You can use any combination of property name/property value pairs, structures, and cell arrays in one call to the `set` function. Additionally, you can specify a property name without regard to case, and you can use property name completion. For example, if `S` is a serial port object, then the following commands are all valid.

```
set(s, 'BaudRate')
set(s, 'baudrate')
set(s, 'BAUD')
```

### See Also

`get`

Introduced before R2006a

## set (tscollection)

Set properties of tscollection object

### Syntax

```
set(tsc, 'Property', Value)
set(tsc, 'Property1', Value1, 'Property2', Value2, ...)
set(tsc, 'Property')
```

### Description

`set(tsc, 'Property', Value)` sets the property 'Property' of the tscollection tsc to the value Value. The following syntax is equivalent:

```
tsc.Property = Value
```

`set(tsc, 'Property1', Value1, 'Property2', Value2, ...)` sets multiple property values for tsc with a single statement.

`set(tsc, 'Property')` displays values for the specified property in the time-series collection tsc.

`set(tsc)` displays all properties and values of the tscollection object tsc.

### See Also

`get (tscollection)`

Introduced before R2006a

## setabstime (tscollection)

Set times of `tscollection` object as date strings

### Syntax

```
tsc = setabstime(tsc,Times)
tsc = setabstime(tsc,Times,format)
```

### Description

`tsc = setabstime(tsc,Times)` sets the times in `tsc` using the date strings `Times`. `Times` must be either a cell array of strings, or a `char` array containing valid date or time values in the same date format.

`tsc = setabstime(tsc,Times,format)` specifies the date-string format used in `Times` explicitly.

### Examples

- 1 Create a `tscollection` object.

```
tsc = tscollection(timeseries(rand(3,1)))
```

- 2 Set the absolute time vector.

```
tsc = setabstime(tsc,{'12-DEC-2005 12:34:56',...
 '12-DEC-2005 13:34:56','12-DEC-2005 14:34:56'})
```

### See Also

`datestr` | `getabstime (tscollection)` | `tscollection`

Introduced before R2006a

## setappdata

Store application-defined data

Use this function to store data in a UI. You can retrieve the data elsewhere in your code using the `getappdata` function. Both of these functions provide a convenient way to share data between callbacks or between separate UIs.

### Syntax

```
setappdata(obj,name,val)
```

### Description

`setappdata(obj,name,val)` stores the contents of `val`. The graphics object, `obj`, and the name identifier, `name`, uniquely identify the data for later retrieval.

### Examples

#### Store and Retrieve Date Information

Create a figure window. Then, get the current time using the `date` function.

```
f = figure;
val = date
```

```
val =
```

```
23-Dec-2014
```

Store the contents of `val` using the `setappdata` function. In this case, `val` is stored in the figure object using the name identifier, `'todaysdate'`.

```
setappdata(f,'todaysdate',val);
```

Retrieve the data and display it.

```
getappdata(f,'todaysdate')
```

ans =

23-Dec-2014

## Input Arguments

### **obj** — Graphics object in which to store the value

figure | uipanel | uibuttongroup | uicontrol | ...

Graphics object in which to store the value, specified as any graphics object (except an ActiveX component). The graphics object must be accessible from within the functions you plan to store and retrieve the data.

### **name** — Name identifier

string

Name identifier, specified as a `string` value. Select a unique name identifier that is easy to remember so that you can easily recall it when you want to retrieve the data.

Data Types: `char`

### **val** — Value to store

any MATLAB data type

Value to store, specified as any MATLAB data type.

getappdata | guidata | isappdata | rmapdata

Introduced before R2006a

## setcats

Set categories in categorical array

## Syntax

```
B = setcats(A,newcats)
```

## Description

`B = setcats(A,newcats)` sets categories in output categorical array **B** using categories defined by `newcats` and elements defined by **A**.

- If an element of **A** is in a category listed in `newcats`, then the corresponding element of **B** has the same value as in **A**.
- If **A** has a category not listed in `newcats`, then **B** does not have that category. The corresponding elements in **B** are undefined.
- If `newcats` lists a category that is not a category of **A**, then **B** has no elements equal to that category.

## Examples

### Set New Categories

Create a categorical array containing various colors.

```
A = categorical({'blue','black','red';'red','blue','black';'black','red','blue'})
```

A =

```
 blue black red
 red blue black
 black red blue
```

Set new categories.

```
B = setcats(A,{'red', 'black'})
```

```
B =
```

```

<undefined> black red
red <undefined> black
black red <undefined>
```

Elements that were blue in A are undefined in B.

### Set New Categories and Assign Elements

Create a categorical array containing various colors.

```
A = categorical({'blue', 'black', 'red'; 'red', 'blue', 'black'; 'black', 'red', 'blue'})
```

```
A =
```

```

blue black red
red blue black
black red blue
```

Set new categories. Include a category that is not a category of A.

```
B = setcats(A,{'red', 'pink', 'blue'})
```

```
B =
```

```

blue <undefined> red
red blue <undefined>
<undefined> red blue
```

No element of B is pink, because pink is not a category of A. Assign an element of B to be pink.

```
B(1,2) = 'pink';
B
```

B =

```
blue pink red
red blue <undefined>
<undefined> red blue
```

## Input Arguments

### A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

### newcats — New categories

string | cell array of strings

New categories, specified as a string or a cell array of strings.

## More About

### Tips

- To change category names in a categorical array, use `renamecats`.

### See Also

`addcats` | `categories` | `iscategory` | `mergocats` | `removecats` | `renamecats` | `reordercats`

**Introduced in R2014b**

# setdiff

Set difference of two arrays

## Syntax

```
C = setdiff(A,B)
C = setdiff(A,B,'rows')
[C,ia] = setdiff(A,B)
[C,ia] = setdiff(A,B,'rows')

[C,ia] = setdiff(___,setOrder)
[C,ia] = setdiff(A,B,'legacy')
[C,ia] = setdiff(A,B,'rows','legacy')
```

## Description

`C = setdiff(A,B)` returns the data in **A** that is not in **B**.

- If **A** and **B** are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `setdiff` returns the values in **A** that are not in **B**. The values of **C** are in sorted order.
- If **A** and **B** are tables, then `setdiff` returns the rows from **A** that are not in **B**, with repetitions removed. The rows of table **C** are in sorted order.

`C = setdiff(A,B,'rows')` treats each row of **A** and each row of **B** as single entities and returns the rows from **A** that are not in **B**. The rows of **C** are in sorted order.

The `'rows'` option does not support cell arrays, unless one of the inputs is either a categorical array or a datetime array.

`[C,ia] = setdiff(A,B)` also returns the index vector **ia**.

- If **A** and **B** are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `C = A(ia)`.
- If **A** and **B** are tables, then `C = A(ia,:)`.

`[C,ia] = setdiff(A,B,'rows')` also returns the index vector `ia`, such that `C = A(ia,:)`.

`[C,ia] = setdiff( ____,setOrder)` returns `C` in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A`. If no value is specified, the default is `'sorted'`.

`[C,ia] = setdiff(A,B,'legacy')` and `[C,ia] = setdiff(A,B,'rows','legacy')` preserve the behavior of the `setdiff` function from R2012b and prior releases.

The `'legacy'` option does not support categorical arrays, tables, datetime arrays, or duration arrays.

## Examples

### Difference of Two Vectors

Define two vectors with values in common.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
```

Find the values in `A` that are not in `B`.

```
C = setdiff(A,B)
```

```
C =
```

```
 1 3 5
```

### Difference of Two Tables

Define two tables with rows in common.

```
A = table([1:5]', ['A';'B';'C';'D';'E'], logical([0;1;0;1;0]))
B = table([1:2:10]', ['A';'C';'E';'G';'I'], logical(zeros(5,1)))
```

```
A =
```

Var1	Var2	Var3
1	A	false

```

2 B true
3 C false
4 D true
5 E false

```

B =

```

Var1 Var2 Var3
---- ---- ----
1 A false
3 C false
5 E false
7 G false
9 I false

```

Find the rows in A that are not in B.

```
C = setdiff(A,B)
```

C =

```

Var1 Var2 Var3
---- ---- ----
2 B true
4 D true

```

### Difference of Two Vectors and Indices to Different Values

Define two vectors with values in common.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
```

Find the values in A that are not in B as well as the index vector `ia`, such that `C = A(ia)`.

```
[C,ia] = setdiff(A,B)
```

C =

```
1 3 5
```

ia =

```
4
1
```

5

**Difference of Two Tables and Indices to Different Rows**

Define a table, A, of gender, age, and height for five people.

```
A = table(['M';'M';'F';'M';'F'],[27;52;31;46;35],[74;68;64;61;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty' 'Bob' 'Judy'})
```

A =

	Gender	Age	Height
	-----	---	-----
Ted	M	27	74
Fred	M	52	68
Betty	F	31	64
Bob	M	46	61
Judy	F	35	64

Define a table, B, with the same variables as A.

```
B = table(['F';'M';'F';'F'],[64;68;62;58],[31;47;35;23],...
'VariableNames',{'Gender' 'Height' 'Age'},...
'RowNames',{'Meg' 'Joe' 'Beth' 'Amy'})
```

B =

	Gender	Height	Age
	-----	-----	---
Meg	F	64	31
Joe	M	68	47
Beth	F	62	35
Amy	F	58	23

Find the rows in A that are not in B, as well as the index vector `ia`, such that `C = A(ia,:)`.

```
[C,ia] = setdiff(A,B)
```

C =

	Gender	Age	Height
	-----	---	-----
Judy	F	35	64
Ted	M	27	74

Bob	M	46	61
Fred	M	52	68

```
ia =
 5
 1
 4
 2
```

The rows of **C** are in sorted order first by **Gender** and next by **Age**.

### Difference of Rows in Two Matrices

Define two matrices with rows in common.

```
A = [7 9 7; 0 0 0; 7 9 7; 5 5 5; 1 4 5];
B = [0 0 0; 5 5 5];
```

Find the rows from **A** that are not in **B** as well as the index vector **ia**, such that **C** = **A(ia,:)**.

```
[C,ia] = setdiff(A,B,'rows')
```

```
C =
 1 4 5
 7 9 7
```

```
ia =
 5
 1
```

### Difference of Two Vectors with Specified Output Order

Use the **setOrder** argument to specify the ordering of the values in **C**.

Specify **'stable'** or **'sorted'** when the order of the values in **C** are important.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
[C,ia] = setdiff(A,B,'stable')
```

```
C =
```

```
 3 1 5
ia =
 1
 4
 5
```

Alternatively, you can specify 'sorted' order.

```
[C,ia] = setdiff(A,B,'sorted')
C =
 1 3 5
ia =
 4
 1
 5
```

## Difference of Vectors Containing NaNs

Define two vectors containing NaN.

```
A = [5 NaN NaN]; B = [5 NaN];
```

Find the set difference of A and B.

```
C = setdiff(A,B)
```

```
C =
 NaN NaN
```

setdiff treats NaN values as distinct.

## Cell Array of Strings with Trailing White Space

Create a cell array of strings, A.

```
A = {'dog','cat','fish','horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ','cat','fish ','horse'};
```

Find the strings in A that are not in B.

```
[C,ia] = setdiff(A,B)
```

```
C =
```

```
 'dog' 'fish'
```

```
ia =
```

```
 1
 3
```

setdiff treats trailing white space in cell arrays of strings as distinct characters.

### Difference of Char and Cell Array of Strings

Create a character array, A.

```
A = ['cat'; 'dog'; 'fox'; 'pig'];
class(A)
```

```
ans =
```

```
char
```

Create a cell array of strings, B.

```
B={'dog', 'cat', 'fish', 'horse'};
class(B)
```

```
ans =
```

```
cell
```

Find the strings in A that are not in B.

```
C = setdiff(A,B)
```

```
C =
```

```
 'fox'
 'pig'
```

The result, C, is a cell array of strings.

```
class(C)
```

```
ans =
```

```
cell
```

## Preserve Legacy Behavior of `setdiff`

Use the `'legacy'` flag to preserve the behavior of `setdiff` from R2012b and prior releases in your code.

Find the difference of A and B with the current behavior.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
[C1,ia1] = setdiff(A,B)
```

```
C1 =
```

```
 1 3 5
```

```
ia1 =
```

```
 4
 1
 5
```

Find the difference of A and B, and preserve the legacy behavior.

```
[C2,ia2] = setdiff(A,B, 'legacy')
```

```
C2 =
```

```
 1 3 5
```

```
ia2 =
```

```
 7 1 5
```

## Input Arguments

### A, B — Input arrays

numeric arrays | logical arrays | character arrays | categorical arrays | datetime arrays  
| duration arrays | cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, cell arrays of strings, or tables.

A and B must belong to the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.
- Datetime arrays can combine with cell arrays of date strings or single date strings.

If A and B are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither A nor B are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names. In this case, the categories of C are the sorted union of the categories from A and B.

If you specify the `'rows'` option, A and B must have the same number of columns.

If A and B are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

If A and B are datetime arrays, they must be consistent with each other in whether they specify a time zone.

Furthermore, A and B can be objects with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)
- `eq`
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

### setOrder – Order flag

`'sorted'` (default) | `'stable'`

Order flag, specified as `'sorted'` or `'stable'`, indicates the order of the values (or rows) in C.

Order Flag	Meaning
<code>'sorted'</code>	The values (or rows) in C return in sorted order. For example: <code>C = setdiff([4 1 3 2],[2 1],'sorted')</code> returns <code>C = [3 4]</code> .

Order Flag	Meaning
'stable'	The values (or rows) in <b>C</b> return in the same order as in <b>A</b> . For example: <code>C = setdiff([4 1 3 2],[2 1],'stable')</code> returns <code>C = [4 3]</code> .

## Output Arguments

### **C** — Difference of **A** and **B**

vector | matrix | table

Difference of **A** and **B**, returned as a vector, matrix, or table. If the inputs **A** and **B** are tables, the order of the variables in the resulting table, **C**, is the same as the order of the variables in **A**.

The following describes the shape of **C** when the inputs are vectors or matrices and when the 'legacy' flag is not specified:

- If the 'rows' flag is not specified and **A** is a row vector, then **C** is a row vector.
- If the 'rows' flag is not specified and **A** is not a row vector, then **C** is a column vector.
- If the 'rows' flag is specified, then **C** is a matrix containing the rows of **A** that are not in **B**.
- If all the values (or rows) of **A** are also in **B**, then **C** is an empty matrix.

The class of **C** is the same as the class of **A**, unless:

- **A** is a character array and **B** is a cell array of strings, in which case **C** is a cell array of strings.
- **A** is a cell array of strings or single string and **B** is a categorical array, in which case **C** is a categorical array.
- **A** is a cell array of strings or single string and **B** is a datetime array, in which case **C** is a datetime array.

### **ia** — Index to **A**

column vector

Index to **A**, returned as a column vector when the 'legacy' flag is not specified. **ia** identifies the values (or rows) in **A** that are not in **B**. If there is a repeated value (or row)

appearing exclusively in **A**, then **ia** contains the index to the first occurrence of the value (or row).

## More About

### Tips

- To find the set difference with respect to a subset of variables from a table, you can use column subscripting. For example, you can use `setdiff(A(:,vars),B(:,vars))`, where *vars* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.
- “Combine Categorical Arrays”

**Introduced before R2006a**

## setDirectory

**Class:** Tiff

Make specified IFD current IFD

### Syntax

```
setDirectory(tiffobj,dirNum)
```

### Description

`setDirectory(tiffobj,dirNum)` sets the image file directory (IFD) specified by `dirNum` as the current IFD. Tiff object methods operate on the current IFD. The directory index number is one-based.

### Examples

Open a TIFF file and move to an IFD in the file by specifying its index number. The TIFF file should contain multiple images.

```
t = Tiff('example.tif','r');
setDirectory(t,2)
close(t)
```

### References

This method corresponds to the `TIFFSetDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

### See Also

`Tiff.currentDirectory` | `Tiff.nextDirectory`

## setenv

Set environment variable

### Syntax

```
setenv(name,value)
setenv(name)
```

### Description

`setenv(name,value)` sets the value of an environment variable belonging to the underlying operating system. Inputs `name` and `value` are both strings. If `name` exists as an environment variable, then `setenv` replaces its current value with the string given in `value`. If `name` does not exist, `setenv` creates an environment variable called `name` and assigns `value` to it.

`setenv(name)` is equivalent to `setenv(name, '')` and assigns a null value to the variable `name`. On the Microsoft Windows platform, this syntax is equivalent to undefining the variable. On most UNIX platforms, it is possible to have an environment variable defined as empty.

The maximum number of characters in `name` is  $2^{15} - 2$  (or 32766). If `name` contains the character `=`, `setenv` throws an error. The behavior of environment variables with `=` in the name is not well-defined.

On all platforms, `setenv` passes the `name` and `value` strings to the operating system unchanged. Special characters such as `;`, `/`, `:`, `$`, `%`, etc. are left unexpanded and intact in the variable value.

A process that is spawned using the `MATLAB system`, `unix`, `dos`, or `!` functions reads the values assigned to variables using the `setenv` function. You can retrieve any value set with `setenv` by using `getenv(name)`.

### Examples

Set and retrieve a new value for the environment variable `TEMP`:

```
setenv('TEMP', 'C:\TEMP');
getenv('TEMP')
```

Append the Perl\bin folder to your system PATH variable:

```
setenv('PATH', [getenv('PATH') 'D:\Perl\bin']);
```

## **See Also**

getenv | system | unix | dos | !

# setfield

Assign values to structure array field

## Syntax

```
s = setfield(s, 'field', value)
s = setfield(s, {sIndx1, ..., sIndxM}, 'field',
{fIndx1, ..., fIndxN}, value)
```

## Description

`s = setfield(s, 'field', value)`, where `s` is a 1-by-1 structure, sets the contents of the specified field, equivalent to `s.field = value`. If `s` does not contain the specified `field`, the `setfield` function creates the field and assigns the specified value. Pass field references as strings.

`s = setfield(s, {sIndx1, ..., sIndxM}, 'field', {fIndx1, ..., fIndxN}, value)` sets the contents of the specified field, equivalent to `s(sIndx1, ..., sIndxM).field(fIndx1, ..., fIndxN) = value`. The `setfield` function supports multiple sets of `field` and `fIndx` inputs. If structure `s` or any of the fields is a nonscalar structure, the `Indx` inputs associated with that input are required. Otherwise, the `Indx` inputs are optional. If you specify a single colon operator for an index input, enclose it in single quotation marks: `' : '`.

## Examples

Add values to a structure that contains nested fields:

```
grades = [];
level = 5;
semester = 'Fall';
subject = 'Math';
student = 'John_Doe';
fieldnames = {semester subject student}
newGrades_Doe = [85, 89, 76, 93, 85, 91, 68, 84, 95, 73];
```

```
grades = setfield(grades, {level}, ...
 fieldnames{:}, {10, 21:30}, ...
 newGrades_Doe);
```

```
% View the new contents.
grades(level).(semester).(subject).(student)(10, 21:30)
```

Using the structure defined in the previous example, remove the tenth row of the specified field:

```
grades = setfield(grades, {level}, fieldnames{:}, {10,':'}, []);
```

## More About

### Tips

- For most cases, add data to a structure array by indexing rather than using the `setfield` function. For more information, see “Access Data in a Structure Array” and “Generate Field Names from Variables”.
- Call `setfield` to simplify references to structure arrays with nested fields, as shown in the Examples section.
- “Generate Field Names from Variables”
- “Access Data in a Structure Array”

### See Also

`getfield` | `fieldnames` | `isfield` | `orderfields` | `rmfield`

**Introduced before R2006a**

# setpixelposition

Set component position in pixels

## Syntax

```
setpixelposition(handle,position)
setpixelposition(handle,position,recursive)
```

## Description

`setpixelposition(handle,position)` sets the position, in pixels, of the component specified by `handle`. The `position` argument is a four-element vector that specifies the location and size of the component: [pixels from left, pixels from bottom, pixels across, pixels high]. The first two values in this vector are the number of pixels from the left and bottom edge of the parent container. The last two values specify the width and height of the component.

`setpixelposition(handle,position,recursive)` sets the position as above. If Boolean `recursive` is true, the position is set relative to the parent figure of `handle`.

## Examples

This example first creates a push button within a panel.

```
f = figure('Position',[300 300 300 200]);
p = uipanel('Position',[.2 .2 .6 .6]);
h1 = uicontrol(p,'Style','PushButton',...
 'Units','normalized',...
 'String','Push Button',...
 'Position',[.1 .1 .5 .2]);
```

The example then retrieves the position of the push button and changes its position with respect to the panel.

```
pos1 = getpixelposition(h1);
setpixelposition(h1,pos1 + [10 10 25 25]);
```

## More About

### Pixels

Distances in pixels are independent of your system resolution on Windows and Macintosh systems:

- On Windows systems, a pixel is 1/96th of an inch.
- On Macintosh systems, a pixel is 1/72nd of an inch.

On Linux systems, the size of a pixel is determined by your system resolution.

### See Also

`getpixelposition` | `uicontrol` | `uipanel`

## setpref

Set preference

### Syntax

```
setpref('group','pref',val)
setpref('group',{'pref1','pref2',...,'prefn'},{val1,val2,...,valn})
```

### Description

`setpref('group','pref',val)` sets the preference specified by `group` and `pref` to the value `val`. Individual preference values can be any MATLAB data type, including numeric types, strings, cell arrays, structures, and objects. Setting a preference that does not yet exist causes it to be created.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g., `'MathWorks_GUIDE_ApplicationPrefs'`. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`setpref('group',{'pref1','pref2',...,'prefn'},{val1,val2,...,valn})` sets each preference specified in the cell array of names to the corresponding value.

---

**Note** Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

---

### Examples

Use `addpref` to create a preference group called `mytoolbox` and a preference within it called `version`, and then modify the contents of `version` using `setpref`:

```
addpref('mytoolbox','version','1.0')
getpref('mytoolbox','version')
```

```
ans =
```

1.0

```
setpref('mytoolbox','version',{'1.0','beta'})
getpref('mytoolbox','version')
```

```
ans =
 '1.0' 'beta'
```

**Introduced before R2006a**

## **setstr**

Set string flag

---

**Note:** `setstr` is not recommended. Use `char` instead.

---

## **Description**

This MATLAB 4 function has been renamed `char` in MATLAB 5.

**Introduced before R2006a**

# setSubDirectory

**Class:** Tiff

Make subIFD specified by byte offset current IFD

## Syntax

```
setSubDirectory(tiffobj,offset)
```

## Description

`setSubDirectory(tiffobj,offset)` sets the subimage file directory (subIFD) specified by `offset` the current IFD. The offset value is given in bytes. Use this method when you want to access subIFDs linked through the SubIFD tag.

## Examples

### Set Subimage File Directory

Open a TIFF file and read the value of the SubIFD tag in the current IFD. The SubIFD tag contains byte offsets that specify the location of subIFDs in the IFD. The TIFF file should contain subIFDs.

```
t = Tiff('example.tif', 'r');
```

Read the value of the SubIFD tag to get subdirectory offsets.

```
offsets = getTag(t, 'SubIFD');
```

Set one of the subdirectories (if more than one) as the current directory.

```
setSubDirectory(t,offsets(1))
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## References

This method corresponds to the `TIFFSetSubDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

## See Also

`Tiff.setDirectory`

## setTag

**Class:** Tiff

Set value of tag

## Syntax

```
setTag(tiffobj, tagId, tagValue)
setTag(tiffobj, tagStruct)
```

## Description

`setTag(tiffobj, tagId, tagValue)` sets the value of the TIFF tag specified by `tagId` to the value specified by `tagValue`. You can specify `tagId` as a character string ('ImageWidth') or using the numeric tag identifier defined by the TIFF specification (256). To see a list of all the tags with their numeric identifiers, view the value of the Tiff object `TagID` property. Use the `TagID` property to specify the value of a tag. For example, `Tiff.TagID.ImageWidth` is equivalent to the tag's numeric identifier.

`setTag(tiffobj, tagStruct)` sets the values of all of the tags with name/value fields in `tagStruct`. The names of fields in `tagstruct` must be the name of TIFF tags.

---

**Note:** If you are modifying a tag rather than creating it, you must use the `Tiff.rewriteDirectory` method after using the `Tiff.setTag` method.

---

## Examples

### Set Tag Values

Write TIFF tags and image data to a new TIFF file.

Read sample data into an array, `imdata`. Create a `Tiff` object associated with a new file, `myfile.tif`, and open the file for writing.

```
imdata = imread('example.tif');
```

```
t = Tiff('myfile.tif','w');
```

Set tag values by specifying the numeric tag identifier. Use the `TagID` property to obtain the tag identifier.

```
setTag(t,Tiff.TagID.ImageLength,size(imdata,1))
setTag(t,Tiff.TagID.ImageWidth,size(imdata,2))
```

Set tag values by specifying the tag name.

```
setTag(t,'Photometric',Tiff.Photometric.RGB)
setTag(t,'PlanarConfiguration',Tiff.PlanarConfiguration.Chunky)
```

Create a structure with fields named after TIFF tags and assign values to the fields. Pass this structure to the `setTag` method to set the values of these tags.

```
tagStruct.BitsPerSample = 8;
tagStruct.SamplesPerPixel = 3;
tagStruct.TileWidth = 128;
tagStruct.TileLength = 128;
tagStruct.Compression = Tiff.Compression.JPEG;
tagStruct.Software = 'MATLAB';
setTag(t,tagStruct)
```

Write the image data to the TIFF file.

```
write(t,imdata)
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## References

This method corresponds to the `TIFFSetField` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

## settimeseriesnames

Change name of `timeseries` object in `tscollection`

### Syntax

```
tsc = settimeseriesnames(tsc,old,new)
```

### Description

`tsc = settimeseriesnames(tsc,old,new)` replaces the old name of `timeseries` object with the new name in `tsc`.

### See Also

`tscollection`

**Introduced before R2006a**

## setxor

Set exclusive OR of two arrays

### Syntax

```
C = setxor(A,B)
C = setxor(A,B, 'rows')
[C,ia,ib] = setxor(A,B)
[C,ia,ib] = setxor(A,B, 'rows')

[C,ia,ib] = setxor(____, setOrder)

[C,ia,ib] = setxor(A,B, 'legacy')
[C,ia,ib] = setxor(A,B, 'rows', 'legacy')
```

### Description

`C = setxor(A,B)` returns the data of `A` and `B` that are not in their intersection (the symmetric difference).

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `setxor` returns the values that occur in `A` or `B`, but not both. The values of `C` are in sorted order.
- If `A` and `B` are tables, then `setxor` returns the rows that occur in one or the other of the two tables, but not both. The rows of table `C` are in sorted order.

`C = setxor(A,B, 'rows')` treats each row of `A` and each row of `B` as single entities and returns the rows of matrices `A` and `B` that are not in their intersection. The rows of `C` are in sorted order.

The `'rows'` option does not support cell arrays, unless one of the inputs is either a categorical array or a datetime array.

`[C,ia,ib] = setxor(A,B)` also returns index vectors `ia` and `ib`.

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `C` is a sorted combination of the elements `A(ia)` and `B(ib)`.

- If A and B are tables, then C is a sorted combination of the rows of A(ia,:) and B(ib,:).

[C,ia,ib] = setxor(A,B,'rows') also returns index vectors ia and ib, such that C is a sorted combination of the rows of A(ia,:) and B(ib,:).

[C,ia,ib] = setxor( \_\_\_\_,setOrder) returns C in a specific order using any of the input arguments in the previous syntaxes. setOrder='sorted' returns the values (or rows) of C in sorted order. setOrder='stable' returns the values (or rows) of C in the same order as A and B. If no value is specified, the default is 'sorted'.

[C,ia,ib] = setxor(A,B,'legacy') and [C,ia,ib] = setxor(A,B,'rows','legacy') preserve the behavior of the setxor function from R2012b and prior releases.

The 'legacy' option does not support categorical arrays, tables, datetime arrays, or duration arrays.

## Examples

### Symmetric Difference of Two Vectors

Define two vectors with a value in common.

```
A = [5 1 3 3 3]; B = [4 1 2];
```

Find the values of A and B that are not in their intersection.

```
C = setxor(A,B)
```

```
C =
```

```
 2 3 4 5
```

### Symmetric Difference of Two Tables

Define two tables with rows in common.

```
A = table([1:5]', ['A'; 'B'; 'C'; 'D'; 'E'], logical([0;1;0;1;0]))
B = table([1:2:10]', ['A'; 'C'; 'E'; 'G'; 'I'], logical(zeros(5,1)))
```

```
A =
```

Var1	Var2	Var3
1	A	false
2	B	true
3	C	false
4	D	true
5	E	false

B =

Var1	Var2	Var3
1	A	false
3	C	false
5	E	false
7	G	false
9	I	false

Find the rows of A and B that are not in their intersection.

C = setxor(A,B)

C =

Var1	Var2	Var3
2	B	true
4	D	true
7	G	false
9	I	false

## Symmetric Difference of Two Vectors and Indices to Different Values

Define two vectors with a value in common.

A = [5 1 3 3 3]; B = [4 1 2];

Find the values of A and B that are not in their intersection as well as the index vectors **ia** and **ib**.

[C,ia,ib] = setxor(A,B)

C =

```

 2 3 4 5

ia =

 3
 1

ib =

 3
 1

```

C is a sorted combination of the elements A(ia) and B(ib).

### Symmetric Difference of Two Tables and Indices to Different Rows

Define a table, A, of gender, age, and height for five people.

```

A = table(['M';'M';'F'],[27;52;31],[74;68;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty'})

```

```

A =

 Gender Age Height
 ----- --- -----
Ted M 27 74
Fred M 52 68
Betty F 31 64

```

Define a table, B, with the same variables as A.

```

B = table(['F';'M'],[64;68],[31;47],...
'VariableNames',{'Gender' 'Height' 'Age'},...
'RowNames',{'Meg' 'Joe'})

```

```

B =

 Gender Height Age
 ----- ----- ---
Meg F 64 31
Joe M 68 47

```

Find the rows of A and B that are not in their intersection, as well as the index vectors `ia` and `ib`.

```
[C,ia,ib] = setxor(A,B)
```

```
C =
```

	Gender	Age	Height
	-----	---	-----
Ted	M	27	74
Joe	M	47	68
Fred	M	52	68

```
ia =
```

```
1
2
```

```
ib =
```

```
2
```

C is a sorted combination of the elements `A(ia,:)` and `B(ib,:)`.

## Symmetric Difference of Rows in Two Matrices

Define two matrices with rows in common.

```
A = [7 8 9; 7 7 1; 7 7 1; 1 2 3; 4 5 6];
B = [1 2 3; 4 5 6; 7 7 2];
```

Find the rows of A and B that are not in their intersection as well as the index vectors `ia` and `ib`.

```
[C,ia,ib] = setxor(A,B,'rows')
```

```
C =
```

7	7	1
7	7	2
7	8	9

```
ia =
```

```
 2
 1
```

```
ib =
```

```
 3
```

C is a sorted combination of the rows of A(ia,:) and B(ib,).

### Symmetric Difference of Two Vectors in Specified Order

Use the `setOrder` argument to specify the ordering of the values in C.

Specify `'stable'` if you want the values in C to have the same order as A and B.

```
A = [5 1 3 3 3]; B = [4 1 2];
[C,ia,ib] = setxor(A,B,'stable')
```

```
C =
```

```
 5 3 4 2
```

```
ia =
```

```
 1
 3
```

```
ib =
```

```
 1
 3
```

Alternatively, you can specify `'sorted'` order.

```
[C,ia,ib] = setxor(A,B,'sorted')
```

```
C =
```

```
 2 3 4 5
```

```
ia =

 3
 1
```

```
ib =

 3
 1
```

## Symmetric Difference of Vectors Containing NaNs

Define two vectors containing NaN.

```
A = [5 NaN NaN]; B = [5 NaN NaN];
```

Find the symmetric difference of vectors A and B.

```
C = setxor(A,B)
```

```
C =

 NaN NaN NaN NaN
```

The `setxor` function treats NaN values as distinct.

## Cell Array of Strings with Trailing White Space

Create a cell array of strings, A.

```
A = {'dog','cat','fish','horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ','cat','fish ','horse'};
```

Find the strings that are not in the intersection of A and B.

```
[C,ia,ib] = setxor(A,B)
```

```
C =

 'dog' 'dog ' 'fish' 'fish '
```

```
ia =
 1
 3
```

```
ib =
 1
 3
```

`setxor` treats trailing white space in cell arrays of strings as distinct characters.

### Symmetric Difference of Vectors of Different Classes and Shapes

Create a column vector character array.

```
A = ['A'; 'B'; 'C'], class(A)
```

```
A =
```

```
A
B
C
```

```
ans =
```

```
char
```

Create a row vector containing elements of numeric type `double`.

```
B = [66 67 68], class(B)
```

```
B =
```

```
 66 67 68
```

```
ans =
```

```
double
```

Find the symmetric difference of A and B.

```
C = setxor(A,B)
```

```
C =
```

```
A
```

```
D
```

The result is a column vector character array.

```
class(C)
```

```
ans =
```

```
char
```

## Symmetric Difference of Char and Cell Array of Strings

Create a character array, A.

```
A = ['cat'; 'dog'; 'fox'; 'pig'];
class(A)
```

```
ans =
```

```
char
```

Create a cell array of strings, B.

```
B={'dog', 'cat', 'fish', 'horse'};
class(B)
```

```
ans =
```

```
cell
```

Find the strings that are not in the intersection of A and B.

```
C = setxor(A,B)
```

```
C =
```

```
 'fish'
 'fox'
 'horse'
 'pig'
```

The result, `C`, is a cell array of strings.

```
class(C)
```

```
ans =
```

```
cell
```

### Preserve Legacy Behavior of `setxor`

Use the `'legacy'` flag to preserve the behavior of `setxor` from R2012b and prior releases in your code.

Find the symmetric difference of `A` and `B` with the current behavior.

```
A = [5 1 3 3 3]; B = [4 1 2 2];
[C1,ia1,ib1] = setxor(A,B)
```

```
C1 =
```

```
 2 3 4 5
```

```
ia1 =
```

```
 3
 1
```

```
ib1 =
```

```
 3
 1
```

Find the symmetric difference and preserve the legacy behavior.

```
[C2,ia2,ib2] = setxor(A,B,'legacy')
```

```
C2 =
```

```
 2 3 4 5
```

```
ia2 =
```

```
 5 1
ib2 =
 4 1
```

## Input Arguments

### A, B — Input arrays

numeric arrays | logical arrays | character arrays | categorical arrays | datetime arrays  
| duration arrays | cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, cell arrays of strings, or tables.

A and B must belong to the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.
- Datetime arrays can combine with cell arrays of date strings or single date strings.

If A and B are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither A nor B are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names. In this case, the categories of C are the sorted union of the categories from A and B.

If you specify the `'rows'` option, A and B must have the same number of columns.

If A and B are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

If A and B are datetime arrays, they must be consistent with each other in whether they specify a time zone.

Furthermore, A and B can be objects with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)

- eq
- ne

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

### setOrder — Order flag

'sorted' (default) | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in **C**.

Order Flag	Meaning
'sorted'	The values (or rows) in <b>C</b> return in sorted order. For example: <code>C = setxor([5 1 3],[4 1 2],'sorted')</code> returns <code>C = [2 3 4 5]</code> .
'stable'	The values (or rows) in <b>C</b> return in the same order as in <b>A</b> and <b>B</b> . For example: <code>C = setxor([5 1 3],[4 1 2],'stable')</code> returns <code>C = [5 3 4 2]</code> .

## Output Arguments

### **C** — Symmetric difference array

vector | matrix | table

Symmetric difference array, returned as a vector, matrix, or table. If the inputs **A** and **B** are tables, the order of the variables in the resulting table, **C**, is the same as the order of the variables in **A**.

The following describes the shape of **C** when the inputs are vector or matrices and when the 'legacy' flag is not specified:

- If the 'rows' flag is not specified, then **C** is a column vector unless both **A** and **B** are row vectors.
- If the 'rows' flag is not specified and both **A** and **B** are row vectors, then **C** is a row vector.

- If the 'rows' flag is specified, then **C** is a matrix containing the rows of **A** and **B** that are not in the intersection.
- If all the values (or rows) of **A** are also in **B**, then **C** is an empty matrix.

The class of the inputs **A** and **B** determines the class of **C**:

- If the class of **A** and **B** are the same, then **C** is the same class.
- If you combine a `char` or nondouble numeric class with `double`, then **C** is the same class as the nondouble input.
- If you combine a `logical` class with `double`, then **C** is `double`.
- If you combine a cell array of strings with `char`, then **C** is a cell array of strings.
- If you combine a categorical array with a cell array of strings or single string, then **C** is a categorical array.
- If you combine a datetime array with a cell array of date strings or single date string, then **C** is a datetime array.

## **ia** — Index to A

column vector

Index to **A**, returned as a column vector when the 'legacy' flag is not specified. **ia** identifies the values (or rows) in **A** that contribute to the symmetric difference. If there is a repeated value (or row) appearing exclusively in **A**, then **ia** contains the index to the first occurrence of the value (or row).

## **ib** — Index to B

column vector

Index to **B**, returned as a column vector when the 'legacy' flag is not specified. **ib** identifies the values (or rows) in **B** that contribute to the symmetric difference. If there is a repeated value (or row) appearing exclusively in **B**, then **ib** contains the index to the first occurrence of the value (or row).

## More About

### Tips

- To find the symmetric difference with respect to a subset of variables from a table, you can use column subscripting. For example, you can use

`setxor(A(:,vars),B(:,vars))`, where *vars* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

- “Combine Categorical Arrays”

**Introduced before R2006a**

# shading

Set color shading properties

## Syntax

```
shading flat
shading faceted
shading interp
shading(axes_handle,...)
```

## Description

The `shading` function controls the color shading of surface and patch graphics objects.

`shading flat` each mesh line segment and face has a constant color determined by the color value at the endpoint of the segment or the corner of the face that has the smallest index or indices.

`shading faceted` flat shading with superimposed black mesh lines. This is the default shading mode.

`shading interp` varies the color in each line segment and face by interpolating the colormap index or true color value across the line or face.

`shading(axes_handle,...)` applies the shading type to the objects in the axes specified by `axes_handle`, instead of the current axes. Use quoted strings when using a function form. For example:

```
shading(gca,'interp')
```

## Examples

### Display Sphere with Different Types of Shading

Plot the `sphere` function and use different types of shading.

```
figure
subplot(2,2,1)
```

```
sphere(16)
title('Faceted Shading (Default)')
```

```
subplot(2,2,2)
sphere(16)
shading flat
title('Flat Shading')
```

```
subplot(2,2,3)
sphere(16)
shading interp
title('Interpolated Shading')
```

**Faceted Shading (Default)**

**Flat Shading**

**Interpolated Shading**

## More About

### Algorithms

`shading` sets the `EdgeColor` and `FaceColor` properties of all surface and patch graphics objects in the current axes. `shading` sets the appropriate values, depending on whether the surface or patch objects represent meshes or solid surfaces.

### See Also

`fill` | `fill3` | `hidden` | `light` | `lighting` | `mesh` | `patch` | `pcolor` | `surf`

**Introduced before R2006a**

## **shg**

Show most recent graph window

### **Syntax**

shg

### **Description**

shg makes the current figure visible and raises it above all other figures on the screen. This is identical to using the command `figure(gcf)`.

### **See Also**

`figure` | `gca` | `gcf`

# shiftdim

Shift dimensions

## Syntax

```
B = shiftdim(X,n)
[B,nshifts] = shiftdim(X)
```

## Description

`B = shiftdim(X,n)` shifts the dimensions of `X` by `n`. When `n` is positive, `shiftdim` shifts the dimensions to the left and wraps the `n` leading dimensions to the end. When `n` is negative, `shiftdim` shifts the dimensions to the right and pads with singletons.

`[B,nshifts] = shiftdim(X)` returns the array `B` with the same number of elements as `X` but with any leading singleton dimensions removed. A singleton dimension is any dimension for which `size(A,dim) = 1`. `nshifts` is the number of dimensions that are removed.

If `X` is a scalar, `shiftdim` has no effect.

## Examples

The `shiftdim` command is handy for creating functions that, like `sum` or `diff`, work along the first nonsingleton dimension.

```
a = rand(1,1,3,1,2);
[b,n] = shiftdim(a); % b is 3-by-1-by-2 and n is 2.
c = shiftdim(b,-n); % c == a.
d = shiftdim(a,3); % d is 1-by-2-by-1-by-1-by-3.
```

## See Also

`circshift` | `reshape` | `squeeze` | `permute` | `ipermute`

Introduced before R2006a

# showplottool

Show or hide figure plot tool

## Syntax

```
showplottool('tool')
showplottool('on', 'tool')
showplottool('off', 'tool')
showplottool('toggle', 'tool')
showplottool(figure_handle, ...)
```

## Description

`showplottool('tool')` shows the specified plot tool on the current figure. *tool* can be one of the following strings:

- `figurepalette`
- `plotbrowser`
- `propertyeditor`

`showplottool('on', 'tool')` shows the specified plot tool on the current figure.

`showplottool('off', 'tool')` hides the specified plot tool on the current figure.

`showplottool('toggle', 'tool')` toggles the visibility of the specified plot tool on the current figure.

`showplottool(figure_handle, ...)` operates on the specified figure instead of the current figure.

---

**Note:** When you dock, undock, resize, or reposition a plotting tool and then close it, it will still be configured as you left it the next time you open it. There is no command to reset plotting tools to their original, default locations.

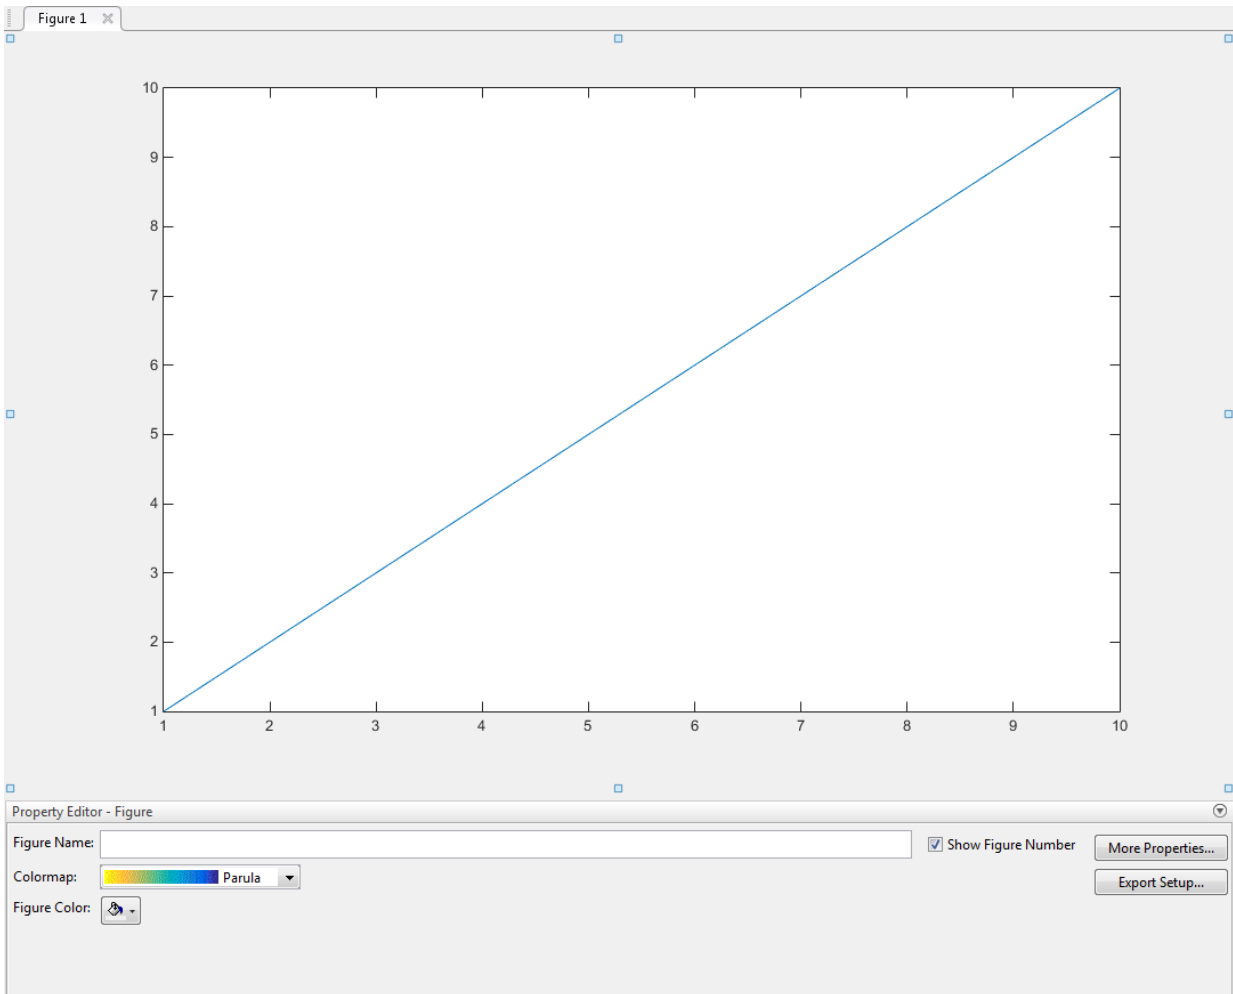

---

## Examples

### Open One of the Plot Tools

Create a simple plot and open the property editor.

```
plot(1:10);
showplottool('propertyeditor')
```

## Alternatives

Click the larger Plotting Tools icon  on the figure toolbar to collectively enable plotting tools, and the smaller icon  to collectively disable them. Individually select

the **Figure Palette**, **Plot Browser**, and **Property Editor** tools from the figure's **View** menu. For details, see “Customize Graph Using Plot Tools”.

### **See Also**

figurepalette | plotbrowser | plottools | propertyeditor

**Introduced before R2006a**

## shrinkfaces

Reduce size of patch faces

### Syntax

```
shrinkfaces(p,sf)
nfv = shrinkfaces(p,sf)
nfv = shrinkfaces(fv,sf)
shrinkfaces(p)
nfv = shrinkfaces(f,v,sf)
[nf,nv] = shrinkfaces(...)
```

### Description

`shrinkfaces(p,sf)` shrinks the area of the faces in patch `p` to shrink factor `sf`. A shrink factor of 0.6 shrinks each face to 60% of its original area. If the patch contains shared vertices, the MATLAB software creates nonshared vertices before performing the face-area reduction.

`nfv = shrinkfaces(p,sf)` returns the face and vertex data in the struct `nfv`, but does not set the Faces and Vertices properties of patch `p`.

`nfv = shrinkfaces(fv,sf)` uses the face and vertex data from the struct `fv`.

`shrinkfaces(p)` and `shrinkfaces(fv)` (without specifying a shrink factor) assume a shrink factor of 0.3.

`nfv = shrinkfaces(f,v,sf)` uses the face and vertex data from the arrays `f` and `v`.

`[nf,nv] = shrinkfaces(...)` returns the face and vertex data in two separate arrays instead of a struct.

### Examples

This example uses the flow data set, which represents the speed profile of a submerged jet within an infinite tank (type `help flow` for more information). Two isosurfaces provide a before and after view of the effects of shrinking the face size.

- First `reducevolume` samples the flow data at every other point and then `isosurface` generates the faces and vertices data.
- The `patch` command accepts the face/vertex struct and draws the first (`p1`) isosurface.
- Use the `daspect`, `view`, and `axis` commands to set up the view and then add a `title`.
- The `shrinkfaces` command modifies the face/vertex data and passes it directly to `patch`.

```
[x,y,z,v] = flow;
[x,y,z,v] = reducevolume(x,y,z,v,2);
fv = isosurface(x,y,z,v,-3);
p1 = patch(fv);
p1.FaceColor = 'red';
p1.EdgeColor = [0.5 0.5 0.5];
daspect([1 1 1]);
view(3);
axis tight
title('Original')
```

```
figure
p2 = patch(shrinkfaces(fv,.3));
p2.FaceColor = 'red';
p2.EdgeColor = [0.5 0.5 0.5];
daspect([1 1 1]);
view(3);
axis tight
title('After Shrinking')
```

### After Shrinking

## sign

Sign function (signum function)

### Syntax

```
sign(x)
```

### Description

$Y = \text{sign}(x)$  returns an array  $Y$  the same size as  $x$ , where each element of  $Y$  is:

- 1 if the corresponding element of  $x$  is greater than 0.
- 0 if the corresponding element of  $x$  equals 0.
- -1 if the corresponding element of  $x$  is less than 0.
- $x ./ \text{abs}(x)$  if  $x$  is complex.

### Examples

#### Find Sign Function

Find the sign function of a number.

```
sign(2)
```

```
ans =
```

```
1
```

Find the sign function of the values of a vector.

```
V = [-11 0 1.5 Inf NaN];
sign(V)
```

```
ans =
 -1 0 1 1 NaN
```

Find the sign function of the values of a matrix.

```
M = magic(3) - 5;
sign(M)
```

```
ans =
 1 -1 1
 -1 0 1
 -1 1 -1
```

Find the sign function of a complex number.

```
z = 4 - 3*i;
sign(z)
```

```
ans =
 0.8000 - 0.6000i
```

### Plot Sign Function

Plot the sign function and show its behavior at the zero-crossing. Use `eps` to represent values just above and below 0.

```
x = [-5 -eps(1) 0 eps(1) 5];
y = sign(x);
plot(x,y)
ylim([-2 2])
grid on
```

### Plot Real and Imaginary Parts of Sign Function

Plot real and imaginary parts of the sign function over  $-3 < x < 3$  and  $-3 < y < 3$ .

First, create a mesh of values over  $-3 < x < 3$  and  $-3 < y < 3$  using `meshgrid`. Then create complex numbers from these values using  $z = x + 1i*y$ .

```
v = -3:0.1:3;
[x, y] = meshgrid(v);
z = x + 1i*y;
```

Find the real and imaginary parts of the sign function of  $z$ .

```
s = sign(z);
```

```
re = real(s);
im = imag(s);
```

Plot the real and imaginary parts.

```
surf(x,y,re)
title('Real part of sign function')
xlabel('x')
ylabel('y')
figure(2)
surf(x,y,im)
title('Imaginary part of sign function')
xlabel('x')
ylabel('y')
```

## Input Arguments

### **x** — Input

number | vector | matrix | multidimensional array

Input, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Complex Number Support: Yes

## More About

### Sign Function

The value of the sign function,  $\text{sign}(x)$ , for:

- $x > 0$  is 1.
- $x = 0$  is 0.
- $x < 0$  is -1.
- complex  $x$  is  $x/|x|$ .

### See Also

`abs` | `conj` | `imag` | `real`

**Introduced before R2006a**

## **sin**

Sine of argument in radians

### **Syntax**

`Y = sin(X)`

### **Description**

`Y = sin(X)` returns the sine of the elements of `X`. The `sin` function operates element-wise on arrays. The function accepts both real and complex inputs. For real values of `X` in the interval `[-Inf, Inf]`, `sin` returns real values in the interval `[-1, 1]`. For complex values of `X`, `sin` returns complex values. All angles are in radians.

### **Examples**

#### **Plot Sine Function**

Plot the sine function over the domain  $-\pi \leq x \leq \pi$ .

```
x = -pi:0.01:pi;
plot(x,sin(x)), grid on
```

### Sine of Vector of Complex Angles

Calculate the sine of the complex angles in vector  $x$ .

```
x = [-i pi+i*pi/2 -1+i*4];
y = sin(x)
```

y =

```
0.0000 - 1.1752i 0.0000 - 2.3013i -22.9791 +14.7448i
```

## Input Arguments

### **X** — Input angle in radians

number | vector | matrix | multidimensional array

Input angle in radians, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Y** — Sine of input angle

scalar value | vector | matrix | N-D array

Sine of input angle, returned as a real-valued or complex-valued scalar, vector, matrix or N-D array.

## More About

### Sine Function

The sine of an angle,  $\alpha$ , defined with reference to a right angled triangle is

$$\sin(\alpha) = \frac{\text{opposite side}}{\text{hypotenuse}} = \frac{a}{h}.$$

The sine of a complex angle,  $\alpha$ , is

$$\sin(\alpha) = \frac{e^{i\alpha} - e^{-i\alpha}}{2i}.$$

### See Also

asin | asind | sind | sinh

Introduced before R2006a

## sind

Sine of argument in degrees

### Syntax

```
Y = sind(X)
```

### Description

`Y = sind(X)` returns the sine of the elements in `X`, which are expressed in degrees.

### Examples

#### Sine of 180 degrees compared to sine of $\pi$ radians

```
sind(180)
```

```
ans =
```

```
0
```

```
sin(pi)
```

```
ans =
```

```
1.2246e-16
```

#### Sine of vector of complex angles, specified in degrees

```
z = [90+i 15+2i 10+3i];
```

```
y = sind(z)
```

```
y =
```

1.0002      0.2590 + 0.0337i      0.1739 + 0.0516i

## Input Arguments

### **X** — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `sind` operation is element-wise when `X` is nonscalar.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Y** — Sine of angle

scalar value | vector | matrix | N-D array

Sine of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

## See Also

`asin` | `asind` | `sin`

**Introduced before R2006a**

# single

Convert to single precision

## Syntax

```
B = single(A)
```

## Description

`B = single(A)` converts the matrix `A` to single precision, returning that value in `B`. `A` can be any numeric object (such as a `double`). If `A` is already single precision, `single` has no effect. Single-precision quantities require less storage than double-precision quantities, but have less precision and a smaller range.

The `single` class is primarily meant to be used to store single-precision values. Hence most operations that manipulate arrays without changing their elements are defined. Examples are `reshape`, `size`, the relational operators, subscripted assignment, and subscripted reference.

You can define your own methods for the `single` class by placing the appropriately named method in an `@single` folder within a folder on your path.

## Examples

```
a = magic(4);
b = single(a);
```

```
whos
 Name Size Bytes Class

 a 4x4 128 double array
 b 4x4 64 single array
```

## More About

**Introduced before R2006a**

## sinh

Hyperbolic sine of argument in radians

### Syntax

$Y = \sinh(X)$

### Description

The `sinh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \sinh(X)$  returns the hyperbolic sine of the elements of  $X$ .

### Examples

#### Graph of Hyperbolic Sine Function

Graph the hyperbolic sine over the domain  $-5 \leq x \leq 5$ .

```
x = -5:0.01:5;
plot(x, sinh(x)), grid on
```

## More About

### Hyperbolic Sine

The hyperbolic sine of  $z$  is

$$\sinh(z) = \frac{e^z - e^{-z}}{2}.$$

### See Also

**Introduced before R2006a**

# size

Array dimensions

## Syntax

```
d = size(X)
[m,n] = size(X)
m = size(X,dim)
[d1,d2,d3,...,dn] = size(X),
```

## Description

`d = size(X)` returns the sizes of each dimension of array `X` in a vector, `d`, with `ndims(X)` elements.

- If `X` is a scalar, then `size(X)` returns the vector `[1 1]`. Scalars are regarded as a 1-by-1 arrays in MATLAB.
- If `X` is a table, `size(X)` returns a two-element row vector consisting of the number of rows and the number of variables in the table. Variables in the table can have multiple columns, but `size` only counts the variables and rows.

`[m,n] = size(X)` returns the size of matrix `X` in separate variables `m` and `n`.

`m = size(X,dim)` returns the size of the dimension of `X` specified by scalar `dim`.

`[d1,d2,d3,...,dn] = size(X)`, for `n > 1`, returns the sizes of the dimensions of the array `X` in the variables `d1,d2,d3,...,dn`, provided the number of output arguments `n` equals `ndims(X)`. If `n` does not equal `ndims(X)`, the following exceptions hold:

- |                              |                                                                                                                                                                                                                                                                                                |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n &lt; ndims(X)</code> | <code>di</code> equals the size of the <code>i</code> th dimension of <code>X</code> for <code>0 &lt; i &lt; n</code> , but <code>dn</code> equals the product of the sizes of the remaining dimensions of <code>X</code> , that is, dimensions <code>n</code> through <code>ndims(X)</code> . |
| <code>n &gt; ndims(X)</code> | <code>size</code> returns ones in the “extra” variables, that is, those corresponding to <code>ndims(X)+1</code> through <code>n</code> .                                                                                                                                                      |

**Note** For a Java array, `size` returns the length of the Java array as the number of rows. The number of columns is always 1. For a Java array of arrays, the result describes only the top level array.

---

## Examples

### Size of Dimensions in 3-D Array

Find the size of `rand(2,3,4)`.

```
d = size(rand(2,3,4))
```

```
d =
```

```
 2 3 4
```

The size is output as a single vector.

Find the size of the second dimension of `rand(2,3,4)`.

```
m = size(rand(2,3,4),2)
```

```
m =
```

```
 3
```

The size is output as a scalar.

Assign the size of each dimension to a separate variable.

```
[m,n,p] = size(rand(2,3,4))
```

```
m =
```

```
 2
```

```
n =
```

```
 3
```

```
p =
```

4

**Size of Table**

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith'; 'Johnson'; 'Williams'; 'Jones'; 'Brown'};
Age = [38; 43; 38; 40; 49];
Height = [71; 69; 64; 67; 64];
Weight = [176; 163; 131; 133; 119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
X = table(Age, Height, Weight, BloodPressure, 'RowNames', LastName)
```

```
X =
```

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Find the size of the table.

```
d = size(X)
```

```
d =
```

```
5 4
```

`size` counts four variables, even though the variable `BloodPressure` contains two columns.

**Specify Different Number of Outputs than `ndims(X)`**

Assign the size of each dimension to a separate variable where the number of outputs matches the number of dimensions.

```
X = ones(3,4,5);
[d1,d2,d3] = size(X)
```

```
d1 =
```

3

d2 =

4

d3 =

5

There is one output for each dimension of  $X$ .

Specify fewer output variables than `ndims(X)`.

```
[d1,d2] = size(X)
```

d1 =

3

d2 =

20

The “extra” dimensions are collapsed into a single product.

Specify more output variables than `ndims(X)`.

```
[d1,d2,d3,d4,d5,d6] = size(X)
```

d1 =

3

d2 =

4

d3 =

```
5
d4 =
 1
d5 =
 1
d6 =
 1
```

The “extra” variables all represent singleton dimensions.

### **See Also**

`exist` | `length` | `ndims` | `numel` | `whos`

**Introduced before R2006a**

## size

**Class:** containers.Map

**Package:** containers

Size of `containers.Map` object

## Syntax

```
dim = size(mapObj,1)
dimVector = size(mapObj)
[dim1,dim2,...,dimN] = size(mapObj)
```

## Description

`dim = size(mapObj,1)` returns a scalar numeric value that indicates the number of key-value pairs in `mapObj`. If you call `size` with a numeric second input argument other than 1, the `size` method returns the scalar numeric value 1.

`dimVector = size(mapObj)` returns a two-element vector `[k,1]`, where `k` is the number of key-value pairs in `mapObj`.

`[dim1,dim2,...,dimN] = size(mapObj)` returns `[k,1,...,1]`.

## Input Arguments

**mapObj**

Object of class `containers.Map`.

## Output Arguments

**dim**

Scalar numeric value that indicates the number of key-value pairs in `mapObj`.

## **dimVector**

Two-element numeric vector `[k, 1]`, where `k` is the number of key-value pairs in `mapObj`.

## **[dim1, dim2, ..., dimN]**

Numeric scalar values. Variable `dim1` equals `k`, where `k` is the number of key-value pairs in `mapObj`. All other outputs equal 1.

# Examples

## Determine the Size of a Map

Construct a map and find the number of key-value pairs:

```
myKeys = {'a', 'b', 'c'};
myValues = [1, 2, 3];
mapObj = containers.Map(myKeys, myValues);
dim = size(mapObj, 1)
```

This code returns a scalar numeric value:

```
dim =
 3
```

If you do not specify a second input argument,

```
dimVector = size(mapObj)
```

then the `size` method returns a vector:

```
dimVector =
 3 1
```

## See Also

[isKey](#) | [keys](#) | [values](#) | [containers.Map](#) | [length](#)

## size

**Class:** matlab.io.MatFile

**Package:** matlab.io

Array dimensions

## Syntax

```
allDims = size(matObj,variable)
[dim1,...,dimN] = size(matObj,variable)
selectedDim = size(matObj,variable,dim)
```

## Description

`allDims = size(matObj,variable)` returns the size of each dimension of the specified variable in the file corresponding to `matObj`. Output `allDims` is a 1-by-`m` vector, where `m = ndims(variable)`.

`[dim1,...,dimN] = size(matObj,variable)` returns the sizes of each dimension in separate output variables `dim1,...,dimN`.

`selectedDim = size(matObj,variable,dim)` returns the size of the specified dimension.

## Tips

- Do not call `size` with the syntax `size(matObj.variable)`. This syntax loads the entire contents of the variable into memory. For very large variables, this load operation results in **Out of Memory** errors.

## Input Arguments

**matObj**

Object created by the `matfile` function.

**variable**

String enclosed in single quotation marks that specifies the name of a variable in the MAT-file corresponding to `matObj`.

**dim**

Nonzero positive scalar integer that specifies a dimension of the variable.

## Output Arguments

**allDims**

1-by-`m` vector of sizes of the dimensions of the specified variable, where `m = ndims(variable)`.

**dim1, ..., dimN**

Scalar numeric values, where `dimK` contains the size of the `K`th dimension of `variable`:

- If `N < ndims(variable)`, then `dimN`, equals the product of the sizes of dimensions `N` through `ndims(variable)`.
- If `N > ndims(variable)`, the `size` method returns ones in the output variables corresponding to dimensions `ndims(variable)+1` through `N`.

**selectedDim**

Scalar numeric value that contains the size of the selected dimension for the specified variable.

## Examples

Find the size of the matrix `topo` in `topography.mat` without loading any data:

```
matObj = matfile('topography.mat');
[nrows,ncols] = size(matObj,'topo');
```

Determine the dimensions of a variable, and process one part of the variable at a time. In this case, calculate and store the average of each column of variable `stocks` in the example file `stocks.mat`:

```
filename = 'stocks.mat';
matObj = matfile(filename);
[nrows, ncols] = size(matObj, 'stocks');

avgs = zeros(1,ncols);
for idx = 1:ncols
 avgs(idx) = mean(matObj.stocks(:,idx));
end
```

Create a three-dimensional array, and call the `size` method with different numbers of output arguments:

```
matObj = matfile('temp.mat', 'Writable', true);
matObj.X = rand(2,3,4);

d = size(matObj, 'X')
d2 = size(matObj, 'X', 2)
[m, n] = size(matObj, 'X')
[m1, m2, m3, m4] = size(matObj, 'X')
```

This code returns

```
d =
 2 3 4

d2 =
 3

m =
 2
n =
 12

m1 =
 2
m2 =
 3
m3 =
 4
m4 =
 1
```

## See Also

`whos` | `matfile`

## size (serial)

Size of serial port object array

### Syntax

```
d = size(obj)
[m,n] = size(obj)
[m1,m2,m3,...,mn] = size(obj)
m = size(obj,dim)
```

### Description

`d = size(obj)` returns the two-element row vector `d` containing the number of rows and columns in the serial port object, `obj`.

`[m,n] = size(obj)` returns the number of rows, `m` and columns, `n` in separate output variables.

`[m1,m2,m3,...,mn] = size(obj)` returns the length of the first `n` dimensions of `obj`.

`m = size(obj,dim)` returns the length of the dimension specified by the scalar `dim`. For example, `size(obj,1)` returns the number of rows.

### See Also

length

Introduced before R2006a

## size

**Class:** TriRep

(Not recommended) Size of triangulation matrix

---

**Note:** `size(TriRep)` is not recommended. Use `size(triangulation)` instead.

`TriRep` is not recommended. Use `triangulation` instead.

---

## Syntax

`size(TR)`

## Description

`size(TR)` provides size information for a triangulation matrix. The matrix is of size `mtri-by-nv`, where `mtri` is the number of simplices and `nv` is the number of vertices per simplex (triangle/tetrahedron, etc).

## Input Arguments

TR            Triangulation matrix

## Definitions

A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

## See Also

`size` | `triangulation` | `delaunayTriangulation`

## size (tscollection)

Size of tscollection object

### Syntax

```
size(tsc)
```

### Description

`size(tsc)` returns `[n m]`, where `n` is the length of the time vector and `m` is the number of `tscollection` members.

### See Also

`length (tscollection)` | `isempty (tscollection)` | `tscollection`

**Introduced before R2006a**

# slice

Volumetric slice plot

## Syntax

```
slice(V, sx, sy, sz)
slice(X, Y, Z, V, sx, sy, sz)
slice(V, XI, YI, ZI)
slice(X, Y, Z, V, XI, YI, ZI)
slice(..., 'method')
slice(axes_handle, ...)
h = slice(...)
```

## Description

`slice` displays orthogonal slice planes through volumetric data.

`slice(V, sx, sy, sz)` draws slices along the  $x$ ,  $y$ ,  $z$  directions in the volume  $V$  at the points in the vectors `sx`, `sy`, and `sz`.  $V$  is an  $m$ -by- $n$ -by- $p$  volume array containing data values at the default location  $X = 1:n$ ,  $Y = 1:m$ ,  $Z = 1:p$ . Each element in the vectors `sx`, `sy`, and `sz` defines a slice plane in the  $x$ -,  $y$ -, or  $z$ -axis direction.

`slice(X, Y, Z, V, sx, sy, sz)` draws slices of the volume  $V$ .  $X$ ,  $Y$ , and  $Z$  are three-dimensional arrays specifying the coordinates for  $V$ .  $X$ ,  $Y$ , and  $Z$  must be monotonic and orthogonally spaced (as if produced by the function `meshgrid`). The color at each point is determined by 3-D interpolation into the volume  $V$ .

`slice(V, XI, YI, ZI)` draws data in the volume  $V$  for the slices defined by `XI`, `YI`, and `ZI`. `XI`, `YI`, and `ZI` are matrices that define a surface, and the volume is evaluated at the surface points. `XI`, `YI`, and `ZI` must all be the same size.

`slice(X,Y,Z,V,XI,YI,ZI)` draws slices through the volume `V` along the surface defined by the arrays `XI`, `YI`, `ZI`.

`slice(..., 'method')` specifies the interpolation method. '`method`' is '`linear`', '`cubic`', or '`nearest`'.

- `linear` specifies trilinear interpolation (the default).
- `cubic` specifies tricubic interpolation.
- `nearest` specifies nearest-neighbor interpolation.

`slice(axes_handle, ...)` plots into the axes with the handle `axes_handle` instead of into the current axes object (`gca`). The axes `clim` property is set to span the finite values of `V`.

`h = slice(...)` returns a vector of handles to surface graphics objects.

## Examples

Visualize the function

$$v = xe^{(-x^2-y^2-z^2)}$$

over the range  $-2 \leq x \leq 2$ ,  $-2 \leq y \leq 2$ ,  $-2 \leq z \leq 2$ :

```
[x,y,z] = meshgrid(-2:.2:2,-2:.25:2,-2:.16:2);
v = x.*exp(-x.^2-y.^2-z.^2);
xslice = [-1.2,.8,2];
yslice = 2;
zslice = [-2,0];
slice(x,y,z,v,xslice,yslice,zslice)
colormap hsv
```

## Slicing At Arbitrary Angles

You can also create slices that are oriented in arbitrary planes. To do this,

- Create a slice surface in the domain of the volume (`surf`, `linspace`).
- Orient this surface with respect to the axes (`rotate`).
- Get the XData, YData, and ZData of the surface.
- Use this data to draw the slice plane within the volume.

For example, these statements slice the volume in the first example with a rotated plane. Placing these commands within a `for` loop “passes” the plane through the volume along the `z`-axis.

```
[x,y,z] = meshgrid(-2:.2:2,-2:.25:2,-2:.16:2);
v = x.*exp(-x.^2-y.^2-z.^2);
figure
colormap hsv
for k = -2:.05:2
 hsp = surf(linspace(-2,2,20),linspace(-2,2,20),...
 zeros(20) + k);
```

```

rotate(hsp,[1,-1,1],30)
xd = hsp.XData;
yd = hsp.YData;
zd = hsp.ZData;
delete(hsp)

slice(x,y,z,v,[-2,2],2,-2) % Draw some volume boundaries
hold on
slice(x,y,z,v,xd,yd,zd)
hold off
view(-5,10)
axis([-2.5 2.5 -2 2 -2 4])
drawnow
end

```

The following picture illustrates three positions of the same slice surface as it passes through the volume.

## Slicing with a Nonplanar Surface

You can slice the volume with any surface. This example probes the volume created in the previous example by passing a spherical slice surface through the volume.

```
[xsp,ysp,zsp] = sphere;
slice(x,y,z,v,[-2,2],2,-2)
colormap hsv
for i = -3:2:3
 hsp = surface(xsp+i,ysp,zsp);
 rotate(hsp,[1 0 0],90)
 xd = hsp.XData;
 yd = hsp.YData;
 zd = hsp.ZData;
 delete(hsp)
 hold on
 hslider = slice(x,y,z,v,xd,yd,zd);
 axis tight
 xlim([-3,3])
 view(-10,35)
 drawnow
 delete(hslider)
 hold off
end
```

The following picture illustrates three positions of the spherical slice surface as it passes through the volume.

## More About

### Tips

The color drawn at each point is determined by interpolation into the volume  $V$ .

## smooth3

Smooth 3-D data

### Syntax

### Description

`W = smooth3(V)` smooths the input data `V` and returns the smoothed data in `W`.

`W = smooth3(V, 'filter')` *filter* determines the convolution kernel and can be the strings

- 'gaussian'
- 'box' (default)

`W = smooth3(V, 'filter', size)` sets the size of the convolution kernel (default is [3 3 3]). If `size` is scalar, then `size` is interpreted as [size, size, size].

`W = smooth3(V, 'filter', size, sd)` sets an attribute of the convolution kernel. When *filter* is gaussian, `sd` is the standard deviation (default is .65).

### Examples

This example smooths some random 3-D data and then creates an isosurface with end caps.

```
rng(9, 'twister')
data = rand(10,10,10);
data = smooth3(data, 'box', 5);
patch(isocaps(data, .5), ...
 'FaceColor', 'interp', 'EdgeColor', 'none');
p1 = patch(isosurface(data, .5), ...
 'FaceColor', 'blue', 'EdgeColor', 'none');
isonormals(data, p1)
view(3);
axis vis3d tight
camlight left;
```

```
colormap jet
lighting gouraud
```

## snapnow

Force snapshot of image for inclusion in published document

### Syntax

snapnow

### Description

The `snapnow` command forces a snapshot of the image or plot that the code has most recently generated for presentation in a published document. The output appears in the published document at the end of the cell that contains the `snapnow` command. When used outside the context of publishing a file, `snapnow` has the same behavior as `drawnow`. That is, if you run a file that contains the `snapnow` command, the MATLAB software interprets it as though it were a `drawnow` command.

### Examples

This example demonstrates the difference between publishing code that contains the `snapnow` command and running that code. The first image shows the results of publishing the code and the second image shows the results of running the code.

Suppose you have a file that contains the following code:

```
%% Scale magic Data and
%% Display as Image:

for i=1:3
 imagesc(magic(i))
 snapnow
end
```

When you publish the code to HTML, the published document contains a title, a table of contents, the commented text, the code, and each of the three images produced by the `for` loop. (In the published document shown, the size of the images have been reduced.)

## Scale magic Data and

### Contents

- [Display as Image:](#)

### Display as Image:

```
for i=1:3
 imagesc(magic(i))
 snapnow
end
```

When you run the code, a single Figure window opens and MATLAB updates the image within this window as it evaluates each iteration of the `for` loop. Each successive image replaces the one that preceded it, so that the Figure window appears as follows when the code evaluation completes.

## sort

Sort array elements

### Syntax

```
B = sort(A)
B = sort(A,dim)
B = sort(____,direction)
[B,I] = sort(____)
```

### Description

`B = sort(A)` sorts the elements of `A` in ascending order along the first array dimension whose size does not equal 1.

- If `A` is a vector, then `sort(A)` sorts the vector elements.
- If `A` is a matrix, then `sort(A)` treats the columns of `A` as vectors and sorts each column.
- If `A` is a multidimensional array, then `sort(A)` operates along the first array dimension whose size does not equal 1, treating the elements as vectors.

`B = sort(A,dim)` returns the sorted elements of `A` along dimension `dim`. For example, if `A` is a matrix, then `sort(A,2)` sorts the elements in each row.

`B = sort( ____,direction)` returns sorted elements of `A` in the order specified by `direction` using any of the previous syntaxes. The single string, `'ascend'`, indicates ascending order (default) and `'descend'` indicates descending order.

`[B,I] = sort( ____ )` also returns a collection of index vectors for any of the previous syntaxes. `I` is the same size as `A` and describes the arrangement of the elements of `A` into `B` along the sorted dimension. For example, if `A` is a numeric vector, `B = A(I)`.

### Examples

#### Sort Vector in Ascending Order

Create a row vector and sort its elements in ascending order.

A = [9 0 -7 5 3 8 -10 4 2];  
B = sort(A)

B =

-10    -7    0    2    3    4    5    8    9

## Sort Matrix Rows in Ascending Order

Create a matrix and sort each of its rows in ascending order.

A = [3 6 5; 7 -2 4; 1 0 -9]

A =

3    6    5  
7    -2    4  
1    0    -9

B = sort(A,2)

B =

3    5    6  
-2    4    7  
-9    0    1

## Sort Matrix Columns in Descending Order

Create a matrix and sort its columns in descending order.

A = [10 -12 4 8; 6 -9 8 0; 2 3 11 -2; 1 1 9 3]

A =

10    -12    4    8  
6    -9    8    0  
2    3    11    -2  
1    1    9    3

```
B = sort(A, 'descend')
```

```
B =
```

```

10 3 11 8
 6 1 9 3
 2 -9 8 0
 1 -12 4 -2
```

### Sort and Index datetime Array

Create an array of `datetime` values and sort them in ascending order, that is, from the earliest to the latest calendar date.

```
ds = {'2012-12-22'; '2063-04-05'; '1992-01-12'};
A = datetime(ds, 'Format', 'yyyy-MM-dd')
```

```
A =
```

```

2012-12-22
2063-04-05
1992-01-12
```

```
[B, I] = sort(A)
```

```
B =
```

```

1992-01-12
2012-12-22
2063-04-05
```

```
I =
```

```

3
1
2
```

**B** lists the sorted dates and **I** contains the corresponding indices of **A**.

Access the sorted elements from the original array directly by using the index array I.

A(I)

ans =

```
1992-01-12
2012-12-22
2063-04-05
```

## Sort 3-D Array

Create a 2-by-2-by-2 array and sort its elements in ascending order along the third dimension.

```
A(:,:,1) = [2 3; 1 6];
A(:,:,2) = [-1 9; 0 12];
A
```

A(:,:,1) =

```
2 3
1 6
```

A(:,:,2) =

```
-1 9
0 12
```

B = sort(A,3)

B(:,:,1) =

```
-1 3
0 6
```

B(:,:,2) =

```
2 9
1 12
```

Use `A(:)`, the column representation of `A`, to sort all of the elements of `A`.

```
B = sort(A(:))
```

```
B =
```

```
-1
 0
 1
 2
 3
 6
 9
12
```

## Input Arguments

### **A** — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

- If `A` is a scalar, then `sort(A)` returns `A`.
- If `A` is an empty 0-by-0 matrix, then `sort(A)` returns an empty 0-by-0 matrix.
- If `A` contains NaN values or undefined `categorical` or `datetime` elements, then `sort(A)` places them on the high end of the sort (as if they were large numbers).
- If `A` is complex, then `sort(A)` sorts the elements by magnitude. If more than one element has equal magnitude, the elements are sorted by phase angle on the interval  $[-\pi, \pi]$ .
- If `A` is a string, then `sort(A)` sorts according to the ASCII dictionary order. The sort is case-sensitive with uppercase letters appearing in the output before the lowercase letters.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `cell` | `categorical` | `datetime` | `duration`

Complex Number Support: Yes

**dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, *A*:

- `sort(A,1)` sorts the elements in the columns of *A*.

- `sort(A,2)` sorts the elements in the rows of *A*.

`sort` returns *A* if `dim` is greater than `ndims(A)`. If *A* is a cell array, then `dim` is not supported.

**direction** — Sorting direction

'ascend' (default) | 'descend'

Sorting direction, specified as 'ascend' or 'descend'. If *A* is a cell array, then `direction` is not supported.

Example: `sort(A,2,'descend')` sorts the rows of *A* in descending order.

Data Types: char

## Output Arguments

### **B — Sorted array**

vector | matrix | multidimensional array

Sorted array, returned as a vector, matrix, or multidimensional array the same size and type as **A**. The ordering of the elements in **B** preserves the order of any equal elements in **A**.

### **I — Sort index**

vector | matrix | multidimensional array

Sort index, returned as a vector, matrix, or multidimensional array the same size as **A**. The index vectors are oriented along the same dimension that `sort` operates on. For example, if **A** is a 2-by-3 matrix, then `[B, I] = sort(A, 2)` sorts the elements in each row of **A**. **I** is a collection of 1-by-3 row index vectors describing the rearrangement. If you do not specify `dim`, then `[B, I] = sort(A)` sorts the columns of **A**, and **I** is a collection of 2-by-1 column index vectors.

## More About

### Tips

- The `sortrows` function provides additional flexibility for subsorting over multiple columns of nonvector input arrays.
- The `sort` function and the relational operators use different orderings for complex numbers. For more information, see “Relational Operations”.
- “Shifting and Sorting Matrices”

### See Also

Introduced before R2006a

## sortrows

Sort array rows

### Syntax

```
B = sortrows(A)
B = sortrows(A,column)
[B,index] = sortrows(___)

tblB = sortrows(tblA)
tblB = sortrows(tblA, 'RowNames')
tblB = sortrows(tblA,vars)

tblB = sortrows(tblA,mode)
tblB = sortrows(tblA, 'RowNames',mode)
tblB = sortrows(tblA,vars,mode)

[tblB,index] = sortrows(tblA, ___)
```

### Description

`B = sortrows(A)` sorts the rows of `A` in ascending order of the first column. Strings are sorted in the familiar dictionary order, which uses ASCII values. When the first column has equal values, `sortrows` sorts according to the next column and repeats this behavior for succeeding equal values.

`B = sortrows(A,column)` sorts matrix `A` based on the columns specified in the vector, `column`. This input is used to perform multiple column sorts in succession. For equal values, the original order is preserved.

`[B,index] = sortrows( ___ )` also returns an index vector using any of the previous syntaxes. The index vector satisfies `B = A(index,:)`.

`tblB = sortrows(tblA)` sorts the rows of table `tblA` in ascending order by the first variable, then by the second variable, and so on.

`tblB = sortrows(tblA, 'RowNames' )` sorts by the row names.

`tblB = sortrows(tblA,vars)` sorts by the variables specified by `vars`.

`tblB = sortrows(tblA,mode)` and `tblB = sortrows(tblA,'RowNames',mode)` sorts `tblA` in the order specified by `mode`. The single string, `'ascend'`, indicates ascending order (default) and `'descend'` indicates descending order.

`tblB = sortrows(tblA,vars,mode)` uses `mode` to specify the sort order. `mode` can be a single string or a cell array of strings containing `'ascend'` for ascending order (default) or `'descend'` for descending order.

- When `mode` is a single string, `sortrows` sorts in the specified direction for all variables in `vars`.
- When `mode` is a cell array of strings, `sortrows` sorts in the specified direction for each variable in `vars`.

`[tblB,index] = sortrows(tblA, ___)` also returns an index vector, `index`, such that `tblB = tblA(index,:)`.

## Examples

### Sort Rows of Matrix

Start with an arbitrary matrix, `A`.

```
A = floor(gallery('uniformdata',[6 7],0)*100);
A(1:4,1) = 95; A(5:6,1) = 76; A(2:4,2) = 7; A(3,3) = 73
```

```
A =
 95 45 92 41 13 1 84
 95 7 73 89 20 74 52
 95 7 73 5 19 44 20
 95 7 40 35 60 93 67
 76 61 93 81 27 46 83
 76 79 91 0 19 41 1
```

Sort the rows of `A`.

```
B = sortrows(A)
```

```
B =
 76 61 93 81 27 46 83
 76 79 91 0 19 41 1
 95 7 40 35 60 93 67
```

```
95 7 73 5 19 44 20
95 7 73 89 20 74 52
95 45 92 41 13 1 84
```

When called with only a single input argument, `sortrows` bases the sort on the first column of the matrix. For any rows that have equal elements in a particular column, (e.g., `A(1:4,1)` for this matrix), sorting is based on the column immediately to the right, (`A(1:4,2)` in this case).

When called with two input arguments, `sortrows` bases the sort entirely on the column specified in the second argument.

Sort the rows of `A` based on the values in the second column.

```
C = sortrows(A,2)
```

```
C =
 95 7 73 89 20 74 52
 95 7 73 5 19 44 20
 95 7 40 35 60 93 67
 95 45 92 41 13 1 84
 76 61 93 81 27 46 83
 76 79 91 0 19 41 1
```

Rows that have equal elements in the specified column, (e.g., `A(2:4, :)`, if sorting matrix `A` by column 2) remain in their original order.

Specify two columns to sort by: columns 1 and 7.

```
D = sortrows(A,[1 7])
```

```
D =
 76 79 91 0 19 41 1
 76 61 93 81 27 46 83
 95 7 73 5 19 44 20
 95 7 73 89 20 74 52
 95 7 40 35 60 93 67
 95 45 92 41 13 1 84
```

`sortrows` sorts by column 1 first, and then for any rows with equal values in column 1, sorts by column 7.

Sort the rows in descending order using the values in column 4.

```
[E,index] = sortrows(A, -4)
```

```
E =
 95 7 73 89 20 74 52
 76 61 93 81 27 46 83
 95 45 92 41 13 1 84
 95 7 40 35 60 93 67
 95 7 73 5 19 44 20
 76 79 91 0 19 41 1
```

```
index =
 2
 5
 1
 4
 3
 6
```

The index vector, `index`, describes the rearrangement of the rows, such that `E = A(index,:)`.

### Sort Rows of Cell Array

Create a 6-by-2 cell array of strings.

```
A = {'Germany' 'Lukas'; 'USA' 'William'; 'USA' 'Andrew'; ...
 'Germany' 'Andreas'; 'USA' 'Olivia'; 'Germany' 'Julia'}
```

```
A =
 'Germany' 'Lukas'
 'USA' 'William'
 'USA' 'Andrew'
 'Germany' 'Andreas'
 'USA' 'Olivia'
 'Germany' 'Julia'
```

The result is a list of countries and names.

Sort the rows of `A`.

```
B = sortrows(A)
```

```
B =
```

```
'Germany' 'Andreas'
'Germany' 'Julia'
'Germany' 'Lukas'
'USA' 'Andrew'
'USA' 'Olivia'
'USA' 'William'
```

The result is an alphabetized list sorted by both country and name.

Sort the names in the second column in descending order.

```
[C,index] = sortrows(A,[1 -2])
```

C =

```
'Germany' 'Lukas'
'Germany' 'Julia'
'Germany' 'Andreas'
'USA' 'William'
'USA' 'Olivia'
'USA' 'Andrew'
```

index =

```
1
6
4
2
5
3
```

The index vector, `index`, describes the rearrangement of the rows, such that `C = A(index,:)`.

## Sort Rows of Table

Sort the rows of a table by the variable values in ascending order.

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith'; 'Johnson'; 'Williams'; 'Jones'; 'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
```

```
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];

tblA = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)

tblA =
```

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Sort the rows of the table.

```
tblB = sortrows(tblA)

tblB =
```

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Williams	38	64	131	125	83
Smith	38	71	176	124	93
Jones	40	67	133	117	75
Johnson	43	69	163	109	77
Brown	49	64	119	122	80

The `sortrows` function sorts the rows in ascending order first by the variable `Age`, and then it sorts by the variable `Height`.

### Sort Rows of Table by Row Names

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];

tblA = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)

tblA =
```

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Sort the rows of the table by the row names and return an index vector, such that `tblB = tblA(index,:)`.

```
[tblB,index] = sortrows(tblA, 'RowNames')
```

```
tblB =
```

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Brown	49	64	119	122	80
Johnson	43	69	163	109	77
Jones	40	67	133	117	75
Smith	38	71	176	124	93
Williams	38	64	131	125	83

```
index =
```

```
5
2
4
1
3
```

The `sortrows` function sorts the rows in ascending order by the row names.

## Sort Rows of Table by Variables

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith'; 'Johnson'; 'Williams'; 'Jones'; 'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
tblA = table(Age,Height,Weight,BloodPressure, 'RowNames', LastName)
```

```
tblA =
```

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Sort the rows of the table in ascending order by **Height**, and then sort in descending order by **Weight**. Also, return an index vector, such that `tblB = tblA(index,:)`.

```
[tblB,index] = sortrows(tblA,{'Height','Weight'},{'ascend','descend'})
```

```
tblB =
```

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Williams	38	64	131	125	83
Brown	49	64	119	122	80
Jones	40	67	133	117	75
Johnson	43	69	163	109	77
Smith	38	71	176	124	93

```
index =
```

```
3
5
4
2
1
```

## Input Arguments

### A — Input array

column vector | matrix

Input array, specified as a column vector or matrix. The data type of **A** can be numeric, logical, char, cell, categorical, datetime, or duration. If **A** contains NaN values or undefined categorical or datetime elements, `sortrows(A)` places them on the high end of the sort (as if they are large numbers).

When **A** is complex, `sortrows` sorts the elements by magnitude, and, where magnitudes are equal, further sorts by phase angle on the interval  $[-\pi, \pi]$ .

Complex Number Support: Yes

**column** — Column sorting vector

vector of integers

Column sorting vector, specified as a vector of integers. Each integer value indicates a column to sort by. The sign of the integer indicates ascending (positive) or descending (negative) sort order.

Example: `sortrows(A, [2 -3])` sorts the rows of **A** first in ascending order for the second column, and then it sorts by descending order for the third column.

**tblA** — Input table

table

Input table, specified as a table. Each variable in **tblA** must be a valid input to `sort` or `sortrows`.

Data Types: table

**'RowNames'** — Row sort input

string

Row sort input, specified as the string **'RowNames'**. Specify the **'RowNames'** option to sort a table by row names rather than by variables. If `tblA.Properties.RowNames` is empty, `sortrows(tblA, 'RowNames')` returns **tblA**.

**vars** — Sorting variables

integer | vector of integers | variable name | cell array of variable names | logical vector

Sorting variables, specified as an integer, a vector of integers, a variable name, a cell array of variable names, or a logical vector. **vars** indicates the table variables to sort by. You also can use the `mode` input to indicate ascending or descending order for each sorting variable.

If an element of **vars** is a positive integer, `sortrows` sorts the corresponding variable in **tblA** in ascending order. If an element of **vars** is a negative integer, `sortrows` sorts the corresponding variable in **tblA** in descending order. If you provide the `mode` input argument, MATLAB ignores the sign of the integers.

Example: `sortrows(tblA, {'Height', 'Weight'})` sorts the rows of **tblA** in ascending order, first by the variable **Height**, and then it sorts by the variable **Weight**.

Example: `sortrows(tblA,[1 4],{'descend' 'ascend'})` sorts the first variable of `tblA` in descending order, then it sorts the fourth variable in ascending order.

**mode — Sorting mode**

single string | cell array of strings

Sorting mode, specified as a single string or cell array of strings composed of the options 'ascend' (default), or 'descend'. If `mode` is a cell array of strings, the number of required entries depends on whether you are sorting by variables or by row names.

- If `tblA` is being sorted by variables, the cell array must have an entry for each variable.
- If `tblA` is being sorted by row names, the cell array must have one entry.

Data Types: `char` | `cell`

## Output Arguments

**B — Sorted array**

array

Sorted array, returned as an array of the same size and class as `A`.

**tblB — Sorted table**

table

Sorted table, returned as a table with the same variables as `tblA`.

**index — Sort index**

index vector

Sort index, returned as an index vector. The sort index describes the rearrangement of elements or rows in the input.

**See Also**

`issorted` | `sort`

Introduced before R2006a

## sound

Convert matrix of signal data to sound

### Syntax

```
sound(y)
sound(y, Fs)
sound(y, Fs, nBits)
```

### Description

`sound(y)` sends audio signal `y` to the speaker at the default sample rate of 8192 hertz.

`sound(y, Fs)` sends audio signal `y` to the speaker at sample rate `Fs`.

`sound(y, Fs, nBits)` uses `nBits` bits per sample for audio signal `y`.

### Examples

#### Play Sample Data at Default Sample Rate

Load the example file `gong.mat`, which contains sample data `y` and rate `Fs`, and listen to the audio.

```
load gong.mat;
sound(y);
```

#### Play Sample Data at Specific Sample Rate

Play an excerpt from Handel's "Hallelujah Chorus" at twice the recorded sample rate.

```
load handel.mat;
sound(y, 2*Fs);
```

#### Play Sample Data with Specific Bit Depth

```
load handel.mat;
nBits = 16;
```

```
sound(y,Fs,nBits);
```

MATLAB plays the audio with a bit depth of 16 bits per sample, if this is supported on your system.

## Input Arguments

### **y** — Audio data

column vector |  $m$ -by-2 matrix

Audio data, specified as an  $m$ -by-1 column vector for single-channel (mono) audio, or an  $m$ -by-2 matrix for stereo playback, where  $m$  is the number of audio samples. If **y** is an  $m$ -by-2 matrix, then the first column corresponds to the left channel, and the second column corresponds to the right channel. Stereo playback is available only if your system supports it.

Data Types: double

### **Fs** — Sample rate

8192 (default) | positive number

Sample rate, in hertz, of audio data **y**, specified as a positive number between 80 and 1000000.

Data Types: single | double

### **nBits** — Bit depth of sample values

8 (default) | 16 | 24

Bit depth of the sample values, specified as an integer. Valid values depend on the audio hardware installed. Most platforms support bit depths of 8 bits or 16 bits.

## More About

### Tips

- The `sound` function supports sound devices on all Windows and most UNIX platforms.
- Most sound cards support sample rates between 5 and 48 kilohertz. Specifying a sample rate outside this range might produce unexpected results.

- “Characteristics of Audio Files”
- “Play Audio”

audioplayer | audioread | audiowrite | soundsc

**Introduced before R2006a**

# soundsc

Scale data and play as sound

## Syntax

```
soundsc(y)
soundsc(y,Fs)
soundsc(y,Fs,nBits)

soundsc(____,yRange)
```

## Description

`soundsc(y)` scales the values of audio signal `y` to fit in the range from  $-1.0$  to  $1.0$ , and then sends the data to the speaker at the default sample rate of 8192 hertz. By first scaling the data, `soundsc` plays the audio as loudly as possible without clipping. The mean of the dynamic range of the data is set to zero.

`soundsc(y,Fs)` sends audio signal `y` to the speaker at sample rate `Fs`.

`soundsc(y,Fs,nBits)` uses `nBits` bits per sample for audio signal `y`.

`soundsc( ____,yRange)`, where `yRange` is a vector of the form `[low,high]`, linearly scales the values in `y` between `low` and `high` to the full sound range `[-1.0,1.0]`. Values outside `[low,high]` scale beyond `[-1.0,1.0]`. You can use `yRange` with any of the input arguments in the previous syntaxes.

## Examples

### Play Sample Data at Default Sample Rate

Load the example file `gong.mat`, which contains sample data `y` and rate `Fs`, and listen to the audio.

```
load gong.mat;
```

```
soundsc(y);
```

## Play Sample Data at Specific Sample Rate

Play an excerpt from Handel's "Hallelujah Chorus" at twice the recorded sample rate.

```
load handel.mat;
soundsc(y, 2*Fs);
```

## Play Sample Data with Specific Bit Depth

```
load handel.mat;
nBits = 16;
soundsc(y, Fs, nBits);
```

MATLAB plays the scaled audio with a bit depth of 16 bits per sample.

## Scale Selected Audio Data

```
load handel.mat;
yRange = [-0.7, 0.7];
soundsc(y, yRange);
```

# Input Arguments

### **y** — Audio data

column vector | *m*-by-2 matrix

Audio data, specified as an *m*-by-1 column vector for single-channel (mono) audio, or an *m*-by-2 matrix for stereo playback, where *m* is the number of audio samples. If *y* is an *m*-by-2 matrix, then the first column corresponds to the left channel, and the second column corresponds to the right channel. Stereo playback is available only if your system supports it.

Data Types: double

### **Fs** — Sample rate

8192 (default) | positive number

Sample rate, in hertz, of audio data *y*, specified as a positive number between 80 and 1000000.

Data Types: single | double

**nBits — Bit depth of sample values**

8 (default) | 16 | 24

Bit depth of the sample values, specified as an integer. Valid values depend on the audio hardware installed. Most platforms support bit depths of 8 bits or 16 bits.

**yRange — Range of audio data to scale**

[ -max(abs(y)), max(abs(y)) ] (default) | two-element vector

Range of audio data to scale, specified as a two-element vector of the form [low, high], where low and high are the lower and upper limits of the range. Values in y that are scaled beyond [-1.0, 1.0] are clipped when played back on a sound device.

Example: [-0.8, 0.8]

Data Types: double

## More About

**Tips**

- The sound function supports sound devices on all Windows and most UNIX platforms.
- Most sound cards support sample rates between 5 and 48 kilohertz. Specifying a sample rate outside this range might produce unexpected results.

## **spalloc**

Allocate space for sparse matrix

### **Syntax**

```
S = spalloc(m,n,nzmax)
```

### **Description**

`S = spalloc(m,n,nzmax)` creates an all zero sparse matrix **S** of size *m*-by-*n* with room to hold *nzmax* nonzeros. The matrix can then be generated column by column without requiring repeated storage allocation as the number of nonzeros grows.

`spalloc(m,n,nzmax)` is shorthand for

```
sparse([],[],[],m,n,nzmax)
```

### **Examples**

To generate efficiently a sparse matrix that has an average of at most three nonzero elements per column

```
S = spalloc(n,n,3*n);
for j = 1:n
 S(:,j) = [zeros(n-3,1)' round(rand(3,1))']';end
```

**Introduced before R2006a**

## sparse

Create sparse matrix

### Syntax

`S = sparse(A)`

`S = sparse(m,n)`

`S = sparse(i,j,v)`

`S = sparse(i,j,v,m,n)`

`S = sparse(i,j,v,m,n,nz)`

### Description

`S = sparse(A)` converts a full matrix into sparse form by squeezing out any zero elements. If a matrix contains many zeros, converting the matrix to sparse storage saves memory.

`S = sparse(m,n)` generates an  $m$ -by- $n$  all zero sparse matrix.

`S = sparse(i,j,v)` generates a sparse matrix  $S$  from the triplets  $i$ ,  $j$ , and  $v$  such that  $S(i(k),j(k)) = v(k)$ . The  $\max(i)$ -by- $\max(j)$  output matrix has space allotted for  $\text{length}(v)$  nonzero elements. `sparse` adds together elements in  $v$  that have duplicate subscripts in  $i$  and  $j$ .

If the inputs  $i$ ,  $j$ , and  $v$  are vectors or matrices, they must have the same number of elements. Alternatively, the argument  $v$  and/or one of the arguments  $i$  or  $j$  can be scalars.

`S = sparse(i,j,v,m,n)` specifies the size of  $S$  as  $m$ -by- $n$ .

`S = sparse(i,j,v,m,n,nz)` allocates space for  $nz$  nonzero elements. Use this syntax to allocate extra space for nonzero values to be filled in after construction.

## Examples

### Save Memory Using Sparse Storage

Create a 10,000-by-10,000 full storage identity matrix.

```
A = eye(10000);
whos A
```

Name	Size	Bytes	Class	Attributes
A	10000x10000	800000000	double	

This matrix uses 800-megabytes of memory.

Convert the matrix to sparse storage.

```
S = sparse(A);
whos S
```

Name	Size	Bytes	Class	Attributes
S	10000x10000	240008	double	sparse

In sparse form, the same matrix uses roughly 0.25-megabytes of memory. In this case, you can avoid full storage completely by using the `speye` function, which creates sparse identity matrices directly.

### Sparse Matrix of All Zeros

```
S = sparse(10000,5000)
```

```
S =
```

```
All zero sparse: 10000-by-5000
```

### Sparse Matrix of Nonzeros with Specified Size

Create a 1500-by-1500 sparse matrix from the triplets `i`, `j`, and `v`.

```
i = [900 1000];
j = [900 1000];
v = [10 100];
S = sparse(i,j,v,1500,1500)
```

```
S =
 (900,900) 10
 (1000,1000) 100
```

When you specify a size larger than  $\max(i)$  -by-  $\max(j)$ , the `sparse` function pads the output with extra rows and columns of zeros.

```
size(S)
```

```
ans =
 1500 1500
```

### Preallocate Storage in Sparse Matrix

Create a sparse matrix with 10 nonzero values, but which has space allocated for 100 nonzero values.

```
S = sparse(1:10,1:10,5,20,20,100);
N = nnz(S)
```

```
N =
 10
```

```
N_alloc = nzmax(S)
```

```
N_alloc =
 100
```

The `spalloc` function is a shorthand way to create a sparse matrix with *no* nonzero elements but which has space allotted for some number of nonzeros.

### Accumulate Values into Sparse Matrix

Use repeated subscripts to accumulate values into a single sparse matrix that would otherwise require one or more loops.

Create a column vector of data and two column vectors of subscripts.

```
i = [6 6 6 5 10 10 9 9]';
j = [1 1 1 2 3 3 10 10]';
v = [100 202 173 305 410 550 323 121]';
```

Visualize the subscripts and values side-by-side.

```
[i,j,v]
```

```
ans =
```

```
 6 1 100
 6 1 202
 6 1 173
 5 2 305
 10 3 410
 10 3 550
 9 10 323
 9 10 121
```

Use the `sparse` function to accumulate the values that have identical subscripts.

```
S = sparse(i,j,v)
```

```
S =
```

```
(6,1) 475
(5,2) 305
(10,3) 960
(9,10) 444
```

## Input Arguments

### **A** — Input matrix

full matrix | sparse matrix

Input matrix, specified as a full or sparse matrix. If *A* is already sparse, then `sparse(A)` returns *A*.

Data Types: `double` | `logical`

Complex Number Support: Yes

### **i, j** — Subscript pairs (as separate arguments)

scalars | vectors | matrices

Subscript pairs, specified as separate arguments of scalars, vectors, or matrices. Corresponding elements in *i* and *j* specify `S(i, j)` subscript pairs, which determine the placement of the values in *v* into the output. If either *i* or *j* is a vector or matrix, then the other input can be a scalar or can be a vector or matrix with the same number of elements. In that case, `sparse` uses `i(:)` and `j(:)` as the subscripts. If *i* and *j* have identical values for several elements in *v*, then those elements are added together.

---

**Note:** If any value in *i* or *j* is larger than  $2^{31} - 1$  for 32-bit platforms, or  $2^{48} - 1$  on 64-bit platforms, then the sparse matrix cannot be constructed.

---

Data Types: `double` | `logical`

### **v** — Values

scalar | vector | matrix

Values, specified as a scalar, vector, or matrix. If *v* is a vector or matrix, then one of the inputs *i* or *j* must also be a vector or matrix with the same number of elements.

Any elements in *v* that are zero are ignored, as are the corresponding subscripts in *i* and *j*. However, if you do not specify the dimension sizes of the output, *m* and *n*, then `sparse` calculates the maxima  $m = \max(i)$  and  $n = \max(j)$  before ignoring any zero elements in *v*.

Data Types: `double` | `logical`

Complex Number Support: Yes

## **m, n — Size of each dimension (as separate arguments)**

integer values

Size of each dimension, specified as separate arguments of integer values. If you specify *m* (the row size), you also must specify *n* (the column size).

If you do not specify *m* and *n*, then `sparse` uses the default values  $m = \max(i)$  and  $n = \max(j)$ . These maxima are computed before any zeros in *v* are removed.

Data Types: double

## **nz — Storage allocation for nonzero elements**

positive integer scalar

Storage allocation for nonzero elements, specified as a positive integer scalar. *nz* must be greater than or equal to  $\max([\text{numel}(i), \text{numel}(j), \text{numel}(v)])$ .

For a sparse matrix, *S*, the `nnz` function returns the number of nonzero elements in the matrix, and the `nzmax` function returns the amount of storage allocated for nonzero matrix elements. If `nnz(S)` and `nzmax(S)` return different results, then more storage might be allocated than is actually required. For this reason, set *nz* only in anticipation of later fill-in.

If you do not specify *nz*, the `sparse` function uses a default value of  $\max([\text{numel}(i), \text{numel}(j), \text{numel}(v)])$ .

Data Types: double

## More About

### Tips

- MATLAB stores sparse matrices in compressed sparse column format. For more information, see John R. Gilbert, Cleve Moler, and Robert Schreiber's *Sparse Matrices In Matlab: Design and Implementation*.
- The `accumarray` function has similar accumulation behavior to that of `sparse`.
  - `accumarray` groups data into bins using *n*-dimensional subscripts, but `sparse` groups data into bins using 2-D subscripts.

- `accumarray` adds elements that have identical subscripts into the output by default, but can optionally apply any function to the bins. `sparse` only adds elements that have identical subscripts into the output.
- “Constructing Sparse Matrices”
- “Sparse Matrix Operations”
- “Accessing Sparse Matrices”

**Introduced before R2006a**

## spaugment

Form least squares augmented system

### Syntax

$S = \text{spaugment}(A, c)$   
 $S = \text{spaugment}(A)$

### Description

$S = \text{spaugment}(A, c)$  creates the sparse, square, symmetric indefinite matrix  $S = [c \cdot I \ A; \ A' \ 0]$ . The matrix  $S$  is related to the least squares problem

$\min \text{norm}(b - A \cdot x)$

by

$r = b - A \cdot x$   
 $S \cdot [r/c; \ x] = [b; \ 0]$

The optimum value of the residual scaling factor  $c$ , involves  $\min(\text{svd}(A))$  and  $\text{norm}(r)$ , which are usually too expensive to compute.

$S = \text{spaugment}(A)$  without a specified value of  $c$ , uses  $\max(\max(\text{abs}(A))) / 1000$ .

---

**Note** In previous versions of MATLAB product, the augmented matrix was used by sparse linear equation solvers, `\` and `/`, for nonsquare problems. Now, MATLAB software performs a least squares solve using the `qr` factorization of  $A$  instead.

---

### See Also

`spparms`

Introduced before R2006a

# spconvert

Import from sparse matrix external format

## Syntax

`S = spconvert(D)`

## Description

`S = spconvert(D)` constructs sparse matrix `S` from the columns of `D` in a manner similar to the `sparse` function.

- If `D` is of size `N`-by-`3`, then `spconvert` uses the columns `[i, j, re]` of `D` to construct `S`, such that  $S(i(k), j(k)) = re(k)$ .
- If `D` is of size `N`-by-`4`, then `spconvert` uses the columns `[i, j, re, im]` of `D` to construct `S`, such that  $S(i(k), j(k)) = re(k) + 1i*im(k)$ .

## Examples

### Convert Data File to Sparse Matrix

Create an ASCII file, `uphill.dat`, which contains the following values. Save the file in your current directory.

```

1 1 1.0000000000000000
1 2 0.5000000000000000
2 2 0.3333333333333333
1 3 0.3333333333333333
2 3 0.2500000000000000
3 3 0.2000000000000000
1 4 0.2500000000000000
2 4 0.2000000000000000
3 4 0.1666666666666667
4 4 0.142857142857143
4 4 0.0000000000000000
```

It is common to purposefully make the last line of the file include the desired size of the matrix with a value of 0. This practice ensures that the converted sparse matrix has that size.

Load the data into MATLAB and convert it into a sparse matrix.

```
load uphill.dat
H = spconvert(uphill)
```

H =

```
(1,1) 1.0000
(1,2) 0.5000
(2,2) 0.3333
(1,3) 0.3333
(2,3) 0.2500
(3,3) 0.2000
(1,4) 0.2500
(2,4) 0.2000
(3,4) 0.1667
(4,4) 0.1429
```

In this case, the last line in the file is not necessary because the earlier lines already specify that the matrix is at least 4-by-4.

## Input Arguments

### D — Input matrix

matrix

Input matrix, specified as a matrix with either three or four columns. In both cases, the first two columns of D are subscripts and the third column is composed of data values. A four column matrix specifies the real (third column) and imaginary (fourth column) parts of complex numbers.

If D is already a sparse matrix, then `spconvert` returns D.

Data Types: `single` | `double`

### See Also

`full` | `sparse`

**Introduced before R2006a**

## spdiags

Extract and create sparse band and diagonal matrices

### Syntax

```
B = spdiags(A)
[B,d] = spdiags(A)
B = spdiags(A,d)
A = spdiags(B,d,A)
A = spdiags(B,d,m,n)
```

### Description

The `spdiags` function generalizes the function `diag`. Four different operations, distinguished by the number of input arguments, are possible.

`B = spdiags(A)` extracts all nonzero diagonals from the  $m$ -by- $n$  matrix  $A$ .  $B$  is a  $\min(m,n)$ -by- $p$  matrix whose columns are the  $p$  nonzero diagonals of  $A$ .

`[B,d] = spdiags(A)` returns a vector  $d$  of length  $p$ , whose integer components specify the diagonals in  $A$ .

`B = spdiags(A,d)` extracts the diagonals specified by  $d$ .

`A = spdiags(B,d,A)` replaces the diagonals specified by  $d$  with the columns of  $B$ . The output is sparse.

`A = spdiags(B,d,m,n)` creates an  $m$ -by- $n$  sparse matrix by taking the columns of  $B$  and placing them along the diagonals specified by  $d$ .

---

**Note** In this syntax, if a column of  $B$  is longer than the diagonal it is replacing, and  $m \geq n$ , `spdiags` takes elements of super-diagonals from the lower part of the column of  $B$ , and elements of sub-diagonals from the upper part of the column of  $B$ . However, if  $m < n$ , then super-diagonals are from the upper part of the column of  $B$ , and sub-diagonals from the lower part. (See “Example 5A” on page 1-8162 and “Example 5B” on page 1-8163, below).

---

## Arguments

The `spdiags` function deals with three matrices, in various combinations, as both input and output.

A	An $m$ -by- $n$ matrix, usually (but not necessarily) sparse, with its nonzero or specified elements located on $p$ diagonals.
B	A $\min(m, n)$ -by- $p$ matrix, usually (but not necessarily) full, whose columns are the diagonals of A.
d	A vector of length $p$ whose integer components specify the diagonals in A.

Roughly, A, B, and d are related by

```
for k = 1:p
 B(:,k) = diag(A,d(k))
end
```

Some elements of B, corresponding to positions outside of A, are not defined by these loops. They are not referenced when B is input and are set to zero when B is output.

## How the Diagonals of A are Listed in the Vector d

An  $m$ -by- $n$  matrix A has  $m+n-1$  diagonals. These are specified in the vector d using indices from  $-m+1$  to  $n-1$ . For example, if A is 5-by-6, it has 10 diagonals, which are specified in the vector d using the indices -4, -3, ..., 4, 5. The following diagram illustrates this for a vector of all ones.

## Examples

### Example 1

For the following matrix,

```
A=[0 5 0 10 0 0;...
0 0 6 0 11 0;...
3 0 0 7 0 12;...
1 4 0 0 8 0;...
0 2 5 0 0 9]
```

A =

0	5	0	10	0	0
0	0	6	0	11	0
3	0	0	7	0	12
1	4	0	0	8	0
0	2	5	0	0	9

the command

```
[B, d] =spdiags(A)
```

returns

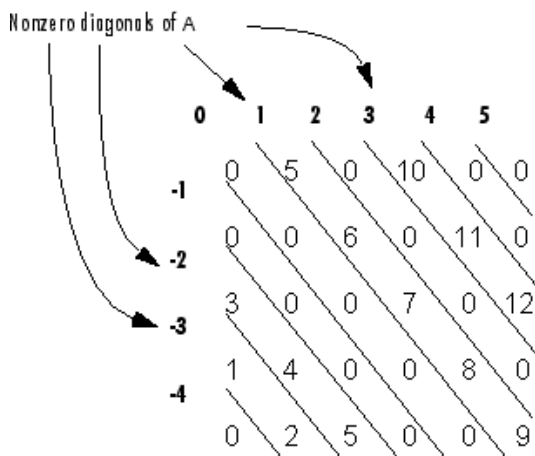

B =

0	0	5	10
0	0	6	11
0	3	7	12
1	4	8	0
2	5	9	0

d =

```
-3
-2
1
3
```

The columns of the first output **B** contain the nonzero diagonals of **A**. The second output **d** lists the indices of the nonzero diagonals of **A**, as shown in the following diagram. See “How the Diagonals of **A** are Listed in the Vector **d**” on page 1-8157.

Note that the longest nonzero diagonal in **A** is contained in column 3 of **B**. The other nonzero diagonals of **A** have extra zeros added to their corresponding columns in **B**, to give all columns of **B** the same length. For the nonzero diagonals below the main diagonal of **A**, extra zeros are added at the tops of columns. For the nonzero diagonals above the main diagonal of **A**, extra zeros are added at the bottoms of columns. This is illustrated by the following diagram.

## Example 2

This example generates a sparse tridiagonal representation of the classic second difference operator on  $n$  points.

```
e = ones(n,1);
A = spdiags([e -2*e e], -1:1, n, n)
```

Turn it into Wilkinson's test matrix (see [gallery](#)):

```
A = spdiags(abs(-(n-1)/2:(n-1)/2)', 0, A)
```

Finally, recover the three diagonals:

```
B = spdiags(A)
```

## Example 3

The second example is not square.

```
A = [11 0 13 0
 0 22 0 24
 0 0 33 0]
```

```

41 0 0 44
 0 52 0 0
 0 0 63 0
 0 0 0 74]

```

Here  $m = 7$ ,  $n = 4$ , and  $p = 3$ .

The statement `[B,d] = spdiags(A)` produces `d = [-3 0 2]'` and

```

B = [41 11 0
 52 22 0
 63 33 13
 74 44 24]

```

Conversely, with the above `B` and `d`, the expression `spdiags(B,d,7,4)` reproduces the original `A`.

## Example 4

This example shows how `spdiags` creates the diagonals when the columns of `B` are longer than the diagonals they are replacing.

```
B = repmat((1:6)', [1 7])
```

```
B =
```

```

 1 1 1 1 1 1 1
 2 2 2 2 2 2 2
 3 3 3 3 3 3 3
 4 4 4 4 4 4 4
 5 5 5 5 5 5 5
 6 6 6 6 6 6 6

```

```

d = [-4 -2 -1 0 3 4 5];
A = spdiags(B,d,6,6);
full(A)

```

```
ans =
```

```

 1 0 0 4 5 6
 1 2 0 0 5 6
 1 2 3 0 0 6
 0 2 3 4 0 0
 1 0 3 4 5 0

```

0 2 0 4 5 6

## Example 5A

This example illustrates the use of the syntax `A = spdiags(B,d,m,n)`, under three conditions:

- `m` is equal to `n`
- `m` is greater than `n`
- `m` is less than `n`

The command used in this example is

```
A = full(spdiags(B, [-2 0 2], m, n))
```

where `B` is the 5-by-3 matrix shown below. The resulting matrix `A` has dimensions `m`-by-`n`, and has nonzero diagonals at `[-2 0 2]` (a sub-diagonal at -2, the main diagonal, and a super-diagonal at 2).

```
B =
 1 6 11
 2 7 12
 3 8 13
 4 9 14
 5 10 15
```

The first and third columns of matrix `B` are used to create the sub- and super-diagonals of `A` respectively. In all three cases though, these two outer columns of `B` are longer than the resulting diagonals of `A`. Because of this, only a part of the columns is used in `A`.

When `m == n` or `m > n`, `spdiags` takes elements of the super-diagonal in `A` from the lower part of the corresponding column of `B`, and elements of the sub-diagonal in `A` from the upper part of the corresponding column of `B`.

When `m < n`, `spdiags` does the opposite, taking elements of the super-diagonal in `A` from the upper part of the corresponding column of `B`, and elements of the sub-diagonal in `A` from the lower part of the corresponding column of `B`.

### Part 1 — `m` is equal to `n`.

```
A = full(spdiags(B, [-2 0 2], 5, 5))
Matrix B Matrix A
```

```

1 6 11 6 0 13 0 0
2 7 12 0 7 0 14 0
3 8 13 == spdiags => 1 0 8 0 15
4 9 14 0 2 0 9 0
5 10 15 0 0 3 0 10

```

A(3,1), A(4,2), and A(5,3) are taken from the upper part of B(:,1).

A(1,3), A(2,4), and A(3,5) are taken from the lower part of B(:,3).

### Part 2 — m is greater than n.

```

A = full(spdiags(B, [-2 0 2], 5, 4))
Matrix B Matrix A
1 6 11 6 0 13 0
2 7 12 0 7 0 14
3 8 13 == spdiags => 1 0 8 0
4 9 14 0 2 0 9
5 10 15 0 0 3 0

```

Same as in Part A.

### Part 3 — m is less than n.

```

A = full(spdiags(B, [-2 0 2], 4, 5))
Matrix B Matrix A
1 6 11 6 0 11 0 0
2 7 12 0 7 0 12 0
3 8 13 == spdiags => 3 0 8 0 13
4 9 14 0 4 0 9 0
5 10 15

```

A(3,1) and A(4,2) are taken from the lower part of B(:,1).

A(1,3), A(2,4), and A(3,5) are taken from the upper part of B(:,3).

## Example 5B

Extract the diagonals from the first part of this example back into a column format using the command

```
B = spdiags(A)
```

You can see that in each case the original columns are restored (minus those elements that had overflowed the super- and sub-diagonals of matrix A).

### Part 1.

Matrix A						Matrix B		
6	0	13	0	0		1	6	0
0	7	0	14	0		2	7	0
1	0	8	0	15	== spdiags =>	3	8	13
0	2	0	9	0		0	9	14
0	0	3	0	10		0	10	15

### Part 2.

Matrix A					Matrix B		
6	0	13	0		1	6	0
0	7	0	14		2	7	0
1	0	8	0	== spdiags =>	3	8	13
0	2	0	9		0	9	14
0	0	3	0				

### Part 3.

Matrix A						Matrix B		
6	0	11	0	0		0	6	11
0	7	0	12	0		0	7	12
3	0	8	0	13	== spdiags =>	3	8	13
0	4	0	9	0		4	9	0

## See Also

[diag](#) | [speye](#)

Introduced before R2006a

## specular

Calculate specular reflectance

### Syntax

`R = specular(Nx,Ny,Nz,S,V)`

### Description

`R = specular(Nx,Ny,Nz,S,V)` returns the reflectance of a surface with normal vector components `[Nx,Ny,Nz]`. `S` and `V` specify the direction to the light source and to the viewer, respectively. You can specify these directions as three vectors `[x,y,z]` or two vectors `[Theta Phi]` (in spherical coordinates).

The specular highlight is strongest when the normal vector is in the direction of  $(S+V)/2$  where `S` is the source direction, and `V` is the view direction.

The surface spread exponent can be specified by including a sixth argument as in `specular(Nx,Ny,Nz,S,V,spread)`.

## speye

Sparse identity matrix

### Syntax

```
S = speye(m,n)
S = speye([m n])
S = speye(n)
S = speye
```

### Description

`S = speye(m,n)` and `S = speye([m n])` form an  $m$ -by- $n$  sparse matrix with 1s on the main diagonal.

`S = speye(n)` abbreviates `speye(n,n)`.

`S = speye` returns the sparse form of the 1-by-1 identity matrix.

### Examples

`I = speye(1000)` forms the sparse representation of the 1000-by-1000 identity matrix, which requires only about 16 kilobytes of storage. This is the same final result as `I = sparse(eye(1000,1000))`, but the latter requires eight megabytes for temporary storage for the full representation.

**Introduced before R2006a**

# spfun

Apply function to nonzero sparse matrix elements

## Syntax

```
f = spfun(fun,S)
```

## Description

The `spfun` function selectively applies a function to only the *nonzero* elements of a sparse matrix `S`, preserving the sparsity pattern of the original matrix (except for underflow or if `fun` returns zero for some nonzero elements of `S`).

`f = spfun(fun,S)` evaluates `fun(S)` on the elements of `S` that are nonzero. `fun` is a function handle.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

## Examples

Given the 4-by-4 sparse diagonal matrix

```
S = spdiags([1:4]',0,4,4)
```

```
S =
 (1,1) 1
 (2,2) 2
 (3,3) 3
 (4,4) 4
```

Because `fun` returns nonzero values for all nonzero element of `S`, `f = spfun(@exp,S)` has the same sparsity pattern as `S`.

```
f =
 (1,1) 2.7183
 (2,2) 7.3891
```

```
(3,3) 20.0855
(4,4) 54.5982
```

whereas `exp(S)` has 1s where `S` has 0s.

```
full(exp(S))
```

```
ans =
 2.7183 1.0000 1.0000 1.0000
 1.0000 7.3891 1.0000 1.0000
 1.0000 1.0000 20.0855 1.0000
 1.0000 1.0000 1.0000 54.5982
```

## More About

### Tips

Functions that operate element-by-element, like those in the `elfun` directory, are the most appropriate functions to use with `spfun`.

- “Create Function Handle”

# sph2cart

Transform spherical coordinates to Cartesian

## Syntax

```
[x,y,z] = sph2cart(azimuth,elevation,r)
```

## Description

`[x,y,z] = sph2cart(azimuth,elevation,r)` transforms the corresponding elements of spherical coordinate arrays to Cartesian, or *xyz*, coordinates. `azimuth`, `elevation`, and `r` must all be the same size (or any of them can be scalar). `azimuth` and `elevation` are angular displacements in radians. `azimuth` is the counterclockwise angle in the *x-y* plane measured from the positive *x*-axis. `elevation` is the elevation angle from the *x-y* plane.

## More About

### Algorithms

The mapping from spherical coordinates to three-dimensional Cartesian coordinates is

```
x = r .* cos(elevation) .* cos(azimuth)
y = r .* cos(elevation) .* sin(azimuth)
z = r .* sin(elevation)
```

# sphere

Generate sphere

## Syntax

```
sphere
sphere(n)
[X,Y,Z] = sphere(n)
```

## Description

The `sphere` function generates the  $x$ -,  $y$ -, and  $z$ -coordinates of a unit sphere for use with `surf` and `mesh`.

`sphere` generates a sphere consisting of 20-by-20 faces.

`sphere(n)` draws a `surf` plot of an  $n$ -by- $n$  sphere in the current figure.

`[X,Y,Z] = sphere(n)` returns the coordinates of a sphere in three matrices that are  $(n+1)$ -by- $(n+1)$  in size. You draw the sphere with `surf(X,Y,Z)` or `mesh(X,Y,Z)`.

## Examples

### Plot Sphere

Generate and plot a sphere.

```
figure
sphere
```

### Plot Multiple Spheres

Define  $x$ ,  $y$ , and  $z$  as coordinates of a sphere.

```
[x,y,z] = sphere;
```

Plot a sphere centered at the origin. Plot two more spheres centered at  $(3, -2, 0)$  and  $(0, 1, -3)$ .

```
figure
surf(x,y,z)
```

```
hold on
surf(x+3,y-2,z) % centered at (3,-2,0)
```

```
surf(x,y+1,z-3) % centered at (0,1,-3)
```

## spinmap

Spin colormap

### Syntax

```
spinmap
spinmap(t)
spinmap(t,inc)
spinmap('inf')
```

### Description

The `spinmap` function shifts the colormap RGB values by some incremental value. For example, if the increment equals 1, color 1 becomes color 2, color 2 becomes color 3, etc.

`spinmap` cyclically rotates the colormap for approximately five seconds using an incremental value of 2.

`spinmap(t)` rotates the colormap for approximately  $10 \cdot t$  seconds. The amount of time specified by `t` depends on your hardware configuration (e.g., if you are running MATLAB software over a network).

`spinmap(t,inc)` rotates the colormap for approximately  $10 \cdot t$  seconds and specifies an increment `inc` by which the colormap shifts. When `inc` is 1, the rotation appears smoother than the default (i.e., 2). Increments greater than 2 are less smooth than the default. A negative increment (e.g., -2) rotates the colormap in a negative direction.

`spinmap('inf')` rotates the colormap for an infinite amount of time. To break the loop, press **Ctrl+C**.

# spline

Cubic spline data interpolation

## Syntax

```
yy = spline(x,Y,xx)
pp = spline(x,Y)
```

## Description

`yy = spline(x,Y,xx)` uses a cubic spline interpolation to find `yy`, the values of the underlying function `Y` at the values of the interpolant `xx`. For the interpolation, the independent variable is assumed to be the final dimension of `Y` with the breakpoints defined by `x`. The values in `x` must be distinct.

The sizes of `xx` and `yy` are related as follows:

- If `Y` is a scalar or vector, `yy` has the same size as `xx`.
- If `Y` is an array that is not a vector,
  - If `xx` is a scalar or vector, `size(yy)` equals `[d1, d2, ..., dk, length(xx)]`.
  - If `xx` is an array of size `[m1,m2,...,mj]`, `size(yy)` equals `[d1,d2,...,dk,m1,m2,...,mj]`.

`pp = spline(x,Y)` returns the piecewise polynomial form of the cubic spline interpolant for later use with `ppval` and the spline utility `unmkpp`. `x` must be a vector with distinct values. `Y` can be a scalar, a vector, or an array of any dimension, subject to the following conditions:

- If `x` and `Y` are vectors of the same size, the not-a-knot end conditions are used.
- If `x` or `Y` is a scalar, it is expanded to have the same length as the other and the not-a-knot end conditions are used. (See Exceptions (1) below).
- If `Y` is a vector that contains two more values than `x` has entries, the first and last value in `Y` are used as the endslopes for the cubic spline. (See Exceptions (2) below.)

## Exceptions

- 1 If  $Y$  is a vector that contains two more values than  $x$  has entries, the first and last value in  $Y$  are used as the endslopes for the cubic spline. If  $Y$  is a vector, this means
  - $f(x) = Y(2:\text{end}-1)$
  - $df(\min(x)) = Y(1)$
  - $df(\max(x)) = Y(\text{end})$
- 2 If  $Y$  is a matrix or an N-dimensional array with  $\text{size}(Y,N)$  equal to  $\text{length}(x)+2$ , the following hold:
  - $f(x(j))$  matches the value  $Y(:,\dots,:,j+1)$  for  $j=1:\text{length}(x)$
  - $Df(\min(x))$  matches  $Y(:,\dots,:,1)$
  - $Df(\max(x))$  matches  $Y(:,\dots,:,\text{end})$

---

**Note** You can also perform spline interpolation using the `interp1` function with the command `interp1(x,y,xx,'spline')`. Note that while `spline` performs interpolation on rows of an input matrix, `interp1` performs interpolation on columns of an input matrix.

---

## Examples

### Spline Interpolation of Sine Data

This generates a sine curve, then samples the spline over a finer mesh.

```
x = 0:10;
y = sin(x);
xx = 0:.25:10;
yy = spline(x,y,xx);
plot(x,y, 'o',xx,yy)
```

### Spline Interpolation of Distribution and Specify Endpoint Slopes

This illustrates the use of clamped or complete spline interpolation where end slopes are prescribed. Zero slopes at the ends of an interpolant to the values of a certain distribution are enforced.

```
x = -4:4;
y = [0 .15 1.12 2.36 2.36 1.46 .49 .06 0];
cs = spline(x,[0 y 0]);
xx = linspace(-4,4,101);
plot(x,y, 'o',xx,ppval(cs,xx), '-');
```

### Extrapolation Using Cubic Spline

The two vectors

```
t = 1900:10:1990;
p = [75.995 91.972 105.711 123.203 131.669 ...
 150.697 179.323 203.212 226.505 249.633];
```

represent the census years from 1900 to 1990 and the corresponding United States population in millions of people. The expression

```
spline(t,p,2000)
```

uses the cubic spline to extrapolate and predict the population in the year 2000. The result is

```
ans =

 270.6060
```

## Spline Interpolation of Angular Data

The statements

```
x = pi*[0:.5:2];
y = [0 1 0 -1 0 1 0;
 1 0 1 0 -1 0 1];
pp = spline(x,y);
yy = ppval(pp, linspace(0,2*pi,101));
plot(yy(1,:),yy(2,:), '-b',y(1,2:5),y(2,2:5), 'or'), axis equal
```

generate the plot of a circle, with the five data points  $y(:,2), \dots, y(:,6)$  marked with o's. Note that this  $y$  contains two more values (i.e., two more columns) than does  $x$ , hence  $y(:,1)$  and  $y(:,end)$  are used as endslopes.

### **Spline Interpolation of Sine and Cosine Data**

The following code generates sine and cosine curves, then samples the splines over a finer mesh.

```
x = 0:.25:1;
Y = [sin(x); cos(x)];
xx = 0:.1:1;
YY = spline(x,Y,xx);
plot(x,Y(1,:), 'o',xx,YY(1,:), '- ')
hold on
plot(x,Y(2,:), 'o',xx,YY(2,:), ': ')
hold off
```

## More About

### Algorithms

A tridiagonal linear system (with, possibly, several right sides) is being solved for the information needed to describe the coefficients of the various cubic polynomials which make up the interpolating spline. `spline` uses the functions `ppval`, `mkpp`, and `unmkpp`. These routines form a small suite of functions for working with piecewise polynomials. For access to more advanced features, see the `interp1` reference page, the command-line help for these functions, and the Curve Fitting Toolbox spline functions.

# split

Split calendar duration into numeric and duration units

## Syntax

```
[X1,X2,...] = split(t,units)
```

## Description

`[X1,X2,...] = split(t,units)` returns the calendar duration values in `t` as separate numeric arrays, one for each of the date or time units specified by `units`. The number of date and time units specified by `units` determines the number of output arguments.

## Examples

### Split Calendar Duration Array

Create a `calendarDuration` array.

```
T = calmonths(15:17) + caldays(8) + hours(1.2345)
```

```
T =
```

```
 1y 3mo 8d 1h 14m 4.2s 1y 4mo 8d 1h 14m 4.2s 1y 5mo 8d 1h 14m 4.2s
```

Get the month, day, and time values.

```
[m,d,t] = split(T,{'months','days','time'})
```

```
m =
```

```
 15 16 17
```

d =

8 8 8

t =

01:14:04 01:14:04 01:14:04

Get the year, month, day, and time values

```
[y,m,d,t] = split(T,{'years','months','days','time'})
```

y =

1 1 1

m =

3 4 5

d =

8 8 8

t =

01:14:04 01:14:04 01:14:04

When you request both the year and month values, `split` carries over month values greater than 12 to the year value.

## Input Arguments

**t** — Input calendar duration  
calendarDuration array

Input calendar duration, specified as a `calendarDuration` array.

### **units** — Date and time units

string | cell array of strings

Date and time units, specified as a string or a cell array of strings. The string values can be one or more of the values in this table.

String Value	Split t into Units of...
'years'	years
'quarters'	quarters
'months'	months
'weeks'	weeks
'days'	days
'time'	time, in the format hours:minutes:seconds

You must specify date and time units from largest to smallest. For example, {'years', 'months'} is valid, but {'months', 'years'} is not.

Example: {'years', 'months', 'days'}

Data Types: char | cell

## Output Arguments

### **X1, X2, ...** — Output arrays

scalar | vector | matrix | multidimensional array

Output arrays, returned as one or more scalars, vectors, matrices, or multidimensional arrays. `split` returns year, month, and day values in numeric arrays and time values in duration arrays.

### See Also

`caldays` | `calmonths` | `calquarters` | `calweeks` | `calyears` | `time`

Introduced in R2014b

# splitapply

Split data into groups and apply function

## Syntax

```
Y = splitapply(func,X,G)
Y = splitapply(func,X1,...,XN,G)
Y = splitapply(func,T,G)
[Y1,...,YM] = splitapply(___)
```

## Description

`Y = splitapply(func,X,G)` splits `X` into groups specified by `G` and applies the function `func` to each group. `splitapply` returns `Y` as an array that contains the concatenated outputs from `func` for the groups split out of `X`. The input argument `G` is a vector of positive integers that specifies the groups to which corresponding elements of `X` belong. If `G` contains NaN values, `splitapply` omits the corresponding values in `X` when it splits `X` into groups. To create `G`, you can use the `findgroups` function.

`splitapply` combines two steps in the “Split-Apply-Combine Workflow” on page 1-8192.

`Y = splitapply(func,X1,...,XN,G)` splits `X1,...,XN` into groups and applies `func`. The `splitapply` function calls `func` once per group, with corresponding elements from `X1,...,XN` as the `N` input arguments to `func`.

`Y = splitapply(func,T,G)` splits variables of table `T` into groups and applies `func`. The `splitapply` function treats the variables of `T` as vectors, matrices, or cell arrays, depending on the data types of the table variables. If `T` has `N` variables, then `func` must accept `N` input arguments.

`[Y1,...,YM] = splitapply( ___ )` splits variables into groups and applies `func` to each group. `func` returns multiple output arguments. `Y1,...,YM` contains the concatenated outputs from `func` for the groups split out of the input data variables. `func` can return output arguments that belong to different classes, but the class of each output must be the same each time `func` is called. You can use this syntax with any of the input arguments of the previous syntaxes.

The number of output arguments from `func` need not be the same as the number of input arguments specified by  $X_1, \dots, X_N$ .

## Examples

### Calculate Mean Values of Groups of Data

Calculate the mean heights by gender for groups of patients and display the results.

Load patient heights and genders from the data file `patients.mat`.

```
load patients
whos Gender Height
```

Name	Size	Bytes	Class	Attributes
Gender	100x1	12212	cell	
Height	100x1	800	double	

Specify groups by gender with `findgroups`.

```
G = findgroups(Gender);
```

Split `Height` into groups specified by `G`. Calculate the mean height by gender. The first row of the output argument is the mean height of the female patients, and the second row is the mean height of the male patients.

```
splitapply(@mean,Height,G)
```

```
ans =
```

```
65.1509
69.2340
```

### Split Two Data Variables and Apply Function

Calculate the variances of the differences in blood pressure readings for groups of patients, and display the results. The blood pressure readings are contained in two data variables. To calculate the differences, use a function that takes two input arguments.

Load blood pressure readings and smoking data for 100 patients from the data file `patients.mat`.

```
load patients
whos Systolic Diastolic Smoker
```

Name	Size	Bytes	Class	Attributes
Diastolic	100x1	800	double	
Smoker	100x1	100	logical	
Systolic	100x1	800	double	

Define `func` as a function that calculates the variances of the differences between systolic and diastolic blood-pressure readings for smokers and nonsmokers. `func` requires two input arguments.

```
func = @(x,y) var(x-y);
```

Use `findgroups` and `splitapply` to split the patient data into groups and calculate the variances of the differences. `findgroups` also returns group identifiers in `smokers`. The `splitapply` function calls `func` once per group, with `Systolic` and `Diastolic` as the two input arguments.

```
[G,smokers] = findgroups(Smoker);
varBP = splitapply(func,Systolic,Diastolic,G)
```

```
varBP =
 44.4459
 48.6783
```

Create a table that contains the variances of the differences, with the number of patients in each group.

```
numPatients = splitapply(@numel,Smoker,G);
T = table(smokers,numPatients,varBP)
```

```
T =
 smokers numPatients varBP
 _____ _____ _____
 false 66 44.446
 true 34 48.678
```

## Return Nonscalar Output for Groups

Calculate the minimum, median, and maximum weights for groups of patients and return these results as arrays for each group. `splitapply` concatenates the output arguments so that you can distinguish output for each group from output for the other groups.

Define a function that returns the minimum, median, and maximum as a row vector.

```
mystats = @(x)[min(x) median(x) max(x)];
```

Load patient weights, genders, and status as smokers from `patients.mat`.

```
load patients
whos Weight Gender Smoker
```

Name	Size	Bytes	Class	Attributes
Gender	100x1	12212	cell	
Smoker	100x1	100	logical	
Weight	100x1	800	double	

Use `findgroups` and `splitapply` to split the patient weights into groups and calculate statistics for each group.

```
G = findgroups(Gender,Smoker);
Y = splitapply(mystats,Weight,G)
```

```
Y =
```

```
111.0000 131.0000 147.0000
115.0000 131.0000 146.0000
158.0000 181.5000 194.0000
164.0000 181.0000 202.0000
```

In this example, you can return nonscalar output as row vectors because the data and grouping variables are column vectors. Each row of `Y` contains statistics for a different group of patients.

## Split Table Data Variables and Apply Function

Calculate the mean body-mass-index (BMI) from tables of patient data. Group the patients by gender and status as smokers or nonsmokers.

Load patient data and grouping variables into tables.

```
load patients
DT = table(Height,Weight);
GT = table(Gender,Smoker);
```

Define a function that calculates mean BMI from the weights and heights of groups or patients.

```
meanBMIFcn = @(h,w)mean((w ./ (h.^2)) * 703);
```

Create a table that contains the mean BMI for each group.

```
[G,results] = findgroups(GT);
meanBMI = splitapply(meanBMIFcn,DT,G);
results.meanBMI = meanBMI
```

```
results =
```

Gender	Smoker	meanBMI
'Female'	false	21.672
'Female'	true	21.669
'Male'	false	26.578
'Male'	true	26.458

## Return Multiple Statistics for Groups

Calculate the minimum, mean, and maximum heights for groups of patients and return results in a table.

Define a function in a file named `multiStats.m` that accepts an input vector and returns the minimum, mean, and maximum values of the vector.

```
function [lo,avg,hi] = multiStats(x)
lo = min(x);
avg = mean(x);
hi = max(x);
```

Load patient data into a table.

```
load patients
```

```
T = table(Gender,Height);
summary(T)
```

Variables:

```
Gender: 100x1 cell string
```

```
Height: 100x1 double
```

```
Values:
```

```
min 60
median 67
max 72
```

Group patient heights by gender. Create a table that contains the outputs from `multiStats` for each group.

```
[G,gender] = findgroups(T.Gender);
[minHeight,meanHeight,maxHeight] = splitapply(@multiStats,T.Height,G);
result = table(gender,minHeight,meanHeight,maxHeight)
```

```
result =
```

gender	minHeight	meanHeight	maxHeight
'Female'	60	65.151	70
'Male'	66	69.234	72

- “Split Table Data Variables and Apply Functions”
- “Split Data into Groups and Calculate Statistics”
- “Calculations on Tables”

## Input Arguments

**func** — Function to apply to groups of data

function handle

Function to apply to groups of data, specified as a function handle.

If `func` returns a nonscalar output argument, then the argument must be oriented so that `splitapply` can concatenate the output arguments from successive calls to `func`.

For example, if the input data variables are column vectors, then `func` must return either a scalar or a row vector as an output argument.

Example: `Y = splitapply(@sum,X,G)` returns the sums of the groups of data in `X`.

## **X — Data variable**

vector | matrix | cell array

Data variable, specified as a vector, matrix, or cell array. The elements of `X` belong to groups specified by the corresponding elements of `G`.

If `X` is a matrix, `splitapply` treats each column or row as a separate data variable. The orientation of `G` determines whether `splitapply` treats the columns or rows of `X` as data variables.

## **G — Group numbers**

vector of positive integers

Group numbers, specified as a vector of positive integers.

- If `X` is a vector or cell array, then `G` must be the same length as `X`.
- If `X` is a matrix, then the length of `G` must be equal to the number of columns or rows of `X`, depending on the orientation of `G`.
- If the input argument is table `T`, then `G` must be a column vector. The length of `G` must be equal to the number of rows of `T`.

## **T — Data variables**

table

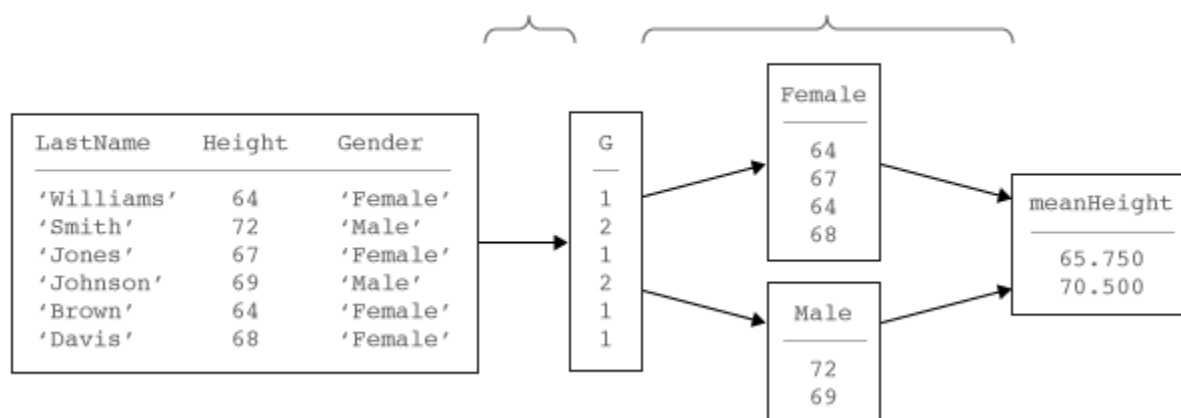

Data variables, specified as a table. `splitapply` treats each table variable as a separate data variable.

# More About

## **Split-Apply-Combine Workflow**

The *Split-Apply-Combine* workflow is common in data analysis. In this workflow, the analyst splits the data into groups, applies a function to each group, and combines the results. The diagram shows a typical example of the workflow and the parts of the workflow implemented by `findgroups` and `splitapply`.

```
G=findgroups(Gender) meanHeight=splitapply(@mean,Height,G)
```

- “Grouping Variables To Split Data”

## spones

Replace nonzero sparse matrix elements with ones

### Syntax

`R = spones(S)`

### Description

`R = spones(S)` generates a matrix `R` with the same sparsity structure as `S`, but with 1's in the nonzero positions.

### Examples

`c = sum(spones(S))` is the number of nonzeros in each column.

`r = sum(spones(S'))'` is the number of nonzeros in each row.

`sum(c)` and `sum(r)` are equal, and are equal to `nnz(S)`.

### See Also

`nnz` | `spalloc` | `spfun`

**Introduced before R2006a**

## spparms

Set parameters for sparse matrix routines

### Syntax

```
spparms('key',value)
spparms
values = spparms
[keys,values] = spparms
spparms(values)
value = spparms('key')
spparms('default')
spparms('tight')
```

### Description

`spparms('key',value)` sets one or more of the *tunable* parameters used in the sparse routines. In ordinary use, you should never need to deal with this function.

The meanings of the `key` parameters are

'spumoni'	Sparse Monitor flag:
0	Produces no diagnostic output, the default
1	Produces information about choice of algorithm based on matrix structure, and about storage allocation
2	Also produces very detailed information about the sparse matrix algorithms
'thr_rel', 'thr_abs'	Minimum degree threshold is <code>thr_rel*mindegree + thr_abs</code> .
'exact_d'	Nonzero to use exact degrees in minimum degree. Zero to use approximate degrees.
'supernd'	If positive, minimum degree amalgamates the supernodes every <code>supernd</code> stages.

'rreduce'	If positive, minimum degree does row reduction every rreduce stages.
'wh_frac'	Rows with density > wh_frac are ignored in colmmd.
'autommd'	Nonzero to use minimum degree (MMD) orderings with QR-based \ and /.
'autoamd'	Nonzero to use colamd ordering with the LU-based \ and /, and to use amd with Cholesky-based \ and /.
'piv_tol'	Pivot tolerance used by the LU-based \ and /.
'bandden'	Band density used by \ and / for banded matrices. Band density is defined as (# nonzeros in the band)/(# nonzeros in a full band). If bandden = 1.0, never use band solver. If bandden = 0.0, always use band solver. Default is 0.5.
'umfpack'	Nonzero to use UMFPACK instead of the v4 LU-based solver in \ and /.
'sym_tol'	Symmetric pivot tolerance. See lu for more information about the role of the symmetric pivot tolerance.

spparms, by itself, prints a description of the current settings.

values = spparms returns a vector whose components give the current settings.

[keys, values] = spparms returns that vector, and also returns a character matrix whose rows are the keywords for the parameters.

spparms(values), with no output argument, sets all the parameters to the values specified by the argument vector.

value = spparms('key') returns the current setting of one parameter.

spparms('default') sets all the parameters to their default settings.

spparms('tight') sets the minimum degree ordering parameters to their *tight* settings, which can lead to orderings with less fill-in, but which make the ordering functions themselves use more execution time.

The key parameters for default and tight settings are

	Keyword	Default	Tight
values(1)	'spumoni'	0.0	

	<b>Keyword</b>	<b>Default</b>	<b>Tight</b>
values(2)	'thr_rel'	1.1	1.0
values(3)	'thr_abs'	1.0	0.0
values(4)	'exact_d'	0.0	1.0
values(5)	'supernd'	3.0	1.0
values(6)	'rreduce'	3.0	1.0
values(7)	'wh_frac'	0.5	0.5
values(8)	'autommd'	1.0	
values(9)	'autoamd'	1.0	
values(10)	'piv_tol'	0.1	
values(11)	'bandden'	0.5	
values(12)	'umfpack'	1.0	
values(13)	'sym_tol'	0.001

## sprand

Sparse uniformly distributed random matrix

### Syntax

```
R = sprand(S)
R = sprand(m,n,density)
R = sprand(m,n,density,rc)
```

### Description

`R = sprand(S)` has the same sparsity structure as `S`, but uniformly distributed random entries.

`R = sprand(m,n,density)` is a random,  $m$ -by- $n$ , sparse matrix with approximately  $\text{density} * m * n$  uniformly distributed nonzero entries ( $0 \leq \text{density} \leq 1$ ).

`R = sprand(m,n,density,rc)` also has reciprocal condition number approximately equal to `rc`. `R` is constructed from a sum of matrices of rank one.

If `rc` is a vector of length `lr`, where  $lr \leq \min(m,n)$ , then `R` has `rc` as its first `lr` singular values, all others are zero. In this case, `R` is generated by random plane rotations applied to a diagonal matrix with the given singular values. It has a great deal of topological and algebraic structure.

### More About

#### Tips

- `sprand` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

#### See Also

`sprandn` | `sprandsym`

**Introduced before R2006a**

## sprandn

Sparse normally distributed random matrix

### Syntax

```
R = sprandn(S)
R = sprandn(m,n,density)
R = sprandn(m,n,density,rc)
```

### Description

`R = sprandn(S)` has the same sparsity structure as `S`, but normally distributed random entries with mean 0 and variance 1.

`R = sprandn(m,n,density)` is a random,  $m$ -by- $n$ , sparse matrix with approximately  $\text{density} * m * n$  normally distributed nonzero entries ( $0 \leq \text{density} \leq 1$ ).

`R = sprandn(m,n,density,rc)` also has reciprocal condition number approximately equal to `rc`. `R` is constructed from a sum of matrices of rank one.

If `rc` is a vector of length `lr`, where  $lr \leq \min(m,n)$ , then `R` has `rc` as its first `lr` singular values, all others are zero. In this case, `R` is generated by random plane rotations applied to a diagonal matrix with the given singular values. It has a great deal of topological and algebraic structure.

### More About

#### Tips

- `sprandn` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

#### See Also

`sprand` | `sprandsym`

**Introduced before R2006a**

## sprandsym

Sparse symmetric random matrix

### Syntax

```
R = sprandsym(S)
R = sprandsym(n,density)
R = sprandsym(n,density,rc)
R = sprandsym(n,density,rc,kind)
R = sprandsym(S,[],rc,3)
```

### Description

`R = sprandsym(S)` returns a symmetric random matrix whose lower triangle and diagonal have the same structure as `S`. Its elements are normally distributed, with mean 0 and variance 1.

`R = sprandsym(n,density)` returns a symmetric random, `n`-by-`n`, sparse matrix with approximately `density*n*n` nonzeros; each entry is the sum of one or more normally distributed random samples, and  $(0 \leq \text{density} \leq 1)$ .

`R = sprandsym(n,density,rc)` returns a matrix with a reciprocal condition number equal to `rc`. The distribution of entries is nonuniform; it is roughly symmetric about 0; all are in  $[-1,1]$ .

If `rc` is a vector of length `n`, then `R` has eigenvalues `rc`. Thus, if `rc` is a positive (nonnegative) vector then `R` is a positive (nonnegative) definite matrix. In either case, `R` is generated by random Jacobi rotations applied to a diagonal matrix with the given eigenvalues or condition number. It has a great deal of topological and algebraic structure.

`R = sprandsym(n,density,rc,kind)` is positive definite.

- If `kind = 1`, `R` is generated by random Jacobi rotation of a positive definite diagonal matrix. `R` has the desired condition number exactly.
- If `kind = 2`, `R` is a shifted sum of outer products. `R` has the desired condition number only approximately, but has less structure.

$R = \text{sprandsym}(S, [], rc, 3)$  has the same structure as the matrix  $S$  and approximate condition number  $1/rc$ .

## More About

### Tips

`sprandsym` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

### See Also

`sprand` | `sprandn`

## sprank

Structural rank

### Syntax

```
r = sprank(A)
```

### Description

`r = sprank(A)` is the structural rank of the sparse matrix `A`. For all values of `A`,

```
sprank(A) >= rank(full(A))
```

In exact arithmetic, `sprank(A) == rank(full(sprandn(A)))` with a probability of one.

### Examples

```
A = [1 0 2 0
 2 0 4 0];
```

```
A = sparse(A);
```

```
sprank(A)
```

```
ans =
 2
```

```
rank(full(A))
```

```
ans =
 1
```

### See Also

`dmperm`

**Introduced before R2006a**

## **sprintf**

Format data into string

### **Syntax**

```
str = sprintf(formatSpec,A1,...,An)
[str,errmsg] = sprintf(formatSpec,A1,...,An)
```

### **Description**

`str = sprintf(formatSpec,A1,...,An)` formats the data in arrays `A1,...,An` according to `formatSpec` in column order, and returns the results to string `str`.

`[str,errmsg] = sprintf(formatSpec,A1,...,An)` returns an error message string when the operation is unsuccessful. Otherwise, `errmsg` is empty.

### **Examples**

#### **Floating-Point Formats**

Format a floating-point number using `%e`, `%f`, and `%g` specifiers.

```
A = 1/eps;
str_e = sprintf('%0.5e',A)
str_f = sprintf('%0.5f',A)
str_g = sprintf('%0.5g',A)
```

```
str_e =
```

```
4.50360e+15
```

```
str_f =
```

```
4503599627370496.00000
```

```
str_g =
```

```
4.5036e+15
```

### Literal Text and Array Inputs

Combine literal text with array values to create a string.

```
formatSpec = 'The array is %dx%d.';
A1 = 2;
A2 = 3;
str = sprintf(formatSpec,A1,A2)
```

```
str =
```

```
The array is 2x3.
```

### Integer Format with Floating-Point Inputs

Explicitly convert double-precision values to integers.

```
str = sprintf('%d',round(pi))
```

```
str =
```

```
3
```

### Specify Field Width of a Printed Value

Specify the minimum width of the printed value.

```
str = sprintf('%025d',[123456])
```

```
str =
```

```
00000000000000000000000123456
```

The 0 flag in the %025d format specifier requests leading zeros in the output.

### Reorder Inputs Using Position Identifier (n\$)

Reorder the input values using the n\$ position identifier.

```
A1 = 'X';
```

```
A2 = 'Y';
A3 = 'Z';
formatSpec = ' %3$s %2$s %1$s';
str = sprintf(formatSpec,A1,A2,A3)

str =
 Z Y X
```

## Create a String from Values in Cell Array

```
C = { 1, 2, 3 ;
 'AA', 'BB', 'CC' };

str = sprintf(' %d %s',C{:})

str =
 1 AA 2 BB 3 CC
```

The syntax `C{:}` creates a comma-separated list of arrays that contain the contents of each cell from `C` in column order. For example, `C{1}==1` and `C{2}=='AA'`.

## Input Arguments

### **formatSpec** — Format of output fields

string containing formatting operators

Format of the output fields, specified as a string containing formatting operators. `formatSpec` also can include ordinary text and special characters.

### Formatting Operator

A formatting operator starts with a percent sign, `%`, and ends with a conversion character. The conversion character is required. Optionally, you can specify identifier, flags, field width, precision, and subtype operators between `%` and the conversion character. (Spaces are invalid between operators and are shown here only for readability).

## Conversion Character

This table shows conversion characters to format numeric and character data as strings.

Value Type	Conversion	Details
Integer, signed	%d or %i	Base 10
Integer, unsigned	%u	Base 10
	%o	Base 8 (octal)
	%x	Base 16 (hexadecimal), lowercase letters a–f
	%X	Same as %x, uppercase letters A–F
Floating-point number	%f	Fixed-point notation (Use a precision operator to specify the number of digits after the decimal point.)
	%e	Exponential notation, such as 3.141593e+00 (Use a precision operator to specify the number of digits after the decimal point.)
	%E	Same as %e, but uppercase, such as 3.141593E+00 (Use a precision operator to specify the number of digits after the decimal point.)
	%g	The more compact of %e or %f, with no trailing zeros (Use a precision operator to specify the number of significant digits.)
	%G	The more compact of %E or %f, with no trailing zeros (Use a precision operator to specify the number of significant digits.)
Characters	%c	Single character
	%s	String of characters

## Optional Operators

The optional identifier, flags, field width, precision, and subtype operators further define the format of the output string.

- **Identifier**

Order for processing values from the input list. Use the syntax  $n\$$ , where  $n$  represents the position of the value in the input list.

**Example:** '%3\$s %2\$s %1\$s %2\$s' prints inputs 'A', 'B', 'C' as follows: C B A B.

- **Flags**

'-'	Left-justify. <b>Example:</b> % <b>-</b> 5.2f
'+'	Always print a sign character (+ or -) for any value. <b>Example:</b> % <b>+</b> 5.2f
' '	Insert a space before the value. <b>Example:</b> % <b> </b> 5.2f
'0'	Pad to field width with zeros before the value. <b>Example:</b> % <b>0</b> 5.2f
'#'	Modify selected numeric conversions: <ul style="list-style-type: none"> <li>• For %o, %x, or %X, print 0, 0x, or 0X prefix.</li> <li>• For %f, %e, or %E, print decimal point even when precision is 0.</li> <li>• For %g or %G, do not remove trailing zeros or decimal point.</li> </ul> <b>Example:</b> % <b>#</b> 5.0f

- **Field Width**

Minimum number of characters to print. The field width operator can be a number, or an asterisk (\*) to refer to an argument in the input list.

**Example:** The input list ('%12d', intmax) is equivalent to ('%\*d', 12, intmax).

The function pads to field width with spaces before the value unless otherwise specified by flags.

- **Precision**

For %f, %e, or %E	Number of digits to the right of the decimal point <b>Example:</b> '%.4f' prints pi as '3.1416'
-------------------	----------------------------------------------------------------------------------------------------

For %g or %G	Number of significant digits <b>Example:</b> '%.4g' prints pi as ' 3.142'
--------------	------------------------------------------------------------------------------

The precision operator can be a number, or an asterisk (\*) to refer to an argument in the input list.

**Example:** The input list ('%6.4f', pi) is equivalent to ('%\*.\*f', 6, 4, pi).

---

**Note:** If you specify a precision operator for floating-point values that exceeds the precision of the input numeric data type, the results might not match the input values to the precision you specified. The result depends on your computer hardware and operating system.

---

- **Subtypes**

Certain conversion characters can support a subtype. The subtype operator immediately precedes the conversion character. This table shows the conversions that can use subtypes.

