values. The memory map is assigned to the variable, `m`. In this example, the command maps the entire file as a sequence of unsigned 8-bit integers and gives the caller read-only access to its contents.

View the mapped data by accessing the `Data` property of `m`.

```
m.Data
```

```
ans =

 1
 2
 3
 4
 5
 6
 7
 8
 9
 10
```

### Map Entire File of Double-Precision Data

Create a memory map for double-precision data. The syntax is similar when specifying other data types.

At the command prompt, create a sample file in your current folder called `records.dat`, containing 10 double values.

```
myData = (1:10)';
```

```
fileID = fopen('records.dat','w');
fwrite(fileID,myData,'double');
fclose(fileID);
```

Create a memory map for `records.dat`, and set the `Format` property for the output to `'double'`.

```
m = memmapfile('records.dat','Format','double')

m =

 Filename: 'd:\matlab\records.dat'
 Writable: false
 Offset: 0
 Format: 'double'
 Repeat: Inf
 Data: 10x1 double array
```

The `Data` property contains the 10 double-precision values in `records.dat`.

## Map and Change Part of a File

Create a memory map for a large array of `int32` data. Specify write access, and nondefault `Format` and `Offset` values.

At the command prompt, create a sample file in your current folder called `records.dat`, containing 10,000 `int32` values.

```
myData = int32([1:10000]);

fileID = fopen('records.dat','w');
fwrite(fileID,myData,'int32');
fclose(fileID);
```

Create a memory map for `records.dat`, and set the `Format` property for the output to `int32`. Also, set the `Offset` property to disregard the first 9000 bytes in the file, and the `Writable` property to permit write access.

```
m = memmapfile('records.dat',...
 'Offset',9000,...
 'Format','int32',...
 'Writable',true);
```

An `Offset` value of 9000 indicates that the first 9000 bytes of `records.dat` are not mapped.

Type the name of the memory map to see the current settings for all properties.

```
m
m =
 Filename: 'd:\matlab\records.dat'
 Writable: true
 Offset: 9000
 Format: 'int32'
 Repeat: Inf
 Data: 7750x1 int32 array
```

The `Format` property indicates that any read or write operation made via the memory map reads and writes the file contents as a sequence of signed 32-bit integers. The `Data` property contains only 7750 elements because the first 9000 bytes of `records.dat`, representing the first 2250 values in the file, are not mapped.

View the first five elements of the mapped data by accessing the `Data` property of `m`.

```
m.Data(1:5)
ans =
 2251
 2252
 2253
 2254
 2255
```

### Map Region of File to Specific Array Shape

Create a memory map for a region of a file containing 100 double-precision values.

At the command prompt, create a sample file in your current folder called `mybinary.bin`, containing 100 double-precision values.

```
randData = gallery('uniformdata',[100,1],0,'double');
fileID = fopen('mybinary.bin','w');
fwrite(fileID,randData,'double');
fclose(fileID);
```

Map the first 75 values in `mybinary.bin` to a 5-by-5-by-3 array of double-precision values that can be referenced in the structure of the memory map using the field name `x`. Specify these parameters with the `Format` name-value pair argument.

```
m = memmapfile('mybinary.bin',...
 'Format',{ 'double' ,[5 5 3] ,'x'})

m =

 Filename: 'd:\matlab\mybinary.bin'
 Writable: false
 Offset: 0
 Format: { 'double' [5 5 3] 'x' }
 Repeat: Inf
 Data: 1x1 struct array with fields:
 x
```

The `Data` property is a structure array that contains the mapped values in the field, `x`.

Assign the mapped data to a variable, `A`. Because the `Data` property is a structure array, you must index into the field, `x`, to access the data.

```
A = m.Data.x;
```

View information about `A`.

```
whos A
```

Name	Size	Bytes	Class	Attributes
A	5x5x3	600	double	

### Map Segments of File to Multiple Arrays

Map segments of a file with different array shapes and data types to memory.

At the command prompt, create a sample file in your current folder called `mybinary.bin`. Write `uint16` data and double-precision data representing sample pressure, temperature, and volume values into the file. In this case, each of the `uint16` arrays are 50-by-1 and the double-precision arrays are 5-by-10. `k` is a sample scaling factor.

```
k = 8.21;
[pres1,temp1] = gallery('integerdata',[1,300],[50,1],0,'uint16');
vol1 = double(reshape(k*temp1./pres1,5,10));
```

```
[pres2,temp2] = gallery('integerdata',[5,500],[50,1],5,'uint16');
vol2 = double(reshape(k*temp2./pres2,5,10));
```

```
fileID = fopen('mybinary.bin','w');
fwrite(fileID,pres1,'uint16');
fwrite(fileID,temp1,'uint16');
fwrite(fileID,vol1,'double');
fwrite(fileID,pres2,'uint16');
fwrite(fileID,temp2,'uint16');
fwrite(fileID,vol2,'double');
fclose(fileID);
```

Map the file to arrays accessible by unique names. Define a field, `pressure`, containing a 50-by-1 array of `uint16` values, followed by a field, `temperature`, containing 50-by-1 `uint16` values. Define a field, `volume`, containing a 5-by-10 array of double-precision values. Use a cell array to define the format of the mapped region and repeat the pattern twice.

```
m = memmapfile('mybinary.bin',...
'Format',{'uint16',[50 1],'pressure';...
'uint16',[50,1],'temperature';...
'double',[5,10],'volume'},'Repeat',2)
```

```
m =
```

```
Filename: 'd:\matlab\mybinary.bin'
Writable: false
Offset: 0
Format: {'uint16' [50 1] 'pressure'
 'uint16' [50 1] 'temperature'
 'double' [5 10] 'volume'}
Repeat: 2
Data: 2x1 struct array with fields:
 pressure
 temperature
 volume
```

The `Data` property of the memory map, `m`, is a 2-by-1 structure array because the `Format` is applied twice.

Copy the `Data` property to a variable, `A`. Then, view the last block of `double` data, which you can access using the field name, `volume`.

```
A = m.Data;
```

```
myVolume = A(2).volume
```

```
myVolume =
```

```
 2 13 32 5 5 16 4 22 3 8
 2 9 53 38 13 19 23 85 2 120
 29 10 6 1 2 5 6 58 20 11
 7 15 4 1 5 18 1 4 14 8
 9 8 4 2 0 9 8 6 3 3
```

- “Map File to Memory”

## Input Arguments

**filename** — Name of file to map

string

Name of the file to map including the file extension, specified as a string. The **filename** argument cannot include any wildcard characters (for example, \* or ?).

Example: 'myFile.dat'

Data Types: char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `m = memmapfile('myFile.dat','Format','int32','Offset',255)` maps int32 data in the file, `myFile.dat`, to memory starting from the 256th byte.

**'Writable'** — Type of access allowed to mapped region

false (default) | true

Type of access allowed to the mapped region, specified as the comma-separated pair consisting of **'Writable'** and either **true** or **false**. If the **Writable** property is set to **false**, the mapped region is read-only. If **true**, then write access is allowed.

Example: `'Writable',true`

Data Types: `logical`

**'Offset'** — Number of bytes from start of file to start of mapped region

0 (default) | nonnegative integer

Number of bytes from the start of the file to the start of the mapped region, specified as the comma-separated pair consisting of `'Offset'` and a nonnegative integer. This value is zero-based. That is, an `Offset` value of 0 represents the start of the file.

Example: `'Offset', 1024`

Data Types: `double`

**'Format'** — Format of mapped region

`'uint8'` (default) | string | n-by-3 cell array

Format of the mapped region contents, specified as the comma-separated pair consisting of `'Format'` and a single string or an n-by-3 cell array.

- If the file region you are mapping contains data of only one type, specify the `Format` value as a string identifying that type.  
**Example:** `'int16'`
- To specify an array shape to apply to the data read or written to the mapped file, and a field name to reference this array, specify the `Format` value as a 1-by-3 cell array. The first cell contains a string identifying the data type to apply to the mapped region. The second cell contains the array dimensions to apply to the region. The third cell contains a string specifying the field name to use in the `Data` structure array of the memory map.  
**Example:** `{'uint64', [30 4 10], 'x'}`
- If the region you are mapping is composed of segments of varying data types or array shapes, you can specify an individual format for each segment using an n-by-3 cell array, where n is the number of segments.  
**Example:** `{'uint64', [30 4 10], 'x'; 'uint32', [30 4 6], 'y'}`

You can use any of the following data types when you specify a `Format` value:

- `'int8'`
- `'int16'`
- `'int32'`
- `'int64'`

- 'uint8'
- 'uint16'
- 'uint32'
- 'uint64'
- 'single'
- 'double'

Data Types: char | cell

### 'Repeat' — Number of times to apply Format parameter

Inf (default) | positive integer

Number of times to apply the `Format` parameter to the mapped region of the file, specified as the comma-separated pair consisting of 'Repeat' and a positive integer. If the value of `Repeat` is `Inf`, then `memmapfile` applies the `Format` parameter until the end of the file.

Example: 'Repeat', 2000

Data Types: double

## Output Arguments

### **m** — Memory map

`memmapfile` object

Memory map, returned as a `memmapfile` object with the following properties.

Property	Description
Filename	Path and name of the mapped file
Writable	Type of access allowed to the mapped region
Offset	Number of bytes from the start of the file to the start of the mapped region
Format	Format of the contents of the mapped region, including data type, array size, and field name by which to access the data

Property	Description
Repeat	Number of times to apply the pattern specified by the <code>Format</code> property to the mapped region of the file
Data	Memory-mapped data from the file. <code>Data</code> can be a numeric array or a structure array with field names specified in the <code>Format</code> property

The values for any property (except for `Data`) are set at the time you call `memmapfile`, using name-value pair arguments.

Access any property of `m` with dot notation similar to accessing fields of a structure array. For example, to access the memory-mapped data in the `Data` property, do one of the following:

- If `Data` is a numeric array, call `m.Data`.
- If `Data` is a scalar (1-by-1) structure array, call `m.Data.fieldname`, where *fieldname* is the name of a field.
- If `Data` is a nonscalar structure array, call `m.Data(index).fieldname` where *index* is the index for the element in the structure array, and *fieldname* is the name of a field. For example, to access the file data in the `temperature` field of the first element of `Data`, call `m.Data(1).temperature`.

After you create a memory map, `m`, you can change the value of any of its properties, except for `Data`. To assign a new value, use dot notation. For example, to set a new `Offset` value for `m`, type:

```
m.Offset = 2048;
```

## More About

### Tips

- You can map only an existing file. You cannot create a new file and map that file to memory in one operation. Use the MATLAB file I/O functions to create the file before attempting to map it to memory.
- After `memmapfile` locates the file, MATLAB stores the file's absolute pathname internally, and then uses this stored path to locate the file from that point on. As

a result, you can work in other directories outside your current work directory and retain access to the mapped file.

- `memmapfile` does not expand or append to a mapped file. Use instead standard file I/O functions like `fopen` and `fwrite`.

## Algorithms

The actual mapping of a file to the MATLAB address space does not take place when you construct a `memmapfile` object. A memory map, based on the information currently stored in the mapped object, is generated the first time you reference or modify the `Data` property for that object.

- “Overview of Memory-Mapping”

**Introduced before R2006a**

# memory

Display memory information

## Syntax

```
memory
userview = memory
[userview systemview] = memory
```

## Limitations

- The `memory` function is available only on Microsoft Windows systems. Results are dependant on your computer hardware and the load on your computer.

## Description

`memory` displays information showing how much memory is available and how much the MATLAB software is currently using. The information displayed at your computer screen includes the following items, each of which is described in a section below:

- “Maximum Possible Array” on page 1-5546
- “Memory Available for All Arrays” on page 1-5547
- “Memory Used By MATLAB” on page 1-5548
- “Physical Memory (RAM)” on page 1-5548

`userview = memory` returns user-focused information on memory use in structure `userview`. The information returned in `userview` includes the following items, each of which is described in a section below:

- “Maximum Possible Array” on page 1-5546
- “Memory Available for All Arrays” on page 1-5547
- “Memory Used By MATLAB” on page 1-5548

`[userview systemview] = memory` returns both user- and system-focused information on memory use in structures `userview` and `systemview`, respectively.

The `userview` structure is described in the command syntax above. The information returned in `systemview` includes the following items, each of which is described in a section below:

- “Virtual Address Space” on page 1-5549
- “System Memory” on page 1-5549
- “Physical Memory (RAM)” on page 1-5548

## Output Arguments

Each of the sections below describes a value that is displayed or returned by the `memory` function.

### Maximum Possible Array

Maximum Possible Array is the size of the largest contiguous free memory block. As such, it is an upper bound on the largest single array MATLAB can create at this time.

MATLAB derives this number from the smaller of the following two values:

- The largest contiguous memory block found in the MATLAB virtual address space
- The total available system memory

To see how many array elements this number represents, divide by the number of bytes in the array class. For example, for a `double` array, divide by 8. The actual number of elements MATLAB can create is always fewer than this number.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

Command	Returned in
<code>memory</code>	String labelled Maximum possible array:
<code>user = memory</code>	Structure field <code>user.MaxPossibleArrayBytes</code>

All values are double-precision and in units of bytes.

## Footnotes

When you enter the `memory` command without specifying any outputs, MATLAB may also display one of the following footnotes. 32-bit systems show either the first or second footnote; 64-bit systems show only the second footnote:

Limited by contiguous virtual address space available.

There is sufficient system memory to allow mapping of all virtual addresses in the largest available block of the MATLAB process. The maximum amount of total MATLAB virtual address space is either 2 GB or 3 GB, depending on whether the `/3GB` switch is in effect or not.

Limited by System Memory (physical + swap file) available.

There is insufficient system memory to allow mapping of all virtual addresses in the largest available block of the MATLAB process.

## Memory Available for All Arrays

Memory Available for All Arrays is the total amount of memory available to hold data. The amount of memory available is guaranteed to be at least as large as this field.

MATLAB derives this number from the smaller of the following two values:

- The total available MATLAB virtual address space
- The total available system memory

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

Command	Returned in
<code>memory</code>	String labelled Memory available for all arrays:
<code>user = memory</code>	Structure field <code>user.MemAvailableAllArrays</code>

## Footnotes

When you enter the `memory` command without specifying any outputs, MATLAB may also display one of the following footnotes. 32-bit systems show either the first or second footnote; 64-bit systems show only the latter footnote:

Limited by virtual address space available.

There is sufficient system memory to allow mapping of all available virtual addresses in the MATLAB process virtual address space to system memory. The maximum amount of total MATLAB virtual address space is either 2 GB or 3 GB, depending on whether the /3GB switch is in effect or not.

Limited by System Memory (physical + swap file) available.

There is insufficient system memory to allow mapping of all available virtual addresses in the MATLAB process.

## Memory Used By MATLAB

Memory Used By MATLAB is the total amount of system memory reserved for the MATLAB process. It is the sum of the physical memory and potential swap file usage.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

Command	Returned in
<code>memory</code>	String labelled Memory used by MATLAB:
<code>user = memory</code>	Structure field <code>user.MemUsedMATLAB</code>

## Physical Memory (RAM)

Physical Memory is the available and total amounts of physical memory (RAM) on the computer running MATLAB.

When you enter the `memory` command without assigning its output, MATLAB displays the total memory as a string. When you do assign the output, MATLAB returns both the available and total memory in a structure field. See the table below.

Command	Value	Returned in
<code>memory</code>	Total memory	String labelled Physical Memory (RAM):
<code>[user,sys] = memory</code>	Available memory	Structure field <code>sys.PhysicalMemory.Available</code>
	Total memory	Structure field <code>sys.PhysicalMemory.Total</code>

Available physical memory is the same as **Available** found in the Windows Task Manager: Performance/Physical Memory, and the total physical memory is the same as **Total**.

You can use the amount of available physical memory as a measure of how much data you can access quickly.

## Virtual Address Space

Virtual Address Space is the amount of available and total virtual memory for the MATLAB process. MATLAB returns the information in two fields of the return structure: **Available** and **Total**.

Command	Return Value	Returned in Structure Field
[user,sys] = memory	Available memory	sys.VirtualAddressSpace.Available
	Total memory	sys.VirtualAddressSpace.Total

You can monitor the difference:

```
VirtualAddressSpace.Total - VirtualAddressSpace.Available
```

as the Virtual Bytes counter in the Windows Performance Monitor (e.g., Windows 7 Control Panel/Administrative Tools/Performance Monitor). If you add a counter, the **Virtual Bytes** counter is found under the **Process** menu. Select the counter, and then select MATLAB from the **Instances of selected object** pane.

## System Memory

System Memory is the amount of available system memory on your computer system. This number includes the amount of available physical memory and the amount of available swap file space on the computer running MATLAB. MATLAB returns the information in the **SystemMemory** field of the return structure.

Command	Return Value	Returned in Structure Field
[user,sys] = memory	Available memory	sys.SystemMemory

This is the same as the difference:

```
limit - total (in bytes)
```

found in the Windows Task Manager: Performance/Commit Charge.

## Examples

Display memory statistics on a 64-bit Windows system:

```
memory
Maximum possible array: 14253 MB (1.495e+10 bytes) *
Memory available for all arrays: 14253 MB (1.495e+10 bytes) *
Memory used by MATLAB: 747 MB (7.833e+08 bytes)
Physical Memory (RAM): 12279 MB (1.288e+10 bytes)
```

\* Limited by System Memory (physical + swap file) available.

Return in the structure `userview`, information on the largest array MATLAB can create at this time, how much memory is available to hold data, and the amount of memory currently being used by your MATLAB process:

```
userview = memory
userview =
 MaxPossibleArrayBytes: 1.4957e+10
 MemAvailableAllArrays: 1.4957e+10
 MemUsedMATLAB: 784044032
```

Assign the output to two structures, `user` and `sys`, to obtain the information shown here:

```
[user sys] = memory;
% --- Largest array MATLAB can create ---
user.MaxPossibleArrayBytes
ans =
 1.4956e+10
% --- Memory available for data ---
user.MemAvailableAllArrays
ans =
 1.4956e+10
% --- Memory used by MATLAB process ---
```

```
user.MemUsedMATLAB

ans =
 784039936

% --- Virtual memory for MATLAB process ---
sys.VirtualAddressSpace

ans =
 Available: 8.7910e+12
 Total: 8.7961e+12

% --- Physical memory and paging file ---
sys.SystemMemory

ans =
 Available: 1.4956e+10

% --- Computer's physical memory ---
sys.PhysicalMemory

ans =
 Available: 2.7093e+09
 Total: 1.2876e+10
```

## More About

### Tips

### Details on Memory Used By MATLAB

MATLAB computes the value for Memory Used By MATLAB by walking the MATLAB process memory structures and summing all the sections that have physical storage allocated in memory or in the paging file on disk.

Using the Windows Task Manager, you have for the MATLAB.exe image:

Mem Usage < MemUsedMATLAB < Mem Usage + VM Size (in bytes)

where both of the following are true:

- Mem Usage is the working set size in kilobytes.

- `VM Size` is the page file usage, or private bytes, in kilobytes.

The working set size is the portion of the MATLAB virtual address space that is *currently* resident in RAM and can be referenced without a memory page fault. The page file usage gives the portion of the MATLAB virtual address space that requires a backup that doesn't already exist. Another name for page file usage is *private bytes*. It includes all MATLAB variables and workspaces. Since some of the pages in the page file may also be part of the working set, this sum is an overestimate of `MemUseMATLAB`. Note that there are virtual pages in the MATLAB process space that already have a backup. For example, code loaded from EXEs and DLLs and memory-mapped files. If any part of those files is in memory when the memory builtin is called, that memory will be counted as part of `MemUsedMATLAB`.

## Reserved Addresses

Reserved addresses are addresses sets aside in the process virtual address space for some specific future use. These reserved addresses reduce the size of `MemAvailableAllArrays` and can reduce the size of the current or future value of `MaxPossibleArrayBytes`.

### Example 1 — Java Virtual Machine (JVM)

At MATLAB startup, part of the MATLAB virtual address space is reserved by the Java Virtual Machine (JVM) and cannot be used for storing MATLAB arrays.

### Example 2 — Standard Windows Heap Manager

MATLAB, by default, uses the standard Windows heap manager except for a set of small preselected allocation sizes. One characteristic of this heap manager is that its behavior depends upon whether the requested allocation is less than or greater than the fixed number of 524,280 bytes. For, example, if you create a sequence of MATLAB arrays, each less than 524,280 bytes, and then clear them all, the `MemUsedMATLAB` value before and after shows little change, and the `MemAvailableAllArrays` value is now smaller by the total space allocated.

The result is that, instead of globally freeing the extra memory, the memory becomes reserved. It can *only* be reused for arrays less than 524,280 bytes. You cannot reclaim this memory for a larger array except by restarting MATLAB.

**Introduced in R2008a**

## menu

(Not recommended) Create multiple-choice dialog box

---

**Note:** The `menu` function is not recommended. Instead, use the `dialog` function to create multiple choice dialog boxes.

---

## Syntax

```
choice = menu('mtitle','opt1','opt2',...,'optn')
choice = menu('mtitle',options)
```

## Description

`choice = menu('mtitle','opt1','opt2',...,'optn')` displays the menu whose title is in the string variable `'mtitle'` and whose choices are string variables `'opt1'`, `'opt2'`, and so on. The menu opens in a modal dialog box. `menu` returns the number of the selected menu item, or 0 if the user clicks the close button on the window.

`choice = menu('mtitle',options)` , where `options` is a 1-by-N cell array of strings containing the menu choices.

If the user's terminal provides a graphics capability, `menu` displays the menu items as push buttons in a figure window (Example 1). Otherwise, they will be given as a numbered list in the Command Window (Example 2).

## Examples

### Example 1

On a system with a display, `menu` displays choices as buttons in a dialog box:

`choice = menu('Choose a color','Red','Blue','Green')`  
 displays the following dialog box.

The number entered by the user in response to the prompt is returned as `choice` (i.e., `choice = 2` implies that the user selected `Blue`).

After input is accepted, the dialog box closes, returning the output in `choice`. You can use `choice` to control the color of a graph:

```
t = 0:.1:60;
s = sin(t);
color = ['r','b','g']
plot(t,s,color(choice))
```

## Example 2

On a system without a display, `menu` displays choices in the Command Window:

```
choice = menu('Choose a color','Red','Blue','Green')
```

displays the following text.

```
----- Choose a color -----
1) Red
2) Blue
3) Green
Select a menu number:
```

## More About

### Tips

To call `menu` from a `uicontrol` or other ui object, set that object's `Interruptible` property to `'on'`. For more information, see `Uicontrol Properties`.

**Introduced before R2006a**

## mergecats

Merge categories in categorical array

### Syntax

```
B = mergecats(A,oldcats)
B = mergecats(A,oldcats,newcat)
```

### Description

`B = mergecats(A,oldcats)` merges two or more categories in `A` into the first category, `oldcats(1)`. Any values in `A` from `oldcats` become `oldcats(1)` in `B`.

`B = mergecats(A,oldcats,newcat)` merges `oldcats` into a single new category, `newcat`. Any values in `A` from `oldcats` become `newcat` in `B`.

### Examples

#### Merge Two Categories into One

Create a categorical array containing various colors.

```
A = categorical({'red';'blue';'pink';'red';'blue';'red'})
```

A =

```
red
blue
pink
red
blue
red
```

A is a 6-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
 'blue'
 'pink'
 'red'
```

The three categories are in alphabetical order.

Merge the categories `red` and `pink` into the category `red`. Specify `red` first in `oldcats` to use it as the merged category.

```
oldcats = {'red', 'pink'};
B = mergecats(A, oldcats)
```

```
B =
 red
 blue
 red
 red
 blue
 red
```

`mergetcats` replaces the value `pink` from `A(3)` with `red`.

Display the categories of `B`.

```
categories(B)
```

```
ans =
 'blue'
 'red'
```

`B` has two categories instead of three.

## Merge Alphabetically Listed Categories

Create a categorical array containing various items.

```
A = categorical({'shirt' 'pants'; 'shoes' 'shirt'; 'dress' 'belt'})
```

```
A =
 shirt pants
 shoes shirt
```

```
dress belt
```

Display the categories of **A**.

```
categories(A)
```

```
ans =
```

```
'belt'
'dress'
'pants'
'shirt'
'shoes'
```

The five categories are in alphabetical order.

Merge the categories **belt** and **shoes** into a new category called **other**.

```
B = mergocats(A,{'belt' 'shoes'}, 'other')
```

```
B =
```

```
shirt pants
other shirt
dress other
```

The value **other** replaces all instances of **belt** and **shoes**.

Display the categories of **B**.

```
categories(B)
```

```
ans =
```

```
'other'
'dress'
'pants'
'shirt'
```

**B** has four categories and the order is no longer alphabetical. **other** appears in place of **belt**.

### Merge Categories of Ordinal Categorical Array

Create an ordinal categorical array.

```
A = categorical([1 2 3 2 1],1:3,{'poor','fair','good'},'Ordinal',true)
```

```
A =
 poor fair good fair poor
```

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
 'poor'
 'fair'
 'good'
```

Since A is ordinal, the categories have the mathematical ordering `poor < fair < good`.

Consider all `fair` or `poor` values to be `bad`. Since A is ordinal, the categories to merge must be consecutive.

```
B = mergecats(A, {'fair' 'poor'}, 'bad')
```

```
B =
```

```
 bad bad good bad bad
```

The value `bad` replaces all instances of `fair` and `poor`.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
 'bad'
 'good'
```

B has two categories with the mathematical ordering: `bad < good`.

## Input Arguments

### A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

**oldcats — Categories to merge**

cell array of strings

Categories to merge, specified as a cell array of strings. If *A* is ordinal, the categories to merge must be consecutive.

**newcat — New category**

oldcats(1) (default) | string

New category, specified as a string.

**See Also**

addcats | categories | iscategory | removecats | renamecats | reordercats  
| setcats

**Introduced in R2013b**

## mesh

Mesh plot

## Syntax

```
mesh(X,Y,Z)
mesh(Z)
mesh(...,C)
mesh(...,'PropertyName',PropertyValue,...)
mesh(axes_handles,...)
h = mesh(...)
```

## Description

`mesh(X,Y,Z)` draws a wireframe mesh with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case,  $(X(j), Y(i), Z(i,j))$  are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices,  $(X(i,j), Y(i,j), Z(i,j))$  are the intersections of the wireframe grid lines.

`mesh(Z)` draws a wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`mesh(...,C)` draws a wireframe mesh with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`mesh(...,'PropertyName',PropertyValue,...)` sets the value of the specified surface property. Multiple property values can be set with a single statement.

`mesh(axes_handles, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = mesh(...)` returns a handle to a Chart Surface Properties graphics object.

## Examples

### Create Mesh Plot of Sinc Function

Create a mesh plot of the sinc function,  $z = \sin(r)/r$ .

```
[X,Y] = meshgrid(-8:.5:8);
R = sqrt(X.^2 + Y.^2) + eps;
Z = sin(R)./R;
```

```
figure
mesh(Z)
```

### Specify Color for Mesh Plot

Specify a color matrix for a mesh plot.

```
[X,Y] = meshgrid(-8:.5:8);
R = sqrt(X.^2 + Y.^2) + eps;
Z = sin(R)./R;
C = gradient(Z);
```

```
figure
mesh(X,Y,Z,C)
```

### Change Lighting and Line Width for Mesh Plot

Change the lighting and the line width for a mesh plot using Name, Value pair arguments.

```
[X,Y] = meshgrid(-8:.5:8);
R = sqrt(X.^2 + Y.^2) + eps;
Z = sin(R)./R;
C = del2(Z);
```

```
figure
mesh(X,Y,Z,C, 'FaceLighting', 'gouraud', 'LineWidth', 0.3)
```

## More About

### Tips

mesh does not accept complex inputs.

A mesh is drawn as a `Surfaceplot` graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background color (to simulate a wireframe with hidden-surface elimination), or `none` when drawing a standard see-through wireframe. The current colormap determines the edge color. The `hidden` command controls the simulation of hidden-surface elimination in the mesh, and the `shading` command controls the shading model.

### Properties

Chart Surface Properties

**Introduced before R2006a**

## meshc

Plot a contour graph under mesh graph

## Syntax

```
meshc(X,Y,Z)
meshc(Z)
meshc(...,C)
meshc(axes_handles,...)
h = meshc(...)
```

## Description

`meshc(X,Y,Z)` draws a wireframe mesh and a contour plot under it with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case, `(X(j), Y(i), Z(i,j))` are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices, `(X(i,j), Y(i,j), Z(i,j))` are the intersections of the wireframe grid lines.

`meshc(Z)` draws a contour plot under wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`meshc(...,C)` draws a `meshc` graph with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`meshc(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = meshc(...)` returns handles to the Chart Surface Properties and Contour Properties graphics object.

## Examples

### Display Contour Plot Under Mesh Plot

Use `meshc` to display a combination of a mesh plot and a contour plot of the `peaks` function.

```
figure
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
meshc(Z)
```

## More About

### Tips

`meshc` does not accept complex inputs.

A mesh is drawn as a `Surfaceplot` graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background color (to simulate a wireframe with hidden-surface elimination), or `none` when drawing a standard see-through wireframe. The current colormap determines the edge color. The `hidden` command controls the simulation of hidden-surface elimination in the mesh, and the `shading` command controls the shading model.

## Algorithms

The range of *X*, *Y*, and *Z*, or the current settings of the axes `XLimMode`, `YLimMode`, and `ZLimMode` properties, determine the axis limits. `axis` sets these properties.

The range of *C*, or the current settings of the axes `CLim` and `CLimMode` properties (also set by the `caxis` function), determine the color scaling. Use the scaled color values are used as indices into the current colormap.

The mesh rendering functions produce color values by mapping the *z* data values (or an explicit color array) onto the current colormap. The MATLAB default behavior is to compute the color limits automatically using the minimum and maximum data values (also set using `caxis auto`). The minimum data value maps to the first color value in the colormap and the maximum data value maps to the last color value in the colormap. MATLAB performs a linear transformation on the intermediate values to map them to the current colormap.

`meshc` calls `mesh`, turns `hold` on, and then calls `contour` and positions the contour on the *x-y* plane. For additional control over the appearance of the contours, issue these commands directly. You can combine other types of graphs in this manner, for example `surf` and `pcolor` plots.

`meshc` assumes that *X* and *Y* are monotonically increasing. If *X* or *Y* is irregularly spaced, `contour3` calculates contours using a regularly spaced contour grid, and then it transforms the data to *X* or *Y*.

## meshz

Plot a curtain around mesh plot

### Syntax

```
meshz(X,Y,Z)
meshz(Z)
meshz(...,C)
meshz(axes_handles,...)
h = meshz(...)
```

### Description

`meshz(X,Y,Z)` draws a curtain around the wireframe mesh with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case, `(X(j), Y(i), Z(i,j))` are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices, `(X(i,j), Y(i,j), Z(i,j))` are the intersections of the wireframe grid lines.

`meshz(Z)` draws a curtain around the wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`meshz(...,C)` draws a `meshz` graph with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`meshz(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = meshz(...)` returns a handle to a Chart Surface Properties graphics object.

## Examples

### Curtain Plot of Peaks Function

Generate a curtain plot of the peaks function using `meshz`.

```
figure
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
meshz(Z)
```

### Specify Color for Curtain Plot

Specify a color matrix for a curtain plot.

```
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
C = gradient(Z);
```

```
figure
meshz(X,Y,Z,C)
```

## More About

### Tips

meshz does not accept complex inputs.

A mesh is drawn as a chart surface graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background color (to simulate a wireframe with hidden-surface elimination), or `none` when drawing a standard see-through wireframe. The current colormap determines the edge color. The `hidden` command controls the simulation of hidden-surface elimination in the mesh, and the `shading` command controls the shading model.

## See Also

### Functions

`axis` | `caxis` | `colormap` | `contour` | `hidden` | `hold` | `mesh` | `meshc` | `meshgrid` | `shading` | `surf` | `surface` | `surfc` | `surf1` | `view` | `waterfall`

### Properties

Chart Surface Properties

**Introduced before R2006a**

# meshgrid

Rectangular grid in 2-D and 3-D space

## Syntax

```
[X,Y] = meshgrid(xgv,ygv)
[X,Y,Z] = meshgrid(xgv,ygv,zgv)
[X,Y] = meshgrid(gv)
[X,Y,Z] = meshgrid(gv)
```

## Description

`[X,Y] = meshgrid(xgv,ygv)` replicates the grid vectors `xgv` and `ygv` to produce a full grid. This grid is represented by the output coordinate arrays `X` and `Y`. The output coordinate arrays `X` and `Y` contain copies of the grid vectors `xgv` and `ygv` respectively. The sizes of the output arrays are determined by the length of the grid vectors. For grid vectors `xgv` and `ygv` of length `M` and `N` respectively, `X` and `Y` will have `N` rows and `M` columns.

`[X,Y,Z] = meshgrid(xgv,ygv,zgv)` produces three-dimensional coordinate arrays. The output coordinate arrays `X`, `Y`, and `Z` contain copies of the grid vectors `xgv`, `ygv`, and `zgv` respectively. The sizes of the output arrays are determined by the length of the grid vectors. For grid vectors `xgv`, `ygv`, and `zgv` of length `M`, `N`, and `P` respectively, `X`, `Y`, and `Z` will have `N` rows, `M` columns, and `P` pages.

`[X,Y] = meshgrid(gv)` is the same as `[X,Y] = meshgrid(gv,gv)`. In other words, you can reuse the same grid vector in each respective dimension. The dimensionality of the output arrays is determined by the number of output arguments.

`[X,Y,Z] = meshgrid(gv)` is the same as `[X,Y,Z] = meshgrid(gv,gv,gv)`. Again, the dimensionality of the output arrays is determined by the number of output arguments.

The output coordinate arrays are typically used to evaluate functions of two or three variables. They are also frequently used to create surface and volumetric plots.

## Input Arguments

**xgv, ygv, zgv**

Grid vectors specifying a series of grid point coordinates in the x, y and z directions, respectively.

**gv**

Generic grid vector specifying a series of point coordinates.

## Output Arguments

**X, Y, Z**

Output arrays that specify the full grid.

## Examples

### 2-D Grid From Vectors

Create a full grid from two monotonically increasing grid vectors:

```
[X,Y] = meshgrid(1:3,10:14)
```

```
X =
```

```
 1 2 3
 1 2 3
 1 2 3
 1 2 3
 1 2 3
```

```
Y =
```

```
 10 10 10
 11 11 11
 12 12 12
 13 13 13
 14 14 14
```

### Plot 3-D Functional Surface

Use `meshgrid` to create a gridded (X,Y) domain.

```
[X,Y] = meshgrid(-2:.2:2, -2:.2:2);
```

Evaluate the function  $z(x,y) = xe^{-x^2-y^2}$  over this domain and generate a surface plot of the results.

```
Z = X .* exp(-X.^2 - Y.^2);
surf(X,Y,Z)
```

## More About

### Tips

The `meshgrid` function is similar to `ndgrid`, however `meshgrid` is restricted to 2-D and 3-D while `ndgrid` supports 1-D to N-D. The coordinates output by each function are the same, but the shape of the output arrays in the first two dimensions are different. For grid vectors `x1gv`, `x2gv` and `x3gv` of length `M`, `N` and `P` respectively, `meshgrid(x1gv, x2gv)` will output arrays of size `N-by-M` while `ndgrid(x1gv, x2gv)` outputs arrays of size `M-by-N`. Similarly, `meshgrid(x1gv, x2gv, x3gv)` will output arrays of size `N-by-M-by-P` while `ndgrid(x1gv, x2gv, x3gv)` outputs arrays of size `M-by-N-by-P`.

See “Grid Representation” in the MATLAB Mathematics documentation for more information.

- “Interpolating Gridded Data”

`griddedInterpolant` | `mesh` | `ndgrid` | `surf`

**Introduced before R2006a**

# meta.class

Describe MATLAB class

## Description

Instances of the `meta.class` class contains information about MATLAB classes. The read/write properties of the `meta.class` class correspond to class attributes and are set only from within class definitions on the `classdef` line. You can query the read-only properties of the `meta.class` object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class).

You cannot instantiate a `meta.class` object directly. You can construct a `meta.class` object from an instance of a class or using the class name:

- `metaclass` — returns a `meta.class` object representing the object passed as an argument.
- `?ClassName` — returns a `meta.class` object representing the named class.
- `fromName` — static method returns a `meta.class` object representing the named class.

For example, the `metaclass` function returns the `meta.class` object representing `MyClass`.

```
ob = MyClass;
obmeta = metaclass(ob);
obmeta.Name
```

```
ans =
MyClass
```

You can use the class name to obtain the `meta.class` object:

```
obmeta = ?MyClass;
```

You can also use the `fromName` static method:

```
obmeta = meta.class.fromName('MyClass');
```

## Properties

Property	Purpose
Abstract attribute, default = false	<p>If <code>true</code>, this class is an abstract class (cannot be instantiated).</p> <p>See “Abstract Classes” for more information.</p>
AllowedSubclasses attribute, write only from <code>classdef</code> statement	<p>List classes that can subclass this class. Specify subclasses as <code>meta.class</code> objects in the form:</p> <ul style="list-style-type: none"> <li>• A single <code>meta.class</code> object</li> <li>• A cell array of <code>meta.class</code> objects</li> </ul> <p>Specify <code>meta.class</code> objects using the <code>?ClassName</code> syntax only.</p>
ConstructOnLoad attribute, default = false	<p>If <code>true</code>, MATLAB calls the class constructor automatically when loading an object from a MAT-file. Therefore, the construction must be implemented so that calling it with no arguments does not produce an error.</p> <p>See “Save and Load Process”</p>
ContainingPackage read only	<p>A <code>meta.package</code> object describing the package within which this class is contained, or an empty object if this class is not in a package.</p> <p>See “Packages Create Namespaces”.</p>
Description read only	Currently not used
DetailedDescription read only	Currently not used
Enumeration attribute, default = false	<p>If <code>true</code>, this class is an enumeration class. See “How to Use Enumerations”.</p>
EventList read only	<p>An array of <code>meta.event</code> objects describing each event defined by this class, including all inherited events.</p> <p>See “Events”.</p>
Events read only	<p>A cell array of <code>meta.event</code> objects describing each event defined by this class, including all inherited events.</p>

Property	Purpose
Use <code>EventList</code> instead	
<code>EnumerationMemberList</code>	An array of <code>meta.EnumeratedValue</code> objects describing the member names defined by an enumeration class.  See “Enumerations” for more information on enumeration classes.
<code>EnumeratedValues</code> read only  Use <code>EnumeratedMemberList</code> instead	A cell array of <code>meta.EnumeratedValue</code> objects describing the member names defined by an enumeration class.  See “Enumerations” for more information on enumeration classes.
<code>Hidden</code> attribute, default = <code>false</code>	If set to <code>true</code> , the class does not appear in the output of MATLAB commands or tools that display class names.
<code>InferiorClasses</code> attribute, default = <code>{}</code>	A cell array of <code>meta.class</code> objects defining the precedence of classes represented by the list as inferior to this class.  See “Class Precedence”
<code>MethodList</code> read only	An array of <code>meta.method</code> objects describing each method defined by this class, including all inherited public and protected methods.  See “How to Use Methods”.
<code>Methods</code> read only  Use <code>MethodList</code> instead	A cell array of <code>meta.method</code> objects describing each method defined by this class, including all inherited public and protected methods.
<code>Name</code> read only	Name of the class associated with this <code>meta.class</code> object ( <code>char</code> array)
<code>PropertyList</code> read only	An array of <code>meta.property</code> objects describing each property defined by this class, including all inherited public and protected properties.  See “Properties”.

Property	Purpose
<b>Properties</b> read only Use <code>PropertyList</code> instead	A cell array of <code>meta.property</code> objects describing each property defined by this class, including all inherited public and protected properties.  See “Properties”.
<b>Sealed</b> attribute, default = <code>false</code>	If <code>true</code> , the class cannot be subclassed.
<b>SuperClassList</b> read only	An array of <code>meta.class</code> objects describing each direct superclass from which this class is derived.  See “Create Subclasses — Syntax and Techniques”.
<b>SuperClasses</b> read only Use <code>SuperClassList</code> instead	A cell array of <code>meta.class</code> objects describing each direct superclass from which this class is derived.

## Methods

Method	Purpose
<code>fromName</code>	Returns the <code>meta.class</code> object associated with the specified class name.
<code>tf = eq(Cls)</code>	Equality function ( <code>a == b</code> ). Use to test if two variables refer to equal classes (classes that contain exactly the same list of elements).
<code>tf = ne(Cls)</code>	Not equal function ( <code>a ~= b</code> ). Use to test if two variables refer to different meta-classes.
<code>tf = lt(ClsA,ClsB)</code>	Less than function ( <code>ClsA &lt; ClsB</code> ). Use to determine if <code>ClsA</code> is a strict subclass of <code>ClsB</code> (i.e., a strict subclass means <code>ClsX &lt; ClsX</code> is <code>false</code> ).
<code>tf = le(ClsA,ClsB)</code>	Less than or equal to function ( <code>ClsA &lt;= ClsB</code> ). Use to determine if <code>ClsA</code> is a subclass of <code>ClsB</code> .
<code>tf = gt(ClsA,ClsB)</code>	Greater than function ( <code>ClsA &gt; ClsB</code> ). Use to determine if <code>ClsA</code> is a strict superclass of <code>ClsB</code> (i.e., a strict superclass means <code>ClsX &gt; ClsX</code> is <code>false</code> ).

Method	Purpose
<code>tf = ge(ClsA,ClsB)</code>	Greater than or equal to function ( <code>ClsA &gt;= ClsB</code> ). Use to determine if <code>ClsA</code> is a superclass of <code>ClsB</code> .

## Events

Event	Purpose
<code>InstanceCreated</code>	If the class is a handle class, this event occurs every time a new instance of this handle class is created, including new instances of any subclasses. The event occurs immediately after all constructor functions finish executing.
<code>InstanceDestroyed</code>	If the class is a handle class, this event occurs every time an instance of this handle class is destroyed, including all subclasses. The event occurs immediately before any destructor functions execute.

## Examples

Find property attributes using the `handle` class `findobj` method and the `audioplayer` `meta.class` object. Determine if a class defines the property named `SampleRate` and does it have public set access.

```
mc = ?audioplayer;
mp = findobj(mc.PropertyList, 'Name', 'SampleRate');
strcmp(mp.SetAccess, 'public')
...
```

- “Class Metadata”

## See Also

`fromName` | `meta.property` | `meta.method` | `meta.event` | `meta.package`

## meta.class.fromName

Return `meta.class` object associated with named class

### Syntax

```
mcls = meta.class.fromName('ClassName')
```

### Description

`mcls = meta.class.fromName('ClassName')` is a static method that returns the `meta.class` object associated with the class *ClassName*. Note that you can also use the `?` operator to obtain the `meta.class` object for a class name:

```
mcls = ?ClassName;
```

The equivalent call to `meta.class.fromName` is:

```
mcls = meta.class.fromName('ClassName');
```

Use `meta.class.fromName` when using a `char` variable for the class name:

```
function mcls = getMetaClass(cname)
 % Do error checking
 mcls = meta.class.fromName(cname);
 ...
end
```

### See Also

`meta.class`

# meta.DynamicProperty

Describe dynamic property of MATLAB object

## Description

The `meta.DynamicProperty` class contains descriptive information about dynamic properties that you have added to an instance of a MATLAB classes. The MATLAB class must be a subclass of `dynamicprops`. The properties of the `meta.DynamicProperty` class correspond to property attributes that you specify from within class definitions. Dynamic properties are not defined in `classdef` blocks, but you can set their attributes by setting the `meta.DynamicProperty` object properties.

You add a dynamic property to an object using the `addprop` method of the `dynamicprops` class. The `addprop` method returns a `meta.DynamicProperty` instance representing the new dynamic property. You can modify the properties of the `meta.DynamicProperty` object to set the attributes of the dynamic property or to add set and get access methods, which would be defined in the `classdef` for regular properties.

You cannot instantiate the `meta.DynamicProperty` class. You must use `addprop` to obtain a `meta.DynamicProperty` object.

To remove the dynamic property, call the `delete` handle class method on the `meta.DynamicProperty` object.

Obtain a `meta.DynamicProperty` object from the `addprops` method, which returns an array of `meta.DynamicProperty` objects, one for each dynamic property.

See “Dynamic Properties — Adding Properties to an Instance” for more information.

## Properties

Property	Purpose
Name	Name of the property.
Description	Currently not used
DetailedDescription	Currently not used

Property	Purpose
AbortSet	If <code>true</code> , and this property belongs to a handle class, then MATLAB does not set the property value if the new value is the same as the current value. This approach prevents the triggering of property <code>PreSet</code> and <code>PostSet</code> events.
Abstract attribute, default = <code>false</code>	<p>If <code>true</code>, the property has no implementation, but a concrete subclass must redefine this property without <code>Abstract</code> being set to <code>true</code>.</p> <ul style="list-style-type: none"> <li>• Abstract properties cannot define set or get access methods. See “Property Access Methods”</li> <li>• Abstract properties cannot define initial values. “Assigning a Default Value”</li> <li>• All subclasses must specify the same values as the superclass for the property <code>SetAccess</code> and <code>GetAccess</code> attributes.</li> <li>• <code>Abstract=true</code> should be used with the class attribute <code>Sealed=false</code> (the default).</li> </ul>
Access	<p><code>public</code> – unrestricted access</p> <p><code>protected</code> – access from class or subclasses</p> <p><code>private</code> – access by class members only (not subclasses)</p> <p>List of classes that have get and set access to this property. Specify classes as <code>meta.class</code> objects in the form:</p> <ul style="list-style-type: none"> <li>• A single <code>meta.class</code> object</li> <li>• A cell array of <code>meta.class</code> objects. An empty cell array, <code>{}</code>, is the same as <code>private</code> access.</li> </ul> <p>Use <code>Access</code> to set both <code>SetAccess</code> and <code>GetAccess</code> to the same value. Query the values of <code>SetAccess</code> and <code>GetAccess</code> directly (not <code>Access</code>).</p>

Property	Purpose
Constant attribute, default = false	<p>Set to <code>true</code> if you want only one value for this property in all instances of the class.</p> <ul style="list-style-type: none"> <li>Subclasses inherit constant properties, but cannot change them.</li> <li>Constant properties cannot be <code>Dependent</code></li> <li><code>SetAccess</code> is ignored.</li> </ul> <p>See “Properties with Constant Values”</p>
DefaultValue	Querying this property returns an error because dynamic properties cannot define default values.
DefiningClass	The <code>meta.class</code> object representing the class that defines this property.
GetAccess attribute, default = public	<p><code>public</code> – unrestricted access</p> <p><code>protected</code> – access from class or subclasses</p> <p><code>private</code> – access by class members only</p>
SetAccess attribute, default = public	<p><code>public</code> – unrestricted access</p> <p><code>protected</code> – access from class or subclasses</p> <p><code>private</code> – access by class members only</p>
Dependent attribute, default = false	<p>If <code>false</code>, property value is stored in object. If <code>true</code>, property value is not stored in object and the set and get functions cannot access the property by indexing into the object using the property name.</p> <p>See “Property Get Methods”</p>
Transient attribute, default = false	If <code>true</code> , property value is not saved when object is saved to a file. See “Save and Load Process” for more about saving objects.
Hidden attribute, default = false	Determines whether the property should be shown in a property list (e.g., Property Inspector, call to <code>properties</code> , etc.).

Property	Purpose
<code>GetObservable</code> attribute, default = <code>false</code>	If <code>true</code> , and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are queried. See “Property-Set and Query Events”
<code>SetObservable</code> attribute, default = <code>false</code>	If <code>true</code> , and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are modified. See “Property-Set and Query Events”
<code>GetMethod</code>	Function handle of the get method associated with this property. Empty if there is no get method specified. See “Get Method Syntax”
<code>SetMethod</code>	Function handle of the set method associated with this property. Empty if there is no set method specified. See “Property Set Methods”
<code>HasDefault</code>	Always <code>false</code> . Dynamic properties cannot define default values.

## Events

See “Listen for Changes to Property Values” for information on using property events.

Event Name	Purpose
<code>PreGet</code>	Event occurs just before property is queried.
<code>PostGet</code>	Event occurs just after property has been queried
<code>PreSet</code>	Event occurs just before this property is modified
<code>PostSet</code>	Event occurs just after this property has been modified
<code>ObjectBeingDestroyed</code>	Inherited from handle

`addprop` | `handle`

# meta.EnumeratedValue

Describe enumeration member of MATLAB class

## Description

The `meta.EnumeratedValue` class contains information about enumeration members defined by MATLAB classes. The properties of a `meta.EnumeratedValue` object correspond to the attributes of the enumeration member being described.

All `meta.EnumeratedValue` properties are read-only. Query the `meta.EnumeratedValue` object to obtain information about the enumeration member it describes.

Obtain a `meta.EnumeratedValue` object from the `EnumerationMemberList` property of the `meta.class` object. `EnumerationMemberList` is an array of `Meta.EnumeratedValue` instances, one per enumeration member.

The `meta.EnumeratedValue` class is a subclass of the handle class.

## Example

To access the `meta.EnumeratedValue` objects for a class, first create a `meta.class` object for that class. For example, give the following `OnOff` class definition:

```
classdef OnOff < logical
 enumeration
 On (true)
 Off (false)
 end
end
```

Obtain a `meta.EnumeratedValue` object from the `EnumerationMemberList` property of the `meta.class` object:

```
% Obtain the meta.class instance for the OnOff class
mc = ?OnOff;
% Get the array of EnumerateValue objects
enumList = mc.EnumerationMemberList;
% Access the Name property of the first object in the array
```

```
enumList(1).Name =
ans =
On
```

## Properties

Property	Purpose
Name read only	Name of the enumeration member associated with this <code>meta.EnumeratedValue</code> object
Description read only	This property is not used
DetailedDescription read only	This property is not used

## Methods

See the handle superclass for inherited methods.

## Events

See the handle superclass for inherited events.

`meta.property` | `meta.event` | `meta.class` | `meta.method`

## meta.event

Describe event of MATLAB class

### Description

The `meta.event` class provides information about MATLAB class events. The read/write properties of the `meta.event` class correspond to event attributes and are specified only from within class definitions.

You can query the read-only properties of the `meta.event` object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class defining the event).

You cannot instantiate a `meta.event` object directly. Obtain a `meta.event` object from the `meta.class` `EventList` property, which contains an array of `meta.event` objects, one for each event defined by the class. For example, replace `ClassName` with the name of the class whose events you want to query:

```
mco = ?ClassName;
elist = mco.EventList;
elist(1).Name; % name of first event in list
```

Use the `metaclass` function to obtain a `meta.class` object from a class instance:

```
mco = metaclass(obj);
```

### Properties

Property	Purpose
Name read only	Name of the event.
Description read only	Currently not used
DetailedDescription read only	Currently not used
Hidden	If <code>true</code> , the event does not appear in the list of events returned by the <code>events</code> function (or other event listing functions or viewers)
ListenAccess	Determines where you can create listeners for the event.

Property	Purpose
	<ul style="list-style-type: none"> <li>• <b>public</b> — unrestricted access</li> <li>• <b>protected</b> — access from methods in class or subclasses</li> <li>• <b>private</b> — access by class methods only (not from subclasses)</li> <li>• List classes that have listen access to this event. Specify classes as <code>meta.class</code> objects in the form:               <ul style="list-style-type: none"> <li>• A single <code>meta.class</code> object</li> <li>• A cell array of <code>meta.class</code> objects. An empty cell array, {}, is the same as <b>private</b> access.</li> </ul> </li> </ul> <p style="text-align: center;">See “Control Access to Class Members”</p>
NotifyAccess	<p>Determines where code can trigger the event.</p> <ul style="list-style-type: none"> <li>• <b>public</b> — any code can trigger event</li> <li>• <b>protected</b> — can trigger event from methods in class or subclasses</li> <li>• <b>private</b> — can trigger event by class methods only (not from subclasses)</li> <li>• List classes that have notify access to this event. Specify classes as <code>meta.class</code> objects in the form:               <ul style="list-style-type: none"> <li>• A single <code>meta.class</code> object</li> <li>• A cell array of <code>meta.class</code> objects. An empty cell array, {}, is the same as <b>private</b> access.</li> </ul> </li> </ul> <p style="text-align: center;">See “Control Access to Class Members”</p>
DefiningClass	<p>The <code>meta.class</code> object representing the class that defines this event.</p>

`meta.property` | `meta.class` | `meta.method` | `metaclass`

## meta.MetaData class

**Package:** meta

**Superclasses:** matlab.mixin.Heterogeneous

Superclass for MATLAB object metadata

### Description

The `meta.MetaData` class of objects represent MATLAB class definitions and the constituent parts of those definitions, such as properties and methods. Metadata enable a program to get information about a class definition.

The `meta.MetaData` class forms the root of the metadata class hierarchy, which enables the formation of arrays of metadata objects belonging to different specific classes.

MATLAB uses instances of the `meta.MetaData` class as the default object to fill in missing array elements.

`findobj` and `findprop`, can search the metadata hierarchy and return an array of different metadata objects. These function require the ability to form heterogeneous arrays containing various metaclass objects.

See the `matlab.mixin.Heterogeneous` class for more information on heterogeneous hierarchies.

### Construction

You cannot create an instance of the `meta.MetaData` class directly. MATLAB constructs instances of this class as required.

### Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

This example shows how the `meta.Metadata` class facilitates working with metaclasses.

Create a `meta.class` instance representing the MATLAB `timeseries` class:

```
>> mc = ?timeseries;
```

MATLAB uses `meta.Metadata` objects to fill empty array elements:

```
>> m(2) = mc
>> class(m(1))
```

```
ans =
```

```
meta.Metadata
>> class(m(2))
```

```
ans =
```

```
meta.class
```

Use `findobj` to find all properties and methods that have protected access:

```
>> protectedMembers = findobj(mc,{'Access','protected'},...
'-or',{'SetAccess','protected'},...
'-or',{'GetAccess','protected'});
```

The `timeseries` class defines both properties and methods that have protected access. Therefore, `findobj` returns a heterogeneous array of class `meta.Metadata`. This array contains both `meta.property` and `meta.method` objects.

```
>> protectedMembers
```

```
protectedMembers =
```

```
1x1 heterogeneous meta.Metadata (meta.property, meta.method)
handle with no properties.
Package: meta
```

```
>> class(protectedMembers(1))
```

```
ans =
```

```
meta.property
```

```
>> protectedMembers(1).Name
```

```
ans =
Length
>> protectedMembers(1).SetAccess
ans =
protected
>> protectedMembers(1).GetAccess
ans =
public
```

# meta.method

Describe method of MATLAB class

## Description

The `meta.method` class provides information about the methods of MATLAB classes. The read/write properties of the `meta.method` class correspond to method attributes and are specified only from within class definitions.

You can query the read-only properties of the `meta.method` object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class defining a method).

You cannot instantiate a `meta.method` object directly. Obtain a `meta.method` object from the `meta.class` `MethodList` property, which contains an array of `meta.method` objects, one for each class method. For example, replace *ClassName* with the name of the class whose methods you want to query:

```
mco = ?ClassName;
mlist = mco.MethodList;
mlist(1).Name; % name of first method in the list
```

Use the `metaclass` function to obtain a `meta.class` object from a class instance:

```
mco = metaclass(obj);
```

## Properties

Property	Purpose
Abstract	<p>If <code>true</code>, the method has no implementation. The method has a syntax line that can include arguments, which subclasses use when implementing the method.</p> <ul style="list-style-type: none"> <li>Subclasses are not required to define the same number of input and output arguments.</li> <li>The method can have comments after the <code>function</code> line</li> </ul>

Property	Purpose
	<ul style="list-style-type: none"> <li>Does not contain <code>function</code> or <code>end</code> keywords, only the function syntax (e.g., <code>[ a , b ] = myMethod( x , y )</code>)</li> </ul>
Access attribute, default = <code>public</code>	<p>Determines what code can call this method.</p> <ul style="list-style-type: none"> <li><code>public</code> — unrestricted access</li> <li><code>protected</code> — access from methods in class or subclasses</li> <li><code>private</code> — access by class methods only (not from subclasses)</li> <li>List classes that have access to this method. Specify classes as <code>meta.class</code> objects in the form: <ul style="list-style-type: none"> <li>A single <code>meta.class</code> object</li> <li>A cell array of <code>meta.class</code> objects. An empty cell array, <code>{}</code>, is the same as <code>private</code> access.</li> </ul> </li> </ul>
DefiningClass	The <code>meta.class</code> object representing the class that defines this method.
Description read only	Currently not used
DetailedDescription read only	Currently not used
Hidden attribute, default = <code>false</code>	When <code>false</code> , the method name shows in the list of methods displayed using the <code>methods</code> or <code>methodsviw</code> commands. If set to <code>true</code> , the method name is not included in these listings.
Name read only	Name of the method.
Sealed attribute, default = <code>false</code>	If <code>true</code> , the method cannot be redefined in a subclass. Attempting to define a method with the same name in a subclass causes an error.

Property	Purpose
Static attribute, default = false	<p>Set to <code>true</code> to define a method that does not depend on an object of the class and does not require an object argument. Call static methods using the class name in place of the object:</p> <pre><i>classname.methodname()</i></pre> <p>Or with an instance of the class, like any method:</p> <pre><i>o.methodname()</i></pre> <p>See “Static Methods”</p>

`meta.property` | `meta.event` | `meta.class` | `meta.method`

## meta.abstractDetails

**Package:** meta

Find abstract methods and properties

### Syntax

```
meta.abstractDetails(ClassName)
meta.abstractDetails(mc)
absMembers = meta.abstractDetails(___)
```

### Description

`meta.abstractDetails(ClassName)` displays a list of abstract methods and properties for the class with name `ClassName`. Use the fully specified name for classes in packages. MATLAB displays all public and protected abstract methods and properties, including those declared `Hidden`.

`meta.abstractDetails(mc)` displays a list of abstract methods and properties for the class represented by the `meta.class` object `mc`.

`absMembers = meta.abstractDetails( ___ )` returns an array of the metaclass objects corresponding to the abstract members of the class, and can include any of the input arguments in previous syntaxes. If the class has both abstract methods and abstract properties, `absMembers` is a heterogeneous array of class `meta.Metadata` containing `meta.method` and `meta.property` objects.

A class can be abstract without defining any abstract methods or properties if it declares the `Abstract` class attribute. In this case, `meta.abstractDetails` returns no abstract members for that class, but the class is abstract. See “Determine If a Class Is Abstract” for more information.

### Input Arguments

#### **ClassName**

Name of the class specified as a character string (for example, 'MyClass')

**mc**

meta.class object representing the class (for example, ?MyClass)

## Output Arguments

**absMembers**

Array of metaclass objects representing abstract class members

## Examples

### Display Abstract Member Names

Define the class, AbsBase, with an abstract property:

```
classdef AbsBase
 properties (Abstract)
 Prop1
 end
 methods(AbsBase)
 result = methodOne(obj)
 output = methodTwo(obj)
 end
end
```

Pass the class name (AbsBase) as a string:

```
meta.abstractDetails('AbsBase')
```

meta.abstractDetails displays the names of the abstract properties and methods defined in the class AbsBase.

```
Abstract methods for class AbsBase:
 methodTwo % defined in AbsBase
 methodOne % defined in AbsBase
```

```
Abstract properties for class AbsBase:
```

```
Prop1 % defined in AbsBase
```

## Return Abstract Member Metaclass Objects

Pass a `meta.class` object representing the `AbsBase` class and return the metaclass objects for the abstract members. Use the definition of the `AbsBase` class from the previous example.

```
mc = ?AbsBase;
absMembers = meta.abstractDetails(mc);
```

`absMembers` is a heterogeneous array containing a `meta.property` object for the `Prop1` abstract property and `meta.method` objects for the `methodOne` and `methodTwo` abstract methods.

List the names of the metaclass objects.

```
for k=1:length(absMembers)
 disp(absMembers(k).Name)
end
```

```
methodTwo
methodOne
Prop1
```

## Find Inherited Abstract Members

Derive the `SubAbsBase` class from `AbsBase`, which is defined in a previous example.

```
classdef SubAbsBase < AbsBase
 properties
 SubProp = 1;
 end
 methods
 function result = methodOne(obj)
 result = obj.SubProp + 1;
 end
 end
end
```

Display the names of the abstract members inherited by `SubAbsBase`.

```
meta.abstractDetails('SubAbsBase')
```

```
Abstract methods for class SubAbsBase:
```

```
methodTwo % defined in AbsBase
```

```
Abstract properties for class SubAbsBase:
 Prop1 % defined in AbsBase
```

To make SubAbsBase a concrete class, you need to implement concrete versions of methodTwo and Prop1 in the subclass.

`meta.class` | `meta.class.forName`

## **meta.package.fromName**

Return `meta.package` object for specified package

### **Syntax**

```
mpkg = meta.package.fromName('pkgname')
```

### **Description**

`mpkg = meta.package.fromName('pkgname')` is a static method that returns the `meta.package` object associated with the named package. If `pkgname` is a nested package, then you must provide the fully qualified name (e.g., `'pkgname1.pkgname2'`).

### **Examples**

List the classes in the `event` package:

```
mev = meta.package.fromName('event');
for k=1:length(mev.Classes)
 disp(mev.Classes{k}.Name)
end
event.EventData
event.PropertyEvent
event.listener
event.propListener
```

### **See Also**

`meta.package` | `meta.package.getAllPackages`

# meta.package.getAllPackages

Get all top-level packages

## Syntax

`P = meta.package.getAllPackages`

## Description

`P = meta.package.getAllPackages` is a static method that returns a cell array of `meta.package` objects representing all the top-level packages that are visible on the MATLAB path or defined as top-level built-in packages. You can access subpackages using the `Packages` property of each `meta.package` object.

Note that the time required to find all the packages on the path might be excessively long in some cases. You should therefore avoid using this method in any code where execution time is a consideration. `getAllPackages` is generally intended for interactive use only.

## See Also

`meta.package` | `meta.package.fromName`

## meta.property

Describe property of MATLAB class

### Description

The `meta.property` class provides information about the properties of MATLAB classes. The read/write properties of the `meta.property` class correspond to property attributes and are specified only from within your class definitions.

You can query the read-only properties of the `meta.property` object to obtain information that is specified syntactically by the class (for example, to obtain the function handle of a property's set access method).

You cannot instantiate a `meta.property` object directly. Obtain a `meta.property` object from the `meta.class` `PropertyList` property, which contains an array of `meta.property` objects, one for each class property. For example, replace `ClassName` with the name of the class whose properties you want to query:

```
mco = ?ClassName;
plist = mco.PropertyList;
plist(1).Name; % name of first property
```

Use the `metaclass` function to obtain a `meta.class` object from a class instance:

```
mco = metaclass(obj);
```

### Properties

Property	Purpose
Name read only	Name of the property.
Description read only	Currently not used
DetailedDescription read only	Currently not used
AbortSet attribute, default = false	If true, and this property belongs to a handle class, then MATLAB does not set the property value if the new

Property	Purpose
	<p>value is the same as the current value. This prevents the triggering of property <code>PreSet</code> and <code>PostSet</code> events.</p> <p>See “Listen for Changes to Property Values”</p>
<p><b>Abstract</b> attribute, default = <code>false</code></p>	<p>If <code>true</code>, the property has no implementation, but a concrete subclass must redefine this property without <b>Abstract</b> being set to <code>true</code>.</p> <ul style="list-style-type: none"> <li>• Abstract properties cannot define set or get access methods. See “Property Access Methods”</li> <li>• Abstract properties cannot define initial values. “Assigning a Default Value”</li> <li>• All subclasses must specify the same values as the superclass for the property <code>SetAccess</code> and <code>GetAccess</code> attributes.</li> <li>• <b>Abstract=true</b> should be used with the class attribute <code>Sealed=false</code> (the default).</li> </ul>
<p><b>Access</b></p>	<p><code>public</code> – unrestricted access</p> <p><code>protected</code> – access from class or subclasses</p> <p><code>private</code> – access by class members only (not subclasses)</p> <p>List of classes that have get and set access to this property. Specify classes as <code>meta.class</code> objects in the form:</p> <ul style="list-style-type: none"> <li>• A single <code>meta.class</code> object</li> <li>• A cell array of <code>meta.class</code> objects. An empty cell array, <code>{}</code>, is the same as <code>private</code> access.</li> </ul> <p>Use <b>Access</b> to set both <code>SetAccess</code> and <code>GetAccess</code> to the same value. Query the values of <code>SetAccess</code> and <code>GetAccess</code> directly (not <b>Access</b>).</p>

Property	Purpose
<p><b>Constant</b> attribute, default = <b>false</b></p>	<p>Set to <b>true</b> if you want only one value for this property in all instances of the class.</p> <ul style="list-style-type: none"> <li>• Subclasses inherit constant properties, but cannot change them.</li> <li>• <b>Constant</b> properties cannot be <b>Dependent</b></li> <li>• <b>SetAccess</b> is ignored.</li> </ul> <p>See “Properties with Constant Values”</p>
<p><b>DefaultValue</b></p>	<p>Property default value (if specified in class definition). See also <b>HasDefault</b> property. Abstract, dependent and dynamic properties cannot specify default values.</p>
<p><b>DefiningClass</b></p>	<p>The <b>meta.class</b> object representing the class that defines this property.</p>
<p><b>GetAccess</b> attribute, default = <b>public</b></p>	<p><b>public</b> – unrestricted access</p> <p><b>protected</b> – access from class or subclasses</p> <p><b>private</b> – access by class members only</p> <p>List classes that have get access to this property. Specify classes as <b>meta.class</b> objects in the form:</p> <ul style="list-style-type: none"> <li>• A single <b>meta.class</b> object</li> <li>• A cell array of <b>meta.class</b> objects. An empty cell array, {}, is the same as <b>private</b> access.</li> </ul> <p>See “Control Access to Class Members”</p>
<p><b>Dependent</b> attribute, default = <b>false</b></p>	<p>If <b>false</b>, property value is stored in object. If <b>true</b>, property value is not stored in object and the set and get functions cannot access the property by indexing into the object using the property name.</p> <p>See “Property Get Methods”</p>

Property	Purpose
Transient attribute, default = false	If <code>true</code> , property value is not saved when object is saved to a file. See “Save and Load Process” for more about saving objects.
GetMethod read only	Function handle of the get method associated with this property. Empty if there is no get method specified. See “Property Get Methods”
GetObservable attribute, default = false	If <code>true</code> , and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are queried. See “Property-Set and Query Events”
HasDefault	Property contains a boolean value indicating if the property defines a default value. Test <code>HasDefault</code> before querying the <code>DefaultValue</code> property to avoid a <code>MATLAB:class:NoDefaultDefined</code> error.
Hidden attribute, default = false	Determines whether the property should be shown in a property list (e.g., Property Inspector, call to <code>properties</code> , etc.).
NonCopyable attribute, default = false	Indicate if property value should be copied when object is copied.  For more information, see “Exclude Properties from Copy”

Property	Purpose
SetAccess attribute, default = public	<p><b>public</b> – unrestricted access</p> <p><b>protected</b> – access from class or subclasses</p> <p><b>private</b> – access by class members only</p> <p><b>immutable</b> — property can be set only in the constructor.</p> <p>See “Mutable and Immutable Properties”</p> <p>List classes that have set access to this property. Specify classes as <code>meta.class</code> objects in the form:</p> <ul style="list-style-type: none"> <li>• A single <code>meta.class</code> object</li> <li>• A cell array of <code>meta.class</code> objects. An empty cell array, <code>{}</code>, is the same as <code>private</code> access.</li> </ul> <p>See “Control Access to Class Members”</p>
SetMethod read only	Function handle of the set method associated with this property. Empty if there is no set method specified. See “Property Set Methods”
SetObservable attribute, default = false	If <code>true</code> , and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are modified. See “Property-Set and Query Events”

## Events

See “Listen for Changes to Property Values” for information on using property events.

Event Name	Purpose
PreGet	Event occurs just before property is queried.
PostGet	Event occurs just after property has been queried
PreSet	Event occurs just before this property is modified
PostSet	Event occurs just after this property has been modified

## More About

**Introduced in R2008a**

## metaclass

Obtain `meta.class` object

### Syntax

```
mc = metaclass(object)
mc = ?ClassName
```

### Description

`mc = metaclass(object)` returns the `meta.class` object for the class of `object`. The `object` input argument can be a scalar or an array of objects. However, `metaclass` always returns a scalar `meta.class` object.

`mc = ?ClassName` returns the `meta.class` object for the class with name, *ClassName*. The `?` operator works only with a class name, not an object.

If you pass a class name as a string to the `metaclass` function, it returns the `meta.class` object for the `char` class. Use the `?` operator or the `meta.class.fromName` method to obtain the `meta.class` object from a class name. Use this method if you want to pass the class name in a string variable.

### Examples

Return the `meta.class` object for an instance of the `MException` class:

```
obj = MException('Msg:ID', 'MsgTxt');
mc = metaclass(obj);
```

Use the `?` operator to get the `meta.class` object for the `matlab.mixin.SetGet` class:

```
mc = ?matlab.mixin.SetGet;
```

### See Also

`meta.class` | `meta.class.fromName`

# methods

Class method names

## Syntax

```
methods('classname')
methods(..., '-full')
m = methods(...)
```

## Description

`methods('classname')` displays the names of the methods for the class *classname*. If *classname* is a MATLAB or Java class, then `methods` displays only public methods, including those methods inherited from superclasses.

`methods(..., '-full')` displays a full description of the methods, including inheritance information and, for MATLAB and Java methods, method attributes and signatures. `methods` does not remove duplicate method names with different signatures. Do not use this option with classes defined before MATLAB 7.6.

`m = methods(...)` returns the method names in a cell array of strings.

`methods` is also a MATLAB class-definition keyword. See `classdef` for more information on class-definition keywords.

This function does not show generic methods from classes based on the Microsoft .NET Framework. Use your product documentation to get information on generic methods.

## Examples

Retrieve the names of the static methods in class `MException`:

```
methods('MException')
```

Methods for class `MException`:

addCause      getReport      ne      throw  
eq            isequal        rethrow     throwAsCaller

Static methods:

last

# methodsview

View class methods

## Syntax

```
methodsview packagename.classname
methodsview classname
methodsview(object)
```

## Description

`methodsview packagename.classname` displays information about the methods in the class, `classname`. If the class is in a package, include `packagename`. If `classname` is a MATLAB or Java class, `methodsview` lists only public methods, including those methods inherited from superclasses.

`methodsview classname` displays information describing the class `classname`.

`methodsview(object)` displays information about the methods of the class of `object`.

`methodsview` creates a window that displays the methods defined in the specified class. `methodsview` provides additional information like arguments, returned values, and superclasses. It also includes method qualifiers (for example, `abstract` or `synchronized`) and possible exceptions thrown.

## Examples

List information on all methods in the `java.awt.MenuItem` class:

```
methodsview java.awt.MenuItem
```

MATLAB displays this information in a new window.

## See Also

`methods` | `import` | `class` | `javaArray`

**Introduced before R2006a**

## mex

Build MEX function from C/C++ or Fortran source code

## Syntax

```
mex filenames
mex option1 ... optionN filenames
mex -setup lang
```

## Description

`mex filenames` compiles and links one or more C, C++, or Fortran source files into a binary MEX file, callable from MATLAB. `filenames` specify the source files. Also builds executable files for standalone MATLAB engine and MAT-file applications.

MATLAB automatically selects a compiler, if installed, based on the language of the `filenames` arguments.

`mex option1 ... optionN filenames` builds with the specified build options. The `option1 ... optionN` arguments supplement or override the default `mex` build configuration.

`mex -setup lang` selects a compiler for the given `lang`. Use this option when you want to change the default compiler for the given language.

## Examples

### Build C MEX File

Build a single C program, `yprime.c`, into a MEX file.

Each example is based on MEX examples in the `matlabroot/extern/examples` subfolders. To build the example code, copy the source file to a writable folder on your path, such as `c:\work`. Set the current folder to `c:\work`.

```
[s,msg,msgid] = mkdir('c:\work');
if (isempty(msgid))
```

```
 mkdir('c:\work')
end
cd c:\work
```

Copy the source code, `yprime.c`.

```
copyfile(fullfile(matlabroot,'extern','examples','mex','yprime.c'),'.','f')
```

Build the MEX file.

```
mex yprime.c
```

```
Building with 'Microsoft Visual C++ 2010 (C)'.
MEX completed successfully.
```

The output displays information specific to your compiler.

Test.

```
T=1;
Y=1:4;
yprime(T,Y)
```

```
ans =
 2.0000 8.9685 4.0000 -1.0947
```

## Display Detailed Build and Troubleshooting Information

To display the compile and link commands and other information useful for troubleshooting, use verbose mode.

```
mex -v -compatibleArrayDims yprime.c
```

The output displays information specific to your platform and compiler.

## Override Default Compiler Switch Option

Build the `yprime.c` MEX file by appending the value `-Wall` to the existing compiler flag. Because the value includes a space character, you must delineate the string; the character you use depends on the platform.

At the MATLAB prompt, use MATLAB single quotes (`'`).

```
mex -v COMPFLAGS='$COMPFLAGS -Wall' yprime.c
```

At the Windows Command Prompt, use double quotes (`"`).

```
mex -v COMPFLAGS="COMPFLAGS -Wall" yprime.c
```

At the shell command line on Mac and Linux, use single quotes (').

```
mex -v CFLAGS='$CFLAGS -Wall' yprime.c
```

### Build MEX File from Multiple Source Files

The MEX file example, `fulltosparse`, consists of two Fortran source files, `loadsparse.F` and `fulltosparse.F`.

To run this example, you need a supported Fortran compiler installed on your system.

Copy the source files to the current folder.

```
copyfile(fullfile(matlabroot, 'extern', 'examples', 'refbook', 'loadsparse.F'), '.', 'f')
copyfile(fullfile(matlabroot, 'extern', 'examples', 'refbook', 'fulltosparse.F'), '.', 'f')
```

Build the `fulltosparse` MEX file.

```
mex -largeArrayDims fulltosparse.F loadsparse.F
```

The MEX file name is `fulltosparse` because `fulltosparse.F` is the first file on the command line.

Test.

```
full = eye(5);
spar = fulltosparse(full)
```

```
spar =
 (1,1) 1
 (2,2) 1
 (3,3) 1
 (4,4) 1
 (5,5) 1
```

### Preview Build Commands

To preview the build command details without executing the commands, use the `-n` option.

```
mex -n yprime.c
```

The output displays information specific to your platform and compiler.

### Create and Link to Separate Object Files

You can link to object files that you compile separately from your source MEX files.

The MEX file example, `fulltosparse`, consists of two Fortran source files, `loadsparse.F` and `fulltosparse.F`. The `fulltosparse` file is the gateway routine (contains the `mexFunction` subroutine) and `loadsparse` contains the computational routine.

To run this example, you need a supported Fortran compiler installed on your system.

Copy the computational subroutine to your current folder.

```
copyfile(fullfile(matlabroot, 'extern', 'examples', 'refbook', 'loadsparse.F'), '.', 'f')
```

Compile the subroutine and place the object file in a separate folder, `c:\objfiles`.

```
mkdir c:\objfiles
mex -largeArrayDims -c -outdir c:\objfiles loadsparse.F
```

Copy the gateway subroutine to your current folder. Compile and link with the `loadsparse` object file.

```
copyfile(fullfile(matlabroot, 'extern', 'examples', 'refbook', 'fulltosparse.F'), '.', 'f')
mex -largeArrayDims fulltosparse.F c:\objfiles\loadsparse.obj
```

### **Specify Path to Include File**

To specify the path to include the MATLAB LAPACK library subroutines for handling complex number routines, use the `-I` option. To use these subroutines, your MEX file must access the header file, `fort.h`.

Copy the `matrixDivideComplex.c` example to the current folder.

```
copyfile(...
fullfile(matlabroot, 'extern', 'examples', 'refbook', 'matrixDivideComplex.c'), '.', 'f')
```

Create the `-I` argument by concatenating `'-I'` with the path to `fort.h` file.

```
ipath = ['-I' fullfile(matlabroot, 'extern', 'examples', 'refbook')];
```

Create variables for the names and paths to the LAPACK library file and the file, `fort.c`, containing the complex number handling routines.

```
lapacklib = fullfile(...
 matlabroot, 'extern', 'lib', computer('arch'), 'microsoft', 'libmwlapack.lib');
fortfile = fullfile(...
 matlabroot, 'extern', 'examples', 'refbook', 'fort.c');
```

Build the MEX file.

```
mex('-v','-largeArrayDims',ipath,'matrixDivideComplex.c',fortfile,lapacklib)
```

### Specify Path to Library File

Build the `matrixDivide.c` example on a Windows platform using the `-L` and `-l` options to specify the `libmwlpack.lib` library. The library file is located in the folder, `matlabroot\extern\lib\arch\microsoft`.

Copy the `matrixDivide.c` example to the current folder.

```
copyfile(fullfile(matlabroot,'extern','examples','refbook','matrixDivide.c'),'.','f')
```

Capture the value of `matlabroot`.

```
matlabroot
```

```
ans =
```

```
C:\Program Files\MATLAB\R2014a
```

Capture the value of `arch`.

```
computer('arch')
```

```
ans =
```

```
win64
```

To build the MEX file, copy the values of `matlabroot` and `arch` into the `mex` command, as shown in the following statement.

```
mex -largeArrayDims '-LC:\Program Files\MATLAB\R2014a\extern\lib\win64\microsoft'...
-lmwlpack matrixDivide.c
```

You must use the `'` characters because `\Program Files` in the path includes a space.

### Define Directive

Define the character to use between strings in a matrix.

The MATLAB example, `mxcreatecharmatrixfromstr.c`, uses a `#define` symbol, `SPACE_PADDING`, to determine what character to use between strings in a matrix. To set the value, build the MEX file with the `-D` option.

Copy the `mxcreatecharmatrixfromstr.c` example to the current folder.

```
copyfile(fullfile(matlabroot,'extern','examples','mx','mxcreatecharmatrixfromstr.c'),'f')
```

Set the `SPACE_PADDING` directive to add a space between strings.

```
mex mxcreatecharmatrixfromstr.c -DSPACE_PADDING
```

## Build Engine Application

Copy the `engwindemo.c` engine example to the current folder.

```
copyfile(fullfile(matlabroot, 'extern', 'examples', 'eng_mat', 'engwindemo.c'), '.', 'f')
```

```
mex -client engine engwindemo.c
```

Run the example.

```
!engwindemo
```

## Select C Compiler

```
mex -setup
```

MATLAB displays the options for your version and system based on the list of Supported and Compatible Compilers.

- “Table of MEX File Source Code Files”

## Input Arguments

### **filenames** — One or more file names

string

One or more file names, including name and file extension, specified as a string. If the file is not in the current folder, specify the full path to the file. File names can be any combination of:

- C, C++, or Fortran language source files
- Simulink S-function files
- object files
- library files

The first source code file listed in `filenames` is the name of the binary MEX file. To override this naming convention, use the `'-output'` option.

Data Types: char

**option1 ... optionN — One or more build options**

strings corresponding to valid option flags

One or more build options, specified as one of these values. Options can appear in any order on any platform, except where indicated.

Option	Description
<code>@rspfile</code>	Uses Windows RSP file. An RSP file is a text file containing command-line options.
<code>-c</code>	Compiles an object file only. Does not build a binary MEX-file.
<code>-client engine</code>	Build engine application.
<code>-compatibleArrayDims</code> (default) <code>-largeArrayDims</code>	<p>Links with the specified MATLAB array-handling API.</p> <ul style="list-style-type: none"> <li><code>-compatibleArrayDims</code> — Uses the MATLAB Version 7.2 array-handling API, which limits arrays to <math>2^{31}-1</math> elements. Default option.</li> <li><code>-largeArrayDims</code> — Uses the MATLAB large-array-handling API. This API handles arrays with more than <math>2^{31}-1</math> elements. Must use this option when calling LAPACK or BLAS functions.</li> </ul> <p>In verbose mode (<code>-v</code> option), if you do not specify either the <code>-compatibleArrayDims</code> or the <code>-largeArrayDims</code> option, MATLAB displays a message showing the default option.</p>
<code>-Dsymbolname</code> <code>-</code> <code>Dsymbolname=symbolvalue</code> <code>-Usymbolname</code>	<p>The <code>-D</code> options define C preprocessor macros. Equivalent to the following in the source file:</p> <ul style="list-style-type: none"> <li><code>#define symbolname</code></li> <li><code>#define symbolname symbolvalue</code></li> </ul> <p>The <code>-U</code> option removes any initial definition of the C preprocessor macro, <code>symbolname</code>. Inverse of the <code>-D</code> option.</p> <p>Do not add a space between <b>D</b> or <b>U</b> and <code>symbolname</code>. Do not add spaces around the <code>=</code> sign.</p>

Option	Description
	Example: “Define Directive” on page 1-5625
<b>-f</b> <i>filepath</i>	To build engine applications, use the <b>-client engine</b> option.  Specifies name and location of the <code>mex</code> configuration file. Overrides the default compiler selection. For information about using a non-default compiler, see “Change Default Compiler”. <i>filepath</i> is the name and full path of the configuration file, specified as a string.
<b>-g</b>	Adds symbolic information and disables optimizing built object code. Use for debugging. To debug with optimization, add the <b>-O</b> option.
<b>-h[elp]</b>	Displays help for <code>mex</code> . Use from an operating system prompt.
<b>-I</b> <i>pathname</i>	Adds <i>pathname</i> to the list of folders to search for <code>#include</code> files.  Do not add a space between <b>I</b> and <i>pathname</i> .  Example: “Specify Path to Include File” on page 1-5624

Option	Description
<p><code>-llibname</code>  <code>-Llibfolder -llibname</code></p>	<p>Links with object library <i>libname</i> in (optional) <i>libfolder</i>.</p> <p>MATLAB expands <i>libname</i> to:</p> <ul style="list-style-type: none"> <li>• <i>libname.lib</i> or <i>liblibname.lib</i> — Windows systems</li> <li>• <i>liblibname.dylib</i> — Mac systems</li> <li>• <i>liblibname.so</i> — Linux systems</li> </ul> <p>If used, the <code>-L</code> option must precede the <code>-l</code> option. When using the <code>-L</code> option on Linux or Mac systems, you also must set the runtime library path, as explained in “Setting Run-Time Library Path”.</p> <p>Do not add a space between <code>l</code> and <i>libname</i> or between <code>L</code> and <i>libfolder</i>.</p> <p>Specify the <code>-l</code> option with the lowercase letter <code>L</code>.</p> <p>Example: “Specify Path to Library File” on page 1-5625</p>
<p><code>-largeArrayDims</code>  <code>-compatibleArrayDims</code>            (default)</p>	<p>Links with the specified MATLAB array-handling API.</p> <ul style="list-style-type: none"> <li>• <code>-compatibleArrayDims</code> — Uses the MATLAB Version 7.2 array-handling API, which limits arrays to <math>2^{31}-1</math> elements. Default option.</li> <li>• <code>-largeArrayDims</code> — Uses the MATLAB large-array-handling API. This API handles arrays with more than <math>2^{31}-1</math> elements. Must use this option when calling LAPACK or BLAS functions.</li> </ul> <p>In verbose mode (<code>-v</code> option), if you do not specify either the <code>-compatibleArrayDims</code> or the <code>-largeArrayDims</code> option, MATLAB displays a message showing the default option.</p>

Option	Description
-n	Displays, but does not execute, commands that <code>mex</code> would execute.  Example: “Preview Build Commands” on page 1-5623
-O	Optimizes the object code. Use this option to compile with optimization.  Optimization is enabled by default. Optimization is disabled when the <code>-g</code> option appears without the <code>-O</code> option.  Specify this option with the capital letter <b>O</b> .
-outdir <i>dirname</i>	Places all output files in folder <i>dirname</i> .  Example: “Create and Link to Separate Object Files” on page 1-5623
-output <i>mexname</i>	Overrides the default MEX-file naming mechanism. Creates binary MEX-file named <i>mexname</i> with the appropriate MEX-file extension.
-setup <i>lang</i>	Change the default compiler to build <i>lang</i> language MEX-files. When you use this option, all other command-line options are ignored.
-silent	Suppresses informational messages. The <code>mex</code> function still reports errors and warnings, even when you specify <code>-silent</code> .
-U <i>symbolname</i>	Removes any initial definition of the C preprocessor macro <i>symbolname</i> . (Inverse of the <code>-D</code> option.)  Do not add a space between <b>U</b> and <i>symbolname</i> .
-v	Builds in verbose mode. Displays values for internal variables after all command-line arguments are considered. Displays each compile and link step fully evaluated. Use for troubleshooting compiler setup problems.  Example: “Display Detailed Build and Troubleshooting Information” on page 1-5622

Option	Description
<code>varname=varvalue</code>	Overrides default setting for variable <i>varname</i> . This option is processed after all command-line arguments are considered.  Example: “Override Default Compiler Switch Option” on page 1-5622.

### lang — Language

C (default) | C++ | CPP | Fortran

Language, specified as one of these values.

C	C compilers, including C++.
C++ or CPP	C++ compilers.
Fortran	Fortran compilers.

## More About

### Tips

- You can run `mex` from:
  - MATLAB Command Window
  - Windows system prompt
  - Mac Terminal
  - Linux shell

For command-line usage outside of MATLAB, the `mex` program is located in the folder specified by `[matlabroot '/bin']`.

- The MEX file has a platform-dependent extension. You can place binary MEX files for different platforms in the same folder.

### MEX-File Platform-Dependent Extension

Platform	Binary MEX-File Extension
Linux (64-bit)	<code>mexa64</code>

<b>Platform</b>	<b>Binary MEX-File Extension</b>
Apple Mac (64-bit)	mexmaci64
Microsoft Windows (32-bit)	mexw32
Windows (64-bit)	mexw64

To identify the MEX file extension, use the `mexext` function.

- To use `mex` to build executable files for standalone MATLAB engine and MAT-file applications, use the `-client engine` option.
  - “Build MEX File”
  - “Change Default Compiler”
  - “Troubleshoot MEX Files”
  - Supported and Compatible Compilers

# mex.getCompilerConfigurations

Get compiler configuration information for building MEX-files

## Syntax

```
cc = mex.getCompilerConfigurations
cc = mex.getCompilerConfigurations(lang)
cc = mex.getCompilerConfigurations(lang,list)
```

## Description

`cc = mex.getCompilerConfigurations` returns an object `CC` containing information about the default compiler configurations used by the `mex` command. There is one configuration for each supported language.

`cc = mex.getCompilerConfigurations(lang)` returns an array of objects for the given language, `lang`.

`cc = mex.getCompilerConfigurations(lang,list)` returns information about the set of configurations, `list`.

## Examples

### Display Information for C Compiler

```
myCCompiler = mex.getCompilerConfigurations('C','Selected')
```

```
myCCompiler =
```

```
 CompilerConfiguration with properties:
```

```
 Name: 'Microsoft Visual C++ 2010 (C)'
 Manufacturer: 'Microsoft'
 Language: 'C'
 Version: '10.0'
 Location: 'c:\Program Files (x86)\Microsoft Visual Studio 10.0'
 ShortName: 'MSVC100'
```

```
Priority: 'A'
Details: [1x1 mex.CompilerConfigurationDetails]
LinkerName: 'link'
LinkerVersion: ''
MexOpt: 'C:\Users\user\AppData\Roaming\MathWorks\MATLAB\R2014a\mex_C_win64'
```

MATLAB displays information depending on your architecture and your version of MATLAB.

### Display Number of Supported C Compilers

```
cLanguageCC = mex.getCompilerConfigurations('C', 'Supported');
length(cLanguageCC)
```

```
ans =
 10
```

The number of compilers for your version of MATLAB might be different.

## Input Arguments

### **lang** — Language

'Any' (default) | 'C' | 'C++' | 'CPP' | 'Fortran'

Language, specified as one of these values.

'Any'	Default value. All supported languages.
'C'	All C compiler configurations, including C++ configurations.
'C++' or 'CPP'	All C++ compiler configurations.
'Fortran'	All Fortran compiler configurations.

### **list** — Set of configurations

'Selected' (default) | 'Installed' | 'Supported'

Set of configurations, specified as one of these values.

'Selected'	The default compiler for each language.
'Installed'	All supported compilers <code>mex</code> finds installed on your system.

'Supported'

All compilers supported in the current release.

## Output Arguments

### cc — Compiler information

mex.CompilerConfiguration object or array of objects

Compiler information, specified as a mex.CompilerConfiguration object or array of mex.CompilerConfiguration objects. The mex.CompilerConfiguration class contains the following read-only properties.

Property	Purpose
Name	Compiler name.
ShortName	Character string used to identify options file for the compiler.
Manufacturer	Name of the manufacturer of the compiler.
Language	Compiler language.
Version	(Windows platforms only) Version of the compiler.
Location	(Windows platforms only) Folder where compiler is installed.
Details	More read-only properties about the compiler configuration. These properties depend on the compiler, platform, and release of MATLAB.
LinkerName	Linker name.
LinkerVersion	(Windows platforms only) Version of the linker.
MexOpt	Name and full path to options file.
Priority	The priority of this compiler.

Capture error information

## Description

Any MATLAB code that detects an error and throws an exception must construct an `MException` object. This class contains retrievable information about errors. MATLAB can throw either predefined exceptions or exceptions that you construct.

## Construction

`ME = MException(msgID,msgtext)` captures information about a specific error and stores it in the `MException` object, `ME`. The `MException` object is constructed with a message identifier, `msgID`, and an error message string, `msgtext`.

`ME = MException(msgID,msgtext,A1,...,An)` allows formatting of the error message string using text or numeric values, `A1,...,An`, to replace conversion specifiers in `msgtext` at run time.

## Input Arguments

### **msgID** — Identifier for error

string

Identifier for the error, specified as a string. Use the message identifier with exception handling to better identify the source of the error or to control a selected subset of the exceptions in your program.

The message identifier includes a component and mnemonic. The identifier must always contain a colon and follows a simple format: `component:mnemonic`. The component and mnemonic fields must each begin with a letter. The remaining characters can be alphanumeric (A–Z, a–z, 0–9) and underscores. No white space characters can appear anywhere in `msgID`. For more information, see “Message Identifiers”.

Example: `'MyComponent:noSuchVariable'`

**msgtext — Information about cause of error**

string

Information about the cause of the error and how you might correct it, specified as a string. To format the string, use escape sequences, such as `\t` or `\n`. You also can use any format specifiers supported by the `sprintf` function, such as `%s` or `%d`. Specify values for the conversion specifiers via the `A1, . . . , An` input arguments. For more information, see “Formatting Strings”.

Example: 'Error opening file.'

Example: 'Error on line %d.'

**A1, . . . , An — Numeric or character arrays**

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array. This input argument provides the values that correspond to and replace the conversion specifiers in `msgtext`.

## Properties

**identifier — Unique identifier of error**

string

String that uniquely identifies the error, specified as a string by the `msgID` input argument. This property is read only. For more information, see “Message Identifiers”.

**message — Error message**

string

String that contains the error message that is displayed when MATLAB throws the exception, specified by the `msgtext` and `A1, . . . , An` input arguments. This property is read only. For more information, see “Text of the Error Message”.

**stack — Stack trace information**

array of structures

Structure array that contains stack trace information including the file name (`file`), function name (`name`), and line number (`line`) where MATLAB throws the exception. If the error occurs in a called function, the `stack` property also contains the file name,

function name, and line number for each of the called functions. MATLAB generates the stack only when it throws the exception.

`stack` is an N-by-1 `struct` array, where N represents the depth of the call stack. This property is read only. For more information, see “The Call Stack”.

### **cause** — Cause of the exception

cell array of `MException` objects

Cell array of `MException` objects that caused MATLAB to create this exception. Use the `addCause` method to add an exception to the `cause` field of the another exception. For more information, see “The Cause Array”.

## Methods

<code>addCause</code>	Record additional causes of exception
<code>getReport</code>	Get error message for exception
<code>last</code>	Return last uncaught exception
<code>rethrow</code>	Rethrow previously caught exception
<code>throw</code>	Throw exception
<code>throwAsCaller</code>	Throw exception as if occurs within calling function

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Create `MException` Object

```
msgID = 'myComponent:inputError';
msgtext = 'Input does not have the expected format.';
```

```
ME = MException(msgID,msgtext)
```

```
ME =
```

```
MException with properties:
```

```
 identifier: 'myComponent:inputError'
 message: 'Input does not have the expected format.'
 cause: {}
 stack: [0x1 struct]
```

## Create MException with Formatted Error Message

```
msgID = 'MATLAB:test';
msgtext = 'There are %d errors on this page';
A1 = 10;
```

```
ME = MException(msgID,msgtext,A1)
```

```
ME =
```

```
MException with properties:
```

```
 identifier: 'MATLAB:test'
 message: 'There are 10 errors on this page'
 cause: {}
 stack: [0x1 struct]
```

## Create and Throw MException Object

Throw an exception if an input variable name does not exist in the workspace.

```
str = input('Type a variable name: ','s');
if ~exist(str,'var')
 ME = MException('MyComponent:noSuchVariable', ...
 'Variable %s not found',str);
 throw(ME)
end
```

At the input prompt, enter any variable that does not exist in your workspace. For example, enter `notaVariable`.

Variable notVariable not found

Since `notVariable` doesn't exist in your workspace, MATLAB creates an `MException` object, and then throws it.

### Use try/catch to Capture Exception

Catch the exception generated by calling a nonexistent function, `notaFunction`. If the function is not defined, issue a warning and assign the output a value of 0.

```
try
 a = notaFunction(5,6);
catch ME
 if strcmp(ME.identifier,'MATLAB:UndefinedFunction')
 warning('Function is undefined. Assigning a value of 0.');
```

```
 else
 rethrow(ME)
 end
end
```

Warning: Function is undefined. Assigning a value of 0.

By itself, the call to `notaFunction` results in an error. Using `try` and `catch`, this code catches the undefined function exception and repackages it as a warning, allowing MATLAB to continue executing subsequent commands. If the caught exception has a different error identifier, MATLAB rethrows the exception.

| `error` | `try`, `catch`

**Introduced in R2007b**

## addCause

**Class:** MException

Record additional causes of exception

### Syntax

```
baseException = addCause(baseException, causeException)
```

### Description

`baseException = addCause(baseException, causeException)` modifies the existing `MException` object `baseException` by appending `causeException` to its `cause` property. Catching the resulting exception in a `try/catch` statement makes the base exception, along with all of the appended cause records, available to help diagnose the error.

### Input Arguments

**baseException** — Primary exception

MException object

Primary exception containing the primary cause and location of an error, specified as an `MException` object.

**causeException** — Related exception

MException object

Related exception containing the cause and location of an error related to `baseException`, specified as an `MException` object.

### Examples

**Add Causes to Exception**

Create an array, and an index into it with a logical array.

```
A = [13 42; 7 20];
idx = [1 0 1; 0 1 0];
```

Create an exception that provides general information about an error. Test the index array and add exceptions with more detailed information about the source of the failure.

```
try
 A(idx);
catch
 msgID = 'MYFUN:BadIndex';
 msg = 'Unable to index into array.';
 baseException = MException(msgID,msg);

 try
 assert(islogical(idx),'MYFUN:notLogical',...
 'Indexing array is not logical.')
 catch causeException
 baseException = addCause(baseException,causeException);
 end

 if any(size(idx) > size(A))
 msgID = 'MYFUN:incorrectSize';
 msg = 'Indexing array is too large.';
 causeException2 = MException(msgID,msg);
 baseException = addCause(baseException,causeException2);
 end
 throw(baseException)
end
```

```
Unable to index into array.
```

```
Caused by:
 Indexing array is not logical.
 Indexing array is too large.
```

Examine the `baseException` object.

```
baseException
```

```
baseException =
```

```
MException with properties:
```

```
 identifier: 'MYFUN:BadIndex'
 message: 'Unable to index into array.'
```

```
cause: {2x1 cell}
stack: [0x1 struct]
```

The value of the `cause` property is a 2x1 cell array.

Examine the first cause of the exception.

```
baseException.cause{1}
```

```
ans =
```

```
MException with properties:
```

```
 identifier: 'MYFUN:notLogical'
 message: 'Indexing array is not logical.'
 cause: {0x1 cell}
 stack: [0x1 struct]
```

Examine the second cause of the exception.

```
baseException.cause{2}
```

```
ans =
```

```
MException with properties:
```

```
 identifier: 'MYFUN:incorrectSize'
 message: 'Indexing array is too large.'
 cause: {}
 stack: [0x1 struct]
```

**Introduced in R2007b**

# getReport

**Class:** MException

Get error message for exception

## Syntax

```
msgString = getReport(exception)
msgString = getReport(exception,type)
msgString = getReport(exception,type,'hyperlinks',hlink)
```

## Description

`msgString = getReport(exception)` gets the error message for an exception and returns it as a formatted string, `msgString`. The message string is the value of the `message` property of the `MException` object, `exception`. It is the same string that MATLAB displays when it throws the exception.

`msgString = getReport(exception,type)` returns the error message using the indicated level of detail, specified by `type`.

`msgString = getReport(exception,type,'hyperlinks',hlink)` uses the value of `hlink` to determine whether to include active hyperlinks to the failing lines of code within the error message.

## Input Arguments

**exception** — Exception object that provides error message

MException object

Exception object that provides the error message, specified as a scalar `MException` object.

**type** — Detail indicator of message string

'extended' (default) | 'basic'

Detail indicator of the message string returned, specified as 'extended' or 'basic'.

type Value	msgString Detail Level
'extended' (default)	msgString includes the line number, error message, cause, and stack summary. To display the proper stack, MATLAB first must throw an exception.
'basic'	msgString includes the error message.

**hlink — Hyperlink indicator of message string**

'on' (default) | 'off' | 'default'

Hyperlink indicator of the message string that includes active hyperlinks to the failing lines of code, specified as 'on', 'off', or 'default'.

hlink Value	Action
'on'	Display hyperlinks to failing lines of code.
'off'	Do not display hyperlinks to failing lines of code.
'default'	Use the default for the Command Window to determine whether or not to use hyperlinks in the error message.

## Examples

**Get Error Message from Exception**

Cause MATLAB to throw an exception.

```
plus
```

```
Error using ±
Not enough input arguments.
```

Get the error message from the exception.

```
exception = MException.last;
msgString = getReport(exception)
```

```
msgString =
```

```
Error using ±
```

Not enough input arguments.

### Specify Detail Level in Error Message

In a file in your current working folder, create the following function in `testFunc.m`.

```
function a = testFunc
try
 a = notaFunction(5,6);
catch a

end
```

Since the function, `notaFunction`, does not exist, `testFunc` returns an `MException` object.

At the command prompt, call `testFunc` and get the error message.

```
m = testFunc;
msgString = getReport(m)

msgString =

Undefined function 'notaFunction' for input arguments of type 'double'.

Error in testFunc (line 3)
 a = notaFunction(5,6);
```

Specify that the error message only contains the error message and not the stack information.

```
msgString = getReport(m,'basic')

msgString =

Undefined function 'notaFunction' for input arguments of type 'double'.
```

### Turn Off Hyperlinks in Error Message

Cause MATLAB to throw an exception.

```
try
 surf
catch exception
end
```

Get the error message from the exception.

```
msgString = getReport(exception)
```

```
msgString =
```

```
Error using surf (line 49)
Not enough input arguments.
```

Get the error message without active hyperlinks to `surf.m`.

```
msgString = getReport(exception, 'extended', 'hyperlinks', 'off')
```

```
msgString =
```

```
Error using surf (line 49)
Not enough input arguments.
```

**Introduced in R2007b**

# MException.last

**Class:** MException

Return last uncaught exception

## Syntax

```
exception = MException.last
MException.last('reset')
```

## Description

`exception = MException.last` returns the contents of the most recently thrown, uncaught MException object. `MException.last` is not set if the last exception is caught by a try/catch statement. `MException.last` is a static method of the MException class.

`MException.last('reset')` clears the properties of the exception returned from `MException.last`. It sets the `MException.identifier` and `message` properties to an empty string, the `stack` property to a 0-by-1 structure, and the `cause` property to an empty cell array.

## Tips

- Use `MException.last` only from the Command Window, not within a function.

## Examples

### Get Last Uncaught Exception

Cause MATLAB to throw, but not catch, an exception.

```
A = 25;
A(2)
```

Index exceeds matrix dimensions.

Get the uncaught exception.

```
exception = MException.last
```

```
exception =
```

```
 MException with properties:
```

```
 identifier: 'MATLAB:badsubscript'
 message: 'Index exceeds matrix dimensions.'
 cause: {}
 stack: [0x1 struct]
```

## **Reset Last Uncaught Exception**

Call the `surf` function with no input arguments.

```
surf
```

```
Error using surf (line 49)
Not enough input arguments.
```

Get the uncaught exception.

```
exception = MException.last
```

```
exception =
```

```
 MException with properties:
```

```
 identifier: 'MATLAB:nargchk:notEnoughInputs'
 message: 'Not enough input arguments.'
 cause: {0x1 cell}
 stack: [1x1 struct]
```

Get the last, uncaught exception.

```
MException.last('reset')
exception = MException.last
```

```
exception =
```

```
 MException with properties:
```

```
identifier: ''
message: ''
cause: {0x1 cell}
stack: [0x1 struct]
```

## See Also

MException.throw | MException.throwAsCaller | MException | assert | error |  
try, catch

**Introduced in R2007b**

## rethrow

**Class:** MException

Rethrow previously caught exception

### Syntax

```
rethrow(exception)
```

### Description

`rethrow(exception)` rethrows a previously caught exception, `exception`. MATLAB typically responds to errors by terminating the currently running program. However, you can use a `try/catch` block to catch the exception. This interrupts the program termination so you can execute your own error handling procedures. End the `catch` block with a `rethrow` statement to terminate the program and redisplay the exception.

`rethrow` handles the stack trace differently from `error`, `assert`, and `throw`. Instead of creating the stack from where MATLAB executes the method, `rethrow` preserves the original exception information and enables you to retrace the source of the original error.

### Input Arguments

**exception** — Exception containing cause and location of error

MException object

Exception containing the cause and location of an error, specified as a scalar MException object.

### Examples

#### Catch and Rethrow Exception

Cause MATLAB to throw an error by calling `surf` with no inputs. Catch the exception, display the error identifier, and rethrow the exception.

```

try
 surf
catch ME
 disp(['ID: ' ME.identifier])
 rethrow(ME)
end

```

```

ID: MATLAB:nargchk:notEnoughInputs
Error using surf (line 49)
Not enough input arguments.

```

### Compare Behavior of throw and rethrow

Create a function, `combineArrays`, in your working folder.

```

function C = combineArrays(A,B)
try
 C = catAlongDim1(A,B); % Line 3
catch exception
 throw(exception) % Line 5
end
end

function V = catAlongDim1(V1,V2)
V = cat(1,V1,V2); % Line 10
end

```

Call the `combineArrays` function with arrays of different sizes.

```

A = 1:5;
B = 1:4;

```

```
combineArrays(A,B)
```

```

Error using combineArrays (line 5)
Dimensions of matrices being concatenated are not consistent.

```

The stack refers to line 5 where MATLAB throws the exception.

Replace `throw(exception)` with `rethrow(exception)` on line 5 of the `combineArrays` function, and call the function again.

```
combineArrays(A,B)
```

```
Error using cat
```

Dimensions of matrices being concatenated are not consistent.

```
Error in combineArrays>catAlongDim1 (line 10)
```

```
V = cat(1,V1,V2); % Line 10
```

```
Error in combineArrays (line 3)
```

```
 C = catAlongDim1(A,B); % Line 3
```

The `rethrow` method maintains the original stack and indicates the error is on line 3.

**Introduced in R2007b**

# throw

**Class:** MException

Throw exception

## Syntax

```
throw(exception)
```

## Description

`throw(exception)` throws an exception based on the information contained in the `MException` object, `exception`. The exception terminates the currently running function and returns control either to the keyboard or to an enclosing `catch` block. When you throw an exception from outside a `try/catch` statement, MATLAB displays the error message in the Command Window.

The `throw` method, unlike the `throwAsCaller` and `rethrow` methods, creates the stack trace from the location where MATLAB executes the method.

You can access the `MException` object via a `try/catch` statement or the `MException.last` method.

## Input Arguments

**exception** — Exception containing cause and location of error

`MException` object

Exception containing the cause and location of an error, specified as a scalar `MException` object.

## Examples

### Create and Throw MException Object

Throw an exception if an input variable name does not exist in the workspace.

```
str = input('Type a variable name: ','s');
if ~exist(str,'var')
 ME = MException('MyComponent:noSuchVariable', ...
 'Variable %s not found',str);
 throw(ME)
end
```

At the input prompt, enter any variable that does not exist in your workspace. For example, enter `notaVariable`.

```
Variable notaVariable not found
```

Since `notaVariable` doesn't exist in your workspace, MATLAB creates an `MException` object, and then throws it.

### Compare Behavior of `throw` and `rethrow`

Create a function, `combineArrays`, in your working folder.

```
function C = combineArrays(A,B)
try
 C = catAlongDim1(A,B); % Line 3
catch exception
 throw(exception) % Line 5
end
end

function V = catAlongDim1(V1,V2)
V = cat(1,V1,V2); % Line 10
end
```

Call the `combineArrays` function with arrays of different sizes.

```
A = 1:5;
B = 1:4;
```

```
combineArrays(A,B)
```

```
Error using combineArrays (line 5)
Dimensions of matrices being concatenated are not consistent.
```

The stack refers to line 5 where MATLAB throws the exception.

Replace `throw(exception)` with `rethrow(exception)` on line 5 of the `combineArrays` function, and call the function again.

```
combineArrays(A,B)
```

```
Error using cat
Dimensions of matrices being concatenated are not consistent.
```

```
Error in combineArrays>catAlongDim1 (line 10)
V = cat(1,V1,V2); % Line 10
```

```
Error in combineArrays (line 3)
 C = catAlongDim1(A,B); % Line 3
```

The `rethrow` method maintains the original stack and indicates the error is on line 3.

## See Also

`MException` | `MException.rethrow` | `MException.throwAsCaller` |  
`MException.addCause` | `MException.getReport` | `MException.last` | | `error` | `try`,  
`catch`

**Introduced in R2007b**

## throwAsCaller

**Class:** MException

Throw exception as if occurs within calling function

### Syntax

```
throwAsCaller(exception)
```

### Description

`throwAsCaller(exception)` throws an exception as if it occurs within the calling function. The exception terminates the currently running function and returns control to the keyboard or an enclosing `catch` block. When you throw an exception from outside a `try/catch` statement, MATLAB displays the error message in the Command Window.

You can access the `MException` object via a `try/catch` statement or the `MException.last` method.

In some cases, it is more informative for the error to point to the location in the calling function that results in the exception rather than pointing to the function that actually throws the exception. You can use `throwAsCaller` to simplify the error display.

### Input Arguments

**exception** — Exception containing cause and location of error

MException object

Exception containing the cause and location of an error, specified as a scalar `MException` object.

### Examples

#### Compare Behavior of `throw` and `throwAsCaller`

Create a function, `sayHello`, in your working folder.

```
function sayHello(N)
 checkInput(N)
 str = ['Hello, ' N '!'];
 disp(str)

function checkInput(N)
if ~ischar(N)
 ME = MException('sayHello:inputError','Input must be char. ');
 throw(ME)
end
```

At the command prompt, call the function with a numeric input.