Input Value Type	Subtype and Conversion Character	Output Value Type
Floating-point number	%bx or %bX %bo %bu	Double-precision hexadecimal, octal, or decimal value <b>Example:</b> %bx prints pi as 400921fb54442d18
	%tx or %tX %to %tu	Single-precision hexadecimal, octal, or decimal value <b>Example:</b> %tx prints pi as 40490fdb
Integer	%ld or %li %lo %lu %lx or %lX	64-bit value
Integer	%hd or %hi %ho %hu	16-bit value

Input Value Type	Subtype and Conversion Character	Output Value Type
	%hX or %hX	

### Text Before or After Formatting Operators

`formatSpec` can also include additional text before a percent sign, %, or after a conversion character. The text can be:

- Ordinary text to print.
- Special characters that you cannot enter as ordinary text. This table shows how to represent special characters in `formatSpec`.

Special Character	Representation
Single quotation mark	' '
Percent character	%%
Backslash	\\
Alarm	\a
Backspace	\b
Form feed	\f
New line	\n
Carriage return	\r
Horizontal tab	\t
Vertical tab	\v
Character whose ASCII code is the hexadecimal number, N	\xN
Character whose ASCII code is the octal number, N	\N

### Notable Behavior of Conversions with Formatting Operators

- Numeric conversions print only the real component of complex numbers.
- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses %e.

**Example:** '%s' converts `pi` to `3.141593e+00`.

- If you apply a string conversion (`%s`) to integer values, MATLAB converts values that correspond to valid character codes to characters.

**Example:** `'%s'` converts `[65 66 67]` to `ABC`.

### **A1, ..., An — Numeric or character arrays**

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

## Output Arguments

### **str — Formatted text**

string

Formatted text, returned as a string.

### **errmsg — Error message**

string

Error message, returned as a string, when the operation is unsuccessful. Otherwise, `errmsg` is empty.

## More About

### Tips

- The `sprintf` function is similar to `fprintf`, but `fprintf` prints to a file or to the Command Window.
- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.
- “Formatting Strings”

## spy

Visualize sparsity pattern

### Syntax

```
spy(S)
spy(S,markersize)
spy(S,'LineStyle')
spy(S,'LineStyle',markersize)
```

### Description

`spy(S)` plots the sparsity pattern of any matrix `S`.

`spy(S,markersize)`, where `markersize` is an integer, plots the sparsity pattern using markers of the specified point size.

`spy(S,'LineStyle')`, where `LineStyle` is a string, uses the specified plot marker type and color.

`spy(S,'LineStyle',markersize)` uses the specified type, color, and size for the plot markers.

`S` is usually a sparse matrix, but full matrices are acceptable, in which case the locations of the nonzero elements are plotted.

---

**Note** `spy` replaces `format +`, which takes much more space to display essentially the same information.

---

### Examples

#### Plot Sparsity Pattern

This example plots the 60-by-60 sparse adjacency matrix of the connectivity graph of the Buckminster Fuller geodesic dome. This matrix also represents the soccer ball and the carbon-60 molecule.

B = bucky;  
spy(B)

# sqrt

Square root

## Syntax

```
B = sqrt(X)
```

## Description

`B = sqrt(X)` returns the square root of each element of the array `X`. For the elements of `X` that are negative or complex, `sqrt(X)` produces complex results.

## Examples

```
sqrt((-2:2)')
ans =
 0 + 1.4142i
 0 + 1.0000i
 0
 1.0000
 1.4142
```

## More About

### Tips

See `sqrtm` for the matrix square root.

### See Also

`nthroot` | `sqrtm` | `realsqrt`

Introduced before R2006a

## **sqrtm**

Matrix square root

### **Syntax**

```
X = sqrtm(A)
[X,residual] = sqrtm(A)
[X,alpha,condx] = sqrtm(A)
```

### **Description**

`X = sqrtm(A)` returns the principal square root of the matrix `A`, that is,  $X^*X = A$ .

`X` is the unique square root for which every eigenvalue has nonnegative real part. If `A` has any eigenvalues with negative real parts, then a complex result is produced. If `A` is singular, then `A` might not have a square root. If exact singularity is detected, a warning is printed.

`[X,residual] = sqrtm(A)` also returns the residual,  $\text{residual} = \text{norm}(A-X^2,1) / \text{norm}(A,1)$ . This syntax does not print warnings if exact singularity is detected.

`[X,alpha,condx] = sqrtm(A)` returns stability factor `alpha` and an estimate of the matrix square root condition number of `X` in 1-norm, `condx`. The residual  $\text{norm}(A-X^2,1) / \text{norm}(A,1)$  is bounded approximately by  $n \cdot \text{alpha} \cdot \text{eps}$  and the 1-norm relative error in `X` is bounded approximately by  $n \cdot \text{alpha} \cdot \text{condx} \cdot \text{eps}$ , where  $n = \max(\text{size}(A))$ .

### **Examples**

#### **Matrix Squareroot of Difference Operator**

Create a matrix representation of the fourth difference operator, `A`. This matrix is symmetric and positive definite.

```
A = [5 -4 1 0 0; -4 6 -4 1 0; 1 -4 6 -4 1; 0 1 -4 6 -4; 0 0 1 -4 6]
```

A =

$$\begin{bmatrix} 5 & -4 & 1 & 0 & 0 \\ -4 & 6 & -4 & 1 & 0 \\ 1 & -4 & 6 & -4 & 1 \\ 0 & 1 & -4 & 6 & -4 \\ 0 & 0 & 1 & -4 & 6 \end{bmatrix}$$

Calculate the unique positive definite square root of A using sqrtm. X is the matrix representation of the second difference operator.

X = round(sqrtm(A))

X =

$$\begin{bmatrix} 2 & -1 & 0 & 0 & 0 \\ -1 & 2 & -1 & 0 & 0 \\ 0 & -1 & 2 & -1 & 0 \\ 0 & 0 & -1 & 2 & -1 \\ 0 & 0 & 0 & -1 & 2 \end{bmatrix}$$

### Matrix with Multiple Squareroots

Consider a matrix that has four squareroots, A.

$$A = \begin{bmatrix} 7 & 10 \\ 15 & 22 \end{bmatrix}$$

Two of the squareroots of A are given by Y1 and Y2:

$$Y_1 = \begin{bmatrix} 1.5667 & 1.7408 \\ 2.6112 & 4.1779 \end{bmatrix}$$

$$Y_2 = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$$

Confirm that Y1 and Y2 are squareroots of matrix A.

```
A = [7 10; 15 22];
Y1 = [1.5667 1.7408; 2.6112 4.1779];
A - Y1*Y1
```

```
ans =
 1.0e-03 *
 -0.1258 -0.1997
 -0.2995 -0.4254
```

```
Y2 = [1 2; 3 4];
A = Y2*Y2
```

```
ans =
 0 0
 0 0
```

The other two squareroots of A are -Y1 and -Y2. All four of these roots can be obtained from the eigenvalues and eigenvectors of A. If  $[V,D] = \text{eig}(A)$ , then the squareroots have the general form  $Y = V*S/V$ , where  $D = S*S$  and S has four choices of sign to produce four different values of Y:

$$S = \begin{bmatrix} \pm 0.3723 & 0 \\ 0 & \pm 5.3723 \end{bmatrix}$$

Calculate the squareroot of A with `sqrtm`. The `sqrtm` function chooses the positive square roots and produces Y1, even though Y2 seems to be a more natural result.

```
Y = sqrtm(A)
```

```
Y =
 1.5667 1.7408
 2.6112 4.1779
```

## Input Arguments

**A** — Input matrix  
square matrix

Input matrix, specified as a square matrix.

Data Types: `single` | `double`

Complex Number Support: Yes

## More About

### Tips

- Some matrices, like  $A = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$ , do not have any square roots, real or complex, and `sqrtm` cannot be expected to produce one.

### Algorithms

The algorithm `sqrtm` uses is described in [3].

`expm` | `funm` | `logm`

Introduced before R2006a

## **squeeze**

Remove singleton dimensions

### **Syntax**

```
B = squeeze(A)
```

### **Description**

`B = squeeze(A)` returns an array `B` with the same elements as `A`, but with all singleton dimensions removed. A singleton dimension is any dimension for which `size(A,dim) = 1`. Two-dimensional arrays are unaffected by `squeeze`; if `A` is a row or column vector or a scalar (1-by-1) value, then `B = A`.

### **Examples**

#### **Remove Singleton Dimension from Array**

Create a 2-by-1-by-3 array and remove the singleton column dimension to form a 2-by-3 matrix.

```
y = rand(2,1,3)
z = squeeze(y)
```

```
y(:, :, 1) =
```

```
 0.8147
 0.9058
```

```
y(:, :, 2) =
```

```
 0.1270
 0.9134
```

```
y(:,:,3) =
```

```
 0.6324
 0.0975
```

```
z =
```

```
 0.8147 0.1270 0.6324
 0.9058 0.9134 0.0975
```

### Create Vector from Array with Singleton Dimensions

Create a 1-by-1-by-5 array of ones.

```
mat = repmat(1,[1,1,5])
```

```
mat(:,:,1) =
```

```
 1
```

```
mat(:,:,2) =
```

```
 1
```

```
mat(:,:,3) =
```

```
 1
```

```
mat(:,:,4) =
```

```
 1
```

```
mat(:,:,5) =
```

```
 1
```

Condense the data in the third dimension to create a 5-by-1 column vector.

```
squeeze(mat)
```

```
ans =
```

```
1
1
1
1
1
```

# ss2tf

Convert state-space representation to transfer function

## Syntax

```
[b,a] = ss2tf(A,B,C,D)
[b,a] = ss2tf(A,B,C,D,ni)
```

## Description

`[b,a] = ss2tf(A,B,C,D)` converts a state-space representation of a system into an equivalent transfer function. `ss2tf` returns the Laplace-transform transfer function for continuous-time systems and the Z-transform transfer function for discrete-time systems.

`[b,a] = ss2tf(A,B,C,D,ni)` returns the transfer function that results when the `ni`th input of a system with multiple inputs is excited by a unit impulse.

## Examples

### Mass-Spring System

A one-dimensional discrete-time oscillating system consists of a unit mass,  $m$ , attached to a wall by a spring of unit elastic constant. A sensor samples the acceleration,  $a$ , of the mass at  $F_s = 5$  Hz.

Generate 50 time samples. Define the sampling interval  $\Delta t = 1/F_s$ .

```
Fs = 5;
```

```
dt = 1/Fs;
N = 50;
t = dt*(0:N-1);
```

The oscillator can be described by the state-space equations

$$\begin{aligned}x(k+1) &= Ax(k) + Bu(k), \\y(k) &= Cx(k) + Du(k),\end{aligned}$$

where  $x = (r \ v)^T$  is the state vector,  $r$  and  $v$  are respectively the position and velocity of the mass, and the matrices

$$A = \begin{pmatrix} \cos \Delta t & \sin \Delta t \\ -\sin \Delta t & \cos \Delta t \end{pmatrix}, \quad B = \begin{pmatrix} 1 - \cos \Delta t \\ \sin \Delta t \end{pmatrix}, \quad C = (-1 \ 0), \quad D = (1).$$

```
A = [cos(dt) sin(dt); -sin(dt) cos(dt)];
B = [1-cos(dt); sin(dt)];
C = [-1 0];
D = 1;
```

The system is excited with a unit impulse in the positive direction. Use the state-space model to compute the time evolution of the system starting from an all-zero initial state.

```
u = [1 zeros(1,N-1)];

x = [0;0];
for k = 1:N
 y(k) = C*x + D*u(k);
 x = A*x + B*u(k);
end
```

Plot the acceleration of the mass as a function of time.

```
stem(t,y,'v','filled')
xlabel('t')
```

Compute the time-dependent acceleration using the transfer function  $H(z)$  to filter the input. Plot the result.

```
[b,a] = ss2tf(A,B,C,D);
yt = filter(b,a,u);
stem(t,yt,'d','filled')
xlabel('t')
```

The transfer function of the system has an analytic expression:

$$H(z) = \frac{1 - z^{-1}(1 + \cos \Delta t) + z^{-2} \cos \Delta t}{1 - 2z^{-1} \cos \Delta t + z^{-2}}.$$

Use the expression to filter the input. Plot the response.

```
bf = [1 -(1+cos(dt)) cos(dt)];
af = [1 -2*cos(dt) 1];
yf = filter(bf,af,u);
stem(t,yf,'o','filled')
xlabel('t')
```

The result is the same in all three cases.

### Two-Body Oscillator

An ideal one-dimensional oscillating system consists of two unit masses,  $m_1$  and  $m_2$ , confined between two walls. Each mass is attached to the nearest wall by a spring of unit elastic constant. Another such spring connects the two masses. Sensors sample  $a_1$  and  $a_2$ , the accelerations of the masses, at  $F_s = 16$  Hz.

Specify a total measurement time of 16 s. Define the sampling interval  $\Delta t = 1/F_s$ .

```
Fs = 16;
dt = 1/Fs;
N = 257;
t = dt*(0:N-1);
```

The system can be described by the state-space model

$$\begin{aligned} x(n+1) &= Ax(n) + Bu(n), \\ y(n) &= Cx(n) + Du(n), \end{aligned}$$

where  $x = (r_1 \ v_1 \ r_2 \ v_2)^T$  is the state vector and  $r_i$  and  $v_i$  are respectively the location and the velocity of the  $i$ -th mass. The input vector  $u = (u_1 \ u_2)^T$  and the output vector  $y = (a_1 \ a_2)^T$ . The state-space matrices are

$$A = \exp(A_c \Delta t), \quad B = A_c^{-1}(A - I)B_c, \quad C = \begin{pmatrix} -2 & 0 & 1 & 0 \\ 1 & 0 & -2 & 0 \end{pmatrix}, \quad D = I,$$

the continuous-time state-space matrices are

$$A_c = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -2 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & -2 & 0 \end{pmatrix}, \quad B_c = \begin{pmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 0 \\ 0 & 1 \end{pmatrix},$$

and  $I$  denotes an identity matrix of the appropriate size.

```

Ac = [0 1 0 0; -2 0 1 0; 0 0 0 1; 1 0 -2 0];
A = expm(Ac*dt);
Bc = [0 0; 1 0; 0 0; 0 1];
B = Ac \ (A-eye(4)) * Bc;
C = [-2 0 1 0; 1 0 -2 0];
D = eye(2);

```

The first mass,  $m_1$ , receives a unit impulse in the positive direction.

```

ux = [1 zeros(1,N-1)];
u0 = zeros(1,N);
u = [ux;u0];

```

Use the model to compute the time evolution of the system starting from an all-zero initial state.

```

x = [0;0;0;0];
for k = 1:N
 y(:,k) = C*x + D*u(:,k);
 x = A*x + B*u(:,k);
end

```

Plot the accelerations of the two masses as functions of time.

```

stem(t,y','.')
xlabel('t')
legend('a_1','a_2')
title('Mass 1 Excited')
grid

```

Convert the system to its transfer function representation. Find the response of the system to a positive unit impulse excitation on the first mass.

```
[b1,a1] = ss2tf(A,B,C,D,1);
y1u1 = filter(b1(1,:),a1,ux);
y1u2 = filter(b1(2,:),a1,ux);
```

Plot the result. The transfer function gives the same response as the state-space model.

```
stem(t,[y1u1;y1u2]','.')
xlabel('t')
legend('a_1','a_2')
title('Mass 1 Excited')
grid
```

The system is reset to its initial configuration. Now the other mass,  $m_2$ , receives a unit impulse in the positive direction. Compute the time evolution of the system.

```

u = [u0;ux];

x = [0;0;0;0];
for k = 1:N
 y(:,k) = C*x + D*u(:,k);
 x = A*x + B*u(:,k);
end

```

Plot the accelerations. The responses of the individual masses are switched.

```
stem(t,y','.')
```

```
xlabel('t')
legend('a_1','a_2')
title('Mass 2 Excited')
grid
```

Find the response of the system to a positive unit impulse excitation on the second mass.

```
[b2,a2] = ss2tf(A,B,C,D,2);
y2u1 = filter(b2(1,:),a2,ux);
y2u2 = filter(b2(2,:),a2,ux);
```

Plot the result. The transfer function gives the same response as the state-space model.

```
stem(t,[y2u1;y2u2]','.')
```

```
xlabel('t')
legend('a_1','a_2')
title('Mass 2 Excited')
grid
```

## Input Arguments

### **A** — State matrix

matrix

State matrix, specified as a matrix. If the system has  $p$  inputs and  $q$  outputs and is described by  $n$  state variables, then  $A$  is  $n$ -by- $n$ .

Data Types: `single` | `double`

## **B — Input-to-state matrix**

matrix

Input-to-state matrix, specified as a matrix. If the system has  $p$  inputs and  $q$  outputs and is described by  $n$  state variables, then **B** is  $n$ -by- $p$ .

Data Types: `single` | `double`

## **C — State-to-output matrix**

matrix

State-to-output matrix, specified as a matrix. If the system has  $p$  inputs and  $q$  outputs and is described by  $n$  state variables, then **C** is  $q$ -by- $n$ .

Data Types: `single` | `double`

## **D — Feedthrough matrix**

matrix

Feedthrough matrix, specified as a matrix. If the system has  $p$  inputs and  $q$  outputs and is described by  $n$  state variables, then **D** is  $q$ -by- $p$ .

Data Types: `single` | `double`

## **ni — Input index**

1 (default) | integer scalar

Input index, specified as an integer scalar. If the system has  $p$  inputs, use `ss2tf` with a trailing argument  $ni = 1, \dots, p$  to compute the response to a unit impulse applied to the  $n$ th input.

Data Types: `single` | `double`

# Output Arguments

## **b — Transfer function numerator coefficients**

vector | matrix

Transfer function numerator coefficients, returned as a vector or matrix. If the system has  $p$  inputs and  $q$  outputs and is described by  $n$  state variables, then **b** is  $q$ -by- $(n + 1)$  for each input. The coefficients are returned in descending powers of  $s$  or  $z$ .

**a** — Transfer function denominator coefficients

vector

Transfer function denominator coefficients, returned as a vector. If the system has  $p$  inputs and  $q$  outputs and is described by  $n$  state variables, then **a** is 1-by- $(n + 1)$  for each input. The coefficients are returned in descending powers of  $s$  or  $z$ .

## More About

### Transfer Function

- For discrete-time systems, the state-space matrices relate the state vector  $x$ , the input  $u$ , and the output  $y$  through

$$\begin{aligned}x(k+1) &= A x(k) + B u(k) \\ y(k) &= C x(k) + D u(k).\end{aligned}$$

The transfer function is the Z-transform of the system's impulse response. It can be expressed in terms of the state-space matrices as

$$H(z) = C(zI - A)^{-1}B + D.$$

- For continuous-time systems, the state-space matrices relate the state vector  $x$ , the input  $u$ , and the output  $y$  through

$$\begin{aligned}\dot{x} &= A x + B u \\ y &= C x + D u.\end{aligned}$$

The transfer function is the Laplace transform of the system's impulse response. It can be expressed in terms of the state-space matrices as

$$H(s) = C(sI - A)^{-1}B + D.$$

## sscanf

Read formatted data from string

### Syntax

```
A = sscanf(str, format)
A = sscanf(str, format, sizeA)
[A, count] = sscanf(...)
[A, count, errmsg] = sscanf(...)
[A, count, errmsg, nextindex] = sscanf(...)
```

### Description

`A = sscanf(str, format)` reads data from string *str*, converts it according to the *format*, and returns the results in array *A*. The `sscanf` function reapplies the *format* until either reaching the end of *str* or failing to match the *format*. If `sscanf` cannot match the *format* to the data, it reads only the portion that matches into *A* and stops processing. If *str* is a character array with more than one row, `sscanf` reads the characters in column order.

`A = sscanf(str, format, sizeA)` reads *sizeA* elements into *A*, where *sizeA* can be an integer or can have the form  $[m, n]$ .

`[A, count] = sscanf(...)` returns the number of elements that `sscanf` successfully reads.

`[A, count, errmsg] = sscanf(...)` returns an error message string when the operation is unsuccessful. Otherwise, *errmsg* is an empty string.

`[A, count, errmsg, nextindex] = sscanf(...)` returns one more than the number of characters scanned in *str*.

## Input Arguments

### format

String enclosed in single quotation marks that describes each type of element (field). Includes one or more of the following specifiers.

Field Type	Specifier	Details
Integer, signed	%d	Base 10
	%i	Base determined from the values. Defaults to base 10. If initial digits are 0x or 0X, it is base 16. If initial digit is 0, it is base 8.
	%ld or %li	64-bit values, base 10, 8, or 16
Integer, unsigned	%u	Base 10
	%o	Base 8 (octal)
	%x	Base 16 (hexadecimal)
	%lu, %lo, %lx	64-bit values, base 10, 8, or 16
Floating-point number	%f	Floating-point fields can contain any of the following (not case sensitive): Inf, -Inf, NaN, or -NaN.
	%e	
	%g	
Character string	%s	Read series of characters, until find white space.
	%c	Read any single character, including white space. (To read multiple characters, specify field length.)
	%[ . . . ]	Read only characters in the brackets, until the first nonmatching character or white space.

Optionally:

- To skip fields, insert an asterisk (\*) after the percent sign (%). For example, to skip integers, specify %\*d.
- To specify the maximum width of a field, insert a number. For example, %10c reads exactly 10 characters at a time, including white space.

- To skip a specific set of characters, insert the literal characters in the *format*. For example, to read only the floating-point number from 'pi=3.14159', specify a *format* of 'pi=%f'.

### **sizeA**

Dimensions of the output array *A*. Specify in one of the following forms:

<i>inf</i>	Read to the end of the input string. (default)
<i>n</i>	Read at most <i>n</i> elements.
[ <i>m,n</i> ]	Read at most <i>m*n</i> elements in column order. <i>n</i> can be <i>inf</i> , but <i>m</i> cannot.

When the *format* includes %s, *A* can contain more than *n* columns. *n* refers to elements, not characters.

### **str**

Character string.

## **Output Arguments**

### **A**

An array. If the *format* includes:

- Only numeric specifiers, *A* is numeric. If *format* includes only 64-bit signed integer specifiers, *A* is of class `int64`. Similarly, if *format* includes only 64-bit unsigned integer specifiers, *A* is of class `uint64`. Otherwise, *A* is of class `double`. If *sizeA* is *inf* or *n*, then *A* is a column vector. If the input contains fewer than *sizeA* elements, MATLAB pads *A* with zeros.
- Only character or string specifiers (%c or %s), *A* is a character array. If *sizeA* is *inf* or *n*, *A* is a row vector. If the input contains fewer than *sizeA* characters, MATLAB pads *A* with `char(0)`.
- A combination of numeric and character specifiers, *A* is numeric, of class `double`. MATLAB converts each character to its numeric equivalent. This conversion occurs even when the *format* explicitly skips all numeric values (for example, a *format* of '%\*d %s').

If MATLAB cannot match the input to the *format*, and the *format* contains both numeric and character specifiers, *A* can be numeric or character. The class of *A* depends on the values MATLAB reads before processing stops.

**count**

Number of elements `sscanf` reads into *A*.

**errmsg**

An error message string when `sscanf` cannot open the specified file. Otherwise, an empty string.

**nextindex**

`sscanf` counts the number of characters `sscanf` reads from *str*, and then adds one.

## Examples

### Example 1

Read multiple floating-point values from a string:

```
s = '2.7183 3.1416';
A = sscanf(s, '%f')
A =
 2.7183
 3.1416
```

### Example 2

Read an octal integer from a string, identified by the '0' prefix, using `%i` to preserve the sign:

```
sscanf('-010', '%i')
ans =
 -8
```

### Example 3

Read numeric values from a two-dimensional character array. By default, `sscanf` reads characters in column order. To preserve the original order of the values, read one row at a time.

```
mixed = ['abc 45 6 ghi'; 'def 7 89 jkl'];

[nrows, ncols] = size(mixed);
for k = 1:nrows
 nums(k,:) = sscanf(mixed(k,:), '%*s %d %d %*s', [1, inf]);
end;

% type the variable name to see the result
nums =
 45 6
 7 89
```

### Example 4

`sscanf` finds one match for `%s`

```
[str count] = sscanf('ThisIsOneString', '%s')
str =
 ThisIsOneString
count =
 1
```

`sscanf` finds four matches for `%s`. Because it does not match space characters, there are no spaces in the output string:

```
[str count] = sscanf('These Are Four Strings', '%s')
str =
 TheseAreFourStrings
count =
 4
```

`sscanf` finds five word matches for `%s` and four space character matches for `%c`. Because the `%c` specifier does match a space character, the output string does include spaces:

```
[str count] = sscanf('Five strings and four spaces', '%s%c')
str =
 Five strings and four spaces
```

```
count =
 9
```

sscanf finds three word matches for %s and two numeric matches for %d. Because the format specifier has a mixed %d and %s format, sscanf converts all nonnumeric characters to numeric:

```
[str count] = sscanf('5 strings and 4 spaces', '%d%s%d%s');
str'
 Columns 1 through 9
 5 115 116 114 105 110 103 115 97
 Columns 10 through 18
 110 100 4 115 112 97 99 101 115
count
count =
 5
```

## Example 5

```
[str, count] = sscanf('one two three', '%c')
str =
 one two three
count =
 13
```

```
[str, count] = sscanf('one two three', '%13c')
str =
 one two three
count =
 1
```

```
[str, count] = sscanf('one two three', '%s')
str =
 onetwothree
count =
 3
```

```
[str, count] = sscanf('one two three', '%1s')
str =
 onetwothree
count =
 11
```

## Example 6

```
tempString = '78°F 72°F 64°F 66°F 49°F';

degrees = char(176);
tempNumeric = sscanf(tempString, ['%d' degrees 'F'])'
tempNumeric =
 78 72 64 66 49
```

## More About

### Tips

- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

### See Also

[fscanf](#) | [sprintf](#) | [textscan](#)

**Introduced before R2006a**

## stack

Stack data from multiple variables into single variable

### Syntax

```
T = stack(W,vars)
T = stack(W,vars,Name,Value)
[T,iw] = stack(___)
```

### Description

`T = stack(W,vars)` converts the wide table, `W`, into an equivalent table, `T`, that is in tall format. `stack` stacks up multiple variables from `W`, specified by `vars`, into a single variable in `T`. In general, `T` contains fewer variables, but more rows, than `W`.

The output table, `T`, contains a new categorical variable to indicate which variable in `W` the stacked data in each row came from. `stack` replicates data from the variables in `W` that are not stacked.

`T = stack(W,vars,Name,Value)` converts the table, `W`, to tall format with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify variable names for the new and stacked variables in `W`.

`[T,iw] = stack( ___ )` also returns an index vector, `iw`, indicating the correspondence between rows in `T` and rows in `W`. You can use any of the previous input arguments.

### Examples

#### Stack Three Variables into One

Create a table containing test scores from three separate tests.

```
Test1 = [93;57;87;89];
Test2 = [89;77;92;86];
Test3 = [95;62;89;91];
```

```
W = table(Test1,Test2,Test3)
```

```
W =
```

Test1	Test2	Test3
93	89	95
57	77	62
87	92	89
89	86	91

The table contains four rows and three variables.

Stack the test scores into a single variable.

```
T = stack(W,1:3)
```

```
T =
```

Test1_Test2_Test3_Indicator	Test1_Test2_Test3
Test1	93
Test2	89
Test3	95
Test1	57
Test2	77
Test3	62
Test1	87
Test2	92
Test3	89
Test1	89
Test2	86
Test3	91

T contains twelve rows and two variables.

The categorical variable, `Test1_Test2_Test3_Indicator`, identifies which test corresponds to the score in the stacked data variable, `Test1_Test2_Test3`.

### Stack Variables and Specify Variable Names

Create a table indicating the amount of snowfall at three locations from five separate storms.

```
Storm = [1;2;3;4;5];
Date = {'12/25/11'; '1/2/12'; '1/23/12'; '2/7/12'; '2/15/12'};
Natick = [20;5;13;0;17];
Boston = [18;9;21;5;12];
Worcester = [26;10;16;3;15];
```

```
W = table(Storm,Date,Natick,Boston,Worcester)
```

```
W =
```

Storm	Date	Natick	Boston	Worcester
1	'12/25/11'	20	18	26
2	'1/2/12'	5	9	10
3	'1/23/12'	13	21	16
4	'2/7/12'	0	5	3
5	'2/15/12'	17	12	15

The variables `Storm` and `Date` contain data that is constant at each location.

Stack the variables `Natick`, `Boston`, and `Worcester` into a single variable. Name the variable containing the stacked data, `Snowfall`, and name the new indicator variable, `Town`.

```
T = stack(W,{'Natick','Boston','Worcester'},...
 'NewDataVariableName','Snowfall',...
 'IndexVariableName','Town')
```

```
T =
```

Storm	Date	Town	Snowfall
1	'12/25/11'	Natick	20
1	'12/25/11'	Boston	18
1	'12/25/11'	Worcester	26
2	'1/2/12'	Natick	5
2	'1/2/12'	Boston	9
2	'1/2/12'	Worcester	10
3	'1/23/12'	Natick	13
3	'1/23/12'	Boston	21
3	'1/23/12'	Worcester	16
4	'2/7/12'	Natick	0
4	'2/7/12'	Boston	5

4	'2/7/12'	Worcester	3
5	'2/15/12'	Natick	17
5	'2/15/12'	Boston	12
5	'2/15/12'	Worcester	15

T contains three rows for each storm, and `stack` repeats the data in the constant variables, `Storm` and `Date`, accordingly.

The categorical variable, `Town`, identifies which variable in `W` contains the corresponding Snowfall data.

### Stack Variables and Output an Index Vector

Create a table containing estimated influenza rates along the east coast of the United States. Create a different variable for the Northeast, Mid Atlantic, and South Atlantic. Data Source: Google Flu Trends (<http://www.google.org/flutrends>).

```
Month = {'October'; 'November'; 'December'; ...
 'January'; 'February'; 'March'};
Year = [2005*ones(3,1); 2006*ones(3,1)];
NE = [1.1902; 1.3610; 1.5003; 1.7772; 2.1350; 2.2345];
MidAtl = [1.1865; 1.4120; 1.6043; 1.8830; 2.1227; 1.9920];
SAtl = [1.2730; 1.5820; 1.8625; 1.9540; 2.4803; 2.0203];
```

```
fluW = table(Month,Year,NE,MidAtl,SAtl)
```

fluW =

Month	Year	NE	MidAtl	SAtl
'October'	2005	1.1902	1.1865	1.273
'November'	2005	1.361	1.412	1.582
'December'	2005	1.5003	1.6043	1.8625
'January'	2006	1.7772	1.883	1.954
'February'	2006	2.135	2.1227	2.4803
'March'	2006	2.2345	1.992	2.0203

The variables `Month` and `Year` contain data that is constant across the row.

Stack the variables `NE`, `MidAtl`, and `SAtl` into a single variable called `FluRate`. Name the new indicator variable `Region` and output an index vector, `ifluW`, to indicate the correspondence between rows in the input wide table, `fluW`, and the output tall table, `flUT`.

```
[fluT,ifluW] = stack(fluW,3:5,...
 'NewDataVariableName','FluRate',...
 'IndexVariableName','Region')
```

```
fluT =
```

Month	Year	Region	FluRate
'October'	2005	NE	1.1902
'October'	2005	MidAtl	1.1865
'October'	2005	SAtl	1.273
'November'	2005	NE	1.361
'November'	2005	MidAtl	1.412
'November'	2005	SAtl	1.582
'December'	2005	NE	1.5003
'December'	2005	MidAtl	1.6043
'December'	2005	SAtl	1.8625
'January'	2006	NE	1.7772
'January'	2006	MidAtl	1.883
'January'	2006	SAtl	1.954
'February'	2006	NE	2.135
'February'	2006	MidAtl	2.1227
'February'	2006	SAtl	2.4803
'March'	2006	NE	2.2345
'March'	2006	MidAtl	1.992
'March'	2006	SAtl	2.0203

```
ifluW =
```

```
1
1
1
2
2
2
3
3
3
4
4
4
5
5
```

5  
6  
6  
6

`ifluW(5)` is 2. The fifth row in the output table, `fluT`, contains data from the second row in the input table `fluW`.

## Input Arguments

### **W** — Wide table

table

Wide table, specified as a table.

### **vars** — Variables in *W* to stack

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables in *W* to stack, specified as a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'NewDataVariableName'`, `'StackedData'` names the new data variable `StackedData`.

### **'ConstantVariables'** — Variables other than `vars` to include in the output

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables other than `vars` to include in the output, specified as the comma-separated pair consisting of `'ConstantVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector. `stack` replicates the data from the constant variables for each stacked entry from a row.

The default is all the variables in *W* not specified by `vars`. You can specify the `'ConstantVariables'` name-value pair argument to exclude variables not specified by `vars` or `'ConstantVariables'` from the output table, *T*.

**'NewDataVariableName' — Name for the new data variable in *T***

string

Name for the new data variable in *T*, specified as the comma-separated pair consisting of `'NewDataVariableName'` and a string. The default is a concatenation of the names of the variables from *W* that are stacked up.

**'IndexVariableName' — Name for the new indicator variable in *T***

string

Name for the new indicator variable in *T*, specified as the comma-separated pair consisting of `'IndexVariableName'` and a string. The default is a name based on `NewDataVariableName`.

## Output Arguments

***T* — Tall table**

table

Tall table, returned as a table. *T* contains a stacked data variable, a categorical indicator variable, and any constant variables.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the table. For more information, see [Table Properties](#).

`stack` assigns the variable units and variable description property values from the first variable listed in `vars` to the corresponding `T.Properties.VariableUnits` and `T.Properties.VariableDescriptions` values for the new data variable.

***iw* — Index to *W***

column vector

Index to *W*, returned as a column vector. The index vector, *iw*, identifies the row in the input table, *W*, containing the corresponding data. `stack` creates the *j*th row in the output table, *T*, using `W(iw(j),vars)`.

## More About

### Tips

- You can specify more than one group of data variables in `W`, and each group becomes a stacked data variable in `T`. Use a cell array to contain multiple values for `vars`, and a cell array of strings to contain multiple values for the `'NewDataVariableName'` name-value pair argument. All groups must contain the same number of variables.

## stairs

Stairstep graph

### Syntax

```
stairs(Y)
stairs(X,Y)
stairs(____,LineStyle)
stairs(____,Name,Value)

stairs(ax, ____)

h = stairs(____)

[xb,yb] = stairs(____)
```

### Description

`stairs(Y)` draws a stairstep graph of the elements in `Y`.

- If `Y` is a vector, then `stairs` draws one line.
- If `Y` is a matrix, then `stairs` draws one line per matrix column.

`stairs(X,Y)` plots the elements in `Y` at the locations specified by `X`. The inputs `X` and `Y` must be vectors or matrices of the same size. Additionally, `X` can be a row or column vector and `Y` must be a matrix with `length(X)` rows.

`stairs( ____,LineStyle)` specifies a line style, marker symbol, and color. For example, `':*r'` specifies a dotted red line with asterisk markers. Use this option with any of the input argument combinations in the previous syntaxes.

`stairs( ____,Name,Value)` specifies stair properties using one or more `Name,Value` pair arguments. For example, `'Marker','o','MarkerSize',8` specifies 8 point circle markers.

`stairs(ax, ____)` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option, `ax`, can precede any of the input argument combinations in the previous syntaxes.

`h = stairs( ___ )` returns one or more stair objects. Use `h` to make changes to properties of a specific stair object after it is created.

`[xb,yb] = stairs( ___ )` does not create a plot, but returns matrices `xb` and `yb` of the same size, such that `plot(xb,yb)` plots the staircase graph.

## Examples

### Plot Single Data Series

Create a staircase plot of sine evaluated at 40 equally spaced values between 0 and  $4\pi$ .

```
X = linspace(0,4*pi,40);
Y = sin(X);
```

```
figure
stairs(Y)
```

The length of  $Y$  automatically determines and generates the  $x$ -axis scale.

### Plot Multiple Data Series

Create a staircase plot of two cosine functions evaluated at 50 equally spaced values between 0 and  $4\pi$ .

```
X = linspace(0,4*pi,50)';
Y = [0.5*cos(X), 2*cos(X)];
```

```
figure
stairs(Y)
```

The number of rows in *Y* automatically determines and generates the *x*-axis scale.

### **Plot Single Data Series at Specified *x*-Values**

Create a staircase plot of a sine wave evaluated at equally spaced values between 0 and  $4\pi$ . Specify the set of *x*-values for the plot.

```
X = linspace(0,4*pi,40);
Y = sin(X);
```

```
figure
stairs(X,Y)
```

The entries in  $Y$  are plotted against the corresponding entries in  $X$ .

### Plot Multiple Data Series at Specified $x$ -Values

Create a staircase plot of two cosine waves evaluated at equally spaced values between 0 and  $4\pi$ . Specify the set of  $x$ -values for the plot.

```
X = linspace(0,4*pi,50)';
Y = [0.5*cos(X), 2*cos(X)];
```

```
figure
stairs(X,Y)
```

The first vector input,  $X$ , determines the  $x$ -axis positions for both data series.

### Plot Multiple Data Series at Unique Sets of $x$ -Values

Create a staircase plot of two sine waves evaluated at different values. Specify a unique set of  $x$ -values for plotting each data series.

```
x1 = linspace(0,2*pi)';
x2 = linspace(0,pi)';
X = [x1,x2];
Y = [sin(5*x1),exp(x2).*sin(5*x2)];
```

```
figure
stairs(X,Y)
```

Each column of  $X$  is plotted against the corresponding column of  $Y$ .

### Specify Line Style, Marker Symbol and Color

Create a staircase plot and set the line style to a dot-dashed line, the marker symbol to circles, and the color to red.

```
X = linspace(0,4*pi,20);
Y = sin(X);
```

```
figure
stairs(Y, '-.or')
```

### Specify Additional Style Options

Create a staircase plot and set the line width to 2, the marker symbols to diamonds, and the marker face color to cyan using `Name, Value` pair arguments.

```
X = linspace(0,4*pi,20);
Y = sin(X);
```

```
figure
stairs(Y, 'LineWidth', 2, 'Marker', 'd', 'MarkerFaceColor', 'c')
```

### Specify Axes for Stairstep Plots

Create a figure with two subplots and return the two axes handles, `s(1)` and `s(2)`. Create a staircase plot in each subplot by referring to the axes handles.

```
figure
s(1) = subplot(2,1,1);
s(2) = subplot(2,1,2);

X = linspace(0,2*pi);
Y1 = 5*sin(X);
Y2 = sin(5*X);
stairs(s(1),X,Y1)
stairs(s(2),X,Y2)
```

## Modify Stairstep Plot After Creation

Create a stairstep plot of two data series and return the two stair objects.

```
X = linspace(0,1,30)';
Y = [cos(10*X), exp(X).*sin(10*X)];
h = stairs(X,Y);
```

Use small circle markers for the first data series. Use magenta filled circles for the second series. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
h(1).Marker = 'o';
h(1).MarkerSize = 4;
h(2).Marker = 'o';
h(2).MarkerFaceColor = 'm';
```

### Create a Stairstep Plot using plot Function

Evaluate two cosine functions at 50 equally spaced values between 0 and  $4\pi$  and create a stairstep plot using `plot`.

```
X = linspace(0,4*pi,50)';
Y = [0.5*cos(X), 2*cos(X)];
[xb,yb] = stairs(X,Y);
```

`stairs` returns two matrices of the same size, `xb` and `yb`, but no plot.

Use `plot` to create the stairstep plot with `xb` and `yb`.

```
figure
```

```
plot(xb,yb)
```

## Input Arguments

### Y — y values

vector or matrix

y values, specified as a vector or matrix. When Y is a vector, `stairs` creates one stair object. When Y is a matrix, `stairs` draws one line per matrix column and creates a separate stair object for each column.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**X — x values**

vector or matrix

x values, specified as a vector or matrix. When Y is a vector, X must be a vector of the same size. When Y is a matrix, X must be a matrix of the same size, or a vector whose length equals the number of rows in Y.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**LineStyle — Line style, marker symbol, and color**

string

Line style, marker symbol, and color, specified as a string. For more information on line style, marker symbol, and color options see `LineStyle`.

Example: `'*r'`

**ax — Axes object**

axes object

Axes object. If you do not specify an axes, then `stairs` plots into the current axes.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Marker', 's', 'MarkerFaceColor', 'red'` plots the staircase graph with red square markers.

The properties listed here are only a subset. For a complete list, see `Stair Properties`.

**'LineStyle' — Line style**

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
<code>'-'</code>	Solid line	

String	Line Style	Resulting Line
'--'	Dashed line	-----
':'	Dotted line	.....
'-.'	Dash-dotted line	-----
'none'	No line	No line

### 'LineWidth' — Line width

0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

### 'Color' — Line color

[0 0.4470 0.7410] (default) | RGB triplet | color string | 'none'

Line color, specified as an RGB triplet, a color string, or 'none'. If you specify the Color as 'none', then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

**'Marker' – Marker symbol**

'none' (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the stairs object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

**'MarkerSize' – Marker size**

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

**'MarkerEdgeColor' — Marker outline color**

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the `Color` property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example:  $[0.5 \ 0.5 \ 0.5]$

Example: 'blue'

**'MarkerFaceColor' — Marker fill color**

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the `Color` property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

Example:  $[0.3 \ 0.2 \ 0.1]$

Example: 'green'

## Output Arguments

### **h** — Stair objects

scalar or column vector

Stair objects, returned as a scalar or a column vector. These are unique identifiers, which you can use to query and modify the properties of a specific stair object after it is created.

### **xb** — x values for use with plot

vector or matrix

x values for use with `plot`, specified as a vector or matrix. `xb` contains the appropriate values such that `plot(xb,yb)` creates the staircase graph.

### **yb** — y values for use with plot

vector or matrix

y values for use with `plot`, specified as a vector or matrix. `yb` contains the appropriate values such that `plot(xb,yb)` creates the staircase graph.

## See Also

### Functions

bar | histogram | LineSpec | stem

### Properties

Stair Properties

**Introduced before R2006a**

## Stair Properties

Control stair appearance and behavior

Stair properties control the appearance and behavior of a stair object. By changing property values, you can modify certain aspects of the stairs.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = stairs(1:10);
c = h.Color;
h.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Line

#### LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	
'--'	Dashed line	
':'	Dotted line	
'-.'	Dash-dotted line	
'none'	No line	No line

#### LineWidth — Line width

0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

**Color — Line color**

[0 0 0] (default) | RGB triplet | color string | 'none'

Line color, specified as an RGB triplet, a color string, or 'none'. The default RGB triplet value of [0 0 0] corresponds to black. If you specify the **Color** as 'none', then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

**Markers****Marker — Marker symbol**

'none' (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the stair object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
'o'	Circle

String	Marker Symbol
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

**MarkerSize — Marker size**

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

**MarkerEdgeColor — Marker outline color**

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the **Color** property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.5 0.5 0.5]

Example: 'blue'

### MarkerFaceColor — Marker fill color

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the Color property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]

Long Name	Short Name	RGB Triplet
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.3 0.2 0.1]

Example: 'green'

## Data

### XData — x values

[ ] (default) | vector

*x* values, specified as a vector. The input argument *X* to the `stairs` function sets the *x* values. If you do not specify the *x* values, then `stairs` uses the indices of `YData`. `XData` and `YData` must have equal lengths.

Example: 1:10

### YData — y values

[ ] (default) | vector

*y* values, specified as a vector. The input argument *Y* to the `stairs` function sets the *y* values. `XData` and `YData` must have equal lengths.

Example: 1:10

### XDataSource — Variable linked to XData

' ' (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'x'

### **YDataSource** — Variable linked to YData

' ' (default) | string containing MATLAB workspace variable name

Variable linked to YData, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the YData.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, then MATLAB does not update the YData values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'y'

### **XDataMode** — Selection mode for XData

'auto' (default) | 'manual'

Selection mode for XData, specified as one of these values:

- 'auto' — Use the indices of the values in YData (or ZData for 3-D plots).
- 'manual' — Use manually specified values. To specify the values, set the XData property or specify the input argument X to the plotting function.

## **Visibility**

### **Visible** — State of visibility

'on' (default) | 'off'

State of visibility, specified as one of these values:

- 'on' — Display the stair.

- 'off' — Hide the stair without deleting it. You still can access the properties of an invisible stair object.

**Clipping — Clipping of stair object to axes limits**

'on' (default) | 'off'

Clipping of the stair object to the axes limits, specified as one of these values:

- 'on' — Do not display parts of the stair object that are outside the axes limits.
- 'off' — Display the entire stair object, even if parts of it appear outside the axes limits. Parts of the stair object might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the stair object so that it is larger than the original plot.

The **Clipping** property of the axes that contains the stair object must be set to 'on', otherwise this property has no effect. For more information about the clipping behavior, see the Clipping property of the axes.

**EraseMode — (removed) Technique to draw and erase objects**

'normal' (default) | 'none' | 'xor' | 'background'

---

**Note:** **EraseMode** has been removed. You can delete code that accesses the **EraseMode** property with minimal impact. If you were using **EraseMode** to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- 'normal' — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- 'none' — Do not erase the object when it is moved or destroyed. After you erase the object with **EraseMode**, 'none', it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- 'xor' — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.

- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### Type — Type of graphics object

`'stair'`

This property is read only.

Type of graphics object, returned as `'stair'`. Use this property to find all objects of a given type within a plotting hierarchy, such as searching for the type using `findobj`.

### Tag — Tag to associate with stair

`''` (default) | string

Tag to associate with the stair, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

### UserData — Data to associate with stair

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the stair object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

## **DisplayName** — Text used by legend

`''` (default) | `string`

Text used by the legend, specified as a string. The text appears next to an icon of the stair.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the stair object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

## **Annotation** — Legend icon display style

`Annotation` object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the stair from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - `'on'` — Include the stair object in the legend as one entry (default).

- `'off'` — Do not include the stair object in the legend.
- `'children'` — Include only children of the stair object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## Parent/Child

### Parent — Parent of stair

`axes object` | `group object` | `transform object`

Parent of stair, specified as an axes, group, or transform object.

### Children — Children of stair

empty `GraphicsPlaceholder` array

The stair has no children. You cannot set this property.

### HandleVisibility — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of stair object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The stair object handle is always visible.
- `'off'` — The stair object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The stair object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the stair at the command-line, but allows callback functions to access it.

If the stair object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### **ButtonDownFcn** — Mouse-click callback

`'` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the stair. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The stair object — You can access properties of the stair object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (`-`) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **UIContextMenu** — Context menu

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the stair. Create the context menu using the `uicontextmenu` function.

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then the context menu does not appear.

---

### **Selected** — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the stair when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the `SelectionHighlight` property also is set to `'on'`, then MATLAB displays selection handles around the stair.
- `'off'` — Not selected.

### **SelectionHighlight** — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the `Selected` property is set to `'on'`.
- `'off'` — Never display selection handles, even when the `Selected` property is set to `'on'`.

## **Callback Execution Control**

### **PickableParts** — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The `Visible` property must be set to `'on'` and you must click a part of the stair that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The `HitTest` property determines if the stair responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the stair passes the click to the object below it in the current view of the figure window. The `HitTest` property of the stair has no effect.

## **HitTest — Response to captured mouse clicks**

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the `ButtonDownFcn` callback of the stair. If you have defined the `UIContextMenu` property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the stair that has a `HitTest` property set to 'on' and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the stair object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

## **HitTestArea — (removed) Extents of clickable area for stair**

'off' (default) | 'on'

---

**Note:** `HitTestArea` has been removed. Use `PickableParts` instead.

---

Extents of clickable area for stair, specified as one of these values:

- 'off' — Click the stair plot to select it. This is the default value.
- 'on' — Click anywhere within the extent of the stair plot to select it, that is, anywhere within the rectangle that encloses the stair plot.

Example: 'off'

## **Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the stair is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the stair tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the stair. Setting the `CreateFcn` property on an existing stair has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during stair creation. MATLAB executes the callback after creating the stair and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The stair object — You can access properties of the stair object from within the callback function. You also can access the stair object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

**DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the stair. MATLAB executes the callback before destroying the stair so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The stair object — You can access properties of the stair object from within the callback function. You also can access the stair object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

**BeingDeleted — Deletion status of stair**

'off' (default) | 'on'

This property is read only.

Deletion status of stair, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the stair begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the stair no longer exists.

Check the value of the `BeingDeleted` property to verify that the stair is not about to be deleted before querying or modifying it.

# standardizeMissing

Insert missing value indicators into table

## Syntax

```
B = standardizeMissing(A,id)
B = standardizeMissing(A,id,'DataVariables',vars)
```

## Description

`B = standardizeMissing(A,id)` replaces all instances of the values specified in `id` occurring within table `A` with the standard missing value indicators. `B` is a table.

The standard missing value indicators depend on the data type:

- NaN for double and single floating-point arrays
- <undefined> for categorical arrays
- empty string, { ' ' }, for cell arrays of strings
- blank string, [ ' ' ], for character arrays

`standardizeMissing` checks double and single variables in `A` against numeric values from `id` and checks string and categorical variables in `A` against strings from `id`. The function `standardizeMissing` ignores integer data types because they cannot contain NaN.

`B = standardizeMissing(A,id,'DataVariables',vars)` replaces values only in variables specified by `vars`.

## Examples

### Replace All Instances of Specified Values

Create a table containing Inf and 'N/A' to represent missing values.

```
dblVar = [NaN;3;Inf;7;9];
```

```
cellstrVar = {'one';'three';'';'NA';'nine'};
charVar = ['A';'C';'E';' ';'I'];
categoryVar = categorical({'red';'yellow';'blue';'violet';''});
```

```
A = table(dblVar,cellstrVar,charVar,categoryVar)
```

```
A =
```

dblVar	cellstrVar	charVar	categoryVar
NaN	'one'	A	red
3	'three'	C	yellow
Inf	''	E	blue
7	'NA'		violet
9	'nine'	I	<undefined>

Replace all instances of `Inf` with `NaN` and replace all instances of `'NA'` with the empty string, `''`.

```
B = standardizeMissing(A,{Inf,'NA'})
```

```
B =
```

dblVar	cellstrVar	charVar	categoryVar
NaN	'one'	A	red
3	'three'	C	yellow
NaN	''	E	blue
7	''		violet
9	'nine'	I	<undefined>

### Replace Only Values in Specified Variables

Replace instances of `Inf`, and `'N/A'`, occurring in specified variables of a table, with the standard missing value indicators.

Create a table containing `Inf` and `'N/A'` to represent missing values.

```
a = {'alpha';'bravo';'charlie';'';'N/A'};
x = [1;NaN;3;Inf;5];
y = [57;732;93;1398;Inf];
```

```
A = table(a,x,y)
```

A =

a	x	y
'alpha'	1	57
'bravo'	NaN	732
'charlie'	3	93
''	Inf	1398
'N/A'	5	Inf

For the variables `a` and `x`, replace instances of `Inf` with `NaN` and `'N/A'` with the empty string, `''`.

```
B = standardizeMissing(A,{Inf, 'N/A'}, 'DataVariables', {'a', 'x'})
```

B =

a	x	y
'alpha'	1	57
'bravo'	NaN	732
'charlie'	3	93
''	NaN	1398
''	5	Inf

`Inf` in the variable `y` remains unchanged because `y` is not included in the `'DataVariables'` name-value pair argument.

## Input Arguments

### A — Input table

table

Input table, specified as a table.

### id — Nonstandard missing value indicators

numeric vector | string | cell array containing numeric values and strings

Nonstandard missing value indicators, specified as a numeric vector, string, or cell array containing numeric values and strings.

## **vars** — Subset of variables to consider

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Subset of variables to consider, specified as a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

## Output Arguments

### **B** — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

## More About

### Algorithms

`standardizeMissing` treats leading and trailing white space differently for cell arrays of strings, character arrays, and categorical arrays.

- For cell arrays of strings, `standardizeMissing` does not ignore white space. All strings must match exactly a string specified in `id`.
- For character arrays, `standardizeMissing` ignores trailing white space.
- For categorical arrays, `standardizeMissing` ignores leading and trailing white space.

---

# startup

Start up file for user-defined options

## Syntax

startup

## Description

startup executes commands of your choosing when the MATLAB program starts.

Create a `startup.m` file in a folder on the MATLAB search path. Add commands you want executed at startup. For example, your `startup.m` file might include physical constants, defaults for Handle Graphics properties, engineering conversion factors, or anything else you want predefined in your workspace.

## More About

### Tips

- To specify the current folder in MATLAB when it starts, set the **Initial working folder** preference, described in “General Preferences”.

### Algorithms

At startup, MATLAB automatically executes the file `matlabrc.m` and, if it exists on the MATLAB search path, `startup.m`. The file `matlabrc.m`, which is in the *matlabroot*/toolbox/local folder, is reserved for use by MathWorks and by system administrators on multiuser systems.

## std

Standard deviation

### Syntax

```
S = std(A)
S = std(A,w)
S = std(A,w,dim)
S = std(____,nanflag)
```

### Description

`S = std(A)` returns the standard deviation of the elements of `A` along the first array dimension whose size does not equal 1.

- If `A` is a vector of observations, then the standard deviation is a scalar.
- If `A` is a matrix whose columns are random variables and whose rows are observations, then `S` is a row vector containing the standard deviations corresponding to each column.
- If `A` is a multidimensional array, then `std(A)` operates along the first array dimension whose size does not equal 1, treating the elements as vectors. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.
- By default, the standard deviation is normalized by `N - 1`, where `N` is the number of observations.

`S = std(A,w)` specifies a weighting scheme for any of the previous syntaxes. When `w = 0` (default), `S` is normalized by `N - 1`. When `w = 1`, `S` is normalized by the number of observations, `N`. `w` also can be a weight vector containing nonnegative elements. In this case, the length of `w` must equal the length of the dimension over which `std` is operating.

`S = std(A,w,dim)` returns the standard deviation along dimension `dim` for any of the previous syntaxes. To maintain the default normalization while specifying the dimension of operation, set `w = 0` in the second argument.

`S = std( ____,nanflag)` specifies whether to include or omit NaN values from the calculation for any of the previous syntaxes. For example, `std(A, 'includenan')` includes all NaN values in `A` while `std(A, 'omitnan')` ignores them.

## Examples

### Standard Deviation of Matrix Columns

Create a matrix and compute the standard deviation of each column.

```
A = [4 -5 1; 2 3 5; -9 1 7];
S = std(A)
```

```
S =

 7.0000 4.1633 3.0551
```

### Standard Deviation of 3-D Array

Create a 3-D array and compute the standard deviation along the first dimension.

```
A(:,:,1) = [2 4; -2 1];
A(:,:,2) = [9 13; -5 7];
A(:,:,3) = [4 4; 8 -3];
S = std(A)
```

```
S(:,:,1) =

 2.8284 2.1213
```

```
S(:,:,2) =

 9.8995 4.2426
```

```
S(:,:,3) =

 2.8284 4.9497
```

### Specify Standard Deviation Weights

Create a matrix and compute the standard deviation of each column according to a weight vector  $w$ .

```
A = [1 5; 3 7; -9 2];
w = [1 1 0.5];
S = std(A,w)
```

```
S =
```

```
4.4900 1.8330
```

## Standard Deviation Along Matrix Rows

Create a matrix and calculate the standard deviation along each row.

```
A = [6 4 23 -3; 9 -10 4 11; 2 8 -5 1];
S = std(A,0,2)
```

```
S =
```

```
11.0303
9.4692
5.3229
```

## Standard Deviation Excluding NaN

Create a vector and compute its standard deviation, excluding NaN values.

```
A = [1.77 -0.005 3.98 -2.95 NaN 0.34 NaN 0.19];
S = std(A, 'omitnan')
```

```
S =
```

```
2.2797
```

## Input Arguments

### A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. If  $A$  is a scalar, then `std(A)` returns 0. If  $A$  is a 0-by-0 empty array, then `std(A)` returns NaN.

Data Types: `single` | `double`

Complex Number Support: Yes

### **w — Weight**

0 (default) | 1 | vector

Weight, specified as one of these values:

- 0 — Normalize by  $N - 1$ , where  $N$  is the number of observations. If there is only one observation, then the weight is 1.
- 1 — Normalize by  $N$ .
- Vector made up of nonnegative scalar weights corresponding to the dimension of  $A$  along which the standard deviation is calculated.

Data Types: `single` | `double`

### **dim — Dimension to operate along**

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to 1. The `size(S, dim)` is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array,  $A$ .

- If `dim = 1`, then `std(A, 0, 1)` returns a row vector containing the standard deviation of the elements in each column.

`std(A,0,1)`

- If `dim = 2`, then `std(A,0,2)` returns a column vector containing the standard deviation of the elements in each row.

`std(A,0,2)`

If `dim` is greater than `ndims(A)`, then `std(A)` returns an array of zeros the same size as `A`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**nanflag — NaN condition**

`'includenan'` (default) | `'omitnan'`

NaN condition, specified as one of these values:

- `'includenan'` — Include NaN values when computing the standard deviation, resulting in NaN.
- `'omitnan'` — Ignore NaN values appearing in either the input array or weight vector.

Data Types: char

## More About

### Standard Deviation

For a random variable vector  $A$  made up of  $N$  scalar observations, the standard deviation is defined as

$$S = \sqrt{\frac{1}{N-1} \sum_{i=1}^N |A_i - \mu|^2} ,$$

where  $\mu$  is the mean of  $A$ :

$$\mu = \frac{1}{N} \sum_{i=1}^N A_i.$$

The standard deviation is the square root of the variance. Some definitions of standard deviation use a normalization factor of  $N$  instead of  $N-1$ , which you can specify by setting `w` to 1.

### See Also

`corrcoef` | `cov` | `mean` | `median` | `var`

Introduced before R2006a

## stem

Plot discrete sequence data

### Syntax

```
stem(Y)
stem(X,Y)
stem(____, 'filled')
stem(____, LineSpec)
stem(____, Name, Value)
```

```
stem(ax, ____)
```

```
h = stem(____)
```

### Description

`stem(Y)` plots the data sequence, `Y`, as stems that extend from a baseline along the  $x$ -axis. The data values are indicated by circles terminating each stem.

- If `Y` is a vector, then the  $x$ -axis scale ranges from 1 to `length(Y)`.
- If `Y` is a matrix, then `stem` plots all elements in a row against the same  $x$  value, and the  $x$ -axis scale ranges from 1 to the number of rows in `Y`.

`stem(X,Y)` plots the data sequence, `Y`, at values specified by `X`. The `X` and `Y` inputs must be vectors or matrices of the same size. Additionally, `X` can be a row or column vector and `Y` must be a matrix with `length(X)` rows.

- If `X` and `Y` are both vectors, then `stem` plots entries in `Y` against corresponding entries in `X`.
- If `X` is a vector and `Y` is a matrix, then `stem` plots each column of `Y` against the set of values specified by `X`, such that all elements in a row of `Y` are plotted against the same value.
- If `X` and `Y` are both matrices, then `stem` plots columns of `Y` against corresponding columns of `X`.

Data values are plotted as stems extending from the baseline and terminating at the data value. The length of Y automatically determines the position of each stem on the x-axis.

### Plot Multiple Data Series

Plot two data series using a two-column matrix.

```
figure
X = linspace(0,2*pi,50)';
Y = [cos(X), 0.5*sin(X)];
stem(Y)
```

Each column of  $Y$  is plotted as a separate series, and entries in the same row of  $Y$  are plotted against the same  $x$  value. The number of rows in  $Y$  automatically generates the position of each stem on the  $x$ -axis.

### Plot Single Data Series at Specified $x$ values

Plot 50 data values of cosine evaluated between 0 and  $2\pi$  and specify the set of  $x$  values for the stem plot.

```
figure
X = linspace(0,2*pi,50)';
Y = cos(X);
stem(X,Y)
```

The first vector input determines the position of each stem on the  $x$ -axis.

### Plot Multiple Data Series at Specified $x$ values

Plot 50 data values of sine and cosine evaluated between 0 and  $2\pi$  and specify the set of  $x$  values for the stem plot.

```
figure
X = linspace(0,2*pi,50)';
Y = [cos(X), 0.5*sin(X)];
stem(X,Y)
```

The vector input determines the  $x$ -axis positions for both data series.

### Plot Multiple Data Series at Unique Sets of $x$ values

Plot 50 data values of sine and cosine evaluated at different sets of  $x$  values. Specify the corresponding sets of  $x$  values for each series.

```
figure
x1 = linspace(0,2*pi,50)';
x2 = linspace(pi,3*pi,50)';
X = [x1, x2];
Y = [cos(x1), 0.5*sin(x2)];
stem(X,Y)
```

Each column of X is plotted against the corresponding column of Y.

### Fill in Plot Markers

Create a stem plot and fill in the circles that terminate each stem.

```
X = linspace(0,10,20)';
Y = (exp(0.25*X));
stem(X,Y,'filled')
```

### Specify Stem and Marker Options

Create a stem plot and set the line style to a dotted line, the marker symbols to diamonds, and the color to red using the `LineStyle` option.

```
figure
X = linspace(0,2*pi,50)';
Y = (exp(X).*sin(X));
stem(X,Y,':diamondr')
```

To color the inside of the diamonds, use the 'fill' option.

### Specify Additional Stem and Marker Options

Create a stem plot and set the line style to a dot-dashed line, the marker face color to red, and the marker edge color to green using Name, Value pair arguments.

```
figure
X = linspace(0,2*pi,25)';
Y = (cos(2*X));
stem(X,Y,'LineStyle','-.',...
 'MarkerFaceColor','red',...
 'MarkerEdgeColor','green')
```

The stem remains the default color.

### Specify Axes for Stem Plot

Create a figure with two subplots and return the handles to each axes, `s(1)` and `s(2)`. Create a stem plot in the lower subplot by referring to its axes handle, `s(2)`.

```
figure
s(1) = subplot(2,1,1);
s(2) = subplot(2,1,2);

X = 0:25;
Y = [exp(0.1*X); -exp(.05*X)]';
stem(s(2),X,Y)
```

## Modify Stem Series After Creation

Create a stem plot.

```
X = 0:25;
Y = [cos(X); exp(0.05*X)]';
h = stem(X,Y);
```

The `stem` function creates a stem series object for each column of data. The output argument, `h`, contains the two stem series objects.

Set the first stem series color to green. Change the markers of the second stem series to squares. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
h(1).Color = 'green';
h(2).Marker = 'square';
```

## Adjust Baseline Properties

Create a stem plot and change properties of the baseline.

```
X = linspace(0,2*pi,50);
Y = exp(0.3*X).*sin(3*X);
h = stem(X,Y);
```

Change the line style of the baseline. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
hbase = h.BaseLine;
hbase.LineStyle = '--';
```

Hide the baseline by setting its `Visible` property to `'off'` .

```
hbase.Visible = 'off';
```

### Change Baseline Level

Create a stem plot with a baseline level at 2.

```
X = linspace(0,2*pi,50)';
Y = (exp(0.3*X).*sin(3*X));
stem(X,Y, 'BaseValue',2);
```

- “Combine Line and Stem Plots”

## Input Arguments

### Y — Data sequence to display

vector or matrix

Data sequence to display, specified as a vector or matrix. When Y is a vector, `stem` creates one stem series. When Y is a matrix, `stem` creates a separate stem series for each column.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**X — Locations to plot data values in Y**

vector or matrix

Locations to plot data values in Y, specified as a vector or matrix. When Y is a vector, X must be a vector of the same size. When Y is a matrix, X must be a matrix of the same size, or a vector whose length equals the number of rows in Y.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

**LineStyle — Line style, marker symbol, and color**

string

Line style, marker symbol, and color, specified as a string. For more information on line style, marker symbol, and color options see `LineStyle`.

Example: `'*r'`

**ax — Axes object**

object

Axes object. Use `ax` to modify the stem series after it is created.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'LineStyle', ':', 'MarkerFaceColor', 'red'` plots the stem as a dotted line and colors the marker face red.

The stem series properties listed here are only a subset. For a complete list, see `Stem Series Properties`.

**'LineStyle' — Line style**

`'-'` (default) | `'--'` | `'.'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
<code>'-'</code>	Solid line	

String	Line Style	Resulting Line
'--'	Dashed line	
':'	Dotted line	
'-.'	Dash-dotted line	
'none'	No line	No line

**'LineWidth' — Line width**

0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

**'Color' — Stem color**

[0 0 0] (default) | RGB triplet | color string | 'none'

Stem color, specified as an RGB triplet, a color string, or 'none'. If you specify the Color as 'none', then the stems are invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

### 'Marker' – Marker symbol

'o' (default) | '+' | '\*' | '.' | 'x' | ...

Marker symbol, specified as one of the marker strings listed in this table.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

### 'MarkerSize' – Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

### 'MarkerEdgeColor' – Marker outline color

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the `Color` property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example:  $[0.5 \ 0.5 \ 0.5]$

Example: 'blue'

**'MarkerFaceColor' — Marker fill color**

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the `Color` property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.3 0.2 0.1]

Example: 'green'

## Output Arguments

### **h** — Stem series object

scalar or column vector

Stem series objects, returned as a scalar or column vector. This is a unique identifier, which you can use to modify the properties of a specific stem series after it is created.

## See Also

### Functions

bar | LineSpec | plot | stairs

### Properties

Stem Series Properties

Introduced before R2006a

## stem3

Plot 3-D discrete sequence data

### Syntax

```
stem3(Z)
stem3(X,Y,Z)
stem3(____, 'filled')
stem3(____, LineSpec)
stem3(____, Name, Value)
```

```
stem3(ax, ____)
```

```
h = stem3(____)
```

### Description

`stem3(Z)` plots entries in `Z` as stems extending from the  $xy$ -plane and terminating with circles at the entry values. The stem locations in the  $xy$ -plane are automatically generated.

`stem3(X,Y,Z)` plots entries in `Z` as stems extending from the  $xy$ -plane where `X` and `Y` specify the stem locations in the  $xy$ -plane. The inputs `X`, `Y`, and `Z` must be vectors or matrices of the same size.

`stem3( ____, 'filled' )` fills the circles. Use this option with any of the input argument combinations in the previous syntaxes.

`stem3( ____, LineSpec)` specifies the line style, marker symbol, and color.

`stem3( ____, Name, Value)` specifies stem series properties using one or more `Name, Value` pair arguments.

`stem3(ax, ____)` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option, `ax`, can precede any of the input argument combinations in the previous syntaxes.

`h = stem3( ___ )` returns the stem series object `h`.

## Examples

### Row Vector Input

Create a 3-D stem plot of cosine values between  $-\pi/2$  and  $\pi/2$  with a row vector input.

```
figure
X = linspace(-pi/2,pi/2,40);
Z = cos(X);
stem3(Z)
```

stem3 plots elements of Z against the same y value at equally space x values.

### Column Vector Input

Create a 3-D stem plot of cosine values between  $-\pi/2$  and  $\pi/2$  with a column vector input.

```
figure
X = linspace(-pi/2,pi/2,40)';
Z = cos(X);
stem3(Z)
```

stem3 plots elements of Z against the same x value at equally spaced y values.

### Matrix Input

Create a 3-D stem plot of sine and cosine values between  $-\pi/2$  and  $\pi/2$  with a matrix input.

```
figure
X = linspace(-pi/2,pi/2,40);
Z = [sin(X); cos(X)];
stem3(Z)
```

stem3 plots each row of Z against the same y value at equally space x values.

### Specify Stem Locations with Vector Inputs

Create a 3-D stem plot and specify the stem locations along a curve. Use `view` to adjust the angle of the axes in the figure.

```
figure
X = linspace(-5,5,60);
Y = cos(X);
Z = X.^2;
stem3(X,Y,Z)
view(-8,30)
```

X and Y determine the stem locations. Z determines the marker heights.

### Specify Stem Locations with Matrix Inputs

Create a 3-D stem plot with matrix data and specify the stem locations in the *xy*-plane.

```
figure
[X,Y] = meshgrid(0:.1:1);
Z = exp(X+Y);
stem3(X,Y,Z)
```

X and Y determine the stem locations. Z determines the marker heights.

### Fill in Markers

Create a 3-D stem plot of cosine values between  $-\pi$  and  $\pi$  and fill in the markers.

```
X = linspace(-pi,pi,40);
Z = cos(X);
stem3(Z,'filled')
```

### Line Style, Marker Symbol, and Color Options

Create a 3-D stem plot of cosine values between  $-\pi$  and  $\pi$ . Use a dashed line style for the stem, set the marker symbols to stars, and set the color to magenta.

```
figure
X = linspace(-pi,pi,40);
Z = cos(X);
stem3(Z, '--*m')
```

To specify only two of the three `LineStyle` options, omit the third option from the string. For example, `'*m'` sets the marker symbol and the color and uses the default line style.

### Line Style, Marker Symbol, and Color Options

Create a 3-D stem plot and specify the stem locations along a circle. Set the stem to a dotted line style, the marker symbols to stars, and the color to magenta.

```
figure
```

```
theta = linspace(0,2*pi);
X = cos(theta);
Y = sin(theta);
Z = theta;
stem3(X,Y,Z, '*m')
```

X and Y determine the stem locations. Z determines the marker heights.

### **Additional Style Options**

Create a 3-D stem plot of cosine values between  $-\pi$  and  $\pi$ . Set the marker symbols to squares with green faces and magenta edges.

figure

```

X = linspace(-pi,pi,40);
Z = cos(X);
stem3(Z,'Marker','s',...
 'MarkerEdgeColor','m',...
 'MarkerFaceColor','g')

```

### Axes Handles

Specify the axes for a 3-D stem plot.

Define vectors X, Y and Z.

```
X = linspace(-2,2,50);
```

```
Y = X.^3;
Z = exp(X);
```

Create a figure with two subplots and return the handles to each axes, `s(1)` and `s(2)`. Plot a 3-D stem plot in the lower subplot by referring to its axes handle, `s(2)`. For comparison, plot a 2-D stem plot in the upper subplot by referring to its axes handle, `s(1)`.

```
figure
s(1) = subplot(2,1,1);
s(2) = subplot(2,1,2);

stem(s(1),X,Z)
stem3(s(2),X,Y,Z)
```

### Modify Stem Series After Creation

Create a 3-D stem plot and return the stem series object.

```
X = linspace(0,2);
Y = X.^3;
Z = exp(X).*cos(Y);
h = stem3(X,Y,Z,'filled');
```

Change the color to magenta and set the marker face color to yellow. Use `view` to adjust the angle of the axes in the figure. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
h.Color = 'm';
h.MarkerFaceColor = 'y';
view(-10,35)
```

- “Combine Line and Stem Plots”

## Input Arguments

### **Z** — Data sequence to display

vector or matrix

Data sequence to display, specified as a vector or matrix. `stem3` plots each element in `Z` as a stem extending from the  $xy$ -plane and terminating at the data value.

- If `Z` is a row vector, `stem3` plots all elements against the same  $y$  value at equally spaced  $x$  values.

- If `Z` is a column vector, `stem3` plots all elements against the same  $x$  value at equally spaced  $y$  values.
- If `Z` is a matrix, `stem3` plots each row of `Z` against the same  $y$  value at equally spaced  $x$  values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

## **X — Locations to plot values of Z**

vector or matrix

Locations to plot values of `Z`, specified as a vector or a matrix. Inputs `X`, `Y` and `Z` must be vectors or matrices of the same size.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

## **Y — Locations to plot values of Z**

vector or matrix

Locations to plot values of `Z`, specified as a vector or a matrix. Inputs `X`, `Y` and `Z` must be vectors or matrices of the same size.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

## **LineStyle — Line style, marker symbol, and color**

string

Line style, marker symbol, and color, specified as a string. For more information on line style, marker symbol, and color options see `LineStyle`.

Example: `' : * r '`

Data Types: `char`

## **ax — Axes object**

axes object

Axes object. If you do not specify an axes, then `stem` plots into the current axes.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'LineStyle', ':', 'MarkerFaceColor', 'red'` plots the stem as a dotted line and sets the marker face color to red.

The properties listed here are only a subset. For a complete list, see [Stem Series Properties](#).

### 'LineStyle' — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	
'--'	Dashed line	
':'	Dotted line	
'-.'	Dash-dotted line	
'none'	No line	No line

### 'LineWidth' — Line width of stem and marker edge

0.5 (default) | positive value

Line width of stem and marker edge, specified as a positive value in point units.

Example: 0.75

### 'Color' — Stem color

[0 0 0] (default) | RGB triplet | color string | 'none'

Stem color, specified as an RGB triplet, a color string, or 'none'. If you specify the `Color` as 'none', then the stems are invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

**'Marker' — Marker symbol**

'o' (default) | '+' | '\*' | '.' | 'x' | ...

Marker symbol, specified as one of the marker strings listed in this table.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle

String	Marker Symbol
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

### 'MarkerSize' — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

### 'MarkerEdgeColor' — Marker outline color

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the `Color` property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]

Long Name	Short Name	RGB Triplet
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.5 0.5 0.5]

Example: 'blue'

### 'MarkerFaceColor' — Marker fill color

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the Color property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.3 0.2 0.1]

Example: 'green'

## Output Arguments

### **h** — Stem series object

scalar

Stem series object, specified as a scalar. This is a unique identifier, which you can use to modify the properties of the stem series after it is created.

## See Also

### **Functions**

bar | plot | stairs | stem

### **Properties**

Stem Series Properties

**Introduced before R2006a**

## Stem Series Properties

Control stem series appearance and behavior

Stem series properties control the appearance and behavior of a stem series object. By changing property values, you can modify certain aspects of the stem series.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = stem(1:10);
c = h.Color;
h.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Stems

#### Color — Stem color

[0 0 0] (default) | RGB triplet | color string | 'none'

Stem color, specified as an RGB triplet, a color string, or 'none'. If you specify the Color as 'none', then the stems are invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

### LineStyle — Stem line style

'-' (default) | '--' | ':' | '-.' | 'none'

Stem line style, specified as one of the strings listed in this table.

String	Line Style
'-'	Solid line
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dotted line
'none'	No stems

Example: '--'

### LineWidth — Line width of stem and marker edge

0.5 (default) | scalar numeric value greater than 0

Line width of stem and marker edge, specified as a scalar numeric value greater than 0 in point units. The default line width is 0.5 points.

Example: 0.75

## Markers

### Marker — Marker symbol

'o' (default) | '+' | '\*' | '.' | 'x' | ...

Marker symbol, specified as one of the marker strings listed in this table.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square

String	Marker Symbol
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

**MarkerSize — Marker size**

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

**MarkerEdgeColor — Marker outline color**

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the **Color** property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]

Long Name	Short Name	RGB Triplet
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.5 0.5 0.5]

Example: 'blue'

### MarkerFaceColor — Marker fill color

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the Color property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0.3 0.2 0.1]

Example: 'green'

## Baseline

### **BaseValue** — Baseline location

0 (default) | numeric scalar value

Baseline location, specified as a numeric scalar value.

### **ShowBaseline** — Baseline visibility

'on' (default) | 'off'

Baseline visibility, specified as one of these values:

- 'on' — Show the baseline.
- 'off' — Hide the baseline.

### **Baseline** — Baseline

baseline object

This property is read only.

Baseline object. For a list of baseline properties, see [Baseline Properties](#).

## Data

### **XData** — Values along x-axis

[] (default) | vector

Values along the *x*-axis, specified as a vector.

- For 2-D stem charts, the input argument *X* to the `stem` function determines the *x*-values. If you do not specify *X*, then `stem` uses the indices of `YData` as the *x*-values. `XData` and `YData` must have equal lengths.
- For 3-D stem charts, the input argument *X* to the `stem3` function determines the *x*-values. If you do not specify *X*, then `stem3` uses the indices of `ZData` as the *x*-values. `XData`, `YData`, and `ZData` must have equal lengths.

### **YData** — Values along y-axis

[] (default) | vector

Values along the *y*-axis, specified as a vector.

- For 2-D stem charts, the input argument `Y` to the `stem` function determines the  $y$ -values. `YData` defines the stem heights. `XData` and `YData` must have equal lengths.
- For 3-D stem charts, the input argument `Y` to the `stem3` function determines the  $y$ -values. `YData` defines the locations of the stems along the  $y$ -axis. `XData`, `YData`, and `ZData` must have equal lengths.

### **ZData — Values along z-axis**

`[]` (default) | vector

Values along the  $z$ -axis, specified as a vector.

- For 2-D stem charts, `ZData` is empty by default.
- For 3-D stem charts, the input argument `Z` to the `stem3` function determines the  $z$ -values. `XData`, `YData`, and `ZData` must have equal lengths.

### **XDataSource — Variable linked to XData**

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: `'x'`

### **YDataSource — Variable linked to YData**

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `YData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `YData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `YData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'y'

### **ZDataSource** — Variable linked to ZData

' ' (default) | string containing MATLAB workspace variable name

Variable linked to **ZData**, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the **ZData**.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, then MATLAB does not update the **ZData** values immediately. To force an update of the data values, use the **refreshdata** function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'z'

### **XDataMode** — Selection mode for XData

'auto' (default) | 'manual'

Selection mode for **XData**, specified as one of these values:

- 'auto' — Use the indices of the values in **YData** (or **ZData** for 3-D plots).
- 'manual' — Use manually specified values. To specify the values, set the **XData** property or specify the input argument **X** to the plotting function.

## **Visibility**

### **Visible** — State of visibility

'on' (default) | 'off'

State of visibility, specified as one of these values:

- 'on' — Display the stem series.

- 'off' — Hide the stem series without deleting it. You still can access the properties of an invisible stem series object.

**Clipping — Clipping of stem series object to axes limits**

'on' (default) | 'off'

Clipping of the stem series object to the axes limits, specified as one of these values:

- 'on' — Do not display parts of the stem series object that are outside the axes limits.
- 'off' — Display the entire stem series object, even if parts of it appear outside the axes limits. Parts of the stem series object might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the stem series object so that it is larger than the original plot.

The **Clipping** property of the axes that contains the stem series object must be set to 'on', otherwise this property has no effect. For more information about the clipping behavior, see the **Clipping** property of the axes.

**EraseMode — (removed) Technique to draw and erase objects**

'normal' (default) | 'none' | 'xor' | 'background'

---

**Note:** **EraseMode** has been removed. You can delete code that accesses the **EraseMode** property with minimal impact. If you were using **EraseMode** to create line animations, use the **animatedline** function instead.

---

Technique to draw and erase objects, specified as one of these values:

- 'normal' — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- 'none' — Do not erase the object when it is moved or destroyed. After you erase the object with **EraseMode**, 'none', it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- 'xor' — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.

- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### **Type — Type of graphics object**

`'stem'` (default)

This property is read only.

Type of graphics object, returned as `'stem'`. Use this property to find all objects of a given type within a plotting hierarchy, such as searching for the type using `findobj`.

### **Tag — Tag to associate with stem series**

`''` (default) | string

Tag to associate with the stem series, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

Data Types: char

### **UserData — Data to associate with stem series**

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the stem series object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

### **DisplayName** — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the stem series.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where N is the number assigned to the stem series object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

### **Annotation** — Legend icon display style

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the stem series from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - `'on'` — Include the stem series object in the legend as one entry (default).

- 'off' — Do not include the stem series object in the legend.
- 'children' — Include only children of the stem series object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## Parent/Child

### Parent — Parent of stem series

axes object | group object | transform object

Parent of stem series, specified as an axes, group, or transform object.

### Children — Children of stem series

empty `GraphicsPlaceholder` array

The stem series has no children. You cannot set this property.

### HandleVisibility — Visibility of object handle

'on' (default) | 'off' | 'callback'

Visibility of stem series object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The stem series object handle is always visible.
- 'off' — The stem series object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The stem series object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the stem series at the command-line, but allows callback functions to access it.

If the stem series object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### **ButtonDownFcn** — Mouse-click callback

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the stem series. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The stem series object — You can access properties of the stem series object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **UIContextMenu** — Context menu

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the stem series. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to `'none'` or if the `HitTest` property is set to `'off'`, then the context menu does not appear.

---

## **Selected** — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the stem series when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the `SelectionHighlight` property also is set to `'on'`, then MATLAB displays selection handles around the stem series.
- `'off'` — Not selected.

## **SelectionHighlight** — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the `Selected` property is set to `'on'`.
- `'off'` — Never display selection handles, even when the `Selected` property is set to `'on'`.

## **Callback Execution Control**

### **PickableParts** — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The `Visible` property must be set to `'on'` and you must click a part of the stem series that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The `HitTest` property determines if the stem series responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the stem series passes the click to the object below it in the current view of the figure window. The `HitTest` property of the stem series has no effect.

**HitTest — Response to captured mouse clicks**

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the `ButtonDownFcn` callback of the stem series. If you have defined the `UIContextMenu` property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the stem series that has a `HitTest` property set to 'on' and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the stem series object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

**HitTestArea — (removed) Extents of clickable area for stem series**

'off' (default) | 'on'

---

**Note:** `HitTestArea` has been removed. Use `PickableParts` instead.

---

Extents of clickable area for stem series, specified as one of these values:

- 'off' — Click the stem series plot to select it. This is the default value.
- 'on' — Click anywhere within the extent of the stem series plot to select it, that is, anywhere within the rectangle that encloses the stem series plot.

Example: 'off'

**Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the stem series is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the stem series tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

`' '` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the stem series. Setting the `CreateFcn` property on an existing stem series has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during stem series creation. MATLAB executes the callback after creating the stem series and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The stem series object — You can access properties of the stem series object from within the callback function. You also can access the stem series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

**DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the stem series. MATLAB executes the callback before destroying the stem series so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The stem series object — You can access properties of the stem series object from within the callback function. You also can access the stem series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

**BeingDeleted — Deletion status of stem series**

'off' (default) | 'on'

This property is read only.

Deletion status of stem series, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the stem series begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the stem series no longer exists.

Check the value of the `BeingDeleted` property to verify that the stem series is not about to be deleted before querying or modifying it.

## stopasync

Stop asynchronous read and write operations

### Syntax

```
stopasync(obj)
```

### Description

`stopasync(obj)` stops any asynchronous read or write operation that is in progress for the serial port object, `obj`.

### More About

#### Tips

You can write data asynchronously using the `fprintf` or `fwrite` function. You can read data asynchronously using the `readasync` function, or by configuring the `ReadAsyncMode` property to `continuous`. In-progress asynchronous operations are indicated by the `TransferStatus` property.

If `obj` is an array of serial port objects and one of the objects cannot be stopped, the remaining objects in the array are stopped and a warning is returned. After an object stops:

- Its `TransferStatus` property is configured to `idle`.
- Its `ReadAsyncMode` property is configured to `manual`.
- The data in its output buffer is flushed.

Data in the input buffer is not flushed. You can return this data to the MATLAB workspace using any of the synchronous read functions. If you execute the `readasync` function, or configure the `ReadAsyncMode` property to `continuous`, then the new data is appended to the existing data in the input buffer.

## **See Also**

`fwrite` | `readasync` | `fprintf` | `ReadAsyncMode` | `TransferStatus`

**Introduced before R2006a**

## str2double

Convert string to double-precision value

### Syntax

```
X = str2double('str')
X = str2double(C)
```

### Description

`X = str2double('str')` converts the string `str`, which should be an ASCII character representation of a real or complex scalar value, to the MATLAB double-precision representation. The string can contain digits, a comma (thousands separator), a decimal point, a leading `+` or `-` sign, an `e` preceding a power of 10 scale factor, and an `i` for a complex unit.

If `str` does not represent a valid scalar value, `str2double` returns `NaN`.

`X = str2double(C)` converts the strings in the cell array of strings `C` to double precision. The matrix `X` returned will be the same size as `C`.

### Examples

Here are some valid `str2double` conversions, for numbers and cell arrays.

```
str2double('123.45e7')
str2double('123 + 45i')
str2double('3.14159')
str2double('2.7i - 3.14')
str2double({'2.71' '3.1415'})
str2double('1,200.34')
```

### See Also

`char` | `hex2num` | `num2str` | `str2num` | `cast`

**Introduced before R2006a**

## str2func

Construct function handle from string

### Syntax

```
fh = str2func(str)
```

### Description

`fh = str2func(str)` constructs a function handle, `fh`, from a function name or a string that defines an anonymous function.

Function handles created using `str2func` do not have access to variables outside of their local workspace or to nested functions. If your function handle contains these variables or functions, MATLAB throws an error when you invoke the handle. Also, if you use an anonymous function string, the resulting function handle does not have access to private or local functions.

### Examples

#### Convert String to Function Handle

Convert the string `'ones'` to a function handle, and call the `ones` function using the handle.

```
str = 'ones';
fh = str2func(str)
```

```
fh(1,5)
```

```
fh =
```

```
 @ones
```

```
ans =
```

1 1 1 1 1

### Convert String to Handle to Anonymous Function

Convert a string that represents an anonymous function to a function handle. Workspace variables are not available to the `str2func` function. Therefore, include values in the string that are necessary to evaluate the expression and that are not defined as function inputs.

Define a string that represents the anonymous function  $7x - 13$ . Convert the string to a function handle.

```
str = '@(x)7*x-13';
fh = str2func(str)

fh =
```

```
@(x)7*x-13
```

Call the anonymous function using the handle.

```
fh(3)

ans =

8
```

If you include workspace variables in your string, `str2func` creates the function handle, but MATLAB throws an error when you invoke the function handle.

```
a = 13;
str = '@(x)7*x-a';
fh = str2func(str);
```

```
fh(3)
```

```
Undefined function or variable 'a'.
```

```

### Examine Differences Between `str2func` and `eval`

Create a function that returns two function handles used to simulate the roll of dice. The first die (`d1`) returns a number from 1 through 6, but the second die (`d2`) always returns the number 1.

Create the following function in a folder on your MATLAB path. When `str2func` is used with an anonymous function string, it does not have access to the local function. Therefore, MATLAB calls the built-in `randi` function, and returns a number from 1 through 6. The `eval` function does have access to the local function, so `d2` uses the overloaded `randi` and always returns 1.

```
% Copyright 2015 The MathWorks, Inc.
```

```
function [d1,d2] = diceRoll
str = '@()randi([1 6],1)';
d1 = str2func(str);
d2 = eval(str);
end
```

```
function r = randi(~,-)
r = 1;
end
```

At the command prompt, call the `diceRoll` function.

```
[p1,p2] = diceRoll
```

```
p1 =
```

```
@()randi([1,6],1)
```

```
p2 =
```

```
@()randi([1,6],1)
```

Both `p1` and `p2` appear to be associated with the same anonymous function.

Invoke the function handles. The result from `p1` varies from 1 through 6. The result from `p2` is always 1.

```
p1()
p2()
```

```
ans =
```

```
 5
```

```
ans =
```

```
 1
```

## Input Arguments

### **str** — String to convert to function handle

function name | anonymous function string

String to convert to a function handle, specified as a function name or anonymous function string.

Example: `str = 'cos'`

Example: `str = '@(x) x.^2'`

## More About

### Tips

- A function handle that stores variable values does not retain its original value when you use `func2str` to convert it to a string, and then convert it back to a handle with `str2func`.
- “Create Function Handle”

### See Also

`func2str` | `functions`

**Introduced before R2006a**

## str2mat

Form blank-padded character matrix from strings

---

**Note:** str2mat is not recommended. Use char instead.

---

## Syntax

```
S = str2mat(T1, T2, T3, ...)
```

## Description

S = str2mat(T1, T2, T3, ...) forms the matrix S containing the text strings T1, T2, T3, ... as rows. The function automatically pads each string with blanks in order to form a valid matrix. Each text parameter, Ti, can itself be a string matrix. This allows the creation of arbitrarily large string matrices. Empty strings are significant.

## Examples

```
x = str2mat('36842', '39751', '38453', '90307');
```

```
whos x
 Name Size Bytes Class
 x 4x5 40 char array
```

```
x(2,3)
```

```
ans =
```

```
7
```

## More About

### Tips

`str2mat` differs from `strvcat` in that empty strings produce blank rows in the output. In `strvcat`, empty strings are ignored.

### See Also

`char`

**Introduced before R2006a**

## str2num

Convert string to number

### Syntax

```
x = str2num('str')
[x, status] = str2num('str')
```

### Description

---

**Note** `str2num` uses the `eval` function to convert the input argument. Side effects can occur if the string contains calls to functions. Using `str2double` can avoid some of these side effects.

---

`x = str2num('str')` converts the string `str`, which is an ASCII character representation of a numeric value, to numeric representation. `str2num` also converts string matrices to numeric matrices. If the input string does not represent a valid number or matrix, `str2num(str)` returns the empty matrix in `x`.

The input string can contain one or more numbers separated by spaces, commas, or semicolons, such as '5', '10, 11, 12', or '5, 10; 15, 20'. In addition to numerical values and delimiters, the input string can also include a decimal point, leading + or - signs, the letter `e` or `d` preceding a power of 10 scale factor, or the letter `i` or `j` indicating a complex or imaginary number.

The following table shows several examples of valid inputs to `str2num`:

String Input	Numeric Output	Output Class
'500'	500	double
'500 250 125 67'	500 250 125 67	1-by-4 row vector of double
'500; 250; 125; 62.5'	500.0000 250.0000 125.0000 62.5000	4-by-1 column vector of double

String Input	Numeric Output	Output Class
'1 23 6 21; 53:56'	1 23 6 21 53 54 55 56	2-by-4 matrix of double
'12e-3 5.9e-3'	0.0120 0.0059	1-by-2 row vector of double
'uint16(500)'	500	16-bit unsigned integer

---

**Note:** `str2num` does not operate on cell arrays. To convert a cell array of strings to a numeric value, use `str2double`.

---

If the input string does not represent a valid number or matrix, `str2num(str)` returns the empty matrix in `x`.

`[x, status] = str2num('str')` returns the status of the conversion in logical `status`, where `status` equals logical 1 (true) if the conversion succeeds, and logical 0 (false) otherwise.

Space characters can be significant. For instance, `str2num('1+2i')` and `str2num('1 + 2i')` produce `x = 1+2i`, while `str2num('1 +2i')` produces `x = [1 2i]`. You can avoid these problems by using the `str2double` function.

## Examples

Input a character string that contains a single number. The output is a scalar double:

```
A = str2num('500')
A =
 500

class(A)
ans =
 double
```

Repeat this operation, but this time using an unsigned 16-bit integer:

```
A = str2num('uint16(500)')
A =
 500
```

```
class(A)
ans =
 uint16
```

Try three different ways of specifying a row vector. Each returns the same answer:

```
str2num('2 4 6 8') % Separate with spaces.
ans =
 2 4 6 8
```

```
str2num('2,4,6,8') % Separate with commas.
ans =
 2 4 6 8
```

```
str2num('[2 4 6 8]') % Enclose in brackets.
ans =
 2 4 6 8
```

Note that the first two of these commands do not need the MATLAB square bracket operator to create a matrix. The `str2num` function inserts the brackets for you if they are needed.

Use a column vector this time:

```
str2num('2; 4; 6; 8')
ans =
 2
 4
 6
 8
```

And now a 2-by-2 matrix:

```
str2num('2 4; 6 8')
ans =
 2 4
 6 8
```

str2double | hex2num | sscanf | sparse | char | cast

**Introduced before R2006a**

## strcat

Concatenate strings horizontally

### Syntax

```
s = strcat(s1,...,sN)
```

### Description

`s = strcat(s1,...,sN)` horizontally concatenates strings `s1,...,sN`. Each input argument can be a single string, a collection of strings in a cell array, or a collection of strings in a character array.

If any input argument is a cell array, the result is a cell array of strings. Otherwise, the result is a character array.

For character array inputs, `strcat` removes trailing ASCII white-space characters: space, tab, vertical tab, newline, carriage return, and form feed. For cell array inputs, `strcat` does not remove trailing white space.

### Examples

#### Concatenate Two Strings

```
s1 = 'Good';
s2 = 'morning';
s = strcat(s1,s2)
```

```
s =
```

```
Goodmorning
```

#### Concatenate Two Cell Arrays

```
s1 = {'abcde','fghi'};
s2 = {'jkl','mn'};
```

```
s = strcat(s1,s2)
s =
 'abcdeijkl' 'fghimn'
```

### Concatenate Two Cell Arrays with Scalar Cell Array

```
firstnames = {'Abraham'; 'George'};
lastnames = {'Lincoln'; 'Washington'};
names = strcat(lastnames, {' ', ' }, firstnames)
names =
 'Lincoln, Abraham'
 'Washington, George'
```

## Input Arguments

### **s1, . . . , sN** — Input strings

character arrays | cell array of strings

Input strings, specified as cell arrays of strings or character arrays with the same number of rows. When combining nonscalar cell arrays and multirow character arrays, cell arrays must be column vectors with the same number of rows as the character arrays.

Data Types: char | cell

## More About

### Tips

- Strings also can be concatenated using left and right square brackets.

```
s1 = 'Good ';
s2 = 'Morning';
s = [s1 s2]
s =
 Good Morning
```

**See Also**

`cat` | `cellstr` | `horzcat` | `strjoin` | `vertcat`

**Introduced before R2006a**

# strcmp

Compare strings

## Syntax

```
tf = strcmp(s1,s2)
```

## Description

`tf = strcmp(s1,s2)` compares strings `s1` and `s2` and returns 1 (true) if the two are identical. Otherwise, `strcmp` returns 0 (false). Strings are considered identical if the size and content of each are the same. The return result, `tf`, is of data type `logical`.

Inputs can be combinations of single strings, strings in scalar cell arrays, character arrays, and cell arrays of strings.

## Examples

### Compare Two Strings

Compare two different strings.

```
s1 = 'Yes';
s2 = 'No';
tf = strcmp(s1,s2)
```

```
tf =
```

```
0
```

`strcmp` returns 0 because the two strings are not equal.

Compare two equal strings.

```
s1 = 'Yes';
s2 = 'Yes';
tf = strcmp(s1,s2)
```

```
tf =
```

1

strcmp returns 1 because the two strings are equal.

## Compare String and Cell Array of Strings

Compare a string, 'upon', to each element of a cell array of strings.

```
s1 = 'upon';
s2 = {'Once', 'upon';
 'a', 'time'};
tf = strcmp(s1,s2)
```

tf =

```
0 1
0 0
```

There is only one occurrence of string s1 in array s2, and it occurs at element s2(1,2).

## Compare Two Cell Arrays of Strings

Compare each element in a cell array of strings to the corresponding element in a second cell array of strings.

```
s1 = {'Time', 'flies', 'when';
 'you're', 'having', 'fun.'};
s2 = {'Time', 'drags', 'when';
 'you're', 'anxiously', 'waiting.'};
tf = strcmp(s1,s2)
```

tf =

```
1 0 1
1 0 0
```

There are three instances of equal strings between s1 and s2. These are 'Time' at indices (1,1), 'when' at indices(1,3), and 'you're' at indices (2,1).

## Input Arguments

### s1, s2 — Input strings

character array | cell array of strings

Input strings, specified as a cell array of strings, or character array with one or more rows. The order of the inputs does not affect the comparison results.

- If both `s1` , `s2` are nonscalar cell arrays, then `s1` , `s2` must be the same size.
- If both `s1` , `s2` are character arrays, then `s1` , `s2` can have different numbers of rows.
- When comparing a nonscalar cell array and a multirow character array, the cell array must be a column vector with the same number of rows as the character array.

Data Types: `char` | `cell`

## Output Arguments

**tf** — True or false

1 | 0 | logical array

True or false result, returned as a 1 or 0 of data type `logical`.

- If both inputs are character arrays, `tf` is a scalar.
- If at least one input is a cell array of strings, `tf` is an array the same size as the cell array.
- If `s1` and `s2` are a string in a scalar cell and a character array with multiple rows, then `tf` is an `n`-by-1 array, where `n` is the number of rows in the character array.

## More About

### Tips

- Use the `strcmp` function for comparison of strings. If you use `strcmp` on numeric arrays, it always returns 0.
- For case-insensitive string comparison, use `strcmpi` instead of `strcmp`.
- The value that `strcmp` returns is not the same as the C language convention.

### See Also

`regexp` | `regexpi` | `strcmpi` | `strfind` | `strncmp` | `strncmpi`

Introduced before R2006a

## **strcmpi**

Compare strings (case insensitive)

### **Syntax**

```
TF = strcmpi(string,string)
TF = strcmpi(string,cellstr)
TF = strcmpi(cellstr,cellstr)
```

### **Description**

`TF = strcmpi(string,string)` compares two strings for equality, ignoring any differences in letter case. The strings are considered to be equal if the size and content of each are the same. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

`TF = strcmpi(string,cellstr)` compares a string with each element of a cell array of strings, ignoring letter case. The function returns a logical array the same size as the `cellstr` input in which logical 1 represents equality. The order of the input arguments is not important.

`TF = strcmpi(cellstr,cellstr)` compares each element of one cell array of strings with the same element of the other, ignoring letter case. The function returns a logical array the same size as the input arrays.

### **Input Arguments**

#### **string**

A single character string or n-by-1 array of strings.

#### **cellstr**

A cell array of strings.

## Output Arguments

### TF

When both inputs are character arrays, **TF** is a scalar logical value. This value is logical 1 (**true**) if the size and content of both arrays are equal, and logical 0 (**false**) if they are not.

When either or both inputs are a cell array of strings, **TF** is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (**true**) for those elements of the input arrays that are a match, and logical 0 (**false**) for those elements that are not.

## Examples

Perform a simple case-insensitive comparison of two strings:

```
strcmpi('Yes', 'No')
ans =
 0
strcmpi('Yes', 'yes')
ans =
 1
```

Create two cell arrays of strings and call **strcmpi** to compare them:

```
A = {'Handle Graphics', 'Statistics'; ...
 'Toolboxes', 'MathWorks'};

B = {'Handle Graphics', 'Signal Processing'; ...
 'Toolboxes', 'MATHWORKS'};

match = strcmpi(A, B)
match =
 1 0
 0 1
```

The result of comparing the two cell arrays is:

- `match{1,1}` is 1 because “Handle Graphics” in `A{1,1}` matches the same text in `B{1,1}`.

- `match{1,2}` is 0 because “Statistics” in `A{1,2}` does not match “Signal Processing” in `B{1,2}`.
- `match{2,1}` is 0 because “ Toolboxes”, in `A{2,1}` contains leading space characters that are not in `B{2,1}`.
- `match{2,2}` is 1 because even though “MathWorks” in `A{2,2}` uses different letter case than “MATHWORKS” in `B{2,2}`, `strcmpi` performs the comparison without sensitivity to letter case.

## More About

### Tips

- The `strcmpi` function is intended for comparison of character data. When used to compare numeric data, it returns logical 0.
- Use `strcmp` for case-sensitive string comparisons.
- Any leading and trailing blanks in either of the strings are explicitly included in the comparison.
- The value returned by `strcmpi` is not the same as the C language convention.
- `strcmpi` supports international character sets.

## stream2

Compute 2-D streamline data

### Syntax

```
XY = stream2(x,y,u,v,startx,starty)
XY = stream2(u,v,startx,starty)
XY = stream2(...,options)
```

### Description

`XY = stream2(x,y,u,v,startx,starty)` computes streamlines from vector data `u` and `v`.

The arrays `x` and `y`, which define the coordinates for `u` and `v`, must be monotonic, but do not need to be uniformly spaced. `x` and `y` must have the same number of elements, as if produced by `meshgrid`.

`startx` and `starty` define the starting positions of the streamlines. The section "Specifying Starting Points for Stream Plots" provides more information on defining starting points.

The returned value `XY` contains a cell array of vertex arrays.

`XY = stream2(u,v,startx,starty)` assumes the arrays `x` and `y` are defined as `[x,y] = meshgrid(1:n,1:m)` where `[m,n] = size(u)`.

`XY = stream2(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

```
[stepsize]
```

or

```
[stepsize, max_number_vertices]
```

If you do not specify a value, MATLAB software uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 10000

Use the `streamline` command to plot the data returned by `stream2`.

## Examples

This example draws 2-D streamlines from data representing air currents over regions of North America.

```
load wind
[sx,sy] = meshgrid(80,20:10:50);
streamline(stream2(x(:,:,5),y(:,:,5),u(:,:,5),v(:,:,5),sx,sy));
```

## More About

- [Specifying Starting Points for Stream Plots](#)

## See Also

[coneplot](#) | [stream3](#) | [streamline](#)

## stream3

Compute 3-D streamline data

### Syntax

```
XYZ = stream3(X,Y,Z,U,V,W,startx,starty,startz)
XYZ = stream3(U,V,W,startx,starty,startz)
XYZ = stream3(...,options)
```

### Description

`XYZ = stream3(X,Y,Z,U,V,W,startx,starty,startz)` computes streamlines from vector data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, and `startz` define the starting positions of the streamlines. The section "Specifying Starting Points for Stream Plots" provides more information on defining starting points.

The returned value `XYZ` contains a cell array of vertex arrays.

`XYZ = stream3(U,V,W,startx,starty,startz)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:N,1:M,1:P)` where `[M,N,P] = size(U)`.

`XYZ = stream3(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

`[stepsize]`

or

`[stepsize, max_number_vertices]`

If you do not specify values, MATLAB software uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 10000

Use the `streamline` command to plot the data returned by `stream3`.

## Examples

This example draws 3-D streamlines from data representing air currents over regions of North America.

```
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamline(stream3(x,y,z,u,v,w,sx,sy,sz))
view(3)
```

## More About

- [Specifying Starting Points for Stream Plots](#)

## See Also

[coneplot](#) | [stream2](#) | [streamline](#)

# streamline

Plot streamlines from 2-D or 3-D vector data

## Syntax

```
streamline(X,Y,Z,U,V,W,startx,starty,startz)
streamline(U,V,W,startx,starty,startz)
streamline(XYZ)
streamline(X,Y,U,V,startx,starty)
streamline(U,V,startx,starty)
streamline(XY)
streamline(...,options)
streamline(axes_handle,...)
h = streamline(...)
```

## Description

`streamline(X,Y,Z,U,V,W,startx,starty,startz)` draws streamlines from 3-D vector data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, `startz` define the starting positions of the streamlines. The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.

`streamline(U,V,W,startx,starty,startz)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:N,1:M,1:P)`, where `[M,N,P] = size(U)`.

`streamline(XYZ)` assumes `XYZ` is a precomputed cell array of vertex arrays (as produced by `stream3`).

`streamline(X,Y,U,V,startx,starty)` draws streamlines from 2-D vector data `U, V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`startx` and `starty` define the starting positions of the streamlines. The output argument `h` contains a vector of line handles, one handle for each streamline.

`streamline(U,V,startx,starty)` assumes the arrays `X` and `Y` are defined as `[X,Y] = meshgrid(1:N,1:M)`, where `[M,N] = size(U)`.

`streamline(XY)` assumes `XY` is a precomputed cell array of vertex arrays (as produced by `stream2`).

`streamline(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

```
[stepsize]
```

or

```
[stepsize, max_number_vertices]
```

If you do not specify values, MATLAB uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 1000

`streamline(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of the into current axes object (`gca`).

`h = streamline(...)` returns a vector of line handles, one handle for each streamline.

## Examples

### Draw Streamlines

Define arrays `x`, `y`, `u`, and `v`.

```
[x,y] = meshgrid(0:0.1:1,0:0.1:1);
u = x;
v = -y;
```

Create a quiver plot of the data. Plot streamlines that start at different points along the line  $y = 1$ .

```
figure
quiver(x,y,u,v)

startx = 0.1:0.1:1;
starty = ones(size(startx));
streamline(x,y,u,v,startx,starty)
```

## More About

- Specifying Starting Points for Stream Plots

- Stream Line Plots of Vector Data

`coneplot` | `stream2` | `stream3` | `streamparticles` | `meshgrid`

**Introduced before R2006a**

# streamparticles

Plot stream particles

## Syntax

```
streamparticles(vertices)
streamparticles(vertices,n)
streamparticles(...,'PropertyName',PropertyValue,...)
streamparticles(line_handle,...)
h = streamparticles(...)
```

## Description

`streamparticles(vertices)` draws stream particles of a vector field. Stream particles are usually represented by markers and can show the position and velocity of a streamline. `vertices` is a cell array of 2-D or 3-D vertices (as if produced by `stream2` or `stream3`).

`streamparticles(vertices,n)` uses `n` to determine how many stream particles to draw. The `ParticleAlignment` property controls how `n` is interpreted.

- If `ParticleAlignment` is set to `off` (the default) and `n` is greater than 1, approximately `n` particles are drawn evenly spaced over the streamline vertices.

If `n` is less than or equal to 1, `n` is interpreted as a fraction of the original stream vertices; for example, if `n` is 0.2, approximately 20% of the vertices are used.

`n` determines the upper bound for the number of particles drawn. The actual number of particles can deviate from `n` by as much as a factor of 2.

- If `ParticleAlignment` is `on`, `n` determines the number of particles on the streamline having the most vertices and sets the spacing on the other streamlines to this value. The default value is `n = 1`.

`streamparticles(...,'PropertyName',PropertyValue,...)` controls the stream particles using named properties and specified values. Any unspecified properties have default values. MATLAB ignores the case of property names.

## Stream Particle Properties

**Animate** — Stream particle motion [nonnegative integer]

The number of times to animate the stream particles. The default is 0, which does not animate. **Inf** animates until you enter **Ctrl+C**.

**FrameRate** — Animation frames per second [nonnegative integer]

This property specifies the number of frames per second for the animation. **Inf**, the default, draws the animation as fast as possible. Note that the speed of the animation might be limited by the speed of the computer. In such cases, the value of **FrameRate** cannot necessarily be achieved.

**ParticleAlignment** — Align particles with streamlines [ on | {off} ]

Set this property to **on** to draw particles at the beginning of each streamline. This property controls how **streamparticles** interprets the argument **n** (number of stream particles).

Stream particles are primitive line objects. In addition to stream particle properties, you can specify any line property, such as **Marker**. **streamparticles** sets the following line properties when called.

Line Property	Value Set by <b>streamparticles</b>
<b>LineStyle</b>	'none'
<b>Marker</b>	'o'
<b>MarkerEdgeColor</b>	'none'
<b>MarkerFaceColor</b>	'red'

You can override any of these properties by specifying a property name and value as arguments to **streamparticles**. For example, this statement uses RGB values to set the **MarkerFaceColor** to medium gray:

```
streamparticles(vertices, 'MarkerFaceColor', [.5 .5 .5])
```

**streamparticles(line\_handle, ...)** uses the line object identified by **line\_handle** to draw the stream particles.

`h = streamparticles(...)` returns a vector of handles to the primitive line objects it creates. For a list of properties, see [Primitive Line Properties](#).

## Examples

### Animate Flow Without Displaying Streamlines

This example uses streamlines in the  $z = 5$  plane to animate the flow along these lines with stream particles.

```
load wind
figure
daspect([1,1,1]);
view(2)
[verts,averts] = streamslice(x,y,z,u,v,w,[],[],[5]);
sl = streamline([verts averts]);
axis tight manual off;
ax = gca;
ax.Position = [0,0,1,1];
set(sl,'Visible','off')
iverts = interpstreamspeed(x,y,z,u,v,w,verts,.05);
zlim([4.9,5.1]);
streamparticles(iverts, 200, ...
 'Animate',15,'FrameRate',40, ...
 'MarkerSize',10,'MarkerFaceColor',[0 .5 0])
```

# streamribbon

3-D stream ribbon plot from vector volume data

## Syntax

```
streamribbon(X,Y,Z,U,V,W,startx,starty,startz)
streamribbon(U,V,W,startx,starty,startz)
streamribbon(vertices,X,Y,Z,cav,speed)
streamribbon(vertices,cav,speed)
streamribbon(vertices,twistangle)
streamribbon(...,width)
streamribbon(axes_handle,...)
h = streamribbon(...)
```

## Description

`streamribbon(X,Y,Z,U,V,W,startx,starty,startz)` draws stream ribbons from vector volume data  $U$ ,  $V$ ,  $W$ .

The arrays  $X$ ,  $Y$ , and  $Z$ , which define the coordinates for  $U$ ,  $V$ , and  $W$ , must be monotonic, but do not need to be uniformly spaced.  $X$ ,  $Y$ , and  $Z$  must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, and `startz` define the starting positions of the stream ribbons at the center of the ribbons. The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.

The twist of the ribbons is proportional to the curl of the vector field. The width of the ribbons is calculated automatically.

`streamribbon(U,V,W,startx,starty,startz)` assumes  $X$ ,  $Y$ , and  $Z$  are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamribbon(vertices,X,Y,Z,cav,speed)` assumes precomputed streamline vertices, curl angular velocity, and flow speed. `vertices` is a cell array of streamline vertices (as produced by `stream3`). `X`, `Y`, `Z`, `cav`, and `speed` are 3-D arrays.

`streamribbon(vertices,cav,speed)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(cav)`.

`streamribbon(vertices,twistangle)` uses the cell array of vectors `twistangle` for the twist of the ribbons (in radians). The size of each corresponding element of `vertices` and `twistangle` must be equal.

`streamribbon(...,width)` sets the width of the ribbons to `width`.

`streamribbon(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

`h = streamribbon(...)` returns a vector of handles (one per start point) to surface objects.

## Examples

This example uses stream ribbons to indicate the flow in the wind data set. Inputs include the coordinates, vector field components, and starting location for the stream ribbons.

```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamribbon(x,y,z,u,v,w,sx,sy,sz);
% Define viewing and lighting
axis tight
shading interp;
view(3);
camlight
lighting gouraud
```

This example uses precalculated vertex data (`stream3`), curl average velocity (`curl`),

and speed  $\sqrt{u^2 + v^2 + w^2}$ . Using precalculated data enables you to use values other than those calculated from the single data source. In this case, the speed is reduced by a factor of 10 compared to the previous example.

```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
cav = curl(x,y,z,u,v,w);
spd = sqrt(u.^2 + v.^2 + w.^2).*0.1;
streamribbon(verts,x,y,z,cav,spd);
% Define viewing and lighting
```

```
axis tight
shading interp
view(3)
camlight;
lighting gouraud
```

This example specifies a twist angle for the stream ribbon.

```
figure
t = 0:.15:15;
verts = {[cos(t)' sin(t)' (t/3)']};
twistangle = {cos(t)'};
streamribbon(verts,twistangle)
% Define viewing and lighting
axis tight
```

```
shading interp
view(3)
camlight
lighting gouraud
```

This example combines cone plots (`coneplot`) and stream ribbon plots in one graph.

```
figure
% Define 3-D arrays x, y, z, u, v, w
xmin = -7; xmax = 7;
ymin = -7; ymax = 7;
zmin = -7; zmax = 7;
x = linspace(xmin,xmax,30);
y = linspace(ymin,ymax,20);
z = linspace(zmin,zmax,20);
```

```
[x y z] = meshgrid(x,y,z);
u = y; v = -x; w = 0*x+1;
[cx cy cz] = meshgrid(linspace(xmin,xmax,30),...
 linspace(ymin,ymax,30),[-3 4]);
h = coneplot(x,y,z,u,v,w,cx,cy,cz,'quiver');
set(h,'Color','k');

% Plot two sets of streamribbons
[sx sy sz] = meshgrid([-1 0 1],[-1 0 1],[-6]);
streamribbon(x,y,z,u,v,w,sx,sy,sz);
[sx sy sz] = meshgrid([1:6],[0],[-6]);
streamribbon(x,y,z,u,v,w,sx,sy,sz);

% Define viewing and lighting
shading interp
view(-30,10) ; axis off tight
camproj perspective; camva(66); camlookat;
camdolly(0,0,.5,'fixtarget')
camlight
```

Introduced before R2006a

## streamslice

Plot streamlines in slice planes

### Syntax

```
streamslice(X,Y,Z,U,V,W,startx,starty,startz)
streamslice(U,V,W,startx,starty,startz)
streamslice(X,Y,U,V)
streamslice(U,V)
streamslice(...,density)
streamslice(...,'arrowsmode')
streamslice(...,'method')
streamslice(axes_handle,...)
h = streamslice(...)
[vertices arrowvertices] = streamslice(...)
```

### Description

`streamslice(X,Y,Z,U,V,W,startx,starty,startz)` draws well-spaced streamlines (with direction arrows) from vector data `U`, `V`, `W` in axis aligned  $x$ -,  $y$ -,  $z$ -planes at the points in the vectors `startx`, `starty`, `startz`. The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`. `U`, `V`, `W` must be  $m$ -by- $n$ -by- $p$  volume arrays.

Do not assume that the flow is parallel to the slice plane. For example, in a stream slice at a constant `Z`, the `Z` component of the vector field `W` is ignored when you are calculating the streamlines for that plane.

Stream slices are useful for determining where to start streamlines, stream tubes, and stream ribbons.

`streamslice(U,V,W,startx,starty,startz)` assumes  $X$ ,  $Y$ , and  $Z$  are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamslice(X,Y,U,V)` draws well-spaced streamlines (with direction arrows) from vector volume data  $U$ ,  $V$ .

The arrays  $X$  and  $Y$ , which define the coordinates for  $U$  and  $V$ , must be monotonic, but do not need to be uniformly spaced.  $X$  and  $Y$  must have the same number of elements, as if produced by `meshgrid`.

`streamslice(U,V)` assumes  $X$ ,  $Y$ , and  $Z$  are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamslice(...,density)` modifies the automatic spacing of the streamlines. `density` must be greater than 0. The default value is 1; higher values produce more streamlines on each plane. For example, 2 produces approximately twice as many streamlines, while 0.5 produces approximately half as many.

`streamslice(...,'arrowmode')` determines if direction arrows are present or not. `arrowmode` can be

- `arrows` — Draw direction arrows on the streamlines (default).
- `noarrows` — Do not draw direction arrows.

`streamslice(...,'method')` specifies the interpolation method to use. `method` can be

- `linear` — Linear interpolation (default)
- `cubic` — Cubic interpolation
- `nearest` — Nearest-neighbor interpolation

See `interp3` for more information on interpolation methods.

`streamslice(axes_handle, ...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

`h = streamslice(...)` returns a vector of handles to the line objects created.

`[vertices arrowvertices] = streamslice(...)` returns two cell arrays of vertices for drawing the streamlines and the arrows. You can pass these values to any of the streamline drawing functions (`streamline`, `streamribbon`, `streamtube`).

## Examples

### Plot Streamlines in Slice Plane

Load the wind data set. Draw a stream slice at  $z = 5$ .

```
load wind
figure
streamslice(x,y,z,u,v,w,[],[],[5])
axis tight
```

## More About

Introduced before R2006a

## streamtube

Create 3-D stream tube plot

### Syntax

```
streamtube(X,Y,Z,U,V,W,startx,starty,startz)
streamtube(U,V,W,startx,starty,startz)
streamtube(vertices,X,Y,Z,divergence)
streamtube(vertices,divergence)
streamtube(vertices,width)
streamtube(vertices)
streamtube(...,[scale n])
streamtube(axes_handle,...)
h = streamtube(...z)
```

### Description

`streamtube(X,Y,Z,U,V,W,startx,starty,startz)` draws stream tubes from vector volume data  $U$ ,  $V$ ,  $W$ .

The arrays  $X$ ,  $Y$ , and  $Z$ , which define the coordinates for  $U$ ,  $V$ , and  $W$ , must be monotonic, but do not need to be uniformly spaced.  $X$ ,  $Y$ , and  $Z$  must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, and `startz` define the starting positions of the streamlines at the center of the tubes. The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.

The width of the tubes is proportional to the normalized divergence of the vector field.

`streamtube(U,V,W,startx,starty,startz)` assumes  $X$ ,  $Y$ , and  $Z$  are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamtube(vertices,X,Y,Z,divergence)` assumes precomputed streamline vertices and divergence. `vertices` is a cell array of streamline vertices (as produced by `stream3`). `X`, `Y`, `Z`, and `divergence` are 3-D arrays.

`streamtube(vertices,divergence)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(divergence)`.

`streamtube(vertices,width)` specifies the width of the tubes in the cell array of vectors, `width`. The size of each corresponding element of `vertices` and `width` must be equal. `width` can also be a scalar, specifying a single value for the width of all stream tubes.

`streamtube(vertices)` selects the width automatically.

`streamtube(...,[scale n])` scales the width of the tubes by `scale`. The default is `scale = 1`. When the stream tubes are created, using start points or divergence, specifying `scale = 0` suppresses automatic scaling. `n` is the number of points along the circumference of the tube. The default is `n = 20`.

`streamtube(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

`h = streamtube(...z)` returns a vector of handles (one per start point) to `surface` objects used to draw the stream tubes.

## Examples

This example uses stream tubes to indicate the flow in the `wind` data set. Inputs include the coordinates, vector field components, and starting location for the stream tubes.

```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
```

```
streamtube(x,y,z,u,v,w,sx,sy,sz);
% Define viewing and lighting
view(3)
axis tight
shading interp;
camlight; lighting gouraud
```

This example uses precalculated vertex data (`stream3`) and divergence (`divergence`).

```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
div = divergence(x,y,z,u,v,w);
```

```
streamtube(verts,x,y,z,-div);
% Define viewing and lighting
view(3)
axis tight
shading interp
camlight
lighting gouraud
```

## strfind

Find one string within another

### Syntax

```
k = strfind(str, pattern)
```

### Description

`k = strfind(str, pattern)` searches `str` for occurrences of `pattern`. The output, `k`, indicates the starting index of each occurrence of `pattern` in `str`. If `pattern` is not found `strfind` returns an empty array, `[]`. The `strfind` function executes a case sensitive search.

- If `str` is a string, `strfind` returns a vector of type `double`.
- If `str` is a cell array, `strfind` returns a cell array of vectors of type `double`.

### Examples

#### Find String Pattern

Define string `S` as follows:

```
S = 'Find the starting indices of the pattern string';
```

Find the pattern `in` in string `S`.

```
k = strfind(S, 'in')
```

```
k =
```

```
 2 15 19 45
```

There are four instances of the substring, `in`, found in `S`.

Find the pattern `IN` in string `S`.

```
k = strfind(S, 'In')
```

```
k =
```

```
[]
```

Since `strfind` is case sensitive, the string, `In`, is not found in `S`, `k` is an empty array.

Find the blank spaces in string `S`.

```
k = strfind(S, ' ')
```

```
k =
```

```
5 9 18 26 29 33 41
```

There are seven occurrences of blank spaces in the string `S`.

## Find String in Cell Array of Strings

Define the cell array of strings, `cstr`, as follows:

```
cstr = {'How much wood would a woodchuck chuck';
 'if a woodchuck could chuck wood?'};
```

Find the pattern, `wood`, in cell array `cstr`.

```
idx = strfind(cstr, 'wood')
```

```
idx =
```

```
 [1x2 double]
 [1x2 double]
```

Examine the output cell array to find the instances of `wood`.

```
idx{:,:}
```

```
ans =
```

```
10 23
```

```
ans =
```

```
6 28
```

The pattern, wood, occurs at indices 10 and 23 in the first string and at indices 6 and 28 in the second string.

## Input Arguments

### **str** — Data to be searched

string | cell array of strings

Data to be searched, specified as a string or cell array of strings.

Data Types: char | cell

### **pattern** — Search pattern

string

Search pattern, specified as a string.

Data Types: char

## Output Arguments

### **k** — Indices of occurrences of pattern

array

Indices of occurrences of **pattern**, returned as an array. If **pattern** is not found, then **k** is an empty array, `[]`.

- If **str** is a string, **k** is an array of doubles indicating the index of each occurrence of **pattern**.
- If **str** is a cell array of strings, **k** is a cell array with each element being an array of type `double` corresponding to the indices of each occurrence of **pattern** in the corresponding element of **str**.

## More About

### Tips

- The `strfind` function does not find a pattern of empty strings, `' '`, within **str**.

# strings

String handling

## Syntax

```
S = 'Any Characters'
S = [S1 S2 ...]
C = {S1 S2 ...}
S = strcat(S1, S2, ...)
S = char(S1, S2, ...)
S = char(X)
X = double(S)
```

## Description

`S = 'Any Characters'` creates a character array, or string. The string is actually a vector that contains the numeric codes for the characters (codes 0 to 127 are ASCII). The length of `S` is the number of characters. A quotation within the string is indicated by two quotation marks.

`S = [S1 S2 ...]` concatenates character arrays `S1`, `S2`, etc. into a new character array, `S`.

`C = {S1 S2 ...}` creates a cell array of strings. Separate each row of the cell array with a semicolon (;).

`S = strcat(S1, S2, ...)` horizontally concatenates `S1`, `S2`, etc., which can be character arrays or cell arrays of strings. If the inputs are character arrays, `strcat` removes trailing white space. For more information, see the `strcat` reference page.

`S = char(S1, S2, ...)` vertically concatenates character arrays `S1`, `S2`, etc., padding each input string as needed so that each row contains the same number of characters.

`S = char(X)` converts an array that contains positive integers representing numeric codes into a MATLAB character array.

`X = double(S)` converts the string to its equivalent integer numeric codes.

## Examples

Create a simple string that includes a single quote.

```
msg = 'You're right!'
```

```
msg =
You're right!
```

Create the string `name` using two methods of concatenation.

```
name = ['Thomas' ' R. ' 'Lee']
name = strcat('Thomas',' R.',' Lee')
```

Create a character array of strings.

```
C = char('Hello','Goodbye','Yes','No')
```

```
C =
Hello
Goodbye
Yes
No
```

Create a cell array of strings.

```
S = {'Hello' 'Goodbye'; 'Yes' 'No'}
```

```
S =
 'Hello' 'Goodbye'
 'Yes' 'No'
```

## More About

### Tips

- To convert between character arrays and cell arrays of strings, use `char` and `cellstr`. Most string functions support both types.
- To determine whether `S` is a character array or cell array, call `ischar(S)` or `iscellstr(S)`.
- “Cell Arrays of Strings”

**See Also**

`char` | `isstrprop` | `ischar` | `cellstr` | `isletter` | `isspace` | `iscellstr` |  
`sprintf` | `sscanf` | `text` | `input`

## strjoin

Join strings in cell array into single string

### Syntax

```
str = strjoin(C)
str = strjoin(C,delimiter)
```

### Description

`str = strjoin(C)` constructs the string, `str`, by linking each string in the cell array, `C`, with a single space.

`str = strjoin(C,delimiter)` constructs the string, `str`, by linking each string of `C` with the elements in `delimiter`.

### Examples

#### Join List of Words with Whitespace

Join individual strings in a cell array of strings, `C`, with a single space.

```
C = {'one', 'two', 'three'};
str = strjoin(C)
```

```
str =
```

```
one two three
```

#### Join Cell Array of Strings

```
C = {'Newton', 'Gauss', 'Euclid', 'Lagrange'};
str = strjoin(C, ', ')
```

```
str =
```

Newton, Gauss, Euclid, Lagrange

### Join Strings with Multiple Different Delimiters

Specify multiple different delimiters in a cell array of strings. The `delimiter` cell array must have one fewer element than `C`.

```
C = {'one', 'two', 'three'};
str = strjoin(C,{' + ', ' = '})
```

```
str =
```

```
one + two = three
```

## Input Arguments

### **C** — Input text

1-by-n cell array of strings

Input text, specified as a 1-by-n cell array of strings. Each element in the cell array must contain a single string in a single row.

Example: {'The', 'rain', 'in', 'Spain'}

Data Types: `cell`

### **delimiter** — Delimiting characters

string | 1-by-n cell array of strings

Delimiting characters, specified as a single string or a 1-by-n cell array of strings.

- If `delimiter` is a single string, then `strjoin` forms `str` by inserting `delimiter` between each element of `C`. The `delimiter` input can include any of these escape sequences:

<code>\\</code>	Backslash
<code>\0</code>	Null
<code>\a</code>	Alarm
<code>\b</code>	Backspace
<code>\f</code>	Form feed

<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab
<code>\v</code>	Vertical tab

- If `delimiter` is a cell array of strings, then it must contain one fewer element than `C`. Each element in the cell array must contain a single string in a single row. `strjoin` forms `str` by interleaving the elements of `delimiter` and `C`. All characters in `delimiter` are inserted as literal text, and escape sequences are not supported.

Example: `' , '`

Example: `{ ' , ' , ' ' }`

Data Types: `char` | `cell`

## See Also

`cellstr` | `regexp` | `strcat` | `strsplit`

**Introduced in R2013a**

# strjust

Justify character array

## Syntax

```
T = strjust(S)
T = strjust(S, 'right')
T = strjust(S, 'left')
T = strjust(S, 'center')
```

## Description

`T = strjust(S)` or `T = strjust(S, 'right')` returns a right-justified version of the character array `S`.

`T = strjust(S, 'left')` returns a left-justified version of `S`.

`T = strjust(S, 'center')` returns a center-justified version of `S`.

## See Also

`deblank` | `strtrim`

**Introduced before R2006a**

## strmatch

Find possible matches for string

---

**Note:** `strmatch` is not recommended. Use `strncmp` or `validatestring`, depending on your requirements, instead. `strncmp` returns a logical array indicating which array elements begin with the specified string, whereas `validatestring` returns a single string that represents the best match to the specified string. See Example 2, below.

To find an exact match for a string, use `strcmp`.

---

## Syntax

```
x = strmatch(str, strarray)
x = strmatch(str, strarray, 'exact')
```

## Description

`x = strmatch(str, strarray)` looks through the rows of the character array or cell array of strings `strarray` to find strings that begin with the text contained in `str`, and returns the matching row indices. If `strmatch` does not find `str` in `strarray`, `x` is an empty matrix (`[]`). Any trailing space characters in `str` or `strarray` are ignored when matching. `strmatch` is fastest when `strarray` is a character array.

`x = strmatch(str, strarray, 'exact')` compares `str` with each row of `strarray`, looking for an exact match of the entire strings. Any trailing space characters in `str` or `strarray` are ignored when matching.

## Examples

### Example 1

The statement

```
x = strmatch('max', char('max', 'minimax', 'maximum'))
```

returns `x = [1; 3]` since rows 1 and 3 begin with 'max'. The statement

```
x = strmatch('max', char('max', 'minimax', 'maximum'),'exact')
```

returns `x = 1`, since only row 1 matches 'max' exactly.

## Example 2

This example shows how to replace use of the `strmatch` function with `validatestring` or `strncmp`.

To start with, use `strmatch` to return the index of those elements for which there is a match:

```
list = {'max', 'minimax', 'maximum', 'max'}
x = strmatch('max',list)
x =
 1
 3
 4
```

`validatestring` returns the string representing the best match. If multiple or no matches exist, this statement would return an error:

```
list = {'max', 'minimax', 'maximum', 'max'};
x = validatestring('max', list)
x =
 max
```

`strncmp` returns a logical array indicating which strings match the specified string:

```
list = {'max', 'minimax', 'maximum', 'max'};
x = strncmp('max', list, 3)
x =
 1 0 1 1
```

If you prefer that MATLAB return the numeric indices of `list`, use `find` as follows:

```
list = {'max', 'minimax', 'maximum', 'max'}
x = find(strncmp(list, 'max', 3))
```

If your input to `strmatch` is a character matrix, then first convert the matrix to a cell array using `cellstr`. Then, pass the output from `cellstr` to `strncmp` or `validatestring`

**See Also**

strcmp | strcmpi | strncmp | strncmpi | strfind | regexp | regexpi |  
regexprep

**Introduced before R2006a**

## strncmp

Compare first *n* characters of strings (case sensitive)

### Syntax

```
TF = strncmp(string,string,n)
TF = strncmp(string,cellstr,n)
TF = strncmp(cellstr,cellstr,n)
```

### Description

`TF = strncmp(string,string,n)` compares the first *n* characters of two strings for equality. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

`TF = strncmp(string,cellstr,n)` compares the first *n* characters of a string with the first *n* characters of each element of a cell array of strings. The function returns a logical array the same size as the `cellstr` input in which logical 1 represents equality. The order of the first two input arguments is not important.

`TF = strncmp(cellstr,cellstr,n)` compares each element of one cell array of strings with the same element of the other. `strncmp` attempts to match only the first *n* characters of these strings. The function returns a logical array the same size as either input array.

### Input Arguments

#### **string**

Single character string or *n*-by-1 array of strings.

#### **cellstr**

Cell array of strings.

**n**

Maximum number of characters to compare. Must be a scalar, integer-valued double.

## Output Arguments

**TF**

When both inputs are character arrays, **TF** is a scalar logical value. This value is logical 1 (**true**) if the size and content of both arrays are equal, and logical 0 (**false**) if they are not.

When either or both inputs are a cell array of strings, **TF** is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (**true**) for those elements of the input arrays that are a match, and logical 0 (**false**) for those elements that are not.

## Examples

Before trying the `strncmp` function, use `strcmp` to perform a simple comparison of the two input strings. Because only the first 13 characters are the same, `strcmp` returns logical 0:

```
strcmp('Kansas City, KS', 'Kansas City, MO')
ans =
 0
```

Do the comparison again, but this time using `strncmp` and specifying the number of characters to compare:

```
chars2compare = length('Kansas City, KS') - 2
ans =
 13
strncmp('Kansas City, KS', 'Kansas City, MO', chars2compare)
ans =
 1
```

From a list of 10 MATLAB functions, find those that apply to using a camera:

```
function_list = {'calendar' 'case' 'camdolly' 'circshift' ...
 'caxis' 'camtarget' 'cast' 'camorbit' ...
```

```

 'callib' 'cart2sph'};

strncmp(function_list, 'cam', 3)
ans =
 0 0 1 0 0 1 0 1 0 0

function_list{strncmp(function_list, 'cam', 3)}
ans =
 camdolly
ans =
 camtarget
ans =
 camorbit

```

Create two 5-by-10 string arrays `str1` and `str2` that are equal, except for the element at row 4, column 3. Using linear indexing, this is element 14:

```

str1 = ['AAAAAAAAA'; 'BBBBBBBBBB'; 'CCCCCCCCC'; ...
 'DDDDDDDDD'; 'EEEEEEEEEE']
str1 =
 AAAAAAAAAA
 BBBBBBBBBB
 CCCCCCCCCC
 DDDDDDDDDD
 EEEEEEEEEE

str2 = str1;
str2(4,3) = '- '
str2 =
 AAAAAAAAAA
 BBBBBBBBBB
 CCCCCCCCCC
 DD-DDDDDDD
 EEEEEEEEEE

```

Because MATLAB compares the arrays in linear order (that is, column by column rather than row by row), `strncmp` finds only the first 13 elements to be the same:

```

str1 A B C D E A B C D E A B C D E
str2 A B C D E A B C D E A B C - E
 |
 element 14

```

```

strncmp(str1, str2, 13)
ans =
 1

```

```
strncmp(str1, str2, 14)
ans =
 0
```

## More About

### Tips

- The `strncmp` function is intended for comparison of character data. When used to compare numeric data, it returns logical `0`.
- Use `strncmpi` for case-insensitive string comparisons.
- Any leading and trailing blanks in either of the strings are explicitly included in the comparison.
- The value returned by `strncmp` is not the same as the C language convention.
- `strncmp` supports international character sets.

**Introduced before R2006a**

# strncmpi

Compare first *n* characters of strings (case insensitive)

## Syntax

```
TF = strncmpi(string,string,n)
TF = strncmpi(string,cellstr,n)
TF = strncmpi(cellstr,cellstr,n)
```

## Description

`TF = strncmpi(string,string,n)` compares the first *n* characters of two strings for equality, ignoring any differences in letter case. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

`TF = strncmpi(string,cellstr,n)` compares the first *n* characters of a string with the first *n* characters of each element of a cell array of strings, ignoring letter case. The function returns a logical array the same size as the `cellstr` input in which logical 1 represents equality. The order of the input arguments is not important.

`TF = strncmpi(cellstr,cellstr,n)` compares each element of one cell array of strings with the same element of the other, ignoring letter case. `strncmpi` attempts to match only the first *n* characters of these strings. The function returns a logical array the same size as either input array.

## Input Arguments

### **string**

A single character string or *n*-by-1 array of strings.

### **cellstr**

A cell array of strings.

### **n**

Maximum number of characters to compare. Must be a scalar, integer-valued double.

## Output Arguments

### TF

When both inputs are character arrays, **TF** is a scalar logical value. This value is logical 1 (**true**) if the size and content of both arrays are equal, and logical 0 (**false**) if they are not.

When either or both inputs are a cell array of strings, **TF** is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (**true**) for those elements of the input arrays that are a match, and logical 0 (**false**) for those elements that are not.

## Examples

From a list of 10 MATLAB functions, find those that apply to using a camera. Do the comparison without sensitivity to letter case:

```
function_list = {'calendar' 'case' 'camdolly' 'circshift' ...
 'caxis' 'Camtarget' 'cast' 'camorbit' ...
 'callib' 'cart2sph'};
```

```
strncmpi(function_list, 'CAM', 3)
ans =
 0 0 1 0 0 1 0 1 0 0
```

```
function_list{strncmpi(function_list, 'CAM', 3)}
ans =
 camdolly
ans =
 Camtarget
ans =
 camorbit
```

## stread

Read formatted data from string

---

**Note** `stread` is not recommended. Use `textscan` instead.

---

### Syntax

```
A = stread('str')
[A, B, ...] = stread('str')
[A, B, ...] = stread('str', 'format')
[A, B, ...] = stread('str', 'format', N)
[A, B, ...] = stread('str', 'format', N, param, value, ...)
```

### Description

`A = stread('str')` reads numeric data from input string `str` into a 1-by-N vector `A`, where N equals the number of whitespace-separated numbers in `str`. Use this form only with strings containing numeric data. See “Example 1” on page 1-8433 below.

`[A, B, ...] = stread('str')` reads numeric data from the string input `str` into scalar output variables `A`, `B`, and so on. The number of output variables must equal the number of whitespace-separated numbers in `str`. Use this form only with strings containing numeric data. See “Example 2” on page 1-8433 below.

`[A, B, ...] = stread('str', 'format')` reads data from `str` into variables `A`, `B`, and so on using the specified `format`. The number of output variables `A`, `B`, etc. must be equal to the number of format specifiers (e.g., `%s` or `%d`) in the `format` argument. You can read all of the data in `str` to a single output variable as long as you use only one format specifier in the command. See “Example 4” on page 1-8433 and “Example 5” on page 1-8434 below.

The table `Formats for stread` lists the valid format specifiers. More information on using formats is available under “Formats” on page 1-8436 in the “Tips” on page 1-8436 section below.

[A, B, ...] = strread('str', 'format', N) reads data from `str` reusing the format string `N` times, where `N` is an integer greater than zero. If `N` is `-1`, `strread` reads the entire string. When `str` contains only numeric data, you can set `format` to the empty string (`' '`). See “Example 3” on page 1-8433 below.

[A, B, ...] = strread('str', 'format', N, param, value, ...) customizes `strread` using `param/value` pairs, as listed in the table Parameters and Values for `strread` below. When `str` contains only numeric data, you can set `format` to the empty string (`' '`). The `N` argument is optional and may be omitted entirely. See “Example 7” on page 1-8435 below.

### Formats for strread

Format	Action	Output
Literals (ordinary characters)	Ignore the matching characters. For example, in a string that has <code>Dept</code> followed by a number (for department number), to skip the <code>Dept</code> and read only the number, use <code>'Dept'</code> in the format string.	None
<code>%d</code>	Read a signed integer value.	Double array
<code>%u</code>	Read an integer value.	Double array
<code>%f</code>	Read a floating-point value.	Double array
<code>%s</code>	Read a white-space separated string.	Cell array of strings
<code>%q</code>	Read a double quoted string, ignoring the quotes.	Cell array of strings
<code>%c</code>	Read characters, including white space.	Character array
<code>%[...]</code>	Read the longest string containing characters specified in the brackets.	Cell array of strings
<code>%[^...]</code>	Read the longest nonempty string containing characters that are not specified in the brackets.	Cell array of strings
<code>%*...</code>	Ignore the characters following <code>*</code> . See “Example 8” on page 1-8435 below.	No output

Format	Action	Output
%w...	Read field width specified by w. The %f format supports %w.pf, where w is the field width and p is the precision.	

### Parameters and Values for `stream`

param	value	Action
whitespace	Any from the list below:	
	\b	Backspace
	\n	New line
	\r	Carriage return
	\t	Horizontal tab
	\\	Backslash
	%% ' '	Percent sign Single quotation mark
delimiter	Delimiter character	Specifies delimiter character. Default is one or more whitespace characters.
expchars	Exponent characters	Default is eEdD.
bufsize	Positive integer	Specifies the maximum string length, in bytes. Default is 4095.
commentstyle	matlab	Ignores characters after %.
commentstyle	shell	Ignores characters after #.
commentstyle	c	Ignores characters between /* and */.
commentstyle	c++	Ignores characters after //.
emptyvalue	Value to return for empty numeric fields in delimited files	Default is NaN.

## Examples

### Example 1

Read numeric data into a 1-by-5 vector:

```
a = strread('0.41 8.24 3.57 6.24 9.27')
a =
 0.4100 8.2400 3.5700 6.2400 9.2700
```

### Example 2

Read numeric data into separate scalar variables:

```
[a b c d e] = strread('0.41 8.24 3.57 6.24 9.27')
a =
 0.4100
b =
 8.2400
c =
 3.5700
d =
 6.2400
e =
 9.2700
```

### Example 3

Read the only first three numbers in the string, also formatting as floating point:

```
a = strread('0.41 8.24 3.57 6.24 9.27', '%4.2f', 3)
a =
 0.4100
 8.2400
 3.5700
```

### Example 4

Truncate the data to one decimal digit by specifying format `%3.1f`. The second specifier, `.*1d`, tells `strread` not to read in the remaining decimal digit:

```
a = streadd('0.41 8.24 3.57 6.24 9.27', '%3.1f %*1d')
```

```
a =
 0.4000
 8.2000
 3.5000
 6.2000
 9.2000
```

## Example 5

Read six numbers into two variables, reusing the format specifiers:

```
[a b] = streadd('0.41 8.24 3.57 6.24 9.27 3.29', '%f %f')
```

```
a =
 0.4100
 3.5700
 9.2700
b =
 8.2400
 6.2400
 3.2900
```

## Example 6

Read string and numeric data to two output variables. Ignore commas in the input string:

```
str = 'Section 4, Page 7, Line 26';

[name value] = streadd(str, '%s %d,')
name =
 'Section'
 'Page'
 'Line'
value =
 4
 7
 26
```

## Example 7

Read the string used in the last example, but this time delimiting with commas instead of spaces:

```
str = 'Section 4, Page 7, Line 26';

[a b c] = strread(str, '%s %s %s', 'delimiter', ',')
a =
 'Section 4'
b =
 'Page 7'
c =
 'Line 26'
```

## Example 8

Read selected portions of the input string:

```
str = '<table border=5 width="100%" cellpadding=0>';

[border width space] = strread(str, ...
 '%*s%*s %c %*s "%4s" %*s %c', 'delimiter', '= ')
border =
 5
width =
 '100%'
space =
 0
```

## Example 9

Read the string into two vectors, restricting the `ANSWER` values to T and F. Also note that two delimiters (comma and space) are used here:

```
str = 'Answer_1: T, Answer_2: F, Answer_3: F';

[a b] = strread(str, '%s %[TF]', 'delimiter', ', ', ' ')
a =
 'Answer_1:'
 'Answer_2:'
 'Answer_3:'
b =
```

```
'T'
'F'
'F'
```

## More About

### Tips

If you terminate the input string with a newline character (`\n`), `stread` returns arrays of equal size by padding arrays of lesser size with the `emptyvalue` character:

```
[A,B,C] = stread(sprintf('5,7,1,9\n'),'%d%d%d', ...
 'delimiter', ',', 'emptyvalue',NaN)
A =
 5
 9
B =
 7
 NaN
C =
 1
 NaN
```

If you remove the `\n` from the input string of this example, array `A` continues to be a 2-by-1 array, but `B` and `C` are now 1-by-1.

### Delimiters

If your data uses a character other than a space as a delimiter, you must use the `stread` parameter `'delimiter'` to specify the delimiter. For example, if the string `str` used a semicolon as a delimiter, you would use this command:

```
[names, types, x, y, answer] = stread(str,'%s %s %f ...
 %d %s','delimiter',';')
```

### Formats

The `format` string determines the number and types of return arguments. The number of return arguments must match the number of conversion specifiers in the `format` string.

The `strread` function continues reading `str` until the entire string is read. If there are fewer format specifiers than there are entities in `str`, `strread` reapplies the format specifiers, starting over at the beginning. See “Example 5” on page 1-8434 below.

The `format` string supports a subset of the conversion specifiers and conventions of the C language `fscanf` routine. White-space characters in the `format` string are ignored.

## Preserving White-Space

If you want to preserve leading and trailing spaces in a string, use the `whitespace` parameter as shown here:

```
str = ' An example of preserving spaces ';
strread(str, '%s', 'whitespace', '')
ans =
 ' An example of preserving spaces '
```

## See Also

`textscan` | `sscanf`

Introduced before R2006a

## strrep

Find and replace substring

### Syntax

```
modifiedStr = strrep(origStr, oldSubstr, newSubstr)
```

### Description

*modifiedStr* = strrep(*origStr*, *oldSubstr*, *newSubstr*) replaces all occurrences of the string *oldSubstr* within string *origStr* with the string *newSubstr*.

### Examples

Replace text in a character array:

```
claim = 'This is a good example.';
new_claim = strrep(claim, 'good', 'great')
```

MATLAB returns:

```
new_claim =
This is a great example.
```

Replace text in a cell array:

```
c_files = {'c:\cookies.m'; ...
 'c:\candy.m'; ...
 'c:\calories.m'};
d_files = strrep(c_files, 'c:', 'd:')
```

MATLAB returns:

```
d_files =
'd:\cookies.m'
'd:\candy.m'
```

```
'd:\calories.m'
```

Replace text in a cell array with values in a second cell array:

```
missing_info = {'Start: __'; ...
 'End: __'};
```

```
dates = {'01/01/2001'; ...
 '12/12/2002'};
```

```
complete = strrep(missing_info, '__', dates)
```

MATLAB returns:

```
complete =
 'Start: 01/01/2001'
 'End: 12/12/2002'
```

Compare the use of `strrep` and `regexprep` to replace a string with a repeated pattern:

```
repeats = 'abc 2 def 22 ghi 222 jkl 2222';
indices = strfind(repeats, '22')
```

```
using_strrep = strrep(repeats, '22', '*')
using_regexprep = regexprep(repeats, '22', '*')
```

MATLAB returns:

```
indices =
 11 18 19 26 27 28
```

```
using_strrep =
abc 2 def * ghi ** jkl ***
```

```
using_regexprep =
abc 2 def * ghi *2 jkl **
```

## More About

### Tips

- `strrep` accepts input combinations of single strings, strings in scalar cells, and same-sized cell arrays of strings. If any inputs are cell arrays, `strrep` returns a cell array.

- The `strrep` function does not find empty strings for replacement. That is, when `origStr` and `oldSubstr` both contain the empty string ( `' '` ), `strrep` does not replace `' '` with the contents of `newSubstr`.
- Before replacing strings, `strrep` finds all instances of `oldSubstr` in `origStr`, like the `strfind` function. For overlapping patterns, `strrep` performs multiple replacements. See the final example in the Examples section.

`strfind` | `regexprep`

**Introduced before R2006a**

# strsplit

Split string at specified delimiter

## Syntax

```
C = strsplit(str)
C = strsplit(str,delimiter)
C = strsplit(str,delimiter,Name,Value)

[C,matches] = strsplit(___)
```

## Description

`C = strsplit(str)` splits the string, `str`, at whitespace into the cell array of strings, `C`. A whitespace character is equivalent to any sequence in the set `{ '\f', '\n', '\r', '\t', '\v' }`.

`C = strsplit(str,delimiter)` splits `str` at the delimiters specified by `delimiter`.

`C = strsplit(str,delimiter,Name,Value)` specifies additional delimiter options using one or more name-value pair arguments.

`[C,matches] = strsplit( ___ )` additionally returns a cell array of strings, `matches`. The `matches` output argument contains all occurrences of delimiters upon which `strsplit` splits `str`. You can use this syntax with any of the input arguments of the previous syntaxes.

## Examples

### Split String on Whitespace

```
str = 'The rain in Spain.';
C = strsplit(str)

C =

 'The' 'rain' 'in' 'Spain.'
```

C is a cell array containing four strings.

### Split String of Values on Specific Delimiter

Split a string of comma-separated values.

```
data = '1.21, 1.985, 1.955, 2.015, 1.885';
C = strsplit(data, ',')
```

```
C =

 '1.21' '1.985' '1.955' '2.015' '1.885'
```

Split a string of values, `data`, which contains the units `m/s` with an arbitrary number of whitespace on either side of the text. The regular expression, `\s*`, matches any whitespace character appearing zero or more times.

```
data = '1.21m/s 1.985m/s 1.955 m/s 2.015 m/s 1.885m/s';
[C,matches] = strsplit(data,'\s*m/s\s*',...
 'DelimiterType','RegularExpression')
```

```
C =

 '1.21' '1.985' '1.955' '2.015' '1.885' ''
```

```
matches =

 'm/s' 'm/s ' ' m/s' ' m/s ' 'm/s'
```

In this case, the last string in `C` is empty. This empty string is the string that follows the last matched delimiter.

### Split Path String on File Separator

```
myPath = 'C:\work\matlab';
C = strsplit(myPath, '\')
```

```
C =

 'C:' 'work' 'matlab'
```

### Split Text String with Multiple Delimiters

Split a string on `' '` and `'ain'`, treating multiple delimiters as one. Specify multiple delimiters in a cell array of strings.

```
str = 'The rain in Spain stays mainly in the plain.';
[C,matches] = strsplit(str,{' ','ain'},'CollapseDelimiters',true)
C =
 'The' 'r' 'in' 'Sp' 'stays' 'm' 'ly' 'in' 'the' 'pl'

matches =
 ' ' 'ain ' ' ' 'ain ' ' ' 'ain' ' ' ' ' ' ' 'ain'
```

Split the same string on whitespace and on 'ain', using regular expressions and treating multiple delimiters separately.

```
[C,matches] = strsplit(str,{'\s','ain'},'CollapseDelimiters',...
 false, 'DelimiterType','RegularExpression')
C =
 'The' 'r' '' 'in' 'Sp' '' 'stays' 'm' 'ly' 'in' 'the'

matches =
 ' ' 'ain' ' ' ' ' 'ain' ' ' ' ' 'ain' ' ' ' ' ' '
```

In this case, `strsplit` treats the two delimiters separately, so empty strings appear in output `C` between the consecutively matched delimiters.

### Split Text with Multiple, Overlapping Delimiters

Split text on the strings ', ' and ', and '.

```
str = 'bacon, lettuce, and tomato';
[C,matches] = strsplit(str,{' ',',',', and '})
C =
 'bacon' 'lettuce' 'and tomato'

matches =
 ', ' ', and ' ', ' ', ' ' ', ' ', ' ' ', ' ' ', ' '
```

Because the command lists `' , '` first and `' , and '` contains `' , '`, the `strsplit` function splits `str` on the first delimiter and never proceeds to the second delimiter.

If you reverse the order of delimiters, `' , and '` takes priority.

```
str = 'bacon, lettuce, and tomato';
[C,matches] = strsplit(str,{' , and ' , ' , ' })
```

C =

```
 'bacon' 'lettuce' 'tomato'
```

matches =

```
 ' , ' ' , and ' ' , ' '
```

## Input Arguments

### **str** — Input text

string

Input text, specified as a string.

Data Types: char

### **delimiter** — Delimiting characters

string | 1-by-n cell array of strings

Delimiting characters, specified as a single string or a 1-by-n cell array of strings. Strings specified in `delimiter` do not appear in the string fragments of the output `C`.

Specify multiple delimiters in a cell array of strings. Each element of the cell array must contain a single string in a single row. The `strsplit` function splits `str` on the elements of `delimiter`. The order in which delimiters appear in `delimiter` does not matter unless multiple delimiters begin a match at the same character in `str`. In that case `strsplit` splits on the first matching delimiter in `delimiter`.

`delimiter` can include the following escape sequences:

<code>\\</code>	Backslash
<code>\0</code>	Null

<code>\a</code>	Alarm
<code>\b</code>	Backspace
<code>\f</code>	Form feed
<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab
<code>\v</code>	Vertical tab

Example: `' , '`

Example: `{ ' - ' , ' , ' }`

Data Types: `char` | `cell`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'DelimiterType', 'RegularExpression'` instructs `strsplit` to treat `delimiter` as a regular expression.

### 'CollapseDelimiters' — Multiple delimiter handling

`1` (`true`) (default) | `0` (`false`)

Multiple delimiter handling, specified as the comma-separated pair consisting of `'CollapseDelimiters'` and either `true` or `false`. If `true`, then consecutive delimiters in `str` are treated as one. If `false`, then consecutive delimiters are treated as separate delimiters, resulting in empty string `' '` elements between matched delimiters.

Example: `'CollapseDelimiters', true`

### 'DelimiterType' — Delimiter type

`'Simple'` (default) | `'RegularExpression'`

Delimiter type, specified as the comma-separated pair consisting of `'DelimiterType'` and one of the following strings.

'Simple'	Except for escape sequences, <code>strsplit</code> treats <code>delimiter</code> as a literal string.
'RegularExpression'	<code>strsplit</code> treats <code>delimiter</code> as a regular expression.

In both cases, `delimiter` can include escape sequences.

## Output Arguments

### **C** — Parts of original string

cell array of strings

Parts of the original string, returned as a cell array of strings. **C** always contains one more element than `matches` contains. Therefore, if the original string, `str`, begins with a delimiter, then the first cell in **C** contains an empty string. If `str` ends with a delimiter, then the last cell in **C** contains an empty string.

### **matches** — Identified delimiters

cell array of strings

Identified delimiters, returned as a cell array of strings. `matches` always contains one fewer element than output **C** contains.

**Introduced in R2013a**

# strtok

Selected parts of string

## Syntax

```
token = strtok(str)
token = strtok(str, delimiter)
[token, remain] = strtok(str, ...)
```

## Description

`token = strtok(str)` parses input string `str` from left to right, returning part or all of that string in `token`. Using the white-space character as a delimiter, the `token` output begins at the start of `str`, skipping any delimiters that might appear at the start, and includes all characters up to either the next delimiter or the end of the string. White-space characters include space (ASCII 32), tab (ASCII 9), and carriage return (ASCII 13).

The `str` argument can be a string of characters enclosed in single quotation marks, a cell array of strings each enclosed in single quotation marks, or a variable representing either of the two. If `str` is a cell array of `N` strings, then `token` is a cell array of `N` tokens, with `token{1}` derived from `str{1}`, `token{2}` from `str{2}`, and so on.

`token = strtok(str, delimiter)` is the same as the above syntax except that you specify the delimiting character(s) yourself using the `delimiter` character vector input. White-space characters are not considered to be delimiters when using this syntax unless you include them in the `delimiter` argument. If the `delimiter` input specifies more than one character, MATLAB treats each character as a separate delimiter; it does not treat the multiple characters as a delimiting string. The number and order of characters in the `delimiter` argument is unimportant. Do not use escape sequences as delimiters. For example, use `char(9)` rather than `'\t'` for tab.

`[token, remain] = strtok(str, ...)` returns in `remain` that part of `str`, if any, that follows `token`. The delimiter is included in `remain`. If no delimiters are found in the body of the input string, then the entire string (excluding any leading delimiting characters) is returned in `token`, and `remain` is an empty string (`' '`). If `str` is a cell array of strings, `token` is a cell array of tokens and `remain` is a cell array of string remainders.

## Examples

### Example 1

This example uses the default white-space delimiter. Note that space characters at the start of the string are not included in the `token` output, but the space character that follows `token` is included in `remain`:

```
s = ' This is a simple example.';
[token, remain] = strtok(s)

token =
This
remain =
 is a simple example.
```

### Example 2

Take a string of HTML code and break it down into segments delimited by the `<` and `>` characters. Write a `while` loop to parse the string and print each segment:

```
s = sprintf('%s%s%s%s', ...
'<ul class=continued><li class=continued>', ...
'<pre>token = strtok', ...
(''str'', delimiter)', ...
'token = strtok(''str'')');

remain = s;

while true
 [str, remain] = strtok(remain, '<>');
 if isempty(str), break; end
 disp(sprintf('%s', str))
end
```

Here is the output:

```
ul class=continued
li class=continued
pre
a name="13474"
/a
token = strtok('str', delimiter)
```

```
a name="13475"
/a
token = strtok('str')
```

### Example 3

Using `strtok` on a cell array of strings returns a cell array of strings in `token` and a character array in `remain`:

```
s = {'all in good time'; ...
 'my dog has fleas'; ...
 'leave no stone unturned'};

remain = s;

for k = 1:4
 [token, remain] = strtok(remain);
 token
end
```

Here is the output:

```
token =
 'all'
 'my'
 'leave'
token =
 'in'
 'dog'
 'no'
token =
 'good'
 'has'
 'stone'
token =
 'time'
 'fleas'
 'unturned'
```

### See Also

`strfind` | `strcmp` | `strncmp` | `textscan` | `strsplit`

**Introduced before R2006a**

## **strtrim**

Remove leading and trailing white space from string

### **Syntax**

```
S = strtrim(str)
C = strtrim(cstr)
```

### **Description**

`S = strtrim(str)` returns a copy of string `str` with all leading and trailing white-space characters removed. A white-space character is one for which the `isspace` function returns logical 1 (`true`).

`C = strtrim(cstr)` returns a copy of the cell array of strings `cstr` with all leading and trailing white-space characters removed from each string in the cell array.

### **Examples**

Remove the leading white-space characters (spaces and tabs) from `str`:

```
str = sprintf(' \t Remove leading white-space')
str =
 Remove leading white-space
```

```
str = strtrim(str)
str =
Remove leading white-space
```

Remove leading and trailing white-space from the cell array of strings:

```
cstr = {' Trim leading white-space';
 'Trim trailing white-space '};

cstr = strtrim(cstr)
cstr =
 'Trim leading white-space'
```

'Trim trailing white-space'

## **See Also**

isspace | cellstr | deblank | strjust

**Introduced before R2006a**

## struct

Create structure array

### Syntax

```
s = struct
s = struct(field,value)
s = struct(field1,value1,...,fieldN,valueN)
s = struct([])

s = struct(obj)
```

### Description

`s = struct` creates a scalar (1-by-1) structure with no fields.

`s = struct(field,value)` creates a structure array with the specified field and values. The `value` input argument can be any data type, such as a numeric, logical, character, or cell array.

- If `value` is *not* a cell array, then `s` is a scalar structure, where `s.(field) = value`.
- If `value` is a cell array, then `s` is a structure array with the same dimensions as `value`. Each element of `s` contains the corresponding element of `value`. For example, `s = struct('f',{'a','b'})` returns `s(1).f = 'a'` and `s(2).f = 'b'`.
- If `value` is an empty cell array `{}`, then `s` is an empty (0-by-0) structure.

`s = struct(field1,value1,...,fieldN,valueN)` creates a structure array with multiple fields. Any nonscalar cell arrays in the set `value1,...,valueN` must have the same dimensions.

- If none of the `value` inputs is a cell array, or if all `value` inputs that are cell arrays are scalars, then `s` is a scalar structure.
- If any of the `value` inputs is a nonscalar cell array, then `s` has the same dimensions as the nonscalar cell array. For any `value` that is a scalar cell array or an array of any other data type, `struct` inserts the contents of `value` in the relevant field for all elements of `s`.

- If any `value` input is an empty cell array, `{}`, then output `s` is an empty (0-by-0) structure. To specify an empty field and keep the values of the other fields, use `[]` as a `value` input instead.

`s = struct([])` creates an empty (0-by-0) structure with no fields.

`s = struct(obj)` creates a scalar structure with field names and values that correspond to properties of `obj`. The `struct` function does not convert `obj`, but rather creates `s` as a new structure. This structure does not retain the class information, so private, protected, and hidden properties become public fields in `s`. The `struct` function issues a warning when you use this syntax.

## Examples

### Structure with One Field

Create a nonscalar structure with one field.