```
sayHello(42)
```

```
Error using sayHello>checkInput (line 9)
Input must be char.
```

```
Error in sayHello (line 2)
checkInput(N)
```

The top of the stack refers to line 9 because this is where MATLAB throws the exception. After the initial stack frame, MATLAB displays information from the calling function.

Replace `throw(ME)` with `throwAsCaller(ME)` in line 9 of `sayHello.m` and call the function again.

```
sayHello(42)
```

```
Error using sayHello (line 2)
Input must be char.
```

The top of the stack refers to line 2 because that is the location of the error in the calling function.

## mexext

Binary MEX-file-name extension

### Syntax

```
ext = mexext
extlist = mexext('all')
```

### Description

`ext = mexext` returns the file-name extension for the current platform.

`extlist = mexext('all')` returns the extensions for all platforms.

### Examples

#### Display File Extension for Your Computer

Find the MEX-file extension for the system you are currently working on.

```
ext = mexext
ext =
 mexw32
```

Your results reflect your system.

#### Find File Extension for Specific Platform

Find the MEX-file extension for the Apple Macintosh systems.

Get the list for supported platforms.

```
extlist = mexext('all');
```

The `mex` function identifies a platform by its `arch` value, which is the output of the `computer('arch')` command. For Macintosh platforms, the value is `maci64`.

Search the `arch` field in the results, `extlist`, for `'maci64'`, and display the corresponding `ext` field.

```
for k=1:length(extlist)
 if strcmp(extlist(k).arch, 'maci64')
 disp(sprintf('Arch: %s Ext: %s', ...
 extlist(k).arch, extlist(k).ext))
 end, end
```

```
Arch: maci64 Ext: mexmaci64
```

The file extension is `mexmaci64`.

## Output Arguments

### **ext** — File-name extension

`mexa64` | `mexmaci64` | `mexw32` | `mexw64`

File-name extension for MEX-file, returned as one of these values.

### **MEX-File Platform-Dependent Extension**

Platform	Binary MEX-File Extension
Linux (64-bit)	<code>mexa64</code>
Apple Mac (64-bit)	<code>mexmaci64</code>
Microsoft Windows (32-bit)	<code>mexw32</code>
Windows (64-bit)	<code>mexw64</code>

### **extlist** — All file-name extensions

structure

All file-name extensions, returned as a structure with these fields:

#### **arch** — Platform

string

Platform, specified as a string. The name of the platform is the output of the `computer('arch')` command.

**ext** — File extension

string

File extension, specified as a string.

## More About

### Tips

- To use the MEX-file-name extension in makefiles or scripts outside MATLAB, type one of the following from the system command prompt. The script is located in the *matlabroot*\bin folder.
  - `mexext.bat`—Windows platform.
  - `mexext.sh`—UNIX platform.

For example, the following commands are in a GNU<sup>®</sup> makefile.

```
ext = $(shell mexext)
yprime.$(ext) : yprime.c
 mex yprime.c
```

- MATLAB continues to execute a MEX-file with a `.dll` extension, but future versions of MATLAB will not support this extension.

**Introduced before R2006a**

# mfilename

File name of currently running code

## Syntax

```
mfilename
p = mfilename('fullpath')
c = mfilename('class')
```

## Description

`mfilename` returns a string containing the file name of the `.m` file in which the function call occurs. When called from within the file, it returns the name of that file. This allows a script or function to determine its name.

`p = mfilename('fullpath')` returns the full path and name of the file in which the call occurs, not including the filename extension.

`c = mfilename('class')` in a method, returns the class of the method, not including the leading `@` sign. If called from a nonmethod, it yields the empty string.

## More About

### Tips

If `mfilename` is called with any argument other than the above two, it behaves as if it were called with no argument.

When called from the command line, `mfilename` returns an empty string.

To get the names of the callers of a MATLAB function file, use `dbstack` with an output argument.

### See Also

`dbstack` | `nargin` | `function` | `nargout` | `inputname`

**Introduced before R2006a**

# mget

**Class:** FTP

Download files from FTP server

## Syntax

```
mget(ftpobj,contents)
mget(ftpobj,contents,target)
```

## Description

`mget(ftpobj,contents)` retrieves the file or folder specified by `contents` from an FTP server into the MATLAB current folder.

`mget(ftpobj,contents,target)` retrieves the file or folder into the local folder specified by `target`, which includes an absolute or relative path.

## Input Arguments

### **ftpobj**

FTP object created by `ftp`.

### **contents**

String enclosed in single quotation marks that specifies either a file name or a folder name. Can include a wildcard character (\*).

### **target**

String enclosed in single quotation marks that specifies the absolute or relative path of the local folder to contain the downloaded contents.

## Examples

Connect to the National Geophysical Data Center (NGDC) FTP server and retrieve the file `README.txt` into the current MATLAB folder:

```
ngdc = ftp('ftp.ngdc.noaa.gov');
mget(ngdc, 'README.txt');
close(ngdc);
```

FTP service courtesy of the NGDC. See [NGDC Privacy Policy](#), [Disclaimer](#), and [Copyright](#) for NGDC terms of service.

# milliseconds

Duration in milliseconds

## Syntax

```
MS = milliseconds(X)
```

## Description

`MS = milliseconds(X)` returns an array of milliseconds equivalent to the values in `X`.

- If `X` is a numeric array, then `MS` is a `duration` array in units of milliseconds.
- If `X` is a `duration` array, then `MS` is a `double` array with each element equal to the number of milliseconds in the corresponding element of `X`.

## Examples

### Create Duration Array of Milliseconds

```
X = magic(3);
MS = milliseconds(X)
```

```
MS =
 0.008 secs 0.001 secs 0.006 secs
 0.003 secs 0.005 secs 0.007 secs
 0.004 secs 0.009 secs 0.002 secs
```

### Convert Durations to Numeric Array of Milliseconds

Create a `duration` array.

```
X = minutes(2) + seconds(1:3)
```

```
X =
 2.0167 mins 2.0333 mins 2.05 mins
```

Convert each duration in `X` to a number of milliseconds.

```
MS = milliseconds(X)
```

```
MS =
 121000 122000 123000
```

MS is a **double** array.

## Input Arguments

### **X** — Input array

numeric array | duration array | logical array

Input array, specified as a numeric array, duration array, or logical array.

## See Also

duration

**Introduced in R2015a**

# min

Smallest elements in array

## Syntax

$M = \text{min}(A)$

$M = \text{min}(A, [], \text{dim})$

$[M, I] = \text{min}(\_\_\_)$

$C = \text{min}(A, B)$

$\_\_\_ = \text{min}(\_\_\_, \text{nanflag})$

## Description

$M = \text{min}(A)$  returns the smallest elements of  $A$ .

- If  $A$  is a vector, then  $\text{min}(A)$  returns the smallest element of  $A$ .
- If  $A$  is a matrix, then  $\text{min}(A)$  is a row vector containing the minimum value of each column.
- If  $A$  is a multidimensional array, then  $\text{min}(A)$  operates along the first array dimension whose size does not equal 1, treating the elements as vectors. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same. If  $A$  is an empty array with first dimension 0, then  $\text{min}(A)$  returns an empty array with the same size as  $A$ .

$M = \text{min}(A, [], \text{dim})$  returns the smallest elements along dimension  $\text{dim}$ . For example, if  $A$  is a matrix, then  $\text{min}(A, [], 2)$  is a column vector containing the minimum value of each row.

$[M, I] = \text{min}(\_\_\_)$  finds the indices of the minimum values of  $A$  and returns them in output vector  $I$ , using any of the input arguments in the previous syntaxes. If the minimum value occurs more than once, then  $\text{min}$  returns the index corresponding to the first occurrence.

$C = \text{min}(A, B)$  returns an array the same size as  $A$  and  $B$  with the smallest elements taken from  $A$  or  $B$ .

Either the dimensions of A and B are the same, or one can be a scalar.

`___ = min( ___, nanflag)` specifies whether to include or omit NaN values in the calculation for any of the previous syntaxes. For the single input case, to specify `nanflag` without specifying `dim`, use `min(A, [], nanflag)`. For example, `min(A, [], 'includenan')` includes all NaN values in A while `min(A, [], 'omitnan')` ignores them.

## Examples

### Smallest Vector Element

Create a vector and compute its smallest element.

```
A = [23 42 37 15 52];
M = min(A)
```

```
M =

 15
```

### Smallest Complex Element

Create a complex vector and compute its smallest element, that is, the element with the smallest magnitude.

```
A = [-2+2i 4+i -1-3i];
min(A)
```

```
ans =

-2.0000 + 2.0000i
```

### Smallest Element in Each Matrix Column

Create a matrix and compute the smallest element in each column.

```
A = [2 8 4; 7 3 9]
```

```
A =
```

```

 2 8 4
 7 3 9

```

```
M = min(A)
```

```
M =
```

```

 2 3 4

```

### Smallest Element in Each Matrix Row

Create a matrix and compute the smallest element in each row.

```
A = [1.7 1.2 1.5; 1.3 1.6 1.99]
```

```
A =
```

```

 1.7000 1.2000 1.5000
 1.3000 1.6000 1.9900

```

```
M = min(A,[],2)
```

```
M =
```

```

 1.2000
 1.3000

```

### Smallest Element Indices

Create a matrix A and compute the smallest elements in each column as well as the row indices of A in which they appear.

```
A = [1 9 -2; 8 4 -5]
```

```
A =
```

```

 1 9 -2
 8 4 -5

```

```
[M,I] = min(A)
```

```
M =
```

```
1 4 -5
```

```
I =
```

```
1 2 2
```

## Smallest Element Comparison

Create a matrix and return the smallest value between each of its elements compared to a scalar.

```
A = [1 7 3; 6 2 9]
```

```
A =
```

```
1 7 3
6 2 9
```

```
B = 5;
```

```
C = min(A,B)
```

```
C =
```

```
1 5 3
5 2 5
```

## Smallest Element in Matrix

Create a matrix A and use its column representation,  $A(:,)$ , to find the value and index of the smallest element.

```
A = [8 2 4; 7 3 9]
```

```
A =
```

```
 8 2 4
 7 3 9
```

```
A(:)
```

```
ans =
```

```
 8
 7
 2
 3
 4
 9
```

```
[M,I] = min(A(:))
```

```
M =
```

```
 2
```

```
I =
```

```
 3
```

I is the index of A(:) containing the smallest element.

Now, use the `ind2sub` function to extract the row and column indices of A corresponding to the smallest element.

```
[I_row, I_col] = ind2sub(size(A),I)
```

```
I_row =
```

```
 1
```

```
I_col =
```

2

If you need only the minimum value of `A` and not its index, call the `min` function twice.

```
M = min(min(A))
```

```
M =
```

2

## Smallest Element Involving NaN

Create a vector and compute its minimum, excluding NaN values.

```
A = [1.77 -0.005 3.98 -2.95 NaN 0.34 NaN 0.19];
M = min(A,[], 'omitnan')
```

```
M =
```

```
-2.9500
```

`min(A)` will also produce this result since `'omitnan'` is the default option.

Use the `'includenan'` flag to return NaN.

```
M = min(A,[], 'includenan')
```

```
M =
```

```
NaN
```

## Input Arguments

### **A** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

- If  $A$  is complex, then  $\min(A)$  returns the complex number with the smallest magnitude. If magnitudes are equal, then  $\min(A)$  returns the value with the smallest magnitude and the smallest phase angle.
- If  $A$  is a scalar, then  $\min(A)$  returns  $A$ .
- If  $A$  is a 0-by-0 empty array, then  $\min(A)$  is as well.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `categorical` | `datetime` | `duration`  
 Complex Number Support: Yes

### **dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension  $\text{dim}$  indicates the dimension whose length reduces to 1. The `size(M, dim)` is 1, while the sizes of all other dimensions remain the same, unless `size(A, dim)` is 0. If `size(A, dim)` is 0, then  $\min(A, \text{dim})$  returns an empty array with the same size as  $A$ .

Consider a two-dimensional input array,  $A$ :

- If  $\text{dim} = 1$ , then  $\min(A, [], 1)$  returns a row vector containing the smallest element in each column.

- If  $\text{dim} = 2$ , then  $\min(A, [], 2)$  returns a column vector containing the smallest element in each row.

min returns A if dim is greater than ndims(A).

**B — Additional input array**

scalar | vector | matrix | multidimensional array

Additional input array, specified as a scalar, vector, matrix, or multidimensional array.

- The dimensions of A and B must match, or one can be a scalar.
- A and B can be the same data type or one can be double with the other single, duration, or any integer data type.
- If A and B are ordinal categorical arrays, they must have the same sets of categories with the same order.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | categorical | datetime | duration

Complex Number Support: Yes

**nanflag — NaN condition**

'omitnan' (default) | 'includenan'

NaN condition, specified as one of these values:

- 'omitnan' — Ignore all NaN values in the input.
- 'includenan' — Include the NaN values in the input for the calculation.

The min function does not support the nanflag option for categorical arrays. For datetime arrays, NaT is treated like NaN.

Data Types: char

---

## Output Arguments

### **M** — Minimum values

scalar | vector | matrix | multidimensional array

Minimum values, returned as a scalar, vector, matrix, or multidimensional array. `size(M, dim)` is 1, while the sizes of all other dimensions match the size of the corresponding dimension in `A`, unless `size(A, dim)` is 0. If `size(A, dim)` is 0, then `M` is an empty array with the same size as `A`.

### **I** — Index to minimum values of `A`

scalar | vector | matrix | multidimensional array

Index to minimum values of `A`, returned as a scalar, vector, matrix, or multidimensional array. `I` is the same size as `M`. If the smallest element occurs more than once, then `I` contains the index to the first occurrence of the value.

### **C** — Minimum elements from `A` or `B`

scalar | vector | matrix | multidimensional array

Minimum elements from `A` or `B`, returned as a scalar, vector, matrix, or multidimensional array.

The size of `C` depends on the sizes of `A` and `B`:

- If `A` and `B` are arrays of the same size, then the size of `C` matches the size of `A` and `B`.
- If either `A` or `B` is a scalar, then the size of `C` matches the size of the nonscalar input array.
- If either `A` or `B` is an empty array with the other a scalar, then `C` is an empty array.

The data type of `C` depends on the data types of `A` and `B`:

- If `A` and `B` are the same data type, then `C` matches the data type of `A` and `B`.
- If either `A` or `B` is `single`, then `C` is `single`.
- If either `A` or `B` is an integer data type with the other a scalar `double`, then `C` assumes the integer data type.

# MinimizeCommandWindow

Minimize size of Automation server window

## Syntax

### IDL Method Signature

```
HRESULT MinimizeCommandWindow(void)
```

### Microsoft Visual Basic Client

```
MinimizeCommandWindow
```

### MATLAB Client

```
MinimizeCommandWindow(h)
```

## Description

MinimizeCommandWindow(h) minimizes the window for the server attached to handle h, and makes it inactive.

If the server window was already in a minimized state, MinimizeCommandWindow does nothing.

## Examples

From a Visual Basic .NET client, modify the size of the command window in a MATLAB Automation server.

```
Dim Matlab As Object
```

```
Matlab = CreateObject("matlab.application")
Matlab.MinimizeCommandWindow
```

```
'Now return the server window to its former state on
'the desktop and make it the currently active window.
```

```
Matlab.MaximizeCommandWindow
```

## **See Also**

MaximizeCommandWindow

# minres

Minimum residual method

## Syntax

```
x = minres(A,b)
minres(A,b,tol)
minres(A,b,tol,maxit)
minres(A,b,tol,maxit,M)
minres(A,b,tol,maxit,M1,M2)
minres(A,b,tol,maxit,M1,M2,x0)
[x,flag] = minres(A,b,...)
[x,flag,relres] = minres(A,b,...)
[x,flag,relres,iter] = minres(A,b,...)
[x,flag,relres,iter,resvec] = minres(A,b,...)
[x,flag,relres,iter,resvec,resveccg] = minres(A,b,...)
```

## Description

`x = minres(A,b)` attempts to find a minimum norm residual solution  $x$  to the system of linear equations  $A*x=b$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be symmetric but need not be positive definite. It should be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `minres` converges, a message to that effect is displayed. If `minres` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual norm  $\|b-A*x\|/\|b\|$  and the iteration number at which the method stopped or failed.

`minres(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `minres` uses the default,  $1e-6$ .

`minres(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `minres` uses the default,  $\min(n,20)$ .

`minres(A,b,tol,maxit,M)` and `minres(A,b,tol,maxit,M1,M2)` use symmetric positive definite preconditioner `M` or `M = M1*M2` and effectively solve the system  $\text{inv}(\text{sqrt}(M)) * A * \text{inv}(\text{sqrt}(M)) * y = \text{inv}(\text{sqrt}(M)) * b$  for `y` and then return `x = inv(sqrt(M))*y`. If `M` is `[]` then `minres` applies no preconditioner. `M` can be a function handle `mfun`, such that `mfun(x)` returns `M\ x`.

`minres(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `minres` uses the default, an all-zero vector.

`[x,flag] = minres(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	<code>minres</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>minres</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	<code>minres</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>minres</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = minres(A,b,...)` also returns the relative residual  $\text{norm}(b - A*x) / \text{norm}(b)$ . If `flag` is 0, `relres <= tol`.

`[x,flag,relres,iter] = minres(A,b,...)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = minres(A,b,...)` also returns a vector of estimates of the `minres` residual norms at each iteration, including  $\text{norm}(b - A*x_0)$ .

`[x,flag,relres,iter,resvec,resveccg] = minres(A,b,...)` also returns a vector of estimates of the Conjugate Gradients residual norms at each iteration.

## Examples

### Using minres with a Matrix Input

```
n = 100; on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50;
M1 = spdiags(4*on,0,n,n);

x = minres(A,b,tol,maxit,M1);
minres converged at iteration 49 to a solution with relative
residual 4.7e-014
```

### Using minres with a Function Handle

This example replaces the matrix *A* in the previous example with a handle to a matrix-vector product function *afun*. The example is contained in a file *run\_minres* that

- Calls *minres* with the function handle *@afun* as its first argument.
- Contains *afun* as a nested function, so that all variables in *run\_minres* are available to *afun*.

The following shows the code for *run\_minres*:

```
function x1 = run_minres
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50;
M = spdiags(4*on,0,n,n);
x1 = minres(@afun,b,tol,maxit,M);

 function y = afun(x)
 y = 4 * x;
 y(2:n) = y(2:n) - 2 * x(1:n-1);
 y(1:n-1) = y(1:n-1) - 2 * x(2:n);
 end
end
```

When you enter

```
x1=run_minres;
```

MATLAB software displays the message

```
minres converged at iteration 49 to a solution with relative
residual 4.7e-014
```

## Using minres instead of pcg

Use a symmetric indefinite matrix that fails with pcg.

```
A = diag([20:-1:1, -1:-1:-20]);
b = sum(A,2); % The true solution is the vector of all ones.
x = pcg(A,b); % Errors out at the first iteration.
```

displays the following message:

```
pcg stopped at iteration 1 without converging to the desired
tolerance 1e-006 because a scalar quantity became too small or
too large to continue computing.
The iterate returned (number 0) has relative residual 1
```

However, minres can handle the indefinite matrix A.

```
x = minres(A,b,1e-6,40);
minres converged at iteration 39 to a solution with relative
residual 1.3e-007
```

## minus, -

Subtraction

### Syntax

```
C = A - B
C = minus(A,B)
```

### Description

`C = A - B` subtracts array `B` from array `A` and returns the result in `C`.

`C = minus(A,B)` is an alternate way to execute `A - B`, but is rarely used. It enables operator overloading for classes.

### Examples

#### Subtract Scalar from Array

Create an array, `A`, and subtract a scalar value from it.

```
A = [2 1; 3 5];
C = A - 2
```

```
C =
```

```
 0 -1
 1 3
```

The scalar is subtracted from each entry of `A`.

#### Subtract Two Arrays

Create two arrays, `A` and `B`, and subtract the second, `B`, from the first, `A`.

```
A = [1 0; 2 4];
B = [5 9; 2 1];
```

```
C = A - B
```

```
C =
```

```
 -4 -9
 0 3
```

The elements of **B** are subtracted from the corresponding elements of **A**.

Use the syntax `-C` to negate the elements of **C**.

```
-C
```

```
ans =
```

```
 4 9
 0 -3
```

## Input Arguments

### **A** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **A** can be a numeric array, logical array, character array, datetime array, duration array, or calendar duration array. Inputs **A** and **B** must be the same size unless one is a scalar. You can add a scalar value to any other value.

If one input is a datetime array, duration array, or calendar duration array, then numeric values in the other input are treated as a number of 24-hour days.

If one input is a datetime array, then the other input also can be a date string or a cell array containing date strings.

Complex Number Support: Yes

### **B** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **B** can be a numeric array, logical array, character array, datetime array, duration array, or calendar duration array. Inputs **A** and **B** must be the same size unless one is a scalar. You can add a scalar value to any other value.

If one input is a datetime array, duration array, or calendar duration array, then numeric values in the other input are treated as a number of 24-hour days.

If one input is a datetime array, then the other input also can be a date string or a cell array containing date strings.

Complex Number Support: Yes

# minute

Minute number

## Syntax

```
m = minute(t)
```

## Description

`m = minute(t)` returns the minute numbers of the datetime values in `t`. The `m` output is a double array the same size as `t` and contains integer values from 0 to 59.

The `minute` function returns the minute numbers of datetime values. To assign minute values to a datetime array, `t`, use `t.Minute` and modify the `Minute` property.

## Examples

### Find Minute Number of Datetime Values

```
t1 = datetime('now');
t = t1 + minutes(2:4)
```

```
t =
```

```
 24-Aug-2015 17:49:25 24-Aug-2015 17:50:25 24-Aug-2015 17:51:25
```

```
m = minute(t)
```

```
m =
```

```
 49 50 51
```

## Input Arguments

**t** — **Input date and time**  
datetime array

Input date and time, specified as a `datetime` array.

### See Also

`datetime` Properties | `hms` | `hour` | `second` | `timeofday`

**Introduced in R2014b**

# minutes

Duration in minutes

## Syntax

```
M = minutes(X)
```

## Description

`M = minutes(X)` returns an array of minutes equivalent to the values in `X`.

- If `X` is a numeric array, then `M` is a duration array in units of minutes.
- If `X` is a duration array, then `M` is a double array with each element equal to the number of minutes in the corresponding element of `X`.

The `minutes` function converts between duration and double values. To display a duration in units of minutes, set its `Format` property to `'m'`.

## Examples

### Create Duration Array of Minutes

```
X = magic(4);
M = minutes(X)
```

```
M =
```

```
16 mins 2 mins 3 mins 13 mins
5 mins 11 mins 10 mins 8 mins
9 mins 7 mins 6 mins 12 mins
4 mins 14 mins 15 mins 1 min
```

### Convert Durations to Numeric Array of Minutes

Create a duration array.

```
X = hours(2:10:38) + minutes(30)
```

```
X =
```

```
 2.5 hrs 12.5 hrs 22.5 hrs 32.5 hrs
```

Convert each duration in X to a number of minutes.

```
M = minutes(X)
```

```
M =
```

```
 150 750 1350 1950
```

View the data type of M.

```
whos M
```

Name	Size	Bytes	Class	Attributes
M	1x4	32	double	

## Input Arguments

### **X** — Input array

numeric array | duration array | logical array

Input array, specified as a numeric array, duration array, or logical array.

## See Also

duration

**Introduced in R2014b**

# mislocked

Determine if function is locked in memory

## Syntax

```
mislocked
mislocked(fun)
```

## Description

`mislocked` by itself returns logical 1 (**true**) if the currently running function is locked in memory, and logical 0 (**false**) otherwise. Functions that are locked cannot be removed with the `clear` function unless you first unlock them using the `munlock` function. You can use locking on functions that reside in MATLAB `.m` files or `.mex` files.

`mislocked(fun)` returns logical 1 (**true**) if the function named *fun* is locked in memory, and logical 0 (**false**) otherwise.

## See Also

`mlock` | `munlock` | `inmem`

**Introduced before R2006a**

# mkdir

Make new folder

## Syntax

```
mkdir('folderName')
mkdir('parentFolder','folderName')
status = mkdir(____)
[status,message,messageid] = mkdir(____)
```

## Description

`mkdir('folderName')` creates the folder `folderName`, where `folderName` can be an absolute or a relative path.

`mkdir('parentFolder','folderName')` creates the folder `folderName` in `parentFolder`, where `parentFolder` is an absolute or relative path. If `parentFolder` does not exist, MATLAB attempts to create it. See the Tips section.

`status = mkdir(____)` creates the specified folder. When the operation is successful, it returns a `status` of logical 1. When the operation is unsuccessful, it returns logical 0.

`[status,message,messageid] = mkdir(____)` creates the specified folder, and returns the status, message string, and MATLAB message ID. The value given to `status` is logical 1 for success, and logical 0 for error.

## Examples

### Creating a Subfolder in the Current Folder

Create a subfolder called `newdir` in the current folder:

```
mkdir('newdir')
```

## Creating a Subfolder in the Specified Parent Folder

Create a subfolder called `newFolder` in the folder `testdata`, using a relative path, where `newFolder` is at the same level as the current folder:

```
mkdir('../testdata','newFolder')
```

## Returning Status When Creating a Folder

In this example, the first attempt to create `newFolder` succeeds, returning a status of 1, and no error or warning message or message identifier:

```
[s, mess, messid] = mkdir('../testdata', 'newFolder')
s =
 1
mess =
 ''
messid =
 ''
```

Attempt to create the same folder again. `mkdir` again returns a success status, and also a warning and message identifier informing you that the folder exists:

```
[s,mess,messid] = mkdir('../testdata','newFolder')
s =
 1
mess =
 Directory "newFolder" already exists.
messid =
 MATLAB:MKDIR:DirectoryExists
```

## More About

### Tips

If an argument specifies a path that includes one or more nonexistent folders, MATLAB attempts to create the nonexistent folder. For example, for

```
mkdir('myFolder\folder1\folder2\targetFolder')
```

if `folder1` does not exist, MATLAB creates `folder1`, creates `folder2` within `folder1`, and creates `targetFolder` within `folder2`.

# mkdir

**Class:** FTP

Create folder on FTP server

## Syntax

```
mkdir(ftpobj, folder)
```

## Description

`mkdir(ftpobj, folder)` creates the specified folder on the FTP server associated with `ftpobj`.

## Input Arguments

### **ftpobj**

FTP object created by `ftp`.

### **folder**

String enclosed in single quotation marks that specifies a path relative to the current folder on the FTP server.

## Examples

Suppose that a hypothetical host, `ftp.testsite.com`, contains a folder named `testfolder`. Connect to the server and add a subfolder:

```
ts = ftp('ftp.testsite.com');
mkdir(ts, 'testfolder/newfolder');
close(ts);
```

**See Also**

rmdir | dir | ftp

**Introduced before R2006a**

# mkpp

Make piecewise polynomial

## Syntax

```
pp = mkpp(breaks,coefs)
pp = mkpp(breaks,coefs,d)
```

## Description

`pp = mkpp(breaks,coefs)` builds a piecewise polynomial, `pp`, from its breaks and coefficients.

- `breaks` is a vector of length `L+1` with strictly increasing elements which represent the start and end of each of `L` intervals.
- `coefs` is an `L`-by-`k` matrix with each row `coefs(i,:)` containing the local coefficients of an order `k` polynomial on the  $i$ th interval, `[breaks(i),breaks(i+1)]`. That is, the polynomial `coefs(i,1)*(X-breaks(i))^(k-1) + coefs(i,2)*(X-breaks(i))^(k-2) + ... + coefs(i,k-1)*(X-breaks(i)) + coefs(i,k)`. Notice that `mkpp` shifts the polynomial in each interval down by `(X-breaks(i))`.

`pp = mkpp(breaks,coefs,d)` indicates that the piecewise polynomial `pp` is `d`-vector valued, i.e., the value of each of its coefficients is a vector of length `d`. `breaks` is an increasing vector of length `L+1`. `coefs` is a `d`-by-`L`-by-`k` array with `coefs(r,i,:)` containing the `k` coefficients of the  $i$ th polynomial piece of the  $r$ th component of the piecewise polynomial.

Use `ppval` to evaluate the piecewise polynomial at specific points. Use `unmkpp` to extract details of the piecewise polynomial.

---

**Note:** The *order* of a polynomial tells you the number of coefficients used in its description. A  $k$ th order polynomial has the form

$$c_1x^{k-1} + c_2x^{k-2} + \dots + c_{k-1}x + c_k$$

It has  $k$  coefficients, some of which can be 0, and maximum exponent  $k - 1$ . So the order of a polynomial is usually one greater than its degree. For example, a cubic polynomial is of order 4.

---

## Examples

### Construct and Plot Piecewise Polynomial

The first plot shows the quadratic polynomial

$$1 - \left(\frac{x}{2} - 1\right)^2 = \frac{-x^2}{4} + x$$

shifted to the interval  $[-8,-4]$ . The second plot shows its negative

$$\left(\frac{x}{2} - 1\right)^2 - 1 = \frac{x^2}{4} - x$$

but shifted to the interval  $[-4,0]$ .

The last plot shows a piecewise polynomial constructed by alternating these two quadratic pieces over four intervals. It also shows its first derivative, which was constructed after breaking the piecewise polynomial apart using `unmkpp`.

```
subplot(2,2,1)
cc = [-1/4 1 0];
pp1 = mkpp([-8 -4],cc);
xx1 = -8:0.1:-4;
plot(xx1,ppval(pp1,xx1),'k-')

subplot(2,2,2)
pp2 = mkpp([-4 0],-cc);
xx2 = -4:0.1:0;
plot(xx2,ppval(pp2,xx2),'k-')

subplot(2,1,2)
pp = mkpp([-8 -4 0 4 8],[cc;-cc;cc;-cc]);
xx = -8:0.1:8;
plot(xx,ppval(pp,xx),'k-')
[breaks,coefs,l,k,d] = unmkpp(pp);
dpp = mkpp(breaks,repmat(k-1:-1:1,d*1,1).*coefs(:,1:k-1),d);
```

```
hold on, plot(xx,ppval(dpp,xx),'r-'), hold off
```

## See Also

Introduced before R2006a

## **mldivide, \**

Solve systems of linear equations  $Ax = B$  for  $x$

### **Syntax**

```
x = A\B
x = mldivide(A,B)
```

### **Description**

$x = A\B$  solves the system of linear equations  $A*x = B$ . The matrices  $A$  and  $B$  must have the same number of rows. MATLAB displays a warning message if  $A$  is badly scaled or nearly singular, but performs the calculation regardless.

- If  $A$  is a scalar, then  $A\B$  is equivalent to  $A.\B$ .
- If  $A$  is a square  $n$ -by- $n$  matrix and  $B$  is a matrix with  $n$  rows, then  $x = A\B$  is a solution to the equation  $A*x = B$ , if it exists.
- If  $A$  is a rectangular  $m$ -by- $n$  matrix with  $m \approx n$ , and  $B$  is a matrix with  $m$  rows, then  $A\B$  returns a least-squares solution to the system of equations  $A*x = B$ .

$x = \text{mldivide}(A,B)$  is an alternative way to execute  $x = A\B$ , but is rarely used. It enables operator overloading for classes.

### **Examples**

#### **System of Equations**

Solve a simple system of linear equations,  $A*x = B$ .

```
A = magic(3);
B = [15; 15; 15];
x = A\B
```

```
x =
```

```
1.0000
1.0000
```

```
1.0000
```

### Linear System with Singular Matrix

Solve a linear system of equations  $A*x = b$  involving a singular matrix,  $A$ .

```
A = magic(4);
b = [34; 34; 34; 34];
x = A\b
```

```
Warning: Matrix is close to singular or badly scaled. Results may be inaccurate. RCOND
1.306145e-17.
```

```
x =
```

```
1.5000
2.5000
-0.5000
0.5000
```

When `rcond` is between 0 and `eps`, MATLAB issues a nearly singular warning, but proceeds with the calculation. When working with ill-conditioned matrices, an unreliable solution can result even though the residual ( $b - A*x$ ) is relatively small. In this particular example, the norm of the residual is zero, and an exact solution is obtained, although `rcond` is small.

When `rcond` is equal to 0, the singular warning appears.

```
A = [1 0; 0 0];
b = [1; 1];
x = A\b
```

```
Warning: Matrix is singular to working precision.
```

```
x =
```

```
1
Inf
```

In this case, division by zero leads to computations with `Inf` and/or `NaN`, making the computed result unreliable.

### Least-Squares Solution of Underdetermined System

Solve a system of linear equations,  $A*x = b$ .

```
A = [1 2 0; 0 4 3];
b = [8; 18];
x = A\b
```

```
ans =
```

```
 0
 4.0000
 0.6667
```

## Linear System with Sparse Matrix

Solve a simple system of linear equations using sparse matrices.

Consider the matrix equation  $A*x = B$ .

```
A = sparse([0 2 0 1 0; 4 -1 -1 0 0; 0 0 0 3 -6; -2 0 0 0 2; 0 0 4 2 0]);
B = sparse([8; -1; -18; 8; 20]);
x = A\b
```

```
x =
```

```
(1,1) 1.0000
(2,1) 2.0000
(3,1) 3.0000
(4,1) 4.0000
(5,1) 5.0000
```

## Input Arguments

### A — Coefficient matrix

vector | full matrix | sparse matrix

Coefficient matrix, specified as a vector, full matrix, or sparse matrix. If **A** has  $m$  rows, then **B** must have  $m$  rows.

Data Types: `single` | `double`

Complex Number Support: Yes

### B — Right-hand side

vector | full matrix | sparse matrix

Right-hand side, specified as a vector, full matrix, or sparse matrix. If **B** has  $m$  rows, then **A** must have  $m$  rows.

Data Types: `single` | `double`  
Complex Number Support: Yes

## Output Arguments

### **x** — Solution

vector | full matrix | sparse matrix

Solution, returned as a vector, full matrix, or sparse matrix. If  $A$  is an  $m$ -by- $n$  matrix and  $B$  is an  $m$ -by- $p$  matrix, then  $x$  is an  $n$ -by- $p$  matrix, including the case when  $p=1$ .

If  $A$  has full storage,  $x$  is also full. If  $A$  is sparse, then  $x$  has the same storage as  $B$ .

## More About

### Tips

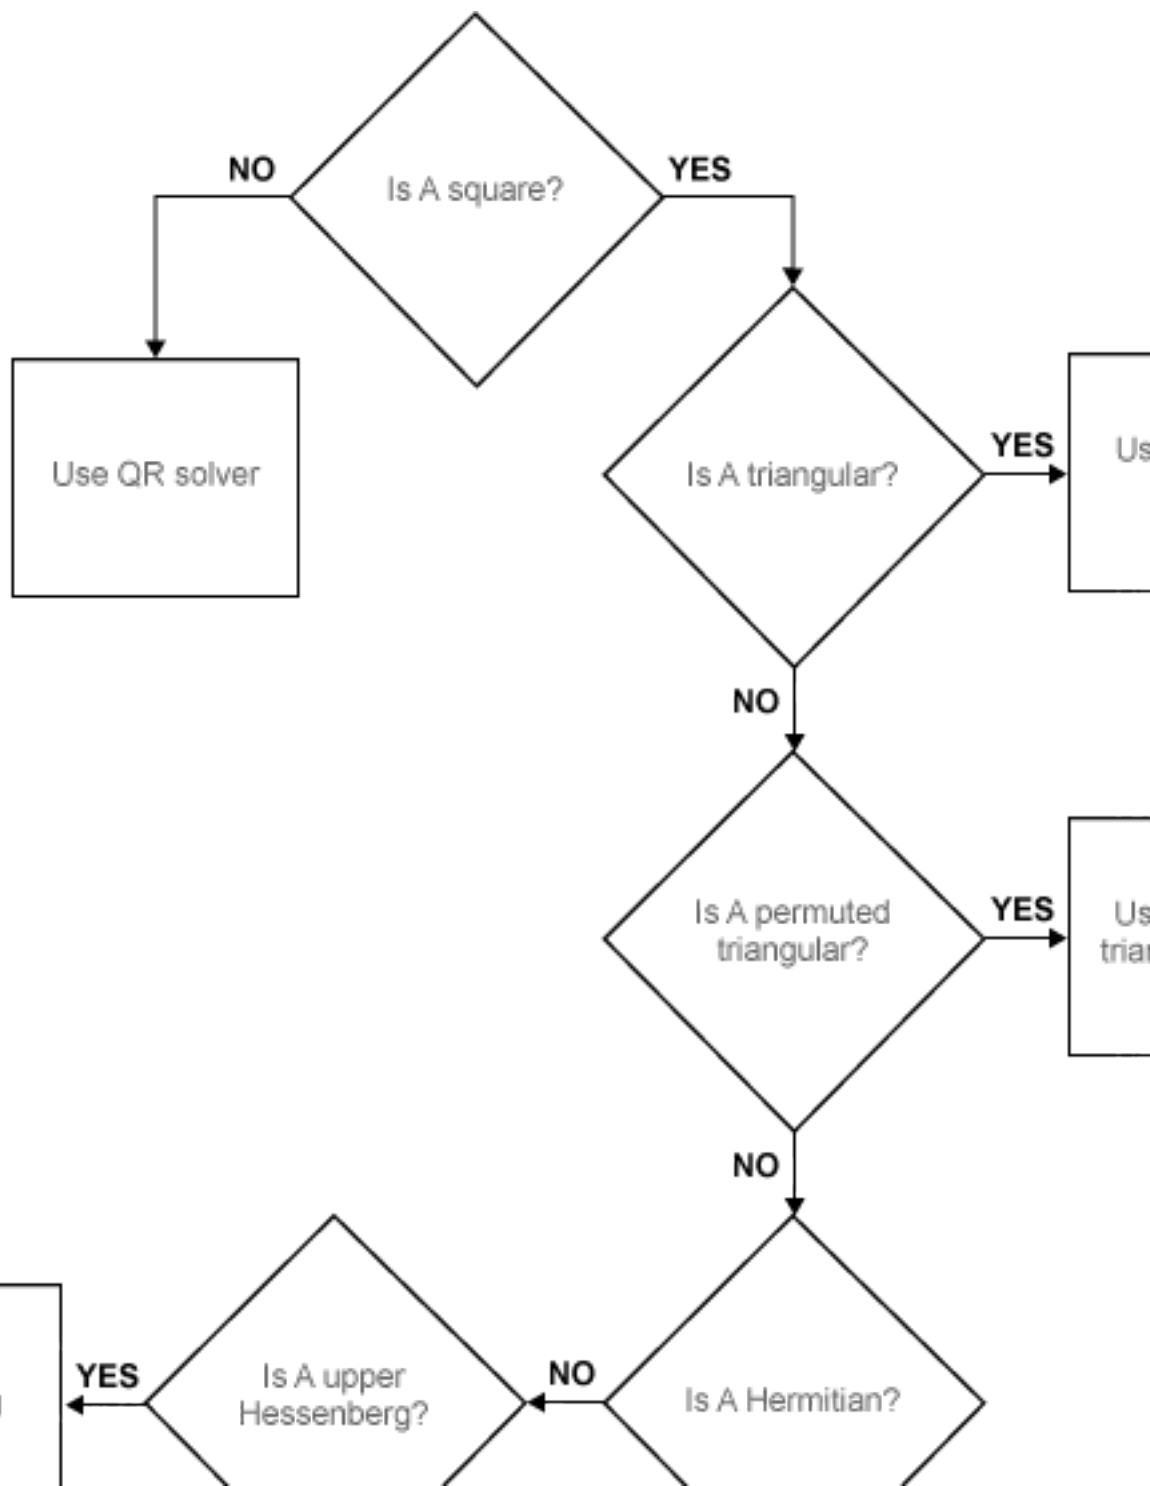

- If  $A$  is a square matrix,  $A \setminus B$  is roughly equal to `inv(A)*B`, but MATLAB processes  $A \setminus B$  differently and more robustly.
- If the rank of  $A$  is less than the number of columns in  $A$ , then  $x = A \setminus B$  is not necessarily the minimum norm solution. The more computationally expensive  $x = \text{pinv}(A) * B$  computes the minimum norm least-squares solution.
- For full singular inputs, you can compute the least-squares solution using the function `linsolve`.

### Algorithms

The versatility of `mldivide` in solving linear systems stems from its ability to take advantage of symmetries in the problem by dispatching to an appropriate solver. This approach aims to minimize computation time. The first distinction the function makes is between *full* (also called “*dense*”) and *sparse* input arrays.

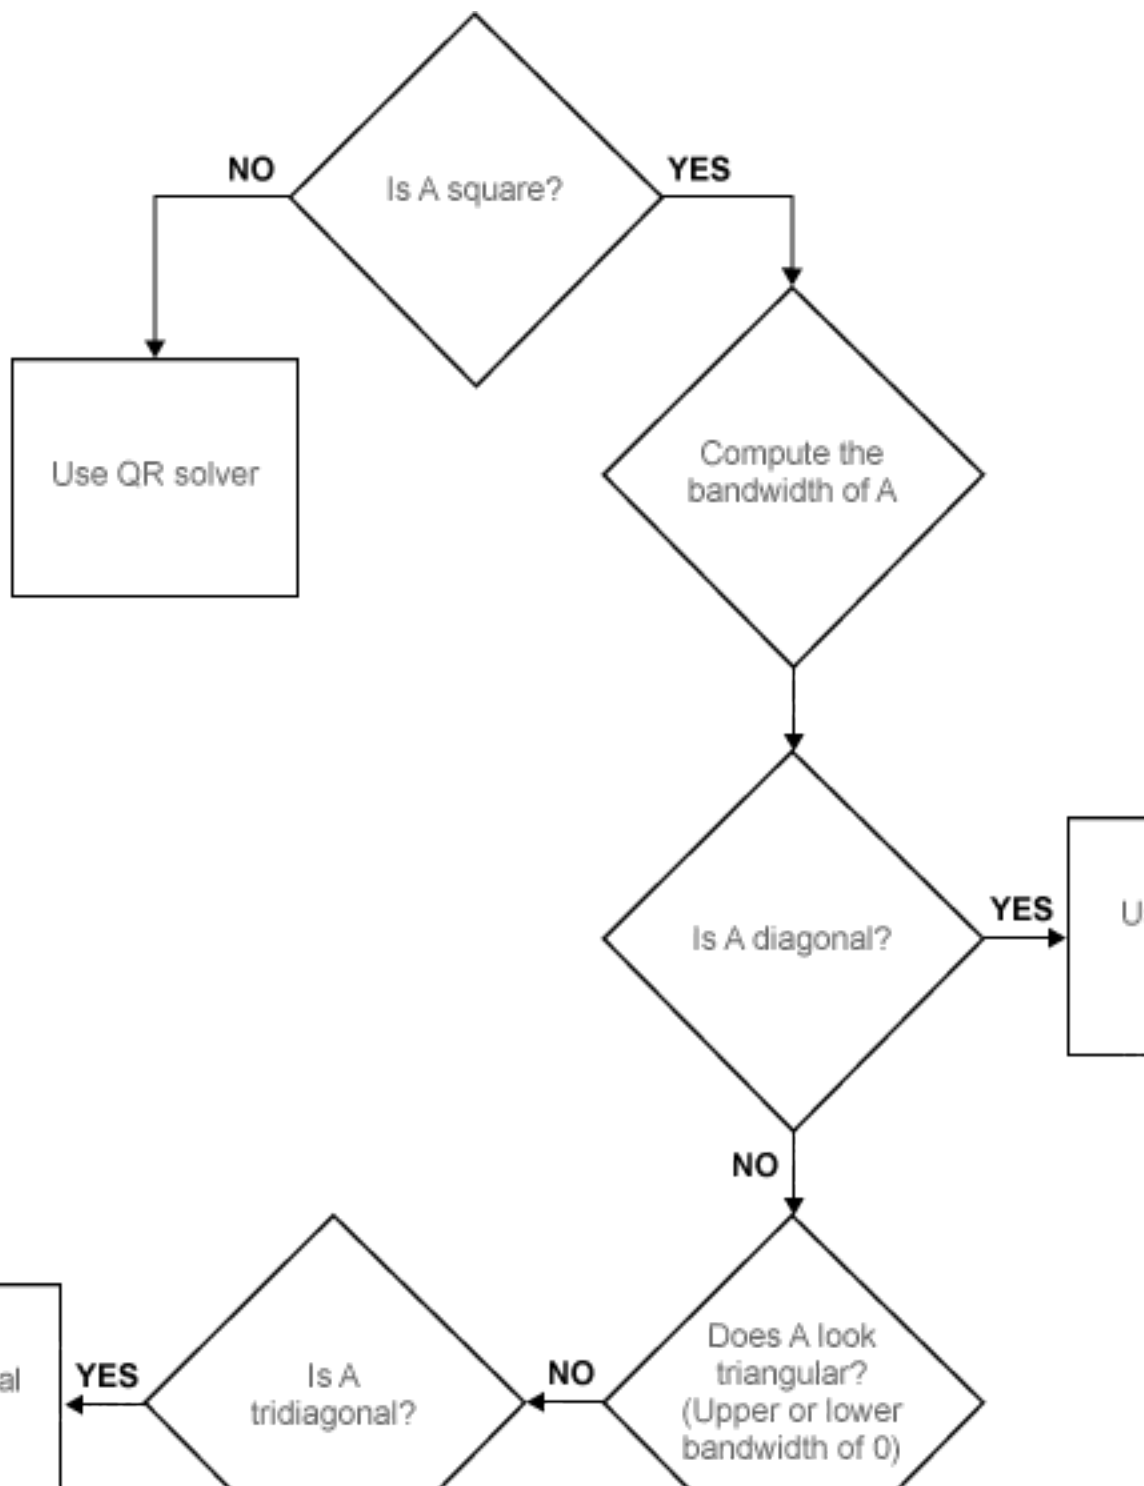

## Algorithm for Full Inputs

The flow chart below shows the algorithm path when inputs  $A$  and  $B$  are **full**.

## mrdivide, /

Solve systems of linear equations  $xA = B$  for  $x$

### Syntax

```
x = B/A
x = mrdivide(B,A)
```

### Description

$x = B/A$  solves the system of linear equations  $x*A = B$  for  $x$ . The matrices  $A$  and  $B$  must contain the same number of columns. MATLAB displays a warning message if  $A$  is badly scaled or nearly singular, but performs the calculation regardless.

- If  $A$  is a scalar, then  $B/A$  is equivalent to  $B ./ A$ .
- If  $A$  is a square  $n$ -by- $n$  matrix and  $B$  is a matrix with  $n$  columns, then  $x = B/A$  is a solution to the equation  $x*A = B$ , if it exists.
- If  $A$  is a rectangular  $m$ -by- $n$  matrix with  $m \approx n$ , and  $B$  is a matrix with  $n$  columns, then  $x = B/A$  returns a least-squares solution of the system of equations  $x*A = B$ .

$x = \text{mrdivide}(B,A)$  is an alternative way to execute  $x = B/A$ , but is rarely used. It enables operator overloading for classes.

### Examples

#### System of Equations

Solve a system of equations that has a unique solution,  $x*A = B$ .

```
A = [1 1 3; 2 0 4; -1 6 -1];
B = [2 19 8];
x = B/A
```

```
x =
```

```
1.0000 2.0000 3.0000
```

### Least-Squares on an Underdetermined System

Solve an underdetermined system,  $x \cdot C = D$ .

```
C = [1 0; 2 0; 1 0];
```

```
D = [1 2];
```

```
x = D/C
```

```
Warning: Rank deficient, rank = 1, tol = 6.280370e-16.
```

```
x =
```

```
0 0.5000 0
```

MATLAB issues a warning but proceeds with calculation.

Verify that  $x$  is not an exact solution.

```
x*C-D
```

```
ans =
```

```
0 -2
```

## Input Arguments

### A — Coefficient matrix

vector | full matrix | sparse matrix

Coefficient matrix, specified as a vector, full matrix, or sparse matrix. If  $A$  has  $n$  columns, then  $B$  must have  $n$  columns.

Data Types: `single` | `double`

Complex Number Support: Yes

### B — Right-hand side

vector | full matrix | sparse matrix

Right-hand side, specified as a vector, full matrix, or sparse matrix. If  $B$  has  $n$  columns, then  $A$  must have  $n$  columns.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **x** — Solution

vector | full matrix | sparse matrix

Solution, returned as a vector, full matrix, or sparse matrix. If  $A$  is an  $m$ -by- $n$  matrix and  $B$  is a  $p$ -by- $n$  matrix, then  $x$  is a  $p$ -by- $m$  matrix.

$x$  is sparse only if both  $A$  and  $B$  are sparse matrices.

## More About

### Tips

- The operators `/` and `\` are related to each other by the equation  $B/A = (A' \setminus B')'$ .
- If  $A$  is a square matrix,  $B/A$  is roughly equal to  $B * \text{inv}(A)$ , but MATLAB processes  $B/A$  differently and more robustly.

Introduced before R2006a

# mlint

Check MATLAB code files for possible problems

---

**Note:** `mlint` is not recommended. Use `checkcode` instead.

---

## Alternatives

For information on using the graphical user interface to the Code Analyzer, see “Check Code for Errors and Warnings”.

## Syntax

```
mlint('filename')
mlint('filename','-config=settings.txt')
mlint('filename','-config=factory')
inform=mlint('filename','-struct')
msg=mlint('filename','-string')
[inform,filepaths]=mlint('filename')
inform=mlint('filename','-id')
inform=mlint('filename','-fullpath')
inform=mlint('filename','-notok')
mlint('filename','-cyc')
mlint('filename','-codegen')
mlint('filename','-eml')
```

## Description

`mlint('filename')` displays Code Analyzer messages about `filename`, where the message reports potential problems and opportunities for code improvement. The line number in the message is a hyperlink that opens the file in the Editor, scrolled to that line. If `filename` is a cell array, information is displayed for each file. For `mlint(F1,F2,F3,...)`, where each input is a character array, MATLAB software

displays information about each input file name. You cannot combine cell arrays and character arrays of file names. Note that the exact text of the `mlint` messages is subject to some change between versions.

`mlint('filename', '-config=settings.txt')` overrides the default active settings file with the settings that enable or suppress messages as indicated in the specified `settings.txt` file.

---

**Note:** If used, you must specify the full path to the `settings.txt` file specified with the `-config` option.

---

For information about creating a `settings.txt` file, see “Save and Reuse Code Analyzer Message Settings”. If you specify an invalid file, `mlint` returns a message indicating that it cannot open or read the file you specified. In that case, `mlint` uses the factory default settings.

`mlint('filename', '-config=factory')` ignores all settings files and uses the factory default preference settings.

`inform=mlint('filename', '-struct')` returns the information in a structure array whose length is the number of messages found. The structure has the fields that follow.

Field	Description
<code>message</code>	Message describing the suspicious construct that code analysis caught.
<code>line</code>	Vector of file line numbers to which the message refers.
<code>column</code>	Two-column array of file columns (column extents) to which the message applies. The first column of the array specifies the column in the Editor where the message begins. The second column of the array specifies the column in the Editor where the message ends. There is one row in the two-column array for each occurrence of a message.

If you specify multiple file names as input, or if you specify a cell array as input, `inform` contains a cell array of structures.

`msg=mlint('filename', '-string')` returns the information as a string to the variable `msg`. If you specify multiple file names as input, or if you specify a cell array as

input, `msg` contains a string where each file's information is separated by 10 equal sign characters (=), a space, the file name, a space, and 10 equal sign characters.

If you omit the **-struct** or **-string** argument and you specify an output argument, the default behavior is **-struct**. If you omit the argument and there are no output arguments, the default behavior is to display the information to the command line.

`[inform,filepath]=mlint('filename')` additionally returns `filepath`s, the absolute paths to the file names, in the same order as you specified them.

`inform=mlint('filename','-id')` requests the message ID, where ID is a string of the form ABC... When returned to a structure, the output also has the `id` field, which is the ID associated with the message.

`inform=mlint('filename','-fullpath')` assumes that the input file names are absolute paths, so that `mlint` does not try to locate them.

`inform=mlint('filename','-notok')` runs `mlint` for all lines in `filename`, even those lines that end with the `mlint` suppression directive,  `%#ok`.

`mlint('filename','-cyc')` displays the McCabe complexity (also referred to as cyclomatic complexity) of each function in the file. Higher McCabe complexity values indicate higher complexity, and there is some evidence to suggest that programs with higher complexity values are more likely to contain errors. Frequently, you can lower the complexity of a function by dividing it into smaller, simpler functions. In general, smaller complexity values indicate programs that are easier to understand and modify. Some people advocate splitting up programs that have a complexity rating over 10.

`mlint('filename','-codegen')` enables code generation messages for display in the Command Window.

`mlint('filename','-eml')` '-eml' is not recommended. Use '-codegen' instead.

## Examples

The following examples use `lengthofline.m`, which is a sample file with MATLAB code that can be improved. You can find it in `matlabroot/help/techdoc/matlab_env/examples`. If you want to run the examples, save a copy of `lengthofline.m` to a location on your MATLAB path.

## Running mlint on a File with No Options

To run `mlint` on the example file, `lengthofline.m`, run

```
mlint('lengthofline')
```

MATLAB displays the M-Lint messages for `lengthofline.m` in the Command Window:

```
L 22 (C 1-9): The value assigned here to variable 'nohandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMP(str1,str2) instead of using LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD.
 Type 'doc struct' for more information.
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages” in the MATLAB Desktop Tools and Development Environment documentation.

## Running mlint with Options to Show IDs and Return Results to a Structure

To store the results to a structure and include message IDs, run

```
inform=mlint('lengthofline', '-id')
```

MATLAB returns

```
inform =
```

```
19x1 struct array with fields:
 message
 line
 column
 id
```

To see values for the first message, run

```
inform(1)
```

MATLAB displays

```
ans =
```

```
message: 'The value assigned here to variable 'nohandle' might never be used.'
line: 22
column: [1 9]
id: 'NASGU'
```

Here, the message is for the value that appears on line 22 that extends from column 1–9 in the file.NASGU is the ID for the message 'The value assigned here to variable 'nohandle' might never be used.'.

## Displaying McCabe Complexity with mlint

To display the McCabe complexity of a MATLAB code file, run `mlint` with the `-cyc` option, as shown in the following example (assuming you have saved `lengthofline.m` to a local folder).

```
mlint lengthofline.m -cyc
```

Results displayed in the Command Window show the McCabe complexity of the file, followed by the M-Lint messages, as shown here:

```
L 1 (C 23-34): The McCabe complexity of 'lengthofline' is 12.
L 22 (C 1-9): The value assigned here to variable 'nohandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMP(str1,str2) instead of using UPPER/LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD. Type 'doc struct' for more information.
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

## See Also

`mlintrpt`, `profile`

## How To

- For information on the suppression directive, `##0k`, and suppressing messages from within your program, see “Adjust Code Analyzer Message Indicators and Messages”.

**Introduced before R2006a**

# mlintrpt

Run `checkcode` for file or folder, reporting results in browser

## Syntax

```
mlintrpt
mlintrpt('filename','file')
mlintrpt('dirname','dir')
mlintrpt('filename','file','settings.txt')
mlintrpt('dirname','dir','settings.txt')
```

## Description

`mlintrpt` scans all files with an `.m` file extension in the current folder for Code Analyzer messages and reports the results in a MATLAB Web browser.

`mlintrpt('filename','file')` scans `filename` for Code Analyzer messages and reports results. You can omit `'file'` in this form of the syntax because it is the default.

`mlintrpt('dirname','dir')` scans the specified folder. Here, `dirname` can be in the current folder or can be a full path.

`mlintrpt('filename','file','settings.txt')` applies the Code Analyzer preference settings to enable or suppress messages as indicated in the specified `settings.txt` file.

`mlintrpt('dirname','dir','settings.txt')` applies the settings indicated in the specified `settings.txt` file.

---

**Note:** If you specify a `settings.txt` file, you must specify the full path to the file.

---

## Examples

`lengthofline.m` is an example file with code that can be improved. It is found in `matlabroot/matlab/help/techdoc/matlab_env/examples`.

## Run Report for All Files in a Folder

Run

```
mlintrpt(fullfile(matlabroot, 'help', 'techdoc', 'matlab_env', 'examples'), 'dir')
```

and MATLAB displays a report of potential problems and improvements for all files with an `.m` file extension in the `examples` folder.

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages”.

## Run Report Using Code Analyzer Preference Settings

You can save preference settings to a text file by clicking the **Preferences** button in the **Environment** section on the **Home** tab and selecting **Code Analyzer** in the left pane.

To save a preferences file, select **Save as** under the  drop-down list. To apply those settings when you run `mlintrpt`, use the `file` option and supply the full path to the settings file name as shown in this example:

```
mlintrpt('lengthofline.m', 'file', ...
'C:\WINNT\Profiles\me\Application Data\MathWorks\MATLAB\R2012b\mymlint.txt')
```

Alternatively, use `fullfile` if the settings file is stored in the preferences folder:

```
mlintrpt('lengthofline.m', 'file', fullfile(prefdir, 'mymlint.txt'))
```

Assuming that in that example `mymlint.txt` file, the setting for **Terminate statement with semicolon to suppress output** has been disabled, the results of `mlintrpt` for `lengthofline` do not show that message for line 49.

When `mlintrpt` cannot locate the settings file, the first message in the report is

```
0: Unable to open or read the configuration file 'mymlint.txt'--using default settings.
```

# mlock

Prevent clearing function from memory

## Syntax

```
mlock
```

## Description

`mlock` locks the currently running function in memory so that subsequent `clear` functions do not remove it. Locking a function in memory also prevents any persistent variables defined in the file from getting reinitialized.

Use the `munlock` function to return the file to its normal, clearable state.

## Examples

The function `testfun` begins with an `mlock` statement.

```
function testfun
mlock
:
```

When you execute this function, it becomes locked in memory. You can check this using the `mislocked` function.

```
testfun

mislocked('testfun')
ans =
 1
```

Using `munlock`, you unlock the `testfun` function in memory. Checking its status with `mislocked` shows that it is indeed unlocked at this point.

```
munlock('testfun')
```

```
mislocked('testfun')
ans =
 0
```

## **See Also**

`mislocked` | `inmem` | `munlock` | `persistent`

**Introduced before R2006a**

# mmfileinfo

Information about multimedia file

## Syntax

```
info = mmfileinfo(filename)
```

## Description

*info* = mmfileinfo(*filename*) returns a structure, *info*, with fields containing information about the contents of the multimedia file identified by *filename*. The *filename* input is a string enclosed in single quotation marks.

If *filename* is a URL, mmfileinfo might take a long time to return because it must first download the file. For large files, downloading can take several minutes. To avoid blocking the MATLAB command line while this processing takes place, download the file before calling mmfileinfo.

The *info* structure contains the following fields, listed in the order they appear in the structure.

Field	Description
Filename	String indicating the name of the file.
Path	String indicating the absolute path to the file.
Duration	Length of the file in seconds.
Audio	Structure containing information about the audio data in the file. See “Audio Data” on page 1-5724 for more information about this data structure.
Video	Structure containing information about the video data in the file. See “Video Data” on page 1-5724 for more information about this data structure.

## Audio Data

The `Audio` structure contains the following fields, listed in the order they appear in the structure. If the file does not contain audio data, the fields in the structure are empty.

Field	Description
Format	Text string, indicating the audio format.
NumberOfChannels	Number of audio channels.

## Video Data

The `Video` structure contains the following fields, listed in the order they appear in the structure. If the file does not contain video data, the fields in the structure are empty.

Field	Description
Format	Text string, indicating the video format.
Height	Height of the video frame.
Width	Width of the video frame.

## Examples

Display information about the example file `xylophone.mpg`:

```
info = mmfileinfo('xylophone.mpg')
audio = info.Audio
video = info.Video
```

MATLAB returns:

```
info =
 Filename: 'xylophone.mpg'
 Path: 'matlabroot\toolbox\matlab\audiovideo'
 Duration: 4.7020
 Audio: [1x1 struct]
 Video: [1x1 struct]

audio =
 Format: 'MPEG'
```

NumberOfChannels: 2

video =

Format: 'MPEG1'

Height: 240

Width: 320

where Path is system-dependent.

## **See Also**

VideoReader

**Introduced before R2006a**

## mod

Remainder after division (modulo operation)

## Syntax

```
b = mod(a,m)
```

## Description

`b = mod(a,m)` returns the remainder after division of `a` by `m`, where `a` is the dividend and `m` is the divisor. This function is often called the modulo operation and is computed using `b = a - m.*floor(a./m)`. The `mod` function follows the convention that `mod(a,0)` returns `a`.

## Examples

### Remainder After Division of Scalar

Compute 23 modulo 5.

```
b = mod(23,5)
```

```
b =
```

```
3
```

### Remainder After Division of Vector

Find the remainder after division for a vector of integers and the divisor 3.

```
a = 1:5;
m = 3;
b = mod(a,m)
```

```
b =
```

1 2 0 1 2

### Remainder After Division for Positive and Negative Values

Find the remainder after division for a set of integers including both positive and negative values. Note that nonzero results are always positive if the divisor is positive.

```
a = [-4 -1 7 9];
m = 3;
b = mod(a,m)
```

b =

2 2 1 0

### Remainder After Division for Negative Divisor

Find the remainder after division by a negative divisor for a set of integers including both positive and negative values. Note that nonzero results are always negative if the divisor is negative.

```
a = [-4 -1 7 9];
m = -3;
b = mod(a,m)
```

b =

-1 -1 -2 0

### Remainder After Division for Floating-Point Values

Find the remainder after division for several angles using a modulus of  $2\pi$ . Note that mod attempts to compensate for floating-point round-off effects to produce exact integer results when possible.

```
theta = [0.0 3.5 5.9 6.2 9.0 4*pi];
m = 2*pi;
b = mod(theta,m)
```

b =

0    3.5000    5.9000    6.2000    2.7168    0

## Input Arguments

### **a** — Dividend

scalar | vector | matrix | multidimensional array

Dividend, specified as a scalar, vector, matrix, or multidimensional array. **a** must be a real-valued array of any numerical type. Inputs **a** and **m** must be the same size unless one is a scalar **double**. If one input has an integer data type, then the other input must be of the same integer data type or be a scalar **double**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `duration`

### **m** — Divisor

scalar | vector | matrix | multidimensional array

Divisor, specified as a scalar, vector, matrix, or multidimensional array. **m** must be a real-valued array of any numerical type. Inputs **a** and **m** must be the same size unless one is a scalar **double**. If one input has an integer data type, then the other input must be of the same integer data type or be a scalar **double**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `duration`

## More About

### Differences Between `mod` and `rem`

The concept of remainder after division is not uniquely defined, and the two functions `mod` and `rem` each compute a different variation. The `mod` function produces a result that is either zero or has the same sign as the divisor. The `rem` function produces a result that is either zero or has the same sign as the dividend.

Another difference is the convention when the divisor is zero. The `mod` function follows the convention that `mod(a, 0)` returns **a**, whereas the `rem` function follows the convention that `rem(a, 0)` returns **NaN**.

Both variants have their uses. For example, in signal processing, the `MOD` function is useful in the context of periodic signals because its output is periodic (with period equal to the divisor).

### **Congruence Relationships**

The `MOD` function is useful for congruence relationships: `a` and `b` are congruent (mod `m`) if and only if `MOD(a, m) == MOD(b, m)`. For example, 23 and 13 are congruent (mod 5).

## mode

Most frequent values in array

### Syntax

`M = mode(A)`

`M = mode(A,dim)`

`[M,F] = mode( ___ )`

`[M,F,C] = mode( ___ )`

### Description

`M = mode(A)` returns the sample mode of `A`, which is the most frequently occurring value in `A`. When there are multiple values occurring equally frequently, `mode` returns the smallest of those values. For complex inputs, the smallest value is the first value in a sorted list.

- If `A` is a vector, then `mode(A)` returns the most frequent value of `A`.
- If `A` is a nonempty matrix, then `mode(A)` returns a row vector containing the mode of each column of `A`.
- If `A` is an empty 0-by-0 matrix, `mode(A)` returns `NaN`.
- If `A` is a multidimensional array, then `mode(A)` treats the values along the first array dimension whose size does not equal 1 as vectors and returns an array of most frequent values. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.

`M = mode(A,dim)` returns the mode of elements along dimension `dim`. For example, if `A` is a matrix, then `mode(A,2)` is a column vector containing the most frequent value of each row

`[M,F] = mode( ___ )` also returns a frequency array `F`, using any of the input arguments in the previous syntaxes. `F` is the same size as `M`, and each element of `F` represents the number of occurrences of the corresponding element of `M`.

`[M,F,C] = mode( ___ )` also returns a cell array `C` of the same size as `M` and `F`. Each element of `C` is a sorted vector of all values that have the same frequency as the corresponding element of `M`.

## Examples

### Mode of Matrix Columns

Define a 3-by-4 matrix.

```
A = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

A =

```

 3 3 1 4
 0 0 1 1
 0 1 2 4
```

Find the most frequent value of each column.

```
M = mode(A)
```

M =

```

 0 0 1 4
```

### Mode of Matrix Rows

Define a 3-by-4 matrix.

```
A = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

A =

```

 3 3 1 4
 0 0 1 1
 0 1 2 4
```

Find the most frequent value of each row.

```
M = mode(A,2)
```

M =

```
3
0
0
```

## Mode of 3-D Array

Create a 1-by-3-by-4 array of integers between 1 and 10.

```
A = gallery('integerdata',10,[1,3,4],1)
```

```
A(:,:,1) =
```

```
10 8 10
```

```
A(:,:,2) =
```

```
6 9 5
```

```
A(:,:,3) =
```

```
9 6 1
```

```
A(:,:,4) =
```

```
4 9 5
```

Find the most frequent values of this 3-D array along the second dimension.

```
M = mode(A)
```

```
M(:,:,1) =
```

```
10
```

```
M(:,:,2) =
```

```
5
```

```
M(:,:,3) =
```

1

M(:, :, 4) =

4

This operation produces a 1-by-1-by-4 array by finding the most frequent value along the second dimension. The size of the second dimension reduces to 1.

Compute the mode along the first dimension of A.

M = mode(A, 1);

isequal(A, M)

ans =

1

This returns the same array as A because the size of the first dimension is 1.

### Mode of Matrix Columns with Frequency Information

Define a 3-by-4 matrix.

A = [3 3 1 4; 0 0 1 1; 0 1 2 4]

A =

3	3	1	4
0	0	1	1
0	1	2	4

Find the most frequent value of each column, as well as how often it occurs.

[M, F] = mode(A)

M =

0	0	1	4
---	---	---	---

F =

```

2 1 2 2

```

$F(1)$  is 2 since  $M(1)$  occurs twice in the first column.

**Mode of Matrix Rows with Frequency and Multiplicity Information**

Define a 3-by-4 matrix.

```
A = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

```
A =
```

```

3 3 1 4
0 0 1 1
0 1 2 4

```

Find the most frequent value of each row, how often it occurs, and which values in that row occur with the same frequency.

```
[M,F,C] = mode(A,2)
```

```
M =
```

```

3
0
0

```

```
F =
```

```

2
2
1

```

```
C =
```

```

[3]
[2x1 double]
[4x1 double]

```

$C\{2\}$  is the 2-by-1 vector  $[0;1]$  since values 0 and 1 in the second row occur with frequency  $F(2)$ .

$C\{3\}$  is the 4-by-1 vector  $[0;1;2;4]$  since all values in the third row occur with frequency  $F(3)$ .

### Mode of 16-bit Unsigned Integer Array

Define a 1-by-4 vector of 16-bit unsigned integers.

```
A = gallery('integerdata',10,[1,4],3,'uint16')
```

```
A =
```

```
 6 3 2 3
```

Find the most frequent value, as well as the number of times it occurs.

```
[M,F] = mode(A),
class(M)
```

```
M =
```

```
 3
```

```
F =
```

```
 2
```

```
ans =
```

```
uint16
```

$M$  is the same class as the input,  $A$ .

## Input Arguments

### A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.  $A$  can be a numeric array, categorical array, datetime array, or duration array.

NaN or NaT (Not a Time) values in the input array,  $A$ , are ignored. Undefined values in categorical arrays are similar to NaNs in numeric arrays.

**dim — Dimension to operate along**

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to 1. The `size(M, dim)` is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, `A`.

- If `dim = 1`, then `mode(A, 1)` returns a row vector containing the most frequent value in each column.

`mode(A, 1)`

- If `dim = 2`, then `mode(A, 2)` returns a column vector containing the most frequent value in each row.

`mode(A, 2)`

`mode` returns `A` if `dim` is greater than `ndims(A)`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

### **M** — Most frequent values

scalar | vector | matrix | multidimensional array

Most frequent values returned as a scalar, vector, matrix, or multidimensional array. When there are multiple values occurring equally frequently, `mode` returns the smallest of those values. For complex inputs, this is taken to be the first value in a sorted list of values.

The class of **M** is the same as the class of the input array, **A**.

### **F** — Frequency array

scalar | vector | matrix | multidimensional array

Frequency array returned as a scalar, vector, matrix, or multidimensional array. The size of **F** is the same as the size of **M**, and each element of **F** represents the number of occurrences of the corresponding element of **M**.

The class of **F** is always `double`.

### **C** — Most frequent values with multiplicity

cell array

Most frequent values with multiplicity returned as a cell array. The size of **C** is the same as the size of **M** and **F**, and each element of **C** is a sorted column vector of all values that have the same frequency as the corresponding element of **M**.

## More About

### Tips

- The `mode` function is most useful with discrete or coarsely rounded data. The mode for a continuous probability distribution is defined as the peak of its density function. Applying the `mode` function to a sample from that distribution is unlikely to provide a good estimate of the peak; it would be better to compute a histogram or density

estimate and calculate the peak of that estimate. Also, the `mode` function is not suitable for finding peaks in distributions having multiple modes.

## **See Also**

**Introduced before R2006a**

# month

Month number and name

## Syntax

```
m = month(t)
m = month(t,monthType)
```

## Description

`m = month(t)` returns the month numbers of the datetime values in `t`. The `m` output contains integer values from 1 to 12.

`m = month(t,monthType)` returns the type of month number or name specified by `monthType`.

The `month` function returns the month numbers or names of datetime values. To assign month numbers to datetime array `t`, use `t.Month` and modify the `Month` property.

## Examples

### Extract Month Number from Dates

Extract the month numbers from an array of dates.

```
t = datetime(2014,05,31):caldays(35):datetime(2014,10,15)
```

```
t =
```

```
 31-May-2014 05-Jul-2014 09-Aug-2014 13-Sep-2014
```

```
m = month(t)
```

```
m =
```

5 7 8 9

## Find Month Names of Dates

Get the month names from an array of dates.

```
t = datetime(2013,01,01):calweeks(12):datetime(2013,12,31)
```

```
t =
```

```
01-Jan-2013 26-Mar-2013 18-Jun-2013 10-Sep-2013 03-Dec-2013
```

```
m = month(t, 'name')
```

```
m =
```

```
'January' 'March' 'June' 'September' 'December'
```

## Input Arguments

### **t** — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

### **monthType** — Type of month values

'monthofyear' (default) | 'name' | 'shortname'

Type of month values, specified as one of the following strings.

Value of monthType	Description
'monthofyear'	Month-of-year number
'name'	Full month names, for example, <b>August</b> or <b>September</b> . For NaT datetime values, the month name is the empty string, ''.

Value of monthType	Description
'shortname'	Abbreviated month names, for example, Aug or Sep. For NaT datetime values, the month name is the empty string, ''.

## Output Arguments

**m** — Month number or name

double array | cell array of strings

Month number or name, returned as a numeric array of type `double`, or a cell array of strings. `m` is the same size as `t`.

## See Also

datetime Properties | `day` | `quarter` | `week` | `year` | `ymd`

**Introduced in R2014b**

## more

Control paged output for Command Window

### Syntax

```
more on
more off
more(n)
A = more(state)
```

### Description

**more on** enables paging of the output in the MATLAB Command Window. MATLAB displays output one page at a time. Use the keys defined in the table below to control paging.

**more off** disables paging of the output in the MATLAB Command Window.

**more(n)** defines the length of a page to be *n* lines.

**A = more(state)** returns in *A* the number of lines that are currently defined to be a page. The *state* input can be one of the quoted strings 'on' or 'off', or the number of lines to set as the new page length.

By default, the length of a page is equal to the number of lines available for display in the MATLAB Command Window. Manually changing the size of the command window adjusts the page length accordingly.

If you set the page length to a specific value, MATLAB uses that value for the page size, regardless of the size of the command window. To have MATLAB return to matching page size to window size, type **more off** followed by **more on**.

To see the status of **more**, type **get(0, 'More')**. MATLAB returns either **on** or **off**, indicating the **more** status.

When you have enabled **more** and are examining output, you can do the following.

Press the...	To...
Return key	Advance to the next line of output.
Space bar	Advance to the next page of output.
Q (for quit) key	Terminate display of the text. Do not use <b>Ctrl+C</b> to terminate <b>more</b> or you might generate error messages in the Command Window.

**more** is in the **off** state, by default.

diary

Introduced before R2006a

## morebins

Increase number of histogram bins

### Syntax

```
N = morebins(h)
N = morebins(h,direction)
```

### Description

`N = morebins(h)` increases the number of bins in histogram `h` by 10% (rounded up to the nearest integer) and returns the new number of bins.

For bivariate histograms, this increases the bin count in both the *x* and *y* directions.

`N = morebins(h,direction)`, where `h` must be a `histogram2` object, only increases the number of bins in the dimension specified by `direction`. The `direction` option can be `'x'`, `'y'`, or `'both'`. The default value is `'both'`.

### Examples

#### Increase Number of Histogram Bins

Plot a histogram of 1,000 random numbers and return a handle to the histogram object.

```
x = randn(1000,1);
h = histogram(x)
```

```
h =
```

```
 Histogram with properties:
```

```
 Data: [1000x1 double]
 Values: [1x23 double]
 NumBins: 23
 BinEdges: [1x24 double]
 BinWidth: 0.3000
```

```
BinLimits: [-3.3000 3.6000]
Normalization: 'count'
FaceColor: 'auto'
EdgeColor: [0 0 0]
```

Use GET to show all properties

Use `morebins` to increase the number of bins in the histogram.

```
morebins(h);
morebins(h)
```

```
ans =
29
```

## Input Arguments

### **h** — Input histogram

histogram object | histogram2 object

Input histogram, specified as a `histogram` or `histogram2` object. For more information, see [Using histogram Objects](#) or [Using histogram2 Objects](#).

`h` cannot be a categorical histogram.

**direction** — Direction to increase number of bins

'both' (default) | 'x' | 'y'

Direction to increase the number of bins, specified as 'x', 'y', or 'both'. Specify 'x' or 'y' to only increase the number of bins in that direction while leaving the number of bins in the other direction constant.

## Output Arguments

**N** — Number of bins

scalar | vector

Number of bins, returned as a scalar or vector. `N` is the new number of bins for the histogram after increase. For bivariate histogram plots, `N` is a two-element vector, [`nx ny`].

## More About

- Using histogram Objects
- Using histogram2 Objects

## See Also

`fewerbins` | `histcounts` | `histcounts2` | `histogram` | `histogram2`

**Introduced in R2014b**

## move

Move or resize control in parent window

### Syntax

```
V = move(h,position)
```

### Description

`V = move(h,position)` moves the control to the position specified by the `position` argument. When you use `move` with only the handle argument, `h`, it returns a four-element vector indicating the current position of the control.

The `position` argument is a four-element vector specifying the position and size of the control in the parent figure window. The elements of the vector are:

```
[x, y, width, height]
```

where `x` and `y` are offsets, in pixels, from the bottom left corner of the figure window to the same corner of the control, and `width` and `height` are the size of the control itself.

### Examples

This example moves the control.

```
f = figure('Position',[100 100 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.1',[0 0 200 200],f);
pos = move(h,[50 50 200 200])
```

```
pos =
 50 50 200 200
```

The next example resizes the control to always be centered in the figure as you resize the figure window. Start by creating the script `resizectrl.m` that contains:

```
% Get the new position and size of the figure window
fpos = get(gcbo,'position');
```

```
% Resize the control accordingly
move(h,[0 0 fpos(3) fpos(4)]);
```

Now execute the following:

```
f = figure('Position',[100 100 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.1',[0 0 200 200]);
set(f,'ResizeFcn','resizectl');
```

As you resize the figure window, notice that the circle moves so that it is always positioned in the center of the window.

## See Also

set (COM) | get (COM)

**Introduced before R2006a**

# movefile

Move file or folder

## Syntax

```
movefile('source')
movefile('source','destination')
movefile('source','destination','f')
[status,message,messageid] = movefile(___)
```

## Description

`movefile('source')` moves the file or folder named **source** to the current folder, where **source** is the absolute or relative path name for the folder or file. To move multiple files or folders, use one or more wildcard characters (\*) after the last file separator in **source**. The **source** argument permits a wildcard character in a path string. `movefile` does not preserve the archive attribute of **source**.

`movefile('source','destination')` moves the file or folder named **source** to the location **destination**, where **source** and **destination** are the absolute or relative paths for the folder or file. To move multiple files or folders, you can use one or more wildcard characters (\*) after the last file separator in **source**. You cannot use a wildcard character in **destination**. To rename a file or folder when moving it, make **destination** a different name than **source**, and specify only one file for **source**. When **source** and **destination** have the same location, `movefile` renames **source** to **destination**.

`movefile('source','destination','f')` moves the file or folder named **source** to the location **destination**, regardless of the read-only attribute of **destination**.

`[status,message,messageid] = movefile( ___ )` moves the file or folder named **source** to the location **destination**, returning the status, a message, and the MATLAB message ID. Here, **status** is logical 1 for success or logical 0 for error. `movefile` requires only one output argument.

## Examples

### Moving a File to the Current Folder

Assuming `myfiles` is a subfolder within the current folder, move the file `myfunction.m` to the current folder:

```
movefile('myfiles/myfunction.m')
```

Assuming `projects/testcases` is the current folder, move `projects/myfiles` and its contents to the current folder:

```
movefile('../myfiles')
```

### Renaming a File in the Current Folder

In the current folder, rename `oldname.m` to `newname.m`:

```
movefile('oldname.m','newname.m')
```

### Using a Wildcard to Move All Matching Files

Assuming `myfiles` is a subfolder of the current folder, move all files whose names that begin with `my` from the `myfiles` folder, to the current folder:

```
movefile('myfiles/my*')
```

### Moving a File to a Different Folder

Assuming `projects` and the current folder are at the same level, move the file `myfunction.m` from the current folder to the folder `projects`:

```
movefile('myfunction.m','../projects')
```

### Moving a Folder Down One Level

Assuming `projects` is a subfolder of the current folder, move the folder `projects/testcases` and all its contents down a level in `projects` into `projects/myfiles`:

```
movefile('projects/testcases','projects/myfiles/')
```

## Moving a File to a Read-Only Folder and Renaming the File

Move the file `myfile.m` from the current folder to `d:/work/restricted`, assigning it the name `test1.m`, where `restricted` is a read-only folder:

```
movefile('myfile.m','d:/work/restricted/test1.m','f')
```

The read-only file `myfile.m` is no longer in the current folder. The file `test1.m` is in `d:/work/restricted` and is read only.

## Returning Status When Moving Files

Move all files in the folder `myfiles` whose names start with `new` to the current folder, when there is an error. You mistype `new*` as `nex*` and no items in the current folder start with `nex*`:

```
[s,mess,messid] = movefile('myfiles/nex*')
```

```
s =
 0
```

```
mess =
```

```
No matching files were found.
```

```
messid =
```

```
MATLAB:MOVEFILE:FileDoesNotExist
```

**Introduced before R2006a**

# movegui

Move UI figure to specified location on screen

## Syntax

```
movegui(h, 'position')
movegui(position)
movegui(h)
movegui
```

## Description

`movegui(h, 'position')` moves the figure identified by handle `h` to the specified screen location, preserving the figure's size. The `position` argument is either a string or a two-element vector, as defined in the tables that follow.

`movegui(position)` moves the callback figure (`gcbf`) or the current figure (`gcf`) to the specified position.

`movegui(h)` moves the figure identified by the handle `h` to the onscreen position.

`movegui` moves the callback figure (`gcbf`) or the current figure (`gcf`) to the onscreen position. You can specify 'movegui' as a `CreateFcn` callback for a figure. Doing so ensures after you save a figure, that figure appears on screen when you reload it, regardless of its saved position. See the following example.

When it is a string, `position` is one of the following descriptors.

Position String	Description
north	Top center edge of screen
south	Bottom center edge of screen
east	Right center edge of screen
west	Left center edge of screen
northeast	Top right corner of screen

Position String	Description
northwest	Top left corner of screen
southeast	Bottom right corner of screen
southwest	Bottom left corner
center	Centered on screen
onscreen	Nearest location to current location that is entirely on screen

You can also specify the *position* argument as a two-element vector,  $[h, v]$ . Depending on sign,  $h$  specifies the figure's offset from the left or right edge of the screen, and  $v$  specifies the figure's offset from the top or bottom of the screen, in pixels. The following table summarizes the possible values.

$h$ (for $h \geq 0$ )	Offset of left side from left edge of screen
$h$ (for $h < 0$ )	Offset of right side from right edge of screen
$v$ (for $v \geq 0$ )	Offset of bottom edge from bottom of screen
$v$ (for $v < 0$ )	Offset of top edge from top of screen

Applying `movegui` to a maximized figure window moves the window towards the task bar and creates a gap on the opposite side of the screen about as wide as the task bar. The window might shrink in size by a few pixels. If you use the `onscreen` option with a maximized figure window, then `movegui` creates a gap on both the left and upper sides of the screen so that the top-left corner of the figure is visible.

`GUIDE` and `openfig` call `movegui` when loading figures to ensure they are visible.

## Examples

Ensure that a saved UI window appears on screen when you reload it, regardless of the target computer screen size and resolution. Create a figure that is off the screen, assign `movegui` as its `CreateFcn` callback, save the figure, and then reload it.

```
f = figure('Position',[10000,10000,400,300]);
% The figure does not display because
% it is created offscreen.
```

```
f.CreateFcn = @movegui;
hgsave(f, 'onscreenfig');
close(f);
f2 = hgload('onscreenfig');
% The reloaded figure is now visible
```

Move a figure to the bottom left corner of the screen.

```
f = figure;
movegui(f, 'southwest');
```

Move a figure so that it is offset 100 pixels from the bottom and left side of the screen.

```
f = figure;
movegui(f, [100,100]);
```

## More About

### Pixels

Distances in pixels are independent of your system resolution on Windows and Macintosh systems:

- On Windows systems, a pixel is 1/96th of an inch.
- On Macintosh systems, a pixel is 1/72nd of an inch.

On Linux systems, the size of a pixel is determined by your system resolution.

## movie

Play recorded movie frames

### Syntax

```
movie(M)
movie(M,n)
movie(M,n,fps)
movie(h,...)
movie(h,M,n,fps,loc)
```

### Description

The `movie` function plays the movie defined by a matrix whose columns are movie frames (usually produced by `getframe`).

`movie(M)` plays the movie in matrix `M` once, using the current axes as the default target. If you want to play the movie in the figure instead of the axes, specify the figure handle (or `gcf`) as the first argument: `movie(figure_handle, ...)`. `M` must be an array of movie frames (usually from `getframe`).

`movie(M,n)` plays the movie `n` times. If `n` is negative, each cycle is shown forward then backward. If `n` is a vector, the first element is the number of times to play the movie, and the remaining elements make up a list of frames to play in the movie.

For example, if `M` has four frames then `n = [10 4 4 2 1]` plays the movie ten times, and the movie consists of frame 4 followed by frame 4 again, followed by frame 2 and finally frame 1.

`movie(M,n,fps)` plays the movie at `fps` frames per second. The default is 12 frames per second. Computers that cannot achieve the specified speed play as fast as possible.

`movie(h, ...)` plays the movie centered in the figure or axes identified by the handle `h`. Specifying the figure or axes enables MATLAB to fit the movie to the available size.

`movie(h,M,n,fps,loc)` specifies `loc`, a four-element location vector, `[x y 0 0]`, where the lower left corner of the movie frame is anchored (only the first two elements in

the vector are used). The location is relative to the lower left corner of the figure or axes specified by handle `h` and in units of pixels, regardless of the object's `Units` property.

## Examples

### Record Frames and Play Movie

Use the `getframe` function in a loop to record frames of the `peaks` function vibrating. Preallocate an array to store the movie frames.

```
figure
Z = peaks;
surf(Z)
axis tight manual
ax = gca;
ax.NextPlot = 'replaceChildren';

loops = 40;
F(loops) = struct('cdata',[],'colormap',[]);
for j = 1:loops
 X = sin(j*pi/10)*Z;
 surf(X,Z)
 drawnow
 F(j) = getframe;
end
```

To play the movie two times, use `movie(F,2)`.

- “Record Animation for Playback”

## More About

### Tips

The `movie` function uses a default figure size of 560-by-420 and does not resize figures to fit movies with larger or smaller frames. To accommodate other frame sizes, you can resize the figure to fit the movie.

`movie` only accepts 8-bit image frames; it does not accept 16-bit grayscale or 24-bit truecolor image frames.

Buffering the movie places all frames in memory. As a result, on Microsoft Windows and perhaps other platforms, a long movie (on the order of several hundred frames) can exhaust memory, depending on system resources. In such cases an error message is issued:

```
??? Error using ==> movie
Could not create movie frame
```

You can abort a movie by typing **Ctrl-C**.

`movie` is not a built-in function. Therefore, you cannot call `movie` using the `builtin` function.

## Limitations with Renderer on Windows Systems

Setting the figure `Renderer` property to `painters` works around limitations of using `getframe` with the OpenGL renderer on some Windows systems.

## movie2avi

Create Audio/Video Interleaved (AVI) file from MATLAB movie

---

**Note:** `movie2avi` will be removed in a future release. Use `VideoWriter` instead.

---

### Syntax

```
movie2avi(mov, filename)
movie2avi(mov, filename, ParameterName, ParameterValue)
```

### Description

`movie2avi(mov, filename)` creates the AVI file `filename` from the MATLAB movie `mov`. The `filename` input is a string. The `mov` input is a 1-by- $n$  structure array, where  $n$  is the number of frames. Each frame is a structure with two fields: `cdata` and `colormap`. For more information, see `getframe`.

`movie2avi(mov, filename, ParameterName, ParameterValue)` accepts one or more comma-separated parameter name/value pairs. The following table lists the available parameters and values.

Parameter Name	Value	Default
'colormap'	An $m$ -by-3 matrix defining the colormap for indexed AVI movies, where $m$ is no more than 256 (236 for Indeo compression).  Valid only when the 'compression' is 'MSVC', 'RLE', or 'None'.	No default
'compression'	A text string specifying the compression codec to use. To create an uncompressed file, specify a value of 'None'.  On UNIX operating systems, the only valid value is 'None'.	'Indeo5' on Windows systems.  'None' on UNIX systems.

Parameter Name	Value	Default
	<p>On Windows systems, valid values include:</p> <ul style="list-style-type: none"> <li>• 'MSVC'</li> <li>• 'RLE'</li> <li>• 'Cinepak' on 32-bit systems.</li> <li>• 'Indeo3' or 'Indeo5' on 32-bit Windows XP systems.</li> </ul> <p>Alternatively, specify a custom compression codec on Windows systems using the four-character code that identifies the codec (typically included in the codec documentation). If MATLAB cannot find the specified codec, it returns an error.</p>	
'fps'	A scalar value specifying the speed of the AVI movie in frames per second (fps).	15 fps
'keyframe'	For compressors that support temporal compression, the number of key frames per second.	2.1429 key frames per second
'quality'	<p>A number from 0 through 100. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes.</p> <p>Valid only for compressed movies.</p>	75
'videoname'	A descriptive name for the video stream, no more than 64 characters.	<i>filename</i>

## Examples

Create a movie and write to an uncompressed AVI file, `myPeaks.avi`:

```
nFrames = 20;

% Preallocate movie structure.
mov(1:nFrames) = struct('cdata', [], ...
 'colormap', []);
```

```
% Create movie.
Z = peaks; surf(Z);
axis tight manual
set(gca,'nextplot','replacechildren');
for k = 1:nFrames
 surf(sin(2*pi*k/20)*Z,Z)
 mov(k) = getframe(gcf);
end

% Create AVI file.
movie2avi(mov, 'myPeaks.avi', 'compression', 'None');
```

## More About

### Tips

- On some Windows systems, including all 64-bit systems, the default Indeo® 5 codec is not available. MATLAB issues a warning, and creates an uncompressed file.
- On 32-bit Windows XP systems, MATLAB can create AVI files compressed with Indeo 3 and Indeo 5 codecs. However, Microsoft Windows XP Service Pack 3 (SP3) with Security Update 954157 disables playback of Indeo 3 and Indeo 5 codecs in Windows Media Player and Internet Explorer®. Consider specifying a `compression` value of `'None'`.

## mpower, ^

Matrix power

### Syntax

```
C = A^B
C = mpower(A,B)
```

### Description

$C = A^B$  computes  $A$  to the  $B$  power and returns the result in  $C$ .

$C = \text{mpower}(A,B)$  is an alternate way to execute  $A^B$ , but is rarely used. It enables operator overloading for classes.

### Examples

#### Square a Matrix

Create a 2-by-2 matrix and square it.

```
A = [1 2; 3 4];
C = A^2
```

```
C =
```

```
 7 10
 15 22
```

The syntax  $A^2$  is equivalent to  $A*A$ .

#### Matrix Exponents

Create a 2-by-2 matrix and use it as the exponent for a scalar.

```
B = [0 1; 1 0];
```

$$C = 2^B$$

$$C =$$

$$\begin{bmatrix} 1.2500 & 0.7500 \\ 0.7500 & 1.2500 \end{bmatrix}$$

Compute **C** by first finding the eigenvalues **D** and eigenvectors **V** of the matrix **B**.

$$[V,D] = \text{eig}(B)$$

$$V =$$

$$\begin{bmatrix} -0.7071 & 0.7071 \\ 0.7071 & 0.7071 \end{bmatrix}$$

$$D =$$

$$\begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}$$

Next, use the formula  $2^B = V \cdot 2^D / V$  to compute the power.

$$C = V \cdot 2^D / V$$

$$C =$$

$$\begin{bmatrix} 1.2500 & 0.7500 \\ 0.7500 & 1.2500 \end{bmatrix}$$

## Input Arguments

### A — Base

scalar | matrix

Base, specified as a scalar or matrix. Inputs **A** and **B** must be one of the following:

- Base **A** is a square matrix and exponent **B** is a scalar. If **B** is a positive integer, the power is computed by repeated squaring. For other values of **B** the calculation involves eigenvalues and eigenvectors.
- Base **A** is a scalar and exponent **B** is a square matrix. The calculation uses eigenvalues and eigenvectors.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

Complex Number Support: Yes

## **B — Exponent**

`scalar` | `matrix`

Exponent, specified as a scalar or matrix. Inputs **A** and **B** must be one of the following:

- Base **A** is a square matrix and exponent **B** is a scalar. If **B** is a positive integer, the power is computed by repeated squaring. For other values of **B** the calculation involves eigenvalues and eigenvectors.
- Base **A** is a scalar and exponent **B** is a square matrix. The calculation uses eigenvalues and eigenvectors.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

Complex Number Support: Yes

## **mput**

**Class:** FTP

Upload file or folder to FTP server

## **Syntax**

```
mput(ftpobj,contents)
paths = mput(ftpobj,contents)
```

## **Description**

`mput(ftpobj,contents)` uploads the file or folder specified by `contents` to the current folder on an FTP server.

`paths = mput(ftpobj,contents)` returns a cell array that lists the paths to the uploaded files on the server.

## **Input Arguments**

### **ftpobj**

FTP object created by `ftp`.

### **contents**

String enclosed in single quotation marks that specifies either a file name or a folder name. Can include a wildcard character (\*).

## **Output Arguments**

### **paths**

Cell array that includes the paths to the uploaded files on the server.

## Examples

Suppose that your current MATLAB folder contains files `myfile1.m` through `myfile10.m`, and that you want to upload to a hypothetical FTP server, `ftp.testsite.com`. Connect to the server and upload the files:

```
ts = ftp('ftp.testsite.com');
mput(ts, 'myfile*.m');
close(ts);
```

## See Also

# msgbox

Create message dialog box

## Syntax

```
h = msgbox(Message)
h = msgbox(Message,Title)
h = msgbox(Message,Title,Icon)
h = msgbox(Message,Title,'custom',IconData,IconCMap)
h = msgbox(____,CreateMode)
```

## Description

`h = msgbox(Message)` creates a message dialog box that automatically wraps `Message` to fit an appropriately sized figure.

`h = msgbox(Message,Title)` specifies the title of the message box.

`h = msgbox(Message,Title,Icon)` specifies which built-in icon to display in the message dialog box.

`h = msgbox(Message,Title,'custom',IconData,IconCMap)` specifies a custom icon to include in the message dialog box. `IconData` is the image data that defines the icon. `IconCMap` is the colormap used for the image. If `IconData` is a true-color image, you do not need to specify an `IconCMap`.

`h = msgbox( ____,CreateMode)` specifies whether the message box is modal. Additionally, you can specify a TeX interpreter for `Message` and `Title`.

## Examples

### Simple Message Dialog Box

Specify the text you want displayed in the message dialog box.

```
h = msgbox('Operation Completed');
```

### Message Dialog Box Text with Line Breaks

Specify the message dialog box text using a cell array of strings to insert line breaks between the display of each string in the cell array.

```
h = msgbox({'Operation' 'Completed'});
```

### Message Dialog Box with a Title

Specify the message dialog box text and give the dialog box a title, Success.

```
h = msgbox('Operation Completed', 'Success');
```

### Message Dialog Box That Uses a Built-in Icon

Include a built-in error icon with an error message in a message dialog box entitled Error.

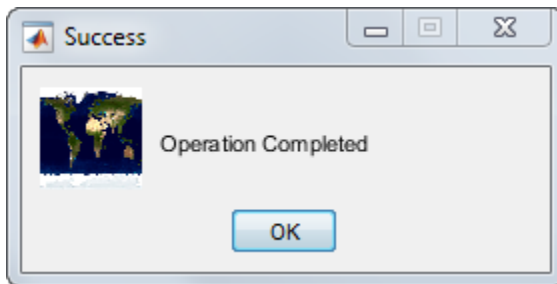

```
h = msgbox('Invalid Value', 'Error', 'error');
```

### Message Dialog Box That Uses a True-Color Custom Icon

Read an RGB image into the workspace. Then, specify it as a custom icon in the dialog box.

```
myicon = imread('landOcean.jpg');
h=msgbox('Operation Completed', 'Success', 'custom', myicon);
```

### Message Dialog Box That Uses an Indexed Color Icon

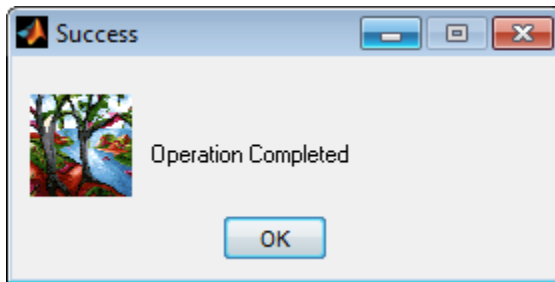

Read the image data and colormap into the workspace.

```
[cdata, map] = imread('trees.tif');
```

Create the message dialog box, including the custom icon.

```
h=msgbox('Operation Completed', ...
 'Success', 'custom', cdata, map);
```

Adjust the image colors by specifying a different colormap. For instance, specify the MATLAB built-in colormap, `summer`

```
h=msgbox('Operation Completed','Success','custom',...
 cdata,summer);
```

### Modal Message Dialog Box

Create a modal message dialog box, wrapping the call to `msgbox` with `uiwait` to make the message dialog box block MATLAB execution until the user responds to the message dialog box.

```
uiwait(msgbox('Operation Completed','Success','modal'));
```

## Modal Message Dialog Box That Uses a TeX Formatted Message

Create a structure to specify that the user must click OK before interacting with another window and that MATLAB interpret the message text as TeX format.

```
CreateStruct.Interpreter = 'tex';
CreateStruct.WindowStyle = 'modal';
```

Create the message dialog box.

```
h=msgbox('Z = X^2 + Y^2', 'Value', CreateStruct);
```

## Input Arguments

### Message — Message dialog box text

string vector | string matrix | cell array

Dialog box text specified as a string vector, string matrix, or cell array.

Example: 'Operation Completed'

Example: ['Operation ', 'Completed']

Example: {'Operation', 'Completed'}

### Title — Message dialog box title bar text

string vector

Dialog box title bar text specified as a string vector.

Example: 'Success'

### Icon — Icon to include in message dialog box

'none' (default) | 'error' | 'help' | 'warn' | 'custom'

Icon to include in message dialog box specified as a string.

Built-in icons appear as follows:

-  Error
-  Help
-  Warn

### IconData — Image data defining a custom icon

matrix

Image data defining a custom icon specified as a matrix. Each element of the matrix specifies the color of a rectangular segment in the image. Use `imread` to get the `IconData` value for an image that you want to use as a message dialog box icon.

Example: `[1:64]*[1:64])/64`

### IconCMap — Colormap for a custom icon that is not true-color

m-by-3 matrix | built-in colormap

Colormap for a custom icon that is not true-color, specified as an m-by-3 matrix of real numbers between 0.0 and 1.0, or as a MATLAB built-in colormap. Use `imread` to get the `IconCMap` value for an image that you want to use as a message dialog box icon.

Example: `[0.5 0.5 0.5]`

Example: `hot(64)`

### CreateMode — Message dialog box mode

'nonmodal' (default) | structure | 'modal' | 'replace'

Mode in which message dialog box is created, specified as a string or a structure.

- If `CreateMode` is a structure, it can have the fields `WindowStyle` and `Interpreter`. The `WindowStyle` field must be one of the strings listed in the list items that

follow this one. The `Interpreter` field must be the string `'tex'` or `'none'`. If the `Interpreter` value is `'tex'`, MATLAB interprets the `Message` and `Title` values as TeX. The default value for `Interpreter` is `'none'`.

- If `CreateMode` is `'nonmodal'`, MATLAB creates a new nonmodal message box with the specified parameters. Existing message boxes with the same `Title` remain.
- If `CreateMode` is `'modal'`, MATLAB replaces the existing message box with the specified `Title` that was last created or clicked on with the specified modal dialog box. MATLAB deletes all other message boxes with the same title. The replaced message box can be either modal or nonmodal.
- If `CreateMode` is `'replace'`, MATLAB replaces the message box having the specified `Title` that was last created or clicked on with a nonmodal message box as specified. MATLAB deletes all other message boxes with the same title. The replaced message box can be either modal or nonmodal.

Example: `CreateStruct.Interpreter='tex';`

## Output Arguments

### **h** — Message dialog box handle

scalar

Message dialog box handle returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of a specific message dialog box.

## More About

### **modal dialog box**

A modal dialog box prevents a user from interacting with other windows before responding to the modal dialog box.

For more information about modal dialog boxes, see `WindowState` in the `Figure Properties` topic.

### **Tips**

- Program execution continues even when a modal dialog box is active. To block MATLAB program execution until the user responds to the modal dialog box, use the `uiwait` function.

- Modal dialogs (created using `errordlg`, `msgbox`, or `warndlg`) replace any existing dialogs created with these functions that also have the same name.

**See Also**

`errordlg` | `helpdlg` | `imread` | `warndlg`

**Introduced before R2006a**

## **mtimes, \***

Matrix Multiplication

### **Syntax**

```
C = A*B
C = mtimes(A,B)
```

### **Description**

$C = A*B$  is the matrix product of **A** and **B**. If **A** is an m-by-p and **B** is a p-by-n matrix, then **C** is an m-by-n matrix defined by

$$C(i, j) = \sum_{k=1}^p A(i, k)B(k, j).$$

This definition says that  $C(i, j)$  is the inner product of the *i*th row of **A** with the *j*th column of **B**. You can write this definition using the MATLAB colon operator as

```
C(i, j) = A(i, :)*B(:, j)
```

For nonscalar **A** and **B**, the number of columns of **A** must equal the number of rows of **B**. Matrix multiplication is *not* universally commutative for nonscalar inputs. That is,  $A*B$  is typically not equal to  $B*A$ . If at least one input is scalar, then  $A*B$  is equivalent to  $A.*B$  and is commutative.

`C = mtimes(A,B)` is an alternative way to execute  $A*B$ , but is rarely used. It enables operator overloading for classes.

### **Examples**

#### **Multiply Two Vectors**

Create a 1-by-4 row vector, **A**, and a 4-by-1 column vector, **B**.

```
A = [1 1 0 0];
B = [1; 2; 3; 4];
```

Multiply A times B.

```
C = A*B
```

```
C =
```

```
3
```

The result is a 1-by-1 scalar, also called the *dot product* or *inner product* of the vectors A and B. Alternatively, you can calculate the dot product  $A \cdot B$  with the syntax `dot(A,B)`.

Multiply B times A.

```
C = B*A
```

```
C =
```

```
1 1 0 0
2 2 0 0
3 3 0 0
4 4 0 0
```

The result is a 4-by-4 matrix, also called the *outer product* of the vectors A and B. The outer product of two vectors,  $A \otimes B$ , returns a matrix.

### Multiply Two Arrays

Create two arrays, A and B.

```
A = [1 3 5; 2 4 7];
```

```
B = [-5 8 11; 3 9 21; 4 0 8];
```

Calculate the product of A and B.

```
C = A*B
```

```
C =
```

```
24 35 114
30 52 162
```

Calculate the inner product of the second row of A and the third column of B.

```
A(2,:) * B(:,3)
```

```
ans =
```

162

This answer is the same as `C(2,3)`.

## Input Arguments

### **A — Left Array**

scalar | vector | matrix

Left Array, specified as a scalar, vector, or matrix. For nonscalar inputs, the number of columns in **A** must be equal to the number of rows in **B**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `duration` | `calendarDuration`

Complex Number Support: Yes

### **B — Right Array**

scalar | vector | matrix

Right Array, specified as a scalar, vector, or matrix. For nonscalar inputs, the number of columns in **A** must be equal to the number of rows in **B**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `duration` | `calendarDuration`

Complex Number Support: Yes

## Output Arguments

### **C — Product Array**

scalar | vector | matrix

Product Array, returned as a scalar, vector, or matrix. Array **C** has the same number of rows as input **A** and the same number of columns as input **B**. For example, if **A** is an  $m$ -by-0 empty matrix and **B** is a 0-by- $n$  empty matrix, then **A\*B** is an  $m$ -by- $n$  matrix of zeros.

## More About

- “Array vs. Matrix Operations”

- “Operator Precedence”

## **See Also**

colon | cross | dot | times

**Introduced before R2006a**

## **mu2lin**

Convert mu-law audio signal to linear

### **Syntax**

```
y = mu2lin(mu)
```

### **Description**

`y = mu2lin(mu)` converts mu-law encoded 8-bit audio signals, stored as “flints” in the range  $0 \leq \mu \leq 255$ , to linear signal amplitude in the range  $-s < Y < s$  where  $s = 32124/32768 \approx .9803$ . The input `mu` is often obtained using `fread(..., 'uchar')` to read byte-encoded audio files. “Flints” are MATLAB integers — floating-point numbers whose values are integers.

# multibandread

Read band-interleaved data from binary file

## Syntax

```
X = multibandread(filename, size, precision, offset, interleave,
byteorder)
X = multibandread(...,subset1,subset2,subset3)
```

## Description

`X = multibandread(filename, size, precision, offset, interleave, byteorder)` reads band-sequential (BSQ), band-interleaved-by-line (BIL), or band-interleaved-by-pixel (BIP) data from the binary file `filename`. The `filename` input is a string enclosed in single quotes. This function defines *band* as the third dimension in a 3-D array, as shown in this figure.

You can use the parameters to `multibandread` to specify many aspects of the read operation, such as which bands to read. See “Parameters” on page 1-5782 for more information.

`X` is a 2-D array if only one band is read; otherwise it is 3-D. `X` is returned as an array of data type `double` by default. Use the `precision` parameter to map the data to a different data type.

`X = multibandread(...,subset1,subset2,subset3)` reads a subset of the data in the file. You can use up to three subsetting parameters to specify the data subset along row, column, and band dimensions. See “Subsetting Parameters” on page 1-5783 for more information.

---

**Note:** In addition to BSQ, BIL, and BIP files, multiband imagery may be stored using the TIFF file format. In that case, use the `imread` function to import the data.

---

## Parameters

This table describes the arguments accepted by `multibandread`.

Argument	Description
<code>filename</code>	String containing the name of the file to be read.
<code>size</code>	<p>Three-element vector of integers consisting of <code>[height, width, N]</code>, where</p> <ul style="list-style-type: none"> <li><code>height</code> is the total number of rows</li> <li><code>width</code> is the total number of elements in each row</li> <li><code>N</code> is the total number of bands.</li> </ul> <p>This will be the dimensions of the data if it is read in its entirety.</p>
<code>precision</code>	<p>String specifying the format of the data to be read, such as <code>'uint8'</code>, <code>'double'</code>, <code>'integer*4'</code>, or any of the other precisions supported by the <code>fread</code> function.</p> <p>Note: You can also use the <code>precision</code> parameter to specify the format of the output data. For example, to read <code>uint8</code> data and output a <code>uint8</code> array, specify a precision of <code>'uint8=&gt;uint8'</code> (or <code>'*uint8'</code>). To read <code>uint8</code> data and output it in the MATLAB software in single precision, specify <code>'uint8=&gt;single'</code>. See <code>fread</code> for more information.</p>
<code>offset</code>	Scalar specifying the zero-based location of the first data element in the file. This value represents the number of bytes from the beginning of the file to where the data begins.
<code>interleave</code>	String specifying the format in which the data is stored

Argument	Description
	<ul style="list-style-type: none"> <li>• 'bsq' — Band-Sequential</li> <li>• 'bil' — Band-Interleaved-by-Line</li> <li>• 'bip' — Band-Interleaved-by-Pixel</li> </ul> <p>For more information about these interleave methods, see the <code>multibandwrite</code> reference page.</p>
byteorder	<p>String specifying the byte ordering (machine format) in which the data is stored, such as</p> <ul style="list-style-type: none"> <li>• 'ieee-le' — Little-endian</li> <li>• 'ieee-be' — Big-endian</li> </ul> <p>See <code>fopen</code> for a complete list of supported formats.</p>

## Subsetting Parameters

You can specify up to three subsetting parameters. Each subsetting parameter is a three-element cell array, `{dim,method,index}`, where

Parameter	Description
<i>dim</i>	<p>Text string specifying the dimension to subset along. It can have any of these values:</p> <ul style="list-style-type: none"> <li>• 'Column'</li> <li>• 'Row'</li> <li>• 'Band'</li> </ul>
<i>method</i>	<p>Text string specifying the subsetting method. It can have either of these values:</p> <ul style="list-style-type: none"> <li>• 'Direct'</li> <li>• 'Range'</li> </ul> <p>If you leave out this element of the subset cell array, <code>multibandread</code> uses 'Direct' as the default.</p>

Parameter	Description
index	<p>If method is 'Direct', index is a vector specifying the indices to read along the Band dimension.</p> <p>If method is 'Range', index is a three-element vector of [start, increment, stop] specifying the range and step size to read along the dimension specified in dim. If index is a two-element vector, multibandread assumes that the value of increment is 1.</p>

## Examples

### Example 1

Setup initial parameters for a data set.

```
rows=3; cols=3; bands=5;
filename = tempname;
```

Define the data set.

```
fid = fopen(filename, 'w', 'ieee-le');
fwrite(fid, 1:rows*cols*bands, 'double');
fclose(fid);
```

Read every other band of the data using the Band-Sequential format.

```
im1 = multibandread(filename, [rows cols bands], ...
 'double', 0, 'bsq', 'ieee-le', ...
 {'Band', 'Range', [1 2 bands]})
```

Read the first two rows and columns of data using Band-Interleaved-by-Pixel format.

```
im2 = multibandread(filename, [rows cols bands], ...
 'double', 0, 'bip', 'ieee-le', ...
 {'Row', 'Range', [1 2]}, ...
 {'Column', 'Range', [1 2]})
```

Read the data using Band-Interleaved-by-Line format.

```
im3 = multibandread(filename, [rows cols bands], ...
```

```
'double', 0, 'bil', 'ieee-le')
```

Delete the file created in this example.

```
delete(filename);
```

## Example 2

Read `int16` BIL data from the FITS file `tst0012.fits`, starting at byte 74880.

```
im4 = multibandread('tst0012.fits', [31 73 5], ...
 'int16', 74880, 'bil', 'ieee-be', ...
 {'Band', 'Range', [1 3]});
im5 = double(im4)/max(max(max(im4)));
imagesc(im5);
```

## See Also

## multibandwrite

Write band-interleaved data to file

### Syntax

```
multibandwrite(data,filename,interleave)
multibandwrite(data,filename,interleave,start,totalsize)
multibandwrite(...,param,value...)
```

### Description

`multibandwrite(data,filename,interleave)` writes `data`, a two- or three-dimensional numeric or logical array, to the binary file specified by `filename`. The `filename` input is a string enclosed in single quotes. The length of the third dimension of `data` determines the number of bands written to the file. The bands are written to the file in the form specified by `interleave`. See “Interleave Methods” on page 1-5787 for more information about this argument.