```
field = 'f';
value = {'some text';
 [10, 20, 30];
 magic(5)};
s = struct(field,value)
```

```
s =
3x1 struct array with fields:
 f
```

View the contents of each element.

```
s.f
```

```
ans =
some text
```

```
ans =
 10 20 30
```

```
ans =
 17 24 1 8 15
 23 5 7 14 16
```

```
4 6 13 20 22
10 12 19 21 3
11 18 25 2 9
```

When you access a field of a nonscalar structure, such as `s.f`, MATLAB returns a comma-separated list. In this case, `s.f` is equivalent to `s(1).f`, `s(2).f`, `s(3).f`.

### Structure with Multiple Fields

Create a nonscalar structure with several fields.

```
field1 = 'f1'; value1 = zeros(1,10);
field2 = 'f2'; value2 = {'a', 'b'};
field3 = 'f3'; value3 = {pi, pi.^2};
field4 = 'f4'; value4 = {'fourth'};

s = struct(field1,value1,field2,value2,field3,value3,field4,value4)
```

```
s =
1x2 struct array with fields:
 f1
 f2
 f3
 f4
```

The cell arrays for `value2` and `value3` are 1-by-2, so `s` is also 1-by-2. Because `value1` is a numeric array and not a cell array, both `s(1).f1` and `s(2).f1` have the same contents. Similarly, because the cell array for `value4` has a single element, `s(1).f4` and `s(2).f4` have the same contents.

```
s(1)

ans =
 f1: [0 0 0 0 0 0 0 0 0 0]
 f2: 'a'
 f3: 3.1416
 f4: 'fourth'
```

```
s(2)

ans =
 f1: [0 0 0 0 0 0 0 0 0 0]
 f2: 'b'
 f3: 9.8696
```

```
f4: 'fourth'
```

### Structure with Empty Field

Create a structure with an empty field. Use `[]` to specify the value of the empty field.

```
s = struct('f1','a','f2',[])
```

```
s =
```

```
f1: 'a'
f2: []
```

### Fields That Contain Cell Arrays

Create a structure with a field that contains a cell array.

```
field = 'mycell';
value = {'a','b','c'};
s = struct(field,value)
```

```
s =
```

```
mycell: {'a' 'b' 'c'}
```

### Empty Structure

Create an empty structure with several fields.

```
s = struct('a', {}, 'b', {}, 'c', {})
```

```
s =
```

```
0x0 struct array with fields:
```

```
a
b
c
```

Assign a value to a field in an empty structure.

```
s(1).a = 'a'
```

```
s =
```

```
a: 'a'
b: []
```

```
c: []
```

## Nested Structure

Create a nested structure. `a` is a structure with a field which contains another structure.

```
a.b = struct('c', {}, 'd', {})
```

```
a =
 b: [0x0 struct]
```

View the names of the fields of `a.b`.

```
fieldnames(a.b)
```

```
ans =
 'c'
 'd'
```

- “Create a Structure Array”
- “Access Data in a Structure Array”
- “Generate Field Names from Variables”

## Input Arguments

### **field** — Field name

string

Field name, specified as a string. Valid field names begin with a letter, and can contain letters, digits, and underscores. The maximum length of a field name is the value that the `namelengthmax` function returns.

### **value** — Values within structure field

cell array | scalar | vector | multidimensional array

Values within a structure field, specified as a cell array or as a scalar, vector, or multidimensional array of any other data type.

If none of the `value` inputs is a cell array, or if all `value` inputs that are cell arrays are scalars, then output `s` is a scalar structure. Otherwise, `value` inputs that are nonscalar cell arrays must have the same dimensions, and output `s` also has those dimensions. For

any **value** that is a scalar cell array or an array of any other data type, **struct** inserts the contents of **value** in the relevant field for all elements of **s**.

If any **value** input is an empty cell array, {}, then output **s** is an empty structure array. To specify an empty field and keep the values of the other fields, use [] as a **value** input instead.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | table | cell | function\_handle | categorical | datetime | duration | calendarDuration  
Complex Number Support: Yes

### **obj** – Object

object of any nonfundamental class

Object. **struct** copies the properties of **obj** to the fields of a new scalar structure. **obj** cannot be an object of a fundamental data type, such as **double** or **char**. See “Fundamental MATLAB Classes” for the list of fundamental data types.

### **See Also**

**Introduced before R2006a**

## struct2cell

Convert structure to cell array

### Syntax

```
c = struct2cell(s)
```

### Description

`c = struct2cell(s)` converts the `m`-by-`n` structure `s` (with `p` fields) into a `p`-by-`m`-by-`n` cell array `c`.

If structure `s` is multidimensional, cell array `c` has size `[p size(s)]`.

### Examples

The commands

```
clear s, s.category = 'tree';
s.height = 37.4; s.name = 'birch';
```

create the structure

```
s =
 category: 'tree'
 height: 37.4000
 name: 'birch'
```

Converting the structure to a cell array,

```
c = struct2cell(s)
```

```
c =
 'tree'
 [37.4000]
 'birch'
```

## More About

### Tips

- Use `fieldnames` to obtain structure field names in the same order as `struct2cell` returns structure values.
- dynamic field names

### See Also

`cell2struct` | `struct2table` | `table2cell` | `cell` | `iscell` | `struct` | `isstruct` | `fieldnames`

**Introduced before R2006a**

## struct2table

Convert structure array to table

### Syntax

```
T = struct2table(S)
T = struct2table(S,Name,Value)
```

### Description

`T = struct2table(S)` converts the structure array, `S`, to a table, `T`. Each field of `S` becomes a variable in `T`.

`T = struct2table(S,Name,Value)` creates a table from a structure array, `S`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify row names to include in the table.

### Examples

#### Convert Scalar Structure to Table

Convert a scalar structure to a table using the default options.

Create a structure array, `S`.

```
S.Name = {'CLARK';'BROWN';'MARTIN'};
S.Gender = {'M';'F';'M'};
S.SystolicBP = [124;122;130];
S.DiastolicBP = [93;80;92];
```

`S`

`S =`

```
 Name: {3x1 cell}
 Gender: {3x1 cell}
```

```
SystolicBP: [3x1 double]
DiastolicBP: [3x1 double]
```

The scalar structure, **S**, has four fields, each with three rows.

Convert the structure array to a table.

```
T = struct2table(S)
```

```
T =
```

Name	Gender	SystolicBP	DiastolicBP
'CLARK'	'M'	124	93
'BROWN'	'F'	122	80
'MARTIN'	'M'	130	92

The structure field names in **S** become the variable names in the output table. The size of **T** is 3-by-4.

Change **Name** from a variable to row names by modifying the table property, **T.Properties.RowNames**, and then deleting the variable **Name**.

```
T.Properties.RowNames = T.Name;
T.Name = [];
```

```
T
```

```
T =
```

	Gender	SystolicBP	DiastolicBP
CLARK	'M'	124	93
BROWN	'F'	122	80
MARTIN	'M'	130	92

### Convert Nonscalar Structure Array to Table

Create a nonscalar structure array, **S**.

```
S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
```

```
S(1,1).DiastolicBP = 93;
```

```
S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;
```

```
S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;
```

```
S
```

```
S =
```

```
3x1 struct array with fields:
```

```
 Name
 Gender
 SystolicBP
 DiastolicBP
```

S is a 3-by-1 structure array with four fields.

Convert the structure array to a table.

```
T = struct2table(S)
```

```
T =
```

Name	Gender	SystolicBP	DiastolicBP
'CLARK'	'M'	124	93
'BROWN'	'F'	122	80
'MARTIN'	'M'	130	92

The structure field names in S become the variable names in the output table. The size of T is 3-by-4.

## Treat Scalar Structure As Array

Use 'AsArray', true to create a table from a scalar structure whose fields have different numbers of rows.

Create a scalar structure, `S`, with fields `name`, `billing`, and `test`.

```
S.name = 'John Doe';
S.billing = 127.00;
S.test = [79, 75, 73; 180, 178, 177.5; 220, 210, 205];
S
```

```
S =
```

```
 name: 'John Doe'
 billing: 127
 test: [3x3 double]
```

The fields have a different number of rows. Therefore, you cannot use `struct2table(S)`, which uses `'AsArray'`, `false` by default.

Treat the scalar structure as an array and convert it to a table.

```
T = struct2table(S, 'AsArray', true)
```

```
T =
```

name	billing	test
'John Doe'	127	[3x3 double]

`T` contains one row.

- “Access Data in a Table”

## Input Arguments

### **S** — Structure array

structure array

Structure array, specified as a scalar structure array.

- If `S` is a scalar structure with `n` fields, all of which have `m` rows, then `T` is an `m`-by-`n` table.
- If `S` is a nonscalar `m`-by-1 structure array with `n` fields, then `T` is an `m`-by-`n` table.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `RowNames` ' , { ' row1 ' , ' row2 ' , ' row3 ' } uses the row names, `row1`, `row2`, and `row3` for the table, `T`.

### 'RowNames' — Row names for T

{ } (default) | cell array of nonempty, distinct strings

Row names for `T`, specified as the comma-separated pair consisting of 'RowNames' and a cell array of nonempty, distinct strings.

### 'AsArray' — Indicator for how to treat scalar structure

false (default) | true | 0 | 1

Indicator for how to treat scalar structure, specified as the comma-separated pair consisting of 'AsArray' and either `false`, `true`, `0`, or `1`.

<code>true</code>	<code>struct2table</code> converts <code>S</code> to a table with one row and <code>n</code> variables. The variables can be different sizes.
<code>false</code>	<code>struct2table</code> converts a scalar structure array with <code>n</code> fields into an <code>m</code> -by- <code>n</code> table. Each field must have <code>m</code> rows. This is the default behavior

## Output Arguments

### T — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

### See Also

`array2table` | `cell2table` | `table` | `table2struct`

**Introduced in R2013b**

## **structfun**

Apply function to each field of scalar structure

### **Syntax**

```
[A1,...,An] = structfun(func,S)
[A1,...,An] = structfun(func,S,Name,Value)
```

### **Description**

[A1,...,An] = structfun(func,S) applies the function specified by function handle `func` to each field of scalar structure `S`. Output arrays `A1,...,An`, where `n` is the number of outputs from function `func`, contain the outputs from the function calls.

[A1,...,An] = structfun(func,S,Name,Value) calls function `func` with additional options specified by one or more `Name,Value` pair arguments. Possible values for `Name` are 'UniformOutput' or 'ErrorHandler'.

### **Input Arguments**

#### **func**

Handle to a function that accepts a single input argument and returns `n` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

#### **S**

Scalar structure.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### 'UniformOutput'

Logical value, as follows:

true (1)	Indicates that for all inputs, each output from function <code>func</code> is a scalar cell array, scalar structure, or scalar value that is always of the same type and size. The <code>structfun</code> function combines the outputs in arrays <code>A1,...,An</code> , where <code>n</code> is the number of function outputs. Each output array is of the same type as the individual function outputs.
false (0)	Requests that the <code>structfun</code> function combine the outputs into scalar structures <code>A1,...,An</code> , with the same fields as input structure <code>S</code> . The outputs of function <code>func</code> can be of any size or type.

**Default:** true

### 'ErrorHandler'

Handle to a function that catches any errors that occur when MATLAB attempts to execute function `func`. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

<code>identifier</code>	Error identifier.
<code>message</code>	Error message text.
<code>index</code>	Linear index corresponding to the element of the input cell array at the time of the error.

- The set of input arguments to function `func` at the time of the error.

## Output Arguments

**A1,...,An**

Arrays that collect the `n` outputs from function `func`.

If `UniformOutput` is `true` (the default):

- The individual outputs from function `func` must be scalar values (numeric, logical, or character), scalar structures, or scalar cell arrays.
- The class of a particular output argument must be the same for each input. The class of the corresponding output array is the same as the class of the individual outputs from function `func`.
- Each array `A` is a column vector whose length equals the number of fields in `S`. The `structfun` function applies function `func` to the fields of `S` in the same order as that returned by the `fieldnames` function.

If `UniformOutput` is `false`, each array `A` is a scalar structure with the same fields as input `S`.

## Examples

Create a scalar structure, and count the number of characters in each field.

```
s.f1 = 'Sunday';
s.f2 = 'Monday';
s.f3 = 'Tuesday';
s.f4 = 'Wednesday';
s.f5 = 'Thursday';
s.f6 = 'Friday';
s.f7 = 'Saturday';
```

```
lengths = structfun(@numel, s)
```

Shorten the text in each field of `s`, created in the previous example. Because the output is nonscalar, set `UniformOutput` to `false`.

```
shortNames = structfun(@(x) (x(1:3)), s, 'UniformOutput', false)
```

The syntax `@(x)` creates an anonymous function.

Define and call a custom error handling function.

```
function result = errorfun(errorinfo, field)
 warning(errorinfo.identifier, errorinfo.message);
 result = NaN;
end
```

```
mystruct.f1 = 'text';
myresult = structfun(@(x) x^2, mystruct, 'ErrorHandler', @errorfun)
```

[cellfun](#) | [arrayfun](#) | [cell2mat](#) | [spfun](#)

**Introduced before R2006a**

## strvcat

Concatenate strings vertically

---

**Note:** `strvcat` is not recommended. Use `char` instead. Unlike `strvcat`, the `char` function does not ignore empty strings.

---

## Syntax

```
S = strvcat(t1, t2, t3, ...)
S = strvcat(c)
```

## Description

`S = strvcat(t1, t2, t3, ...)` forms the character array `S` containing the text strings (or string matrices) `t1, t2, t3, ...` as rows. Spaces are appended to each string as necessary to form a valid matrix. Empty arguments are ignored.

`S = strvcat(c)` when `c` is a cell array of strings, passes each element of `c` as an input to `strvcat`. Empty strings in the input are ignored.

## Examples

The command `strvcat('Hello', 'Yes')` is the same as `['Hello'; 'Yes ']`, except that `strvcat` performs the padding automatically.

```
t1 = 'first'; t2 = 'string'; t3 = 'matrix'; t4 = 'second';
```

```
S1 = strvcat(t1, t2, t3) S2 = strvcat(t4, t2, t3)
```

```
S1 = S2 =
```

```
first second
string string
```

```
matrix matrix
S3 = strvcat(S1, S2)
S3 =
first
string
matrix
second
string
matrix
```

## More About

### Tips

If each text parameter, `ti`, is itself a character array, `strvcat` appends them vertically to create arbitrarily large string matrices.

**Introduced before R2006a**

## sub2ind

Convert subscripts to linear indices

### Syntax

```
linearInd = sub2ind(matrixSize, rowSub, colSub)
linearInd = sub2ind(arraySize, dim1Sub, dim2Sub, dim3Sub, ...)
```

### Description

*linearInd* = sub2ind(*matrixSize*, *rowSub*, *colSub*) returns the linear index equivalents to the row and column subscripts *rowSub* and *colSub* for a matrix of size *matrixSize*. The *matrixSize* input is a 2-element vector that specifies the number of rows and columns in the matrix as [nRows, nCols]. The *rowSub* and *colSub* inputs are positive, whole number scalars or vectors that specify one or more row-column subscript pairs for the matrix. Example 3 demonstrates the use of vectors for the *rowSub* and *colSub* inputs.

*linearInd* = sub2ind(*arraySize*, *dim1Sub*, *dim2Sub*, *dim3Sub*, ...) returns the linear index equivalents to the specified subscripts for each dimension of an N-dimensional array of size *arraySize*. The *arraySize* input is an n-element vector that specifies the number of dimensions in the array. The *dimNSub* inputs are positive, whole number scalars or vectors that specify one or more row-column subscripts for the matrix.

All subscript inputs can be `single`, `double`, or any integer type. The *linearInd* output is always of class `double`.

If needed, `sub2ind` assumes that unspecified trailing subscripts are 1. See Example 2, below.

## Examples

### Example 1

This example converts the subscripts (2, 1, 2) for three-dimensional array A to a single linear index. Start by creating a 3-by-4-by-2 array A:

```
rng(0, 'twister'); % Initialize random number generator.
A = rand(3, 4, 2)
```

```
A(:,:,1) =
 0.8147 0.9134 0.2785 0.9649
 0.9058 0.6324 0.5469 0.1576
 0.1270 0.0975 0.9575 0.9706
A(:,:,2) =
 0.9572 0.1419 0.7922 0.0357
 0.4854 0.4218 0.9595 0.8491
 0.8003 0.9157 0.6557 0.9340
```

Find the linear index corresponding to (2, 1, 2):

```
linearInd = sub2ind(size(A), 2, 1, 2)
linearInd =
 14
```

Make sure that these agree:

```
A(2, 1, 2) A(14)
ans = and =
 0.4854 0.4854
```

## Example 2

Using the 3-dimensional array `A` defined in the previous example, specify only 2 of the 3 subscript arguments in the call to `sub2ind`. The third subscript argument defaults to 1.

The command

```
linearInd = sub2ind(size(A), 2, 4)
ans =
 11
```

is the same as

```
linearInd = sub2ind(size(A), 2, 4, 1)
ans =
 11
```

## Example 3

Using the same 3-dimensional input array `A` as in Example 1, accomplish the work of five separate `sub2ind` commands with just one.

Replace the following commands:

```
sub2ind(size(A), 3, 3, 2);
sub2ind(size(A), 2, 4, 1);
sub2ind(size(A), 3, 1, 2);
sub2ind(size(A), 1, 3, 2);
sub2ind(size(A), 2, 4, 1);
```

with a single command:

```
sub2ind(size(A), [3 2 3 1 2], [3 4 1 3 4], [2 1 2 2 1])
ans =
 21 11 15 19 11
```

Verify that these linear indices access the same array elements as their subscripted counterparts:

```
[A(3,3,2), A(2,4,1), A(3,1,2), A(1,3,2), A(2,4,1)]
ans =

# subplot

Create axes in tiled positions

## Syntax

```
subplot(m,n,p)
subplot(m,n,p,'replace')
subplot(m,n,p,'align')
subplot('Position',positionVector)
subplot(m,n,p,ax)
subplot(____,Name,Value)
```

```
h = subplot(____)
```

```
subplot(h)
```

## Description

`subplot(m,n,p)` divides the current figure into an  $m$ -by- $n$  grid and creates an axes for a subplot in the position specified by  $p$ . MATLAB numbers its subplots by row, such that the first subplot is the first column of the first row, the second subplot is the second column of the first row, and so on. If the axes already exists, then the command `subplot(m,n,p)` makes the subplot in position  $p$  the current axes.

`subplot(m,n,p,'replace')` deletes any existing axes in position  $p$  and creates a new axes.

`subplot(m,n,p,'align')` creates a new axes so that the plot boxes are aligned. This is the default behavior.

`subplot('Position',positionVector)` creates a new axes at the position specified by `positionVector`. The `positionVector` is a four-element vector of the form `[left,bottom,width,height]`, such that the entries are normalized values between 0.0 to 1.0. If the position vector specifies an axes that overlaps any previous axes, then the new axes replaces the existing ones.

`subplot(m,n,p,ax)` converts the existing axes, `ax`, into a subplot axes in the same figure.

`subplot( ____,Name,Value)` specifies properties for the axes using any of the input argument combinations in the previous syntaxes and one or more `Name,Value` pair arguments.

`h = subplot( ____)` returns the axes object created by the `subplot` function.

`subplot(h)` makes the axes with handle `h` the current axes of its figure, but does not make its figure the current figure if it is not already the current figure.

## Examples

### Upper and Lower Subplots

Create a figure with two stacked subplots. Plot a sine wave in each axes.

```
x = linspace(0,10);
y1 = sin(x);
y2 = sin(5*x);
```

```
figure
subplot(2,1,1);
plot(x,y1)
```

```
subplot(2,1,2);
plot(x,y2)
```

## Quadrant of Subplots

Create a figure divided into four subplots.

Define the data.

```
x = linspace(0,10);
y1 = sin(x);
y2 = sin(2*x);
y3 = sin(4*x);
y4 = sin(8*x);
```

Plot the four sine waves and title each subplot.

```
figure
subplot(2,2,1)
plot(x,y1)
title('Subplot 1: sin(x)')

subplot(2,2,2)
plot(x,y2)
title('Subplot 2: sin(2x)')

subplot(2,2,3)
plot(x,y3)
title('Subplot 3: sin(4x)')

subplot(2,2,4)
plot(x,y4)
title('Subplot 4: sin(8x)')
```

## Subplots with Different Sizes

Create a figure containing subplots with different sizes.

Define a vector of sine values and a vector of polynomial values.

```
x = linspace(-3.8,3.8);
y_cos = cos(x);
y_poly = 1 - x.^2./2 + x.^4./24;
```

Plot the sine wave in the first subplot and the polynomial in the second subplot. Create a third subplot that spans the lower half of the figure and plot both vectors together. Add titles to each subplot.

```
figure
subplot(2,2,1);
plot(x,y_cos);
title('Subplot 1: Cosine')

subplot(2,2,2);
plot(x,y_poly,'g');
title('Subplot 2: Polynomial')

subplot(2,2,[3,4]);
plot(x,y_cos,'b',x,y_poly,'g');
title('Subplot 3 and 4: Both')
```

## Replace Subplot with Empty Axes

Initialize the random number generator. Use a loop to create a figure with four stem plots of random data.

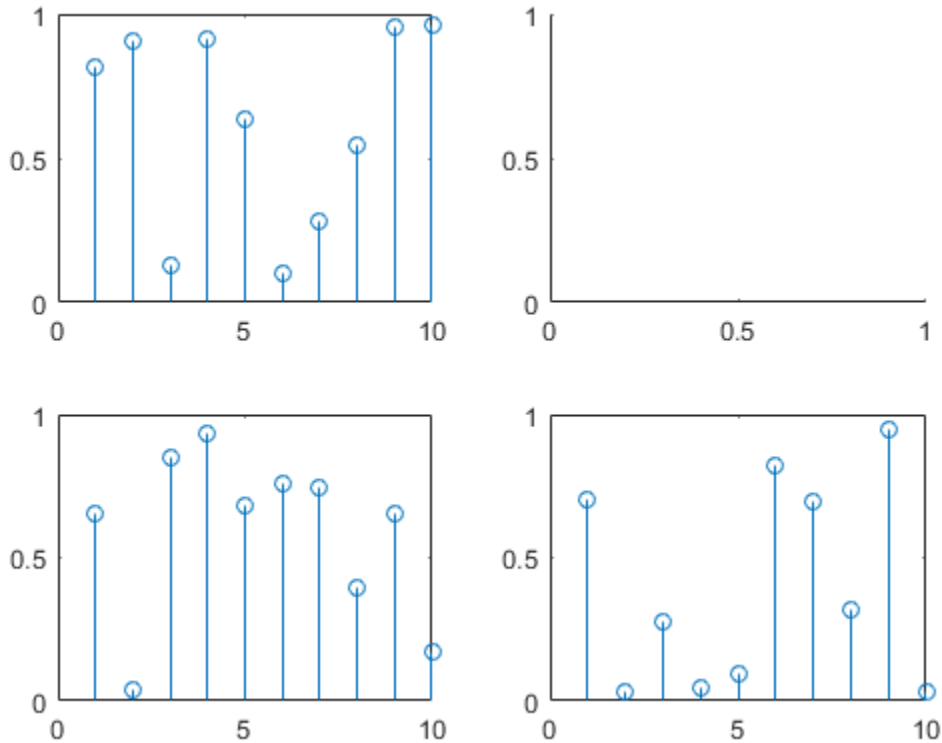

```
rng default
figure
for k = 1:4
 data = rand(1,10);
 subplot(2,2,k)
 stem(data)
end
```

Replace the second subplot with an empty axes.

```
subplot(2,2,2, 'replace')
```

## Subplots at Specified Positions

Create a figure with two subplots that are not aligned.

Define `y` as data from the `magic` function.

```
y = magic(4);
```

Plot `y` in one subplot. Create a bar graph of `y` in a second subplot. Specify a custom position for each subplot.

```
figure
positionVector1 = [0.1, 0.2, 0.3, 0.3];
```

```
subplot('Position',positionVector1)
plot(y)

positionVector2 = [0.5, 0.1, 0.4, 0.7];
subplot('Position',positionVector2)
bar(y)
```

## Return Subplot Axes Handle

Create a figure with two subplots. Plot the first 20 rows of the `peaks` function in the upper subplot. Plot the entire data set in the lower subplot.

```
ax1 = subplot(2,1,1);
```

```
Z = peaks;
plot(ax1,Z(1:20,:))

ax2 = subplot(2,1,2);
plot(ax2,Z)
```

Change the tick marks for the lower subplot. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
ax2.XTick = [0,10,25,40,50];
```

Some plotting functions set axes properties. Execute plotting functions before specifying axes properties to avoid overriding existing axes property settings.

## Make Subplot Axes the Current Axes

Make a subplot the current axes using its axes handle.

Create a figure with multiple subplots. Store the subplot axes handles in vector `h`.

```
figure;
for k = 1:4
 h(k) = subplot(2,2,k);
end
```

Make the second subplot the current axes. Plot a sine wave and change the axis limits.

```
x = linspace(1,50);
y = sin(x);

subplot(h(2))
plot(x,y,'Color',[0.1, 0.5, 0.1])
title('Second Subplot')
axis([0,50,-1,1])
```

## Convert Existing Axes to Subplot

Create a plot with a title.

```
x = linspace(1,10);
y = sin(x);
plot(x,y)
title('Sine Plot')
```

Get the current axes object using `gca`. Convert the current axes so that it is the lower subplot of the figure.

```
ax1 = gca;
subplot(2,1,2,ax1)
```

The `subplot` function uses the figure in which the original axes existed.

## Combine Two Axes Into Single Figure With Subplots

Create two plots in two different figures and store the axes objects.

```
x = linspace(0,10);
y1 = sin(x);
figure
plot(x,y1)
ax1 = gca;

y2 = 2*sin(x);
```

```
figure
plot(x,y2)
leg = legend('2*Sin(x)');
ax2 = gca;
```

Create copies of the two axes objects using `copyobj`. Set the parent of the copied axes to a third figure. Since legends and colorbars objects do not get copied with the associated axes, copy the legend with the axes.

```
f3 = figure;
ax1_copy = copyobj(ax1,f3);
subplot(2,1,1,ax1_copy)

copies = copyobj([ax2,leg],f3);
ax2_copy = copies(1);
subplot(2,1,2,ax2_copy)
```

## Input Arguments

**m** — Number of grid rows

1 (default) | positive integer

Number of grid rows, specified as a positive integer.

Data Types: `single` | `double`

**n** — Number of grid columns

1 (default) | positive integer

Number of grid columns, specified as a positive integer.

Data Types: `single` | `double`

**p** — **Grid position for new axes**

positive integer | vector

Grid position for the new axes, specified as a positive integer or a vector of positive integers.

- If **p** is a positive integer, then `subplot` creates a new axes in grid position **p**.
- If **p** is a vector of positive integers, then `subplot` creates a new axes that spans the grid positions listed in **p**. For example, `subplot(2,3,[2,5])` creates one axes spanning positions 2 and 5. Use `subplot(2,3,[2,6])` to create one axes spanning positions 2, 3, 5, and 6.

Data Types: `single` | `double`

**positionVector** — **Normalized position for new axes**

four-element vector of values between 0.0 and 1.0

Normalized position for the new axes, specified as a four-element vector of values between 0.0 and 1.0 with the form `[left,bottom,width,height]`. The values are normalized with respect to the interior of the figure. The first two elements specify the position of the bottom-left corner of the axes in relation to the bottom-left corner of the figure. The last two elements specify the width and height of the new axes. Use this syntax to position an axes that does not align with grid positions.

Example: `[0.1, 0.1, 0.35, 0.35]`

Data Types: `single` | `double`

**ax** — **Existing axes to convert to subplot**

axes object

Existing axes to convert to a subplot axes, specified as an axes object. Use `gca` to refer to the current axes.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

You can set any axes properties for a subplot. Some plotting functions override existing axes property settings. Execute plotting functions before specifying axes properties to avoid overriding them. For a list of axes properties see Axes Properties.

Example: 'XGrid', 'on'

## Output Arguments

### **h** — Axes object

scalar

Axes object, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of a specific axes.

## More About

### Tips

- `subplot(111)` is an exception and not identical in behavior to `subplot(1,1,1)`. For reasons of backwards compatibility, `subplot(111)` is a special case of `subplot` that does not immediately create an axes, but sets up the figure so that the next graphics command executes `clf reset`. The next graphics command deletes all the figure children and creates a new axes in the default position. `subplot(111)` does not return a handle and an error occurs if code specifies a return argument.
- If a new subplot axes overlaps an existing axes, then MATLAB deletes the existing axes. To overlay a new axes on top of existing subplots, use the `axes` command. For example, `subplot('Position',[.35 .35 .3 .3])` deletes any underlying subplots, but `axes('Position',[.35 .35 .3 .3])` positions a new axes in the middle of the figure without deleting any underlying axes.
- When using a script to create subplots, MATLAB does not finalize the `Position` property value until either a `drawnow` command is issued or MATLAB returns to await a user command. The `Position` property value for a subplot is subject to change until the script either refreshes the plot or exits.

# subsasgn

Redefine subscripted assignment

## Syntax

`A = subsasgn(A,S,B)`

## Description

`A = subsasgn(A,S,B)` called by MATLAB for the syntax `A(i) = B`, `A{i} = B`, or `A.i = B` when `A` is an object.

MATLAB uses the built-in `subsasgn` function to interpret indexed assignment statements. Modify the indexed assignment behavior of classes by overloading `subsasgn` in the class.

---

**Note:** You must call `subsasgn` with an output argument. `subsasgn` does not modify the object used in the indexing operation (the first input argument). You must assign the output to obtain a modified object.

---

## Input Arguments

### A

Object used in indexing operation

### S

Structure with two fields, `type` and `subs`. For compound indexing expressions, `S` is an array of structures, one for each level of indexing.

- `type` is a string containing `'()'` , `'{}'` , or `'.'`, indicating the type of indexing used.
- `subs` is a cell array or character array containing the actual subscripts.

**B**

Value being assigned (right side of assignment statement)

## Output Arguments

**A**

Result of the assignment statement, which is the modified object passed in as the first argument.

## Examples

Argument values for the `subsasgn` for the expression shown:

```
A(1:2,:) = B;
```

The syntax `A(1:2,:) = B` calls `A = subsasgn(A,S,B)` where `S` is a structure with `S.type = '()'` and `S.subs = {1:2, ':'}`. The string `':'` indicates a colon used as a subscript.

For the expression:

```
A{1:2} = B;
```

The syntax `A{1:2} = B` calls `A = subsasgn(A,S,B)` where `S.type = '{}'` and `S.subs = {[1 2]}`.

For the expression:

```
A.field = B;
```

The syntax `A.field = B` calls `A = subsasgn(A,S,B)` where `S.type = '.'` and `S.subs = 'field'`.

For the expression:

```
A(1,2).name(3:5) = B;
```

Simple calls combine in a straightforward way for more complicated indexing expressions. In such cases, `length(S)` is the number of subscripting levels. For instance,

$A(1,2).name(3:5) = B$  calls  $A = \text{subsasgn}(A, S, B)$  where  $S$  is a 3-by-1 array of structures with the following values:

```
S(1).type = '()' S(2).type = '.' S(3).type = '()'
S(1).subs = {1,2} S(2).subs = 'name' S(3).subs = {[3 4 5]}
```

## More About

### Tips

Within the `subsasgn` method defined by a class, MATLAB calls the built-in `subsasgn`. Calling the built-in enables you to use the default indexing behavior when defining specialized indexing. For more information, see “Built-In `subsref` and `subsasgn` Called in Methods”.

### Algorithms

In the assignment  $A(J, K, \dots) = B(M, N, \dots)$ , subscripts  $J, K, M, N$ , and so on, can be scalar, vector, or arrays, when all the following are true:

- The number of subscripts specified for  $B$ , excluding trailing subscripts equal to 1, does not exceed the value returned by `ndims(B)`.
- The number of nonscalar subscripts specified for  $A$  equals the number of nonscalar subscripts specified for  $B$ . For example,  $A(5, 1:4, 1, 2) = B(5:8)$  is valid because both sides of the equation use one nonscalar subscript.
- The order and length of all nonscalar subscripts specified for  $A$  matches the order and length of nonscalar subscripts specified for  $B$ . For example,  $A(1:4, 3, 3:9) = B(5:8, 1:7)$  is valid because both sides of the equation (ignoring the one scalar subscript 3) use a 4-element subscript followed by a 7-element subscript.

`numArgumentsFromSubscript` | `subsref` | `substruct`

Introduced before R2006a

## subsindex

Convert object to array index

### Syntax

```
ind = subsindex(A)
```

### Description

MATLAB calls `subsindex` to convert an object into an integer index. Define a `subsindex` method for your class if you want to use objects of the class as array indices.

`ind = subsindex(A)` called by MATLAB for the expression `X(A)` when `A` is an object. MATLAB does not call `subsindex` if the indexing expression results in a call to an overloaded `subsref` or `subsasgn` method for the class of `X`. `subsindex` must return the value of the object as a zero-based integer index. `ind` must contain integer values in the range 0 to `prod(size(X)) - 1`.

MATLAB invokes `subsindex` separately on all the subscripts in an expression, such as `X(A,B)`.

### Tutorials

- 
- “Objects In Index Expressions”

**Introduced before R2006a**

# subspace

Angle between two subspaces

## Syntax

```
theta = subspace(A,B)
```

## Description

`theta = subspace(A,B)` finds the angle between two subspaces specified by the columns of `A` and `B`. If `A` and `B` are column vectors of unit length, this is the same as `acos(abs(A'*B))`.

## Examples

Consider two subspaces of a Hadamard matrix, whose columns are orthogonal.

```
H = hadamard(8);
A = H(:,2:4);
B = H(:,5:8);
```

Note that matrices `A` and `B` are different sizes — `A` has three columns and `B` four. It is not necessary that two subspaces be the same size in order to find the angle between them. Geometrically, this is the angle between two hyperplanes embedded in a higher dimensional space.

```
theta = subspace(A,B)
theta =
 1.5708
```

That `A` and `B` are orthogonal is shown by the fact that `theta` is equal to  $\pi/2$ .

```
theta - pi/2
ans =
 0
```

## More About

### Tips

If the angle between the two subspaces is small, the two spaces are nearly linearly dependent. In a physical experiment described by some observations  $A$ , and a second realization of the experiment described by  $B$ ,  $\text{subspace}(A, B)$  gives a measure of the amount of new information afforded by the second experiment not associated with statistical errors of fluctuations.

**Introduced before R2006a**

# subsref

Redefine subscripted reference for objects

## Syntax

`B = subsref(A,S)`

## Description

`B = subsref(A,S)` is called by MATLAB for the syntax `A(i)`, `A{i}`, or `A.i` when `A` is an object.

MATLAB uses the built-in `subsref` function to interpret indexed references to objects. To modify the indexed reference behavior of objects, overload `subsref` in the class.

## Input Arguments

### A

Object used in indexing operation

### S

Structure with two fields, `type` and `subs`. For compound indexing expressions, `S` is an array of structures, one for each level of indexing.

- `type` is a string containing `'()'`, `'{}'`, or `'.'`, indicating the type of indexing used.
- `subs` is a cell array or character array containing the actual subscripts.

## Output Arguments

### B

Result of the indexed expression.

## Examples

See how MATLAB calls `subsref` for the expression:

```
A(1:2, :)
```

The syntax `A(1:2, :)` calls `B = subsref(A,S)` where `S` is a 1-by-1 structure with `S.type='()'` and `S.subs={1:2, ':'}`. The string `':'` indicates a colon used as a subscript.

See how MATLAB calls `subsref` for the expression:

```
A{1:2}
```

The syntax `A{1:2}` calls `B = subsref(A,S)` where `S.type='{'` and `S.subs={ [1 2] }`.

See how MATLAB calls `subsref` for the expression:

```
A.field
```

The syntax `A.field` calls `B = subsref(A,S)` where `S.type='.'` and `S.subs='field'`.

See how MATLAB calls `subsref` for the expression:

```
A(1,2).name(3:5)
```

Simple calls combine in a straightforward way for more complicated indexing expressions. In such cases, `length(S)` is the number of subscript levels. For instance, `A(1,2).name(3:5)` calls `subsref(A,S)` where `S` is a 3-by-1 structure array with the following values:

<code>S(1).type='()'</code>	<code>S(2).type='.'</code>	<code>S(3).type='()'</code>
<code>S(1).subs={1,2}</code>	<code>S(2).subs='name'</code>	<code>S(3).subs={[3 4 5]}</code>

## More About

### Tips

Within the `subsref` method defined by a class, MATLAB calls the built-in `subsref`. Calling the built-in enables you to use the default indexing behavior when defining

specialized indexing. For more information, see “Built-In subsref and subsasgn Called in Methods”.

## **See Also**

numArgumentsFromSubscript | subsasgn | substruct

**Introduced before R2006a**

## substruct

Create structure argument for `subsasgn` or `subsref`

### Syntax

```
S = substruct(type1, subs1, type2, subs2, ...)
```

### Description

`S = substruct(type1, subs1, type2, subs2, ...)` creates a structure with the fields required by an overloaded `subsref` or `subsasgn` method. Each `type` string must be one of `.'`, `'()`, or `'{'`. The corresponding `subs` argument must be either a field name (for the `.'` type) or a cell array containing the index vectors (for the `'()` or `'{'` types).

### Output Arguments

**s**

struct with these fields:

- `type`: one of `.'`, `'()`, or `'{'`
- `subs`: subscript values (field name or cell array of index vectors)

### Examples

Call `subsref` with arguments equivalent to the syntax:

```
B = A(3,5).field;
```

where `A` is an object of a class that implements a `subsref` method

Use `substruct` to form the input `struct`, `S`:

```
S = substruct('()', {3,5}, '.', 'field');
```

Call the class method:

```
B = subsref(A,S);
```

The `struct` created by `substruct` in this example contains:

```
S(1)
```

```
ans =
```

```
 type: '()'
 subs: {[3] [5]}
```

```
S(2)
```

```
ans =
```

```
 type: '.'
 subs: 'field'
```

## See Also

`subsasgn` | `subsref`

**Introduced before R2006a**

## subvolume

Extract subset of volume data set

### Syntax

```
[Nx,Ny,Nz,Nv] = subvolume(X,Y,Z,V,limits)
[Nx,Ny,Nz,Nv] = subvolume(V,limits)
Nv = subvolume(...)
```

### Description

`[Nx,Ny,Nz,Nv] = subvolume(X,Y,Z,V,limits)` extracts a subset of the volume data set `V` using the specified axis-aligned `limits`. `limits = [xmin,xmax,ymin,ymax,zmin,zmax]` (Any NaNs in the limits indicate that the volume should not be cropped along that axis.)

The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`. The subvolume is returned in `NV` and the coordinates of the subvolume are given in `NX`, `NY`, and `NZ`.

`[Nx,Ny,Nz,Nv] = subvolume(V,limits)` assumes the arrays `X`, `Y`, and `Z` are defined as

```
[X,Y,Z] = meshgrid(1:N,1:M,1:P)
```

where `[M,N,P] = size(V)`.

`Nv = subvolume(...)` returns only the subvolume.

### Examples

This example uses a data set that is a collection of MRI slices of a human skull. The data is processed in a variety of ways:

- The 4-D array is squeezed (`squeeze`) into three dimensions and then a subset of the data is extracted (`subvolume`).

- The outline of the skull is an isosurface generated as a patch (p1) whose vertex normals are recalculated to improve the appearance when lighting is applied (patch, isosurface, isonormals).
- A second patch (p2) with interpolated face color draws the end caps (FaceColor, isocaps).
- The view of the object is set (view, axis, daspect).
- A 100-element grayscale colormap provides coloring for the end caps (colormap).
- Adding lights to the right and left of the camera illuminates the object (camlight, lighting).

```
load mri
D = squeeze(D);
[x,y,z,D] = subvolume(D,[60,80,nan,80,nan,nan]);
p1 = patch(isosurface(x,y,z,D, 5),...
 'FaceColor','red','EdgeColor','none');
isonormals(x,y,z,D,p1);
p2 = patch(isocaps(x,y,z,D, 5),...
 'FaceColor','interp','EdgeColor','none');
view(3); axis tight; daspect([1,1,.4])
colormap(gray(100))
camlight right; camlight left; lighting gouraud
```

## sum

Sum of array elements

### Syntax

```
S = sum(A)
S = sum(A,dim)
S = sum(____,outtype)
S = sum(____,nanflag)
```

### Description

`S = sum(A)` returns the sum of the elements of `A` along the first array dimension whose size does not equal 1.

- If `A` is a vector, then `sum(A)` returns the sum of the elements.
- If `A` is a matrix, then `sum(A)` returns a row vector containing the sum of each column.
- If `A` is a multidimensional array, then `sum(A)` operates along the first array dimension whose size does not equal 1, treating the elements as vectors. This dimension becomes 1 while the sizes of all other dimensions remain the same.

`S = sum(A,dim)` returns the sum along dimension `dim`. For example, if `A` is a matrix, then `sum(A,2)` is a column vector containing the sum of each row.

`S = sum( ____,outtype)` returns the sum with a specified data type, using any of the input arguments in the previous syntaxes. `outtype` can be `'default'`, `'double'`, or `'native'`.

`S = sum( ____,nanflag)` specifies whether to include or omit NaN values from the calculation for any of the previous syntaxes. `sum(A, 'includenan')` includes all NaN values in the calculation while `sum(A, 'omitnan')` ignores them.

## Examples

### Sum of Vector Elements

Create a vector and compute the sum of its elements.

```
A = 1:10;
S = sum(A)
```

```
S =

55
```

## Sum of Matrix Columns

Create a matrix and compute the sum of the elements in each column.

```
A = [1 3 2; 4 2 5; 6 1 4]
```

```
A =

1 3 2
4 2 5
6 1 4
```

```
S = sum(A)
```

```
S =

11 6 11
```

## Sum of Matrix Rows

Create a matrix and compute the sum of the elements in each row.

```
A = [1 3 2; 4 2 5; 6 1 4]
```

```
A =

1 3 2
4 2 5
6 1 4
```

```
S = sum(A,2)
```

```
S =
```

```
 6
 11
 11
```

### Sum of 3-D Array

Create a 4-by-2-by-3 array of ones and compute the sum along the third dimension.

```
A = ones(4,2,3);
S = sum(A,3)
```

```
S =
```

```
 3 3
 3 3
 3 3
 3 3
```

### Integer Output Type Saturation

Create a vector of 8-bit integers and compute the `int8` sum of its elements by specifying the output type as `native`.

```
A = int8(1:20);
S = sum(A, 'native')
```

```
S =
```

```
127
```

Compute the sum using the default `double` output type (equivalent to `S = sum(A, 'default')`).

```
S = sum(A)
```

```
S =
```

210

The two sums differ because the `int8` output is saturated while the `double` output reflects the expected sum of elements.

### Sum Excluding NaN

Create a vector and compute its sum, excluding NaN values.

```
A = [1.77 -0.005 3.98 -2.95 NaN 0.34 NaN 0.19];
S = sum(A, 'omitnan')
```

```
S =
```

```
3.3250
```

If you do not specify `'omitnan'`, then `sum(A)` returns NaN.

## Input Arguments

### **A** — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

- If **A** is a scalar, then `sum(A)` returns **A**.
- If **A** is an empty 0-by-0 matrix, then `sum(A)` returns 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `duration`

Complex Number Support: Yes

### **dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to 1. The `size(S, dim)` is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, `A`:

- `sum(A, 1)` operates on successive elements in the columns of `A` and returns a row vector of the sums of each column.

`sum(A, 1)`

- `sum(A, 2)` operates on successive elements in the rows of `A` and returns a column vector of the sums of each row.

`sum(A, 2)`

`sum` returns `A` when `dim` is greater than `ndims(A)` or when `size(A, dim)` is 1.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**out\_type** — Output data type

'default' (default) | 'double' | 'native'

Output data type, specified as `'default'`, `'double'`, or `'native'`. These options also specify the data type in which the operation is performed.

<b>outtype</b>	<b>Output data type</b>
<code>'default'</code>	<code>double</code> , unless the input data type is <code>single</code> or <code>duration</code> , in which case, the output is <code>'native'</code>
<code>'double'</code>	<code>double</code> , unless the data type is <code>duration</code> , in which case, <code>'double'</code> is not supported
<code>'native'</code>	same data type as the input, unless the input data type is <code>char</code> , in which case, <code>'native'</code> is not supported

Data Types: `char`

### **nanflag — NaN condition**

`'includenan'` (default) | `'omitnan'`

NaN condition, specified as one of these values:

- `'includenan'` — Include NaN values when computing the sum, resulting in NaN.
- `'omitnan'` — Ignore all NaN values in the input.

The `sum` function does not support the `nanflag` option for `duration` arrays.

Data Types: `char`

### **See Also**

**Introduced before R2006a**

## summary

Print summary of table or categorical array

### Syntax

`summary(T)`

`summary(A)`

`summary(A, dim)`

### Description

`summary(T)` prints a summary of the table, `T`. The table summary displays the table description from `T.Properties.Description` followed by a summary of the table variables.

`summary(A)` prints a summary of the categorical array, `A`.

- If `A` is a vector, then `summary(A)` displays the category names along with the number of elements in each category (the category counts). Furthermore, the summary contains the number of elements that are undefined.
- If `A` is a matrix, then `summary` treats the columns of `A` as vectors and displays the category counts for each column of `A`.
- If `A` is a multidimensional array, then `summary` acts along the first array dimension whose size does not equal 1.

`summary(A, dim)` prints the category counts of the categorical array, `A`, along dimension `dim`.

For example, you can display the counts of each row in a categorical array using `counts(A, 2)`.

### Examples

#### Summary of Table

Create a table.

```
load patients
BloodPressure = [Systolic Diastolic];
T = table(Gender, Age, Smoker, BloodPressure, 'RowNames', LastName);
```

Add descriptions and units to table T.

```
T.Properties.Description = 'Simulated patient data';
T.Properties.VariableUnits = {' ' 'Yrs' ' ' 'mm Hg'};
T.Properties.VariableDescriptions{4} = 'Systolic/Diastolic';
```

Print a summary of table T.

```
format compact
```

```
summary(T)
```

```
Description: Simulated patient data
Variables:
 Gender: 100x1 cell string
 Age: 100x1 double
 Units: Yrs
 Values:
 min 25
 median 39
 max 50
 Smoker: 100x1 logical
 Values:
 true 34
 false 66
 BloodPressure: 100x2 double
 Units: mm Hg
 Description: Systolic/Diastolic
 Values:
 BloodPressure_1 BloodPressure_2
 min 109 68
 median 122 81.5
 max 138 99
```

`summary` displays the minimum, median, and maximum values for each column of the variable `BloodPressure`.

## Summary of Categorical Vector

Create a 1-by-5 categorical vector.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'})
```

```
A =
```

```
 plane car train car plane
```

A has three categories, `car`, `plane`, and `train`.

Print a summary of A.

```
summary(A)
```

```
 car plane train
 2 2 1
```

`car` appears in two elements of A, `plane` appears in two elements, and `train` appears in one element.

Since A is a row vector, `summary` lists the occurrences of each category horizontally.

### Summary of Each Column in Categorical Array

Create a 3-by-2 categorical array, A, from a numeric array.

```
X = [1 3; 2 1; 3 1; 4 2];
valueset = 1:3;
catnames = {'red' 'green' 'blue'};
```

```
A = categorical(X,valueset,catnames)
```

```
A =
```

```
 red blue
 green red
 blue red
 <undefined> green
```

A has three categories, `red`, `green`, and `blue`. The value, 4, was not included in the `valueset` input to the `categorical` function. Therefore, the corresponding element, `A(4,1)`, does not have a corresponding category and is undefined.

Print a summary of A.

```
summary(A)
```

```
 red 1 2
 green 1 1
```

```
blue 1 1
<undefined> 1 0
```

red appears in one element in the first column of **A** and two in the second column.

green appears in one element in the first column of **A** and none in the second column.

blue appears in one element in the first column of **A** and one in the second column.

**A** contains only one undefined element. It occurs in the first column.

### Category Counts of Each Row in Categorical Array

Create a 3-by-2 categorical array, **A**, from a numeric array.

```
A = categorical([1 3; 2 1; 3 1],1:3,{'red' 'green' 'blue'})
```

A =

```
red blue
green red
blue red
```

**A** has three categories, red, green, and blue.

Print a summary of **A** along the second dimension.

```
summary(A,2)
```

```
red green blue
1 0 1
1 1 0
1 0 1
```

red appears in one element in the first row of **A**, one in the second row, and one in the third row.

green appears in only one element. It occurs in the second row of **A**.

blue appears in one element in the first row of **A** and one in the third column.

## Input Arguments

**T** — Input table

table

Input table, specified as a table.

**A — Categorical array**

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

**dim — Dimension of A to operate along**

positive integer scalar

Dimension of **A** to operate to along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional categorical array, **A**:

If  $\text{dim} = 1$ , then `summary(A, 1)` displays the category counts for each column of **A**.

If  $\text{dim} = 2$ , then `summary(A, 2)` returns the category counts of each row of **A**.

If `dim` is greater than `ndims(A)`, then `summary(A)` returns an array the same size as `A` for each category. `summary` returns 1 for elements in the corresponding category and 0 otherwise.

## More About

### Table Summary

The table summary displays the table description from `T.Properties.Description` followed by information on the variables of `T`.

The summary contains the following information on the variables:

- Name: Size and Data Type — variable name from `T.Properties.VariableNames`, the size of the variable, and the data type of the variable.
- Units — variable's units from `T.Properties.VariableUnits`.
- Description — variable's description from `T.Properties.VariableDescriptions`.
- Values — only included for numeric, logical, categorical, `datetime`, or `duration` variables.
  - numeric, `datetime`, or `duration` variables — minimum, median, and maximum values.
  - logical variables — number of values that are `true` and the number of values that are `false`.
  - categorical variables — number of elements from each category.

## superclasses

Superclass names

### Syntax

```
superclasses('ClassName')
superclasses(obj)
s = superclasses(...)
```

### Description

`superclasses('ClassName')` displays the names of all visible superclasses of the MATLAB class with the name *ClassName*. Visible classes have a `Hidden` attribute value of `false` (the default).

`superclasses(obj)` `obj` is an instance of a MATLAB class. `obj` can be either a scalar object or an array of objects.

`s = superclasses(...)` returns the superclass names in a cell array of strings.

### Examples

Get the name of the `matlab.mixin.SetGet` class superclass:

```
superclasses('matlab.mixin.SetGet')
```

Superclasses for class `matlab.mixin.SetGet`:

```
handle
```

### See Also

# superiorto

Establish superior class relationship

## Syntax

```
superiorto('class1', 'class2', ...)
```

## Description

`superiorto('class1', 'class2', ...)` establishes that the class invoking this function in its constructor has higher precedence than the classes in the argument list.

The `superiorto` function establishes a precedence that determines which object method MATLAB calls. Use this function only from a constructor that calls the `class` function to create an object. For classes defined with `classdef` statements, see “Class Precedence”.

## Examples

Show function dispatching:

`a` is an object of class `class_a`, `b` is an object of class `class_b`, and `c` is an object of class `class_c`. The constructor method for `class_c` contains the statement `superiorto('class_a')`. Then, either of the following two statements:

```
e = fun(a,c);
e = fun(c,a);
```

invokes `class_c/fun`.

If you call a function with two objects having an unspecified relationship, MATLAB considers the two objects to have equal precedence. In this case, MATLAB calls the left-most object method. So `fun(b,c)` calls `class_b/fun`, while `fun(c,b)` calls `class_c/fun`.

# Support Package Installer

Install support for third-party hardware or software

## Description

Use Support Package Installer to install support packages. The support packages add support for specific third-party hardware or software to specific MathWorks products.

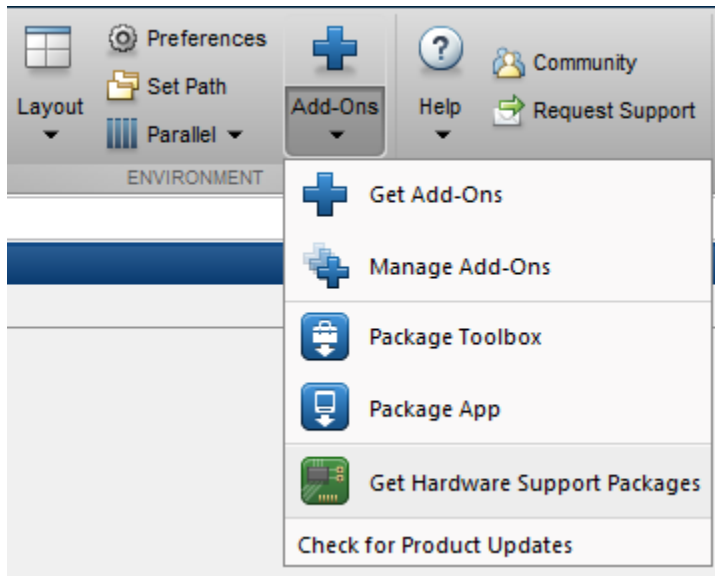

Support Package Installer can:

- Display a list of available, installable, installed, or updatable support packages.
- Install, update, download, or uninstall a support package.
- Update the firmware on specific third-party hardware.

If the support package installs third-party software, Support Package Installer displays a list of the software and licenses for you to review before continuing with the installation.

## Open the Support Package Installer App

- On the MATLAB toolstrip, click **Add-Ons > Get Hardware Support Packages**.

- In the MATLAB Command Window, enter `supportPackageInstaller`.
- Double-click a support package installation file (\*.mlpkginstall).

## See Also

## surf

3-D shaded surface plot

## Syntax

```
surf(Z)
surf(Z,C)
surf(X,Y,Z)
surf(X,Y,Z,C)
surf(...,'PropertyName',PropertyValue)
surf(axes_handles,...)
h = surf(...)
```

## Description

`surf(Z)` creates a three-dimensional shaded surface from the  $z$  components in matrix  $Z$ , using  $x = 1:n$  and  $y = 1:m$ , where  $[m,n] = \text{size}(Z)$ . The height,  $Z$ , is a single-valued function defined over a geometrically rectangular grid.  $Z$  specifies the color data, as well as surface height, so color is proportional to surface height.

`surf(Z,C)` plots the height of  $Z$ , a single-valued function defined over a geometrically rectangular grid, and uses matrix  $C$ , assumed to be the same size as  $Z$ , to color the surface. See [Coloring Mesh and Surface Plots](#) for information on defining  $C$ .

`surf(X,Y,Z)` uses  $Z$  for the color data and surface height.  $X$  and  $Y$  are vectors or matrices defining the  $x$  and  $y$  components of a surface. If  $X$  and  $Y$  are vectors,  $\text{length}(X) = n$  and  $\text{length}(Y) = m$ , where  $[m,n] = \text{size}(Z)$ . In this case, the vertices of the surface faces are  $(X(j), Y(i), Z(i,j))$  triples. To create  $X$  and  $Y$  matrices for arbitrary domains, use the `meshgrid` function.

`surf(X,Y,Z,C)` uses  $C$  to define color. MATLAB performs a linear transformation on this data to obtain colors from the current colormap.

`surf(..., 'PropertyName', PropertyValue)` specifies surface properties along with the data. For a list of properties, see [Chart Surface Properties](#).

`surf(axes_handles, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = surf(...)` returns a handle to a chart surface graphics object.

## Examples

### Surface Plot of Peaks Function

Use the `peaks` function to define `X`, `Y`, and `Z` as 25-by-25 matrices. Then, create a surface plot.

```
[X,Y,Z] = peaks(25);
```

```
figure
surf(X,Y,Z);
```

`surf` creates the surface plot from corresponding values in X, Y, and Z. If you do not define the color data C, then `surf` uses Z to determine the color, so color is proportional to surface height.

### **Sphere With Two Colors**

Create a sphere and color it using the pattern from a Hadamard matrix, which is a matrix that contains the values 1 and -1. Change the colors used in the plot by setting the colormap to an array of two RGB triplet values.

```
k = 5;
n = 2^k-1;
[x,y,z] = sphere(n);
c = hadamard(2^k);
```

```
figure
surf(x,y,z,c);
colormap([1 1 0; 0 1 1])
axis equal
```

## More About

### Tips

surf does not accept complex inputs.

## Algorithms

Consider a parametric surface parameterized by two independent variables,  $i$  and  $j$ , which vary continuously over a rectangle; for example,  $1 \leq i \leq m$  and  $1 \leq j \leq n$ . The three functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  specify the surface. When  $i$  and  $j$  are integer values, they define a rectangular grid with integer grid points. The functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  become three  $m$ -by- $n$  matrices,  $X$ ,  $Y$ , and  $Z$ . Surface color is a fourth function,  $c(i, j)$ , denoted by matrix  $C$ .

Each point in the rectangular grid can be thought of as connected to its four nearest neighbors.

$$\begin{array}{c} i-1, j \\ | \\ i, j-1 - i, j - i, j+1 \\ | \\ i+1, j \end{array}$$

This underlying rectangular grid induces four-sided patches on the surface. To express this another way,  $[X(:) Y(:) Z(:)]$  returns a list of triples specifying points in 3-D space. Each interior point is connected to the four neighbors inherited from the matrix indexing. Points on the edge of the surface have three neighbors. The four points at the corners of the grid have only two neighbors. This defines a mesh of quadrilaterals or a *quad-mesh*.

You can specify surface color in two different ways: at the vertices or at the centers of each patch. In this general setting, the surface need not be a single-valued function of  $x$  and  $y$ . Moreover, the four-sided surface patches need not be planar. For example, you can have surfaces defined in polar, cylindrical, and spherical coordinate systems.

The `shading` function sets the shading. If the shading is `interp`,  $C$  must be the same size as  $X$ ,  $Y$ , and  $Z$ ; it specifies the colors at the vertices. The color within a surface patch is a bilinear function of the local coordinates. If the shading is `faceted` (the default) or `flat`,  $C(i, j)$  specifies the constant color in the surface patch:

$$\begin{array}{ccc} (i, j) & - & (i, j+1) \\ | & C(i, j) & | \\ (i+1, j) & - & (i+1, j+1) \end{array}$$

In this case,  $C$  can be the same size as  $X$ ,  $Y$ , and  $Z$  and its last row and column are ignored. Alternatively, its row and column dimensions can be one less than those of  $X$ ,  $Y$ , and  $Z$ .

The `surf` function specifies the viewpoint using `view(3)`.

The range of X, Y, and Z or the current setting of `XLimMode`, `YLimMode`, and `ZLimMode` axes properties determines the axis labels. You can also set these properties using `axis` function.

The range of `C` or the current setting of the `CLim` and `CLimMode` axes properties determines the color scaling. You can also set the properties using `caxis` function. The scaled color values are indices into the current colormap.

## surf

Contour plot under a 3-D shaded surface plot

## Syntax

```
surf(Z)
surf(Z,C)
surf(X,Y,Z)
surf(X,Y,Z,C)
surf(..., 'PropertyName', PropertyValue)
surf(axes_handles,...)
h = surf(...)
```

## Description

`surf(Z)` creates a contour plot under the three-dimensional shaded surface from the  $z$  components in matrix  $Z$ , using  $x = 1:n$  and  $y = 1:m$ , where  $[m,n] = \text{size}(Z)$ . The height,  $Z$ , is a single-valued function defined over a geometrically rectangular grid.  $Z$  specifies the color data, as well as surface height, so color is proportional to surface height.

`surf(Z,C)` plots the height of  $Z$ , a single-valued function defined over a geometrically rectangular grid, and uses matrix  $C$ , assumed to be the same size as  $Z$ , to color the surface.

`surf(X,Y,Z)` uses  $Z$  for the color data and surface height.  $X$  and  $Y$  are vectors or matrices defining the  $x$  and  $y$  components of a surface. If  $X$  and  $Y$  are vectors,  $\text{length}(X) = n$  and  $\text{length}(Y) = m$ , where  $[m,n] = \text{size}(Z)$ . In this case, the vertices of the surface faces are  $(X(j), Y(i), Z(i,j))$  triples. To create  $X$  and  $Y$  matrices for arbitrary domains, use the `meshgrid` function.

`surf(X,Y,Z,C)` uses `C` to define color. MATLAB performs a linear transformation on this data to obtain colors from the current colormap.

`surf(...,'PropertyName',PropertyValue)` specifies surface properties along with the data.

`surf(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = surf(...)` returns handles to a chart surface and a contour object.

## Examples

### Display Contour Plot Under Surface Plot

Display a contour plot under a surface plot of the `peaks` function.

```
[X,Y,Z] = peaks(30);
figure
surf(X,Y,Z)
```

## More About

### Tips

surfz does not accept complex inputs.

### Algorithms

Consider a parametric surface parameterized by two independent variables,  $i$  and  $j$ , which vary continuously over a rectangle; for example,  $1 \leq i \leq m$  and  $1 \leq j \leq n$ . The three functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  specify the surface. When  $i$  and  $j$  are integer

values, they define a rectangular grid with integer grid points. The functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  become three  $m$ -by- $n$  matrices,  $X$ ,  $Y$ , and  $Z$ . Surface color is a fourth function,  $c(i, j)$ , denoted by matrix  $C$ .

Each point in the rectangular grid can be thought of as connected to its four nearest neighbors.

$$\begin{array}{c}
 i-1, j \\
 | \\
 i, j-1 - i, j - i, j+1 \\
 | \\
 i+1, j
 \end{array}$$

This underlying rectangular grid induces four-sided patches on the surface. To express this another way,  $[X(:) Y(:) Z(:)]$  returns a list of triples specifying points in 3-D space. Each interior point is connected to the four neighbors inherited from the matrix indexing. Points on the edge of the surface have three neighbors. The four points at the corners of the grid have only two neighbors. This defines a mesh of quadrilaterals or a *quad-mesh*.

You can specify surface color in two different ways: at the vertices or at the centers of each patch. In this general setting, the surface need not be a single-valued function of  $x$  and  $y$ . Moreover, the four-sided surface patches need not be planar. For example, you can have surfaces defined in polar, cylindrical, and spherical coordinate systems.

The `shading` function sets the shading. If the shading is `interp`,  $C$  must be the same size as  $X$ ,  $Y$ , and  $Z$ ; it specifies the colors at the vertices. The color within a surface patch is a bilinear function of the local coordinates. If the shading is `faceted` (the default) or `flat`,  $C(i, j)$  specifies the constant color in the surface patch:

$$\begin{array}{c}
 (i, j) \quad - \quad (i, j+1) \\
 | \quad C(i, j) \quad | \\
 (i+1, j) \quad - \quad (i+1, j+1)
 \end{array}$$

In this case,  $C$  can be the same size as  $X$ ,  $Y$ , and  $Z$  and its last row and column are ignored. Alternatively, its row and column dimensions can be one less than those of  $X$ ,  $Y$ , and  $Z$ .

The `surf` function specifies the viewpoint using `view(3)`.

The range of  $X$ ,  $Y$ , and  $Z$  or the current setting of the axes `XLimMode`, `YLimMode`, and `ZLimMode` properties (also set by the `axis` function) determines the axis labels.

The range of `C` or the current setting of the axes `CLim` and `CLimMode` properties (also set by the `caxis` function) determines the color scaling. The scaled color values are used as indices into the current colormap.

# surf2patch

Convert surface data to patch data

## Syntax

```
fvc = surf2patch(Z)
fvc = surf2patch(Z,C)
fvc = surf2patch(X,Y,Z)
fvc = surf2patch(X,Y,Z,C)
fvc = surf2patch(...,'triangles')
[f,v,c] = surf2patch(...)
```

## Description

`fvc = surf2patch(h)`

converts the geometry and color data from the **surface** object identified by the handle `h` into patch format and returns the face, vertex, and color data in the struct `fvc`. You can pass this struct directly to the `patch` command.

`fvc = surf2patch(Z)` calculates the patch data from the surface's `ZData` matrix `Z`.

`fvc = surf2patch(Z,C)` calculates the patch data from the surface's `ZData` and `CData` matrices `Z` and `C`.

`fvc = surf2patch(X,Y,Z)` calculates the patch data from the surface's `XData`, `YData`, and `ZData` matrices `X`, `Y`, and `Z`.

`fvc = surf2patch(X,Y,Z,C)` calculates the patch data from the surface's `XData`, `YData`, `ZData`, and `CData` matrices `X`, `Y`, `Z`, and `C`.

`fvc = surf2patch(...,'triangles')` creates triangular faces instead of the quadrilaterals that compose surfaces.

`[f,v,c] = surf2patch(...)` returns the face, vertex, and color data in the three arrays `f`, `v`, and `c` instead of a struct.

## Examples

### Calculate Patch Data from Surface Data

Use the `sphere` command to generate the `XData`, `YData`, and `ZData` of a surface. Then, calculate the patch data. Pass the `ZData` (`z`) to `surf2patch` as both the third and fourth arguments - the third argument is the `ZData` and the fourth argument is taken as the `CData`. You must do this since the `patch` command does not automatically use the `z`-coordinate data for the color data, as does the `surface` command.

Since `patch` is a low-level command, you must set the view and shading to produce the same results produced by the `surf` command.

```
[x,y,z] = sphere;
figure
patch(surf2patch(x,y,z,z));
shading faceted;
view(3)
```

### Calculate Patch Data Using Surface Object

Calculate face, vertex, and color data from a surface whose handle has been passed as an argument.

```
figure
s = surf(peaks);
patch(surf2patch(s));
delete(s)
shading faceted;
view(3)
```

**See Also**

`patch` | `reducepatch` | `shrinkfaces` | `surface` | `surf`

**Introduced before R2006a**

# surface

Create surface object

## Syntax

```
surface(Z)
surface(Z,C)
surface(X,Y,Z)
surface(X,Y,Z,C)
surface(x,y,Z)
surface(... 'PropertyName',PropertyValue,...)
h = surface(...)
```

## Properties

For a list of properties, see [Primitive Surface Properties](#).

## Description

`surface` is the low-level function for creating surface graphics objects. Surfaces are plots of matrix data created using the row and column indices of each element as the  $x$ - and  $y$ -coordinates and the value of each element as the  $z$ -coordinate.

`surface(Z)` plots the surface specified by the matrix  $Z$ . Here,  $Z$  is a single-valued function, defined over a geometrically rectangular grid.

`surface(Z,C)` plots the surface specified by  $Z$  and colors it according to the data in  $C$  (see "Examples").

`surface(X,Y,Z)` uses  $C = Z$ , so color is proportional to surface height above the  $x$ - $y$  plane.

`surface(X,Y,Z,C)` plots the parametric surface specified by  $X$ ,  $Y$ , and  $Z$ , with color specified by  $C$ .

`surface(x,y,Z)`, `surface(x,y,Z,C)` replaces the first two matrix arguments with vectors and must have `length(x) = n` and `length(y) = m` where `[m,n] = size(Z)`. In this case, the vertices of the surface facets are the triples `(x(j),y(i),Z(i,j))`. Note that `x` corresponds to the columns of `Z` and `y` corresponds to the rows of `Z`. For a complete discussion of parametric surfaces, see the `surf` function.

`surface(... 'PropertyName',PropertyValue,...)` follows the `X`, `Y`, `Z`, and `C` arguments with property name/property value pairs to specify additional surface properties. For a description of the properties, see Primitive Surface Properties.

`h = surface(...)` returns a handle to the created primitive surface object.

## Examples

### Create Surface Plot

Plot the function  $z = xe^{-x^2-y^2}$  on the domain  $-2 \leq x \leq 2$  and  $-2 \leq y \leq 2$ . Use `meshgrid` to define `X` and `Y`. Then, define `Z` and create a surface plot. Change the view of the plot using `view`.

```
[X,Y] = meshgrid(-2:0.2:2,-2:0.2:2);
Z = X.*exp(-X.^2 - Y.^2);
figure
surface(X,Y,Z)
view(3)
```

`surface` creates the plot from corresponding values in X, Y, and Z. If you do not define the color data C, then `surface` uses Z to determine the color, so color is proportional to surface height.

### Display Image Along Surface Plot

Use the `peaks` function to define XD, YD, and ZD as 25-by-25 matrices.

```
[XD,YD,ZD] = peaks(25);
```

Load the `clown` data set to get the image data X and its associated colormap, `map`. Flip X using the `flipud` function and define the flipped image as the color data for the surface, C.

```
load clown
C = flipud(X);
```

Create a surface plot and display the image along the surface. Since the surface data ZD and the color data C have different dimensions, you must set the surface FaceColor to 'texturemap'.

```
figure
surface(XD,YD,ZD,C,...
 'FaceColor','texturemap',...
 'EdgeColor','none',...
 'CDataMapping','direct')
colormap(map)
view(-35,45)
```

The clown data is typically viewed with the `image` function, which uses 'ij' axis numbering. This example reverses the image data in the vertical direction using `flipud`.

## Tutorials

For examples, see [Representing a Matrix as a Surface](#).

## More About

### Tips

`surface` does not respect the settings of the figure and axes `NextPlot` properties. It simply adds the surface object to the current axes.

If you do not specify separate color data (**C**), MATLAB uses the matrix (**Z**) to determine the coloring of the surface. In this case, color is proportional to values of **Z**. You can specify a separate matrix to color the surface independently of the data defining the area of the surface.

You can specify properties as property name/property value pairs or using dot notation.

`surface` provides convenience forms that allow you to omit the property name for the `XData`, `YData`, `ZData`, and `CData` properties. For example,

```
surface('XData',X,'YData',Y,'ZData',Z,'CData',C)
```

is equivalent to

```
surface(X,Y,Z,C)
```

When you specify only a single matrix input argument,

```
surface(Z)
```

MATLAB assigns the data properties as if you specified

```
surface('XData',[1:size(Z,2)],...
 'YData',[1:size(Z,1)],...
 'ZData',Z,...
 'CData',Z)
```

The `axis`, `caxis`, `colormap`, `hold`, `shading`, and `view` commands set graphics properties that affect surfaces. You can also set and query surface property values after creating them using dot notation.

# surfl

Surface plot with colormap-based lighting

## Syntax

```
surfl(Z)
surfl(...,'light')
surfl(...,s)
surfl(X,Y,Z,s,k)
h = surfl(...)
```

## Description

The `surfl` function displays a shaded surface based on a combination of ambient, diffuse, and specular lighting models.

`surfl(Z)` and `surfl(X,Y,Z)` create three-dimensional shaded surfaces using the default direction for the light source and the default lighting coefficients for the shading model. `X`, `Y`, and `Z` are vectors or matrices that define the  $x$ ,  $y$ , and  $z$  components of a surface.

`surfl(...,'light')` produces a colored, lighted surface using a MATLAB light object. This produces results different from the default lighting method, `surfl(...,'cdata')`, which changes the color data for the surface to be the reflectance of the surface.

`surfl(...,s)` specifies the direction of the light source. `s` is a two- or three-element vector that specifies the direction from a surface to a light source. `s = [sx sy sz]` or `s = [azimuth elevation]`. The default `s` is  $45^\circ$  counterclockwise from the current view direction.

`surf1(X,Y,Z,s,k)` specifies the reflectance constant. `k` is a four-element vector defining the relative contributions of ambient light, diffuse reflection, specular reflection, and the specular shine coefficient. `k = [ka kd ks shine]` and defaults to `[.55, .6, .4, 10]`.

`h = surf1(...)` returns a handle to a surface graphics object. If you specify the `'light'` option, `h` contains the handle to the surface and the light objects.

## Examples

### Create Surface Plot With Colormap-Based Lighting

Create a surface plot of the `peaks` function using colormap-based lighting. Set the shading to `interp` to interpolate the colors across lines and faces.

```
[x,y] = meshgrid(-3:1/8:3);
z = peaks(x,y);
surf1(x,y,z)
shading interp
```

## More About

### Tips

`surf1` does not accept complex inputs.

For smoother color transitions, use colormaps that have linear intensity variations (e.g., `gray`, `copper`, `bone`, `pink`).

The ordering of points in the `X`, `Y`, and `Z` matrices defines the inside and outside of parametric surfaces. If you want the opposite side of the surface to reflect the light

source, use `surf1(X', Y', Z')`. Because of the way surface normal vectors are computed, `surf1` requires matrices that are at least 3-by-3.

# surfnorm

Compute and display 3-D surface normals

## Syntax

```
surfnorm(Z)
surfnorm(X,Y,Z)
surfnorm(axes_handle, ___)
surfnorm(___,Name,Value)
[Nx,Ny,Nz] = surfnorm(___)
```

## Description

`surfnorm(Z)` plots a surface of the matrix `Z` with `surf` and displays its surface normals as radiating vectors.

`surfnorm(X,Y,Z)` plots a surface and its surface normals from the vectors or matrices `X`, `Y`, and matrix `Z`. `X`, `Y`, and `Z` must be the same size.

`surfnorm(axes_handle, ___ )` plots into `axes_handle` instead of `gca` and it can include any of the input arguments in previous syntaxes.

`surfnorm( ___,Name,Value)` can be used to set the value of the specified Chart Surface Properties properties.

`[Nx,Ny,Nz] = surfnorm( ___ )` returns the components of the 3-D surface normals for the surface without plotting the surface or surface normals.

## Input Arguments

### **Z**

2-D array of real numbers representing a surface

**Default:**

**X**

2-D array of real numbers that defines the  $x$  component of the surface grid

**Y**

2-D array of real numbers that defines the  $y$  component of the surface grid

**axes\_handle**

Handle to the target axes in which to plot the surface

If you do not specify `axes_handle`, MATLAB uses current axes.

**Name, Value**

Specify optional comma-separated pairs of Name, Value arguments, where Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Property names and values of the surface object

See Chart Surface Properties for description of property names and values.

## Output Arguments

**[Nx, Ny, Nz]**

$x$ ,  $y$ , and  $z$  components of the three-dimensional surface normals for the surface

## Examples

**Display 3-D Surface Normals for Cone Plot**

Compute and plot the normal vectors for a truncated cone. Set the axis limits using the `axis` function.

```
[x,y,z] = cylinder(1:10);
figure
surfnorm(x,y,z)
axis([-12 12 -12 12 -0.1 1])
```

### Use Computed Surface Normals for Lighting

Compute the normal vectors of an expression representing a surface.

```
[nx, ny, nz] = surfnorm(peaks);
```

Assign these normals to the `VertexNormals` property which MATLAB® uses to calculate the surface lighting. Set the lighting algorithm to `gouraud` and add a light using `camlight`.

```
b = reshape([nx ny nz], 49,49,3);
figure
surf(ones(49), 'VertexNormals', b, 'EdgeColor', 'none');
lighting gouraud
```

camlight

## More About

### Surface Normal

An imaginary line perpendicular to a flat surface or perpendicular to the tangent plane at a point on a non-flat surface

### Tips

- `surfnorm` does not accept complex inputs.

- Reverse the direction of the normals by calling `surfnorm` with transposed arguments:  
`surfnorm(X',Y',Z')`
- The surface normals represent conditions at vertices and are not normalized. Normals for surface elements that face away from the viewer do not display.
- `surf1` uses `surfnorm` to compute surface normals when calculating the reflectance of a surface.

### Algorithms

After performing a bicubic fit of the data in the  $x$ ,  $y$ , and  $z$  directions, diagonal vectors are computed and crossed to form the normal at each vertex.

## svd

Singular value decomposition

### Syntax

```
s = svd(X)
[U,S,V] = svd(X)
[U,S,V] = svd(X,0)
[U,S,V] = svd(X,'econ')
```

### Description

The `svd` command computes the matrix singular value decomposition.

`s = svd(X)` returns a vector of singular values.

`[U,S,V] = svd(X)` produces a diagonal matrix **S** of the same dimension as **X**, with nonnegative diagonal elements in decreasing order, and unitary matrices **U** and **V** so that  $X = U*S*V'$ .

`[U,S,V] = svd(X,0)` produces the “economy size” decomposition. If **X** is *m*-by-*n* with *m* > *n*, then `svd` computes only the first *n* columns of **U** and **S** is *n*-by-*n*.

`[U,S,V] = svd(X,'econ')` also produces the “economy size” decomposition. If **X** is *m*-by-*n* with *m* ≥ *n*, it is equivalent to `svd(X,0)`. For *m* < *n*, only the first *m* columns of **V** are computed and **S** is *m*-by-*m*.

### Examples

For the matrix

```
X =
 1 2
 3 4
 5 6
 7 8
```

the statement

$$[U, S, V] = \text{svd}(X)$$

produces

$$U = \begin{bmatrix} -0.1525 & -0.8226 & -0.3945 & -0.3800 \\ -0.3499 & -0.4214 & 0.2428 & 0.8007 \\ -0.5474 & -0.0201 & 0.6979 & -0.4614 \\ -0.7448 & 0.3812 & -0.5462 & 0.0407 \end{bmatrix}$$

$$S = \begin{bmatrix} 14.2691 & & & \\ & 0 & 0.6268 & \\ & & 0 & \\ & & & 0 \end{bmatrix}$$

$$V = \begin{bmatrix} -0.6414 & 0.7672 \\ -0.7672 & -0.6414 \end{bmatrix}$$

The economy size decomposition generated by

$$[U, S, V] = \text{svd}(X, 0)$$

produces

$$U = \begin{bmatrix} -0.1525 & -0.8226 \\ -0.3499 & -0.4214 \\ -0.5474 & -0.0201 \\ -0.7448 & 0.3812 \end{bmatrix}$$

$$S = \begin{bmatrix} 14.2691 & & \\ & 0 & 0.6268 \end{bmatrix}$$

$$V = \begin{bmatrix} -0.6414 & 0.7672 \\ -0.7672 & -0.6414 \end{bmatrix}$$

## Diagnostics

If the limit of 75 QR step iterations is exhausted while seeking a singular value, this message appears:

Solution will not converge.

**See Also**

gsvd | svds

**Introduced before R2006a**

## svds

Find singular values and vectors

### Syntax

```
s = svds(A)
s = svds(A,k)
s = svds(A,k,sigma)
s = svds(A,k,'L')
s = svds(A,k,sigma,options)
[U,S,V] = svds(A,...)
[U,S,V,flag] = svds(A,...)
```

### Description

`s = svds(A)` computes the six largest singular values and associated singular vectors of matrix `A`. If `A` is `m`-by-`n`, `svds(A)` manipulates eigenvalues and vectors returned by `eigs(B)`, where `B = [sparse(m,m) A; A' sparse(n,n)]`, to find a few singular values and vectors of `A`. The positive eigenvalues of the symmetric matrix `B` are the same as the singular values of `A`.

`s = svds(A,k)` computes the `k` largest singular values and associated singular vectors of matrix `A`.

`s = svds(A,k,sigma)` computes the `k` singular values closest to the scalar shift `sigma`. For example, `s = svds(A,k,0)` computes the `k` smallest singular values and associated singular vectors.

`s = svds(A,k,'L')` computes the `k` largest singular values (the default).

`s = svds(A,k,sigma,options)` sets some parameters (see `eigs`):

#### Option Structure Fields and Descriptions

Field name	Parameter	Default
<code>options.tol</code>	Convergence tolerance: $\text{norm}(AV - US, 1) \leq \text{tol} * \text{norm}(A, 1)$	<code>1e-10</code>

Field name	Parameter	Default
<code>options.maxit</code>	Maximum number of iterations	300
<code>options.disp</code>	Number of values displayed each iteration	0

`svds` checks the accuracy of the computed singular vectors. If the vectors are not accurate enough, then `svds` returns fewer singular values than requested. To obtain the requested number of singular values, try decreasing the error tolerance in the options structure.

`[U,S,V] = svds(A,...)` returns three output arguments, and if `A` is `m`-by-`n`:

- `U` is `m`-by-`k` with orthonormal columns
- `S` is `k`-by-`k` diagonal
- `V` is `n`-by-`k` with orthonormal columns
- `U*S*V'` is the closest rank `k` approximation to `A`

`[U,S,V,flag] = svds(A,...)` returns a convergence flag. If `eigs` converged, then `norm(A*V-U*S,1) <= tol*norm(A,1)` and `flag` is 0. If `eigs` did not converge, then `flag` is 1.

---

**Note** `svds` is best used to find a few singular values of a large, sparse matrix. To find all the singular values of such a matrix, `svd(full(A))` will usually perform better than `svds(A,min(size(A)))`.

---

## Examples

### Singular Values of Sparse Matrix

`west0479` is a real 479-by-479 sparse matrix. `svd` calculates all 479 singular values. `svds` picks out only the largest and smallest singular values.

```
load west0479
s = svd(full(west0479));
s1 = svds(west0479,4);
ss = svds(west0479,6,0);
```

```
Warning: NORMEST did not converge for 100 iterations with tolerance 1e-06
```

These plots show some of the singular values of west0479 as computed by svd and svds.

```
subplot(2,1,1)
plot(s(1:4), 'ks')
hold on
plot(s1, 'k+')
hold off
title('4 largest singular values of west0479')
legend('svd(A)', 'svds(A,4)')
xlim([0.5 4.5])

subplot(2,1,2)
plot(s(end-5:end), 'ks')
hold on
plot(ss, 'k+')
hold off
title('6 smallest singular values of west0479')
legend('svd(A)', 'svds(A,6,0)')
xlim([0.5 6.5])
```

The largest singular value of `west0479` can be computed a few different ways:

```
svds(west0479,1)
max(svd(full(west0479)))
norm(full(west0479))
```

```
ans =
```

```
3.1895e+05
```

```
ans =
```

```
3.1895e+05
```

```
ans =
```

```
3.1895e+05
```

Or, to estimate the largest singular value:

```
normest(west0479)
```

```
Warning: NORMEST did not converge for 100 iterations with tolerance 1e-06
```

```
ans =
```

```
3.1854e+05
```

## More About

### Algorithms

`svds(A,k)` uses `eigs` to find the  $k$  largest magnitude eigenvalues and corresponding eigenvectors of  $B = \begin{bmatrix} 0 & A \\ A' & 0 \end{bmatrix}$ .

`svds(A,k,0)` uses `eigs` to find the  $2k$  smallest magnitude eigenvalues and corresponding eigenvectors of  $B = \begin{bmatrix} 0 & A \\ A' & 0 \end{bmatrix}$ , and then selects the  $k$  positive eigenvalues and their eigenvectors.

### See Also

# swapbytes

Swap byte ordering

## Syntax

`Y = swapbytes(X)`

## Description

`Y = swapbytes(X)` reverses the byte ordering of each element in array `X`, converting little-endian values to big-endian (and vice versa). The input array must contain all full, noncomplex, numeric elements.

## Examples

### Example 1

Reverse the byte order for a scalar 32-bit value, changing hexadecimal 12345678 to 78563412:

```
A = uint32(hex2dec('12345678'));
```

```
B = dec2hex(swapbytes(A))
```

```
B =
 78563412
```

### Example 2

Reverse the byte order for each element of a 1-by-4 matrix:

```
X = uint16([0 1 128 65535])
```

```
X =
 0 1 128 65535
```

```
Y = swapbytes(X);
Y =
 0 256 32768 65535
```

Examining the output in hexadecimal notation shows the byte swapping:

```
format hex
```

```
X, Y
X =
 0000 0001 0080 ffff
Y =
 0000 0100 8000 ffff
```

### Example 3

Create a three-dimensional array *A* of 16-bit integers and then swap the bytes of each element:

```
format hex
```

```
A = uint16(magic(3) * 150);
A(:,:,2) = A * 40;
```

```
A
A(:,:,1) =
 04b0 0096 0384
 01c2 02ee 041a
 0258 0546 012c
A(:,:,2) =
 bb80 1770 8ca0
 4650 7530 a410
 5dc0 d2f0 2ee0
```

```
swapbytes(A)
ans(:,:,1) =
 b004 9600 8403
 c201 ee02 1a04
 5802 4605 2c01
ans(:,:,2) =
 80bb 7017 a08c
 5046 3075 10a4
 c05d f0d2 e02e
```

**See Also**  
typecast

**Introduced before R2006a**

# switch, case, otherwise

Execute one of several groups of statements

## Syntax

```
switch switch_expression
 case case_expression
 statements
 case case_expression
 statements
 ...
 otherwise
 statements
end
```

## Description

`switch switch_expression, case case_expression, end` evaluates an expression and chooses to execute one of several groups of statements. Each choice is a case.

The `switch` block tests each case until one of the case expressions is true. A case is true when:

- For numbers, `case_expression == switch_expression`.
- For strings, `strcmp(case_expression,switch_expression) == 1`.
- For objects that support the `eq` function, `case_expression == switch_expression`.
- For a cell array `case_expression`, at least one of the elements of the cell array matches `switch_expression`, as defined above for numbers, strings, and objects.

When a case expression is true, MATLAB executes the corresponding statements and exits the `switch` block.

An evaluated `switch_expression` must be a scalar or string. An evaluated `case_expression` must be a scalar, a string, or a cell array of scalars or strings.

The `otherwise` block is optional. MATLAB executes the statements only when no case is true.

## Examples

### Compare Single Values

Display different text conditionally, depending on a value entered at the command prompt.

```
n = input('Enter a number: ');

switch n
 case -1
 disp('negative one')
 case 0
 disp('zero')
 case 1
 disp('positive one')
 otherwise
 disp('other value')
end
```

At the command prompt, enter the number 1.

```
positive one
```

Repeat the code and enter the number 3.

```
other value
```

### Compare Against Multiple Values

Determine which type of plot to create based on the value of the string `plottype`. If `plottype` is either `'pie'` or `'pie3'`, create a 3-D pie chart. Use a cell array to contain both values.

```
x = [12 64 24];
plottype = 'pie3';

switch plottype
 case 'bar'
```

```

 bar(x)
 title('Bar Graph')
 case {'pie', 'pie3'}
 pie3(x)
 title('Pie Chart')
 otherwise
 warning('Unexpected plot type. No plot created.')
end

```

## More About

### Tips

- A *case\_expression* cannot include relational operators such as `<` or `>` for comparison against the *switch\_expression*. To test for inequality, use `if`, `elseif`, `else` statements.
- The MATLAB `switch` statement does not fall through like a C language `switch` statement. If the first `case` statement is `true`, MATLAB does not execute the other `case` statements. For example:

```

result = 52;

switch(result)
 case 52
 disp('result is 52')
 case {52, 78}
 disp('result is 52 or 78')
end

```

```

result is 52

```

- Define all variables necessary for code in a particular case within that case. Since MATLAB executes only one case of any `switch` statement, variables defined within one case are not available for other cases. For example, if your current workspace does not contain a variable `x`, only cases that define `x` can use it:

```

switch choice
 case 1
 x = -pi:0.01:pi;
 case 2
 % does not know anything about x
end

```

- Do not use a `break` statement within a `switch` block. `break` is not defined outside a `for` or `while` loop.

## **See Also**

`end` | `for` | `if` | `while`

**Introduced before R2006a**

# sylvester

Solve Sylvester equation  $AX + XB = C$  for  $X$

## Syntax

```
X = sylvester(A,B,C)
```

## Description

`X = sylvester(A,B,C)` returns the solution,  $X$ , to the Sylvester equation.

Input  $A$  is an  $m$ -by- $m$  matrix, input  $B$  is an  $n$ -by- $n$  matrix, and both  $C$  and  $X$  are  $m$ -by- $n$  matrices.

## Examples

### Solve Sylvester Equation with 3-by-3 Output

Create the coefficient matrices  $A$  and  $B$ .

```
A = [1 -1 1; 1 1 -1; 1 1 1];
B = magic(3);
```

Define  $C$  as the 3-by-3 identity matrix.

```
C = eye(3);
```

Use the `sylvester` function to solve the Sylvester equation for these values of  $A$ ,  $B$ , and  $C$ .

```
X = sylvester(A,B,C)
```

```
X =
```

```
 0.1223 -0.0725 0.0131
 -0.0806 -0.0161 0.1587
 -0.0164 0.1784 -0.1072
```

The result is a 3-by-3 matrix.

### Solve Sylvester Equation with 4-by-2 Output

Create a 4-by-4 coefficient matrix, **A**, and 2-by-2 coefficient matrix, **B**.

```
A = [1 0 2 3; 4 1 0 2; 0 5 5 6; 1 7 9 0];
B = [0 -1; 1 0];
```

Define **C** as a 4-by-2 matrix to match the corresponding sizes of **A** and **B**.

```
C = [1 0; 2 0; 0 3; 1 1]
```

```
C =
```

```
 1 0
 2 0
 0 3
 1 1
```

Use the `sylvester` function to solve the Sylvester equation for these values of **A**, **B**, and **C**.

```
X = sylvester(A,B,C)
```

```
X =
```

```
 0.4732 -0.3664
 -0.4006 0.3531
 0.3305 -0.1142
 0.0774 0.3560
```

The result is a 4-by-2 matrix.

## Input Arguments

**A, B, C** — Input matrices  
matrices

Input matrices, specified as matrices. Input **A** is an m-by-m square matrix, input **B** is an n-by-n square matrix, and input **C** is an m-by-n rectangular matrix. The function returns an error if any input matrix is sparse.

Data Types: `single` | `double`  
Complex Number Support: Yes

## Output Arguments

### **X** – Solution

matrix

Solution, returned as a matrix of the same size as **C**. The function returns an error if the eigenvalues of **A** and **-B** are not distinct (in this case, the solution, **X**, is singular or not unique).

## More About

### Sylvester Equation

The Sylvester equation is

$$AX + XB = C.$$

The equation has a unique solution when the eigenvalues of **A** and **-B** are distinct. In terms of the Kronecker tensor product,  $\otimes$ , the equation is

$$\left[ I \otimes A + B^T \otimes I \right] X(:) = C(:),$$

where **I** is the identity matrix, and  $X(:)$  and  $C(:)$  denote the matrices **X** and **C** as single column vectors.

## symamd

Symmetric approximate minimum degree permutation

### Syntax

```
p = symamd(S)
p = symamd(S, knobs)
[p, stats] = symamd(...)
```

### Description

`p = symamd(S)` for a symmetric positive definite matrix **S**, returns the permutation vector **p** such that **S(p, p)** tends to have a sparser Cholesky factor than **S**. To find the ordering for **S**, `symamd` constructs a matrix **M** such that `spones(M'*M) = spones(S)`, and then computes `p = colamd(M)`. The `symamd` function may also work well for symmetric indefinite matrices.

**S** must be square; only the strictly lower triangular part is referenced.

`p = symamd(S, knobs)` where `knobs` is a scalar. If **S** is *n*-by-*n*, rows and columns with more than `knobs*n` entries are removed prior to ordering, and ordered last in the output permutation **p**. If the `knobs` parameter is not present, then `knobs = spparms('wh_frac')`.

`[p, stats] = symamd(...)` produces the optional vector **stats** that provides data about the ordering and the validity of the matrix **S**.

<code>stats(1)</code>	Number of dense or empty rows ignored by <code>symamd</code>
<code>stats(2)</code>	Number of dense or empty columns ignored by <code>symamd</code>
<code>stats(3)</code>	Number of garbage collections performed on the internal data structure used by <code>symamd</code> (roughly of size <code>8.4*nnz(tril(S, -1)) + 9n</code> integers)
<code>stats(4)</code>	0 if the matrix is valid, or 1 if invalid

<code>stats(5)</code>	Rightmost column index that is unsorted or contains duplicate entries, or 0 if no such column exists
<code>stats(6)</code>	Last seen duplicate or out-of-order row index in the column index given by <code>stats(5)</code> , or 0 if no such row index exists
<code>stats(7)</code>	Number of duplicate and out-of-order row indices

Although, MATLAB built-in functions generate valid sparse matrices, a user may construct an invalid sparse matrix using the MATLAB C or Fortran APIs and pass it to `symamd`. For this reason, `symamd` verifies that `S` is valid:

- If a row index appears two or more times in the same column, `symamd` ignores the duplicate entries, continues processing, and provides information about the duplicate entries in `stats(4:7)`.
- If row indices in a column are out of order, `symamd` sorts each column of its internal copy of the matrix `S` (but does not repair the input matrix `S`), continues processing, and provides information about the out-of-order entries in `stats(4:7)`.
- If `S` is invalid in any other way, `symamd` cannot continue. It prints an error message, and returns no output arguments (`p` or `stats`).

The ordering is followed by a symmetric elimination tree post-ordering.

## Examples

### Compare Reverse Cuthill-McKee and Minimum Degree

Here is a comparison of reverse Cuthill-McKee and minimum degree on the Bucky ball example mentioned in the `symrcm` reference page.

```
B = bucky+4*speye(60);
r = symrcm(B);
p = symamd(B);
R = B(r,r);
S = B(p,p);
subplot(2,2,1), spy(R,4), title('B(r,r)')
subplot(2,2,2), spy(S,4), title('B(s,s)')
subplot(2,2,3), spy(chol(R),4), title('chol(B(r,r))')
subplot(2,2,4), spy(chol(S),4), title('chol(B(s,s))')
```

Even though this is a very small problem, the behavior of both orderings is typical. RCM produces a matrix with a narrow bandwidth which fills in almost completely during the Cholesky factorization. Minimum degree produces a structure with large blocks of contiguous zeros which do not fill in during the factorization. Consequently, the minimum degree ordering requires less time and storage for the factorization.

## References

The authors of the code for `symamd` are Stefan I. Larimore and Timothy A. Davis ([davis@cise.ufl.edu](mailto:davis@cise.ufl.edu)), University of Florida. The algorithm was developed in collaboration with John Gilbert, Xerox PARC, and Esmond Ng, Oak Ridge National

Laboratory. Sparse Matrix Algorithms Research at the University of Florida: <http://www.cise.ufl.edu/research/sparse/>

# **symbfact**

Symbolic factorization analysis

## **Syntax**

```
count = symbfact(A)
count = symbfact(A, 'sym')
count = symbfact(A, 'col')
count = symbfact(A, 'row')
count = symbfact(A, 'lo')
[count, h, parent, post, R] = symbfact(...)
[count, h, parent, post, L] = symbfact(A, type, 'lower')
```

## **Description**

`count = symbfact(A)` returns the vector of row counts of  $R = \text{chol}(A)$ . `symbfact` should be much faster than `chol(A)`.

`count = symbfact(A, 'sym')` is the same as `count = symbfact(A)`.

`count = symbfact(A, 'col')` returns row counts of  $R = \text{chol}(A' * A)$  (without forming it explicitly).

`count = symbfact(A, 'row')` returns row counts of  $R = \text{chol}(A * A')$ .

`count = symbfact(A, 'lo')` is the same as `count = symbfact(A)` and uses `tril(A)`.

`[count, h, parent, post, R] = symbfact(...)` has several optional return values.

The flop count for a subsequent Cholesky factorization is `sum(count.^2)`

<b>Return Value</b>	<b>Description</b>
h	Height of the elimination tree
parent	The elimination tree itself
post	Postordering of the elimination tree

Return Value	Description
R	0-1 matrix having the structure of <code>chol(A)</code> for the symmetric case, <code>chol(A'*A)</code> for the 'col' case, or <code>chol(A*A')</code> for the 'row' case.

`symbfact(A)` and `symbfact(A, 'sym')` use the upper triangular part of `A` (`triu(A)`) and assume the lower triangular part is the transpose of the upper triangular part. `symbfact(A, 'lo')` uses `tril(A)` instead.

`[count,h,parent,post,L] = symbfact(A,type,'lower')` where `type` is one of 'sym', 'col', 'row', or 'lo' returns a lower triangular symbolic factor `L=R'`. This form is quicker and requires less memory.

# symmlq

Symmetric LQ method

## Syntax

```
x = symmlq(A,b)
symmlq(A,b,tol)
symmlq(A,b,tol,maxit)
symmlq(A,b,tol,maxit,M)
symmlq(A,b,tol,maxit,M1,M2)
symmlq(A,b,tol,maxit,M1,M2,x0)
[x,flag] = symmlq(A,b,...)
[x,flag,relres] = symmlq(A,b,...)
[x,flag,relres,iter] = symmlq(A,b,...)
[x,flag,relres,iter,resvec] = symmlq(A,b,...)
[x,flag,relres,iter,resvec,resveccg] = symmlq(A,b,...)
```

## Description

`x = symmlq(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be symmetric but need not be positive definite. It should also be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `symmlq` converges, a message to that effect is displayed. If `symmlq` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`symmlq(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `symmlq` uses the default,  $1e-6$ .

`symmlq(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `symmlq` uses the default,  $\min(n,20)$ .

`symmlq(A,b,tol,maxit,M)` and `symmlq(A,b,tol,maxit,M1,M2)` use the symmetric positive definite preconditioner  $M$  or  $M = M1 * M2$  and effectively solve the system  $\text{inv}(\text{sqrt}(M)) * A * \text{inv}(\text{sqrt}(M)) * y = \text{inv}(\text{sqrt}(M)) * b$  for  $y$  and then return  $x = \text{in}(\text{sqrt}(M)) * y$ . If  $M$  is `[]` then `symmlq` applies no preconditioner.  $M$  can be a function handle `mfun` such that `mfun(x)` returns  $M \backslash x$ .

`symmlq(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If  $x0$  is `[]`, then `symmlq` uses the default, an all-zero vector.

`[x,flag] = symmlq(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	<code>symmlq</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>symmlq</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner $M$ was ill-conditioned.
3	<code>symmlq</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>symmlq</code> became too small or too large to continue computing.
5	Preconditioner $M$ was not symmetric positive definite.

Whenever `flag` is not 0, the solution  $x$  returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = symmlq(A,b,...)` also returns the relative residual  $\text{norm}(b - A * x) / \text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = symmlq(A,b,...)` also returns the iteration number at which  $x$  was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = symmlq(A,b,...)` also returns a vector of estimates of the `symmlq` residual norms at each iteration, including  $\text{norm}(b - A * x0)$ .

`[x,flag,relres,iter,resvec,resveccg] = symmlq(A,b,...)` also returns a vector of estimates of the conjugate gradients residual norms at each iteration.

## Examples

### Example 1

```
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50; M1 = spdiags(4*on,0,n,n);

x = symmlq(A,b,tol,maxit,M1);
symmlq converged at iteration 49 to a solution with relative
residual 4.3e-015
```

### Example 2

This example replaces the matrix **A** in Example 1 with a handle to a matrix-vector product function **afun**. The example is contained in the function **run\_symmlq** that:

- Calls **symmlq** with the function handle **@afun** as its first argument.
- Contains **afun** as a nested function, so that all variables in **run\_symmlq** are available to **afun**.

The following shows the code for **run\_symmlq**:

```
function x1 = run_symmlq
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = symmlq(@afun,b,tol,maxit,M1);

 function y = afun(x)
 y = 4 * x;
 y(2:n) = y(2:n) - 2 * x(1:n-1);
 y(1:n-1) = y(1:n-1) - 2 * x(2:n);
 end
```

end

When you enter

```
x1=run_symmlq;
```

MATLAB software displays the message

```
symmlq converged at iteration 49 to a solution with relative
residual 4.3e-015
```

### Example 3

Use a symmetric indefinite matrix that fails with pcg.

```
A = diag([20:-1:1,-1:-1:-20]);
b = sum(A,2); % The true solution is the vector of all ones.
x = pcg(A,b); % Errors out at the first iteration.
pcg stopped at iteration 1 without converging to the desired
tolerance 1e-006 because a scalar quantity became too small or
too large to continue computing.
The iterate returned (number 0) has relative residual 1
```

However, symmlq can handle the indefinite matrix A.

```
x = symmlq(A,b,1e-6,40);
symmlq converged at iteration 39 to a solution with relative
residual 1.3e-007
```

## symrcm

Sparse reverse Cuthill-McKee ordering

### Syntax

```
r = symrcm(S)
```

### Description

`r = symrcm(S)` returns the symmetric reverse Cuthill-McKee ordering of **S**. This is a permutation **r** such that **S(r,r)** tends to have its nonzero elements closer to the diagonal. This is a good preordering for LU or Cholesky factorization of matrices that come from long, skinny problems. The ordering works for both symmetric and nonsymmetric **S**.

For a real, symmetric sparse matrix, **S**, the eigenvalues of **S(r,r)** are the same as those of **S**, but `eig(S(r,r))` probably takes less time to compute than `eig(S)`.

### Examples

#### Reverse Cuthill-McKee Ordering

The statement

```
B = bucky;
```

uses a function in the **demos** toolbox to generate the adjacency graph of a truncated icosahedron. This is better known as a soccer ball, a Buckminster Fuller geodesic dome (hence the name **bucky**), or, more recently, as a 60-atom carbon molecule. There are 60 vertices. The vertices have been ordered by numbering half of them from one hemisphere, pentagon by pentagon; then reflecting into the other hemisphere and gluing the two halves together.

With this numbering, the matrix does not have a particularly narrow bandwidth, as the first spy plot shows:

```
figure();
subplot(1,2,1),spy(B),title('B')
```

The reverse Cuthill-McKee ordering is obtained with:

```
p = symrcm(B);
R = B(p,p);
```

The spy plot shows a much narrower bandwidth.

```
subplot(1,2,2),spy(R),title('B(p,p)')
```

This example is continued in the reference page for `symamd`.

The bandwidth can also be computed with:

```
[i,j] = find(B);
bw = max(i-j) + 1;
```

The bandwidths of **B** and **R** are 35 and 12, respectively.

## More About

### Algorithms

The algorithm first finds a pseudoperipheral vertex of the graph of the matrix. It then generates a level structure by breadth-first search and orders the vertices by decreasing distance from the pseudoperipheral vertex. The implementation is based closely on the SPARSPAK implementation described by George and Liu.

## symvar

Determine symbolic variables in expression

### Syntax

```
symvar 'expr'
s = symvar('expr')
```

### Description

`symvar 'expr'` searches the expression, `expr`, for identifiers other than `i`, `j`, `pi`, `inf`, `nan`, `eps`, and common functions. `symvar` displays those variables that it finds or, if no such variable exists, displays an empty cell array, `{}`.

`s = symvar('expr')` returns the variables in a cell array of strings, `s`. If no such variable exists, `s` is an empty cell array.

### Examples

`symvar` finds variables `beta1` and `x`, but skips `pi` and the `cos` function.

```
symvar 'cos(pi*x - beta1)'
```

```
ans =
```

```
 'beta1'
 'x'
```

`strfind`

Introduced before R2006a

## **syntax**

Two ways to call MATLAB functions

### **Description**

You can call MATLAB functions using either *command syntax* or *function syntax*, as described below.

### **Command Syntax**

A function call in this syntax consists of the function name followed by one or more arguments separated by spaces:

```
functionname arg1 arg2 ... argn
```

Command syntax does not allow you to obtain any values that might be returned by the function. Attempting to assign output from the function to a variable using command syntax generates an error. Use function syntax instead.

Examples of command syntax:

```
save mydata.mat x y z
import java.awt.Button java.lang.String
```

Arguments are treated as string literals. See the examples below, under “Argument Passing” on page 1-8597.

### **Function Syntax**

A function call in this syntax consists of the function name followed by one or more arguments separated by commas and enclosed in parentheses:

```
functionname(arg1, arg2, ..., argn)
```

You can assign the output of the function to one or more output values. When assigning to more than one output variable, separate the variables by commas or spaces and enclose them in square brackets ([ ]):

```
[out1,out2,...,outn] = functionname(arg1, arg2, ..., argn)
```

Examples of function syntax:

```
copyfile('srcfile', '..\mytests', 'writable')
[x1,x2,x3,x4] = deal(A{:})
```

Arguments are passed to the function by value. See the examples below, under “Argument Passing” on page 1-8597.

## Argument Passing

When calling a function using command syntax, MATLAB passes the arguments as string literals. When using function syntax, arguments are passed by value.

In the following example, assign a value to **A** and then call **disp** on the variable to display the value passed. Calling **disp** with command syntax passes the variable name, 'A':

```
A = pi;
disp A
 A
```

while function syntax passes the value assigned to **A**:

```
A = pi;
disp(A)
 3.1416
```

The next example passes two strings to **strcmp** for comparison. Calling the function with command syntax compares the variable names, 'str1' and 'str2':

```
str1 = 'one'; str2 = 'one';
strcmp str1 str2
ans =
 0 (unequal)
```

while function syntax compares the values assigned to the variables, 'one' and 'one':

```
str1 = 'one'; str2 = 'one';
strcmp(str1, str2)
ans =
 1 (equal)
```

## Passing Strings

When using the function syntax to pass a string literal to a function, you must enclose the string in single quotes, ('string'). For example, to create a new folder called `myapptests`, use

```
mkdir('myapptests')
```

On the other hand, variables that contain strings do not need to be enclosed in quotes:

```
folder = 'myapptests';
mkdir(folder)
```

## More About

- “Check Code for Errors and Warnings”

## See Also

`mlint`

## system

Execute operating system command and return output

### Syntax

```
status = system(command)
[status,cmdout] = system(command)
[status,cmdout] = system(command, '-echo')
```

### Description

`status = system(command)` calls the operating system to execute the specified command. The operation waits for the command to finish execution before returning the exit status of the command to the `status` variable.

`[status,cmdout] = system(command)` also returns the output of the command to `cmdout`. This syntax is most useful for commands that do not require user input, such as `dir`.

`[status,cmdout] = system(command, '-echo')` also displays (echoes) the command output in the MATLAB Command Window. This syntax is most useful for commands that require user input and that run correctly in the MATLAB Command Window.

### Examples

#### Display Windows Operating System Command Status and Output

On a Windows system, display the current folder using the `cd` command.

```
command = 'cd';
[status,cmdout] = system(command)

status =
 0
cmdout =
C:\matlab\myfiles
```

A **status** of zero indicates that the command completed successfully. MATLAB returns a string containing the current folder in `cmdout`.

## Save UNIX Command Exit Status and Output

List all users who are currently logged in, and save the command exit status and output. Then, view the status.

```
command = 'who';
[status,cmdout] = system(command);
status

status =

 0
```

A **status** of zero indicates that the command completed successfully. MATLAB returns a string containing the list of users in `cmdout`.

## Input Arguments

**command** — Operating system command

string

Operating system command, specified as a string. The `command` executes in a system shell, which might not be the shell from which you started MATLAB.

Example: 'dir'

Example: 'ls'

## Output Arguments

**status** — Command exit status

0 | nonzero integer

Command exit status, returned as either 0 or a nonzero integer. When the command is successful, `status` is 0. Otherwise, `status` is a nonzero integer.

- If `command` includes the ampersand character (&), then `status` is the exit status when `command` starts

- If `command` does not include the ampersand character (&), then `status` is the exit status upon `command` completion.

### **cmdout** — Output of operating system command

string

Output of the operating system command, returned as a string. The system shell might not properly represent non-Unicode characters.

## Limitations

- MATLAB converts characters to the encoding that your operating system shell accepts. Output from the `command` is converted to the MATLAB encoding to be displayed in the command window. If you get unexpected results from the command, enter the `command` argument directly at the operating system prompt to see how the operating system treats your input.
- MS-DOS does not support UNC path names. Therefore, if the current folder uses a UNC path name, then running `system` with a DOS `command` that relies on the current folder fails. To work around this limitation, change the folder to a mapped drive before calling `system`.

## More About

### Tips

- To execute the operating system command in the background, include the trailing character, &, in the `command` argument (for example, 'notepad &' on a Windows platform, or 'emacs &' on UNIX). The exit status is immediately returned to the `status` variable. This syntax is useful for console programs that require interactive user command input while they run, and that do not run correctly in the MATLAB Command Window.

---

**Note:** If `command` includes the trailing & character, `cmdout` is empty.

---

- On a UNIX system, the `system` function redirects `stdin` to the invoked command, `command`, by default. This redirection also passes MATLAB script commands and the keyboard type-ahead buffer to the invoked command while the `system` function

executes. This can lead to corrupted output when `system` does not complete execution immediately. To disable `stdin` and type-ahead redirection, include the formatted string `< /dev/null` in the call to the invoked command.

## Algorithms

On UNIX, MATLAB uses a shell program to execute the given command. It determines which shell program to use by checking environment variables on your system. MATLAB first checks the `MATLAB_SHELL` variable, and if either empty or not defined, then checks `SHELL`. If `SHELL` is also empty or not defined, MATLAB uses `/bin/sh`.

- “Run External Commands, Scripts, and Programs”
- Why does the output of my FORTRAN script not show up in the MATLAB command window when I execute it using the `SYSTEM` function in MATLAB 7.14 (R2012a)?

**Introduced before R2006a**

# table

Create table from workspace variables

## Syntax

```
T = table(var1,...,varN)
T = table(var1,...,varN,Name,Value)
T = table
```

## Description

`T = table(var1,...,varN)` creates a table from the input variables, `var1`, ..., `varN`. Variables can be of different sizes and data types, but all variables must have the same number of rows.

For more information on creating and using the `table` data type, see “Tables”.

`T = table(var1,...,varN,Name,Value)` includes additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify row names or variable names to include in the table.

`T = table` creates an empty 0-by-0 table.

## Examples

### Create Table from Workspace Variables

Define workspace variables with the same number of rows.

```
LastName = {'Smith'; 'Johnson'; 'Williams'; 'Jones'; 'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

Create a table, `T`, as a container for the workspace variables.

```
T = table(Age,Height,Weight,BloodPressure,...
 'RowNames',LastName)
```

T =

	Age	Height	Weight	BloodPressure	
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

table names the variables with the workspace variable names.

## Create Table and Specify Variable Names

Create a table from arrays with different data types.

```
T = table(['M';'F';'M'],[45;32;34],...
 {'NY';'CA';'MA'},logical([1;0;0]),...
 'VariableNames',{'Gender' 'Age' 'State' 'Vote'})
```

T =

Gender	Age	State	Vote
M	45	'NY'	true
F	32	'CA'	false
M	34	'MA'	false

Each variable in T contains 3 rows.

**Gender** is a character array, **Age** is a double-precision array, **State** is a cell array of strings, and **Vote** is a logical array. You can use the function `summary` to print the data type and other information about the variables in the table.

## Input Arguments

### **var1, ..., varN — Input variables**

arrays with the same number of rows

Input variables, specified as arrays with the same number of rows. The input variables can be of different sizes and different data types.

Common input variables are numeric arrays, logical arrays, character arrays, structure arrays, or cell arrays. Furthermore, input variables can be objects that are arrays that support indexing of the form `var(index1, ... indexN)`, where `index1` is a numeric or logical vector that corresponds to rows of the variable `var`. In addition, the array must implement a `vertcat` method and a `size` method with a `dim` argument.

Example: `table([1:4]', ones(4,3,2), eye(4,2))` creates a table from variables with 4 rows, but different sizes.

Example: `table([1:3]', {'one'; 'two'; 'three'}, ['A'; 'B'; 'C'])` creates a table from variables with 3 rows, but different data types.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'RowNames', {'row1', 'row2', 'row3'}` names the rows `row1`, `row2`, and `row3`.

### **'RowNames' — Row names**

`{}` (default) | cell array of nonempty, distinct strings

Row names, specified as the comma-separated pair consisting of `'RowNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of rows in the table.

### **'VariableNames' — Variable names**

cell array of nonempty, distinct strings

Variable names, specified as the comma-separated pair consisting of `'VariableNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the

number of variables. The strings must be valid MATLAB variable names. You can determine valid variable names using the function `isvarname`.

## Output Arguments

### **T** — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

Unless you specify the table variable names using the `VariableNames` name-value pair argument, the `table` function generates them automatically. If an input argument is a variable in the current workspace, `table` uses that variable's name as the table variable name. Otherwise, it generates a string from `Var` followed by an integer, such as `Var2`.

**Introduced in R2013b**

# table2array

Convert table to homogeneous array

## Syntax

A = table2array(T)

## Description

A = table2array(T) converts the table, T, to a homogeneous array, A.

## Examples

### Convert Table of Numeric Data to Array

Create a table, T, consisting of numeric data.

```
T = table([1;2;3],[2 8; 4 10; 6 12],[3 12 21; 6 15 24; 9 18 27],...
 'VariableNames',{'One' 'Two' 'Three'})
```

T =

One	Two		Three		
—	—		—		
1	2	8	3	12	21
2	4	10	6	15	24
3	6	12	9	18	27

Convert table, T, to an array.

```
A = table2array(T)
```

A =

1	2	8	3	12	21
2	4	10	6	15	24

3      6      12      9      18      27

A contains two columns from variable TWO and three columns from variable Three.

### Convert Numeric Subset of Table to Array

Define the numeric subset of a table to convert to an array.

Create a table with nonnumeric data in the first variable.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
 [71;69;64;67;64],[176;163;131;133;119],...
 'VariableNames',{'Gender' 'Age' 'Height' 'Weight'})
```

T =

Gender	Age	Height	Weight
M	38	71	176
M	43	69	163
F	38	64	131
F	40	67	133
F	49	64	119

Convert T(:,2:4) to an array.

```
A = table2array(T(:,2:4))
```

A =

38	71	176
43	69	163
38	64	131
40	67	133
49	64	119

A does not include data from the variable Gender.

### Convert Table with Three-Dimensional Variables to Array

Create a table, T, with two rows and three variables where each variable has three dimensions.

```
T = table(ones(2,1,3),2*ones(2,2,3),3*ones(2,3,3),...)
```

```
'VariableNames',{ 'One' 'Two' 'Three' })
```

T =

One	Two	Three
[1x1x3 double]	[1x2x3 double]	[1x3x3 double]
[1x1x3 double]	[1x2x3 double]	[1x3x3 double]

The size of the table is 2-by-3.

Convert table T to an array.

```
A = table2array(T)
```

```
A(:, :, 1) =
```

1	2	2	3	3	3
1	2	2	3	3	3

```
A(:, :, 2) =
```

1	2	2	3	3	3
1	2	2	3	3	3

```
A(:, :, 3) =
```

1	2	2	3	3	3
1	2	2	3	3	3

The size of A is 2-by-6-by-3.

## Input Arguments

### T — Input table

table

Input table, specified as a table. All variables in T must have sizes and data types that are compatible for horizontal concatenation. Specifically, the size of all variable dimensions greater than 2 must match.

- If `T` is an `m`-by-`n` table with variables that each have one column, then each variable becomes one column in `A`, and `A` is an `m`-by-`n` array.
- If `T` contains variables that consist of more than one column, those variables become multiple columns in `A`, and the size of `A` is greater than the size of `T`.
- If `T` contains variables with more than two dimensions, the number of dimensions of `A` is the same as the number of variable dimensions.

## More About

### Tips

- `table2array` horizontally concatenates the variables in `T` to create `A`. If the variables in `T` are cell arrays, `table2array` does not concatenate their contents, and `A` is a cell array, equivalent to `table2cell(T)`. To create an array containing the contents of variables that are all cell arrays, use `cell2mat(table2cell(T))`.
- `table2array(T)` is equivalent to `T{:, :}`.

### Algorithms

If `T` contains variables with different data types that are compatible for horizontal concatenation, `table2array` creates a homogeneous array, `A`, of the dominant data type. For example, if `T` contains `double` and `single` numeric data, `table2array(T)` returns an array with data type `single`.

- “Concatenating Objects of Different Classes”

`array2table` | `table` | `table2cell` | `table2struct`

Introduced in R2013b

# table2cell

Convert table to cell array

## Syntax

```
C = table2cell(T)
```

## Description

`C = table2cell(T)` converts the table, `T`, to a cell array, `C`. Each variable in `T` becomes a column of cells in `C`.

## Examples

### Convert Table to Cell Array

Create a table, `T`, with five rows and three variables.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
 [124 93;109 77; 125 83; 117 75; 122 80],...
 'VariableNames',{'Gender' 'Age' 'BloodPressure'},...
 'RowNames',{'Smith' 'Johnson' 'Williams' 'Jones' 'Brown'})
```

`T =`

	Gender	Age	BloodPressure	
	_____	_____	_____	_____
Smith	M	38	124	93
Johnson	M	43	109	77
Williams	F	38	125	83
Jones	F	40	117	75
Brown	F	49	122	80

Convert `T` to a cell array.

```
C = table2cell(T)
```

```
C =

 'M' [38] [1x2 double]
 'M' [43] [1x2 double]
 'F' [38] [1x2 double]
 'F' [40] [1x2 double]
 'F' [49] [1x2 double]
```

**C** is a 5-by-3 cell array.

Vertically concatenate the table property, `T.Properties.VariableNames`, with **C** to include column headings for the cell array.

```
[T.Properties.VariableNames;C]

ans =

 'Gender' 'Age' 'BloodPressure'
 'M' [38] [1x2 double]
 'M' [43] [1x2 double]
 'F' [38] [1x2 double]
 'F' [40] [1x2 double]
 'F' [49] [1x2 double]
```

`T.Properties.VariableNames` is a cell array of strings.

## Input Arguments

### **T** — Input table

table

Input table, specified as a table.

If **T** is an *m*-by-*n* table, then **C** is an *m*-by-*n* cell array.

### See Also

`cell2table` | `table` | `table2array` | `table2struct`

**Introduced in R2013b**

# table2struct

Convert table to structure array

## Syntax

```
S = table2struct(T)
S = table2struct(T, 'ToScalar', true)
```

## Description

`S = table2struct(T)` converts the table, `T`, to a structure array, `S`. Each variable of `T` becomes a field in `S`. If `T` is an `m`-by-`n` table, then `S` is a `m`-by-1 structure array with `n` fields.

`S = table2struct(T, 'ToScalar', true)` converts the table, `T`, to a scalar structure `S`. Each variable of `T` becomes a field in `S`. If `T` is a `m`-by-`n` table, then `S` has `n` fields, each of which has `m` rows.

## Examples

### Convert Table to Structure Array

Create a table, `T`, with five rows and three variables.

```
T = table(['M'; 'M'; 'F'; 'F'; 'F'], [38; 43; 38; 40; 49], ...
 [124 93; 109 77; 125 83; 117 75; 122 80], ...
 'VariableNames', {'Gender' 'Age' 'BloodPressure'})
```

`T =`

Gender	Age	BloodPressure	
M	38	124	93
M	43	109	77
F	38	125	83
F	40	117	75

```
F 49 122 80
```

Convert T to a structure array.

```
S = table2struct(T)
```

```
S =
```

```
5x1 struct array with fields:
```

```
Gender
Age
BloodPressure
```

The structure is 5-by-1, corresponding to the five rows of the table, T. The three fields of S correspond to the three variables from T.

Display the field data for the first element of S.

```
S(1)
```

```
ans =
```

```
Gender: 'M'
Age: 38
BloodPressure: [124 93]
```

The information corresponds to the first row of the table.

## Convert Table to Scalar Structure

Create a table, T, with five rows and three variables.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
[124 93;109 77; 125 83; 117 75; 122 80],...
'VariableNames',{'Gender' 'Age' 'BloodPressure'})
```

```
T =
```

Gender	Age	BloodPressure	
M	38	124	93
M	43	109	77
F	38	125	83

```

F 40 117 75
F 49 122 80

```

Convert T to a scalar structure.

```
S = table2struct(T, 'ToScalar', true)
```

```
S =
```

```

 Gender: [5x1 char]
 Age: [5x1 double]
BloodPressure: [5x2 double]

```

The data in the fields of the scalar structure are 5-by-1, corresponding to the five rows in the table T.

Display the data for the field BloodPressure.

```
S.BloodPressure
```

```
ans =
```

```

124 93
109 77
125 83
117 75
122 80

```

The structure field BloodPressure contains all of the data that was in the variable of the same name from table T.

### Convert Table with Row Names to Structure

Create a table, T, that includes row names.

```

T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
 [124 93;109 77; 125 83; 117 75; 122 80],...
 'VariableNames',{'Gender' 'Age' 'BloodPressure'},...
 'RowNames',{'Smith' 'Johnson' 'Williams' 'Jones' 'Brown'})

```

```
T =
```

```

 Gender Age BloodPressure
 _____ _____ _____

```

Smith	M	38	124	93
Johnson	M	43	109	77
Williams	F	38	125	83
Jones	F	40	117	75
Brown	F	49	122	80

Convert `T` to a scalar structure.

```
S = table2struct(T, 'ToScalar', true)
```

```
S =
```

```
 Gender: [5x1 char]
 Age: [5x1 double]
BloodPressure: [5x2 double]
```

Add a field for the row names from the table.

```
S.RowNames = T.Properties.RowNames
```

```
S =
```

```
 Gender: [5x1 char]
 Age: [5x1 double]
BloodPressure: [5x2 double]
 RowNames: {5x1 cell}
```

If `S` is a nonscalar structure, use `[S.RowNames] = T.Properties.RowNames{:}` to include a field with the row names from the table.

## Input Arguments

### **T** — Input table

table

Input table, specified as a table.

### See Also

Introduced in R2013b

# Table Properties

Access and modify table metadata properties

## Access and Modify Properties

A table, *T*, has properties that store metadata such as its variable names, row names, descriptions, and variable units. *T.Properties* returns a summary of all of the table properties.

You can access a property using *T.Properties.PropName*, where *T* is the name of the table and *PropName* is one of the table properties. For example, to access the *VariableDescriptions* property of a table named *Patients*, use *Patients.Properties.VariableDescriptions*.

You can modify a property value using *T.Properties.PropName = P* where *T* is the name of the table, *PropName* is one of the table properties, and *P* is the desired property value. For example, to modify the *VariableUnits* property of a table named *Patients*, use *Patients.Properties.VariableUnits = P* where *P* is a cell array of strings containing the specified information.

In contrast, you can access and modify variables within a table using *T.Variable* or *T.Variable = V*, where *T* is the name of the table, *Variable* is the name of the variable you want to access or modify, and *V* is the variable value you want.

## Properties

### **VariableNames** — Variable names

cell array of nonempty, distinct strings

Variable names, specified as a cell array of nonempty, distinct strings. Variable names must be valid MATLAB variable names. The number of strings must equal the number of variables. MATLAB removes any leading or trailing white space from the strings.

If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of *N* strings of the form { 'Var1' ... 'Var*N*' } where *N* is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

The variable names are visible when viewing the table and when using the `summary` function. Furthermore, you can use the variable names within parentheses, within curly braces, or with dot indexing to access table data.

## Example

```
%% Create a table
```

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
 [71;69;64;67;64],[176;163;131;133;119])
```

```
T =
```

Var1	Var2	Var3	Var4
M	38	71	176
M	43	69	163
F	38	64	131
F	40	67	133
F	49	64	119

```
%% Modify variable names
```

```
T.Properties.VariableNames = {'Gender' 'Age' 'Height' 'Weight'}
```

```
T =
```

Gender	Age	Height	Weight
M	38	71	176
M	43	69	163
F	38	64	131
F	40	67	133
F	49	64	119

```
%% Create a subtable
```

```
%
```

```
% Use variable names within parentheses to create a subtable.
```

```
% Include all the rows, but only the variables Age and Gender.
```

```
T(:,{'Age','Gender'})
```

```
ans =
```

Age	Gender
-----	--------

```

38 M
43 M
38 F
40 F
49 F

%% Extract data from the table
%
% Use variable names within curly braces to extract the
% numeric data from the variables Height and Weight.
T{:, {'Height', 'Weight'}}

ans =

 71 176
 69 163
 64 131
 67 133
 64 119

% Use variable names with dot indexing to extract
% all the data from the variable Gender.
T.Gender

ans =

M
M
F
F
F

```

### RowNames — Row names

{ } (default) | cell array of nonempty, distinct strings

Row names, specified as a cell array of nonempty, distinct strings. This property can be empty, but if not empty, the number of strings must equal the number of rows in the table. MATLAB removes any leading or trailing white space from the strings. The default property value is an empty cell array.

The row names are visible when you view the table. Furthermore, you can use the row names within parentheses or curly braces to access the table data.

### Example

```
% Create a table
load patients
T = table(Gender, Age, Height, Weight, Smoker, Systolic, Diastolic);

% Add row names
T.Properties.RowNames = LastName;

% Remove row names
T.Properties.RowNames = {};
```

## **DimensionNames — Dimension names**

{'Row' 'Variable'} (default) | two-element cell array of strings

Dimension names, specified as a two-element cell array of strings.

### **Example**

```
% Create a table
load patients
T = table(Gender, Age, Height, Weight, Smoker, Systolic, Diastolic, ...
 'RowNames', LastName);

% Add dimension names
T.Properties.DimensionNames = {'Patient' 'Data'};
```

## **Description — Table description**

'' (default) | string

Table description, specified as a string. This string is visible when using the `summary` function.

### **Example**

```
% Create a table
load patients
T = table(Gender, Age, Height, Weight);

% Add a table description
T.Properties.Description = 'Simulated patient data';

%View the summary
format compact
summary(T)
```

Description: Simulated patient data

```

Variables:
 Gender: 100x1 char
 Age: 100x1 double
 Values:
 min 25
 median 39
 max 50
 Height: 100x1 double
 Values:
 min 60
 median 67
 max 72
 Weight: 100x1 double
 Values:
 min 111
 median 142.5
 max 202

```

### VariableDescriptions – Variable descriptions

{ } (default) | cell array of strings

Variable descriptions, specified as a cell array of strings. This property can be an empty cell array, which is the default. If the cell array is not empty, the number of strings must equal the number of variables. You can specify an individual empty string within the cell array for a variable that does not have a description.

The variable descriptions are visible when using the `summary` function.

### Example

```

% Create a table
load patients
T = table(Gender, Age, Height, Weight, Smoker, Systolic, Diastolic);

% Add variable descriptions
T.Properties.VariableDescriptions = {' ' ' ' ' ' ...
 'Has the patient ever been a smoker' ...
 'Systolic Pressure' 'Diastolic Pressure'};

% View the summary
format compact
summary(T)

Variables:

```

```
Gender: 100x1 char
Age: 100x1 double
 Values:
 min 25
 median 39
 max 50
Height: 100x1 double
 Values:
 min 60
 median 67
 max 72
Weight: 100x1 double
 Values:
 min 111
 median 142.5
 max 202
Smoker: 100x1 logical
 Description: Has the patient ever been a smoker
 Values:
 true 34
 false 66
Systolic: 100x1 double
 Description: Systolic Pressure
 Values:
 min 109
 median 122
 max 138
Diastolic: 100x1 double
 Description: Diastolic Pressure
 Values:
 min 68
 median 81.5
 max 99
```

```
% Remove all the variable descriptions
T.Properties.VariableDescriptions = {};
```

## **VariableUnits — Variable units**

`{}` (default) | cell array of strings

Variable units, specified as a cell array of strings. This property can be an empty cell array, which is the default. If the cell array is not empty, the number of strings must equal the number of variables. You can specify an individual empty string within the cell array for a variable that does not have units.

The variable units are visible when using the `summary` function.

### Example

```
% Create a table
load patients
T = table(Gender, Age, Height, Weight, Smoker, Systolic, Diastolic);

% Add variable units
T.Properties.VariableUnits = {' ' 'Yrs' 'In' 'Lbs' ' ' 'mm Hg' 'mm Hg'};

% View the summary
format compact
summary(T)
```

```
Variables:
 Gender: 100x1 char
 Age: 100x1 double
 Units: Yrs
 Values:
 min 25
 median 39
 max 50
 Height: 100x1 double
 Units: In
 Values:
 min 60
 median 67
 max 72
 Weight: 100x1 double
 Units: Lbs
 Values:
 min 111
 median 142.5
 max 202
 Smoker: 100x1 logical
 Values:
 true 34
 false 66
 Systolic: 100x1 double
 Units: mm Hg
 Values:
 min 109
 median 122
 max 138
```

```
Diastolic: 100x1 double
Units: mm Hg
Values:
 min 68
 median 81.5
 max 99
```

```
% Remove all the variable units
T.Properties.VariableUnits = {};
```

## **UserData — Additional table information**

`{}` (default) | variable containing information in any data type

Additional table information, specified as a variable containing information in any data type.

### **Example**

```
% Create a table
load patients
T = table(Gender, Age, Height, Weight, Smoker, Systolic, Diastolic);

% Add an anonymous function to the table metadata
formula = @(x) x.^2;
T.Properties.UserData = formula;
```

## **More About**

- “Access Data in a Table”

`isvarname` | `summary` | `table`

# TabularTextDatastore Properties

Access and modify `TabularTextDatastore` properties

`TabularTextDatastore` properties describe the files associated with a `TabularTextDatastore` object. Specifically, the properties describe the format of the data in the files and control how the data should be read from the datastore. By changing property values, you can modify certain aspects of the datastore. Use dot notation to view or modify a particular property of a `TabularTextDatastore` object:

```
ds = datastore('airlinesmall.csv');
ds.TreatAsMissing = 'NA';
ds.MissingValue = 0;
```

You also can specify the value of `TabularTextDatastore` properties using name-value pair arguments when you create a datastore using the `datastore` function:

```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
 'MissingValue',0)
```

The first file specified by the `Files` property determines the variable names and format information. The `datastore` function reevaluates this information when you change any of the following properties of a `TabularTextDatastore`:

<code>Files</code>	<code>Delimiter</code>	<code>CommentStyle</code>
<code>FileEncoding</code>	<code>RowDelimiter</code>	<code>Whitespace</code>
<code>ReadVariableNames</code>	<code>TreatAsMissing</code>	<code>MultipleDelimitersAsOne</code>
<code>NumHeaderLines</code>		

## File Properties

### **Files** — Files included in datastore

cell array of strings

Files included in the datastore, specified as an n-by-1 cell array of strings, where each string is a full path to a file.

The first file specified by the `Files` property determines the variable names and format information for all files in the datastore.

Example: `{'C:\dir\data\mydata1.csv';'C:\dir\data\mydata2.csv'}`

**FileEncoding** — File encoding

'UTF-8' (default) | string

File encoding, specified as one of the following strings.

'IBM866'	'ISO-8859-1'	'windows-847'
'KOI8-R'	'ISO-8859-2'	'windows-1250'
'KOI8-U'	'ISO-8859-3'	'windows-1251'
'Macintosh'	'ISO-8859-4'	'windows-1252'
'US-ASCII'	'ISO-8859-5'	'windows-1253'
'UTF-8'	'ISO-8859-6'	'windows-1254'
	'ISO-8859-7'	'windows-1255'
	'ISO-8859-8'	'windows-1256'
	'ISO-8859-9'	'windows-1257'
	'ISO-8859-11'	'windows-1258'
	'ISO-8859-13'	
	'ISO-8859-15'	

If each file in the datastore fits into memory, then `FileEncoding` also can be one of the following strings.

'Big5'	'EUC-KR'	'GB18030'	'Shift_JIS'
'Big5-HKSCS'	'EUC-JP'	'GB2312'	'windows-949'
'CP949'	'EUC-TW'	'GBK'	

**ReadVariableNames** — Indicator for reading first row of first file as variable names

true (default) | false | 1 | 0

Indicator for reading first row of the first file in the datastore as variable names, specified as either `true` (1) or `false` (0).

- If `true`, then the first nonheader row of the first file determines the variable names for the data.
- If `false`, then the first nonheader row of the first file contains the first row of data. The data is assigned default variable names, `Var1`, `Var2`, and so on.

Data Types: logical

**VariableNames — Names of variables**

cell array of strings

Names of variables in the datastore, specified as a cell array of strings. Specify the variable names in the order in which they appear in the files. If you do not specify the variable names, they are detected from the first nonheader line in the first file of the datastore. When modifying the `VariableNames` property, the number of new variable names must match the number of original variable names.

If `ReadVariableNames` is `false`, then `VariableNames` defaults to `{'Var1', 'Var2', ...}`.

Example: `{'Time', 'Name', 'Quantity'}`

**Text Format Properties****NumHeaderLines — Number of lines to skip at beginning of file**

0 (default) | positive integer

Number of lines to skip at the beginning of the file, specified as a positive integer.

`datastore` ignores the specified number of header lines before reading the variable names or data.

Data Types: `double`

**Delimiter — Field delimiter characters**

', ' (default) | string | cell array of strings

Field delimiter characters, specified as a string or a cell array of strings. Specify multiple delimiters in a cell array of strings.

Example: `'|'`

Example: `{';', '*'}`

Repeated delimiter characters in a file are interpreted as separate delimiters with empty fields between them.

When you specify one of the following escape sequences as a delimiter, it is converted to the corresponding control character:

`\b`                      Backspace

<code>\n</code>	Newline
<code>\r</code>	Carriage return
<code>\t</code>	Tab
<code>\\</code>	Backslash ( <code>\</code> )

## **RowDelimiter** — Row delimiter character

`\r\n` (default) | string

Row delimiter character, specified as a string. The string must be a single character or one of the strings, '`\r`', '`\n`', or '`\r\n`'.

Example: `':'`

## **TreatAsMissing** — Numeric values to treat as missing values

`''` (default) | string | cell array of strings

Numeric values to treat as missing values, specified as a single string or cell array of strings. This option only applies to numeric fields. This property is equivalent to the `TreatAsEmpty` name-value pair argument for the `textscan` function.

Example: `'NA'`

Example: `{' - ', ''}`

Data Types: `char` | `cell`

## **MissingValue** — Value for missing numeric fields

`NaN` (default) | scalar

Value for missing numeric fields in delimited text files, specified as a scalar. This property is equivalent to the `EmptyValue` name-value pair argument for the `textscan` function.

Data Types: `double`

## **Advanced Text Format Properties**

### **TextscanFormats** — Format of the data fields

cell array of strings

Format of the data fields, specified as a cell array of strings, where each string contains one conversion specifier.

When you specify or modify the `TextscanFormats` property, you can use the same conversion specifiers that the `textscan` function accepts for the `formatSpec` argument. This includes specifiers that skip fields using an asterisk (\*) character and specifiers that skip literal text. The number of conversion specifiers must match the number of variables in the `VariableNames` property.

If the value of `TextscanFormats` includes conversion specifiers that skip fields using asterisk characters (\*), then the value of the `SelectedVariableNames` property automatically updates. MATLAB uses the `%*q` conversion specifier to skip fields omitted by the `SelectedVariableNames` property and treats the field contents as literal strings. For fixed width files, indicate a skipped field using the appropriate conversion specifier along with the field width. For example, `%*52c` skips a field that contains 52 characters.

If you do not specify a value for `TextscanFormats`, then `datastore` determines the format of the data fields by scanning text from the first non-header line in the first file of the datastore.

Example: `{ '%s ', '%s ', '%f ' }`

### **ExponentCharacters — Exponent characters**

`'eEdD'` (default) | string

Exponent characters, specified as a string. The default exponent characters are `e`, `E`, `d`, and `D`.

### **CommentStyle — Style of comments**

`' '` (default) | string | cell array of strings

Style of comments in the file, specified as a string or cell array of strings.

For example, specify a string such as `'%'` to ignore characters following the string on the same line. Specify a cell array of two strings, such as `{ '/*', '*/' }`, to ignore characters between the strings.

When reading from a `TabularTextDatastore`, the `read` function checks for comments only at the start of each field, not within a field.

Example: `'CommentStyle', { '/*', '*/' }`

Data Types: `char` | `cell`

### **Whitespace — White-space characters**

`' \b\t'` (default) | string

White-space characters, specified as a string of one or more characters.

When you specify one of the following escape sequences as any white-space character, `datastore` converts that sequence to the corresponding control character:

<code>\b</code>	Backspace
<code>\n</code>	Newline
<code>\r</code>	Carriage return
<code>\t</code>	Tab
<code>\\</code>	Backslash (\)

Example: `' \b\t '`

Data Types: `char`

### **MultipleDelimitersAsOne — Multiple delimiter handling**

0 (`false`) (default) | 1 (`true`)

Multiple delimiter handling, specified as either `true` or `false`. If `true`, then `datastore` treats consecutive delimiters as a single delimiter. Repeated delimiters separated by white-space are also treated as a single delimiter.

## **Properties that Control the Table Returned by `preview`, `read`, `readall` Functions**

### **SelectedVariableNames — Variables to read**

cell array of strings

Variables to read from the file, specified as a cell array of strings, where each string contains the name of one variable. You can specify the variable names in any order.

Example: `{ 'Var3' , 'Var7' , 'Var4' }`

### **SelectedFormats — Formats of selected variables**

cell array of strings

Formats of the selected variables to read, specified as a cell array of strings, where each string contains one conversion specifier. The variables to read are indicated by the `SelectedVariableNames` property. The number of strings in `SelectedFormats` must match the number of variables to read.

You can use the same conversion specifiers that the `textscan` function accepts, including specifiers that skip literal text. However, you cannot use a conversion specifier that skips a field. That is, the conversion specifier cannot include an asterisk character (\*).

Example: { '%d' , '%d' }

### **ReadSize — Amount of data to read**

20000 (default) | positive scalar | 'file'

Amount of data to read in a call to the `read` function, specified as a positive scalar or the string, 'file'.

- If `ReadSize` is a positive integer, then each call to `read` reads up to the specified number of rows from the datastore.
- If `ReadSize` is 'file', then each call to `read` reads all of the data in one file.

When you change `ReadSize` from a numeric scalar to 'file' or vice versa, MATLAB resets the datastore to the state where no data has been read from it.

### **RowsPerRead — Upper limit on number of rows to read**

20000 (default) | positive scalar

---

**Note:** `RowsPerRead` will be removed in a future release. Use `ReadSize` instead.

---

Upper limit on number of rows to read from a file in a call to the `read` function, specified as a positive scalar.

### **See Also**

`datastore` | `reset` | `textscan`

### **More About**

- Using TabularTextDatastore Objects

## **tan**

Tangent of argument in radians

### **Syntax**

`Y = tan(X)`

### **Description**

`Y = tan(X)` returns the tangent of each element of `X`. The `tan` function operates element-wise on arrays. The function accepts both real and complex inputs. For real values of `X` in the interval `[-Inf, Inf]`, `tan` returns real values in the interval `[-Inf, Inf]`. For complex values of `X`, `tan` returns complex values. All angles are in radians.

### **Examples**

#### **Plot Tangent Function**

Plot the tangent function over the domain  $-\pi/2 \leq x \leq \pi/2$ .

```
x = (-pi/2)+0.01:0.01:(pi/2)-0.01;
plot(x,tan(x)), grid on
```

### Tangent of Vector of Complex Angles

Calculate the tangent of the complex angles in vector  $x$ .

```
x = [-i pi+i*pi/2 -1+i*4];
y = tan(x)
```

y =

```
0.0000 - 0.7616i -0.0000 + 0.9172i -0.0006 + 1.0003i
```

## Input Arguments

### **X** — Input angle in radians

number | vector | matrix | multidimensional array

Input angle in radians, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Y** — Tangent of input angle

scalar value | vector | matrix | N-D array

Tangent of input angle, returned as a real-valued or complex-valued scalar, vector, matrix or N-D array.

## More About

### Tangent Function

The tangent of an angle,  $\alpha$ , defined with reference to a right angled triangle is

$$\tan(\alpha) = \frac{\text{opposite side}}{\text{adjacent side}} = \frac{a}{b}.$$

The tangent of a complex angle,  $\alpha$ , is

$$\tan(\alpha) = \frac{e^{i\alpha} - e^{-i\alpha}}{i(e^{i\alpha} + e^{-i\alpha})}.$$

.

### See Also

atan | atan2 | atan2d | atand | tand | tanh

Introduced before R2006a

## tand

Tangent of argument in degrees

### Syntax

$Y = \text{tand}(X)$

### Description

$Y = \text{tand}(X)$  returns the tangent of the elements of  $X$ , which are expressed in degrees.

### Examples

#### Tangent of 90 degrees compared to tangent of $\pi/2$ radians

```
tand(90)
```

```
ans =
```

```
 Inf
```

```
tan(pi/2)
```

```
ans =
```

```
1.6331e+16
```

$\text{tand}(90)$  is infinite, whereas  $\tan(\pi/2)$  is large but finite.

#### Tangent of vector of complex angles, specified in degrees

```
z = [180+i 15+2i 10+3i];
```

```
y = tand(z)
```

```
y =
```

0 + 0.0175i    0.2676 + 0.0374i    0.1758 + 0.0539i

## Input Arguments

### **X — Angle in degrees**

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `tand` operation is element-wise when `X` is nonscalar.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Y — Tangent of angle**

scalar value | vector | matrix | N-D array

Tangent of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

## See Also

`atan` | `atand` | `tan`

**Introduced before R2006a**

## **tanh**

Hyperbolic tangent

### **Syntax**

$Y = \tanh(X)$

### **Description**

The `tanh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

$Y = \tanh(X)$  returns the hyperbolic tangent of each element of  $X$ .

### **Examples**

#### **Graph Hyperbolic Tangent Function**

Graph the hyperbolic tangent function over the domain  $-5 \leq x \leq 5$ .

```
x = -5:0.01:5;
plot(x,tanh(x)), grid on
```

## More About

### Hyperbolic Tangent

The hyperbolic tangent of  $z$  is

$$\tanh(z) = \frac{\sinh(z)}{\cosh(z)}.$$

### See Also

# tar

Compress files into tar file

## Syntax

```
tar(tarfilename,files)
tar(tarfilename,files,rootfolder)
entrynames = tar(...)
```

## Description

`tar(tarfilename,files)` creates a tar file named *tarfilename* from the list of files and folders specified in *files*. Folders recursively include all of their content. If *files* includes relative paths, the tar file also contains relative paths. The tar file does not include absolute paths.

`tar(tarfilename,files,rootfolder)` specifies the path for *files* relative to *rootfolder* rather than the current folder. Relative paths in the tar file reflect the relative paths in *files*, and do not include path information from *rootfolder*.

`entrynames = tar(...)` returns a string cell array of the names of the files contained in *tarfilename*. If *files* includes relative paths, *entrynames* also contains relative paths.

## Input Arguments

### **tarfilename**

String specifying the name of the tar file. If *tarfilename* has no extension, MATLAB appends the `.tar` extension. The *tarfilename* extension can end in `.tgz` or `.gz`. In this case, *tarfilename* is gzipped.

### **files**

String or cell array of strings containing the list of files or folders included in *tarfilename*.

Individual files that are on the MATLAB path can be specified as partial path names. Otherwise an individual file can be specified relative to the current folder or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~username/`, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

## **rootfolder**

String specifying the path for *files*.

## **Examples**

Tar all files in the current folder to the file `backup.tgz`.

```
tar('backup.tgz','.');
```

## **More About**

### **Tips**

`tar` cannot compress folders larger than 2 GB.

### **See Also**

`gzip` | `gunzip` | `untar` | `unzip` | `zip`

**Introduced before R2006a**

# targetupdater

Set up support package that is already installed

## Syntax

targetupdater

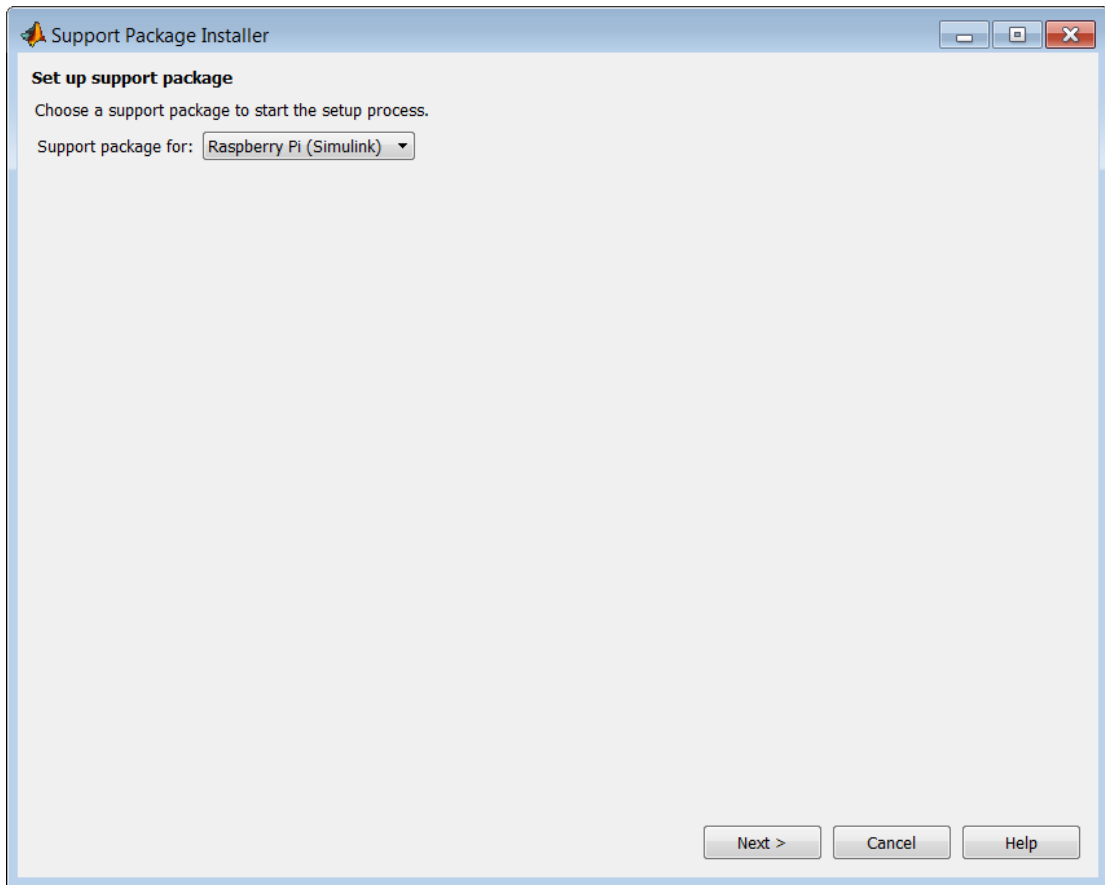

## Description

targetupdater sets up a support package that is already installed.

Setting up a support package can include:

- Updating firmware on the target hardware.
- Validating the installation folder of third-party software.
- Validating licenses.

The `targetupdater` function starts Support Package Installer at the **Set up support package** screen.

---

**Tip** Some support packages do not require set up. If the **Set up support package** screen does not display an installed support package, the support package does not require set up.

To check whether a support package is installed, use the `matlabshared.supportpkg.getInstalled` function.

---

## **See Also**

`matlabshared.supportpkg.checkForUpdate` |

`matlabshared.supportpkg.getInstalled` | `supportPackageInstaller`

## tcpclient

Create TCP/IP client object to communicate over TCP/IP

### Syntax

```
t = tcpclient('Address',Port)
t = tcpclient('Address',Port, 'Timeout', <timeout_value>)
```

### Description

`t = tcpclient('Address',Port)` constructs a TCP/IP object, `t`, associated with remote host, `Address`, and remote port value, `Port`. The address can be either a remote host name or a remote IP address. The port must be a positive integer between 1 and 65535.

If an invalid address or port is specified, or the connection to the server cannot be established, the object will not be created.

`t = tcpclient('Address',Port, 'Timeout', <timeout_value>)` additionally sets a timeout value. The `Timeout` property specifies the waiting time to complete read and write operations in seconds, and the default is 10.

### Examples

#### Create Object Using Host Name

Create a TCP/IP object called `t`, using the host address shown, and Port of 4012.

```
t = tcpclient('www.mathworks.com', 4012)
t =
```

tcpclient with properties:

```
Address: 'www.mathworks.com'
Port: 4012
Timeout: 10
```

```
BytesAvailable: 0
```

### Create Object Using IP Address

Create a TCP/IP object called `t`, using the IP address shown, and Port of 4012.

```
t = tcpclient('172.28.154.231', 4012)
```

```
t =
```

```
tcpclient with properties:
```

```
 Address: '172.28.154.231'
 Port: 4012
 Timeout: 10
 BytesAvailable: 0
```

### Create Object Setting the Timeout Property

Create a TCP/IP object called `t`, and increase the `Timeout` to 20 seconds.

```
t = tcpclient('172.28.154.231', 4012, 'Timeout', 20)
```

```
t =
```

```
tcpclient with properties:
```

```
 Address: '172.28.154.231'
 Port: 4012
 Timeout: 20
 BytesAvailable: 0
```

The output reflects the `Timeout` property change.

## Input Arguments

### Address — Remote host name or IP address for connection

character string

Remote host name or IP address for connection, specified as a character string. Specify address as the first argument when you create the `tcpclient` object.

Example: `t = tcpclient('www.mathworks.com', 4012)`

Data Types: char

**Port** — Remote host port for connection

numeric scalar

Remote host port for connection, specified as a numeric scalar. Specify port number as the second argument when you create the `tcpclient` object. The **Port** must be a positive integer between 1 and 65535.

```
Example: t = tcpclient('www.mathworks.com', 4012)
```

Data Types: double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

```
Example: t = tcpclient('172.28.154.231', 120, 'Timeout', 15)
```

**'Timeout'** — Timeout for read/write operation

10 (default) | numeric scalar

Timeout for read/write operation specified as the comma-separated pair consisting of "Timeout" and a positive value of type **double**. You can change the value either during object creation or after you create the object.

For information on how to change the timeout value after object creation, see [Configure Properties for TCP/IP Communication](#).

```
Example: t = tcpclient('172.28.154.231', 4012, 'Timeout', 20)
```

Data Types: double

# tempdir

Name of system's temporary folder

## Syntax

```
tmp_folder = tempdir
```

## Description

`tmp_folder = tempdir` returns the name of the system's temporary folder, if one exists. This function does not create a new folder.

## More About

- “Create Temporary Files”

## See Also

`delete` | `recycle` | `tempname`

**Introduced before R2006a**

## tempname

Unique name for temporary file

### Syntax

```
tmpName = tempname
```

### Description

`tmpName = tempname` returns a string, `tmpName`, suitable for use as a temporary file path in your system's temporary folder.

### Examples

#### Create Temporary File Name with Extension

Create a temporary file name that has the extension, `.dat`, by concatenating two strings.

```
tmpName = [tempname, '.dat'];
```

#### Write Data to Temporary File

Create a temporary file name.

```
filename = tempname;
```

Create a new file with the temporary file name, and write data to the file.

```
fileID = fopen(filename, 'w');
fwrite(fileID, magic(5));
fclose(fileID);
```

### Limitations

- In most cases, `tempname` generates a universally unique identifier (UUID). However, if you run MATLAB without JVM software, then `tempname` generates a random

string using the CPU counter and time, and this string is not guaranteed to be unique. For more information about the MATLAB startup option that does not load JVM software, see “Commonly Used Startup Options”.

## More About

- “Create Temporary Files”

## See Also

tempdir

**Introduced before R2006a**

## tetramesh

Tetrahedron mesh plot

### Syntax

```
tetramesh(T,X,c)
tetramesh(T,X)
tetramesh(TR)
h = tetramesh(...)
tetramesh(..., 'param', 'value', 'param', 'value' ...)
```

### Description

`tetramesh(T,X,c)` displays the tetrahedrons defined in the  $m$ -by-4 matrix `T` as mesh. `T` is usually the output of a Delaunay triangulation of a 3-D set of points. A row of `T` contains indices into `X` of the vertices of a tetrahedron. `X` is an  $n$ -by-3 matrix, representing  $n$  points in 3 dimension. The tetrahedron colors are defined by the vector `C`, which is used as indices into the current colormap.

`tetramesh(T,X)` uses `C = 1:m` as the color for the  $m$  tetrahedra. Each tetrahedron has a different color (modulo the number of colors available in the current colormap).

`tetramesh(TR)` displays the tetrahedra in a triangulation representation.

`h = tetramesh(...)` returns a vector of tetrahedron handles. Each element of `h` is a handle to the set of patches forming one tetrahedron. You can use these handles to view a particular tetrahedron by turning the patch `'Visible'` property `'on'` or `'off'`.

`tetramesh(..., 'param', 'value', 'param', 'value' ...)` allows additional patch property name/property value pairs to be used when displaying the tetrahedrons. For example, the default transparency parameter is set to `0.9`. You can overwrite this value by using the property name/property value pair (`'FaceAlpha', value`) where `value` is a number between `0` and `1`. See Patch Properties for information about the available properties.

## Examples

### Plot Tetrahedrons of 3-D Delaunay Triangulation

Generate a 3-D Delaunay triangulation, then use `tetramesh` to visualize the tetrahedrons.

```
d = [-1 1];
[x,y,z] = meshgrid(d,d,d); % a cube
x = [x(:);0];
y = [y(:);0];
z = [z(:);0];
```

[x,y,z] are corners of a cube plus the center.

```
DT = delaunayTriangulation(x,y,z);
tetramesh(DT);
camorbit(20,0)
```

**Introduced before R2006a**

# matlab.unittest.Test class

**Package:** matlab.unittest

**Superclasses:** matlab.unittest.TestSuite

Specification of a single test method

## Description

The `matlab.unittest.Test` class holds the information needed for the `TestRunner` object to be able to run a single `Test` method of a `TestCase` class. A scalar `Test` instance is the fundamental element contained in `TestSuite` arrays. A simple array of `Test` instances is a commonly used form of a `TestSuite` array.

## Properties

### Name

Name of the `Test` element.

### Parameterization

Row vector of parameters required for the `Test`. The `Parameterization` property contains all the parameterized data needed by the `TestRunner`.

### SharedTestFixtures

Row vector of fixtures required for the `Test`. The `SharedTestFixtures` property contains all the fixtures specified by the `SharedTestFixtures` class-level attribute of the `TestCase` class.

## Examples

### Show Class of a TestSuite Array

Create a suite of `Test` objects of all test methods in the `BankAccountTest` class.

```
import matlab.unittest.TestSuite;
suite = TestSuite.fromClass(?BankAccountTest);
whos suite
```

Name	Size	Bytes	Class	Attributes
suite	1x5	1636	matlab.unittest.Test	

Each test is a `matlab.unittest.Test` object.

Display test method names.

```
{suite.Name}'
ans =
 'BankAccountTest/testConstructor'
 'BankAccountTest/testConstructorNotEnoughInputs'
 'BankAccountTest/testDesposit'
 'BankAccountTest/testWithdraw'
 'BankAccountTest/testNotifyInsufficientFunds'
```

## See Also

`matlab.unittest.TestSuite` | `matlab.unittest.TestRunner` | `matlab.unittest.TestCase` | `matlab.unittest.fixtures`

# matlab.unittest.TestCase class

**Package:** matlab.unittest

Superclass of all matlab.unittest test classes

## Description

The `TestCase` class is the means by which a test is written in the `matlab.unittest` framework. It provides the means to write and identify test content, as well as test fixture setup and teardown routines. Creating such a test requires deriving from `TestCase` to produce a `TestCase` subclass. Then, subclasses can leverage the metadata attributes to specify tests and test fixtures.

## Construction

---

**Note:** The ability to directly construct `TestCase` instances by calling the `matlab.unittest.TestCase` constructor has been removed. For interactive, command line use, instantiate a `TestCase` using the `forInteractiveUse` static method.

---

Use the `forInteractiveUse` static method to create a `TestCase` for interactive, command line use. When tests are run in the framework, `TestCase` instances are constructed by the `matlab.unittest.TestRunner`.

## Methods

<code>addTeardown</code>	Dynamically add teardown routine
<code>applyFixture</code>	Use fixture with <code>TestCase</code>
<code>forInteractiveUse</code>	Create <code>TestCase</code> for interactive use
<code>getSharedTestFixtures</code>	Provide access to shared test fixtures
<code>log</code>	Record diagnostic information
<code>run</code>	Run <code>TestCase</code> test

## Inherited Methods

The `TestCase` class inherits methods from the following classes:

<code>matlab.unittest.qualifications.Assertable</code>	Qualification to validate preconditions of a test
<code>matlab.unittest.qualifications.Assumable</code>	Qualification to filter test content
<code>matlab.unittest.qualifications.FatalAssertable</code>	Qualification to abort test execution
<code>matlab.unittest.qualifications.Verifiable</code>	Qualification to produce soft-failure conditions

## Attributes

### Class Attributes

`TestCase` objects support the following class level attributes. Specify class-level attributes in the `classdef` block before the class name.

<code>SharedTestFixtures</code>	Class block to contain shared test fixtures. You must define <code>SharedTestFixtures</code> as a cell array of <code>matlab.unittest.fixtures.Fixture</code> instances.
<code>TestTags</code>	Class block to contain tests tagged with a specified value. You must define <code>TestTags</code> as a cell array of non-empty strings, where each string is a tag for the test.

### Method Attributes

Classes that derive from `TestCase` can define `methods` blocks which contain `matlab.unittest` framework-specific attributes to specify test content.

<code>Test</code>	Method block to contain test methods.
<code>TestMethodSetup</code>	Method block to contain setup code.
<code>TestMethodTeardown</code>	Method block to contain teardown code.
<code>TestClassSetup</code>	Method block to contain class level setup code.
<code>TestClassTeardown</code>	Method block to contain class level teardown code.
<code>ParameterCombination</code>	Method block to contain parameterized testing code. This attribute accepts the following values: <ul style="list-style-type: none"> <li>• <code>'exhaustive'</code> (default): Test methods are invoked for all combinations of parameters.</li> <li>• <code>'sequential'</code>: Test methods are invoked with corresponding values from each parameter. Each parameter must contain the same number of values.</li> <li>• <code>'pairwise'</code>: Test methods are invoked for every pair of parameter values at least once.</li> </ul>
<code>TestTags</code>	Method block to contain tests tagged with a specified value. You must define <code>TestTags</code> as a cell array of non-empty strings, where each string is a tag for the test.

## Property Attributes

Classes that derive from `TestCase` can define `properties` blocks which contain `matlab.unittest` framework-specific attributes to specify test content.

<code>ClassSetupParameter</code>	Property block to define parameterized testing properties for methods in the <code>TestClassSetup</code> block
<code>MethodSetupParameter</code>	Property block to define parameterized testing properties for methods in the <code>MethodSetup</code> block

`TestParameter` Property block to define parameterized testing properties for methods in the `Test` block

## Events

`VerificationFailed` Triggered upon failing verification. A `QualificationEventData` object is passed to listener callback functions.

`VerificationPassed` Triggered upon passing verification. A `QualificationEventData` object is passed to listener callback functions.

`AssertionFailed` Triggered upon failing assertion. A `QualificationEventData` object is passed to listener callback functions.

`AssertionPassed` Triggered upon passing assertion. A `QualificationEventData` object is passed to listener callback functions.

`FatalAssertionFailed` Triggered upon failing fatal assertion. A `QualificationEventData` object is passed to listener callback functions.

`FatalAssertionPassed` Triggered upon passing fatal assertion. A `QualificationEventData` object is passed to listener callback functions.

`AssumptionFailed` Triggered upon failing assumption. A `QualificationEventData` object is passed to listener callback functions.

`AssumptionPassed` Triggered upon passing assumption. A `QualificationEventData` object is passed to listener callback functions.

`ExceptionThrown` Triggered by the `TestRunner` when an exception is thrown. An `ExceptionEventData` object is passed to listener callback functions.

DiagnosticLogged

Triggered by the TestRunner upon a call to the log method. A LoggedDiagnosticEventData object is passed to the listener callback functions.

## Examples

### Create Test Case Class

Create a test case class, FigurePropertiesTest, with TestMethodSetup and TestMethodTeardown methods.

```
classdef FigurePropertiesTest < matlab.unittest.TestCase

 properties
 TestFigure
 end

 methods(TestMethodSetup)
 function createFigure(testCase)
 testCase.TestFigure = figure;
 end
 end

 methods(TestMethodTeardown)
 function closeFigure(testCase)
 close(testCase.TestFigure)
 end
 end

 methods(Test)

 function defaultCurrentPoint(testCase)

 cp = testCase.TestFigure.CurrentPoint;
 testCase.verifyEqual(cp, [0 0], ...
 'Default current point is incorrect')
 end

 function defaultCurrentObject(testCase)
 import matlab.unittest.constraints.IsEmpty

```

```
 co = testCase.TestFigure.CurrentObject;
 testCase.verifyThat(co, IsEmpty, ...
 'Default current object should be empty')
 end
end
end
```

## Introduced in R2013a

# addTeardown

**Class:** matlab.unittest.TestCase

**Package:** matlab.unittest

Dynamically add teardown routine

## Syntax

```
addTeardown(testCase,tearDownFcn)
addTeardown(testCase,tearDownFcn,arg1,...,argN)
```

## Description

`addTeardown(testCase,tearDownFcn)` adds the `tearDownFcn` function handle that defines fixture teardown code to the `testCase` instance. The teardown code is executed in the reverse order to which it is added. This is known as LIFO (or Last-In-First-Out).

`addTeardown(testCase,tearDownFcn,arg1,...,argN)` provides input arguments to the `tearDownFcn`.

## Input Arguments

### **testCase**

matlab.unittest.TestCase instance

### **Default:**

### **tearDownFcn**

Function, specified as a function handle, that defines the fixture teardown code

### **Default:**

### **arg1,...,argN**

Input arguments, 1 through N (if any), required by `tearDownFcn`, specified by any type. The argument type is specified by the function argument list.

Default:

## Examples

### Call `addTeardown` in a `TestMethodSetup` Method

```
classdef SomeTest < matlab.unittest.TestCase

 methods(TestMethodSetup)
 function createFixture(testCase)
 p = path;
 testCase.addTeardown(@path, p);
 addpath(fullfile(pwd, 'testHelpers'));
 end
 end
end
```

# applyFixture

**Class:** matlab.unittest.TestCase

**Package:** matlab.unittest

Use fixture with TestCase

## Syntax

```
applyFixture(testCase, fixture)
```

## Description

`applyFixture(testCase, fixture)` prepares the specified fixture for use with the `TestCase`. This method enables the use of a fixture within the scope of a single `Test` method or `TestCase` class. The life cycle of the fixture is tied to the `TestCase`. When the `TestCase` goes out of scope, the test framework tears down the fixture.

Call `applyFixture` within a `Test` method or `TestMethodSetup` method to use a fixture for the current test method alone. Use `applyFixture` within a `TestClassSetup` method to set up a fixture for the entire class.

## Input Arguments

### **testCase**

matlab.unittest.TestCase instance

### **fixture**

matlab.unittest.fixtures.Fixture instance

## Examples

### **Apply Fixtures to TestCase Class**

Create a temporary folder and make it the current working folder.

```
classdef applyFixtureTest < matlab.unittest.TestCase
 methods(TestMethodSetup)
 function addHelpers(testCase)
 import matlab.unittest.fixtures.TemporaryFolderFixture;
 import matlab.unittest.fixtures.CurrentFolderFixture;

 % Create a temporary folder and make it the current working
 % folder.
 tempFolder = testCase.applyFixture(TemporaryFolderFixture);
 testCase.applyFixture(CurrentFolderFixture(tempFolder.Folder));
 end
 end
end
```

Each test method can write files to the current working folder, which is the temporary folder. After each test method runs, the test framework restores the working folder to its previous state and deletes the temporary folder.

## See Also

`matlab.unittest.fixtures`

# matlab.unittest.TestCase.forInteractiveUse

**Class:** matlab.unittest.TestCase

**Package:** matlab.unittest

Create TestCase for interactive use

## Syntax

```
tc = matlab.unittest.TestCase.forInteractiveUse
tc = matlab.unittest.TestCase.forInteractiveUse(testclass)
```

## Description

`tc = matlab.unittest.TestCase.forInteractiveUse` creates a `TestCase` instance for interactive use. The `TestCase` is configured for experimentation at the command prompt. It reacts to qualification tests by printing messages to the screen for both passing and failing conditions.

`tc = matlab.unittest.TestCase.forInteractiveUse(testclass)` creates an instance of the `testclass` class for interactive use.

## Input Arguments

### **testclass**

meta.class instance that describes a `matlab.unittest.TestCase` subclass

## Examples

### **Verify Values Using Interactive TestCase**

Create a `TestCase` for interactive use.

```
import matlab.unittest.TestCase;
```

```
testCase = TestCase.forInteractiveUse;
Produce a passing verification.
testCase.verifyTrue(true, 'true should be true');
```

```
Interactive verification passed.
```

```
Produce a failing verification.
```

```
testCase.verifyTrue(false);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyTrue failed.
--> The value must evaluate to "true".
```

```
Actual Value:
 0
```

## Create Interactive TestCase for Specified Class

In a file in your working folder, create `ExampleTest.m`. This class is a subclass of `TestCase` and provides a helper verification method, `verifySameSize`.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods
 function verifySameSize(testCase, actual, expected)
 import matlab.unittest.constraints.ReturnsTrue;

 diagnostic = ['Actual and expected value sizes do not match.'...
 '\nActual size: ' num2str(size(actual)) ...
 '\nExpected size: ' num2str(size(expected))];

 testCase.verifyThat(@()isequal(size(actual),size(expected)),...
 ReturnsTrue, sprintf(diagnostic));
 end
 end
end
```

At the command prompt, create an interactive test case from the `ExampleTest` class.

```
tc = matlab.unittest.TestCase.forInteractiveUse(?ExampleTest);
```

Use the test case at the command prompt to call the `verifySameSize` method interactively.

```
tc.verifySameSize(1:10,5)
```

```
Interactive verification failed.
```

```

Test Diagnostic:

```

```
Actual and expected value sizes do not match.
```

```
Actual size: 1 10
```

```
Expected size: 1 1
```

```

Framework Diagnostic:

```

```
ReturnsTrue failed.
```

```
--> The function handle should have evaluated to "true".
```

```
--> Returned value:
```

```
 0
```

```
Actual function_handle:
```

```
@()isequal(size(actual),size(expected))
```

# getSharedTestFixtures

**Class:** matlab.unittest.TestCase

**Package:** matlab.unittest

Provide access to shared test fixtures

## Syntax

```
fixtures = getSharedTestFixtures(testCase)
fixtures = getSharedTestFixtures(testCase,fixtureClassName)
```

## Description

`fixtures = getSharedTestFixtures(testCase)` provides access to the array of all shared test fixtures for `testCase`. `getSharedTestFixtures` returns an array of fixture objects, `fixtures`. Specify shared fixtures are using the `SharedTestFixtures` attribute for the `testCase` class.

`fixtures = getSharedTestFixtures(testCase,fixtureClassName)` returns only the shared fixtures that have the class name `fixtureClassName`.

## Input Arguments

### **testCase**

matlab.unittest.TestCase instance

**Default:**

### **fixtureClassName**

Name of test fixture class, specified as a string

## Examples

### Obtain Array of All Shared Fixtures

Create the following class, `myTest`, on your MATLAB path. Two shared fixtures are used within the test method. This example assumes that the subfolder `helperFiles` exists in your working folder. Create the subfolder `helperFiles` in your working folder if it does not exist.

```
classdef (SharedTestFixtures={...
matlab.unittest.fixtures.PathFixture('helperFiles'),...
 matlab.unittest.fixtures.TemporaryFolderFixture}) ...
 myTest < matlab.unittest.TestCase
 methods(Test)
 function accessFixtures(testCase)
 myFixtures = testCase.getSharedTestFixtures
 end
 end
end
end
```

At the command prompt, run the test.

```
run(myTest);
```

```
Setting up PathFixture.
```

```
Description: Adds 'H:\Documents\doc_examples\helperFiles' to the path.
```

```

```

```
Setting up TemporaryFolderFixture.
```

```
Description: Creates a temporary folder.
```

```

```

```
Running myTest
```

```
myFixtures =
```

```
 1x2 heterogeneous Fixture (PathFixture, TemporaryFolderFixture) array with no properties
```

```
.
```

```
Done myTest
```

```

```

```
Tearing down TemporaryFolderFixture.
```

Description: Deletes the temporary folder and all its contents.

---

Tearing down PathFixture.

Description: Restores the path to its previous state.

---

## Access Shared Fixtures of Particular Class

Create the class, `mySecondTest`, on your MATLAB path.

```
classdef (SharedTestFixtures={...
 matlab.unittest.fixtures.TemporaryFolderFixture})...
 mySecondTest < matlab.unittest.TestCase
 methods(Test)
 function accessTemporaryFolderFixture(testCase)
 tempFolderFixture = testCase.getSharedTestFixtures...
 ('matlab.unittest.fixtures.TemporaryFolderFixture');
 temporaryFolder = tempFolderFixture.Folder
 end
 end
end
```

At the command prompt, run the test. The name of the temporary folder varies.

```
run(mySecondTest);
```

Setting up `TemporaryFolderFixture`.

Description: Creates a temporary folder.

---

Running `mySecondTest`

```
temporaryFolder =
```

```
C:\Temp\tpb92c9c67_02fa_4714_bfb0_b2127df0f31d
```

```
.
Done mySecondTest
```

---

Tearing down `TemporaryFolderFixture`.

Description: Deletes the temporary folder and all its contents.

---

- [Class Attributes](#)

## log

**Class:** `matlab.unittest.TestCase`

**Package:** `matlab.unittest`

Record diagnostic information

## Syntax

```
log(testCase,diagnostic)
```

```
log(testCase,v,diagnostic)
```

## Description

`log(testCase,diagnostic)` logs the supplied diagnostic. The `log` method provides a means for tests to log information during their execution. The testing framework displays logged messages only if you configure it to do so by adding an appropriate plugin, such as the `matlab.unittest.plugins.LoggingPlugin`.

`log(testCase,v,diagnostic)` logs the diagnostic at the specified verbosity level, `v`.

## Input Arguments

**testCase** — Instance of test case

`matlab.unittest.TestCase` instance

Instance of test case, specified as a `matlab.unittest.TestCase`.

**diagnostic** — Diagnostic information to display upon a failure

string | function handle | `matlab.unittest.diagnostics.Diagnostic` instance

Diagnostic information to display upon a failure, specified as a string, function handle, or `matlab.unittest.diagnostics.Diagnostic` instance.

**v** — Verbosity level

2 (default) | 1 | 3 | 4 | `matlab.unittest.Verbosity` enumeration

Verbosity level, specified as an integer value between 1 and 4 or a `matlab.unittest.Verbosity` enumeration object. The default verbosity level for diagnostic messages is `Concise`. Integer values correspond to the members of the `matlab.unittest.Verbosity` enumeration.

Numeric Representation	Corresponding Enumeration Member	Verbosity Description
1	<code>matlab.unittest.Verbosity.Terse</code>	minimal amount of information
2	<code>matlab.unittest.Verbosity.Concise</code>	typical amount of information
3	<code>matlab.unittest.Verbosity.Detail</code>	supplemental amount of information
4	<code>matlab.unittest.Verbosity.Verbose</code>	surplus of information

## Examples

### Log Diagnostic Information

Create a function-based test in a file, `sampleLogTest.m`, in your working folder.

```
function tests = sampleLogTest
tests = functiontests(localfunctions);

function svdTest(testCase)
import matlab.unittest.Verbosity

log(testCase, 'Generating matrix. ');
m = rand(1000);

log(testCase, 1, 'About to call SVD. ');
[U,S,V] = svd(m);

log(testCase, Verbosity.Terse, 'SVD finished. ');

verifyEqual(testCase, U*S*V', m, 'AbsTol', 1e-6)
```

At the command prompt, run the test.

```
results = run(sampleLogTest);
```

```
Running sampleLogTest
 [Terse] Diagnostic logged (2014-04-14T14:20:59): About to call SVD.
 [Terse] Diagnostic logged (2014-04-14T14:20:59): SVD finished.
.
Done sampleLogTest
```

---

The default runner reports the diagnostics at level 1 (**Terse**).

Create a test runner to report the diagnostics at levels 1 and 2, and rerun the test.

```
import matlab.unittest.TestRunner
import matlab.unittest.plugins.LoggingPlugin

runner = TestRunner.withNoPlugins;
p = LoggingPlugin.withVerbosity(2);
runner.addPlugin(p);

results = runner.run(sampleLogTest);

[Concise] Diagnostic logged (2014-04-14T14:28:14): Generating matrix.
 [Terse] Diagnostic logged (2014-04-14T14:28:14): About to call SVD.
 [Terse] Diagnostic logged (2014-04-14T14:28:15): SVD finished.
```

## run

**Class:** matlab.unittest.TestCase

**Package:** matlab.unittest

Run TestCase test

## Syntax

```
result = run(testCase)
result = run(testCase, testMethod)
```

## Description

`result = run(testCase)` uses `testCase` as a prototype to run a `TestSuite` array created from all test methods in the class defining `testCase`. This suite is run using a `TestRunner` object configured for text output.

`result = run(testCase, testMethod)` uses `testCase` as a prototype to run a `TestSuite` array created from `testMethod`. This test is run using a `TestRunner` object configured for text output.

This is a convenience method to allow interactive experimentation of `TestCase` classes in MATLAB, yet running the tests contained in them using a supported `TestRunner` object.

## Input Arguments

### **testCase**

matlab.unittest.TestCase instance

### **Default:**

### **testMethod**

Name of desired test method, specified as one of the following:

- string
- `meta.method` instance

The method must correspond to a valid `Test` method of the `testCase` instance.

**Default:**

## Output Arguments

### result

A `matlab.unittest.TestResult` object containing the result of the test run.

## Examples

### Run Test Directly from Test Case

Add the `FigurePropertiesTest.m` test case file to a folder on your MATLAB path.

```
classdef FigurePropertiesTest < matlab.unittest.TestCase
```

```
 properties
 TestFigure
 end

 methods(TestMethodSetup)
 function createFigure(testCase)
 % comment
 testCase.TestFigure = figure;
 end
 end

 methods(TestMethodTeardown)
 function closeFigure(testCase)
 close(testCase.TestFigure)
 end
 end

 methods(Test)
```

```
function defaultCurrentPoint(testCase)
 cp = testCase.TestFigure.CurrentPoint;
 testCase.verifyEqual(cp, [0 0], ...
 'Default current point is incorrect')
end

function defaultCurrentObject(testCase)
 import matlab.unittest.constraints.IsEmpty

 co = testCase.TestFigure.CurrentObject;
 testCase.verifyThat(co, IsEmpty, ...
 'Default current object should be empty')
end

end

end
```

Create a testcase object.

```
tc = FigurePropertiesTest;
```

Run the tests.

```
tc.run;
```

```
Running FigurePropertiesTest
```

```
..
```

```
Done FigurePropertiesTest
```

---

All tests passed.

[matlab.unittest.TestSuite.run](#) | [matlab.unittest.TestRunner.run](#)

## matlab.unittest.TestResult class

**Package:** matlab.unittest

Result of running test suite

### Description

The `matlab.unittest.TestResult` class holds the information describing the result of running a test suite using the `matlab.unittest` framework. The results include information describing whether the test passed, failed, or ran to completion, as well as the duration of each test.

### Construction

`TestResult` arrays are created and returned by the test runner, and are of the same size as the suite which was run.

### Properties

#### Duration

Time elapsed running test.

The `Duration` property indicates the amount of time taken to run a particular test, including the time taken setting up and tearing down any test fixtures.

Fixture setup time is accounted for in the duration of the first test suite array element that uses the fixture. Fixture teardown time is accounted for in the duration of the last test suite array element that uses the fixture.

The total run time for a suite of tests exceeds the sum of the durations for all the elements of the suite because the `Duration` property does not include all the overhead of the `TestRunner` object, nor any of the time consumed by test runner plugins.

#### Failed

Logical value showing if test failed.

A **TRUE Failed** property indicates some form of test failure. When **Failed** is **FALSE**, then no failing conditions were encountered. A failing result can occur with a failure condition either in a test or in setting up and tearing down test fixtures. Failures can occur due to the following:

- Verification failures
- Assertion failures
- Uncaught MExceptions

Fatal assertions are also failing conditions, but in the event of a fatal assertion failure, the entire framework aborts and a **TestResult** object is never produced.

### **Incomplete**

Logical value showing if test did not run to completion.

A **TRUE Incomplete** property indicates a test did not run to completion. When it is **FALSE**, then no conditions were encountered that prevented the test from completing. In other words, when **FALSE** there were no stack disruptions out of the running test content. An incomplete result can occur with a stack disruption in either a test or when setting up and tearing down test fixtures. Incomplete tests can occur due to the following:

- Assertion failures
- Tests filtered through assumption
- Uncaught MExceptions

Fatal assertions are also conditions that prevent the completion of tests, but in the event of a fatal assertion failure the entire framework aborts and a **TestResult** object is never produced.

### **Name**

The name of the **TestSuite** object for the result.

The **Name** property is a string that holds the name of the test corresponding to this result.

### **Passed**

Logical value showing if the test passed.

When the **Passed** property is **TRUE**, then the test completed as expected without any failure. When it is **FALSE**, then the test did not run to completion and/or encountered a failure condition.

## Tips

- Create a table from the `TestResult` object for access to `table` functionality such as sorting rows, displaying a summary, and writing the table to a file. For example,

```
rt = table(results);
```

## See Also

`table` | `TestRunner` | `TestSuite`

## Related Examples

- “Analyze Failed Test Results”

## More About

- `Property Attributes`

# matlab.unittest.TestRunner class

**Package:** matlab.unittest

Class for running tests in matlab.unittest framework

## Description

The `matlab.unittest.TestRunner` class is the fundamental API used to run a suite of tests in the `matlab.unittest` framework. It runs and operates on `TestSuite` arrays. Use this class to customize running tests.

The `TestRunner` class is a sealed class; you cannot derive classes from the `TestRunner` class.

## Construction

To create a simple, silent `TestRunner` object, call the static `withNoPlugins` method.

```
runner = matlab.unittest.TestRunner.withNoPlugins
```

To create a `TestRunner` object to run tests from the MATLAB Command Window, call the static `withTextOutput` method.

```
runner = matlab.unittest.TestRunner.withTextOutput
```

To create a customized `TestRunner` object, call the `addPlugin` method.

```
runner = TestRunner.withNoPlugins;
runner.addPlugin(SomePlugin())
```

## Properties

### **PrebuiltFixtures** — Fixtures set up outside the test runner

scalar `Fixture` instance | row vector of `Fixture` instances

Fixtures that are set up outside the test runner, specified as a scalar or row vector of `matlab.unittest.fixture.Fixture` instances. Use this property to specify that the

environmental configuration is performed manually instead of automatically during fixture setup and teardown.

The test runner considers these fixtures as already set up and never attempts to set up or tear down any fixtures specified by the `PrebuiltFixtures` property. If a test suite requires a shared test fixture and that test fixture is specified as a prebuilt fixture, the test runner does not perform set up or tear down actions.

---

**Note:** The test runner uses a prebuilt fixture only if it is specified by the `PrebuiltFixtures` property and is listed as a `SharedTestFixture` in the test class definition. The test runner does not use a prebuilt fixture if the fixture is registered using the `TestCase.applyFixture` method.

---

## Methods

<code>addPlugin</code>	Add plugin to <code>TestRunner</code> object
<code>run</code>	Run all tests in <code>TestSuite</code> array
<code>runInParallel</code>	Run all tests in <code>TestSuite</code> array in parallel
<code>withNoPlugins</code>	Create simplest runner possible
<code>withTextOutput</code>	Create <code>TestRunner</code> object for command window output

## Examples

### Create `TestRunner` Object Configured for Text Output

Add `matlab.unittest` classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a `TestSuite` array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create the `TestRunner` object and run the suite.

```
runner = TestRunner.withTextOutput;
result = run(runner,suite);
```

### Include Prebuilt Fixture

This example uses a shared test fixture and then specifies the fixture as prebuilt. The test runner does not set up and tear down the prebuilt fixture. Since the test assumes that the fixture exists, you must manually perform the setup work that the fixture ordinarily performs.

Create a test class in a file in your working folder. The test class uses a `PathFixture` as a shared test fixture. This example assumes that the subfolder, `helperFiles`, exists in your working folder.

```
classdef (SharedTestFixtures={ ...
 matlab.unittest.fixtures.PathFixture('helperFiles')}) ...
 SampleTest < matlab.unittest.TestCase
 methods(Test)
 function test1(testCase)
 f = testCase.getSharedTestFixtures;

 import matlab.unittest.constraints.ContainsSubstring
 testCase.assertThat(path,ContainsSubstring(f.Folder))
 end
 end
end
```

Create a test suite and test runner at the command prompt.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;

suite = TestSuite.fromClass(?SampleTest);
runner = TestRunner.withTextOutput;
```

Run the tests using the shared test fixture. In this case, the fixture is not prebuilt.

```
runner.run(suite);
```

```
Setting up PathFixture
Done setting up PathFixture: Added 'C:\Work\helperFiles' to the path.
```

```
Running SampleTest
```

```
.
Done SampleTest
```

```

Tearing down PathFixture
Done tearing down PathFixture: Restored the path to its original state.

```

The test runner sets up and tears down the shared test fixture.

Create an instance of the fixture and add it to the test runner.

```
f = matlab.unittest.fixtures.PathFixture('helperFiles');
runner.PrebuiltFixtures = f;
```

Manually add the 'helperFiles' folder to your path. The `PathFixture` adds the specified folder to your path, and the tests rely on this setup action. However, since the fixture is defined as prebuilt, the test runner does not perform set up or tear down actions, and you must perform them manually. In this case, if you do not manually add it to your path, the test fails.

```
p = fullfile(pwd, 'helperFiles');
oldPath = addpath(p);
```

Run the tests.

```
runner.run(suite);
```

```
Running SampleTest
.br/>Done SampleTest
```

```

The test runner assumes that the fixture is prebuilt and does not set it up or tear it down.
```

Manually reset your path.

```
path(oldPath)
```

- “Write Tests Using Shared Fixtures”

## addPlugin

**Class:** matlab.unittest.TestRunner

**Package:** matlab.unittest

Add plugin to TestRunner object

### Syntax

```
addPlugin(runner,plugin)
```

### Description

addPlugin(runner,plugin) adds plugin to runner.

### Input Arguments

**runner**

matlab.unittest.TestRunner object.

**Default:**

**plugin**

Mechanism provided to customize the manner in which a TestSuite array is run, specified as a TestRunnerPlugin object.

**Default:**

### Examples

#### Run Test with Custom Plugin

Add matlab.unittest classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a TestSuite array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create a TestRunner object.

```
runner = TestRunner.withNoPlugins;
```

Add a custom plugin.

```
import matlab.unittest.plugins.DiagnosticsValidationPlugin;
runner.addPlugin(DiagnosticsValidationPlugin);
```

Run the test.

```
result = run(runner,suite);
```

## run

**Class:** matlab.unittest.TestRunner

**Package:** matlab.unittest

Run all tests in `TestSuite` array

## Syntax

```
result = run(runner,suite)
```

## Description

`result = run(runner,suite)` runs the `TestSuite` array defined by `suite` using the `TestRunner` object provided in `runner`, and returns the result in `result`.

This method runs all of the appropriate methods of the `TestCase` class to set up fixtures and run test content. It handles errors and qualification failures and records the information in `result`.

## Input Arguments

### runner

matlab.unittest.TestRunner object.

### Default:

### suite

Set of tests, specified as a `matlab.unittest.TestSuite` array.

## Output Arguments

### result

A `matlab.unittest.TestResult` object containing the result of the test run. `result` is the same size as `suite` and each element is the result of the corresponding element in `suite`.

## Examples

### Run All Tests in a Package

Add `matlab.unittest` classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a test suite, and a test runner that displays text.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
runner = TestRunner.withTextOutput;
```

Run the test suite.

```
result = runner.run(suite)
```

### See Also

`matlab.unittest.TestSuite.run` | `matlab.unittest.TestCase.run`

## runInParallel

**Class:** matlab.unittest.TestRunner

**Package:** matlab.unittest

Run all tests in `TestSuite` array in parallel

### Syntax

```
result = runInParallel(runner,suite)
```

### Description

`result = runInParallel(runner,suite)` runs all tests in the `TestSuite` array in parallel and returns the results in a `TestResult` object. The `runInParallel` method divides `suite` into separate groups and uses `runner` to run each group on the current parallel pool.

---

**Note:** The `runInParallel` method requires the Parallel Computing Toolbox. The testing framework might vary the order and number of groups or which tests it includes in each group.

---

When you select a test suite to run in parallel, consider possible resource contention. For example, if your test fixtures access global resources, such as a shared file on the same network, the parallel sessions could conflict with each other. In such cases, consider using a prebuilt shared test fixture.

### Input Arguments

**runner** — Test runner for parallel test groups

matlab.unittest.TestRunner instance

Test runner for parallel test groups, specified as a `matlab.unittest.TestRunner` instance.

Consider your test runner configuration before running tests in parallel. Since the `runInParallel` method runs separate groups of tests on different workers, some plugins, such as `StopOnFailuresPlugin` or `CodeCoveragePlugin`, are not well suited for parallelization. The framework does not support running parallelized tests using a test runner with a custom plugin.

### **suite** — Set of tests to run in parallel

`matlab.unittest.Test` array

Set of tests to run in parallel, specified as a `matlab.unittest.Test` array.

## Examples

### Run Tests in Parallel

Create the following parameterized test in a file in your current working folder.

```
classdef TestRand < matlab.unittest.TestCase
 properties (TestParameter)
 dim1 = createDimensionSizes;
 dim2 = createDimensionSizes;
 dim3 = createDimensionSizes;
 type = {'single','double'};
 end

 methods (Test)
 function testRepeatable(testCase,dim1,dim2,dim3)
 state = rng;
 firstRun = rand(dim1,dim2,dim3);
 rng(state)
 secondRun = rand(dim1,dim2,dim3);
 testCase.verifyEqual(firstRun,secondRun);
 end
 function testClass(testCase,dim1,dim2,type)
 testCase.verifyClass(rand(dim1,dim2,type),type)
 end
 end
end

function sizes = createDimensionSizes
% Create logarithmicly spaced sizes up to 100
sizes = num2cell(round(logspace(0,2,10)));
end
```

At the command prompt, create a suite from `TestRand.m` and a test runner that displays text in the Command Window.

```
suite = matlab.unittest.TestSuite.fromClass(?TestRand);
runner = matlab.unittest.TestRunner.withTextOutput();

# matlab.unittest.TestRunner.withNoPlugins

**Class:** matlab.unittest.TestRunner

**Package:** matlab.unittest

Create simplest runner possible

## Syntax

```
runner = matlab.unittest.TestRunner.withNoPlugins
```

## Description

`runner = matlab.unittest.TestRunner.withNoPlugins` creates a `TestRunner` that is guaranteed to have no plugins installed and returns it in `runner`. It is the method one can use to create the simplest runner possible without violating the guarantees a test writer has when writing `TestCase` classes. This runner is a silent runner, meaning that regardless of passing or failing tests, this runner produces no command window output, although the results returned after running a test suite are accurate.

This method can also be used when it is desirable to have complete control over which plugins are installed and in what order. It is the only method guaranteed to produce the minimal `TestRunner` with no plugins, so one can create it and add additional plugins as desired.

## Output Arguments

**runner**

matlab.unittest.TestRunner object.

**Default:**

## Attributes

Static

true

To learn about attributes of methods, see [Method Attributes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

### Create a Silent TestRunner Object with no Plugins

Add `matlab.unittest` classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a `TestSuite` array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create a `TestRunner` object.

```
runner = TestRunner.withNoPlugins;
```

```
% Run the suite silently
result = run(runner,suite)
```

### Control Plugins

Using the `TestRunner` object created in the previous example, control which plugins are installed and in what order they are installed.

Add `matlab.unittest` class to the current import list.

```
import matlab.unittest.plugins;
```

Add specific plugins.

```
runner.addPlugin(DiagnosticsValidationPlugin);
runner.addPlugin(TestRunProgressPlugin.withVerbosity(2));
```

Rerun the tests.

```
result = run(runner,suite)
```

# matlab.unittest.TestRunner.withTextOutput

**Class:** matlab.unittest.TestRunner

**Package:** matlab.unittest

Create `TestRunner` object for command window output

## Syntax

```
runner = matlab.unittest.TestRunner.withTextOutput
runner = matlab.unittest.TestRunner.withTextOutput('Verbosity',v)
```

## Description

`runner = matlab.unittest.TestRunner.withTextOutput` creates a `TestRunner` object that is configured for running tests from the MATLAB Command Window and returns it in `runner`. The output produced includes test progress as well as diagnostics in the event of test failures.

`runner = matlab.unittest.TestRunner.withTextOutput('Verbosity',v)` reacts to messages logged at or below the specified verbosity level and controls the level of detail about the test run that is displayed in the Command Window.

## Input Arguments

**v** — Verbosity levels supported by test runner

1 | 2 | 3 | 4 | `matlab.unittest.Verbosity` enumeration

Verbosity levels supported by the test runner, specified as an integer value between 1 and 4 or a `matlab.unittest.Verbosity` enumeration object. The runner reacts to diagnostics that are logged at this level and lower. Integer values correspond to the members of the `matlab.unittest.Verbosity` enumeration.

Numeric Representation	Corresponding Enumeration Object	Verbosity Description
1	<code>matlab.unittest.Verbosity.Terse</code>	Minimal amount of information

Numeric Representation	Corresponding Enumeration Object	Verbosity Description
2	<code>matlab.unittest.Verbosity.Concise</code>	Typical amount of information
3	<code>matlab.unittest.Verbosity.Detailed</code>	Supplemental amount of information
4	<code>matlab.unittest.Verbosity.Verbose</code>	Surplus of information

## Output Arguments

### **runner**

`matlab.unittest.TestRunner` object.

**Default:**

## Attributes

Static true

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

## Examples

### **Display Test Results in Command Window**

Add `matlab.unittest` classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a `TestSuite` array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create a `TestRunner` object that produced output to the Command Window.

```
runner = TestRunner.withTextOutput;
```

```
% Run the suite
result = run(runner,suite)
```

## Specify Output Verbosity

Create the follow class In a file in your current working folder, ExampleLogTest.m.

```
classdef ExampleLogTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase)
 log(testCase,matlab.unittest.Verbosity.Detailed,'Starting Test')
 log(testCase,'Testing 5==5')
 testCase.verifyEqual(5,5)
 log(testCase,matlab.unittest.Verbosity.Verbose,'Test Complete')
 end
 end
end
```

At the command prompt, run the test.

```
result = run(ExampleLogTest);
```

```
Running ExampleLogTest
.
Done ExampleLogTest
```

Create a test runner to display logged messages at verbosity level 4 and lower, and then run the test.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
suite = TestSuite.fromClass(?ExampleLogTest);
runner = TestRunner.withTextOutput('Verbosity',4);

results = runner.run(suite);
```

```
Running ExampleLogTest
Setting up ExampleLogTest
Done setting up ExampleLogTest in 0 seconds
Running ExampleLogTest/testOne
Evaluating Test: testOne
[Detailed] Diagnostic logged (2014-04-18T14:28:19): Starting Test
```

```
[Concise] Diagnostic logged (2014-04-18T14:28:19): Testing 5==5
[Verbose] Diagnostic logged (2014-04-18T14:28:20): Test Complete
 Done ExampleLogTest/testOne in 0.21106 seconds
 Tearing down ExampleLogTest
 Done tearing down ExampleLogTest in 0 seconds
Done ExampleLogTest in 0.21106 seconds
```

---

## matlab.unittest.TestSuite class

**Package:** matlab.unittest

Class for grouping tests to run

### Description

The `matlab.unittest.TestSuite` class is the fundamental interface used to group and run a set of tests in the unit test framework. The `matlab.unittest.TestRunner` object can only run arrays of `TestSuite` objects.

### Construction

`TestSuite` arrays are created using static methods of the `TestSuite` class. These methods may return subclasses of the `TestSuite` class depending on the method call and context.

### Methods

<code>fromClass</code>	Create suite from <code>TestCase</code> class
<code>fromFile</code>	Create <code>TestSuite</code> array from test file
<code>fromFolder</code>	Create <code>TestSuite</code> array from all tests in folder
<code>fromMethod</code>	Create <code>TestSuite</code> array from single test method
<code>fromName</code>	Create <code>Test</code> object from name of test element
<code>fromPackage</code>	Create <code>TestSuite</code> array from all tests in package
<code>run</code>	Run <code>TestSuite</code> array using <code>TestRunner</code> object configured for text output
<code>selectIf</code>	Select test suite elements that satisfy conditions

## Examples

### Create Test Suite of Every Type of Test Set

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;
```

Create test suites using each method.

```
fileSuite = TestSuite.fromFile('SomeTestFile.m');
folderSuite = TestSuite.fromFolder(pwd);
packageSuite = TestSuite.fromPackage('mypackage.subpackage');
classSuite = TestSuite.fromClass(?mypackage.MyTestClass);
methodSuite = TestSuite.fromMethod(?SomeTestClass, 'testMethod');
```

Concatenate the suites.

```
largeSuite = [fileSuite, folderSuite, packageSuite, classSuite, methodSuite];
```

Run the full suite.

```
result = run(largeSuite)
```

### See Also

Test | TestResult | TestRunner

## matlab.unittest.TestSuite.fromClass

**Class:** matlab.unittest.TestSuite

**Package:** matlab.unittest

Create suite from `TestCase` class

### Syntax

```
suite = matlab.unittest.TestSuite.fromClass(testClass)
suite = matlab.unittest.TestSuite.fromClass(testClass,s)
suite = matlab.unittest.TestSuite.fromClass(____,Name,Value)
```

### Description

`suite = matlab.unittest.TestSuite.fromClass(testClass)` creates a `TestSuite` array from all of the `Test` methods contained in `testClass` and returns that array in `suite`.

`suite = matlab.unittest.TestSuite.fromClass(testClass,s)` creates a `TestSuite` array from all of the `Test` methods contained in `testClass` that satisfy the conditions specified by the selector, `s`.

`suite = matlab.unittest.TestSuite.fromClass( ____,Name,Value)` creates a `TestSuite` array with additional options specified by one or more `Name,Value` pair arguments. You can use this syntax with any of the input arguments of the previous syntaxes.

### Tips

- `testClass` must be on the MATLAB path when using this method to create `suite`, as well as when `suite` is run.

## Input Arguments

### **testClass**

Class containing test methods, specified as a `meta.class` instance. Use the `?` operator to create a `meta.class` instance. `testClass` must derive from `matlab.unittest.TestCase`.

### **s**

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

## Name-Value Pair Arguments

### **'Name'**

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'ParameterProperty'**

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'ParameterName'**

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'BaseFolder'**

String indicating the name of the folder that contains the file defining the test class or function. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one

character. For test classes defined in packages, the base folder is the parent of the top-level package folder.

## 'Tag'

String indicating the name of the tag applied to the test suite element. Use the wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match exactly one character.

## Output Arguments

### **suite**

Set of tests, specified as a `matlab.unittest.Test` array.

## Attributes

Static true

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

## Examples

### **Run Tests in a Package Class**

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromClass(?mypackage.MyTestClass);
result = run(suite)
```

### **Run Tests in a Class Without a Package**

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;
```

```
suite = TestSuite.fromClass(?MyTestClass);
result = run(suite)
```

### Create Suite of Test Elements Using Selector

In your working folder, create the following `testZeros.m` test file. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
 type = {'single', 'double', 'uint16'};
 outSize = struct('s2d', [3 3], 's3d', [2 5 4]);
 end

 methods (Test)
 function testClass(testCase, type, outSize)
 testCase.verifyClass(zeros(outSize, type), type);
 end

 function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
 end

 function testDefaultClass(testCase)
 testCase.verifyClass(zeros, 'double');
 end

 function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
 end

 function testDefaultValue(testCase)
 testCase.verifyEqual(zeros, 0);
 end
 end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from the test elements that tests the 'double' data type.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasParameter;

suite = TestSuite.fromClass(?testZeros, ...
```

```
 HasParameter('Property','type','Name','double'));
{suite.Name}'

ans =

 'testZeros/testClass(type=double,outSize=s2d)'
 'testZeros/testClass(type=double,outSize=s3d)'
```

## Create Suite of Test Elements Using Name-Value Arguments

Create the `testZeros.m` class from the previous example.

At the command prompt, create a test suite from the test elements that tests the 'double' data type.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromClass(?testZeros, ...
 'ParameterProperty','type', 'ParameterName','double');
{suite.Name}'

ans =

 'testZeros/testClass(type=double,outSize=s2d)'
 'testZeros/testClass(type=double,outSize=s3d)'
```

## See Also

[fromMethod](#) | [fromPackage](#) | [matlab.unittest.selectors](#) | [TestRunner](#)

**Introduced in R2013a**

# matlab.unittest.TestSuite.fromFile

**Class:** matlab.unittest.TestSuite

**Package:** matlab.unittest

Create `TestSuite` array from test file

## Syntax

```
suite = matlab.unittest.TestSuite.fromFile(file)
suite = matlab.unittest.TestSuite.fromFile(file,s)
suite = matlab.unittest.TestSuite.fromFile(___,Name,Value)
```

## Description

`suite = matlab.unittest.TestSuite.fromFile(file)` creates a `TestSuite` array from all of the tests in `file`. When the test suite is run, MATLAB changes the current folder to the folder that defines the test content, and adds it to the path for the duration of the test run.

`suite = matlab.unittest.TestSuite.fromFile(file,s)` creates a `TestSuite` array from all of the tests in `file` that satisfy the conditions specified by the selector, `s`.

`suite = matlab.unittest.TestSuite.fromFile( ___,Name,Value)` creates a `TestSuite` array with additional options specified by one or more `Name,Value` pair arguments. You can use this syntax with any of the input arguments of the previous syntaxes.

## Input Arguments

### **file**

Absolute or relative path to the test file, specified as a string.

### **s**

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

### 'Name'

String indicating the name of the suite element. To include a test element in the suite, the **Name** property of the test element must match the specified name. Use the wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match to exactly one character.

### 'ParameterProperty'

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match to exactly one character.

### 'ParameterName'

String indicating the name of a parameter used by the test suite element. Use the wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match to exactly one character.

### 'BaseFolder'

String indicating the name of the folder that contains the file defining the tests. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use the wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match to exactly one character. For tests defined in packages, the base folder is the parent of the top-level package folder.

### 'Tag'

String indicating the name of the tag applied to the test suite element. Use the wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match exactly one character.

## Output Arguments

### suite

Set of tests, specified as a `matlab.unittest.Test` array.

## Attributes

Static true

To learn about attributes of methods, see [Method Attributes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

### Run Tests in Class File

Function for unit testing:

```
function res = add5(x)
% ADD5 Increment input by 5.
if ~isa(x,'numeric')
 error('add5:InputMustBeNumeric','Input must be numeric.')
end
res = x + 5;
end
```

TestCase class containing test methods:

```
classdef Add5Test < matlab.unittest.TestCase
 methods (Test)
 function testDoubleOut(testCase)
 actOutput = add5(1);
 testCase.verifyClass(actOutput,'double')
 end
 function testNonNumericInput(testCase)
 testCase.verifyError(@()add5('0'),'add5:InputMustBeNumeric')
 end
 end
end
```

end

Create a test suite from the `Add5Test` class file.

```
suite = matlab.unittest.TestSuite.fromFile('Add5Test.m')
```

```
result = run(suite);
```

```
Running Add5Test
```

```
..
```

```
Done Add5Test
```

---

### Create Suite of Test Elements Using Selector

In your working folder, create `testZeros.m`. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
 type = {'single', 'double', 'uint16'};
 outSize = struct('s2d', [3 3], 's3d', [2 5 4]);
 end

 methods (Test)
 function testClass(testCase, type, outSize)
 testCase.verifyClass(zeros(outSize, type), type);
 end

 function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
 end

 function testDefaultClass(testCase)
 testCase.verifyClass(zeros, 'double');
 end

 function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
 end

 function testDefaultValue(testCase)
 testCase.verifyEqual(zeros, 0);
 end
 end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from all parameterized test methods in `testZeros.m` using the `HasParameter` selector.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasParameter;

suite = TestSuite.fromFile('testZeros.m', HasParameter)
```

```
suite =
```

```
 1x8 Test array with properties:
```

```
 Name
 Parameterization
 SharedTestFixtures
 Tags
```

```
Tests Include:
```

```
 5 Unique Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.
```

Create a test suite from only the test elements from the `testSize` method using the `HasName` selector with the `StartsWithSubstring` constraint.

```
import matlab.unittest.selectors.HasName;
import matlab.unittest.constraints.StartsWithSubstring;

suite = TestSuite.fromFile('testZeros.m',...
 HasName(StartsWithSubstring('testZeros/testSize')));
{suite.Name}'
```

```
ans =
```

```
 'testZeros/testSize(outSize=s2d)'
 'testZeros/testSize(outSize=s3d)'
```

The test suite contains the two parameterized tests from the `testSize` method.

### Create Suite of Test Elements Using Name-Value Arguments

Create the `testZeros.m` class from the previous example.

At the command prompt, create a test suite from all test methods in `testZeros.m` that have a name starting with `'testZeros/testSize'`. This test suite contains parameterized tests from the `testSize` method.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromFile('testZeros.m', 'Name', 'testZeros/testSize*');
{suite.Name}

ans =

 'testZeros/testSize(outSize=s2d)'
 'testZeros/testSize(outSize=s3d)'
```

To ensure that a test suite is comprised of test elements associated with one particular test method, use the `fromMethod` method of `TestSuite`.

At the command prompt, create a test suite from all test methods in `testZeros.m` that have a name ending in `'Size'`.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromFile('testZeros.m', 'Name', '*Size');
{suite.Name}

ans =

 'testZeros/testDefaultSize'
```

Note that elements from the `testSize` method are not included in the test suite. The name of these elements contains information about the parameterization, and therefore it does not end with `'Size'`.

Create a test suite of all tests that use the parameter name `'double'`.

```
suite = TestSuite.fromFile('testZeros.m', 'ParameterName', 'double');
{suite.Name}

ans =

 'testZeros/testClass(type=double,outSize=s2d)'
 'testZeros/testClass(type=double,outSize=s3d)'
```

To construct the same test suite using selectors, use `suite = TestSuite.fromFile('testZeros.m', HasParameter('Name','double'))`.

## See Also

`fromFolder` | `matlab.unittest.selectors` | `TestRunner`

**Introduced in R2013a**

# matlab.unittest.TestSuite.fromFolder

**Class:** matlab.unittest.TestSuite

**Package:** matlab.unittest

Create `TestSuite` array from all tests in folder

## Syntax

```
suite = matlab.unittest.TestSuite.fromFolder(folder)
suite = matlab.unittest.TestSuite.fromFolder(folder,s)
suite = matlab.unittest.TestSuite.fromFolder(___,Name,Value)
```

## Description

`suite = matlab.unittest.TestSuite.fromFolder(folder)` creates a `TestSuite` array from all of the `Test` methods of all concrete `TestCase` classes contained in `folder` and returns that array in `suite`. If tests are function-based or script-based, a `Test` file is included in the `TestSuite` array if it follows the naming convention of starting or ending in the word ‘test’, which is case-insensitive. Class-based tests do not need to follow this naming convention. The method is not recursive, returning only those tests directly in the specified folder.

When the test suite is run, MATLAB changes the current folder to the folder that defines the test content, and adds it to the path for the duration of the test run.

`suite = matlab.unittest.TestSuite.fromFolder(folder,s)` creates a `TestSuite` array from all of the `Test` methods contained in `folder` that satisfy the conditions specified by the selector, `s`.

`suite = matlab.unittest.TestSuite.fromFolder( ___,Name,Value)` creates a `TestSuite` array with additional options specified by one or more `Name,Value` pair arguments. You can use this syntax with any of the input arguments of the previous syntaxes.

## Input Arguments

### **folder**

Folder containing tests, specified as a string. `folder` can be either an absolute or relative path to the desired folder.

### **s**

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

## Name-Value Pair Arguments

### **'IncludingSubfolders'**

Indicator for whether to include tests from any `folder` subfolders, excluding package, class, and private folders, specified as `false` or `true` (logical 0 or 1). This property is `false` by default. You can specify it as `true` during construction.

### **'Name'**

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'ParameterProperty'**

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'ParameterName'**

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'BaseFolder'**

String indicating the name of the folder that contains the file defining the tests. For a test element to be included in the suite, the test element must be contained in the

specified base folder. Use the wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match to exactly one character. For tests defined in packages, the base folder is the parent of the top-level package folder.

### 'Tag'

String indicating the name of the tag applied to the test suite element. Use the wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match exactly one character.

## Output Arguments

### **suite**

Set of tests, specified as a `matlab.unittest.Test` array.

## Attributes

Static

true

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

## Examples

### **Run Tests in Current Folder**

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromFolder(pwd);
result = run(suite);
```

### **Run Tests in Subfolders**

```
suite = TestSuite.fromFolder(pwd, 'IncludingSubfolders', true);
```

```
result = run(suite);
```

### Create Suite of Test Elements Using Selector

In your working folder, create a new folder, `myTests`. In that folder, create the following `testZeros.m` test file. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
 type = {'single', 'double', 'uint16'};
 outSize = struct('s2d', [3 3], 's3d', [2 5 4]);
 end

 methods (Test)
 function testClass(testCase, type, outSize)
 testCase.verifyClass(zeros(outSize, type), type);
 end

 function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
 end

 function testDefaultClass(testCase)
 testCase.verifyClass(zeros, 'double');
 end
 function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
 end

 function testDefaultValue(testCase)
 testCase.verifyEqual(zeros, 0);
 end
 end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from all parameterized tests that use the parameter name `'double'`.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasParameter;

suite = TestSuite.fromFolder('myTests', HasParameter('Name', 'double'));
{suite.Name}'
```

```
ans =

 'testZeros/testClass(type=double,outSize=s2d)'
 'testZeros/testClass(type=double,outSize=s3d)'
```

## Create Suite of Test Elements Using Name-Value Arguments

Create the `myTests` folder and `testZeros.m` class from the previous example.

Create a test suite of all tests that use the parameter name `'double'`.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromFolder('myTests', 'ParameterName', 'double');
{suite.Name}'

ans =

 'testZeros/testClass(type=double,outSize=s2d)'
 'testZeros/testClass(type=double,outSize=s3d)'
```

## See Also

`fromFile` | `matlab.unittest.selectors` | `TestRunner`

**Introduced in R2013a**

# matlab.unittest.TestSuite.fromMethod

**Class:** matlab.unittest.TestSuite

**Package:** matlab.unittest

Create `TestSuite` array from single test method

## Syntax

```
suite = matlab.unittest.TestSuite.fromMethod(testClass,testMethod)
suite = matlab.unittest.TestSuite.fromMethod(testClass,testMethod,s)
suite = matlab.unittest.TestSuite.fromMethod(____,Name,Value)
```

## Description

`suite = matlab.unittest.TestSuite.fromMethod(testClass,testMethod)` creates a `TestSuite` array from the test class described by `testClass` and the test method described by `testMethod` and returns it in `suite`.

`suite = matlab.unittest.TestSuite.fromMethod(testClass,testMethod,s)` creates a `TestSuite` array from all of the `Test` methods contained in `testMethod` that satisfy the conditions specified by the selector, `s`.

`suite = matlab.unittest.TestSuite.fromMethod( ____,Name,Value)` creates a `TestSuite` array with additional options specified by one or more `Name,Value` pair arguments. You can use this syntax with any of the input arguments of the previous syntaxes.

## Tips

- `testClass` must be on the MATLAB path when using this method to create `suite`, as well as when `suite` is run.

## Input Arguments

### **testClass**

Class describing the test methods, specified as a `meta.class` instance which must derive from `matlab.unittest.TestCase`.

### **testMethod**

Test method, specified by either the `meta.method` instance or the name as a string. The method must be defined with a `Test` method attribute.

### **s**

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

## Name-Value Pair Arguments

### **'Name'**

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'ParameterProperty'**

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'ParameterName'**

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'BaseFolder'**

String indicating the name of the folder that contains the file defining the test class or function. For a test element to be included in the suite, the test element must be

contained in the specified base folder. Use the wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match to exactly one character. For test classes defined in packages, the base folder is the parent of the top-level package folder.

### 'Tag'

String indicating the name of the tag applied to the test suite element. Use the wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match exactly one character.

## Output Arguments

### suite

Set of tests, specified as a `matlab.unittest.Test` array.

## Attributes

Static true

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

## Examples

### Run a Single Test Method

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;

cls = ?mypackage.MyTestClass;

% Create the suite using the method name
suite = TestSuite.fromMethod(cls, 'testMethod');
result = run(suite)
```

```
% Create the suite using the meta.method instance
metaMethod = findobj(cls.MethodList, 'Name', 'testMethod');
suite = TestSuite.fromMethod(cls, metaMethod);
result = run(suite)
```

## Create Suite of Test Elements Using Selector

In your working folder, create the following `testZeros.m` test file. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
 type = {'single', 'double', 'uint16'};
 outSize = struct('s2d', [3 3], 's3d', [2 5 4]);
 end

 methods (Test)
 function testClass(testCase, type, outSize)
 testCase.verifyClass(zeros(outSize, type), type);
 end

 function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
 end

 function testDefaultClass(testCase)
 testCase.verifyClass(zeros, 'double');
 end

 function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
 end

 function testDefaultValue(testCase)
 testCase.verifyEqual(zeros, 0);
 end
 end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from all parameterized tests from the `testClass` method that use the parameter name `'single'`.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasParameter;
```

```
suite = TestSuite.fromMethod(?testZeros, 'testClass', ...
 HasParameter('Name', 'single'));
{suite.Name}'

ans =

 'testZeros/testClass(type=single,outSize=s2d)'
 'testZeros/testClass(type=single,outSize=s3d)'
```

### Create Suite of Test Elements Using Name-Value Arguments

Create the `testZeros.m` class from the previous example.

At the command prompt, create a test suite from all parameterized tests from the `testClass` method that use the parameter name `'single'`.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromMethod(?testZeros, 'testClass', ...
 'ParameterName', 'single');
{suite.Name}'

ans =

 'testZeros/testClass(type=single,outSize=s2d)'
 'testZeros/testClass(type=single,outSize=s3d)'
```

**Introduced in R2013a**

## matlab.unittest.TestSuite.fromName

**Class:** matlab.unittest.TestSuite

**Package:** matlab.unittest

Create `Test` object from name of test element

### Syntax

```
testObj = matlab.unittest.TestSuite.fromName(name)
```

### Description

`testObj = matlab.unittest.TestSuite.fromName(name)` creates a scalar `Test` object, `testObj`, from the name of the test element, `name`.

### Input Arguments

#### **name**

Name of the `matlab.unittest.Test` element, specified as a string. For class-based tests, `name` contains the name of the `TestCase` class and the test method, as well as information about parameterization. For function-based tests, `name` contains the name of the main function and the local test function. For script-based tests, `name` contains the name of the script and the title of the test section or cell. If the section does not have a title, MATLAB assigns one. The `name` argument corresponds to the `Name` property of the `Test` object.

The test class, function or script described by `name` must be on the MATLAB path when you are creating and running the `TestSuite`.

### Attributes

Static

true

To learn about attributes of methods, see [Method Attributes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

### Create and Run Test from Test Suite Element

Create a function to test, `add5`, in a file on your MATLAB path.

```
function res = add5(x)
% ADD5 Increment input by 5.
if ~isa(x,'numeric')
 error('add5:InputMustBeNumeric','Input must be numeric.')
end
res = x + 5;
end
```

Create a file, `Add5Test.m`, on your MATLAB path that contains the following `TestCase` class.

```
classdef Add5Test < matlab.unittest.TestCase
 properties (TestParameter)
 Type = {'double','single','int8','int32'};
 end

 methods (Test)
 function testNonNumericInput(testCase)
 testCase.verifyError(@(x)add5('0'),'add5:InputMustBeNumeric')
 end
 function testResultType(testCase, Type)
 actOutput = add5(cast(1,Type));
 testCase.verifyClass(actOutput, Type)
 end
 end
end
```

At the command prompt, create a test object for the `testNonNumericInput` method in the `Add5Test` class.

```
import matlab.unittest.TestSuite
testObj = TestSuite.fromName('Add5Test/testNonNumericInput');
```

Run the test

```
result = run(testObj);
```

```
Running Add5Test
```

```
.
```

```
Done Add5Test
```

---

Create a parameterized test for the `testResultType` method in the `Add5Test` class, and run the test.

```
testObj = TestSuite.fromName('Add5Test/testResultType(Type=single)');
result = run(testObj);
```

```
Running Add5Test
```

```
.
```

```
Done Add5Test
```

---

TestRunner

# matlab.unittest.TestSuite.fromPackage

**Class:** matlab.unittest.TestSuite

**Package:** matlab.unittest

Create `TestSuite` array from all tests in package

## Syntax

```
suite = matlab.unittest.TestSuite.fromPackage(package)
suite = matlab.unittest.TestSuite.fromPackage(package,s)
suite = matlab.unittest.TestSuite.fromPackage(___,Name,Value)
```

## Description

`suite = matlab.unittest.TestSuite.fromPackage(package)` creates a `TestSuite` array from all of the `Test` methods of all the tests contained in `package` and returns that array in `suite`. The method is not recursive, returning only those tests directly in the package specified.

`suite = matlab.unittest.TestSuite.fromPackage(package,s)` creates a `TestSuite` array from all the tests contained in `package` that satisfy the conditions specified by the selector, `s`.

`suite = matlab.unittest.TestSuite.fromPackage( ___,Name,Value)` creates a `TestSuite` array with additional options specified by one or more `Name,Value` pair arguments. You can use this syntax with any of the input arguments of the previous syntaxes.

## Tips

- The root folder(s) where `package` is defined must be on the MATLAB path when creating `suite` using this method as well as when `suite` is run.

## Input Arguments

### **package**

The name of the desired package to find tests, specified as a string.

### **s**

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

## Name-Value Pair Arguments

### **'IncludingSubpackages'**

Indicator for whether to include subpackages in the `TestSuite` array, specified as `false` or `true` (logical 0 or 1). This property is `false` by default. You can specify it as `true` during construction.

### **'Name'**

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'ParameterProperty'**

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'ParameterName'**

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'BaseFolder'**

String indicating the name of the folder that contains the tests. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use

the wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match to exactly one character. For tests defined in packages, the base folder is the parent of the top-level package folder.

### 'Tag'

String indicating the name of the tag applied to the test suite element. Use the wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match exactly one character.

## Output Arguments

### suite

Set of tests, specified as a `matlab.unittest.Test` array.

## Attributes

Static

true

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

## Examples

### Run All Tests in a Package

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromPackage('mypackage.subpackage');
result = run(suite)
```

Run tests in `mypackage` including all subpackages.

```
suite = TestSuite.fromPackage('mypackage', 'IncludingSubpackages', true);
```

```
result = run(suite)
```

### Create Suite of Test Elements Using Selector

In your working folder, create a new package by creating a new folder, `+myPackage`. In that folder, create the following `testZeros.m` test file. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
 type = {'single', 'double', 'uint16'};
 outSize = struct('s2d', [3 3], 's3d', [2 5 4]);
 end

 methods (Test)
 function testClass(testCase, type, outSize)
 testCase.verifyClass(zeros(outSize, type), type);
 end

 function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
 end

 function testDefaultClass(testCase)
 testCase.verifyClass(zeros, 'double');
 end
 function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
 end

 function testDefaultValue(testCase)
 testCase.verifyEqual(zeros, 0);
 end
 end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from all parameterized tests that use the parameter property `'outSize'`.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasParameter;
```

```

suite = TestSuite.fromPackage('myPackage', ...
 HasParameter('Property','outSize'));
{suite.Name}'

ans =

 'myPackage.testZeros/testClass(type=single,outSize=s2d)'
 'myPackage.testZeros/testClass(type=single,outSize=s3d)'
 'myPackage.testZeros/testClass(type=double,outSize=s2d)'
 'myPackage.testZeros/testClass(type=double,outSize=s3d)'
 'myPackage.testZeros/testClass(type=uint16,outSize=s2d)'
 'myPackage.testZeros/testClass(type=uint16,outSize=s3d)'
 'myPackage.testZeros/testSize(outSize=s2d)'
 'myPackage.testZeros/testSize(outSize=s3d)'

```

### Create Suite of Test Elements Using Name-Value Arguments

Create the `+myPackage` folder and `testZeros.m` class from the previous example.

At the command prompt, create a test suite from all parameterized tests that use the parameter property `'outSize'`.

```

import matlab.unittest.TestSuite;

suite = TestSuite.fromPackage('myPackage', ...
 'ParameterProperty', 'outSize');
{suite.Name}'

ans =

 'myPackage.testZeros/testClass(type=single,outSize=s2d)'
 'myPackage.testZeros/testClass(type=single,outSize=s3d)'
 'myPackage.testZeros/testClass(type=double,outSize=s2d)'
 'myPackage.testZeros/testClass(type=double,outSize=s3d)'
 'myPackage.testZeros/testClass(type=uint16,outSize=s2d)'
 'myPackage.testZeros/testClass(type=uint16,outSize=s3d)'
 'myPackage.testZeros/testSize(outSize=s2d)'
 'myPackage.testZeros/testSize(outSize=s3d)'

```

### See Also

[fromClass](#) | [fromMethod](#) | [matlab.unittest.selectors](#) | [TestRunner](#)

Introduced in R2013a

## run

**Class:** matlab.unittest.TestSuite

**Package:** matlab.unittest

Run `TestSuite` array using `TestRunner` object configured for text output

## Syntax

```
result = run(suite)
```

## Description

`result = run(suite)` runs the `TestSuite` object defined by `suite` using a `TestRunner` object configured for text output.

## Tips

- This is a convenience method which is equivalent to using a `TestRunner` object created from the `TestRunner.withTextOutput` method to run `suite`.

## Input Arguments

### **suite**

Set of tests, specified as a `matlab.unittest.TestSuite` array.

## Output Arguments

### **result**

A `matlab.unittest.TestResult` object containing the result of the test run. `result` is the same size as `suite` and each element is the result of the corresponding element in `suite`.

## Examples

### Compare `TestSuite.run` with `TestRunner.run`

Add `matlab.unittest` classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a test suite and a test runner.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
runner = TestRunner.withTextOutput;
```

The following test results are equivalent.

```
result = runner.run(suite)
result = run(suite)
```

### See Also

[matlab.unittest.TestRunner.run](#) | [matlab.unittest.TestCase.run](#)

## selectIf

**Class:** matlab.unittest.TestSuite

**Package:** matlab.unittest

Select test suite elements that satisfy conditions

## Syntax

```
newsuite = selectIf(suite,s)
newsuite = selectIf(suite,Name,Value)
```

## Description

`newsuite = selectIf(suite,s)` selects from `suite` the test elements that satisfy the conditions specified by the selector, `s`, and returns them in the `TestSuite` array, `newsuite`.

`newsuite = selectIf(suite,Name,Value)` creates a `TestSuite` array with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **suite**

Set of tests, specified as a `matlab.unittest.TestSuite` array.

### **s**

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

#### **'Name'**

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

#### **'ParameterProperty'**

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

#### **'ParameterName'**

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

#### **'BaseFolder'**

String indicating the name of the folder that contains the tests. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character. For tests defined in packages, the base folder is the parent of the top-level package folder.

#### **'Tag'**

String indicating the name of the tag applied to the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match exactly one character.

## Examples

### Select Test Elements Using Selector

In your working folder, create the file `ExampleTest.m` containing the following test class.

```
classdef (SharedTestFixtures={...
 matlab.unittest.fixtures.PathFixture(fullfile(...
 matlabroot, 'help', 'techdoc', 'matlab_oop', 'examples'))})...
 ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testPathAdd(testCase)
 % test code
 end
 function testOne(testCase)
 % test code
 end
 function testTwo(testCase)
 % test code
 end
 end
end
```

At the command prompt, create a test suite from the ExampleTest class.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasSharedTestFixture;
import matlab.unittest.selectors.HasName;
import matlab.unittest.fixtures.PathFixture;
import matlab.unittest.constraints.EndsWithSubstring;
import matlab.unittest.constraints.ContainsSubstring;
```

```
suite = TestSuite.fromClass(?ExampleTest)
```

```
suite =
```

```
1x3 Test array with properties:
```

```
 Name
Parameterization
SharedTestFixtures
Tags
```

```
Tests Include:
```

```
0 Parameterizations, 1 Unique Shared Test Fixture Class, 0 Tags.
```

The test suite contains three test elements.

Create a filtered test suite of tests comprising tests with names that contain the case-insensitive substring 'pAtH'.

```
newSuite = selectIf(suite, HasName(ContainsSubstring('pAtH', 'IgnoringCase', true)))
```

```
newSuite =
```

```
Test with properties:
```

```

 Name: 'ExampleTest/testPathAdd'
 Parameterization: []
 SharedTestFixtures: [1x1 matlab.unittest.fixtures.PathFixture]
 Tags: {0x1 cell}

```

```
Tests Include:
```

```
0 Parameterizations, 1 Unique Shared Test Fixture Class, 0 Tags.
```

Only the `testPathAdd` test is part of the suite.

Alternatively, create the same suite using a name-value pair.

```
newSuite = selectIf(suite, 'Name', '*Path*');
```

However, unlike the `ContainsSubstring` constraint, the name-value pair does not have an option to ignore case.

Create a filtered suite of tests comprising tests that use a shared path fixture and do not have names ending with `'One'`.

```
newSuite = suite.selectIf(~HasName(EndsWithSubstring('One')) ...
 & HasSharedTestFixture(PathFixture(fullfile(matlabroot, 'help', ...
 'techdoc', 'matlab_oop', 'examples'))));
{newSuite.Name}
```

```
ans =
```

```
'ExampleTest/testPathAdd' 'ExampleTest/testTwo'
```

The test suite contains two tests. All of the tests use the specified path fixture, but the test named `'testOne'` is excluded from the suite.

### Select Test Elements Using Parameterization

In your working folder, create `testZeros.m`. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
```

```
 type = {'single', 'double', 'uint16'};
 outSize = struct('s2d', [3 3], 's3d', [2 5 4]);
end

methods (Test)
function testClass(testCase, type, outSize)
 testCase.verifyClass(zeros(outSize, type), type);
end

function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
end

function testDefaultClass(testCase)
 testCase.verifyClass(zeros, 'double');
end
function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
end

function testDefaultValue(testCase)
 testCase.verifyEqual(zeros, 0);
end
end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from the file.

```
s = matlab.unittest.TestSuite.fromFile('testZeros.m');
{s.Name}'
```

```
ans =

 'testZeros/testClass(type=single,outSize=s2d)'
 'testZeros/testClass(type=single,outSize=s3d)'
 'testZeros/testClass(type=double,outSize=s2d)'
 'testZeros/testClass(type=double,outSize=s3d)'
 'testZeros/testClass(type=uint16,outSize=s2d)'
 'testZeros/testClass(type=uint16,outSize=s3d)'
 'testZeros/testSize(outSize=s2d)'
 'testZeros/testSize(outSize=s3d)'
 'testZeros/testDefaultClass'
 'testZeros/testDefaultSize'
```

```
'testZeros/testDefaultValue'
```

The suite contains 11 test elements. Six from the parameterized `testClass` method, two from the parameterized `testSize` method, and one from each of the `testDefaultClass`, `testDefaultSize`, and `testDefaultValue` methods.

Select all of the test elements from parameterized test methods.

```
import matlab.unittest.selectors.HasParameter;
```

```
s1 = s.selectIf(HasParameter);
{s1.Name}'
```

```
ans =
```

```
'testZeros/testClass(type=single,outSize=s2d)'
'testZeros/testClass(type=single,outSize=s3d)'
'testZeros/testClass(type=double,outSize=s2d)'
'testZeros/testClass(type=double,outSize=s3d)'
'testZeros/testClass(type=uint16,outSize=s2d)'
'testZeros/testClass(type=uint16,outSize=s3d)'
'testZeros/testSize(outSize=s2d)'
'testZeros/testSize(outSize=s3d)'
```

The suite contains the eight test elements from the two parameterized test methods.

Select all of the test elements from non-parameterized test methods.

```
s2 = s.selectIf(~HasParameter);
{s2.Name}'
```

```
ans =
```

```
'testZeros/testDefaultClass'
'testZeros/testDefaultSize'
'testZeros/testDefaultValue'
```

Select all test elements that are parameterized and have a property named `'type'` with a parameter name `'double'`.

```
s3 = s.selectIf('ParameterProperty','type','ParameterName','double');
{s3.Name}'
```

```
ans =
```

```
'testZeros/testClass(type=double,outSize=s2d)'
'testZeros/testClass(type=double,outSize=s3d)'
```

The resulting suite contains two elements. The `testClass` method is the only method in `testZeros` that uses the `'type'` property, and selecting only `'double'` from the parameters results in two test elements — one for each value of `'outSize'`.

Select all test elements that are parameterized and have a parameters defined by a property starting with `'t'`.

```
s4 = s.selectIf('ParameterProperty','t*');
{s4.Name}'
```

```
ans =
```

```
'testZeros/testClass(type=single,outSize=s2d)'
'testZeros/testClass(type=single,outSize=s3d)'
'testZeros/testClass(type=double,outSize=s2d)'
'testZeros/testClass(type=double,outSize=s3d)'
'testZeros/testClass(type=uint16,outSize=s2d)'
'testZeros/testClass(type=uint16,outSize=s3d)'
```

The resulting suite contains the six parameterized test elements from the `testClass` method. The `testSize` method is parameterized, but the elements from the method are not included in the suite because the method does not use a property that starts with `'t'`.

Select all test elements that are parameterized and test the `zeros` function with a 2-D array. A parameter value representing a 2-D array will have a length of 1 (e.g. `zeros(3)`) or 2 (e.g. `zeros(2,3)`).

```
import matlab.unittest.constraints.HasLength;
```

```
s5 = s.selectIf(HasParameter('Property','outSize',...
 'Value', HasLength(1)|HasLength(2)));
{s5.Name}'
```

```
ans =
```

```
'testZeros/testClass(type=single,outSize=s2d)'
'testZeros/testClass(type=double,outSize=s2d)'
'testZeros/testClass(type=uint16,outSize=s2d)'
'testZeros/testSize(outSize=s2d)'
```

Select only the test element that tests that the output is a `double` data type and the has the correct size for a 2-D array.

```
s6 = s.selectIf(HasParameter('Property','type','Name','double')...
 & HasParameter('Property','outSize','Name','s2d'))
```

```
s6 =
```

```
Test with properties:
```

```
 Name: 'testZeros/testClass(type=double,outSize=s2d)'
 Parameterization: [1x2 matlab.unittest.parameters.TestParameter]
 SharedTestFixtures: []
 Tags: {0x1 cell}
```

```
Tests Include:
```

```
 2 Unique Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.
```

## Select Test Elements Using Tags

Create the following test class in a file, `ExampleTest.m`, in your current working folder.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods (Test)
 function testA (testCase)
 % test code
 end
 end
 methods (Test, TestTags = {'Unit'})
 function testB (testCase)
 % test code
 end
 function testC (testCase)
 % test code
 end
 end
 methods (Test, TestTags = {'Unit','FeatureA'})
 function testD (testCase)
 % test code
 end
 end
 methods (Test, TestTags = {'System','FeatureA'})
 function testE (testCase)
 % test code
 end
 end
end
```

```
end
end
```

At the command prompt, create a test suite from the `ExampleTest` class and examine the contents.

```
import matlab.unittest.TestSuite
import matlab.unittest.selectors.HasTag

suite = TestSuite.fromClass(?ExampleTest)
```

```
suite =
```

```
1x5 Test array with properties:
```

```
Name
Parameterization
SharedTestFixtures
Tags
```

```
Tests Include:
```

```
0 Parameterizations, 0 Shared Test Fixture Classes, 3 Unique Tags.
```

Click the hyperlink for **3 Unique Tags** to display all the tags in the suite.

```
Tag
```

```

'FeatureA'
'System'
'Unit'
```

Select all the test suite elements that have the tag `'Unit'`.

```
s1 = suite.selectIf(HasTag('Unit'))
```

```
s1 =
```

```
1x3 Test array with properties:
```

```
Name
Parameterization
SharedTestFixtures
Tags
```

```
Tests Include:
 0 Parameterizations, 0 Shared Test Fixture Classes, 2 Unique Tags.
```

Select all the test suite elements that do not contain the tag 'FeatureA'.

```
s2 = suite.selectIf(~HasTag('FeatureA'));
{s2.Name}
```

```
ans =
```

```
 'ExampleTest/testB' 'ExampleTest/testC' 'ExampleTest/testA'
```

Select all the test suite elements that have no tags.

```
s3 = suite.selectIf(~HasTag)
```

```
s3 =
```

```
Test with properties:
```

```
 Name: 'ExampleTest/testA'
 Parameterization: []
 SharedTestFixtures: []
 Tags: {0x1 cell}
```

```
Tests Include:
 0 Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.
```

## texlabel

Format text into TeX string

### Syntax

```
TeXString = texlabel(f)
TeXString = texlabel(f, 'literal')
```

### Description

`TeXString = texlabel(f)` converts the MATLAB expression `f` into the TeX equivalent for use in text strings. `texlabel` converts Greek variable names (for example, `lambda`, `delta`, and so on) into a string that is displayed as Greek letters. The `TeXString` output is useful as an argument to annotation functions such as `title`, `xlabel`, and `text`.

If `TeXString` is too long to fit into a figure window, then the center of the expression is replaced with a tilde ellipsis (~~~).

`TeXString = texlabel(f, 'literal')` interprets Greek variable names literally.

### Examples

#### Insert TeX String in Figure

Create a figure and a TeX string for use in a text graphics object.

```
figure
plot((1:10).^2)
TeXString = texlabel('lambda12^(3/2)/pi - pi*delta^(2/3)');
```

Add a text object containing the TeX string to the figure.

```
text(3,90,TeXString)
```

If you include the 'literal' argument, `textlabel` interprets Greek variable names literally. Add a text object containing the literal string.

```
text(4,60,textlabel('lambda12^(3/2)/pi - pi*delta^(2/3)','literal'))
```

## Input Arguments

**f** — Input MATLAB expression

string

Input MATLAB expression, specified as a string.

Example: 'theta (degrees)'

Data Types: char

**See Also**

text | title | xlabel | ylabel | zlabel

**Introduced before R2006a**

## text

Add text descriptions to data points

### Syntax

```
text(x,y,str)
text(x,y,z,str)
text(____,Name,Value)

t = text(____)
```

### Description

`text(x,y,str)` adds a text description to one or more data points in the current axes using the text specified by `str`. To add text to one point, specify `x` and `y` as scalars in data units. To add text to multiple points, specify `x` and `y` as vectors with equal length.

`text(x,y,z,str)` positions the text in 3-D coordinates.

`text( ____,Name,Value)` specifies text object properties using one or more name-value pairs. For example, `'FontSize',14` sets the font size to 14 points. You can specify text properties with any of the input argument combinations in the previous syntaxes. If you specify the `Position` and `String` properties as name-value pairs, then you do not need to specify the `x`, `y`, `z`, and `str` inputs.

`t = text( ____ )` returns one or more text objects. Use `t` to modify properties of the text objects after they are created. For a list of properties and descriptions, see `Text Properties`. You can specify an output with any of the previous syntaxes.

### Examples

#### Add Text Description to Data Point

Plot a sine curve. At the point  $(\pi, 0)$ , add the text description  $\sin(\pi)$ . Use the TeX markup `\pi` for the Greek letter  $\pi$ . Use `\leftarrow` to display a left-pointing arrow.

```
x = 0:pi/20:2*pi;
y = sin(x);
plot(x,y)
text(pi,0,'\leftarrow sin(\pi)')
```

For a list of Greek characters and other TeX markup, see the [Interpreter](#) property description.

### Add Text to Multiple Data Points

Plot a line. Add the same text to two points along the line.

```
x = linspace(-5,5);
```

```
y = x.^3-12*x;
plot(x,y)

xt = [-2 2];
yt = [16 -16];
str = 'dy/dx = 0';
text(xt,yt,str)
```

Add different text to each point by specifying `str` as a cell array.

```
x = linspace(-5,5);
y = x.^3-12*x;
plot(x,y)
```

```
xt = [-2 2];
yt = [16 -16];
str = {'local max','local min'};
text(xt,yt,str)
```

## Display Multiline Text

Create a line plot and add one text description to the axes. Display multiline text by specifying `str` as a cell array.

```
plot(1:10)
str = {'A simple plot','from 1 to 10'};
text(2,7,str)
```

Create a line plot and add two text descriptions to the axes. When adding multiple text descriptions to the axes, display multiline text by specifying nested cell arrays.

```
plot(1:10)
str = {'A simple plot', 'from 1 to 10'}, 'y = x';
text([2 8],[7 7],str)
```

## Specify Text Size and Color

Create a line plot and add a text description to the axes. Use red, size 14 font.

```
plot(1:10)
text(2,8, 'A Simple Plot', 'Color', 'red', 'FontSize', 14)
```

### Modify Existing Text

Create a line plot and add two text descriptions along the line. Return the text objects, `t`.

```
x = linspace(-5,5);
y = x.^3-12*x;
plot(x,y)
t = text([-2 2],[16 -16], 'dy/dx = 0')
```

`t =`

2x1 Text array:

```
Text (dy/dx = 0)
Text (dy/dx = 0)
```

The `text` function creates one text object for each text description. Thus, `t` contains two text objects.

Change the color and font size for the first text object using `t(1)`. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
t(1).Color = 'red';
t(1).FontSize = 14;
```

- “Include Variable Values in Graph Text”
- “Greek Letters and Special Characters in Graph Text”
- “Text with Mathematical Expression Using LaTeX”

## Input Arguments

**x** — Text placement along x-axis

scalar | vector

Text placement along the x-axis, specified in one of these forms:

- **Scalar** — Add text to single point.
- **Vector** — Add text to multiple points.

$x$  and  $y$  must be equal sizes. The default units are data units. To change the units, set the `Units` property for the text object.

To control the placement of the text with relation to the specified point, use the `HorizontalAlignment`, `VerticalAlignment`, and `Extent` properties of the text object.

Data Types: `double`

## **y** — Text placement along y-axis

scalar | vector

Text placement along the  $y$ -axis, specified in one of these forms:

- **Scalar** — Add text to single point.
- **Vector** — Add text to multiple points.

$x$  and  $y$  must be equal sizes. The default units are data units. To change the units, set the `Units` property for the text object.

To control the placement of the text with relation to the specified point, use the `HorizontalAlignment`, `VerticalAlignment`, and `Extent` properties of the text object.

Data Types: `double`

## **z** — Text placement along z-axis

0 (default) | scalar | vector

Text placement along the  $z$ -axis, specified in one of these forms:

- **Scalar** — Add text to single point.
- **Vector** — Add text to multiple points.

$x$ ,  $y$ , and  $z$  must be equal sizes. The default units are data units. To change the units, set the `Units` property for the text object.

Data Types: `double`

## **str** — Text to display

character string | character array | cell array

Text to display, specified as a character string, character array, or cell array.

## Text for Single Data Point

To add text to a single point, specify `str` as a character string. For example, `text(.5,.5,'my text')`.

For multiline text:

- Use a cell array, where each cell contains a line of text. For example, `text(.5,.5,{'first','second'})`.
- Use a character array with multiple rows, where each row contains the same number of characters. For example, `text(.5,.5,['first '; 'second'])`.
- Use `sprintf` to create a string with a new line character. For example, `text(.5,.5,sprintf('first \nsecond'))`.

## Text for Multiple Data Points

To display the same text at each location, specify `str` as a character string. For example, `text([0 1],[0 1],'my text')`.

To display different text at each location, use a cell array. For example, `text([0 1],[0 1],{'first','second'})`.

For multiline text, use nested cell arrays. For example, `text([0 1],[0 1],{'first','new line'},'second')`.

## Greek Letters, Special Characters, and Numeric Variables

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols, use TeX markup. For a list of supported markup, see the `Interpreter` property.

To include numeric variables in the text, use the `num2str` function.

```
v = 42;
```

```
str = ['The value is ',num2str(v)];
```

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `text(.5,.5,'my text','FontSize',14,'Color','red')`

The properties listed here are only a subset. For a full list, see [Text Properties](#).

### 'FontSize' — Font size

10 (default) | scalar value greater than zero

Font size, specified as a scalar value greater than zero in point units. One point equals 1/72 inch. To change the font units, use the `FontUnits` property.

Example: 12

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### 'FontWeight' — Thickness of text characters

'normal' (default) | 'bold'

Thickness of the text characters, specified as one of these values:

- 'normal' — Default weight as defined by the particular font
- 'bold' — Thicker character outlines than normal

MATLAB uses the `FontWeight` property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight still can result in the normal font weight.

---

**Note:** The 'light' and 'demi' font weight values have been removed. Use 'normal' instead.

---

### 'FontName' — Font name

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string `'FixedWidth'`. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. The `'FixedWidth'` value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

### **'Color' — Text color**

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. The default color is black with an RGB triplet value of `[0 0 0]`. If you set the color to `'none'`, then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
<code>'yellow'</code>	<code>'y'</code>	<code>[1 1 0]</code>
<code>'magenta'</code>	<code>'m'</code>	<code>[1 0 1]</code>
<code>'cyan'</code>	<code>'c'</code>	<code>[0 1 1]</code>
<code>'red'</code>	<code>'r'</code>	<code>[1 0 0]</code>
<code>'green'</code>	<code>'g'</code>	<code>[0 1 0]</code>
<code>'blue'</code>	<code>'b'</code>	<code>[0 0 1]</code>
<code>'white'</code>	<code>'w'</code>	<code>[1 1 1]</code>
<code>'black'</code>	<code>'k'</code>	<code>[0 0 0]</code>

Example: `'blue'`

Example: `[0 0 1]`

### **'HorizontalAlignment' — Horizontal alignment of text with respect to position point**

`'left'` (default) | `'center'` | `'right'`

Horizontal alignment of the text with respect to the **x** value in the **Position** property, specified as one of the values in this table. The vertical line indicates where the **x** value lies in relation to the text.

Value	Result
'left' (default)	
'center'	
'right'	

**'Position' — Location of text**

[0 0 0] (default) | two-element vector of form [x y] | three-element vector of form [x y z]

Location of the text, specified as a two-element vector of the form [x y] or a three-element vector of the form [x y z]. If you omit the third element, z, then MATLAB sets it to 0.

By default, the position value is defined in data units. To change the units, use the **Units** property.

Example: [0.5 0.5 0]

**'Units' — Position and extent units**

'data' (default) | 'normalized' | 'inches' | 'centimeters' | 'characters' | 'points' | 'pixels'

Position units, specified as one of the values in this table.

Units	Description
'data' (default)	Data coordinates.
'normalized'	Normalized with respect to the axes. The lower left corner of the axes maps to (0,0) and the upper right corner maps to (1,1).

Units	Description
'inches'	Inches.
'centimeters'	Centimeters.
'characters'	Based on the default system font character size. <ul style="list-style-type: none"> <li>• Character width = width of letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>
'points'	Points. One point equals 1/72 inch.
'pixels'	<p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p>

All units, except for 'data', are measured from the lower left corner of the axes. This property affects the **Position** and **Extent** properties.

If you specify the **Position** and **Units** properties as **Name, Value** pairs when creating the text object, then the order of specification matters. To define the position with particular units, set the **Units** property before the **Position** property.

### 'Interpreter' — Interpretation of text characters

'tex' (default) | 'latex' | 'none'

Interpretation of text characters, specified as one of these values:

- 'tex' — Interpret text strings using a subset of TeX markup.
- 'latex' — Interpret text strings using LaTeX markup.

- 'none' — Display literal characters.

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers with the `Interpreter` property set to 'tex'. Modifiers remain in effect until the end of the string. Superscripts and subscripts are an exception because they only modify the next character or the text within the curly braces {}.

Modifier	Description	Example of String
<code>^{ }</code>	Superscript	<code>'text^{superscript}'</code>
<code>_{ }</code>	Subscript	<code>'text_{subscript}'</code>
<code>\bf</code>	Bold font	<code>'\bf text'</code>
<code>\it</code>	Italic font	<code>'\it text'</code>
<code>\sl</code>	Oblique font (usually the same as italic font)	<code>'\sl text'</code>
<code>\rm</code>	Normal font	<code>'\rm text'</code>
<code>\fontname{specifier}</code>	Font name — Set <code>specifier</code> as the name of a font family. You can use this in combination with other modifiers.	<code>'\fontname{Courier} text'</code>
<code>\fontsize{specifier}</code>	Font size — Set <code>specifier</code> as a numeric scalar value in point units to change the font size.	<code>'\fontsize{15} text'</code>
<code>\color{specifier}</code>	Font color — Set <code>specifier</code> as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue.	<code>'\color{magenta} text'</code>

Modifier	Description	Example of String
<code>\color[rgb]{specifier}</code>	Custom font color — Set specifier as a three-element RGB triplet.	<code>'\color[rgb]{0,0.5,0.5} text'</code>

This table lists the supported special characters with the Interpreter property set to 'tex'.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
<code>\alpha</code>	$\alpha$	<code>\upsilon</code>	$\upsilon$	<code>\sim</code>	$\sim$
<code>\angle</code>	$\angle$	<code>\phi</code>	$\Phi$	<code>\leq</code>	$\leq$
<code>\ast</code>	$*$	<code>\chi</code>	$\chi$	<code>\infty</code>	$\infty$
<code>\beta</code>	$\beta$	<code>\psi</code>	$\psi$	<code>\clubsuit</code>	$\clubsuit$
<code>\gamma</code>	$\gamma$	<code>\omega</code>	$\omega$	<code>\diamondsuit</code>	$\diamondsuit$

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
<code>\tau</code>	$\tau$	<code>\Re</code>	$\Re$	<code>\neq</code>	$\neq$
<code>\equiv</code>	$\equiv$	<code>\oplus</code>	$\oplus$	<code>\aleph</code>	$\aleph$
<code>\Im</code>	$\Im$	<code>\cup</code>	$\cup$	<code>\wp</code>	$\wp$
<code>\otimes</code>	$\otimes$	<code>\subseteq</code>	$\subseteq$	<code>\oslash</code>	$\oslash$
<code>\cap</code>	$\cap$	<code>\in</code>	$\in$	<code>\supseteq</code>	$\supseteq$
<code>\supset</code>	$\supset$	<code>\lceil</code>	$\lceil$	<code>\subset</code>	$\subset$
<code>\int</code>	$\int$	<code>\cdot</code>	$\cdot$	<code>\o</code>	$\circ$
<code>\rfloor</code>	$\rfloor$	<code>\neg</code>	$\neg$	<code>\nabla</code>	$\nabla$
<code>\lfloor</code>	$\lfloor$	<code>\times</code>	$\times$	<code>\ldots</code>	$\dots$
<code>\perp</code>	$\perp$	<code>\surd</code>	$\surd$	<code>\prime</code>	$'$
<code>\wedge</code>	$\wedge$	<code>\varpi</code>	$\varpi$	<code>\emptyset</code>	$\emptyset$
<code>\rceil</code>	$\rceil$	<code>\rangle</code>	$\rangle$	<code>\mid</code>	$ $
<code>\vee</code>	$\vee$	<code>\langle</code>	$\langle$	<code>\copyright</code>	$\copyright$

## LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at <http://www.latex-project.org/>.

## Output Arguments

**t** — One or more text objects  
 scalar | vector

One or more text objects, returned as a scalar or a vector. Use the elements of `t` to modify a specific text object after it is created. For a list of properties, see [Text Properties](#).

## More About

### Tips

- By default, the `Clipping` property for text objects is set to `'off'` so the text might appear outside the axes. To clip the text to the axes boundaries, set the property to `'on'`.

### See Also

#### Functions

[annotation](#) | [int2str](#) | [num2str](#) | [title](#) | [xlabel](#) | [ylabel](#) | [zlabel](#)

#### Properties

[Text Properties](#)

Introduced before R2006a

## Text Properties

Control text appearance and behavior

Text properties control the appearance and behavior of a text object. By changing property values, you can modify certain aspects of the text.

Starting in R2014b, you can use dot notation to query and set properties.

```
t = text(0.5,0.5,'text here');
s = t.FontSize;
t.FontSize = 12;
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Text

#### **String** – Text to display

' ' (default) | character array | cell array | numeric value

Text to display, specified as a character array, cell array, or numeric value.

Example: 'my label'

Example: {'first line','second line'}

Example: 123

To include numeric variables with text, use the `num2str` function. For example:

```
x = 42;
str = ['The value is ',num2str(x)];
```

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols use TeX markup. For a list of supported markup, see the `Interpreter` property.

To create multiline text:

- Use a cell array, where each cell contains a line of text, such as {'first line','second line'}.
- Use a character array, where each row contains the same number of characters, such as ['abc'; 'ab '].

- Use `sprintf` to create a string with a new line character, such as `sprintf('first line \n second line')`. This property converts strings with new line characters to cell arrays.

Text that contains only a numeric value is converted to a string using `sprintf('%g', value)`. For example, `12345678` displays as `1.23457e+07`.

---

**Note:** The words `default`, `factory`, and `remove` are reserved words that will not appear in text when quoted as a normal string. To display any of these words individually, precede them with a backslash, such as `'\default'` or `'\remove'`.

---

### Interpreter — Interpretation of text characters

'tex' (default) | 'latex' | 'none'

Interpretation of text characters, specified as one of these values:

- 'tex' — Interpret text strings using a subset of TeX markup.
- 'latex' — Interpret text strings using LaTeX markup.
- 'none' — Display literal characters.

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers with the `Interpreter` property set to 'tex'. Modifiers remain in effect until the end of the string. Superscripts and subscripts are an exception because they only modify the next character or the text within the curly braces {}.

Modifier	Description	Example of String
<code>^{ }</code>	Superscript	<code>'text^{superscript}'</code>
<code>_{ }</code>	Subscript	<code>'text_{subscript}'</code>
<code>\bf</code>	Bold font	<code>'\bf text'</code>
<code>\it</code>	Italic font	<code>'\it text'</code>

Modifier	Description	Example of String
<code>\sl</code>	Oblique font (usually the same as italic font)	<code>'\sl text'</code>
<code>\rm</code>	Normal font	<code>'\rm text'</code>
<code>\fontname{specifier}</code>	Font name — Set <b>specifier</b> as the name of a font family. You can use this in combination with other modifiers.	<code>'\fontname{Courier} text'</code>
<code>\fontsize{specifier}</code>	Font size — Set <b>specifier</b> as a numeric scalar value in point units to change the font size.	<code>'\fontsize{15} text'</code>
<code>\color{specifier}</code>	Font color — Set <b>specifier</b> as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue.	<code>'\color{magenta} text'</code>
<code>\color[rgb]{specifier}</code>	Custom font color — Set <b>specifier</b> as a three-element RGB triplet.	<code>'\color[rgb]{0,0.5,0.5} text'</code>

This table lists the supported special characters with the `Interpreter` property set to `'tex'`.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol

## LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at <http://www.latex-project.org/>.

## Font Style

### Color — Text color

[0 0 0] (default) | RGB triplet | color string | 'none'

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. The default color is black with an RGB triplet value of [0 0 0]. If you set the color to `'none'`, then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: `'blue'`

Example: [0 0 1]

### FontName — Font name

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. The 'FixedWidth' value relies on the root FixedWidthFontName property. Setting the root FixedWidthFontName property causes an immediate update of the display to use the new font.

Example: 'Cambria'

### FontSize — Font size

10 (default) | scalar value greater than zero

Font size, specified as a scalar value greater than zero in point units. One point equals 1/72 inch. To change the font units, use the FontUnits property.

Example: 12

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### FontUnits — Font size units

'points' (default) | 'inches' | 'centimeters' | 'normalized' | 'pixels'

Font size units, specified as one of the values in this table.

Units	Description
'points'	Points. One point equals 1/72 inch.
'inches'	Inches.
'centimeters'	Centimeters.
'normalized'	Interpret font size as a fraction of the axes height. If you resize the axes, the font size modifies accordingly. For example, if the FontSize is 0.1 in normalized units, then the text is 1/10 of the axes height.
'pixels'	Pixels.

Units	Description
	<p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"><li>• On Windows systems, a pixel is 1/96th of an inch.</li><li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li></ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p>

If you set both the font size and the font units in one function call, you must set the `FontUnits` property first so that the axes correctly interprets the specified font size.

### **FontAngle** — Character slant

`'normal'` (default) | `'italic'`

Character slant, specified as `'normal'` or `'italic'`. Not all fonts have both font styles. Therefore, the italic font might look the same as the normal font.

---

**Note:** The `'oblique'` value has been removed. Use `'italic'` instead.

---

### **FontWeight** — Thickness of text characters

`'normal'` (default) | `'bold'`

Thickness of the text characters, specified as one of these values:

- `'normal'` — Default weight as defined by the particular font
- `'bold'` — Thicker character outlines than normal

MATLAB uses the `FontWeight` property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight still can result in the normal font weight.

---

**Note:** The `'light'` and `'demi'` font weight values have been removed. Use `'normal'` instead.

---

**FontSmoothing — Smooth font character appearance**

'on' (default) | 'off'

Smooth font character appearance, specified as one of these values:

- 'on' — Apply font smoothing. Reduce the appearance of jaggedness in the text characters to make the text easier to read.
- 'off' — Do not apply font smoothing.

**Text Box****EdgeColor — Color of box outline**

'none' (default) | RGB triplet | color string

Color of box outline, specified as 'none', a three-element RGB triplet, or a color string. The default edge color of 'none' makes the box outline invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

**BackgroundColor — Color of text box background**

'none' (default) | RGB triplet | color string

Color of text box background, specified as 'none', a three-element RGB triplet, or a color string. The default background color of 'none' makes the text box background transparent.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

**Margin — Space around text within the text box**

3 (default) | scalar numeric value

The space around the text within the text box, specified as scalar numeric value in point units.

MATLAB uses the `Extent` property value plus the `Margin` property value to determine the size of the text box.

Example: 8

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**LineStyle — Line style of box outline**

'-' (default) | '--' | ':' | '-.' | 'none'

Line style of box outline, specified as one of the strings in this table.

String	Line Style	Resulting Line
'_'	Solid line	
'--'	Dashed line	
':'	Dotted line	
'-.'	Dash-dotted line	
'none'	Line is invisible	

### LineWidth — Width of box outline

0.5 (default) | scalar numeric value

Width of box outline, specified as a scalar numeric value in point units. One point equals 1/72 inch.

Example: 1.5

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Location and Size

### Position — Location of text

[0 0 0] (default) | two-element vector of form [x y] | three-element vector of form [x y z]

Location of the text, specified as a two-element vector of the form [x y] or a three-element vector of the form [x y z]. If you omit the third element, z, then MATLAB sets it to 0.

By default, the position value is defined in data units. To change the units, use the `Units` property.

Example: [0.5 0.5 0]

### Extent — Size and location of rectangle that encloses text string

four-element vector

This property is read only.

Size and location of the rectangle that encloses the text string, not including the margin, returned as a four-element vector of the form `[left bottom width height]`. The first two elements, `left` and `bottom`, define the position of the lower left corner of the rectangle. The last two elements, `width` and `height`, define the dimensions of the rectangle.

By default, the extent value is defined in data units. To change the units, use the `Units` property.

Example: `[0.5 0.5 0.4 0.2]`

**Units — Position and extent units**

'data' (default) | 'normalized' | 'inches' | 'centimeters' | 'characters' | 'points' | 'pixels'

Position units, specified as one of the values in this table.

Units	Description
'data' (default)	Data coordinates.
'normalized'	Normalized with respect to the axes. The lower left corner of the axes maps to (0,0) and the upper right corner maps to (1,1).
'inches'	Inches.
'centimeters'	Centimeters.
'characters'	Based on the default system font character size. <ul style="list-style-type: none"> <li>• Character width = width of letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>
'points'	Points. One point equals 1/72 inch.
'pixels'	<p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p>

Units	Description
	<ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p>

All units, except for 'data', are measured from the lower left corner of the axes. This property affects the **Position** and **Extent** properties.

If you specify the **Position** and **Units** properties as **Name, Value** pairs when creating the text object, then the order of specification matters. To define the position with particular units, set the **Units** property before the **Position** property.

### Rotation — Text orientation

0 (default) | scalar value in degrees

Text orientation, specified as a scalar value in degrees. The default rotation of 0 degrees makes the text horizontal. For vertical text, set this property to **90** or **-90**. Positive values rotate the text counterclockwise. Negative values rotate the text clockwise.

Example: 90

Example: -90

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### HorizontalAlignment — Horizontal alignment of text with respect to position point

'left' (default) | 'center' | 'right'

Horizontal alignment of the text with respect to the **x** value in the **Position** property, specified as one of the values in this table. The vertical line indicates where the **x** value lies in relation to the text.

Value	Result
'left' (default)	

Value	Result
'center'	
'right'	

**VerticalAlignment** — Vertical alignment of text with respect to position point

'middle' (default) | 'top' | 'bottom' | 'baseline' | 'cap'

Vertical alignment of the text with respect to the **y** value in the **Position** property, specified as one of the values in this table. The horizontal line indicates where the **y** value lies in relation to the text.

Value	Result
'middle'	
'top'	
'cap'	
'bottom'	
'baseline'	

**Visibility****Visible** — State of visibility

'on' (default) | 'off'

State of visibility, specified as one of these values:

- 'on' — Display the text.

- 'off' — Hide the text without deleting it. You still can access the properties of an invisible text object.

**Clipping — Clipping of text to axes plot box**

'off' (default) | 'on'

Clipping of the text to the axes plot box, which is the box defined by the axis limits, specified as one of these values:

- 'off' — Do not clip the text. Portions of it might appear outside the axes plot box.
- 'on' — Clips the text to the axes plot box.
- If the axes `ClippingStyle` property is set to '3dbox', which is the default, then MATLAB either displays the entire text or none of the text, depending on the text position. If the point defined by the text `Position` property lies inside the axes, then MATLAB displays the entire text. If the point lies outside the axes, then MATLAB displays none of it.
- If the axes `ClippingStyle` property is set to 'rectangle', then MATLAB displays portions of the text lying inside the axes plot box and does not display portions of the text lying outside the axes plot box.

---

**Note:** If the `Clipping` property of the associated axes is set to 'on', which is the default, then each individual object controls its own clipping behavior. If the `Clipping` property of the axes is set to 'off', then MATLAB does not clip any objects in the axes, regardless of the `Clipping` property of the individual object.

---

**EraseMode — (removed) Technique to draw and erase objects**

'normal' (default) | 'none' | 'xor' | 'background'

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- 'normal' — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces

the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.

- 'none' — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, 'none', it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- 'xor' — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- 'background' — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is 'none'. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to 'normal'. This means graphics objects created with `EraseMode` set to 'none', 'xor', or 'background' can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### Type — Type of graphics object

'text'

This property is read only.

Type of graphics object, returned as 'text'. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

### Tag — Tag to associate with text

'' (default) | string

Tag to associate with the text, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

### **UserData** — Data to associate with text

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the text object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: 1:100

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | table | cell

## **Parent/Child**

### **Parent** — Parent of text

axes object | group object | transform object

Parent of text, specified as an axes, group, or transform object.

### **Children** — Children of text

empty `GraphicsPlaceholder` array

The text has no children. You cannot set this property.

### **HandleVisibility** — Visibility of object handle

'on' (default) | 'off' | 'callback'

Visibility of text object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The text object handle is always visible.
- 'off' — The text object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The text object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command

line. This option blocks access to the text at the command-line, but allows callback functions to access it.

If the text object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles regardless of their `HandleVisibility` property setting.

## Interactive Control

### Editing — Interactive edit mode

`'off'` (default) | `'on'`

Interactive edit mode, specified as one of these values:

- `'off'` — Do not allow interactive string editing. To change the text string you must set the `String` property. This is the default value.
- `'on'` — Allow interactive string editing. MATLAB places an insert cursor within the text and typing changes the text. To apply the new text string, do any of the following:
  - Press the **Esc** key.
  - Click anywhere away from the text string.
  - Reset the `Editing` property to `'off'`.

MATLAB updates the `String` property to contain the new text and resets the `Editing` property to `'off'`.

### ButtonDownFcn — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the text. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The text object — You can access properties of the text object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **UIContextMenu — Context menu**

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the text. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

### **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the text when in plot edit mode, then MATLAB sets its `Selected` property to 'on'. If the `SelectionHighlight` property also is set to 'on', then MATLAB displays selection handles around the text.
- 'off' — Not selected.

### **SelectionHighlight — Display of selection handles when selected**

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the **Selected** property is set to 'on'.
- 'off' — Never display selection handles, even when the **Selected** property is set to 'on'.

## **Callback Execution Control**

### **PickableParts — Ability to capture mouse clicks**

'visible' (default) | 'all' | 'none'

Ability to capture mouse clicks, specified as one of these values:

- 'visible' — Can capture mouse clicks only when visible. The **Visible** property must be set to 'on'. The **HitTest** property determines if the text responds to the click or if an ancestor does.
- 'all' — Can capture mouse clicks regardless of visibility. The **Visible** property can be set to 'on' or 'off'. The **HitTest** property determines if the text responds to the click or if an ancestor does.
- 'none' — Cannot capture mouse clicks. Clicking the text passes the click to the object below it in the current view of the figure window, which is typically the axes or the figure. The **HitTest** property has no effect.

If you want an object to be clickable when it is underneath other objects that you do not want to be clickable, then set the **PickableParts** property of the other objects to 'none' so that the click passes through them.

### **HitTest — Response to captured mouse clicks**

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the **ButtonDownFcn** callback of the text. If you have defined the **UIContextMenu** property, then invoke the context menu.
- 'off' — Trigger the callbacks for the nearest ancestor of the text that has a **HitTest** property set to 'on' and a **PickableParts** property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the text object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
- 

If the `ButtonDownFcn` callback of the text is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the text tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the text. Setting the `CreateFcn` property on an existing text has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during text creation. MATLAB executes the callback after creating the text and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The text object — You can access properties of the text object from within the callback function. You also can access the text object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **DeleteFcn — Deletion callback**

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the text. MATLAB executes the callback before destroying the text so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The text object — You can access properties of the text object from within the callback function. You also can access the text object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: {@myCallback, arg3}

## **BeingDeleted** — Deletion status of text

'off' (default) | 'on'

This property is read only.

Deletion status of text, returned as 'on' or 'off'. MATLAB sets the **BeingDeleted** property to 'on' when the delete function of the text begins execution (see the **DeleteFcn** property). The **BeingDeleted** property remains set to 'on' until the text no longer exists.

Check the value of the **BeingDeleted** property to verify that the text is not about to be deleted before querying or modifying it.

## **More About**

- “Access Property Values”
- “Graphics Object Properties”

# textread

Read data from text file; write to multiple outputs

---

**Note:** `textread` is not recommended. Use `textscan` instead.

---

## Syntax

```
[A,B,C,...] = textread(filename,format)
[A,B,C,...] = textread(filename,format,N)
[...] = textread(...,param,value,...)
```

## Description

`[A,B,C,...] = textread(filename,format)` reads data from the file `filename` into the variables `A`, `B`, `C`, and so on, using the specified `format`, until the entire file is read. The `filename` and `format` inputs are strings, each enclosed in single quotes. `textread` is useful for reading text files with a known format. `textread` handles both fixed and free format files.

---

**Note** When reading large text files, reading from a specific point in a file, or reading file data into a cell array rather than multiple outputs, you might prefer to use the `textscan` function.

---

`textread` matches and converts groups of characters from the input. Each input field is defined as a string of non-white-space characters that extends to the next white-space or delimiter character, or to the maximum field width. Repeated delimiter characters are significant, while repeated white-space characters are treated as one.

The `format` string determines the number and types of return arguments. The number of return arguments is the number of items in the `format` string. The `format` string supports a subset of the conversion specifiers and conventions of the C language

`fscanf` routine. Values for the `format` string are listed in the table below. White-space characters in the `format` string are ignored.

<b>format</b>	<b>Action</b>	<b>Output</b>
Literals (ordinary characters)	Ignore the matching characters. For example, in a file that has <code>Dept</code> followed by a number (for department number), to skip the <code>Dept</code> and read only the number, use <code>'Dept'</code> in the <code>format</code> string.	None
<code>%d</code>	Read a signed integer value.	Double array
<code>%u</code>	Read an integer value.	Double array
<code>%f</code>	Read a floating-point value.	Double array
<code>%s</code>	Read a white-space or delimiter-separated string.	Cell array of strings
<code>%q</code>	Read a double quoted string, ignoring the quotes.	Cell array of strings
<code>%c</code>	Read characters, including white space.	Character array
<code>%[...]</code>	Read the longest string containing characters specified in the brackets.	Cell array of strings
<code>%[^...]</code>	Read the longest nonempty string containing characters that are not specified in the brackets.	Cell array of strings
<code>%*... instead of %</code>	Ignore the matching characters specified by <code>*</code> .	No output
<code>%w... instead of %</code>	Read field width specified by <code>w</code> . The <code>%f</code> format supports <code>%w.pf</code> , where <code>w</code> is the field width and <code>p</code> is the precision.	

`[A,B,C,...] = textread(filename,format,N)` reads the data, reusing the `format` string `N` times, where `N` is an integer greater than zero. If `N` is smaller than zero, `textread` reads the entire file.

`[...] = textread(...,param,value,...)` customizes `textread` using `param/value` pairs, as listed in the table below.

<b>param</b>	<b>value</b>	<b>Action</b>
<code>bufsize</code>	Positive integer	Specifies the maximum string length, in bytes. Default is 4095.

param	value	Action
commentstyle	matlab	Ignores characters after %.
commentstyle	shell	Ignores characters after #.
commentstyle	c	Ignores characters between /* and */.
commentstyle	c++	Ignores characters after //.
delimiter	One or more characters	Act as delimiters between elements. Default is none.
emptyvalue	Scalar double	Value given to empty cells when reading delimited files. Default is 0.
endofline	Single character or '\r\n'	Character that denotes the end of a line.  Default is determined from file
expchars	Exponent characters	Default is eEdD.
headerlines	Positive integer	Ignores the specified number of lines at the beginning of the file.
whitespace	Any from the list below:	Treats vector of characters as white space. Default is '\b\t'.
	' '	
	\b	Backspace
	\n	Newline
	\r	Carriage return
	\t	Horizontal tab

---

**Note** When `textread` reads a consecutive series of `whitespace` values, it treats them as one white space. When it reads a consecutive series of `delimiter` values, it treats each as a separate delimiter.

---

## Examples

### Example 1 — Read All Fields in Free Format File Using %

The first line of `mydata.dat` is

```
Sally Level1 12.34 45 Yes
```

Read the first line of the file as a free format file using the % format.

```
[names, types, x, y, answer] = textread('mydata.dat', ...
'%s %s %f %d %s', 1)
```

returns

```
names =
 'Sally'
types =
 'Level1'
x =
 12.340000000000000
y =
 45
answer =
 'Yes'
```

## Example 2 — Read as Fixed Format File, Ignoring the Floating Point Value

The first line of mydata.dat is

```
Sally Level1 12.34 45 Yes
```

Read the first line of the file as a fixed format file, ignoring the floating-point value.

```
[names, types, y, answer] = textread('mydata.dat', ...
'%9c %6s %*f %2d %3s', 1)
```

returns

```
names =
Sally
types =
 'Level1'
y =
 45
answer =
 'Yes'
```

`%*f` in the format string causes `textread` to ignore the floating point value, in this case, `12.34`.

### Example 3 — Read Using Literal to Ignore Matching Characters

The first line of `mydata.dat` is

```
Sally Type1 12.34 45 Yes
```

Read the first line of the file, ignoring the characters `Type` in the second field.

```
[names, typenum, x, y, answer] = textread('mydata.dat', ...
 '%s Type%d %f %d %s', 1)
```

returns

```
names =
 'Sally'
typenum =
 1
x =
 12.340000000000000
y =
 45
answer =
 'Yes'
```

`Type%d` in the format string causes the characters `Type` in the second field to be ignored, while the rest of the second field is read as a signed integer, in this case, 1.

### Example 4 — Specify Value to Fill Empty Cells

For files with empty cells, use the `emptyvalue` parameter. Suppose the file `data.csv` contains:

```
1,2,3,4,,6
7,8,9,,11,12
```

Read the file using `NaN` to fill any empty cells:

```
data = textread('data.csv', ',', 'delimiter', ',', ...
 'emptyvalue', NaN);
```

### Example 5 — Read File into a Cell Array of Strings

Read the file `fft.m` into cell array of strings.

```
file = textread('fft.m', '%s', 'delimiter', '\n', ...
 'whitespace', '');
```

## More About

### Tips

If you want to preserve leading and trailing spaces in a string, use the `whitespace` parameter as shown here:

```
textread('myfile.txt', '%s', 'whitespace', '')
ans =
 ' An example of preserving spaces '
```

`textscan` | `fscanf` | `dlmread`

**Introduced before R2006a**

## textscan

Read formatted data from text file or string

### Syntax

```
C = textscan(fileID,formatSpec)
C = textscan(fileID,formatSpec,N)

C = textscan(str,formatSpec)
C = textscan(str,formatSpec,N)

C = textscan(____,Name,Value)

[C,position] = textscan(____)
```

### Description

`C = textscan(fileID,formatSpec)` reads data from an open text file into a cell array, `C`. The text file is indicated by the file identifier, `fileID`. Use `fopen` to open the file and obtain the `fileID` value. When you finish reading from a file, close the file by calling `fclose(fileID)`.

`textscan` attempts to match the data in the file to `formatSpec`, which is a string of conversion specifiers. `textscan` reapplies `formatSpec` throughout the entire file and stops when it cannot match `formatSpec` to the data.

`C = textscan(fileID,formatSpec,N)` reads file data using the `formatSpec` `N` times, where `N` is a positive integer. To read additional data from the file after `N` cycles, call `textscan` again using the original `fileID`. If you resume a text scan of a file by calling `textscan` with the same file identifier (`fileID`), then `textscan` automatically resumes reading at the point where it terminated the last read.

`C = textscan(str,formatSpec)` reads data from a string, `str`, into cell array `C`. For strings, repeated calls to `textscan` restart the scan from the beginning each time. To restart a scan from the last position, request a `position` output.

`textscan` attempts to match the data in the string, `str`, to `formatSpec`, which is a string of conversion specifiers.

`C = textscan(str,formatSpec,N)` reads string data using the `formatSpec` `N` times, where `N` is a positive integer.

`C = textscan( ____,Name,Value)` specifies options using one or more `Name,Value` pair arguments, in addition to any of the input arguments in the previous syntaxes.

`[C,position] = textscan( ____)` returns the file or string position at the end of the scan as the second output argument, using any of the input arguments in the previous syntaxes. For a file, this is the value that `ftell(fileID)` would return after calling `textscan`. For a string, `position` indicates how many characters `textscan` read.

## Examples

### Read a String

Read a string of floating-point numbers.

```
str = '0.41 8.24 3.57 6.24 9.27';
C = textscan(str,'%f');
```

The `formatSpec` string `'%f'` tells `textscan` to match each field in `str` to a double-precision floating-point number.

Display the contents of cell array `C`.

```
celldisp(C)
```

```
C{1} =

 0.4100
 8.2400
 3.5700
 6.2400
 9.2700
```

Read the same string, truncating each value to one decimal digit.

```
C = textscan(str,'%3.1f %*1d');
```

The specifier `%3.1f` indicates a field width of 3 digits and a precision of 1. `textscan` reads a total of 3 digits, including the decimal point and the 1 digit after the decimal point. The specifier, `%*1d`, tells `textscan` to skip the remaining digit.

Display the contents of cell array `C`.

```
celldisp(C)
```

```
C{1} =
 0.4000
 8.2000
 3.5000
 6.2000
 9.2000
```

### Read Different Types of Data

Using a text editor, create a file `scan1.dat` that contains data in the following form:

```
09/12/2005 Level1 12.34 45 1.23e10 inf Nan Yes 5.1+3i
10/12/2005 Level2 23.54 60 9e19 -inf 0.001 No 2.2-.5i
11/12/2005 Level3 34.90 12 2e5 10 100 No 3.1+.1i
```

Open the file, and read each column with the appropriate conversion specifier.

```
fileID = fopen('scan1.dat');
C = textscan(fileID, '%s %s %f32 %d8 %u %f %f %s %f');
fclose(fileID);
celldisp(C)
```

```
C{1}{1} =
```

```
09/12/2005
```

```
C{1}{2} =
```

```
10/12/2005
```

```
C{1}{3} =
```

11/12/2005

C{2}{1} =

Level1

C{2}{2} =

Level2

C{2}{3} =

Level3

C{3} =

12.3400

23.5400

34.9000

C{4} =

45

60

12

C{5} =

4294967295

4294967295

200000

C{6} =

```
Inf
-Inf
10
```

```
C{7} =
```

```
NaN
0.0010
100.0000
```

```
C{8}{1} =
```

```
Yes
```

```
C{8}{2} =
```

```
No
```

```
C{8}{3} =
```

```
No
```

```
C{9} =
```

```
5.1000 + 3.0000i
2.2000 - 0.5000i
3.1000 + 0.1000i
```

**textscan** returns a 1-by-9 cell array **C**.

View the MATLAB data type of each of the cells in **C**.

```
C
```

```
C =
```

```
Columns 1 through 5
```

```
{3x1 cell} {3x1 cell} [3x1 single] [3x1 int8] [3x1 uint32]

Columns 6 through 9

[3x1 double] [3x1 double] {3x1 cell} [3x1 double]
```

For example, `C{1}` and `C{2}` are cell arrays. `C{5}` is of data type `uint32`, so the first two elements of `C{5}` are the maximum values for a 32-bit unsigned integer, or `intmax('uint32')`.

## Remove a Literal String

Remove the text 'Level' from each field in the second column of the data from the previous example.

Match the literal string in the `formatSpec` input.

```
fileID = fopen('scan1.dat');
C = textscan(fileID, '%s Level%d %f32 %d8 %u %f %f %s %f');
fclose(fileID);
C{2}

ans =

 1
 2
 3
```

View the MATLAB data type of the second cell in `C`.

```
class(C{2})

ans =

int32
```

The second cell of the 1-by-9 cell array, `C`, is now of data type `int32`.

## Skip the Remainder of a Line

Read the first column of the file in the previous example into a cell array, skipping the rest of the line.

```
fileID = fopen('scan1.dat');
dates = textscan(fileID, '%s %*[^\\n]');
```

```
fclose(fileID);
dates{1}

ans =

 '09/12/2005'
 '10/12/2005'
 '11/12/2005'
```

textscan returns a 1-by-1 cell array `dates`.

### Specify Delimiter and Empty Value Conversion

Using a text editor, create a comma-delimited file, `data.csv`, that contains

```
1, 2, 3, 4, , 6
7, 8, 9, , 11, 12
```

Read the file, converting empty cells to `-Inf`.

```
fileID = fopen('data.csv');
C = textscan(fileID, '%f %f %f %f %u8 %f',...
'Delimiter',' ','EmptyValue',-Inf);
fclose(fileID);
column4 = C{4}, column5 = C{5}

column4 =

 4
 -Inf

column5 =

 0
 11
```

textscan returns a 1-by-6 cell array, `C`. The `textscan` function converts the empty value in `C{4}` to `-Inf`, where `C{4}` is associated with a floating-point format. Because MATLAB represents unsigned integer `-Inf` as `0`, `textscan` converts the empty value in `C{5}` to `0`, and not `-Inf`.

### Read Custom Empty Value Strings and Comments

Using a text editor, create a comma-delimited file, `data2.csv`, that contains the lines

```
abc, 2, NA, 3, 4
// Comment Here
def, na, 5, 6, 7
```

Designate the input that `textscan` should treat as comments or empty values.

```
fileID = fopen('data2.csv');
C = textscan(fileID, '%s %n %n %n %n', 'Delimiter', ',', ...
 'TreatAsEmpty', {'NA', 'na'}, 'CommentStyle', '//');
fclose(fileID);
celldisp(C)
```

```
C{1}{1} =
abc
```

```
C{1}{2} =
def
```

```
C{2} =
 2
 NaN
```

```
C{3} =
 NaN
 5
```

```
C{4} =
 3
 6
```

```
C{5} =
 4
 7
```

## Treat Repeated Delimiters as One

Using a text editor, create a file, `data3.csv`, that contains

```
1,2,3,,4
5,6,7,,8
```

To treat the repeated commas as a single delimiter, use the `MultipleDelimsAsOne` parameter, and set the value to `1` (`true`).

```
fileID = fopen('data3.csv');
```

```
C = textscan(fileID, '%f %f %f %f', 'Delimiter', ',', '...',
'MultipleDelimsAsOne', 1);
fclose(fileID);
celldisp(C)
```

```
C{1} =
 1
 5
```

```
C{2} =
 2
 6
```

```
C{3} =
 3
 7
```

```
C{4} =
 4
 8
```

### Specify Repeated Conversion Specifiers and Collect Numeric Data

Using a text editor, create a file, `grades.txt`, that contains:

Student_ID	Test1	Test2	Test3
1	91.5	89.2	77.3
2	88.0	67.8	91.0
3	76.3	78.1	92.5
4	96.4	81.2	84.6

Read the column headers using the format `'%s'` four times.

```
fileID = fopen('grades.txt');

formatSpec = '%s';
N = 4;
C_text = textscan(fileID, formatSpec, N, 'Delimiter', '|');
```

Read the numeric data in the file.

```
C_data0 = textscan(fileID, '%d %f %f %f')

C_data0 =
 [4x1 int32] [4x1 double] [4x1 double] [4x1 double]
```

The default value for `CollectOutput` is 0 (`false`), so `textscan` returns each column of the numeric data in a separate array.

Set the file position indicator to the beginning of the file.

```
frewind(fileID);
```

Reread the file and set `CollectOutput` to 1 (`true`) to collect the consecutive columns of the same class into a single array. You can use the `repmat` function to indicate that the `%f` conversion specifier should appear three times. This technique is useful when a format repeats many times.

```
C_text = textscan(fileID, '%s', N, 'Delimiter', '|');
```

```
C_data1 = textscan(fileID, ['%d', repmat('%f', [1,3])], 'CollectOutput', 1)
```

```
C_data1 =
 [4x1 int32] [4x3 double]
```

The test scores, which are all `double`, are collected into a single 4-by-3 array.

Close the file, `grades.txt`.

```
fclose(fileID);
```

### **Read or Skip Quoted Strings and Numeric Fields**

Read the first and last columns of data from a text file. Skip a column of strings and a column of integer data.

In a text editor, create a comma-delimited text file called `names.txt` that contains:

```
"Smith, J.", "M", 38, 71.1
"Bates, G.", "F", 43, 69.3
"Curie, M.", "F", 38, 64.1
"Murray, G.", "F", 40, 133.0
"Brown, K.", "M", 49, 64.9
```

Read the first and last columns of data in the file. Use the conversion specifier, `%q` to read a string enclosed by double quotation marks (`"`). `.*q` skips a quoted string, `.*d` skips an integer field, and `%f` reads a floating-point number. Specify the comma delimiter using the `'Delimiter'` name-value pair argument.

```
fileID = fopen('names.txt', 'r');
C = textscan(fileID, '%q .*q .*d .*f', 'Delimiter', ',');
```

```
fclose(fileID);
celldisp(C)
```

```
C{1}{1} =
```

```
Smith, J.
```

```
C{1}{2} =
```

```
Bates, G.
```

```
C{1}{3} =
```

```
Curie, M.
```

```
C{1}{4} =
```

```
Murray, G.
```

```
C{1}{5} =
```

```
Brown, K.
```

```
C{2} =
```

```
71.1000
```

```
69.3000
```

```
64.1000
```

```
133.0000
```

```
64.9000
```

`textscan` returns a 1-by-2 cell array, `C`. Double quotation marks enclosing the strings are removed.

### **Read Foreign-Language Dates**

Create a sample file named `myfile.txt` that contains comma-separated values. The first column of values contains dates in German and the second and third columns are numeric values.

```
fileID = fopen('myfile.txt','w','n','ISO-8859-15');
fprintf(fileID,'1 Januar 2014, 20.2, 100.5 \n');
fprintf(fileID,'1 Februar 2014, 21.6, 102.7 \n');
fprintf(fileID,'1 März 2014, 20.7, 99.8 \n');
fclose(fileID);
```

The sample file looks like this:

```
1 Januar 2014, 20.2, 100.5
1 Februar 2014, 21.6, 102.7
1 März 2014, 20.7, 99.8
```

Open the file. Specify the character encoding scheme associated with the file as the last input to `fopen`.

```
fileID = fopen('myfile.txt','r','n','ISO-8859-15');
```

Read the file. Specify the format of the dates in the file using the `%{dd % MMMM yyyy}D` specifier. Specify the locale of the dates using the `DateLocale` name-value pair argument.

```
C = textscan(fileID,'%{dd MMMM yyyy}D %f %f',...
 'DateLocale','de_DE','Delimiter',' ');
fclose(fileID);
```

View the contents of the first cell in `C`.

```
C{1}
```

```
ans =
```

```
01 January 2014
01 February 2014
01 March 2014
```

The dates display in the language MATLAB uses depending on your system locale.

## Read Nondefault Control Characters

Use `sprintf` to convert nondefault escape sequences in your data.

Create a string that includes a form feed character, `\f`. Then, to read the string using `textscan`, call `sprintf` to explicitly convert the form feed.

```
lyric = sprintf('Blackbird\fsinging\fin\the\dead\fof\fnight');
C = textscan(lyric, '%s', 'delimiter', sprintf('\f'));
C{1}
```

```
ans =
```

```
 'Blackbird'
 'singing'
 'in'
 'the'
 'dead'
 'of'
 'night'
```

`textscan` returns a 1-by-1 cell array, `C`.

### Resume a Text Scan of a String

Resume a scan of a string from a position other than the beginning.

If you resume a text scan of a string, `textscan` reads from the beginning of the string each time. To resume a scan from any other position in the string, use the two-output argument syntax in your initial call to `textscan`.

For example, create a string called `lyric`. Read the first word of the string, and then resume the scan.

```
lyric = 'Blackbird singing in the dead of night';
[firstword,pos] = textscan(lyric, '%9c', 1);
lastpart = textscan(lyric(pos+1:end), '%s');
```

- “Import Data from a Nonrectangular Text File”
- “Import Large Text File Data in Blocks”
- “Access Data in a Cell Array”

## Input Arguments

### **fileID** — File identifier

numeric scalar

File identifier of an open text file, specified as a number. Before reading a file with `textscan`, you must use `fopen` to open the file and obtain the `fileID`.

Data Types: `double`

**formatSpec — Format of the data fields**

string

Format of the data fields, specified as a string of one or more conversion specifiers. When `textscan` reads a file or string, it attempts to match the data to the `formatSpec` string. If `textscan` fails to match a data field, it stops reading and returns all fields read before the failure.

The number of conversion specifiers determines the number of cells in output array, `C`.

**Numeric Fields**

This table lists available conversion specifiers for numeric inputs.

Numeric Input Type	Conversion Specifier	Output Class
Integer, signed	%d	int32
	%d8	int8
	%d16	int16
	%d32	int32
	%d64	int64
Integer, unsigned	%u	uint32
	%u8	uint8
	%u16	uint16
	%u32	uint32
	%u64	uint64
Floating-point number	%f	double
	%f32	single
	%f64	double
	%n	double

## Nonnumeric Fields

This table lists available conversion specifiers for inputs that include nonnumeric characters.

Strings	Conversion Specifier	Details
Character	%C	Read any single character, including a delimiter.
Text string	%S	Read a string.
	%q	<p>Read a string. If the string begins with a double quotation mark ("), omit the leading quotation mark and its accompanying closing mark, which is the second instance of a lone double quotation mark. Replace escaped double quotation marks (for example, " "abc" ") with lone double quotation marks (" abc"). %q ignores any double quotation marks that appear after the closing double quotation mark.</p> <p>Example: '%q' reads '"Joe "Lightning" Smith, Jr."' as 'Joe "Lightning" Smith, Jr.'.</p>
Dates and time	%D	Read a string in the same way as %q above, and then convert to a datetime value.
	%{ <i>fmt</i> }D	<p>Read a string in the same way as %q above, and then convert to a datetime value. <i>fmt</i> describes the format of the input string. The <i>fmt</i> input is a string of letter identifiers that is a valid value for the Format property of a datetime. textscan converts strings that do not match this format to NaT values.</p> <p>For more information about datetime display formats, see the Format property for datetime arrays.</p> <p>Example: '%{dd-MMM-yyyy}D' specifies the format of a date such as '01-Jan-2014' .</p>

Strings	Conversion Specifier	Details
Category string	%C	Read a string in the same way as %q, and then convert to a category name in a categorical array. <code>textscan</code> converts the string, <code>&lt;undefined&gt;</code> to an undefined value in the output categorical array.
Pattern-matching strings	%[ . . . ]	Read only the characters inside the brackets up to the first nonmatching character. To include ] in the set, specify it first: %[ ] . . . ].  Example: %[mus] reads 'summer ' as 'summ'.
	%[^ . . . ]	Exclude characters inside the brackets, reading until the first matching character. To exclude ], specify it first: %[^ ] . . . ].  Example: %[^xrg] reads 'summer ' as 'summe'.

### Optional Operators

Conversion specifiers in `formatSpec` can include optional operators, which appear in the following order (includes spaces for clarity):

Optional operators include:

- Fields and Characters to Ignore

`textscan` reads all characters in your file in sequence, unless you tell it to ignore a particular field or a portion of a field.

Insert an asterisk character (\*) after the percent character (%) to skip a field or a portion of a character field.

Operator	Action Taken
<code>%*k</code>	<p>Skip the field. <i>k</i> is any conversion specifier identifying the field to skip. <code>textscan</code> does not create an output cell for any such fields.</p> <p>Example: <code>'%s %*s %s %s %*s %*s %s'</code> (spaces are optional) converts the string <code>'Blackbird singing in the dead of night'</code> to four output cells with the strings <code>'Blackbird'</code> <code>'in'</code> <code>'the'</code> <code>'night'</code></p>
<code>'%*ns'</code>	<p>Skip up to <i>n</i> characters, where <i>n</i> is an integer less than or equal to the number of characters in the field.</p> <p>Example: <code>'%*3s %s'</code> converts <code>'abcdefg'</code> to <code>'defg'</code>. When the delimiter is a comma, the same delimiter converts <code>'abcde, fghijkl'</code> to a cell array containing <code>'de'; 'ijkl'</code>.</p>
<code>'%*nc'</code>	Skip <i>n</i> characters, including delimiter characters.

- Field Width

`textscan` reads the number of characters or digits specified by the field width or precision, or up to the first delimiter, whichever comes first. A decimal point, sign (+ or -), exponent character, and digits in the numeric exponent are counted as characters and digits within the field width. For complex numbers, the field width refers to the individual widths of the real part and the imaginary part. For the imaginary part, the field width includes + or - but not `i` or `j`. Specify the field width by inserting a number after the percent character (%) in the conversion specifier.

Example: `%5f` reads `'123.456'` as `123.4`.

Example: `%5c` reads `'abcdefg'` as `'abcde'`.

When the field width operator is used with single characters (`%c`), `textscan` also reads delimiter, white-space, and end-of-line characters.

Example: `%7c` reads 7 characters, including white-space, so `'Day and night'` reads as `'Day and'`.

- Precision

For floating-point numbers (`%n`, `%f`, `%f32`, `%f64`), you can specify the number of decimal digits to read.

Example: `%7.2f` reads `'123.456'` as `123.45`.

- **Literal Text to Ignore**

`textscan` ignores specified text appended to the `formatSpec` string.

Example: `Level%u8` reads `'Level1'` as `1`.

Example: `%u8Step` reads `'2Step'` as `2`.

## **N** — Number of times to apply `formatSpec`

`Inf` (default) | positive integer

Number of times to apply `formatSpec`, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **str** — Input string

string

Input string to read.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Names are not case sensitive.

Example: `C = textscan(fileID,formatSpec,'HeaderLines',3,'Delimiter','(',')` skips the first three lines of the data, and then reads the remaining data, treating commas as a delimiter.

## **'CollectOutput'** — Logical indicator determining data concatenation

`false` (default) | `true`

Logical indicator determining data concatenation, specified as the comma-separated pair consisting of `'CollectOutput'` and either `true` or `false`. If `true`, then `textscan` concatenates consecutive output cells of the same fundamental MATLAB class into a single array.

### **'CommentStyle' — Symbols designating text to ignore**

string | cell array of strings

Symbols designating text to ignore, specified as the comma-separated pair consisting of `'CommentStyle'` and a string or cell array of strings.

For example, specify a string such as `'%'` to ignore characters following the string on the same line. Specify a cell array of two strings, such as `{'/*', '*/'}`, to ignore characters between the strings.

`textscan` checks for comments only at the start of each field, not within a field.

Example: `'CommentStyle', {'/*', '*/'}`

### **'DateLocale' — Locale for reading dates**

string

Locale for reading dates, specified as the comma-separated pair consisting of `'DateLocale'` and a string in the form `xx_YY`, where `xx` is a lowercase ISO 639-1 two-letter code that specifies a language, and `YY` is an uppercase ISO 3166-1 alpha-2 code that specifies a country. For a list of common values for the locale, see the `Locale` name-value pair argument for the `datetime` function.

Use `DateLocale` to specify the locale in which `textscan` should interpret month and day of week names and abbreviations when reading text as dates using the `%D` format specifier.

Example: `'DateLocale', 'ja_JP'`

### **'Delimiter' — Field delimiter characters**

string | cell array of strings

Field delimiter characters, specified as the comma-separated pair consisting of `'Delimiter'` and a string or a cell array of strings. Specify multiple delimiters in a cell array of strings.

Example: `'Delimiter', {';', '*'}`

`textscan` interprets repeated delimiter characters as separate delimiters, and returns an empty value to the output cell.

Within each row of data, the default field delimiter is white-space. White-space can be any combination of space (' '), backspace ('\b'), or tab ('\t') characters. If you do not specify a delimiter, then:

- the delimiter characters are the same as the white-space characters. The default white-space characters are ' ', '\b', and '\t'. Use the 'Whitespace' name-value pair argument to specify alternate white-space characters.
- `textscan` interprets repeated white-space characters as a single delimiter.

When you specify one of the following escape sequences as a delimiter, `textscan` converts that sequence to the corresponding control character:

<code>\b</code>	Backspace
<code>\n</code>	Newline
<code>\r</code>	Carriage return
<code>\t</code>	Tab
<code>\\</code>	Backslash (\)

### 'EmptyValue' — Returned value for empty numeric fields

NaN (default) | scalar

Returned value for empty numeric fields in delimited text files, specified as the comma-separated pair consisting of 'EmptyValue' and a scalar.

### 'EndOfLine' — End-of-line characters

string

End-of-line characters, specified as the comma-separated pair consisting of 'EndOfLine' and a string. The string must be '\r\n' or it must specify a single character. Common end-of-line characters are a newline character ('\n') or a carriage return ('\r'). If you specify '\r\n', then `textscan` treats any of \r, \n, and the combination of the two (\r\n) as end-of-line characters.

The default end-of-line sequence is \n, \r, or \r\n, depending on the contents of your file.

If there are missing values and an end-of-line sequence at the end of the last line in a file, then `textscan` returns empty values for those fields. This ensures that individual cells in output cell array, `C`, are the same size.

Example: `'EndOfLine', ':'`

### **'ExpChars' — Exponent characters**

`'eEdD'` (default) | string

Exponent characters, specified as the comma-separated pair consisting of `'ExpChars'` and a string. The default exponent characters are `e`, `E`, `d`, and `D`.

### **'HeaderLines' — Number of header lines**

`0` (default) | positive integer

Number of header lines, specified as the comma-separated pair consisting of `'HeaderLines'` and a positive integer. `textscan` skips the header lines, including the remainder of the current line.

### **'MultipleDelimsAsOne' — Multiple delimiter handling**

`0` (`false`) (default) | `1` (`true`)

Multiple delimiter handling, specified as the comma-separated pair consisting of `'MultipleDelimsAsOne'` and either `true` or `false`. If `true`, `textscan` treats consecutive delimiters as a single delimiter. Repeated delimiters separated by white-space are also treated as a single delimiter. You must also specify the `Delimiter` option.

Example: `'MultipleDelimsAsOne', 1`

### **'ReturnOnError' — Behavior when textscan fails to read or convert**

`1` (`true`) (default) | `0` (`false`)

Behavior when `textscan` fails to read or convert, specified as the comma-separated pair consisting of `'ReturnOnError'` and either `true` or `false`. If `true`, `textscan` terminates without an error and returns all fields read. If `false`, `textscan` terminates with an error and does not return an output cell array.

### **'TreatAsEmpty' — Strings to treat as empty value**

string | cell array of strings

Strings to treat as empty values, specified as the comma-separated pair consisting of `'TreatAsEmpty'` and a single string or cell array of strings. This option only applies to numeric fields.

**'Whitespace' — White-space characters**`' \b\t' (default) | string`

White-space characters, specified as the comma-separated pair consisting of 'Whitespace' and a string of one or more characters. `textscan` adds a space character, `char(32)`, to any specified `Whitespace`, unless `Whitespace` is empty ( `' '` ) and `formatSpec` includes any string conversion specifier.

When you specify one of the following escape sequences as any white-space character, `textscan` converts that sequence to the corresponding control character:

<code>\b</code>	Backspace
<code>\n</code>	Newline
<code>\r</code>	Carriage return
<code>\t</code>	Tab
<code>\\</code>	Backslash ( <code>\</code> )

## Output Arguments

**C — File or string data**`cell array`

File or string data, returned as a cell array.

For each numeric conversion specifier in `formatSpec`, the `textscan` function returns a `K`-by-1 MATLAB numeric vector to the output cell array, `C`, where `K` is the number of times that `textscan` finds a field matching the specifier.

For each string conversion specifier in `formatSpec`, the `textscan` function returns a `K`-by-1 cell vector of strings, where `K` is the number of times that `textscan` finds a field matching the specifier. For each character conversion that includes a field width operator, `textscan` returns a `K`-by-`M` character array, where `M` is the field width.

For each datetime or categorical conversion specifier in `formatSpec`, the `textscan` function returns a `K`-by-1 datetime or categorical vector to the output cell array, `C`, where `K` is the number of times that `textscan` finds a field matching the specifier.

**position — File or string position**`integer`

File or string position at the end of the scan, returned as an integer of class `double`. For a file, `ftell(fileID)` would return the same value after calling `textscan`. For a string, `position` indicates how many characters `textscan` read.

## More About

### Algorithms

`textscan` converts numeric fields to the specified output type according to MATLAB rules regarding overflow, truncation, and the use of `NaN`, `Inf`, and `-Inf`. For example, MATLAB represents an integer `NaN` as zero. If `textscan` finds an empty field associated with an integer format specifier (such as `%d` or `%u`), it returns the empty value as zero and not `NaN`.

When matching data to a string conversion specifier, `textscan` reads until it finds a delimiter or an end-of-line character. When matching data to a numeric conversion specifier, `textscan` reads until it finds a nonnumeric character. When `textscan` can no longer match the data to a particular conversion specifier, it attempts to match the data to the next conversion specifier in the `formatSpec` string. Sign (+ or -), exponent characters, and decimal points are considered numeric characters.

Sign	Digits	Decimal Point	Digits	Exponent Character	Sign	Digits
Read one sign character if it exists.	Read one or more digits.	Read one decimal point if it exists.	If there is a decimal point, read one or more digits that immediately follow it.	Read one exponent character if it exists.	If there is an exponent character, read one sign character.	If there is an exponent character, read one or more digits that follow it.

`textscan` imports any complex number as a whole into a complex numeric field, converting the real and imaginary parts to the specified numeric type (such as `%d` or `%f`). Valid forms for a complex number are:

`±<real>±<imag>i|j`

Example: `5.7-3.1i`

`±<imag>i|j`

Example: `-7j`

Do not include embedded white space in a complex number. `textscan` interprets embedded white space as a field delimiter.

## textwrap

Wrapped string matrix for given uicontrol

### Syntax

```
outstring = textwrap(h,instring)
outstring = textwrap(h,instring,columns)
[outstring,position] = textwrap(...)
```

### Description

`outstring = textwrap(h,instring)` returns a wrapped string cell array, `outstring`, that fits inside the uicontrol with handle `h`. `instring` is a cell array, with each cell containing a single line of text. `outstring` is the wrapped string matrix in cell array format. Each cell of the input string is considered a paragraph.

`outstring = textwrap(h,instring,columns)` returns an `outstring` with each line wrapped at `columns` characters. Spaces are included in the character count.

`[outstring,position] = textwrap(...)` returns the recommended position of the uicontrol in the units of the uicontrol. `position` considers the extent of the multiline text in the  $x$  and  $y$  directions.

`textwrap` maintains the original line breaks in the input cell array and adds new ones. It can calculate uicontrol positions with any type of `Units`, including normalized units.

### Examples

Place two text-wrapped strings in text uicontrols. The left one has a `Position` calculated by `textwrap` in `Units of pixels`; the right one's `Position` is calculated manually in `Units of characters`:

```
figure('Position',[560 528 350 250]);
% Make a text uicontrol to wrap in Units of Pixels
% Create it in Units of Pixels, 100 wide, 10 high
pos = [10 100 100 10];
ht = uicontrol('Style','Text','Position',pos);
```

```
string = {'This is a string for the left text uicontrol.',...
 'to be wrapped in Units of Pixels,',...
 'with a position determined by TEXTWRAP.'};
% Wrap string, also returning a new position for ht
[outstring,newpos] = textwrap(ht,string) %#ok<NOPRT>

outstring =
 'This is a string for'
 'the left text'
 'uicontrol.'
 'to be wrapped in'
 'Units of Pixels,'
 'with a position'
 'determined by'
 'TEXTWRAP.'

newpos =
 10 100 91 124

set(ht,'String',outstring,'Position',newpos)

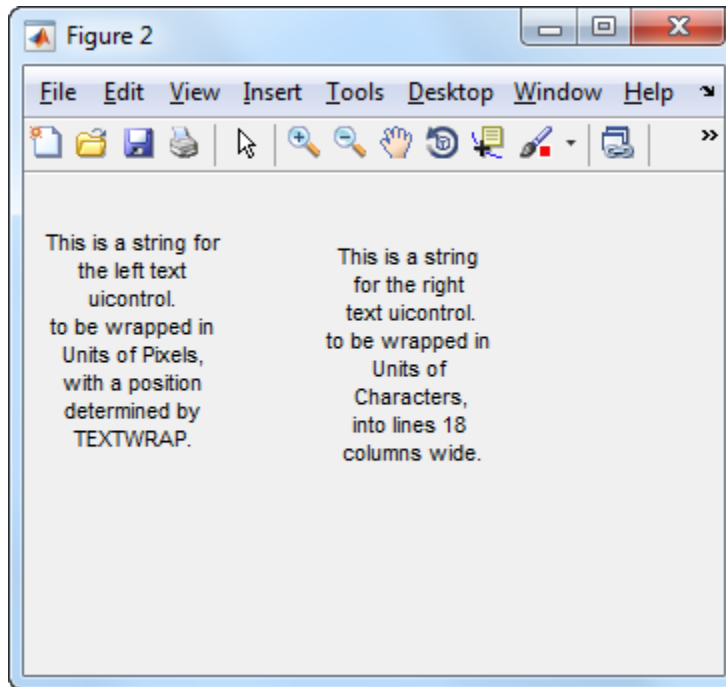

% Make another text uicontrol to wrap to a column width of 18
colwidth = 18;
% Create it in Units of Pixels, 100 wide, 10 high
pos1 = [150 100 100 10];
ht1 = uicontrol('Style','Text','Position',pos1);
string1 = {'This is a string for the right text uicontrol.',...
 'to be wrapped in Units of Characters,',...
 'into lines 18 columns wide.'};
outstring1 = textwrap(ht1,string1,colwidth);
% Reset Units of ht1 to Characters to use the result
set(ht1,'Units','characters')
newpos1 = get(ht1,'Position')

newpos1 =
 29.8000 7.6154 20.0000 0.7692

% Set new Position in Characters to be specified colwidth
% with height the length of the outstring1 cell array + 1.
newpos1(3) = colwidth;
newpos1(4) = length(outstring1)+1

newpos1 =
 29.8000 7.6154 15.0000 10.0000
```

```
set(ht1,'String',outstring1,'Position',newpos1)
```

## More About

### Tips

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. Copying the uicontrol object fires the `CreateFcn` callback repeatedly, which raises a series of error messages.

## tfqmr

Transpose-free quasi-minimal residual method

### Syntax

```
x = tfqmr(A,b)
x = tfqmr(afun,b)
x = tfqmr(a,b,tol)
x = tfqmr(a,b,tol,maxit)
x = tfqmr(a,b,tol,maxit,m)
x = tfqmr(a,b,tol,maxit,m1,m2,x0)
[x,flag] = tfqmr(A,B,...)
[x,flag,relres] = tfqmr(A,b,...)
[x,flag,relres,y]y(A,b,...)
[x,flag,relres,iter,resvec] = tfqmr(A,b,...)
```

### Description

`x = tfqmr(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and the right-hand side column vector  $b$  must have length  $n$ .

`x = tfqmr(afun,b)` accepts a function handle, `afun`, instead of the matrix  $A$ . The function, `afun(x)`, accepts a vector input  $x$  and returns the matrix-vector product  $A*x$ . In all of the following syntaxes, you can replace  $A$  by `afun`. “Parameterizing Functions” explains how to provide additional parameters to the function `afun`.

`x = tfqmr(a,b,tol)` specifies the tolerance of the method. If `tol` is `[]` then `tfqmr` uses the default,  $1e-6$ .

`x = tfqmr(a,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]` then `tfqmr` uses the default,  $\min(N,20)$ .

`x = tfqmr(a,b,tol,maxit,m)` and `x = tfqmr(a,b,tol,maxit,m1,m2)` use preconditioners  $m$  or  $m=m1*m2$  and effectively solve the system  $A*inv(M)*x = B$  for  $x$ . If

M is [] then a preconditioner is not applied. M may be a function handle `mfun` such that `mfun(x)` returns  $m \backslash x$ .

`x = tfqmr(a,b,tol,maxit,m1,m2,x0)` specifies the initial guess. If `x0` is [] then `tfqmr` uses the default, an all zero vector.

`[x,flag] = tfqmr(A,B,...)` also returns a convergence flag:

Flag	Convergence
0	<code>tfqmr</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>tfqmr</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>m</code> was ill-conditioned.
3	<code>tfqmr</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>tfqmr</code> became too small or too large to continue computing.

`[x,flag,relres] = tfqmr(A,b,...)` also returns the relative residual  $\text{norm}(b - A*x) / \text{norm}(b)$ . If `flag` is 0, then `relres`  $\leq$  `tol`.

`[x,flag,relres,y]y(A,b,...)` also returns the iteration number at which `x` was computed:  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = tfqmr(A,b,...)` also returns a vector of the residual norms at each iteration, including  $\text{norm}(b - A*x_0)$ .

## Examples

### Using `tfqmr` with Matrix or Function Handle Input

This example shows how to use `tfqmr` with a matrix input and with a function input.

```
n = 100; on = ones(n,1);
A = spdiags([-2*on 4*on -on],[-1:1,n,n]);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
```

```
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x = tfqmr(A,b,tol,maxit,M1,M2,[]);
```

You can also use a matrix-vector product function as input:

```
function y = afun(x,n)
y = 4 * x;
y(2:n) = y(2:n) - 2 * x(1:n-1);
y(1:n-1) = y(1:n-1) - x(2:n);
x1 = tfqmr(@(x)afun(x,n),b,tol,maxit,M1,M2);
```

If `applyOp` is a function suitable for use with `qmr`, it may be used with `tfqmr` by wrapping it in an anonymous function:

```
x1 = tfqmr(@(x)applyOp(x,'notransp'),b,tol,maxit,M1,M2);
```

## Using `tfqmr` with a Preconditioner

This example demonstrates the use of a preconditioner.

Load `A = west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12;
maxit = 20;
```

Use `tfqmr` to find a solution at the requested tolerance and number of iterations.

```
[x0,f10,rr0,it0,rv0] = tfqmr(A,b,tol,maxit);
```

`f10` is 1 because `tfqmr` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. The seventeenth iterate is the best approximate solution and is the one returned as indicated by `it0 = 17`. MATLAB® stores the residual history in `rv0`.

Plot the behavior of `tfqmr`.

```
semilogy(0:maxit,rv0(1:maxit+1)/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

Note that like `bigstab`, `tfqmr` keeps track of half iterations. The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create the preconditioner with `ilu`, since the matrix `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the 'udiag' option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,f11,rr1,it1,rv1] = tfqmr(A,b,tol,maxit,L,U);
```

f11 is 0 because tfqmr drives the relative residual to  $4.1410e-014$  (the value of rr1). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of it1) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output rv1(1) is norm(b), and the output rv1(7) is norm(b-A\*x2).