If `filename` already exists, `multibandwrite` overwrites it unless you specify the optional `offset` parameter. See the last alternate syntax for `multibandwrite` for information about other optional parameters.

`multibandwrite(data,filename,interleave,start,totalsize)` writes `data` to the binary file `filename` in chunks. In this syntax, `data` is a subset of the complete data set.

`start` is a 1-by-3 array [`firstrow firstcolumn firstband`] that specifies the location to start writing data. `firstrow` and `firstcolumn` specify the location of the upper left image pixel. `firstband` gives the index of the first band to write. For example, `data(I,J,K)` contains the data for the pixel at [`firstrow+I-1, firstcolumn+J-1`] in the (`firstband+K-1`)-th band.

`totalsize` is a 1-by-3 array, [`totalrows,totalcolumns,totalbands`], which specifies the full, three-dimensional size of the data to be written to the file.

---

**Note** In this syntax, you must call `multibandwrite` multiple times to write all the data to the file. The first time it is called, `multibandwrite` writes the complete file,

using the fill value for all values outside the data subset. In each subsequent call, `multibandwrite` overwrites these fill values with the data subset in `data`. The parameters `filename`, `interleave`, `offset`, and `totalsize` must remain constant throughout the writing of the file.

`multibandwrite(..., param, value...)` writes the multiband data to a file, specifying any of these optional parameter/value pairs.

Parameter	Description
'precision'	String specifying the form and size of each element written to the file. See the help for <code>fwrite</code> for a list of valid values. The default precision is the class of the data.
'offset'	The number of bytes to skip before the first data element. If the file does not already exist, <code>multibandwrite</code> writes ASCII null values to fill the space. To specify a different fill value, use the parameter 'fillvalue'.  This option is useful when you are writing a header to the file before or after writing the data. When writing the header to the file after the data is written, open the file with <code>fopen</code> using 'r+' permission.
'machfmt'	String to control the format in which the data is written to the file. Typical values are 'ieee-le' for little endian and 'ieee-be' for big endian. See the help for <code>fopen</code> for a complete list of available formats. The default machine format is the local machine format.
'fillvalue'	A number specifying the value to use in place of missing data. 'fillvalue' can be a single number, specifying the fill value for all missing data, or a 1-by-Number-of-bands vector of numbers specifying the fill value for each band. This value is used to fill space when data is written in chunks.

## Interleave Methods

`interleave` is a string that specifies how `multibandwrite` interleaves the bands as it writes data to the file. If `data` is two-dimensional, `multibandwrite` ignores the

interleave argument. The following table lists the supported methods and uses this example multiband file to illustrate each method.

Supported methods of interleaving bands include those listed below.

Method	String	Description	Example
Band-Interleaved-by-Line	'bil'	Write an entire row from each band	AAAAABBBBBCCCC AAAAABBBBBCCCC AAAAABBBBBCCCC
Band-Interleaved-by-Pixel	'bip'	Write a pixel from each band	ABCABCABCABC...
Band-Sequential	'bsq'	Write each band in its entirety	AAAA AAAA AAAA BBBB BBBB BBBB BBBB CCCC CCCC CCCC

## Examples

**Note** To run these examples successfully, you must be in a writable directory.

### Example 1

Write all data (interleaved by line) to the file in one call.

```
data = reshape(uint16(1:600), [10 20 3]);
multibandwrite(data, 'data.bil', 'bil');
```

## Example 2

Write a single-band tiled image with one call for each tile. This is only useful if a subset of each band is available at each call to `multibandwrite`.

```
numBands = 1;
dataDims = [1024 1024 numBands];
data = reshape(uint32(1:(1024 * 1024 * numBands)), dataDims);

for band = 1:numBands
 for row = 1:2
 for col = 1:2

 subsetRows = ((row - 1) * 512 + 1):(row * 512);
 subsetCols = ((col - 1) * 512 + 1):(col * 512);

 upperLeft = [subsetRows(1), subsetCols(1), band];
 multibandwrite(data(subsetRows, subsetCols, band), ...
 'banddata.bsq', 'bsq', upperLeft, dataDims);

 end
 end
end
```

## **munlock**

Allow clearing functions from memory

### **Syntax**

```
munlock
munlock fun
munlock('fun')
```

### **Description**

`munlock` unlocks the currently running `.m` or `.mex` function in memory so that subsequent `clear` functions can remove it.

`munlock fun` unlocks the `.m` or `.mex` file named `fun` from memory. By default, these files are unlocked so that changes to the file are picked up. Calls to `munlock` are needed only to unlock `.m` or `.mex` functions that have been locked with `mlock`.

`munlock('fun')` is the function form of `munlock`.

### **Examples**

The function `testfun` begins with an `mlock` statement.

```
function testfun
mlock
 :
 :
```

When you execute this function, it becomes locked in memory. You can check this using the `mislocked` function.

```
testfun

mislocked testfun
ans =
```

1

Using `munlock`, you unlock the `testfun` function in memory. Checking its status with `mislocked` shows that it is indeed unlocked at this point.

```
munlock testfun
```

```
mislocked testfun
ans =
 0
```

### **See Also**

**Introduced before R2006a**

# **namelengthmax**

Maximum identifier length

## **Syntax**

```
len = namelengthmax
```

## **Description**

`len = namelengthmax` returns the maximum length allowed for MATLAB identifiers, which include:

- Variable names
- Structure field names
- Script, function, and class names
- Model names

Rather than hard-coding a specific maximum name length into your programs, use the `namelengthmax` function. This saves you the trouble of having to update these limits should the identifier length change in some future MATLAB release.

## **Examples**

Call `namelengthmax` to get the maximum identifier length:

```
maxid = namelengthmax
maxid =
 63
```

# NaN

Not-a-Number

## Syntax

NaN

`N = NaN(n)`

`N = NaN(sz1, ..., szN)`

`N = NaN(sz)`

`N = NaN(classname)`

`N = NaN(n, classname)`

`N = NaN(sz1, ..., szN, classname)`

`N = NaN(sz, classname)`

`N = NaN('like', p)`

`N = NaN(n, 'like', p)`

`N = NaN(sz1, ..., szN, 'like', p)`

`N = NaN(sz, 'like', p)`

## Description

NaN returns the IEEE arithmetic representation for Not-a-Number (NaN). These values result from operations which have undefined numerical results.

`N = NaN(n)` is an  $n$ -by- $n$  matrix of NaN values.

`N = NaN(sz1, ..., szN)` is a  $sz1$ -by-...-by- $szN$  array of NaN values where  $sz1, \dots, szN$  indicates the size of each dimension. For example, `NaN(3, 4)` returns a 3-by-4 array of NaN values.

`N = NaN(sz)` is an array of NaN values where the size vector, `sz`, defines `size(N)`. For example, `NaN([3, 4])` returns a 3-by-4 array of NaN values.

---

**Note** The size inputs `sz1, \dots, szN`, as well as the elements of the size vector `sz`, should be nonnegative integers. Negative integers are treated as 0.

---

`N = NaN(classname)` returns a NaN value where the string, `classname`, specifies the data type. `classname` can be either `'single'` or `'double'`.

`N = NaN(n,classname)` returns an `n`-by-`n` array of NaN values of data type `classname`.

`N = NaN(sz1,...,szN,classname)` returns a `sz1`-by-...-by-`szN` array of NaN values of data type `classname`.

`N = NaN(sz,classname)` returns an array of NaN values where the size vector, `SZ`, defines `size(N)` and `classname` defines `class(N)`.

`N = NaN('like',p)` returns a NaN value of the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`N = NaN(n,'like',p)` returns an `n`-by-`n` array of NaN values like `p`.

`N = NaN(sz1,...,szN,'like',p)` returns a `sz1`-by-...-by-`szN` array of NaN values like `p`.

`N = NaN(sz,'like',p)` returns an array of NaN values like `p` where the size vector, `SZ`, defines `size(N)`.

## Examples

These operations produce NaN:

- Any arithmetic operation on a NaN, such as `sqrt(NaN)`
- Addition or subtraction, such as magnitude subtraction of infinities as `(+Inf)+(-Inf)`
- Multiplication, such as `0*Inf`
- Division, such as `0/0` and `Inf/Inf`
- Remainder, such as `rem(x,y)` where `y` is zero or `x` is infinity

## More About

### Tips

Because two NaNs are not equal to each other, logical operations involving NaNs always return false, except `~=` (not equal). Consequently,

```
NaN ~= NaN
ans =
 1
NaN == NaN
ans =
 0
```

and the NaNs in a vector are treated as different unique elements.

```
unique([1 1 NaN NaN])
ans =
 1 NaN NaN
```

Use the `isnan` function to detect NaNs in an array.

```
isnan([1 1 NaN NaN])
ans =
 0 0 1 1
```

- “Class Support for Array-Creation Functions”

**Introduced before R2006a**

# nargchk

Validate number of input arguments

---

**Note:** nargchk will be removed in a future version. Use narginchk instead.

---

## Syntax

```
msgstring = nargchk(minargs, maxargs, numargs)
msgstring = nargchk(minargs, maxargs, numargs, 'string')
msgstruct = nargchk(minargs, maxargs, numargs, 'struct')
```

## Description

Use `nargchk` inside a function to check that the desired number of input arguments is specified in the call to that function.

`msgstring = nargchk(minargs, maxargs, numargs)` returns an error message string `msgstring` if the number of inputs specified in the call `numargs` is less than `minargs` or greater than `maxargs`. If `numargs` is between `minargs` and `maxargs` (inclusive), `nargchk` returns an empty matrix.

It is common to use the `nargin` function to determine the number of input arguments specified in the call.

`msgstring = nargchk(minargs, maxargs, numargs, 'string')` is essentially the same as the command shown above, as `nargchk` returns a string by default.

`msgstruct = nargchk(minargs, maxargs, numargs, 'struct')` returns an error message structure `msgstruct` instead of a string. The fields of the return structure contain the error message string and a message identifier. If `numargs` is between `minargs` and `maxargs` (inclusive), `nargchk` returns an empty structure.

When too few inputs are supplied, the message string and identifier are

```
message: 'Not enough input arguments.'
```

```
identifier: 'MATLAB:nargchk:notEnoughInputs'
```

When too many inputs are supplied, the message string and identifier are

```
message: 'Too many input arguments.'
identifier: 'MATLAB:nargchk:tooManyInputs'
```

## Examples

Given the function `CheckInputs`,

```
function CheckInputs(x, y, z)
error(nargchk(2, 3, nargin))
```

Then typing `CheckInputs(1)` produces

```
Not enough input arguments.
```

## More About

### Tips

`nargchk` is often used together with the `error` function. The `error` function accepts either type of return value from `nargchk`: a message string or message structure. For example, this command provides the `error` function with a message string and identifier regarding which error was caught:

```
error(nargchk(2, 4, nargin, 'struct'))
```

If `nargchk` detects no error, it returns an empty string or structure. When `nargchk` is used with the `error` function, as shown here, this empty string or structure is passed as an input to `error`. When `error` receives an empty string or structure, it simply returns and no error is generated.

### See Also

`narginchk` | `nargin` | `nargoutchk` | `nargout` | `varargin` | `varargout` | `error`

**Introduced before R2006a**

## nargin

Number of function input arguments

### Syntax

```
nargin
nargin(fx)
```

### Description

`nargin` returns the number of input arguments passed in the call to the currently executing function. Use this `nargin` syntax only in the body of a function.

`nargin(fx)` returns the number of input arguments that appear in the definition statement for function `fx`. If the function includes `varargin` in its definition, then `nargin` returns the negative of the number of inputs. For example, if function `foo` declares inputs `a`, `b`, and `varargin`, then `nargin('foo')` returns `-3`.

### Input Arguments

`fx`

Either a function handle or a string in single quotes that specifies the name of a function.

### Examples

#### Inputs to Current Function

Create a function in a file named `addme.m` that accepts up to two inputs, and identify the number of inputs with `nargin`.

```
function c = addme(a,b)

switch nargin
 case 2
```

```

 c = a + b;
 case 1
 c = a + a;
 otherwise
 c = 0;
end

```

### Inputs Defined for a Function

Determine how many inputs a function can accept.

The function `addme` created in the previous example has two inputs in its declaration statement (a and b).

```

fx = 'addme';
nargin(fx)

ans =
 2

```

### Function with varargin Input

Determine how many inputs a function that uses `varargin` can accept.

Define a function in a file named `mynewplot.m` that accepts numeric inputs `x` and `y` and any number of additional plot inputs using `varargin`.

```

function mynewplot(x,y,varargin)
 figure
 plot(x,y,varargin{:})
 title('My New Plot')

```

At the command line, query how many inputs `newplot` can accept.

```

fx = 'mynewplot';
nargin(fx)

ans =
 -3

```

The minus sign indicates that the third input is `varargin`. The `mynewplot` function can accept an indeterminate number of additional input arguments.

### See Also

**Introduced before R2006a**

# narginchk

Validate number of input arguments

## Syntax

```
narginchk(minargs, maxargs)
```

## Description

`narginchk(minargs, maxargs)` throws an error if the number of inputs specified in the call to the currently executing function is less than `minargs` or greater than `maxargs`. If the number of inputs is between `minargs` and `maxargs` (inclusive), `narginchk` does nothing.

When too few inputs are supplied, the message identifier and message are:

```
identifier: 'MATLAB:narginchk:notEnoughInputs'
message: 'Not enough input arguments.'
```

When too many inputs are supplied, the message identifier and message are:

```
identifier: 'MATLAB:narginchk:tooManyInputs'
message: 'Too many input arguments.'
```

## Examples

This function uses `narginchk` to verify that a minimum of 2 and maximum of 5 input arguments are received from the calling function:

```
function check_inputs(A, B, varargin)
minargs=2; maxargs=5;

% Number of inputs must be >=minargs and <=maxargs.
narginchk(minargs, maxargs)

fprintf('Received 2 required, %d optional inputs.\n\n', ...
 size(varargin, 2))
```

Call the example function, passing 1 input argument:

```
check_inputs(23)
Error using check_inputs
Not enough input arguments.
```

Call the function, passing 5 arguments:

```
check_inputs(23, 9, 15, 34, 62)
Received 2 required, 3 optional inputs.
```

Call the function, passing 6 arguments:

```
check_inputs(23, 9, 15, 34, 62, 6)
Error using check_inputs
Too many input arguments.
```

## More About

### Tips

- To verify that there are a minimum of N arguments, specify `inf` as `maxargs`. For example: `narginchk(5,inf)` throws an error when there are not at least five inputs.

### See Also

`nargoutchk` | `nargin` | `nargout` | `varargin` | `varargout`

**Introduced in R2011b**

# nargout

Number of function output arguments

## Syntax

```
nargout
nargout (fx)
```

## Description

`nargout` returns the number of output arguments specified in the call to the currently executing function. Use this `nargout` syntax only in the body of a function.

`nargout (fx)` returns the number of outputs that appear in the definition statement of function `fx`. If the function includes `varargout` in its definition, then `nargout` returns the negative of the number of outputs. For example, if function `foo` declares outputs `a`, `b`, and `varargout`, then `nargout ('foo')` returns `-3`.

## Input Arguments

**fx**

Either a function handle or a string in single quotes that specifies the name of a function.

## Examples

### Outputs for Current Function

Create a function in a file named `subtract.m` that calculates a second return value only when requested.

```
function [dif,absdif] = subtract(y,x)
```

```
dif = y - x;
if nargout > 1
 disp('Calculating absolute value')
 absdif = abs(dif);
end
```

## Outputs Defined for a Function

Determine how many outputs a function can return.

The function named `subtract` created in the previous example has two outputs in its declaration statement (`dif` and `absdif`).

```
fx = 'subtract';
nargout(fx)
```

```
ans =
 2
```

## Function with `varargout` Output

Determine how many outputs a function that uses `varargout` can return.

Define a function in a file named `mysize.m` that returns a vector of dimensions from the `size` function and the individual dimensions using `varargout`.

```
function [sizeVector,varargout] = mysize(x)
 sizeVector = size(x);
 varargout = cell(1,nargout-1);
 for k = 1:length(varargout)
 varargout{k} = sizeVector(k);
 end
```

At the command line, query how many outputs `mysize` can return.

```
fx = 'mysize';
nargout(fx)
```

```
ans =
 -2
```

The minus sign indicates that the second output is `varargout`. The `mysize` function can return an indeterminate number of additional outputs.

## More About

### Tips

- When you use a function as part of an expression, MATLAB calls the function with one output argument, so `nargout` within the function returns 1. For example, given the following `if` statement and the `subtract` function defined in the Examples section, the value of `nargout` within the `subtract` function is 1.

```
a = 1;
b = 2;
if subtract(a,b) < 0
 disp('Result is negative')
end
```

### See Also

**Introduced before R2006a**

## nargoutchk

Validate number of output arguments

### Syntax

```
nargoutchk(minargs, maxargs)
```

### Description

`nargoutchk(minargs, maxargs)` throws an error if the number of outputs specified in the call is less than `minargs` or greater than `maxargs`. If the number of outputs is between `minargs` and `maxargs` (inclusive), `nargoutchk` does nothing.

When too few outputs are supplied, the identifier and message are:

```
identifier: 'MATLAB:nargoutchk:notEnoughOutputs'
message: 'Not enough output arguments.'
```

When too many outputs are supplied, the identifier and message are:

```
identifier: 'MATLAB:nargoutchk:tooManyOutputs'
message: 'Too many output arguments.'
```

### Examples

This function uses `nargoutchk` to verify that a minimum of 2 and maximum of 5 input arguments are passed back to the calling function:

```
function [varargout] = check_outputs(array_in)
minargs=2; maxargs=5;

% Number of outputs must be >=minargs and <=maxargs.
nargoutchk(minargs, maxargs)

for k=1:nargout
 varargout{k} = array_in(k)*3;
end
```

Initialize input array `X` to a vector of 6 elements:

```
X = 5:7:40
X =
 5 12 19 26 33 40
```

Call the example function with 1 output argument. This is less than the minimum (2) that was specified by `nargoutchk` and results in an error:

```
A = check_outputs(X);
```

```
Error using check_outputs
Not enough output arguments.
```

Call the function with 4 output arguments. This is within the allowable bounds (2 to 5) specified by `nargoutchk`:

```
[A, B, C, D] = check_outputs(X);
```

```
[A, B, C, D]
ans =
 15 36 57 78
```

Call the function with 6 output arguments. This exceeds the maximum (5) that was specified by `nargoutchk` and results in an error:

```
[A, B, C, D, E, F] = check_outputs(X);
```

```
Error using check_outputs
Too many output arguments.
```

## More About

### Tips

- To verify that there are a minimum of `N` arguments, specify `inf` as `maxargs`. For example: `nargoutchk(5, inf)` throws an error when there are not at least five outputs.

# NaT

Not-a-Time

NaT is the representation for Not-a-Time, a value that can be stored in a `datetime` array to indicate an unknown or missing `datetime` value.

The `datetime` function creates a NaT value automatically when it cannot read a date string, or for elements in a `datetime` array where the `Year`, `Month`, `Day`, `Hour`, `Minute`, or `Second` properties are set to `NaN`. You also can assign the string, 'NaT', to elements of an existing `datetime` array. Use the NaT function to create a new `datetime` array containing only NaT values.

## Syntax

NaT

```
t = NaT(n)
```

```
t = NaT(sz1, ..., szN)
```

```
t = NaT(sz)
```

```
t = NaT(____, 'Format', fmt)
```

```
t = NaT(____, 'TimeZone', tz)
```

## Description

NaT returns a scalar Not-a-Time (NaT) `datetime` value.

`t = NaT(n)` returns an `n`-by-`n` matrix of NaT values.

`t = NaT(sz1, ..., szN)` returns a `sz1`-by-...-by-`szN` array of NaT values where `sz1, ..., szN` indicates the size of each dimension. For example, `NaT(3,4)` returns a 3-by-4 array of NaT values.

`t = NaT(sz)` returns an array of NaT values where the size vector, `sz`, defines `size(t)`. For example, `NaT([3,4])` returns a 3-by-4 array of NaT values.

`t = NaT( ____, 'Format', fmt)` returns a `datetime` array with the specified display format. Use this syntax to initialize a `datetime` array. Not-a-Time values always display as NaT, but non-NaT values assigned to the array will display using the specified format.

`t = NaT( ____, 'TimeZone', tz)` returns an array of NaT values in the time zone specified by `tz`.

## Examples

### Square NaT Matrix

Create a 3-by-3 matrix of NaT values.

```
t = NaT(3)
t =
 NaT NaT NaT
 NaT NaT NaT
 NaT NaT NaT
```

### Initialize Rectangular datetime Array and Specify Format

Create a 2-by-3 array of NaT values and specify a date format.

```
t = NaT(2,3, 'Format', 'dd/MM/yyyy')
t =
 NaT NaT NaT
 NaT NaT NaT
```

Assign a `datetime` value to an element of `t`.

```
t(1,2) = datetime('today')
t =
 NaT 06/04/2015 NaT
 NaT NaT NaT
```

## Input Arguments

### **n** — Size of square matrix

integer

Size of square matrix, specified as an integer.

- If `n` is 0, then `t` is an empty matrix.

- If `n` is negative, then it is treated as 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **sz1, . . . , szN — Size of each dimension (as separate arguments)**

integer values

Size of each dimension, specified as separate arguments of integer values.

- If the size of any dimension is 0, then `t` is an empty array.
- If the size of any dimension is negative, then it is treated as 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **sz — Size of each dimension (as a row vector)**

integer values

Size of each dimension, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension:

- If the size of any dimension is 0, then `t` is an empty array.
- If the size of any dimension is negative, then it is treated as 0.

Example: `sz = [2,3,4]` creates a 2-by-3-by-4 array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **fmt — Date format**

'default' (default) | 'defaultdate' | string

Date format, specified as a string. Use the letters A-Z and a-z to define the format. For a complete list of valid letter identifiers, see the Format property for datetime arrays.

Alternatively, use one of the following strings to specify a default format.

Value of <code>fmt</code>	Description
'default'	Use the default display format.
'defaultdate'	Use the default display format for datetime values created without time components.

Example: 'yyyy MMM dd'

Data Types: char

**tz** — Time zone region

' ' (default) | string

Time zone region, specified as a string.

The value of `tz` can be:

- ' ', to create an “unzoned” `datetime` array that does not belong to a specific time zone.
- The name of a time zone region from the IANA Time Zone Database, for example, 'America/Los\_Angeles'. The name of a time zone region accounts for the current and historical rules for standard and daylight offsets from UTC that are observed in a geographic region.
- An ISO 8601 string of the form `+HH:mm` or `-HH:mm`, for example, '+01:00', to specify a time zone that is a fixed offset from UTC.
- 'UTC', to create a `datetime` array in Universal Coordinated Time.
- 'UTCLeapSeconds', to create a `datetime` array in Universal Coordinated Time that accounts for leap seconds.
- 'local', to create a `datetime` array in the system time zone.

This table lists some common names of time zone regions from the IANA Time Zone Database.

Value of <code>TimeZone</code>	UTC Offset	UTC DST Offset
'Africa/Johannesburg'	+02:00	+02:00
'America/Chicago'	-06:00	-05:00
'America/Denver'	-07:00	-06:00
'America/Los_Angeles'	-08:00	-07:00
'America/New_York'	-05:00	-04:00
'America/Sao_Paulo'	-03:00	-02:00
'Asia/Hong_Kong'	+08:00	+08:00
'Asia/Kolkata'	+05:30	+05:30

---

Value of TimeZone	UTC Offset	UTC DST Offset
'Asia/Tokyo'	+09:00	+09:00
'Australia/Sydney'	+10:00	+11:00
'Europe/London'	+00:00	+01:00
'Europe/Zurich'	+01:00	+02:00

Data Types: char

## native2unicode

Convert numeric bytes to Unicode character representation

### Syntax

```
unicodestr = native2unicode(bytes)
unicodestr = native2unicode(bytes, encoding)
```

### Description

`unicodestr = native2unicode(bytes)` converts a numeric vector, `bytes`, from the user default encoding to Unicode character representation. `bytes` is treated as a stream of 8-bit bytes, and each value must be in the range [0,255]. Return value `unicodestr` is a `char` vector having the same general array shape as `bytes`.

`unicodestr = native2unicode(bytes, encoding)` converts `bytes` to Unicode representation assuming that the byte stream is in the character encoding scheme specified by the string `encoding`. `encoding` must be the empty string ( `' '` ) or a name or alias for an encoding scheme. Some examples are `'UTF-8'`, `'latin1'`, `'US-ASCII'`, and `'Shift_JIS'`. If `encoding` is unspecified or is the empty string ( `' '` ), the default encoding scheme is used.

---

**Note** If `bytes` is a `char` vector, it is returned unchanged.

---

### Examples

This example begins with a vector of bytes in an unknown character encoding scheme. The user-written function `detect_encoding` determines the encoding scheme. If successful, it returns the encoding scheme name or alias as a string. If unsuccessful, it throws an error represented by an `MException` object, `ME`. The example calls `native2unicode` to convert the bytes to Unicode representation:

```
try
 enc = detect_encoding(bytes);
```

```
 str = native2unicode(bytes, enc);
 disp(str);
catch ME
 rethrow(ME);
end
```

Note that the computer must be configured to display text in a language represented by the detected encoding scheme for the output of `disp(str)` to be correct.

unicode2native

**Introduced before R2006a**

## nchoosek

Binomial coefficient or all combinations

### Syntax

`b = nchoosek(n, k)`

`C = nchoosek(v, k)`

### Description

`b = nchoosek(n, k)` returns the binomial coefficient, defined as  $n!/((n-k)! k!)$ . This is the number of combinations of  $n$  items taken  $k$  at a time.

`C = nchoosek(v, k)` returns a matrix containing all possible combinations of the elements of vector  $v$  taken  $k$  at a time. Matrix  $C$  has  $k$  columns and  $n!/((n-k)! k!)$  rows, where  $n$  is `length(v)`.

### Examples

#### Binomial Coefficient, "5 Choose 4"

`b = nchoosek(5, 4)`

`b =`

5

#### All Combinations of Five Numbers Taken Four at a Time

`v = 2:2:10;`

`C = nchoosek(v, 4)`

`C =`

2	4	6	8
2	4	6	10
2	4	8	10

```

2 6 8 10
4 6 8 10

```

### All Combinations of Three Unsigned Integers Taken Two at a Time

```

v = uint16([10 20 30]);
C = nchoosek(v,uint16(2))

```

C =

```

10 20
10 30
20 30

```

## Input Arguments

### **n** — Number of possible choices

scalar, real, nonnegative value

Number of possible choices, specified as a scalar value of any numeric type that is real and nonnegative.

Example: 10

Example: int16(10)

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **k** — Number of selected choices

scalar, real, nonnegative value

Number of selected choices, specified as a scalar value that is real and nonnegative. **k** can be any numeric type. However, `nchoosek(n,k)` requires that **n** and **k** be the same type or that at least one of them be of type double.

There are no restrictions on combining inputs of different types for `nchoosek(v,k)`.

Example: 3

Example: int16(3)

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**v — Set of all choices**

vector of numeric, logical, or char values

Set of all choices, specified as a vector of numeric, logical, or char values.

Example: [1 2 3 4 5]

Example: [1+1i 2+1i 3+1i 4+1i]

Example: int16([1 2 3 4 5])

Example: [true false true false]

Example: ['abcd']

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 |  
uint32 | uint64 | logical | char

Complex Number Support: Yes

## Output Arguments

**b — Binomial coefficient**

nonnegative scalar value

Binomial coefficient, returned as a nonnegative scalar value. **b** is the same type as **n** and **k**. If **n** and **k** are of different types, then **b** is returned as the nondouble type.

**C — All combinations of v**

matrix

All combinations of **v**, returned as a matrix of the same type as **v**. Matrix **C** has **k** columns and  $n!/((n-k)! k!)$  rows, where **n** is `length(v)`.

Each row of **C** contains a combination of **k** items chosen from **v**. The elements in each row of **C** are listed in the same order as they appear in **v**.

## Limitations

- When **b** = `nchoosek(n, k)` is sufficiently large, `nchoosek` displays a warning that the result might not be exact. In this case, the result is only accurate to 15 digits for double-precision inputs, or 8 digits for single-precision inputs.

- $C = \text{nchoosek}(v, k)$  is only practical for situations where  $\text{length}(v)$  is less than about 15.

perms

**Introduced before R2006a**

# ndgrid

Rectangular grid in N-D space

## Syntax

```
[X1,X2,X3,...,Xn] = ndgrid(x1gv,x2gv,x3gv,...,xngv)
[X1,X2,...,Xn] = ndgrid(xgv)
```

## Description

`[X1,X2,X3,...,Xn] = ndgrid(x1gv,x2gv,x3gv,...,xngv)` replicates the grid vectors `x1gv,x2gv,x3gv,...,xngv` to produce a full grid. This grid is represented by the output coordinate arrays `X1,X2,X3,...,Xn`. The *i*th dimension of any output array `Xi` contains copies of the grid vector `xigv`.

`[X1,X2,...,Xn] = ndgrid(xgv)` is the same as `[X1,X2,...,Xn] = ndgrid(xgv,xgv,...,xgv)`. In other words, you can reuse the same grid vector in each respective dimension. The dimensionality of the output arrays is determined by the number of output arguments.

The coordinate arrays `[X1,X2,X3,...,Xn]` are typically used to evaluate functions of several variables and to create surface and volumetric plots.

## Input Arguments

### **xigv**

Grid vector specifying a series of grid point coordinates in the *i*th dimension.

### **xgv**

Generic grid vector specifying a series of point coordinates.

## Output Arguments

### **`Xi`**

The `Xi` dimension of the output array `Xi` are copies of elements of the grid vector `xigv`. The output arrays specify the full grid.

## Examples

### **Evaluate Function Over Gridded Domain**

Evaluate the function  $x_1 e^{-x_1^2 - x_2^2}$  over the gridded domain  $-2 < x_1 < 2$  and  $-2 < x_2 < 2$ .

Create a grid of values for the domain.

```
[X1,X2] = ndgrid(-2:.2:2, -2:.2:2);
```

Evaluate the function over the domain.

```
Z = X1 .* exp(-X1.^2 - X2.^2);
```

Generate a mesh plot of the function.

```
mesh(X1,X2,Z)
```

## More About

### Tips

The `ndgrid` function is similar to `meshgrid`, however `ndgrid` supports 1-D to N-D while `meshgrid` is restricted to 2-D and 3-D. The coordinates output by each function are the same, but the shape of the output arrays in the first two dimensions are different. For grid vectors `x1gv`, `x2gv` and `x3gv` of length `M`, `N` and `P` respectively, `ndgrid(x1gv, x2gv)` will output arrays of size `M-by-N` while `meshgrid(x1gv, x2gv)` outputs arrays of size `N-by-M`. Similarly, `ndgrid(x1gv, x2gv, x3gv)` will output arrays of size `M-by-N-by-P` while `meshgrid(x1gv, x2gv, x3gv)` outputs arrays of size `N-by-M-by-P`.

See “Grid Representation” in the MATLAB Mathematics documentation for more information.

- “Interpolating Gridded Data”

## ndims

Number of array dimensions

### Syntax

```
N = ndims(A)
```

### Description

`N = ndims(A)` returns the number of dimensions in the array `A`. The number of dimensions is always greater than or equal to 2. The function ignores trailing singleton dimensions, for which `size(A,dim) = 1`.

### Examples

#### Find Dimensions of Vector

Create a row vector.

```
A = 1:5;
```

Find the number of dimensions in the vector.

```
ndims(A)
```

```
ans =
```

```
2
```

The result is 2 because the vector has a size of 1-by-5.

#### Find Dimensions of Cell Array

Create a cell array of strings.

```
C{1,1,1} = 'cell_1';
C{1,1,2} = 'cell_2';
C{1,1,3} = 'cell_3'
```

```
C(:,:,1) =
 'cell_1'

C(:,:,2) =
 'cell_2'

C(:,:,3) =
 'cell_3'
```

Find the number of dimensions of the cell array.

```
ndims(A)

ans =

 3
```

The result is **3** because the cell array has a size of 1-by-1-by-3.

## Input Arguments

### **A** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. This includes numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, calendarDuration arrays, tables, structure arrays, cell arrays, and object arrays.

## More About

### Algorithms

The number of dimensions in an array is the same as the length of the size vector of the array. In other words, `ndims(A) = length(size(A))`.

**See Also**

length | size

**Introduced before R2006a**

## ne, ~=

Determine inequality

## Syntax

```
A ~= B
ne(A,B)
```

## Description

`A ~= B` returns a logical array with elements set to logical 1 (**true**) where arrays `A` and `B` are not equal; otherwise, it returns logical 0 (**false**). The test compares both real and imaginary parts of numeric arrays. `ne` returns logical 1 (**true**) where `A` or `B` have NaN or undefined categorical elements.

`ne(A,B)` is an alternative way to execute `A ~= B`, but is rarely used. It enables operator overloading for classes.

## Examples

### Inequality of Two Vectors

Create two vectors containing both real and imaginary numbers, then compare the vectors for inequality.

```
A = [1+i 3 2 4+i];
B = [1 3+i 2 4+i];
A ~= B
```

```
ans =
```

```
1 1 0 0
```

The `ne` function tests both real and imaginary parts for inequality, and returns logical 1 (`true`) where one or both parts are not equal.

## Find Characters in String

Create a character array.

```
M = 'masterpiece';
```

Test for the presence of a specific character using `~=`.

```
M ~= 'n'
```

```
ans =
```

```
 1 1 1 1 1 1 1 1 1 1 1
```

The value of logical 1 (`true`) indicates the absence of the character `'n'`. The character is not present in the array.

## Find Values in Categorical Array

Create a categorical array with two values: `'heads'` and `'tails'`.

```
A = categorical({'heads' 'heads' 'tails'; 'tails' 'heads' 'tails'})
```

```
A =
```

```
 heads heads tails
 tails heads tails
```

Find all values not in the `'heads'` category.

```
A ~= 'heads'
```

```
ans =
```

```
 0 0 1
 1 0 1
```

A value of logical 1 (`true`) indicates a value not in the category. Since `A` only has two categories, `A ~= 'heads'` returns the same answer as `A == 'tails'`.

Compare the rows of `A` for inequality.

```
A(1,:) ~= A(2,:)
```

```
ans =
```

```
 1 0 0
```

A value of logical 1 (`true`) indicates where the rows have unequal category values.

### Compare Floating-Point Numbers

Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the `~=` operator reflects.

Perform a few subtraction operations on a floating-point number and store the result in `C`.

```
C = 0.5-0.4-0.1
```

```
C =
```

```
-2.7756e-17
```

Intuitively, `C` should be equal to *exactly* 0. Its small value is due to the nature of floating-point arithmetic.

Compare `C` to 0 for inequality.

```
C ~= 0
```

```
ans =
```

```
 1
```

Compare floating-point numbers using a tolerance, `tol`, instead of using `~=`.

```
tol = eps(0.5);
abs(C-0) > tol
```

```
ans =

0
```

The two numbers, `C` and `0`, are closer to one another than two consecutive floating-point numbers. They are essentially equal.

## Inequality of Two Datetime Arrays

Compare the elements of two `datetime` arrays for inequality.

Create two `datetime` arrays in different time zones.

```
t1 = [2014,04,14,9,0,0;2014,04,14,10,0,0];
A = datetime(t1,'TimeZone','America/Los_Angeles');
A.Format = 'd-MMM-y HH:mm:ss Z'
```

```
A =

14-Apr-2014 09:00:00 -0700
14-Apr-2014 10:00:00 -0700
```

```
t2 = [2014,04,14,12,0,0;2014,04,14,12,30,0];
B = datetime(t2,'TimeZone','America/New_York');
B.Format = 'd-MMM-y HH:mm:ss Z'
```

```
B =

14-Apr-2014 12:00:00 -0400
14-Apr-2014 12:30:00 -0400
```

Check where elements in `A` and `B` are not equal.

```
A~=B
```

```
ans =
```

0  
1

## Input Arguments

### A — Left array

numeric array | logical array | character array | categorical array | datetime array | duration array

Left array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

Complex Number Support: Yes

### B — Right array

numeric array | logical array | character array | categorical array | datetime array | duration array

Right array, specified as a numeric array, logical array, character array, or categorical array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must

have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

Complex Number Support: Yes

# nearestNeighbor

**Class:** DelaunayTri

(Not recommended) Point closest to specified location

---

**Note:** nearestNeighbor(DelaunayTri) is not recommended. Use nearestNeighbor(triangulation) instead.

DelaunayTri is not recommended. Use delaunayTriangulation instead.

---

## Syntax

```
PI = nearestNeighbor(DT,QX)
PI = nearestNeighbor(DT,QX,QY)
PI = nearestNeighbor(DT,QX,QY,QZ)
[PI,D] = nearestNeighbor(DT,QX,...)
```

## Description

PI = nearestNeighbor(DT,QX) returns the index of the nearest point in DT.X for each query point location in QX.

PI = nearestNeighbor(DT,QX,QY) and PI = nearestNeighbor(DT,QX,QY,QZ) allow the query points to be specified in column vector format when working in 2-D and 3-D.

[PI,D] = nearestNeighbor(DT,QX,...) returns the index of the nearest point in DT.X for each query point location in QX. The corresponding Euclidean distances between the query points and their nearest neighbors are returned in D.

---

**Note:** nearestNeighbor is not supported for 2-D triangulations that have constrained edges.

---

## Input Arguments

- DT** Delaunay triangulation.
- QX** The matrix **QX** is of size **mpts**-by-**ndim**, **mpts** being the number of query points and **ndim** the dimension of the space where the points reside.

## Output Arguments

- PI** **PI** is a column vector of point indices that index into the points **DT.X**. The length of **PI** is equal to the number of query points **mpts**
- D** **D** is a column vector of length **mpts**.

## Examples

Create a Delaunay triangulation:

```
x = rand(10,1);
y = rand(10,1);
dt = DelaunayTri(x,y);
Create query points:
```

```
qrypts = [0.25 0.25; 0.5 0.5];
Find the nearest neighbors to the query points:
```

```
pid = nearestNeighbor(dt, qrypts)
```

## See Also

delaunayTriangulation | pointLocation | triangulation

# neighbors

**Class:** TriRep

(Not recommended) Simplex neighbor information

---

**Note:** `neighbors(TriRep)` is not recommended. Use `neighbors(triangulation)` instead.

`TriRep` is not recommended. Use `triangulation` instead.

---

## Syntax

```
SN = neighbors(TR, SI)
```

## Description

`SN = neighbors(TR, SI)` returns the simplex neighbor information for the specified simplices `SI`.

## Input Arguments

TR	Triangulation representation.
SI	SI is a column vector of simplex indices that index into the triangulation matrix <code>TR.Triangulation</code> . If SI is not specified the neighbor information for the entire triangulation is returned, where the neighbors associated with simplex <code>i</code> are defined by the <code>i</code> 'th row of <code>SN</code> .

## Output Arguments

SN	SN is an <code>m</code> -by- <code>n</code> matrix, where <code>m = length(SI)</code> , the number of specified simplices, and <code>n</code> is the number of neighbors per simplex. Each row <code>SN(i, :)</code> represents the neighbors of the simplex <code>SI(i)</code> .
----	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

By convention, the simplex opposite `vertex(j)` of simplex `SI(i)` is `SN(i,j)`. If a simplex has one or more boundary facets, the nonexistent neighbors are represented by `NaN`.

## Definitions

A *simplex* is a triangle/tetrahedron or higher-dimensional equivalent. A *facet* is an edge of a triangle or a face of a tetrahedron.

## Examples

### Example 1

Load a 3-D triangulation and use `TriRep` to compute the neighbors of all tetrahedra.

```
load tetmesh
trep = TriRep(tet, X)
nbrs = neighbors(trep)
```

### Example 2

Query a 2-D triangulation created using `DelaunayTri`.

```
x = rand(10,1)
y = rand(10,1)
dt = DelaunayTri(x,y)
Find the neighbors of the first triangle:

n1 = neighbors(dt, 1)
```

# NET

Summary of functions in MATLAB .NET interface

## Description

Use the following functions to bring assemblies from the Microsoft .NET Framework into the MATLAB environment. The functions are implemented as a package called NET. To use these functions, prefix the function name with package name NET.

BeginInvoke	Initiate asynchronous .NET delegate call
cell	Create cell array
Combine	Convenience function for static .NET System.Delegate Combine method
enableNETfromNetworkDrive	Enable access to .NET commands from network drive
EndInvoke	Retrieve result of asynchronous call initiated by .NET System.Delegate BeginInvoke method
NET.addAssembly	Make .NET assembly visible to MATLAB
NET.Assembly	Members of .NET assembly
NET.convertArray	Convert numeric MATLAB array to .NET array
NET.createArray	Array for nonprimitive .NET types
NET.createGeneric	Create instance of specialized .NET generic type
NET.disableAutoRelease	Lock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release COM object
NET.enableAutoRelease	Unlock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB releases COM object
NET.GenericClass	Represent parameterized generic type definitions

NET.invokeGenericMethod	Invoke generic method of object
NET.isNETSupported	Check for supported Microsoft .NET Framework
NET.NetException	Capture error information for .NET exception
NET.setStaticProperty	Static property or field name
Remove	Convenience function for static .NET System.Delegate Remove method
RemoveAll	Convenience function for static .NET System.Delegate RemoveAll method

## More About

- “Call .NET Libraries”

# NET.addAssembly

**Package:** NET

Make .NET assembly visible to MATLAB

## Syntax

```
asmInfo = NET.addAssembly(globalName)
asmInfo = NET.addAssembly(privateName)
```

## Description

`asmInfo = NET.addAssembly(globalName)` loads a global .NET assembly into MATLAB.

`asmInfo = NET.addAssembly(privateName)` loads a private .NET assembly.

## Limitations

- `NET.addAssembly` does not support assemblies generated by the MATLAB Compiler SDK product.

## Input Arguments

### **globalName**

One of the following:

- String representing the name of a global assembly.
- Instance of `System.Reflection.AssemblyName` class.

### **Default:**

### **privateName**

String representing the full path of a private assembly.

Default:

## Output Arguments

### **asmInfo**

NET.Assembly object containing names of the members of the assembly.

## Examples

Display today's date using `System.DateTime` in the `microsoft.dll` assembly.

```
System.DateTime.Now.ToLongDateString
```

Call the `System.Windows.Forms.MessageBox.Show` method in the global assembly `System.Windows.Forms`.

```
asm = NET.addAssembly('System.Windows.Forms');
import System.Windows.Forms.*
MessageBox.Show('Simple Message Box')
```

Display classes in the private assembly `NetSample.dll`.

```
asm = NET.addAssembly('c:\work\NetSample.dll');
asm.Classes
```

## More About

### Tips

- MATLAB dynamically loads the `microsoft.dll` and `system.dll` assemblies from the .NET Framework class library the first time you type "NET." or "System.". You do not need to call `NET.addAssembly` to access classes in these assemblies.
- Refer to your .NET product documentation for the name of the assembly and its deployment type (global or private).
- “Assembly is Library of .NET Classes”
- MSDN AssemblyName Class

## **See Also**

NET.Assembly

**Introduced in R2009a**

# NET.Assembly class

**Package:** NET

Members of .NET assembly

## Description

NET.Assembly object returns names of the members of an assembly.

## Construction

The NET.addAssembly function creates an instance of this class.

## Properties

### AssemblyHandle

Instance of System.Reflection.Assembly class of the added assembly.

### Classes

nClassx1 cell array of class names of the assembly, where nClass is the number of classes.

### Enums

nEnumx1 cell array of enumerations of the assembly, where nEnum is the number of enumerations.

### Structures

nStructx1 cell array of structures of the assembly, where nStruct is the number of structures.

### GenericTypes

nGenTypex1 cell array of generic types of the assembly, where nGenType is the number of generic types.

**Interfaces**

nInterfacex1 cell array of interface names of the assembly, where nInterface is the number of interfaces.

**Delegates**

nDelegatex1 cell array of delegates of the assembly, where nDelegate is the number of delegates.

**See Also**

NET.addAssembly

**How To**

- “What Classes Are in a .NET Assembly?”

# NET.convertArray

**Package:** NET

Convert numeric MATLAB array to .NET array

---

**Note:** MATLAB automatically converts arrays to .NET types. For information, see “Use Arrays with .NET Applications”.

---

## Syntax

```
arrObj = NET.convertArray(V, 'arrType', [m,n])
```

## Description

`arrObj = NET.convertArray(V, 'arrType', [m,n])` converts a MATLAB array `V` to a .NET array. Optional value `arrType` is a string representing a namespace-qualified .NET array type. To convert a MATLAB vector to a two-dimensional .NET array (either 1-by-`n` or `m`-by-1), use optional values `m`, `n`. If `V` is a MATLAB vector and you do not specify the number of dimensions and their sizes, the output `arrObj` is a one-dimensional .NET array.

If you do not specify `arrType`, MATLAB converts the type according to the MATLAB Primitive Type Conversion Table. See “Pass Primitive .NET Types”.

## Examples

Create a list `L` of random `System.Int32` integers using the `System.Collections.Generic.List` class, and then sort the results.

```
% Create array R of random integers
nInt = 5;
R = randi(100,1,nInt);
% Create .NET array A
```

```
A = NET.convertArray(R, 'System.Int32');
% Put A into L, a generic collections list
L = NET.createGeneric('System.Collections.Generic.List', {'System.Int32'}, A.Length);
L.AddRange(A)
% Sort the values in L
L.Sort
```

## See Also

NET.createArray

**Introduced in R2009a**

# NET.createArray

**Package:** NET

Array for nonprimitive .NET types

## Syntax

```
array = NET.createArray(typeName, [m, n, p, ...])
array = NET.createArray(typeName, m, n, p, ...)
```

## Description

`array = NET.createArray(typeName, [m, n, p, ...])` creates an m-by-n-by-p-by-... array of type `typeName`, which is either a fully qualified .NET array type name (namespace and array type name) or an instance of the `NET.GenericClass` class, in case of arrays of generic type. `m, n, p, ...` are the number of elements in each dimension of the array.

`array = NET.createArray(typeName, m, n, p, ...)` alternative syntax for creating an array.

You cannot specify the lower bound of an array.

## Examples

### Create .NET Array of Generic Type

This example creates a .NET array of `List<Int32>` generic type.

```
genType = NET.GenericClass('System.Collections.Generic.List', ...
 'System.Int32');
arr = NET.createArray(genType, 5)

arr =
```

```
List<System*Int32>[] with properties:
```

```

 Length: 5
 LongLength: 5
 Rank: 1
 SyncRoot: [1x1 System.Collections.Generic.List<System*Int32>[]]
 IsReadOnly: 0
 IsFixedSize: 1
 IsSynchronized: 0

```

## Create and Initialize Jagged Array

This example creates a jagged .NET array of three elements.

```
jaggedArray = NET.createArray('System.Double[]', 3)
```

```
jaggedArray =
```

```
Double[][] with properties
```

```

 Length: 3
 LongLength: 3
 Rank: 1
 SyncRoot: [1x1 System.Double[][]]
 IsReadOnly: 0
 IsFixedSize: 1
 IsSynchronized: 0

```

Assign values:

```

jaggedArray(1) = [1, 3, 5, 7, 9];
jaggedArray(2) = [0, 2, 4, 6];
jaggedArray(3) = [11, 22];

```

Access first value of third array:

```
jaggedArray(3,1)
```

```

ans =
 11

```

## Create Jagged Array of Generic Type

This example creates a jagged array of List<Double> generic type.

```
genCls = NET.GenericClass('System.Collections.Generic.List[]',...
 'System.Double');
```

Create the array, genArr.

```
genArr = NET.createArray(genCls,3)
```

```
genArr =
```

```
List<System*Double>[][] with properties:
```

```
 Length: 3
 LongLength: 3
 Rank: 1
 SyncRoot: [1x1 System.Collections.Generic.List`1[][]]
 IsReadOnly: 0
 IsFixedSize: 1
 IsSynchronized: 0
```

## Create Nested Jagged Array

This command creates a jagged array of type `System.Double[][][]`.

```
netArr = NET.createArray('System.Double[][]', 3)
```

```
netArr =
```

```
Double[][][] with properties:
```

```
 Length: 3
 LongLength: 3
 Rank: 1
 SyncRoot: [1x1 System.Double[][][]]
 IsReadOnly: 0
 IsFixedSize: 1
 IsSynchronized: 0
```

**Introduced in R2009a**

# NET.createGeneric

**Package:** NET

Create instance of specialized .NET generic type

## Syntax

```
genObj = createGeneric(className,paramTypes,varargin ctorArgs)
```

## Description

genObj = createGeneric(className,paramTypes,varargin ctorArgs) creates an instance genObj of generic type className.

## Input Arguments

className	Fully qualified string with the generic type name.
paramTypes	Allowed cell types are: strings with fully qualified parameter type names and instances of the NET.GenericClass class when parameterization with another parameterized type is needed.
ctorArgs	Optional, variable length (0 to N) list of constructor arguments matching the arguments of the .NET generic class constructor intended to be invoked.

## Output Arguments

genObj	Handle to the specialized generic class instance.
--------	---------------------------------------------------

## Examples

### Create List of System.Double Objects

Create a strongly typed list dblLst of objects of type System.Double.

```
t = NET.createGeneric('System.Collections.Generic.List',{System.Double'},10);
```

## Create List with Key/Value Pairs

Create the `kvpType` generic association where `Key` is of `System.Int32` type and `Value` is a `System.String`.

```
kvpType = NET.GenericClass(...
 'System.Collections.Generic.KeyValuePair',...
 'System.Int32','System.String');
```

Create the list `kvpList` with initial storage capacity for 10 key-value pairs.

```
kvpList = NET.createGeneric('System.Collections.Generic.List',{kvpType},10);
```

## Add Item to List

Create a `KeyValuePair` item.

```
kvpItem = NET.createGeneric(...
 'System.Collections.Generic.KeyValuePair',...
 {'System.Int32','System.String'},...
 42,'myString');
```

Add this item to the list `kvpList`.

```
kvpList.Add(kvpItem);
```

## See Also

[NET.GenericClass](#)

**Introduced in R2009a**

# NET.disableAutoRelease

**Package:** NET

Lock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release COM object

## Syntax

A = NET.disableAutoRelease(obj)

## Description

A = NET.disableAutoRelease(obj) locks a .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release the COM object. obj is a .NET object representing a COM Wrapper.

Before passing a .NET object representing a COM Wrapper to another process, lock the object using this function so that MATLAB does not release it. After using the object, call NET.enableAutoRelease to release the COM object.

## Examples

The following user-defined function, `GetComApp.m`, has access to a COM object defined in the **pseudo-class** `ComNamespace.ComClass`. One of its methods is `readData`, with the signature:

```
System.StringRetVal readData(ComNamespace.ComClass this, System.String strIn)
```

The input argument is defined in the **pseudo-class** `NetDocTest.MyClass`, which has a property named `MyApp`.

```
function GetComApp(obj)
comObj = ComNamespace.ComClass;
obj.MyApp = comObj;
% To pass a COM object to another process, lock the object
NET.disableAutoRelease(comObj);
end
```

The example in `NET.enableAutoRelease` shows how to call the `GetComApp` function.

## **More About**

- “How MATLAB Handles `System.__ComObject`”

## **See Also**

`NET.enableAutoRelease`

**Introduced in R2010b**

# NET.enableAutoRelease

**Package:** NET

Unlock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB releases COM object

## Syntax

```
A = NET.enableAutoRelease(obj)
```

## Description

`A = NET.enableAutoRelease(obj)` releases the COM wrapper when the object goes out of scope, where `obj` is a .NET object representing a COM Wrapper.

Call this function only if the object was locked using `NET.disableAutoRelease`.

## Examples

The following **pseudo-code** shows how to call a function (`GetComApp.m`, described in `NET.disableAutoRelease`) which returns a COM object. The object, `mainObj` of type `NetDocTest.MyClass`, has a property, `MyApp`. Call `GetComApp` to get a COM object, and use its `readData` method.

```
mainObj = NetDocTest.MyClass;
GetComApp(mainObj);
app = mainObj.MyApp;
app.readData('hello');
% Unlock the COM object
NET.enableAutoRelease(mainObj.MyApp);
```

## More About

- “How MATLAB Handles System.\_\_ComObject”

# NET.GenericClass class

**Package:** NET

Represent parameterized generic type definitions

## Description

The `NET.createGeneric` function uses instances of this class to create a generic specialization that requires parameterization with another parameterized type.

## Construction

```
genType = NET.GenericClass(className, paramTypes)
```

## Input Arguments

### **className**

Fully qualified string containing the generic type name.

**Default:**

### **paramTypes**

Optional, variable length (1 to N) list of types for the generic class parameterization. Allowed argument types are:

- Fully qualified string containing the generic type name.
- Instance of the `NET.GenericClass` class when deeper nested parameterization with another parameterized type is needed.

**Default:**

## Examples

Create an instance of `System.Collections.Generic.List` of `System.Collections.Generic.KeyValuePair` generic associations where `Key` is of

System.Int32 type and Value is a System.String class with initial storage capacity for 10 key-value pairs.

```
kvpType = NET.GenericClass(...
 'System.Collections.Generic.KeyValuePair',...
 'System.Int32', 'System.String');
kvpList = NET.createGeneric('System.Collections.Generic.List',...
 { kvpType }, 10);
```

## See Also

NET.createGeneric | NET.createArray | NET.invokeGenericMethod

## How To

- “.NET Generic Classes”

**Introduced in R2009a**

# NET.invokeGenericMethod

**Package:** NET

Invoke generic method of object

## Syntax

```
[varargout] =
NET.invokeGenericMethod(obj, 'genericMethodName', paramTypes, args, ...)
```

## Description

```
[varargout] =
NET.invokeGenericMethod(obj, 'genericMethodName', paramTypes, args, ...)
calls instance or static generic method genericMethodName.
```

## Input Arguments

<b>obj</b>	Allowed argument types are: <ul style="list-style-type: none"><li>• Instances of class containing the generic method</li><li>• Strings with fully qualified class name, if calling static generic methods</li><li>• Instances of <code>NET.GenericClass</code> definitions, if calling static generic methods of a generic class</li></ul>
<b><i>genericMethodName</i></b>	Generic method name to invoke
<b>paramTypes</b>	Cell vector (1 to N) with the types for generic method parameterization, where allowed cell types are: <ul style="list-style-type: none"><li>• Strings with fully qualified parameter type name.</li><li>• Instances of <code>NET.GenericClass</code> definitions, if using nested parameterization with another parameterized type</li></ul>
<b>args</b>	Optional, variable length (0 to N) list of method arguments

## Output Arguments

`varargout` Variable-length output argument list, `varargout`, from method *genericMethodName*

## Examples

The following syntax calls a generic method that takes two parameterized types and returns a parameterized type:

```
a = NET.invokeGenericMethod(obj, ...
 'myGenericSwapMethod', ...
 {'System.Double', 'System.Double'}, ...
 5, 6);
```

To display generic methods in MATLAB, see the example “Display .NET Generic Methods Using Reflection”.

# NET.isNETSupported

Check for supported Microsoft .NET Framework

## Syntax

```
tf = NET.isNETSupported
```

## Description

`tf = NET.isNETSupported` returns logical 1 (**true**) if a supported version of the Microsoft .NET Framework is found. Otherwise, it returns logical 0 (**false**) and you cannot use the .NET Framework in MATLAB.

## Examples

### Display Message If Supported Microsoft .NET Framework Not Found

```
if ~NET.isNETSupported
 disp('Supported .NET Framework not found')
end
```

Introduced in R2013a

# NET.NetException class

**Package:** NET

Capture error information for .NET exception

## Description

Process information from a NET.NetException object to handle .NET errors. This class is derived from MException.

## Construction

`e = NET.NetException(msgID, errMsg, netObj)` constructs instance `e` of NET.NetException class.

## Input Arguments

**msgID**

message identifier

**errMsg**

error message string

**netObj**

System.Exception object that caused the exception

## Properties

**ExceptionObject**

System.Exception class causing the error.

## Methods

### Inherited Methods

See the methods of the base class `MException`.

## Examples

Display error information after trying to load an unknown assembly:

```
try
 NET.addAssembly('C:\Work\invalidfile.dll')
catch e
 e.message;
 if(isa(e, 'NET.NetException'))
 eObj = e.ExceptionObject
 end
end

ans =
Message: Could not load file or assembly
'file:///C:\Work\invalidfile.dll' or
one of its dependencies. The system cannot
find the file specified.
Source: mscorlib
HelpLink:

eObj =
FileNotFoundException with properties:

 Message: [1x1 System.String]
 FileName: [1x1 System.String]

# NET.setStaticProperty

**Package:** NET

Static property or field name

## Syntax

```
NET.setStaticProperty('propName', value)
```

## Description

`NET.setStaticProperty('propName', value)` sets the static property or field name specified in the string `propName` to the given `value`.

## Examples

To set the `myStaticProperty` in the given class and namespace, use the syntax:

```
NET.setStaticProperty('MyTestObject.MyClass.myStaticProperty', 5);
```

**Introduced in R2009b**

## nccreate

Create variable in NetCDF file

### Syntax

```
nccreate(filename, varname)
nccreate(filename, varname, Name, Value)
```

### Description

`nccreate(filename, varname)` creates a scalar `double` variable named `varname` in the NetCDF file specified by `filename`. If `filename` does not exist, then `nccreate` creates the file using the `netcdf4_classic` format.

`nccreate(filename, varname, Name, Value)` creates a variable with additional options specified by one or more name-value pair arguments. For example, to create a nonscalar variable, use the `Dimensions` name-value pair argument.

### Examples

#### Create New Variables in NetCDF File

Create a NetCDF file named `myexample.nc` that contains a variable named `Var1`.

```
nccreate('myexample.nc', 'Var1')
```

Create a second variable in the same file.

```
nccreate('myexample.nc', 'Var2')
```

Display the contents of the NetCDF file.

```
ncdisp('myexample.nc')
```

Source:

```

 pwd\myexample.nc
Format:
 netcdf4_classic
Variables:
 Var1
 Size: 1x1
 Dimensions:
 Datatype: double
 Var2
 Size: 1x1
 Dimensions:
 Datatype: double

```

### Create Variable and Specify Dimensions and File Format

Create a new two-dimensional variable named `peaks` in a classic (NetCDF 3) format file named `myncclassic.nc`. Use the `'Dimensions'` name-value pair argument to specify the names and lengths of the two dimensions. Use the `'Format'` name-value pair argument to specify the file format.

```

nccreate('myncclassic.nc','peaks',...
 'Dimensions',{ 'r',200, 'c',200},...
 'Format','classic')

```

Write data to the variable.

```

ncwrite('myncclassic.nc','peaks',peaks(200))

```

Display the contents of the NetCDF file.

```

ncdisp('myncclassic.nc')

```

```

Source:
 pwd\myncclassic.nc
Format:
 classic
Dimensions:
 r = 200
 c = 200
Variables:
 peaks
 Size: 200x200
 Dimensions: r,c

```

Datatype: double

## Input Arguments

### **filename** — File name

string

File name, specified as a string. The file is an existing NetCDF file, or the name you want to assign to a new NetCDF file.

Example: 'myFile.nc'

### **varname** — Name of new variable

string

Name of the new variable, specified as a string.

Example: 'myVar'

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example:

```
nccreate('myFile.nc','Var1','Datatype','double','Format','classic')
creates a variable named Var1 of type NC_DOUBLE in a NetCDF 3 file named
myFile.nc.
```

### **'Dimensions'** — Dimensions of variable

cell array

Dimensions of the new variable, specified as the comma-separated pair consisting of **'Dimensions'** and a cell array. The cell array lists the dimension name as a string followed by its numerical length, in this form: {**dname1**, **dlength1**, **dname2**, **dlength2**, ...}. The **dname1** input is the name of the first dimension, **dlength1** is the length of the first dimension, **dname2** is the name of the second dimension, and so on. If a dimension exists, specifying its length is optional. A variable with a single dimension is always treated as a column vector.

Use `Inf` to specify an unlimited dimension. A `netcdf4` format file can have any number of unlimited dimensions in any order. All other formats can have only one unlimited dimension per file and it must be specified last in the cell array.

`nccreate` creates the dimension at the same location as the variable. For `netcdf4` format files, you can specify a different location for the dimension using a fully qualified dimension name.

Example: `'Dimensions',{'dim1',100,'dim2',150,'dim3','Inf'}`

### 'Datatype' — MATLAB data type

'double' (default) | string

MATLAB data type, specified as the comma-separated pair consisting of 'Datatype' and a string. When `nccreate` creates the variable in the NetCDF file, it uses a corresponding NetCDF datatype. This table lists valid values for 'Datatype' and the corresponding NetCDF variable type that `nccreate` creates.

Value of Datatype	NetCDF Variable Type
'double'	NC_DOUBLE
'single'	NC_FLOAT
'int64'	NC_INT64*
'uint64'	NC_UINT64*
'int32'	NC_INT
'uint32'	NC_UINT*
'int16'	NC_SHORT
'uint16'	NC_USHORT*
'int8'	NC_BYTE
'uint8'	NC_UBYTE*
'char'	NC_CHAR

\* These data types are only available when the file is a `netcdf4` format file.

Example: `'Datatype','uint16'`

### 'Format' — NetCDF file format

'netcdf4\_classic' (default) | string

NetCDF file format, specified as the comma-separated pair consisting of 'Format' and one of the following strings.

Value of Format	Description
'classic'	NetCDF 3
'64bit'	NetCDF 3, with 64-bit offsets
'netcdf4_classic'	NetCDF 4 classic model
'netcdf4'	NetCDF 4 model (Use this format to enable group hierarchy)

If `varname` specifies a group (for example, '/grid3/temperature'), then `nccreate` sets the value of `Format` to 'netcdf4'.

Example: 'Format', 'classic'

#### 'FillValue' — Replacement value for missing values

scalar | 'disable'

Replacement value for missing values, specified as the comma-separated pair consisting of 'FillValue' and a scalar or 'disable'. The default value is specified by the NetCDF library. To disable replacement values, specify 'FillValue', 'disable'.

This argument is available for `netcdf4` or `netcdf4_classic` formats only.

Example: 'FillValue', NaN

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char

#### 'ChunkSize' — Chunk size along each dimension

vector

Chunk size along each dimension, specified as the comma-separated pair consisting of 'ChunkSize' and a vector. The first element specifies the number of rows, the second element specifies the number of columns, the third element specifies the length of the third dimension, and so on. The default value is specified by the NetCDF library.

This argument is available for `netcdf4` or `netcdf4_classic` formats only.

Example: 'ChunkSize', [5 6 9]

Data Types: double

**'DeflateLevel' — Amount of compression**

0 (default) | scalar value between 0 and 9

Amount of compression, specified as the comma-separated pair consisting of 'DeflateLevel' and a scalar value between 0 and 9. 0 indicates no compression and 9 indicates the most compression.

This argument is available for netcdf4 or netcdf4\_classic formats only.

Example: 'DeflateLevel',5

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**'Shuffle' — Status of shuffle filter**

false (default) | true

Status of the shuffle filter, specified as the comma-separated pair consisting of 'Shuffle' and false or true. false disables the shuffle filter and true enables it. The shuffle filter can assist with the compression of integer data by changing the byte order in the data stream.

This argument is available for netcdf4 or netcdf4\_classic formats only.

Example: 'Shuffle',true

Data Types: logical

## More About

ncdisp | ncinfo | ncwrite | ncwritschema | netcdf

**Introduced in R2011a**

## **ncdisp**

Display contents of NetCDF data source in Command Window

### **Syntax**

```
ncdisp(source)
ncdisp(source,location)
ncdisp(source,location,dispFormat)
```

### **Description**

`ncdisp(source)` displays all the groups, dimensions, variable definitions, and all attributes in the NetCDF data source, `source`, as text in the Command Window.

`ncdisp(source,location)` displays information about the variable or group specified by `location`.

`ncdisp(source,location,dispFormat)` displays the contents of the NetCDF data source, in the display format specified by `dispFormat`.

### **Examples**

#### **Display Contents of NetCDF File**

Display the contents of the example NetCDF file, `example.nc`.

```
ncdisp('example.nc')
```

```
Source:
```

```
 matlabroot\toolbox\matlab\demos\example.nc
```

```
Format:
```

```
 netcdf4
```

```
Global Attributes:
```

```
 creation_date = '29-Mar-2010'
```

```
Dimensions:
```

```
 x = 50
```

```
 y = 50
```

```
 z = 5
```

```
Variables:
 avagadros_number
 Size: 1x1
 Dimensions:
 Datatype: double
 Attributes:
 description = 'this variable has no dimensions'

 temperature
 Size: 50x1
 Dimensions: x
 Datatype: int16
 Attributes:
 scale_factor = 1.8
 add_offset = 32
 units = 'degrees_fahrenheit'

 peaks
 Size: 50x50
 Dimensions: x,y
 Datatype: int16
 Attributes:
 description = 'z = peaks(50);'

Groups:
 /grid1/
 Attributes:
 description = 'This is a group attribute.'
 Dimensions:
 x = 360
 y = 180
 time = 0 (UNLIMITED)
 Variables:
 temp
 Size: []
 Dimensions: x,y,time
 Datatype: int16

 /grid2/
 Attributes:
 description = 'This is another group attribute.'
 Dimensions:
 x = 360
 y = 180
 time = 0 (UNLIMITED)
 Variables:
 temp
```

```
Size: []
Dimensions: x,y,time
Datatype: int16
```

MATLAB displays all the groups, dimensions, and variable definitions in `example.nc`.

## Display Contents of NetCDF Variable

Display the contents of the variable `peaks` in the file, `example.nc`.

```
ncdisp('example.nc','peaks')

Source:
 matlabroot\toolbox\matlab\demos\example.nc
Format:
 netcdf4
Dimensions:
 x = 50
 y = 50
Variables:
 peaks
 Size: 50x50
 Dimensions: x,y
 Datatype: int16
 Attributes:
 description = 'z = peaks(50);'
```

## Display Contents of NetCDF File and Hide Attributes

Display only the group hierarchy and variable definitions of the example file, `example.nc`.

```
ncdisp('example.nc','/','min')

Source:
 matlabroot\toolbox\matlab\demos\example.nc
Format:
 netcdf4
Variables:
 avagadros_number
 Size: 1x1
 Dimensions:
 Datatype: double
 temperature
 Size: 50x1
 Dimensions: x
```

```

 Datatype: int16
 peaks
 Size: 50x50
 Dimensions: x,y
 Datatype: int16
Groups:
 /grid1/
 Variables:
 temp
 Size: []
 Dimensions: x,y,time
 Datatype: int16

 /grid2/
 Variables:
 temp
 Size: []
 Dimensions: x,y,time
 Datatype: int16

```

## Input Arguments

### **source** — Name of NetCDF file

string

Name of a NetCDF file, specified as a string. **source** also can be the URL of an OPeNDAP NetCDF data source that resolves to a NetCDF file or a variable in a NetCDF file.

Example: 'myNetCDFfile.nc'

Data Types: char

### **location** — Location of variable or group

'/' (default) | string

Location of a variable or group in the NetCDF file, specified as a string. Set **location** to '/' (forward slash) to display the entire contents of the file.

Data Types: char

### **dispFormat** — Display format

'full' (default) | 'min'

Display format, specified as one of the following strings.

'full'	Display group hierarchy with dimensions, attributes, and variable definitions.
'min'	Display group hierarchy and variable definitions.

Data Types: char

## More About

### Tips

- If source is an OPeNDAP URL with string constraints, use the syntax, `ncdisp(source)` with no other input arguments.
- “Import NetCDF Files and OPeNDAP Data”

### See Also

`ncinfo` | `ncread` | `ncreadatt` | `ncwrite` | `netcdf`

**Introduced in R2011a**

## ncinfo

Return information about NetCDF data source

### Syntax

```
finfo = ncinfo(source)
vinfo = ncinfo(source,varname)
ginfo = ncinfo(source,groupname)
```

### Description

`finfo = ncinfo(source)` returns information in the structure `finfo` about the entire NetCDF data source specified by `source`, where `source` can be the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

`vinfo = ncinfo(source,varname)` returns information in the structure `vinfo` about the variable `varname` in `source`.

`ginfo = ncinfo(source,groupname)` returns information in the structure `ginfo` about the group `groupname` in `source` (only NetCDF4 data sources).

---

**Note:** Use `ncdisp` for visual inspection of a NetCDF source.

---

### Input Arguments

#### **source**

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

#### **Default:**

#### **varname**

Text string specifying the name of a variable in a NetCDF file or OPeNDAP data source.

**Default:**

**groupname**

Text string specifying the name of a group in a NetCDF file or OPeNDAP data source.

**Default:**

## Output Arguments

**finfo**

A structure with the following fields.

Field	Description	
Filename	NetCDF file name or OPeNDAP URL	
Name	' / ', indicating the full file	
Dimensions	An array of structures with these fields:	
	Name	Dimension name
	Length	Current length of dimension
	Unlimited	Boolean flag, true for unlimited dimensions
Variables	An array of structures with these fields:	
	Name	Variable name
	Dimensions	Associated dimensions
	Size	Current variable size
	Datatype	MATLAB datatype
	Attributes	Associated variable attributes
	ChunkSize	Chunk size, if defined. [ ] otherwise
	FillValue	Fill value of the variable.
	DeflateLevel	Deflate filter level, if enabled.
	Shuffle	Shuffle filter enabled flag

Field	Description
Attributes	An array of global attributes with these fields:
	Name Attribute name
	Value Attribute value
Groups	An array of groups present in the file, for <code>netcdf4</code> files; An empty array ( <code>[]</code> ) for all other NetCDF file formats.
Format	The format of the NetCDF file

**vinfo**

A structure containing only the variable fields from `finfo`.

Field	Description
Filename	NetCDF file name
Name	Name of the variable
Dimensions	Dimensions of the variable
Size	Size of the current variable
Datatype	MATLAB datatype
Attributes	Attributes associated with the variable
ChunkSize	Chunk size, if defined. <code>[]</code> otherwise.
FillValue	Fill value used in the variable.
DeflateLevel	Deflate filter level, if enabled.
Shuffle	Shuffle filter enabled flag
Format	The format of the NetCDF file

**ginfo**

A structure containing only the group fields from `finfo`.

Field	Description
Filename	NetCDF file name
Name	Name of the group
Dimensions	Only dimensions defined in the specified group

Field	Description
Variables	Only variables defined in the specified group
Attributes	Attributes associated with the variable
Groups	Names of groups, if defined. [ ] otherwise.
Format	The format of the NetCDF file

## Examples

Search for dimensions with names that start with the character x in the file.

```
finfo = ncinfo('example.nc');
disp(finfo);
dimNames = {finfo.Dimensions.Name};
dimMatch = strncmpi(dimNames,'x',1);
disp(finfo.Dimensions(dimMatch));
```

Obtain the size of a variable and check if it has any unlimited dimensions.

```
vinfo = ncinfo('example.nc','peaks');
varSize = vinfo.Size;
disp(vinfo);
hasUnLimDim = any([vinfo.Dimensions.Unlimited]);
```

Find all unlimited dimensions defined in a group.

```
ginfo = ncinfo('example.nc','/grid2/');
unlimDims = [ginfo.Dimensions.Unlimited];
disp(ginfo.Dimensions(unlimDims));
```

## See Also

**Introduced in R2011a**

# ncread

Read data from variable in NetCDF data source

## Syntax

```
vardata = ncread(source, varname)
vardata = ncread(source, varname, start, count, stride)
```

## Description

`vardata = ncread(source, varname)` reads data from the variable `varname` in `source`, which can be either the name of a NetCDF file or an OPeNDAP NetCDF data source.

`vardata = ncread(source, varname, start, count, stride)` reads data from the variable `varname` in `source` beginning at the location given by `start`. `count` specifies the number of elements to read along the corresponding dimension. The optional argument `stride` specifies the inter-element spacing along each dimension.

## Input Arguments

### **source**

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

### **Default:**

### **varname**

Text string specifying the name of a variable in the NetCDF file or OPeNDAP NetCDF data source.

### **Default:**

**start**

For an  $N$ -dimensional variable, **start** is a vector of length  $N$  of indices specifying the starting location. Indices are 1-based.

**count**

Vector of length  $N$  specifying the number of elements to read along the corresponding dimensions. If a particular element of **count** is `Inf`, `ncread` reads data until the end of the corresponding dimension.

**stride**

Optional argument that specifies the inter-element spacing along each dimension.

**Default:** Vector of 1s (ones)

## Output Arguments

**vardata**

The data in the variable. `ncread` uses the MATLAB datatype that is the closest type to the corresponding NetCDF datatype, except when at least one of `_FillValue`, `scale_offset`, and `add_offset` variables attribute is present. `ncread` applies the following attribute conventions, in sequence, to **vardata** if the corresponding attribute exists for this variable:

- If the `_FillValue` attribute exists, `ncread` replaces values in **vardata** equal to the value of `_FillValue` with NaNs. If the `_FillValue` attribute does not exist, `ncread` queries the NetCDF library for the variable's fill value.
- If the `scale_factor` attribute exists, `ncread` multiplies **vardata** by the value of the `scale_factor` attribute.
- If the `add_offset` attribute exists, `ncread` adds the value of the `add_offset` attribute to **vardata**.

## Examples

Read and display the data in the `peaks` variable in the example file.

```
ncdisp('example.nc','peaks');
peaksData = ncread('example.nc','peaks');
peaksDesc = ncreadatt('example.nc','peaks','description');
surf(double(peaksData));
title(peaksDesc);
```

Subsample the peaks data by a factor of 2 (read every other value along each dimension).

```
subsetdata = ncread('example.nc','peaks',...
 [1 1], [Inf Inf], [2 2]);
surf(double(subsetdata));
```

## See Also

**Introduced in R2011a**

## ncreadatt

Read attribute value from NetCDF data source

### Syntax

```
attvalue = ncreadatt(source,location,attname)
```

### Description

`attvalue = ncreadatt(source,location,attname)` reads the attribute `attname` from the group or variable specified by `location` in `source`, where `source` is the name of a NetCDF file or the URL of a NetCDF data source.

### Input Arguments

#### **source**

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

#### **location**

Text string specifying a group or variable in the NetCDF data source. To read global attributes, set `location` to `' / '` (forward slash).

#### **attname**

Text string specifying the name of an attribute that you want to read in the NetCDF data source.

### Output Arguments

#### **attvalue**

Data associated with the attribute.

## Examples

### Read Global Attribute

```
creation_date = ncreadatt('example.nc', '/', 'creation_date')
```

```
creation_date =
```

```
29-Mar-2010
```

### Read Attribute Associated with Variable

Read an attribute associated with a variable.

```
scale_factor = ncreadatt('example.nc', 'temperature', 'scale_factor')
```

```
scale_factor =
```

```
1.8000
```

### Read Attribute Associated with Group

Read an attribute associated with a group. This example applies to netcdf4 format files only.

```
desc_value = ncreadatt('example.nc', '/grid2', 'description')
```

```
desc_value =
```

```
This is another group attribute.
```

- “Import NetCDF Files and OPeNDAP Data”

## See Also

`ncdisp` | `ncinfo` | `ncread` | `netcdf` | `ncwriteatt`

**Introduced in R2011a**

## **ncwrite**

Write data to NetCDF file

### **Syntax**

```
ncwrite(filename,varname,vardata)
ncwrite(filename,varname,vardata,start, stride)
```

### **Description**

`ncwrite(filename, varname, vardata)` writes the numerical or char data in `vardata` to an existing variable `varname` in the NetCDF file `filename`. `ncwrite` writes the data in `vardata` starting at the beginning of the variable and extends unlimited dimensions automatically, if needed.

If the NetCDF file or the variable do not exist, use `nccreate` to create them first.

`ncwrite(filename, varname, vardata, start, stride)` writes `vardata` to an existing variable `varname` in file `filename` beginning at the location given by `start`. `stride` is an optional argument that specifies the inter-element spacing of the data written. Use this syntax to append data to an existing variable or write partial data.

### **Input Arguments**

#### **filename**

Text string specifying the name of a NetCDF file. If the file does not exist, use `nccreate` to create it first.

#### **Default:**

#### **varname**

Text string specifying the name of a variable in a NetCDF file. If the variable does not exist, use `nccreate` to create it first.

**vardata**

Data to write to the variable in the NetCDF file.

**start**

For an  $N$ -dimensional variable, **start** is a vector of indices of length  $N$  specifying the starting location. Indices are 1-based.

**stride**

(Optional) Vector of length  $N$ , specifying the inter-element spacing.

**Default:** Vector of ones

## Examples

Create a new `netcdf4_classic` file, and write a scalar variable with no dimensions. Add the creation time as a global attribute.

```
nccreate('myfile.nc','pi');
ncwrite('myfile.nc','pi',3.1);
ncwriteatt('myfile.nc','/','creation_time',datestr(now));
% overwrite existing data
ncwrite('myfile.nc','pi',3.1416);
ncdisp('myfile.nc');
```

Create a `netcdf4_classic` file with a variable defined on an unlimited dimension. Write data incrementally to the variable.

```
nccreate('mynctest.nc','vmark',...
 'Dimensions', {'time', inf, 'cols', 6},...
 'ChunkSize', [3 3],...
 'DeflateLevel', 2);
ncwrite('mynctest.nc','vmark', eye(3),[1 1]);
varData = ncread('mynctest.nc','vmark');
disp(varData);
ncwrite('mynctest.nc','vmark',fliplr(eye(3)),[1 4]);
varData = ncread('mynctest.nc','vmark');
disp(varData);
```

## More About

### Tips

- If the variable `varname` already exists, `ncwrite` expects the datatype of `vardata` to match the NetCDF variable data type.
- If the variable `varname` has a `_FillValue`, `scale_factor` or `add_offset` attribute, `ncwrite` expects data in `double` format and casts `vardata` to the NetCDF data type, after applying the following attribute conventions in sequence:
  - 1 Subtract the value of the `add_offset` attribute from `vardata`.
  - 2 Divide `vardata` by the value of the `scale_factor` attribute.
  - 3 Replace NaNs in `vardata` by the value of the `_FillValue` attribute. If this attribute does not exist, `ncwrite` tries to use the fill value for this variable as reported by the NetCDF library.

### See Also

**Introduced in R2011a**

## ncwriteatt

Write attribute to NetCDF file

### Syntax

```
ncwriteatt(filename,location,attname,attvalue)
```

### Description

`ncwriteatt(filename,location,attname,attvalue)` creates or modifies the attribute specified by `attname` in the group or variable specified by `location`, in the NetCDF file specified by `filename`. `attvalue` can be a numeric vector or a string.

### Input Arguments

#### **filename**

Text string specifying the name of a NetCDF file

#### **location**

Text string specifying a group or variable in the NetCDF file. To write global attributes, set `location` to `'/'` (forward slash).

#### **attname**

Text string specifying the name of an existing attribute in a NetCDF file or the name of the attribute that you want to create.

#### **attvalue**

Numeric vector or a string.

### Examples

Create a global attribute.

```
copyfile(which('example.nc'),'myfile.nc');
fileattrib('myfile.nc','+w');
ncdisp('myfile.nc');
ncwriteatt('myfile.nc','/','creation_date',datestr(now));
ncdisp('myfile.nc');
```

Modify an existing attribute.

```
copyfile(which('example.nc'),'myfile.nc');
fileattrib('myfile.nc','+w');
ncdisp('myfile.nc','peaks');
ncwriteatt('myfile.nc','peaks','description','Output of PEAKS');
ncdisp('myfile.nc','peaks');
```

## See Also

[ncdisp](#) | [ncreadatt](#) | [ncwrite](#) | [ncread](#) | [nccreate](#) | [netcdf](#)

**Introduced in R2011a**

# ncwritescema

Add NetCDF schema definitions to NetCDF file

## Syntax

```
ncwritescema(filename, schema)
```

## Description

`ncwritescema(filename, schema)` creates or adds attributes, dimensions, variable definitions and group structure defined in `schema` to the file `filename`.

Use `ncwritescema` in combination with `ncinfo` to create a new NetCDF file based on the schema of an existing file. You can also use `ncwritescema` to add variable definitions, attributes, dimensions, or group structure to an existing file.

---

**Note:** `ncwritescema` does not write variable data. Use `ncwrite` to write data to the created variables. Created unlimited dimensions will have an initial size of 0 until you write data.

---

---

**Note:** `ncwritescema` cannot change the format of an existing file. It cannot redefine existing variables and dimensions in `filename`. If your schema contains attributes, dimensions, variable definitions, or a group structure that already exist in the file, `writescema` issues a warning but continues processing.

---

## Input Arguments

### **filename**

Text string specifying the name of a NetCDF file. If `filename` does not exist, `ncwritescema` creates a new file using the `netcdf4_classic` format, unless the `Format` field in `schema` specifies another format.

**Default:**

**schema**

A structure, or array of structures, representing either a dimension, variable, an entire NetCDF file, or a `netcdf4` group. A group or file schema can contain a dimension or variable schema, or both. You can use the output returned by `ncinfo` as a `schema` structure. The following table lists the fields in the various types of schema structures. Optional fields are marked with asterisk (\*).

Schema Type	Structure Field	Description
Group/File Schema	Name	Text string identifying the group name. Use ' / ' to indicate the entire file.
	Dimensions*	Dimension schema
	Variables*	Variable schema
	Attributes*	Structure array of group/global attributes with Name and Value fields
	Format*	Text string identifying a NetCDF file format
Dimension schema	Name	Text string identifying the dimension
	Length	Length of the dimension. Can be <code>Inf</code> .
	Unlimited*	Boolean flag indicating if the dimension is unlimited
	Format*	Text string identifying a NetCDF file format
Variable schema	Name	Text string identifying a variable name
	Dimensions	Variable's dimension schema
	Datatype	Text string identifying a MATLAB datatype
	Attributes*	Structure array of variable attributes with Name and Value fields
	ChunkSize*	Numeric value specifying chunk size of the variable
	FillValue*	Character or numeric fill value

Schema Type	Structure Field	Description
	DeflateValue*	Deflate compression level
	Shuffle*	Boolean flag to turn on the Shuffle filter
	Format*	Text string identifying a NetCDF file format

**Default:**

## Examples

Create a classic format file with two dimension definitions.

```
mySchema.Name = '/';
mySchema.Format = 'classic';
mySchema.Dimensions(1).Name = 'time';
mySchema.Dimensions(1).Length = Inf;
mySchema.Dimensions(2).Name = 'rows';
mySchema.Dimensions(2).Length = 10;
ncwritescema('emptyFile.nc', mySchema);
ncdisp('emptyFile.nc');
```

Create a `netcdf4_classic` format file to store a single variable from an existing file. First use `ncinfo` to get the schema of the `peaks` variable from the file. Then use `ncwritescema` to create a NetCDF file, defining the `peaks` variable. Use `ncread` to get the data associated with the `peaks` variable and then use `ncwrite` to write the data to the variable in the new NetCDF file.

```
myVarSchema = ncinfo('example.nc','peaks');
ncwritescema('peaksFile.nc',myVarSchema);
peaksData = ncread('example.nc','peaks');
ncwrite('peaksFile.nc','peaks',peaksData);
ncdisp('peaksFile.nc');
```

**Introduced in R2011a**

# netcdf

Interact directly with NetCDF Library

## Description

Functions in the MATLAB `netcdf` package provide interfaces to dozens of functions in the NetCDF library. The MATLAB functions enable reading data from and writing data to NetCDF files (known as *data sets* in NetCDF terminology). To use these functions, you should be familiar with the NetCDF C Interface.

MATLAB supports NetCDF version 4.3.3.1.

In most cases, the syntax of the MATLAB function matches the syntax of the NetCDF library function. The functions are implemented as a package called `netcdf`. To use these functions, prefix the function name with the package name, `netcdf`. For example, to call the NetCDF library routine used to open existing NetCDF files, use the following MATLAB syntax:

```
ncid = netcdf.open(ncfile,mode);
```

For copyright information, see the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

---

**Note:** For information about MATLAB support for the Common Data Format (CDF), which is a completely separate and incompatible format, see `cdflib`.

---

## Library Functions

<code>netcdf.getChunkCache</code>	Retrieve chunk cache settings for NetCDF library
<code>netcdf.inqLibVers</code>	Return NetCDF library version information
<code>netcdf.setChunkCache</code>	Set default chunk cache settings for NetCDF library
<code>netcdf.setDefaultFormat</code>	Change default netCDF file format

## File Operations

netcdf.abort	Revert recent netCDF file definitions
netcdf.close	Close netCDF file
netcdf.create	Create new NetCDF dataset
netcdf.endDef	End netCDF file define mode
netcdf.inq	Return information about netCDF file
netcdf.inqFormat	Determine format of NetCDF file
netcdf.inqGrps	Retrieve array of child group IDs
netcdf.inqUnlimDims	Return list of unlimited dimensions in group
netcdf.open	Open NetCDF data source
netcdf.reDef	Put open netCDF file into define mode
netcdf.setFill	Set netCDF fill mode
netcdf.sync	Synchronize netCDF file to disk

## Dimensions

netcdf.defDim	Create netCDF dimension
netcdf.inqDim	Return netCDF dimension name and length
netcdf.inqDimID	Return dimension ID
netcdf.renameDim	Change name of netCDF dimension

## Groups

netcdf.defGrp	Create group in NetCDF file
netcdf.inqDimIDs	Retrieve list of dimension identifiers in group
netcdf.inqGrpName	Retrieve name of group
netcdf.inqGrpNameFull	Complete pathname of group
netcdf.inqGrpParent	Retrieve ID of parent group.

netcdf.inqNcid	Return ID of named group
netcdf.inqVarIDs	IDs of all variables in group

## Variables

netcdf.defVar	Create NetCDF variable
netcdf.defVarChunking	Define chunking behavior for NetCDF variable
netcdf.defVarDeflate	Define compression parameters for NetCDF variable
netcdf.defVarFill	Define fill parameters for NetCDF variable
netcdf.defVarFletcher32	Define checksum parameters for NetCDF variable
netcdf.getVar	Read data from NetCDF variable
netcdf.inqVarChunking	Determine chunking settings for NetCDF variable
netcdf.inqVarDeflate	Determine compression settings for NetCDF variable
netcdf.inqVarFill	Determine values of fill parameters for NetCDF variable
netcdf.inqVarFletcher32	Fletcher32 checksum setting for NetCDF variable
netcdf.inqVar	Information about variable
netcdf.inqVarID	Return ID associated with variable name
netcdf.putVar	Write data to netCDF variable
netcdf.renameVar	Change name of netCDF variable

## Attributes

netcdf.copyAtt	Copy attribute to new location
netcdf.delAtt	Delete netCDF attribute
netcdf.getAtt	Return netCDF attribute
netcdf.inqAtt	Return information about netCDF attribute

netcdf.inqAttID	Return ID of netCDF attribute
netcdf.inqAttName	Return name of netCDF attribute
netcdf.putAtt	Write netCDF attribute
netcdf.renameAtt	Change name of attribute

## Utilities

netcdf.getConstant	Return numeric value of named constant
netcdf.getConstantNames	Return list of constants known to netCDF library

## netcdf.abort

Revert recent netCDF file definitions

### Syntax

```
netcdf.abort(ncid)
```

### Description

`netcdf.abort(ncid)` reverts a netCDF file to its previous state, backing out any definitions made since the file last entered define mode. A file enters define mode when you create it (using `netcdf.create`) or when you explicitly enter define mode (using `netcdf.redef`). Once you leave define mode (using `netcdf.endDef`), you cannot revert the definitions you made while in define mode. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`. A call to `netcdf.abort` closes the file.

This function corresponds to the `nc_abort` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example creates a new file, performs an operation on the file, and then reverts the file back to its original state. To run this example, you must have write permission in your current directory.

```
% Create a netCDF file
ncid = netcdf.create('foo.nc', 'NC_NOGLOBBER');

% Perform an operation, such as defining a dimension.
dimid = netcdf.defDim(ncid, 'lat', 50);

% Revert the file back to its previous state.
netcdf.abort(ncid)

% Verify that the file is now closed.
```

```
dimid = netcdf.defDim(ncid, 'lat', 50); % should fail
??? Error using ==> netcdflib
NetCDF: Not a valid ID
```

```
Error in ==> defDim at 22
dimid = netcdflib('def_dim', ncid,dimname,dimlen);
```

## See Also

[netcdf.create](#) | [netcdf.endDef](#) | [netcdf.reDef](#)

## netcdf.close

Close netCDF file

### Syntax

```
netcdf.close(ncid)
```

### Description

`netcdf.close(ncid)` terminates access to the netCDF file identified by `ncid`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_close` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example creates a new netCDF file, and then closes the file. You must have write permission in your current directory to run this example.

```
ncid = netcdf.open('foo.nc', 'NC_WRITE')
netcdf.close(ncid)
```

### See Also

`netcdf.create` | `netCDF.open`

# netcdf.copyAtt

Copy attribute to new location

## Syntax

```
netcdf.copyAtt(ncid_in,varid_in,attname,ncid_out,varid_out)
```

## Description

`netcdf.copyAtt(ncid_in,varid_in,attname,ncid_out,varid_out)` copies an attribute from one variable to another, possibly across files. `ncid_in` and `ncid_out` are netCDF file identifiers returned by `netcdf.create` or `netcdf.open`. `varid_in` identifies the variable with an attribute that you want to copy. `varid_out` identifies the variable to which you want to associate a copy of the attribute.

This function corresponds to the `nc_copy_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example makes a copy of the attribute associated with the first variable in the netCDF example file, `example.nc`, in a new file. To run this example, you must have write permission in your current directory.

```
% Open example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get identifier for a variable in the file.
varid = netcdf.inqVarID(ncid,'avagadros_number');

% Create new netCDF file.
ncid2 = netcdf.create('foo.nc','NC_NOCLlobber');

% Define a dimension in the new file.
dimid2 = netcdf.defDim(ncid2,'x',50);
```

```
% Define a variable in the new file.
varid2 = netcdf.defVar(ncid2,'myvar','double',dimid2);

% Copy the attribute named 'description' into the new file,
% associating the attribute with the new variable.
netcdf.copyAtt(ncid,varid,'description',ncid2,varid2);
%
% Check the name of the attribute in new file.
attname = netcdf.inqAttName(ncid2,varid2,0)

attname =

description
```

## See Also

[netcdf.inqAtt](#) | [netcdf.inqAttID](#) | [netcdf.inqAttName](#) | [netcdf.putAtt](#) | [netcdf.renameAtt](#)

# netcdf.create

Create new NetCDF dataset

## Syntax

```
ncid = netcdf.create(filename,cmode)
[chunksize_out,ncid] =
netcdf.create(filename,cmode,initpsz,chunksize)
```

## Description

`ncid = netcdf.create(filename,cmode)` creates a new NetCDF file according to the file creation mode. The return value `ncid` is a file ID. The `cmode` parameter is a text string that describes the type of file access, which can have any of the following values.

Value of <code>cmode</code>	Description
NOCLOBBER	Prevent overwriting of existing file with the same name.
CLOBBER	Overwrite any existing file with the same name.
SHARE	Allow synchronous file updates.
64BIT_OFFSET	Allow easier creation of files and variables which are larger than two gigabytes.
NETCDF4	Create a NetCDF-4/HDF5 file
CLASSIC_MODEL	Enforce the classic model; has no effect unless used in a bitwise-or with NETCDF4

---

**Note:** You can specify the mode as a numeric value, retrieved using the `netcdf.getConstant` function. To specify more than one mode, use a bitwise-OR of the numeric values of the modes.

---

`[chunksize_out,ncid] = netcdf.create(filename,cmode,initpsz,chunksize)` creates a new NetCDF file, but with additional performance tuning parameters. `initpsz` sets the initial size of the

file. `chunksizes` can affect I/O performance. The actual value chosen by the NetCDF library might not correspond to the input value.

This function corresponds to the `nc_create` and `nc__create` functions in the NetCDF library C API. To use this function, you should be familiar with the NetCDF programming paradigm. See `netcdf` for more information.

## Examples

### Create NetCDF File Without Overwriting Existing File

Create a NetCDF dataset named `foo.nc`, only if no other file with the same name exists in the current directory. To run this example, you must have write permission in your current directory.

```
ncid = netcdf.create('foo.nc', 'NO_CLOBBER')
```

```
ncid =
 65536
```

`netcdf.create` returns a file identifier.

Close the file

```
netcdf.close(ncid)
```

### Create NetCDF-4 File Using Classic Model

Get the numeric values corresponding to the `NETCDF4` and `CLASSIC_MODEL` constants defined by the NetCDF library. Use a bitwise-OR of the numeric values to specify more than one creation mode.

```
cmode = netcdf.getConstant('NETCDF4');
cmode = bitor(cmode, netcdf.getConstant('CLASSIC_MODEL'));
```

Create a NetCDF-4 file that uses the classic model by specifying the creation mode value, `cmode`.

```
ncid = netcdf.create('myfile.nc', cmode);
```

Close the file.

```
netcdf.close(ncid);
```

### **See Also**

[netcdf.getConstant](#) | [netcdf.open](#)

## netcdf.defDim

Create netCDF dimension

### Syntax

```
dimid = netcdf.defDim(ncid,dimname,dimlen)
```

### Description

`dimid = netcdf.defDim(ncid,dimname,dimlen)` creates a new dimension in the netCDF file specified by `ncid`, where `dimname` is a character string that specifies the name of the dimension and `dimlen` is a numeric value that specifies its length. To define an unlimited dimension, specify the predefined constant `'NC_UNLIMITED'` for `dimlen`, using `netcdf.getConstant` to retrieve the value.

`netcdf.defDim` returns `dimid`, a numeric ID corresponding to the new dimension.

This function corresponds to the `nc_def_dim` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

### Examples

Create a new file and define two dimensions in the file. One dimension is an unlimited dimension. To run this example, you must have write permission in your current folder.

```
% Create a netCDF file.
ncid = netcdf.create('foo.nc','NC_NOCLlobber')

% Define a dimension.
lat_dimID = netcdf.defDim(ncid,'latitude',360);

% Define an unlimited dimension.
```

```
long_dimID = netcdf.defDim(ncid, 'longitude', ...
 netcdf.getConstant('NC_UNLIMITED'));
```

## See Also

[netcdf.getConstant](#)

## netcdf.defGrp

Create group in NetCDF file

### Syntax

```
childGrpID = netcdf.defGrp(parentGroupId,childGroupName)
```

### Description

`childGrpID = netcdf.defGrp(parentGroupId,childGroupName)` creates a child group with the name specified by `childGroupName`, that is the child of the parent group specified by `parentGroupId`

### Input Arguments

#### **parentGroupId**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

#### **childGroupName**

Text string specifying the name that you want to assign to the group.

**Default:**

### Output Arguments

#### **childGrpID**

Identifier of a NetCDF group.

## Examples

This example creates a NetCDF dataset and then defines a group.

```
ncid = netcdf.create('myfile.nc', 'netcdf4');
childGroupId = netcdf.defGrp(ncid, 'mygroup');
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_def_grp` function in the NetCDF library C API.

For copyright information, read the files `netcdfcopyright.txt` and `mexnccopyright.txt`.

## See Also

`netcdf` | `netcdf.inqGrps`

## netcdf.defVar

Create NetCDF variable

### Syntax

```
varid = netcdf.defVar(ncid,varname,xtype,dimids)
```

### Description

`varid = netcdf.defVar(ncid,varname,xtype,dimids)` creates a new variable in the dataset identified by `ncid`.

`varname` is a character string that specifies the name of the variable.

`xtype` specifies the NetCDF data type of the variable, using one of the following strings.

Value of xtype	MATLAB Class
'NC_BYTE'	int8 or uint8 <sup>a</sup>
'NC_CHAR'	char
'NC_SHORT'	int16
'NC_INT'	int32
'NC_FLOAT'	single
'NC_DOUBLE'	double

a. NetCDF interprets byte data as either signed or unsigned.

Alternatively, `xtype` can be the numeric equivalent returned by the `netcdf.getConstant` function.

`dimids` specifies a list of dimension IDs.

`netcdf.defVar` returns `varid`, a numeric identifier for the new variable.

This function corresponds to the `nc_def_var` function in the NetCDF library C API. Because MATLAB uses FORTRAN-style ordering, the fastest-varying dimension comes

first and the slowest comes last. Any unlimited dimension is therefore last in the list of dimension IDs. This ordering is the reverse of that found in the C API. To use this function, you should be familiar with the NetCDF programming paradigm. See `netcdf` for more information.

## Examples

### Define Dimension and Variable in NetCDF File

Create a new NetCDF file, define a dimension in the file, and then define a variable on that dimension. In NetCDF files, you must create a dimension before you can create a variable. To run this example, you must have write permission in your current folder.

Create a new NetCDF file named `foo.nc`.

```
ncid = netcdf.create('foo.nc', 'NC_NOCLIBBER');
```

Define a dimension in the new file.

```
dimid = netcdf.defDim(ncid, 'x', 50);
```

Define a variable in the new file using `netcdf.defVar`.

```
varid = netcdf.defVar(ncid, 'myvar', 'double', dimid)
```

```
varid =
```

```
0
```

`netcdf.defVar` returns a numeric identifier for the new variable.

Close the file.

```
netcdf.close(ncid)
```

### See Also

`netCDF.getConstant` | `netCDF.inqVar` | `netCDF.putVar`

## netcdf.defVarChunking

Define chunking behavior for NetCDF variable

### Syntax

```
netcdf.defVarChunking(ncid, varid, storage, chunkDims)
```

### Description

`netcdf.defVarChunking(ncid, varid, storage, chunkDims)`. sets the chunk settings for the variable specified by `varid`. Chunking is a technique to improve performance. `storage` specifies the type of chunking to use and `chunkDims` specifies the extents of the chunk size. You must specify the chunk size used with a variable after creating the variable but before you write data to the variable.

You cannot specify the chunk size for variables in a NetCDF file created with the netCDF-3 mode (`CLASSIC_MODEL`).

### Input Arguments

#### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

#### **varid**

Identifier of a NetCDF variable, returned by `netcdf.defVar`.

**Default:**

#### **storage**

Text string specifying whether NetCDF should break the variable into chunks when writing to a file. If set to `CHUNKED`, NetCDF breaks the variable into chunks; if set to `CONTIGUOUS`, NetCDF does not break the data into chunks.

**Default:****chunkDims**

Array specifying the dimensions of the chunk.

Because MATLAB uses FORTRAN-style ordering, the order of dimensions in `chunkDims` is reversed relative to what would be in the C API.

If storage is `CONTIGUOUS`, you can omit `chunkDims`.

**Default:** Chunk size determined by the NetCDF library.

## Examples

This example creates a NetCDF file and specifies the chunking behavior of a variable.

```
ncid = netcdf.create('myfile.nc','NETCDF4');
latdimid = netcdf.defDim(ncid,'lat',1800);
londimid = netcdf.defDim(ncid,'col',3600);
varid = netcdf.defVar(ncid,'earthgrid','double',[latdimid londimid]);
netcdf.defVarChunking(ncid,varid,'CHUNKED',[180 360]);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_def_var_chunking` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.inqVarChunking`

## netcdf.defVarDeflate

Define compression parameters for NetCDF variable

### Syntax

```
netcdf.defVarDeflate(ncid, varid, shuffle, deflate, deflateLevel)
```

### Description

`netcdf.defVarDeflate(ncid, varid, shuffle, deflate, deflateLevel)` sets the compression parameters for the NetCDF variable specified by `varid` in the location specified by `ncid`.

### Input Arguments

#### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

#### **varid**

Identifier of a NetCDF variable, returned by `netcdf.defVar`.

**Default:**

#### **shuffle**

Boolean value. To turn on the shuffle filter, set this argument to `true`. The shuffle filter can assist with the compression of integer data by changing the byte order in the data stream.

**Default:**

**deflate**

Boolean value. To turn on compression, set this argument to `true` and set the `deflateLevel` argument to the desired compression level.

**Default:**

**deflateLevel**

Numeric value between `0` and `9` specifying the amount of compression, where `0` is no compression and `9` is the most compression.

**Default:**

## Examples

This example create a variable with dimensions [1800 3600] and a compression level of 5. This results in a chunked layout that is a 10-by-10 grid.

```
ncid = netcdf.create('myfile.nc', 'NETCDF4');
latdimid = netcdf.defDim(ncid, 'lat', 1800);
londimid = netcdf.defDim(ncid, 'col', 3600);
varid = netcdf.defVar(ncid, 'earthgrid', 'double', [latdimid londimid]);
netcdf.defVarDeflate(ncid, varid, true, true, 5);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_def_var_deflate` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.inqVarDeflate`

## netcdf.defVarFill

Define fill parameters for NetCDF variable

### Syntax

```
netcdf.defVarFill(ncid, varid, noFillMode, fillValue)
```

### Description

`netcdf.defVarFill(ncid, varid, noFillMode, fillValue)` sets the fill parameters for the NetCDF variable identified by `varid`. `ncid` specifies the location.

For netCDF-4 files, you can only specify fill values when the NetCDF is in definition mode (before calling `netcdf.endDef`). For NetCDF files in classic and 64-bit offset modes, you can turn no-fill mode on and off at any time.

### Input Arguments

#### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

#### **varid**

Identifier of a NetCDF variable, returned by `netcdf.defVar`.

**Default:**

#### **noFillMode**

Boolean value. When set to `true`, turns off use of fill values for the variable, which can be helpful in high performance applications. When `true`, `netcdf.defVarFill` ignores the value of the `fillValue` argument. To use the fill value, set this to `false`.

**Default:**

### **fillValue**

Specifies the value to use in the variable when no other value is specified. The data type must be the same data type as the variable.

**Default:**

## **Examples**

This example creates a NetCDF file and defines a fill value for a variable.

```
ncid = netcdf.create('myfile.nc', 'NETCDF4');
dimid = netcdf.defDim(ncid, 'latitude', 180);
varid = netcdf.defVar(ncid, 'latitude', 'double', dimid);
netcdf.defVarFill(ncid, varid, false, -999);
netcdf.close(ncid);
```

## **References**

This function corresponds to the `nc_def_var_fill` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

### **See Also**

`netcdf` | `netcdf.setFill` | `netcdf.inqVarFill`

## netcdf.defVarFletcher32

Define checksum parameters for NetCDF variable

### Syntax

```
netcdf.defVarFletcher32(ncid, varid, setting)
```

### Description

`netcdf.defVarFletcher32(ncid, varid, setting)` defines the checksum settings for the NetCDF variable specified by `varid` in the file specified by `ncid`.

### Input Arguments

#### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

#### **varid**

Identifier of a NetCDF variable, returned by `netcdf.defVar`.

**Default:**

#### **setting**

Text string specifying whether Fletcher32 checksum error detection is used with the variable. To turn on Fletcher32 checksum, specify the value `FLETCHER32`. To turn off the use of checksum error detection, specify the value `NOCHECKSUM`.

**Default:**

## Examples

This example creates a NetCDF dataset and turns on the Fletcher32 checksum for a variable.

```
ncid = netcdf.create('myfile.nc', 'NETCDF4');
latdimid = netcdf.defDim(ncid, 'lat', 1800);
londimid = netcdf.defDim(ncid, 'col', 3600);
varid = netcdf.defVar(ncid, 'earthgrid', 'double', [latdimid londimid]);
netcdf.defVarFletcher32(ncid, varid, 'FLETCHER32');
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_def_var_fletcher32` function in the NetCDF library C API.

For copyright information, read the files `netcdfcopyright.txt` and `mexnccopyright.txt`.

## See Also

`netcdf` | `netcdf.inqVarFletcher32`

## netcdf.delAtt

Delete netCDF attribute

### Syntax

```
netcdf.delAtt(ncid,varid,attName)
```

### Description

`netcdf.delAtt(ncid,varid,attName)` deletes the attribute identified by the text string `attName`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` is a numeric value that identifies the variable. To delete a global attribute, use `netcdf.getConstant('GLOBAL')` for the `varid`. You must be in define mode to delete an attribute.

This function corresponds to the `nc_del_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example opens a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open a netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Determine number of global attributes in file.
[numdims numvars numatts unlimdimID] = netcdf.inq(ncid);

numatts =

 1
```

```
% Get name of attribute; it is needed for deletion.
attname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0)

% Put file in define mode to delete an attribute.
netcdf.reDef(ncid);

% Delete the global attribute in the netCDF file.
netcdf.delAtt(ncid,netcdf.getConstant('GLOBAL'),attname);

% Verify that the global attribute was deleted.
[numdims numvars numatts unlimdimID] = netcdf.inq(ncid);

numatts =

 0
```

## See Also

[netcdf.getConstant](#) | [netcdf.inqAttName](#)

## netcdf.endDef

End netCDF file define mode

### Syntax

```
netcdf.endDef(ncid)
netcdf.endDef(ncid,h_minfree,v_align,v_minfree,r_align)
```

### Description

`netcdf.endDef(ncid)` takes a netCDF file out of define mode and into data mode. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`netcdf.endDef(ncid,h_minfree,v_align,v_minfree,r_align)` takes a netCDF file out of define mode, specifying four additional performance tuning parameters. For example, one reason for using the performance parameters is to reserve extra space in the netCDF file header using the `h_minfree` parameter:

```
ncid = netcdf.endDef(ncid,20000,4,0,4);
```

This reserves 20,000 bytes in the header, which can be used later when adding attributes. This can be extremely efficient when working with very large netCDF 3 files. To understand how to use these performance tuning parameters, see the netCDF library documentation.

This function corresponds to the `nc_enddef` and `nc__enddef` functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

#### Take File out of Define Mode

When you create a file using `netcdf.create`, the functions opens the file in define mode. This example uses `netcdf.endDef` to take the file out of define mode.