You can follow the progress of tfqmr by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:0.5:it1,rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

## **tic**

Start stopwatch timer

### **Syntax**

```
tic
timerVal = tic
```

### **Description**

`tic` starts a stopwatch timer to measure performance. The function records the internal time at execution of the `tic` command. Display the elapsed time with the `toc` function.

`timerVal = tic` returns the value of the internal timer at the execution of the `tic` command, so that you can record time for simultaneous time spans.

### **Output Arguments**

#### **timerVal**

Value of the internal timer at the execution of the `tic` command. This value is used as an input argument for a subsequent call to `toc`. You should not rely on the meaning of this value.

### **Examples**

Measure time to generate two random matrices and compute element-by-element multiplication of their transposes.

```
tic
A = rand(12000, 4400);
B = rand(12000, 4400);
toc
C = A' .* B';
```

```
toc
```

Measure how the time required to solve a linear system varies with the order of a matrix:

```
t = zeros(1,100);
for n = 1:100
 A = rand(n,n);
 b = rand(n,1);
 tic;
 x = A\b;
 t(n) = toc;
end
plot(t)
```

Measure multiple time spans simultaneously using two pairs of `tic/toc` calls. To do this, measure the minimum and average time to compute a summation of Bessel functions:

```
REPS = 1000; minTime = Inf; nsum = 10;
tic; % TIC, pair 1

for i=1:REPS
 tStart = tic; % TIC, pair 2
 total = 0;
 for j=1:nsum
 total = total + besselj(j,REPS);
 end

 tElapsed = toc(tStart); % TOC, pair 2
 minTime = min(tElapsed, minTime);
end
averageTime = toc/REPS; % TOC, pair 1
```

## More About

### Tips

- Consecutive `tic` commands overwrite the internally recorded starting time.
- The `clear` function does not reset the starting time recorded by a `tic` command.
- The following actions result in unexpected output:
  - Using `tic` and `toc` to time `timeit`

- Using `tic` and `toc` within a function timed by `timeit`

**See Also**

`clock` | `cputime` | `etime` | `profile` | `timeit` | `toc`

**Introduced before R2006a**

# timeit

Measure time required to run function

## Syntax

```
t = timeit(f)
t = timeit(f,numOutputs)
```

## Description

`t = timeit(f)` measures the typical time (in seconds) required to run the function specified by the function handle `f`.

`t = timeit(f,numOutputs)` calls `f` with the desired number of outputs, `numOutputs`. By default, `timeit` calls the function `f` with one output (or no outputs, if the function does not return any outputs).

## Examples

### Determine Time to Obtain Current Date

Use `timeit` to time a function call to `date`. This example uses a handle to a function that accepts no input.

```
f = @date;
t = timeit(f)
```

```
t =
```

```
5.5696e-05
```

### Determine Time to Compute Matrix Summation

Time the combination of several mathematical matrix operations: matrix transposition, element-by-element multiplication, and summation of columns.

```
A = rand(12000,400);
B = rand(400,12000);
f = @() sum(A.'.*B, 1);
timeit(f)
```

```
ans =

 0.0493
```

## Compare Time to Run svd with Multiple Outputs

Determine how long it takes to run `svd` with one output argument, `s = svd(X)`.

```
X = rand(100);
f = @() svd(X);
t1 = timeit(f)
```

```
t1 =

 0.0019
```

Compare the results to `svd` with three output arguments, `[U,S,V] = svd(X)`.

```
t2 = timeit(f,3)
```

```
t2 =

 0.0066
```

## Compare Time to Execute Custom Preallocation to Calling zeros

Create a short function to allocate a matrix using nested loops. Preallocating an array using a nested loop is inefficient, but is shown here for illustrative purposes.

```
function mArr = preAllocFcn(x,y)
for m = 1:x
 for n = 1:y
 mArr(m,n) = 0;
 end
end
```

```
end
end
```

Compare the time to allocate zeros to a matrix using nested loops and using the `zeros` function.

```
x = 1000;
y = 500;
g = @() preAllocFcn(x,y);
h = @() zeros(x,y);
diffRunTime = timeit(g)-timeit(h)

diffRunTime =

 0.2004
```

## Input Arguments

### **f** — function to be measured

function handle

Function to be measured, specified as a function handle. **f** is either a handle to a function that takes no input, or a handle to an anonymous function with an empty argument list.

### **numOutputs** — Number of desired outputs from **f**

integer

Number of desired outputs from **f**, specified as an integer. If the function specified by **f** has a variable number of outputs, **numOutputs** specifies which syntax `timeit` uses to call the function. For example, the `svd` function returns a single output, **s**, or three outputs, **[U,S,V]**. Set **numOutputs** to 1 to time the `s = svd(X)` syntax, or set it to 3 to time the `[U,S,V] = svd(X)` syntax.

## More About

### Tips

- The following actions result in unexpected output:
  - Using `timeit` between `tic` and `toc`

- Using `timeit` to time a function that includes calls to `tic` and `toc`
- Using `timeit` recursively

## Algorithms

`timeit` calls the specified function multiple times, and computes the median of the measurements.

- “Create Function Handle”
- Anonymous Functions
- Analyzing Your Program's Performance
- MATLAB Performance Measurement White Paper on MATLAB Central File Exchange

## See Also

`cputime` | `tic` | `toc`

**Introduced in R2013b**

## toc

Read elapsed time from stopwatch

### Syntax

```
toc
elapsedTime = toc
toc(timerVal)
elapsedTime = toc(timerVal)
```

### Description

`toc` reads the elapsed time from the stopwatch timer started by the `tic` function. The function reads the internal time at the execution of the `toc` command, and displays the elapsed time since the most recent call to the `tic` function that had no output, in seconds.

`elapsedTime = toc` returns the elapsed time in a variable.

`toc(timerVal)` displays the time elapsed since the `tic` command corresponding to `timerVal`.

`elapsedTime = toc(timerVal)` returns the elapsed time since the `tic` command corresponding to `timerVal`.

### Input Arguments

#### **timerVal**

Value of the internal timer saved from a previous call to the `tic` command.

## Output Arguments

### **elapsedTime**

Scalar **double** representing the time elapsed between **tic** and **toc** commands, in seconds.

## Examples

Measure time to generate two random matrices and compute element-by-element multiplication of their transposes.

```
tic
A = rand(12000, 4400);
B = rand(12000, 4400);
toc
C = A' .* B';
toc
```

Measure how the time required to solve a linear system varies with the order of a matrix:

```
t = zeros(1,100);
for n = 1:100
 A = rand(n,n);
 b = rand(n,1);
 tic;
 x = A\b;
 t(n) = toc;
end
plot(t)
```

Measure multiple time spans simultaneously using two pairs of **tic/toc** calls. To do this, measure the minimum and average time to compute a summation of Bessel functions:

```
REPS = 1000; minTime = Inf; nsum = 10;
tic; % TIC, pair 1

for i=1:REPS
 tStart = tic; % TIC, pair 2
 total = 0;
 for j=1:nsum
```

```
 total = total + besselj(j,REPS);
 end

 tElapsed = toc(tStart); % TOC, pair 2
 minTime = min(tElapsed, minTime);
end
averageTime = toc/REPS; % TOC, pair 1
```

## More About

### Tips

- Consecutive calls to the `toc` function with no input return the elapsed since the most recent `tic`. Therefore, you can take multiple measurements from a single point in time.

Consecutive calls to the `toc` function with the same `timerVal` input return the elapsed time since the `tic` function call that corresponds to that input.

- The following actions result in unexpected output:
  - Using `tic` and `toc` to time `timeit`
  - Using `tic` and `toc` within a function timed by `timeit`

## Tiff class

MATLAB Gateway to LibTIFF library routines

### Description

The `Tiff` class represents a connection to a Tagged Image File Format (TIFF) file and provides access to many of the capabilities of the LibTIFF library. Use the methods of the `Tiff` object to call routines in the LibTIFF library. While you can use the `imread` and `imwrite` functions to read and write TIFF files, the `Tiff` class offers capabilities that these functions don't provide, such as reading subimages, writing tiles and strips of image data, and modifying individual TIFF tags.

In most cases, the syntax of the `Tiff` method is similar to the syntax of the corresponding LibTIFF library function. To get the most out of the `Tiff` object, you must be familiar with the LibTIFF API, as well as the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

MATLAB supports LibTIFF version 4.0.0.

For copyright information, see the `libtiffcopyright.txt` file.

### Construction

`obj = Tiff(filename,mode)` creates a `Tiff` object associated with the TIFF file `filename`. `mode` specifies the type of access to the file.

A TIFF file is made up of one or more image file directories (IFDs). An IFD contains image data and associated metadata. IFDs can also contain subIFDs which also contain image data and metadata. When you open a TIFF file for reading, the `Tiff` object makes the first IFD in the file the *current* IFD. `Tiff` methods operate on the current IFD. You can use `Tiff` object methods to navigate among the IFDs and the subIFDs in a TIFF file.

When you open a TIFF file for writing or appending, the `Tiff` object automatically creates a IFD in the file for writing subsequent data. This IFD has all the default values specified in TIFF Revision 6.0.

When creating a new TIFF file, before writing any image to the file, you must create certain required fields (tags) in the file. These tags include `ImageWidth`, `ImageHeight`, `BitsPerSample`, `SamplesPerPixel`, `Compression`, `PlanarConfiguration`, and `Photometric`. If the image data has a stripped layout, the IFD contains the `RowsPerStrip` tag. If the image data has a tiled layout, the IFD contains the `TileWidth` and `TileHeight` tags. Use the `setTag` method to define values for these tags.

## Input Arguments

### **filename**

Text string specifying name of file.

### **mode**

One of the following text strings specifying the type of access to the TIFF file.

### Supported Values

Parameter	Description
'r'	Open file for reading (default)
'w'	Open file for writing; discard existing contents
'w8'	Open file for writing a BigTIFF file; discard existing contents
'a'	Open or create file for writing; append data to end of file.
'r+'	Open (do not create) file for reading and writing

## Properties

### **Compression**

Specify scheme used to compress image data

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

**Supported Values**

None
CCITTRLE (Read-only)
CCITTFax3
CCITTFax4
LZW
JPEG
CCITTRLEW (Read-only)
PackBits
SGILog
SGILog24
Deflate
AdobeDeflate (Same as deflate)

Example: Set the `Compression` tag to the value `JPEG`. Note how you use the property to specify the value.

```
tiffobj.setTag('Compression', Tiff.Compression.JPEG);
```

**ExtraSamples**

Describe extra components

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

This field is required if there are extra channels in addition to the usual colormetric channels.

**Supported Values**

Value of ExtraSamples	Description
Unspecified	Unspecified data

Value of ExtraSamples	Description
AssociatedAlpha	Associated alpha (pre-multiplied)
UnassociatedAlpha	Unassociated alpha data

Example: Set the `ExtraSamples` tag to the value `AssociatedAlpha`. Note how you use the property to specify the value.

```
tiffobj.setTag('ExtraSamples', Tiff.ExtraSamples.AssociatedAlpha);
```

See Also “Specify Tiff object properties and describe alpha channel” on page 1-8857

### Group3Options

Options for Group 3 Fax Compression

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

This property is also referred to as `Fax3` and `T4Options`. This value is a bit mask controlled by the first three bits.

### Supported Values

Supported values include the following.

Encoding2D	Bit 0 is 1. This specifies two-dimensional coding. If more than one strip is specified, each strip must begin with a one-dimensionally coded line. That is, <code>RowsPerStrip</code> should be a multiple of Parameter K, as documented in the CCITT specification.
Uncompressed	Bit 1 is 1. This specifies an uncompressed mode when encoding.
FillBits	Bit 2 is 1. Fill bits are added as necessary before EOL codes such that EOL always ends on a byte boundary. This ensures an EOL-sequence of 1 byte preceded by a zero nibble, for example, <code>xxxx-0000 0000-0001</code> .

Example:

```
mask = bitor(Tiff.Group3Options.Encoding2D,Tiff.Group3Options.Uncompressed)
```

```
tiffobj.setTag('Group3Options',mask);
```

### **InkSet**

Specify set of inks used in separated image

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

In this context, separated refers to photometric interpretation, not the planar configuration.

### **Supported Values**

CMYK	Order of components: cyan, magenta, yellow, black. Usually, a value of 0 represents 0% ink coverage and a value of 255 represents 100% ink coverage for that component, but consult the TIFF specification for <code>DotRange</code> . When you specify CMYK, do not set the <code>InkNames</code> tag.
MultiInk	Any ordering other than CMYK. Consult the TIFF specification for <code>InkNames</code> field for a description of the inks used.

Example:

```
tiffobj.setTag('InkSet', Tiff.InkSet.CMYK);
```

### **JPEGColorMode**

Specify control of YCbCr/RGB conversion

Use these values only when the photometric interpretation is YCbCr.

This property should not be used for the purpose of reading YCbCr imagery as RGB. In this case, use the RGBA interface provided by the `readRGBImage`, `readRGBAStrip`, and `readRGBATile` methods.

### **Supported Values**

Raw (default)	Keep input as separate Y, Cb, and Cr matrices.
RGB	Convert RGB input to YCbCr.

Example:

```
tiffobj.setTag('JPEGColorMode',Tiff/JPEGColorMode.RGB);
```

See also “Create YCbCr/JPEG image from RGB data” on page 1-8858

### **Orientation**

Specify visual orientation of the image data.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

The first row represents the top of the image, and the first column represents the left side. Support for this tag is for informational purposes only, and it does not affect how MATLAB reads or writes the image data.

### **Supported Values**

TopLeft
TopRight
BottomRight
BottomLeft
LeftTop
RightTop
RightBottom
LeftBottom

Example:

```
tiffobj.setTag('Orientation', Tiff.Orientation.TopRight);
```

### **Photometric**

Specify color space of image data

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

**Supported Values**

MinIsWhite
MinIsBlack
RGB
Palette
Mask
Separated (CMYK)
YCbCr
CIELab
ICCLab
ITULab
LogL
LogLUV
CFA
LinearRaw

Example:

```
tiffobj.setTag('Photometric', Tiff.Photometric.RGB);
```

**PlanarConfiguration**

Specifies how image data components are stored on disk

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

**Supported Values**

Chunky	Store component values for each pixel contiguously. For example, in the case of RGB data, the first three pixels would be stored in the file as RGBRGBRGB etc. Almost all TIFF images have contiguous planar configurations.
--------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Separate	Store component values for each pixel separately. For example, in the case of RGB data, the red component would be stored separately in the file from the green and blue components.
----------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Example:

```
tiffobj.setTag('PlanarConfiguration', Tiff.PlanarConfiguration.Chunky);
```

### ResolutionUnit

Specify unit of measure used to interpret the XResolution and YResolution tags.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

#### Supported Values

None (default)
Inch
Centimeter

Example: Set `ResolutionUnit` tag to the value `Inch`. Then, setting `XResolution` tag to 300 means pixels per inch.

```
tiffObj.setTag('ResolutionUnit', Tiff.ResolutionUnit.Inch);
tiffObj.setTag('XResolution', 300);
tiffObj.setTag('YResolution', 300);
```

### SampleFormat

Specify how to interpret each pixel sample

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the examples.

#### Supported Values

UInt (default)
Int

**IEEEFP**

Void, ComplexInt, and ComplexIEEEFP are not supported.

Example:

```
tiffobj.setTag('SampleFormat', Tiff.SampleFormat.IEEFP);
```

**SGILogDataFmt**

Specify control of client data for SGILog codec

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

These enumerated values should only be used when the photometric interpretation value is `LogL` or `LogLUV`. The `BitsPerSample`, `SamplesPerPixel`, and `SampleFormat` tags should not be set if the image type is `LogL` or `LogLUV`. The choice of `SGILogDataFmt` will set these tags automatically. The `Float` and `Bits8` settings imply a `SamplesPerPixel` value of 3 for `LogLUV` images, but only 1 for `LogL` images.

**Supported Values**

<code>Float</code>	Single precision samples
<code>Bits8</code>	<code>uint8</code> samples (read only)

This tag can be set only once per instance of a `LogL/LogLuv` Tiff image object instance.

Example:

```
tiffobj = Tiff('example.tif','r');
tiffobj.setDirectory(3); % image three is a LogLuv image
tiffobj.setTag('SGILogDataFmt', Tiff.SGILogDataFmt.Float);
imdata = tiffobj.read();
```

**SubFileType**

Specify type of image

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

SubFileType is a bitmask that indicates the type of the image.

### Supported Values

Default	Default value for single image file or first image.
ReducedImage	The current image is a thumbnail or reduced-resolution image that typically would be found in a sub-IFD.
Page	The image is a single image of a multi-image (or multipage) file.
Mask	The image is a transparency mask for another image in the file. The photometric interpretation value must be Photometric.Mask.

Example:

```
tiffobj.setTag('SubFileType', Tiff.SubFileType.Mask);
```

### TagID

List of recognized TIFF tag names with their ID numbers

This property identifies all the supported TIFF tags with their ID numbers. Use this property to specify a tag when using the `setTag` method. For example, `Tiff.TagID.ImageWidth` returns the ID of the `ImageWidth` tag. To get a list of the names of supported tags, use the `getTagNames` method.

Example:

```
tiffobj.setTag(Tiff.TagID.ImageWidth, 300);
```

### Thresholding

Specifies technique used to convert from gray to black and white pixels.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

### Supported Values

BiLevel (default)
HalfTone
ErrorDiffuse

Example:

```
tiffobj.setTag('Thresholding', Tiff.Thresholding.HalfTone);
```

### **YCbCrPositioning**

Specify relative positioning of chrominance samples

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

This property identifies all supported values for the `YCbCrPositioning` tag.

#### **Supported Values**

Centered	Specify for compatibility with industry standards such as PostScript Level 2
Cosited	Specify for compatibility with most digital video standards such as CCIR Recommendation 601-1.

Example:

```
tiffobj.setTag('YCbCrPositioning', Tiff.YCbCrPositioning.Centered);
```

## **Methods**

<code>close</code>	Close Tiff object
<code>computeStrip</code>	Index number of strip containing specified coordinate
<code>computeTile</code>	Index number of tile containing specified coordinates
<code>currentDirectory</code>	Index of current IFD
<code>getTag</code>	Value of specified tag
<code>getTagNames</code>	List of recognized TIFF tags
<code>getVersion</code>	LibTIFF library version
<code>isTiled</code>	Determine if tiled image
<code>lastDirectory</code>	Determine if current IFD is last in file

---

<code>nextDirectory</code>	Make next IFD current IFD
<code>numberOfStrips</code>	Total number of strips in image
<code>numberOfTiles</code>	Total number of tiles in image
<code>read</code>	Read entire image
<code>readEncodedStrip</code>	Read data from specified strip
<code>readEncodedTile</code>	Read data from specified tile
<code>readRGBAImage</code>	Read image using RGBA interface
<code>readRGBAStrip</code>	Read strip data using RGBA interface
<code>readRGBATile</code>	Read tile data using RGBA interface
<code>rewriteDirectory</code>	Write modified metadata to existing IFD
<code>setDirectory</code>	Make specified IFD current IFD
<code>setSubDirectory</code>	Make subIFD specified by byte offset current IFD
<code>setTag</code>	Set value of tag
<code>write</code>	Write entire image
<code>writeDirectory</code>	Create new IFD and make it current IFD
<code>writeEncodedStrip</code>	Write data to specified strip
<code>writeEncodedTile</code>	Write data to specified tile

## Examples

### Create New TIFF File Using Tiff object

Create a new file called `myfile.tif`. To run this example, your directory must be writable.

```
t = Tiff('myfile.tif', 'w');
```

Close the Tiff object.

```
t.close();
```

### Specify Tiff object properties and describe alpha channel

Create an array of data, `data`, that contains colormetric channels and an alpha channel.

```
rgb = imread('example.tif');
numrows = size(rgb,1);
numcols = size(rgb,2);
alpha = 255*ones([numrows numcols], 'uint8');
data = cat(3,rgb,alpha);
```

Create a Tiff object, `t`, and set the object properties. Set the value of the `ExtraSamples` tag because the data contains the alpha channel in addition to the colormetric channels.

```
t = Tiff('myfile.tif','w');
t.setTag('Photometric',Tiff.Photometric.RGB);
t.setTag('Compression',Tiff.Compression.None);
t.setTag('BitsPerSample',8);
t.setTag('SamplesPerPixel',4);
t.setTag('SampleFormat',Tiff.SampleFormat.UInt);
t.setTag('ExtraSamples',Tiff.ExtraSamples.Unspecified);
t.setTag('ImageLength',numrows);
t.setTag('ImageWidth',numcols);
t.setTag('TileLength',32);
t.setTag('TileWidth',32);
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);
```

Write the data to the Tiff object.

```
t.write(data);
t.close();
```

## Create YCbCr/JPEG image from RGB data

Get RGB data.

```
rgb = imread('example.tif');
```

Create a Tiff object, `t`, and set the object properties. Specify RGB input data using the `JPEGColorMode` property.

```
t = Tiff('myfile.tif','w');
t.setTag('Photometric',Tiff.Photometric.YCbCr);
t.setTag('Compression',Tiff.Compression.JPEG);
t.setTag('YCbCrSubSampling',[2 2]);
t.setTag('BitsPerSample',8);
t.setTag('SamplesPerPixel',3);
t.setTag('SampleFormat',Tiff.SampleFormat.UInt);
t.setTag('ImageLength',size(rgb,1));
```

```
t.setTag('ImageWidth',size(rgb,2));
t.setTag('TileLength',32);
t.setTag('TileWidth',32);
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);
t.setTag('JPEGColorMode',Tiff.JPEGColorMode.RGB);
t.setTag('JPEGQuality',75);
```

Write the data to the Tiff object.

```
t.write(rgb);
t.close();
```

- “Reading Image Data and Metadata from TIFF Files”

## See Also

`imread` | `imwrite` | `imfinfo`

## time

Convert time of calendar duration to duration

## Syntax

```
t = time(d)
```

## Description

`t = time(d)` returns the time components of the calendar duration values in `d` as durations. The `t` output is the same size as `d`.

## Examples

### Convert Time of Calendar Durations to Durations

Create an array of calendar durations.

```
d = caldays(8:10) + hours(1.2345)
```

```
d =
```

```
 8d 1h 14m 4.2s 9d 1h 14m 4.2s 10d 1h 14m 4.2s
```

Convert the time components of the array to durations.

```
t = time(d)
```

```
t =
```

```
 01:14:04 01:14:04 01:14:04
```

View the data type of `t`.

```
whos t
```

Name	Size	Bytes	Class	Attributes
t	1x3	144	duration	

## Input Arguments

### **d** — Input calendar duration

scalar | vector | matrix | multidimensional array

Input calendar duration, specified as a scalar, vector, matrix, or multidimensional `calendarDuration` array.

## See Also

`caldays` | `calmonths` | `calquarters` | `calweeks` | `calyears` | `duration`

**Introduced in R2014b**

## timeofday

Elapsed time since midnight for datetimes

### Syntax

```
d = timeofday(t)
```

### Description

`d = timeofday(t)` returns an array of durations equal to the elapsed time since midnight for each of the `datetime` values in `t`. The output argument, `d`, is equal to the result of `t - dateshift(t, 'start', 'day')`, and is the same size as `t`.

- If you have `datetime` values with no time zone, then `d` also is equal to  
`e = hours(t.Hour) + minutes(t.Minute) + seconds(t.Second)`
- If a `datetime` value has its `TimeZone` property set to a time zone that does not observe Daylight Saving Time (DST), then `d` is equal to `e`.
- If a `datetime` value has its `TimeZone` property set to a time zone that observes DST, then `timeofday` accounts for the DST shift on days when the shift occurs. On those days, for times after the DST shift occurs, `d` differs from `e` by the amount of the shift.

### Examples

#### Calculate Times of Day

Create a `datetime` array. Calculate the elapsed time since midnight for each `datetime` value.

```
t = datetime('now') + hours(1:3)
```

```
t =
```

```
24-Aug-2015 18:53:00 24-Aug-2015 19:53:00 24-Aug-2015 20:53:00
```

```
d = timeofday(t)
```

```
d =
```

```
 18:53:00 19:53:00 20:53:00
```

List the data type of `d`. The `timeofday` function returns a `duration` array, not a `datetime` array.

```
whos d
```

Name	Size	Bytes	Class	Attributes
d	1x3	144	duration	

### Calculate Elapsed Times on DST Shift

Calculate elapsed times since midnight on a day with a Daylight Saving Time (DST) shift.

Create a `datetime` array. Set its `TimeZone` property to a time zone that observes DST. Set the date to a date when a DST shift occurred.

```
tz = 'America/New_York';
fmt = 'dd-MMM-yyyy HH:mm:ss z';
t = datetime(2015,3,8, 'TimeZone',tz, 'Format',fmt) + hours(1:4)
```

```
t =
```

```
Columns 1 through 2
```

```
 08-Mar-2015 01:00:00 EST 08-Mar-2015 03:00:00 EDT
```

```
Columns 3 through 4
```

```
 08-Mar-2015 04:00:00 EDT 08-Mar-2015 05:00:00 EDT
```

Calculate the elapsed times. The DST shift occurred at 02:00 on March 8, 2015 in this time zone. `timeofday` accounts for the shift for times at or after 02:00 on this date.

```
d = timeofday(t)
```

```
d =
```

```
01:00:00 02:00:00 03:00:00 04:00:00
```

## Set Times of Day for Datetimes

Set the times of day in a `datetime` array according to the times of day in another `datetime` array. There are two ways to set the times of day. Only the second method is correct across Daylight Saving Time (DST) shifts.

Create a `datetime` array. Each element has a different time component.

```
t1 = datetime(2015,3,7) + hours(1:4)
```

```
t1 =
```

```
Columns 1 through 3
```

```
07-Mar-2015 01:00:00 07-Mar-2015 02:00:00 07-Mar-2015 03:00:00
```

```
Column 4
```

```
07-Mar-2015 04:00:00
```

Create a second `datetime` array. Each element has the same date and time components.

```
t2 = datetime(2015,3,[8 8 8 8])
```

```
t2 =
```

```
08-Mar-2015 08-Mar-2015 08-Mar-2015 08-Mar-2015
```

Set the times of day in `t2` according to the times of day in `t1`.

```
t2 = dateshift(t2,'start','day') + timeofday(t1)
```

```
t2 =
```

Columns 1 through 3

```
08-Mar-2015 01:00:00 08-Mar-2015 02:00:00 08-Mar-2015 03:00:00
```

Column 4

```
08-Mar-2015 04:00:00
```

Create a `datetime` array with elements that have the `TimeZone` property set to `'America/New_York'`.

```
tz = 'America/New_York';
fmt = 'dd-MMM-yyyy HH:mm:ss z';
t3 = datetime(2015,3,8,'TimeZone',tz,'Format',fmt) + hours(1:4)
```

t3 =

Columns 1 through 2

```
08-Mar-2015 01:00:00 EST 08-Mar-2015 03:00:00 EDT
```

Columns 3 through 4

```
08-Mar-2015 04:00:00 EDT 08-Mar-2015 05:00:00 EDT
```

Calculate the elapsed time since midnight. `timeofday` accounts for the DST shift that occurred on March 8, 2015.

```
d = totimeofday(t3)
```

d =

```
01:00:00 02:00:00 03:00:00 04:00:00
```

Set the times of day in `t4` according to times of day in `t1`. To set the times of day correctly regardless of the time zone or the day of year, use the `Hour`, `Minute`, and `Second` properties of `t1`.

```
t4 = datetime(2015,3,[8 8 8],'TimeZone',tz,'Format',fmt);
```

```
t4.Hour = t1.Hour;
t4.Minute = t1.Minute;

In this time zone 2:00 a.m. Eastern Standard Time did not exist on March 8, 2015, because the DST shift occurred then. The second element of the result has a time component of 3:00 a.m. Eastern Daylight Time.

## Input Arguments

**t** — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

## See Also

`dateshift` | `duration` | `hms` | `hour` | `minute` | `second`

**Introduced in R2014b**

# timer class

Create object to schedule execution of MATLAB commands

## Description

Use a `timer` object to schedule the execution of MATLAB commands one or multiple times. If you schedule the timer to execute multiple times, you can define the time between executions and how to handle queuing conflicts.

The `timer` object uses callback functions to execute commands. Callback functions execute code during some event. For the `timer` object, you can specify the callback function as a function handle or as a string. If the callback function is a string, MATLAB evaluates it as executable code. The timer object supports callback functions when a timer starts (`StartFcn`), executes (`TimerFcn`), stops (`StopFcn`), or encounters an error (`ErrorFcn`).

---

**Note:** The `timer` object is subject to the limitations of your hardware, operating system, and software. Avoid using timer objects for real-time applications.

---

## Construction

`t = timer` creates an empty `timer` object to schedule execution of MATLAB commands. An error occurs if the timer starts and `TimerFcn` is not defined.

`t = timer(Name,Value)` creates a `timer` object with additional options that you specify using one or more `Name,Value` pair arguments.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes ( ' ' ). You can specify several name and value pair arguments in any order as Name1,Value1, . . . ,NameN,ValueN.

The argument name, Name, corresponds to a timer property name. In the constructor, the property values are specified using Name,Value pair arguments.

**'BusyMode'**

String that indicates action taken when a timer has to execute TimerFcn before the completion of previous execution of the TimerFcn. When Running= 'on', BusyMode is read only. This table summarizes the busy modes.

BusyMode Values	Behavior if Queue Empty	Behavior if Queue Not Empty	Notes
'drop'	Adds task to queue	Drops task	Possible skipping of TimerFcn calls
'error'	Adds task to queue	Completes task; throws error specified by ErrorFcn; stops timer	Stops timer after completing task in execution queue
'queue'	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts Period property to manage tasks in execution queue

See “Handling Timer Queuing Conflicts” for more information.

**Default:** 'drop'

**'ErrorFcn'**

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls StopFcn.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the timer object and an event structure to the callback function.

The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.

- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

### 'ExecutionMode'

String that defines how the `timer` object schedules timer events. When `Running='on'`, `ExecutionMode` is read only. This table summarizes the execution modes.

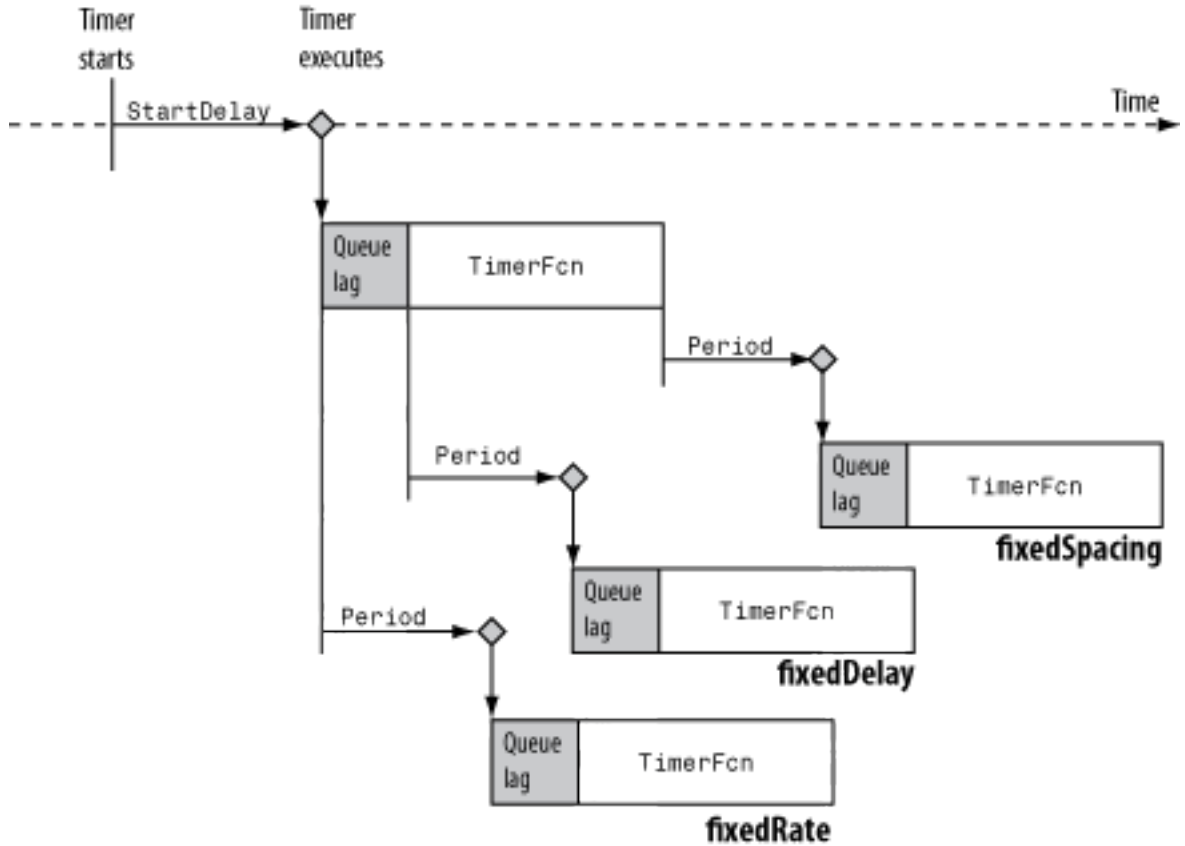

Execution Mode	Time Period Start Point
'singleShot'	In this mode, the timer callback function is only executed once. Therefore, the <code>Period</code> property has no effect. This is the default execution mode.
'fixedRate'	Starts immediately after the timer callback function is added to the MATLAB execution queue
'fixedDelay'	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
'fixedSpacing'	Starts when the timer callback function finishes executing.

- 'singleShot' is the single execution mode for the `timer` class, and is the default value.

### singleShot

- 'fixedDelay', 'fixedRate', and 'fixedSpacing' are the three supported multiexecution modes. These modes define the starting point of the `Period` property. The `Period` property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.

**Default:** 'singleShot'

**'Name'**

String representing the timer name.

**Default:** 'timer-*i*', where *i* is a number indicating the *i*th timer object created this session. To reset *i* to 1, execute the `clear classes` command.

**'ObjectVisibility'**

String with possible values of 'on' or 'off', that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function does not return an object whose `ObjectVisibility` property is set to 'off'. Objects that are not visible are still valid. To retrieve a list of all the timer objects in memory, including the invisible ones, use the `timerfindall` function.

**Default:** 'on'

**'Period'**

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

**Default:** 1.0

**'StartDelay'**

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

**Default:** 0

**'StartFcn'**

String, function handle, or cell array defining the function that executes when the timer starts.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

## **'StopFcn'**

String, function handle, or cell array defining the function that executes when the timer stops.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

The timer stops when

- You call the timer `stop` method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.
- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

## **'Tag'**

String that represents a label for the object.

## **'TasksToExecute'**

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

**Default:** Inf

### **'TimerFcn'**

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

### **'UserData'**

Generic field for data that you want to add to the object.

## **Properties**

### **AveragePeriod**

Average time in seconds between `TimerFcn` executions since the timer started. Value is NaN until timer executes two timer callbacks.

### **InstantPeriod**

The time in seconds between the last two executions of `TimerFcn`. Value is NaN until timer executes two timer callbacks.

### **Running**

String defined as `'off'` or `'on'`, indicating whether the timer is currently executing callback functions.

## TasksExecuted

The number of times the timer called `TimerFcn` since the timer started.

## Type

String that identifies the object type.

## Methods

<code>delete</code>	Remove timer object from memory
<code>get</code>	Query property values for timer object
<code>isvalid</code>	Determine timer object validity
<code>set</code>	Set property values for timer object
<code>start</code>	Start timer object
<code>startat</code>	Schedule timer to fire at specified time
<code>stop</code>	Stop timer object
<code>timerfind</code>	Find timer object
<code>timerfindall</code>	Find timer object, regardless of visibility
<code>wait</code>	Block command prompt until timer stops running

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Display Message Using Timer

Display a message using an anonymous function as a callback function. It is important to note that the first two arguments the callback function passes are a handle to the

timer object and an event structure. Even if the function doesn't use these arguments, the function definition requires them.

Wait 3 seconds, and then display the message '3 seconds have elapsed'.

```
t = timer;
t.StartDelay = 3;
t.TimerFcn = @(myTimerObj, thisEvent)disp('3 seconds have elapsed');
start(t)
```

```
3 seconds have elapsed
```

Suppose the function does not require the timer or event object. Use the tilde (~) operator to ignore the inputs.

```
t.TimerFcn = @(~,~) disp('3 seconds have elapsed');
start(t)
```

```
3 seconds have elapsed
```

Delete the timer object.

```
delete(t)
```

### Execute Callback Function Multiple Times

Display the event and date/time output when the timer starts, fires, and stops. The timer callback function will be executed 3 times with 2 seconds between calls. The first two arguments the callback function passes are a handle to the timer object and an event structure. The event structure contains two fields: **Type** is a string that identifies the type of event that caused the callback, and **Data** is a structure that contains a date time vector of when the event occurred.

```
t = timer;
t.StartFcn = @(~,thisEvent)disp([thisEvent.Type ' executed '...
 datestr(thisEvent.Data.time,'dd-mmm-yyyy HH:MM:SS.FFF')]);
t.TimerFcn = @(~,thisEvent)disp([thisEvent.Type ' executed '...
 datestr(thisEvent.Data.time,'dd-mmm-yyyy HH:MM:SS.FFF')]);
t.StopFcn = @(~,thisEvent)disp([thisEvent.Type ' executed '...
 datestr(thisEvent.Data.time,'dd-mmm-yyyy HH:MM:SS.FFF')]);
t.Period = 2;
t.TasksToExecute = 3;
t.ExecutionMode = 'fixedRate';
start(t)
```

```
StartFcn executed 14-Mar-2013 09:08:50.865
TimerFcn executed 14-Mar-2013 09:08:50.865
TimerFcn executed 14-Mar-2013 09:08:52.865
TimerFcn executed 14-Mar-2013 09:08:54.866
StopFcn executed 14-Mar-2013 09:08:54.869
```

Delete the timer object.

```
delete(t)
```

## Define Custom Callback Functions

Create a timer object to remind yourself to take 30-second ergonomic breaks every 10 minutes over the course of 8 hours.

Create a function in a file named `createErgoTimer.m` that returns a timer object. Have this file include three local functions to handle timer start, execute, and stop tasks.

```
function t = createErgoTimer()
secondsBreak = 30;
secondsBreakInterval = 600;
secondsPerHour = 60^2;
secondsWorkTime = 8*secondsPerHour;

t = timer;
t.UserData = secondsBreak;
t.StartFcn = @ergoTimerStart;
t.TimerFcn = @takeBreak;
t.StopFcn = @ergoTimerCleanup;
t.Period = secondsBreakInterval+secondsBreak;
t.StartDelay = t.Period-secondsBreak;
t.TasksToExecute = ceil(secondsWorkTime/t.Period);
t.ExecutionMode = 'fixedSpacing';
end
```

Using `StartDelay` allows the timer to start without directing you to take a break immediately. Set the execution mode to `'fixedSpacing'` so that 10 minutes and 30 seconds (`t.Period`) elapses after the completion of a `TimerFcn` execution. This allows you to stretch for 30 seconds before the start of the next 10 minute interval.

In the `createErgoTimer.m` file, add a local function to handle the tasks associated with starting the timer. By default, the `timer` object passes itself and event data to the callback function. The function disregards the event data.

```

function ergoTimerStart(mTimer,~)
secondsPerMinute = 60;
secondsPerHour = 60*secondsPerMinute;
str1 = 'Starting Ergonomic Break Timer. ';
str2 = sprintf('For the next %d hours you will be notified',...
 round(mTimer.TasksToExecute*(mTimer.Period + ...
 mTimer.UserData)/secondsPerHour));
str3 = sprintf(' to take a %d second break every %d minutes.',...
 mTimer.UserData, (mTimer.Period - ...
 mTimer.UserData)/secondsPerMinute);
disp([str1 str2 str3])
end

```

Add a local function to handle the tasks associated with executing the timer. The `TimerFcn` callback should tell you to take a 30 second break.

```

function takeBreak(mTimer,~)
disp('Take a 30 second break.')
end

```

Add a local function to handle the tasks associated with stopping the timer.

```

function ergoTimerCleanup(mTimer,~)
disp('Stopping Ergonomic Break Timer.')
delete(mTimer)
end

```

Deleting the timer object removes it from memory.

From the command line, call the `createErgoTimer` function to create and start a timer.

```

t = createErgoTimer;
start(t)

```

Starting Ergonomic Break Timer. For the next 8 hours you will be notified to take a 30

Every 10 minutes, you will be reminded to take a 30 second break.

Take a break.

You can leave the timer running for 8 hours or stop it manually. Recall that you included the task of deleting the timer from memory in the `StopFcn` callback.

```

stop(t)

```

Stopping Ergonomic Break Timer.

## Tips

- To force the execution of the callback functions in the event queue, include a call to the `drawnow` function in your code. The `drawnow` function flushes the event queue.

**Introduced before R2006a**

# delete

**Class:** timer

Remove timer object from memory

## Syntax

```
delete(t)
```

## Description

`delete(t)` removes the timer object, `t`, from memory. If `t` is an array of timer objects, `delete` removes all the objects from memory.

When you delete a timer object, it becomes invalid and you cannot reuse it. If multiple references to a timer object exist in the workspace, deleting the timer object invalidates the remaining references. To remove invalid timer objects references from the workspace, use the `clear` command.

## Tips

- Use the `isvalid` method to determine if a timer object exists in memory, but is not cleared from the workspace.
- Use the `timerfind` and `timerfindall` methods to return timer objects currently existing in memory. This approach is useful if the reference to the timer object is cleared from the workspace (using the `clear` command), but not deleted from memory.

## Input Arguments

**t**

Object of class `timer`.

## Examples

### Delete a Timer

Create and start a timer that generates a 10-by-10 array of random numbers.

```
t = timer('TimerFcn', 'rand(10);');
start(t)
```

Delete the timer from memory.

```
delete(t)
```

Call the `whos` function to see if a reference still exists in the workspace.

```
whos
```

Name	Size	Bytes	Class	Attributes
ans	10x10	800	double	
t	1x1	104	timer	

Try to restart the timer.

```
start(t)
```

```
Error using timer/start (line 27)
```

```
Invalid timer object. This object has been deleted and should be removed from your workspace.
```

The timer cannot be restarted.

Clear the timer object reference from the workspace.

```
clear t
```

### Delete Multiple Timers Using `timerfind`

Use `delete` with the `timerfind` method to remove all visible timers from memory. This is an alternative to deleting individual timers by variable name.

Create and start three timers that compute the sine, cosine and tangent of  $\pi/4$ .

```
t1 = timer('TimerFcn', 'sin(pi/4);');
t2 = timer('TimerFcn', 'cos(pi/4);');
t3 = timer('TimerFcn', 'tan(pi/4);');
```

Delete the timers from memory using `timerfind`. This removes all visible timer objects from memory.

```
delete(timerfind)
```

## See Also

`timer` | `isvalid` | `timerfind` | `timerfindall`

**Introduced before R2006a**

## get

**Class:** timer

Query property values for timer object

## Syntax

```
get(t)
V = get(t)
V = get(t,propName)
```

## Description

`get(t)` queries property values for timer object, `t`, and displays all property names and current values. `t` must be a scalar timer object.

`V = get(t)` queries property values for timer object, `t` and returns a structure, `V`, where each field name is the name of a property of `t` and each field contains the value of that property. If `t` is an `M`-by-1 vector of timer objects, `V` is an `M`-by-1 array of structures.

`V = get(t,propName)` returns the value, `V`, of the timer object property specified in `propName`. If `propNames` is a vector cell array of `N` property names, and `t` is a vector of `M` timer objects, `v` is an `M`-by-`N` cell array of property values.

## Input Arguments

**t**

Object of class timer.

**propName**

String enclosed in single quotation marks that specifies a timer property.

## Examples

### Display All Properties of Timer

```
t = timer;
get(t)

AveragePeriod: NaN
 BusyMode: 'drop'
 ErrorFcn: ''
 ExecutionMode: 'singleShot'
 InstantPeriod: NaN
 Name: 'timer-1'
ObjectVisibility: 'on'
 Period: 1
 Running: 'off'
 StartDelay: 0
 StartFcn: ''
 StopFcn: ''
 Tag: ''
 TasksExecuted: 0
 TasksToExecute: Inf
 TimerFcn: ''
 Type: 'timer'
 UserData: []
```

Delete the timer from memory.

```
delete(t)
```

### Obtain Properties for Array of Timers

Create three timers.

```
t1 = timer;
t2 = timer;
t3 = timer;
```

Get properties of an array of timers.

```
V = get([t1,t2,t3])
```

```
V =
```

3x1 struct array with fields:

```
AveragePeriod
BusyMode
ErrorFcn
ExecutionMode
InstantPeriod
Name
ObjectVisibility
Period
Running
StartDelay
StartFcn
StopFcn
Tag
TasksExecuted
TasksToExecute
TimerFcn
Type
UserData
```

Delete the timers from memory.

```
delete([t1,t2,t3])
```

### **Obtain Single Property for Timer**

Create a timer and determine if it is running.

```
t = timer;
get(t, 'Running')
```

```
ans =
```

```
off
```

Delete the timer from memory.

```
delete(t)
```

### **Obtain Specified Properties for Array of Timers**

Create three timers.

```
t1 = timer;
t2 = timer;
t3 = timer;
```

Obtain name, period, and running property values from the array of timers.

```
V = get([t1,t2,t3],{'Name','Running','Period'})
```

V =

```
 'timer-1' 'off' [1]
 'timer-2' 'off' [1]
 'timer-3' 'off' [1]
```

Delete the timers

```
delete([t1,t2,t3])
```

## Alternatives

You can also use dot notation can also be used to query timer object properties. For example, `t.Running` returns the same value as `get(t, 'Running')`.

## See Also

[timer](#) | [set](#)

**Introduced before R2006a**

## isvalid

**Class:** timer

Determine timer object validity

## Syntax

```
validCheck = isvalid(t)
```

## Description

`validCheck = isvalid(t)` determines timer object validity and returns a logical array, `validCheck`, that contains a 0 where the elements of `t` are invalid timer objects and a 1 where the elements of `t` are valid timer objects.

An invalid timer object is an object that is deleted from memory using `delete` and cannot be reused. Use the `clear` command to remove an invalid timer object from the workspace.

## Tips

- To return timer objects existing in memory, use the `timerfind` and `timerfindall` methods. This practice is useful if the reference to the timer object is cleared from the workspace (using the `clear` function), but the object has not been deleted from memory.

## Input Arguments

**t**

Object or array of objects of class timer

## Examples

### Check Timer Object Validity

Create a timer object. While this timer object is valid, it cannot start because a `TimerFcn` is not defined.

```
t = timer;
out = isvalid(t)
```

```
out =
```

```
 1
```

Delete the timer object, making it invalid.

```
delete(t)
out1 = isvalid(t)
```

```
out1 =
```

```
 0
```

### See Also

**Introduced before R2006a**

## set

**Class:** timer

Set property values for timer object

## Syntax

```
set(t)
propStruct = set(t)
```

```
set(t,Name)
propCell = set(t,Name)
```

## Description

`set(t)` displays the property names and their possible values for all configurable properties of timer object `t`.

`propStruct = set(t)` returns the values in a **struct**.

`set(t,Name)` displays the possible values for the specified property, `Name`, of timer object, `t`.

`propCell = set(t,Name)` returns the values in a cell.

`set(t,Name,Value)` sets the properties specified by one or more `Name,Value` pair arguments. `t` can be a single timer object or a vector of timer objects, in which case `set` configures the property values for all timer objects, `t`.

`set(t,S)` configures the properties of `t`, with the values specified in `S`, where `S` is a structure whose field names are object property names.

`set(t,PN,PV)` configures the properties specified in the cell array of strings, `PN`, to the corresponding values in the cell array `PV`, for the timer object `t`.

## Input Arguments

**t**

Object of class timer.

**S**

Structure whose field names are timer property names.

**PN, PV**

Cell array of strings, **PN**, and corresponding cell array of values, **PV**. The cell array of **PN** must be a 1-by-*N* or *N*-by-1 array. If **t** is an array of timer objects, **PV** can be an *M*-by-*N* cell array, where *M* is equal to the length of **t** and *N* is equal to the length of **PN**. In this case, each timer object is updated with a different set of values for the list of property names contained in **PN**.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

**'BusyMode'**

String that indicates action taken when a timer has to execute **TimerFcn** before the completion of previous execution of the **TimerFcn**. When **Running** = 'on', **BusyMode** is read only. This table summarizes the busy modes.

<b>BusyMode Values</b>	<b>Behavior if Queue Empty</b>	<b>Behavior if Queue Not Empty</b>	<b>Notes</b>
'drop'	Adds task to queue	Drops task	Possible skipping of <b>TimerFcn</b> calls
'error'	Adds task to queue	Completes task; throws error specified by <b>ErrorFcn</b> ; stops timer	Stops timer after completing task in execution queue

BusyMode Values	Behavior if Queue Empty	Behavior if Queue Not Empty	Notes
'queue'	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts <b>Period</b> property to manage tasks in execution queue

See “Handling Timer Queuing Conflicts” for more information.

**Default:** 'drop'

**'ErrorFcn'**

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls **StopFcn**.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the **timer** object and an event structure to the callback function. The event structure contains the type of event in the **Type** field and the time of the event in the **Data** field.
- If your callback function accepts arguments in addition to the **timer** object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

**'ExecutionMode'**

String that defines how the **timer** object schedules timer events. When **Running**='on', **ExecutionMode** is read only. This table summarizes the execution modes.

Execution Mode	Time Period Start Point
'singleShot'	In this mode, the timer callback function is only executed once. Therefore, the <b>Period</b> property has no effect. This is the default execution mode.
'fixedRate'	Starts immediately after the timer callback function is added to the MATLAB execution queue

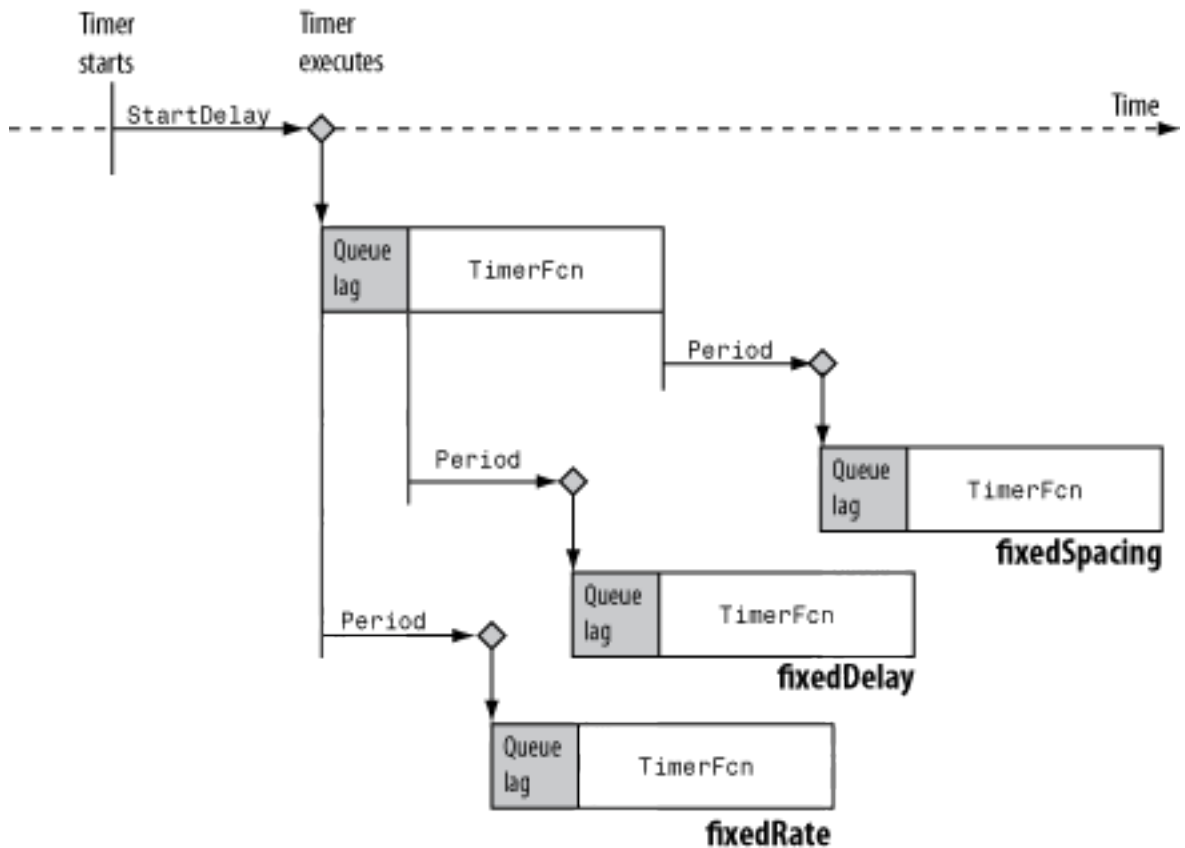

Execution Mode	Time Period Start Point
'fixedDelay'	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
'fixedSpacing'	Starts when the timer callback function finishes executing.

- 'singleShot' is the single execution mode for the `timer` class, and is the default value.

### singleShot

- 'fixedDelay', 'fixedRate', and 'fixedSpacing' are the three supported multiexecution modes. These modes define the starting point of the `Period` property. The `Period` property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.

**Default:** 'singleShot'

**'Name'**

String representing the `timer` name.

**Default:** 'timer-*i*', where *i* is a number indicating the *i*th timer object created this session. To reset *i* to 1, execute the `clear classes` command.

**'ObjectVisibility'**

String with possible values of 'on' or 'off', that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function

does not return an object whose `ObjectVisibility` property is set to `'off'`. Objects that are not visible are still valid. To retrieve a list of all the timer objects in memory, including the invisible ones, use the `timerfindall` function.

**Default:** `'on'`

**'Period'**

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

**Default:** 1.0

**'StartDelay'**

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

**Default:** 0

**'StartFcn'**

String, function handle, or cell array defining the function that executes when the timer starts.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

**'StopFcn'**

String, function handle, or cell array defining the function that executes when the timer stops.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

The timer stops when

- You call the timer `stop` method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.
- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

## **'Tag'**

String that represents a label for the object.

## **'TasksToExecute'**

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

**Default:** `Inf`

## **'TimerFcn'**

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

### 'UserData'

Generic field for data that you want to add to the object.

## Output Arguments

### **propStruct**

Configurable properties of `t`, returned as a structure. The field names of `propStruct` are the property names of `t`, and the associated values of `propStruct` are cell arrays of the possible property values. If the property in `t` does not have a finite set of possible values, the property value in `propStruct` is an empty cell array.

### **propCell**

Possible values of a given property name, returned as cell array of strings. If the property does not have a finite set of possible string values, `set` returns an empty cell array.

## Examples

### Display Configurable Timer Object Properties

Instantiate a timer object and call the `set` method.

```
t = timer;
set(t)
```

```
 BusyMode: [{drop} | queue | error]
```

```
ErrorFcn: string -or- function handle -or- cell array
ExecutionMode: [{singleShot} | fixedSpacing | fixedDelay | fixedRate]
Name
ObjectVisibility: [{on} | off]
Period
StartDelay
StartFcn: string -or- function handle -or- cell array
StopFcn: string -or- function handle -or- cell array
Tag
TasksToExecute
TimerFcn: string -or- function handle -or- cell array
UserData
```

Some of the timer properties, such as `Running`, are not displayed because they are read only.

Use the `set` method to output a structure.

```
out = set(t)
```

```
out =
```

```
 BusyMode: {3x1 cell}
 ErrorFcn: {}
 ExecutionMode: {4x1 cell}
 Name: {}
ObjectVisibility: {2x1 cell}
 Period: {}
 StartDelay: {}
 StartFcn: {}
 StopFcn: {}
 Tag: {}
TasksToExecute: {}
 TimerFcn: {}
 UserData: {}
```

Delete the timer object from memory.

```
delete(t)
```

## Display Possible Property Values

Instantiate a timer object and display possible values for the `BusyMode` property.

```
t = timer;
set(t, 'BusyMode')

[{drop} | queue | error]
```

The output shows the three possible values for `BusyMode`. The default value, `drop`, is indicated by curly braces.

Display the possible values for `ErrorFcn`.

```
set(t, 'ErrorFcn')

string -or- function handle -or- cell array
```

A description of the possible values is displayed since `ErrorFcn` does not have a set list of possible values.

Output the possible property values.

```
out1 = set(t, 'BusyMode')
out2 = set(t, 'ErrorFcn')
```

```
out1 =

 'drop'
 'queue'
 'error'
```

```
out2 =

 {}
```

While `set(t, 'ErrorFcn')` displays a description of the possible values, `out2 = set(t, 'ErrorFcn')` returns an empty cell.

Delete the timer from memory.

```
delete(t)
```

### Set Timer Object Property

Instantiate a timer object and make the object invisible. Display the object's visibility and delete the object.

```
t = timer;
set(t, 'ObjectVisibility', 'off')
get(t, 'ObjectVisibility')
delete(t)
```

```
ans =
```

```
off
```

## Set Timer Object Properties Using Structure

Construct a structure to modify several timer object properties.

```
s.BusyMode = 'queue';
s.ExecutionMode = 'fixedDelay';
s.ObjectVisibility = 'off'
```

```
s =
```

```
 BusyMode: 'queue'
 ExecutionMode: 'fixedDelay'
 ObjectVisibility: 'off'
```

Create a timer, display the properties in `s`, modify the timer, display the new values of the properties, and delete the timer.

```
t = timer;
get(t, {'BusyMode', 'ExecutionMode', 'ObjectVisibility'})
set(t, s)
get(t, {'BusyMode', 'ExecutionMode', 'ObjectVisibility'})
delete(t)
```

```
ans =
```

```
 'drop' 'singleShot' 'on'
```

```
ans =
```

```
 'queue' 'fixedDelay' 'off'
```

## Set Timer Objects Using Cell Arrays

Create a cell array of properties to modify, and a cell array of the values of the corresponding properties. Instantiate a timer, and display the initial values of the properties in the property name cell array, `nameArr`.

```
nameArr = {'BusyMode', 'ExecutionMode', 'Period'};
valArr = {'queue', 'fixedDelay', 3};
t = timer;
get(t, nameArr)
```

```
ans =
 'drop' 'singleShot' [1]
```

Modify the timer object and display the new property values. Delete the timer.

```
set(t, nameArr, valArr)
get(t, nameArr)
delete(t)
```

```
ans =
 'queue' 'fixedDelay' [3]
```

Instantiate an array of three timers. Create a new property name cell array to modify the `BusyMode`, `ExecutionMode`, and `UserData` properties. Display the initial values of the properties for each timer.

```
tArr = [timer timer timer];
nameArr = {'BusyMode', 'ExecutionMode', 'UserData'};
get(tArr, nameArr)
```

```
ans =
 'drop' 'singleShot' []
 'drop' 'singleShot' []
 'drop' 'singleShot' []
```

Assign each property a different value in each timer. Create a cell array containing the new values. Each row indicates the values for the properties in the corresponding timer.

```
valArr = {'queue', 'fixedDelay', 3; ...
 'error', 'fixedSpacing', 42; ...
 'drop', 'fixedRate', 'hello'};
```

Modify the timer object properties and display the updated values.

```
set(tArr, nameArr, valArr)
get(tArr, nameArr)
```

ans =

```
 'queue' 'fixedDelay' [3]
 'error' 'fixedSpacing' [42]
 'drop' 'fixedRate' 'hello'
```

Delete the timers from memory.

```
delete(tArr)
```

## Alternatives

You can also use dot notation to set timer object properties. For example, `t.ObjectVisibility = 'off'` sets the property to the same value as `set(t, 'ObjectVisibility', 'off')`.

## See Also

timer | get

**Introduced before R2006a**

## start

**Class:** timer

Start timer object

## Syntax

start(t)

## Description

start(t) starts the timer object, t. If t is an array of timer objects, start starts all the timers.

The start method sets the **Running** property of the timer object to 'on', executes the StartFcn callback, and initiates TimerFcn callback .

## Input Arguments

**t**

Object of class timer.

## Examples

### Start Timer

Create and start a timer that displays the message 'timer started.' as the StartFcn callback and generates a random number as the TimerFcn callback. Delete the timer.

```
t = timer('StartFcn',@(~,~)disp('timer started.'), 'TimerFcn',@(~,~)disp(rand(1)));
start(t)
delete(t)
```

```
timer started.
```

0.9706

Your output from `rand` will vary.

## Start Several Timers

Create and start three timers that displays a message for the `StartFcn` callbacks and compute the sine, cosine, and tangent of  $\pi/4$  as the `TimerFcn` callbacks. Delete the timers.

```
t1 = timer('StartFcn',@(~,~)disp('t1 started.'),'TimerFcn',@(~,~)sin(pi/4));
t2 = timer('StartFcn',@(~,~)disp('t2 started.'),'TimerFcn',@(~,~)cos(pi/4));
t3 = timer('StartFcn',@(~,~)disp('t3 started.'),'TimerFcn',@(~,~)tan(pi/4));
start([t1 t2 t3]);
delete([t1 t2 t3]);
```

```
t1 started.
t2 started.
t3 started.
```

## See Also

[timer](#) | [delete](#) | [startat](#) | [stop](#)

**Introduced before R2006a**

## startat

**Class:** timer

Schedule timer to fire at specified time

## Syntax

```
startat(t, firingTime)
startat(t, Y, M, D)
startat(t, Y, M, D, H, MI, S)
```

## Description

`startat(t, firingTime)` schedules timer, `t`, to fire at specified time, `firingTime`. A timer fires by executing the callback function, `timerFcn`. `firingTime` must be within 25 days of the current time.

- If `t` is an array of timer objects and `firingTime` is a scalar, `startat` sets all the timers to fire at the specified time.
- If `t` is an array of timer objects and `firingTime` is an array of the same size as `t`, `startat` sets each timer to fire at the corresponding time.

`startat(t, Y, M, D)` starts the timer and schedules execution of `TimerFcn` at the year (`Y`), month (`M`), and day (`D`) specified.

`startat(t, Y, M, D, H, MI, S)` also specifies the hour (`H`), minute (`MI`), and second (`S`) specified.

## Algorithms

- The `startat` method specifies when the timer object executes the `TimerFcn` callback, not when the timer starts running. The timer starts running with the call to the `startat` method.
- Based on the specified time, `startat` computes and sets the required `StartDelay` property of the timer object, `t`. Additionally, it sets the `Running` property of the timer object to 'on', and executes the `StartFcn` callback.

- `startat` modifies the `timer` object's `startDelay` property. As such, `startat` overrides specified values of the timer's `startDelay` property.

## Input Arguments

### **t**

Object of class `timer`.

### **firingTime**

Time at which the timer object is to fire, specified as a serial date number, date string, or a date vector. `firingTime` can be a single date or an array of dates with the same number of rows as timer objects in `t`.

- A serial date number indicates the number of days that have elapsed since 1-Jan-0000 (starting at 1). See `datenum` for additional information about serial date numbers.
- To specify date strings, use the following date formats defined by the `datestr` function: 0, 1, 2, 6, 13, 14, 15, 16, or 23. These numeric identifiers correspond to formats defined by the `formatOut` property of the `datestr` function. Date strings with two-character years are interpreted to be within the 100 years centered on the current year.
- Date vectors are specified as an `m-by-6` or `m-by-3` matrix containing `m` full or partial date vectors, respectively. A full date vector has six elements indicating year, month, day, hour, minute, and second, in that order. A partial date vector has three elements indicating year, month, and day, in that order.

### **Y,M,D**

Time at which the timer object is to fire, specified as numbers indicating the year (`Y`), month (`M`), and day (`D`). Month values less than 1 are set to 1; other arguments can wrap and have negative values.

### **Y,M,D,H,MI,S**

Time at which the timer object is to fire, specified as numbers indicating the year (`Y`), month (`M`), day (`D`), hour (`H`), minute (`MI`), and second (`S`) specified. Month values less than 1 are set to 1; other arguments can wrap and have negative values.

## Examples

### Start Timer in 2 Seconds

Create a timer that displays messages at start time and firing time.

```
t = timer('TimerFcn', @(~,~)disp('Fired.'), ...
 'StartFcn', @(~,~)disp('Started.'));
```

Set the timer to fire 2 seconds from the present time using a serial date. A serial date is specified in days.

```
two = 2/(60^2*24); % two seconds in serial time
fTime = now + two
startat(t,fTime);
```

```
fTime =
 7.3527e+05
```

```
Started.
Fired.
```

Wait for the timer to fire, and then delete the timer.

```
delete(t)
```

### Start Timer Using Year, Month, Day

Create a timer that displays messages at start time and firing time.

```
t = timer('TimerFcn', @(~,~)disp('Fired.'), ...
 'StartFcn', @(~,~)disp('Started.'));
```

Schedule the timer to start 2 days from present at 00:00:00

```
[Y, M, D, H, MI, S] = datevec(now+2);
startat(t,Y,M,D)
```

```
Started.
```

Manually stop and delete the timer.

```
stop(t)
```

`delete(t)`

### **See Also**

`timer` | `delete` | `start` | `stop`

### **More About**

- “Carryover in Date Vectors and Strings”

**Introduced before R2006a**

# stop

**Class:** timer

Stop timer object

## Syntax

stop(t)

## Description

stop(t) stops the timer object, t. If t is an array of timer objects, the stop method stops each timer.

The stop method sets the Running property of the timer object to 'off' and executes the StopFcn callback .

## Tips

- Use the stop method to stop a timer manually. The timer automatically stops when the TimerFcn callback executes the number of times specified by the ExecutionMode and TaskSToExecute properties or when an error occurs while executing a TimerFcn callback.

## Input Arguments

**t**

Object of class timer.

## Examples

### Stop Timer

Create a timer object that generates 100 random numbers and executes one million times. Define a `StopFcn` callback that displays the message 'Timer has stopped.' Start the timer and verify the timer is running

```
t = timer('TimerFcn','rand(100,1);',...
 'ExecutionMode','fixedSpacing','TasksToExecute',1e6,...
 'StopFcn','disp(''Timer has stopped.'')');
start(t)
t.Running
```

```
ans =
```

```
on
```

Manually stop the timer and verify it is no longer running. Delete the timer.

```
stop(t)
t.Running
delete(t)
```

```
Timer has stopped.
```

```
ans =
```

```
off
```

**Introduced before R2006a**

# timerfind

**Class:** timer

Find timer object

## Syntax

```
out = timerfind
out = timerfind(Name,Value)
out = timerfind(t,Name,Value)
out = timerfind(S)
```

## Description

`out = timerfind` finds the “visible timer objects” on page 1-8917 and returns an array, `out`.

`out = timerfind(Name,Value)` finds “visible timer objects” on page 1-8917 with property values matching those passed as `Name,Value` pair arguments and returns an array, `out`.

`out = timerfind(t,Name,Value)` matches `Name,Value` pair arguments to the timer objects listed in `t`, where `t` can be an array of timer objects, and returns an array, `out`.

`out = timerfind(S)` matches property values defined in the structure, `S`, and returns an array, `out`. The field names of `S` are timer object property names and the field values are the corresponding property values.

## Tips

- `timerfind` only finds “visible timer objects” on page 1-8917. Visible timer objects are those that are in memory and have the `ObjectVisibility` property set to 'on'. To find objects that are hidden, but still valid, use `timerfindall`.

## Input Arguments

### t

Array of objects of class timer

### s

Structure with field names corresponding to timer object property names. Field values are the corresponding property values.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### 'BusyMode'

String that indicates action taken when a timer has to execute `TimerFcn` before the completion of previous execution of the `TimerFcn`. When `Running = 'on'`, `BusyMode` is read only. This table summarizes the busy modes.

BusyMode Values	Behavior if Queue Empty	Behavior if Queue Not Empty	Notes
'drop'	Adds task to queue	Drops task	Possible skipping of <code>TimerFcn</code> calls
'error'	Adds task to queue	Completes task; throws error specified by <code>ErrorFcn</code> ; stops timer	Stops timer after completing task in execution queue
'queue'	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts <code>Period</code> property to manage tasks in execution queue

See “Handling Timer Queuing Conflicts” for more information.

**Default:** 'drop'

### 'ErrorFcn'

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls `StopFcn`.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

### 'ExecutionMode'

String that defines how the `timer` object schedules timer events. When `Running='on'`, `ExecutionMode` is read only. This table summarizes the execution modes.

Execution Mode	Time Period Start Point
'singleShot'	In this mode, the timer callback function is only executed once. Therefore, the <code>Period</code> property has no effect. This is the default execution mode.
'fixedRate'	Starts immediately after the timer callback function is added to the MATLAB execution queue
'fixedDelay'	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
'fixedSpacing'	Starts when the timer callback function finishes executing.

- 'singleShot' is the single execution mode for the `timer` class, and is the default value.

### singleShot

- 'fixedDelay', 'fixedRate', and 'fixedSpacing' are the three supported multiexecution modes. These modes define the starting point of the `Period` property. The `Period` property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.

**Default:** 'singleShot'

**'Name'**

String representing the `timer` name.

**Default:** 'timer-*i*', where *i* is a number indicating the *i*th timer object created this session. To reset *i* to 1, execute the `clear classes` command.

**'ObjectVisibility'**

String with possible values of 'on' or 'off', that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function

does not return an object whose `ObjectVisibility` property is set to `'off'`. Objects that are not visible are still valid. To retrieve a list of all the timer objects in memory, including the invisible ones, use the `timerfindall` function.

**Default:** `'on'`

**'Period'**

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

**Default:** 1.0

**'StartDelay'**

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

**Default:** 0

**'StartFcn'**

String, function handle, or cell array defining the function that executes when the timer starts.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

**'StopFcn'**

String, function handle, or cell array defining the function that executes when the timer stops.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

The timer stops when

- You call the timer `stop` method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.
- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

### **'Tag'**

String that represents a label for the object.

### **'TasksToExecute'**

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

**Default:** `Inf`

### **'TimerFcn'**

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

## **'UserData'**

Generic field for data that you want to add to the object.

## **Read Only Name-Value Pair Arguments**

### **AveragePeriod**

Average time in seconds between `TimerFcn` executions since the timer started. Value is NaN until timer executes two timer callbacks.

### **InstantPeriod**

The time in seconds between the last two executions of `TimerFcn`. Value is NaN until timer executes two timer callbacks.

### **Running**

String defined as 'off' or 'on', indicating whether the timer is currently executing callback functions.

### **TasksExecuted**

The number of times the timer called `TimerFcn` since the timer started.

### **Type**

String that identifies the object type.

## Definitions

### visible timer objects

*Visible timer objects* are timer objects that are in memory and have the `ObjectVisibility` property set to 'on'.

## Examples

### Find Timer Objects Existing in Memory

Create several individual timers and an array of timers.

```
t1 = timer('Tag', 'broadcastProgress', 'UserData', 'Monday');
t2 = timer('Tag', 'displayProgress', 'UserData', 'Monday');
timerArr = [timer('Tag', 'broadcastProgress', 'UserData', 'Tuesday');
 timer('Tag', 'displayProgress', 'UserData', 'Tuesday');
 timer('Tag', 'displayProgress', 'UserData', 'Wednesday')];
```

Find all the timers in memory.

```
out1 = timerfind
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-1
2	singleShot	1	''	timer-2
3	singleShot	1	''	timer-3
4	singleShot	1	''	timer-4
5	singleShot	1	''	timer-5

Find only those timers in memory that have the string value, 'displayProgress', as the Tag property.

```
out2 = timerfind('Tag', 'displayProgress')
```

Timer Object Array

```
Index: ExecutionMode: Period: TimerFcn: Name:
1 singleShot 1 '' timer-2
2 singleShot 1 '' timer-4
3 singleShot 1 '' timer-5
```

Limit the search for timers with the string value, 'displayProgress', as the Tag property to timer objects in timerArr.

```
out3 = timerfind(timerArr, 'Tag', 'displayProgress')
```

Timer Object Array

```
Index: ExecutionMode: Period: TimerFcn: Name:
1 singleShot 1 '' timer-4
2 singleShot 1 '' timer-5
```

Define a struct containing the Tag and UserData properties of interest.

```
searchStruct = struct('Tag', 'broadcastProgress', 'UserData', 'Monday')
```

```
searchStruct =
```

```
 Tag: 'broadcastProgress'
 UserData: 'Monday'
```

Use the struct as the search criteria to find timer objects in memory.

```
out4 = timerfind(searchStruct)
```

```
Timer Object: timer-1
```

```
Timer Settings
```

```
 ExecutionMode: singleShot
 Period: 1
 BusyMode: drop
 Running: off
```

```
Callbacks
```

```

TimerFcn: ''
ErrorFcn: ''
StartFcn: ''
StopFcn: ''

```

Delete the timer objects.

```

delete(t1)
delete(t2)
delete(timerArr)

```

### Delete Timer by Name

Simulate having existing timers in memory by creating an array of timers. Create a new timer with a custom name. List all visible timers.

```

existingTimers = [timer timer timer];

myTimerName = 'myTimer';
anotherTimer = timer('Name',myTimerName);

```

```
timerfind
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-1
2	singleShot	1	''	timer-2
3	singleShot	1	''	timer-3
4	singleShot	1	''	myTimer

Delete the specified timer and list all visible timers.

```

delete(timerfind('Name',myTimerName));
timerfind

```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-1
2	singleShot	1	''	timer-2
3	singleShot	1	''	timer-3

Delete all visible timers from memory.

```
delete(timerfind)
```

### Find Valid Timer Objects Cleared from Workspace

Use `timerfind` to find 'lost' timer object references. References are lost when you clear the timer object from the workspace, but do not delete it from memory.

Create two timer objects. Since the callback function does not require the timer or event object, you can use the tilde (~) operator to ignore the inputs in the function handle.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));
whos
```

Name	Size	Bytes	Class	Attributes
t1	1x1	104	timer	
t2	1x1	104	timer	

Clear one of the timer objects from the workspace. To actually remove the timer from memory, you need to both clear it and delete it.

```
clear t1
whos
```

Name	Size	Bytes	Class	Attributes
t2	1x1	104	timer	

Try to delete the timer, `t1`.

```
delete(t1)
```

```
Undefined function or variable 't1'.
```

The timer, `t1`, can not be removed from memory using `delete` because its reference has been cleared.

Find valid timer objects in memory.

```
out = timerfind
```

```
Timer Object Array
```

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	1x1 function_handle	arraytimer-1

```
2 singleShot 1 1x1 function_handle arraytimer-2
```

Since two timers were found, determine which timer does not exist in the workspace.

```
out ~= t2
```

```
ans =
```

```
1 0
```

The first timer object in `out` is not equal to `t2`. This was previously `t1`. It is reassigned to `t1`. Since it is still valid, the timer can be started.

```
t1 = out(1);
start(t1)
```

```
Timer 1 Fired!
```

Delete timer objects. `timerfind` provides a way of accessing timer objects in memory. It does not copy the objects; therefore you do not need to delete `out` from memory. To verify, use `timerfind`.

```
delete(t1)
delete(t2)
timerfind
```

```
ans =
```

```
[]
```

### Delete All Timer Objects in Memory

Create four timer objects.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));
t3 = timer('TimerFcn',@(~,~)disp('Timer 3 Fired!'));
t4 = timer('TimerFcn',@(~,~)disp('Timer 4 Fired!'));
```

Clear two timers from the workspace.

```
clear t2 t3
```

Pass `timerfind` to `delete` to remove all timer objects from memory, whether or not they exist in the workspace.

```
delete(timerfind)
timerfind
```

```
ans =
```

```
 []
```

**Introduced before R2006a**

# timerfindall

**Class:** timer

Find timer object, regardless of visibility

## Syntax

```
out = timerfindall
out = timerfindall(Name, Value)
out = timerfindall(t, Name, Value)
out = timerfindall(S)
```

## Description

`out = timerfindall` finds timer objects existing in memory, regardless of visibility and returns an array, `out`. Use the `ObjectVisibility` property to set the object's visibility.

`out = timerfindall(Name, Value)` finds timer objects existing in memory, regardless of visibility whose property values match those passed as `Name, Value` pair arguments and returns an array, `out`.

`out = timerfindall(t, Name, Value)` matches `Name, Value` pair arguments to the timer objects listed in `t`, where `t` can be an array of timer objects, and returns an array, `out`.

`out = timerfindall(S)` matches property values defined in the structure, `S` and returns an array, `out`. The field names of `S` are timer object property names and the field values are the corresponding property values.

## Tips

- `timerfindall` finds timer objects in memory, regardless of the value of the `ObjectVisibility` property. To limit the search to objects with `ObjectVisibility` set to 'on', use `timerfind..`

## Input Arguments

### t

Array of objects of class timer.

### s

Structure with field names corresponding to timer object property names. Field values are the corresponding property values.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### 'BusyMode'

String that indicates action taken when a timer has to execute `TimerFcn` before the completion of previous execution of the `TimerFcn`. When `Running = 'on'`, `BusyMode` is read only. This table summarizes the busy modes.

BusyMode Values	Behavior if Queue Empty	Behavior if Queue Not Empty	Notes
'drop'	Adds task to queue	Drops task	Possible skipping of <code>TimerFcn</code> calls
'error'	Adds task to queue	Completes task; throws error specified by <code>ErrorFcn</code> ; stops timer	Stops timer after completing task in execution queue
'queue'	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts <code>Period</code> property to manage tasks in execution queue

See “Handling Timer Queuing Conflicts” for more information.

**Default:** 'drop'

### 'ErrorFcn'

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls `StopFcn`.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

### 'ExecutionMode'

String that defines how the `timer` object schedules timer events. When `Running='on'`, `ExecutionMode` is read only. This table summarizes the execution modes.

Execution Mode	Time Period Start Point
'singleShot'	In this mode, the timer callback function is only executed once. Therefore, the <code>Period</code> property has no effect. This is the default execution mode.
'fixedRate'	Starts immediately after the timer callback function is added to the MATLAB execution queue
'fixedDelay'	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
'fixedSpacing'	Starts when the timer callback function finishes executing.

- 'singleShot' is the single execution mode for the `timer` class, and is the default value.

### singleShot

- 'fixedDelay', 'fixedRate', and 'fixedSpacing' are the three supported multiexecution modes. These modes define the starting point of the **Period** property. The **Period** property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.

**Default:** 'singleShot'

**'Name'**

String representing the `timer` name.

**Default:** 'timer-*i*', where *i* is a number indicating the *i*th timer object created this session. To reset *i* to 1, execute the `clear classes` command.

**'ObjectVisibility'**

String with possible values of 'on' or 'off', that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function

does not return an object whose `ObjectVisibility` property is set to `'off'`. Objects that are not visible are still valid. To retrieve a list of all the timer objects in memory, including the invisible ones, use the `timerfindall` function.

**Default:** `'on'`

**'Period'**

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

**Default:** 1.0

**'StartDelay'**

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

**Default:** 0

**'StartFcn'**

String, function handle, or cell array defining the function that executes when the timer starts.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

**'StopFcn'**

String, function handle, or cell array defining the function that executes when the timer stops.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

The timer stops when

- You call the timer `stop` method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.
- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

### **'Tag'**

String that represents a label for the object.

### **'TasksToExecute'**

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

**Default:** `Inf`

### **'TimerFcn'**

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

## **'UserData'**

Generic field for data that you want to add to the object.

## **Read Only Name-Value Pair Arguments**

### **AveragePeriod**

Average time in seconds between `TimerFcn` executions since the timer started. Value is NaN until timer executes two timer callbacks.

### **InstantPeriod**

The time in seconds between the last two executions of `TimerFcn`. Value is NaN until timer executes two timer callbacks.

### **Running**

String defined as 'off' or 'on', indicating whether the timer is currently executing callback functions.

### **TasksExecuted**

The number of times the timer called `TimerFcn` since the timer started.

### **Type**

String that identifies the object type.

## Examples

### Find and Delete All Timers From Memory

Create four timer objects.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));
t3 = timer('TimerFcn',@(~,~)disp('Timer 3 Fired!'));
t4 = timer('TimerFcn',@(~,~)disp('Timer 4 Fired!'));
```

Set timers t2 and t4 to be invisible.

```
t2.ObjectVisibility = 'off';
t4.ObjectVisibility = 'off';
```

Clear timers t1 and t2 from the workspace.

```
clear t1 t2
whos
```

Name	Size	Bytes	Class	Attributes
t3	1x1	104	timer	
t4	1x1	104	timer	

Find all visible timers in memory.

```
timerfind
```

```
Timer Object Array
```

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	1x1 function_handle_arraytimer-1	
2	singleShot	1	1x1 function_handle_arraytimer-3	

`timerfind` finds only timers t1 and t2, since they are visible. Timer t2 is still valid and in memory even though it was cleared from the workspace

Find all timers in memory.

```
timerfindall
```

```
Timer Object Array
```

```
Index: ExecutionMode: Period: TimerFcn: Name:
1 singleShot 1 1x1 function_handle arraytimer-1
2 singleShot 1 1x1 function_handle arraytimer-2
3 singleShot 1 1x1 function_handle arraytimer-3
4 singleShot 1 1x1 function_handle arraytimer-4
```

`timerfindall` finds all four valid timers in memory even though `t2` and `t4` are invisible and `t1` and `t2` were cleared from the workspace.

Delete all timers from memory.

```
delete(timerfindall)
```

## Find Timer Objects Existing in Memory

Create several individual timers and an array of timers.

```
t1 = timer('Tag', 'broadcastProgress', 'UserData', 'Monday');
t2 = timer('Tag', 'displayProgress', 'UserData', 'Monday');
timerArr = [timer('Tag', 'broadcastProgress', 'UserData', 'Tuesday');
 timer('Tag', 'displayProgress', 'UserData', 'Tuesday');
 timer('Tag', 'displayProgress', 'UserData', 'Wednesday')];
```

Make timer `t1` and `timerArr(2)` invisible.

```
t1.ObjectVisibility = 'off';
timerArr(2).ObjectVisibility = 'off';
```

Find all the timers in memory using `timerfind`.

```
out1 = timerfind
```

Timer Object Array

```
Index: ExecutionMode: Period: TimerFcn: Name:
1 singleShot 1 '' timer-2
2 singleShot 1 '' timer-3
3 singleShot 1 '' timer-5
```

`timerfind` does not find the hidden timers.

Find all the timers in memory using `timerfindall`.

```
out2 = timerfindall
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-1
2	singleShot	1	''	timer-2
3	singleShot	1	''	timer-3
4	singleShot	1	''	timer-4
5	singleShot	1	''	timer-5

timerfindall finds all timers, even the invisible ones.

Find only those timers in memory that have the string value, 'displayProgress', as the Tag property.

```
out3 = timerfindall('Tag','displayProgress')
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-2
2	singleShot	1	''	timer-4
3	singleShot	1	''	timer-5

Limit the search for timers that have the string value, 'displayProgress', as the Tag property to timer objects in timerArr.

```
out4 = timerfindall(timerArr,'Tag','displayProgress')
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-4
2	singleShot	1	''	timer-5

Define a struct containing the Tag and UserData properties of interest.

```
searchStruct = struct('Tag','broadcastProgress','UserData','Monday')
```

```
searchStruct =
```

```
 Tag: 'broadcastProgress'
 UserData: 'Monday'
```

Use the struct as the search criteria to find timer objects in memory.

```
out5 = timerfindall(searchStruct)
```

```
Timer Object: timer-1

Timer Settings
 ExecutionMode: singleShot
 Period: 1
 BusyMode: drop
 Running: off

Callbacks
 TimerFcn: ''
 ErrorFcn: ''
 StartFcn: ''
 StopFcn: ''
```

Delete the timer objects.

```
delete(timerfindall)
```

## Find Invisible Timers

Create four timer objects.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));
t3 = timer('TimerFcn',@(~,~)disp('Timer 3 Fired!'));
t4 = timer('TimerFcn',@(~,~)disp('Timer 4 Fired!'));
```

Set timers `t2` and `t4` to be invisible, and clear timers `t1` and `t2` from the workspace.

```
t2.ObjectVisibility = 'off';
t4.ObjectVisibility = 'off';
clear t1 t2;
whos
```

Name	Size	Bytes	Class	Attributes
t3	1x1	104	timer	
t4	1x1	104	timer	

Find all valid invisible timers.

```
out = timerfindall('ObjectVisibility','off')
```

```
Timer Object Array
```

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	1x1 function_handle	arraytimer-2
2	singleShot	1	1x1 function_handle	arraytimer-4

Both valid invisible timers were found by `timerfindall`, regardless of whether they were in the workspace.

## See Also

`timer` | `delete` | `timerfind`

**Introduced before R2006a**

## wait

**Class:** timer

Block command prompt until timer stops running

## Syntax

```
wait(t)
```

## Description

`wait(t)` blocks the command prompt until timer, `t`, stops running. If `t` is an array of timer objects, `wait` blocks the MATLAB command line until each timer in `t` has stopped running.

To block the command line, the timer object must first start via `start` or `startat` before calling the `wait` method. If the timer is not running, `wait` returns immediately.

## Input Arguments

**t**

Array of timer objects

**Default:**

## Examples

### Block Command Prompt While Timer Runs

Create a timer that waits 10 seconds, and then displays a message. Start the timer and wait for it to finish.

```
T = timer('TimerFcn',@(~,~)disp('Fired.'), 'StartDelay',10);
start(T)
```

Fired.

Notice that after the timer starts, the MATLAB prompt returns.

Start the timer and use the wait method to block anyone from entering commands at the MATLAB command line. You must start the timer before calling the wait command.

```
start(T)
wait(T)
```

Fired.

Notice that after the timer starts, the MATLAB prompt disappears until the timer stops.

Delete the timer.

```
delete(T)
```

## See Also

timer | start

**Introduced before R2006a**

## **times, .\***

Element-wise multiplication

### **Syntax**

```
C = A.*B
C = times(A,B)
```

### **Description**

`C = A.*B` multiplies arrays `A` and `B` element by element and returns the result in `C`.

`C = times(A,B)` is an alternate way to execute `A.*B`, but is rarely used. It enables operator overloading for classes.

### **Examples**

#### **Multiply Two Vectors**

Create two vectors, `A` and `B`, and multiply them element by element.

```
A = [1 0 3];
B = [2 3 7];
C = A.*B
```

```
C =
```

```
 2 0 21
```

#### **Multiply Two Arrays**

Create two 3-by-3 arrays, `A` and `B`, and multiply them element by element.

```
A = [1 0 3; 5 3 8; 2 4 6];
B = [2 3 7; 9 1 5; 8 8 3];
C = A.*B
```

```
C =
```

```

 2 0 21
 45 3 40
 16 32 18

```

- “Combine Categorical Arrays Using Multiplication”

## Input Arguments

### A — Left array

scalar | vector | matrix | multidimensional array

Left array, specified as a scalar, vector, matrix, or multidimensional array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `categorical` | `duration` | `calendarDuration`

Complex Number Support: Yes

### B — Right array

scalar | vector | matrix | multidimensional array

Right array, specified as a scalar, vector, matrix, or multidimensional array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `categorical` | `duration` | `calendarDuration`

Complex Number Support: Yes

# timezones

List time zones

## Syntax

```
timezones
timezones(region)
```

```
T = (____)
```

## Description

`timezones` displays a list of all IANA time zones accepted by the `datetime` function. For each time zone, the list includes the offset from UTC (in hours, where east is positive) and the daylight saving time shift (in hours).

`timezones(region)` displays a list containing all IANA time zones in the specified region.

`T = ( ____ )` returns the list in a table.

## Examples

### List All Time Zones in Australia

Store all Australian time zones accepted by the `datetime` function in a table.

```
T = timezones('Australia')
```

```
T =
```

Name	Area	UTCOffset	DSTOffset
'Australia/Adelaide'	Australia	9.5	1
'Australia/Brisbane'	Australia	10	0
'Australia/Broken_Hill'	Australia	9.5	1
'Australia/Currie'	Australia	10	1

'Australia/Darwin'	Australia	9.5	0
'Australia/Eucla'	Australia	8.75	0
'Australia/Hobart'	Australia	10	1
'Australia/Lindeman'	Australia	10	0
'Australia/Lord_Howe'	Australia	10.5	0.5
'Australia/Melbourne'	Australia	10	1
'Australia/Perth'	Australia	8	0
'Australia/Sydney'	Australia	10	1

Sort the table by UTC offset.

```
sortrows(T, 'UTCOffset')
```

ans =

Name	Area	UTCOffset	DSTOffset
'Australia/Perth'	Australia	8	0
'Australia/Eucla'	Australia	8.75	0
'Australia/Adelaide'	Australia	9.5	1
'Australia/Broken_Hill'	Australia	9.5	1
'Australia/Darwin'	Australia	9.5	0
'Australia/Brisbane'	Australia	10	0
'Australia/Currie'	Australia	10	1
'Australia/Hobart'	Australia	10	1
'Australia/Lindeman'	Australia	10	0
'Australia/Melbourne'	Australia	10	1
'Australia/Sydney'	Australia	10	1
'Australia/Lord_Howe'	Australia	10.5	0.5

## Input Arguments

**region** — Geographic region

'All' | 'Africa' | 'America' | 'Antarctica' | ...

Geographic region, specified as one of the following strings.

'Africa'	'Asia'	'Europe'
'America'	'Atlantic'	'Indian'
'Antarctica'	'Australia'	'Pacific'
'Arctic'	'Etc'	'All'

## title

Add title to current axes

### Syntax

```
title(str)
title(str,Name,Value)

title(ax, ___)
h = title(___)
```

### Description

`title(str)` adds the title consisting of a string, `str`, at the top and in the center of the current axes. Reissuing the `title` command causes the new title to replace the old title.

`title(str,Name,Value)` additionally specifies the title properties using one or more `Name,Value` pair arguments.

`title(ax, ___ )` adds the title to the axes specified by `ax`. This syntax allows you to specify the axes to which to add a title. `ax` can precede any of the input argument combinations in the previous syntaxes.

`h = title( ___ )` returns the handle to the text object used as the title. The handle is useful when making future modifications to the title.

### Examples

#### Add Title to Current Figure

Create a figure and display a title in the current axes.

```
figure
plot((1:10).^2)
title('My Title')
```

You also can call `title` with a function that returns a string. For example, the `date` function returns a string containing today's date.

```
title(date)
```

MATLAB® sets the output of `date` as the axes title.

### Include Variable's Value in Title

Include the value of variable `c` in a title.

```
figure
plot((1:10).^2)
f = 70;
c = (f-32)/1.8;
title(['Temperature is ', num2str(c), ' C'])
```

### Create Multicolored Title Using TeX Markup

In a TeX string, use the color modifier `\color` to change the color of characters following it from the previous color.

```
figure
plot((1:10).^2)
title(['\fontsize{16}black {\color{magenta}magenta '...
'\color[rgb]{0 .5 .5}teal \color{red}red} black again'])
```

### Create Colored Title Using Name,Value Pair Argument

Use the Name,Value pair 'Color', 'm' to set the color of the title to magenta.

```
figure
plot((1:10).^2)
title('Case number # 3','Color', 'm')
```

### Include Greek Symbols in Title

Use a TeX string to include Greek symbols in a title.

```
t = (0:0.01:0.2);
y = exp(-25*t);
figure
plot(t,y)
title('y = \ite^{\lambda t}','Color','b')
```

The 'Interpreter' property must be 'tex' (the default).

### Include Superscript or Subscript Character in Title

```
figure
plot((1:10).^2)
title('\alpha^2 and X_1')
```

The superscript character, "^", and the subscript character, "\_", modify the character or substring defined in braces immediately following.

### Create Multiline Title

Create a multiline title using a multiline cell array.

```
figure
plot((1:10).^2)
title({'First line'; 'Second line'})
```

### Display Text As Typed

Set the Interpreter property as 'none' so that the string X<sub>1</sub> is displayed in the figure as typed, without making 1 a subscript of X.

```
figure
plot((1:10).^2)
title('X1', 'Interpreter', 'none')
```

MATLAB® displays the string X\_1 in the title of the figure.

### Add Title to Specific Axes

Create two subplots and return the handles to the axes objects, `s(1)` and `s(2)`.

```
figure
s(1) = subplot(2,1,1);
plot((1:10).^2)
s(2) = subplot(2,1,2);
plot((1:10).^3)
```

Add a title to each subplot by referring to its axes handle, `s(1)`, or `s(2)`.

```
title(s(1), 'Top Plot')
title(s(2), 'Bottom Plot')
```

### Add Title and Return Text Handle

Add a title to a plot and return the text object.

```
plot((1:10).^2)
t = title('My Title');
```

Set the color of the title to red. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
t.Color = 'red';
```

## Input Arguments

### **str** — Text to display as title

character array | cell array | numeric value

Text to display as title, specified as a character array, cell array, or numeric value.

Example: 'my label'

Example: {'first line', 'second line'}

Example: 123

To include numeric variables with text in a title, use the `num2str` function. For example:

```
x = 42;
str = ['The value is ', num2str(x)];
```

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols use TeX markup. For a list of supported markup, see the `Interpreter` property.

To create multiline titles:

- Use a cell array, where each cell contains a line of text, such as `{'first line', 'second line'}`.
- Use a character array, where each row contains the same number of characters, such as `['abc'; 'ab ']`.
- Use `sprintf` to create a string with a new line character, such as `sprintf('first line \n second line')`.

Numeric titles are converted to text using `sprintf('%g', value)`. For example, `12345678` displays as `1.23457e+07`.

---

**Note:** The words `default`, `factory`, and `remove` are reserved words that will not appear in a title when quoted as a normal string. To display any of these words individually, precede them with a backslash, such as `'\default'` or `'\remove'`.

---

## **ax** — Axes object

axes object

Axes object. If you do not specify an axes, then the `title` function uses the current axes.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Color', 'red', 'FontSize', 14` adds a title with red, 14-point font.

---

In addition to the following, you can specify other text object properties using Name, Value pair arguments. See Text Properties.

**'FontSize' — Font size**

11 (default) | scalar value greater than 0

Font size, specified as a scalar value greater than 0 in point units. One point equals 1/72 inch. To change the font units, use the FontUnits property.

Setting the font size properties for the associated axes also affects the title font size. The title font size updates to equal the axes font size times the title scale factor. The FontSize property of the axes contains the axes font size. The TitleFontSizeMultiplier property of the axes contains the scale factor. By default, the axes font size is 10 points and the scale factor is 1.1, so the title font size is 11 points.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**'FontWeight' — Thickness of text characters**

'bold' (default) | 'normal'

Thickness of the text characters, specified as one of these values:

- 'bold' — Thicker characters outlines than normal
- 'normal' — Normal weight as defined by the particular font

MATLAB uses the FontWeight property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight could still result in the normal font weight.

The TitleFontWeight property for the associated axes affects the FontWeight value for the title.

---

**Note:** The 'light' and 'demi' font weight values have been removed. Use 'normal' instead.

---

**'FontName' — Font name**

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. The `'FixedWidth'` value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

**'Color' — Text color**

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. The default color is black with an RGB triplet value of `[0 0 0]`. If you set the color to `'none'`, then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
<code>'yellow'</code>	<code>'y'</code>	<code>[1 1 0]</code>
<code>'magenta'</code>	<code>'m'</code>	<code>[1 0 1]</code>
<code>'cyan'</code>	<code>'c'</code>	<code>[0 1 1]</code>
<code>'red'</code>	<code>'r'</code>	<code>[1 0 0]</code>
<code>'green'</code>	<code>'g'</code>	<code>[0 1 0]</code>
<code>'blue'</code>	<code>'b'</code>	<code>[0 0 1]</code>
<code>'white'</code>	<code>'w'</code>	<code>[1 1 1]</code>
<code>'black'</code>	<code>'k'</code>	<code>[0 0 0]</code>

Example: `'blue'`

Example: `[0 0 1]`

**'Interpreter' — Interpretation of text characters**

`'tex'` (default) | `'latex'` | `'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup.
- `'latex'` — Interpret text strings using LaTeX markup.

- 'none' — Display literal characters.

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers with the `Interpreter` property set to 'tex'. Modifiers remain in effect until the end of the string. Superscripts and subscripts are an exception because they only modify the next character or the text within the curly braces {}.

Modifier	Description	Example of String
<code>^{ }</code>	Superscript	<code>'text^{superscript}'</code>
<code>_{ }</code>	Subscript	<code>'text_{subscript}'</code>
<code>\bf</code>	Bold font	<code>'\bf text'</code>
<code>\it</code>	Italic font	<code>'\it text'</code>
<code>\sl</code>	Oblique font (usually the same as italic font)	<code>'\sl text'</code>
<code>\rm</code>	Normal font	<code>'\rm text'</code>
<code>\fontname{specifier}</code>	Font name — Set <code>specifier</code> as the name of a font family. You can use this in combination with other modifiers.	<code>'\fontname{Courier} text'</code>
<code>\fontsize{specifier}</code>	Font size — Set <code>specifier</code> as a numeric scalar value in point units to change the font size.	<code>'\fontsize{15} text'</code>
<code>\color{specifier}</code>	Font color — Set <code>specifier</code> as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue.	<code>'\color{magenta} text'</code>

Modifier	Description	Example of String
<code>\color[rgb]{specifier}</code>	Custom font color — Set specifier as a three-element RGB triplet.	<code>'\color[rgb]{0,0.5,0.5} text'</code>

This table lists the supported special characters with the Interpreter property set to 'tex'.

## LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at <http://www.latex-project.org/>.

## Output Arguments

### **h** — Text object

text object

Text object used as the title. Use `h` to access and modify properties of the title after its created.

# todatenum

Convert CDF epoch object to MATLAB serial date number

## Syntax

```
n = todatenum(obj)
```

## Description

`n = todatenum(obj)` converts the CDF epoch object `ep_obj` into a MATLAB serial date number. Note that a CDF epoch is the number of milliseconds since 01-Jan-0000 whereas a MATLAB datenum is the number of days since 00-Jan-0000.

## Examples

Construct a CDF epoch object from a date string, and then convert the object back into a MATLAB date string:

```
dstr = datestr(today)
dstr =
 08-Oct-2003

obj = cdfepoch(dstr)
obj =
 cdfepoch object:
 08-Oct-2003 00:00:00

dstr2 = datestr(todatenum(obj))
dstr2 =
 08-Oct-2003
```

## See Also

`cdfepoch` | `cdfinfo` | `cdfread` | `datenum` | `datetime`

**Introduced before R2006a**

## toeplitz

Toeplitz matrix

### Syntax

```
T = toeplitz(c,r)
T = toeplitz(r)
```

### Description

`T = toeplitz(c,r)` returns a nonsymmetric Toeplitz matrix with `c` as its first column and `r` as its first row. If the first elements of `c` and `r` differ, `toeplitz` issues a warning and uses the column element for the diagonal.

`T = toeplitz(r)` returns the symmetric Toeplitz matrix where:

- If `r` is a real vector, then `r` defines the first row of the matrix.
- If `r` is a complex vector with a real first element, then `r` defines the first row and `r'` defines the first column.
- If the first element of `r` is complex, the Toeplitz matrix is Hermitian off the main diagonal, which means  $T_{i,j} = \text{conj}(T_{j,i})$  for  $i \neq j$ . The elements of the main diagonal are set to `r(1)`.

### Examples

#### Create Symmetric Toeplitz Matrix

```
r = [1 2 3];
toeplitz(r)
```

```
ans =
```

```
 1 2 3
 2 1 2
```

```
3 2 1
```

### Create Nonsymmetric Toeplitz Matrix

Create a nonsymmetric Toeplitz matrix with a specified column and row vector. Because the first elements of the column and row vectors do not match, `toeplitz` issues a warning and uses the column for the diagonal element.

```
c = [1 2 3 4];
r = [4 5 6];
toeplitz(c,r)
```

```
Warning: First element of input column does not match first element of input
row.
```

```
Column wins diagonal conflict.
```

```
ans =
```

```
1 5 6
2 1 5
3 2 1
4 3 2
```

Create a Toeplitz matrix with complex row and column vectors. The Toeplitz matrix is Hermitian off the main diagonal such that  $T_{i,j} = \text{conj}(T_{j,i})$  for  $i \neq j$ .

```
c = [1+3i 2-5i -1+3i];
r = [1+3i 3-1i -1-2i];
T = toeplitz(c,r)
```

```
T =
```

```
1.0000 + 3.0000i 3.0000 - 1.0000i -1.0000 - 2.0000i
2.0000 - 5.0000i 1.0000 + 3.0000i 3.0000 - 1.0000i
-1.0000 + 3.0000i 2.0000 - 5.0000i 1.0000 + 3.0000i
```

### Create Circulant Matrices Using `toeplitz` Function

You can create circulant matrices using `toeplitz`. Circulant matrices are used in applications such as circular convolution.

Create a circulant matrix from vector  $v$  using `toeplitz`.

```
v = [9 1 3 2];
toeplitz([v(1) flip1r(v(2:end))], v)
```

```
ans =
```

```
 9 1 3 2
 2 9 1 3
 3 2 9 1
 1 3 2 9
```

Perform discrete-time circular convolution by using `toeplitz` to form the circulant matrix for convolution.

Define the periodic input  $x$  and the system response  $h$ .

```
x = [1 8 3 2 5];
h = [3 5 2 4 1];
```

Form the column vector  $c$  to create a circulant matrix where `length(c) = length(h)`.

```
c = [x(1) flip1r(x(end-length(h)+2:end))]
```

```
c =
```

```
 1 5 2 3 8
```

Form the row vector  $r$  from  $x$ .

```
r = x;
```

Form the convolution matrix `xConv` using `toeplitz`. Find the convolution using `h*xConv`.

```
xConv = toeplitz(c,r)
h*xConv
```

```
xConv =
```

```

1 8 3 2 5
5 1 8 3 2
2 5 1 8 3
3 2 5 1 8
8 3 2 5 1

```

```
ans =
```

```
52 50 73 46 64
```

If you have the Signal Processing Toolbox™, you can use the `cconv` function to find the circular convolution.

### Discrete-Time Convolution Using Toeplitz

Perform discrete-time convolution by using `toeplitz` to form the arrays for convolution.

Define the input  $x$  and system response  $h$ .

```
x = [1 8 3 2 5];
h = [3 5 2];
```

Form  $r$  by padding  $x$  with zeros. The length of  $r$  is the convolution length  $x + h - 1$ .

```
r = [x zeros(1,length(h)-1)]
```

```
r =
```

```
1 8 3 2 5 0 0
```

Form the column vector  $c$ . Set the first element to  $x(1)$  because the column determines the diagonal. Pad  $c$  because `length(c)` must equal `length(h)` for convolution.

```
c = [x(1) zeros(1,length(h)-1)]
```

```
c =
```

```
1 0 0
```

Form the convolution matrix `xConv` using `toeplitz`. Then, find the convolution using `h*xConv`.

```
xConv = toeplitz(c,r)
h*xConv
```

```
xConv =
```

```
 1 8 3 2 5 0 0
 0 1 8 3 2 5 0
 0 0 1 8 3 2 5
```

```
ans =
```

```
 3 29 51 37 31 29 10
```

Check that the result is correct using `conv`.

```
conv(x,h)
```

```
ans =
```

```
 3 29 51 37 31 29 10
```

## Input Arguments

### **c** — Column of Toeplitz matrix

scalar | vector

Column of Toeplitz matrix, specified as a scalar or vector. If the first elements of `c` and `r` differ, `toeplitz` uses the column element for the diagonal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Complex Number Support: Yes

### **r** — Row of Toeplitz matrix

scalar | vector

Row of Toeplitz matrix, specified as a scalar or vector. If the first elements of `c` and `r` differ, then `toeplitz` uses the column element for the diagonal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Complex Number Support: Yes

## More About

### Toeplitz Matrix

A Toeplitz matrix is a diagonal-constant matrix, which means all elements along a diagonal have the same value. For a Toeplitz matrix  $A$ , we have  $A_{i,j} = a_{i-j}$  which results in the form

$$A = \begin{bmatrix} a_0 & a_{-1} & a_{-2} & \cdots & \cdots & a_{1-n} \\ a_1 & a_0 & a_{-1} & \ddots & \ddots & \vdots \\ a_2 & a_1 & a_0 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & \ddots & a_{-3} \\ \vdots & \ddots & \ddots & \ddots & a_0 & a_{-1} \\ a_{n-1} & \cdots & \cdots & a_2 & a_1 & a_0 \end{bmatrix}.$$

Introduced before R2006a

## toolboxdir

Root folder for specified toolbox

### Syntax

```
toolboxdir('tbxFolderName')
s = toolboxdir('tbxFolderName')
s = toolboxdir tbxFolderName
```

### Description

`toolboxdir('tbxFolderName')` returns a string that is the absolute path to the specified toolbox, `tbxFolderName`, where `tbxFolderName` is the folder name for the toolbox.

`s = toolboxdir('tbxFolderName')` returns the absolute path to the specified toolbox to the output argument, `s`.

`s = toolboxdir tbxFolderName` is the command form of the syntax.

### Examples

Obtain the path for the Control System Toolbox software:

```
s = toolboxdir('control')
```

MATLAB returns:

```
s = C:\Program Files\MATLAB\R2012a\toolbox\control
```

### More About

#### Tips

`toolboxdir` is particularly useful for MATLAB Compiler software. The base folder of all toolboxes installed with MATLAB software is:

```
matlabroot/toolbox/tbxFolderName
```

However, in deployed mode, the base folders of the toolboxes are different. `toolboxdir` returns the correct root folder, whether running from MATLAB or from an application deployed with the MATLAB Compiler software.

To determine the folder name for a given toolbox, run the following code, substituting the name of a product function for *toolboxfcn*:

```
n = 'toolboxfcn';
pat = '(?<=^[\\/]toolbox[\\/])[^\\/]+';
regexp(which(n), pat, 'match', 'once')
```

For example, to determine the product name for Control System Toolbox set `n` to the name of a function unique to Control System Toolbox, such as `dss`:

```
n = 'dss'
pat = '(?<=^[\\/]toolbox[\\/])[^\\/]+'
regexp(which(n), pat, 'match', 'once')
```

```
control
```

## **trace**

Sum of diagonal elements

### **Syntax**

```
b = trace(A)
```

### **Description**

`b = trace(A)` is the sum of the diagonal elements of the matrix `A`.

### **More About**

#### **Algorithms**

```
t = sum(diag(A));
```

#### **See Also**

`det` | `eig`

**Introduced before R2006a**

## transpose, .'

Transpose vector or matrix

### Syntax

```
B = A.'
B = transpose(A)
```

### Description

`B = A.'` returns the nonconjugate transpose of `A`, that is, interchanges the row and column index for each element. If `A` contains complex elements, then `A.'` does not affect the sign of the imaginary parts. For example, if `A(3,2)` is `1+2i` and `B = A.'`, then the element `B(2,3)` is also `1+2i`.

`B = transpose(A)` is an alternate way to execute `A.'` and enables operator overloading for classes.

### Examples

#### Real Matrix

Create a matrix of real numbers and compute its transpose. `B` has the same elements as `A`, but the rows of `B` are the columns of `A` and the columns of `B` are the rows of `A`.

```
A = magic(4)
```

```
A =
```

```
16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

$B = A.'$

$B =$

16	5	9	4
2	11	7	14
3	10	6	15
13	8	12	1

## Complex Matrix

Create a matrix containing complex elements and compute its nonconjugate transpose.  $B$  contains the same elements as  $A$ , except the rows and columns are interchanged. The signs of the imaginary parts are unchanged.

$A = [1\ 3\ 4-1i\ 2+2i; 0+1i\ 1-1i\ 5\ 6-1i]$

$A =$

1.0000 + 0.0000i	3.0000 + 0.0000i	4.0000 - 1.0000i	2.0000 + 2.0000i
0.0000 + 1.0000i	1.0000 - 1.0000i	5.0000 + 0.0000i	6.0000 - 1.0000i

$B = A.'$

$B =$

1.0000 + 0.0000i	0.0000 + 1.0000i
3.0000 + 0.0000i	1.0000 - 1.0000i
4.0000 - 1.0000i	5.0000 + 0.0000i
2.0000 + 2.0000i	6.0000 - 1.0000i

## Input Arguments

### **A** — Input array

vector | matrix

Input array, specified as a vector or matrix.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | cell | categorical | datetime | duration | calendarDuration  
Complex Number Support: Yes

## More About

### Tips

- The complex conjugate transpose operator,  $A'$ , also negates the sign of the imaginary part of the complex elements in  $A$ .
- “Array vs. Matrix Operations”
- “Operator Precedence”

### See Also

conj | ctranspose | permute

**Introduced before R2006a**

## trapz

Trapezoidal numerical integration

### Syntax

```
Q = trapz(Y)
Q = trapz(X,Y)
Q = trapz(____,dim)
```

### Description

`Q = trapz(Y)` returns the approximate integral of `Y` via the trapezoidal method with unit spacing. The size of `Y` determines the dimension to integrate along:

- If `Y` is a vector, then `trapz(Y)` is the approximate integral of `Y`.
- If `Y` is a matrix, then `trapz(Y)` integrates over each column and returns a row vector of integration values.
- If `Y` is a multidimensional array, then `trapz(Y)` integrates over the first dimension whose size does not equal 1. The size of this dimension becomes 1, and the sizes of other dimensions remain unchanged.

`Q = trapz(X,Y)` integrates `Y` with spacing increment `X`. By default, `trapz` operates on the first dimension of `Y` whose size does not equal 1. `length(X)` must be equal to the size of this dimension. If `X` is a scalar, then `trapz(X,Y)` is equivalent to `X*trapz(Y)`.

`Q = trapz( ____,dim)` integrates along the dimension `dim` using any of the previous syntaxes. You must specify `Y`, and optionally can specify `X`. The length of `X`, if specified, must be the same as `size(Y,dim)`. For example, if `Y` is a matrix, then `trapz(X,Y,2)` integrates each row of `Y`.

### Examples

#### Integrate Vector of Data with Unit Spacing

Create a numeric vector of data.

```
Y = [1 4 9 16 25];
```

Y contains function values for  $f(x) = x^2$  in the domain [1, 5].

Use `trapz` to integrate the data points with unit spacing.

```
Q = trapz(Y)
```

```
Q =
```

```
42
```

This approximate integration yields a value of 42. In this case, the exact answer is a little less,  $41\frac{1}{3}$ . The `trapz` function overestimates the value of the integral because  $f(x)$  is concave up.

### **Integrate Vector of Data with Nonunit Spacing**

Create a domain vector, X.

```
X = 0:pi/100:pi;
```

Calculate the sine of X and store the result in Y.

```
Y = sin(X);
```

Integrate the function values contained in Y using `trapz`.

```
Q = trapz(X,Y)
```

```
Q =
```

```
1.9998
```

When the spacing between points is constant, but not equal to 1, you can multiply by the spacing value, in this case  $\text{pi}/100 * \text{trapz}(Y)$ . The answer is the same if you pass the value directly to the function with `trapz(X,Y)`.

### **Integrate Matrix with Nonuniform Spacing**

Create a vector of time values, X. Also create a matrix, Y, containing values evaluated at the irregular intervals in X.

```
X = [1 2.5 7 10]';
```

```
Y = [5.2 4.8 4.9 5.1; 7.7 7.0 6.5 6.8; 9.6 10.5 10.5 9.0; 13.2 14.5 13.8 15.2]
```

```
Y =
```

```
 5.2000 4.8000 4.9000 5.1000
 7.7000 7.0000 6.5000 6.8000
 9.6000 10.5000 10.5000 9.0000
 13.2000 14.5000 13.8000 15.2000
```

The columns of  $Y$  represent velocity data, taken at the times contained in  $X$ , for several different trials.

Use `trapz` to integrate each column independently and find the total distance traveled in each trial. Since the function values are not evaluated at constant intervals, specify  $X$  to indicate the spacing between the data points.

```
Q = trapz(X,Y)
```

```
Q =
```

```
 82.8000 85.7250 83.2500 80.7750
```

The result is a row vector of integration values, one for each column in  $Y$ . By default, `trapz` integrates along the first dimension of  $Y$  whose size does not equal 1.

Alternatively, you can integrate the rows of a matrix by specifying `dim = 2`.

In this case, use `trapz` on  $Y'$ , which contains the velocity data in the rows.

```
dim = 2;
```

```
Q1 = trapz(X,Y',dim)
```

```
Q1 =
```

```
 82.8000
 85.7250
 83.2500
 80.7750
```

The result is a column vector of integration values, one for each row in  $Y'$ .

## Multiple Numerical Integrations

Created a grid of domain values.

```
x = -3:.1:3;
```

```
y = -5:.1:5;
[X,Y] = meshgrid(x,y);
```

Calculate the function  $f(x,y) = x^2 + y^2$  over the grid.

```
F = X.^2 + Y.^2;
```

`trapz` integrates numeric data rather than functional expressions, so in general the expression does not need to be known to use `trapz` on a matrix of data.

Use `trapz` to approximate the double integral

$$I = \int_{-5}^5 \int_{-3}^3 (x^2 + y^2) dx dy$$

To perform double or triple integrations on an array of numeric data, nest function calls to `trapz`.

```
I = trapz(y, trapz(x,F,2))
```

```
I =
```

```
680.2000
```

`trapz` performs the integration over  $x$  first, producing a column vector. Then, the integration over  $y$  reduces the column vector to a single scalar. `trapz` slightly overestimates the exact answer of 680 because  $f(x,y)$  is concave up.

## Input Arguments

### Y — Numeric data

vector | matrix | multidimensional array

Numeric data, specified as a vector, matrix, or multidimensional array. By default, `trapz` integrates along the first dimension of `Y` whose size does not equal 1.

Data Types: `single` | `double`

Complex Number Support: Yes

### X — Point spacing

1 (default) | uniform scalar spacing | vector of nonuniform spacings

Point spacing, specified as 1 (default), a uniform scalar spacing, or a vector of nonuniform spacings. If  $X$  is a vector, then  $\text{length}(X)$  must be the same as the size of the integration dimension in  $Y$ .

Data Types: `single` | `double`

Complex Number Support: Yes

**dim** – Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array,  $Y$ :

- `trapz(Y,1)` works on successive elements in the columns of  $Y$  and returns a row vector of integration values.

- `trapz(Y,2)` works on successive elements in the rows of  $Y$  and returns a column vector of integration values.

If `dim` is greater than `ndims(Y)`, then `trapez` returns an array of zeros of the same size as `Y`.

## More About

### Trapezoidal Method

`trapez` performs numerical integration via the trapezoidal method. This method approximates the integration over an interval by breaking the area down into trapezoids with more easily computable areas.

For an integration with `N+1` evenly spaced points, the approximation is

$$\begin{aligned} \int_a^b f(x) dx &\approx \frac{b-a}{2N} \sum_{n=1}^N (f(x_n) + f(x_{n+1})) \\ &= \frac{b-a}{2N} [f(x_1) + 2f(x_2) + \dots + 2f(x_N) + f(x_{N+1})], \end{aligned}$$

where the spacing between each point is equal to the scalar value  $\frac{b-a}{N}$ .

If the spacing between the points is not constant, then the formula generalizes to

$$\int_a^b f(x) dx \approx \frac{1}{2} \sum_{n=1}^N (x_{n+1} - x_n) [f(x_n) + f(x_{n+1})],$$

where  $(x_{n+1} - x_n)$  is the spacing between each consecutive pair of points.

### Tips

- `trapez` reduces the size of the dimension it operates on to 1, and returns only the final integration value. `cumtrapez` also returns the intermediate integration values, preserving the size of the dimension it operates on.
- “Integration of Numeric Data”

# treelayout

Lay out tree or forest

## Syntax

```
[x,y] = treelayout(parent,post)
[x,y,h,s] = treelayout(parent,post)
```

## Description

`[x,y] = treelayout(parent,post)` lays out a tree or a forest. `parent` is the vector of parent pointers, with 0 for a root. `post` is an optional postorder permutation on the tree nodes. If you omit `post`, `treelayout` computes it. `x` and `y` are vectors of coordinates in the unit square at which to lay out the nodes of the tree to make a nice picture.

`[x,y,h,s] = treelayout(parent,post)` also returns the height of the tree `h` and the number of vertices `s` in the top-level separator.

## See Also

`etree` | `treeplot` | `etreeplot` | `symbfact`

Introduced before R2006a

## treeplot

Plot picture of tree

### Syntax

```
treeplot(p)
treeplot(p,nodeSpec,edgeSpec)
```

### Description

`treeplot(p)` plots a picture of a tree given a vector of parent pointers, with  $p(i) = 0$  for a root.

`treeplot(p,nodeSpec,edgeSpec)` allows optional parameters `nodeSpec` and `edgeSpec` to set the node or edge color, marker, and linestyle. Use `' '` to omit one or both.

### Examples

To plot a tree with 12 nodes, call `treeplot` with a 12-element input vector. The index of each element in the vector is shown adjacent to each node in the figure below. (These indices are shown only for the point of illustrating the example; they are not part of the `treeplot` output.)

To generate this plot, set the value of each element in the `nodes` vector to the index of its parent, (setting the parent of the root node to zero).

The node marked 1 in the figure is represented by `nodes(1)` in the input vector, and because this is the root node which has a parent of zero, you set its value to zero:

```
nodes(1) = 0; % Root node
```

`nodes(2)` and `nodes(8)` are children of `nodes(1)`, so set these elements of the input vector to 1:

```
nodes(2) = 1; nodes(8) = 1;
```

`nodes(5:7)` are children of `nodes(4)`, so set these elements to 4:

```
nodes(5) = 4; nodes(6) = 4; nodes(7) = 4;
```

Continue in this manner until each element of the vector identifies its parent. For the plot shown above, the `nodes` vector now looks like this:

```
nodes = [0 1 2 2 4 4 4 1 8 8 10 10];
```

Now call `treeplot` to generate the plot:

```
treeplot(nodes)
```

# tril

Lower triangular part of matrix

## Syntax

```
L = tril(X)
L = tril(X,k)
```

## Description

`L = tril(X)` returns the lower triangular part of `X`.

`L = tril(X,k)` returns the elements on and below the `k`th diagonal of `X`. `k = 0` is the main diagonal, `k > 0` is above the main diagonal, and `k < 0` is below the main diagonal.

## Examples

```
tril(ones(4,4),-1)
```

```
ans =
```

```
0 0 0 0
1 0 0 0
1 1 0 0
1 1 1 0
```

**See Also**

diag | triu

**Introduced before R2006a**

# trimesh

Triangular mesh plot

## Syntax

```
trimesh(Tri,X,Y,Z,C)
trimesh(Tri,X,Y,Z)
trimesh(Tri,X,Y)
trimesh(TR)
trimesh(... 'PropertyName',PropertyValue...)
h = trimesh(...)
```

## Description

`trimesh(Tri,X,Y,Z,C)` displays triangles defined in the  $m$ -by-3 face matrix `Tri` as a mesh. Each row of `Tri` defines a single triangular face by indexing into the vectors or matrices that contain the X, Y, and Z vertices. The edge color is defined by the vector `C`.

`trimesh(Tri,X,Y,Z)` uses `C = Z` so color is proportional to surface height.

`trimesh(Tri,X,Y)` displays the triangles in a 2-D plot.

`trimesh(TR)` displays the triangles in a triangulation representation.

`trimesh(... 'PropertyName',PropertyValue...)` specifies additional patch property names and values for the patch graphics object created by the function.

`h = trimesh(...)` returns a handle to the displayed triangles.

## Examples

### Create Triangular Mesh Plot

Create vertex vectors and a face matrix, and then create a triangular mesh plot.

```
[x,y] = meshgrid(1:15,1:15);
tri = delaunay(x,y);
z = peaks(15);
trimesh(tri,x,y,z)
```

If the surface is already a triangulation representation, then you can pass the triangulation to `trimesh`:

```
tr = triangulation(tri,x(:),y(:),z(:));
trimesh(tr)
```

### See Also

Introduced before R2006a

# triplequad

Numerically evaluate triple integral

## Compatibility

triplequad will be removed in a future release. Use `integral3` instead.

## Syntax

```
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax)
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol)
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol,method)
```

## Description

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax)` evaluates the triple integral  $\text{fun}(x,y,z)$  over the three dimensional rectangular region  $x_{\min} \leq x \leq x_{\max}$ ,  $y_{\min} \leq y \leq y_{\max}$ ,  $z_{\min} \leq z \leq z_{\max}$ . The first input, `fun`, is a function handle. `fun(x,y,z)` must accept a vector `x` and scalars `y` and `z`, and return a vector of values of the integrand.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol)` uses a tolerance `tol` instead of the default, which is `1.0e-6`.

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol,method)` uses the quadrature function specified as `method`, instead of the default `quad`. Valid values for `method` are `@quadl` or the function handle of a user-defined quadrature method that has the same calling sequence as `quad` and `quadl`.

## Examples

Pass function handle `@integrnd` to `triplequad`:P

```
Q = triplequad(@integrnd,0,pi,0,1,-1,1);
```

where the file `integrnd.m` is

```
function f = integrnd(x,y,z)
f = y*sin(x)+z*cos(x);
```

Pass anonymous function handle `F` to `triplequad`:

```
F = @(x,y,z)y*sin(x)+z*cos(x);
Q = triplequad(F,0,pi,0,1,-1,1);
```

This example integrates  $y \sin(x) + z \cos(x)$  over the region  $0 \leq x \leq \pi$ ,  $0 \leq y \leq 1$ ,  $-1 \leq z \leq 1$ . Note that the integrand can be evaluated with a vector  $x$  and scalars  $y$  and  $z$ .

## More About

## triplot

2-D triangular plot

---

**Note:** The behavior of `h = triplot(...)` has changed. The new behavior returns a single chart line handle.

---

### Syntax

```
triplot(TRI,x,y)
triplot(TRI,x,y,color)
triplot(TR)
h = triplot(...)
triplot(...,'param','value','param','value'...)
```

### Description

`triplot(TRI,x,y)` displays the triangles defined in the `m`-by-3 matrix `TRI`. A row of `TRI` contains indices into the vectors `x` and `y` that define a single triangle. The default line color is blue.

`triplot(TRI,x,y,color)` uses the string `color` as the line color. `color` can also be a line specification. See `ColorSpec` for a list of valid color strings. See `LineStyle` for information about line specifications.

`triplot(TR)` displays the triangles in a triangulation representation.

`h = triplot(...)` returns a single chart line handle to the displayed triangles.

`triplot(...,'param','value','param','value'...)` allows additional line property name/property value pairs to be used when creating the plot. See `Chart Line Properties` for information about the available properties.

## Examples

### Plot Delaunay Triangulation

Plot a Delaunay triangulation for 10 randomly generated points.

```
P = gallery('uniformdata',10,2,2);
DT = delaunayTriangulation(P);
triplot(DT)
```

**Introduced before R2006a**

# TriRep class

(Not recommended) Triangulation representation

---

**Note:** TriRep is not recommended. Use triangulation instead.

---

## Description

TriRep provides topological and geometric queries for triangulations in 2-D and 3-D space. For example, for triangular meshes you can query triangles attached to a vertex, triangles that share an edge, neighbor information, circumcenters, or other features. You can create a TriRep directly using existing triangulation data. Alternatively, you can create a Delaunay triangulation, via DelaunayTri, which provides access to the TriRep functionality.

## Construction

.TriRep (Not recommended) Triangulation representation

## Methods

baryToCart (Not recommended) Convert point coordinates from barycentric to Cartesian

cartToBary (Not recommended) Convert point coordinates from cartesian to barycentric

circumcenters (Not recommended) Circumcenters of specified simplices

edgeAttachments (Not recommended) Simplices attached to specified edges

edges	(Not recommended) Triangulation edges
faceNormals	(Not recommended) Unit normals to specified triangles
featureEdges	(Not recommended) Sharp edges of surface triangulation
freeBoundary	(Not recommended) Facets referenced by only one simplex
incenters	(Not recommended) Incenters of specified simplices
isEdge	(Not recommended) Test if vertices are joined by edge
neighbors	(Not recommended) Simplex neighbor information
size	(Not recommended) Size of triangulation matrix
vertexAttachments	(Not recommended) Return simplices attached to specified vertices

## Properties

X	Coordinates of the points in the triangulation
Triangulation	Triangulation data structure

## Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## Indexing

TriRep objects support indexing into the triangulation using parentheses (). The syntax is the same as for arrays.

## Examples

Load a 2-D triangulation and use the `TriRep` constructor to build an array of the free boundary edges:

```
load trimesh2d
```

This loads triangulation `tri` and vertex coordinates `x`, `y`:

```
trep = TriRep(tri, x,y);
fe = freeBoundary(trep)';
triplot(trep);
```

You can add the free edges `fe` to the plot:

```
hold on;
```

```
plot(x(fe), y(fe), 'r','LineWidth',2);
hold off;
axis([-50 350 -50 350]);
axis equal;
```

### See Also

[triangulation](#) | [delaunayTriangulation](#) | [scatteredInterpolant](#)

# TriRep

**Class:** TriRep

(Not recommended) Triangulation representation

---

**Note:** TriRep is not recommended. Use triangulation instead.

---

## Syntax

```
TR = TriRep(TRI, X, Y)
TR = TriRep(TRI, X, Y, Z)
TR = TriRep(TRI, X)
```

## Description

`TR = TriRep(TRI, X, Y)` creates a 2-D triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `(X, Y)`. `TRI` is an `m`-by-3 matrix that defines the triangulation in face-vertex format, where `m` is the number of triangles. Each row of `TRI` is a triangle defined by indices into the column vector of vertex coordinates `(X, Y)`.

`TR = TriRep(TRI, X, Y, Z)` creates a 3-D triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `(X, Y, Z)`. `TRI` is an `m`-by-3 or `m`-by-4 matrix that defines the triangulation in simplex-vertex format, where where `m` is the number of simplices; triangles or tetrahedra in this case. Each row of `TRI` is a simplex defined by indices into the column vector of vertex coordinates `(X, Y, Z)`.

`TR = TriRep(TRI, X)` creates a triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `X`. `TRI` is an `m`-by-`n` matrix that defines the triangulation in simplex-vertex format, where `m` is the number of simplices and `n` is the number of vertices per simplex. Each row of `TRI` is a simplex defined by indices into the array of vertex coordinates `X`. `X` is an `mpts`-by-`ndim` matrix where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside, where  $2 \leq \text{ndim} \leq 3$ .

## Examples

Load a 3-D tetrahedral triangulation compute the free boundary. First, load triangulation `tet` and vertex coordinates `X`.

```
load tetmesh
```

Create the triangulation representation and compute the free boundary.

```
trep = TriRep(tet, X);
[tri, Xb] = freeBoundary(trep);
```

[scatteredInterpolant](#) | [delaunayTriangulation](#)

# TriScatteredInterp class

(Not recommended) Interpolate scattered data

---

**Note:** TriScatteredInterp is not recommended. Use scatteredInterpolant instead.

---

## Description

TriScatteredInterp is used to perform interpolation on a scattered dataset that resides in 2-D or 3-D space. A scattered data set defined by locations  $X$  and corresponding values  $V$  can be interpolated using a Delaunay triangulation of  $X$ . This produces a surface of the form  $V = F(X)$ . The surface can be evaluated at any query location  $QX$ , using  $QV = F(QX)$ , where  $QX$  lies within the convex hull of  $X$ . The interpolant  $F$  always goes through the data points specified by the sample.

## Definitions

The *Delaunay triangulation* of a set of points is a triangulation such that the unique circle circumscribed about each triangle contains no other points in the set. The *convex hull* of a set of points is the smallest convex set containing all points of the original set. These definitions extend naturally to higher dimensions.

## Construction

.TriScatteredInterp (Not recommended) Interpolate scattered data

## Properties

X	Defines locations of scattered data points in 2-D or 3-D space.
---	-----------------------------------------------------------------

V	Defines value associated with each data point.	
Method	Defines method used to interpolate the data .	
	natural	Natural neighbor interpolation
	linear	Linear interpolation (default)
	nearest	Nearest neighbor interpolation

## Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

Create a data set:

```
x = rand(100,1)*4-2;
y = rand(100,1)*4-2;
z = x.*exp(-x.^2-y.^2);
```

Construct the interpolant:

```
F = TriScatteredInterp(x,y,z);
```

Evaluate the interpolant at the locations (qx, qy). The corresponding value at these locations is qz:

```
ti = -2:.25:2;
[qx,qy] = meshgrid(ti,ti);
qz = F(qx,qy);
mesh(qx,qy,qz);
hold on;
plot3(x,y,z,'o');
```

### See Also

[triangulation](#) | [delaunayTriangulation](#) | [scatteredInterpolant](#) | [interp1](#) | [interp2](#) | [interp3](#) | [meshgrid](#)

# TriScatteredInterp

**Class:** TriScatteredInterp

(Not recommended) Interpolate scattered data

---

**Note:** TriScatteredInterp is not recommended. Use scatteredInterpolant instead.

---

## Syntax

```
F = TriScatteredInterp()
F = TriScatteredInterp(X, V)
F = TriScatteredInterp(X, Y, V)
F = TriScatteredInterp(X, Y, Z, V)
F = TriScatteredInterp(DT, V)
F = TriScatteredInterp(..., method)
```

## Description

`F = TriScatteredInterp()` creates an empty scattered data interpolant. This can subsequently be initialized with sample data points and values (`Xdata`, `Vdata`) via `F.X = Xdata` and `F.V = Vdata`.

`F = TriScatteredInterp(X, V)` creates an interpolant that fits a surface of the form  $V = F(X)$  to the scattered data in  $(X, V)$ . `X` is a matrix of size `mpts-by-ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside (`ndim` is 2 or 3). The column vector `V` defines the values at `X`, where the length of `V` equals `mpts`.

`F = TriScatteredInterp(X, Y, V)` and `F = TriScatteredInterp(X, Y, Z, V)` allow the data point locations to be specified in alternative column vector format when working in 2-D and 3-D.

`F = TriScatteredInterp(DT, V)` uses the specified `DelaunayTri` object `DT` as a basis for computing the interpolant. `DT` is a Delaunay triangulation of the scattered data locations, `DT.X`. The matrix `DT.X` is of size `mpts-by-ndim`, where `mpts` is the number

of points and `ndim` is the dimension of the space where the points reside,  $2 \leq \text{ndim} \leq 3$ . `V` is a column vector that defines the values at `DT.X`, where the length of `V` equals `mpts`.

`F = TriScatteredInterp(..., method)` allows selection of the technique `method` used to interpolate the data.

## Input Arguments

<code>X</code>	Matrix of size <code>mpts</code> -by- <code>ndim</code> , where <code>mpts</code> is the number of points and <code>ndim</code> is the dimension of the space where the points reside. Input may also be specified as column vectors ( <code>X, Y</code> ) or ( <code>X, Y, Z</code> )	
<code>V</code>	Column vector that defines the values at <code>X</code> , where the length of <code>V</code> equals <code>mpts</code> .	
<code>DT</code>	Delaunay triangulation of the scattered data locations	
<code>method</code>	<code>natural</code>	Natural neighbor interpolation
	<code>linear</code>	Linear interpolation (default)
	<code>nearest</code>	Nearest-neighbor interpolation

## Output Arguments

<code>F</code>	Creates an interpolant that fits a surface of the form $V = F(X)$ to the scattered data.
----------------	------------------------------------------------------------------------------------------

## Evaluation

To evaluate the interpolant, express the statement in Monge's form  $Vq = F(Xq)$ ,  $Vq = F(Xq, Yq)$ , or  $Vq = F(Xq, Yq, Zq)$  where  $Vq$  is the value of the interpolant at the query location and  $Xq$ ,  $Yq$ , and  $Zq$  are the vectors of point locations.

## Definitions

The *Delaunay triangulation* of a set of points is a triangulation such that the unique circle circumscribed about each triangle contains no other points in the set.

## Examples

Create a data set:

```
x = rand(100,1)*4-2;
y = rand(100,1)*4-2;
z = x.*exp(-x.^2-y.^2);
```

Construct the interpolant:

```
F = TriScatteredInterp(x,y,z);
```

Evaluate the interpolant at the locations (qx, qy). The corresponding value at these locations is qz .

```
ti = -2:.25:2;
[qx,qy] = meshgrid(ti,ti);
qz = F(qx,qy);
mesh(qx,qy,qz);
hold on;
plot3(x,y,z,'o');
```

## **See Also**

`delaunayTriangulation` | `interp1` | `interp2` | `interp3` | `meshgrid`

## trisurf

Triangular surface plot

### Syntax

```
trisurf(Tri,X,Y,Z,C)
trisurf(Tri,X,Y,Z)
trisurf(TR)
trisurf(... 'PropertyName',PropertyValue...)
h = trisurf(...)
```

### Description

`trisurf(Tri,X,Y,Z,C)` displays triangles defined in the  $m$ -by-3 face matrix `Tri` as a surface. Each row of `Tri` defines a single triangular face by indexing into the vectors or matrices that contain the X, Y, and Z vertices. The color is defined by the vector `C`.

`trisurf(Tri,X,Y,Z)` uses `C=Z` so color is proportional to surface height.

`trisurf(TR)` displays the triangles in a triangulation representation. It uses `C = TR.Points(:,3)` to make sure the surface color is proportional to height.

`trisurf(... 'PropertyName',PropertyValue...)` specifies additional patch property names and values for the patch graphics object created by the function.

`h = trisurf(...)` returns a patch handle.

### Examples

#### Create Triangular Surface Plot

Create vertex vectors and a face matrix, then create a triangular surface plot.

```
[x,y] = meshgrid(1:15,1:15);
```

```
tri = delaunay(x,y);
z = peaks(15);
trisurf(tri,x,y,z)
```

If the surface is in the form of a triangulation representation, you can pass it to `trisurf` alone:

```
tr = triangulation(tri,x(:),y(:),z(:));
trisurf(tr)
```

### See Also

**Introduced before R2006a**

## triu

Upper triangular part of matrix

### Syntax

```
U = triu(X)
U = triu(X,k)
```

### Description

`U = triu(X)` returns the upper triangular part of `X`.

`U = triu(X,k)` returns the element on and above the `k`th diagonal of `X`. `k = 0` is the main diagonal, `k > 0` is above the main diagonal, and `k < 0` is below the main diagonal.

### Examples

```
triu(ones(4,4),-1)
```

```
ans =
```

```
1 1 1 1
1 1 1 1
0 1 1 1
0 0 1 1
```

**See Also**

diag | tril

**Introduced before R2006a**

# true

Logical 1 (true)

## Syntax

```
true
T = true(n)
T = true(sz)
T = true(sz1,...,szN)
T = true(____, 'like', p)
```

## Description

`true` is shorthand for `logical(1)`.

`T = true(n)` is an  $n$ -by- $n$  matrix of logical ones.

`T = true(sz)` is an array of logical ones where the size vector, `SZ`, defines `size(T)`. For example, `true([2 3])` returns a 2-by-3 array of logical ones.

`T = true(sz1,...,szN)` is a `sz1`-by-...-by-`szN` array of logical ones where `sz1,...,szN` indicates the size of each dimension. For example, `true(2,3)` returns a 2-by-3 array of logical ones.

`T = true( ____, 'like', p)` returns an array of logical ones of the same sparsity as the logical variable `p` using any of the previous size syntaxes.

## Examples

### Generate Square Matrix of Logical Ones

Use `true` to generate a 3-by-3 square matrix of logical ones.

```
A = true(3)
class(A)
```

```
A =
 1 1 1
 1 1 1
 1 1 1
ans =
logical
```

The result is of class `logical`.

## Generate Array of Logical Ones with Arbitrary Dimensions

Use `true` to generate a 3-by-2-by-2 matrix of logical ones.

```
true(3,2,2)
```

```
ans(:,:,1) =
 1 1
 1 1
 1 1
```

```
ans(:,:,2) =
 1 1
 1 1
 1 1
```

Alternatively, you can use a size vector to specify the size of the matrix.

```
true([3,2,2])
```

```
ans(:,:,1) =
 1 1
 1 1
 1 1
```

```
ans(:,:,2) =
 1 1
 1 1
 1 1
```

Note that specifying multiple vector inputs returns an error.

## Execute Logic Statement

`true` along with `false` can be used to execute logic statements.

Test the logical statement  $\sim(A \text{ and } B) \equiv (\sim A) \text{ or } (\sim B)$  for  $A = \text{logical true}$  and  $B = \text{logical false}$ .

```
~(true & false) == (~true) | (~false)

ans =
 1
```

The result is logical 1 (true), since the logical statements on both sides of the equation are equivalent. This logical statement is an instance of De Morgan's Law.

### Generate Logical Array of Selected Sparsity

Generate a logical array of the same sparsity as the selected array.

```
A = logical(sparse(5,3));
whos A
T = true(4,'like',A);
whos T
```

Name	Size	Bytes	Class	Attributes
A	5x3	41	logical	sparse
Name	Size	Bytes	Class	Attributes
T	4x4	184	logical	sparse

The output array  $T$  has the same `sparse` attribute and data-type as the specified array  $A$ .

## Input Arguments

### **n** — Size of square matrix

integer

Size of square matrix, specified as an integer.  $n$  sets the output array size to  $n$ -by- $n$ . For example, `true(3)` returns a 3-by-3 array of logical ones.

- If  $n$  is 0, then  $T$  is an empty matrix.
- If  $n$  is negative, then it is treated as 0.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **sz** — Size vector

row vector of integers

Size vector, specified as a row vector of integers. For example, `true([2 3])` returns a 2-by-3 array of logical ones.

- If the size of any dimension is 0, then T is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, T, does not include those dimensions.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **sz1, ..., szN** — Size inputs

comma-separated list of integers

Size inputs, specified by a comma-separated list of integers. For example, `true(2,3)` returns a 2-by-3 array of logical ones.

- If the size of any dimension is 0, then T is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, T, does not include those dimensions.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **p** — Prototype

logical variable

Prototype, specified as a logical variable.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Complex Number Support: Yes

# Output Arguments

## **T** — Output of logical ones

scalar | vector | matrix | N-D array

Output of logical ones, returned as a scalar, vector, matrix, or N-D array.

Data Types: `logical`

## More About

### Tips

- `true(n)` is much faster and more memory efficient than `logical(true(n))`.
- “Class Support for Array-Creation Functions”

### See Also

`false` | `logical`

**Introduced before R2006a**

## try, catch

Execute statements and catch resulting errors

### Syntax

```
try
 statements
catch exception
 statements
end
```

### Description

`try statements, catch statements end` executes the statements in the `try` block and catches resulting errors in the `catch` block. This approach allows you to override the default error behavior for a set of program statements. If any statement in a `try` block generates an error, program control goes immediately to the `catch` block, which contains your error handling statements.

*exception* is an `MException` object that allows you to identify the error. The `catch` block assigns the current exception object to the variable in *exception*.

Both `try` and `catch` blocks can contain nested `try/catch` statements.

### Examples

#### Supplement Error Message

Create two matrices that you cannot concatenate vertically.

```
A = rand(3);
B = ones(5);
```

```
C = [A; B];
```

```
Error using vertcat
Dimensions of matrices being concatenated are not consistent.
```

Use `try/catch` to display more information about the dimensions.

```
try
 C = [A; B];
catch ME
 if (strcmp(ME.identifier, 'MATLAB:catenate:dimensionMismatch'))
 msg = ['Dimension mismatch occurred: First argument has ', ...
 num2str(size(A,2)), ' columns while second has ', ...
 num2str(size(B,2)), ' columns.'];
 causeException = MException('MATLAB:myCode:dimensions',msg);
 ME = addCause(ME,causeException);
 end
 rethrow(ME)
end
```

Error using `vertcat`

Dimensions of matrices being concatenated are not consistent.

Caused by:

Dimension mismatch occurred: First argument has 3 columns while second has 5 columns

If matrix dimensions do not agree, MATLAB displays more information about the mismatch. Any other errors appear as usual.

### Repackage Error as Warning

Catch any exception generated by calling the nonexistent function, `notaFunction`. If there is an exception, issue a warning and assign the output a value of 0.

```
try
 a = notaFunction(5,6);
catch
 warning('Problem using function. Assigning a value of 0.');
```

a = 0;

```
end
```

Warning: Problem using function. Assigning a value of 0.

By itself, the call to `notaFunction` results in an error. If you use `try` and `catch`, this code catches any exception and repackages it as a warning, allowing MATLAB to continue executing subsequent commands.

### Handle Different Types of Errors

Use `try/catch` to handle different types of errors in different ways.

- If the function `notaFunction` is undefined, issue a warning instead of an error and assign the output a value of `NaN`.
- If `notaFunction.m` exists, but is a script instead of a function, issue a warning instead of an error, run the script, and assign the output a value of `0`.
- If MATLAB throws an error for any other reason, rethrow the exception.

```
try
 a = notaFunction(5,6);
catch ME
 switch ME.identifier
 case 'MATLAB:UndefinedFunction'
 warning('Function is undefined. Assigning a value of NaN.');
```

```
Warning: Function is undefined. Assigning a value of NaN.
```

## More About

### Tips

- You cannot use multiple `catch` blocks within a `try` block, but you can nest complete `try/catch` blocks.
- Unlike some other languages, MATLAB does not allow the use of a `finally` block within `try/catch` statements.

# tscollection

Create `tscollection` object

## Syntax

```
tsc = tscollection(TimeSeries)
tsc = tscollection(Time)
tsc = tscollection(..., 'Parameter', Value, ...)
```

## Description

`tsc = tscollection(TimeSeries)` creates a `tscollection` object `tsc` with one or more `timeseries` objects already in the MATLAB workspace. The argument `TimeSeries` can be a

- Single `timeseries` object
- Cell array of `timeseries` objects

`tsc = tscollection(Time)` creates an empty `tscollection` object with the time vector `Time`. When time values are date strings, you must specify `Time` as a cell array of date strings.

`tsc = tscollection(..., 'Parameter', Value, ...)` creates a `tscollection` object with optional parameter-value pairs you enter after specifying either a time vector or a `timeseries` object. You can specify the following parameter:

- `Name` — String that specifies the name of this `tscollection` object

## Examples

The following example shows how to create a `tscollection` object.

- 1 Import the sample data.

```
load count.dat
```

- 2 Create three `timeseries` objects to store each set of data:

```
count1 = timeseries(count(:,1),1:24,'name', 'ts1');
count2 = timeseries(count(:,2),1:24,'name', 'ts2');
count3 = timeseries(count(:,3),1:24,'name', 'ts3');
```

- 3 Create a `tscollection` object named `tsc` and add to it two out of three time series already in the MATLAB workspace, by using the following syntax:

```
tsc = tscollection({count1 count2},'name','tsc')
```

## More About

### Tips

### Definition: Time Series Collection

A time series collection object is a MATLAB variable that groups several time series with a common time vector. The time series that you include in the collection are called members of this collection.

### Properties of Time Series Collection Objects

This table lists the properties of the `tscollection` object. You can specify the `Time`, `TimeSeries`, and `Name` properties as input arguments in the constructor.

Property	Description
Name	<code>tscollection</code> name as a string. This can differ from the <code>tscollection</code> name in the MATLAB workspace.
Time	When <code>TimeInfo.StartDate</code> is empty, values are measured relative to 0. When <code>TimeInfo.StartDate</code> is defined, values represent date strings measured relative to the <code>StartDate</code> .  The length of <code>Time</code> must be the same as the first or the last dimension of <code>Data</code> for each collection.

Property	Description
TimeInfo	<p>Contains fields for contextual information about Time:</p> <ul style="list-style-type: none"><li>• <b>Units</b> — Time units with any of the following values: 'weeks', 'days', 'hours', 'minutes', 'seconds', 'milliseconds', 'microseconds', 'nanoseconds'</li><li>• <b>Start</b> — Start time</li><li>• <b>End</b> — End time (read only)</li><li>• <b>Increment</b> — Interval between subsequent time values. NaN when times are not uniformly sampled.</li><li>• <b>Length</b> — Length of the time vector (read only)</li><li>• <b>Format</b> — String defining the date string display format. See <code>datestr</code>.</li><li>• <b>StartDate</b> — Date string defining the reference date. See <code>setabstime</code> (<code>tscollection</code>).</li><li>• <b>UserData</b> — Any additional user-defined information</li></ul>

## See Also

`addts` | `datestr` | `setabstime` (`tscollection`) | `timeseries`

**Introduced before R2006a**

## **tsdata.event**

Construct event object for `timeseries` object

### **Syntax**

```
e = tsdata.event(Name,Time)
e = tsdata.event(Name,Time,'Datenum')
```

### **Description**

`e = tsdata.event(Name,Time)` creates an event object with the specified `Name` that occurs at the time `Time`. `Time` can either be a real value or a date string.

`e = tsdata.event(Name,Time,'Datenum')` uses `'Datenum'` to indicate that the `Time` value is a serial date number generated by the `datenum` function. The `Time` value is converted to a date string after the event is created.

### **More About**

#### **Tips**

You add events by using the `addevent` method.

Fields of the `tsdata.event` object include the following:

- `EventData` — MATLAB array that stores any user-defined information about the event
- `Name` — String that specifies the name of the event
- `Time` — Time value when this event occurs, specified as a real number
- `Units` — Time units
- `StartDate` — A reference date, specified in MATLAB `datestr` format. `StartDate` is empty when you have a numerical (non-date-string) time vector.

**Introduced before R2006a**

# tsearchn

N-D closest simplex search

## Syntax

```
t = tsearchn(X,TRI,XI)
[t,P] = tsearchn(X,TRI,XI)
```

## Description

`t = tsearchn(X, TRI, XI)` returns the indices `t` of the enclosing simplex of the Delaunay triangulation `TRI` for each point in `XI`. `X` is an `m`-by-`n` matrix, representing `m` points in `N`-dimensional space. `XI` is a `p`-by-`n` matrix, representing `p` points in `N`-dimensional space. `tsearchn` returns `NaN` for all points outside the convex hull of `X`. `tsearchn` requires a triangulation `TRI` of the points `X` obtained from `delaunayn`.

`[t,P] = tsearchn(X, TRI, XI)` also returns the barycentric coordinate `P` of `XI` in the simplex `TRI`. `P` is a `p`-by-`n+1` matrix. Each row of `P` is the barycentric coordinate of the corresponding point in `XI`. It is useful for interpolation.

## See Also

`delaunayTriangulation`

**Introduced before R2006a**

## **type**

Display contents of file

### **Syntax**

```
type('filename')
type filename
```

### **Description**

`type('filename')` displays the contents of the specified file in the MATLAB Command Window. Use the full path for `filename`, or use a MATLAB relative partial path.

If you do not specify a file extension and there is no `filename` file without an extension, the `type` function adds the `.m` extension by default. The `type` function checks the folders specified in the MATLAB search path, which makes it convenient for listing the contents of files on the screen. Use `type` with `more on` to see the listing one screen at a time.

`type filename` is the command form of the syntax.

### **Examples**

`type('foo.bar')` lists the contents of the file `foo.bar`.

`type foo` lists the contents of the file `foo`. If `foo` does not exist, `type foo` lists the contents of the file `foo.m`.

# typecast

Convert data types without changing underlying data

## Syntax

```
Y = typecast(X, type)
```

## Description

`Y = typecast(X, type)` converts a numeric value in `X` to the data type specified by `type`. Input `X` must be a full, noncomplex, numeric scalar or vector. The `type` input is a string set to one of the following: `'uint8'`, `'int8'`, `'uint16'`, `'int16'`, `'uint32'`, `'int32'`, `'uint64'`, `'int64'`, `'single'`, or `'double'`.

`typecast` is different from the MATLAB `cast` function in that it does not alter the input data. `typecast` always returns the same number of bytes in the output `Y` as were in the input `X`. For example, casting the 16-bit integer 1000 to `uint8` with `typecast` returns the full 16 bits in two 8-bit segments (3 and 232) thus keeping its original value ( $3 \times 256 + 232 = 1000$ ). The `cast` function, on the other hand, truncates the input value to 255.

The output of `typecast` can be formatted differently depending on what system you use it on. Some computer systems store data starting with its most significant byte (an ordering called *big-endian*), while others start with the least significant byte (called *little-endian*).

---

**Note** MATLAB issues an error if `X` contains fewer values than are needed to make an output value.

---

## Examples

### Example 1

This example converts between data types of the same size:

```
uint8(255)
ans =
 -1
```

```
int16(-1)
ans =
 65535
```

## Example 2

Set *X* to a 1-by-3 vector of 32-bit integers, then cast it to an 8-bit integer type:

```
X = uint32([1 255 256])
X =
 1 255 256
```

Running this on a little-endian system produces the following results. Each 32-bit value is divided up into four 8-bit segments:

```
Y = typecast(X, 'uint8')
Y =
 1 0 0 0 255 0 0 0 0 1 0 0
```

The third element of *X*, 256, exceeds the 8 bits that it is being converted to in *Y*(9) and thus overflows to *Y*(10):

```
Y(9:12)
ans =
 0 1 0 0
```

Note that `length(Y)` is equal to `4.*length(X)`. Also note the difference between the output of `typecast` versus that of `cast`:

```
Z = cast(X, 'uint8')
Z =
 1 255 255
```

## Example 3

This example casts a smaller data type (`uint8`) into a larger one (`uint16`). Displaying the numbers in hexadecimal format makes it easier to see just how the data is being rearranged:

```
format hex
```

```
X = uint8([44 55 66 77])
X =
 2c 37 42 4d
```

The first `typecast` is done on a big-endian system. The four 8-bit segments of the input data are combined to produce two 16-bit segments:

```
Y = typecast(X, 'uint16')
Y =
 2c37 424d
```

The second is done on a little-endian system. Note the difference in byte ordering:

```
Y = typecast(X, 'uint16')
Y =
 372c 4d42
```

You can format the little-endian output into big-endian (and vice versa) using the `swapbytes` function:

```
Y = swapbytes(typecast(X, 'uint16'))
Y =
 2c37 424d
```

## Example 4

This example attempts to make a 32-bit value from a vector of three 8-bit values. MATLAB issues an error because there are an insufficient number of bytes in the input:

```
format hex
typecast(uint8([120 86 52]), 'uint32')
```

```
Error using typecast
Too few input values to make output type.
```

Repeat the example, but with a vector of four 8-bit values, and it returns the expected answer:

```
typecast(uint8([120 86 52 18]), 'uint32')
ans =
 12345678
```

## See Also

`cast` | `class` | `swapbytes`

**Introduced before R2006a**

# tzoffset

Time zone offset from UTC

## Syntax

```
dt = tzoffset(t)
[dt,dst] = tzoffset(t)
```

## Description

`dt = tzoffset(t)` returns an array of durations equal to the time zone offset from UTC of each datetime value in `t`. That is, `dt` is the amount of time that each datetime in `t` differs from UTC. For datetimes that occur during Daylight Saving Time (DST), `dt` includes the time shift for DST. The offset for unzoned datetime values is not defined.

`[dt,dst] = tzoffset(t)` additionally returns the time shift for Daylight Saving Time for each datetime in `t`.

## Examples

### Find Time Zone Offset

Create a datetime array in the time zone for New York City.

```
t1 = datetime('today','TimeZone','America/New_York');
t = dateshift(t1,'end','month',[1:3:9])
```

```
t =
```

```
 30-Sep-2015 31-Dec-2015 31-Mar-2016
```

Find the time zone offset from UTC and the time shift for Daylight Saving Time for each datetime value.

```
[dt,dst] = tzoffset(t)
```

```
dt =
 -4:00 -5:00 -4:00

dst =
 01:00 00:00 01:00
```

## Input Arguments

**t** — **Input date and time**  
datetime array

Input date and time, specified as a `datetime` array.

## Output Arguments

**dt** — **Time zone offset from UTC**  
scalar | vector | matrix | multidimensional array

Time zone offset from UTC, returned as a scalar, vector, matrix, or multidimensional duration array. `dt` is the same size as `t`.