Create a netCDF file.

```
ncid = netcdf.create('foo.c', 'NC_NOCLONBER');
```

Define a dimension.

```
dimid = netcdf.defDim(ncid, 'lat', 50);
```

Leave define mode.

```
netcdf.endDef(ncid)
```

Test if still in define mode.

```
dimid = netcdf.defDim(ncid, 'lon', 50);
```

Error using netcdf:lib

The NetCDF library encountered an error during execution of 'defDim' function - 'Operation not defined' (NC\_ENOTINDEFINE)'.  
(NC\_ENOTINDEFINE)'.  
(NC\_ENOTINDEFINE)'.  
(NC\_ENOTINDEFINE)'.  
(NC\_ENOTINDEFINE)'.

Error in netcdf.defDim (line 25)

```
dimid = netcdf:lib('defDim', ncid, dimname, dimlen);
```

netcdf.defDim errors, as expected.

## See Also

[netcdf.create](#) | [netcdf.reDef](#)

## netcdf.getAtt

Return netCDF attribute

### Syntax

```
attrvalue = netcdf.getAtt(ncid,varid,attname)
attrvalue = netcdf.getAtt(ncid,varid,attname,output_datatype)
```

### Description

`attrvalue = netcdf.getAtt(ncid,varid,attname)` returns `attrvalue`, the value of the attribute specified by the text string `attname`. When it chooses the data type of `attrvalue`, MATLAB attempts to match the netCDF class of the attribute. For example, if the attribute has the netCDF data type `NC_INT`, MATLAB uses the `int32` class for the output data. If an attribute has the netCDF data type `NC_BYTE`, the class of the output data is `int8` value.

`attrvalue = netcdf.getAtt(ncid,varid,attname,output_datatype)` returns `attrvalue`, the value of the attribute specified by the text string `attname`, using the output class specified by `output_datatype`. You can specify any of the following strings for the output data type.

'int'	'double'	'int16'
'short'	'single'	'int8'
'float'	'int32'	'uint8'

This function corresponds to several attribute I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example opens the example netCDF file included with MATLAB, `example.nc`, and gets the value of the attribute associated with the first variable. The example also gets the value of the global variable in the file.

```
% Open a netCDF file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get name of first variable.
[varname vartype vardimIDs varatts] = netcdf.inqVar(ncid,0);

% Get ID of variable, given its name.
varid = netcdf.inqVarID(ncid,varname);

% Get attribute name, given variable id.
attname = netcdf.inqAttName(ncid,varid,0);

% Get value of attribute.
attval = netcdf.getAtt(ncid,varid,attname);

% Get name of global attribute
gattname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0);

% Get value of global attribute.
gattval = netcdf.getAtt(ncid,netcdf.getConstant('NC_GLOBAL'),gattname)

gattval =

09-Jun-2008
```

## See Also

netcdf.inqAtt | netcdf.putAtt

## netcdf.getChunkCache

Retrieve chunk cache settings for NetCDF library

### Syntax

```
[csize, nelems, premp] = netcdf.getChunkCache()
```

### Description

[csize, nelems, premp] = netcdf.getChunkCache() returns the default chunk cache settings.

### Output Arguments

#### **csize**

Scalar double specifying the total size of the raw data chunk cache in bytes.

#### **nelems**

Scalar double specifying the number of chunk slots in the raw data chunk cache hash table.

#### **premp**

Double, between 0 and 1, inclusive, that specifies how the library handles preempting fully read chunks in the chunk cache. A value of zero means fully read chunks are treated no differently than other chunks, that is, preemption occurs solely based on the Least Recently Used (LRU) algorithm. A value of 1 means fully read chunks are always preempted before other chunks.

### Examples

Determine information about the chunk cache size used by the NetCDF library.

```
[csize, nelems, premp] = netcdf.getChunkCache();
```

## References

This function corresponds to the `nc_get_chunk_cache` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.setChunkCache`

## netcdf.getConstant

Return numeric value of named constant

### Syntax

```
val = netcdf.getConstant(param_name)
```

### Description

`val = netcdf.getConstant(param_name)` returns the numeric value corresponding to the name of a constant defined by the netCDF library. For example, `netcdf.getConstant('NC_NOCLOBBER')` returns the numeric value corresponding to the netCDF constant `NC_NOCLOBBER`.

The value for `param_name` can be either upper- or lowercase, and does not need to include the leading three characters `'NC_'`. To retrieve a list of all the names defined by the netCDF library, use the `netcdf.getConstantNames` function.

This function has no direct equivalent in the netCDF C interface. To find out more about NetCDF, see `netcdf`.

### Examples

This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Determine contents of the file.
[ndims nvars natts dimm] = netcdf.inq(ncid);

% Get name of global attribute.
% Note: You must use netcdf.getConstant to specify NC_GLOBAL.
attname = netcdf.inqattname(ncid,netcdf.getConstant('NC_GLOBAL'),0)

attname =
```

creation\_date

**See Also**

netcdf.getConstantNames

## netcdf.getConstantNames

Return list of constants known to netCDF library

### Syntax

```
val = netcdf.getConstantNames(param_name)
```

### Description

`val = netcdf.getConstantNames(param_name)` returns a list of names of netCDF library constants, definitions, and enumerations. When these strings are supplied as actual parameters to MATLAB netCDF package functions, the functions automatically convert the constant to the appropriate numeric value.

This MATLAB function has no direct equivalent in the netCDF C interface. To find out more about netCDF, see `netcdf`.

### Examples

```
nc_constants = netcdf.getConstantNames
```

```
nc_constants =

 'NC2_ERR'
 'NC_64BIT_OFFSET'
 'NC_BYTE'
 'NC_CHAR'
 'NC_CLOBBER'
 'NC_DOUBLE'
 'NC_EBADDIM'
 'NC_EBADID'
 'NC_EBADNAME'
 'NC_EBADTYPE'
 ...
```

### See Also

`netcdf.getConstantNames`

# netcdf.getVar

Read data from NetCDF variable

## Syntax

```
data = netcdf.getVar(ncid, varid)
data = netcdf.getVar(ncid, varid, start)
data = netcdf.getVar(ncid, varid, start, count)
data = netcdf.getVar(ncid, varid, start, count, stride)
data = netcdf.getVar(____, output_type)
```

## Description

`data = netcdf.getVar(ncid, varid)` returns `data`, the value of the variable specified by `varid`. MATLAB attempts to match the class of the output data to NetCDF class of the variable.

`ncid` is a NetCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`data = netcdf.getVar(ncid, varid, start)` returns a single value starting at the specified index, `start`.

`data = netcdf.getVar(ncid, varid, start, count)` returns a contiguous section of a variable. `start` specifies the starting point and `count` specifies the amount of data to return.

`data = netcdf.getVar(ncid, varid, start, count, stride)` returns a subset of a section of a variable. `start` specifies the starting point, `count` specifies the extent of the section, and `stride` specifies which values to return.

`data = netcdf.getVar( ____, output_type)` specifies the data type of the return value `data`. You can specify any of the following strings for the output data type.

'int8'
'uint8'
'int16'

'int32'
'single'
'double'

This function corresponds to several functions in the NetCDF library C API. To use this function, you should be familiar with the NetCDF programming paradigm. See `netcdf` for more information.

## Examples

### Read Value of Variable in NetCDF File

Open the example file, `example.nc`.

```
ncid = netcdf.open('example.nc', 'NC_NOWRITE');
```

Get the name of the first variable in the file.

```
varname = netcdf.inqVar(ncid,0)
```

```
varname =
```

```
avagadros_number
```

Get variable ID of the first variable, given its name.

```
varid = netcdf.inqVarID(ncid,varname)
```

```
varid =
```

```
0
```

Get the value of the variable. Use the variable ID as the second input to the `netcdf.getVar` function.

```
data = netcdf.getVar(ncid,varid)
```

```
data =
 6.0221e+23
```

Display the data type of the output value.

```
whos data
```

Name	Size	Bytes	Class	Attributes
data	1x1	8	double	

Get the value of the `avogadros_number` variable again, specifying that the output data type should be `single`.

```
data = netcdf.getVar(ncid,varid,'single');
```

Display the data type of the output value.

```
whos data
```

Name	Size	Bytes	Class	Attributes
data	1x1	4	single	

Close the NetCDF file.

```
netcdf.close(ncid)
```

## netcdf.inq

Return information about netCDF file

### Syntax

```
[ndims,nvars,ngatts,unlimdimid] = netcdf.inq(ncid)
```

### Description

`[ndims,nvars,ngatts,unlimdimid] = netcdf.inq(ncid)` returns the number of dimensions, variables, and global attributes in a netCDF file. The function also returns the ID of the dimension defined with unlimited length, if one exists.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`. You can call `netcdf.inq` in either define mode or data mode.

This function corresponds to the `nc_inq` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example opens the example netCDF file included with MATLAB, `example.nc`, and uses the `netcdf.inq` function to get information about the contents of the file.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE')

% Get information about the contents of the file.
[numdims, numvars, numglobalatts, unlimdimID] = netcdf.inq(ncid)

numdims =

 4
```

```
numvars =
```

```
 4
```

```
numglobalatts =
```

```
 1
```

```
unlimdimID =
```

```
 3
```

### **See Also**

`netcdf.create` | `netcdf.open`

## netcdf.inqDimIDs

Retrieve list of dimension identifiers in group

### Syntax

```
dimIDs = netcdf.inqDimIDs(ncid)
dimIDs = netcdf.inqDimIDs(ncid,includeParents)
```

### Description

`dimIDs = netcdf.inqDimIDs(ncid)` returns a list of dimension identifiers in the group specified by `ncid`.

`dimIDs = netcdf.inqDimIDs(ncid,includeParents)` includes all dimensions in all parent groups if `includeParents` is true.

### Input Arguments

#### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

#### **includeParents**

Boolean value. If set to true, `netcdf.inqDimIDs` includes the dimensions of all parent groups.

**Default:** false

### Output Arguments

#### **dimIDs**

Array of dimension IDs

## Examples

This example opens the NetCDF sample file and gets the IDs of all the dimensions.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
gid = netcdf.inqNcid(ncid, 'grid1');
dimids = netcdf.inqDimIDs(gid);
dimids_all = netcdf.inqDimIDs(gid, true);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_dimids` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

## netcdf.inqFormat

Determine format of NetCDF file

### Syntax

```
format = netcdf.inqFormat(ncid)
```

### Description

`format = netcdf.inqFormat(ncid)` returns the format for the file specified by NetCDF file identifier, `ncid`.

### Input Arguments

#### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

### Output Arguments

#### **format**

Text string that specifies the format of the NetCDF file. Values include:

Format String	Description
FORMAT_CLASSIC	Classic format — Original NetCDF format, used by all NetCDF files created between 1989 and 2004
FORMAT_64BIT	Classic format, 64-bit — Original format with 64-bit addressing capability to allow creation and access of much larger files.

Format String	Description
FORMAT_NETCDF4	Enhanced model, HDF5-based — Introduced in 2008, NetCDF, version 4, extends the classic model and is based on HDF5.
FORMAT_NETCDF4_CLASSIC	Classic model, HDF5-based — Introduced in 2008, NetCDF, version 4, implements classic model but is based on HDF5.

## Examples

This example opens the sample NetCDF file and determines the format.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
fmt = netcdf.inqFormat(ncid)

format =

FORMAT_NETCDF4

netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_format` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

## netcdf.inqGrpName

Retrieve name of group

### Syntax

```
groupName = netcdf.inqGrpName(ncid)
```

### Description

`groupName = netcdf.inqGrpName(ncid)` returns the name of a group specified by `ncid`.

### Input Arguments

#### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

### Output Arguments

#### **groupName**

Text string specifying name of a group. The root group has the name `'/'`.

### Examples

This example opens the NetCDF sample file and gets the names of groups in the dataset.

```
ncid = netcdf.open('example.nc', 'nowrite');
name = netcdf.inqGrpName(ncid);
```

```
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_grpname` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.inqGrpNameFull`

## netcdf.inqGrpNameFull

Complete pathname of group

### Syntax

```
groupName = netcdf.inqGrpNameFull(ncid)
```

### Description

`groupName = netcdf.inqGrpNameFull(ncid)` returns the complete pathname of the group specified by `ncid`.

### Input Arguments

#### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

### Output Arguments

#### **groupName**

Text string specifying complete path of group.

The root group has the name `' / '`. The names of parent groups and child groups use the forward slash `' / '` separator, as in UNIX folder names, for example, `/group1/subgrp2/subsubgrp3`.

### Examples

Open the NetCDF sample dataset and retrieve the names of all groups.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
gid = netcdf.inqNcid(ncid, 'grid2');
fullName = netcdf.inqGrpNameFull(gid);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_grpname_full` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

## netcdf.inqGrpParent

Retrieve ID of parent group.

### Syntax

```
parentGroupID = netcdf.inqGrpParent(ncid)
```

### Description

`parentGroupID = netcdf.inqGrpParent(ncid)` returns the ID of the parent group given the location of the child group, specified by `ncid`.

### Input Arguments

#### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

### Output Arguments

#### **parentGroupID**

Identifier of the NetCDF group or file that is the parent of the specified file or group.

### Examples

This example opens the NetCDF sample file and gets the full path of the parent of the specified group.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
```

```
gid = netcdf.inqNcid(ncid,'grid2');
parentId = netcdf.inqGrpParent(gid);
fullName = netcdf.inqGrpNameFull(parentId);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_grp_parent` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

`netcdf` | `netcdf.inqGrps`

## netcdf.inqGrps

Retrieve array of child group IDs

### Syntax

```
childGrps = netcdf.inqGrps(ncid)
```

### Description

`childGrps = netcdf.inqGrps(ncid)` returns all the child group IDs in the parent group, specified by `ncid`.

### Input Arguments

#### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

### Output Arguments

#### **childGrps**

Array containing identifiers of child groups in the specified NetCDF file or group.

### Examples

This example opens the sample NetCDF file and then gets information about the groups it contains.

```
ncid = netcdf.open('example.nc', 'nowrite');
```

```
childGroups = netcdf.inqGrps(ncid);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_grps` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.inqNcid`

## **netcdf.inqNcid**

Return ID of named group

### **Syntax**

```
childGroupId = netcdf.inqNcid(ncid,childGroupName)
```

### **Description**

`childGroupId = netcdf.inqNcid(ncid,childGroupName)` returns the ID of the child group, specified by the name `childGroupName`, in the file or group specified by `ncid`.

### **Input Arguments**

#### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

#### **childGroupName**

Text string specifying the name of a NetCDF group.

**Default:**

### **Output Arguments**

#### **childGroupID**

Identifier of a NetCDF group.

## Examples

This example opens the sample NetCDF dataset and then gets the ID of a group in the dataset.

```
ncid = netcdf.open('example.nc', 'nowrite');
gid = netcdf.inqNcid(ncid, 'grid1');
netcdf.close(ncid);
```

## netcdf.inqUnlimDims

Return list of unlimited dimensions in group

### Syntax

```
unlimdimIDs = netcdf.inqUnlimDims(ncid)
```

### Description

`unlimdimIDs = netcdf.inqUnlimDims(ncid)` returns the IDs of all unlimited dimensions in the group specified by `ncid`.

### Input Arguments

#### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or group, returned by `netcdf.defGrp`.

**Default:**

### Output Arguments

#### **unlimDimIDs**

An array containing the identifiers of each unlimited dimension. `unlimDimIDs` is empty if there are no unlimited dimensions.

### Examples

This example opens the NetCDF sample dataset and gets the IDs of all the unlimited dimensions.

```
ncid = netcdf.open('example.nc','NOWRITE');
dimids = netcdf.inqUnlimDims(ncid)

dimids =

 []

netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_unlim_dims` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

`netcdf.renameDim` | `netcdf.inqDimIDs`

## **netcdf.inqVarIDs**

IDs of all variables in group

### **Syntax**

```
varids = netcdf.inqVarIDs(ncid)
```

### **Description**

`varids = netcdf.inqVarIDs(ncid)` returns IDs of the all the variables in the group specified by `ncid`.

### **Input Arguments**

#### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

### **Output Arguments**

#### **varids**

Array containing identifiers of variables in a NetCDF file or group.

### **Examples**

This example opens the NetCDF sample file and gets the IDs of all the variables in a group.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
```

```
gid = netcdf.inqNcid(ncid,'grid1');
varids = netcdf.inqVarIDs(gid);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_varids` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

## netcdf.inqVarChunking

Determine chunking settings for NetCDF variable

### Syntax

```
[storage,chunkSizes] = netcdf.inqVarChunking(ncid,varid)
```

### Description

`[storage,chunkSizes] = netcdf.inqVarChunking(ncid,varid)` returns the type of chunking and the dimensions of a chunk for the NetCDF variable specified by `varid`, in the file or group specified by `ncid`.

### Input Arguments

#### **ncid**

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

#### **varid**

Identifier of NetCDF variable, returned by `netcdf.defVar`.

**Default:**

### Output Arguments

#### **storage**

Text string specifying if NetCDF breaks the data into chunks when writing to a file. `CHUNKED` indicates the data is chunked; `CONTIGUOUS` indicates that the data is not chunked.

## chunkSizes

Array specifying the dimensions of the chunk.

Because MATLAB uses FORTRAN-style ordering, the order of dimensions in `chunkdims` is reversed relative to what would be in the NetCDF C API.

If the storage type specified is `CONTIGUOUS`, `netcdf.inqVarChunking` returns an empty array, `[]`.

## Examples

This example opens the NetCDF sample dataset and gets the values of chunking parameters associated with a variable.

```
ncid = netcdf.open('example.nc','NOWRITE');
groupid = netcdf.inqNcid(ncid,'grid1');
varid = netcdf.inqVarID(groupid,'temp');
[storage,chunkSize] = netcdf.inqVarChunking(groupid,varid);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_var_chunking` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.defVar` | `netcdf.defVarChunking`

## netcdf.inqVarDeflate

Determine compression settings for NetCDF variable

### Syntax

```
[shuffle,deflate,deflateLevel] = netcdf.inqVarDeflate(ncid,varid)
```

### Description

```
[shuffle,deflate,deflateLevel] = netcdf.inqVarDeflate(ncid,varid)
```

returns the compression parameters for the NetCDF variable specified by `varid` in the location specified by `ncid`.

### Input Arguments

#### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Default:**

#### **varid**

Identifier of NetCDF variable, returned by `netcdf.defVar`.

**Default:**

### Output Arguments

#### **shuffle**

Boolean value. `true` indicates that the shuffle filter is enabled for the specified variable. The shuffle filter can assist with the compression of integer data by changing the byte order in the data stream.

**deflate**

Boolean value. `true` indicates that compression is enabled for this variable. The `deflateLevel` argument specifies the level of compression.

**deflateLevel**

Scalar value between 0 and 9 specifying the amount of compression, where 0 is no compression and 9 is the most compression

## Examples

This example opens the NetCDF sample file and gets information about variable compression.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
groupid = netcdf.inqNcid(ncid, 'grid1');
varid = netcdf.inqVarID(groupid, 'temp');
[shuffle, deflate, deflateLevel] = netcdf.inqVarDeflate(groupid, varid);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_var_deflate` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

## netcdf.inqVarFill

Determine values of fill parameters for NetCDF variable

### Syntax

```
[noFillMode,fillValue] = netcdf.inqVarFill(ncid,varid)
```

### Description

[noFillMode,fillValue] = netcdf.inqVarFill(ncid,varid) returns the fill mode and the fill value for the variable varid in the file or group specified by ncid.

### Input Arguments

#### ncid

Identifier of a NetCDF file, returned by netcdf.create or netcdf.open, or a NetCDF group, returned by netcdf.defGrp.

**Default:**

#### varid

Identifier of NetCDF variable.

**Default:**

### Output Arguments

#### noFillMode

Boolean value. true indicates that use of the fill values for the variable has been disabled.

**fillValue**

Specifies the value to use in the variable when no other value is specified and use of fill values has been enabled.

## Examples

This example opens the NetCDF sample dataset and gets the fill mode and fill value used with a variable.

```
ncid = netcdf.open('example.nc','NOWRITE');
varid = netcdf.inqVarID(ncid,'temperature');
[noFillMode,fillValue] = netcdf.inqVarFill(ncid,varid);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_var_fill` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.defVarFill` | `netcdf.setFill`

## netcdf.inqVarFletcher32

Fletcher32 checksum setting for NetCDF variable

### Syntax

```
setting = netcdf.inqVarFletcher32(ncid,varid)
```

### Description

`setting = netcdf.inqVarFletcher32(ncid,varid)` returns the Fletcher32 checksum setting for the NetCDF variable specified by `varid` in the file or group specified by `ncid`.

### Input Arguments

#### **ncid**

Identifier for NetCDF file, returned by `netcdf.create` or `netcdf.open`, or group, returned by `netcdf.defGrp`.

#### **Default:**

#### **varid**

Identifier of NetCDF variable.

#### **Default:**

### Output Arguments

#### **setting**

Text string specifying whether the Fletcher32 checksum is turned on for the specified variable. `netcdf.inqVarFletcher32` returns the text string `FLETCHER32` if the checksum is turned on for the variable; otherwise, `NOCHECKSUM`.

## Examples

This example opens the sample NetCDF file and gets information about the checksum setting for a variable.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
varid = netcdf.inqVarID(ncid, 'temperature');
setting = netcdf.inqVarFletcher32(ncid, varid);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_inq_var_fletcher32` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` for more information.

## See Also

`netcdf` | `netcdf.defVarFletcher32`

## netcdf.inqAtt

Return information about netCDF attribute

### Syntax

```
[xtype,attlen] = netcdf.inqAtt(ncid,varid,attname)
```

### Description

`[xtype,attlen] = netcdf.inqAtt(ncid,varid,attname)` returns the data type, `xtype`, and length, `attlen`, of the attribute identified by the text string `attname`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` identifies the variable that the attribute is associated with. To get information about a global attribute, specify `netcdf.getConstant('NC_GLOBAL')` in place of `varid`.

This function corresponds to the `nc_inq_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example opens the example netCDF file included with MATLAB, `example.nc`, and gets information about an attribute in the file.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NOWRITE');

% Get identifier of a variable in the file, given its name.
varid = netcdf.inqVarID(ncid,'avagadros_number');

% Get attribute name, given variable id and attribute number.
attname = netcdf.inqAttName(ncid,varid,0);
```

```
% Get information about the attribute.
[xtype,attlen] = netcdf.inqAtt(ncid,varid,'description')

xtype =

 2

attlen =

 31

% Get name of global attribute
gattname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0);

% Get information about global attribute.
[gxtype gattlen] = netcdf.inqAtt(ncid,netcdf.getConstant('NC_GLOBAL'),gattname)

gxtype =

 2

gattlen =

 11
```

## See Also

netcdf.inqAttID | netcdf.inqAttName

## netcdf.inqAttID

Return ID of netCDF attribute

### Syntax

```
attnum = netcdf.inqAttID(ncid,varid,attname)
```

### Description

`attnum = netcdf.inqAttID(ncid,varid,attname)` retrieves `attnum`, the identifier of the attribute specified by the text string `attname`.

`varid` specifies the variable the attribute is associated with.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_attid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example opens the netCDF example file included with MATLAB, `example.nc`.

```
% Open the netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get the identifier of a variable in the file.
varid = netcdf.inqVarID(ncid,'avagadros_number');

% Retrieve the identifier of the attribute associated with the variable.
attid = netcdf.inqAttID(ncid,varid,'description');
```

### See Also

`netcdf.inqAtt` | `netcdf.inqAttName`

## netcdf.inqAttName

Return name of netCDF attribute

### Syntax

```
attname = netcdf.inqAttName(ncid,varid,attnum)
```

### Description

`attname = netcdf.inqAttName(ncid,varid,attnum)` returns `attname`, a text string specifying the name of an attribute.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` is a numeric identifier of a variable in the file. If you want to get the name of a global attribute in the file, use `netcdf.getConstant('NC_GLOBAL')` in place of `attnum` is a zero-based numeric value specifying the attribute, with 0 indicating the first attribute, 1 the second attribute, and so on.

This function corresponds to the `nc_inq_attname` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get identifier of a variable in the file.
varid = netcdf.inqVarID(ncid,'avagadros_number')

% Get the name of the attribute associated with the variable.
attname = netcdf.inqAttName(ncid,varid,0)
```

```
attname =
```

```
description
```

```
% Get the name of the global attribute associated with the variable.
gattname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0)
```

```
gattname =
```

```
creation_date
```

## **See Also**

`netcdf.inqAtt` | `netcdf.inqAttID`

## netcdf.inqDim

Return netCDF dimension name and length

### Syntax

```
[dimname, dimlen] = netcdf.inqDim(ncid,dimid)
```

### Description

`[dimname, dimlen] = netcdf.inqDim(ncid,dimid)` returns the name, `dimname`, and length, `dimlen`, of the dimension specified by `dimid`. If `ndims` is the number of dimensions defined for a netCDF file, each dimension has an ID between 0 and `ndims - 1`. For example, the dimension identifier of the first dimension is 0, the second dimension is 1, and so on.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_dim` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

The example opens the example netCDF file include with MATLAB, `example.nc`.

```
ncid = netcdf.open('example.nc','NC_NOWRITE');
```

```
% Get name and length of first dimension
[dimname, dimlen] = netcdf.inqDim(ncid,0)
```

```
dimname =
```

```
x
```

```
dimlen =
```

50

**See Also**

netcdf.inqDimID

# netcdf.inqDimID

Return dimension ID

## Syntax

```
dimid = netcdf.inqDimID(ncid,dimname)
```

## Description

`dimid = netcdf.inqDimID(ncid,dimname)` returns `dimid`, the identifier of the dimension specified by the character string `dimname`. You can use the `netcdf.inqDim` function to retrieve the dimension name. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_dimid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get name and length of first dimension
[dimname, dimlen] = netcdf.inqDim(ncid,0);

% Retrieve identifier of dimension.
dimid = netcdf.inqDimID(ncid,dimname)

dimid =

 0
```

## See Also

`netcdf.inqDim`

## **netcdf.inqLibVers**

Return NetCDF library version information

### **Syntax**

```
libvers = netcdf.inqLibVers
```

### **Description**

`libvers = netcdf.inqLibVers` returns a string identifying the version of the NetCDF library.

This function corresponds to the `nc_inq_libvers` function in the NetCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### **Examples**

```
libvers = netcdf.inqLibVers
```

```
libvers =
```

```
4.1.3
```

# netcdf.inqVar

Information about variable

## Syntax

```
[varname,xtype,dimids,natts] = netcdf.inqVar(ncid,varid)
```

## Description

`[varname,xtype,dimids,natts] = netcdf.inqVar(ncid,varid)` returns information about the variable identified by `varid`. The argument, `ncid`, is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

The output argument, `varname`, is the name of the variable. `xtype` is the data type, `dimids` is the dimension IDs, and `natts` is the number of attributes associated with the variable. Dimension IDs are zero-based.

This function corresponds to the `nc_inq_var` function in the netCDF library C API. Because MATLAB uses FORTRAN-style ordering, however, the order of the dimension IDs is reversed relative to what would be obtained from the C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

Open the example netCDF file included with MATLAB, `example.nc`, and get information about a variable in the file.

```
% Open the example netCDF file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get information about third variable in the file.
[varname, xtype, dimids, numatts] = netcdf.inqVar(ncid,2)

varname =
```

peaks

xtype =

dimids =

0 1

numatts =

1 1

## See Also

[netcdf.create](#) | [netcdf.inqVarID](#) | [netcdf.open](#)

# netcdf.inqVarID

Return ID associated with variable name

## Syntax

```
varid = netcdf.inqVarID(ncid,varname)
```

## Description

`varid = netcdf.inqVarID(ncid,varname)` returns `varid`, the ID of a netCDF variable specified by the text string, `varname`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_varid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example opens the example netCDF file included with MATLAB, `example.nc`, and uses several inquiry functions to get the ID of the first variable.

```
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get information about first variable in the file.
[varname, xtype, dimids, atts] = netcdf.inqVar(ncid,0);

% Get variable ID of the first variable, given its name
varid = netcdf.inqVarID(ncid,varname)

varid =

 0
```

## See Also

`netcdf.create` | `netcdf.inqVar` | `netcdf.open`

## netcdf.open

Open NetCDF data source

### Syntax

```
ncid = netcdf.open(source)
ncid = netcdf.open(source,mode)
[chosen_chunksize, ncid] = netcdf.open(source,mode,chunksize)
```

### Description

`ncid = netcdf.open(source)` opens `source`, which can be the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source, for read-only access. Returns a NetCDF ID in `ncid`.

`ncid = netcdf.open(source,mode)` opens `source` with the type of access specified by `mode`, which can have any of the following values.

Value	Description
'WRITE '	Read-write access
'SHARE '	Synchronous file updates
'NOWRITE '	Read-only access (Default)

You can also specify `mode` as a numeric value that can be retrieved using `netcdf.getConstant`. Use these numeric values when you want to specify a bitwise-OR of several modes.

`[chosen_chunksize, ncid] = netcdf.open(source,mode,chunksize)` opens `source`, an existing netCDF data source, specifying the additional I/O performance tuning parameter, `chunksize`. The actual value used by the NetCDF library might not correspond to the input value you specify.

This function corresponds to the `nc_open` and `nc__open` functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example opens the example NetCDF file included with MATLAB, `example.nc`.

```
ncid = netcdf.open('example.nc','NOWRITE');
netcdf.close(ncid);
```

## See Also

`netcdf.close` | `netcdf` | `netcdf.getConstant`

## netcdf.putAtt

Write netCDF attribute

### Syntax

```
netcdf.putAtt(ncid,varid,attrname,attrvalue)
```

### Description

`netcdf.putAtt(ncid,varid,attrname,attrvalue)` writes the attribute named `attrname` with value `attrvalue` to the netCDF variable specified by `varid`. To specify a global attribute, use `netcdf.getConstant('NC_GLOBAL')` for `varid`.

`ncid` is a netCDF file identifier returned by `netCDF.create` or `netCDF.open`.

---

**Note:** You cannot use `netcdf.putAtt` to set the `'_FillValue'` attribute of NetCDF4 files. Use the `netcdf.defVarFill` function to set the fill value for a variable.

---

This function corresponds to several attribute I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example creates a new netCDF file, defines a dimension and a variable, adds data to the variable, and then creates an attribute associated with the variable. To run this example, you must have writer permission in your current directory.

```
% Create a variable in the workspace.
my_vardata = linspace(0,50,50);

% Create a netCDF file.
ncid = netcdf.create('foo.nc','NC_WRITE');
```

```
% Define a dimension in the file.
dimid = netcdf.defDim(ncid,'my_dim',50);

% Define a new variable in the file.
varid = netcdf.defVar(ncid,'my_var','double',dimid);

% Leave define mode and enter data mode to write data.
netcdf.endDef(ncid);

% Write data to variable.
netcdf.putVar(ncid,varid,my_vardata);

% Re-enter define mode.
netcdf.reDef(ncid);

% Create an attribute associated with the variable.
netcdf.putAtt(ncid,0,'my_att',10);

% Verify that the attribute was created.
[xtype xlen] = netcdf.inqAtt(ncid,0,'my_att')

xtype =

 6

xlen =

 1
```

This example creates a new netCDF file, specifies a global attribute, and assigns a value to the attribute.

```
ncid = netcdf.create('myfile.nc','CLOBBER');
varid = netcdf.getConstant('GLOBAL');
netcdf.putAtt(ncid,varid,'creation_date',datestr(now));
netcdf.close(ncid);
```

## See Also

[netcdf.getAtt](#) | [netcdf.defVarFill](#) | [netcdf.getConstant](#)

## netcdf.putVar

Write data to netCDF variable

### Syntax

```
netcdf.putVar(ncid, varid, data)
netcdf.putVar(ncid, varid, start, data)
netcdf.putVar(ncid, varid, start, count, data)
netcdf.putVar(ncid, varid, start, count, stride, data)
```

### Description

`netcdf.putVar(ncid, varid, data)` writes data to a netCDF variable identified by `varid`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`netcdf.putVar(ncid, varid, start, data)` writes a single data value into the variable at the index specified by `start`.

`netcdf.putVar(ncid, varid, start, count, data)` writes a section of values into the netCDF variable at the index specified by the vector `start` to the extent specified by the vector `count`, along each dimension of the specified variable.

`netcdf.putVar(ncid, varid, start, count, stride, data)` writes the subsection specified by sampling interval, `stride`, of the values in the section of the variable beginning at the index `start` and to the extent specified by `count`.

This function corresponds to several variable I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

#### Write Variable to New netCDF File

Create a new netCDF file and write a variable to the file.

Create a 50 element vector for a variable.

```
my_vardata = linspace(0,50,50);
```

Open the netCDF file.

```
ncid = netcdf.create('foo.nc', 'NOCLOBBER');
```

Define the dimensions of the variable.

```
dimid = netcdf.defDim(ncid, 'my_dim', 50);
```

Define a new variable in the file.

```
my_varID = netcdf.defVar(ncid, 'my_var', 'double', dimid);
```

Leave define mode and enter data mode to write data.

```
netcdf.endDef(ncid);
```

Write data to variable.

```
netcdf.putVar(ncid, my_varID, my_vardata);
```

Verify that the variable was created.

```
[varname xtype dimid natts] = netcdf.inqVar(ncid, 0)
```

```
varname =
```

```
my_var
```

```
xtype =
```

```
6
```

```
dimid =
```

```
0
```

```
natts =
```

```
0
```

Close the file.

```
netcdf.close(ncid)
```

## Write Elements of Variable

Write to the first ten elements of the example `temperature` variable.

```
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'example.nc');
copyfile(srcFile, 'myfile.nc');
fileattrib('myfile.nc', '+w');
ncid = netcdf.open('myfile.nc', 'WRITE');
varid = netcdf.inqVarID(ncid, 'temperature');
data = [100:109];
netcdf.putVar(ncid, varid, 0, 10, data);
netcdf.close(ncid);
```

## See Also

`netcdf.getVar`

# netcdf.reDef

Put open netCDF file into define mode

## Syntax

```
netcdf.reDef(ncid)
```

## Description

`netcdf.reDef(ncid)` puts an open netCDF file into define mode so that dimensions, variables, and attributes can be added or renamed. Attributes can also be deleted in define mode. `ncid` is a valid NetCDF file ID, returned from a previous call to `netcdf.open` or `netcdf.create`.

This function corresponds to the `nc_redef` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example opens a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open a netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Try to define a dimension.
dimid = netcdf.defdim(ncid, 'lat', 50); % should fail.
??? Error using ==> netcdflib
NetCDF: Operation not allowed in data mode

Error in ==> defDim at 22
dimid = netcdflib('def_dim', ncid,dimname,dimlen);

% Put file in define mode.
netcdf.reDef(ncid);
```

```
% Try to define a dimension again. Should succeed.
dimid = netcdf.defDim(ncid, 'lat', 50);
```

## **See Also**

# netcdf.renameAtt

Change name of attribute

## Syntax

```
netcdf.renameAtt(ncid,varid,oldName,newName)
```

## Description

`netcdf.renameAtt(ncid,varid,oldName,newName)` changes the name of the attribute specified by the character string `oldName`.

`newName` is a character string that specifies the new name.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` identifies the variable to which the attribute is associated. To specify a global attribute, use `netcdf.getConstant('NC_GLOBAL')` for `varid`.

This function corresponds to the `nc_rename_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Get the ID of a variable the attribute is associated with.
varID = netcdf.inqVarID(ncid,'avagadros_number')

% Rename the attribute.
netcdf.renameAtt(ncid,varID,'description','Description');
```

```
% Verify that the name changed.
attname = netcdf.inqAttName(ncid,varID,0)
```

```
attname =
```

```
Description
```

## **See Also**

```
netcdf.inqAttName
```

# netcdf.renameDim

Change name of netCDF dimension

## Syntax

```
netcdf.renameDim(ncid,dimid,newName)
```

## Description

`netcdf.renameDim(ncid,dimid,newName)` renames the dimension identified by the dimension identifier, `dimid`.

`newName` is a character string specifying the new name. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`

This function corresponds to the `nc_rename_dim` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This examples modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Put file is define mode.
netcdf.reDef(ncid)

% Get the identifier of a dimension to rename.
dimid = netcdf.inqDimID(ncid,'x');

% Rename the dimension.
netcdf.renameDim(ncid,dimid,'Xdim')
```

```
% Verify that the name changed.
data = netcdf.inqDim(ncid,dimid)
```

```
data =
```

```
Xdim
```

## **See Also**

`netcdf.defDim`

## netcdf.renameVar

Change name of netCDF variable

### Syntax

```
netcdf.renameVar(ncid,varid,newName)
```

### Description

`netcdf.renameVar(ncid,varid,newName)` renames the variable identified by `varid` in the netCDF file identified by `ncid`. `newName` is a character string specifying the new name.

This function corresponds to the `nc_rename_var` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Put file in define mode.
netcdf.redef(ncid)

% Get name of first variable
[varname, xtype, varDimIDs, varAtts] = netcdf.inqVar(ncid,0);

varname

varname =

avagadros_number
```

```
% Rename the variable, using a capital letter to start the name.
netcdf.renameVar(ncid,0,'Avagadros_number')
```

```
% Verify that the name of the variable changed.
[varname, xtype, varDimIDs, varAtts] = netcdf.inqVar(ncid,0);
```

```
varname
```

```
varname =
```

```
Avagadros_number
```

## **See Also**

# netcdf.setChunkCache

Set default chunk cache settings for NetCDF library

## Syntax

```
netcdf.setChunkCache(csize,nelems,premp)
```

## Description

`netcdf.setChunkCache(csize,nelems,premp)` sets the default chunk cache settings used by the NetCDF library.

Settings apply for subsequent file open or create operations, for the remainder of the MATLAB session or until you issue a `clear mex` call. This function does not change the chunk cache settings of files already open.

## Input Arguments

### **csize**

Scalar double specifying the total size of the raw data chunk cache in bytes.

**Default:**

### **nelems**

Scalar double specifying the number of chunk slots in the raw data chunk cache hash table.

**Default:**

### **premp**

Scalar double, between 0 and 1, inclusive, that specifies how the library handles preempting fully read chunks in the chunk cache. A value of 0 means fully read chunks are treated no differently than other chunks, that is, preemption occurs solely based

on the Least Recently Used (LRU) algorithm. A value of 1 means fully read chunks are always preempted before other chunks.

**Default:**

## Examples

This example sets the cache chunk size used by the NetCDF library.

```
netcdf.setChunkCache(32000000, 2003, .75)
```

## References

This function corresponds to the `nc_set_chunk_cache` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## See Also

`netcdf` | `netcdf.getChunkCache`

# netcdf.setDefaultFormat

Change default netCDF file format

## Syntax

```
oldFormat = netcdf.setDefaultFormat(newFormat)
```

## Description

`oldFormat = netcdf.setDefaultFormat(newFormat)` changes the default format used by `netCDF.create` when creating new netCDF files, and returns the value of the old format. You can use this function to change the format used by a netCDF file without having to change the creation mode flag used in each call to `netCDF.create`.

`newFormat` can be either of the following values.

Value	Description
'NC_FORMAT_CLASSIC'	Original netCDF file format
'NC_FORMAT_64BIT'	64-bit offset format; relaxes limitations on creating very large files

You can also specify the numeric equivalent of these values, as retrieved by `netcdf.getConstant`.

This function corresponds to the `nc_set_default_format` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

```
oldFormat = netcdf.setDefaultFormat('NC_FORMAT_64BIT');
```

## See Also

`netcdf.create`

## netcdf.setFill

Set netCDF fill mode

### Syntax

```
old_mode = netcdf.setFill(ncid,new_mode)
```

### Description

`old_mode = netcdf.setFill(ncid,new_mode)` sets the fill mode for a netCDF file identified by `ncid`.

`new_mode` can be either 'FILL' or 'NOFILL' or their numeric equivalents, as retrieved by `netcdf.getConstant`. The default mode is 'FILL'. netCDF pre-fills data with fill values. Specifying 'NOFILL' can be used to enhance performance, because it avoids the duplicate writes that occur when the netCDF writes fill values that are later overwritten with data.

This function corresponds to the `nc_set_fill` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

### Examples

This example creates a new file and specifies the fill mode used by netCDF with the file.

```
ncid = netcdf.open('foo.nc','NC_WRITE');

% Set filling behavior
old_mode = netcdf.setFill(ncid,'NC_NOFILL');
```

### See Also

`netcdf.getConstant`

# netcdf.sync

Synchronize netCDF file to disk

## Syntax

```
netcdf.sync(ncid)
```

## Description

`netcdf.sync(ncid)` synchronizes the state of a netCDF file to disk. The netCDF library normally buffers accesses to the underlying netCDF file, unless you specify the `NC_SHARE` mode when you opened the file with `netcdf.open` or `netcdf.create`. To call `netcdf.sync`, the netCDF file must be in data mode.

This function corresponds to the `nc_sync` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example creates a new netCDF file for write access, performs an operation on the file, takes the file out of define mode, and then synchronizes the file to disk.

```
% Create a netCDF file.
ncid = netcdf.create('foo.nc', 'NC_WRITE');

% Perform an operation.
dimid = netcdf.defDim(ncid, 'Xdim', 50);

% Take file out of define mode.
netcdf.endDef(ncid);

% Synchronize the file to disk.
netcdf.sync(ncid)
```

## See Also

`netcdf.close` | `netcdf.create` | `netcdf.open` | `netcdf.endDef`

## newplot

Determine where to draw graphics objects

### Syntax

```
newplot
h = newplot
h = newplot(hsave)
```

### Description

`newplot` prepares a figure and axes for subsequent graphics commands.

`h = newplot` prepares a figure and axes for subsequent graphics commands and returns a handle to the current axes.

`h = newplot(hsave)` prepares and returns an axes, but does not delete any objects whose handles you have assigned to the `hsave` argument, which can be a vector of handles. If `hsave` is not empty, the figure and axes containing `hsave` are prepared for plotting instead of the current axes of the current figure. If `hsave` is empty, `newplot` behaves as if it were called without any inputs.

### More About

#### Tips

To create a simple 2-D plot, use the `plot` function instead.

Use `newplot` at the beginning of high-level graphics code to determine which figure and axes to target for graphics output. Calling `newplot` can change the current figure and current axes. Basically, there are three options when you are drawing graphics in existing figures and axes:

- Add the new graphics without changing any properties or deleting any objects.
- Delete all existing objects whose handles are not hidden before drawing the new objects.

- Delete all existing objects regardless of whether or not their handles are hidden, and reset most properties to their defaults before drawing the new objects (refer to the following table for specific information).

The figure and axes `NextPlot` properties determine how `newplot` behaves. The following two tables describe this behavior with various property values.

First, `newplot` reads the current figure's `NextPlot` property and acts accordingly.

<b>NextPlot</b>	<b>What Happens</b>
<code>new</code>	Create a new figure and use it as the current figure.
<code>add</code>	Draw to the current figure without clearing any graphics objects already present.
<code>replacechildren</code>	Remove all child objects whose <code>HandleVisibility</code> property is set to <code>on</code> and reset figure <code>NextPlot</code> property to <code>add</code> .
<code>replace</code>	<p>This clears the current figure and is equivalent to issuing the <code>clf</code> command.</p> <p>Remove all child objects (regardless of the setting of the <code>HandleVisibility</code> property) and reset figure properties to their defaults, except</p> <p><code>NextPlot</code> is reset to <code>add</code> regardless of user-defined defaults.</p> <ul style="list-style-type: none"> <li>• <code>Position</code>, <code>Units</code>, <code>PaperPosition</code>, and <code>PaperUnits</code> are not reset.</li> </ul> <p>This clears and resets the current figure and is equivalent to issuing the <code>clf reset</code> command.</p>

After `newplot` establishes which figure to draw in, it reads the current axes' `NextPlot` property and acts accordingly.

<b>NextPlot</b>	<b>Description</b>
<code>add</code>	Draw into the current axes, retaining all graphics objects already present.

<b>NextPlot</b>	<b>Description</b>
<code>replacechildren</code>	Remove all child objects whose <code>HandleVisibility</code> property is set to <code>on</code> , but do not reset axes properties. This clears the current axes like the <code>cla</code> command.
<code>replace</code>	Remove all child objects (regardless of the setting of the <code>HandleVisibility</code> property) and reset axes properties to their defaults, except <code>Position</code> and <code>Units</code> .  This clears and resets the current axes like the <code>cla reset</code> command.

**Introduced before R2006a**

# nextDirectory

**Class:** Tiff

Make next IFD current IFD

## Syntax

```
nextDirectory(tiffobj)
```

## Description

`nextDirectory(tiffobj)` makes the next image file directory (IFD) in the file the current IFD. Tiff object methods operate on the current IFD. Use this method to navigate among IFDs in a TIFF file containing multiple images.

## Examples

### Make Next Directory the Current Directory

Open a Tiff object and change the current IFD to the next IFD in the file.

```
t = Tiff('example.tif', 'r');
nextDirectory(t);
close(t);
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## References

This method corresponds to the `TIFFReadDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**See Also**

Tiff.setDirectory

# nextpow2

Exponent of next higher power of 2

## Syntax

`P = nextpow2(A)`

## Description

`P = nextpow2(A)` returns the exponents for the smallest powers of two that satisfy

$$2^p \geq |A|$$

for each element in `A`.

You can use `nextpow2` to pad the signal you pass to `fft`. Doing so can speed up the computation of the FFT when the signal length is not an exact power of 2.

## Examples

### Next Power of 2 of Double Integer Values

Define a vector of `double` integer values and calculate the exponents for the next power of 2 higher than those values.

```
a = [1 -2 3 -4 5 9 519];
p = nextpow2(a)
```

```
p =
```

```
0 1 2 2 3 4 10
```

Calculate the positive next powers of 2.

```
np2 = 2.^p
```

```
np2 =
 1 2 4 4 8 16 1024
```

Preserve the sign of the original input values.

```
np2.*sign(a)
ans =
 1 -2 4 -4 8 16 1024
```

## Next Power of 2 of Unsigned Integer Values

Define a vector of unsigned integers and calculate the exponents for the next power of 2 higher than those values.

```
a = uint32([1020 4000 32700]);
p = nextpow2(a)
```

```
p =
 10 12 15
```

Calculate the next powers of 2 higher than the values in **a**.

```
2.^p
ans =
 1024 4096 32768
```

## Optimize FFT with Padding

Use `nextpow2` to increase the performance of `fft` when the length of your signal is not a power of 2.

Create a 1-D vector containing 8191 sample values.

```
x = gallery('uniformdata',[1,8191],0);
```

Calculate the next power of 2 higher than 8191.

```
p = nextpow2(8191);
n = 2^p
```

```
n =
 8192
```

Pass the signal and the next power of 2 to the `fft` function.

```
y = fft(x,n);
```

## Input Arguments

### A — Input values

scalar, vector, or array of real numbers

Input values, specified as a scalar, vector, or array of real numbers of any numeric type.

Example: 15

Example: [-15.123 32.456 63.111]

Example: int16([-15 32 63])

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 |  
uint32 | uint64

## See Also

fft | log2 | pow2

**Introduced before R2006a**

## **nnz**

Number of nonzero matrix elements

### **Syntax**

```
n = nnz(X)
```

### **Description**

`n = nnz(X)` returns the number of nonzero elements in matrix `X`.

The density of a sparse matrix is `nnz(X)/prod(size(X))`.

### **Examples**

The matrix

```
w = sparse(wilkinson(21));
```

is a tridiagonal matrix with 20 nonzeros on each of three diagonals, so `nnz(w) = 60`.

### **See Also**

`find` | `isa` | `nonzeros` | `nzmax` | `size` | `whos`

**Introduced before R2006a**

## noanimate

Change EraseMode of all objects to normal

---

**Note:** noanimate has been removed.

---

### Syntax

```
noanimate(state,fig_handle)
noanimate(state)
```

### Description

`noanimate(state,fig_handle)` sets the `EraseMode` of all image, line, patch, surface, and text graphics objects in the specified figure to `normal`. `state` can be the following strings:

- 'save' — Set the values of the `EraseMode` properties to `normal` for all the appropriate objects in the designated figure.
- 'restore' — Restore the `EraseMode` properties to the previous values (i.e., the values before calling `noanimate` with the 'save' argument).

`noanimate(state)` operates on the current figure.

`noanimate` is useful if you want to print the figure to a TIFF or JPEG format.

### See Also

`print`

**Introduced before R2006a**

## **nonzeros**

Nonzero matrix elements

### **Syntax**

```
s = nonzeros(A)
```

### **Description**

`s = nonzeros(A)` returns a full column vector of the nonzero elements in `A`, ordered by columns.

This gives the `s`, but not the `i` and `j`, from `[i,j,s] = find(A)`. Generally,

```
length(s) = nnz(A) <= nzmax(A) <= prod(size(A))
```

### **See Also**

`find` | `isa` | `nnz` | `nzmax` | `size` | `whos`

**Introduced before R2006a**

# norm

Vector and matrix norms

## Syntax

```
n = norm(v)
n = norm(v,p)

n = norm(X)
n = norm(X,p)
n = norm(X,'fro')
```

## Description

`n = norm(v)` returns the 2-norm or Euclidean norm of vector  $v$ .

`n = norm(v,p)` returns the vector norm defined by  $\sum(\text{abs}(v)^p)^{(1/p)}$ , where  $p$  is any positive real value, `Inf`, or `-Inf`.

- If  $p$  is `Inf`, then  $n = \max(\text{abs}(v))$ .
- If  $p$  is `-Inf`, then  $n = \min(\text{abs}(v))$ .

`n = norm(X)` returns the 2-norm or maximum singular value of matrix  $X$ .

`n = norm(X,p)` returns the  $p$ -norm of matrix  $X$ , where  $p$  is 1, 2, or `Inf`.

`n = norm(X,'fro')` returns the Frobenius norm,  $\sqrt{\text{sum}(\text{diag}(X'*X))}$ .

## Examples

### 1- and 2- Norm of Vector

Calculate the 2-norm of a vector corresponding to the point (-2,3,-1) in 3-D space. The 2-norm is equal to the Euclidean length of the vector.

```
X = [-2 3 -1];
n = norm(X)
```

```
n =
```

```
3.7417
```

Calculate the 1-norm of the vector, which is the sum of the element magnitudes.

```
n = norm(X,1)
```

```
n =
```

```
6
```

## 2-Norm of Matrix

Calculate the 2-norm of a matrix, which is the largest singular value.

```
X = [2 0 1; -1 1 0; -3 3 0];
```

```
n = norm(X)
```

```
n =
```

```
4.7234
```

## Frobenius Norm of Sparse Matrix

Use 'fro' to calculate the Frobenius norm of a sparse matrix, which calculates the 2-norm of the column vector,  $S(:)$ .

```
S = sparse(1:25,1:25,1);
```

```
n = norm(S, 'fro')
```

```
n =
```

```
5
```

## Input Arguments

### **v** — Input vector

vector

Input vector.

Data Types: `single` | `double`

Complex Number Support: Yes

**X — Input matrix**

matrix

Input matrix. Use `norm(X, 'fro')` when X is sparse.

Data Types: `single` | `double`

Complex Number Support: Yes

**p — Norm type**

2 (default) | positive integer scalar | `Inf` | `-Inf`

Norm type, specified as 2 (default), a different positive integer scalar, `Inf`, or `-Inf`. The valid values of `p` and what they return depend on whether the first input to `norm` is a matrix or vector, as shown in the table.

---

**Note:** This table does not reflect the actual algorithms used in calculations.

---

<b>p</b>	<b>Matrix</b>	<b>Vector</b>
1	<code>max(sum(abs(X)))</code>	<code>sum(abs(X))</code>
2	<code>max(svd(X))</code>	<code>sum(abs(X).^2)^(1/2)</code>
Positive, real-valued numeric p	—	<code>sum(abs(X).^p)^(1/p)</code>
<code>Inf</code>	<code>max(sum(abs(X')))</code>	<code>max(abs(X))</code>
<code>-Inf</code>	—	<code>min(abs(X))</code>

## Output Arguments

**n — Matrix or vector norm**

scalar

Matrix or vector norm, returned as a scalar. The norm gives a measure of the magnitude of the elements. By convention, `norm` returns NaN if the input contains NaN values.

## See Also

`cond` | `condest` | `hypot` | `normest` | `rcond`

# normest

2-norm estimate

## Syntax

```
nrm = normest(S)
nrm = normest(S,tol)
[nrm,count] = normest(...)
```

## Description

This function is intended primarily for sparse matrices, although it works correctly and may be useful for large, full matrices as well.

`nrm = normest(S)` returns an estimate of the 2-norm of the matrix `S`.

`nrm = normest(S,tol)` uses relative error `tol` instead of the default tolerance `1.e-6`. The value of `tol` determines when the estimate is considered acceptable.

`[nrm,count] = normest(...)` returns an estimate of the 2-norm and also gives the number of power iterations used.

## More About

### Algorithms

The power iteration involves repeated multiplication by the matrix `S` and its transpose, `S'`. The iteration is carried out until two successive estimates agree to within the specified relative tolerance.

### See Also

`cond` | `condest` | `norm` | `rcond` | `svd`

Introduced before R2006a

## not, ~

Find logical NOT

### Syntax

~A  
not(A)

### Description

~A performs a logical NOT of input array A, and returns an array containing elements set to either logical 1 (**true**) or logical 0 (**false**). An element of the output array is set to 1 if the input array contains a zero value element at that same array location. Otherwise, that element is set to 0.

The input of the expression can be an array or can be a scalar value. If the input is an array, then the output is an array of the same dimensions. If the input is scalar, then the output is scalar.

not(A) is called for the syntax ~A when A is an object.

### Examples

If matrix A is

0	29	0	36	0
23	34	35	0	39
0	24	31	27	0
0	29	0	0	34

then

~A  
ans =

1	0	1	0	1
0	0	0	1	0

1	0	0	0	1
1	0	1	1	0

## notebook

Open MATLAB Notebook in Microsoft Word software (on Microsoft Windows platforms)

### Syntax

```
notebook
notebook('filename')
notebook('-setup')
```

### Description

`notebook` starts Microsoft Word software and creates a new MATLAB Notebook titled Document 1.

`notebook('filename')` starts Microsoft Word and opens the notebook `filename`, where `filename` is either in the MATLAB current folder or is a full path. If `filename` does not exist, MATLAB creates a new notebook titled `filename`. If the file name extension is not specified, MATLAB assumes `.doc`.

`notebook('-setup')` runs an interactive setup function for MATLAB Notebook. It copies the notebook template, `m-book.dot`, to the Microsoft Word template folder, whose location MATLAB automatically determines from the Windows system registry. Upon completion, MATLAB displays a message indicating whether or not the setup was successful.

### More About

- “Create a MATLAB Notebook with Microsoft Word”
- “Publishing MATLAB Code”

**Introduced before R2006a**

## now

Current date and time as serial date number

## Syntax

```
t = now
```

## Description

`t = now` returns the current date and time as a serial date number. A serial date number represents the whole and fractional number of days from a fixed, preset date (January 0, 0000).

`floor(now)` returns the current date as a serial date number, and `rem(now, 1)` returns the current time as a serial date number. `datestr(now)` returns the current date and time as a string.

## Examples

```
t1 = now, t2 = rem(now, 1)
```

```
t1 =
```

```
7.2908e+05
```

```
t2 =
```

```
0.4013
```

## More About

### Tips

- To return a datetime scalar representing the current date and time, type:

```
t = datetime('now')
```

### **See Also**

clock | date | datenum | datestr | datetime

**Introduced before R2006a**

# nthroot

Real nth root of real numbers

## Syntax

`Y = nthroot(X,N)`

## Description

`Y = nthroot(X,N)` returns the real nth root of the elements of X. Both X and N must be real scalars or arrays of the same size. If an element in X is negative, then the corresponding element in N must be an odd integer.

## Examples

### Calculate Real Root of Negative Number

Find the real cube root of -27.