**dst** — **Time shift for Daylight Saving Time**  
scalar | vector | matrix | multidimensional array

Time shift for Daylight Saving Time, returned as a scalar, vector, matrix, or multidimensional duration array. `dst` is the same size as `t`. A value of `01:00` indicates that the corresponding datetime in `t` occurs during Daylight Saving Time in a location that observes it. For locations that do not observe Daylight Saving Time, the elements of the `dst` array are all `00:00`.

**See Also**  
`isdst`

**Introduced in R2014b**

# uibuttongroup

Create button group to manage radio buttons and toggle buttons

## Syntax

```
b = uibuttongroup
b = uibuttongroup(Name,Value,...)
b = uibuttongroup(parent)
b = uibuttongroup(parent,Name,Value,...)
```

## Description

`b = uibuttongroup` creates a `uibuttongroup` in an existing figure and returns the `uibuttongroup` object, `b`. If there is no figure available, then MATLAB creates a new figure to serve as the parent.

`b = uibuttongroup(Name,Value,...)` creates a `uibuttongroup` and specifies one or more `uibuttongroup` property names and corresponding values. Use this syntax to override the default `uibuttongroup` properties.

`b = uibuttongroup(parent)` creates a `uibuttongroup` and designates a specific parent object. The `parent` argument can be a figure, `uipanel`, `uitab`, or another `uibuttongroup` object.

`b = uibuttongroup(parent,Name,Value,...)` creates a `uibuttongroup` with a specific parent and one or more `uibuttongroup` properties.

`Uibuttongroups` are containers that group UI components together and manage exclusive selection of radio buttons and toggle buttons. These are some of the important characteristics of the `uibuttongroups` and some recommended best practices:

- `Uibuttongroups` can contain any UI component type (except anActiveX control), but it only manages the selection of radio buttons and toggle buttons.
- Define a `SelectionChangedFcn` callback function for the `uibuttongroup` to make your program respond when the user selects a radio button or toggle button that is inside the button group. Do not define callbacks for in the individual buttons.

- Query the `SelectedObject` property of the `uibuttongroup` to determine which radio button or toggle button is currently selected. You can execute this query anywhere in your code that can access the `uibuttongroup` object.

## Examples

This example creates a `uibuttongroup` with three radio buttons. It manages the radio buttons with the `SelectionChangedFcn` callback, `bselection`.

When the user selects a new radio button, the `bselection` function displays the previous and current selection.

Copy and paste this code into the Editor and run it to see how it works.

```
function myui
bg = uibuttongroup('Visible','off',...
 'Position',[0 0 .2 1],...
 'SelectionChangedFcn',@bselection);

% Create three radio buttons in the button group.
r1 = uicontrol(bg,'Style','...
 'radiobutton',...
 'String','Option 1',...
 'Position',[10 350 100 30],...
 'HandleVisibility','off');

r2 = uicontrol(bg,'Style','radiobutton',...
 'String','Option 2',...
 'Position',[10 250 100 30],...
 'HandleVisibility','off');

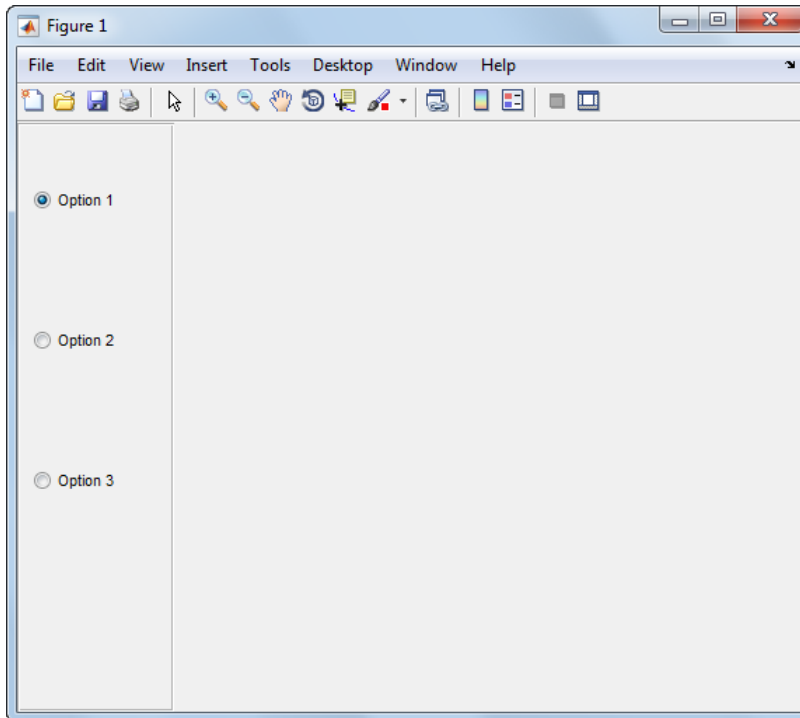

r3 = uicontrol(bg,'Style','radiobutton',...
 'String','Option 3',...
 'Position',[10 150 100 30],...
 'HandleVisibility','off');

% Make the uibuttongroup visible after creating child objects.
bg.Visible = 'on';

function bselection(source,callbackdata)
 display(['Previous: ' callbackdata.OldValue.String]);
 display(['Current: ' callbackdata.NewValue.String]);
 display('-----');
end
end
```

The `bselection` function displays the `OldValue` and `NewValue` properties of the `callbackdata` object. MATLAB passes the `callbackdata` object to this callback function when you specify the `SelectionChangedFcn` property as a function handle

(or a cell array containing a function handle). See `SelectionChangedFcn` for more information.

## More About

### Tips

If you set the `Visible` property of a `uibuttongroup` object to `'off'`, then any child objects it contains (buttons, other button groups, etc.) become invisible along with the parent `uibuttongroup`. However, the `Visible` *property value* of each child object remains unaffected.

- “Access Property Values”

`Uibuttongroup` Properties | `uicontrol` | `uipanel`

**Introduced before R2006a**

# Uibuttongroup Properties

Control appearance and behavior of button group

Uibuttongroups are containers for grouping together and managing the exclusive selection of radio buttons and toggle buttons. The `uibuttongroup` function creates a button group and sets any required properties. By changing uibuttongroup property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
b = uibuttongroup;
bgcolor = b.BackgroundColor;
b.BackgroundColor = [.5 .5 .5];
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Appearance

### Visible — Uibuttongroup visibility

'on' (default) | 'off'

Uibuttongroup visibility, specified as 'on' or 'off'. The **Visible** property determines whether the uibuttongroup displays on the screen. If the **Visible** property of a uibuttongroup is set to 'off', the entire uibuttongroup is invisible, but you can still specify and access its properties.

Changing the size of an invisible uibuttongroup triggers the `SizeChangedFcn` callback when the uibuttongroup becomes visible.

---

**Note** Changing the **Visible** property of a uibuttongroup does *not* change the **Visible** property of its child components even though hiding the uibuttongroup prevents its children from displaying.

---

### BackgroundColor — Uibuttongroup background color

[.94 .94 .94] (default) | RGB triplet | short name | long name

Uibuttongroup background color, specified as an RGB triplet, short name, or long name. The color you specify fills the area bounded by the uibuttongroup.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

---

**Note:** Some operating systems override the `BackgroundColor` value.

---

Data Types: `double` | `char`

**ForegroundColor** — **Uibuttongroup title color**

`[0 0 0]` (default) | RGB triplet | short name | long name

Uibuttongroup title color, specified as an RGB triplet, short name, or long name.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]

Long Name	Short Name	RGB Triplet
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

Example: [ 0 0 1 ]

Example: 'b'

Example: 'blue'

### **BorderType — Border of the uibuttongroup**

'etchedin' (default) | 'etchedout' | 'beveledin' | 'beveledout' | 'line' | 'none'

Border of the uibuttongroup area, specified as 'etchedin', 'none', 'etchedout', 'beveledin', 'beveledout', or 'line'.

- For a 3-D look, use etched or beveled borders.

Use the `HighlightColor` and `ShadowColor` properties to specify the color of 3-D borders.

- For a 2-D look, use a line border.

Use the `HighlightColor` property to specify the line border color.

### **BorderWidth — Width of uibuttongroup border**

1 (default) | positive integer value

Width of the uibuttongroup border, specified as a positive integer value. The unit of measurement is pixels. Etched and beveled borders wider than three pixels might not appear correctly at the corners.

### **HighlightColor — Uibuttongroup border highlight color**

RGB triplet | short name | long name

Uibuttongroup border highlight color, specified as an RGB triplet, short name, or long name.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

**ShadowColor — Uibuttongroup border shadow color**

RGB triplet | short name | long name

Uibuttongroup border shadow color, specified as an RGB triplet, short name, or long name.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]

Long Name	Short Name	RGB Triplet
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

### Clipping — Clipping of child components to uibuttongroup

'on' (default) | 'off'

---

**Note:** The behavior of the Clipping property has changed. It no longer has any effect on uibuttongroups. Child objects are now clipped to the uibuttongroup boundary regardless of the value of this property. This property might be removed in a future release.

---

## Location and Size

### Position — Location and size of uibuttongroup relative to parent

[left bottom width height]

Location and size of the uibuttongroup relative to the parent, specified as the vector, [left bottom width height]. This table describes each element in the vector.

Element	Description
left	Distance from the inner left edge of the parent container to the outer left edge of the uibuttongroup
bottom	Distance from the inner bottom edge of the parent container to the outer bottom edge of the uibuttongroup
width	Distance between the right and left outer edges of the uibuttongroup
height	Distance between the top and bottom outer edges of the uibuttongroup

All measurements are in units specified by the Units property.

---

**Note:** If the parent of the uibuttongroup is a figure, then the Position values are relative to the figure's *drawable area*. The drawable area of a figure is the area inside the window borders, excluding the menu bar and tool bar.

---

## Example: Modify One Value in the Position Vector

You can combine dot notation and array indexing when you want to change one value in the `Position` vector. For example, this code sets the width of the `Uibuttongroup` to 0.5:

```
b = uibuttongroup;
b.Position(3) = 0.5;
b.Position

ans =

 0 0 0.5000 1.0000
```

### Units — Units of measurement

'normalized' (default) | 'pixels' | 'inches' | 'centimeters' | 'points' | 'characters'

Units of measurement, specified one of the values from this table.

Units Value	Description
'normalized'	These units are normalized with respect to the parent container. The lower-left corner of the container maps to (0,0) and the upper-right corner maps to (1,1).
'pixels' (default)	<p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p>
'inches'	Inches.
'centimeters'	Centimeters.
'points'	Points. One point equals 1/72nd of an inch.

Units Value	Description
'characters'	<p>These units are based on the default system font character size.</p> <ul style="list-style-type: none"> <li>• Character width = width of the letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>

MATLAB measures all units from the lower left corner of the parent object.

If you change the value of the **Units** property, it is good practice to return it to its default value after completing your computation to avoid affecting other functions that assume the **Units** property is set to the default value.

The order in which you specify the **Units** and **Position** properties has these effects:

- If you specify the **Units** property before the **Position** property, then MATLAB sets **Position** using the units you specified.
- If you specify the **Units** property after the **Position** property, MATLAB sets the position using the default **Units**. Then, MATLAB converts the **Position** values to the equivalent values in the units you specified.

### **SizeChangedFcn — Uibuttongroup resize callback function**

' ' (default) | function handle | cell array | string

Uibuttongroup resize callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

Define this callback function to control the UI layout when the size of the uibuttongroup changes.

The **SizeChangedFcn** callback executes under these circumstances:

- The uibuttongroup becomes visible for the first time.
- The uibuttongroup is visible while its drawable area changes. The drawable area is the area inside the outer bounds of the uibuttongroup.

- The `uibuttongroup` becomes visible for the first time after its drawable area changes. This situation occurs when the drawable area changes while the `uibuttongroup` is invisible, and then it becomes visible later.

These are some of the important characteristics of the `SizeChangedFcn` callback and some recommended best practices:

- Consider delaying the display of the figure until after all the variables that the `uibuttongroup`'s `SizeChangedFcn` uses are defined. This practice can prevent the `uibuttongroup`'s `SizeChangedFcn` callback from returning an error. To delay the display of the figure, set its `Visible` property to `'off'`. Then, set the `Visible` property to `'on'` after you define the variables that your `SizeChangedFcn` callback uses.
- Use the `gcbo` function in your `SizeChangedFcn` code to get the `uibuttongroup` object that the user is resizing. See the description of the figure `SizeChangedFcn` for an example that uses `gcbo`.
- All visible `Uibuttongroups` that are specified in normalized units resize before the parent figure does. All visible, nested `uibuttongroups` resize from inside-out.

---

**Tip** As an easy alternative to specifying a `SizeChangedFcn` callback, you can set the `Units` property of all the objects you put inside the `uibuttongroup` to `'normalized'`. Doing so makes those components scale proportionally with the `uibuttongroup`.

---

See “Managing the Layout in Resizable UIs” for more information on controlling the resize behavior of programmatic UIs.

See `Resize Behavior` for more information on the resize behavior of GUIDE UIs.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

## **ResizeFcn — Uibuttongroup resize callback function**

`'` (default) | `function handle` | `cell array` | `string`

Callback function that executes when the `uibuttongroup` size changes, specified as one of these values:

- `Function handle`

- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

---

**Note:** Use of the `ResizeFcn` property is not recommended. It might be removed in a future release. Use `SizeChangedFcn` instead.

---

Data Types: `function_handle` | `cell` | `char`

## Font Style

### **FontName** — Font for displaying uibuttongroup title

string

Font for displaying the uibuttongroup title, specified as a string. To display and print properly, the font name must refer to a font that the user's system supports. The default font is system dependent.

To use a fixed-width font, set the `FontName` property to the string, `'FixedWidth'`. This setting instructs MATLAB to use the value of the root `FixedWidthFontName` property, which you can set in the `startup.m` file.

See “Startup Options in MATLAB Startup File” for more information about the `startup.m` file.

Example: `'Arial'`

### **FontSize** — Font size for uibuttongroup title

positive number

Font size for the uibuttongroup title, specified as a positive number. The `FontUnits` property specifies the units. The default size is system-dependent.

Example: `12`

Example: `12.5`

Data Types: `double`

### **FontUnits** — Units of font size for uibuttongroup title

`'points'` (default) | `'normalized'` | `'inches'` | `'centimeters'` | `'pixels'`

Units of font size for the `uibuttongroup` title, specified as one of the values from this table.

Units Value	Description
'points'	Points. One point is 1/72nd of an inch.
'normalized'	Normalized values for specifying the font size as a fraction of the <code>uibuttongroup</code> height. When you resize the <code>uibuttongroup</code> , MATLAB scales the displayed font to maintain that fraction.
'inches'	Inches.
'centimeters'	Centimeters.
'pixels'	Pixels.  Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems: <ul style="list-style-type: none"><li>• On Windows systems, a pixel is 1/96th of an inch.</li><li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li></ul> On Linux systems, the size of a pixel is determined by your system resolution.

**FontWeight** — Font weight for the `uibuttongroup` title

'normal' (default) | 'bold'

Font weight of `uibuttongroup` title, specified as a value from the following table.

FontWeight Value	Description
'normal'	Normal font weight
'bold'	Heavy font weight

Not all fonts support all font weights. Therefore, if you specify an unsupported value for the `FontWeight` property, the result might appear the same as the default.

---

**Note:** The 'light' and 'demi' font weight values have been removed in R2014b. If you specify either of these values, the result is a normal font weight.

---

**FontAngle — Character slant of the uibuttongroup title**`'normal'` (default) | `'italic'`

Character slant of uibuttongroup title, specified as `'normal'` or `'italic'`. MATLAB uses this property to select a font from those available on your system. Setting this property to `'italic'` selects a slanted version of the font, if it is available on your system.

---

**Note:** The `'oblique'` value has been removed. Use `'italic'` instead.

---

**Text****Title — Uibuttongroup title**

string

Uibuttongroup title, specified as a string.

MATLAB does not interpret a vertical slash (`'|'`) character as a line break, it displays as a vertical slash in the uibuttongroup title.

If you want to specify a Unicode character, pass the Unicode decimal code to the `char` function. For example, [`'Multiples of '` `char(960)`] displays as Multiples of  $\pi$ .

Example: `'Options'`

Example: [`'Multiples of '` `char(960)`]

**TitlePosition — Location of uibuttongroup title**`'lefttop'` (default) | `'centertop'` | `'righttop'` | `'leftbottom'` | `'centerbottom'` | `'rightbottom'`

Location of the uibuttongroup title, specified as `'lefttop'`, `'centertop'`, `'righttop'`, `'leftbottom'`, `'centerbottom'`, or `'rightbottom'`.

**Interactive Control****SelectionChangedFcn — Callback that executes when user selects a different button**`''` (default) | function handle | cell array | string

Callback that executes when the user selects a different button, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback function executes when the user selects a different button within the `uibuttongroup`.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in this table. You can access these properties inside the callback function using dot notation.

Property	Description
<code>OldValue</code>	Previously selected button, or [ ] if none was selected
<code>NewValue</code>	Currently selected button
<code>Source</code>	The parent <code>uibuttongroup</code> object
<code>EventName</code>	' <code>SelectionChanged</code> '

Define a `uibuttongroup` `SelectionChangedFcn` callback to make your program respond when the user selects different buttons within the `uibuttongroup`. Do not code the response in the individual `uicontrol` `Callback` functions.

If you want another component to respond to the selection, then that component's callback function can access the selected radio button or toggle button from the `uibuttongroup`'s `SelectedObject` property.

Example: `@myfun`

Example: `{@myfun,x}`

### **ButtonDownFcn** — Button-press callback function

' ' (default) | function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `ButtonDownFcn` callback is a function that executes when the user clicks a mouse button on the `uibuttongroup`.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

### **UIContextMenu** — Uibuttongroup context menu

empty `GraphicsPlaceholder` array (default) | `uicontextmenu` object

`Uibuttongroup` context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when the user right-clicks on the `uibuttongroup`. Create the context menu using the `uicontextmenu` function.

### **Selected** — Selection status of uibuttongroup

'off' (default) | 'on'

---

**Note:** The behavior of the `Selected` property changed in R2014b, and it is not recommended. It no longer has any effect on `uibuttongroups`. This property might be removed in a future release.

---

### **SelectionHighlight** — Ability to highlight selection handles

'on' (default) | 'off'

---

**Note:** The behavior of the `SelectionHighlight` property changed in R2014b, and it is not recommended. It no longer has any effect on `uibuttongroups`. This property might be removed in a future release.

---

## Callback Execution Control

### **Interruptible** — Callback interruption

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put into a queue.

If a `uibuttongroup` callback is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- 'on' — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
- If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.

- If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

---

**Note:** Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a `DeleteFcn`, `CloseRequestFcn`, or `SizeChangedFcn` callback, then the interruption occurs regardless of the `Interruptible` property value.
  - If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the `Interruptible` property value.
  - MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.
- 

See “Interrupt Callback Execution” for an example that shows how the `Interruptible` and `BusyAction` properties affect the behavior of a program.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' (default) or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- 'cancel' — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The `Interruptible` property of the object whose callback is running determines if interruption is allowed. If `Interruptible` is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The `BusyAction` property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the `BusyAction` and `Interruptible` properties affect the behavior of a program.

### **HitTest — Ability to become current object**

'on' (default) | 'off'

Ability to become current object, specified as 'on' or 'off':

- Setting the value to 'on' allows the uibuttongroup to become the current object when the user clicks on it. A value of 'on' also allows the figure `CurrentObject` property and the `gco` function to report the uibuttongroup as the current object.
- Setting the value to 'off' sets the figure `CurrentObject` property to an empty `GraphicsPlaceholder` array when the user clicks on the uibuttongroup.

## **Creation and Deletion Control**

### **BeingDeleted — Deletion status of uibuttongroup**

'off' (default) | 'on'

This property is read only.

Deletion status of uibuttongroup, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the uibuttongroup begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the uibuttongroup no longer exists.

Check the value of the `BeingDeleted` property to verify that the uibuttongroup is not about to be deleted before querying or modifying it.

### **CreateFcn — Uibuttongroup creation function**

function handle | cell array | string

Uibuttongroup creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This property specifies a callback function to execute when MATLAB creates the uibuttongroup. MATLAB initializes all uibuttongroup property values before executing the `CreateFcn` callback. If you do not specify the `CreateFcn` property, then MATLAB executes a default creation function.

Use the `gcbo` function in your `CreateFcn` code to get the handle to the uibuttongroup that is being created.

Setting the `CreateFcn` property on an existing uibuttongroup has no effect.

---

**Note:** Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. Copying the uibuttongroup object causes the `CreateFcn` callback to execute repeatedly.

---

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

### **DeleteFcn — Uibuttongroup deletion function**

`function handle` | `cell array` | `string`

Uibuttongroup deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `DeleteFcn` property specifies a callback function to execute when MATLAB deletes the `uibuttongroup` (for example, when the end user deletes the figure). MATLAB executes the `DeleteFcn` callback before destroying the properties of the `uibuttongroup`. If you do not specify the `DeleteFcn` property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your `DeleteFcn` code to get the handle to the `uibuttongroup` that is being deleted.

Example: `@myfun`

Example: `{@myfun, x}`

Data Types: `function_handle` | `cell` | `char`

## Identifiers

### Type — Type of graphics object

`'uibuttongroup'`

This property is read only.

Type of graphics object, returned as `'uibuttongroup'`.

### Tag — Uibuttongroup identifier

`''` (default) | `string`

`Uibuttongroup` identifier, specified as a string. You can specify a unique `Tag` value to serve as an identifier for the `uibuttongroup`. When you need access to the `uibuttongroup` elsewhere in your code, you can use the `findobj` function to search for the `uibuttongroup` based on the `Tag` value.

Example: `'buttongroup1'`

Data Types: `char`

### UserData — Data to associate with the uibuttongroup object

empty array (default) | `array`

Data to associate with the `uibuttongroup` object, specified as any array. Specifying `UserData` can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: [1 2 3]

Example: 'April 21'

Example: struct('value1',[1 2 3],'value2','April 21')

Example: {[1 2 3],'April 21'}

## **SelectedObject** — Currently selected radio button or toggle button

uicontrol object | []

Currently selected radio button or toggle button, specified as a uicontrol object.

Use this property to determine the currently selected button within a uibuttongroup. You can also use this property to set a default button selection. If you want no selection, then set this property to [].

The default value of the **SelectedObject** property is the first uicontrol radio button or toggle button that you add to the uibuttongroup.

---

**Note:** The **SelectionChangedFcn** callback does not execute when you set the **SelectedObject** property programmatically..

---

## **Parent/Child**

### **Parent** — Uibuttongroup parent

figure | uipanel | uibuttongroup | uitab

Uibuttongroup parent, specified as a figure, uipanel, uibuttongroup, or uitab. You can move a uibuttongroup to a different figure, uipanel, uibuttongroup, or uitab by setting this property to the handle of the target figure, uipanel, uibuttongroup, or uitab.

### **Children** — Children of uibuttongroup

empty GraphicsPlaceholder array (default) | 1-D array of component objects

Children of uibuttongroup, returned as an empty **GraphicsPlaceholder** or a 1-D array of component objects. Although a uibuttongroup manages only the user selection of radio buttons and toggle buttons, its children can be axes, uipanels, uibuttongroups, and any style of uicontrol.

You cannot add or remove children using the **Children** property of the uibuttongroup. Use this property to view the list of children or to reorder the children. The order of the

children in this array reflects the front-to-back order (stacking order) of the components on the screen.

To add a child to this list, set the `Parent` property of the child component to be the `uibuttongroup` object.

Objects with the `HandleVisibility` property set to `'off'` do not list in the `Children` property. For more information, see the `HandleVisibility` property description.

### **HandleVisibility – Visibility of uibuttongroup handle**

`'on'` (default) | `'callback'` | `'off'`

Visibility of `Uibuttongroup` handle, specified as `'on'`, `'callback'`, or `'off'`.

This property controls the visibility of the `uibuttongroup` handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The `HandleVisibility` property also controls the visibility of the object's handle in the parent figure's `CurrentObject` property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

<b>HandleVisibility Value</b>	<b>Description</b>
<code>'on'</code>	The <code>uibuttongroup</code> handle is always visible.
<code>'callback'</code>	The <code>uibuttongroup</code> handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the <code>uibuttongroup</code> at the command-line, but allows callback functions to access it.
<code>'off'</code>	The <code>uibuttongroup</code> handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the <code>HandleVisibility</code> to <code>'off'</code> to temporarily hide the handle during the execution of that function.

Set the graphics root `ShowHiddenHandles` property to `'on'` to make all handles visible, regardless of their `HandleVisibility` value. This setting has no effect on their `HandleVisibility` values.

---

**Note:** Do not try to access radio buttons and toggle buttons that are managed by a `uibuttongroup` outside of the button group. Set the `HandleVisibility` of those radio buttons and toggle buttons to 'off' to prevent accidental access.

---

## More About

- “Access Property Values”
- “Default Property Values”

# uicontextmenu

Create context menu

## Syntax

```
c = uicontextmenu
c = uicontextmenu(Name,Value)

c = uicontextmenu(parent)
c = uicontextmenu(parent,Name,Value)
```

## Description

`c = uicontextmenu` creates a context menu in the current figure and returns the `uicontextmenu` object as `c`. If no figure is available, then MATLAB creates a new figure to serve as the parent.

`c = uicontextmenu(Name,Value)` specifies one or more `uicontextmenu` property names and corresponding values. Use this syntax to override the default `uicontextmenu` property values.

`c = uicontextmenu(parent)` creates a `uicontextmenu` and specifies the parent figure.

`c = uicontextmenu(parent,Name,Value)` specifies a parent figure and one or more `uicontextmenu` properties.

## Examples

### Context Menu Attached to a Plot Line

Specify a value for the line object's `UIContextMenu` property to attach a `uicontextmenu` to that line. The context menu becomes visible when the user right-clicks on the line. For instance, create a program file called `myprogram.m` that creates a plot and attaches a `uicontextmenu` to the plot line:

```
function myprogram

 f = figure('WindowStyle','normal');
 ax = axes;
 x = 0:100;
 y = x.^2;

 plotline = plot(x,y);
 c = uicontextmenu;

 % Set c to be the plot line's UIContextMenu
 plotline.UIContextMenu = c;

 % Create menu items for the uicontextmenu
 m1 = uimenu(c,'Label','dashed','Callback',@setlinestyle);
 m2 = uimenu(c,'Label','dotted','Callback',@setlinestyle);
 m3 = uimenu(c,'Label','solid','Callback',@setlinestyle);

 function setlinestyle(source,callbackdata)
 switch source.Label
 case 'dashed'
 plotline.LineStyle = '--';
 case 'dotted'
 plotline.LineStyle = ':';
 case 'solid'
 plotline.LineStyle = '-';
 end
 end
end
```

The context menu appears when the user right-clicks the plot line.

Selecting an item from the context menu changes the line style.

### Context Menu with Submenus

Specify the `Parent` property value of any `uimenu` to make it into a submenu. For instance, create a program file called `myprogram2` that creates a `uicontextmenu` containing one top-level menu and two submenu items:

```
function myprogram2
 f = figure('WindowStyle','normal');
 c = uicontextmenu(f);

 % Assign the uicontextmenu to the figure
 f.UIContextMenu = c;
```

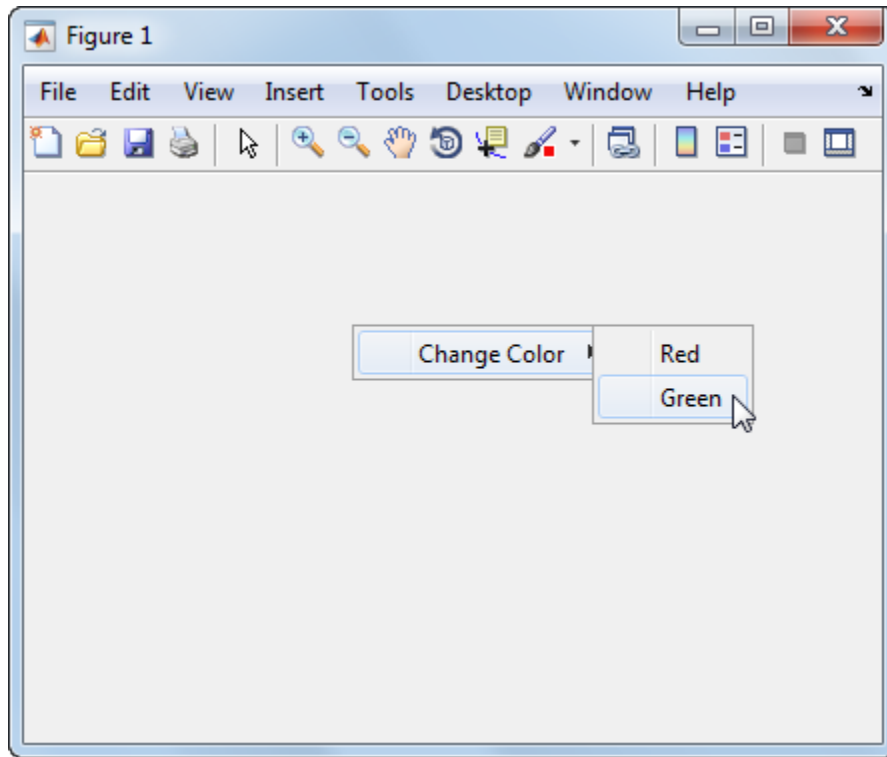

```
% Create top-level menu item
topmenu = uimenu('Parent',c,'Label','Change Color');

% Create submenu items
m1 = uimenu('Parent',topmenu,'Label','Red','Callback',@change_color);
m2 = uimenu('Parent',topmenu,'Label','Green','Callback',@change_color);

function change_color(source,callbackdata)
 switch source.Label
 case 'Red'
 f.Color = [1.0 0.80 0.80];
 case 'Green'
 f.Color = [0.80 1.0 0.80];
 end
end
end
```

The resulting context menu appears when the user right-clicks the mouse inside the figure.

Selecting a color from the context menu changes the color of the window.

## Input Arguments

**parent** — Parent figure

figure

Parent figure, specified as a figure object.

## Name-Value Pair Arguments

The properties listed here are only a subset, for a complete list see Uicontextmenu Properties.

Example: 'Callback',@myfunction specifies myfunction to be the function that executes when the user interacts with the context menu.

**'Callback' — Callback function that executes when user selects the uicontextmenu**

' ' (default) | function handle | cell array | string

Callback function that executes when user selects the `uicontextmenu`, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

**'Children' — Children of uicontextmenu**

empty `GraphicsPlaceholder` array (default) | 1-D array of `uimenu` objects

Children of `uicontextmenu`, returned as an empty `GraphicsPlaceholder` or a 1-D array of `uimenu` objects. The children of `uicontextmenus` are other `uimenu`s that function as submenus.

You cannot add or remove children using the `Children` property of the `uicontextmenu`. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the order of the displayed menu items.

To add a child to this list, set the `Parent` property of the child component to be the `uicontextmenu` object.

Objects with the `HandleVisibility` property set to `'off'` do not list in the `Children` property. For more information, see the `HandleVisibility` property description.

## More About

### Tips

The context menu becomes accessible in the UI when both of these requirements are met:

- You create at least one uimenu and set its parent to be the uicontextmenu. Here is an example:

```
c = uicontextmenu;
m = uimenu('Parent',c,'Label','Disable');
```

- You assign the uicontextmenu to be another component's UIContextMenu property value. Here is an example:

```
c = uicontextmenu;
b = uicontrol('UIContextMenu',c);
b must be a descendant of the same figure as c.
```

## See Also

**Introduced before R2006a**

## Uicontextmenu Properties

Control appearance and behavior of context menu

A `uicontextmenu` is a context menu that appears when the user right-clicks on a graphics object or UI component. The `uicontextmenu` function creates a context menu and sets any required properties. By changing `uicontextmenu` property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
c = uicontextmenu;
pos = c.Position;
c.Position = [20 20];
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Appearance

#### Visible — Uicontextmenu visibility

'off' (default) | 'on'

Uicontextmenu visibility, specified as 'on' or 'off'. You can use the `Visible` property in one of two ways:

- Query the value to find out if the context menu is currently posted. The context menu is posted while the `Visible` property value is set to 'on'.
- Set the `Visible` property to 'on' to make the context menu to appear. Set this property to 'off' to make the context menu to disappear.

### Location and Size

#### Position — Uicontextmenu location

[left bottom]

Uicontextmenu location, specified as the vector, [left bottom]. This table describes each element in the vector.

Element	Description
left	Distance from the inner left edge of the figure to the left edge of the <code>uicontextmenu</code>

Element	Description
bottom	Distance from the inner bottom edge of the figure to the top edge of the uicontextmenu

The **Position** property defines the location of a context menu when its **Visible** property is set to 'on'.

Data Types: double

## Interactive Control

### Callback — Callback function that executes when user selects the uicontextmenu

' ' (default) | function handle | cell array | string

Callback function that executes when user selects the uicontextmenu, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

Example: @myfun

Example: {@myfun,x}

Data Types: function\_handle | cell | char

## Callback Execution Control

### Interruptible — Callback interruption

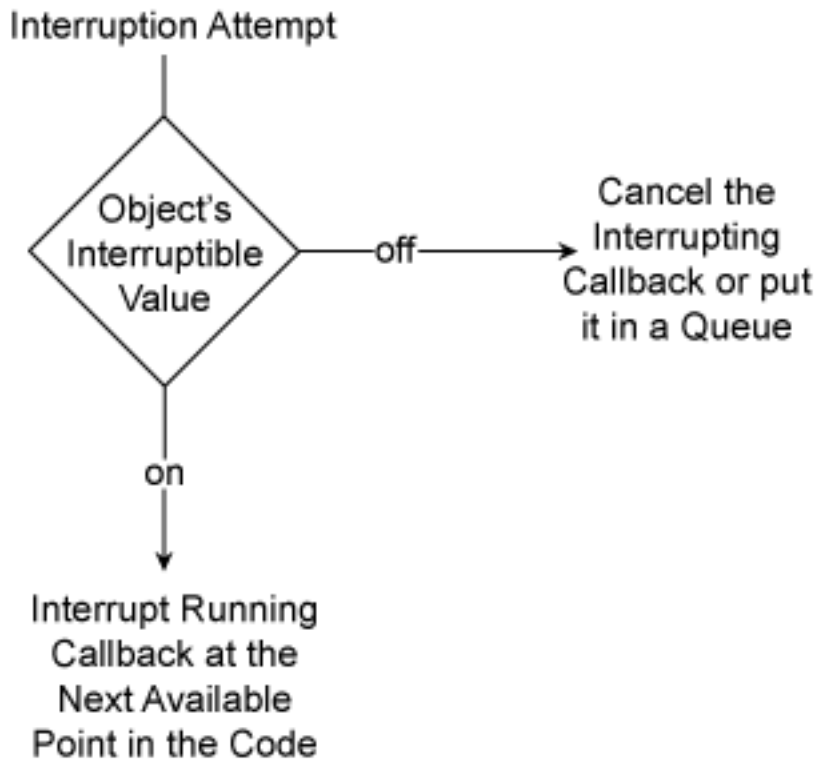

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The **Interruptible** property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put into a queue.

If a `uicontextmenu` callback is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- 'on' — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

---

**Note:** Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a `DeleteFcn`, `CloseRequestFcn`, or `SizeChangedFcn` callback, then the interruption occurs regardless of the `Interruptible` property value.
  - If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the `Interruptible` property value.
  - MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.
- 

See “Interrupt Callback Execution” for an example that shows how the `Interruptible` and `BusyAction` properties affect the behavior of a program.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' (default) or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The **BusyAction** property of the source of the interrupting callback determines how MATLAB handles its execution. The **BusyAction** property has these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- 'cancel' — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The **Interruptible** property of the object whose callback is running determines if interruption is allowed. If **Interruptible** is set to:

- on — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- off — The **BusyAction** property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the **BusyAction** and **Interruptible** properties affect the behavior of a program.

## Creation and Deletion Control

### **BeingDeleted** — Deletion status of uicontextmenu

'off' (default) | 'on'

This property is read only.

Deletion status of uicontextmenu, returned as 'on' or 'off'. MATLAB sets the **BeingDeleted** property to 'on' when the delete function of the uicontextmenu begins execution (see the **DeleteFcn** property). The **BeingDeleted** property remains set to 'on' until the uicontextmenu no longer exists.

Check the value of the **BeingDeleted** property to verify that the uicontextmenu is not about to be deleted before querying or modifying it.

### **CreateFcn** — Uicontextmenu creation function

function handle | cell array | string

Uicontextmenu creation function, specified as one of these values:

- Function handle

- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This property specifies a callback function to execute when MATLAB creates the `uicontextmenu`. MATLAB initializes all `uicontextmenu` property values before executing the `CreateFcn` callback. If you do not specify the `CreateFcn` property, then MATLAB executes a default creation function.

Use the `gcb0` function in your `CreateFcn` code to get the handle to the `uicontextmenu` that is being created.

Setting the `CreateFcn` property on an existing `uicontextmenu` has no effect.

---

**Note:** Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. Copying the `uicontextmenu` object causes the `CreateFcn` callback to execute repeatedly.

---

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

### **DeleteFcn — Uicontextmenu deletion function**

`function handle` | `cell array` | `string`

`Uicontextmenu` deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `DeleteFcn` property specifies a callback function to execute when MATLAB deletes the `uicontextmenu` (for example, when the end user deletes the figure). MATLAB executes the `DeleteFcn` callback before destroying the properties of the `uicontextmenu`. If you do not specify the `DeleteFcn` property, then MATLAB executes a default deletion function.

Use the `gcb0` function in your `DeleteFcn` code to get the handle to the `uicontextmenu` that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

## Identifiers

### **Type — Type of graphics object**

'`uicontextmenu`'

This property is read only.

Type of graphics object, returned as '`uicontextmenu`'.

### **Tag — Uicontextmenu identifier**

' ' (default) | string

Uicontextmenu identifier, specified as a string. You can specify a unique `Tag` value to serve as an identifier for the `uicontextmenu`. When you need access to the `uicontextmenu` elsewhere in your code, you can use the `findobj` function to search for the `uicontextmenu` based on the `Tag` value.

Example: '`contextmenu1`'

Data Types: `char`

### **UserData — Data to associate with the uicontextmenu object**

empty array (default) | array

Data to associate with the `uicontextmenu` object, specified as any array. Specifying `UserData` can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: 'April 21'

Example: struct('value1',[1 2 3],'value2','April 21')

Example: {[1 2 3],'April 21'}

## Parent/Child

### Parent — Uicontextmenu parent

figure

Uicontextmenu parent, specified as a figure. You can move a uicontextmenu to a different figure by setting this property to the handle of the target figure.

### Children — Children of uicontextmenu

empty GraphicsPlaceholder array (default) | 1-D array of uimenu objects

Children of uicontextmenu, returned as an empty GraphicsPlaceholder or a 1-D array of uimenu objects. The children of uicontextmenus are other uimenus that function as submenus.

You cannot add or remove children using the Children property of the uicontextmenu. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the order of the displayed menu items.

To add a child to this list, set the Parent property of the child component to be the uicontextmenu object.

Objects with the HandleVisibility property set to 'off' do not list in the Children property. For more information, see the HandleVisibility property description.

### HandleVisibility — Visibility of Uicontextmenu handle

'on' (default) | 'callback' | 'off'

Visibility of Uicontextmenu handle, specified as 'on', 'callback', or 'off'.

This property controls the visibility of the uicontextmenu handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include get, findobj, gca, gcf, gco, newplot, cla, clf, and close. The HandleVisibility property also controls the visibility of the object's handle in the parent figure's CurrentObject property. Handles are still valid even if

they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
'on'	The uicontextmenu handle is always visible.
'callback'	The uicontextmenu handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uicontextmenu at the command-line, but allows callback functions to access it.
'off'	The uicontextmenu handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the <b>HandleVisibility</b> to 'off' to temporarily hide the handle during the execution of that function.

Set the graphics root **ShowHiddenHandles** property to 'on' to make all handles visible, regardless of their **HandleVisibility** value. This setting has no effect on their **HandleVisibility** values.

## More About

- “Access Property Values”
- “Default Property Values”

# uicontrol

Create user interface control object

## Syntax

```
c = uicontrol
c = uicontrol(Name,Value,...)
c = uicontrol(parent)
c = uicontrol(parent,Name,Value,...)
uicontrol(c)
```

## Description

`c = uicontrol` creates a `uicontrol` (push button) in the current figure and returns the `uicontrol` object, `c`. If there is no figure available, then MATLAB creates a new figure to serve as the parent.

`c = uicontrol(Name,Value,...)` creates a `uicontrol` and specifies one or more `uicontrol` property names and corresponding values. Use this syntax to override the default `uicontrol` properties. The default `uicontrol` style is `'pushbutton'`.

`c = uicontrol(parent)` creates a `uicontrol` and designates a specific parent object. The `parent` argument can be a figure, `uipanel`, `uibuttongroup`, or `uitab` object.

`c = uicontrol(parent,Name,Value,...)` creates a `uicontrol` with a specific parent and one or more `uicontrol` properties.

`uicontrol(c)` gives focus to a specific `uicontrol` object, `c`.

## Specifying the Uicontrol Style

When selected, most `uicontrol` objects perform a predefined action. To create a specific type of `uicontrol`, set the `Style` property as one of the strings that follow. You can specify a partial string if it is unique among all the styles. For example, instead of `'radiobutton'`, you can specify `'radio'`.

- 'checkbox' – A check box generates an action when you select it. Use check boxes to provide a number of independent choices. To activate a check box, click the mouse button on the object. The check box updates its appearance when its state changes.
- 'edit' – Editable text fields enable you to enter or modify text values. Use editable text when you want free text as input. To enable multiple lines of text, set `Max-Min > 1`. Multiline edit boxes provide a vertical scroll bar for scrolling. The arrow keys also provide a way to scroll. Obtain the current text by getting the `String` property. The `String` property does not update as you type in an edit box. To execute the callback routine for an edit text control, type in the desired text and then do one of the following:
  - Click another component, the menu bar, or elsewhere on the window.
  - For a single line editable text box, press **Enter**.
  - For a multiline editable text box, press **Ctrl+Enter**.
- 'frame'

---

**Note** MathWorks recommends you use `uipanel` or `uibuttongroup` instead of frames.

GUIDE continues to support frames in UIs that contain them, but the frame component does not appear in the GUIDE Layout Editor component palette.

---

- 'listbox' – List boxes display a list of items, from which you can select one or more items. Unlike pop-up menus, list boxes do not expand when clicked. The `Min` and `Max` properties control the selection mode:
  - To enable multiple selection of items, set `Max-Min > 1`.
  - To enable selection of only one item at a time, set `Max-Min <= 1`

The `Value` property stores the row indexes of currently selected list box items, and is a vector value when you select multiple items. After any mouse button up event that changes the `Value` property, MATLAB evaluates the list box's callback routine. To delay action when multiple items can be selected, you can associate a "Done" push button with the list box. Use the callback for that button to evaluate the list box `Value` property.

List boxes with the `Enable` property set to `on` differentiate between single and double left clicks. MATLAB sets the figure `SelectionType` property to `normal` or `open` accordingly before evaluating the list box `Callback` property. For enabled list boxes,

**Ctrl**-left click and **Shift**-left click also set the figure `SelectionType` property to `normal` or `open`, respectively indicating a single or double click.

- `'popupmenu'` – Pop-up menus (also known as drop-down menus) display a list of choices when you open them with a button-press. When closed, a pop-up menu indicates the current choice. Pop-up menus are useful when you want to provide a number of mutually exclusive choices, but do not want to take up the amount of space that a group of radio buttons requires.
- `'pushbutton'` – Push buttons generate an action when activated. Left-click a push button to activate it. The button appears to depress until you release the mouse button. The callback activates when you release the mouse button while still pointing within the push button.
- `'radiobutton'` – Radio buttons are similar to check boxes, but are intended to be mutually exclusive within a group of related radio buttons. When used this way, you can only select one radio button at any given time). To activate a radio button, click and release the mouse button over it. The easiest way to implement mutually exclusive behavior for a set of radio buttons is to place them within a `uibuttongroup`.
- `'slider'` – Sliders accept numeric input within a specific range when you move the “thumb” button along a bar. The location of the thumb indicates a numeric value, assigned to the `Value` property when you release the mouse button. You can set the minimum, maximum, and current values, and step sizes of a slider.

Move the thumb by doing any one of the following:

- Press the mouse button on the thumb, and drag it along the bar.
- Click in the bar or on arrow buttons located at both ends of the bar.
- Click the keyboard arrow keys when the slider is in focus.
- `'text'` – Static text boxes display lines of text. You typically use static text to label other controls, provide information to the user, or indicate values associated with a slider. If you assign the `Callback` property of a static text object to a function (or a string of commands), the static text will not respond when users try to interact with the text. However, you can code the `ButtonDownFcn` callback to respond to mouse clicks on the static text. See “Tips” on page 1-9086 for more information.
- `'togglebutton'` – Toggle buttons are similar in appearance to push buttons, but they visually indicate their state, either `'on'` (depressed) or `'off'` (up). Clicking a toggle button changes its state, and switches its `Value` property between the toggle button’s `Min` and `Max` values.

## Examples

Create uicontrols to allow users to adjust the appearance of a plot. For instance, create a program file called `myui.m` that contains the following code.

```
function myui
% Create a figure and axes
f = figure('Visible','off');
ax = axes('Units','pixels');
surf(peaks)

% Create pop-up menu
popup = uicontrol('Style','popup',...
 'String',{ 'parula','jet','hsv','hot','cool','gray'},...
 'Position',[20 340 100 50],...
 'Callback', @setmap);

% Create push button
btn = uicontrol('Style','pushbutton','String','Clear',...
 'Position',[20 20 50 20],...
 'Callback','cla');

% Create slider
sld = uicontrol('Style','slider',...
 'Min',1,'Max',50,'Value',41,...
 'Position',[400 20 120 20],...
 'Callback', @surfzlim);

% Add a text uicontrol to label the slider.
txt = uicontrol('Style','text',...
 'Position',[400 45 120 20],...
 'String','Vertical Exaggeration');

% Make figure visible after adding all components
f.Visible = 'on';
% This code uses dot notation to set properties.
% Dot notation runs in R2014b and later.
% For R2014a and earlier: set(f,'Visible','on');

function setmap(source,callbackdata)
 val = source.Value;
 maps = source.String;
 % For R2014a and earlier:
 % val = get(source,'Value');
```

```

 % maps = get(source,'String');

 newmap = maps{val};
 colormap(newmap);
end

function surfzlim(source,callbackdata)
 val = 51 - source.Value;
 % For R2014a and earlier:
 % val = 51 - get(source,'Value');

 zlim(ax,[-val val]);
end
end

```

The resulting UI displays a plot. Users can adjust the color map, change the vertical scaling, or clear the axes.

## More About

### Tips

- To make static text respond to mouse clicks, set the text object's `Enable` property to `'Inactive'`. Then, define a `ButtonDownFcn` callback that responds when the user clicks on the text. For example, the following code displays `'Text was clicked'` in the Command Window when the user clicks on the text in the UI.

```
mytxt = uicontrol('Style','text','String','Click Me!');
mytxt.Enable = 'Inactive';
mytxt.ButtonDownFcn = 'disp(''Text was clicked'')';
```

Note that this code uses dot notation to set properties. Dot notation runs in R2014b and later. If you are using an earlier release, use the `set` function instead.

- “Access Property Values”

**Introduced before R2006a**

# Uicontrol Properties

Control appearance and behavior of user interface control

Uicontrols are interface components, such as buttons and sliders, that users can interact with. The `uicontrol` function creates an interface component and sets any required properties before displaying it. By changing uicontrol property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
b = uicontrol('Style','pushbutton');
pos = b.Position;
b.Position = [100 100 50 20];
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Appearance

### Visible — Uicontrol visibility

'on' (default) | 'off'

Uicontrol visibility, specified as 'on' or 'off'. When `Visible` is 'off', the uicontrol is not visible, but you can query and set its properties.

To make your program start faster, set the `Visible` property of all uicontrols that are not initially displayed to 'off'.

### BackgroundColor — Uicontrol background color

[.94 .94 .94] (default) | RGB triplet | short name | long name

Uicontrol background color, specified as an RGB triplet, short name, or long name. The color you specify fills the area bounded by the uicontrol.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]

Long Name	Short Name	RGB Triplet
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

---

**Note:** Some operating systems override the `BackgroundColor` value.

---

Data Types: `double` | `char`

**ForegroundColor** — **Uicontrol text color**

[ 0 0 0 ] (default) | RGB triplet | short name | long name

Uicontrol text color, specified as an RGB triplet, short name, or long name from the table below.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]

Long Name	Short Name	RGB Triplet
'black'	'k'	[0 0 0]

---

**Note:** If you change the value of `ForegroundColor` for a listbox, then MATLAB uses that color for all listbox items, except for the currently selected listbox item. For selected items, MATLAB uses a color that ensures good contrast between the text of selected items and the selection color.

---

Example: `[0 0 1]`

Example: `'b'`

Example: `'blue'`

Data Types: `double` | `char`

### **CData** — Optional image to display on uicontrol

3-D array of truecolor RGB values

Optional image to display on the uicontrol, specified as a 3-D array of truecolor RGB values. The values in the array can be:

- Double-precision values between 0.0 and 1.0
- `uint8` values between 0 and 255

Push buttons and toggle buttons are the only uicontrols that fully support `CData`. If you specify the `CData` property for a radio button or check box, the image might overlap with the text string. Also, specifying an image for radio button or check box disables the ability to show when they are selected or deselected.

Example: `zeros(16,16,3)`

Example: `uint8(zeros(16,16,3))`

Data Types: `double` | `uint8`

## **Location and Size**

### **Position** — Location and size of uicontrol

`[left bottom width height]`

Location and size of the uicontrol relative to the parent, specified as the vector, [`left` `bottom` `width` `height`]. This table describes each element in the vector.

Element	Description
<code>left</code>	Distance from the inner left edge of the parent container to the outer left edge of the uicontrol
<code>bottom</code>	Distance from the inner bottom edge of the parent container to the outer bottom edge of the uicontrol
<code>width</code>	Distance between the right and left outer edges of the uicontrol
<code>height</code>	Distance between the top and bottom outer edges of the uicontrol

All measurements are in units specified by the `Units` property.

---

**Note:** If the parent of the uicontrol is a figure, then the `Position` values are relative to the figure's *drawable area*. The drawable area of a figure is the area inside the window borders, excluding the menu bar and tool bar.

---

## Modify One Value in the Position Vector

You can combine dot notation and array indexing when you want to change one value in the `Position` vector. For example, this code changes the width of the uicontrol to 52:

```
b = uicontrol;
b.Position(3) = 52;
b.Position
```

```
ans =
```

```
 20 20 52 20
```

```
Data Types: double
```

### Units — Units of measurement

```
'pixels' (default) | 'normalized' | 'inches' | 'centimeters' | 'points' |
'characters'
```

Units of measurement, specified one of the values from this table.

Units Value	Description
'pixels' (default)	<p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p>
'normalized'	These units are normalized with respect to the parent container. The lower-left corner of the container maps to (0,0) and the upper-right corner maps to (1,1).
'inches'	Inches.
'centimeters'	Centimeters.
'points'	Points. One point equals 1/72nd of an inch.
'characters'	<p>These units are based on the default system font character size.</p> <ul style="list-style-type: none"> <li>• Character width = width of the letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>

MATLAB measures all units from the lower left corner of the parent object.

This property affects the **Position** property. If you change the units, then it is good practice to return it to its default value after completing your computation to prevent affecting other functions that assume **Units** is the default value.

The order in which you specify the **Units** and **Position** properties has these effects:

- If you specify the **Units** before the **Position** property, then MATLAB sets **Position** using the units you specify.

- If you specify the `Units` property after the `Position` property, MATLAB sets the position using the default `Units`. Then, MATLAB converts the `Position` value to the equivalent value in units you specify.

## **Extent** — Size of uicontrol rectangle

four-element row vector

This property is read only.

Size of uicontrol rectangle, returned as a four-element row vector. The first two elements of the vector are always zero. The third and fourth elements are the width and height of the rectangle containing the uicontrol, respectively. All measurements are in units specified by the `Units` property.

MATLAB determines the size of the rectangle based on the size of the `String` property value and the font characteristics. To adjust the width and height of the uicontrol to accommodate the size of the `String` value, set the `Position` width and height values to be slightly larger than the `Extent` width and height values.

For single line strings, the height element of the `Extent` property indicates the height of a single line. The width element indicates the width of the longest line, even if the string wraps when displayed on the control. For multiline strings, the `Extent` rectangle encompasses all lines of text. Editable text fields are considered multiline if `Max - Min > 1`.

When the uicontrol `Units` property is `'normalized'`, the `Extent` values are measured relative to the figure, regardless of whether the uicontrol is contained in (parented to) a `uipanel`.

## **Font Style**

### **FontName** — Font for displaying uicontrol text

`'Helvetica'` (default) | string

Font for displaying the uicontrol text, specified as a string. This property specifies the name of the font to use to display the text specified in the uicontrol `'String'` property.

To use a fixed-width font, set the `FontName` property to the string, `'FixedWidth'`. This setting instructs MATLAB to use the value of the root `FixedWidthFontName` property, which you can set in the `startup.m` file.

For more information about the `startup.m` file, see “Startup Options in MATLAB Startup File”.

Example: `'Arial'`

### **FontSize** — Font size for uicontrol text

positive number

Font size for the uicontrol text, specified as a positive number. The `FontUnits` property specifies the units. The default size is system-dependent.

Example: 12

Example: 12.5

Data Types: `double`

### **FontUnits** — Units of font size for uicontrol text

`'points'` (default) | `'normalized'` | `'inches'` | `'centimeters'` | `'pixels'`

Units of font size for the uicontrol text, specified as one of the values from this table.

Units Value	Description
<code>'points'</code>	Points. One point is 1/72nd of an inch.
<code>'normalized'</code>	Normalized values for specifying the font size as a fraction of the uicontrol height. When you resize the uicontrol, MATLAB scales the displayed font to maintain that fraction.
<code>'inches'</code>	Inches.
<code>'centimeters'</code>	Centimeters.
<code>'pixels'</code>	<p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p>

**FontWeight** — Font weight for uicontrol text`'normal'` (default) | `'bold'`

Font weight for the uicontrol text, specified as a value from the table below.

FontWeight Value	Description
<code>'normal'</code>	Normal font weight
<code>'bold'</code>	Heavy font weight

Not all fonts support all font weights. Therefore, if you specify an unsupported value for the `FontWeight` property, the result might appear the same as the default.

---

**Note:** The `'light'` and `'demi'` font weight values have been removed in R2014b. If you specify either of these values, the result is a normal font weight.

---

**FontAngle** — Character slant of uicontrol text`'normal'` (default) | `'italic'`

Character slant of uicontrol text, specified as `'normal'` or `'italic'`. MATLAB uses this property to select a font from those available on your system. Setting this property to `'italic'` selects a slanted version of the font, if it is available on your system.

---

**Note:** The `'oblique'` value has been removed. Use `'italic'` instead.

---

**Text****String** — Text to display`string` | cell array of `char` values | pipe-delimited row vector | padded column matrix

Text to display, specified as a string, cell array, a pipe-delimited row vector, or a padded column matrix. The uicontrol `Style` property value determines the array format you can use.

Style Property Value	Supported Array Formats	Examples
<code>'checkbox'</code>	• String	<code>'Item 1'</code> { <code>'Item 1'</code> }

Style Property Value	Supported Array Formats	Examples
	<ul style="list-style-type: none"> <li>Cell array of char values</li> </ul>	
'edit'	<ul style="list-style-type: none"> <li>String</li> <li>Cell array of char values</li> </ul>	'Default text' {'Default text'}
'pushbutton'	<ul style="list-style-type: none"> <li>String</li> <li>Cell array of char values</li> </ul>	'Evaluate' {'Evaluate'}
'radiobutton'	<ul style="list-style-type: none"> <li>String</li> <li>Cell array of char values</li> </ul>	'Round to nearest integer' {'Round to nearest integer'}
'text'	<ul style="list-style-type: none"> <li>String</li> <li>Cell array of char values</li> </ul>	'Enter values' {'Enter values'}
'togglebutton'	<ul style="list-style-type: none"> <li>String</li> <li>Cell array of char values</li> </ul>	'Activate' {'Activate'}
'listbox'	<ul style="list-style-type: none"> <li>String</li> <li>Cell array of char values</li> <li>Pipe-delimited row vector</li> <li>Padded column matrix</li> </ul>	'Red' {'Red', 'Blue', 'Orange'} 'Red Blue Orange' ['Red   '; 'Blue   '; 'Orange']
'popupmenu'	<ul style="list-style-type: none"> <li>String</li> <li>Cell array of char values</li> <li>Pipe-delimited row vector</li> <li>Padded column matrix</li> </ul>	'Red' {'Red', 'Blue', 'Orange'} 'Red Blue Orange' ['Red   '; 'Blue   '; 'Orange']

---

**Note:** Some important characteristics of the `String` property:

- If you specify a cell array for a check box, push button, radio button, or toggle button, then MATLAB displays only the first element in the cell array.
  - If you want to specify multiple lines of text of different lengths, specify the each line of text as a separate element in a cell array. For example, you might use a cell array to display sentences in separate paragraphs.
  - If you programmatically replace the string of an 'edit' style of uicontrol, the cursor moves to the beginning of the text.
  - If you want to specify a Unicode character, pass the Unicode decimal code to the `char` function. For example, `['Multiples of ' char(960)]` displays as Multiples of  $\pi$ .
- 

Data Types: `char`

### **HorizontalAlignment** — Alignment of uicontrol text

'center' (default) | 'left' | 'right'

Alignment of the uicontrol text, specified as 'center', 'left', or 'right'. This property determines the justification of the `String` property text.

The `HorizontalAlignment` property has no effect on listboxes and pop-up menus.

## **Interactive Control**

### **Callback** — Callback function that executes when user interacts with uicontrol

' ' (default) | function handle | cell array | string

Uicontrol action, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

This is a function that makes the uicontrol respond to user inputs, such as push button clicks, slider movements, or check box selections.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

Example: @myfun

Example: {@myfun,x}

Data Types: `function_handle` | `cell` | `char`

### **ButtonDownFcn — Button-press callback function**

' ' (default) | function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `ButtonDownFcn` callback is a function that executes when the user clicks a mouse button on the uicontrol. The callback executes in the following situations:

- The user right-clicks the uicontrol, and the uicontrol `Enable` property is set to 'on'.
- The end user right-clicks or left-clicks the Uicontrol, and the uicontrol `Enable` property is set to 'off' or 'inactive'.

Example: @myfun

Example: {@myfun,x}

Data Types: `function_handle` | `cell` | `char`

### **KeyPressFcn — Key press callback function**

' ' (default) | function handle | cell array | string

Key press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.

- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback function executes when the uicontrol object has focus and the user presses a key. If you do not define a function for this property, MATLAB passes key presses to the parent figure. Repeated key presses retain the focus of the uicontrol, and the function executes with each key press. If the user presses multiple keys at approximately the same time, MATLAB detects the key press for the last key pressed.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Property	Description	Examples:			
		a	=	Shift	Shift-a
Character	The character that displays as a result of pressing a key or keys. The character can be empty or unprintable.	'a'	'='	' '	'A'
Modifier	A cell array containing the names of one or more modifier keys that are being pressed (such as, <b>Ctrl</b> , <b>Alt</b> , <b>Shift</b> ).	{1x0 cell}	{1x0 cell}	{'shift'}	{'shift'}
Key	The key being pressed, identified by the (lowercase) label on the key, or a descriptive string.	'a'	'equal'	'shift'	'a'
Source	The object that has focus when the user presses the key.	uicontrol object	uicontrol object	uicontrol object	uicontrol object
EventName	The action that caused the callback function to execute.	'KeyPress'	'KeyPress'	'KeyPress'	'KeyPress'

Pressing modifier keys affects the callback data in the following ways:

- Modifier keys can affect the **Character** property, but do not change the **Key** property.

- Certain keys, and keys modified with **Ctrl**, put unprintable characters in the **Character** property.
- **Ctrl**, **Alt**, **Shift**, and several other keys, do not generate **Character** property data.

You also can query the **CurrentCharacter** property of the figure to determine which character the user pressed.

Example: @myfun

Example: {@myfun,x}

Data Types: `function_handle` | `cell` | `char`

### **KeyReleaseFcn** — Key-release callback function

' ' (default) | function handle | cell array | string

Key-release callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback function executes when the uicontrol object has focus and the user releases a key.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Property	Description	Examples:			
		a	=	Shift	Shift-a
Character	Character interpretation of the key that was released.	'a'	'='	' '	'A'

Property	Description	Examples:			
		a	=	Shift	Shift-a
Modifier	Current modifier, such as 'control'. This value is always an empty cell array for aseFcn callbacks.	{1x0 cell}	{1x0 cell}	{1x0 cell}	{1x0 cell}
Key	Name of the key that was released, identified by the lowercase label on the key, or a descriptive string.	'a'	'equal'	'shift'	'a'
Source	The object that has focus when the user presses the key.	uicontrol object	uicontrol object	uicontrol object	uicontrol object
EventName	The action that caused the callback function to execute.	'ase'	'ase'	'ase'	'ase'

Pressing modifier keys affects the callback data in the following ways:

- Modifier keys can affect the **Character** property, but do not change the **Key** property.
- Certain keys, and keys modified with **Ctrl**, put unprintable characters in the **Character** property.
- **Ctrl**, **Alt**, **Shift**, and several other keys, do not generate **Character** property data.

You also can query the **CurrentCharacter** property of the figure to determine which character the user pressed.

Example: @myfun

Example: {@myfun,x}

Data Types: function\_handle | cell | char

### **Enable** — Operational state of uicontrol

'on' (default) | 'off' | 'inactive'

Operational state of the uicontrol, specified as 'on', 'off', or 'inactive'. The **Enable** property controls whether the uicontrol responds to button clicks. These are the possible values:

- 'on' – The uicontrol is operational.

- 'off' – The uicontrol is not operational and appears grayed-out.
- 'inactive' – The uicontrol is not operational, but it has the same appearance as when `Enable` is set to 'on'.

The value of the `Enable` property and the type of button click determine the response.

Enable Value	Response to Left-Click	Response to Right-Click
'on'	The uicontrol's <code>Callback</code> function executes.	<ol style="list-style-type: none"> <li>1 The figure's <code>WindowButtonDownFcn</code> callback executes.</li> <li>2 The uicontrol's <code>ButtonDownFcn</code> callback executes.</li> </ol>
'off' or 'inactive'	<ol style="list-style-type: none"> <li>1 The figure's <code>WindowButtonDownFcn</code> callback executes.</li> <li>2 The uicontrol's <code>ButtonDownFcn</code> callback executes.</li> </ol>	<ol style="list-style-type: none"> <li>1 The figure's <code>WindowButtonDownFcn</code> callback executes.</li> <li>2 The uicontrol's <code>ButtonDownFcn</code> callback executes.</li> </ol>

### **TooltipString** – Tooltip text

string

Tooltip text, specified as a string. When the user hovers the mouse pointer over the uicontrol and leaves it there, the tooltip displays. If you want to create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that string.

## Specify TooltipString Containing Two Lines

```
b = uicontrol;
s = sprintf('Tooltip line 1\nTooltip line 2');
b.TooltipString = s;
```

### **UIContextMenu** – Uicontrol context menu

empty `GraphicsPlaceholder` array (default) | `uicontextmenu` object

Uicontrol context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when the user right-clicks on the uicontrol. Create the context menu using the `uicontextmenu` function.

## **Selected** — Selection status of uicontrol

'off' (default) | 'on'

---

**Note:** The behavior of the `Selected` property changed in R2014b, and it is not recommended. It no longer has any effect on uicontrols. This property might be removed in a future release.

---

## **SelectionHighlight** — Ability to highlight selection handles

'on' (default) | 'off'

---

**Note:** The behavior of the `SelectionHighlight` property changed in R2014b, and it is not recommended. It no longer has any effect on uicontrols. This property might be removed in a future release.

---

## **Callback Execution Control**

### **Interruptible** — Callback interruption

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put into a queue.

If a uicontrol callback is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- 'on' — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
- If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.

- If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

---

**Note:** Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a `DeleteFcn`, `CloseRequestFcn`, or `SizeChangedFcn` callback, then the interruption occurs regardless of the `Interruptible` property value.
  - If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the `Interruptible` property value.
  - MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.
- 

See “Interrupt Callback Execution” for an example that shows how the `Interruptible` and `BusyAction` properties affect the behavior of a program.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' (default) or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- 'cancel' — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The `Interruptible` property of the object whose callback is running determines if interruption is allowed. If `Interruptible` is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The `BusyAction` property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the `BusyAction` and `Interruptible` properties affect the behavior of a program.

### **HitTest — Ability to become current object**

'on' (default) | 'off'

This property has no effect on the uicontrol.

## **Creation and Deletion Control**

### **BeingDeleted — Deletion status of uicontrol**

'off' (default) | 'on'

This property is read only.

Deletion status of uicontrol, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the uicontrol begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the uicontrol no longer exists.

Check the value of the `BeingDeleted` property to verify that the uicontrol is not about to be deleted before querying or modifying it.

### **CreateFcn — Uicontrol creation function**

function handle | cell array | string

Uicontrol creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.

- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This property specifies a callback function to execute when MATLAB creates the `uicontrol`. MATLAB initializes all `uicontrol` property values before executing the `CreateFcn` callback. If you do not specify the `CreateFcn` property, then MATLAB executes a default creation function.

Use the `gcb0` function in your `CreateFcn` code to get the handle to the `uicontrol` that is being created.

Setting the `CreateFcn` property on an existing `uicontrol` has no effect.

---

**Note:** Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. Copying the `uicontrol` object causes the `CreateFcn` callback to execute repeatedly.

---

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

### **DeleteFcn — Uicontrol deletion function**

`function handle` | `cell array` | `string`

Uicontrol deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `DeleteFcn` property specifies a callback function to execute when MATLAB deletes the `uicontrol` (for example, when the end user deletes the figure). MATLAB executes

the `DeleteFcn` callback before destroying the properties of the uicontrol. If you do not specify the `DeleteFcn` property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your `DeleteFcn` code to get the handle to the uicontrol that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

## Identifiers

### Type — Type of graphics object

`'uicontrol'`

This property is read only.

Type of graphics object, returned as `'uicontrol'`.

### Tag — Uicontrol identifier

`''` (default) | `string`

Uicontrol identifier, specified as a string. You can specify a unique `Tag` value to serve as an identifier for the uicontrol. When you need access to the uicontrol elsewhere in your code, you can use the `findobj` function to search for the uicontrol based on the `Tag` value.

Example: `'pushbutton1'`

Data Types: `char`

### UserData — Data to associate with the uicontrol object

empty array (default) | `array`

Data to associate with the uicontrol object, specified as any array. Specifying `UserData` can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: {[1 2 3], 'April 21'}

## Parent/Child

### Parent — Uicontrol parent

figure | uipanel | uibuttongroup | uitab

Uicontrol parent, specified as a figure, uipanel, uibuttongroup, or uitab. You can move a uicontrol to a different figure, uipanel, uibuttongroup, or uitab by setting this property to the handle of the target figure, uipanel, uibuttongroup, or uitab.

### Children — Children of uicontrol

empty array

Children of uicontrol, returned as an empty array. Uicontrol objects have no children. Setting this property has no effect.

### HandleVisibility — Visibility of uicontrol handle

'on' (default) | 'callback' | 'off'

Visibility of Uicontrol handle, specified as 'on', 'callback', or 'off'.

This property controls the visibility of the uicontrol handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The `HandleVisibility` property also controls the visibility of the object's handle in the parent figure's `CurrentObject` property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
'on'	The uicontrol handle is always visible.
'callback'	The uicontrol handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uicontrol at the command-line, but allows callback functions to access it.

HandleVisibility Value	Description
'off'	The uicontrol handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the <code>HandleVisibility</code> to 'off' to temporarily hide the handle during the execution of that function.

Set the graphics root `ShowHiddenHandles` property to 'on' to make all handles visible, regardless of their `HandleVisibility` value. This setting has no effect on their `HandleVisibility` values.

---

**Note:** Do not try to access radio buttons and toggle buttons that are managed by a `uibuttongroup` outside of the button group. Set the `HandleVisibility` of those radio buttons and toggle buttons to 'off' to prevent accidental access.

---

## Type of Control

### Style — Style of uicontrol

'pushbutton' (default) | string

Style of uicontrol, specified as a string from the following table. See “Specifying the Uicontrol Style” on page 1-9081 for more details about each style.

Style Value	Description
'pushbutton'	Button that appears to depress until you release the mouse button.
'togglebutton'	Button that can have two states: up or depressed. The state of the toggle button changes every time you click it.
'checkbox'	Check box that can have two states: checked or unchecked. The state changes when the user clicks and releases the mouse button over it.
'radiobutton'	Button that can have two states: selected or deselected. Radio buttons are intended to be mutually exclusive within a group of related radio buttons.
'edit'	Editable text field.

Style Value	Description
'text'	Static text field.
'slider'	Button that the user pushes along a horizontal or vertical bar. The position of the button indicates a value within a specified range.
'listbox'	List of items from which the user can select one or more items. Unlike pop-up menus, list boxes do not expand when clicked.
'popupmenu'	Isolated menu that expands to display a list of choices when you click it. When it is collapsed, the menu shows the current choice.

**Value — Current value of uicontrol**

number

Current value of uicontrol, specified as a number. The Value property is useful in querying or modifying the status of certain uicontrols:

Style of uicontrol	Description of Value Property
'togglebutton'	<ul style="list-style-type: none"> <li>• <b>Raised:</b> Value property equals the value of the Min property.</li> <li>• <b>Depressed:</b> Value property equals the value of the Max property.</li> </ul>
'checkbox'	<ul style="list-style-type: none"> <li>• <b>Unchecked:</b> Value property changes to the value of the Min property.</li> <li>• <b>Checked:</b> Value property changes to the value of the Max property.</li> </ul>
'radiobutton'	<ul style="list-style-type: none"> <li>• <b>Deselected:</b> Value property changes to the value of the Min property.</li> <li>• <b>Selected:</b> Value property changes to the value of the Max property.</li> </ul>
'slider'	Value property equals the corresponding slider value.
'listbox'	Value property equals an array index corresponding to the selected item in the list box. A value of 1 corresponds to the first item in the list.

Style of uicontrol	Description of Value Property
'popupmenu'	Value property equals an array index corresponding to the selected item in the pop-up menu. A value of 1 corresponds to the first item in the pop-up menu.

**Max — Maximum value of uicontrol**

1 (default) | number

Maximum value of uicontrol, specified as a number. The Max property affects the presentation of certain uicontrols:

Style of uicontrol	Description of Value Property
'togglebutton'	When the toggle button is depressed, the Value property changes to the value of the Max property.
'checkbox'	When the check box is checked, the Value property changes to the value of the Max property.
'radiobutton'	When the radio button is selected, the Value property changes to the value of the Max property.
'edit'	<p>The edit text box accepts multiple lines of input when <math>\text{Max} - \text{Min} &gt; 1</math>. Otherwise, the edit text box accepts a single line of input.</p> <p>The absolute values of Max and Min have no effect on the number of possible lines. As long as the difference is greater than 1, the edit box can contain any number of lines.</p>
'slider'	The Max property value is the maximum slider value, which must be greater than the Min property value.
'listbox'	The Max property value helps determine whether the user can select multiple items in the list box simultaneously. If $\text{Max} - \text{Min} > 1$ , then the user can select multiple items simultaneously. Otherwise, the user cannot select multiple items simultaneously. If you set the Max and Min properties to allow multiple selections, then the Value property value can be a vector of indices.

**Min — Minimum value of uicontrol**

0 (default) | number

Minimum value of uicontrol, specified as a number. The `Min` property affects the presentation of certain uicontrols:

Style of uicontrol	Description of Value Property
'togglebutton'	When the toggle button is raised, the <code>Value</code> property changes to the value of the <code>Min</code> property.
'checkbox'	When the check box is unchecked, the <code>Value</code> property changes to the value of the <code>Min</code> property.
'radiobutton'	When the radio button is deselected, the <code>Value</code> property changes to the value of the <code>Min</code> property.
'edit'	The edit text box accepts multiple lines of input when $\text{Max} - \text{Min} > 1$ . Otherwise, the edit text box accepts a single line of input.  The absolute values of <code>Max</code> and <code>Min</code> have no effect on the number of possible lines. As long as the difference is greater than 1, the edit box can contain any number of lines.
'slider'	The <code>Min</code> property value is the minimum slider value, which must be less than the <code>Max</code> property value.
'listbox'	The <code>Max</code> property value helps determine whether the user can select multiple items in the list box simultaneously. If $\text{Max} - \text{Min} > 1$ , then the user can select multiple items simultaneously. Otherwise, the user cannot select multiple items simultaneously. If you set the <code>Max</code> and <code>Min</code> properties to allow multiple selections, then the <code>Value</code> property value can be a vector of indices.

**SliderStep – Slider step size**

[0.01 0.10] (default) | [minorstep majorstep]

Slider step size, specified as the array, [minorstep majorstep]. This property controls the magnitude of the slider value change when the user clicks the arrow buttons or the slider trough (slider channel):

- `minorstep` is the fraction of the slider range by which the `Value` property increases or decreases when the user clicks one of the arrow buttons.

- `majorstep` is the fraction of the slider range by which the `Value` property increases or decreases when the user clicks the slider trough.

When the value of `majorstep` is greater than 1, the slider fraction is no greater than 100%.

Both `minorstep` and `majorstep` must be greater than  $1e-6$ , and `minorstep` must be less than or equal to `majorstep`.

As `majorstep` increases, the slider thumb indicator grows longer. When `majorstep` is equal to 1, the thumb indicator is half as long as the trough. The thumb indicator is larger for `majorstep` values greater than 1.

## Example

This slider has a range of `Max - Min = 1`. The slider `Value` property changes by 1% when the user presses an arrow button. It changes by 10% when the user clicks in the trough.

```
s = uicontrol('Style','Slider','Min',0,'Max',1,'SliderStep',[0.01 0.10]);
```

### ListboxTop — Index of top item in list box

1 (default) | integer value

Index of top item in list box, specified as an integer value. This property applies only to the listbox style of uicontrol. This property specifies which string appears in the top-most position in a list box that is not large enough to display all list entries. The `ListboxTop` value is an index into the array of strings you specify as the `String` property value. The `ListboxTop` value must be between 1 and the number of strings in the array. Noninteger values are fixed to the next lowest integer.

---

**Note:** The `String` and `Value` properties might override the value of the `ListboxTop` property regardless of the `ListboxTop` value you specify. The `ListboxTop` value can change depending on the value of other uicontrol properties. For example, explicitly setting the `Value` property scrolls the list to that value.

For the most reliable results, query or modify the `ListboxTop` property after MATLAB finishes drawing the uicontrol on the screen.

---

Example: 3

Data Types: `double`

# uigetdir

Open folder selection dialog box

## Syntax

```
folder_name = uigetdir
folder_name = uigetdir(start_path)
folder_name = uigetdir(start_path,dialog_title)
```

## Description

`folder_name = uigetdir` displays a modal dialog box showing the folders that are inside the current working directory. This dialog allows you to navigate to a folder and select it (or type the name of a folder). If the folder you specify exists, `uigetdir` returns the selected path when you click **OK**. If you click **Cancel** (or the window's close box), `uigetdir` returns 0.

`folder_name = uigetdir(start_path)` shows the folders that are inside the folder, `start_path`. If `start_path` is an empty string ( ' ' ) or is not a valid path, the dialog box opens in the current working directory.

`folder_name = uigetdir(start_path,dialog_title)` opens a dialog box with the title, `dialog_title`. The default `dialog_title` is **Select folder to Open**.

---

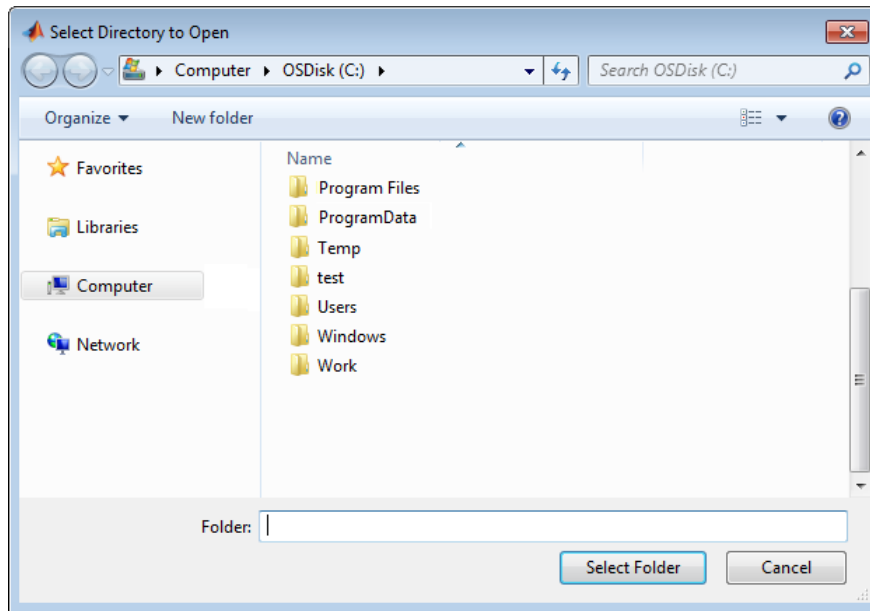

**Note:** The visual characteristics of the dialog box depend on the operating system that is running MATLAB.

---

## Examples

The following statement displays directories on the **C:** drive.

```
dname = uigetdir('C:\');
```

This statement uses `matlabroot` to display the MATLAB root folder in the dialog box:

```
uigetdir(matlabroot, 'MATLAB Root Directory')
```

## See Also

`uigetfile` | `uiputfile`

**Introduced before R2006a**

# uigetfile

Open file selection dialog box

## Syntax

```
filename = uigetfile
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec)
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,DialogTitle)
[FileName,PathName,FilterIndex] =
uigetfile(FilterSpec,DialogTitle,DefaultName)
[FileName,PathName,FilterIndex] =
uigetfile(...,'MultiSelect',selectmode)
```

## Description

`filename = uigetfile` displays a modal dialog box that lists files in the current folder and enables you to select or enter the name of a file. If the file name is valid (and the file exists), `uigetfile` returns the file name as a string when you click **Open**. If you click **Cancel** (or the window's close box), `uigetfile` returns 0.

`[FileName,PathName,FilterIndex] = uigetfile(FilterSpec)` displays only those files with extensions that match `FilterSpec`. On some platforms `uigetfile` also displays in gray the files that do not match `FilterSpec`. `FilterSpec` can be a string or a cell array of strings, and can include the `*` wildcard.

- If `FilterSpec` is a file name, that file name displays, selected in the **File name** field. The extension of the file is the default filter.
- `FilterSpec` can include a path. That path can contain `'.'`, `'..'`, `'\'`, `'/'`, or `'~'`. For example, `'../*.m'` lists all code files in the folder above the current folder.
- If `FilterSpec` is a folder name, `uigetfile` displays the contents of that folder, the **File name** field is empty, and no filter applies. To specify a folder name, make the last character of `FilterSpec` either `'\'` or `'/'`.
- If `FilterSpec` is a cell array of strings, it can include two columns. The first column contains a list of file extensions. The optional second column contains a corresponding

list of descriptions. These descriptions replace standard descriptions in the **Files of type** field. A description cannot be an empty string. The second and third examples illustrate use of a cell array as **FilterSpec**.

If **FilterSpec** is missing or empty, **uigetfile** uses the default list of file types (for example, all MATLAB files).

After you click **Open** and if the file name exists, **uigetfile** returns the name of the file in **FileName** and its path in **PathName**. If you click **Cancel** or the window's close box, the function sets **FileName** and **PathName** to 0.

**FilterIndex** is the index of the filter selected in the dialog box. Indexing starts at 1. If you click **Cancel** or the window's close box, the function sets **FilterIndex** to 0.

`[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,DialogTitle)` displays a dialog box that has the title **DialogTitle**. To use the default file types and specify a dialog title, enter

```
uigetfile(' ',DialogTitle)
```

`[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,DialogTitle,DefaultName)` displays a dialog box in which the file name specified by **DefaultName** appears in the **File name** field. **DefaultName** can also be a path or a path/filename. In this case, **uigetfile** opens the dialog box in the folder specified by the **path**. You can use '.', '..', '\', or '/' in the **DefaultName** argument. To specify a folder name, make the last character of **DefaultName** either '\ ' or '/ '. If the specified path does not exist, **uigetfile** opens the dialog box in the current folder.

`[FileName,PathName,FilterIndex] = uigetfile(...,'MultiSelect',selectmode)` opens the dialog box in *multiselect* mode. Valid values for *selectmode* are 'on' and 'off' (the default, which allows single selection only). If 'MultiSelect' is 'on' and you select more than one file in the dialog box, then **FileName** is a cell array of strings. Each array element contains the name of a selected file. File names in the cell array are sorted in the order your platform uses. If you select multiple files, they must be in the same folder, otherwise MATLAB displays a warning dialog box. Be aware that Microsoft Windows libraries can span multiple folders. **PathName** is a string identifying the folder containing the files.

If you include either of the wildcard characters, '\*' or '?', in a file name, **uigetfile** does not respond to clicking **Open**. The dialog box remains open until you cancel it or

remove the wildcard characters. This restriction applies to all platforms, even to file systems that permit these characters in file names.

---

**Note:** The visual characteristics of the dialog box depend on the operating system that is running MATLAB.

---

## Examples

This dialog box lists all MATLAB code files in the current directory. `uigetfile` returns the name and path to the file you select.

```
[FileName,PathName] = uigetfile('*.*','Select the MATLAB code file');
```

To create a list of file types that appears in the file type drop-down list, separate the file extensions with semicolons, as in the following code. `uigetfile` displays a default description for each known file type.

```
[filename, pathname] = ...
 uigetfile({'*.m'; '*.slx'; '*.mat'; '*.*'}, 'File Selector');
```

If you want to create a list of file types and give them descriptions that are different from the defaults, use a cell array, as in the following code. This example also associates multiple file types with the 'MATLAB Files' and 'Models' descriptions.

```
[filename, pathname] = uigetfile(...
{ '*.m'; '*.fig'; '*.mat'; '*.slx'; '*.mdl', ...
'MATLAB Files (*.m,*.fig,*.mat,*.slx,*.mdl)';
'*.m', 'Code files (*.m)'; ...
'*.fig', 'Figures (*.fig)'; ...
```

```

 '*.mat','MAT-files (*.mat)'; ...
 '*.mdl;*.slx','Models (*.slx, *.mdl)'; ...
 '*,*', 'All Files (*.*)'}, ...
 'Pick a file');

```

The first column of the cell array contains the file extensions, while the second contains your descriptions of the file types. In this example, the first entry of column one contains several extensions, separated by semicolons, which are all associated with the description 'MATLAB Files (\*.m,\*.fig,\*.mat,\*.mdl)'. The code produces the dialog box shown in the following figure.

The following code lets you select a file, and then displays a message in the Command Window that summarizes the result.

```

 [filename, pathname] = uigetfile('*.*', 'Select a MATLAB code file');
 if isequal(filename,0)
 disp('User selected Cancel')
 else
 disp(['User selected ', fullfile(pathname, filename)])

```

end

This code creates a list of file types and gives them descriptions that are different from the defaults. It also enables multiple-file selection. Select multiple files by holding down the **Shift** or **Ctrl** key and clicking on additional file names.

```
[filename, pathname, filterindex] = uigetfile(...
{ '*.mat','MAT-files (*.mat)'; ...
 '*.slx;*.mdl','Models (*.slx, *.mdl)'; ...
 '*.*', 'All Files (*.*)'}, ...
 'Pick a file', ...
 'MultiSelect', 'on');
```

You can use the `DefaultName` argument to specify a start path and a default file name for the dialog box.

```
filename = uigetfile({'*.jpg;*.tif;*.png;*.gif','All Image Files';...
 '*.*','All Files' },'mytitle',...
 'C:\Work\setpos1.png')
```

## Alternatives

Use the `dir` function to return a filtered or unfiltered list of files in your current folder or a folder you specify. `dir` also can return file attributes.

**Introduced before R2006a**

## uigetpref

Conditionally open dialog box according to user preference

### Syntax

```
pref_value = uigetpref(group,pref,title,question,pref_choices)
[pref_value,dlgshown] = uigetpref(...)
[...] = uigetpref(... 'Name',value)
```

### Description

`pref_value = uigetpref(group,pref,title,question,pref_choices)` returns one of the strings in `pref_choices` in either of two ways:

- Displays a multiple-choice dialog box that prompts you to answer a question. The dialog box includes a check box with the label **Do not show this dialog again**.
- Retrieves a previous answer from the preferences data base and returns it without displaying a dialog. No dialog is displayed if you previously selected the check box **Do not show this dialog again**.

`[pref_value,dlgshown] = uigetpref(...)` also returns in `dlgshown` whether or not the dialog displayed.

`[...] = uigetpref(... 'Name',value)` specify optional name-value pairs to control how dialogs display.

### Input Arguments

#### group

String specifying the name of the preference group that preference `pref` belongs to. If the group does not already exist, `uigetpref` creates it.

**Default:** None

**pref**

String specifying the name of the preference that controls whether the dialog displays. If the preference does not already exist, `uigetpref` creates it.

**Default:** None

**title**

String to display in the dialog box title bar

**Default:**

**question**

String or cell array of strings specifying a descriptive paragraph for the dialog to display. Use `question` to define what you are asking the user to decide. Clearly state the alternatives and the consequences of choosing among them. The dialog box that `uigetpref` generates inserts line breaks between rows of the string array, between elements of the cell array of strings, and between `'|'` or newline characters within a string vector.

**Default:** None

**pref\_choices**

String, cell array of strings, or `'|'`-separated strings specifying the labels for the dialog box push buttons. The string on the selected push button is returned.

If the internal preference values are different from the strings displayed on the push buttons, provide a 2-by-n cell array of strings. The first row contains the preference strings, and the second row contains the associated push button strings. When `pref_choices` is not a 2-by-n cell array, MATLAB constructs lowercase versions of the button labels and returns them in `pref_value`. If your code tests returned values, make sure it compares them against the appropriate strings.

**Default:** None

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'CheckboxState'**

State of check box when dialog box opens:

- `false` or `0`: Check box is not initially selected.
- `true` or `1`: Check box is initially selected.

**Default:** `0`

**'CheckboxString'**

String specifying the label for the check box.

**Default:** `'Do not show this dialog again'`

**'HelpString'**

String specifying the label for **Help** button.

**Default:** No **Help** button displays.

**'HelpFcn'**

String or function handle specifying the callback that executes when you click the **Help** button. Also, to have a button to trigger the callback, you must specify the `HelpString` option.

**Default:** `doc('uigetpref')`

**'ExtraOptions'**

String or cell array of strings specifying extra buttons. The additional buttons are not mapped to any preference settings. If you click any of these buttons, the dialog closes and `uigetpref` returns the string in `value`.

**Default:** `{}`

**'DefaultButton'**

String specifying the value that `uigetpref` returns if you close the dialog without clicking a button. This string does not have to correspond to any preference or `ExtraOption`.

**Default:** The first button specified in `pref_choices`

## Output Arguments

### pref\_value

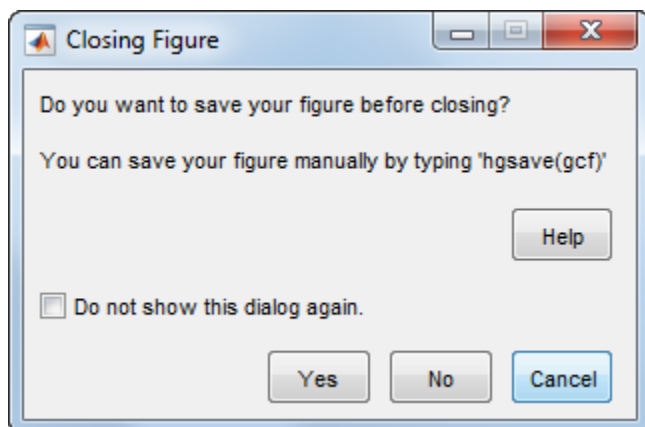

String containing the preference corresponding to the button you press. If you cancel the dialog by clicking its close box, `uigetpref` returns the label of the first button specified in `pref_choices` or the value for `DefaultButton`, if specified. After you select the **Do not show this dialog again** check box, `uigetpref` does not display a dialog box when you call it with the same `group` and `pref` arguments. Instead, it returns the last choice you made (your registered preference) in `pref_value` immediately.

### dlgshown

Logical value that indicates whether or not the dialog displayed. The value is 1 when the dialog displays. The value is 0 when the dialog does not display. If the user selects the **Do not show this dialog again** check box, then the dialog does not display the next time your code calls the `uigetpref` function with the same `group` and `pref` arguments.

## Examples

Create a preference dialog for the 'savefigurebeforeclosing' preference in the 'mygraphics' group of preferences.

This function, `save_figure_maybe`, displays a dialog that asks the user to save current figure. The function responds appropriately, depending on the value returned by `uigetpref`.

```

function save_figure_perhaps
% Closes figure conditionally, asking whether to save it first.
% User can suppress the dialog from UIGETPREF permanently by selecting
% "Do not show this dialog again".

fig = gcf;
[selectedButton dlgshown] = uigetpref(...
 'mygraphics',... % Group
 'savefigurebeforeclosing',... % Preference
 'Closing Figure',... % Window title
 {'Do you want to save your figure before closing?'
 ''
 'You can save your figure manually by typing ''hgsave(gcf)''},...
 {'always','never';'Yes','No'},... % Values and button strings
 'ExtraOptions','Cancel',... % Additional button
 'DefaultButton','Cancel',... % Default choice
 'HelpString','Help',... % String for Help button
 'HelpFcn','doc(''closereq'');'); % Callback for Help button
switch selectedButton
case 'always' % Open a Save dialog (without testing if saved before)
 [fileName,pathName,filterIndex] = uiputfile('fig', ...
 'Save current figure', ...
 'untitled.fig');
 if filterIndex == 0 % User cancelled save or named no file
 delete(fig);
 else % Use filename returned from UIPUTFILE
 saveas(fig,[pathName fileName])
 delete(fig);
 end
case 'never' % Close the figure without saving it
 delete(fig);
case 'cancel' % Do not close the figure
 return
end
end

```

To run this example, copy and paste the code into a new program file. Name the file `save_figure_perhaps.m` and save it on your search path. To use the function as a `CloseRequestFcn` callback, create a figure as follows:

```
figure('CloseRequestFcn','save_figure_perhaps');
```

Clicking the figure's close box displays the dialog box until you select **Do not show this dialog again**.

## More About

### Preferences

Preferences provide the ability to specify how applications behave and how users interact with them. For example, you can set a preference for which products display their

documentation in the Help browser, or which messages the Code Analyzer displays. In MathWorks software products, preferences persist across sessions and are stored in a preference data base, the location of which is system-dependent. Use the **Preferences** option on the **File** menu to access all built-in preferences.

`uigetpref` uses the same preference data base as `addpref`, `getpref`, `ispref`, `rmpref`, and `setpref`. However, `uigetpref` registers the preferences it sets as a separate list, so that it and `uisetpref` can manage those preferences.

To modify preferences registered with `uigetpref`, you can use `setpref` and `uisetpref` to explicitly change preference values to 'ask'. If you specify a preference that does not already exist in the preference data base, `uigetpref` creates it.

### Tips

- You must supply all input arguments up to and including `pref_choices`.
- `uigetpref` creates specified groups and preferences, if they do not currently exist. To delete a preference group you no longer need, use `rmpref`.
- The string returned in `pref_value` is a preference name (as specified in `pref`), not its button label (as specified in `pref_choices`).
- After you select the check box **Do not show this dialog again** and close the dialog box, the dialog box does not display again for the same preference. To reenab dialog boxes that are being suppressed by preferences, use the command:

```
uisetpref('clearall')
```

Executing `uisetpref` with this command re-enables *all* preference dialogs you have defined with `uigetpref`, not just the most recent one.

## uiimport

Import data interactively

### Syntax

```
uiimport
uiimport(filename)
uiimport('-file')
uiimport('-pastespecial')
S = uiimport(___)
```

### Description

`uiimport` opens a dialog to interactively load data from a file or the clipboard. MATLAB displays a preview of the data in the file.

`uiimport(filename)` opens the file specified in `filename`.

`uiimport('-file')` presents the file selection dialog first.

`uiimport('-pastespecial')` presents the clipboard contents first.

`S = uiimport( ___ )` stores the resulting variables as fields in the struct `S`.

### More About

- “Supported File Formats for Import and Export”

**Introduced before R2006a**

# uimenu

Create menus and menu items on figure windows

## Syntax

```
m = uimenu
m = uimenu(Name,Value,...)
m = uimenu(parent)
m = uimenu(parent,Name,Value,...)
```

## Description

`m = uimenu` creates a `uimenu` in an existing figure's menu bar and returns the `uimenu` object, `m`. If there is no figure available, then MATLAB creates a new figure to serve as the parent.

`m = uimenu(Name,Value,...)` creates a `uimenu` and specifies one or more `uimenu` property names and corresponding values. Use this syntax to override the default `uimenu` properties.

`m = uimenu(parent)` creates a `uimenu` and designates a specific parent object. The `parent` argument can be a figure, `uicontextmenu`, or another `uimenu` object. Setting the `parent` to a `uicontextmenu` or another `uimenu` makes `m` a submenu of the parent menu.

`m = uimenu(parent,Name,Value,...)` creates a `uimenu` with a specific parent and one or more `uimenu` properties.

## Examples

This example creates a menu labeled **Workspace** with menu options for creating a new figure window, saving workspace variables, and exiting MATLAB. In addition, it defines an accelerator key for the Quit option.

```
f = uimenu('Label','Workspace');
 uimenu(f,'Label','New Figure','Callback','disp('figure'));
```

```

uimenu(f,'Label','Save','Callback','disp('save')');
uimenu(f,'Label','Quit','Callback','disp('exit')',...
 'Separator','on','Accelerator','Q');

```

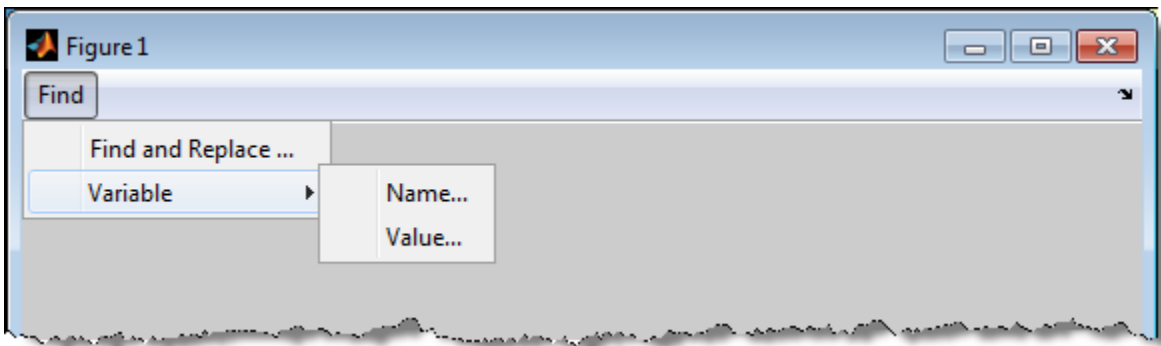

This example creates a new figure with a menu bar that excludes the built-in menus. It creates a **F**ind menu with options **F**ind & **R**eplace, and **V**ariable. For the Variable option, it creates a submenu with options of **N**ame and **V**alue.

```

f = figure('MenuBar','None');
mh = uimenu(f,'Label','Find');
frh = uimenu(mh,'Label','Find and Replace ...',...
 'Callback','disp('goto')');
frh = uimenu(mh,'Label','Variable');
uimenu(frh,'Label','Name...', ...
 'Callback','disp('variable')');

uimenu(frh,'Label','Value...', ...
 'Callback','disp('value')');

```

This example creates a context menu, **Font**, on a figure with menu options **Helvetica** and **Monospace**. When you run the code and then right-click anywhere within the figure window, the context menu displays.

```
f = figure;
% Create the UICONTEXTMENU
cmenu = uicontextmenu;

% Create the parent menu
fontmenu = uimenu(cmenu,'label','Font');

% Create the submenus
font1 = uimenu(fontmenu,'label','Helvetica',...
 'Callback','disp(''HelvFont'')');
font2 = uimenu(fontmenu,'label',...
 'Monospace','Callback','disp(''MonoFont'')');
f.UIContextMenu = cmenu;
```

## More About

### Tips

If you want the uimenu to respond when the user activates the uimenu, set its Callback property to be a function handle (or a string of MATLAB commands). Uimenu's respond to different actions, depending on their location:

- Top level (in the menu bar) — Responds to a single mouse click

- Submenu that contains other submenus — Responds to hovering the mouse
- Terminating submenu — Responds to a single mouse click

The value of the figure's `MenuBar` property determines the content in the menu bar. When the `MenuBar` property is set to `'figure'`, a default set of menus appear alongside the `uimenu`s defined in your code. When the `MenuBar` property is set to `'none'`, the default menus do not appear, but the `uimenu`s you create appear in the menu bar.

`Uimenu`s do not appear in figures whose `WindowStyle` property is set to `'Modal'`. If a figure containing `uimenu` children is changed to `'Modal'`, the `uimenu` children still exist in the `Children` property of the figure. However, the `uimenu`s do not display while `WindowStyle` is set to `'Modal'`.

- “Create Menus for Programmatic UIs”
- “Create Menus for GUIDE UIs”
- “Access Property Values”

`figure` | `uicontextmenu` | `Uimenu` Properties

**Introduced before R2006a**

# Uimenu Properties

Control appearance and behavior of menu

A `uimenu` is a menu in a figure's menu bar. The `uimenu` function adds a menu to a figure or adds a submenu to an existing menu and sets any required properties. By changing `uimenu` property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
m = uimenu;
color = m.ForegroundColor;
m.ForegroundColor = [0 0 1];
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Appearance

### Visible — Uimenu visibility

'on' (default) | 'off'

Uimenu visibility, specified as 'on' or 'off'. When the `Visible` property is set to 'off', the `uimenu` is not visible, but you can query and set its properties.

### Label — Menu label

string

Menu label, specified as a string. This property specifies the text that appears on the menu (or menu item).

You can specify a mnemonic for the label using the ampersand (&) character. The character that follows the ampersand appears underlined in the menu. The user can select the menu item by pressing the **Alt** key followed by the underlined character.

In order for the mnemonic system to work, you must specify a mnemonic for all menu items you define in the UI.

If you want to display an ampersand in the menu label, specify two consecutive ampersands in the string.

Here are some examples:

String	Resulting Menu Label
'&Open Selection'	<b>Open Selection</b> (pressing <b>Alt</b> underlines O)
'O&open Selection'	<b>Open Selection</b> (pressing <b>Alt</b> underlines p)
'&Save && Go'	<b>Save &amp; Go</b> (pressing <b>Alt</b> underlines S)
'Save& Go'	<b>Save&amp; Go</b> (space cannot be a mnemonic character)

---

**Note:** Avoid using these case-sensitive reserved words: “default”, “remove”, and “factory”. If you must use a reserved word, then escape that word by preceding it with a back-slash character. For instance, '`\default`' escapes “default”.

---

Example: 'Open Selection'

Example: '&Open Selection'

Data Types: char

#### **Checked — Menu check indicator**

'off' (default) | 'on'

Menu check indicator, specified as 'off' or 'on'. Setting this property to 'on' places a check mark next to the corresponding menu item. Setting it to 'off' removes the check mark. You can use this feature to show the state of menu items that enable or disable functionality in your application.

#### **Separator — Separator line mode**

'off' (default) | 'on'

Separator line mode, specified as 'off' or 'on'. Setting this property to 'on' draws a dividing line above the uimenu.

#### **ForegroundColor — Uimenu text color**

[0 0 0] (default) | RGB triplet | short name | long name

Uimenu text color, specified as an RGB triplet, short name, or long name from the table below.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0 0 1]

Example: 'b'

Example: 'blue'

Data Types: double | char

## Location and Size

### Position — Relative menu position

scalar integer value

Relative menu position, specified as a scalar integer value. The value of **Position** property indicates placement on the menu bar or within a menu. Top-level menus appear from left to right on the menu bar according to the value of their **Position** property, with 1 representing the left-most position. The individual items within a given menu appear from top to bottom according to the value of their **Position** property, with 1 representing the top-most position.

Data Types: double

## Interactive Control

### Callback — Callback function that executes when user selects the uimenu

' ' (default) | function handle | cell array | string

Callback function that executes when user selects the uimenu, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

---

**Note:** Do not use a uimenu callback to dynamically change menu items. Deleting, adding, and replacing menu items in a callback can result in a blank menu on some platforms. You can hide, show, and disable menu items in a callback to achieve the same effect. To fully repopulate menu items, delete and create them outside the callback.

---

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

Example: @myfun

Example: {@myfun, x}

Data Types: `function_handle` | `cell`

### **Enable — Operational state of uimenu**

'on' (default) | 'off'

Operational state of uimenu, specified as 'on' or 'off'. This property controls whether the user can select a menu item. When the value is 'off', the menu label appears dimmed, indicating that the user cannot select it.

### **Accelerator — Keyboard equivalent**

character

Keyboard equivalent, specified as a character. This property defines a keyboard equivalent character for selecting the menu item. Specifying an `Accelerator` value allows users to select the menu item by pressing a character and another key, instead of selecting the menu item with the mouse. The key sequence is platform specific:

- For Windows, the sequence is **Ctrl+Accelerator**. Windows reserves these keys for default menu items: **a**, **c**, **v**, and **x**

- For Macintosh systems, the sequence is **Command+Accelerator**. Apple reserves these keys for default menu items: **a**, **c**, **v**, and **x**.
- For Linux systems, the sequence is **Ctrl+Accelerator**. Linux systems reserve these keys for default menu items: **o**, **p**, **s**, and **w**. Like the other platforms, many Linux applications also use **a**, **c**, **v**, and **x**.

Accelerated menu items do not have to be displayed for the accelerator key to work. However, some restrictions apply:

- You can define the **Accelerator** property for only menu items that do not have submenus.
- Accelerators work only for menu items that execute a callback function.
- The figure must be in focus when entering the accelerator key sequence.

To remove an **Accelerator** value, set the **Accelerator** property to an empty string, `''`.

Example: `'f'`

## Callback Execution Control

### **Interruptible** — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The **Interruptible** property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The **Interruptible** property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the **BusyAction** property of the object owning the interrupting callback determines if it is discarded or put into a queue.

If a uimenu callback is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- 'on' — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
- If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.

- If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

---

**Note:** Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a `DeleteFcn`, `CloseRequestFcn`, or `SizeChangedFcn` callback, then the interruption occurs regardless of the `Interruptible` property value.
  - If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the `Interruptible` property value.
  - MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.
- 

See “Interrupt Callback Execution” for an example that shows how the `Interruptible` and `BusyAction` properties affect the behavior of a program.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' (default) or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- 'cancel' — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The `Interruptible` property of the object whose callback is running determines if interruption is allowed. If `Interruptible` is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The `BusyAction` property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the `BusyAction` and `Interruptible` properties affect the behavior of a program.

### **HitTest — Ability to become current object**

'on' (default) | 'off'

This property has no effect on the `uimenu`.

## **Creation and Deletion Control**

### **BeingDeleted — Deletion status of `uimenu`**

'off' (default) | 'on'

This property is read only.

Deletion status of `uimenu`, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the `uimenu` begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the `uimenu` no longer exists.

Check the value of the `BeingDeleted` property to verify that the `uimenu` is not about to be deleted before querying or modifying it.

### **CreateFcn — `Uimenu` creation function**

function handle | cell array | string

`Uimenu` creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.

- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This property specifies a callback function to execute when MATLAB creates the uimenu. MATLAB initializes all uimenu property values before executing the `CreateFcn` callback. If you do not specify the `CreateFcn` property, then MATLAB executes a default creation function.

Use the `gcb0` function in your `CreateFcn` code to get the handle to the uimenu that is being created.

Setting the `CreateFcn` property on an existing uimenu has no effect.

---

**Note:** Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. Copying the uimenu object causes the `CreateFcn` callback to execute repeatedly.

---

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

### **DeleteFcn — Uimenu deletion function**

`function handle` | `cell array` | `string`

Uimenu deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `DeleteFcn` property specifies a callback function to execute when MATLAB deletes the uimenu (for example, when the end user deletes the figure). MATLAB executes the

`DeleteFcn` callback before destroying the properties of the `uimenu`. If you do not specify the `DeleteFcn` property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your `DeleteFcn` code to get the handle to the `uimenu` that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

## Identifiers

### Type — Type of graphics object

`'uimenu'`

This property is read only.

Type of graphics object, returned as `'uimenu'`.

### Tag — Uimenu identifier

`''` (default) | `string`

Uimenu identifier, specified as a string. You can specify a unique `Tag` value to serve as an identifier for the `uimenu`. When you need access to the `uimenu` elsewhere in your code, you can use the `findobj` function to search for the `uimenu` based on the `Tag` value.

Example: `'menu1'`

Data Types: `char`

### UserData — Data to associate with the uimenu object

empty array (default) | `array`

Data to associate with the `uimenu` object, specified as any array. Specifying `UserData` can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: {[1 2 3], 'April 21'}

## Parent/Child

### Parent — Uimenu parent

figure | uicontextmenu | uimenu

This property is read only.

Uimenu parent, specified as a figure, uicontextmenu, or another uimenu object. You can move a uimenu to a different figure, or move it under a different uimenu by setting this property to the target figure, uicontextmenu, or uimenu object.

### Children — Children of uimenu

empty GraphicsPlaceholder array (default) | 1-D array of uimenu objects

Children of uimenu, returned as an empty GraphicsPlaceholder or a 1-D array of uimenu objects. The children of uimenus are other uimenus that function as submenus.

You cannot add or remove children using the Children property of the uimenu. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the order of the displayed menu items.

To add a child to this list, set the Parent property of the child component to be the uimenu object.

Objects with the HandleVisibility property set to 'off' do not list in the Children property. For more information, see the HandleVisibility property description.

### HandleVisibility — Visibility of Uimenu handle

'on' (default) | 'callback' | 'off'

Visibility of Uimenu handle, specified as 'on', 'callback', or 'off'.

This property controls the visibility of the uimenu handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The HandleVisibility property also controls the visibility of the object's handle in the parent figure's CurrentObject property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

<b>HandleVisibility Value</b>	<b>Description</b>
'on'	The uimenu handle is always visible.
'callback'	The uimenu handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uimenu at the command-line, but allows callback functions to access it.
'off'	The uimenu handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the <code>HandleVisibility</code> to 'off' to temporarily hide the handle during the execution of that function.

Set the graphics root `ShowHiddenHandles` property to 'on' to make all handles visible, regardless of their `HandleVisibility` value. This setting has no effect on their `HandleVisibility` values.

## More About

- “Default Property Values”

## uint8

Convert to 8-bit unsigned integer

### Syntax

```
intArray = uint8(array)
```

### Description

`intArray = uint8(array)` converts the elements of an array into unsigned 8-bit (1-byte) integers of class `uint8`.

### Input Arguments

#### **array**

Array of any numeric class, such as `single` or `double`. If `array` is already of class `uint8`, the `uint8` function has no effect.

### Output Arguments

#### **intArray**

Array of class `uint8`. Values range from 0 to  $2^8 - 1$ .

The `uint8` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
uint8(2^8) % 2^8 = 256
```

returns

```
ans =
 255
```

## Examples

Convert a double array to uint8:

```
mydata = uint8(magic(10));
```

## Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = uint8(zeros(100)); % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'uint8'); % Preferred
```

## See Also

`double` | `single` | `uint16` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64` | `intmax` | `intmin`

**Introduced before R2006a**

## uint16

Convert to 16-bit unsigned integer

### Syntax

```
intArray = uint16(array)
```

### Description

`intArray = uint16(array)` converts the elements of an array into unsigned 16-bit (2-byte) integers of class `uint16`.

### Input Arguments

#### **array**

Array of any numeric class, such as `single` or `double`. If `array` is already of class `uint16`, the `uint16` function has no effect.

### Output Arguments

#### **intArray**

Array of class `uint16`. Values range from 0 to  $2^{16} - 1$ .

The `uint16` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
uint16(2^16) % 2^16 = 65536
```

returns

```
ans =
 65535
```

## Examples

Convert a double array to uint16:

```
mydata = uint16(magic(100));
```

## Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = uint16(zeros(100)); % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'uint16'); % Preferred
```

## See Also

`double` | `single` | `uint8` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64` | `intmax` | `intmin`

**Introduced before R2006a**

## uint32

Convert to 32-bit unsigned integer

### Syntax

```
intArray = uint32(array)
```

### Description

`intArray = uint32(array)` converts the elements of an array into unsigned 32-bit (4-byte) integers of class `uint32`.

### Input Arguments

#### **array**

Array of any numeric class, such as `single` or `double`. If `array` is already of class `uint32`, the `uint32` function has no effect.

### Output Arguments

#### **intArray**

Array of class `uint32`. Values range from 0 to  $2^{32} - 1$ .

The `uint32` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
uint32(2^32) % 2^32 = 4294967296
```

returns

```
ans =
 4294967295
```

## Examples

Convert a double array to uint32:

```
mydata = uint32(magic(1000));
```

## Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = uint32(zeros(100)); % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'uint32'); % Preferred
```

## See Also

`double` | `single` | `uint8` | `uint16` | `uint64` | `int8` | `int16` | `int32` | `int64` | `intmax` | `intmin`

**Introduced before R2006a**

# uint64

Convert to 64-bit unsigned integer

## Syntax

```
intArray = uint64(array)
```

## Description

`intArray = uint64(array)` converts the elements of an array into unsigned 64-bit (8-byte) integers of class `uint64`.

## Input Arguments

### array

Array of any numeric class, such as `single` or `double`. If `array` is already of class `uint64`, the `uint64` function has no effect.

## Output Arguments

### intArray

Array of class `uint64`. Values range from 0 to  $2^{64} - 1$ .

The `uint64` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
uint64(2^64) % 2^64 = 18446744073709551616
```

returns

```
ans =
 18446744073709551615
```

## Examples

Convert a literal value to `uint64`:

```
x = uint64(9007199254740993);
```

## Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = uint64(zeros(100)); % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'uint64'); % Preferred
```

## More About

### Tips

Double-precision floating-point numbers have only 52 bits in the mantissa. Therefore, `double` values cannot represent all integers greater than  $2^{53}$  correctly. Before performing arithmetic operations on values larger than  $2^{53}$  in magnitude, convert the values to 64-bit integers. For example,

```
x = uint64(2^53+1); % Floating-point arithmetic, loses precision
```

is not as accurate as the 64-bit integer arithmetic operation:

```
x = uint64(2^53) + 1; % Preferred
```

# uiopen

Open dialog box for selecting file to load into workspace

## Syntax

```
uiopen
uiopen(type)
uiopen(filename)
uiopen(filename, TF)
```

## Description

uiopen displays the dialog box with the file filter set to all MATLAB files (with file extensions \*.m, \*.mat, \*.fig, \*.mdl, and \*.slx).

uiopen(type) sets the file filter according to the type.

uiopen(filename) displays filename as the default value for **File name** in the dialog box and lists only files having the same extension.

uiopen(filename, TF) directly opens file filename without displaying a dialog box if TF is true, and displays the dialog box if TF is false.

## Input Arguments

### type

String that specifies the kind of file to show in the dialog box (the file filter). Acceptable values for type are the following.

Type string	Files Displayed
matlab	All MATLAB files (with file extensions *.m, *.mat, *.fig, *.mdl, and *.slx.)

Type string	Files Displayed
load	All MAT-files (*.mat)
figure	All figure files (*.fig)
simulink	All Simulink model files (*.mdl and *.slx)
editor	All MATLAB files except for .mat, .fig, and .slx files.

**Default:****filename**

A string, including the file extension, naming a file to open. The filename can be a wildcard character plus extension. For example, \*.txt displays a list of all files with the file extension .txt.

**TF**

A MATLAB expression that evaluates to true or false. If true, filename opens directly, without displaying the dialog.

## Examples

Filter to display only FIG-files by setting the **Files of type** field to **Figures (\*.fig)**:

```
uiopen('figure')
```

## Alternatives

In MATLAB code or in a command:

- To open a file appropriately based on its file extension, use the `open` function.
- To open a file in the Editor, use the `edit` function.
- To open a MAT-file and load its contents into the workspace, use the `load` function.
- To open a FIG-file, use the `openfig` function.
- To open a file in an application in Microsoft Windows, use the `winopen` function.

## More About

### Modal Dialog

A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

## Tips

When you select a file and click **open**, `uiopen` does the following:

- Gets the file using `uigetfile`.
- Opens the file using the `open` command.
  - Files with a file extension of `.m` open in the Editor.
  - Variables stored in files with a file extension of `.mat` appear in the caller's workspace.
  - Files with a file extension of `.fig` open as figure windows.
  - Files with a file extension of `.mdl` or `.slx` open as models in Simulink.
- `uiopen('load')` is the only the form of `uiopen` that you can compile into a standalone application. You can create a file selection dialog box that you can compile using `uigetfile`.
- The `uiopen` dialog box is modal. A modal dialog box prevents you from interacting with other windows until you respond to the modal one.
- `uiopen` displays the same dialog box that opens when you use the MATLAB desktop toolbar to open a file. (On the **Home** tab, in the **File** section, click **Open** )

Introduced before R2006a

# uipanel

Create panel container object

## Syntax

```
p = uipanel
p = uipanel(Name,Value,...)
p = uipanel(parent)
p = uipanel(parent,Name,Value,...)
```

## Description

`p = uipanel` creates a uipanel in an existing figure and returns the uipanel object, `p`. If there is no figure available, then MATLAB creates a new figure to serve as the parent.

`p = uipanel(Name,Value,...)` creates a uipanel and specifies one or more uipanel property names and corresponding values. Use this syntax to override the default uipanel properties.

`p = uipanel(parent)` creates a uipanel and designates a specific parent object. The `parent` argument can be a figure, `uitab`, `uibbuttongroup` or another uipanel object.

`p = uipanel(parent,Name,Value,...)` creates a uipanel with a specific parent and one or more uipanel properties.

Uipanel is a container that groups UI components together. Uipanel can contain `uicontrols`, `axes`, `uitable`, `uitab`, `uibbuttongroups`, and other uipanel. Uipanel cannot contain ActiveX controls.

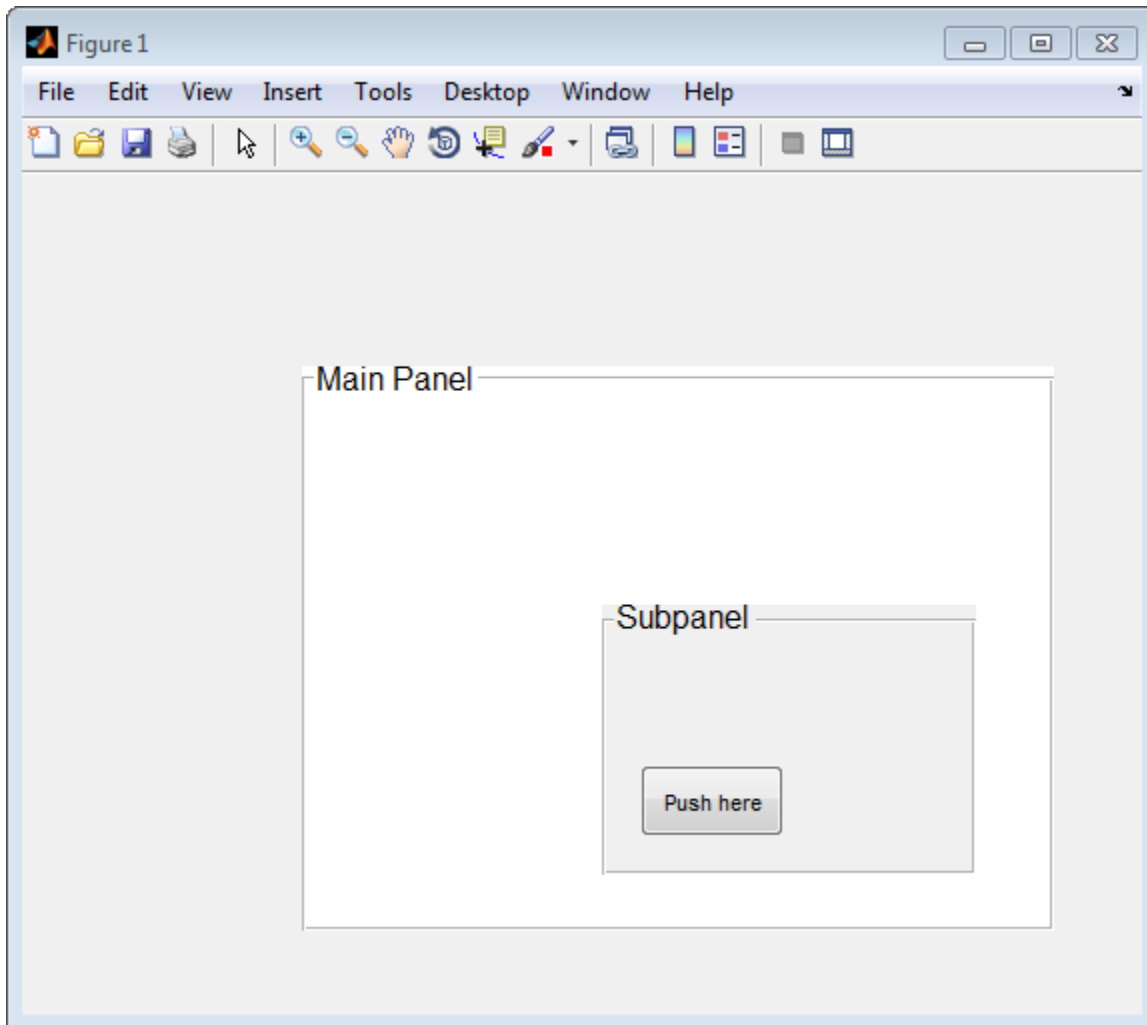

## Examples

### Create uipanel With Children

Create a figure containing two panels and a push button. The panels use the default `Units` property value, `'normalized'`. The default units for the `uicontrol` is `'pixels'`.

```
h = figure;
```

```
hp = uipanel('Title', 'Main Panel', 'FontSize', 12, ...
 'BackgroundColor', 'white', ...
 'Position', [.25 .1 .67 .67]);
hsp = uipanel('Parent', hp, 'Title', 'Subpanel', 'FontSize', 12, ...
 'Position', [.4 .1 .5 .5]);
hbsp = uicontrol('Parent', hsp, 'String', 'Push here', ...
 'Position', [18 18 72 36]);
```

### Uipanel That Always Matches Figure Window Width

Create a uipanel that always matches the width of the figure, but maintains a constant height. Use the `SizeChangedFcn` callback to keep the panel's width equal to the width of the figure's drawable area.

To see how this code works, copy and paste this code into the Editor and run it.

```
function myui
f = figure('Visible','off','SizeChangedFcn',@match_width);
u = uipanel('Units','Pixels','Tag','StatusBar',...
 'BackgroundColor','blue');
f.Visible= 'on';
 function match_width(hObject,eventdata)
 fig = gcbo;
 u = findobj(fig,'Tag','StatusBar');

 % change panel units to pixels and adjust position
 panelunits = u.Units;
 u.Units = 'pixels';
 figpos = fig.Position;
 upos = [1, figpos(4) - 20, figpos(3), 20];
 u.Position = upos;

 % restore original panel units
 u.Units = panelunits;

 end
end
```

## More About

### Tips

If you set the `Visible` property of a `uipanel` object to `'off'`, then any child objects it contains (buttons, button groups, axes, etc.) become invisible along with the parent `uipanel`. However, the `Visible` *property value* of each child object remains unaffected.

- “Access Property Values”

**Introduced before R2006a**

# Uipanel Properties

Control appearance and behavior of panel

Uipanel is a container for grouping together graphics objects or UI components. The `uipanel` function creates a panel in a figure and sets any required properties before displaying it. By changing the uipanel property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
p = uipanel;
pos = p.Position;
p.Position = [.1 .1 .7 .8];
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Appearance

### Visible — Uipanel visibility

'on' (default) | 'off'

Uipanel visibility, specified as 'on' or 'off'. The **Visible** property determines whether the uipanel displays on the screen. If the **Visible** property of a uipanel is set to 'off', the entire uipanel is invisible, but you can still specify and access its properties.

Changing the size of an invisible uipanel triggers the `SizeChangedFcn` callback when the uipanel becomes visible.

---

**Note** Changing the **Visible** property of a uipanel does *not* change the **Visible** property of its child components even though hiding the uipanel prevents its children from displaying.

---

### BackgroundColor — Uipanel background color

[.94 .94 .94] (default) | RGB triplet | short name | long name

Uipanel background color, specified as an RGB triplet, short name, or long name. The color you specify fills the area bounded by the uipanel.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

---

**Note:** Some operating systems override the `BackgroundColor` value.

---

Data Types: double | char

### **ForegroundColor** — Uipanel title color

[0 0 0] (default) | RGB triplet | short name | long name

Uipanel title color, specified as an RGB triplet, short name, or long name.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]

Long Name	Short Name	RGB Triplet
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0 0 1]

Example: 'b'

Example: 'blue'

### **BorderType** — Border of the uipanel

'etchedin' (default) | 'etchedout' | 'beveledin' | 'beveledout' | 'line' | 'none'

Border of the uipanel area, specified as 'etchedin', 'none', 'etchedout', 'beveledin', 'beveledout', or 'line'.

- For a 3-D look, use etched or beveled borders.

Use the `HighlightColor` and `ShadowColor` properties to specify the color of 3-D borders.

- For a 2-D look, use a line border.

Use the `HighlightColor` property to specify the line border color.

### **BorderWidth** — Width of uipanel border

1 (default) | positive integer value

Width of the uipanel border, specified as a positive integer value. The unit of measurement is pixels. Etched and beveled borders wider than three pixels might not appear correctly at the corners.

### **HighlightColor** — Uipanel border highlight color

RGB triplet | short name | long name

Uipanel border highlight color, specified as an RGB triplet, short name, or long name.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

**ShadowColor** — Uipanel border shadow color

RGB triplet | short name | long name

Uipanel border shadow color, specified as an RGB triplet, short name, or long name.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

**Clipping** — Clipping of child components to uipanel

'on' (default) | 'off'

---

**Note:** The behavior of the `Clipping` property has changed. It no longer has any effect on uipanel. Child objects are now clipped to the uipanel boundary regardless of the value of this property. This property might be removed in a future release.

---

## Location and Size

### Position — Location and size of uipanel relative to parent

[left bottom width height]

Location and size of the uipanel relative to the parent, specified as the vector, [left bottom width height]. This table describes each element in the vector.

Element	Description
left	Distance from the inner left edge of the parent container to the outer left edge of the uipanel
bottom	Distance from the inner bottom edge of the parent container to the outer bottom edge of the uipanel
width	Distance between the right and left outer edges of the uipanel
height	Distance between the top and bottom outer edges of the uipanel

All measurements are in units specified by the `Units` property.

---

**Note:** If the parent of the uipanel is a figure, then the `Position` values are relative to the figure's *drawable area*. The drawable area of a figure is the area inside the window borders, excluding the menu bar and tool bar.

---

## Example: Modify One Value in the Position Vector

You can combine dot notation and array indexing when you want to change one value in the `Position` vector. For example, this code changes the width of the uipanel to 0.5:

```
p = uipanel;
```

```
p.Position(3) = 0.5;
p.Position

ans =

 0 0 0.5000 1.0000
```

Data Types: double

**Units – Units of measurement**

'normalized' (default) | 'pixels' | 'inches' | 'centimeters' | 'points' | 'characters'

Units of measurement, specified one of the values from this table.

Units Value	Description
'normalized'	These units are normalized with respect to the parent container. The lower-left corner of the container maps to (0,0) and the upper-right corner maps to (1,1).
'pixels' (default)	<p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p>
'inches'	Inches.
'centimeters'	Centimeters.
'points'	Points. One point equals 1/72nd of an inch.
'characters'	<p>These units are based on the default system font character size.</p> <ul style="list-style-type: none"> <li>• Character width = width of the letter x.</li> </ul>

Units Value	Description
	<ul style="list-style-type: none"> <li>Character height = distance between the baselines of two lines of text.</li> </ul>

MATLAB measures all units from the lower left corner of the parent object.

If you change the value of the **Units** property, it is good practice to return it to its default value after completing your computation to avoid affecting other functions that assume the **Units** property is set to the default value.

The order in which you specify the **Units** and **Position** properties has these effects:

- If you specify the **Units** property before the **Position** property, then MATLAB sets **Position** using the units you specified.
- If you specify the **Units** property after the **Position** property, MATLAB sets the position using the default **Units**. Then, MATLAB converts the **Position** values to the equivalent values in the units you specified.

### **SizeChangedFcn** — Uipanel resize callback function

' ' (default) | function handle | cell array | string

Uipanel resize callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

Define this callback function to control the UI layout when the size of the uipanel changes.

The **SizeChangedFcn** callback executes under these circumstances:

- The uipanel becomes visible for the first time.
- The uipanel is visible while its drawable area changes. The drawable area is the area inside the outer bounds of the uipanel.
- The uipanel becomes visible for the first time after its drawable area changes. This situation occurs when the drawable area changes while the uipanel is invisible, and then it becomes visible later.

These are some of the important characteristics of the `SizeChangedFcn` callback and some recommended best practices:

- Consider delaying the display of the figure until after all the variables that the uipanel's `SizeChangedFcn` uses are defined. This practice can prevent the uipanel's `SizeChangedFcn` callback from returning an error. To delay the display of the figure, set its `Visible` property to `'off'`. Then, set the `Visible` property to `'on'` after you define the variables that your `SizeChangedFcn` callback uses.
- Use the `gcbo` function in your `SizeChangedFcn` code to get the uipanel object that the user is resizing. See the description of the figure `SizeChangedFcn` for an example that uses `gcbo`.
- All visible Uipanel objects that are specified in normalized units resize before the parent figure does. All visible, nested uipanel objects resize from inside-out.

---

**Tip** As an easy alternative to specifying a `SizeChangedFcn` callback, you can set the `Units` property of all the objects you put inside the uipanel to `'normalized'`. Doing so makes those components scale proportionally with the uipanel.

---

See “Managing the Layout in Resizable UIs” for more information on controlling the resize behavior of programmatic UIs.

See [Resize Behavior](#) for more information on the resize behavior of GUIDE UIs.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

## **ResizeFcn — Uipanel resize callback function**

`'` (default) | function handle | cell array | string

Callback function that executes when the uipanel size changes, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

---

**Note:** Use of the `ResizeFcn` property is not recommended. It might be removed in a future release. Use `SizeChangedFcn` instead.

---

Data Types: `function_handle` | `cell` | `char`

## Font Style

### FontName — Font for displaying uipanel title

string

Font for displaying the uipanel title, specified as a string. To display and print properly, the font name must refer to a font that the user's system supports. The default font is system dependent.

To use a fixed-width font, set the `FontName` property to the string, `'FixedWidth'`. This setting instructs MATLAB to use the value of the root `FixedWidthFontName` property, which you can set in the `startup.m` file.

See “Startup Options in MATLAB Startup File” for more information about the `startup.m` file.

Example: `'Arial'`

### FontSize — Font size for uipanel title

positive number

Font size for the uipanel title, specified as a positive number. The `FontUnits` property specifies the units. The default size is system-dependent.

Example: 12

Example: 12.5

Data Types: `double`

### FontUnits — Units of font size for uipanel title

`'points'` (default) | `'normalized'` | `'inches'` | `'centimeters'` | `'pixels'`

Units of font size for the uipanel title, specified as one of the values from this table.

Units Value	Description
<code>'points'</code>	Points. One point is 1/72nd of an inch.

Units Value	Description
'normalized'	Normalized values for specifying the font size as a fraction of the uipanel height. When you resize the uipanel, MATLAB scales the displayed font to maintain that fraction.
'inches'	Inches.
'centimeters'	Centimeters.
'pixels'	<p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p>

**FontWeight** — Font weight for the uipanel title

'normal' (default) | 'bold'

Font weight of uipanel title, specified as a value from the following table.

FontWeight Value	Description
'normal'	Normal font weight
'bold'	Heavy font weight

Not all fonts support all font weights. Therefore, if you specify an unsupported value for the **FontWeight** property, the result might appear the same as the default.

---

**Note:** The 'light' and 'demi' font weight values have been removed in R2014b. If you specify either of these values, the result is a normal font weight.

---

**FontAngle** — Character slant of the uipanel title

'normal' (default) | 'italic'

Character slant of uipanel title, specified as 'normal' or 'italic'. MATLAB uses this property to select a font from those available on your system. Setting this property to 'italic' selects a slanted version of the font, if it is available on your system.

---

**Note:** The 'oblique' value has been removed. Use 'italic' instead.

---

## Text

### **Title** — Uipanel title

string

Uipanel title, specified as a string.

MATLAB does not interpret a vertical slash ('|') character as a line break, it displays as a vertical slash in the uipanel title.

If you want to specify a Unicode character, pass the Unicode decimal code to the `char` function. For example, `['Multiples of ' char(960)]` displays as Multiples of ∞.

Example: 'Options'

Example: `['Multiples of ' char(960)]`

### **TitlePosition** — Location of uipanel title

'lefttop' (default) | 'centertop' | 'righttop' | 'leftbottom' |  
'centerbottom' | 'righttbottom'

Location of the uipanel title, specified as 'lefttop', 'centertop', 'righttop', 'leftbottom', 'centerbottom', or 'righttbottom'.

## Interactive Control

### **ButtonDownFcn** — Button-press callback function

' ' (default) | function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.

- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `ButtonDownFcn` callback is a function that executes when the user clicks a mouse button on the uipanel.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

### **UIContextMenu** — Uipanel context menu

empty `GraphicsPlaceholder` array (default) | `uicontextmenu` object

Uipanel context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when the user right-clicks on the uipanel. Create the context menu using the `uicontextmenu` function.

### **Selected** — Selection status of uipanel

'off' (default) | 'on'

---

**Note:** The behavior of the `Selected` property changed in R2014b, and it is not recommended. It no longer has any effect on uipanel. This property might be removed in a future release.

---

### **SelectionHighlight** — Ability to highlight selection handles

'on' (default) | 'off'

---

**Note:** The behavior of the `SelectionHighlight` property changed in R2014b, and it is not recommended. It no longer has any effect on uipanel. This property might be removed in a future release.

---

## **Callback Execution Control**

### **Interruptible** — Callback interruption

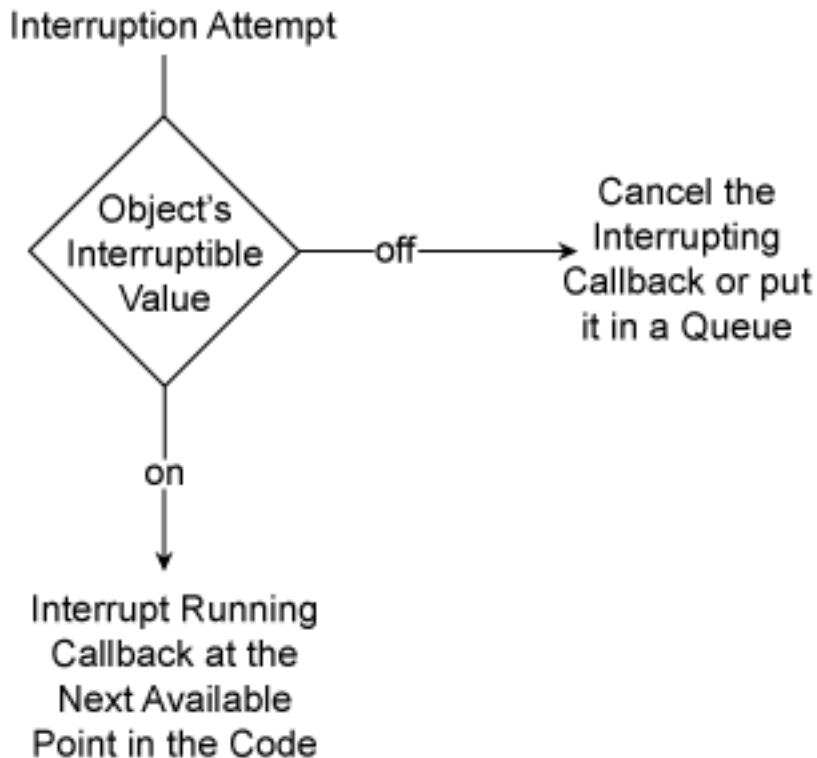

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put into a queue.

If a `uipanel` callback is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- `'on'` — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

---

**Note:** Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a `DeleteFcn`, `CloseRequestFcn`, or `SizeChangedFcn` callback, then the interruption occurs regardless of the `Interruptible` property value.
  - If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the `Interruptible` property value.
  - MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.
- 

See “Interrupt Callback Execution” for an example that shows how the `Interruptible` and `BusyAction` properties affect the behavior of a program.

### **BusyAction — Callback queuing**

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- `'cancel'` — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The `Interruptible` property of the object whose callback is running determines if interruption is allowed. If `Interruptible` is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The `BusyAction` property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the `BusyAction` and `Interruptible` properties affect the behavior of a program.

### **HitTest — Ability to become current object**

`'on'` (default) | `'off'`

Ability to become current object, specified as `'on'` or `'off'`:

- Setting the value to `'on'` allows the uipanel to become the current object when the user clicks on it. A value of `'on'` also allows the figure `CurrentObject` property and the `gco` function to report the uipanel as the current object.
- Setting the value to `'off'` sets the figure `CurrentObject` property to an empty `GraphicsPlaceholder` array when the user clicks on the uipanel.

## **Creation and Deletion Control**

### **BeingDeleted — Deletion status of uipanel**

`'off'` (default) | `'on'`

This property is read only.

Deletion status of uipanel, returned as `'on'` or `'off'`. MATLAB sets the `BeingDeleted` property to `'on'` when the delete function of the uipanel begins execution (see the

DeleteFcn property). The `BeingDeleted` property remains set to 'on' until the `uipanel` no longer exists.

Check the value of the `BeingDeleted` property to verify that the `uipanel` is not about to be deleted before querying or modifying it.

### **CreateFcn — Uipanel creation function**

function handle | cell array | string

Uipanel creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This property specifies a callback function to execute when MATLAB creates the `uipanel`. MATLAB initializes all `uipanel` property values before executing the `CreateFcn` callback. If you do not specify the `CreateFcn` property, then MATLAB executes a default creation function.

Use the `gcb0` function in your `CreateFcn` code to get the handle to the `uipanel` that is being created.

Setting the `CreateFcn` property on an existing `uipanel` has no effect.

---

**Note:** Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. Copying the `uipanel` object causes the `CreateFcn` callback to execute repeatedly.

---

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

### **DeleteFcn — Uipanel deletion function**

function handle | cell array | string

Uipanel deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `DeleteFcn` property specifies a callback function to execute when MATLAB deletes the uipanel (for example, when the end user deletes the figure). MATLAB executes the `DeleteFcn` callback before destroying the properties of the uipanel. If you do not specify the `DeleteFcn` property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your `DeleteFcn` code to get the handle to the uipanel that is being deleted.

Example: `@myfun`

Example: `{@myfun, x}`

Data Types: `function_handle` | `cell` | `char`

## Identifiers

### Type — Type of graphics object

`'uipanel'`

This property is read only.

Type of graphics object, returned as `'uipanel'`.

### Tag — Uipanel identifier

`''` (default) | `string`

Uipanel identifier, specified as a string. You can specify a unique `Tag` value to serve as an identifier for the uipanel. When you need access to the uipanel elsewhere in your code, you can use the `findobj` function to search for the uipanel based on the `Tag` value.

Example: `'panel1'`

Data Types: char

**UserData** — Data to associate with the uipanel object

empty array (default) | array

Data to associate with the uipanel object, specified as any array. Specifying `UserData` can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: [1 2 3]

Example: 'April 21'

Example: struct('value1',[1 2 3],'value2','April 21')

Example: {[1 2 3],'April 21'}

**Parent/Child****Parent** — Uipanel parent

figure | uipanel | uibuttongroup | uitab

Uipanel parent, specified as a figure, uipanel, uibuttongroup, or uitab. You can move a uipanel to a different figure, uipanel, uibuttongroup, or uitab by setting this property to the handle of the target figure, uipanel, uibuttongroup, or uitab.

**Children** — Children of uipanel

empty `GraphicsPlaceholder` array (default) | 1-D array of component objects

Children of uipanel, returned as an empty `GraphicsPlaceholder` or a 1-D array of component objects. The children of uipanel can be axes, uipanels, uibuttongroups, and uicontrols.

You cannot add or remove children using the `Children` property of the uipanel. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the front-to-back order (stacking order) of the components on the screen.

To add a child to this list, set the `Parent` property of the child component to be the uipanel object.

Objects with the `HandleVisibility` property set to 'off' do not list in the `Children` property. For more information, see the `HandleVisibility` property description.

**HandleVisibility – Visibility of Uipanel handle**

'on' (default) | 'callback' | 'off'

Visibility of Uipanel handle, specified as 'on', 'callback', or 'off'.

This property controls the visibility of the uipanel handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The `HandleVisibility` property also controls the visibility of the object's handle in the parent figure's `CurrentObject` property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
'on'	The uipanel handle is always visible.
'callback'	The uipanel handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uipanel at the command-line, but allows callback functions to access it.
'off'	The uipanel handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the <code>HandleVisibility</code> to 'off' to temporarily hide the handle during the execution of that function.

Set the graphics root `ShowHiddenHandles` property to 'on' to make all handles visible, regardless of their `HandleVisibility` value. This setting has no effect on their `HandleVisibility` values.

- “Default Property Values”

# uipushtool

Create push button on toolbar

## Syntax

```
p = uipushtool
p = uipushtool(Name,Value,...)
p = uipushtool(parent)
p = uipushtool(parent,Name,Value,...)
```

## Description

`p = uipushtool` creates a `uipushtool` in the current figure's `uitoolbar` and returns the `uipushtool` object, `p`. If there is no `uitoolbar` available, then MATLAB creates a new `uitoolbar` in the current figure to serve as the parent. Similarly, if there no figure is available, then MATLAB creates a new figure with a `uitoolbar`.

`p = uipushtool(Name,Value,...)` creates a `uipushtool` and specifies one or more `uipushtool` property names and corresponding values. Use this syntax to override the default `uipushtool` properties.

`p = uipushtool(parent)` creates a `uipushtool` and designates a specific parent object. The `parent` argument must be a `uitoolbar` object.

`p = uipushtool(parent,Name,Value,...)` creates a `uipushtool` with a specific parent and one or more `uipushtool` properties.

A `uipushtool` is a push button that appears in the figure's tool bar. The button has no icon, but its borders highlight when the user hovers over it with the mouse. You can create a button icon by setting the `uipushtool`'s `CData` property.

## Examples

### Create `uipushtool` With Icon and Tool Tip

```
f = figure('ToolBar','none');
```

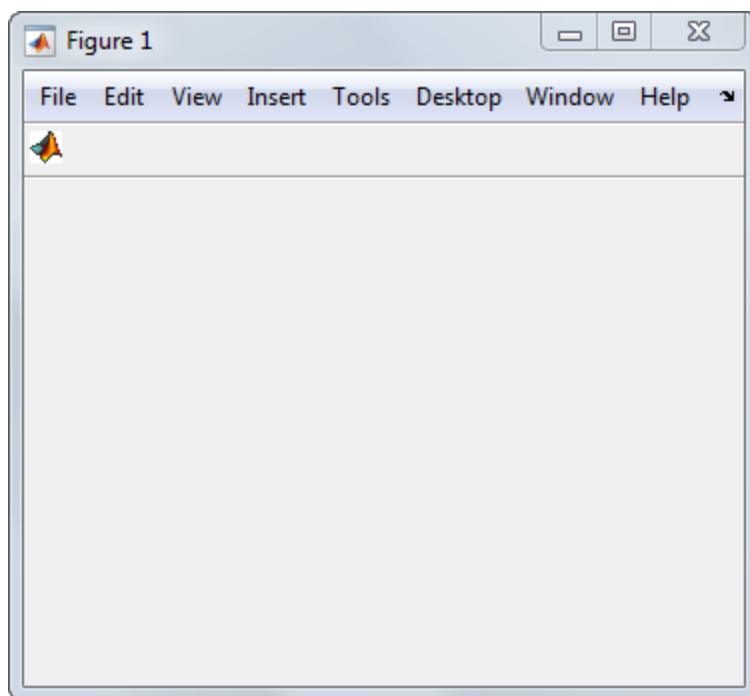

```
t = uicontrol(f);

% Read an image
[img,map] = imread(fullfile(matlabroot,...
 'toolbox','matlab','icons','matlabicon.gif'));

% Convert image from indexed to truecolor
icon = ind2rgb(img,map);

% Create a uipushtool in the toolbar
p = uipushtool(t,'TooltipString','Toolbar push button',...
 'ClickedCallback',...
 'disp(''Clicked uipushtool.'')');

% Set the button icon
p.CData = icon;
```

## More About

### Tips

- Uitoolbars (and their child uipushtools) do not appear in figures whose `WindowStyle` property is set to `'Modal'`. If a figure containing a uitoolbar is changed to `'Modal'`, the uitoolbar still exists in the `Children` property of the figure. However, the uitoolbar does not display while `WindowStyle` is set to `'Modal'`.
- Unlike `uicontrol` push buttons, `uipushtools` do not set the figure's `SelectionType` property to `'open'` on the second click.
- “Access Property Values”
- “Create Toolbars for Programmatic UIs”

**Introduced before R2006a**

# Uipushtool Properties

Control appearance and behavior of uipushtool

Uipushtools are push buttons that appear on the tool bar at the top of the a figure. The `uipushtool` function creates a push button on a tool bar and sets any required properties before displaying it. By changing uipushtool property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
p = uipushtool;
sep = p.Separator;
p.Separator = 'on';
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Appearance

### Visible — Uipushtool visibility

'on' (default) | 'off'

Uipushtool visibility, specified as 'on' or 'off'. When the **Visible** property is set to 'off', the uipushtool is not visible, but you can query and set its properties.

### Separator — Separator line mode

'off' (default) | 'on'

Separator line mode, specified as 'off' or 'on'. Setting this property to 'on' draws a dividing line to left of the uipushtool.

### CData — Optional image to display on uipushtool

3-D array of truecolor RGB values

Optional image to display on the uipushtool, specified as a 3-D array of truecolor RGB values. The values in the array can be:

- Double-precision values between 0.0 and 1.0
- `uint8` values between 0 and 255

The length of the array's first and second dimensions must be less than or equal to 16. Otherwise, it might be clipped or distorted when it displays.

Data Types: `double` | `uint8`

## Interactive Control

### **ClickedCallback** — Callback function that executes when user clicks uipushtool

`'` (default) | function handle | cell array | string

Callback function that executes when a user clicks the uipushtool, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying callback functions as function handles, cell arrays, or strings, see “How to Specify Callback Property Values”.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

### **Enable** — Operational state of uipushtool

`'on'` (default) | `'off'`

Operational state of uipushtool, specified as `'on'` or `'off'`. The `Enable` property controls whether the uipushtool responds to button clicks. There are two possible values:

- `'on'` – The uipushtool is operational.
- `'off'` – The uipushtool is not operational and appears grayed out.

The value of the `Enable` property and the type of button click determine the response.

Enable Value	Response to Left-Click	Response to Right-Click
<code>'on'</code>	The uipushtool's <code>ClickedCallback</code> function executes.	The uipushtool is not operational. No callback executes.

Enable Value	Response to Left-Click	Response to Right-Click
'off'	The uipushtool is not operational. No callback executes.	The uipushtool is not operational. No callback executes.

**TooltipString — Tooltip text**

string

Tooltip text, specified as a string. When the user hovers the mouse pointer over the uipushtool and leaves it there, the tooltip appears.

Example: 'Some string'

**UIContextMenu — Context menu**

empty GraphicsPlaceholder array (default) | uicontextmenu handle

This property has no effect on uipushtools.

**Callback Execution Control****Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The **Interruptible** property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The **Interruptible** property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the **BusyAction** property of the object owning the interrupting callback determines if it is discarded or put into a queue.

If a `uipushtool` callback is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- 'on' — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
- If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.

- If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

---

**Note:** Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a `DeleteFcn`, `CloseRequestFcn`, or `SizeChangedFcn` callback, then the interruption occurs regardless of the `Interruptible` property value.
  - If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the `Interruptible` property value.
  - MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.
- 

See “Interrupt Callback Execution” for an example that shows how the `Interruptible` and `BusyAction` properties affect the behavior of a program.

### **BusyAction — Callback queuing**

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- `'cancel'` — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The `Interruptible` property of the object whose callback is running determines if interruption is allowed. If `Interruptible` is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The `BusyAction` property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the `BusyAction` and `Interruptible` properties affect the behavior of a program.

### **HitTest — Ability to become current object**

'on' (default) | 'off'

This property has no effect on the `uipushtool`.

## **Creation and Deletion Control**

### **BeingDeleted — Deletion status of `uipushtool`**

'off' (default) | 'on'

This property is read only.

Deletion status of `uipushtool`, returned as `'on'` or `'off'`. MATLAB sets the `BeingDeleted` property to `'on'` when the delete function of the `uipushtool` begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to `'on'` until the `uipushtool` no longer exists.

Check the value of the `BeingDeleted` property to verify that the `uipushtool` is not about to be deleted before querying or modifying it.

### **CreateFcn — `Uipushtool` creation function**

function handle | cell array | string

`Uipushtool` creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.

- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This property specifies a callback function to execute when MATLAB creates the uipushtool. MATLAB initializes all uipushtool property values before executing the `CreateFcn` callback. If you do not specify the `CreateFcn` property, then MATLAB executes a default creation function.

Use the `gcbo` function in your `CreateFcn` code to get the handle to the uipushtool that is being created.

Setting the `CreateFcn` property on an existing uipushtool has no effect.

---

**Note:** Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. Copying the uipushtool object causes the `CreateFcn` callback to execute repeatedly.

---

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

### **DeleteFcn — Uipushtool deletion function**

`function handle` | `cell array` | `string`

Uipushtool deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `DeleteFcn` property specifies a callback function to execute when MATLAB deletes the uipushtool (for example, when the end user deletes the figure). MATLAB executes

the `DeleteFcn` callback before destroying the properties of the `uipushtool`. If you do not specify the `DeleteFcn` property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your `DeleteFcn` code to get the handle to the `uipushtool` that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

## Identifiers

### **Type** — Type of graphics object

'uipushtool'

This property is read only.

Type of graphics object, returned as 'uipushtool'.

### **Tag** — Uipushtool identifier

' ' (default) | string

Uipushtool identifier, specified as a string. You can specify a unique `Tag` value to serve as an identifier for the `uipushtool`. When you need access to the `uipushtool` elsewhere in your code, you can use the `findobj` function to search for the `uipushtool` based on the `Tag` value.

Example: `'pushtool1'`

Data Types: `char`

### **UserData** — Data to associate with the uipushtool object

empty array (default) | array

Data to associate with the `uipushtool` object, specified as any array. Specifying `UserData` can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: {[1 2 3], 'April 21'}

## Parent/Child

### Parent — Uipushtool parent

uitoolbar

Uipushtool parent, specified as a uitoolbar. You can move a uipushtool to a different uitoolbar by setting this property to the handle of the target uitoolbar.

### HandleVisibility — Visibility of Uipushtool handle

'on' (default) | 'callback' | 'off'

Visibility of Uipushtool handle, specified as 'on', 'callback', or 'off'.

This property controls the visibility of the uipushtool handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The `HandleVisibility` property also controls the visibility of the object's handle in the parent figure's `CurrentObject` property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
'on'	The uipushtool handle is always visible.
'callback'	The uipushtool handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uipushtool at the command-line, but allows callback functions to access it.
'off'	The uipushtool handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the <code>HandleVisibility</code> to 'off' to temporarily hide the handle during the execution of that function.

Set the graphics root `ShowHiddenHandles` property to 'on' to make all handles visible, regardless of their `HandleVisibility` value. This setting has no effect on their `HandleVisibility` values.

- “Default Property Values”

# uiputfile

Open dialog box for saving files

## Syntax

```
FileName = uiputfile
[FileName,PathName] = uiputfile
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec)
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,DialogTitle)
[FileName,PathName,FilterIndex] =
uiputfile(FilterSpec,DialogTitle,DefaultName)
```

## Description

---

**Note:** Successful execution of `uiputfile` does not create a file; it only returns the name of a new or existing file that you designate.

---

`FileName = uiputfile` displays a modal dialog box for selecting or specifying a file you want to create or save. The dialog box lists the files and folders in the current folder. If the selected or specified file name is valid, `uiputfile` returns that name in `FileName`.

`[FileName,PathName] = uiputfile` also returns the path to `FileName` in `PathName`, or if you cancel the dialog, returns 0 for both arguments. If you do not provide any output arguments, the file name alone is returned in `ans`.

`[FileName,PathName,FilterIndex] = uiputfile(FilterSpec)` displays only those files with extensions that match `FilterSpec`. On some platforms `uiputfile` also displays in gray any files that do not match `FilterSpec`. The `uiputfile` function appends 'All Files' to the list of file types. `FilterSpec` can be a string or a cell array of strings, and can include the \* and ? wildcard characters. For example, '\*.m' lists all MATLAB program files in a folder.

`FilterSpec` can be a string that contains a file name. `uiputfile` displays the file name selected in the **File name** field and uses the file extension as the default filter.

The `FilterSpec` string can include a path, or consist of a path only. To specify a folder only, make the last character in `DefaultName` `'\'` or `'/'`. A path can contain special path characters, such as `'.'`, `'..'`, `'/'`, `'\'`, or `'~'`. For example, `'../*.m'` lists all program files in the folder above the current folder. If `FilterSpec` is a cell array of strings, the first column contains a list of file extensions. The optional second column contains a corresponding list of descriptions. These descriptions replace the default descriptions in the **Save as type** pop-up menu. A description cannot be an empty string. See the “Examples” on page 1-9197 for illustration of using cell arrays as `FilterSpec`. If you do not specify `FilterSpec`, `uiputfile` uses the default list of file types (all MATLAB files). `FilterIndex` is the index of the filter selected in the dialog box. Indexing starts at 1. If you click the **Cancel** button, the window’s close box, or if the file does not exist, `uiputfile` returns `FilterIndex` as 0.

```
[FileName,PathName,FilterIndex] =
uiputfile(FilterSpec,DialogTitle) displays a dialog box that has the title
DialogTitle. To use the default file types and to specify a dialog title, enter
uiputfile('','DialogTitle')
```

```
[FileName,PathName,FilterIndex] =
uiputfile(FilterSpec,DialogTitle,DefaultName) displays a dialog box in which
the file name specified by DefaultName appears in the File name field. DefaultName
can also be a path or a path+filename. To specify a folder only, make the last character
in DefaultName '\' or '/'. In this case, uiputfile opens the dialog box in the
folder specified by the path. If you specify a path in DefaultName that does not exist,
uiputfile opens the dialog box in the current folder. You can use '.', '..', '\', '/',
or ~ in the DefaultName argument.
```

When typing into the dialog box, if you include either of the wildcard characters `'*'` or `'?'` in a file name, `uiputfile` does not respond to clicking **Save**. The dialog box remains open until you cancel it or remove the wildcard characters. This restriction applies to all platforms, even to file systems that permit these characters in file names.

If you select or specify an existing file name, a warning dialog box opens stating that the file already exists and asks if you want to replace it.

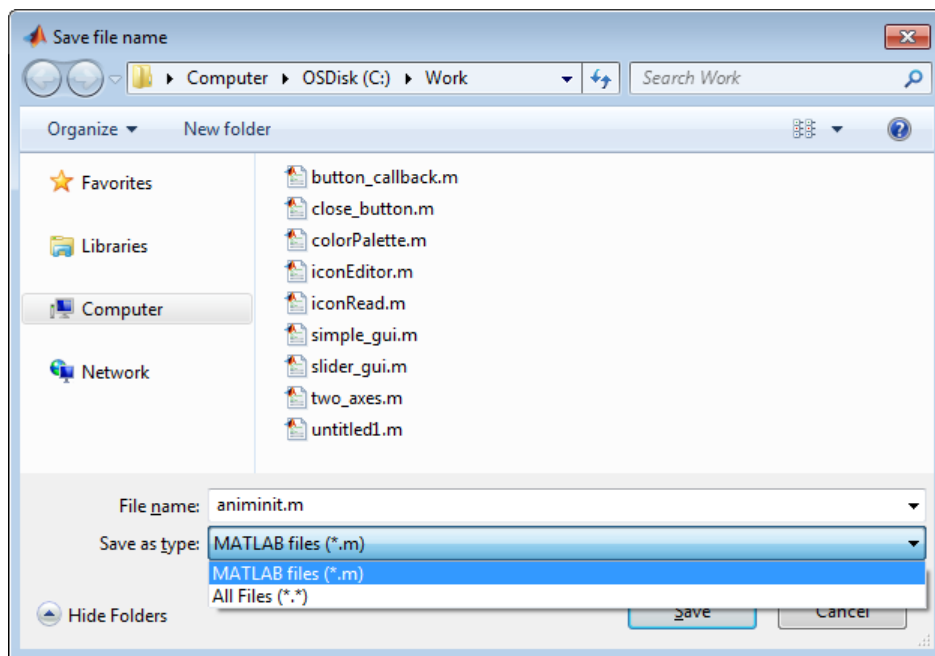

Select **Yes** to replace the existing file or **No** to return to the dialog to select another file name. Selecting **Yes** returns the name of the file. Selecting **No** returns 0.

The visual characteristics of the dialog box depend on the operating system that is running MATLAB.

## Examples

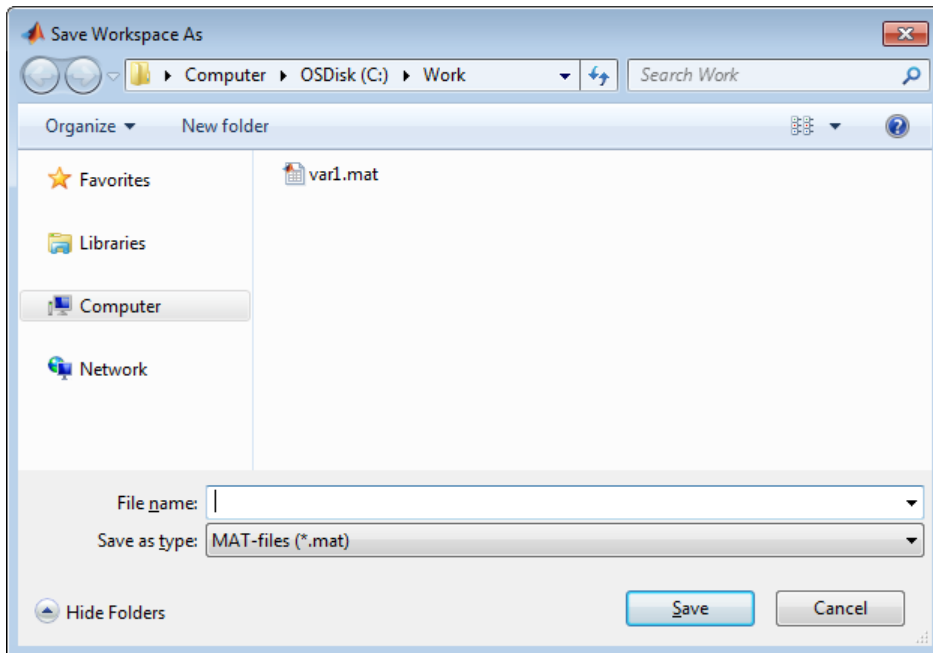

The following statement displays a dialog box entitled 'Save file name'. This command also sets the **File name** field to `animinit.m`, and it sets the filter to program files (`*.m`).

```
[file,path] = uiputfile('animinit.m','Save file name');
```

The following statement displays a dialog box entitled 'Save Workspace As' with the filter set to MAT-files.

```
[file,path] = uiputfile('*.mat','Save Workspace As');
```

To display several file types in the **Save as type** list box, separate each file extension with a semicolon, as in the following code. `uiputfile` displays a default description for each known file type, such as "Model files" for Simulink `.mdl` and `.slx` files.

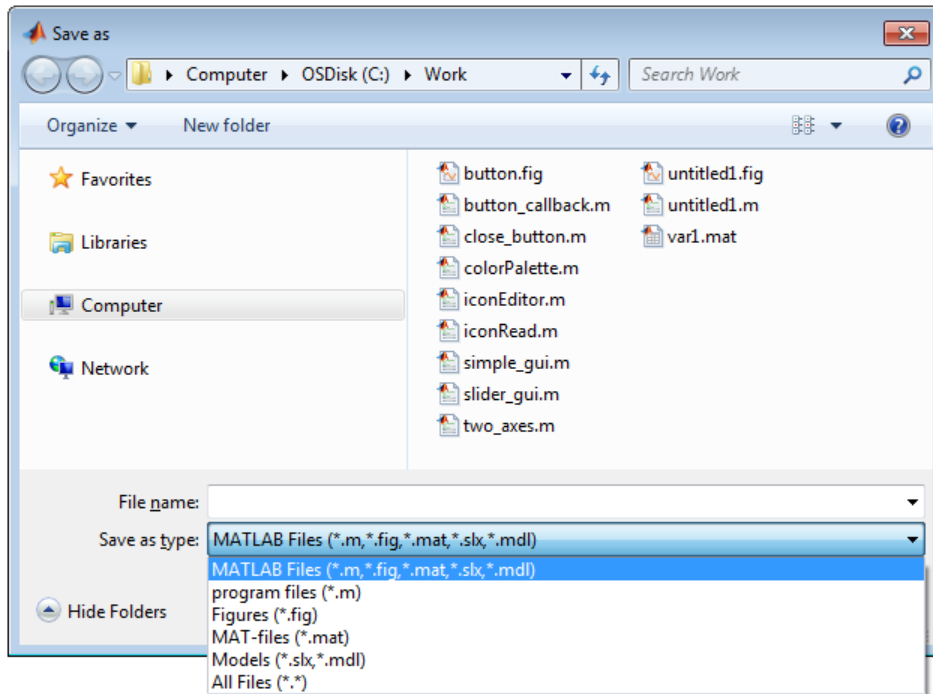

```
[filename, pathname] = uiputfile(...
 {'*.m'; '*.slx'; '*.mat'; '*.*'}, ...
 'Save as');
```

To create a list of file types and give them descriptions that are different from the defaults, use a cell array. This example also associates multiple file types with the 'MATLAB Files' and 'Models' descriptions.

```
[filename, pathname, filterindex] = uiputfile(...
{'*.m;*.fig;*.mat;*.slx;*.mdl',...
'MATLAB Files (*.m,*.fig,*.mat,*.slx,*.mdl)';
 '*.m', 'program files (*.m)';...
 '*.fig', 'Figures (*.fig)';...
 '*.mat', 'MAT-files (*.mat)';...
 '*.slx;*.mdl', 'Models (*.slx,*.mdl)';...
 '*.*', 'All Files (*.*)'},...
'Save as');
```

The first column of the cell array contains the file extensions, while the second contains the descriptions you want to provide for the file types. The first entry of column one contains several extensions separated by semicolons. These file types all associate with the description 'MATLAB Files (\*.m,\*.fig,\*.mat,\*.slx,\*.mdl)'. The code produces the dialog box shown in the following figure.

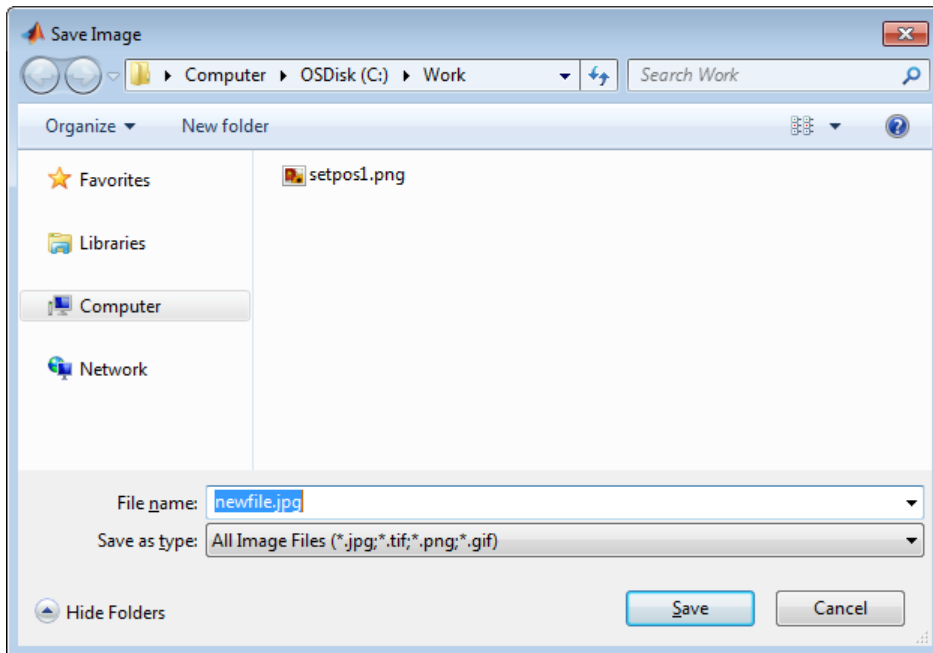

The following code checks for the existence of the file and displays a message about the result of the file selection operation.

```
[filename, pathname] = uiputfile('*.*',...
 'Pick a MATLAB program file');
if isequal(filename,0) || isequal(pathname,0)
 disp('User selected Cancel')
else
 disp(['User selected ',fullfile(pathname,filename)])
end
```

Select or enter a file name for saving a figure as an image in one of four formats, described in a cell array.

```
uiputfile({'*.jpg;*.tif;*.png;*.gif','All Image Files';...
 '*.*','All Files'},'Save Image',...
 'C:\Work\newfile.jpg')
```

Introduced before R2006a

## **uiresume**

Resume execution of blocked program

### **Syntax**

```
uiresume(h)
```

### **Description**

`uiresume(h)` resumes the program execution that `uiwait` suspended.

### **Examples**

This example code creates a window containing a push button. The `uiwait` function blocks MATLAB execution until the user clicks the push button.

```
f = figure;
h = uicontrol('Position',[20 20 200 40],'String','Continue',...
 'Callback','uiresume(gcf)');
disp('This will print immediately');
uiwait(gcf);
disp('This will print after you click Continue');
close(f);
```

The `gcbf` function returns the current figure.

### **More About**

#### **Tips**

The `uiwait` and `uiresume` functions block and resume MATLAB program execution. When creating a dialog box, you should have a `uicontrol` component with a callback that calls `uiresume` or a callback that destroys the dialog box. These are the only methods that resume program execution after the `uiwait` function blocks execution.

When used in conjunction with a modal dialog box, `uiresume` can resume the execution of the program that `uiwait` suspended while presenting a dialog box.

**Introduced before R2006a**

## **uisave**

Open dialog box for saving variables to MAT-file

### **Syntax**

```
uisave
uisave(variables)
uisave(variables,filename)
```

### **Description**

`uisave`, with no arguments, prompts you for a file name, and then saves all variables from your workspace to that file.

`uisave(variables)` saves one or more workspace variables listed in `variables`. The `variables` argument is a string or a cell array of strings.

`uisave(variables,filename)` uses the specified `filename` as the default **File name** in the Save Workspace Variables dialog box, instead of the default `matlab.mat`.

### **Input Arguments**

#### **variable**

String containing the name of a variable in the current workspace or cell array of strings when specifying more than one variable.

**Default:** All variables in the current workspace are saved to a MAT-file.

#### **filename**

String naming a file to appear in the dialog **File name** field when the dialog opens. You can omit a file extension, or specify the file extension as `.mat`.

**Default:** `matlab.mat`

## Examples

Create workspace variables `h` and `g`, and then display the Save Workspace Variables dialog box in the current folder with the default **File name** set to `var1`.

```
h = 365;
g = 52;
uisave({'h','g'}, 'var1');
```

Clicking **Save** stores the workspace variables `h` and `g` in the file `var1.mat` in the displayed folder.

## More About

### Modal Dialog

A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in Figure Properties.

## Tips

- If you type a name in the **File name** field, such as `my_vars`, and click **Save**, the dialog saves all workspace variables to the file `my_vars.mat`. The default filename is `matlab.mat`.
- `uisave` calls `uiputfile` to choose a filename.
- If the filename you specify exists in that folder, `uisave` informs you and gives you a chance to cancel the operation.
- The `uisave` dialog box is modal.
- The `uisave` dialog is modal. A modal dialog box prevents you from interacting with other windows until you respond to it.
- “Save, Load, and Delete Workspace Variables”

# uicolor

Open color selection dialog box

## Syntax

```
c = uicolor
c = uicolor([r g b])
c = uicolor(h)
c = uicolor(..., 'dialogTitle')
```

## Description

`c = uicolor` displays a modal color selection dialog appropriate to the platform, and returns the color selected by the user. The dialog box is initialized to `white`.

`c = uicolor([r g b])` displays a dialog box initialized to the specified color, and returns the color selected by the user. `r`, `g`, and `b` must be values between 0 and 1.

`c = uicolor(h)` displays a dialog box initialized to the color of the object specified by handle `h`, returns the color selected by the user, and applies it to the object. `h` must be the handle to an object containing a color property.

`c = uicolor(..., 'dialogTitle')` displays a dialog box with the specified title.

If the user presses **Cancel** from the dialog box, or if any error occurs, the output value is set to the input RGB triple, if provided; otherwise, it is set to 0.

## More About

### Modal Dialog

A window that blocks interaction with other windows until the user closes the blocking window. For more information, see the figure `WindowState` property description.

# uifont

Open font selection dialog box

## Syntax

```
uifont
uifont(h)
uifont(S)
uifont(..., 'DialogTitle')
S = uifont(...)
```

## Description

`uifont` enables you to change font properties (`FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle`) for a `text`, `axes`, or `uicontrol` object. The function returns a structure consisting of font properties and values. You can specify an alternate title for the dialog box.

`uifont` displays a modal dialog box and returns the selected font properties.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in `Figure Properties`.

---

`uifont(h)` displays a modal dialog box, initializing the font property values with the values of those properties for the object whose handle is `h`. Selected font property values are applied to the current object. If a second argument is supplied, it specifies a name for the dialog box.

`uifont(S)` displays a modal dialog box, initializing the font property values with the values defined for the specified structure (`S`). `S` must define legal values for one or more of these properties: `FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle` and the field names must match the property names exactly. If other properties are defined, they are ignored. If a second argument is supplied, it specifies a name for the dialog box.

`uisetfont(..., 'DialogTitle')` displays a modal dialog box with the title `DialogTitle` and returns the values of the font properties selected in the dialog box.

`S = uisetfont(...)` returns the properties `FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle` as fields in a structure. If the user presses **Cancel** from the dialog box or if an error occurs, the output value is set to 0.

## Examples

These statements create a text object, then display a dialog box (labeled Update Font) that enables you to change the font characteristics:

```
h = text(.5,.5,'Figure Annotation');
uisetfont(h,'Update Font')
```

These statements create two push buttons, then set the font properties of one based on the values set for the other:

```
% Create push button with string ABC
c1 = uicontrol('Style','pushbutton', ...
 'Position',[10 10 100 20], 'String','ABC');
% Create push button with string XYZ
c2 = uicontrol('Style','pushbutton', ...
 'Position',[10 50 100 20], 'String','XYZ');
% Display set font dialog box for c1, make selections,
& and save to d
d = uisetfont(c1);
% Apply those settings to c2
set(c2, d)
```

# uipref

Manage preferences used in `uigetpref`

## Syntax

```
uipref('clearall')
```

## Description

`uipref('clearall')` resets the value of all preferences registered through `uigetpref` to 'ask'. This causes the dialog box to display when you call `uigetpref`.

---

**Note** Use `setpref` to set the value of a particular preference to 'ask'.

---

## See Also

`setpref` | `uigetpref`

**Introduced before R2006a**

## uistack

Reorder visual stacking order of objects

---

**Note:** The `uistack` function might return different results, starting in R2014b. For more information about how the stacking behavior of UI components has changed, see “Why Are Some Components Missing or Partially Obscured?”.

---

### Syntax

```
uistack(h)
uistack(h,stackopt)
uistack(h,stackopt,step)
```

### Description

`uistack(h)` shifts object `h` up one level within the visual stacking order of UI objects. You can also specify `h` to be a vector of UI objects. When `h` is a vector, the objects stack according to their order in the vector. All items in the stack must share the same parent.

`uistack(h,stackopt)` moves the object `h` to another place in the stack according to `stackopt`:

- 'up' – moves `h` up one position in the stacking order
- 'down' – moves `h` down one position in the stacking order
- 'top' – moves `h` to the top of the current stack
- 'bottom' – moves `h` to the bottom of the current stack

`uistack(h,stackopt,step)` moves object `h` up or down the number of levels specified by `step`. For example, `uistack(h,'up',2)` moves `h` up two levels in the stack.

## Examples

### Change Stacking Order of Two Plots in a Figure

Create a figure containing a uipanel and a child axes. Then, plot a sine function in the axes.

```
f = figure;
p1 = uipanel(f, 'Position', [.10 .10 .80 .80], ...
 'Tag', 'Panel with Sine Plot');
ax1 = axes('Parent', p1, 'Position', [.1 .1 .8 .8]);

theta = -3*pi:pi/64:3*pi;
y1 = sin(theta);
plot(ax1, theta, y1);
```

In the same figure, create a second uipanel with a child axes. Then, create a surface plot in this axes.

```
p2 = uipanel(f, 'Position', [.10 .10 .80 .80], ...
 'Tag', 'Panel with Surface Plot');
ax2 = axes('Parent', p2, 'Position', [.1 .1 .8 .8]);
Z = peaks(25);
surf(ax2, Z);
```

Next, move the uipanel containing the sine function to the top.

```
uistack(p1, 'top');
f.Children
```

```
ans =
```

```
2x1 Panel array:
```

```
Panel (Panel with Sine Plot)
Panel (Panel with Surface Plot)
```

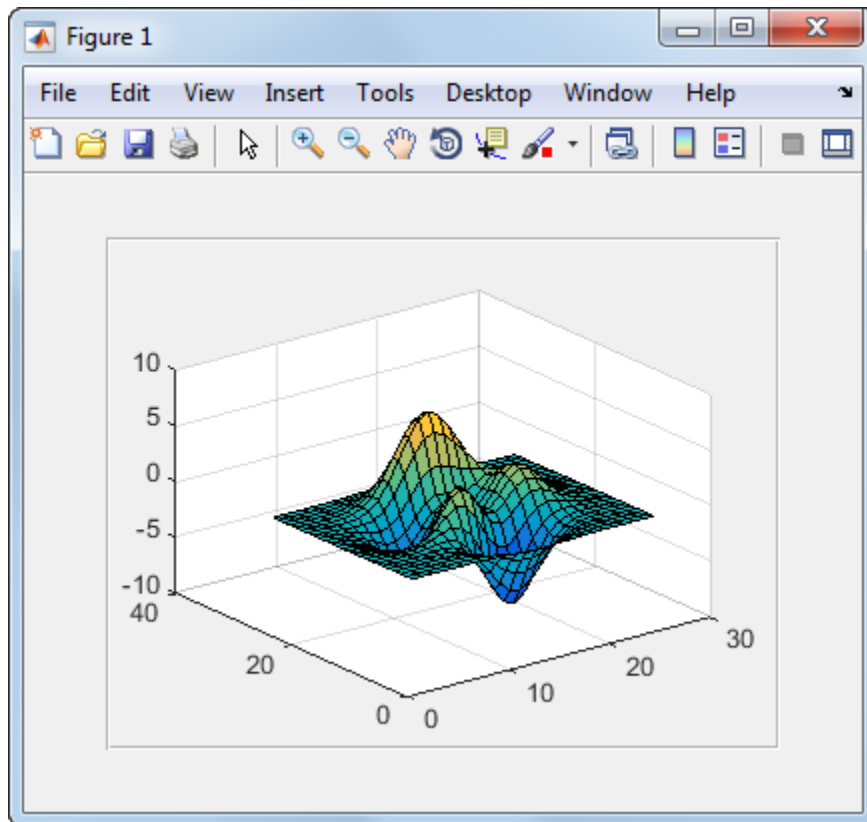

Now, move the other uipanel to the top.

```
uistack(p2, 'top');
f.Children
```

```
ans =
```

```
2x1 Panel array:
```

```
Panel (Panel with Surface Plot)
Panel (Panel with Sine Plot)
```

## More About

### Visual Stacking Order

The order of overlapping components in a UI window. Components on top of the stack appear in front of components that are lower in the stack.

- “Manage the Stacking Order of Grouped Components”

**Introduced before R2006a**

# uitab

Create tabbed panel

## Syntax

```
t = uitab
t = uitab(Name,Value)

t = uitab(parent)
t = uitab(parent,Name,Value)
```

## Description

`t = uitab` creates a uitab in an existing uitabgroup and returns the uitab object in the variable, `t`. If there is no uitabgroup available, then MATLAB creates a new uitabgroup in a figure to serve as the parent.

`t = uitab(Name,Value)` creates a uitab and specifies one or more uitab property names and corresponding values. Use this syntax to override the default uitab property values.

`t = uitab(parent)` creates a uitab and specifies the parent uitabgroup object for the uitab.

`t = uitab(parent,Name,Value)` creates a uitab with a specific parent and one or more uitab properties.

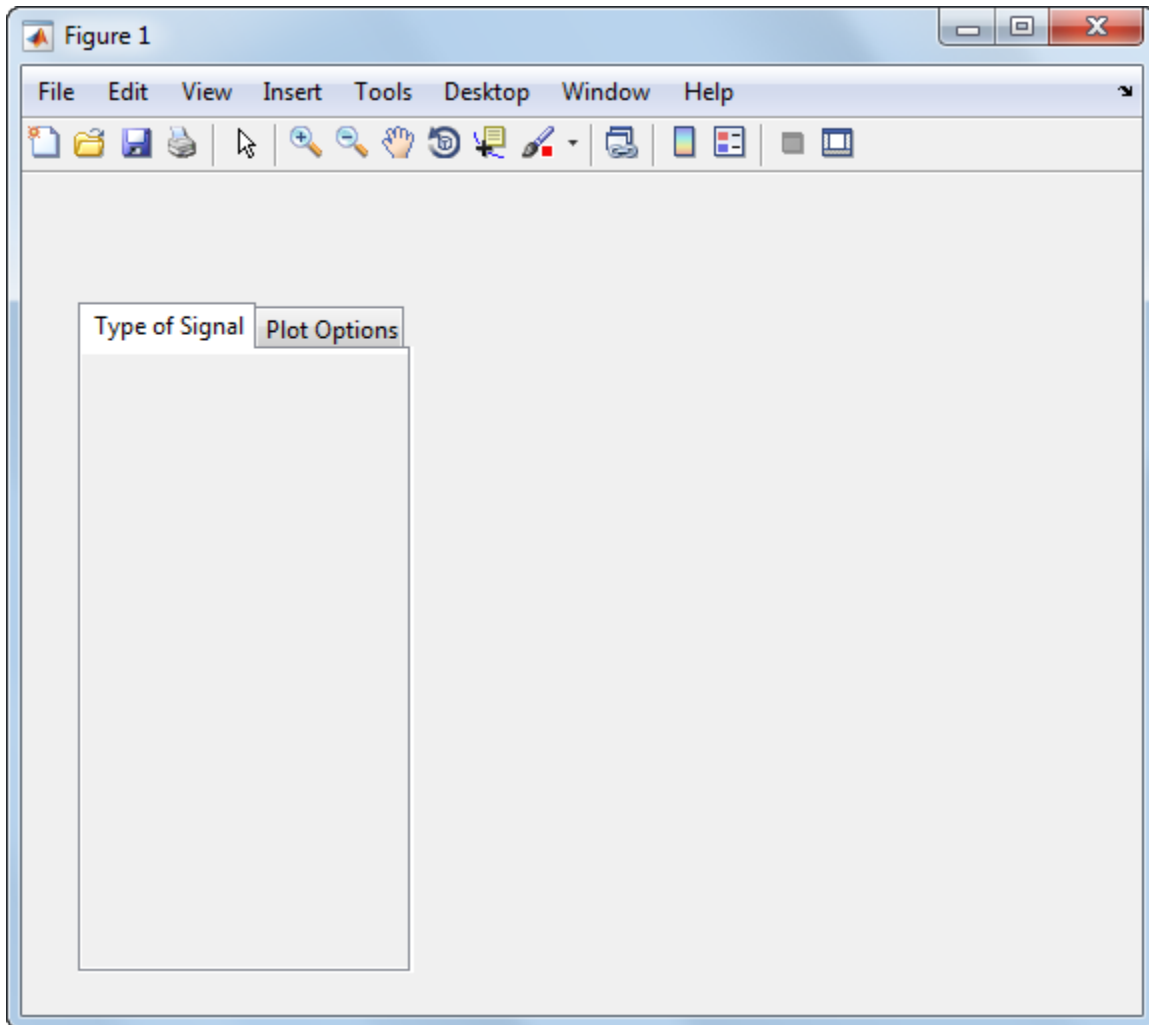

## Examples

### Create Two Tabs in a Figure

Create a figure containing a uitabgroup and two uitabs.

```
f = figure;
tabgp = uitabgroup(f, 'Position', [.05 .05 .3 .8]);
tab1 = uitab(tabgp, 'Title', 'Type of Signal');
```

```
tab2 = uitab(tabgp, 'Title', 'Plot Options');
```

Get the title of the first uitab.

```
tab1.Title
```

```
ans =
```

Type of Signal

## Input Arguments

### **parent** — Uitab parent

uitabgroup

Uitab parent, specified as a uitabgroup object. You can move a uitab to a different uitabgroup by setting this value to the target uitabgroup object.

## Name-Value Pair Arguments

The properties listed here are only a subset, for a complete list see Uitab Properties.

Example: 'Title', 'Plot Options'

### **'Title'** — uitab title

string

uitab title, specified as a string.

MATLAB does not interpret a vertical slash ( `'|'` ) character as a line break, it displays as a vertical slash in the uitab title.

If you want to specify a Unicode character, pass the Unicode decimal code to the `char` function. For example, `['Multiples of ' char(960)]` displays as `Multiples of ∞`.

Example: 'Options'

Example: `['Multiples of ' char(960)]`

### **'BackgroundColor'** — uitab background color

`[.94 .94 .94]` (default) | RGB triplet | short name | long name

uitab background color, specified as an RGB triplet, short name, or long name. The color you specify fills the area bounded by the uitab.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[ 1 1 0 ]
'magenta'	'm'	[ 1 0 1 ]
'cyan'	'c'	[ 0 1 1 ]
'red'	'r'	[ 1 0 0 ]
'green'	'g'	[ 0 1 0 ]
'blue'	'b'	[ 0 0 1 ]
'white'	'w'	[ 1 1 1 ]
'black'	'k'	[ 0 0 0 ]

---

**Note:** Some operating systems override the `BackgroundColor` value.

---

Data Types: `double` | `char`

**'Position' — Location and size of uitab relative to parent**

[`left bottom width height`]

This property is read only.

Location and size of uitab relative to parent, returned as the vector, [`left bottom width height`]. The `left` value is the distance from the inner left edge of the parent container to the outer left edge of the uitab. The `bottom` value is the distance from the inner bottom edge of the parent container to the outer bottom edge of the uitab. The `width` value specifies the distance between the right and left outer edges of the uitab. The `height` value specifies the distance between the top and bottom outer edges of the uitab. All measurements are in units specified by the `Units` property.

**'Units' — Units of measurement**

'normalized' (default) | 'pixels' | 'inches' | 'centimeters' | 'points' | 'characters'

Units of measurement, specified one of the values from this table.

Units Value	Description
'normalized'	These units are normalized with respect to the parent container. The lower-left corner

Units Value	Description
	of the container maps to (0,0) and the upper-right corner maps to (1,1).
'pixels' (default)	<p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p>
'inches'	Inches.
'centimeters'	Centimeters.
'points'	Points. One point equals 1/72nd of an inch.
'characters'	<p>These units are based on the default system font character size.</p> <ul style="list-style-type: none"> <li>• Character width = width of the letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>

MATLAB uses these units to display the location and size values in the **Position** property.

MATLAB measures all units from the lower left corner of the parent object.

If you change the value of the **Units** property, it is good practice to return it to its default value after completing your computation to avoid affecting other functions that assume the **Units** property is set to the default value.

**Introduced in R2014b**

# Uitab Properties

Control appearance and behavior of tabbed panel

Uitabs are tabbed panels for grouping UI components together. The `uitab` function creates a uitab in a figure and sets any required properties before displaying it. By changing uitab property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
t = uitab;
bgcolor = t.BackgroundColor;
t.BackgroundColor = [.5 .5 .5];
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Appearance

### BackgroundColor — Uitab background color

[.94 .94 .94] (default) | RGB triplet | short name | long name

Uitab background color, specified as an RGB triplet, short name, or long name. The color you specify fills the area bounded by the uitab.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]

Long Name	Short Name	RGB Triplet
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

---

**Note:** Some operating systems override the `BackgroundColor` value.

---

Data Types: double | char

**ForegroundColor** — **Uitab title color**

[0 0 0] (default) | RGB triplet | short name | long name

Uitab title color, specified as an RGB triplet, short name, or long name.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black'	'k'	[0 0 0]

Example: [0 0 1]

Example: 'b'

Example: 'blue'

## Location and Size

### Position — Location and size of uitab relative to parent

[left bottom width height]

This property is read only.

Location and size of uitab relative to parent, returned as the vector, [left bottom width height]. The `left` value is the distance from the inner left edge of the parent container to the outer left edge of the uitab. The `bottom` value is the distance from the inner bottom edge of the parent container to the outer bottom edge of the uitab. The `width` value specifies the distance between the right and left outer edges of the uitab. The `height` value specifies the distance between the top and bottom outer edges of the uitab. All measurements are in units specified by the `Units` property.

### Units — Units of measurement

'normalized' (default) | 'pixels' | 'inches' | 'centimeters' | 'points' | 'characters'

Units of measurement, specified one of the values from this table.

Units Value	Description
'normalized'	These units are normalized with respect to the parent container. The lower-left corner of the container maps to (0,0) and the upper-right corner maps to (1,1).
'pixels' (default)	<p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p>
'inches'	Inches.

Units Value	Description
'centimeters'	Centimeters.
'points'	Points. One point equals 1/72nd of an inch.
'characters'	<p>These units are based on the default system font character size.</p> <ul style="list-style-type: none"> <li>• Character width = width of the letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>

MATLAB uses these units to display the location and size values in the `Position` property.

MATLAB measures all units from the lower left corner of the parent object.

If you change the value of the `Units` property, it is good practice to return it to its default value after completing your computation to avoid affecting other functions that assume the `Units` property is set to the default value.

**SizeChangedFcn — Uitable resize callback function**

' ' (default) | function handle | cell array | string

Uitable resize callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

Define this callback function to control the UI layout when the size of the uitable changes.

The `SizeChangedFcn` callback executes in these circumstances:

- The uitable becomes visible for the first time.
- The uitable is visible while its drawable area changes. The drawable area is the area inside the outer bounds of the uitable.
- The uitable becomes visible for the first time after its drawable area changes. This situation occurs when the drawable area changes while the uitable is invisible, and then it becomes visible later.

These are some of the important characteristics of the `SizeChangedFcn` callback and some recommended best practices:

- Consider delaying the display of the figure until after all the variables that the uitab's `SizeChangedFcn` uses are defined. This practice can prevent the uitab's `SizeChangedFcn` callback from returning an error. To delay the display of the figure, set its `Visible` property to `'off'`. Then, set the `Visible` property to `'on'` after you define the variables that your `SizeChangedFcn` callback uses.
- Use the `gcb0` function in your `SizeChangedFcn` code to get the uitab object that the user is resizing. See the description of the figure `SizeChangedFcn` for an example that uses `gcb0`.
- All visible Uitabs that are specified in normalized units resize before the parent figure does. All visible, nested uitabs resize from inside-out.

---

**Tip** As an easy alternative to specifying a `SizeChangedFcn` callback, you can set the `Units` property of all the objects you put inside the uitab to `'normalized'`. Doing so makes those components scale proportionally with the uitab.

---

See “Managing the Layout in Resizable UIs” for more information on controlling the resize behavior of a programmatic UIs.

Example: `@myfun`

Example: `{@myfun,x}`

## Text

### Title — Uitab title

string

Uitab title, specified as a string.

MATLAB does not interpret a vertical slash (`'|'`) character as a line break, it displays as a vertical slash in the uitab title.

If you want to specify a Unicode character, pass the Unicode decimal code to the `char` function. For example, `['Multiples of ' char(960)]` displays as Multiples of  $\pi$ .

Example: `'Options'`

Example: `['Multiples of ' char(960)]`

## Interactive Control

### **ButtonDownFcn** — Button-press callback function

' ' (default) | function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The **ButtonDownFcn** callback is a function that executes when the user clicks a mouse button on the `uitab`.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

### **UIContextMenu** — Uitable context menu

empty `GraphicsPlaceholder` array (default) | `uicontextmenu` object

Uitable context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when the user right-clicks on the `uitab`. Create the context menu using the `uicontextmenu` function.

### **TooltipString** — Tooltip text

string

Tooltip text, specified as a string. When the user hovers the mouse pointer over the `uitab` and leaves it there, the tooltip displays.

Example: `'Some string'`

## Callback Execution Control

### **Interruptible** — Callback interruption

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put into a queue.

If a `uitab` callback is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- `'on'` — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

---

**Note:** Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a `DeleteFcn`, `CloseRequestFcn`, or `SizeChangedFcn` callback, then the interruption occurs regardless of the `Interruptible` property value.
  - If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the `Interruptible` property value.
  - MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.
- 

See “Interrupt Callback Execution” for an example that shows how the `Interruptible` and `BusyAction` properties affect the behavior of a program.

### **BusyAction — Callback queuing**

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The **BusyAction** property of the source of the interrupting callback determines how MATLAB handles its execution. The **BusyAction** property has these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- 'cancel' — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The **Interruptible** property of the object whose callback is running determines if interruption is allowed. If **Interruptible** is set to:

- **on** — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- **off** — The **BusyAction** property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the **BusyAction** and **Interruptible** properties affect the behavior of a program.

## Creation and Deletion Control

### **BeingDeleted** — Deletion status of uitab

'off' (default) | 'on'

This property is read only.

Deletion status of uitab, returned as 'on' or 'off'. MATLAB sets the **BeingDeleted** property to 'on' when the delete function of the uitab begins execution (see the **DeleteFcn** property). The **BeingDeleted** property remains set to 'on' until the uitab no longer exists.

Check the value of the **BeingDeleted** property to verify that the uitab is not about to be deleted before querying or modifying it.

### **CreateFcn** — Uitab creation function

function handle | cell array | string

Uitab creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This property specifies a callback function to execute when MATLAB creates the uitab. MATLAB initializes all uitab property values before executing the `CreateFcn` callback. If you do not specify the `CreateFcn` property, then MATLAB executes a default creation function.

Use the `gcbo` function in your `CreateFcn` code to get the handle to the uitab that is being created.

Setting the `CreateFcn` property on an existing uitab has no effect.

---

**Note:** Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. Copying the uitab object causes the `CreateFcn` callback to execute repeatedly.

---

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

### **DeleteFcn — Uitab deletion function**

`function handle` | `cell array` | `string`

Uitab deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `DeleteFcn` property specifies a callback function to execute when MATLAB deletes the uitab (for example, when the end user deletes the figure). MATLAB executes the `DeleteFcn` callback before destroying the properties of the uitab. If you do not specify the `DeleteFcn` property, then MATLAB executes a default deletion function.

Use the `gcb0` function in your `DeleteFcn` code to get the handle to the uitab that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

## Identifiers

### Type — Type of graphics object

`'uitab'`

This property is read only.

Type of graphics object, returned as `'uitab'`.

### Tag — Uitab identifier

`''` (default) | string

Uitab identifier, specified as a string. You can specify a unique `Tag` value to serve as an identifier for the uitab. When you need access to the uitab elsewhere in your code, you can use the `findobj` function to search for the uitab based on the `Tag` value.

Example: `'tab1'`

Data Types: `char`

### UserData — Data to associate with the uitab object

empty array (default) | array

Data to associate with the uitab object, specified as any array. Specifying `UserData` can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: [1 2 3]

Example: 'April 21'

Example: struct('value1',[1 2 3],'value2','April 21')

Example: {[1 2 3],'April 21'}

## Parent/Child

### Parent — Uitab parent

uitabgroup

Uitab parent, specified as a uitabgroup. You can move a uitab to a different uitabgroup by setting this property to the handle of the target uitabgroup.

### Children — Children of uitab

empty GraphicsPlaceholder array (default) | 1-D array of component objects

Children of uitab, returned as an empty `GraphicsPlaceholder` or a 1-D array of UI component objects. The children of uitab can be axes, uipanel, uibuttongroups, and uicontrols.

You cannot add or remove children using the `Children` property of the uitab. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the front-to-back order (stacking order) of the components on the screen.

To add a child to this list, set the `Parent` property of the child component to be the uitab object.

Objects with the `HandleVisibility` property set to 'off' do not list in the `Children` property. For more information, see the `HandleVisibility` property description.

### HandleVisibility — Visibility of Uitab handle

'on' (default) | 'callback' | 'off'

Visibility of Uitab handle, specified as 'on', 'callback', or 'off'.

This property controls the visibility of the uitab handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

The `HandleVisibility` property also controls the visibility of the object's handle in the parent figure's `CurrentObject` property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
'on'	The uitab handle is always visible.
'callback'	The uitab handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uitab at the command-line, but allows callback functions to access it.
'off'	The uitab handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the <code>HandleVisibility</code> to 'off' to temporarily hide the handle during the execution of that function.

Set the graphics root `ShowHiddenHandles` property to 'on' to make all handles visible, regardless of their `HandleVisibility` value. This setting has no effect on their `HandleVisibility` values.

## More About

- “Access Property Values”
- “Default Property Values”

# uitabgroup

Create container for tabbed panels

## Syntax

```
g = uitabgroup
g = uitabgroup(Name,Value)

g = uitabgroup(parent)
g = uitabgroup(parent,Name,Value)
```

## Description

`g = uitabgroup` creates a `uitabgroup` in the current figure and returns the `uitabgroup` object in the variable, `g`. If no figure exists, then MATLAB creates a new figure and places the `uitabgroup` in it. `Uitabgroups` are `uitab` containers. They allow you to group `uitabs` together, identify the currently selected `uitab`, and detect when the user selects a different `uitab`.

`g = uitabgroup(Name,Value)` creates a `uitabgroup` and specifies one or more `uitabgroup` property names and corresponding values. Use this syntax to override the default `uitabgroup` property values.

`g = uitabgroup(parent)` creates a `uitabgroup` and specifies the parent object for the `uitabgroup` (a figure, `uipanel`, or `uibuttongroup`).

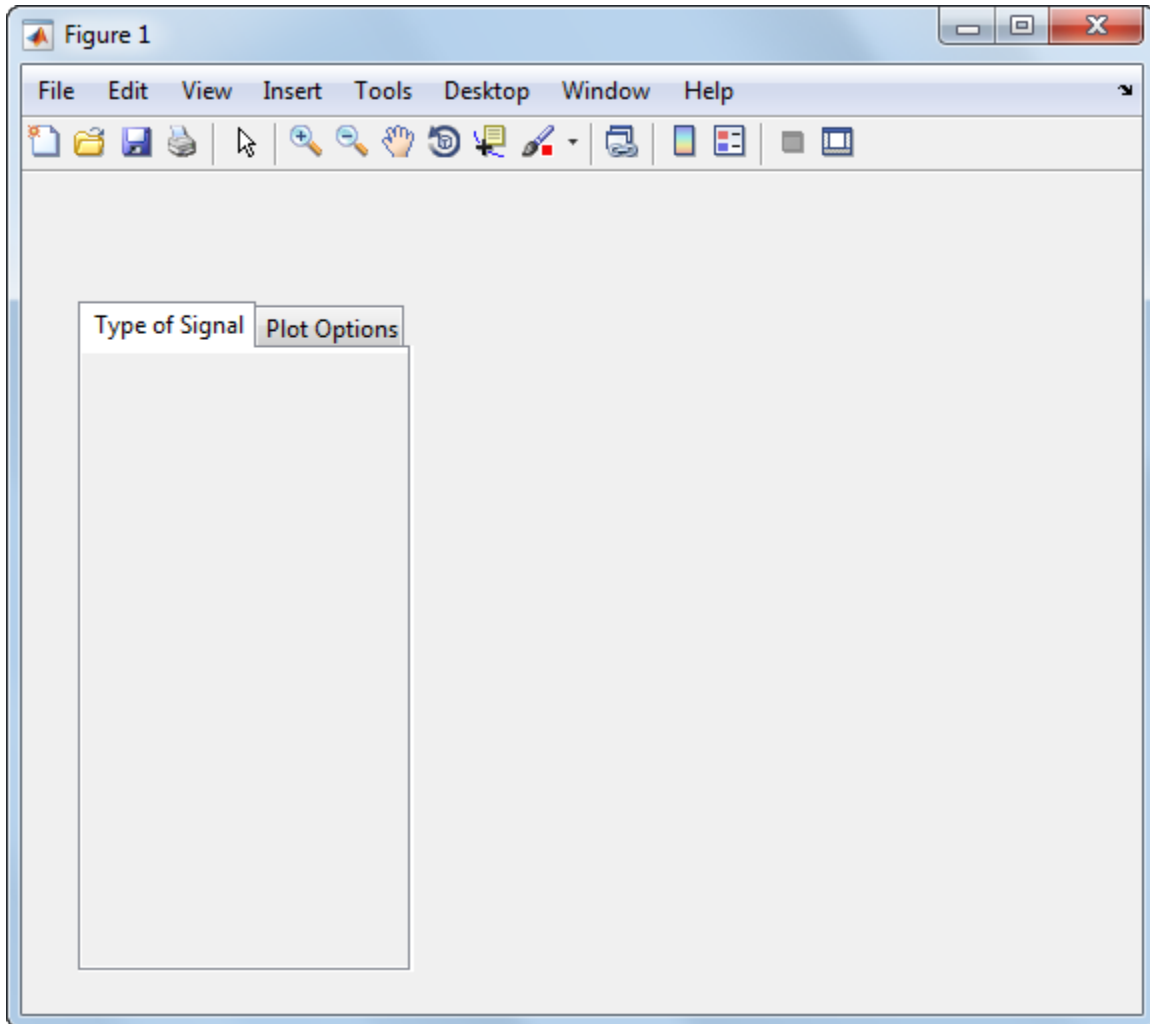

`g = uitabgroup(parent,Name,Value)` creates a `uitabgroup` with a specific parent and one or more `uitabgroup` properties.

## Examples

### Create Two Tabs in a Figure

Create a figure containing a `uitabgroup` and two `uitabs`.

```
f = figure;
tabgp = uitabgroup(f, 'Position', [.05 .05 .3 .8]);
tab1 = uitab(tabgp, 'Title', 'Type of Signal');
tab2 = uitab(tabgp, 'Title', 'Plot Options');
```

Get the currently selected uitab.

```
currenttab = tabgp.SelectedTab
```

```
currenttab =

 Tab (Type of Signal) with properties:

 Title: 'Type of Signal'
 BackgroundColor: [0.9400 0.9400 0.9400]
 Position: [0.0119 0.0089 0.9702 0.9107]
 Units: 'normalized'
```

## Input Arguments

### **parent** — Uitablegroup parent

figure | uipanel | uitab

Uitablegroup parent, specified as a figure, uipanel, or uitab object. You can move a uitablegroup to a different figure, uipanel, or uitab by setting this value to the target parent object.

## Name-Value Pair Arguments

The properties listed here are only a subset, for a complete list see Uitablegroup Properties.

Example: 'TabLocation', 'left'

### **'SelectedTab'** — Currently selected tab

uitable object

Currently selected tab, specified as a uitable object.

Use this property to determine the currently selected uitable within a uitablegroup. You can also use this property to set the default uitable selection.

The default value of the **SelectedTab** property is the first uitable that you add to the uitablegroup.

### **'SelectionChangedFcn'** — Uitable selection callback

' ' (default) | function handle | cell array | string

Uitable selection callback, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

This callback function executes when the user selects a different tab within the uitabgroup.

If you set the `SelectionChangedFcn` property to a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Callbackdata Field	Description
OldValue	Previously selected uitab, or [ ] if none was selected
NewValue	Currently selected uitab
Source	The parent uitabgroup object
EventName	'SelectionChanged'

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

Example: `@myfun`

Example: `{@myfun,x}`

#### 'TabLocation' — Tab label location

'top' (default) | 'bottom' | 'left' | 'right'

Tab label location, specified as 'top', 'bottom', 'left', or 'right'. This property specifies the location of the tab labels with respect to the uitabgroup.

#### 'Position' — Location and size of uitabgroup relative to parent

[left bottom width height]

Location and size of the uitabgroup relative to the parent, specified as the vector, [left bottom width height]. This table describes each element in the vector.

Element	Description
left	Distance from the inner left edge of the parent container to the outer left edge of the uitabgroup
bottom	Distance from the inner bottom edge of the parent container to the outer bottom edge of the uitabgroup
width	Distance between the right and left outer edges of the uitabgroup
height	Distance between the top and bottom outer edges of the uitabgroup

All measurements are in units specified by the `Units` property.

---

**Note:** If the parent of the uitabgroup is a figure, then the `Position` values are relative to the figure's *drawable area*. The drawable area of a figure is the area inside the window borders, excluding the menu bar and tool bar.

---

## Example: Modify One Value in the Position Vector

You can combine dot notation and array indexing when you want to change one value in the `Position` vector. For example, this code sets the width of the uitabgroup to `.5` without changing any of the other `Position` values:

```
tg = uitabgroup;
tg.Position(3) = .5;
```

### 'Units' — Units of measurement

```
'normalized' (default) | 'pixels' | 'inches' | 'centimeters' | 'points' |
'characters'
```

Units of measurement, specified one of the values from this table.

Units Value	Description
'normalized'	These units are normalized with respect to the parent container. The lower-left corner of the container maps to <code>(0,0)</code> and the upper-right corner maps to <code>(1,1)</code> .
'pixels' (default)	Pixels.

Units Value	Description
	<p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p>
'inches'	Inches.
'centimeters'	Centimeters.
'points'	Points. One point equals 1/72nd of an inch.
'characters'	<p>These units are based on the default system font character size.</p> <ul style="list-style-type: none"> <li>• Character width = width of the letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>

MATLAB measures all units from the lower left corner of the parent object.

If you change the value of the `Units` property, it is good practice to return it to its default value after completing your computation to avoid affecting other functions that assume the `Units` property is set to the default value.

The order in which you specify the `Units` and `Position` properties has these effects:

- If you specify the `Units` property before the `Position` property, then MATLAB sets `Position` using the units you specified.
- If you specify the `Units` property after the `Position` property, MATLAB sets the position using the default `Units`. Then, MATLAB converts the `Position` values to the equivalent values in the units you specified.

# Uitabgroup Properties

Control appearance and behavior of tabbed panel container

Uitabgroups are uitab containers that allow to you identify the currently selected uitab and detect when the user selects a different uitab. By changing uitabgroup property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
g = uitabgroup;
pos = g.Position;
g.Position = [.1 .1 .8 .8];
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Appearance

### Visible — Uitabgroup visibility

'on' (default) | 'off'

Uitabgroup handle visibility, specified as 'on' or 'off'. The **Visible** property determines whether the uitabgroup displays on the screen. If the **Visible** property of a uitabgroup is set to 'off', the entire uitabgroup is invisible, but you can still specify and access its properties.

Changing the size of an invisible uitabgroup triggers the `SizeChangedFcn` callback if and when the uitabgroup becomes visible.

---

**Note** Changing the **Visible** property of a uitabgroup does *not* change the settings of the **Visible** property of its child components even though hiding the uitabgroup causes them to be hidden.

---

## Location and Size

### TabLocation — Tab label location

'top' (default) | 'bottom' | 'left' | 'right'

Tab label location, specified as 'top', 'bottom', 'left', or 'right'. This property specifies the location of the tab labels with respect to the uitabgroup.

**Position — Location and size of uitabgroup relative to parent**`[left bottom width height]`

Location and size of the uitabgroup relative to the parent, specified as the vector, `[left bottom width height]`. This table describes each element in the vector.

Element	Description
<code>left</code>	Distance from the inner left edge of the parent container to the outer left edge of the uitabgroup
<code>bottom</code>	Distance from the inner bottom edge of the parent container to the outer bottom edge of the uitabgroup
<code>width</code>	Distance between the right and left outer edges of the uitabgroup
<code>height</code>	Distance between the top and bottom outer edges of the uitabgroup

All measurements are in units specified by the `Units` property.

---

**Note:** If the parent of the uitabgroup is a figure, then the `Position` values are relative to the figure's *drawable area*. The drawable area of a figure is the area inside the window borders, excluding the menu bar and tool bar.

---

**Example: Modify One Value in the Position Vector**

You can combine dot notation and array indexing when you want to change one value in the `Position` vector. For example, this code sets the width of the `Uitabgroup` to `.5` without changing any of the other `Position` values:

```
tg = uitabgroup;
tg.Position(3) = .5;
```

**Units — Units of measurement**`'normalized' (default) | 'pixels' | 'inches' | 'centimeters' | 'points' | 'characters'`

Units of measurement, specified one of the values from this table.

Units Value	Description
'normalized'	These units are normalized with respect to the parent container. The lower-left corner of the container maps to (0,0) and the upper-right corner maps to (1,1).
'pixels' (default)	<p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p>
'inches'	Inches.
'centimeters'	Centimeters.
'points'	Points. One point equals 1/72nd of an inch.
'characters'	<p>These units are based on the default system font character size.</p> <ul style="list-style-type: none"> <li>• Character width = width of the letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>

MATLAB measures all units from the lower left corner of the parent object.

If you change the value of the `Units` property, it is good practice to return it to its default value after completing your computation to avoid affecting other functions that assume the `Units` property is set to the default value.

The order in which you specify the `Units` and `Position` properties has these effects:

- If you specify the `Units` property before the `Position` property, then MATLAB sets `Position` using the units you specified.

- If you specify the `Units` property after the `Position` property, MATLAB sets the position using the default `Units`. Then, MATLAB converts the `Position` values to the equivalent values in the units you specified.

**SizeChangedFcn — Uitablegroup resize callback function**

' ' (default) | function handle | cell array | string

Uitablegroup resize callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

Define this callback function to control the UI layout when the size of the uitablegroup changes.

The `SizeChangedFcn` callback executes in these circumstances:

- The uitablegroup becomes visible for the first time.
- The uitablegroup is visible while its size changes.
- The uitablegroup becomes visible for the first time after its size changes. This situation occurs when the size changes while the uitablegroup is invisible, and then it becomes visible later.

These are some of the important characteristics of the `SizeChangedFcn` callback and some recommended best practices:

- Consider delaying the display of the figure until after all the variables that the uitablegroup `SizeChangedFcn` uses are defined. This practice can prevent the uitablegroup `SizeChangedFcn` callback from returning an error. To delay the display of the figure, set its `Visible` property to `'off'`. Then, set the `Visible` property to `'on'` after you define all the variables that your `SizeChangedFcn` callback uses.
- Use the `gcbo` function in your `SizeChangedFcn` code to get the uitablegroup object that the user is resizing. See the description of the figure `SizeChangedFcn` for an example that uses `gcbo`.
- All visible Uitablegroups that are specified in normalized units resize before the parent figure does. All visible, nested uitablegroups resize from inside-out.

---

**Tip** As an easy alternative to specifying a `SizeChangedFcn` callback, you can set the `Units` property of all the objects you put inside the `uitabgroup` to `'normalized'`. Doing so makes those components scale proportionally with the `uitabgroup`.

---

See “Managing the Layout in Resizable UIs” for more information.

Example: `@myfun`

Example: `{@myfun,x}`

## Interactive Control

### SelectionChangedFcn — Uitable selection callback

`' '` (default) | function handle | cell array | string

Uitable selection callback, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

This callback function executes when the user selects a different tab within the `uitabgroup`.

If you set the `SelectionChangedFcn` property to a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Callbackdata Field	Description
<code>OldValue</code>	Previously selected <code>uitab</code> , or <code>[]</code> if none was selected
<code>NewValue</code>	Currently selected <code>uitab</code>
<code>Source</code>	The parent <code>uitabgroup</code> object
<code>EventName</code>	<code>'SelectionChanged'</code>

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

Example: `@myfun`

Example: `{@myfun,x}`

## **ButtonDownFcn** — Button-press callback function

' ' (default) | function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The **ButtonDownFcn** callback is a function that executes when the user clicks a mouse button on the `uitabgroup`.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

## **UIContextMenu** — Uitable context menu

empty `GraphicsPlaceholder` array (default) | `uicontextmenu` object

Uitable context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when the user right-clicks on the `uitablegroup`. Create the context menu using the `uicontextmenu` function.

## **Callback Execution Control**

### **Interruptible** — Callback interruption

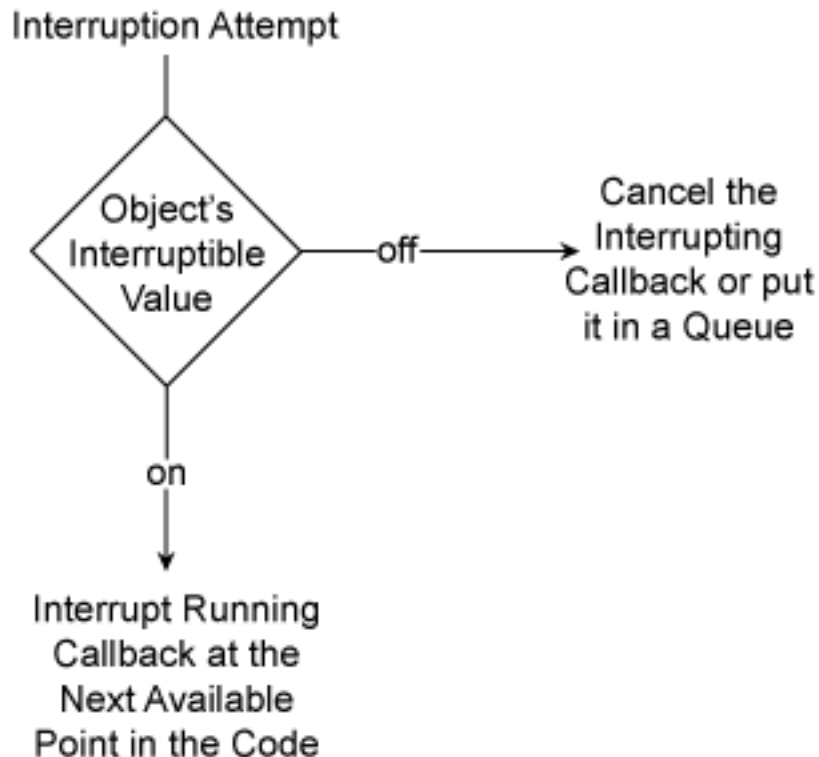

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The **Interruptible** property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put into a queue.

If a uitabgroup callback is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- 'on' — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

---

**Note:** Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a `DeleteFcn`, `CloseRequestFcn`, or `SizeChangedFcn` callback, then the interruption occurs regardless of the `Interruptible` property value.
  - If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the `Interruptible` property value.
  - MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.
- 

See “Interrupt Callback Execution” for an example that shows how the `Interruptible` and `BusyAction` properties affect the behavior of a program.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' (default) or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The **BusyAction** property of the source of the interrupting callback determines how MATLAB handles its execution. The **BusyAction** property has these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- 'cancel' — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The **Interruptible** property of the object whose callback is running determines if interruption is allowed. If **Interruptible** is set to:

- on — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- off — The **BusyAction** property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the **BusyAction** and **Interruptible** properties affect the behavior of a program.

## Creation and Deletion Control

### **BeingDeleted** — Deletion status of uitabgroup

'off' (default) | 'on'

This property is read only.

Deletion status of uitabgroup, returned as 'on' or 'off'. MATLAB sets the **BeingDeleted** property to 'on' when the delete function of the uitabgroup begins execution (see the **DeleteFcn** property). The **BeingDeleted** property remains set to 'on' until the uitabgroup no longer exists.

Check the value of the **BeingDeleted** property to verify that the uitabgroup is not about to be deleted before querying or modifying it.

### **CreateFcn** — Uitabgroup creation function

function handle | cell array | string

Uitabgroup creation function, specified as one of these values:

- Function handle

- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This property specifies a callback function to execute when MATLAB creates the `uitabgroup`. MATLAB initializes all `uitabgroup` property values before executing the `CreateFcn` callback. If you do not specify the `CreateFcn` property, then MATLAB executes a default creation function.

Use the `gcb0` function in your `CreateFcn` code to get the handle to the `uitabgroup` that is being created.

Setting the `CreateFcn` property on an existing `uitabgroup` has no effect.

---

**Note:** Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. Copying the `uitabgroup` object causes the `CreateFcn` callback to execute repeatedly.

---

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

## **DeleteFcn — Uitablegroup deletion function**

`function handle` | `cell array` | `string`

Uitablegroup deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `DeleteFcn` property specifies a callback function to execute when MATLAB deletes the uitabgroup (for example, when the end user deletes the figure). MATLAB executes the `DeleteFcn` callback before destroying the properties of the uitabgroup. If you do not specify the `DeleteFcn` property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your `DeleteFcn` code to get the handle to the uitabgroup that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

## Identifiers

### **SelectedTab** — Currently selected tab

uitab object

Currently selected tab, specified as a uitab object.

Use this property to determine the currently selected uitab within a uitabgroup. You can also use this property to set the default uitab selection.

The default value of the `SelectedTab` property is the first uitab that you add to the uitabgroup.

### **Type** — Type of graphics object

'uitabgroup'

This property is read only.

Type of graphics object, returned as 'uitabgroup'.

### **Tag** — Uitabgroup identifier

' ' (default) | string

Uitabgroup identifier, specified as a string. You can specify a unique `Tag` value to serve as an identifier for the uitabgroup. When you need access to the uitabgroup elsewhere in your code, you can use the `findobj` function to search for the uitabgroup based on the `Tag` value.

Example: `'tabgroup1'`

Data Types: char

**UserData** — Data to associate with the uitabgroup object

empty array (default) | array

Data to associate with the uitabgroup object, specified as any array. Specifying **UserData** can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: [1 2 3]

Example: 'April 21'

Example: struct('value1',[1 2 3],'value2','April 21')

Example: {[1 2 3],'April 21'}

**Parent/Child****Parent** — Uitabgroup parent

figure | uipanel | uitab

Uitabgroup parent, specified as a figure, uipanel, or uitab. You can move a uitabgroup to a different figure, uipanel, or uitab by setting this property to the handle of the target figure, uipanel, or uitab.

**Children** — Children of uitabgroup

empty `GraphicsPlaceholder` array (default) | 1-D array of component objects

Children of the uitabgroup, returned as an empty `GraphicsPlaceholder` or a 1-D array of component objects. The children of uitabgroup are uitabs.

You cannot add or remove children using the **Children** property of the uitabgroup. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the order of the tabs displayed on the screen.

To add a child to this list, set the **Parent** property of the child component to be the uitabgroup object.

Objects with the **HandleVisibility** property set to 'off' do not list in the **Children** property. For more information, see the **HandleVisibility** property description.

**HandleVisibility** — Visibility of Uitabgroup handle

'on' (default) | 'callback' | 'off'

Visibility of Uitabgroup handle, specified as 'on', 'callback', or 'off'.

This property controls the visibility of the uitabgroup handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The `HandleVisibility` property also controls the visibility of the object's handle in the parent figure's `CurrentObject` property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
'on'	The uitabgroup handle is always visible.
'callback'	The uitabgroup handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uitabgroup at the command-line, but allows callback functions to access it.
'off'	The uitabgroup handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the <code>HandleVisibility</code> to 'off' to temporarily hide the handle during the execution of that function.

Set the graphics root `ShowHiddenHandles` property to 'on' to make all handles visible, regardless of their `HandleVisibility` value. This setting has no effect on their `HandleVisibility` values.

uitab | uitabgroup

## More About

- “Access Property Values”
- “Default Property Values”

# uitable

Create table UI component

## Syntax

```
t = uitable
t = uitable(Name,Value,...)
t = uitable(parent)
t = uitable(parent,Name,Value,...)
```

## Description

`t = uitable` creates a `uitable` in an existing figure and returns the `uitable` object, `t`. If there is no figure available, then MATLAB creates a new figure to serve as the parent.

`t = uitable(Name,Value,...)` creates a `uitable` and specifies one or more `uitable` property names and corresponding values. Use this syntax to override the default `uitable` properties.

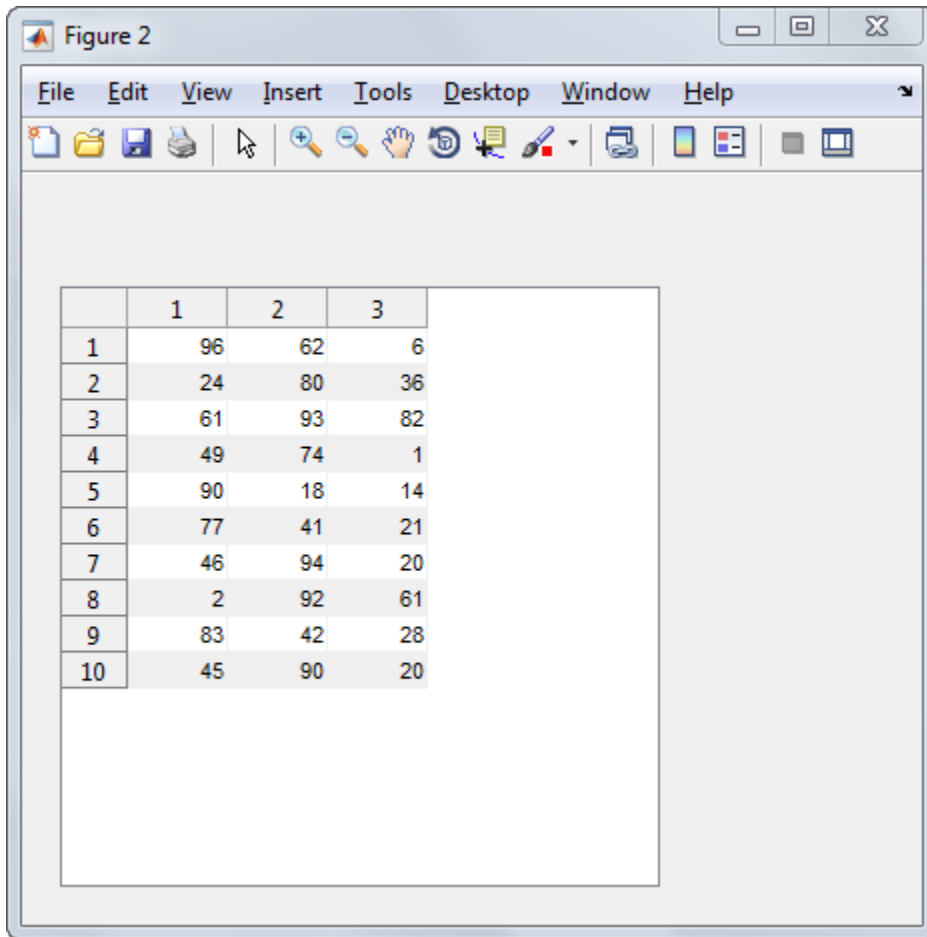

`t = uitable(parent)` creates a `uitable` and designates a specific parent object. The `parent` argument can be a figure, `uipanel`, `uibuttongroup`, or `uitab` object.

`t = uitable(parent,Name,Value,...)` creates a `uitable` with a specific parent and one or more `uitable` properties.

## Examples

This example creates a `uitable` containing three columns of random numbers. The columns in this `uitable` are 50 pixels wide.

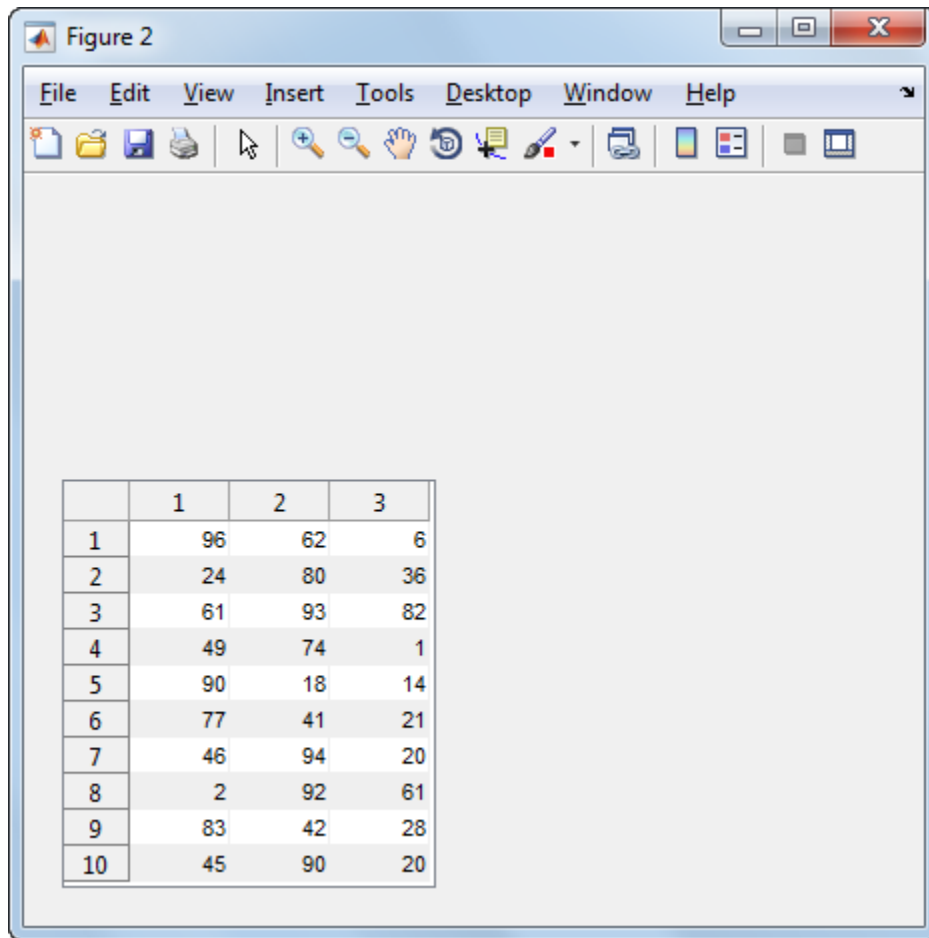

```
f = figure;
d = gallery('integerdata',100,[10 3],0);
t = uitable(f,'Data',d,'ColumnWidth',{50});
```

	1	2	3
1	96	62	6
2	24	80	36
3	61	93	82
4	49	74	1
5	90	18	14
6	77	41	21
7	46	94	20
8	2	92	61
9	83	42	28
10	45	90	20

Next, set the width and height of the uitable to match the size of the enclosing rectangle:

```
t.Position(3) = t.Extent(3);
t.Position(4) = t.Extent(4);
```

This example creates a uitable with specific column names and row names:

```
f = figure('Position',[440 500 461 146]);

% create the data
d = [1 2 3; 4 5 6; 7 8 9];

% Create the column and row names in cell arrays
cnames = {'X-Data', 'Y-Data', 'Z-Data'};
rnames = {'First', 'Second', 'Third'};
```

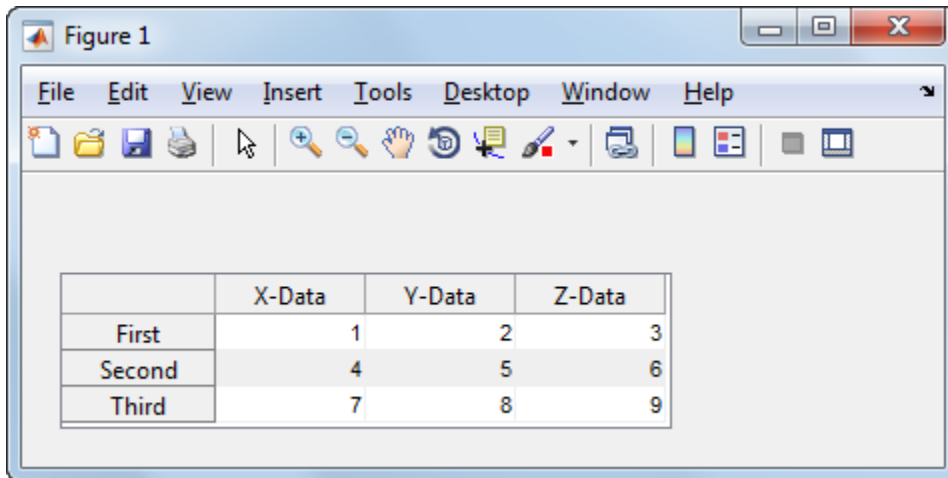

```

% Create the uitable
t = uitable(f,'Data',d,...
 'ColumnName',cnames,...
 'RowName',rnames);

% Set width and height
t.Position(3) = t.Extent(3);
t.Position(4) = t.Extent(4);

```

This example creates a table containing different types of data:

- First two columns are numeric. The first column displays values with up to four decimal places. The second column displays values in currency format.
- Third column contains check boxes (specified as `logical` values in the `Data` array).
- Fourth column contains pop-up menus, each having two choices: `Fixed` and `Adjustable`.

```
f = figure('Position',[100 100 400 150]);
```

```

% Column names and column format
columnname = {'Rate','Amount','Available','Fixed/Adj'};
columnformat = {'numeric','bank','logical',{'Fixed' 'Adjustable'}};

```

```

% Define the data
d = [6.125678 456.3457 true 'Fixed';...
 6.75 510.2342 false 'Adjustable'];...

```

```
 7 658.2 false 'Fixed'}};

% Create the uitable
t = uitable('Data', d,...
 'ColumnName', columnname,...
 'ColumnFormat', columnformat,...
 'ColumnEditable', [false false true true],...
 'RowName', []);

% Set width and height
t.Position(3) = t.Extent(3);
t.Position(4) = t.Extent(4);
```

## More About

### Pixels

Distances in pixels are independent of your system resolution on Windows and Macintosh systems:

- On Windows systems, a pixel is 1/96th of an inch.
- On Macintosh systems, a pixel is 1/72nd of an inch.

On Linux systems, the size of a pixel is determined by your system resolution.

## Tips

If the `ColumnEditable` property is set to `true` for specific columns, the user can edit values in that column. By default, this property is set to `false` for all columns. If a noneditable column contains pop-up choices, then only the current choice is visible in the table.

The `CellEditCallback` function executes after the user edits a value and perform any of these actions:

- Press the **Enter** key.
- Click anywhere else within the table.
- Click anywhere else within the same figure window, or in another figure window.

The `CellSelectionCallback` function executes when the user selects one or more table cells or modifies the current selection.

You cannot select table cells programmatically. Directly clicking cells is the only method of selection.

- “Access Property Values”

`figure` | `format` | `Uitable` Properties

**Introduced in R2008a**

## Uitable Properties

Control appearance and behavior of table

Uitable objects are tables that list data in a figure. The `uitable` function creates a table and sets any required properties before displaying it. By changing uitable property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
t = uitable;
fgcolor = t.ForegroundColor;
t.ForegroundColor = [0 0 1];
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Appearance

#### **Visible** — Uitable visibility

'on' (default) | 'off'

Uitable visibility, specified as 'on' or 'off'. When `Visible` is 'off', the uitable is not visible, but you can query and set its properties.

To make your program start faster, set the `Visible` property of all uitables that are not initially displayed to 'off'.

#### **BackgroundColor** — Uitable cell background color

RGB triplet | m-by-3 matrix of RGB triplets

Uitable cell background color, specified as an RGB triplet or an m-by-3 matrix of RGB triplets. An RGB triplet is a row vector that specifies the intensities of the red, green, and blue components of the color. The intensities must be in the range, [0, 1]. Color names are not valid.

Specify an m-by-3 matrix when you want the shading of the table rows to follow a repeating pattern of m different colors. Each row of the matrix must be an RGB triplet. MATLAB uses the rows of the matrix when the `RowStripping` property is 'on'. The table background is not striped unless both `RowStripping` is 'on' and the background color is an m-by-3 matrix.

The following table lists the RGB triplets for commonly used colors.

Color	RGB Triplet
Yellow	[1 1 0]
Magenta	[1 0 1]
Cyan	[0 1 1]
Red	[1 0 0]
Green	[0 1 0]
Blue	[0 0 1]
White	[1 1 1]
Black	[0 0 0]

Example: [1 1 1]

Example: [1 1 1; .9 .9 .9]

### **ForegroundColor** — Cell text color

[0 0 0] (default) | RGB triplet | short name | long name

Cell text color, specified as an RGB triplet, short name, or long name. The color you specify sets the text color for all cells.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]

Long Name	Short Name	RGB Triplet
'black'	'k'	[0 0 0]

Example: [0 0 1]

Example: 'b'

Example: 'blue'

## Location and Size

### Position — Location and size of uitable

[left bottom width height]

Location and size of the uitable relative to the parent, specified as the vector, [left bottom width height]. This table describes each element in the vector.

Element	Description
left	Distance from the inner left edge of the parent container to the outer left edge of the uitable
bottom	Distance from the inner bottom edge of the parent container to the outer bottom edge of the uitable
width	Distance between the right and left outer edges of the uitable
height	Distance between the top and bottom outer edges of the uitable

All measurements are in units specified by the `Units` property.

---

**Note:** If the parent of the uitable is a figure, then the `Position` values are relative to the figure's *drawable area*. The drawable area of a figure is the area inside the window borders, excluding the menu bar and tool bar.

---

Use the `Extent` property to determine proper sizing for a uitable with respect to the table data. Set the `width` and `height` of `Position` property to the width and height of the `Extent` property. Be aware that if the table has large extents, doing this can cause the table to extend beyond the right or top edge of its parent container.

Example: [0 0 300 300]

## Example: Set Width and Height to Accommodate Data Size

You can combine dot notation and array indexing when you want to change one or two consecutive values in the `Position` vector. For example, this code sets the width and height of the uitable to match the `Extent` of the table:

```
t = uitable('Data',rand(10,3));
t.Position(3:4) = t.Extent(3:4);
```

### Units — Units of measurement

'pixels' (default) | 'normalized' | 'inches' | 'centimeters' | 'points' | 'characters'

Units of measurement, specified one of the values from this table.

Units Value	Description
'pixels' (default)	<p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p>
'normalized'	<p>These units are normalized with respect to the parent container. The lower-left corner of the container maps to (0,0) and the upper-right corner maps to (1,1).</p>
'inches'	Inches.
'centimeters'	Centimeters.

Units Value	Description
'points'	Points. One point equals 1/72nd of an inch.
'characters'	These units are based on the default system font character size. <ul style="list-style-type: none"> <li>• Character width = width of the letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>

MATLAB measures all units from the lower left corner of the parent object.

This property affects the **Position** property. If you change the units, then it is good practice to return it to its default value after completing your computation to prevent affecting other functions that assume **Units** is the default value.

The order in which you specify the **Units** and **Position** properties has these effects:

- If you specify the **Units** before the **Position** property, then MATLAB sets **Position** using the units you specify.
- If you specify the **Units** property after the **Position** property, MATLAB sets the position using the default **Units**. Then, MATLAB converts the **Position** value to the equivalent value in units you specify.

### **Extent — Size of uitable rectangle**

four-element row vector

This property is read only.

Size of the uitable rectangle, returned as a four-element row vector. The first two elements of the vector are always zero. The third and fourth elements are the width and height of the rectangle containing the uitable, respectively. All measurements are in units specified by the **Units** property.

MATLAB determines the size of the rectangle based on the current **Data**, **RowName** and **ColumnName** property values. MATLAB estimates the width and height values using the column and row widths. The estimated extent can be larger than the figure.

When the uitable **Units** property is set to 'normalized', the **Extent** values are measured relative to the figure, regardless of whether the uitable is contained in (parented to) a uipanel.

Consider using the `Extent` property value when specifying the width and height values of the uitable `Position` property.

## Font Style

### FontName — Font for displaying cell content

string

Font for displaying the cell content, specified as a string. To display and print properly, the font name must refer to a font that the user's system supports. The default font is system dependent.

To use a fixed-width font, set the `FontName` property to the string, `'FixedWidth'`. This setting instructs MATLAB to use the value of the root `FixedWidthFontName` property, which you can set in the `startup.m` file.

For more information about the `startup.m` file, see “Startup Options in MATLAB Startup File”

Example: `'Arial'`

### FontSize — Font size for uitable cell content

positive number

Font size for the uitable cell content, specified as a positive number. MATLAB uses the units specified by `FontUnits`. The default size is system-dependent. If you set `FontUnits` to `'normalized'`, then the `FontSize` value is a number between 0 and 1.

Example: 12

Example: 12.5

Data Types: double

### FontUnits — Units of font size for uitable cell contents

`'points'` (default) | `'normalized'` | `'inches'` | `'centimeters'` | `'pixels'`

Units of font size for the uitable cell contents, specified as one of the values from this table.

Units Value	Description
<code>'points'</code>	Points. One point is 1/72nd of an inch.

Units Value	Description
'normalized'	Normalized values for specifying the font size as a fraction of the uitable height. When you resize the uitable, MATLAB scales the displayed font to maintain that fraction.
'inches'	Inches.
'centimeters'	Centimeters.
'pixels'	<p>Pixels.</p> <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p>

**FontWeight** — Font weight for uitable cell contents

'normal' (default) | 'bold'

Font weight for the uitable cell contents, specified as a value from the following table.

FontWeight Value	Description
'normal'	Normal font weight
'bold'	Heavy font weight

Not all fonts support all font weights. Therefore, if you specify an unsupported value for the FontWeight property, the result might appear the same as the default.

---

**Note:** The 'light' and 'demi' font weight values have been removed in R2014b. If you specify either of these values, the result is a normal font weight.

---

**FontAngle** — Character slant of uitable cell contents

'normal' (default) | 'italic'

Character slant of the uitable cell contents, specified as 'normal' or 'italic'. MATLAB uses this property to select a font from those available on your system. Setting this property to 'italic' selects a slanted version of the font, if it is available on your system.

---

**Note:** The 'oblique' value has been removed. Use 'italic' instead.

---

## Interactive Control

### CellEditCallback — Cell edit callback function

function handle | cell array | string

Cell edit callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This function makes the uitable respond when the user changes the contents of a table cell. You can use this callback function to perform calculations or validate user input.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Property	Description
Indices	1-by-2 array containing the row and column indices of the cell the user edited.
PreviousData	Previous cell data. The default is an empty matrix, [ ].
EditData	User-entered string.
NewData	Value that MATLAB wrote to the Data property array. It is either the same as EditData or a converted value.

Property	Description
	The <code>NewData</code> property is empty if MATLAB detects an error in the user-entered data.
<code>Error</code>	<p>Error message returned if MATLAB detects an error in the user-entered data.</p> <p>The <code>Error</code> property is empty when MATLAB successfully writes the value to the <code>Data</code> property.</p> <p>If the <code>Error</code> property is not empty, then the <code>CellEditCallback</code> can display the string, or it can attempt to fix the problem.</p>

When the user edits a cell, MATLAB attempts to store the user-entered value in the `Data` property, converting the value if necessary. Next, MATLAB calls the `CellEditCallback` function and passes the callback data. If there is no `CellEditCallback` function, and the user-entered data results in an error, then the contents of the cell reverts to its previous value and no error displays.

## Example: Evaluate User Input

This example shows how to create a callback function that evaluates a user-entered data in a numeric table cell. Paste this code into an editor and run it to see how it works.

```
function myui
 f = figure;
 myData = { 'A' 31; 'B' 41; 'C' 5; 'D' 2.6};
 t = uitable('Parent',f,...
 'Position', [25 25 700 200], ...
 'Data',myData,...
 'ColumnEditable', [false true], ...
 'CellEditCallback',@converttonum);
 function converttonum(hObject,callbackdata)
 numval = eval(callbackdata.EditData);
 r = callbackdata.Indices(1)
 c = callbackdata.Indices(2)
 hObject.Data{r,c} = numval;
 end
end
```

When you run `myui`, you can change a value in the second column of the table. In response, the `converttonum` callback function executes. The `converttonum` function

uses the `eval` function to evaluate your input. Then, it sets the cell data to the value of `numval`. For example, if you enter `pi` or `1+1`, the `converttonum` function sets the table cell value to a numeric representation of the input. Because there is no error checking in the `converttonum` function, invalid expressions return an error and the new value of the table cell becomes NaN.

### **CellSelectionCallback** — Cell selection callback function

function handle | cell array | string

Cell selection callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback function executes when the user performs one of the following actions:

- Highlights a data cell (not a row or column header cell) by clicking it or navigating to it with an arrow key
- Adds a new cell to their selection by **Shift**-clicking it
- Deselects a cell by **Ctrl**-clicking it

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains one property, `Indices`. The `Indices` property is an n-by-2 array containing the row index and column index of the selected cells.

Example: `@myfun`

Example: `{@myfun,x}`

### **ColumnEditable** — Ability to edit column cells

empty matrix (`[]`) (default) | logical 1-by-n array | scalar logical value

Ability to edit column cells, specified as:

- An empty matrix (`[]`) — No columns are editable.

- A logical 1-by-n array — Specify which columns are editable. The value of n is equal to the number of columns in the table. Each value in the array corresponds to a table column. A value of `true` in the array makes the cells in that column editable. A value of `false` makes the cells in that column uneditable.
- A scalar logical value — Make the entire table editable or uneditable.

Table columns that contain check boxes or pop-up menus must be editable so the user can interact with these controls.

Example: `[]`

Example: `[false true true]`

Example: `false`

### **RearrangeableColumns** — Ability to rearrange table columns

`'off'` (default) | `'on'`

Ability to rearrange table columns, specified as `'off'` or `'on'`. This property provides a way to let users reorder the table columns (but not the labels) by clicking and dragging the column headers.

---

**Note:** Rearranging table columns in the UI does not affect the columns in the `Data` property array.

---

### **ButtonDownFcn** — Button-press callback function

`''` (default) | function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `ButtonDownFcn` callback is a function that executes when the user clicks a mouse button on the `uitable`. The callback executes in the following situations:

- The user right-clicks the uitable, and the uitable **Enable** property is set to 'on'.
- The end user right-clicks or left-clicks the Uitable, and the uitable **Enable** property is set to 'off' or 'inactive'.

Example: @myfun

Example: {@myfun, x}

Data Types: function\_handle | cell | char

### KeyPressFcn — Key press callback function

' ' (default) | function handle | cell array | string

Key press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback function executes when the uitable object has focus and the user presses a key. If you do not define a function for this property, MATLAB passes key presses to the parent figure. Repeated key presses retain the focus of the uitable, and the function executes with each key press. If the user presses multiple keys at approximately the same time, MATLAB detects the key press for the last key pressed.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Property	Description	Examples:			
		a	=	Shift	Shift-a
Character	The character that displays as a result of pressing a key or keys. The character can be empty or unprintable.	' a '	' = '	' '	' A '

Property	Description	Examples:			
		a	=	Shift	Shift-a
Modifier	A cell array containing the names of one or more modifier keys that are being pressed (such as, <b>Ctrl</b> , <b>Alt</b> , <b>Shift</b> ).	{1x0 cell}	{1x0 cell}	{'shift'}	{'shift'}
Key	The key being pressed, identified by the (lowercase) label on the key, or a descriptive string.	'a'	'equal'	'shift'	'a'
Source	The object that has focus when the user presses the key.	uitable object	uitable object	uitable object	uitable object
EventName	The action that caused the callback function to execute.	'KeyPress'	'KeyPress'	'KeyPress'	'KeyPress'

Pressing modifier keys affects the callback data in the following ways:

- Modifier keys can affect the **Character** property, but do not change the **Key** property.
- Certain keys, and keys modified with **Ctrl**, put unprintable characters in the **Character** property.
- **Ctrl**, **Alt**, **Shift**, and several other keys, do not generate **Character** property data.

You also can query the **CurrentCharacter** property of the figure to determine which character the user pressed.

Example: @myfun

Example: {@myfun, x}

Data Types: function\_handle | cell | char

### KeyReleaseFcn — Key-release callback function

' ' (default) | function handle | cell array | string

Key-release callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback function executes when the uitable object has focus and the user releases a key.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Property	Description	Examples:			
		a	=	Shift	Shift-a
Character	Character interpretation of the key that was released.	'a'	'='	' '	'A'
Modifier	Current modifier, such as 'control'. This value is always an empty cell array for aseFcn callbacks.	{1x0 cell}	{1x0 cell}	{1x0 cell}	{1x0 cell}
Key	Name of the key that was released, identified by the lowercase label on the key, or a descriptive string.	'a'	'equal'	'shift'	'a'
Source	The object that has focus when the user presses the key.	uitable object	uitable object	uitable object	uitable object
EventName	The action that caused the callback function to execute.	'ase'	'ase'	'ase'	'ase'

Pressing modifier keys affects the callback data in the following ways:

- Modifier keys can affect the **Character** property, but do not change the **Key** property.
- Certain keys, and keys modified with **Ctrl**, put unprintable characters in the **Character** property.
- **Ctrl**, **Alt**, **Shift**, and several other keys, do not generate **Character** property data.

You also can query the **CurrentCharacter** property of the figure to determine which character the user pressed.

Example: @myfun

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

**Enable – Operational state of uitable**

'on' (default) | 'inactive' | 'off'

Operational state of uitable, specified as 'on', 'off', or 'inactive'. The Enable property controls whether the uitable responds to button clicks. There are three possible values:

- 'on' – The uitable is operational.
- 'off' – The uitable is not operational and appears grayed-out.
- 'inactive' – The uitable is not operational, but it has the same appearance as when Enable is 'on'.

The value of the Enable property and the type of button click determine how the UI responds.

Enable Value	Response to Left-Click	Response to Right-Click
'on'	The uitable's <code>CellSelectionCallback</code> function executes (only for table cells, not header cells). The <code>Indices</code> property updates in the callback data object that MATLAB passes to the callback function.	<ol style="list-style-type: none"> <li>1 The figure's <code>WindowButtonDownFcn</code> callback executes.</li> <li>2 The uitable <code>ButtonDownFcn</code> callback executes.</li> </ol>
'off' or 'inactive'	<ol style="list-style-type: none"> <li>1 The figure's <code>WindowButtonDownFcn</code> callback executes.</li> <li>2 The uitable's <code>ButtonDownFcn</code> callback executes.</li> </ol>	<ol style="list-style-type: none"> <li>1 The figure's <code>WindowButtonDownFcn</code> callback executes.</li> <li>2 The uitable's <code>ButtonDownFcn</code> callback executes.</li> </ol>

**TooltipString – Tooltip text**

string

Tooltip text, specified as a string. When the user hovers the mouse pointer over the uitable and leaves it there, the tooltip displays. If you want to create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that string.

Example: 'Some string'

## Example: Specify TooltipString Containing Two Lines

```
t = uitable;
s = sprintf('UITable tooltip line 1\nUITable tooltip line 2');
t.TooltipString = s;
```

Data Types: char

### **UIContextMenu** — Uitable context menu

empty GraphicsPlaceholder array (default) | uicontextmenu object

Uitable context menu, specified as a uicontextmenu object. Use this property to display a context menu when the user right-clicks on the uitable. Create the context menu using the uicontextmenu function.

### **Selected** — Selection status of uitable

'off' (default) | 'on'

---

**Note:** The behavior of the Selected property changed in R2014b, and it is not recommended. It no longer has any effect on uitable. This property might be removed in a future release.

---

### **SelectionHighlight** — Ability to highlight selection handles

'on' (default) | 'off'

---

**Note:** The behavior of the SelectionHighlight property changed in R2014b, and it is not recommended. It no longer has any effect on uitable. This property might be removed in a future release.

---

## Callback Execution Control

### **Interruptible** — Callback interruption

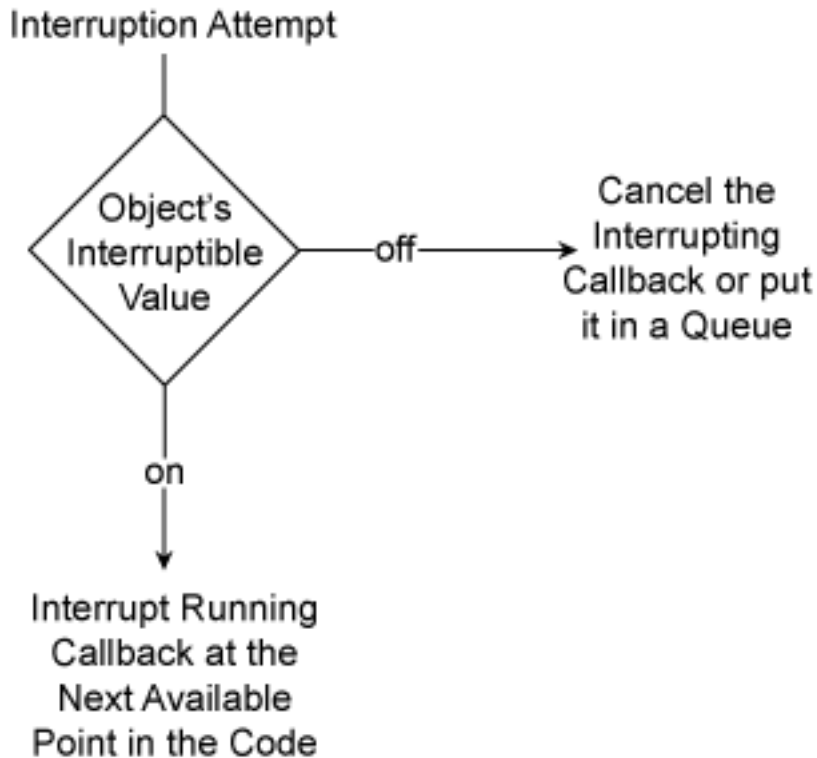

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The Interruptible property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put into a queue.

If a uitable callback is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- 'on' — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

---

**Note:** Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a `DeleteFcn`, `CloseRequestFcn`, or `SizeChangedFcn` callback, then the interruption occurs regardless of the `Interruptible` property value.
  - If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the `Interruptible` property value.
  - MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.
- 

See “Interrupt Callback Execution” for an example that shows how the `Interruptible` and `BusyAction` properties affect the behavior of a program.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' (default) or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The **BusyAction** property of the source of the interrupting callback determines how MATLAB handles its execution. The **BusyAction** property has these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- 'cancel' — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The **Interruptible** property of the object whose callback is running determines if interruption is allowed. If **Interruptible** is set to:

- on — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- off — The **BusyAction** property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the **BusyAction** and **Interruptible** properties affect the behavior of a program.

### **HitTest — Ability to become current object**

'on' (default) | 'off'

Ability to become current object, specified as 'on' or 'off':

- Setting the value to 'on' allows the uitable to become the current object when the user clicks on it. A value of 'on' also allows the figure **CurrentObject** property and the **gco** function to report the uitable as the current object.
- Setting the value to 'off' sets the figure **CurrentObject** property to an empty **GraphicsPlaceholder** array when the user clicks on the uitable.

---

**Note:** Use the **Enable** property to enable or disable a uitable.

---

## **Creation and Deletion Control**

### **BeingDeleted — Deletion status of uitable**

'off' (default) | 'on'

This property is read only.

Deletion status of uitable, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the uitable begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the uitable no longer exists.

Check the value of the `BeingDeleted` property to verify that the uitable is not about to be deleted before querying or modifying it.

### **CreateFcn — Uitable creation function**

function handle | cell array | string

Uitable creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This property specifies a callback function to execute when MATLAB creates the uitable. MATLAB initializes all uitable property values before executing the `CreateFcn` callback. If you do not specify the `CreateFcn` property, then MATLAB executes a default creation function.

Use the `gcbo` function in your `CreateFcn` code to get the handle to the uitable that is being created.

Setting the `CreateFcn` property on an existing uitable has no effect.

---

**Note:** Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. Copying the uitable object causes the `CreateFcn` callback to execute repeatedly.

---

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

**DeleteFcn — Uitable deletion function**

function handle | cell array | string

Uitable deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `DeleteFcn` property specifies a callback function to execute when MATLAB deletes the uitable (for example, when the end user deletes the figure). MATLAB executes the `DeleteFcn` callback before destroying the properties of the uitable. If you do not specify the `DeleteFcn` property, then MATLAB executes a default deletion function.

Use the `gcb0` function in your `DeleteFcn` code to get the handle to the uitable that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

**Identifiers****Type — Type of graphics object**`'uitable'`

This property is read only.

Type of graphics object, returned as `'uitable'`.

**Tag — Uitable identifier**`''` (default) | string

Uitable identifier, specified as a string. You can specify a unique `Tag` value to serve as an identifier for the uitable. When you need access to the uitable elsewhere in your code, you can use the `findobj` function to search for the uitable based on the `Tag` value.

Example: `'table1'`

Data Types: `char`

### **UserData** — Data to associate with the uitable object

empty array (default) | array

Data to associate with the uitable object, specified as any array. Specifying `UserData` can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: `{[1 2 3],'April 21'}`

## **Parent/Child**

### **Parent** — Uitable parent

`figure` | `uipanel` | `uibbuttongroup` | `uitab`

Uitable parent, specified as a `figure`, `uipanel`, `uibbuttongroup`, or `uitab`. You can move a uitable to a different `figure`, `uipanel`, `uibbuttongroup`, or `uitab` by setting this property to the handle of the target `figure`, `uipanel`, `uibbuttongroup`, or `uitab`.

### **Children** — Children of uitable

empty array

Children of uitable, returned as an empty array. Uitable objects have no children. Setting this property has no effect.

### **HandleVisibility** — Visibility of Uitable handle

`'on'` (default) | `'callback'` | `'off'`

Visibility of Uitable handle, specified as `'on'`, `'callback'`, or `'off'`.

This property controls the visibility of the uitable handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

The `HandleVisibility` property also controls the visibility of the object's handle in the parent figure's `CurrentObject` property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
'on'	The uitable handle is always visible.
'callback'	The uitable handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uitable at the command-line, but allows callback functions to access it.
'off'	The uitable handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the <code>HandleVisibility</code> to 'off' to temporarily hide the handle during the execution of that function.

Set the graphics root `ShowHiddenHandles` property to 'on' to make all handles visible, regardless of their `HandleVisibility` value. This setting has no effect on their `HandleVisibility` values.

## Table Data

### Data — Table content

numeric array | cell array

Table content, specified as a numeric array or cell array. The table data can be any numeric type, `logical`, or `char`. Use a cell array to specify a mixture of different data types.

The `ColumnFormat` property specifies the format for displaying the table contents. Therefore, if there is a mismatch between the data type of the `Data` property array and the `ColumnFormat` property, MATLAB converts the data value or displays a warning. See the `ColumnFormat` property description for more information.

To prevent warnings that might occur when users enter invalid data, write a `CellEditCallback` function to convert the data to the appropriate type.

If the number of rows in the **Data** property array does not match the number of elements in the **RowName** array, then the number of rows in the resulting table is the larger of the two values. The same is true when the **ColumnName** property does not match the number of columns in the **Data** property array.

Example: `rand(10,3)`

Example: `{'blue' 5 true; 'orange' 25 false}`

## Table Layout

### RowName — Row heading names

'numbered' (default) | n-by-1 cell array of strings | empty cell array ({} ) | empty matrix ([])

Row heading names, specified as one of these values:

- 'numbered' — The row headings are sequential numbers that start at 1.
- Cell array — Each element of the cell array becomes the name of a row. Row names are restricted to one line of text. If you specify a 1-by-n cell array, MATLAB stores and returns the value as a n-by-1 cell array.
- Empty cell array ({} ) — The resulting table has no row headings.
- Empty matrix ([]) — The resulting table has no row headings

If the number of rows in the **Data** property array does not match the number of elements in the **RowName** array, then the number of rows in the resulting table is the larger of the two values.

Example: `{'Name'; 'Telephone Number'}`

Example: `{'Name'; []}`

### ColumnName — Column heading names

'numbered' (default) | n-by-1 cell array of strings | empty cell array ({} ) | empty matrix ([])

Column heading names, specified as one of these values:

- 'numbered' — The column headings are sequential numbers that start at 1.
- Cell array — Each element of the cell array becomes the name of a column. If you specify a 1-by-n cell array, MATLAB stores and returns the value as a n-by-1 cell

array. Specify a multiline column name as a string vector separated by vertical slash (`|`) characters. For example, the value, `'Telephone|Number'`, produces a column heading with a newline character between the words, “Telephone” and “Number”.

- Empty cell array (`{}`) — The resulting table has no column headings.
- Empty matrix (`[]`) — The resulting table has no column headings

If the number of columns in the `Data` property array does not match the number of elements in the `ColumnName` array, then the number of columns in the resulting table is the larger of the two values.

Example: `{'Name'; 'Telephone Number'}`

Example: `{'Name'; []}`

Example: `{'Name'; 'Telephone|Number'}`

### **ColumnWidth — Width of table columns**

`'auto'` (default) | 1-by-n cell array

Width of table columns, specified as a 1-by-n cell array or `'auto'`.

Each column in the cell array corresponds to a column in the table. The values are in pixel units. If you specify `'auto'`, then MATLAB calculates the width of the column automatically using several factors, one of which is the `ColumnName` property value.

You can combine fixed column widths and `'auto'` column widths in a cell array, or you can specify a single value of `'auto'` to make all column widths automatic.

Selecting **Auto Width** in the Table Property Editor has the same effect as setting the `ColumnWidth` property to `'auto'`.

Example: `'auto'`

Example: `{64 60 40}`

Example: `{64 'auto' 40}`

### **ColumnFormat — Cell display format**

empty cell array (`{}`) (default) | 1-by-n cell array of strings

Cell display format, specified as an empty cell array or a cell array of strings.

This property determines how the data in each column displays and the constraints for editing that data in the UI. The length of the cell array must equal the number of

columns in the table, and the elements of the cell array correspond to columns in the `Data` property array. If you do not want to specify a display format for a particular column, specify `[]` for that column. If you do not specify a format for a column, MATLAB determines the default display by the data type of the data in the cell.

Elements of the cell array must be one of the strings described in the following table.

Cell Format	Description
'char'	<p>Display a left-justified string.</p> <p>To edit a cell, the user types a string that replaces the existing string.</p>
'logical'	<p>Display a check box.</p> <p>To edit a cell, the user selects or clears the check box. Then, MATLAB sets the corresponding <code>Data</code> value to <code>true</code> or <code>false</code> accordingly.</p> <p>The <code>ColumnEditable</code> property value must be <code>true</code> to allow users to select or deselect the check boxes.</p> <p>Initially, a check box is selected when the corresponding <code>Data</code> value is <code>true</code>. The corresponding values in the <code>Data</code> property array must be of type <code>logical</code> to ensure the data displays correctly in the table.</p>
'numeric'	<p>Display a right-justified string equivalent to the Command Window display for numeric data. If an element in the <code>Data</code> property array is logical, then <code>1</code> or <code>0</code> appears in the table. If an element in the <code>Data</code> property array is not numeric and not logical, then <code>NaN</code> appears in the table.</p> <p>To edit a cell, the user can enter any string.</p> <p>If a user enters a string representing a constant, such as <code>pi</code>, you can code the <code>CellEditCallback</code> function to convert the value to the numeric equivalent. In this case, MATLAB attempts to convert the user-entered string to a numeric value and stores it in the <code>Data</code> property. Then, the <code>CellEditCallback</code> function executes. See the <code>CellEditCallback</code> description for an example.</p>

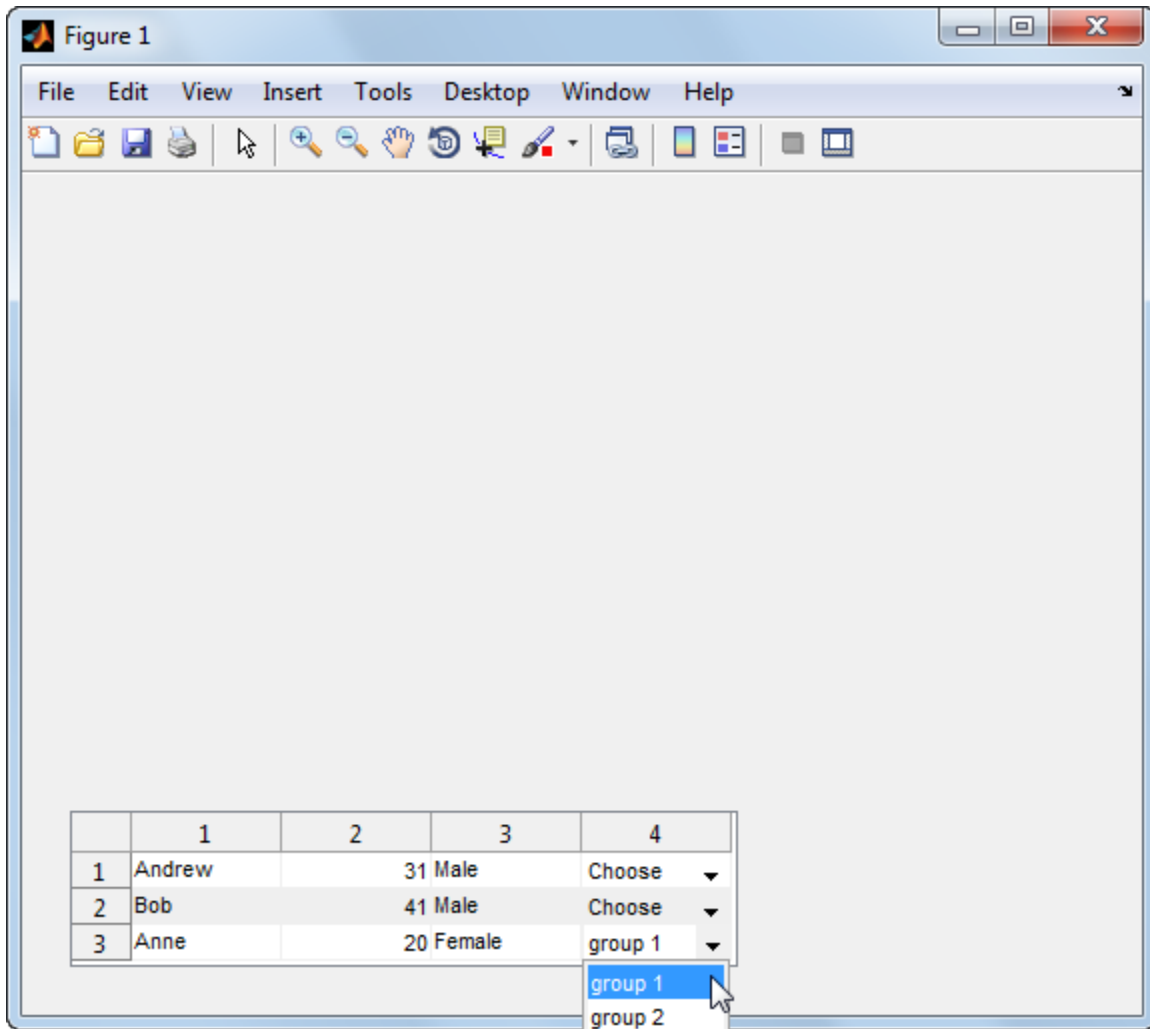

Cell Format	Description
A 1-by-n cell array of strings. For example, <code>{'one' 'two' 'three'}</code>	Display a pop-up menu.  To edit a cell, the user selects an item from the pop-up menu. MATLAB sets the corresponding <code>Data</code> property array value to the selected menu item. The <code>ColumnEditable</code> property value must be <code>true</code> to allow users to select items in the pop-up menu.
A string accepted by the <code>format</code> function, such as: <code>'short'</code> , <code>'bank'</code> , <code>'long'</code>	Display the <code>Data</code> property values using the specified format.

## Effect of Pop-Up Menu `ColumnFormat` and Various Data Types

The initial `Data` values do not have to be items in the pop-up menu. If the `ColumnFormat` value defines a pop-up menu, that pop-up menu displays the corresponding value in `Data` property until the user makes a selection.

For instance, suppose the `Data` property value for a given column is the string, `'Choose'` in all the rows, and the `ColumnFormat` value specifies a pop-up menu with the choices of `'group 1'` and `'group 2'`. When MATLAB creates the table, those table cells display `'Choose'` until the user selects an item in the pop-up menu:

```
f = figure;
myData = {'Andrew' 31 'Male' 'Choose'; ...
 'Bob' 41 'Male' 'Choose'; ...
 'Anne' 20 'Female' 'Choose'};
t = uitable('Parent', f,...
 'Position', [25 25 334 78],...
 'ColumnFormat', ({[] [] [] {'group 1' 'group 2'}}),...
 'ColumnEditable', true,...
 'Data', myData);
```

## Data Display of Editable Columns

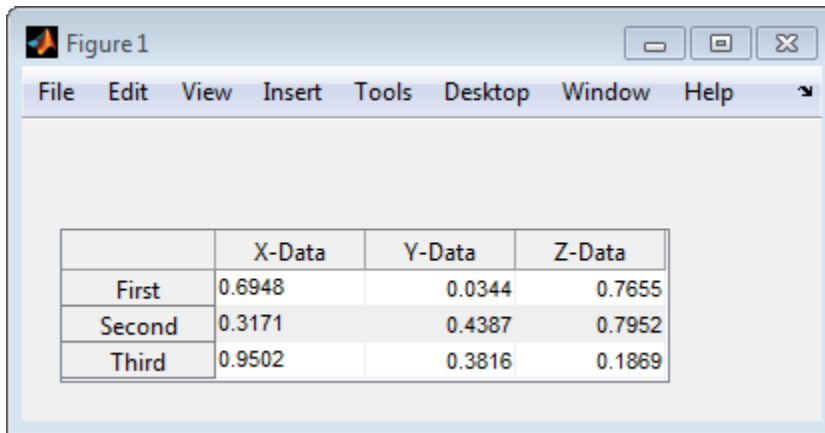

This table describes how various data types display with specific `ColumnFormat` values.

<code>ColumnFormat</code>
---------------------------

		'numeric'	'char'	'logical'
<b>Data Type of Data Array Value</b>	Any numeric type	Table displays number as-is.	MATLAB converts the value to a text string and displays it left-justified in the table.	Not recommended. MATLAB might return a warning when the user edits the cell, unless you define a <b>CellEditCallback</b> function.
	char	MATLAB converts the text string to a <b>double</b> value. If MATLAB cannot convert the string, then <b>NaN</b> displays. See <b>str2double</b> for more information.	Table displays the string as is.	Not recommended. MATLAB might return a warning when the user edits the cell, unless you define a <b>CellEditCallback</b> function.
	logical	Table displays logical values as numbers. MATLAB might return a warning when the user edits the cell, unless you define a <b>CellEditCallback</b> function.	Table displays 'true' or 'false'. MATLAB might return a warning when the user edits the cell, unless you define a <b>CellEditCallback</b> function.	Table displays logical values as check boxes.

For example, in the following table, the first column (X-Data) is left justified because the **ColumnFormat** value for that column is 'char'.

	X-Data	Y-Data	Z-Data
First	0.6948	0.0344	0.7655
Second	0.3171	0.4387	0.7952
Third	0.9502	0.3816	0.1869

### RowStripping — Alternate row shading

'on' (default) | 'off'

Alternate row shading, specified as 'on' or 'off'. This property controls the shading pattern of the table rows.

When the `RowStripping` value is set to 'on', the `BackgroundColor` matrix specifies the row colors to display in a repeating pattern. If the `BackgroundColor` matrix has only one row, then the shading is the same in all table rows.

When `RowStripping` is set to 'off', then the first color in the `BackgroundColor` property defines the shading for all rows in the table.

### More About

- “Access Property Values”
- “Default Property Values”

## uitoggletool

Create toggle button on toolbar

### Syntax

```
t = uitoggletool
t = uitoggletool(Name,Value,...)
t = uitoggletool(parent)
t = uitoggletool(parent,Name,Value,...)
```

### Description

`t = uitoggletool` creates a `uitoggletool` in the current figure's `uitoolbar` and returns the `uitoggletool` object, `t`. If there is no `uitoolbar` available, then MATLAB creates a new `uitoolbar` in the current figure to serve as the parent. Similarly, if there no figure is available, then MATLAB creates a new figure with a `uitoolbar`.

`t = uitoggletool(Name,Value,...)` creates a `uitoggletool` and specifies one or more `uitoggletool` property names and corresponding values. Use this syntax to override the default `uitoggletool` properties.

`t = uitoggletool(parent)` creates a `uitoggletool` and designates a specific parent object. The `parent` argument must be a `uitoolbar` object.

`t = uitoggletool(parent,Name,Value,...)` creates a `uitoggletool` with a specific parent and one or more `uitoggletool` properties.

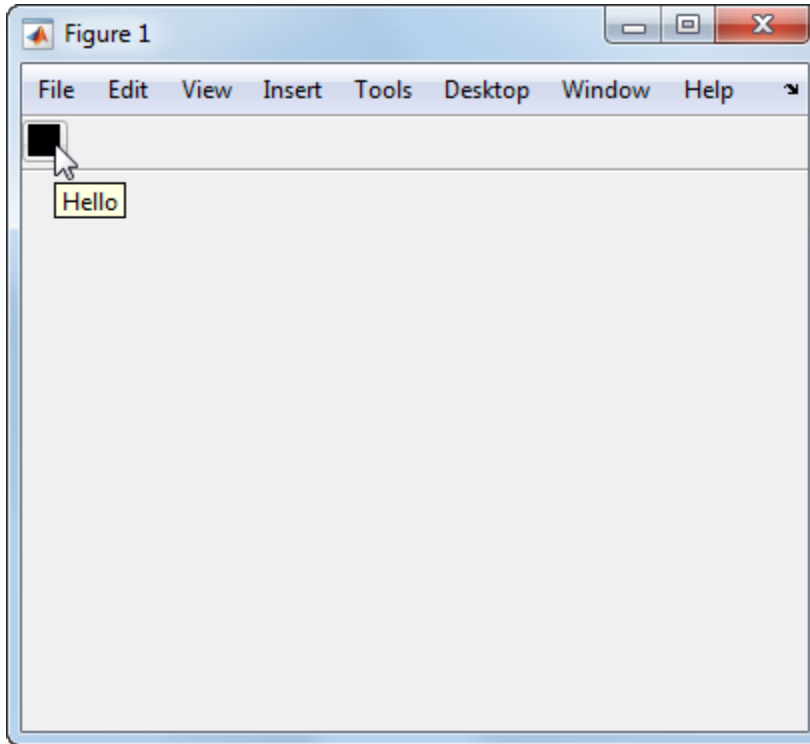

A `uitoggletool` is a toggle button that appears in the figure's tool bar. The button has no icon, but its borders highlight when the user hovers over it with the mouse. You can create a button icon by setting the `uitoggletool`'s `CData` property.

### Examples

This example creates a `uitoolbar` and places a `uitoggletool` inside it.

```
f = figure('ToolBar','none');
tb = uitoolbar(f);
img = zeros(16,16,3);
```

```
t = uitoggletool(tb,'CData',img,'TooltipString','Hello');
```

The `CData` property is set to a 16-by-16-by-3 array in which all elements are 0. The zero values make the `uitoggletool` appear black.

## Alternatives

You can create toolbars with toggle tools using GUIDE.

## More About

### Tips

- `Uitoolbars` (and their child `uitoggletools`) do not appear in figures whose `WindowState` property is set to `'Modal'`. If a figure containing a `uitoolbar` is changed to `'Modal'`,

the `uitoolbar` still exists in the `Children` property of the figure. However, the `uitoolbar` does not display while `WindowState` is set to `'Modal'`.

- “Access Property Values”
- “Create Toolbars for Programmatic UIs”

# Uitoggletool Properties

Control appearance and behavior of uitoggletool

Uitoggletools are toggle buttons that appear on the tool bar at the top of the a figure. The `uitoggletool` function creates a toggle button on a tool bar and sets any required properties before displaying it. By changing uitoggletool property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
t = uitoggletool;
sep = t.Separator;
t.Separator = 'on';
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Appearance

### Visible — Uitoggletool visibility

'on' (default) | 'off'

Uitoggletool visibility, specified as 'on' or 'off'. When the `Visible` property is set to 'off', the uitoggletool is not visible, but you can query and set its properties.

### Separator — Separator line mode

'off' (default) | 'on'

Separator line mode, specified as 'off' or 'on'. Setting this property to 'on' draws a dividing line to left of the uitoggletool.

### CData — Optional image to display on uitoggletool

3-D array of truecolor RGB values

Optional image to display on the uitoggletool, specified as a 3-D array of truecolor RGB values. The values in the array can be:

- Double-precision values between 0.0 and 1.0
- `uint8` values between 0 and 255

The length of the array's first and second dimensions must be less than or equal to 16. Otherwise, it might be clipped or distorted when it displays.

Data Types: `double` | `uint8`

## Interactive Control

### **State** — Toggle button state

'off' (default) | 'on'

Toggle button state, specified as 'off' or 'on'. When this property value is 'on', the toggle button appears in the down (depressed) position. When this property value is 'off', the toggle button appears in the up position. Changing the state causes the appropriate `OnCallback` or `OffCallback` function to execute.

### **ClickedCallback** — Callback function that executes when user clicks `uitoggletool`

' ' (default) | function handle | cell array | string

Callback function that executes when a user clicks the `uitoggletool`, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

This callback function executes after the `OnCallback` function or `OffCallback` function executes (depending on the state of the button).

For more information about specifying callback functions as function handles, cell arrays, or strings, see “How to Specify Callback Property Values”.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

### **OnCallback** — Callback to execute when user turns on toggle button

' ' (default) | function handle | cell array | string

Callback to execute when user turns on the toggle button, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying callback functions as function handles, cell arrays, or strings, see “How to Specify Callback Property Values”.

Example: @myfun

Example: {@myfun,x}

Data Types: `function_handle` | `cell` | `char`

### **OffCallback** — Callback to execute when user turns off the toggle button

' ' (default) | function handle | cell array | string

Callback to execute when user turns off toggle button, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying callback functions as function handles, cell arrays, or strings, see “How to Specify Callback Property Values”.

Example: @myfun

Example: {@myfun,x}

Data Types: `function_handle` | `cell` | `char`

### **Enable** — Operational state of uitoggletool

'on' (default) | 'off'

Operational state of uitoggletool, specified as 'on' or 'off'. The **Enable** property controls whether the uitoggletool responds to button clicks. There are two possible values:

- 'on' — The uitoggletool is operational.
- 'off' — The uitoggletool is not operational and appears grayed-out.

The value of the `Enable` property and the type of button click determine the response.

Enable Value	Response to Left-Click	Response to Right-Click
'on'	<ol style="list-style-type: none"> <li>1 The <code>OnCallback</code> or <code>OffCallback</code> function execute, depending on the current state of the <code>uitoggetool</code>.</li> <li>2 The <code>uitoggetool</code>'s <code>ClickedCallback</code> function executes.</li> </ol>	The <code>uitoggetool</code> is not operational. No callback executes.
'off'	The <code>uitoggetool</code> is not operational. No callback executes.	The <code>uitoggetool</code> is not operational. No callback executes.

**TooltipString — Tooltip text**

string

Content of `uitoggetool` tooltip, specified as a string. When the user moves the mouse pointer over the `uitoggetool` and leaves it there, the tooltip displays.

Example: 'Some string'

**UIContextMenu — Context menu**

empty `GraphicsPlaceholder` array (default) | `uicontextmenu` handle

This property has no effect on `uitoggetools`.

**Callback Execution Control**

**Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

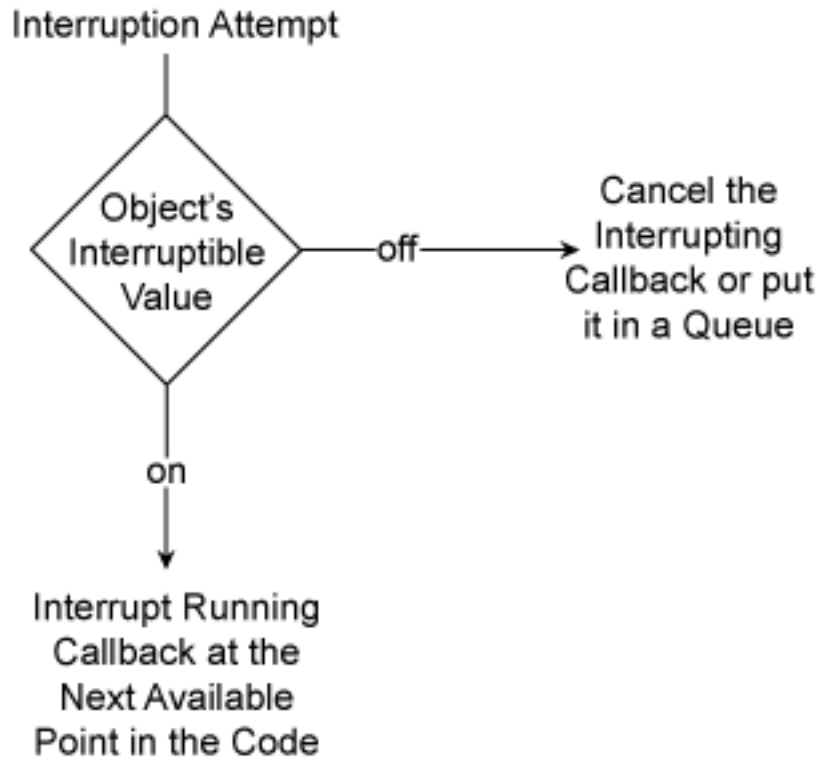

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The `Interruptible` property of the object owning the running

callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put into a queue.

If a `uitoggletool` callback is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- 'on' — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
- If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback.

MATLAB resumes executing the running callback when the interrupting callback completes.

- If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

---

**Note:** Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a `DeleteFcn`, `CloseRequestFcn`, or `SizeChangedFcn` callback, then the interruption occurs regardless of the `Interruptible` property value.
  - If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the `Interruptible` property value.
  - MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.
- 

See “Interrupt Callback Execution” for an example that shows how the `Interruptible` and `BusyAction` properties affect the behavior of a program.

### **BusyAction — Callback queuing**

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution.

- 'cancel' — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The `Interruptible` property of the object whose callback is running determines if interruption is allowed. If `Interruptible` is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The `BusyAction` property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the `BusyAction` and `Interruptible` properties affect the behavior of a program.

### **HitTest — Ability to become current object**

'on' (default) | 'off'

This property has no effect on the uitoggetool.

## **Creation and Deletion Control**

### **BeingDeleted — Deletion status of uitoggetool**

'off' (default) | 'on'

This property is read only.

Deletion status of uitoggetool, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the delete function of the uitoggetool begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the uitoggetool no longer exists.

Check the value of the `BeingDeleted` property to verify that the uitoggetool is not about to be deleted before querying or modifying it.

### **CreateFcn — Uitoggetool creation function**

function handle | cell array | string

Uitoggetool creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.

- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This property specifies a callback function to execute when MATLAB creates the `uitoggletool`. MATLAB initializes all `uitoggletool` property values before executing the `CreateFcn` callback. If you do not specify the `CreateFcn` property, then MATLAB executes a default creation function.

Use the `gcbo` function in your `CreateFcn` code to get the handle to the `uitoggletool` that is being created.

Setting the `CreateFcn` property on an existing `uitoggletool` has no effect.

---

**Note:** Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. Copying the `uitoggletool` object causes the `CreateFcn` callback to execute repeatedly.

---

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

### **DeleteFcn — Uitoggletool deletion function**

`function handle` | `cell array` | `string`

Uitoggletool deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `DeleteFcn` property specifies a callback function to execute when MATLAB deletes the `uitoggletool` (for example, when the end user deletes the figure). MATLAB executes

the `DeleteFcn` callback before destroying the properties of the `uitoggletool`. If you do not specify the `DeleteFcn` property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your `DeleteFcn` code to get the handle to the `uitoggletool` that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

## Identifiers

### Type — Type of graphics object

'uitoggletool'

This property is read only.

Type of graphics object, returned as 'uitoggletool'.

### Tag — Uitoggletool identifier

'' (default) | string

Uitoggletool identifier, specified as a string. You can specify a unique `Tag` value to serve as an identifier for the `uitoggletool`. When you need access to the `uitoggletool` elsewhere in your code, you can use the `findobj` function to search for the `uitoggletool` based on the `Tag` value.

Example: `'toggletool1'`

Data Types: `char`

### UserData — Data to associate with the uitoggletool object

empty array (default) | array

Data to associate with the `uitoggletool` object, specified as any array. Specifying `UserData` can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: {[1 2 3], 'April 21'}

## Parent/Child

### Parent — Uitoggletool parent

uitoolbar

Uitoggletool parent, specified as a uitoolbar. You can move a uitoggletool to a different uitoolbar by setting this property to the handle of the target uitoolbar.

### HandleVisibility — Visibility of Uitoggletool handle

'on' (default) | 'callback' | 'off'

Visibility of Uitoggletool handle, specified as 'on', 'callback', or 'off'.

This property controls the visibility of the uitoggletool handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The `HandleVisibility` property also controls the visibility of the object's handle in the parent figure's `CurrentObject` property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
'on'	The uitoggletool handle is always visible.
'callback'	The uitoggletool handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uitoggletool at the command-line, but allows callback functions to access it.
'off'	The uitoggletool handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the <code>HandleVisibility</code> to 'off' to temporarily hide the handle during the execution of that function.

Set the graphics root `ShowHiddenHandles` property to 'on' to make all handles visible, regardless of their `HandleVisibility` value. This setting has no effect on their `HandleVisibility` values.

## More About

- “Access Property Values”
- “Default Property Values”

## uitoolbar

Create toolbar on figure

### Syntax

```
t = uitoolbar
t = uitoolbar(Name,Value,...)
t = uitoolbar(parent)
t = uitoolbar(parent,Name,Value,...)
```

### Description

`t = uitoolbar` creates a `uitoolbar` in an existing figure and returns the `uitoolbar` object, `t`. If there is no figure available, then MATLAB creates a new figure to serve as the parent.

`t = uitoolbar(Name,Value,...)` creates a `uitoolbar` and specifies one or more `uitoolbar` property names and corresponding values. Use this syntax to override the default `uitoolbar` properties.

`t = uitoolbar(parent)` creates a `uitoolbar` in a specific parent figure. The `parent` input argument is the parent figure object.

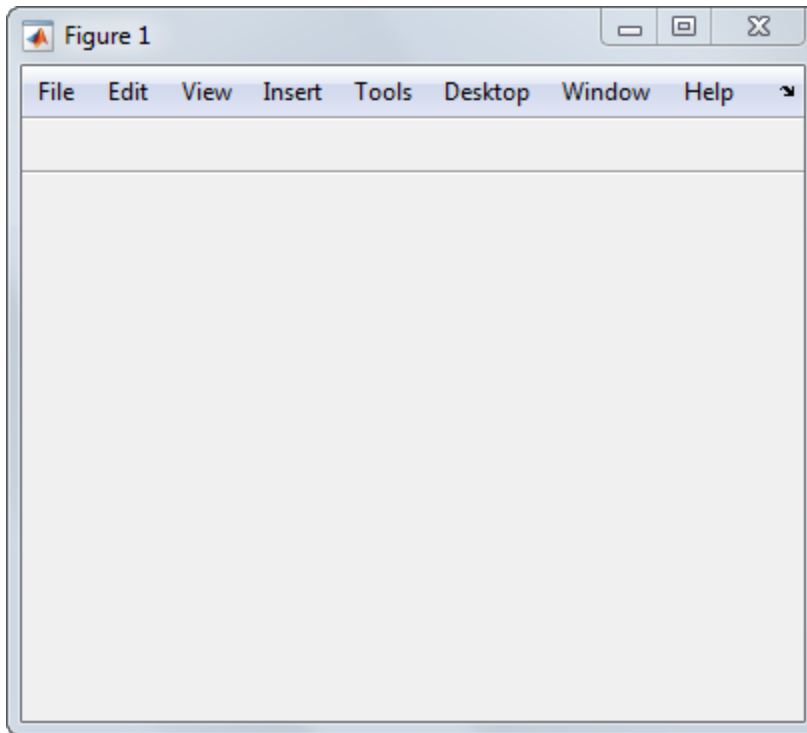

`t = uitoolbar(parent,Name,Value,...)` creates a `uitoolbar` with a specific parent and one or more `uitoolbar` properties.

### Examples

This example creates a figure containing an empty `uitoolbar`.

```
f = figure('ToolBar','none')
t = uitoolbar(f)
```

## More About

### Tips

Uitoolbars do not appear in figures whose `WindowState` property is set to `'Modal'`. If a figure containing a `uitoolbar` child is changed to `'Modal'`, the `uitoolbar` child still exist in the `Children` property of the figure. However, the `uitoolbar` does not display while `WindowState` is set to `'Modal'`.

**Introduced before R2006a**

# Uitoolbar Properties

Control appearance and behavior tool bar

A uitoolbar is a tool bar containing buttons at the top of a figure window. The `uitoolbar` function creates a tool bar in a figure and sets any required properties before displaying it. By changing uitoolbar property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
t = uitoolbar;
invisible = t.Visible;
t.Visible = 'off';
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Appearance

### **Visible** — Uitoolbar visibility

'on' (default) | 'off'

Uitoolbar visibility, specified as 'on' or 'off'. When the `Visible` property is set to 'off', the uitoolbar is not visible, but you can query and set its properties.

## Interactive Control

### **UIContextMenu** — Context menu

empty `GraphicsPlaceholder` array (default) | `uicontextmenu` handle

This property has no effect on uitoolbars.

## Callback Execution Control

### **Interruptible** — Callback interruption

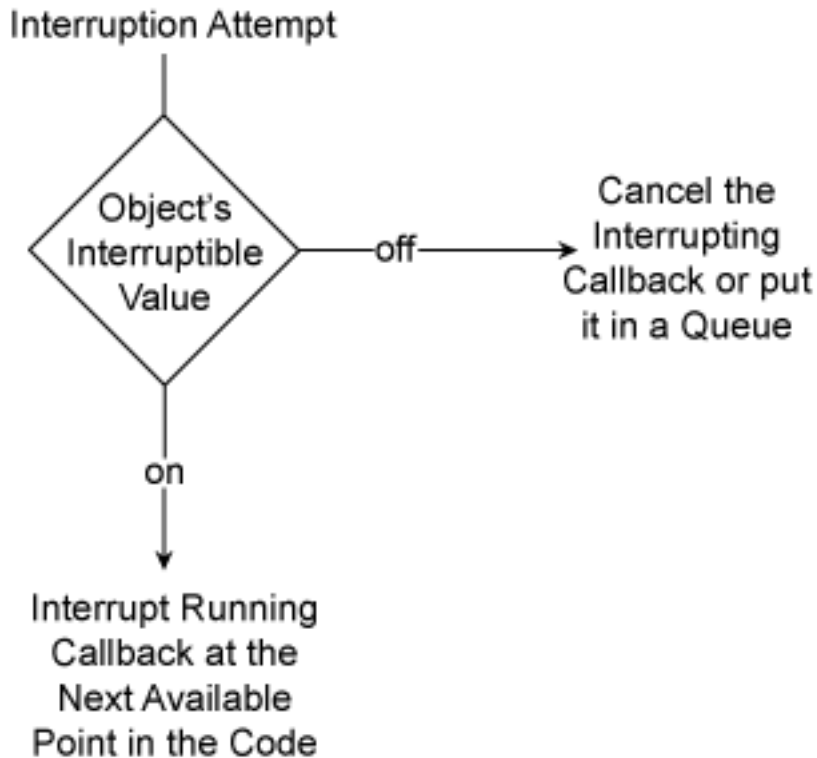

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put into a queue.

If a `uitoolbar` callback is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- 'on' — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

---

**Note:** Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a `DeleteFcn`, `CloseRequestFcn`, or `SizeChangedFcn` callback, then the interruption occurs regardless of the `Interruptible` property value.
  - If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the `Interruptible` property value.
  - MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.
- 

See “Interrupt Callback Execution” for an example that shows how the `Interruptible` and `BusyAction` properties affect the behavior of a program.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' (default) or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The **BusyAction** property of the source of the interrupting callback determines how MATLAB handles its execution. The **BusyAction** property has these values:

- **'queue'** — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- **'cancel'** — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The **Interruptible** property of the object whose callback is running determines if interruption is allowed. If **Interruptible** is set to:

- **on** — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- **off** — The **BusyAction** property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the **BusyAction** and **Interruptible** properties affect the behavior of a program.

### **HitTest** — Ability to become current object

'on' (default) | 'off'

This property has no effect on the uicontrol.

## **Creation and Deletion Control**

### **BeingDeleted** — Deletion status of uicontrol

'off' (default) | 'on'

This property is read only.

Deletion status of uicontrol, returned as 'on' or 'off'. MATLAB sets the **BeingDeleted** property to 'on' when the delete function of the uicontrol begins execution (see the **DeleteFcn** property). The **BeingDeleted** property remains set to 'on' until the uicontrol no longer exists.

Check the value of the **BeingDeleted** property to verify that the uicontrol is not about to be deleted before querying or modifying it.

### **CreateFcn** — Uicontrol creation function

function handle | cell array | string

Uitoolbar creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This property specifies a callback function to execute when MATLAB creates the uitoolbar. MATLAB initializes all uitoolbar property values before executing the `CreateFcn` callback. If you do not specify the `CreateFcn` property, then MATLAB executes a default creation function.

Use the `gcbo` function in your `CreateFcn` code to get the handle to the uitoolbar that is being created.

Setting the `CreateFcn` property on an existing uitoolbar has no effect.

---

**Note:** Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. Copying the uitoolbar object causes the `CreateFcn` callback to execute repeatedly.

---

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

### **DeleteFcn — Uitoolbar deletion function**

`function handle` | `cell array` | `string`

Uitoolbar deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `DeleteFcn` property specifies a callback function to execute when MATLAB deletes the `uitoolbar` (for example, when the end user deletes the figure). MATLAB executes the `DeleteFcn` callback before destroying the properties of the `uitoolbar`. If you do not specify the `DeleteFcn` property, then MATLAB executes a default deletion function.

Use the `gcb0` function in your `DeleteFcn` code to get the handle to the `uitoolbar` that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

## Identifiers

### Type — Type of graphics object

`'uitoolbar'`

This property is read only.

Type of graphics object, returned as `'uitoolbar'`.

### Tag — Uitoolbar identifier

`''` (default) | `string`

Uitoolbar identifier, specified as a string. You can specify a unique `Tag` value to serve as an identifier for the `uitoolbar`. When you need access to the `uitoolbar` elsewhere in your code, you can use the `findobj` function to search for the `uitoolbar` based on the `Tag` value.

Example: `'toolbar1'`

Data Types: `char`

### UserData — Data to associate with the uitoolbar object

empty array (default) | `array`

Data to associate with the `uitoolbar` object, specified as any array. Specifying `UserData` can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: [1 2 3]

Example: 'April 21'

Example: struct('value1',[1 2 3],'value2','April 21')

Example: {[1 2 3],'April 21'}

## Parent/Child

### Parent — Uitoolbar parent

figure

Uitoolbar parent, specified as a figure. You can move a uitoolbar to a different figure by setting this property to the handle of the target figure.

### Children — Children of uitoolbar

empty GraphicsPlaceholder array (default) | 1-D array of component objects

Children of uitoolbar, returned as an empty `GraphicsPlaceholder` or a 1-D array of component objects. The children of uitoolbars are `uipushtools` and `uitoggletools`.

You cannot add or remove children using the `Children` property of the uitoolbar. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the order of the components displayed in the Uitoolbar.

To add a child to this list, set the `Parent` property of the child component to be the uitoolbar object.

Objects with the `HandleVisibility` property set to 'off' do not list in the `Children` property. For more information, see the `HandleVisibility` property description.

### HandleVisibility — Visibility of Uitoolbar handle

'on' (default) | 'callback' | 'off'

Visibility of Uitoolbar handle, specified as 'on', 'callback', or 'off'.

This property controls the visibility of the uitoolbar handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The `HandleVisibility` property also controls the visibility of the object's handle in the parent figure's `CurrentObject` property. Handles are still valid even if they are not

visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

<b>HandleVisibility Value</b>	<b>Description</b>
'on'	The uitoolbar handle is always visible.
'callback'	The uitoolbar handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uitoolbar at the command-line, but allows callback functions to access it.
'off'	The uitoolbar handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the <code>HandleVisibility</code> to 'off' to temporarily hide the handle during the execution of that function.

Set the graphics root `ShowHiddenHandles` property to 'on' to make all handles visible, regardless of their `HandleVisibility` value. This setting has no effect on their `HandleVisibility` values.

# uiwait

Block program execution and wait to resume

## Syntax

```
uiwait
uiwait(h)
uiwait(h,timeout)
```

## Description

`uiwait` blocks execution until `uiresume` is called or the current figure is deleted. This syntax is the same as `uiwait(gcf)`.

`uiwait(h)` blocks execution until `uiresume` is called or the figure `h` is deleted.

`uiwait(h,timeout)` blocks execution until `uiresume` is called, the figure `h` is deleted, or `timeout` seconds elapse. The minimum value of `timeout` is 1. If `uiwait` receives a smaller value, it issues a warning and uses a 1 second `timeout`.

## Examples

This example creates a UI with a **Continue** push button. The example calls `uiwait` to block MATLAB execution until `uiresume` is called. This happens when the user clicks the **Continue** push button because the push button's `Callback`, which responds to the click, calls `uiresume`.

```
f = figure;
h = uicontrol('Position',[20 20 200 40],'String','Continue',...
 'Callback','uiresume(gcf)');
disp('This will print immediately');
uiwait(gcf);
disp('This will print after you click Continue');
close(f);
```

`gcbf` is the handle of the figure that contains the object whose callback is executing.

## More About

### Tips

The `uiwait` and `uiresume` functions block and resume MATLAB and Simulink program execution. `uiwait` also blocks the execution of Simulink models. The functions `pause` (with no argument) and `waitfor` also block execution in this manner. `uiwait` is a convenient way to use the `waitfor` command. You typically use it in conjunction with a dialog box. It provides a way to block the execution of the MATLAB program that created the dialog, until the user responds to the dialog box. When used in conjunction with a modal dialog, `uiwait` can block the execution of the program file *and* restrict user interaction to the dialog only.

**Introduced before R2006a**

# uminus, -

Unary minus

## Syntax

```
C = -A
```

```
C = uminus(A)
```

## Description

`C = -A` negates the elements of `A` and stores the result in `C`.

`C = uminus(A)` is an alternative way to execute `-A`, but is rarely used. It enables operator overloading for classes.

## Examples

### Negate Elements of Matrix

Create a 2-by-2 matrix, `A`.

```
A = [1 -3; -2 4]
```

```
A =
```

```
 1 -3
 -2 4
```

Negate the elements of `A`.

```
C = -A
```

```
C =
```

```
 -1 3
```

2 -4

## Input Arguments

### **A — Input array**

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. A can be a numeric array, logical array, character array, duration array, or calendar duration array. Complex Number Support: Yes

# undocheckout

(To be removed) Undo previous checkout from source control system (UNIX platforms)

---

**Note:** undocheckout will be removed in a future release.

---

## Syntax

```
undocheckout('filename')
undocheckout({'filename1','filename2', ..., 'filenamen'})
```

## Description

`undocheckout('filename')` makes the file `filename` available for checkout, where `filename` does not reflect any of the changes you made after you last checked it out. Use the full path for `filename` and include the file extension.

`undocheckout({'filename1','filename2', ..., 'filenamen'})` makes `filename1` through `filenamen` available for checkout, where the files do not reflect any of the changes you made after you last checked them out. Use the full paths for the file names and include the file extensions.

## Examples

Undo the checkouts of `/myserver/myfiles/clock.m` and `/myserver/myfiles/calendar.m` from the source control system:

```
undocheckout({'/myserver/myfiles/clock.m', ...
 '/myserver/myfiles/calendar.m'})
```

**Introduced before R2006a**

## unicode2native

Convert Unicode character representation to numeric bytes

### Syntax

```
bytes = unicode2native(unicodestr)
bytes = unicode2native(unicodestr,encoding)
```

### Description

`bytes = unicode2native(unicodestr)` converts a `char` vector of Unicode character representations, `unicodestr`, to the user default encoding, and returns the bytes as a `uint8` vector, `bytes`. Output vector `bytes` has the same general array shape as the `unicodestr` input. You can save the output of `unicode2native` to a file using the `fwrite` function.

`bytes = unicode2native(unicodestr,encoding)` converts `unicodestr` to the character encoding scheme specified by the string `encoding`. `encoding` must be the empty string ( `' '` ) or a name or alias for an encoding scheme. Some examples are `'UTF-8'`, `'latin1'`, `'US-ASCII'`, and `'Shift_JIS'`. If `encoding` is unspecified or is the empty string ( `' '` ), the default encoding scheme is used.

### Examples

This example begins with two strings containing Unicode character representations. It assumes that string `str1` contains text in a Western European language and string `str2` contains Japanese text. The example writes both strings into the same file, using the ISO-8859-1 character encoding scheme for the first string and the Shift-JIS encoding scheme for the second string. The example uses `unicode2native` to convert the two strings to the appropriate encoding schemes.

```
fid = fopen('mixed.txt', 'w');
bytes1 = unicode2native(str1, 'ISO-8859-1');
fwrite(fid, bytes1, 'uint8');
bytes2 = unicode2native(str2, 'Shift_JIS');
```

```
fwrite(fid, bytes2, 'uint8');
fclose(fid);
```

## **See Also**

## union

Set union of two arrays

### Syntax

```
C = union(A,B)
C = union(A,B,'rows')
[C,ia,ib] = union(A,B)
[C,ia,ib] = union(A,B,'rows')

[C,ia,ib] = union(____,setOrder)

[C,ia,ib] = union(A,B,'legacy')
[C,ia,ib] = union(A,B,'rows','legacy')
```

### Description

`C = union(A,B)` returns the combined data from **A** and **B** with no repetitions.

- If **A** and **B** are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `union` returns the combined values from **A** and **B**. The values of **C** are in sorted order.
- If **A** and **B** are tables, then `union` returns the combined set of rows from both tables. The rows of table **C** are in sorted order.

`C = union(A,B,'rows')` treats each row of **A** and each row of **B** as single entities and returns the combined rows from **A** and **B** with no repetitions. The rows of **C** are in sorted order.

The `'rows'` option does not support cell arrays, unless one of the inputs is either a categorical array or a datetime array.

`[C,ia,ib] = union(A,B)` also returns index vectors **ia** and **ib**.

- If **A** and **B** are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then the values in **C** are a sorted combination of the values of **A**(**ia**) and **B**(**ib**).

- If **A** and **B** are tables, then **C** is a sorted combination of the rows of **A(ia,:)** and **B(ib,:)**.

`[C,ia,ib] = union(A,B,'rows')` also returns index vectors **ia** and **ib**, such that the rows of **C** are a sorted combination of the rows of **A(ia,:)** and **B(ib,:)**.

`[C,ia,ib] = union( ____,setOrder)` returns **C** in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of **C** in sorted order. `setOrder='stable'` returns the values (or rows) of **C** in the same order as **A**, and then **B**. If no value is specified, the default is `'sorted'`.

`[C,ia,ib] = union(A,B,'legacy')` and `[C,ia,ib] = union(A,B,'rows','legacy')` preserve the behavior of the `union` function from R2012b and prior releases.

The `'legacy'` option does not support categorical arrays, tables, datetime arrays, or duration arrays.

## Examples

### Union of Two Vectors

Define two vectors with a value in common.

```
A = [5 7 1]; B = [3 1 1];
```

Find the union of vectors **A** and **B**.

```
C = union(A,B)
```

```
C =
```

```
 1 3 5 7
```

### Union of Two Tables

Define two tables with rows in common.

```
A = table([1:5]', ['A';'B';'C';'D';'E'], logical([0;1;0;1;0]))
B = table([1:2:10]', ['A';'C';'E';'G';'I'], logical(zeros(5,1)))
```

```
A =
```

Var1	Var2	Var3
1	A	false
2	B	true
3	C	false
4	D	true
5	E	false

B =

Var1	Var2	Var3
1	A	false
3	C	false
5	E	false
7	G	false
9	I	false

Find the union of tables A and B.

C = union(A,B)

C =

Var1	Var2	Var3
1	A	false
2	B	true
3	C	false
4	D	true
5	E	false
7	G	false
9	I	false

## Union of Two Vectors and Their Indices

Define two vectors with a value in common.

A = [5 7 1]; B = [3 1 1];

Find the union of vectors A and B, as well as the index vectors, ia and ib.

[C,ia,ib] = union(A,B)

C =

```

 1 3 5 7

ia =

 3
 1
 2

ib =

 1

```

The values in C are the combined values of A(ia) and B(ib).

### Union of Two Tables and Their Indices

Define a table, A, of gender, age, and height for three people.

```

A = table(['M';'M';'F'],[27;52;31],[74;68;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty'})

```

A =

	Gender	Age	Height
	-----	---	-----
Ted	M	27	74
Fred	M	52	68
Betty	F	31	64

Define a table, B with the same variables as A.

```

B = table(['F';'M'],[64;68],[31;47],...
'VariableNames',{'Gender' 'Height' 'Age'},...
'RowNames',{'Meg' 'Joe'})

```

B =

	Gender	Height	Age
	-----	-----	---
Meg	F	64	31
Joe	M	68	47

Find the union of tables A and B, as well as the index vectors, `ia` and `ib`.

```
[C,ia,ib] = union(A,B)
```

```
C =
```

	Gender	Age	Height
	-----	---	-----
Betty	F	31	64
Ted	M	27	74
Joe	M	47	68
Fred	M	52	68

```
ia =
```

```
3
1
2
```

```
ib =
```

```
2
```

The data for Meg and Betty are the same. `union` only returns the index from A, which corresponds to Betty.

### Union of Rows in Two Matrices

Define two matrices with a row in common.

```
A = [2 2 2; 0 0 1];
```

```
B = [1 2 3; 2 2 2; 2 2 2];
```

Find the combined rows of A and B, with no repetition, as well as the index vectors `ia` and `ib`.

```
[C,ia,ib] = union(A,B, 'rows')
```

```
C =
```

0	0	1
1	2	3
2	2	2

```
ia =
 2
 1
```

```
ib =
 1
```

The rows of **C** are the combined rows of **A(ia, :)** and **B(ib, :)**.

### Union of Two Vectors with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in **C**.

Specify `'stable'` if you want the values in **C** to have the same order as in **A** and **B**.

```
A = [5 7 1]; B = [3 1 1];
[C,ia,ib] = union(A,B,'stable')
```

```
C =
 5 7 1 3
```

```
ia =
 1
 2
 3
```

```
ib =
 1
```

Alternatively, you can specify `'sorted'` order.

```
A = [5 7 1]; B = [3 1 1];
[C,ia,ib] = union(A,B,'sorted')
```

```
C =
```

```
 1 3 5 7

ia =

 3
 1
 2
```

```
ib =

 1
```

### **Union of Vectors Containing NaNs**

Define two vectors containing NaN.

```
A = [5 NaN 1]; B = [4 NaN NaN];
```

Find the union of vectors A and B.

```
C = union(A,B)
```

```
C =

 1 4 5 NaN NaN NaN
```

union treats NaN values as distinct.

### **Cell Array of Strings with Trailing White Space**

Create a cell array of strings, A.

```
A = {'dog', 'cat', 'fish', 'horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ', 'cat', 'fish ', 'horse'};
```

Combine the elements of A and B.

```
[C,ia,ib] = union(A,B)
```

```
C =
```

```
'cat' 'dog' 'dog ' 'fish' 'fish ' 'horse'
```

```
ia =
 2
 1
 3
 4
```

```
ib =
 1
 3
```

union treats trailing white space in cell arrays of strings as distinct characters.

### Union of Vectors of Different Classes and Shapes

Create a column vector character array.

```
A = ['A'; 'B'; 'C'], class(A)
```

```
A =
```

```
A
B
C
```

```
ans =
```

```
char
```

Create a row vector containing elements of numeric type double.

```
B = [68 69 70], class(B)
```

```
B =
```

```
68 69 70
```

```
ans =
```

```
double
```

The union of A and B returns a column vector character array.

```
C = union(A,B), class(C)
```

```
C =
```

```
A
```

```
B
```

```
C
```

```
D
```

```
E
```

```
F
```

```
ans =
```

```
char
```

## Union of Char and Cell Array of Strings

Create a character array containing the letters a , b, and c.

```
A = ['a'; 'b'; 'c'];
class(A)
```

```
ans =
```

```
char
```

Create a cell array of strings containing the letters c, d, and e.

```
B = {'c', 'd', 'e'};
class(B)
```

```
ans =
```

```
cell
```

Combine the elements of A and B.

```
C = union(A,B)
```

```
C =
```

```
 'a'
 'b'
 'c'
 'd'
 'e'
```

The result, `C`, is a cell array of strings.

```
class(C)
```

```
ans =
```

```
cell
```

### Preserve Legacy Behavior of union

Use the `'legacy'` flag to preserve the behavior of `union` from R2012b and prior releases in your code.

Find the union of `A` and `B` with the current behavior.

```
A = [5 7 1]; B = [3 1 1];
[C1,ia1,ib1] = union(A,B)
```

```
C1 =
```

```
 1 3 5 7
```

```
ia1 =
```

```
 3
 1
 2
```

```
ib1 =
```

```
 1
```

Find the union of `A` and `B`, and preserve the legacy behavior.

```
A = [5 7 1]; B = [3 1 1];
[C2,ia2,ib2] = union(A,B,'legacy')
```

```
C2 =
```

```
 1 3 5 7
```

```
ia2 =
```

```
 1 2
```

```
ib2 =
```

```
 3 1
```

## Input Arguments

### A, B — Input arrays

numeric arrays | logical arrays | character arrays | categorical arrays | datetime arrays  
| duration arrays | cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, cell arrays of strings, or tables.

A and B must be of the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.
- Datetime arrays can combine with cell arrays of date strings or single date strings.

If A and B are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither A nor B are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names. In this case, the categories of C are the sorted union of the categories from A and B.

If you specify the `'rows'` option, A and B must have the same number of columns.

If **A** and **B** are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

If **A** and **B** are datetime arrays, they must be consistent with each other in whether they specify a time zone.

Furthermore, **A** and **B** can be objects with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

### **setOrder** — Order flag

`'sorted'` (default) | `'stable'`

Order flag, specified as `'sorted'` or `'stable'`, indicates the order of the values (or rows) in **C**.

Order Flag	Meaning
<code>'sorted'</code>	The values (or rows) in <b>C</b> return in sorted order. For example: <code>C = union([5 5 3],[1 2],'sorted')</code> returns <code>C = [1 2 3 5]</code> .
<code>'stable'</code>	The values (or rows) in <b>C</b> return in the same order as they appear in <b>A</b> and <b>B</b> . For example: <code>C = union([5 5 3],[1 2],'stable')</code> returns <code>C = [5 3 1 2]</code> .

## Output Arguments

### **C** — Combined data of **A** and **B**

vector | matrix | table

Combined data of **A** and **B**, returned as a vector, matrix, or table. If the inputs **A** and **B** are tables, the order of the variables in the resulting table, **C**, is the same as the order of the variables in **A**.

The following describes the shape of **C** when the inputs are vector or matrices and when the 'legacy' flag is not specified:

- If the 'rows' flag is not specified, then **C** is a column vector unless both **A** and **B** are row vectors.
- If the 'rows' flag is not specified and both **A** and **B** are row vectors, then **C** is a row vector.
- If the 'rows' flag is specified, then **C** is a matrix containing the combined rows of **A** and **B**.

The class of the inputs **A** and **B** determines the class of **C**:

- If the class of **A** and **B** are the same, then **C** is the same class.
- If you combine a `char` or nondouble numeric class with `double`, then **C** is the same class as the nondouble input.
- If you combine a `logical` class with `double`, then **C** is `double`.
- If you combine a cell array of strings with `char`, then **C** is a cell array of strings.
- If you combine a categorical array with a cell array of strings or single string, then **C** is a categorical array.
- If you combine a datetime array with a cell array of date strings or single date string, then **C** is a datetime array.

## **ia** — Index to A

column vector

Index to **A**, returned as a column vector when the 'legacy' flag is not specified. **ia** indicates the values (or rows) in **A** that contribute to the union. If a value (or row) appears multiple times in **A**, then **ia** contains the index to the first occurrence of the value (or row). If a value appears in both **A** and **B**, then **ia** contains the index to the first occurrence in **A**.

## **ib** — Index to B

column vector

Index to **B**, returned as a column vector when the 'legacy' flag is not specified. **ib** indicates the values (or rows) in **B** that contribute to the union. If there is a repeated value (or row) appearing exclusively in **B**, then **ib** contains the index to the first occurrence of the value. If a value (or row) appears in both **A** and **B**, then **ib** does not contain an index to the value (or row).

## More About

### Tips

- To find the union with respect to a subset of variables from a table, you can use column subscripting. For example, you can use `union(A(:,vars),B(:,vars))`, where `vars` is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.
- “Combine Categorical Arrays”

**Introduced before R2006a**

## unique

Unique values in array

### Syntax

```
C = unique(A)
C = unique(A, 'rows')
[C,ia,ic] = unique(A)
[C,ia,ic] = unique(A, 'rows')

[C,ia,ic] = unique(A,setOrder)
[C,ia,ic] = unique(A, 'rows',setOrder)

[C,ia,ic] = unique(A, 'legacy')
[C,ia,ic] = unique(A, 'rows', 'legacy')
[C,ia,ic] = unique(A,occurrence, 'legacy')
[C,ia,ic] = unique(A, 'rows',occurrence, 'legacy')
```

### Description

`C = unique(A)` returns the same data as in `A`, but with no repetitions.

- If `A` is a numeric array, logical array, character array, categorical array, datetime array, duration array, or a cell array of strings, then `unique` returns the unique values in `A`. The values of `C` are in sorted order.
- If `A` is a table, then `unique` returns the unique rows in `A`. The rows of table `C` are in sorted order.

`C = unique(A, 'rows')` treats each row of `A` as a single entity and returns the unique rows of `A`. The rows of the array `C` are in sorted order.

The `'rows'` option does not support cell arrays.

`[C,ia,ic] = unique(A)` also returns index vectors `ia` and `ic`.

- If `A` is a vector, then `C = A(ia)` and `A = C(ic)`.
- If `A` is a matrix or array, then `C = A(ia)` and `A(:) = C(ic)`.