```
nthroot(-27, 3)
```

```
ans =
```

```
 -3
```

For comparison, also calculate  $(-27)^{(1/3)}$ .

```
(-27)^(1/3)
```

```
ans =
```

```
 1.5000 + 2.5981i
```

The result is the complex cube root of -27.

### Calculate Several Real Roots of Scalar

Create a vector of roots to calculate, N.

$N = [5 \ 3 \ -1];$

Use `nthroot` to calculate several real roots of  $-8$ .

$Y = \text{nthroot}(-8,N)$

$Y =$

$-1.5157 \quad -2.0000 \quad -0.1250$

The result is a vector of the same size as  $N$ .

## Elementwise Roots of Matrix

Create a matrix of bases,  $X$ , and a matrix of  $n$ th roots,  $N$ .

$X = [-2 \ -2 \ -2; \ 4 \ -3 \ -5]$

$N = [1 \ -1 \ 3; \ 1/2 \ 5 \ 3]$

$X =$

$-2 \quad -2 \quad -2$   
 $4 \quad -3 \quad -5$

$N =$

$1.0000 \quad -1.0000 \quad 3.0000$   
 $0.5000 \quad 5.0000 \quad 3.0000$

Each element in  $X$  corresponds to an element in  $N$ .

Calculate the real  $n$ th roots of the elements in  $X$ .

$Y = \text{nthroot}(X,N)$

$Y =$

$-2.0000 \quad -0.5000 \quad -1.2599$   
 $16.0000 \quad -1.2457 \quad -1.7100$

Except for the signs (which are treated separately), the result is comparable to  $\text{abs}(X) . ^ ( 1 . / N )$ . By contrast, you can calculate the complex roots using  $X . ^ ( 1 . / N )$ .

## Input Arguments

### **X — Input array**

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. X can be either a scalar or an array of the same size as N. The elements of X must be real.

Data Types: single | double

### **N — Roots to calculate**

scalar | array of same size as X

Roots to calculate, specified as a scalar or array of the same size as X. The elements of N must be real. If an element in X is negative, the corresponding element in N must be an odd integer.

Data Types: single | double

## More About

### Tips

- While `power` is a more efficient function for computing the roots of numbers, in cases where both real and complex roots exist, `power` returns only the complex roots. In these cases, use `nthroot` to obtain the real roots.

### See Also

`power` | `sqrt`

Introduced before R2006a

# null

Null space

## Syntax

```
Z = null(A)
Z = null(A, 'r')
```

## Description

`Z = null(A)` is an orthonormal basis for the null space of `A` obtained from the singular value decomposition. That is, `A*Z` has negligible elements, `size(Z,2)` is the nullity of `A`, and `Z'*Z = I`.

`Z = null(A, 'r')` is a “rational” basis for the null space obtained from the reduced row echelon form. `A*Z` is zero, `size(Z,2)` is an estimate for the nullity of `A`, and, if `A` is a small matrix with integer elements, the elements of the reduced row echelon form (as computed using `rref`) are ratios of small integers.

The orthonormal basis is preferable numerically, while the rational basis may be preferable pedagogically.

## Examples

### Example 1

Compute the orthonormal basis for the null space of a matrix `A`.

```
A = [1 2 3
 1 2 3
 1 2 3];
```

```
Z = null(A);
A*Z
```

```
ans =
```

```

1.0e-015 *
 0.2220 0.2220
 0.2220 0.2220
 0.2220 0.2220

```

Z' \* Z

```

ans =
 1.0000 -0.0000
 -0.0000 1.0000

```

## Example 2

Compute the 1-norm of the matrix  $A*Z$  and determine that it is within a small tolerance.

```

norm(A*Z,1) < 1e-12
ans =
 1

```

## Example 3

Compute the rational basis for the null space of the same matrix A.

```
ZR = null(A, 'r')
```

```

ZR =
 -2 -3
 1 0
 0 1

```

A\*ZR

```

ans =
 0 0
 0 0
 0 0

```

## See Also

## numArgumentsFromSubscript

Number of arguments for customized indexing methods

### Syntax

```
n = numArgumentsFromSubscript(obj,s,callingContext)
```

### Description

`n = numArgumentsFromSubscript(obj,s,callingContext)` returns the number of expected inputs to `subsasgn` or the number of expected outputs from `subsref`.

Overload `numArgumentsFromSubscript` to describe the number of values to return from indexing expressions that return or assign to a comma-separated list. That is, indexing expression that end in `'{}'` or `'.'` indexing. The `numArgumentsFromSubscript` can:

- Access the indexing operations and indices used in the indexing expression.
- Determine if an indexing operation is made in the context of a reference statement, an expression passed to a function, or an assignment.

If a class overloads `numArgumentsFromSubscript`, MATLAB calls it to determine the number of array elements involved in an indexing operation when the number of elements is greater than one. For example, these `'.'` indexing operations generate a call to `numArgumentsFromSubscript`:

- `objArray.a` — Number of elements referenced in a statement (Statement)
- `func(objArray.a)` — Number of elements returned in an expression (Expression)
- `[objArray.a] = rhs` — Number of values assigned with a comma-separated list (Assignment)

MATLAB uses the calling context to determine when to apply the value returned by `numArgumentsFromSubscript`. Your implementation of `numArgumentsFromSubscript` can provide different outputs for the three types of indexing statements. For example, this overload of `numArgumentsFromSubscript`:

- Changes the expected number of output arguments from `subsref` for indexing expressions that are passed to functions.
- Uses the indexing substructure `s` to determine the number of arguments required by the indexing operation

```
function n = numArgumentsFromSubscript(obj,s,callingContext)
 if callingContext == matlab.mixin.util.IndexingContext.Expression
 n = 1;
 else
 n = length(s(1).subs{:});
 end
end
```

Implement the `subsref` method with a `varargout` output to enable MATLAB to call this method with the specified number of output arguments.

```
function varargout = subsref(obj,s)
 ...
end
```

## Examples

### Indexing with Character Array Keywords

Use words as indices for object properties.

By default, MATLAB treats each character in a character array as a separate element. Therefore, MATLAB interprets a character array index as multiple index values.

Without overloading `numArgumentsFromSubscript`, keyword indexing statements request too many arguments for `subsref` and `subsasgn` methods. To implement indexing that uses character arrays as a single keyword, define a `numArgumentsFromSubscript` method to return 1 as the number of elements referenced or assigned.

Overload `numArgumentsFromSubscript` to support the following kinds of indexed reference and assignment.

Index reference with character array:

```
obj{'keyword'}
```

Index reference in function argument:

```
func(obj{'keyword'})
```

Assign comma-separated list to object array:

```
[obj{'keyword'}] = right-side values;
```

In these cases, `subsref` and `subsasgn` cannot determine the number of required output and input arguments, respectively, from the calling context. Provide this information using the `numArgumentsFromSubscript` function.

Define the `KeyIndex` class with two properties. `KeyCell` stores key names. `DataArray` stores corresponding data. To customize indexing:

- Implement a `subsref` method that returns the data values that correspond to the specified keyword.
- Implement a `subsasgn` method that assigns the specified values to the corresponding element in `DataArray` properties.
- Overload `numArgumentsFromSubscript` to return a value of 1 or scalar objects and a value of `numel(objArray)` for object arrays.

Specify a cell array containing the names of months for the `KeyCell` property. Specify a numeric array of the snow fall for the corresponding months in the `DataArray` property.

```
snow15 = KeyIndex({'Jan', 'Feb', 'March'}, [36 42 2])
```

```
snow15 =
```

```
KeyIndex with properties:
```

```
KeyCell: {'Jan' 'Feb' 'March'}
DataArray: [36 42 2]
```

Reference the snow amount for a particular month using the keyword:

```
snow15{'Feb'}
```

```
ans =
```

```
42
```

Assign to the corresponding element using `'{}'` indexing with the keyword:

```
snow15{'Feb'} = 52;
```

The value corresponding to the key `'Feb'` changes:

```
snow15{'Feb'}
```

```
ans =
```

```
52
```

Create an array with the snow fall for 2 years:

```
snow14 = KeyIndex({'Jan', 'Feb', 'March'}, [12 8 2]);
sTotal = [snow14, snow15];
```

Show the snow fall for both years for February:

```
sTotal{'Feb'}
```

```
ans =
```

```
8
```

```
ans =
```

```
52
```

Update the values of snow fall for both years for the month of February. Indexing into a cell array returns a comma-separated list:

```
c{1} = 34;
c{2} = 56;
[sTotal{'Feb'}] = c{:};
```

Here is the `KeyIndex` class. This class shows a particular programming technique. It does not include error checking and other features that your class can require.

```
classdef KeyIndex
 properties
 KeyCell
 DataArray
 end
 methods
 function obj = KeyIndex(key, data)
 if nargin > 0
 obj.KeyCell = key;
 obj.DataArray = data;
 end
 end
 end
end
```

```
function n = numArgumentsFromSubscript(obj,~,~)
 n = numel(obj);
end
function varargout = subsref(obj,s)
 a = numel(obj);
 switch s(1).type
 case '{}'
 varargout = cell(1,a);
 for j = 1:a
 for k = 1:numel(obj(j).KeyCell)
 if strcmp(s.subs(:),obj(j).KeyCell{k})
 varargout{j} = obj(j).DataArray(k);
 end
 end
 end
 case '.'
 varargout = {builtin('subsref',obj,s)};
 case '()'
 varargout = {builtin('subsref',obj,s)};
 end
end
function obj = subsasgn(obj,s,varargin)
 a = numel(varargin);
 switch s(1).type
 case '{}'
 for j = 1:a
 for k = 1:numel(obj(j).KeyCell)
 if strcmp(s.subs(:),obj(j).KeyCell{k})
 obj(j).DataArray(k) = varargin{j};
 end
 end
 end
 case '.'
 obj = builtin('subsasgn',obj,s,varargin{:});
 case '()'
 obj = builtin('subsasgn',obj,s,varargin{:});
 end
end
end
end
end
```

### Reference Property Value Once Per Array

Define a class that supports per-element and per-array indexing for properties.

The `numArgumentsFromSubscript` function enables classes to customize references to specific properties. The indexing substructure argument (`s`) to `numArgumentsFromSubscript` contains the name of the property referenced in a dot indexing expression (that is, a reference of the form `obj.PropertyName`). Using the indexing substructure, `numArgumentsFromSubscript` can return a unique value for any given property.

The `PerArray` class uses the information in the indexing substructure to specify the number of outputs for each property reference.

Overload `numArgumentsFromSubscript` to return:

- A comma-separated list of values for the `ByElement` property, one value per array element
- A single value for the `ByArray` property for the entire array

Create an array of `PerArray` objects:

```
for k = 1:4
 pa(k) = PerArray(rand(k));
end
```

Query the `ByElement` property to return a comma-separated list of property values:

```
pa.ByElement
```

```
ans =
```

```
 0.7513
```

```
ans =
```

```
 0.2551 0.6991
 0.5060 0.8909
```

```
ans =
```

```
 0.9593 0.1493 0.2543
 0.5472 0.2575 0.8143
 0.1386 0.8407 0.2435
```

```
ans =

 0.9293 0.6160 0.5853 0.7572
 0.3500 0.4733 0.5497 0.7537
 0.1966 0.3517 0.9172 0.3804
 0.2511 0.8308 0.2858 0.5678
```

Query the `ByArray` property to return a single value for the array:

```
pa.ByArray

ans =

 3.1416
```

Here is the `PerArray` class. This class shows a particular programming technique. It does not include error checking and other features that your class can require.

```
classdef PerArray
 properties
 ByElement
 end
 properties (Constant)
 ByArray = pi;
 end
 methods
 function obj = PerArray(be)
 if nargin > 0
 obj.ByElement = be;
 end
 end
 function n = numArgumentsFromSubscript(obj,s,ctext)
 import matlab.mixin.util.IndexingContext
 if ~(ctext == IndexingContext.Assignment)
 if length(s) < 2
 switch (s.subs(:)')
 case 'ByElement'
 n = numel(obj);
 case 'ByArray'
 if strcmp(s(1).type, '.')
 n = 1;
 end
 end
 end
 elseif length(s) > 1
```

```

 n = length([s(1).subs{:}]);
 end
end
end
function varargout = subsref(obj,s)

 switch s(1).type
 case '.'
 varargout = cell(1,numel(obj));
 for k = 1:numel(obj)
 varargout{k} = obj(k).(s.subs{:});
 end
 case '()'
 if length([s(1).subs{:}]) > 1
 ind = [s(1).subs{:}];
 numInd = length(ind);
 varargout = cell(1,numInd);
 for k = 1:numInd
 varargout{k} = obj(ind(k)).(s(2).subs{:});
 end
 else
 varargout = {builtin('subsref',obj,s)};
 end
 end
end
end
end
end
end

```

## Input Arguments

### **obj** — Object of overloading class

object

Object of overloading class used in the indexing operation. The class of this object determines which `subsref` or `subsasgn` method MATLAB calls as a result of an indexing operation.

### **s** — Indexing structure

struct

Indexing structure or array of indexing structures containing information about the specific indexing expression. Each structure has two fields:

- **type** — Indexing expression can be '()', '{}', '.'
- **subs** — Subscript values (property name or cell array of index numbers)

Data Types: `struct`

## **callingContext** — Context in which result applies

`matlab.mixin.util.IndexingContext`

Context in which result applies, specified as one of these enumerations:

- `matlab.mixin.util.IndexingContext.Statement` — Indexed reference used as a statement (`obj.a`)
- `matlab.mixin.util.IndexingContext.Expression` — Indexed reference used as an argument to a function (`func(obj.a)`)
- `matlab.mixin.util.IndexingContext.Assignment` — Indexed assignment (`[obj.a] = x`).

## Output Arguments

### **n** — Number of arguments

scalar integer

Number of arguments returned by overloaded `subsref` or passed to overloaded `subsasgn`. Overload `numArgumentsFromSubscript` to return the values required by your class for various indexing scenarios.

## More About

### Tips

- Overload `numArgumentsFromSubscript` instead of `numel` to control the results from overloaded `subsref` and `subsasgn`.
- “Number of Arguments for `subsref` and `subsasgn`”
- “Modify `nargout` and `nargin` for Indexing Methods”

### See Also

`subsasgn` | `subsref`

**Introduced in R2015b**

## num2cell

Convert array to cell array with consistently sized cells

### Syntax

```
C = num2cell(A)
C = num2cell(A,dim)
```

### Description

`C = num2cell(A)` converts array `A` into cell array `C` by placing each element of `A` into a separate cell in `C`. Array `A` need not be numeric.

`C = num2cell(A,dim)` splits the contents of `A` into separate cells of `C`, where `dim` specifies which dimensions of `A` to include in each cell. `dim` can be a scalar or a vector of dimensions. For example, if `A` has 2 rows and 3 columns, then:

- `num2cell(A,1)` creates a 1-by-3 cell array `C`, where each cell contains a 2-by-1 column of `A`.
- `num2cell(A,2)` creates a 2-by-1 cell array `C`, where each cell contains a 1-by-3 row of `A`.
- `num2cell(A,[1 2])` creates a 1-by-1 cell array `C`, where the cell contains the entire array `A`.

### Examples

#### Convert Arrays to Cell Array

Place all elements of a numeric array into separate cells.

```
a = magic(3)
c = num2cell(a)
```

```
a =
```

```

8 1 6
3 5 7
4 9 2

```

```
c =
```

```

[8] [1] [6]
[3] [5] [7]
[4] [9] [2]

```

Place individual letters of a word into separate cells of an array.

```

a = ['four'; 'five'; 'nine']
c = num2cell(a)

```

```
a =
```

```

four
five
nine

```

```
c =
```

```

'f' 'o' 'u' 'r'
'f' 'i' 'v' 'e'
'n' 'i' 'n' 'e'

```

### Create Cell Array of Numeric Arrays

Generate a 4-by-3-by-2 numeric array, and then create a 1-by-3-by-2 cell array of 4-by-1 column vectors.

```

A = reshape(1:12,4,3);
A(:,:,2) = A*10
C = num2cell(A,1)

```

```
A(:,:,1) =
```

```
1 5 9
2 6 10
3 7 11
4 8 12
```

```
A(:, :, 2) =
```

```
10 50 90
20 60 100
30 70 110
40 80 120
```

```
C(:, :, 1) =
```

```
[4x1 double] [4x1 double] [4x1 double]
```

```
C(:, :, 2) =
```

```
[4x1 double] [4x1 double] [4x1 double]
```

Each 4-by-1 vector contains elements from along the *first* dimension of A:

```
C{1}
```

```
ans =
```

```
1
2
3
4
```

Create a 4-by-1-by-2 cell array of 1-by-3 numeric arrays.

```
C = num2cell(A, 2)
```

```
C(:, :, 1) =
```

```
[1x3 double]
```

```
[1x3 double]
[1x3 double]
[1x3 double]
```

```
C(:, :, 2) =
```

```
[1x3 double]
[1x3 double]
[1x3 double]
[1x3 double]
```

Each 1-by-3 row vector contains elements from along the *second* dimension of A:

```
C{1}
```

```
ans =
```

```
1 5 9
```

Finally, create a 4-by-3 cell array of 1-by-1-by-2 numeric arrays.

```
C = num2cell(A, 3)
```

```
C =
```

```
[1x1x2 double] [1x1x2 double] [1x1x2 double]
[1x1x2 double] [1x1x2 double] [1x1x2 double]
[1x1x2 double] [1x1x2 double] [1x1x2 double]
[1x1x2 double] [1x1x2 double] [1x1x2 double]
```

Each 1-by-1-by-2 vector contains elements from along the *third* dimension of A:

```
C{1}
```

```
ans(:, :, 1) =
```

```
1
```

```
ans(:,:,2) =
```

```
10
```

## Combine Across Multiple Dimensions

Create a cell array by combining elements into numeric arrays along several dimensions.

```
A = reshape(1:12,4,3);
A(:,:,2) = A*10
c = num2cell(A,[1 3])
```

```
A(:,:,1) =
```

```
1 5 9
2 6 10
3 7 11
4 8 12
```

```
A(:,:,2) =
```

```
10 50 90
20 60 100
30 70 110
40 80 120
```

```
c =
```

```
[4x1x2 double] [4x1x2 double] [4x1x2 double]
```

Each 4-by-1-by-2 array contains elements from along the first and third dimension of A:

```
c{1}
```

```
ans(:,:,1) =
```

```
1
2
```

```
 3
 4

ans(:,:,2) =

 10
 20
 30
 40

c = num2cell(A,[2 3])

c =

 [1x3x2 double]
 [1x3x2 double]
 [1x3x2 double]
 [1x3x2 double]
```

## Input Arguments

### **A** — Input

any type of multidimensional array

Input, specified as any type of multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `cell` | `function_handle`

### **dim** — Dimension of A

positive integer | positive vector of integers

Dimension of **A**, specified as a positive integer or a vector of positive integers. **dim** must be between 1 and `ndims(A)`.

Elements need not be in numeric order. However, `num2cell` permutes the dimensions of the arrays in each cell of **C** to match the order of the specified dimensions.

Data Types: `double`

## Output Arguments

### C — Resulting array

cell array

Resulting array, returned as a cell array. The size of **C** depends on the size of **A** and the values of **dim**.

- If **dim** is not specified, then **C** is the same size as **A**.
- If **dim** is a scalar, then **C** contains  $\text{numel}(\mathbf{A}) / \text{size}(\mathbf{A}, \text{dim})$  cells. If **dim** is 1 or 2, then each cell contains a column or row vector, respectively. If **dim** > 2, then each cell contains an array whose **dim**th dimensional length is  $\text{size}(\mathbf{A}, \text{dim})$ , and whose other dimensions are all singletons.

For example, given a 4-by-7-by-3 array, **A**, this figure shows how `num2cell` creates cells corresponding to **dim** values of 1, 2, and 3.

- If **dim** is a vector containing **N** values, then **C** has  $\text{numel}(\mathbf{A}) / \text{prod}([\text{size}(\mathbf{A}, \text{dim}(1)), \dots, \text{size}(\mathbf{A}, \text{dim}(\mathbf{N}))])$  cells. Each cell contains an array whose **dim**(*i*)th dimension has a length of  $\text{size}(\mathbf{A}, \text{dim}(i))$  and whose other dimensions are singletons.

For example, given a 4-by-7-by-3 array, you can specify **dim** as an positive integer vector to create cell arrays of different dimensions.

## num2hex

Convert singles and doubles to IEEE hexadecimal strings

### Syntax

num2hex(X)

### Description

If X is a single or double precision array with n elements, num2hex(X) is an n-by-8 or n-by-16 char array of the hexadecimal floating-point representation. The same representation is printed with format hex.

### Examples

```
num2hex([1 0 0.1 -pi Inf NaN])
```

returns

ans =

```
3ff0000000000000
0000000000000000
3fb999999999999a
c00921fb54442d18
7ff0000000000000
fff8000000000000
num2hex(single([1 0 0.1 -pi Inf NaN]))
```

returns

ans =

```
3f800000
00000000
3dcccccd
c0490fdb
```

7f800000  
ffc00000

## **See Also**

hex2num | format | dec2hex

## num2str

Convert number to string

### Syntax

```
s = num2str(A)
s = num2str(A,precision)
s = num2str(A,formatSpec)
```

### Description

`s = num2str(A)` converts a numeric array into a string representation. The output format depends on the magnitudes of the original values. `num2str` is useful for labeling and titling plots with numeric values.

`s = num2str(A,precision)` returns a string representation with the maximum number of significant digits specified by `precision`.

`s = num2str(A,formatSpec)` applies a format specified by `formatSpec` to all elements of `A`.

### Examples

#### Default Conversions of Floating-Point Values

Convert the floating-point values returned by `pi` and `eps` to strings.

```
s = num2str(pi)
```

```
s =
```

```
3.1416
```

```
s = num2str(eps)
```

```
s =
2.2204e-16
```

### Specify Precision

Specify the maximum number of significant digits for floating-point values.

```
A = gallery('normaldata',[2,2],0);
s = num2str(A,3)
```

```
s =
-0.433 0.125
-1.67 0.288
```

### Specify Formatting

Specify the width, precision, and other formatting for an array of floating-point values.

```
A = gallery('uniformdata',[2,3],0) * 9999;
s = num2str(A,'%10.5e\n')
```

```
s =
9.50034e+03
6.06782e+03
8.91210e+03
2.31115e+03
4.85934e+03
7.62021e+03
```

The format `'%10.5e'` prints each value in exponential format with five decimal places, and `'\n'` prints a new line character.

## Input Arguments

**A** — Input array  
numeric array

Input array, specified as a numeric array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Complex Number Support: Yes

**precision** — Maximum number of significant digits

positive integer

Maximum number of significant digits in the output string, specified as a positive integer.

---

**Note:** If you specify **precision** to exceed the precision of the input floating-point data type, the results might not match the input values to the precision you specified. The result depends on your computer hardware and operating system.

---

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**formatSpec** — Format of output fields

string containing formatting operators

Format of the output fields, specified as a string containing formatting operators. **formatSpec** also can include ordinary text and special characters.

**Formatting Operator**

A formatting operator starts with a percent sign, %, and ends with a conversion character. The conversion character is required. Optionally, you can specify identifier, flags, field width, precision, and subtype operators between % and the conversion character. (Spaces are invalid between operators and are shown here only for readability).

**Conversion Character**

This table shows conversion characters to format numeric and character data as strings.

Value Type	Conversion	Details
Integer, signed	%d or %i	Base 10
Integer, unsigned	%u	Base 10
	%o	Base 8 (octal)
	%x	Base 16 (hexadecimal), lowercase letters a–f
	%X	Same as %x, uppercase letters A–F
Floating-point number	%f	Fixed-point notation (Use a precision operator to specify the number of digits after the decimal point.)
	%e	Exponential notation, such as 3.141593e+00 (Use a precision operator to specify the number of digits after the decimal point.)
	%E	Same as %e, but uppercase, such as 3.141593E+00 (Use a precision operator to specify the number of digits after the decimal point.)
	%g	The more compact of %e or %f, with no trailing zeros (Use a precision operator to specify the number of significant digits.)
	%G	The more compact of %E or %f, with no trailing zeros (Use a precision operator to specify the number of significant digits.)
Characters	%c	Single character
	%s	String of characters

### Optional Operators

The optional identifier, flags, field width, precision, and subtype operators further define the format of the output string.

- **Identifier**

Order for processing values from the input list. Use the syntax  $n\$$ , where  $n$  represents the position of the value in the input list.

**Example:** '%3\$s %2\$s %1\$s %2\$s' prints inputs 'A', 'B', 'C' as follows: C B A B.

- **Flags**

'-'	Left-justify. <b>Example:</b> %-5.2f
'+'	Always print a sign character (+ or -) for any value. <b>Example:</b> %+5.2f
' '	Insert a space before the value. <b>Example:</b> % 5.2f
'0'	Pad to field width with zeros before the value. <b>Example:</b> %05.2f
'#'	Modify selected numeric conversions: <ul style="list-style-type: none"> <li>• For %o, %x, or %X, print 0, 0x, or 0X prefix.</li> <li>• For %f, %e, or %E, print decimal point even when precision is 0.</li> <li>• For %g or %G, do not remove trailing zeros or decimal point.</li> </ul> <b>Example:</b> %#5.0f

- **Field Width**

Minimum number of characters to print. The field width operator can be a number, or an asterisk (\*) to refer to an argument in the input list.

**Example:** The input list ('%12d', intmax) is equivalent to ('%\*d', 12, intmax).

The function pads to field width with spaces before the value unless otherwise specified by flags.

- **Precision**

For %f, %e, or %E	Number of digits to the right of the decimal point <b>Example:</b> '%.4f' prints pi as '3.1416'
-------------------	----------------------------------------------------------------------------------------------------

For %g or %G	Number of significant digits <b>Example:</b> '%.4g' prints pi as ' 3.142'
--------------	------------------------------------------------------------------------------

The precision operator can be a number, or an asterisk (\*) to refer to an argument in the input list.

**Example:** The input list ('%6.4f', pi) is equivalent to ('%\*.\*f', 6, 4, pi).

---

**Note:** If you specify a precision operator for floating-point values that exceeds the precision of the input numeric data type, the results might not match the input values to the precision you specified. The result depends on your computer hardware and operating system.

---

- **Subtypes**

Certain conversion characters can support a subtype. The subtype operator immediately precedes the conversion character. This table shows the conversions that can use subtypes.

Input Value Type	Subtype and Conversion Character	Output Value Type
Floating-point number	%bx or %bX %bo %bu	Double-precision hexadecimal, octal, or decimal value <b>Example:</b> %bx prints pi as 400921fb54442d18
	%tx or %tX %to %tu	Single-precision hexadecimal, octal, or decimal value <b>Example:</b> %tx prints pi as 40490fdb
Integer	%ld or %li %lo %lu %lx or %lX	64-bit value
Integer	%hd or %hi %ho %hu	16-bit value

Input Value Type	Subtype and Conversion Character	Output Value Type
	%hX or %hX	

### Text Before or After Formatting Operators

`formatSpec` can also include additional text before a percent sign, %, or after a conversion character. The text can be:

- Ordinary text to print.
- Special characters that you cannot enter as ordinary text. This table shows how to represent special characters in `formatSpec`.

Special Character	Representation
Single quotation mark	' '
Percent character	%%
Backslash	\\
Alarm	\a
Backspace	\b
Form feed	\f
New line	\n
Carriage return	\r
Horizontal tab	\t
Vertical tab	\v
Character whose ASCII code is the hexadecimal number, N	\xN
Character whose ASCII code is the octal number, N	\N

### Notable Behavior of Conversions with Formatting Operators

- Numeric conversions print only the real component of complex numbers.
- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses %e.

**Example:** '%s' converts `pi` to `3.141593e+00`.

- If you apply a string conversion (`%s`) to integer values, MATLAB converts values that correspond to valid character codes to characters.

**Example:** `'%s'` converts `[65 66 67]` to `ABC`.

## Output Arguments

**s** — String representation of input array

character array

String representation of the input array, returned as a character array.

## More About

### Algorithms

`num2str` trims any leading spaces from a string, even when `formatSpec` includes a space character flag. For example, `num2str(42.67, '% 10.2f')` returns a 1-by-5 character array `'42.67'`.

## numberOfStrips

**Class:** Tiff

Total number of strips in image

### Syntax

```
numStrips = numberOfStrips(tiffobj)
```

### Description

`numStrips = numberOfStrips(tiffobj)` returns the total number of strips in the image.

### Examples

#### Determine Number of Strips in Image

Determine the number of strips in the second image of a file.

Create a Tiff object associated with the example file, `example.tif`.

```
t = Tiff('example.tif', 'r');
```

When the Tiff object is created, the first image in the file is the current image file directory.

Make the second image the current directory.

```
nextDirectory(t)
```

Get the number of strips in the image if the image has a stripped organization.

```
if ~isTiled(t)
 numStrips = numberOfStrips(t)
end
```

```
numStrips =
```

7

The image has 7 strips.

Close the Tiff object.

```
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## References

This method corresponds to the `TIFFNumberOfStrips` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

## See Also

`Tiff.numberOfTiles` | `Tiff.isTiled`

## numberOfTiles

**Class:** Tiff

Total number of tiles in image

## Syntax

```
numTiles = numberOfTiles(tiffobj)
```

## Description

`numTiles = numberOfTiles(tiffobj)` returns the total number of tiles in the image.

## Examples

### Determine Number of Tiles in Image

Create a Tiff object associated with the example file, `example.tif`. Get the number of tiles in the image if the image has a tiled organization.

```
t = Tiff('example.tif', 'r');
if isTiled(t)
 nTiles = numberOfTiles(t)
end
```

```
nTiles =

 110
```

The image has 110 tiles.

Close the Tiff object.

```
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## numel

Number of array elements

## Syntax

```
n = numel(A)
```

## Description

`n = numel(A)` returns the number of elements, `n`, in array `A`, equivalent to `prod(size(A))`.

## Examples

### Number of Elements in 3-D Matrix

Create a 4-by-4-by-2 matrix.

```
A = magic(4);
A(:,:,2) = A'
```

```
A(:,:,1) =
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

```
A(:,:,2) =
 16 5 9 4
 2 11 7 14
 3 10 6 15
 13 8 12 1
```

`numel` counts 32 elements in the matrix.

```
n = numel(A)
```

```
n =
 32
```

### Number of Elements in Cell Array of Strings

Create a cell array of strings.

```
A = {'dog', 'cat', 'fish', 'horse'};
```

numel counts 4 string elements in the array.

```
n = numel(A)
```

```
n =
 4
```

### Number of Elements in Table

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith'; 'Johnson'; 'Williams'; 'Jones'; 'Brown'};
Age = [38; 43; 38; 40; 49];
Height = [71; 69; 64; 67; 64];
Weight = [176; 163; 131; 133; 119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
A = table(Age, Height, Weight, BloodPressure, 'RowNames', LastName)
```

```
A =
 Age Height Weight BloodPressure
 --- -
 Smith 38 71 176 124 93
 Johnson 43 69 163 109 77
 Williams 38 64 131 125 83
 Jones 40 67 133 117 75
 Brown 49 64 119 122 80
```

Find the number of elements in the table.

```
n = numel(A)
```

`n =`

`20`

`numel` returns a value equivalent to `prod(size(A))` corresponding to the 5 rows and 4 variables.

## Input Arguments

### **A** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. This includes numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, `calendarDuration` arrays, tables, structure arrays, cell arrays, and object arrays.

## Limitations

- If `A` is a table, `numel` returns the number of elements in the table, `A`, equivalent to `prod(size(A))`. Variables in a table can have multiple columns, but `numel(A)` only accounts for the number of rows and number of variables.

## More About

- “Modify `nargout` and `nargin` for Indexing Methods”

### See Also

`prod` | `size` | `subsref`

Introduced before R2006a

# Numeric Ruler Properties

Control individual axis appearance and behavior

Numeric ruler properties control the appearance and behavior of the *x*-axis, *y*-axis, or *z*-axis. Each individual axis has its own numeric ruler object. By changing property values of the rulers, you can modify certain aspects of a specific axis.

Use dot notation to refer to a particular ruler and property. Access the numeric ruler objects through the `XAxis`, `YAxis`, and `ZAxis` properties for the axes.

```
ax = gca;
co = ax.XAxis.Color;
ax.XAxis.Color = 'blue';
```

## Appearance

### Color — Line and text color

RGB triplet | color string | 'none'

Line and text color, specified as an RGB triplet, a color string, or 'none'. If you set the color to 'none', then the axis is invisible.

Example: `ax.XAxis.Color = 'red';`

Example: `ax.YAxis.Color = [0.1 0.7 0.8];`

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]

Long Name	Short Name	RGB Triplet
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

---

**Note:** The `Color` property for the ruler and the associated `XColor`, `YColor`, or `ZColor` property for the parent axes always have the same value. Setting one also sets the other.

---

### **LineWidth** — Width of line and tick values

0.5 (default) | positive value

Width of line and tick values, specified as a positive value in point units. One point equals 1/72 inch.

Example: `ax.XAxis.LineWidth = 2;`

---

**Note:** Setting the `LineWidth` property for the parent axes sets the `LineWidth` property for the ruler to the same value. However, setting the ruler property does not set the axes property. To prevent the axes property value from overriding the ruler property value, set the axes value first, and then set the ruler value.

---

### **Label** — Axis label

text object (default)

Axis label, which is a text object. This text object contains properties that control the text to be displayed. Use the `Label` property to access the text object.

By default, the label does not contain text. To display text or change existing text, set the `String` property for the text object. Use other properties to change the text appearance, such as the font style or color.

```
ax = gca;
ax.XAxis.Label.String = 'X Axis';
ax.XAxis.Label.FontSize = 12;
```

For a full list of options, see [Text Properties](#).

Alternatively, use the `xlabel`, `ylabel`, and `zlabel` functions to modify the axis labels.

---

**Note:** The text object is not a child of the numeric ruler object, so it cannot be returned by `findobj` and it does not use the default text property values.

---

### **Visible — State of visibility**

'on' (default) | 'off'

State of visibility, specified as one of these values:

- 'on' — Display the axis.
- 'off' — Hide the axis without deleting it. You still can access properties of an invisible axis using the numeric ruler object.

Example: `ax.XAxis.Visible = 'off';`

## **Scale and Direction**

### **Limits — Minimum and maximum axis limits**

[0 1] (default) | two-element vector of the form [min max]

Minimum and maximum axis limits, specified as a two-element vector of the form [min max].

If you assign a value to this property, then MATLAB sets the associated mode to 'manual'. When the associated mode property is set to 'auto', MATLAB chooses the axis limits.

---

**Note:** The `Limits` property for the ruler and the associated `XLim`, `YLim`, or `ZLim` property for the parent axes always have the same value. Setting one also sets the other.

---

Example: `ax.XAxis.Limits = [-10 10];`

### **LimitsMode — Selection mode for Limits property**

'auto' (default) | 'manual'

Selection mode for the `Limits` property, specified as one of these values:

- 'auto' — Select axis limits based on the data plotted.
- 'manual' — Use manually specified axis limits. To specify the axis limits, set the `Limits` property.

---

**Note:** The `LimitsMode` property for the ruler and the associated `XLimMode`, `YLimMode`, or `ZLimMode` property for the parent axes always have the same value. Setting one also sets the other.

---

## **Scale — Scale of values along axis**

'linear' (default) | 'log'

Scale of values along axis, specified as 'linear' or 'log'.

---

**Note:** The `Scale` property for the ruler and the associated `XScale`, `YScale`, or `ZScale` property for the parent axes always have the same value. Setting one also sets the other.

---

Example: `ax.XAxis.Scale = 'log';`

## **Direction — Direction of increasing values**

'normal' (default) | 'reverse'

Direction of increasing values, specified as one of these values:

- 'normal' — Values increase from left to right or bottom to top.
- 'reverse' — Values increase from right to left or top to bottom.

---

**Note:** The `Direction` property for the ruler and the associated `XDir`, `YDir`, or `ZDir` property for the parent axes always have the same value. Setting one also sets the other.

---

Example: `ax.XAxis.Direction = 'reverse';`

## **Tick Values and Labels**

### **TickValues — Tick value locations**

[] (default) | vector of increasing values

Tick value locations, specified as a vector of increasing values.

Example: `ax.XAxis.TickValues = [2 4 6 8 10];`

Example: `ax.XAxis.TickValues = 0:10:100;`

If you assign a value to this property, then MATLAB sets the associated mode property to 'manual'. When the associated mode is set to 'auto', MATLAB chooses the tick values.

---

**Note:** The `TickValues` property for the ruler and the associated `XTick`, `YTick`, or `ZTick` property for the parent axes always have the same value. Setting one also sets the other.

---

### **TickValuesMode — Selection mode for TickValues property**

'auto' (default) | 'manual'

Selection mode for the `TickValues` property, specified as one of these values:

- 'auto' — Select tick values based on the data plotted.
- 'manual' — Use manually specified tick values. To specify the values, set the `TickValues` property.

---

**Note:** The `TickValuesMode` property for the ruler and the associated `XTickMode`, `YTickMode`, or `ZTickMode` property for the parent axes always have the same value. Setting one also sets the other.

---

### **Exponent — Exponential notation common to all tick values**

integer value

Exponential notation common to all tick values, specified as an integer value. The axis displays an exponent label showing the base and exponent value, for example:

The base value is always 10. However, you can change the exponent value by setting the `Exponent` property. For example, change the exponent to 2.

```
ax = gca;
ax.YAxis.Exponent = 2;
```

If the exponent value is 0, then the exponent label does not display.

If you assign a value to this property, then MATLAB sets the associated mode property to `'manual'`. When the associated mode is set to `'auto'`, MATLAB chooses the exponent value.

### **ExponentMode — Selection mode for Exponent property**

`'auto'` (default) | `'manual'`

Selection mode for the `Exponent` property, specified as one of these values:

- `'auto'` — Select the exponent value based on the axis limits.
- `'manual'` — Use a manually specified exponent value. To specify the value, set the `Exponent` property.

### **TickLabels — Tick value labels**

`''` (default) | cell array of strings

Tick value labels, specified as a cell array of strings. If you do not specify enough strings for all the tick values, then the axis cycles through the specified strings. Tick value labels support TeX and LaTeX markup. See the `TickLabelInterpreter` property for more information.

```
Example: ax.XAxis.TickLabels =
{'January', 'February', 'March', 'April', 'May'}';
```

```
Example: ax.YAxis.TickLabels = {'\pi', '2\pi', '3\pi'}'
```

If you set this property, then MATLAB sets the associated mode property to `'manual'`. When the associated mode is set to `'auto'`, MATLAB chooses the tick value labels.

---

**Note:** The `TickLabels` property for the ruler and the associated `XTickLabel`, `YTickLabel`, or `ZTickLabel` property for the parent axes always have the same value. Setting one also sets the other.

---

**TickLabelsMode — Selection mode for TickLabels property**

'auto' (default) | 'manual'

Selection mode for the `TickLabels` property, specified as one of these values:

- 'auto' — Select the labels based on the data plotted.
- 'manual' — Use manually specified labels. To specify the labels, set the `TickLabels` property.

---

**Note:** The `TickLabelsMode` property for the ruler and the associated `XTickLabelMode`, `YTickLabelMode`, or `ZTickLabelMode` property for the parent axes always have the same value. Setting one also sets the other.

---

**TickLabelInterpreter — Interpretation of characters in tick labels**

'tex' (default) | 'latex' | 'none'

Interpretation of characters in tick labels, specified as one of these values:

- 'tex' — Interpret strings using a subset of TeX markup.
- 'latex' — Interpret strings using LaTeX markup.
- 'none' — Display literal characters.

---

**Note:** Setting the `TickLabelInterpreter` property for the parent axes sets the `TickLabelInterpreter` property for the ruler to the same value. However, setting the ruler property does not set the axes property. To prevent the axes property value from overriding the ruler property value, set the axes value first, and then set the ruler value.

---

```
Example: ax.XAxis.TickLabelInterpreter = 'latex';
```

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers with the `TickLabelInterpreter` property set to `'tex'`. Modifiers remain in effect until the end of the string. Superscripts and subscripts are an exception because they only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
<code>^{ }</code>	Superscript	<code>'text^{superscript}'</code>
<code>_{ }</code>	Subscript	<code>'text_{subscript}'</code>
<code>\bf</code>	Bold font	<code>'\bf text'</code>
<code>\it</code>	Italic font	<code>'\it text'</code>
<code>\sl</code>	Oblique font (rarely available)	<code>'\sl text'</code>
<code>\rm</code>	Normal font	<code>'\rm text'</code>
<code>\fontname{specifier}</code>	Set <code>specifier</code> as the name of a font family to change the font style. You can use this in combination with other modifiers.	<code>'\fontname{Courier} text'</code>
<code>\fontsize{specifier}</code>	Set <code>specifier</code> as a scalar numeric value to change the font size.	<code>'\fontsize{15} text'</code>
<code>\color{specifier}</code>	Set <code>specifier</code> as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue.	<code>'\color{magenta} text'</code>
<code>\color[rgb]{specifier}</code>	Set <code>specifier</code> as a three-element RGB triplet to change the font color.	<code>'\color[rgb]{0,0.5,0.5} text'</code>

This table lists the supported special characters with the `Interpreter` property set to `'tex'`.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
<code>\alpha</code>	$\alpha$	<code>\upsilon</code>	$\upsilon$	<code>\sim</code>	$\sim$
<code>\angle</code>	$\angle$	<code>\phi</code>	$\Phi$	<code>\leq</code>	$\leq$
<code>\ast</code>	$*$	<code>\chi</code>	$\chi$	<code>\infty</code>	$\infty$
<code>\beta</code>	$\beta$	<code>\psi</code>	$\psi$	<code>\clubsuit</code>	$\clubsuit$
<code>\gamma</code>	$\gamma$	<code>\omega</code>	$\omega$	<code>\diamondsuit</code>	$\diamondsuit$
<code>\delta</code>	$\delta$	<code>\Gamma</code>	$\Gamma$	<code>\heartsuit</code>	$\heartsuit$
<code>\epsilon</code>	$\epsilon$	<code>\Delta</code>	$\Delta$	<code>\spadesuit</code>	$\spadesuit$
<code>\zeta</code>	$\zeta$	<code>\Theta</code>	$\Theta$	<code>\leftrightarrow</code>	$\leftrightarrow$
<code>\eta</code>	$\eta$	<code>\Lambda</code>	$\Lambda$	<code>\leftarrow</code>	$\leftarrow$
<code>\theta</code>	$\Theta$	<code>\Xi</code>	$\Xi$	<code>\Leftarrow</code>	$\Leftarrow$
<code>\vartheta</code>	$\vartheta$	<code>\Pi</code>	$\Pi$	<code>\uparrow</code>	$\uparrow$
<code>\iota</code>	$\iota$	<code>\Sigma</code>	$\Sigma$	<code>\rightarrow</code>	$\rightarrow$
<code>\kappa</code>	$\kappa$	<code>\Upsilon</code>	$\Upsilon$	<code>\Rightarrow</code>	$\Rightarrow$
<code>\lambda</code>	$\lambda$	<code>\Phi</code>	$\Phi$	<code>\downarrow</code>	$\downarrow$
<code>\mu</code>	$\mu$	<code>\Psi</code>	$\Psi$	<code>\circ</code>	$\circ$
<code>\nu</code>	$\nu$	<code>\Omega</code>	$\Omega$	<code>\pm</code>	$\pm$
<code>\xi</code>	$\xi$	<code>\forall</code>	$\forall$	<code>\geq</code>	$\geq$
<code>\pi</code>	$\pi$	<code>\exists</code>	$\exists$	<code>\propto</code>	$\propto$
<code>\rho</code>	$\rho$	<code>\ni</code>	$\ni$	<code>\partial</code>	$\partial$
<code>\sigma</code>	$\sigma$	<code>\equiv</code>	$\equiv$	<code>\bullet</code>	$\bullet$
<code>\varsigma</code>	$\varsigma$	<code>\approx</code>	$\approx$	<code>\div</code>	$\div$
<code>\tau</code>	$\tau$	<code>\Re</code>	$\Re$	<code>\neq</code>	$\neq$
<code>\equiv</code>	$\equiv$	<code>\oplus</code>	$\oplus$	<code>\aleph</code>	$\aleph$
<code>\Im</code>	$\Im$	<code>\cup</code>	$\cup$	<code>\wp</code>	$\wp$
<code>\otimes</code>	$\otimes$	<code>\subseteq</code>	$\subseteq$	<code>\oslash</code>	$\oslash$
<code>\cap</code>	$\cap$	<code>\in</code>	$\in$	<code>\supseteq</code>	$\supseteq$
<code>\supset</code>	$\supset$	<code>\lceil</code>	$\lceil$	<code>\subset</code>	$\subset$

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
<code>\int</code>	$\int$	<code>\cdot</code>	$\cdot$	<code>\o</code>	$\circ$
<code>\rfloor</code>	$\rfloor$	<code>\neg</code>	$\neg$	<code>\nabla</code>	$\nabla$
<code>\lfloor</code>	$\lfloor$	<code>\times</code>	$\times$	<code>\ldots</code>	$\dots$
<code>\perp</code>	$\perp$	<code>\surd</code>	$\surd$	<code>\prime</code>	$'$
<code>\wedge</code>	$\wedge$	<code>\varpi</code>	$\varpi$	<code>\o</code>	$\emptyset$
<code>\rceil</code>	$\rceil$	<code>\rangle</code>	$\rangle$	<code>\mid</code>	$ $
<code>\vee</code>	$\vee$	<code>\langle</code>	$\langle$	<code>\copyright</code>	$\copyright$

## LaTeX Markup

To use LaTeX markup, set the `TickLabelInterpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this is reduced by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project website at <http://www.latex-project.org/>.

### TickLabelFormat — Tick label format and decimal precision

format string

Tick label format and decimal precision, specified as a format string. For example, you can use format strings to display the tick labels in a currency format, control the number of decimals that appear in each label, or add text after all the labels.

Example: `ax.XAxis.TickLabelFormat = '%g%%'`; displays a percent sign after all the tick labels.

This table lists some common formats and the associated format strings.

Common Format	Format String to Use	Examples of Resulting Format
Currency — Display dollar sign before values, use two	<code>'\$, .2f'</code>	\$0.01 \$1.00

Common Format	Format String to Use	Examples of Resulting Format
decimal places, and use commas.		\$1,000.00
Temperatures — Display degree symbol after values.	'%g\\circ'	0.01° 1° 1000°
Percentages — Display percent sign after values.	'%g%%'	0.01% 1% 1000%
Commas — Display commas in the thousandth place.	'%,g'	0.01 1 1,000

## Custom Format String

If none of the formats mentioned in the table gives your desired format, then create a custom format string instead. Create a custom format string using a percent sign followed by one or more of these options:

- One or more flags — Indicate options such as left-justification or adding a plus sign before positive values. For a full list of options, see the table of Optional Flags.
- Field width — Indicate the minimum number of characters to print. Specify the field width as a number. If the number of significant digits in the tick value is smaller than the field width, then the value is padded with either zeros or spaces. Use the optional flags to control the padding.
- Precision — Indicate the number of digits to the right of the decimal point or the number of significant digits, depending on the conversion character. Specify the precision as an integer value.
- Conversion character — Indicate the value type. For a full list of options, see the table of Conversion Characters.

Arguments are optional, except the percent sign and conversion character. You must construct the string in the order shown in this example (spaces included for clarity only):

Additionally, you can specify literal text at the beginning or end of the string. For example:

- `'$.2f'` — Display a dollar sign before each value. The rest of the format string specifies fixed-point notation with two decimal values.
- `'%.3f Million'` — Display `Million` after each value. The rest of the format string specifies fixed-point notation with three decimal values.

To print a single quotation mark, use `' '`. To print a percent character, use `%%`.

### Optional Flags

Flag	Description	Example
<code>' , '</code>	Display commas every three digits.	<code>'%,5.2f'</code>
<code>' _ '</code>	Left-justify.	<code>'%-5.2f'</code>
<code>' + '</code>	Print sign character (+) for positive values.	<code>'%+5.2f'</code>
<code>' ' '</code>	Pad the field width with spaces before the value.	<code>'% 5.2f'</code>
<code>' 0 '</code>	Pad the field width with zeros.	<code>'%05.2f'</code>
<code>' # '</code>	Modify selected numeric conversions: <ul style="list-style-type: none"> <li>• For <code>%f</code> or <code>%e</code>, print the decimal point even when the precision is 0.</li> </ul>	<code>'%#5.2f'</code>

Flag	Description	Example
	<ul style="list-style-type: none"> <li>For %g, do not remove trailing zeros or the decimal point.</li> </ul>	

**Conversion Characters**

Conversion Character	Description	Example
%d or %i	Signed integer with base 10	'%6.4d'
%f	Fixed-point notation	'%6.4f'
%e	Exponential notation, such as $3.141593 \times 10^3$	'%6.4e'
%g	The more compact of %e or %f, with no trailing zeros	'%6.4g'

---

**Note:** If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses %e.

---

For an example, see “Customize Format of Tick Value Labels”.

**TickLabelRotation – Rotation of tick labels**

scalar value in degrees

Rotation of tick labels, specified as a scalar value in degrees. Negative values give clockwise rotation.

---

**Note:** The TickLabelRotation property for the ruler and the associated XTickLabelRotation, YTickLabelRotation, or ZTickLabelRotation property for the parent axes always have the same value. Setting one also sets the other.

---

Example: `ax.XAxis.TickLabelRotation = -45;`

**TickDirection – Tick mark direction**

'in' (default) | 'out' | 'both'

Tick mark direction, specified as one of these values:

- 'in' — Direct the tick marks inward from the axis lines. This is the default for 2-D views.
- 'out' — Direct the tick marks outward from the axis lines. This is the default for 3-D views.
- 'both' — Center the tick marks over the axis lines.

If you assign a value to this property, then MATLAB sets the associated `mod` property to 'manual'. When the associated mode property is set to 'auto', MATLAB chooses the tick direction.

---

**Note:** Setting the `TickDir` property for the parent axes sets the `TickDirection` property for the ruler to the same value. However, setting the ruler property does not set the axes property. To prevent the axes property value from overriding the ruler property value, set the axes value first, and then set the ruler value.

---

Example: `ax.YAxis.TickDirection = 'out';`

### **TickDirectionMode** — Selection mode for `TickDirection` property

'auto' (default) | 'manual'

Selection mode for the `TickDirection` property, specified as one of these values:

- 'auto' — Automatically select the tick direction.
- 'manual' — Use a manually specified tick direction. To specify the tick direction, set the `TickDirection` property.

### **TickLength** — Tick mark length

scalar in points

Tick mark length, specified as a scalar in point units.

---

**Note:** Setting the `TickLength` property for the parent axes sets the `TickLength` property for the ruler to the same value. However, setting the ruler property does not set the axes property. To prevent the axes property value from overriding the ruler property value, set the axes value first, and then set the ruler value.

---

Example: `ax.YAxis.TickLength = 0.02;`

**MinorTick — Minor tick mark display**

'off' (default) | 'on'

Minor tick mark display, specified as one of these values:

- 'off' — Do not display minor tick marks.
- 'on' — Display minor tick marks between the major tick marks on the axis. The space between the major tick marks determines the number of minor tick marks.

---

**Note:** The `MinorTick` property for the ruler and the associated `XMinorTick`, `YMinorTick`, or `ZMinorTick` property for the parent axes always have the same value. Setting one also sets the other.

---

Example: `ax.XAxis.MinorTick = 'on';`

**MinorTickValues — Minor tick value locations**

[] (default) | vector of increasing values

Minor tick value locations, specified as a vector of increasing values.

Example: `ax.XAxis.MinorTickValues = [0 0.5 1 1.5 2 2.5];`

Example: `ax.YAxis.MinorTickValues = 0:5:100;`