- If `A` is a table, then `C = A(ia,:)` and `A = C(ic,:)`.

`[C,ia,ic] = unique(A,'rows')` also returns index vectors `ia` and `ic`, such that `C = A(ia,:)` and `A = C(ic,:)`.

`[C,ia,ic] = unique(A,setOrder)` and `[C,ia,ic] = unique(A,'rows',setOrder)` return `C` in a specific order. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A`. If no value is specified, the default is `'sorted'`.

`[C,ia,ic] = unique(A,'legacy')`, `[C,ia,ic] = unique(A,'rows','legacy')`, `[C,ia,ic] = unique(A,occurrence,'legacy')`, and `[C,ia,ic] = unique(A,'rows',occurrence,'legacy')` preserve the behavior of the `unique` function from R2012b and prior releases.

The `'legacy'` option does not support categorical arrays or tables.

## Examples

### Unique Values in Vector

Define a vector with a repeated value.

```
A = [9 2 9 5];
```

Find the unique values of `A`.

```
C = unique(A)
```

```
C =
```

```
 2 5 9
```

### Unique Rows in Table

Define a table with repeated data.

```
Name = {'Fred';'Betty';'Bob';'George';'Jane'};
```

```
Age = [38;43;38;40;38];
```

```
Height = [71;69;64;67;64];
```

```
Weight = [176;163;131;185;131];
```

```
A = table(Age,Height,Weight,'RowNames',Name)
```

A =

	Age	Height	Weight
	---	-----	-----
Fred	38	71	176
Betty	43	69	163
Bob	38	64	131
George	40	67	185
Jane	38	64	131

Find the unique rows of A.

C = unique(A)

C =

	Age	Height	Weight
	---	-----	-----
Bob	38	64	131
Fred	38	71	176
George	40	67	185
Betty	43	69	163

unique returns the rows of A in sorted order by the first variable, Age and then by the second variable, Height.

## Unique Values and Their Indices

Define a vector with a repeated value.

A = [9 2 9 5];

Find the unique values of A and the index vectors ia and ic, such that C = A(ia) and A = C(ic).

[C, ia, ic] = unique(A)

C =

2 5 9

ia =

2  
4

```

1
ic =
3
1
3
2

```

### Unique Rows in Matrix

Define a matrix with a repeated row.

```
A = [9 2 9 5; 9 2 9 0; 9 2 9 5];
```

Find the unique rows of  $A$  and the index vectors  $ia$  and  $ic$ , such that  $C = A(ia,:)$  and  $A = C(ic,:)$ .

```
[C, ia, ic] = unique(A, 'rows')
```

```

C =
9 2 9 0
9 2 9 5

```

```

ia =
2
1

```

```

ic =
2
1
2

```

Notice that the second row in  $A$  is identified as unique even though the elements 9, 2, and 9 are repeated in the other rows.

### Unique Values in Vector with Specified Order

Use the `setOrder` argument to specify the ordering of the values in  $C$ .

Specify 'stable' if you want the values in C to have the same order as in A.

```
A = [9 2 9 5];
[C, ia, ic] = unique(A, 'stable')
```

```
C =
```

```
 9 2 5
```

```
ia =
```

```
 1
 2
 4
```

```
ic =
```

```
 1
 2
 1
 3
```

Alternatively, you can specify 'sorted' order.

```
[C, ia, ic] = unique(A, 'sorted')
```

```
C =
```

```
 2 5 9
```

```
ia =
```

```
 2
 4
 1
```

```
ic =
```

```
 3
 1
 3
```

2

**Unique Values in Array Containing NaNs**

Define a vector containing NaN.

```
A = [5 5 NaN NaN];
```

Find the unique values of A.

```
C = unique(A)
```

```
C =
```

```
 5 NaN NaN
```

`unique` treats NaN values as distinct.

**Unique Entries in Cell Array of Strings**

Define a cell array of strings.

```
A = {'one', 'two', 'twenty-two', 'One', 'two'};
```

Find the unique strings contained in A.

```
C = unique(A)
```

```
C =
```

```
 'One' 'one' 'twenty-two' 'two'
```

**Cell Array of Strings with Trailing White Space**

Define a cell array of strings, A, where some of the strings have trailing white space.

```
A = {'dog', 'cat', 'fish', 'horse', 'dog ', 'fish '};
```

Find the unique strings contained in A.

```
C = unique(A)
```

```
C =
```

```
 'cat' 'dog' 'dog ' 'fish' 'fish ' 'horse'
```

`unique` treats trailing white space in cell arrays of strings as distinct characters.

## Preserve Legacy Behavior of `unique`

Use the `'legacy'` flag to preserve the behavior of `unique` from R2012b and prior releases in your code.

Find the unique elements of `A` with the current behavior.

```
A = [9 2 9 5];
[C1, ia1, ic1] = unique(A)
```

```
C1 =

 2 5 9
```

```
ia1 =

 2
 4
 1
```

```
ic1 =

 3
 1
 3
 2
```

Find the unique elements of `A`, and preserve the legacy behavior.

```
[C2, ia2, ic2] = unique(A, 'legacy')
```

```
C2 =

 2 5 9
```

```
ia2 =

 2 4 3
```

```
ic2 =
 3 1 3 2
```

## Input Arguments

### A — Input array

numeric array | logical array | character array | categorical array | datetime arrays | duration arrays | cell array of strings | table

Input array, specified as a numeric array, logical array, character array, categorical array, datetime array, duration array, cell array of strings, or table.

If A is a table, `unique` does not take row names into account. Two rows that have the same values, but different names, are considered equal.

Furthermore, A can be an object with the following class methods:

- `sort` (or `sortrows` for the 'rows' option)
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

### setOrder — Order flag

'sorted' (default) | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in C.

Order Flag	Meaning
'sorted'	The values (or rows) in C return in sorted order. For example: <code>C = unique([5 5 3 4], 'sorted')</code> returns <code>C = [3 4 5]</code> .
'stable'	The values (or rows) in C return in the same order as in A. For example: <code>C = unique([5 5 3 4], 'stable')</code> returns <code>C = [5 3 4]</code> .

**occurrence** — Occurrence flag for legacy behavior

'last' (default) | 'first'

Occurrence flag for legacy behavior, specified as 'first' or 'last', indicates whether `ia` should contain the first or last indices to repeated values found in `A`.

Occurrence Flag	Meaning
'last'	If there are repeated values (or rows) in <code>A</code> , then <code>ia</code> contains the index to the last occurrence of the repeated value. For example: <code>[C,ia,ic] = unique([9 9 9], 'last', 'legacy')</code> returns <code>ia = 3</code> .
'first'	If there are repeated values (or rows) in <code>A</code> , then <code>ia</code> contains the index to the first occurrence of the repeated value. For example: <code>[C,ia,ic] = unique([9 9 9], 'first', 'legacy')</code> returns <code>ia = 1</code> .

## Output Arguments

**C** — Unique data of `A`

vector | matrix | table

Unique data of `A`, returned as a vector, matrix, or table. The following describes the shape of `C` when the input, `A`, is a vector or a matrix:

- If the 'rows' flag is not specified and `A` is a row vector, then `C` is a row vector.
- If the 'rows' flag is not specified and `A` is not a row vector, then `C` is a column vector.
- If the 'rows' flag is specified, then `C` is a matrix containing the unique rows of `A`.

The class of `C` is the same as the class of the input `A`.

**ia** — Index to `A`

column vector

Index to `A`, returned as a column vector of indices to the *first* occurrence of repeated elements. When the 'legacy' flag is specified, `ia` is a row vector that contains indices to the *last* occurrence of repeated elements.

The indices generally satisfy  $C = A(ia)$ . If  $A$  is a table, or if the 'rows' option is specified, then  $C = A(ia, :)$ .

**ic** — Index to C

column vector

Index to C, returned as a column vector when the 'legacy' flag is not specified. `ic` contains indices that satisfy the following properties.

- If  $A$  is a vector, then  $A = C(ic)$ .
- If  $A$  is a matrix or array, then  $A(:) = C(ic)$ .
- If  $A$  is a table, or if the 'rows' option is specified, then  $A = C(ic, :)$ .

## More About

### Tips

- To find unique rows in table  $A$  with respect to a subset of variables, you can use column subscripting. For example, you can use `unique(A(:, vars))`, where `vars` is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

**Introduced before R2006a**

# unique\_tol

Unique values within tolerance

## Syntax

```
C = unique_tol(A,tol)
C = unique_tol(A)
[C,IA,IC] = unique_tol(___)
[___] = unique_tol(___ ,Name,Value)
```

## Description

`C = unique_tol(A,tol)` returns the unique elements in `A` using tolerance `tol`. Two values, `u` and `v`, are within tolerance if

$$\text{abs}(u-v) \leq \text{tol} * \max(\text{abs}(A(:)))$$

That is, `unique_tol` scales the `tol` input based on the magnitude of the data.

`unique_tol` is similar to `unique`. Whereas `unique` performs exact comparisons, `unique_tol` performs comparisons using a tolerance.

`C = unique_tol(A)` uses a default tolerance of  $1e-6$  for single-precision inputs and  $1e-12$  for double-precision inputs.

`[C,IA,IC] = unique_tol( ___ )` returns index vectors `IA` and `IC`, such that `C = A(IA)` and `A~C(IC)` (or `A(:)~C(IC)` if `A` is a matrix), where `~` means the values are within tolerance of each other. You can use any of the input arguments in previous syntaxes.

`[ ___ ] = unique_tol( ___ ,Name,Value)` uses additional options specified by one or more `Name-Value` pair arguments using any of the input or output argument combinations in previous syntaxes. For example, `unique_tol(A, 'ByRows', true)` determines the unique rows in `A`.

## Examples

### Unique Elements in Presence of Numerical Error

Create a vector,  $x$ . Obtain a second vector,  $y$ , by transforming and untransforming  $x$ . This transformation introduces round-off differences to  $y$ .

```
x = (1:6)'*pi;
y = 10.^log10(x);
```

Verify that  $x$  and  $y$  are not identical by taking the difference.

```
x-y
```

```
ans =
 1.0e-14 *
 0.0444
 0
 0
 0
 0
 -0.3553
```

Use `unique` to find the unique elements in the concatenated vector  $[x;y]$ . The `unique` function performs exact comparisons and determines that some values in  $x$  are not exactly equal to values in  $y$ . These are the same elements that have a nonzero difference in  $x-y$ . Thus,  $c$  contains values that *appear* to be duplicates.

```
c = unique([x;y])
```

```
c =
 3.1416
 3.1416
 6.2832
 9.4248
 12.5664
 15.7080
```

```
18.8496
18.8496
```

Use `uniquetol` to perform the comparison using a small tolerance. `uniquetol` treats elements that are within tolerance as equal.

```
C = uniquetol([x;y])
```

```
C =
```

```
3.1416
6.2832
9.4248
12.5664
15.7080
18.8496
```

## Determine Unique Rows

By default, `uniquetol` looks for unique *elements* that are within tolerance, but it also can find unique *rows* of a matrix that are within tolerance.

Create a numeric matrix, **A**. Obtain a second matrix, **B**, by transforming and untransforming **A**. This transformation introduces round-off differences to **B**.

```
A = [0.05 0.11 0.18; 0.18 0.21 0.29; 0.34 0.36 0.41; 0.46 0.52 0.76];
B = log10(10.^A);
```

Use `unique` to find the unique rows in **A** and **B**. The `unique` function performs exact comparisons and determines that all of the rows in the concatenated matrix `[A;B]` are unique, even though some of the rows differ by only a small amount.

```
unique([A;B], 'rows')
```

```
ans =
```

```
0.0500 0.1100 0.1800
0.0500 0.1100 0.1800
0.1800 0.2100 0.2900
```

```

0.1800 0.2100 0.2900
0.3400 0.3600 0.4100
0.3400 0.3600 0.4100
0.4600 0.5200 0.7600
0.4600 0.5200 0.7600

```

Use `uniquetol` to find the unique rows. `uniquetol` treats rows that are within tolerance as equal.

```
uniquetol([A;B], 'ByRows', true)
```

```
ans =
```

```

0.0500 0.1100 0.1800
0.1800 0.2100 0.2900
0.3400 0.3600 0.4100
0.4600 0.5200 0.7600

```

### Prepare Vectors for Exact Comparison

Create a vector, `x`. Obtain a second vector, `y`, by transforming and untransforming `x`. This transformation introduces round-off differences to some elements in `y`.

```

x = (1:6)'*pi;
y = 10.^log10(x);

```

Combine `x` and `y` into a single tall vector, `A`. Use `uniquetol` to reconstruct `A`, treating the values that are within tolerance as equal.

```

A = [x;y]
[C,IA,IC] = uniquetol(A);
newA = C(IC)

```

```
A =
```

```

3.1416
6.2832
9.4248
12.5664
15.7080

```

```
18.8496
3.1416
6.2832
9.4248
12.5664
15.7080
18.8496
```

```
newA =
```

```
3.1416
6.2832
9.4248
12.5664
15.7080
18.8496
3.1416
6.2832
9.4248
12.5664
15.7080
18.8496
```

You can use `newA` with `==` or functions that use exact equality like `isequal` or `unique` in subsequent code.

```
D1 = unique(A)
D2 = unique(newA)
```

```
D1 =
```

```
3.1416
3.1416
6.2832
9.4248
12.5664
15.7080
18.8496
18.8496
```

```
D2 =
```

```
3.1416
6.2832
9.4248
12.5664
15.7080
18.8496
```

### Subset Data Using Large Tolerance

Create a cloud of 2-D sample points constrained to be inside a circle of radius 0.5 centered at the point  $(\frac{1}{2}, \frac{1}{2})$ .

```
x = rand(10000,2);
insideCircle = sqrt((x(:,1)-.5).^2+(x(:,2)-.5).^2)<0.5;
y = x(insideCircle,:);
```

Find a reduced set of points, such that each point of the original dataset is within tolerance of a point.

```
tol = 0.05;
C = uniquetol(y,tol,'ByRows',true);
```

Plot the reduced set of points as red dots on top of the original data set. The red dots are all members of the original data set. All the red dots are at least a distance `tol` apart.

```
plot(y(:,1),y(:,2),'.')
hold on
axis equal
plot(C(:,1), C(:,2), '.r', 'MarkerSize', 10)
```

### Average Similar Values in Vector

Create a vector of random numbers and determine the unique elements using a tolerance. Specify `OutputAllIndices` as `true` to return all of the indices for the elements that are within tolerance of the unique values.

```
A = rand(100,1);
[C,IA] = uniquetol(A,1e-2, 'OutputAllIndices',true);
```

Find the average value of the elements that are within tolerance of the value `C(2)`.

```
C(2)
allA = A(IA{2})
aveA = mean(allA)
```

```
ans =
 0.0318

allA =
 0.0357
 0.0318
 0.0344

aveA =
 0.0340
```

### Specify Absolute Tolerance

By default, `uniquetol` uses a tolerance test of the form  $\text{abs}(u-v) \leq \text{tol} \cdot \text{DS}$ , where `DS` automatically *scales* based on the magnitude of the input data. You can specify a different `DS` value to use with the `DataScale` option. However, absolute tolerances (where `DS` is a scalar) do not scale based on the magnitude of the input data.

First, compare two small values that are a distance `eps` apart. Specify `tol` and `DS` to make the within tolerance equation:  $\text{abs}(u-v) \leq 10^{-6}$ .

```
x = 0.1;
uniquetol([x, exp(log(x))], 10^-6, 'DataScale', 1)
```

```
ans =
 0.1000
```

Next, increase the magnitude of the values. The round-off error in the calculation  $\text{exp}(\log(x))$  is proportional to the magnitude of the values, specifically to  $\text{eps}(x)$ . Even though the two large values are a distance `eps` from one another,  $\text{eps}(x)$  is now much larger. Therefore,  $10^{-6}$  is no longer a suitable tolerance.

```
x = 10^10;
uniquetol([x, exp(log(x))], 10^-6, 'DataScale', 1)
```

```
ans =

1.0e+10 *

1.0000 1.0000
```

Correct this issue by using the default (scaled) value of DS.

```
format long
Y = [0.1 10^10];
uniquetol([Y, exp(log(Y))])
```

```
ans =

1.0e+10 *

0.000000000010000 1.0000000000000000
```

## Specify DataScale by Column

Create a set of random 2-D points, then use `uniquetol` to group the points into vertical bands that have a similar (within tolerance) x-coordinate. Use these options with `uniquetol`:

- Specify `ByRows` as `true` since the point coordinates are in the rows of `A`.
- Specify `OutputAllIndices` as `true` to return the indices for all points that have an x-coordinate within tolerance of each other.
- Specify `DataScale` as `[1 Inf]` to use an absolute tolerance for the x-coordinate while ignoring the y-coordinate.

```
A = rand(1000,2);
DS = [1 Inf];
[C,IA] = uniquetol(A, 0.1, 'ByRows', true, ...
 'OutputAllIndices', true, 'DataScale', DS);
```

Plot the points and average value for each band.

```
hold on
for k = 1:length(IA)
 plot(A(IA{k},1), A(IA{k},2), '.')
```

```

meanAi = mean(A(IA{k},:));
plot(meanAi(1), meanAi(2), 'xr')
end

```

- “Average Similar Data Points Using a Tolerance”

## Input Arguments

### **A** — Query array

scalar | vector | matrix

Query array, specified as a scalar, vector, or matrix. **A** must be full.

Data Types: `single` | `double`

### **tol** — Comparison tolerance

positive, real scalar

Comparison tolerance, specified as a positive, real scalar. `unique(tol)` scales the `tol` input using the maximum absolute value in input array `A`. Then `unique(tol)` uses the resulting scaled comparison tolerance to determine which elements in `A` are unique. If two elements in `A` are within tolerance of each other, then `unique(tol)` considers them to be equal.

Two values, `u` and `v`, are within tolerance if  $\text{abs}(u - v) \leq \text{tol} * \text{max}(\text{abs}(A))$ .

To specify an absolute tolerance, specify both `tol` and the `'DataScale'` Name-Value pair.

Example: `tol = 0.05`

Example: `tol = 1e-8`

Example: `tol = eps`

Data Types: `single` | `double`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `C = unique(tol(A, 'ByRows', true))`

### **'OutputAllIndices'** — Output index type

`false` (default) | `true` | `0` | `1`

Output index type, specified as the comma-separated pair consisting of `'OutputAllIndices'` and either `false` (default), `true`, `0`, or `1`. `unique(tol)` interprets numeric `0` as `false` and numeric `1` as `true`.

When `OutputAllIndices` is `true`, the `unique(tol)` function returns the second output, `IA`, as a cell array. The cell array contains the indices for *all* elements in `A` that are within tolerance of a value in `C`. That is, each cell in `IA` corresponds to a value in `C`, and the values in each cell correspond to locations in `A`.

Example: `[C,IA] = uniquetol(A,tol,'OutputAllIndices',true)`

### 'ByRows' — Row comparison toggle

false (default) | true | 0 | 1

Row comparison toggle, specified as the comma-separated pair consisting of 'ByRows' and either false (default), true, 0, or 1. `uniquetol` interprets numeric 0 as false and numeric 1 as true. Use this option to find rows in A that are unique, within tolerance.

When `ByRows` is true:

- `uniquetol` compares the rows of A by considering each column separately. For two rows to be within tolerance of one another, each column has to be in tolerance.
- Each row in A is within tolerance of a row in C. However, no two rows in C are within tolerance of each other.

Two rows, u and v, are within tolerance if  $\text{abs}(u-v) \leq \text{tol} \cdot \max(\text{abs}(A), [], 1)$ .

Example: `C = uniquetol(A,tol,'ByRows',true)`

### 'DataScale' — Scale of data

scalar | vector

Scale of data, specified as the comma-separated pair consisting of 'DataScale' and either a scalar or vector. Specify `DataScale` as a numeric scalar, DS, to change the tolerance test to be  $\text{abs}(u-v) \leq \text{tol} \cdot \text{DS}$ .

When used together with the `ByRows` option, the `DataScale` value also can be a vector. In this case, each element of the vector specifies DS for a corresponding column in A. If a value in the `DataScale` vector is Inf, then `uniquetol` ignores the corresponding column in A.

Example: `C = uniquetol(A,'DataScale',1)`

Example: `[C,IA,IC] = uniquetol(A,'ByRows',true,'DataScale',[eps(1) eps(10) eps(100)])`

Data Types: single | double

## Output Arguments

### C — Unique elements in A

vector | matrix

Unique elements in **A** (within tolerance), returned as a vector or matrix. If **A** is a row vector, then **C** is also a row vector. Otherwise, **C** is a column vector. The elements in **C** are sorted in ascending order. Each element in **A** is within tolerance of an element in **C**, but no two elements in **C** are within tolerance of each other.

If the **ByRows** option is **true**, then **C** is a matrix containing the unique rows in **A**. In this case, the rows in **C** are sorted in ascending order by the first column. Each row in **A** is within tolerance of a row in **C**, but no two rows in **C** are within tolerance of each other.

### **IA — Index to A**

column vector | cell array

Index to **A**, returned as a column vector of indices to the first occurrence of repeated elements, or as a cell array. **IA** generally satisfies  $C = A(IA)$ , with the following exceptions:

- If the **ByRows** option is **true**, then  $C = A(IA, :)$ .
- If the **OutputAllIndices** option is **true**, then **IA** is a cell array and  $C(i) \sim A(IA\{i\})$  where  $\sim$  means the values are within tolerance of each other.

### **IC — Index to C**

column vector

Index to **C**, returned as a column vector of indices. **IC** satisfies the following properties, where  $\sim$  means the values are within tolerance of each other.

- If **A** is a vector, then  $A \sim C(IC)$ .
- If **A** is a matrix, then  $A(:) \sim C(IC)$ .
- If the **ByRows** option is **true**, then  $A \sim C(IC, :)$ .

## **More About**

### **Tips**

- There can be multiple valid **C** outputs that satisfy the condition, *no two elements in C are within tolerance of each other*. The **unique\_tol** function just returns one of the valid outputs.

**unique\_tol** sorts the input lexicographically, and then starts at the lowest value to find unique values within tolerance. As a result, changing the sorting of the input

could change the output. For example, `uniquetol(-A)` might not give the same results as `-uniquetol(A)`.

# matlab.unittest

Summary of packages and classes in MATLAB Unit Test Framework

## Description

The `matlab.unittest` package consists of the following classes and packages:

<code>matlab.unittest.constraints</code>	Summary of classes in MATLAB Constraints Interface
<code>matlab.unittest.diagnostics</code>	Summary of classes in MATLAB Diagnostics Interface
<code>matlab.unittest.fixtures</code>	Summary of classes in MATLAB Fixtures Interface
<code>matlab.unittest.FunctionTestCase</code>	TestCase used for function-based tests
<code>matlab.unittest.parameters</code>	Summary of classes associated with MATLAB Unit Test parameters
<code>matlab.unittest.plugins</code>	Summary of classes in MATLAB Plugins Interface
<code>matlab.unittest.plugins.plugindata</code>	Summary of classes in MATLAB Plugin Data Interface
<code>matlab.unittest.qualifications</code>	Summary of classes in MATLAB Qualifications Interface
<code>matlab.unittest.selectors</code>	Summary of classes in MATLAB Selectors Interface
<code>matlab.unittest.Test</code>	Specification of a single test method
<code>matlab.unittest.TestCase</code>	Superclass of all <code>matlab.unittest</code> test classes
<code>matlab.unittest.TestResult</code>	Result of running test suite
<code>matlab.unittest.TestRunner</code>	Class for running tests in <code>matlab.unittest</code> framework
<code>matlab.unittest.TestSuite</code>	Class for grouping tests to run

matlab.unittest.Verbose

Verbose level enumeration class

## unix

Execute UNIX command and return output

### Syntax

```
status = unix(command)
[status,cmdout] = unix(command)
[status,cmdout] = unix(command, '-echo')
```

### Description

`status = unix(command)` calls the UNIX operating system to execute the specified command. The operation waits for the command to finish execution before returning the exit status of the command to the `status` variable.

`[status,cmdout] = unix(command)` additionally returns the standard output of the command to `cmdout`. This syntax is most useful for commands that do not require user input.

`[status,cmdout] = unix(command, '-echo')` also displays (echoes) the command output in the MATLAB Command Window. This syntax is most useful for commands that require user input and that run correctly in the MATLAB Command Window.

### Examples

#### Save UNIX Command Exit Status and Output

List all users who are currently logged in, and save the command exit status and output. Then, view the status.

```
command = 'who';
[status,cmdout] = unix(command);
status

status =
```

0

A **status** of zero indicates that the command completed successfully. MATLAB returns a string containing the list of users in `cmdout`.

## Input Arguments

**command** — UNIX command

string

UNIX command, specified as a string. The `command` executes in a UNIX shell, which might not be the shell from which you started MATLAB.

Example: 'ls'

## Output Arguments

**status** — Command exit status

0 | nonzero integer

Command exit status, returned as either 0 or a nonzero integer. When the command is successful, `status` is 0. Otherwise, `status` is a nonzero integer.

- If `command` includes the ampersand character (&), then `status` is the exit status when `command` starts
- If `command` does not include the ampersand character (&), then `status` is the exit status upon `command` completion.

**cmdout** — Output of operating system command

string

Output of the operating system command, returned as a string. The system shell might not properly represent non-Unicode characters.

## Limitations

- MATLAB converts characters to the encoding that your operating system shell accepts. Output from the `command` is converted to the MATLAB encoding to be

displayed in the command window. If you get unexpected results from the command, enter the `command` argument directly at the operating system prompt to see how the operating system treats your input.

## More About

### Tips

- To execute the operating system command in the background, include the trailing character, `&`, in the `command` argument (for example, `'emacs &'`). The exit status is immediately returned to the `status` variable. This syntax is useful for console programs that require interactive user command input while they run, and that do not run correctly in the MATLAB Command Window.

---

**Note:** If `command` includes the trailing `&` character, `cmdout` is empty.

---

- The `unix` function redirects `stdin` to the invoked command, `command`, by default. This redirection also passes MATLAB script commands and the keyboard type-ahead buffer to the invoked command while the `unix` function executes. This can lead to corrupted output when `unix` does not complete execution immediately. To disable `stdin` and type-ahead redirection, include the formatted string `< /dev/null` in the call to the invoked command.

### Algorithms

MATLAB uses a shell program to execute the given command. It determines which shell program to use by checking environment variables on your system. MATLAB first checks the `MATLAB_SHELL` variable, and if either empty or not defined, then checks `SHELL`. If `SHELL` is also empty or not defined, MATLAB uses `/bin/sh`.

- “Run External Commands, Scripts, and Programs”

**Introduced before R2006a**

# unloadlibrary

Unload shared library from memory

## Syntax

```
unloadlibrary libname
```

## Description

`unloadlibrary libname` unloads library `libname` from memory.

## Examples

### Unload Library

Add path to `examples` folder.

```
addpath(fullfile(matlabroot, 'extern', 'examples', 'shrlib'))
```

Load the library, if it is not already loaded.

```
if ~libisloaded('shrlibsample')
 loadlibrary('shrlibsample')
end
```

Cleanup.

```
unloadlibrary shrlibsample
```

## Input Arguments

**libname** — Name of shared library

string

Name of shared library, specified as a string. Do not include the path or file extension in `libname`.

If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

Data Types: `char`

## Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

## More About

### Tips

- To unload a MEX file, use the `clear` function.

### See Also

`clear` | `libisloaded` | `loadlibrary`

**Introduced before R2006a**

# unmesh

Convert edge matrix to coordinate and Laplacian matrices

## Syntax

`[L,XY] = unmesh(E)`

## Description

`[L,XY] = unmesh(E)` returns the Laplacian matrix `L` and mesh vertex coordinate matrix `XY` for the `M`-by-4 edge matrix `E`. Each row of the edge matrix must contain the coordinates `[x1 y1 x2 y2]` of the edge endpoints.

## Input Arguments

`E`                      `M`-by-4 edge matrix `E`.

## Output Arguments

`L`                      Laplacian matrix representation of the graph.  
`XY`                      Mesh vertex coordinate matrix.

## Examples

Take a simple example of a square with vertices at  $(1,1)$ ,  $(1,-1)$ ,  $(-1,-1)$ , and  $(-1,1)$ , where the connections between vertices are the four perpendicular edges of the square plus one diagonal connection between  $(-1, -1)$  and  $(1,1)$ .

The edge matrix E for this graph is:

```
E=[1 1 1 -1; % edge from 1 to 2
1 -1 -1 -1; % edge from 2 to 3
-1 -1 -1 1; % edge from 3 to 4
-1 -1 1 1; % edge from 4 to 1
-1 1 1 1] % edge from 3 to 1
```

Use `unmesh` to create the output matrices,

```
[A,XY]=unmesh(E);
```

```
4 vertices:
```

```
4/4
```

The Laplacian matrix is defined as

$$L_{ij} = \begin{cases} \deg(v_i) & \text{if } i = j \\ -1 & \text{if } i \neq j \text{ and } v_i \text{ is adjacent to } v_j \\ 0 & \text{otherwise} \end{cases}$$

`unmesh` returns the Laplacian matrix L in sparse notation.

```
L
```

```
L =
```

```
(1,1) 3
(2,1) -1
(3,1) -1
(4,1) -1
(1,2) -1
(2,2) 2
(4,2) -1
(1,3) -1
(3,3) 2
(4,3) -1
(1,4) -1
(2,4) -1
(3,4) -1
```

To see L in regular matrix notation, use the `full` command.

```
full(L)
```

```
ans =
```

```
 3 -1 -1 -1
 -1 2 0 -1
 -1 0 2 -1
 -1 -1 -1 3
```

The mesh coordinate matrix `XY` returns the coordinates of the corners of the square.

```
XY
```

```
XY =
```

```
 -1 -1
 -1 1
 1 -1
 1 1
```

## See Also

`gplot` | `treepplot`

## unmkpp

Piecewise polynomial details

### Syntax

```
[breaks,coefs,l,k,d] = unmkpp(pp)
```

### Description

[breaks,coefs,l,k,d] = unmkpp(pp) extracts, from the piecewise polynomial pp, its breaks breaks, coefficients coefs, number of pieces l, order k, and dimension d of its target. Create pp using spline or the spline utility mkpp.

### Examples

This example creates a description of the quadratic polynomial

$$\frac{-x^2}{4} + x$$

as a piecewise polynomial pp, then extracts the details of that description.

```
pp = mkpp([-8 -4],[-1/4 1 0]);
[breaks,coefs,l,k,d] = unmkpp(pp)
```

```
breaks =
 -8 -4
```

```
coefs =
 -0.2500 1.0000 0
```

```
l =
 1
```

```
k =
 3
```

d =  
1

### **See Also**

mkpp | ppval | spline

## unregisterallevents

Unregister all event handlers associated with COM object events at run time

### Syntax

```
unregisterallevents(h)
```

### Description

`unregisterallevents(h)` unregisters all events previously registered with COM object `h`. After calling `unregisterallevents`, the object no longer responds to any events until you register them again using the `registerevent` function.

COM functions are available on Microsoft Windows systems only.

### Examples

Register and unregister events for an instance of the `mwsamp` control, using the `eventlisteners` function to see the event handler associated with each event.

- 1 Register three events and their respective handler routines.

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],f, ...
 {'Click' 'myclick'; 'DbClick' 'my2click'; 'MouseDown' 'mymoused'});
eventlisteners(h)

ans =
 'click' 'myclick'
 'dblclick' 'my2click'
 'mousedown' 'mymoused'
```

- 2 Unregister all events simultaneously with `unregisterallevents`. `eventlisteners` returns an empty cell array, indicating that there are no longer any events registered with the control.

```
unregisterallevents(h)
```

```
eventlisteners(h)
```

```
ans =
 {}
```

## See Also

events (COM) | eventlisteners | registerevent | unregisterevent | isevent

**Introduced before R2006a**

## unregisterevent

Unregister event handler associated with COM object event at run time

### Syntax

```
unregisterevent(h,eventhandler)
```

### Description

`unregisterevent(h,eventhandler)` unregisters specific event handler routines from their corresponding events. Once you unregister an event, the object no longer responds to the event.

You can unregister events at any time after creating a control. The `eventhandler` argument, which is a cell array, specifies both events and event handlers.

```
unregisterevent(h,{'event_name',@event_handler});
```

Specify events in the `eventhandler` argument using the names of the events. Strings used in the `eventhandler` argument are not case-sensitive. `unregisterevent` does not accept numeric event identifiers.

COM functions are available on Microsoft Windows systems only.

### Examples

Unregister events for a control.

- 1 Create an `mwsamp` control and register all events with the same handler routine, `sampev`. Use `eventlisteners` to see the event handler used by each event. In this case, each event, when fired, calls `sampev.m`.

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],f,'sampev');
eventlisteners(h)
```

```
ans =
 'Click' 'sampev'
 'DbLcLick' 'sampev'
 'MouseDown' 'sampev'
 'Event_Args' 'sampev'
```

- 2 Unregister just the `dblclick` event. Now, when you list the registered events using `eventlisteners`, `dblclick` is no longer registered and the control does not respond when you double-click the mouse over it.

```
unregisterevent(h,{'dblclick' 'sampev'})
eventlisteners(h)
```

```
ans =
 'Click' 'sampev'
 'MouseDown' 'sampev'
 'Event_Args' 'sampev'
```

- 3 Register the `click` and `dblclick` events with a different event handler for `myclick` and `my2click`, respectively.

```
unregisterallevents(h)
registerevent(h,{'click' 'myclick'; 'dblclick' 'my2click'});
eventlisteners(h)
```

```
ans =
 'click' 'myclick'
 'dblclick' 'my2click'
```

- 4 Unregister these same events by specifying event names and their handler routines in a cell array. `eventlisteners` now returns an empty cell array, meaning that no events are registered for the `mwsamp` control.

```
unregisterevent(h,{'click' 'myclick'; 'dblclick' 'my2click'})
eventlisteners(h)
```

```
ans =
 {}
```

Unregister Microsoft Excel workbook events:

- 1 Create a `Workbook` object and register two events with the event handler routines, `EvtActivateHndlr` and `EvtDeactivateHndlr`. MATLAB shows the events with the corresponding event handlers.

```
myApp = actxserver('Excel.Application');
```

```
wbs = myApp.Workbooks;
wb = Add(wbs);
registerevent(wb,...
 {'Activate' 'EvtActivateHndlr'; 'Deactivate' 'EvtDeactivateHndlr'})
eventlisteners(wb)
```

```
ans =
 'Activate' 'EvtActivateHndlr'
 'Deactivate' 'EvtDeactivateHndlr'
```

- 2 Unregister the `Deactivate` event handler. MATLAB shows the remaining registered event (`Activate`) with its corresponding event handler.

```
unregisterevent(wb,{'Deactivate' 'EvtDeactivateHndlr'})
eventlisteners(wb)
```

```
ans =
 'Activate' 'EvtActivateHndlr'
```

## More About

**Introduced before R2006a**

# unstack

Unstack data from single variable into multiple variables

## Syntax

```
W = unstack(T,vars,ivar)
W = unstack(T,vars,ivar,Name,Value)
[W,it] = unstack(___)
```

## Description

`W = unstack(T,vars,ivar)` converts the tall table, `T`, to an equivalent table, `W`, that is in wide format. `unstack` unstacks a single variable in `T`, specified by `vars`, into multiple variables in `W`. In general, `W` contains more variables, but fewer rows, than `T`.

An indicator variable in `T`, specified by `ivar`, determines which variable in `W` contains each value in `var` after it is unstacked. `unstack` treats the remaining variables in `T` as grouping variables. Each unique combination of values in the grouping variables identifies a group of rows in `T` that will be unstacked into a single row of `W`.

`W = unstack(T,vars,ivar,Name,Value)` converts the table `T` to wide format with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify how `unstack` converts variables from `T` to variables in `W`.

`[W,it] = unstack( ___ )` also returns an index vector, `it`, indicating the correspondence between rows in `W` and rows in `T`. You can use any of the previous input arguments.

## Examples

### Separate One Variable into Three Variables

Create a table indicating the amount of snowfall in various towns for various storms.

```
Storm = [3;3;1;3;1;1;4;2;4;2;4;2];
Town = {'T1';'T3';'T1';'T2';'T2';'T3';...
 'T2';'T1';'T3';'T3';'T1';'T2'};
Snowfall = [0;3;5;5;9;10;12;13;15;16;17;21];
```

```
T = table(Storm,Town,Snowfall)
```

T =

Storm	Town	Snowfall
3	'T1'	0
3	'T3'	3
1	'T1'	5
3	'T2'	5
1	'T2'	9
1	'T3'	10
4	'T2'	12
2	'T1'	13
4	'T3'	15
2	'T3'	16
4	'T1'	17
2	'T2'	21

T contains three snowfall entries for each storm, one for each town.

Separate the variable `Snowfall` into three variables, one for each town specified in the variable, `Town`.

```
W = unstack(T, 'Snowfall', 'Town')
```

W =

Storm	T1	T2	T3
3	0	5	3
1	5	9	10
4	17	12	15
2	13	21	16

Each row in *W* contains data from rows in *T* that have the same value in the grouping variable, *Stock*. The order of the unique values in *Stock* determines the order of the data in *W*.

### Apply Aggregation Function to Each Group

Unstack data and apply an aggregation function to multiple rows in the same group that have the same values in the indicator variable.

Create a table containing data on the price of two stocks over 2 days.

```
Date = [repmat({'4/12/2008'},6,1);...
 repmat({'4/13/2008'},5,1)];
Stock = {'Stock1';'Stock2';'Stock1';'Stock2';...
 'Stock2';'Stock2';'Stock1';'Stock2';...
 'Stock2';'Stock1';'Stock2'};
Price = [60.35;27.68;64.19;25.47;28.11;27.98;...
 63.85;27.55;26.43;65.73;25.94];
```

```
T = table(Date,Stock,Price)
```

```
T =
```

Date	Stock	Price
'4/12/2008'	'Stock1'	60.35
'4/12/2008'	'Stock2'	27.68
'4/12/2008'	'Stock1'	64.19
'4/12/2008'	'Stock2'	25.47
'4/12/2008'	'Stock2'	28.11
'4/12/2008'	'Stock2'	27.98
'4/13/2008'	'Stock1'	63.85
'4/13/2008'	'Stock2'	27.55
'4/13/2008'	'Stock2'	26.43
'4/13/2008'	'Stock1'	65.73
'4/13/2008'	'Stock2'	25.94

*T* contains two prices for **STOCK1** during the first day and four prices for **STOCK2** during the first day.

Create a table containing separate variables for each stock and one row for each day. Use *Date* as the grouping variable and apply the aggregation function, `@mean`, to the numeric values from the variable, *Price*, for each group.

```
[W,it] = unstack(T,'Price','Stock',...
 'AggregationFunction',@mean)
```

W =

Date	Stock1	Stock2
'4/12/2008'	62.27	27.31
'4/13/2008'	64.79	26.64

it =

1  
7

W contains the average price for each stock grouped by date.

it identifies the index of the first value for each group of rows in T. The first value for the group '4/13/2008' is in the seventh row of T.

## Input Arguments

### T — Tall table

table

Tall table, specified as a table. T must contain data variables to unstack, `vars`, and an indicator variable, `ivar`. The remaining variables in T are either grouping variables or constant variables.

### vars — Variables in T to unstack

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables in T to unstack, specified as a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

### ivar — Indicator variable in T

positive integer | variable name

Indicator variable in T, specified as a positive integer or a variable name. The variable specified by `ivar` indicates which variable in W each value in `var` is unstacked into.

`ivar` can be a numeric vector, logical vector, character array, cell array of strings, or categorical vector.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'AggregationFunction', @mean` applies the aggregation function `@mean` to the values in `vars`.

### 'GroupingVariables' — Grouping variables in T that define groups of rows

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Grouping variables in `T` that define groups of rows, specified as the comma-separated pair consisting of `'GroupingVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector. Each group of rows in `T` becomes one row in `W`.

The default is all the variables in `T` not listed in `vars` or `ivar`.

### 'ConstantVariables' — Variables constant within a group

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables constant within a group, specified as the comma-separated pair consisting of `'ConstantVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector. The default is no variables.

The values for these variables in `W` are taken from the first row in each group in `T`.

### 'NewDataVariableNames' — Names for new data variables in W

cell array of strings

Names for new data variables in `W`, specified as the comma-separated pair consisting of `'NewDataVariableNames'` and a cell array of strings. The default is strings based on the values of the grouping variable specified in `ivar`.

### 'AggregationFunction' — Aggregation function from values in vars to single value

function handle

Aggregation function from values in `vars` to single value, specified as the comma-separated pair consisting of 'AggregationFunction' and a function handle. `unstack` applies this function to rows from the same group that have the same value in `ivar`. The function must aggregate the data values into a single value.

For a numeric data variable, the default is `@sum`. For nonnumeric variables, there is no default function, and you must specify the 'AggregationFunction' name-value pair argument if multiple rows in the same group have the same value in `ivar`.

## Output Arguments

### **W** — Wide table

table

Wide table, returned as a table. `W` contains the unstacked data variables, the grouping variables, and the first value of each group from any constant variables.

The order of the data in `W` is based on the order of the unique values in the grouping variables.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the table. For more information, see [Table Properties](#).

### **it** — Index to T

column vector

Index to `T`, returned as a column vector. For each row in `W`, the index vector, `it`, identifies the index of the first value in the corresponding group of rows in `T`.

## More About

### Grouping Variables

Grouping variables are utility variables used to group, or categorize, data. Grouping variables are useful for summarizing or visualizing data by group. You can define groups in your table by specifying one or more grouping variables.

A grouping variable can be any of the following:

- Categorical vector
- Cell array of strings
- Character array
- Numeric vector, typically containing positive integers
- Logical vector

Rows that have the same grouping variable value belong to the same group. If you use multiple grouping variables, rows that have the same combination of grouping variable values belong to the same group.

### Tips

- You can specify more than one data variable in `T`, and each variable becomes a set of unstacked data variables in `W`. Use a vector of positive integers, a cell array containing multiple variable names, or a logical vector to specify `vars`. The one indicator variable, specified by the input argument, `ivar`, applies to all data variables specified by `vars`.

### See Also

`join` | `stack`

**Introduced in R2013b**

## untar

Extract contents of tar file

### Syntax

```
untar(tarfilename)
untar(tarfilename,outputdir)
untar(url, ___)
filenames = untar(___)
```

### Description

`untar(tarfilename)` extracts the archived contents of `tarfilename` into the current directory and sets the files' attributes. It overwrites any existing files with the same names as those in the archive if the existing files' attributes and ownerships permit it. For example, if you rerun `untar` on the same `tarfilename`, MATLAB software does not overwrite files with a read-only attribute; instead, `untar` displays a warning for such files. On Microsoft Windows platforms, the hidden, system, and archive attributes are not set.

`tarfilename` is a string specifying the name of the tar file. `tarfilename` is gunzipped to a temporary directory and deleted if its extension ends in `.tgz` or `.gz`. If an extension is omitted, `untar` searches for `tarfilename` appended with `.tgz`, `.tar.gz`, or `.tar`. `tarfilename` can include the directory name; otherwise, the file must be in the current directory or in a directory on the MATLAB path.

`untar(tarfilename,outputdir)` uncompresses the archive `tarfilename` into the directory `outputdir`. If `outputdir` does not exist, MATLAB creates it.

`untar(url, ___ )` extracts the tar archive from an Internet URL. The URL must include the protocol type (for example, `'http://'` or `'ftp://'`). MATLAB downloads the URL to a temporary directory, and then deletes it.

`filenames = untar( ___ )` extracts the tar archive and returns the names of the extracted files in the string cell array `filenames`. If `outputdir` specifies a relative path, `filenames` contains the relative path. If `outputdir` specifies an absolute path, `filenames` contains the absolute path.

## Examples

### Using tar and untar to Copy Files

Copy all `.m` files in the current directory to the directory `backup`.

```
tar('myfiles.tar.gz','*.m');
untar('myfiles','backup');
```

### Using untar with URL

Run `untar` to list Cleve Moler's "Numerical Computing with MATLAB" examples to the output directory `ncm`.

```
url = 'http://www.mathworks.com/moler/ncm.tar.gz';
ncmFiles = untar(url,'ncm');
```

### See Also

`gzip` | `gunzip` | `tar` | `unzip` | `zip`

**Introduced before R2006a**

## unwrap

Correct phase angles to produce smoother phase plots

### Syntax

```
Q = unwrap(P)
Q = unwrap(P,tol)
Q = unwrap(P,[],dim)
Q = unwrap(P,tol,dim)
```

### Description

`Q = unwrap(P)` corrects the radian phase angles in a vector `P` by adding multiples of  $\pm 2\pi$  when absolute jumps between consecutive elements of `P` are greater than or equal to the default jump tolerance of  $\pi$  radians. If `P` is a matrix, `unwrap` operates columnwise. If `P` is a multidimensional array, `unwrap` operates on the first nonsingleton dimension.

`Q = unwrap(P,tol)` uses a jump tolerance `tol` instead of the default value,  $\pi$ .

`Q = unwrap(P,[],dim)` unwraps along `dim` using the default tolerance.

`Q = unwrap(P,tol,dim)` uses a jump tolerance of `tol`.

---

**Note** A jump tolerance less than  $\pi$  has the same effect as a tolerance of  $\pi$ . For a tolerance less than  $\pi$ , if a jump is greater than the tolerance but less than  $\pi$ , adding  $\pm 2\pi$  would result in a jump larger than the existing one, so `unwrap` chooses the current point. If you want to eliminate jumps that are less than  $\pi$ , try using a finer grid in the domain.

---

## Examples

### Example 1

The following phase data comes from the frequency response of a third-order transfer function. The phase curve jumps 3.5873 radians between  $w = 3.0$  and  $w = 3.5$ , from -1.8621 to 1.7252.

```
w = [0:.2:3,3.5:1:10];
p = [0
 -1.5728
 -1.5747
 -1.5772
 -1.5790
 -1.5816
 -1.5852
 -1.5877
 -1.5922
 -1.5976
 -1.6044
 -1.6129
 -1.6269
 -1.6512
 -1.6998
 -1.8621
 1.7252
 1.6124
 1.5930
 1.5916
 1.5708
 1.5708
 1.5708];
semilogx(w,p,'b*-'), hold
```

Using `unwrap` to correct the phase angle, the resulting jump is `2.6959`, which is less than the default jump tolerance  $\pi$ . This figure plots the new curve over the original curve.

```
semilogx(w,unwrap(p), 'r*-')
```

## Example 2

Array P features smoothly increasing phase angles except for discontinuities at elements (3,1) and (1,2).

```
P = [
 0 7.0686 1.5708 2.3562
 0.1963 0.9817 1.7671 2.5525
 6.6759 1.1781 1.9635 2.7489
 0.5890 1.3744 2.1598 2.9452]
```

The function  $Q = \text{unwrap}(P)$  eliminates these discontinuities.

```
Q =
 0 7.0686 1.5708 2.3562
 0.1963 7.2649 1.7671 2.5525
 0.3927 7.4613 1.9635 2.7489
 0.5890 7.6576 2.1598 2.9452
```

## See Also

**Introduced before R2006a**

# unzip

Extract contents of zip file

## Syntax

```
unzip(zipfilename)
unzip(zipfilename,outputdir)
filenames = unzip(zipfilename,outputdir)
```

## Description

`unzip(zipfilename)` extracts the archived contents of `zipfilename` into the current folder, preserving the files' attributes and timestamps. The `unzip` function can extract files from your local system or files from an Internet URL.

`unzip(zipfilename,outputdir)` extracts the contents of `zipfilename` into the folder `outputdir`.

`filenames = unzip(zipfilename,outputdir)` returns the names of the extracted files in the string cell array `filenames`. Specifying `outputdir` is optional.

## Input Arguments

### **zipfilename**

String that specifies the name of the zip file.

If `zipfilename` does not include the full path, `unzip` searches for the file in the current folder and along the MATLAB path. If you do not specify the file extension, `unzip` appends `.zip`.

If you are downloading a URL, `zipfilename` must include the protocol type (for example, `http://`). The `unzip` function downloads the URL to the temporary folder on your system, and deletes the URL on cleanup.

### **outputdir**

String that specifies the target folder for the extracted files.

**Default:** current folder ('.')

## Output Arguments

### **entrynames**

Cell array of strings that contain the paths of the extracted files.

If `outputdir` specifies a relative path, `filenames` contains the relative path. If `outputdir` specifies an absolute path, `filenames` contains the absolute path.

## Examples

Copy the example MAT-files to the folder `archive`:

```
% Zip the example MAT-files to examples.zip
zip('examples.zip','*.mat',...
 fullfile(matlabroot,'toolbox','matlab','demos'))
```

```
% Unzip examples.zip to the folder 'archive'
unzip('examples','archive')
```

Download Cleve Moler's "Numerical Computing with MATLAB" examples to the output folder `ncm`:

```
url = 'http://www.mathworks.com/moler/ncm.zip';
ncmFiles = unzip(url,'ncm')
```

## Alternatives

To extract files from a zip file using the Current Folder browser, select the zip file, right-click to open the context menu, and then select **Extract**.

## More About

### Tips

- `unzip` does not support password-protected or encrypted zip archives.

- If any files in the target folder have the same name as files in the zip file, and you have write permission to the files, `unzip` overwrites the existing files with the archived versions. If you do not have write permission, `unzip` issues a warning.
- Extract files that contain non-7-bit ASCII characters on a machine that has the appropriate language/encoding settings.

### **See Also**

`gzip` | `gunzip` | `tar` | `untar` | `zip` | `fileattrib`

**Introduced before R2006a**

## **uplus, +**

Unary plus

### **Syntax**

```
C = +A
C = uplus(A)
```

### **Description**

`C = +A` returns array `A` and stores it in `C`.

`C = uplus(A)` is an alternate way to execute `+A`, but is rarely used. It enables operator overloading for classes.

### **Examples**

#### **Unary Plus of Matrix**

Create a 2-by-2 matrix, `A`.

```
A = [1 -3; -2 4]
```

```
A =
```

```
 1 -3
 -2 4
```

Use unary plus on `A`.

```
C = +A
```

```
C =
```

```
 1 -3
 -2 4
```

C and A are the same.

## Input Arguments

### A — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

Complex Number Support: Yes

## More About

- “Array vs. Matrix Operations”
- “Operator Precedence”

## See Also

`plus` | `uminus`

**Introduced before R2006a**

## upper

Convert string to uppercase

### Syntax

```
t = upper('str')
B = upper(A)
```

### Description

`t = upper('str')` converts any lowercase characters in the string `str` to the corresponding uppercase characters and leaves all other characters unchanged.

`B = upper(A)` when `A` is a cell array of strings, returns a cell array the same size as `A` containing the result of applying `upper` to each string within `A`.

### Examples

```
upper('attention!') is ATTENTION!.
```

### More About

#### Tips

Character sets supported:

- PC: Windows Latin-1
- Other: ISO Latin-1 (ISO 8859-1)

#### See Also

`lower`

**Introduced before R2006a**

# urlread

Download URL content to MATLAB string (not recommended)

## Compatibility

urlread is not recommended. Use `webread` or `webwrite` instead.

## Syntax

```
str = urlread(URL)
str = urlread(URL,Name,Value)
[str,status] = urlread(___)
```

## Description

`str = urlread(URL)` downloads the HTML web content from the specified URL into the string `str`. `urlread` does not retrieve hyperlink targets and images.

`str = urlread(URL,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[str,status] = urlread( ___ )` suppresses the display of error messages, using any of the input arguments in the previous syntaxes. When the operation is successful, `status` is 1. Otherwise, `status` is 0

## Examples

### Download Web Content by Specifying Complete URL

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlread`.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
```

```
'?term=urlread'];
str = urlread(fullURL);
```

`urlread` reads from the specified URL and downloads the HTML content to the string `str`.

## Download Web Content Related to a Term

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlread`.

```
URL = 'http://www.mathworks.com/matlabcentral/fileexchange';
str = urlread(URL, 'Get', {'term', 'urlread'});
```

`urlread` reads from `http://www.mathworks.com/matlabcentral/fileexchange/?term=urlread` and downloads the HTML content to the string `str`.

## Specify Timeout Duration

Download content from a page on the MATLAB Central File Exchange as in the first example, and specify a timeout duration of 5 seconds.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
 '?term=urlread'];
str = urlread(fullURL, 'Timeout', 5);
```

# Input Arguments

## URL — Content location

string

Content location, specified as a string. Include the transfer protocol, such as `http`, `ftp`, or `file`.

Example: `'http://www.mathworks.com/matlabcentral'`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Timeout',10,'Charset','UTF-8'` specifies that `urlread` should time out after 10 seconds, and the character encoding of the file is UTF-8.

### **'Get' — Data to send to the web form using the GET method**

cell array

Parameters of the data to send to the web form using the GET method, specified as the comma-separated pair consisting of `'get'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Get'` includes the data in the URL, separated by `?` and `&` characters.

Example: `'Get',{'term','urlread'}`

### **'Post' — Data to send to the web form using the POST method**

cell array

Parameters of the data to send to the web form using the POST method, specified as the comma-separated pair consisting of `'post'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Post'` submits the data as part of the request headers, not explicitly in the URL.

### **'Charset' — Character encoding**

string

Character encoding, specified as the comma-separated pair consisting of `'Charset'` and a string. If you do not specify `Charset`, the function attempts to determine the character encoding from the headers of the file. If the character encoding cannot be determined, `Charset` defaults to the native encoding for the file protocol, and UTF-8 for all other protocols.

Example: `'Charset','ISO-8859-1'`

### **'Timeout' — Timeout duration**

scalar

Timeout duration in seconds, specified as the comma-separated pair consisting of `'Timeout'` and a scalar. The timeout duration determines when the function errors rather than continues to wait for the server to respond or send data.

Example: 'Timeout',10

## **'UserAgent' — Client user agent identification**

string

Client user agent identification, specified as the comma-separated pair consisting of 'UserAgent' and a string.

Example: 'UserAgent', 'MATLAB R2012b'

## **'Authentication' — HTTP authentication mechanism**

'Basic'

HTTP authentication mechanism, specified as the comma-separated pair consisting of 'Authentication' and a string. Currently, only the value 'Basic' is supported. 'Authentication', 'Basic' specifies basic authentication.

If you include the `Authentication` argument, you must also include the `Username` and `Password` arguments.

## **'Username' — User identifier**

string

User identifier, specified as the comma-separated pair consisting of 'Username' and a string. If you include the `Username` argument, you must also include the `Password` and `Authentication` arguments.

Example: 'Username', 'myName'

## **'Password' — User authentication password**

string

User authentication password, specified as the comma-separated pair consisting of 'Password' and a string. If you include the `Password` argument, you must also include the `Username` and `Authentication` arguments.

Example: 'Password', 'myPassword123'

## **Output Arguments**

### **str — Contents of the file at the specified URL**

string

Contents of the file at the specified URL, returned as a string. For example, if the URL corresponds to an HTML page, `str` contains the text and markup in the HTML file. If the URL corresponds to a binary file, `str` is not readable.

**status** — Download status

1 | 0

Download status, returned as either 1 or 0. When the download is successful, `status` is 1. Otherwise, `status` is 0.

## More About

### Tips

- `urldread` saves web content to a string. To save content to a file, use `urlwrite`.
- `urldread` and `urlwrite` can download content from FTP sites. Alternatively, use the `ftp` function to connect to an FTP server and the `mget` function to download a file.
- “Specify Proxy Server Settings for Connecting to the Internet”

### See Also

`ftp` | `mget` | `urlwrite` | `web` | `webread` | `webwrite`

Introduced before R2006a

## urlwrite

Download URL content and save to file (not recommended)

## Compatibility

urlwrite is not recommended. Use websave instead.

## Syntax

```
urlwrite(URL,filename)
urlwrite(URL,filename,Name,Value)

[filestr,status] = urlwrite(___)
```

## Description

urlwrite(URL,filename) reads web content at the specified URL and saves it to the file specified by filename.

urlwrite(URL,filename,Name,Value) uses additional options specified by one or more Name,Value pair arguments.

[filestr,status] = urlwrite( \_\_\_ ) stores the file path in variable filestr, and suppresses the display of error messages, using any of the input arguments in the previous syntaxes. When the operation is successful, status is 1. Otherwise, status is 0.

## Examples

### Download Web Content by Specifying Complete URL

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to urlwrite. Save the results to samples.html in the current folder.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
 '?term=urlwrite'];
filename = 'samples.html';
urlwrite(fullURL,filename);
```

View the file.

```
web(filename)
```

### Download Web Content Related to a Term

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlwrite`. Save the results to `samples.html` in the current folder.

```
URL = 'http://www.mathworks.com/matlabcentral/fileexchange';
filename = 'samples.html';
urlwrite(URL,filename,'get',{'term','urlwrite'});
```

`urlwrite` downloads the HTML content from `http://www.mathworks.com/matlabcentral/fileexchange/?term=urlwrite` and writes it to `samples.html`.

### Specify Timeout Duration

Download content from a page on the MATLAB Central File Exchange as in the first example, and specify a timeout duration of 5 seconds.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
 '?term=urlwrite'];
filename = 'samples.html';
urlwrite(fullURL,filename,'Timeout',5);
```

## Input Arguments

### URL — Content location

string

Content location, specified as a string. Include the transfer protocol, such as `http`, `ftp`, or `file`.

Example: `'http://www.mathworks.com/matlabcentral'`

### filename — Name of file to store web content

string

Name of the file to store the web content, specified as a string. If you do not specify the path for `filename`, `urlwrite` saves the file in the current folder.

Example: `'myfile.html'`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Timeout', 10, 'Charset', 'UTF-8'` specifies that `urlread` should time out after 10 seconds, and the character encoding of the file is UTF-8.

### 'Get' — Data to send to the web form using the GET method

cell array

Parameters of the data to send to the web form using the GET method, specified as the comma-separated pair consisting of `'get'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

'Get' includes the data in the URL, separated by `?` and `&` characters.

Example: `'Get', {'term', 'urlread'}`

### 'Post' — Data to send to the web form using the POST method

cell array

Parameters of the data to send to the web form using the POST method, specified as the comma-separated pair consisting of `'post'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

'Post' submits the data as part of the request headers, not explicitly in the URL.

### 'Charset' — Character encoding

string

Character encoding, specified as the comma-separated pair consisting of `'Charset'` and a string. If you do not specify `Charset`, the function attempts to determine the character encoding from the headers of the file. If the character encoding cannot be determined, `Charset` defaults to the native encoding for the file protocol, and UTF-8 for all other protocols.

Example: 'Charset', 'ISO-8859-1'

**'Timeout' — Timeout duration**

scalar

Timeout duration in seconds, specified as the comma-separated pair consisting of 'Timeout' and a scalar. The timeout duration determines when the function errors rather than continues to wait for the server to respond or send data.

Example: 'Timeout', 10

**'UserAgent' — Client user agent identification**

string

Client user agent identification, specified as the comma-separated pair consisting of 'UserAgent' and a string.

Example: 'UserAgent', 'MATLAB R2012b'

**'Authentication' — HTTP authentication mechanism**

'Basic'

HTTP authentication mechanism, specified as the comma-separated pair consisting of 'Authentication' and a string. Currently, only the value 'Basic' is supported. 'Authentication', 'Basic' specifies basic authentication.

If you include the `Authentication` argument, you must also include the `Username` and `Password` arguments.

**'Username' — User identifier**

string

User identifier, specified as the comma-separated pair consisting of 'Username' and a string. If you include the `Username` argument, you must also include the `Password` and `Authentication` arguments.

Example: 'Username', 'myName'

**'Password' — User authentication password**

string

User authentication password, specified as the comma-separated pair consisting of 'Password' and a string. If you include the `Password` argument, you must also include the `Username` and `Authentication` arguments.

Example: 'Password', 'myPassword123'

## Output Arguments

### **filestr** — Path of the file

string

Path of the file specified by `filename`, returned as a string.

### **status** — Download status

1 | 0

Download status, returned as either 1 or 0. When the download is successful, `status` is 1. Otherwise, `status` is 0.

## More About

### Tips

- `urlread` and `urlwrite` can download content from FTP sites. Alternatively, use the `ftp` function to connect to an FTP server and the `mget` function to download a file.
- “Specify Proxy Server Settings for Connecting to the Internet”

Introduced before R2006a

## usejava

Determine if Java feature is available

### Syntax

```
tf = usejava(feature)
```

### Description

`tf = usejava(feature)` returns logical 1 (**true**) if the specified feature is supported. Otherwise, it returns logical 0 (**false**). Use for error handling if Java feature is unavailable.

### Examples

#### Display Error Message

Use the following code snippet to test that the AWT GUI components are available before attempting to display a Java Frame.

```
if usejava('awt')
 myFrame = java.awt.Frame;
else
 disp('Unable to open a Java Frame')
end
```

If the AWT is not available on your system, MATLAB displays the message.

#### Call error Function

Use the following code snippet to terminate a script if MATLAB does not have access to JVM software.

The variable, `filename`, is a function that contains Java code.

```
if ~usejava('jvm')
 error([filename ' requires Java to run.'])
end
```

end

## Input Arguments

### feature — Java feature

'awt' | 'desktop' | 'jvm' | 'swing'

Java feature, specified as one of these values:

'awt'	UI components in the Java Abstract Window Toolkit (AWT) are available.
'desktop'	MATLAB interactive desktop is running.
'jvm'	Java Virtual Machine software (JVM) is running.
'swing'	Swing components (Java lightweight UI components in the Java Foundation Classes) are available.

# userpath

View or change user portion of search path

## Syntax

`userpath`

```
userpath(newpath)
userpath('reset')
userpath('clear')
```

## Description

`userpath` returns a string specifying the first folder on the search path. MATLAB adds the *userpath* to the search path upon startup.

`userpath(newpath)` sets the primary *userpath* folder to `newpath`. The `newpath` folder appears at the top of the search path immediately and at startup in future sessions. MATLAB removes the folder previously specified by *userpath* from the search path.

`userpath('reset')` sets the primary *userpath* folder to the default for that platform, creating the Documents/MATLAB folder, if it does not exist. MATLAB immediately adds the default folder to the top of the search path, and also adds it to the search path at startup in future sessions. On Linux, the MATLAB directory is not created if the Documents directory does not exist.

`userpath('clear')` clears the value for the primary *userpath* immediately, and for future MATLAB sessions. MATLAB removes the folder previously specified by *userpath* from the search path.

## Examples

### View userpath Folder

This example assumes `userpath` is set to the default value on the Windows platform, Documents\MATLAB. Start MATLAB and display the current folder:

```
pwd
```

```
H:\Documents\MATLAB
```

In this example, H is the drive at which Documents is located.

Confirm that the current folder is the *userpath*.

```
userpath
```

```
H:\Documents\MATLAB;
```

Display the search path.

```
path
```

```
MATLABPATH
```

```
H:\Documents\MATLAB
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

MATLAB returns the search path. The *userpath* portion is at the top.

## Set New Value for *userpath*

Assume *userpath* is set to the default value on the Windows platform, Documents \MATLAB. Change the value from the default for *userpath* to C:\Research\_Project.

```
newpath = 'C:\Research_Project';
userpath(newpath)
```

View the effect of the change on the search path.

```
path
```

```
MATLABPATH
```

```
C:\Research_Project
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

MATLAB displays the search path, with the new value for *userpath* portion at the top. Note that MATLAB automatically removed the previous value of *userpath*, H:\Documents\MATLAB, from the search path when you assigned a new value to *userpath*.

### Clear the Value for userpath

Assume *userpath* is set to the default value and you do not want any folders to be added to the search path upon startup. Confirm the default is currently set.

```
userpath
```

```
H:\Documents\MATLAB;
```

Verify that the *userpath* folder is at the top of the search path.

```
path
```

```
MATLABPATH
```

```
H:\Documents\MATLAB
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

Clear the value.

```
userpath('clear')
```

Verify the result.

```
userpath
```

```
ans =
 ''
```

Confirm the *userpath* folder was removed from the search path.

```
path
```

```
MATLABPATH
```

```
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

---

**Note:** If you clear the value for *userpath*, the startup folder will not necessarily be on the search path. Removing the *userpath* folder from the search path *and* saving the changes to the path has the same effect.

---

## Input Arguments

**newpath** — New *userpath* value

string

New *userpath* value, specified as a string. **newpath** must be an absolute path.

Example: 'C:\myFolder'

## More About

### Tips

- By default, the startup folder is the *userpath* folder when you start MATLAB by double-clicking the shortcut on Windows platforms, or by double-clicking the application on Mac platforms. If you clear the value for *userpath*, the startup folder will not necessarily be on the search path. Removing the *userpath* folder from the search path *and* saving the changes to the path has the same effect.

To specify the current folder, set the **Initial working folder** preference, described in “General Preferences”.

- On Mac and Linux platforms, you can automatically add subfolders to the top of the search path upon startup by specifying the path for the subfolders via the `MATLABPATH` environment variable.
- “What Is the MATLAB Search Path?”
- “MATLAB Startup Folder”

**Introduced in R2008a**

# Using ValueIterator Objects

An iterator over intermediate values for use with mapreduce

## Description

The `mapreduce` function automatically creates a `ValueIterator` object during execution and uses it to store the values associated with each unique intermediate key added by the map function. Although you never need to explicitly create a `ValueIterator` object to use `mapreduce`, you do need to interact with this object in the reduce function. Use the `hasnext` and `getnext` object functions to retrieve the values associated with each unique key in the intermediate `KeyValueStore` object.

## Examples

### Get Values from ValueIterator in Reduce Function

Use the `hasnext` and `getnext` functions in a `while` loop within the reduce function to iteratively get values from the `ValueIterator`. For example,

```
function MeanDistReduceFun(sumLenKey, sumLenIter, outKVStore)
 sumLen = [0, 0];
 while hasNext(sumLenIter)
 sumLen = sumLen + getnext(sumLenIter);
 end
 add(outKVStore, 'Mean', sumLen(1)/sumLen(2));
end
```

Always call `hasnext` before `getnext` to confirm availability of a value. `mapreduce` returns an error if you call `getnext` with no remaining values in the `ValueIterator`.

## Properties

### Key — Intermediate key

numeric scalar | string

This property is read only.

Intermediate key, specified as a numeric scalar or string. **Key** is one of the unique keys added by a map function. All the values in the `ValueIterator` object are associated with this key.

## Object Functions

`hasnext`

Determine if `ValueIterator` has one or more values available

`getnext`

Get next value from `ValueIterator`

## Create Object

The `mapreduce` function automatically creates `ValueIterator` objects during execution.

## See Also

`mapreduce`

## More About

- Using `KeyValueStore` Objects

**Introduced in R2014b**

# validateattributes

Check validity of array

## Syntax

```
validateattributes(A,classes,attributes)
validateattributes(A,classes,attributes,argIndex)
validateattributes(A,classes,attributes,funcName)
validateattributes(A,classes,attributes,funcName,varName)
validateattributes(A,classes,attributes,funcName,varName,argIndex)
```

## Description

`validateattributes(A,classes,attributes)` validates that array `A` belongs to at least one of the specified classes (or its subclass) and has all of the specified attributes. If `A` does not meet the criteria, MATLAB throws an error and displays a formatted error message. Otherwise, `validateattributes` completes without displaying any output.

`validateattributes(A,classes,attributes,argIndex)` includes the position of the input in your function argument list as part of any generated error messages.

`validateattributes(A,classes,attributes,funcName)` includes the specified function name in generated error identifiers.

`validateattributes(A,classes,attributes,funcName,varName)` includes the specified variable name in generated error messages.

`validateattributes(A,classes,attributes,funcName,varName,argIndex)` includes the specified information in generated error messages or identifiers.

## Examples

### Validate the Size of an Array

```
classes = {'numeric'};
attributes = {'size',[4,6,2]};
```

```
A = rand(3,5,2);
validateattributes(A,classes,attributes)
```

Expected input to be of size 4x6x2 when it is actually size 3x5x2.

Because A did not match the specified attributes, MATLAB throws an error message.

## Validate Array Monotonicity

Determine if an array is increasing or nondecreasing.

```
A = [1 5 8 2;
 9 6 9 4]
validateattributes(A, {'double'}, {'nondecreasing'})
validateattributes(A, {'double'}, {'increasing'})
```

```
A =

 1 5 8 2
 9 6 9 4
```

Since A is both increasing and nondecreasing, `validateattributes` does not throw an error for either attribute check.

Setting `A(2,3)` equal to `A(1,3)` results in a column that is no longer strictly increasing, so `validateattributes` throws an error.

```
A(2,3) = 8
validateattributes(A, {'double'}, {'increasing'})
```

```
A =

 1 5 8 2
 9 6 8 4
```

Expected input to be increasing valued.

However, the columns remain nondecreasing since each column element is equal to or greater than the next. The following code does not throw an error.

```
validateattributes(A, {'double'}, {'nondecreasing'})
```

## Check the Attributes of a Complex Number

Assuming that `a` is to be the second input argument to a function, check that it is nonnegative.

```
a = complex(1,1);
validateattributes(a,{'numeric'},{'nonnegative'},2)
```

Expected input number 2 to be nonnegative.

Because complex numbers lack a well-defined ordering in the complex plane, `validateattributes` does not recognize them as positive or negative.

### Ensure Array Values Are Within a Specified Range

Check that the values in an array are 8-bit integers between 0 and 10.

Assume that this code occurs in a function called `Rankings`.

```
classes = {'uint8','int8'};
attributes = {'>',0,'<',10};
funcName = 'Rankings';
A = int8(magic(4));

validateattributes(A,classes,attributes,funcName)
```

Error using `Rankings`

Expected input to be an array with all of the values < 10.

### Validate Function Input Parameters Using `inputParser`

Create a custom function that checks input parameters with `inputParser`, and use `validateattributes` as the validating function for the `addRequired` and `addOptional` methods.

Define the function.

```
function a = findArea(shape,dim1,varargin)
 p = inputParser;
 charchk = {'char'};
 numchk = {'numeric'};
 nempty = {'nonempty'};

 addRequired(p,'shape',@(x)validateattributes(x,charchk,nempty))
 addRequired(p,'dim1',@(x)validateattributes(x,numchk,nempty))
 addOptional(p,'dim2',1,@(x)validateattributes(x,numchk,nempty))
 parse(p,shape,dim1,varargin{:})

 switch shape
```

```
 case 'circle'
 a = pi * dim1.^2;
 case 'rectangle'
 a = dim1 .* p.Results.dim2;
end
end
```

Call the function with a nonnumeric third input.

```
myarea = findArea('rectangle',3,'x')
```

```
Error using findArea (line 10)
Argument 'dim2' failed validation with error:
Expected input to be one of these types:
```

```
double, single, uint8, uint16, uint32, uint64, int8, int16, int32, int64
```

```
Instead its type was char.
```

## Validate Arguments of a Function

Check the inputs of a function and include information about the input name and position in generated error.

Define the function.

```
function v = findVolume(shape,ht,wd,ln)
 validateattributes(shape,{'char'},{'nonempty'},mfilename,'Shape',1)
 validateattributes(ht,{'numeric'},{'nonempty'},mfilename,'Height',2)
 validateattributes(wd,{'numeric'},{'nonempty'},mfilename,'Width',3)
 validateattributes(ln,{'numeric'},{'nonempty'},mfilename,'Length',4)
```

Call the function without the shape input string.

```
vol = findVolume(10,7,4)
```

```
Error using findVolume
Expected input number 1, Shape, to be one of these types:
```

```
char
```

```
Instead its type was double.
```

```
Error in findVolume (line 2)
validateattributes(shape,{'char'},{'nonempty'},mfilename,'Shape',1)
```

The function name becomes part of the error identifier.

```
MException.last.identifier
```

```
ans =
```

```
MATLAB:findVolume:invalidType
```

## Input Arguments

### A — Input

any type of array

Input, specified as any type of array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `cell` | `function_handle`

Complex Number Support: Yes

### classes — Valid data types

cell array of strings

Valid data types, specified as a cell array of strings. Each string can be the name of any built-in or custom class, including:

'single'	Single-precision number
'double'	Double-precision number
'int8'	Signed 8-bit integer
'int16'	Signed 16-bit integer
'int32'	Signed 32-bit integer
'int64'	Signed 64-bit integer
'uint8'	Unsigned 8-bit integer
'uint16'	Unsigned 16-bit integer
'uint32'	Unsigned 32-bit integer
'uint64'	Unsigned 64-bit integer
'logical'	Logical true or false
'char'	Character or string

'struct'	Structure array
'cell'	Cell array
'function_handle'	function handle
'numeric'	Any data type for which the <code>isa(A, 'numeric')</code> function returns true, including <code>int8</code> , <code>int16</code> , <code>int32</code> , <code>int64</code> , <code>uint8</code> , <code>uint16</code> , <code>uint32</code> , <code>uint64</code> , <code>single</code> , or <code>double</code>
'<class_name>'	Any other class name

Data Types: `cell`

**attributes – Valid attributes**

cell array of strings

Valid attributes, specified as a cell array of strings.

Some attributes also require numeric values, such as attributes that specify the size or number of elements of **A**. For these attributes, the numeric value or vector must immediately follow the attribute name string in the cell array.

Attributes that describe the size and shape of array **A**:

'2d'	Two-dimensional array, including scalars, vectors, matrices, and empty arrays
'3d'	Array with three or fewer dimensions
'column'	Column vector, N-by-1
'row'	Row vector, 1-by-N
'scalar'	Scalar value, 1-by-1
'vector'	Row or column vector, or a scalar value
'size', [d1,...,dN]	Array with dimensions d1-by-...-by-dN. To skip checking a particular dimension, specify NaN for that dimension, such as <code>[3,4,NaN,2]</code> .
'numel', N	Array with N elements
'ncols', N	Array with N columns
'nrows', N	Array with N rows

'ndims', N	N-dimensional array
'square'	Square matrix; in other words, a two-dimensional array with equal number of rows and columns
'diag'	Diagonal matrix
'nonempty'	No dimensions that equal zero
'nonsparse'	Array that is not sparse

Attributes that specify valid ranges for values in **A**:

'>', N	All values greater than N
'>=', N	All values greater than or equal to N
'<', N	All values less than N
'<=', N	All values less than or equal to N

Attributes that check types of values in a numeric or logical array, **A**:

'binary'	Array of ones and zeros
'even'	Array of even integers (includes zero)
'odd'	Array of odd integers
'integer'	Array of integer values
'real'	Array of real values
'finite'	Array of finite values
'nonnan'	No NaN (Not a Number) elements
'nonnegative'	No elements less than zero
'nonzero'	No elements equal to zero
'positive'	No elements less than or equal to zero
'decreasing'	Each element of a column is less than the previous element and no element is NaN
'increasing'	Each element of a column is greater than the previous element and no element is NaN
'nondecreasing'	Each element of a column is greater than or equal to the previous element and no element is NaN

'nonincreasing'	Each element of a column is less than or equal to the previous element and no element is NaN
-----------------	----------------------------------------------------------------------------------------------

Data Types: cell

**funcName** — Name of function whose input you are validating

string

Name of function whose input you are validating, specified as a string. If you specify an empty string, '', the `validateattribute` function ignores the `funcName` input.

Data Types: char

**varName** — Name of input variable

string

Name of input variable, specified as a string. If you specify an empty string, '', the `validateattribute` function ignores the `varName` input.

Data Types: char

**argIndex** — Position of input argument

positive integer

Position of input argument, specified as a positive integer.

Data Types: double

## See Also

**Introduced in R2007b**

# validatestring

Check validity of text string

## Syntax

```
validStr = validatestring(str,validStrings)
validStr = validatestring(str,validStrings,argIndex)
validStr = validatestring(str,validStrings,funcName)
validStr = validatestring(str,validStrings,funcName,varName)
validStr = validatestring(str,validStrings,funcName,varName,
argIndex)
```

## Description

`validStr = validatestring(str,validStrings)` checks the validity of text string `str`. If `str` is an unambiguous, case-insensitive match to a string in cell array `validStrings`, the `validatestring` function returns the matching string in `validStr`. Otherwise, MATLAB throws an error and issues a formatted error message.

`validStr = validatestring(str,validStrings,argIndex)` includes the position of the input in your function argument list as part of any generated error messages.

`validStr = validatestring(str,validStrings,funcName)` includes the specified function name in generated error identifiers.

`validStr = validatestring(str,validStrings,funcName,varName)` includes the specified variable name in generated error messages.

`validStr = validatestring(str,validStrings,funcName,varName,argIndex)` includes the specified information in generated error messages or identifiers.

## Input Arguments

### **str**

String to validate, of type `char`.

**validStrings**

Cell array of allowed strings.

**funcName**

String that specifies the name of the function whose input you are validating. If you specify an empty string, '', the `validatestring` function ignores the `funcname` input.

**varName**

String that specifies the name of the input variable. If you specify an empty string, '', the `validatestring` function ignores the `varName` input.

**argIndex**

Positive integer that specifies the position of the input argument.

## Output Arguments

**validStr**

String that contains the element of `validStrings` that is an unambiguous, case-insensitive match to `str`.

Example — Match 'ball' with ...	Return Value	Type of Match
ball, barn, bell	ball	Exact match
balloon, barn	balloon	Partial match (leading characters)
ballo, balloo, balloon	ballo (shortest match)	Multiple partial matches where each string is a subset of another
balloon, ballet	Error	Multiple partial matches to unique strings
barn, bell	Error	No match

## Examples

Check whether a string is in a set of valid values.

```
str = 'won';
validStrings = {'wind','wonder','when'};

validStr = validatestring(str,validStrings)
```

Because `str` is a partial match to a unique string, this code returns

```
validStr =
 wonder
```

However, if `str` is a partial match to multiple strings, and the strings are not subsets of each other, `validatestring` throws an error and displays a formatted message.

```
str = 'won';
validStrings = {'wonder','wondrous','wonderful'};

validStr = validatestring(str,validStrings)
```

The error message is

Expected argument to match one of these strings:

```
 wonder, wondrous, wonderful
```

The input, 'won', matched more than one valid string.

Check inputs to a custom function, and include information about the input name and position in generated errors.

```
function a = findArea(shape,ht,wd,units)
 a = 0;
 expectedShapes = {'square','rectangle','triangle'};
 expectedUnits = {'cm','m','in','ft','yds'};

 shapeName = validatestring(shape,expectedShapes,mfilename,'Shape',1)
 unitAbbrev = validatestring(units,expectedUnits,mfilename,'Units',4)
```

When you call the function with valid input strings,

```
myarea = findArea('rect',10,3,'cm')
```

the function stores the inputs in local variables `shapeName` and `unitAbbrev`:

```
shapeName =
 rectangle
```

```
unitAbbrev =
 cm
```

However, if the inputs are not valid, such as

```
myarea = findArea('circle',10,3,'cm')
```

MATLAB displays

```
Error using findArea
Expected argument 1, Shape, to match one of these strings:
```

```
 square, rectangle, triangle
```

The input, 'circle', did not match any of the valid strings.

The function name is part of the error identifier, so

```
MException.last.identifier
```

returns

```
MATLAB:findArea:unrecognizedStringChoice
```

## See Also

[validateattributes](#) | [is\\*](#) | [isa](#) | [inputParser](#)

# values

**Class:** `containers.Map`

**Package:** `containers`

Identify values in `containers.Map` object

## Syntax

```
valueSet = values(mapObj)
valueSet = values(mapObj, keySet)
```

## Description

`valueSet = values(mapObj)` returns all of the values in `mapObj`.

`valueSet = values(mapObj, keySet)` returns values that correspond to the specified keys.

## Input Arguments

**mapObj**

Object of class `containers.Map`.

**keySet**

Cell array that specifies keys in `mapObj`.

## Output Arguments

**valueSet**

Cell array containing values from `mapObj`. If you specify `keySet`, the `valueSet` array has the same size and dimensions as `keySet`.

## Examples

### Get All Values in a Map

Create a map, and view all values in the map:

```
myKeys = {'a', 'b', 'c'};
myValues = [1,2,3];
mapObj = containers.Map(myKeys,myValues);

valueSet = values(mapObj)
```

This code returns 1-by-3 cell array `valueSet`:

```
valueSet =
 [1] [2] [3]
```

### Get Selected Values in a Map

View the values corresponding to keys `a` and `c` in `mapObj`, created in the previous example:

```
keySet = {'a', 'c'};
valueSet = values(mapObj, keySet)
```

This code returns 1-by-2 cell array `valueSet`:

```
valueSet =
 [1] [3]
```

### See Also

`keys` | `isKey` | `containers.Map`

# vander

Vandermonde matrix

## Syntax

`A = vander(v)`

## Description

`A = vander(v)` returns the “Vandermonde Matrix” on page 1-9432 such that its columns are powers of the vector `v`.

## Examples

### Find the Vandermonde Matrix for Vector Input

Use the colon operator to create vector `v`. Find the Vandermonde matrix for `v`.

```
v = 1:.5:3
A = vander(v)

v =
 1.0000 1.5000 2.0000 2.5000 3.0000

A =
 1.0000 1.0000 1.0000 1.0000 1.0000
 5.0625 3.3750 2.2500 1.5000 1.0000
 16.0000 8.0000 4.0000 2.0000 1.0000
 39.0625 15.6250 6.2500 2.5000 1.0000
 81.0000 27.0000 9.0000 3.0000 1.0000
```

Find the alternate form of the Vandermonde matrix using `fliplr`.

```
A = fliplr(vander(v))

A =
 1.0000 1.0000 1.0000 1.0000 1.0000
 1.0000 1.5000 2.2500 3.3750 5.0625
 1.0000 2.0000 4.0000 8.0000 16.0000
```

1.0000	2.5000	6.2500	15.6250	39.0625
1.0000	3.0000	9.0000	27.0000	81.0000

## Input Arguments

### **v** — Input

numeric vector

Input, specified as a numeric vector.

Data Types: `single` | `double`

Complex Number Support: Yes

## More About

### Vandermonde Matrix

For input vector  $v = [v_1 \ v_2 \ \dots \ v_N]$ , the Vandermonde matrix is

$$\begin{bmatrix} v_1^{N-1} & \dots & v_1^1 & v_1^0 \\ v_2^{N-1} & \dots & v_2^1 & v_2^0 \\ \vdots & & \vdots & \vdots \\ v_N^{N-1} & & v_N^1 & v_N^0 \end{bmatrix}$$

The matrix is described by the formula  $A(i,j) = v(i)^{(N-j)}$  such that its columns are powers of the vector  $v$ .

An alternate form of the Vandermonde matrix flips the matrix along the vertical axis, as shown. Use `fliplr(vander(v))` to return this form.

$$\begin{bmatrix} v_1^0 & v_1^1 & \dots & v_1^{N-1} \\ v_2^0 & v_2^1 & \dots & v_2^{N-1} \\ \vdots & \vdots & \ddots & \vdots \\ v_N^0 & v_N^1 & & v_N^{N-1} \end{bmatrix}$$

## **var**

Variance

### **Syntax**

```
V = var(A)
V = var(____,w)
V = var(____,dim)
V = var(____,nanflag)
```

### **Description**

`V = var(A)` returns the variance of the elements of `A` along the first array dimension whose size does not equal 1.

- If `A` is a vector of observations, the variance is a scalar.
- If `A` is a matrix whose columns are random variables and whose rows are observations, `V` is a row vector containing the variances corresponding to each column.
- If `A` is a multidimensional array, then `var(A)` treats the values along the first array dimension whose size does not equal 1 as vectors. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.
- The variance is normalized by the number of observations - 1 by default.
- If `A` is a scalar, `var(A)` returns 0. If `A` is a 0-by-0 empty array, `var(A)` returns NaN.

`V = var( ____,w)` specifies a weighting scheme for any of the previous syntaxes. When `w = 0` (default), `V` is normalized by the number of observations - 1. When `w = 1`, it is normalized by the number of observations. `w` can also be a weight vector containing nonnegative elements. In this case, the length of `w` must equal the length of the dimension over which `var` is operating.

`V = var( ____,dim)` returns the variance along the dimension `dim` for any of the previous syntaxes. To maintain the default normalization while specifying the dimension of operation, set `w = 0` in the second argument.

`V = var( ____,nanflag)` specifies whether to include or omit NaN values from the calculation for any of the previous syntaxes. For example, `var(A, 'includenan')` includes all NaN values in `A` while `var(A, 'omitnan')` ignores them.

## Examples

### Variance of Matrix

Create a matrix and compute its variance.

```
A = [4 -7 3; 1 4 -2; 10 7 9];
var(A)
```

```
ans =
```

```
21.0000 54.3333 30.3333
```

### Variance of Array

Create a 3-D array and compute its variance.

```
A(:,:,1) = [1 3; 8 4];
A(:,:,2) = [3 -4; 1 2];
var(A)
```

```
ans(:,:,1) =
```

```
24.5000 0.5000
```

```
ans(:,:,2) =
```

```
2 18
```

### Specify Variance Weight Vector

Create a matrix and compute its variance according to a weight vector w.

```
A = [5 -4 6; 2 3 9; -1 1 2];
w = [0.5 0.25 0.25];
var(A,w)
```

```
ans =
```

```
6.1875 9.5000 6.1875
```

## Specify Dimension for Variance

Create a matrix and compute its variance along the first dimension.

```
A = [4 -2 1; 9 5 7];
var(A,0,1)
```

```
ans =
```

```
12.5000 24.5000 18.0000
```

Compute the variance of **A** along the second dimension.

```
var(A,0,2)
```

```
ans =
```

```
9
4
```

## Variance Excluding NaN

Create a vector and compute its variance, excluding NaN values.

```
A = [1.77 -0.005 3.98 -2.95 NaN 0.34 NaN 0.19];
V = var(A, 'omitnan')
```

```
V =
```

```
5.1970
```

## Input Arguments

### **A** — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `single` | `double`

Complex Number Support: Yes

### **w** — Weight

0 (default) | 1 | vector

Weight, specified as one of:

- 0 — normalizes by the number of observations - 1. If there is only one observation, the weight is 1.
- 1 — normalizes by the number of observations.
- a vector made up of nonnegative scalar weights corresponding to the dimension of **A** along which the variance is calculated.

Data Types: `single` | `double`

### **dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension **dim** indicates the dimension whose length reduces to 1. The `size(V, dim)` is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, **A**.

- If **dim** = 1, then `var(A, 0, 1)` returns a row vector containing the variance of the elements in each column.

`var(A,0,1)`

- If `dim = 2`, then `var(A,0,2)` returns a column vector containing the variance of the elements in each row.

`var(A,0,2)`

`var` returns an array of zeros the same size as `A` when `dim` is greater than `ndims(A)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**nanflag — NaN condition**

`'includenan'` (default) | `'omitnan'`

NaN condition, specified as one of these values:

- `'includenan'` — the variance of input containing NaN values is also NaN.
- `'omitnan'` — all NaN values appearing in either the input array or weight vector are ignored.

Data Types: `char`

## More About

### Variance

For a random variable vector  $A$  made up of  $N$  scalar observations, the variance is defined as

$$V = \frac{1}{N-1} \sum_{i=1}^N |A_i - \mu|^2$$

where  $\mu$  is the mean of  $A$ ,

$$\mu = \frac{1}{N} \sum_{i=1}^N A_i.$$

Some definitions of variance use a normalization factor of  $N$  instead of  $N-1$ , which can be specified by setting  $w$  to 1. In either case, the mean is assumed to have the usual normalization factor  $N$ .

### See Also

`corrcoef` | `cov` | `mean` | `std`

Introduced before R2006a

## varargin

Variable-length input argument list

### Syntax

`varargin`

### Description

`varargin` is an input variable in a function definition statement that allows the function to accept any number of input arguments. Specify `varargin` using lowercase characters, and include it as the last input argument after any explicitly declared inputs. When the function executes, `varargin` is a 1-by- $N$  cell array, where  $N$  is the number of inputs that the function receives after the explicitly declared inputs.

### Examples

#### Variable Number of Function Inputs

Define a function in a file named `varlist.m` that accepts a variable number of inputs and displays the values of each input.

```
function varlist(varargin)
 fprintf('Number of arguments: %d\n',nargin)
 celldisp(varargin)
```

Call `varlist` with several inputs.

```
varlist(ones(3),'some text',pi)
```

```
Number of arguments: 3
```

```
varargin{1} =
 1 1 1
 1 1 1
 1 1 1
```

```
varargin{2} =
some text
```

```
varargin{3} =
 3.1416
```

### varargin and Declared Inputs

Define a function in a file named `varlist2.m` that expects inputs `X` and `Y`, and accepts a variable number of additional inputs.

```
function varlist2(X,Y,varargin)
 fprintf('Total number of inputs = %d\n',nargin);

 nVarargs = length(varargin);
 fprintf('Inputs in varargin(%d):\n',nVarargs)
 for k = 1:nVarargs
 fprintf(' %d\n', varargin{k})
 end
```

Call `varlist2` with more than two inputs.

```
varlist2(10,20,30,40,50)
```

```
Total number of inputs = 5
Inputs in varargin(3):
 30
 40
 50
```

- “Support Variable Number of Inputs”

## More About

- “Argument Checking in Nested Functions”

`inputname` | `nargin` | `narginchk` | `nargout` | `nargoutchk` | `varargout`

**Introduced before R2006a**

## varargout

Variable-length output argument list

### Syntax

varargout

### Description

varargout is an output variable in a function definition statement that allows the function to return any number of output arguments. Specify **varargout** using lowercase characters, and include it as the last output argument after any explicitly declared outputs. When the function executes, **varargout** is a 1-by-*N* cell array, where *N* is the number of outputs requested after the explicitly declared outputs.

### Examples

#### Variable Number of Function Outputs

Define a function in a file named `sizeout.m` that returns an output size vector **s** and a variable number of additional scalar values.

```
function [s,varargout] = sizeout(x)
nout = max(nargout,1) - 1;
s = size(x);
for k = 1:nout
 varargout{k} = s(k);
end
```

Output **s** contains the dimensions of the input array **x**. Additional outputs correspond to the individual dimensions within **s**.

Call `sizeout` on a three-dimensional array and request three outputs.

```
[s,rows,cols] = sizeout(rand(4,5,2))
s =
```

```
 4 5 2
rows =
 4
cols =
 5
```

## See Also

varargin | nargin | nargout | nargoutchk | narginchk | inputname

**Introduced before R2006a**

## varfun

Apply function to table variables

### Syntax

```
B = varfun(func,A)
B = varfun(func,A,Name,Value)
```

### Description

`B = varfun(func,A)` applies the function `func` separately to each variable of the table `A` and returns the results in the table `B`.

The function `func` must take one input argument and return arrays with the same number of rows each time it is called. The `i`th variable in the output table, `B{: , i}`, is equal to `func(A{: , i})`.

`B = varfun(func,A,Name,Value)` applies the function `func` separately to each variable of the table `A` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify which variables to pass to the function.

## Examples

### Apply Element-wise Function

Define and apply an element-wise function to the variables of a table to square all the elements.

Define a table containing numeric variables.

```
A = table([0.71;-2.05;-0.35;-0.82;1.57],[0.23;0.12;-0.18;0.23;0.41])
```

```
A =
```

```
 Var1 Var2
```

-----	-----
0.71	0.23
-2.05	0.12
-0.35	-0.18
-0.82	0.23
1.57	0.41

Define the anonymous function to find the square of an input.

```
func = @(x) x.^2;
```

Apply the function to all the variables of table A.

```
B = varfun(func,A)
```

```
B =
```

-----	-----
Fun_Var1	Fun_Var2
0.5041	0.0529
4.2025	0.0144
0.1225	0.0324
0.6724	0.0529
2.4649	0.1681

The variables of B have names based on the function and the variable names from A.

### Apply Function that Returns Scalar From Vector

Compute the mean of each variable in a 5-by-2 table.

Define a table containing numeric variables.

```
A = table([0.71;-2.05;-0.35;-0.82;1.57],[0.23;0.12;-0.18;0.23;0.41])
```

```
A =
```

-----	-----
Var1	Var2
0.71	0.23
-2.05	0.12
-0.35	-0.18
-0.82	0.23

```
1.57 0.41
```

Define the anonymous function to find the mean of an input.

```
func = @mean;
```

`func` uses an existing MATLAB function to define the operation.

Apply the function to all the variables of table `A`.

```
B = varfun(func,A)
```

```
B =
```

```
mean_Var1 mean_Var2

-0.188 0.162
```

`B` is a table containing the average value from each variable. To return a numeric vector instead of a table, you can use `B = varfun(func,A, 'OutputFormat', 'uniform')`.

### Apply Function to Groups Within Variables

Compute the group-wise means of variables in a table, `A`, and return them as rows in a table, `B`.

Create a table where one variable defines groups.

```
A = table({'test2';'test1';'test2';'test3';'test1'},...
 [0.71;-2.05;-0.35;-0.82;1.57],[0.23;0.12;-0.18;0.23;0.41])
```

```
A =
```

```
Var1 Var2 Var3

'test2' 0.71 0.23
'test1' -2.05 0.12
'test2' -0.35 -0.18
'test3' -0.82 0.23
'test1' 1.57 0.41
```

Define the anonymous function to find the mean of an input.

```
func = @mean;
```

`func` uses an existing MATLAB function to define the operation.

Apply the function to each group of data defined by `Var1`.

```
B = varfun(func,A,'GroupingVariables','Var1')
```

B =

	Var1	GroupCount	mean_Var2	mean_Var3
test1	'test1'	2	-0.24	0.265
test2	'test2'	2	0.18	0.025
test3	'test3'	1	-0.82	0.23

B contains row names based on the grouping variables and a variable called `GroupCount` to indicate the number of entries from table A in that group.

- “Calculations on Tables”
- “Split Table Data Variables and Apply Functions”

## Input Arguments

### **func** — Function

function handle

Function, specified as a function handle. You can define the function in a file or as an anonymous function. If `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

Use the `'OutputFormat','cell'` name-value pair argument, if the function `func` take one input argument and returns arrays with a different numbers of rows each time it is called. Otherwise, `func` must return arrays with the same number of rows.

Example: `func = @(x) x.^2`; computes the square of each element of an input.

### **A** — Input table

table

Input table, specified as a table.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'InputVariables', 2` uses only the second variable in `A` as an input to `func`.

### **'InputVariables' — Variables of A to pass to func**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector | ...

Variables of `A` to pass to `func`, specified as the comma-separated pair consisting of `'InputVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector, or an anonymous function that returns a logical scalar. If you specify `'InputVariables'` as an anonymous function that returns a logical scalar, `varfun` only passes the variables in `A` where the specified function returns 1 (true).

### **'GroupingVariables' — One or more variables in A that define groups of rows**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

One or more variables in `A` that define groups of rows, specified as the comma-separated pair consisting of `'GroupingVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

A grouping variable can be a numeric vector, logical vector, string (or character array), cell array of strings, or a categorical vector. Rows in `A` that have the same grouping variable values belong to the same group. `varfun` applies `func` to each group of rows within each of the variables of `A`, rather than to each entire variable.

The output, `B`, has one row for each group when you specify `'OutputFormat', 'uniform'` or `'OutputFormat', 'cell'`. When you specify `'OutputFormat', 'table'`, the sizes of the outputs from `func` determine how many rows of `B` correspond to each group. When multiple rows of `B` correspond to a group, `varfun` appends a unique identifier to the row names.

### **'OutputFormat' — Format of B**

'table' (default) | 'uniform' | 'cell'

Format of **B**, specified as the comma-separated pair consisting of `'OutputFormat'` and either the string `'uniform'`, `'table'`, or `'cell'`.

<code>'table'</code>	<p><code>varfun</code> returns a table with one variable for each variable in <b>A</b> (or each variable specified with <code>'InputVariables'</code>). For grouped computation, <b>B</b>, also contains the grouping variables.</p> <p><code>'table'</code> allows you to use a function that returns values of different sizes or data types for the different variables in <b>A</b>. However, for ungrouped computation, <code>func</code> must return arrays with the same number of rows each time it is called. For grouped computation, <code>func</code> must return values with the same number of rows each time it is called for a given group.</p> <p>This is the default output format.</p>
<code>'uniform'</code>	<code>varfun</code> concatenates the values into a vector. <code>func</code> must return a scalar with the same data type each time it is called.
<code>'cell'</code>	<code>varfun</code> returns <b>B</b> as a cell array. <code>'cell'</code> allows you to use a function that returns values of different sizes or data types.

### **'ErrorHandler'** — Function to call if `func` fails

function handle

Function to call if `func` fails, specified as the comma-separated pair consisting of `'ErrorHandler'` and a function handle. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

<code>identifier</code>	Error identifier.
<code>message</code>	Error message text.
<code>index</code>	Index of the variable for which the error occurred.
<code>name</code>	Name of the variable for which the error occurred.

- The set of input arguments to function `func` at the time of the error.

For example,

```
function [A, B] = errorFunc(S, varargin)
warning(S.identifier, S.message)
A = NaN; B = NaN;
```

## Output Arguments

### **B** — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

# vectorize

Vectorize expression

## Syntax

```
vectorize(s)
vectorize(f)
```

## Description

`vectorize(s)` where `s` is a string expression, inserts a `.` before any `^`, `*` or `/` in `s`. The result is a character string.

---

**Note:** `vectorize` will not accept inline function objects (`f`) in a future release.

---

`vectorize(f)` where `f` is an inline function object, vectorizes the formula for `f`. The result is the vectorized version of the function.

## See Also

`inline` | `cd` | `dbtype` | `delete` | `dir` | `path` | `what` | `who`

**Introduced before R2006a**

## ver

Version information for MathWorks products

## Syntax

```
ver
ver product

product_info = ver(product)
```

## Description

`ver` displays:

- A header containing the current MATLAB product family version number, license number, operating system, and version of Java software for the MATLAB product.
- The version numbers for MATLAB and all other installed MathWorks products.

`ver product` displays, in addition to the header information:

- The current version number for `product`, where `product` is the name of the folder that contains the `Contents.m` file for the product you are inquiring about.

`product_info = ver(product)` returns product information to the structure array, `product_info`.

## Examples

### Version for All Installed Products

Display version information for all installed products. The output shown here is representative. Your results might differ.

```
ver
```

```

MATLAB Version: 8.2.0.29 (R2013b)
MATLAB License Number: 234567
```

```
Operating System: Microsoft Windows 7 Version 6.1 (Build 7601: Service Pack 1)
Java Version: Java 1.7.0_11-b21 with Oracle Corporation Java HotSpot(TM) 64-Bit Server VM mixed mode
```

```

MATLAB Version 8.2 (R2013b)
Simulink Version 8.2 (R2013b)
Control System Toolbox Version 9.6 (R2013b)
```

## Version for a Particular Product

Display version information for MATLAB and the Control System Toolbox product. The output shown here is representative. Your results might differ.

Determine the product name for Control System Toolbox by setting `n` to the name of a function unique to Control System Toolbox, such as `dss`:

```
n = 'dss';
pat = '(?<=^[\\/]toolbox[\\/])(^\\/[\\/]?)+';
regexp(which(n), pat, 'match', 'once')
```

```
ans=
control
```

Specify the value returned in the previous step as an argument to `ver`:

```
ver control
```

```

MATLAB Version: 8.2.0.29 (R2013b)
MATLAB License Number: 234567
Operating System: Microsoft Windows 7 Version 6.1 (Build 7601: Service Pack 1)
Java Version: Java 1.7.0_11-b21 with Oracle Corporation Java HotSpot(TM) 64-Bit Server VM mixed mode

Control System Toolbox Version 9.6 (R2013b)
```

## Structure Containing Version for MATLAB Products

Create a structure containing version information, and then display the structure values. The output shown here is representative. Your results might differ.

```
v = ver;
for k = 1:length(v)
 fprintf('%s\n', v(k).Name)
 fprintf(' Version: %s\n', v(k).Version)
end
```

```
MATLAB
 Version: 8.2

MATLAB Compiler
```

```
Version: 5.0
```

```
My Custom Toolbox
Version: 1.0
```

## Structure Containing Version for a Particular Product

Create a structure containing version information for just the Symbolic Math Toolbox product. The output shown here is representative. Your results might differ.

Determine the product name for Symbolic Math Toolbox by setting `n` to the name of a function unique to Symbolic Math Toolbox, such as `sym`.

```
n = 'sym';
pat = '(?<=^.+[\\\/]toolbox[\\\/])[\^\\\/]+';
regexp(which(n), pat, 'match', 'once')

ans =
symbolic
```

Specify the value returned in the previous step as an argument to `ver`.

```
v = ver('symbolic')

v =

Name: 'Symbolic Math Toolbox'
Version: '5.11'
Release: '(R2013b)'
Date: '19-May-2013'
```

## Input Arguments

### **product** — product-specific information

string

The product or toolbox for which you want to view version information, specified as a string.

To determine the string to use, run the following code, substituting the name of a product function for `toolboxfcn`:

```
n = 'toolboxfcn';
```

```
fullDir = fileparts(which(n));
[~,lastComp,ext] = fileparts(fullDir);
product = [lastComp ext];
```

## Output Arguments

**product\_info** — product name, version, release, and date

structure array

Product name, version, release, and date, returned as a structure array with these fields: **Name**, **Version**, **Release**, and **Date**. If a license is a trial version, the letter **T** precedes the value in the **Version** field.

## More About

Introduced before R2006a

# matlab.unittest.Verbose class

**Package:** matlab.unittest

Verbosity level enumeration class

## Description

The `matlab.unittest.Verbose` enumeration class provides a means to specify the level of detail related to running tests. A higher value results in a higher level of detail. The enumeration class contains the following members.

Numeric Representation	Enumeration Member Name	Verbosity Description
1	Terse	Minimal amount of information
2	Concise	Typical amount of information
3	Detailed	Supplemental amount of information
4	Verbose	Surplus of information

## Construction

`matlab.unittest.Verbose.MemberName` creates an instance of the verbosity level enumeration class.

## Examples

### Create Instance of Enumeration Class

```
n = matlab.unittest.Verbose.Detailed
```

```
n =
```

```
 Detailed
```

Display information about the variables.

whos n

Name	Size	Bytes	Class	Attributes
n	1x1	112	matlab.unittest.Verbose	

- “How to Use Enumerations”

**Introduced in R2014b**

## verctrl

(To be removed) Source control actions (Windows platforms)

---

**Note:** `verctrl` will be removed in a future release. Access source control actions through the context menu instead.

---

### Syntax

```
verctrl('action',{ 'filename1', 'filename2', ... },0)
result=verctrl('action',{ 'filename1', 'filename2', ... },0)
verctrl('action', 'filename',0)
result=verctrl('isdiff', 'filename',0)
list = verctrl('all_systems')
```

### Description

`verctrl('action',{ 'filename1', 'filename2', ... },0)` performs the source control operation specified by `'action'` for a single file or multiple files. Enter one file as a string; specify multiple files using a cell array of strings. Use the full paths for each file name and include the extensions. Specify 0 as the last argument. Complete the resulting dialog box to execute the operation. Available values for `'action'` are as follows:

action Argument	Purpose
'add'	Adds files to the source control system. Files can be open in the Editor or closed when added.
'checkin'	Checks files into the source control system, storing the changes and creating a new version.
'checkout'	Retrieves files for editing.
'get'	Retrieves files for viewing and compiling, but not editing. When you open the files, they are labeled as read-only.

action Argument	Purpose
'history'	Displays the history of files.
'remove'	Removes files from the source control system. It does not delete the files from disk, but only from the source control system.
'runsc'	Starts the source control system. The file name can be an empty string.
'uncheckout'	Cancels a previous checkout operation and restores the contents of the selected files to the precheckout version. All changes made to the files since the checkout are lost.

`result=verctrl('action',{'filename1','filename2',...},0)` performs the source control operation specified by *action* on a single file or multiple files. The action can be any one of: 'add', 'checkin', 'checkout', 'get', 'history', or 'uncheckout'. `result` is a logical 1 (true) when you complete the operation by clicking **OK** in the resulting dialog box, and is a logical 0 (false) when you abort the operation by clicking **Cancel** in the resulting dialog box.

`verctrl('action','filename',0)` performs the source control operation specified by *action* for a single file. Use the absolute path for *filename*. Specify 0 as the last argument. Complete any resulting dialog boxes to execute the operation. Available values for *action* are as follows:

action Argument	Purpose
'showdiff'	Displays the differences between a file and the latest checked in version of the file in the source control system.
'properties'	Displays the properties of a file.

`result=verctrl('isdiff','filename',0)` compares *filename* with the latest checked in version of the file in the source control system. `result` is a logical 1 (true) when the files are different, and is a logical 0 (false) when the files are identical. Use the full path for *filename*. Specify 0 as the last argument.

`list = verctrl('all_systems')` displays in the Command Window a list of all source control systems installed on your computer.

## Examples

### Check In a File

Check in `D:\file1.ext` to the source control system:

```
result = verctrl('checkin','D:\file1.ext', 0)
```

This opens the Check in file(s) dialog box. Click **OK** to complete the check in. MATLAB displays

```
result = 1
```

indicating the checkin was successful.

### Add Files to the Source Control System

Add `D:\file1.ext` and `D:\file2.ext` to the source control system.

```
verctrl('add',{'D:\file1.ext','D:\file2.ext'}, 0)
```

This opens the Add to source control dialog box. Click **OK** to complete the operation.

### Display the Properties of a File

Display the properties of `D:\file1.ext`.

```
verctrl('properties','D:\file1.ext', 0)
```

This opens the source control properties dialog box for your source control system. The function is complete when you close the properties dialog box.

### Show Differences for a File

To show the differences between the version of `file1.ext` that you just edited and saved, with the last version in source control, run

```
verctrl('showdiff','D:\file1.ext',0)
```

MATLAB displays differences dialog boxes and results specific to your source control system. After checking in the file, if you run this statement again, MATLAB displays

??? The file is identical to latest version under source control.

## List All Installed Source Control Systems

To view all of the source control systems installed on your computer, type

```
list = verctrl ('all_systems')
```

MATLAB displays all the source control systems currently installed on your computer.

For example:

```
list =
'Microsoft Visual SourceSafe'
'ComponentSoftware RCS'
```

## More About

- “MSSCCI Source Control Interface”

**Introduced before R2006a**

## verLessThan

Compare toolbox release or version to specified string

### Syntax

```
tf = verLessThan(toolbox,version)
```

### Description

`tf = verLessThan(toolbox,version)` returns logical 1 (`true`) if the release or version of the toolbox is older than the value specified by `version`. Otherwise, it returns logical 0 (`false`). Use this function to write code that runs on multiple versions of MATLAB, when there are differences in the behavior of the code in the different versions.

### Examples

#### Write Version-Specific Code

Modify code that runs in MATLAB R2014a, but that generates an error in R2014b or later.

Create two surface plots. The default color palates are different depending on which version of MATLAB you are using.

```
s1 = surface(magic(5));
s2 = surface(magic(5)*10, 'FaceColor', 'yellow');
```

Modify surface `s2` by the color of the surface underneath. Starting in R2014b, the `EraseMode` property has been removed from all graphics objects. Replace the `EraseMode` property with a value of the `FaceAlpha` property for code running in MATLAB R2014b and later.

```
if verLessThan('matlab','8.4')
 % -- Code to run in MATLAB R2014a and earlier here --
 s2.EraseMode = 'xor';
else
```

```

% -- Code to run in MATLAB R2014b and later here --
s2.FaceAlpha = .25;
end

```

### Check for Minimum Required Version

Compare the Simulink version that is running against version 4.0. If the version is earlier than 4.0, display an error message because the feature is not supported.

```

if verLessThan('simulink','4.0')
 error('Simulink 4.0 or higher is required.')
end

```

### Check Toolbox Version

Compare the Data Acquisition Toolbox version that MATLAB is running against release R2015a.

Find the name of the toolbox folder. Your output depends on the toolboxes installed on your system.

```

dir([matlabroot '/toolbox/d*'])

 daq database des distcomp dotnetbuilder
 dastudio datafeed dials dml dspblks

```

Use the toolbox folder name, `daq`.

```

verLessThan('daq','3.8')

ans =

 0

```

## Input Arguments

### **toolbox** — Name of MATLAB toolbox folder

string

Name of MATLAB toolbox folder, specified as a string. To specify `toolbox`, find the folder containing the `Contents.m` file for the toolbox and use that folder name. To see a list of all toolbox folder names, type:

```
dir([matlabroot '/toolbox'])
```

If `toolbox` does not exist, MATLAB displays an error.

Example: `'images'`

**version** — Version number or release to compare against  
string

Version number or release of the program or toolbox to compare against, specified as a string. Specify the version number in the form of `major[.minor[.revision]]`, for example `'9.2'`.

Example: `'9.2'`

## More About

### Tips

- When running MATLAB R2015b or later, you can specify a release string instead of a version number. For example, you can call `verLessThan` with `'R2015b'` instead of `'8.6'`. In MATLAB R2015b, the `verLessThan` function always returns false for all released versions.

The following example displays a disclaimer message based on MATLAB version.

```
function myfunc
 % Display warning in future versions of MATLAB
 if ~verLessThan('matlab','R2015b')
 warning('This function has been tested only with MATLAB R2015a and earlier.')
 end

 % Function code
end
```

### See Also

**Introduced in R2007a**

# version

Version number for MATLAB and libraries

## Syntax

```
version
version -date
version -description
version -release
version -java
v = version('-versionOption')
[v d] = version
```

## Description

`version` returns in `ans` the version and release number for the MATLAB software currently running.

`version -date` returns in `ans` the release date for the MATLAB software.

`version -description` returns in `ans` a description of the version. Usually, the description is for special versions, such as beta versions.

`version -release` returns in `ans` the release number for the MATLAB software currently running.

`version -java` returns in `ans` the version of the Oracle JVM software that MATLAB is using.

`v = version('-versionOption')`, where *versionOption* is one of the above option strings, is an alternate form of the syntax.

`[v d] = version` returns the version and release number in string `v` and the release date in string `d`. No input arguments are allowed in this syntax.

## Examples

### Display MATLAB Version

```
version
```

```
ans =
```

```
8.2.0.29 (R2013b)
```

### Display MATLAB Release

Display the release, prefaced by a descriptor.

```
['Release R' version('-release')]
```

```
ans =
```

```
Release R2013b
```

### Get Release Version and Date as Separate Strings

```
[v d] = version
```

```
v =
```

```
8.2.0.29 (R2013b)
```

```
d =
```

```
May 19, 2013
```

### Display Java Version

```
version -java
```

```
ans =
```

```
Java 1.7.0_11-b21 with Oracle Corporation Java HotSpot(TM) 64-Bit Server VM mixed mode
```

## vertcat

Concatenate arrays vertically

### Syntax

`C = vertcat(A1, ..., AN)`

### Description

`C = vertcat(A1, ..., AN)` vertically concatenates arrays `A1, ..., AN`. All arrays in the argument list must have the same number of columns.

- If the inputs are multidimensional arrays, `vertcat` concatenates N-dimensional arrays along the first dimension. The remaining dimensions must match.
- If the inputs are tables, `vertcat` concatenates by matching variable names. Variable names for all tables must be identical, except for order. Row names, when present, must be unique across tables.

`vertcat` fills in default row names when some of the inputs have names and some do not. `vertcat` assigns values for each table property (except for `RowNames`) using the first nonempty value for the corresponding property in the tables `A1, ..., AN`.

`vertcat` also concatenates character strings. Each string being concatenated must have the same number of characters.

MATLAB calls `C = vertcat(A1, A2, ...)` for the syntax `C = [A1; A2; ...]` when any of the inputs are an object.

### Tips

You can concatenate categorical arrays with cell arrays of strings. For more information, see “Combine Categorical Arrays”.

If all the input arrays are ordinal categorical arrays, they must have the same sets of categories including their order. For more information, see “Ordinal Categorical Arrays”.

You can concatenate datetime arrays with cell arrays of strings.

You can concatenate duration arrays and calendar duration arrays. The result is a calendar duration array.

You can concatenate duration or calendar duration arrays with numeric arrays. Prior to concatenation, MATLAB converts the numeric array to an array of equivalent days using the `days` function.

For information on combining unlike integer types, integers with nonintegers, cell arrays with non-cell arrays, or empty matrices with other elements, see “Valid Combinations of Unlike Classes”.

## Examples

### Vertically Concatenate Two Matrices

Create a 5-by-3 matrix, **A**.

```
A = magic(5);
A(:, 4:5) = []
```

A =

```
 17 24 1
 23 5 7
 4 6 13
 10 12 19
 11 18 25
```

Create a 3-by-3 matrix, **B**.

```
B = magic(3)*100
```

B =

```
 800 100 600
 300 500 700
 400 900 200
```

Vertically concatenate **A** and **B**.

```
C = vertcat(A,B)
```

C =

```

17 24 1
23 5 7
 4 6 13
10 12 19
11 18 25
800 100 600
300 500 700
400 900 200

```

## Vertically Concatenate Two Tables

Create a table, A, with three rows and five variables.

```

A = table([5;6;5],['M'; 'M'; 'M'],[45;41;40],[45;32;34],{'NY'; 'CA'; 'MA'},...
'VariableNames',{'Age' 'Gender' 'Height' 'Weight' 'Birthplace'},...
'RowNames',{'Thomas' 'Gordon' 'Percy'})

```

A =

	Age	Gender	Height	Weight	Birthplace
Thomas	5	M	45	45	'NY'
Gordon	6	M	41	32	'CA'
Percy	5	M	40	34	'MA'

Create a table, B, with the same variables as A except for order.

```

B = table(['F'; 'M'; 'F'],[6;6;5],{'AZ'; 'NH'; 'CO'},[31;42;33],[39;43;40],...
'VariableNames',{'Gender' 'Age' 'Birthplace' 'Weight' 'Height'})

```

B =

Gender	Age	Birthplace	Weight	Height
F	6	'AZ'	31	39
M	6	'NH'	42	43
F	5	'CO'	33	40

Vertically concatenate tables A and B.

```
C = vertcat(A,B)
```

C =

	Age	Gender	Height	Weight	Birthplace
	---	-----	-----	-----	-----
Thomas	5	M	45	45	'NY'
Gordon	6	M	41	32	'CA'
Percy	5	M	40	34	'MA'
Row4	6	F	39	31	'AZ'
Row5	6	M	43	42	'NH'
Row6	5	F	40	33	'CO'

The variables of **C** are in the same order as the variables of **A** and default row names are used for the rows from **B**.

horzcat | cat

**Introduced before R2006a**

## **vertcat (tscollection)**

Vertical concatenation for `tscollection` objects

### **Syntax**

```
tsc = vertcat(tsc1,tsc2,...)
```

### **Description**

`tsc = vertcat(tsc1,tsc2,...)` performs

```
tsc = [tsc1;tsc2;...]
```

This operation appends `tscollection` objects. The time vectors must not overlap. The last time in `tsc1` must be earlier than the first time in `tsc2`. All `tscollection` objects to be concatenated must have the same `timeseries` members.

# vertexAttachments

**Class:** TriRep

(Not recommended) Return simplices attached to specified vertices

---

**Note:** `vertexAttachments(TriRep)` is not recommended. Use `vertexAttachments(triangulation)` instead.

`TriRep` is not recommended. Use `triangulation` instead.

---

## Syntax

`SI = vertexAttachments(TR, VI)`

## Description

`SI = vertexAttachments(TR, VI)` returns the vertex-to-simplex information for the specified vertices `VI`. For 2-D triangulations in MATLAB, the triangles `SI` are arranged in counter-clockwise order around the attached vertex `VI`.

## Input Arguments

<code>TR</code>	Triangulation representation
<code>VI</code>	<code>VI</code> is a column vector of indices into the array of points representing the vertex coordinates, <code>TR.X</code> . The simplices associated with vertex <code>i</code> are the <code>i</code> 'th entry in the cell array. If <code>VI</code> is not specified the vertex-simplex information for the entire triangulation is returned.

## Output Arguments

<code>SI</code>	Cell array of indices of the simplices attached to a vertex. A cell array is used to store the information because the number of simplices
-----------------	--------------------------------------------------------------------------------------------------------------------------------------------

associated with each vertex can vary. The simplices associated with vertex  $i$  are in the  $i$ 'th entry in the cell array `SI`.

## Definitions

A simplex is a triangle/tetrahedron or higher dimensional equivalent.

## Examples

### Example 1

Load a 2-D triangulation and use `TriRep` to compute the vertex-to-triangle relations.

```
load trimesh2d
trep = TriRep(tri, x, y);
Find the indices of the tetrahedra attached to the first vertex:

Tv = vertexAttachments(trep, 1)
Tv{:}
```

### Example 2

Perform a direct query of a 2-D triangulation created using `DelaunayTri`.

```
x = rand(20,1);
y = rand(20,1);
dt = DelaunayTri(x,y);
Find the triangles attached to vertex 5:

t = vertexAttachments(dt,5);
Plot the triangulation:

triplot(dt);
hold on;
Plot the triangles attached to vertex 5 (in red):

triplot(dt(t{:},:),x,y,'Color','r');
hold off;
```

triangulation | delaunayTriangulation

# VideoReader

Create object to read video files

## Syntax

```
v = VideoReader(filename)
v = VideoReader(filename,Name,Value)
```

## Description

`v = VideoReader(filename)` creates object `v` to read video data from the file named `filename`.

`v = VideoReader(filename,Name,Value)` creates the object with additional options specified by one or more name-value pair arguments.

## Examples

### Create VideoReader Object and Read Video

Create a `VideoReader` object for the example movie file, `xylophone.mp4`.

```
v = VideoReader('xylophone.mp4');
```

Read all video frames.

```
while hasFrame(v)
 video = readFrame(v);
end
whos video
```

Name	Size	Bytes	Class	Attributes
video	240x320x3	230400	uint8	

## Input Arguments

### **filename** – File name

string

File name, specified as a string.

VideoReader supports these file formats:

Platforms	File Formats
All Platforms	AVI, including uncompressed, indexed, grayscale, and Motion JPEG-encoded video (.avi) Motion JPEG 2000 (.mj2)
All Windows	MPEG-1 (.mpg) Windows Media Video (.wmv, .asf, .asx) Any format supported by Microsoft DirectShow®
Windows 7 or later	MPEG-4, including H.264 encoded video (.mp4, .m4v) Apple QuickTime Movie (.mov) Any format supported by Microsoft Media Foundation
Macintosh	Most formats supported by QuickTime Player, including: MPEG-1 (.mpg) MPEG-4, including H.264 encoded video (.mp4, .m4v) Apple QuickTime Movie (.mov) 3GPP 3GPP2 AVCHD DV
Linux	Any format supported by your installed plug-ins for GStreamer 0.10, as listed

Platforms	File Formats
	on <a href="http://gstreamer.freedesktop.org/documentation/plugins.html">http://gstreamer.freedesktop.org/documentation/plugins.html</a> , including Ogg Theora (.ogg). <b>Note:</b> Support is provided for GStreamer 0.10 only, not later versions.

Example: 'myFile.mp4'

Example: '../dir/videos/myFile.avi'

Data Types: char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `v = VideoReader('myFile.avi', 'CurrentTime', 35.2)` creates a `VideoReader` object to read `myFile.avi`, starting from the video frame that is 35.2 seconds from the beginning of the file.

### 'CurrentTime' — Timestamp of video frame to read

0 (default) | numeric scalar

Timestamp of the video frame to read, specified as the name-value pair consisting of 'CurrentTime' and a numeric scalar. The timestamp is specified in seconds from the start of the video file. The value of `CurrentTime` can be between zero and the duration of the video.

Example: 'CurrentTime', 5.6

Data Types: double

### 'Tag' — String data

' ' (default) | string

String data, specified as the name-value pair consisting of 'Tag' and a string.

Example: 'Tag', 'Experiment 109'

Data Types: char

**'UserData' — User-defined data**

[] (default) | any

User-defined data, specified as the name-value pair consisting of 'UserData' and a value of any data type.

## Output Arguments

**v — Output VideoReader object**

VideoReader object

Output VideoReader object. After you create a VideoReader object, you can read video files using object functions. See Using VideoReader Objects for details.

# Using VideoReader Objects

Read video files

## Description

VideoReader objects are associated with files containing video data.

VideoReader supports the following file formats.

Platforms	File Formats
All Platforms	AVI, including uncompressed, indexed, grayscale, and Motion JPEG-encoded video (.avi) Motion JPEG 2000 (.mj2)
All Windows	MPEG-1 (.mpg) Windows Media Video (.wmv, .asf, .asx) Any format supported by Microsoft DirectShow
Windows 7 or later	MPEG-4, including H.264 encoded video (.mp4, .m4v) Apple QuickTime Movie (.mov) Any format supported by Microsoft Media Foundation
Macintosh	Most formats supported by QuickTime Player, including: MPEG-1 (.mpg) MPEG-4, including H.264 encoded video (.mp4, .m4v) Apple QuickTime Movie (.mov) 3GPP 3GPP2 AVCHD DV
Linux	Any format supported by your installed plug-ins for GStreamer 0.10, as listed

Platforms	File Formats
	on <a href="http://gstreamer.freedesktop.org/documentation/plugins.html">http://gstreamer.freedesktop.org/documentation/plugins.html</a> , including Ogg Theora (.ogg). <b>Note:</b> Support is provided for GStreamer 0.10 only, not later versions.

Use dot notation to view or modify a particular property of a `VideoReader` object. For example, this command finds the value of the `Duration` property of the `VideoReader` object, `v`.

```
D = v.Duration;
```

Properties are read only, except `CurrentTime`, `Tag`, and `UserData`. Modify the `CurrentTime` property to begin reading from a particular time in the video file.

## Examples

### Create VideoReader Object and Read Video

Create a `VideoReader` object for the example movie file, `xylophone.mp4`.

```
v = VideoReader('xylophone.mp4');
```

Read all video frames.

```
while hasFrame(v)
 video = readFrame(v);
end
whos video
```

Name	Size	Bytes	Class	Attributes
video	240x320x3	230400	uint8	

### Read Video Starting at Specific Time

Create an object to read the sample file, `xylophone.mp4`.

```
v = VideoReader('xylophone.mp4');
```

Specify that reading should begin 2.5 seconds from the beginning of the video.

```
v.CurrentTime = 2.5;
```

Create an axes. Then, read video frames until no more frames are available to read.

```
currAxes = axes;
while hasFrame(v)
 vidFrame = readFrame(v);
 image(vidFrame, 'Parent', currAxes);
 currAxes.Visible = 'off';
 pause(1/v.FrameRate);
end
```

- “Read Video Files”

## Properties

### **BitsPerPixel** — Bits per pixel of video data

numeric scalar

This property is read only.

Bits per pixel of the video data, specified as a numeric scalar.

Data Types: double

### **CurrentTime** — Timestamp of video frame to read

numeric scalar

Timestamp of the video frame to read, specified as a numeric scalar. Specify the timestamp in seconds from the start of the video file. The value of `CurrentTime` can be between zero and the duration of the video.

Example: 120.54

Data Types: double

### **Duration** — Length of file

numeric scalar

This property is read only.

Length of the file in seconds, specified as a numeric scalar.

Data Types: double

**FrameRate — Number of video frames per second**

numeric scalar

This property is read only.

Number of video frames per second, specified as a numeric scalar. For variable-frame rate video, `FrameRate` is the average frame rate.

Data Types: `double`

**Height — Height of video frame**

numeric scalar

This property is read only.

Height of the video frame in pixels, specified as a numeric scalar.

Data Types: `double`

**Name — File name**

string

This property is read only.

File name, specified as a string.

Data Types: `char`

**NumberOfFrames — Number of frames in video stream**

numeric scalar

This property is read only.

---

**Note:** `NumberOfFrames` will be removed in a future release.

---

Number of frames in the video stream, specified as a numeric scalar.

Data Types: `double`

**Path — Full path to video file**

string

This property is read only.

Full path to the video file associated with the reader object, specified as a string.

Data Types: char

**Tag — Generic string**

' ' (default) | string

Generic string field

Data Types: char

**UserData — User-defined data**

[] (default)

User-defined data. `UserData` can be any data type.

**VideoFormat — MATLAB representation of video format**

string

This property is read only.

MATLAB representation of the video format, specified as a string.

For all file types except Motion JPEG 2000 files, `VideoFormat` is one of the following.

Video Format	Value of VideoFormat
AVI or MPEG-4 files with RGB24 video	'RGB24'
AVI files with indexed video	'Indexed'
AVI files with grayscale video	'Grayscale'

For Motion JPEG 2000 files, `VideoFormat` is one of the following.

Format of Image Data	Value of VideoFormat
Single-band uint8	'Mono8'
Single-band int8	'Mono8 Signed'
Single-band uint16	'Mono16'
Single-band int16	'Mono16 Signed'
Three-banded uint8	'RGB24'
Three-banded int8	'RGB24 Signed'

Format of Image Data	Value of VideoFormat
Three-banded uint16	'RGB48 '
Three-banded int16	'RGB48 Signed '

### Width — Width of video frame

numeric scalar.

This property is read only.

Width of the video frame in pixels, specified as a numeric scalar.

Data Types: double

## Object Functions

read	Read video frame data from file
VideoReader.getFileFormats	File formats that VideoReader supports
readFrame	Read video frame from video file
hasFrame	Determine if frame is available to read

## Create Object

Create VideoReader objects using the VideoReader function.

## See Also

VideoWriter

Introduced in R2010b

# VideoReader.getFileFormats

File formats that VideoReader supports

## Syntax

```
formats = VideoReader.getFileFormats()
```

## Description

`formats = VideoReader.getFileFormats()` returns an array of `audiovideo.FileFormatInfo` objects that indicate which formats VideoReader can read on the current system.

## Examples

### View Supported File Formats for Your System

View the list of file formats that VideoReader supports on your system.

```
fmts = VideoReader.getFileFormats()
```

```
Video File Formats:
 .asf - ASF File
 .asx - ASX File
 .avi - AVI File
 .m4v - MPEG-4 Video
 .mj2 - Motion JPEG2000
 .mov - QuickTime movie
 .mp4 - MPEG-4
 .mpg - MPEG-1
 .wmv - Windows Media Video
```

This output is for a Linux® system. Your results might differ.

### Check if File Format is Supported

Check whether VideoReader can read AVI files on the current system.

```

fmtList = VideoReader.getFileFormats();

if any(ismember({fmtList.Extension},'avi'))
 disp('VideoReader can read AVI files on this system.');
```

```

else
 disp('VideoReader cannot read AVI files on this system.');
```

### Create Dialog Box to Select Video File

Create a dialog box that allows a user to select a video file interactively.

Get the supported file formats.

```

formats = VideoReader.getFileFormats()
```

```

Video File Formats:
 .asf - ASF File
 .asx - ASX File
 .avi - AVI File
 .m4v - MPEG-4 Video
 .mj2 - Motion JPEG2000
 .mov - QuickTime movie
 .mp4 - MPEG-4
 .mpg - MPEG-1
 .wmv - Windows Media Video
```

This output is for a Windows system. Your results might differ.

Convert the `formats` array to a filter list.

```

filterSpec = getFilterSpec(formats)
```

```

filterSpec =
```

```

 '*.asf;*.asx;*.avi;*.m4v;*.mj2;*.mov;*.mp4;*.mpg;*.wmv; '
 '*.asf'
 '*.asx'
 '*.avi'
 '*.m4v'
 '*.mj2'
 '*.mov'
 '*.mp4'
 'All Video Files'
 'ASF File (*.asf)'
 'ASX File (*.asx)'
 'AVI File (*.avi)'
 'MPEG-4 Video (*.m4v)'
 'Motion JPEG2000 (*.mj2)'
 'QuickTime movie (*.mov)'
 'MPEG-4 (*.mp4)'
```

```
'*.mpg'
'*.wmv'
'*.*'
```

```
'MPEG-1 (*.mpg)'
'Windows Media Video ('
'All Files (*.*)'
```

`filterSpec` is a cell array that includes 'All Video Files' in the first row, and 'All Files (\*.\*)' in the last row.

Create the dialog box using `uigetfile`.

```
[filename,pathname] = uigetfile(filterSpec);
```

## Output Arguments

### formats — Supported video file formats

array of `audiovideo.FileFormatInfo` objects

Supported video file formats, returned as an array of `audiovideo.FileFormatInfo` objects with the following properties.

Extension	File extension.
Description	Text description of the file format.
ContainsVideo	Logical value that indicates whether <code>VideoReader</code> can read video from this format.
ContainsAudio	Logical value that indicates whether <code>VideoReader</code> can read audio from this format.

`VideoReader` cannot always read a particular video file even if `getFileFormats` lists its format. For more information, see [Supported Video File Formats](#).

On Windows and UNIX systems, the list of file formats does not always contain all the formats that `VideoReader` can read on your system. `getFileFormats` returns a platform-dependent, static list of formats that `VideoReader` can read on most systems.

### See Also

`uigetfile` | `VideoReader`

**Introduced in R2010b**

# hasFrame

Determine if frame is available to read

## Syntax

```
tf = hasFrame(v)
```

## Description

`tf = hasFrame(v)` returns logical 1 (`true`) if there is a video frame available to read from the file. Otherwise, it returns logical 0 (`false`).

## Examples

### Create VideoReader Object and Read Video

Create a `VideoReader` object for the example movie file, `xylophone.mp4`.

```
v = VideoReader('xylophone.mp4');
```

Read all video frames.

```
while hasFrame(v)
 video = readFrame(v);
end
whos video
```

Name	Size	Bytes	Class	Attributes
video	240x320x3	230400	uint8	

### Read and Play Back Movie File

Read and play back the sample movie file, `xylophone.mp4`.

Create a `VideoReader` object to read data from the sample file. Then, determine the width and height of the video.

```
xyloObj = VideoReader('xylophone.mp4');
```

```
vidWidth = xyloObj.Width;
vidHeight = xyloObj.Height;
```

Create a movie structure array, `mov`.

```
mov = struct('cdata',zeros(vidHeight,vidWidth,3,'uint8'),...
 'colormap',[]);
```

Read one frame at a time until the end of the video is reached.

```
k = 1;
while hasFrame(xyloObj)
 mov(k).cdata = readFrame(xyloObj);
 k = k+1;
end
```

Size a figure based on the width and height of the video. Then, play back the movie once at the video frame rate.

```
hf = figure;
set(hf,'position',[150 150 vidWidth vidHeight]);

movie(hf,mov,1,xyloObj.FrameRate);
```

- “Read Video Files”

## Input Arguments

### **v** — Input VideoReader object

VideoReader object

Input VideoReader object. Use the `VideoReader` function to create a VideoReader object from your video file.

## See Also

`movie` | `readFrame` | Using VideoReader Objects

**Introduced in R2014b**

# read

Read video frame data from file

## Compatibility

`VideoReader.read` will be removed in a future release. Use `VideoReader.readFrame` instead.

## Syntax

```
video = read(v)
video = read(v,index)
video = read(____, 'native')
```

## Description

`video = read(v)` reads all video frames from the file associated with `v`.

`video = read(v,index)` reads only the frames specified by `index`.

`video = read( ____, 'native' )` returns data in the format specified by the `VideoFormat` property and can include any of the input arguments in the previous syntaxes.

## Examples

### Select Video Frames to Read

Create a `VideoReader` object for the example movie file, `xylophone.mp4`.

```
v = VideoReader('xylophone.mp4');
```

Read only the first video frame.

```
video = read(v,1);
```

Read only the last video frame.

```
video = read(v, Inf);
```

Read frames 5 through 10.

```
video = read(v, [5 10]);
```

Read from the 50th frame to the end of the video file.

```
video = read(v, [50 Inf]);
```

## Input Arguments

### **v** — Input VideoReader object

VideoReader object

Input VideoReader object. Use the `VideoReader` function to create a VideoReader object from your video file.

### **index** — Frames to read

[1 Inf] (default) | numeric scalar | two-element array

Frames to read, specified as a numeric scalar or a two-element array.

- To read a single frame, specify a numeric scalar.
- To read a range of frames, specify a two-element array.

The first frame number is 1, and `Inf` represents the last frame of the file.

Example: 10

Example: Inf

Example: [1 20]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## Output Arguments

### **video** — Video frame data

numeric array | structure array

Video frame data, returned as a numeric or structure array. The size and format of `video` depends on the `VideoFormat` property of `v`. When the `VideoFormat` property of `v` is `'Indexed'` or `'Grayscale'`, the data type and dimensions of `video` depend on whether you call `read` with the `'native'` argument. For most files, the data type and dimensions of `video` are as follows.

H is the image frame height, W is the image frame width, and F is the number of frames read.

Value of <code>obj.VideoFormat</code>	Data Type of <code>video</code>	Dimensions of <code>video</code>	Description
<code>'RGB24'</code> , with or without specifying <code>'native'</code>	<code>uint8</code>	H-by-W-by-3-by-F	RGB24 image
<code>'Grayscale'</code> , without specifying <code>'native'</code>	<code>uint8</code>	H-by-W-by-1-by-F	Grayscale image
<code>'Indexed'</code> , without specifying <code>'native'</code>	<code>uint8</code>	H-by-W-by-3-by-F	RGB24 image
<code>'Grayscale'</code> or <code>'Indexed'</code> , specifying <code>'native'</code>	<code>struct</code>	1-by-F	MATLAB movie, which is an array of frame structure arrays, each containing the fields <code>cdata</code> and <code>colormap</code> .

For Motion JPEG 2000 files, the data type and dimensions of `video` are as follows.

Value of <code>obj.VideoFormat</code>	Data Type of <code>video</code>	Dimensions of <code>video</code>	Description
<code>'Mono8'</code>	<code>uint8</code>	H-by-W-by-1-by-F	Mono image
<code>'Mono8 Signed'</code>	<code>int8</code>	H-by-W-by-1-by-F	Mono signed image
<code>'Mono16'</code>	<code>uint16</code>	H-by-W-by-1-by-F	Mono image
<code>'Mono16 Signed'</code>	<code>int16</code>	H-by-W-by-1-by-F	Mono signed image
<code>'RGB24'</code>	<code>uint8</code>	H-by-W-by-3-by-F	RGB24 image

<b>Value of obj.VideoFormat</b>	<b>Data Type of video</b>	<b>Dimensions of video</b>	<b>Description</b>
'RGB24 Signed'	int8	H-by-W-by-3-by-F	RGB24 signed image
'RGB48'	uint16	H-by-W-by-3-by-F	RGB48 image
'RGB48 Signed'	int16	H-by-W-by-3-by-F	RGB48 signed image

### **See Also**

movie | VideoReader

**Introduced in R2010b**

# readFrame

Read video frame from video file

## Syntax

```
video = readFrame(v)
video = readFrame(v, 'native')
```

## Description

`video = readFrame(v)` reads the next available video frame from the file associated with `v`.

`video = readFrame(v, 'native')` returns data in the format specified by the `VideoFormat` property.

## Examples

### Create VideoReader Object and Read Video

Create a `VideoReader` object for the example movie file, `xylophone.mp4`.

```
v = VideoReader('xylophone.mp4');
```

Read all video frames.

```
while hasFrame(v)
 video = readFrame(v);
end
whos video
```

Name	Size	Bytes	Class	Attributes
video	240x320x3	230400	uint8	

### Read Video Starting at Specific Time

Create an object to read the sample file, `xylophone.mp4`.

```
v = VideoReader('xylophone.mp4');
```

Specify that reading should begin 2.5 seconds from the beginning of the video.

```
v.CurrentTime = 2.5;
```

Create an axes. Then, read video frames until no more frames are available to read.

```
currAxes = axes;
while hasFrame(v)
 vidFrame = readFrame(v);
 image(vidFrame, 'Parent', currAxes);
 currAxes.Visible = 'off';
 pause(1/v.FrameRate);
end
```

### **Read and Play Back Movie File**

Read and play back the sample movie file, `xylophone.mp4`.

Create a `VideoReader` object to read data from the sample file. Then, determine the width and height of the video.

```
xyloObj = VideoReader('xylophone.mp4');
```

```
vidWidth = xyloObj.Width;
vidHeight = xyloObj.Height;
```

Create a movie structure array, `mov`.

```
mov = struct('cdata', zeros(vidHeight, vidWidth, 3, 'uint8'), ...
 'colormap', []);
```

Read one frame at a time until the end of the video is reached.

```
k = 1;
while hasFrame(xyloObj)
 mov(k).cdata = readFrame(xyloObj);
 k = k+1;
end
```

Size a figure based on the width and height of the video. Then, play back the movie once at the video frame rate.

```
hf = figure;
```

```
set(hf, 'position', [150 150 vidWidth vidHeight]);
```

```
movie(hf, mov, 1, xyloObj.FrameRate);
```

- “Read Video Files”

## Input Arguments

### **v** — Input VideoReader object

VideoReader object

Input VideoReader object. Use the `VideoReader` function to create a VideoReader object from your video file.

## Output Arguments

### **video** — Video frame data

array

Video frame data, returned as an array. The dimensions and data type of `video` depend on the `VideoFormat` property of `obj`.

The following table lists the data type and dimensions of `video` for most files. `H` is the image frame height and `W` is the image frame width. When the `VideoFormat` property of `obj` is `'Indexed'`, the data type and dimensions of `video` depend on whether you call `read` with the `'native'` argument.

Value of <code>obj.VideoFormat</code>	Data Type of <code>video</code>	Dimensions of <code>video</code>	Description
<code>'RGB24'</code> , with or without specifying <code>'native'</code>	<code>uint8</code>	H-by-W-by-3	RGB24 image
<code>'Grayscale'</code> , without specifying <code>'native'</code>	<code>uint8</code>	H-by-W-by-1	Grayscale image
<code>'Indexed'</code> , without specifying <code>'native'</code>	<code>uint8</code>	H-by-W-by-3	RGB24 image

Value of <code>obj.VideoFormat</code>	Data Type of <code>video</code>	Dimensions of <code>video</code>	Description
'Grayscale' or 'Indexed', specifying 'native'	struct	1-by-1	MATLAB movie, which is an array of frame structure arrays, each containing the fields <code>cdata</code> and <code>colormap</code> .

For Motion JPEG 2000 files, the data type and dimensions of `video` are as follows.

Value of <code>obj.VideoFormat</code>	Data Type of <code>video</code>	Dimensions of <code>video</code>	Description
'Mono8'	uint8	H-by-W-by-1	Mono image
'Mono8 Signed'	int8	H-by-W-by-1	Mono signed image
'Mono16'	uint16	H-by-W-by-1	Mono image
'Mono16 Signed'	int16	H-by-W-by-1	Mono signed image
'RGB24'	uint8	H-by-W-by-3	RGB24 image
'RGB24 Signed'	int8	H-by-W-by-3	RGB24 signed image
'RGB48'	uint16	H-by-W-by-3	RGB48 image
'RGB48 Signed'	int16	H-by-W-by-3	RGB48 signed image

Introduced in R2014b

# VideoWriter

Create object to write video files

## Syntax

```
v = VideoWriter(filename)
v = VideoWriter(filename,profile)
```

## Description

`v = VideoWriter(filename)` creates a `VideoWriter` object to write video data to an AVI file with Motion JPEG compression.

`v = VideoWriter(filename,profile)` creates a `VideoWriter` object and applies a set of properties tailored to a specific file format (such as 'MPEG-4' or 'Uncompressed AVI').

## Examples

### Create VideoWriter Object and Write Video

Create a `VideoWriter` object to write a Motion JPEG AVI file named `newfile.avi`.

```
v = VideoWriter('newfile.avi');
```

Open the file for writing and write a 300-by-300 matrix of data to the file.

```
open(v)
writeVideo(v,rand(300))
```

Close the file.

```
close(v)
```

### Specify Profile for Uncompressed AVI and Write Video

Create an array containing data from the sample still image, `peppers.png`.

```
A = imread('peppers.png');
```

Create a `VideoWriter` object for a new uncompressed AVI file for RGB24 video.

```
v = VideoWriter('newfile.avi', 'Uncompressed AVI');
```

Open the file for writing.

```
open(v)
```

Write the image in `A` to the video file.

```
writeVideo(v,A)
```

Close the file.

```
close(v)
```

## Input Arguments

### **filename** — File name

string

File name, specified as a string. `VideoWriter` creates the file.

`VideoWriter` supports these file extensions.

<code>.avi</code>	AVI file
<code>.mj2</code>	Motion JPEG 2000 file
<code>.mp4</code> or <code>.m4v</code>	MPEG-4 file (systems with Windows 7 or later, or Mac OS X 10.7 and later)

If you do not specify a valid file extension, `VideoWriter` appends the extension `.avi`, `.mj2` or `.mp4`, depending on the value of the `profile` argument. If you do not specify a value for `profile`, then `VideoWriter` creates a Motion JPEG compressed AVI file with the extension `.avi`.

Example: 'myFile.avi'

Example: '../dir/videos/myFile.mj2'

Data Types: char

**profile** — File type

'Motion JPEG AVI' (default) | 'Archival' | 'Motion JPEG 2000' | ...

File type, specified as one of the following strings.

Value of profile	Description
'Archival'	Motion JPEG 2000 file with lossless compression
'Motion JPEG AVI'	AVI file using Motion JPEG encoding
'Motion JPEG 2000'	Motion JPEG 2000 file
'MPEG-4'	MPEG-4 file with H.264 encoding (systems with Windows 7 or later, or Mac OS X 10.7 and later)
'Uncompressed AVI'	Uncompressed AVI file with RGB24 video
'Indexed AVI'	Uncompressed AVI file with indexed video
'Grayscale AVI'	Uncompressed AVI file with grayscale video

profile sets default values for video properties such as VideoCompressionMethod.

## Output Arguments

**v** — Output VideoWriter object

VideoWriter

Output VideoWriter object. After you create a VideoWriter object, you can write video files using object functions. See Using VideoWriter Objects for details.

## More About

**Introduced in R2010b**

# Using VideoWriter Objects

Write video files

## Description

VideoWriter objects allow you to create video files from arrays or MATLAB movies.

You can use the `VideoWriter` function with a predefined *profile* to create a `VideoWriter` object with properties tailored to a specific format, such as 'Uncompressed AVI' or 'MPEG-4'. After you create the object, you can use dot notation to view or modify a particular property:

```
v = VideoWriter('newfile.mj2','Motion JPEG 2000');
v.CompressionRatio = 3;
```

Modify property values before opening the video file for writing. After you call the `open` function, you cannot change the value of a property.

## Examples

### Create VideoWriter Object and Write Video

Create a `VideoWriter` object to write a Motion JPEG AVI file named `newfile.avi`.

```
v = VideoWriter('newfile.avi');
```

Open the file for writing and write a 300-by-300 matrix of data to the file.

```
open(v)
writeVideo(v,rand(300))
```

Close the file.

```
close(v)
```

### Specify Profile for Uncompressed AVI and Write Video

Create an array containing data from the sample still image, `peppers.png`.

```
A = imread('peppers.png');
```

Create a `VideoWriter` object for a new uncompressed AVI file for RGB24 video.

```
v = VideoWriter('newfile.avi', 'Uncompressed AVI');
```

Open the file for writing.

```
open(v)
```

Write the image in `A` to the video file.

```
writeVideo(v,A)
```

Close the file.

```
close(v)
```

## Create AVI File from Animation

Write a sequence of frames to a compressed AVI file named `peaks.avi`.

Prepare the new file.

```
v = VideoWriter('peaks.avi');
open(v);
```

Generate initial data and set axes and figure properties.

```
Z = peaks;
surf(Z);
axis tight manual
set(gca, 'nextplot', 'replacechildren');
```

Create a set of frames and write each frame to the file.

```
for k = 1:20
 surf(sin(2*pi*k/20)*Z,Z)
 frame = getframe;
 writeVideo(v,frame);
end

close(v);
```

## Properties

### **ColorChannels** — Number of color channels

positive integer

This property is read only.

Number of color channels in each output video frame, specified as a positive integer:

- Uncompressed AVI, Motion JPEG AVI, and MPEG-4 files have three color channels.
- Indexed and grayscale AVI files have one color channel.
- For Motion JPEG 2000 files, the number of channels depends on the input data to the `writeVideo` function: one for monochrome image data, three for color data.

Data Types: `double`

### **Colormap** — Color information for video file

P-by-3 numeric matrix

Color information for video file, specified as a numeric matrix with three columns and a maximum of 256 rows. Each row in the matrix defines one color using an RGB triplet. An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`.

You can set the colormap explicitly before the call to `open`, or by using the `colormap` field of a movie frame structure at the time of writing the first frame.

The `Colormap` property only applies to objects used for writing indexed AVI files.

Example: `colormap(summer(256))`

Data Types: `double` | `uint8`

### **CompressionRatio** — Target compression ratio

10 (default) | integer greater than 1

Target compression ratio, specified as an integer greater than 1. The compression ratio is the ratio between the number of bytes in the input image and the number of bytes in the compressed image. The video data is compressed as much as possible, up to the specified target.

`CompressionRatio` is available only for objects used for writing Motion JPEG 2000 files. After you call `open`, you cannot change the `CompressionRatio` value. If you previously set `LosslessCompression` to `true`, setting `CompressionRatio` generates an error.

Example: 5

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

**Duration** — Duration of output file

scalar value

This property is read only.

Duration of the output file in seconds, specified as a scalar value.

Data Types: `double`

**FileFormat** — Type of file to write

`'avi'` | `'mp4'` | `'mj2'`

This property is read only.

Type of file to write, specified as `'avi'`, `'mp4'`, or `'mj2'`.

**Filename** — Name of file

string

This property is read only.

Name of file, specified as a string.

Data Types: `char`

**FrameCount** — Number of frames

integer

This property is read only.

Number of frames written to the video file, specified as an integer.

Data Types: `double`

**FrameRate** — Rate of video playback

30 (default) | positive number

Rate of video playback in frames per second, specified as a positive number.

After you call `open`, you cannot change the `FrameRate` value.

Example: 10

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Height** — Height of each video frame

scalar

This property is read only.

Height of each video frame in pixels, specified as a scalar. The `writeVideo` method sets values for `Height` and `Width` based on the dimensions of the first frame.

MPEG-4 files require frame dimensions that are divisible by two. If the input frame height for an MPEG-4 file is not an even number, `VideoWriter` pads the frame with a row of black pixels at the bottom. For MPEG-4 files on Windows systems, `Height` is in the range [64, 1088].

Data Types: `double`

### **LosslessCompression** — Lossless compression

`true` | `false`

Lossless compression, specified as `true` or `false`. The `LosslessCompression` property is only available for objects used for writing Motion JPEG 2000 files.

If `LosslessCompression` is `true`, then:

- The `writeVideo` function writes data so that the decompressed data is identical to the input data.
- `VideoWriter` ignores any specified value for `CompressionRatio`.

After you call `open`, you cannot change the `LosslessCompression` value.

By default, `LosslessCompression` is `false` for the 'Motion JPEG 2000' profile and `true` for the 'Archival' profile.

Data Types: `logical`

### **MJ2BitDepth** — Bit depth for Motion JPEG 2000 files

integer in the range [1, 16]

Bit depth for Motion JPEG 2000 files, specified as an integer in the range [1, 16]. The bit depth is the number of least-significant bits in the input image data

`MJ2BitDepth` is available only for objects used for writing Motion JPEG 2000 files. If you do not specify a value before calling the `open` method, `VideoWriter` sets the bit depth based on the input data type. For example, if the input data to `writeVideo` is an array of `uint8` or `int8` values, then `MJ2BitDepth` is 8.

Example: 8

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **Path — Full path to video file**

string

This property is read only.

Full path to the video file, specified as a string.

Data Types: `char`

### **Quality — Video quality**

75 (default) | integer in the range [0,100]

Video quality, specified as an integer in the range, [0, 100]. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes.

`Quality` is available only for objects associated with the MPEG-4 or Motion JPEG AVI profile. After you call `open`, you cannot change the `Quality` value.

Example: 50

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **VideoBitsPerPixel — Number of bits per pixel**

numeric scalar

This property is read only.

Number of bits per pixel in each output video frame, specified as a numeric scalar.

AVI files with truecolor video, Motion JPEG AVI, and MPEG-4 files have 24 bits per pixel (8 bits for each of three color bands).

Indexed and grayscale AVI files have 8 bits per pixel.

For Motion JPEG 2000 files, the number of bits per pixel depends on the value of `MJ2BitDepth` and the number of bands of image data. For example, if the input data to `writeVideo` is a three-dimensional array of `uint16` or `int16` values, the default value of `MJ2BitDepth` is 16, and `VideoBitsPerPixel` is 48 (three times the bit depth).

Data Types: `double`

### **VideoCompressionMethod** — Type of video compression

'None' | 'H.264' | 'Motion JPEG' | 'Motion JPEG 2000'

This property is read only.

Type of video compression, specified as 'None', 'H.264', 'Motion JPEG', or 'Motion JPEG 2000'.

Data Types: `char`

### **VideoFormat** — MATLAB representation of video format

string

This property is read only.

MATLAB representation of the video format, specified as a string.

For file types other than Motion JPEG 2000 files, `VideoFormat` is one of the following.

<b>Video Format</b>	<b>Value of VideoFormat</b>
Uncompressed AVI, Motion JPEG AVI, or MPEG-4 files	'RGB24'
AVI files with indexed video	'Indexed'
AVI files with grayscale video	'Grayscale'

For Motion JPEG 2000 files, `VideoFormat` depends on the value of `MJ2BitDepth` and the format of the input image data to the `writeVideo` method. For example, if you do not specify the `MJ2BitDepth` property, `VideoWriter` sets the format as shown in this table.

<b>Format of Image Data</b>	<b>Value of VideoFormat</b>
Single-band <code>uint8</code>	'Mono8'
Single-band <code>int8</code>	'Mono8 Signed'
Single-band <code>uint16</code>	'Mono16'

Format of Image Data	Value of VideoFormat
Single-band int16	'Mono16 Signed'
Three-banded uint8	'RGB24'
Three-banded int8	'RGB24 Signed'
Three-banded uint16	'RGB48'
Three-banded int16	'RGB48 Signed'

## Width — Width of each video frame

numeric scalar

This property is read only.

Width of each video frame in pixels, specified as a numeric scalar. The `writeVideo` function sets values for `Height` and `Width` based on the dimensions of the first frame.

MPEG-4 files require frame dimensions that are divisible by two. If the input frame width for an MPEG-4 file is not an even number, then `VideoWriter` pads the frame with a column of black pixels along the right side. For MPEG-4 files on Windows systems, `Width` is in the range [64, 1920].

Data Types: double

## Object Functions

`open`

Open file for writing video data

`close`

Close file after writing video data

`writeVideo`

Write video data to file

`VideoWriter.getProfiles`

Profiles and file formats that `VideoWriter` supports

## Create Object

Create `VideoWriter` objects using the `VideoWriter` function.

## More About

- “Export to Video”

**Introduced in R2010b**

## close

Close file after writing video data

## Syntax

```
close(v)
```

## Description

`close(v)` closes the video file associated with `v`. You must call `close` to ensure that all data is written to the file. The object, `v`, remains in the workspace. If you call the `open` function after closing the video file, `open` discards all existing contents of the file.

## Examples

### Open and Close Video File for Writing

Create a `VideoWriter` object to write a new Motion JPEG AVI file.

```
v = VideoWriter('newfile');
```

Open the file for writing.

```
open(v)
```

Write a 300-by-300 matrix of data to the file.

```
writeVideo(v,rand(300))
```

Close the file.

```
close(v)
```

## Input Arguments

**v** — Input `VideoWriter` object

`VideoWriter` object

Input `VideoWriter` object. Use `VideoWriter` to create the object.

### **See Also**

`open` | `VideoWriter` | `writeVideo`

**Introduced in R2010b**

# VideoWriter.getProfiles

Profiles and file formats that VideoWriter supports

## Syntax

```
profiles = VideoWriter.getProfiles()
```

## Description

`profiles = VideoWriter.getProfiles()` returns an array of `audiovideo.writer.ProfileInfo` objects that indicate the types of files that VideoWriter can create.

## Examples

### Get Profile Information

View available profiles and get specific information about the 'Uncompressed AVI' profile.

View profiles that VideoWriter supports.

```
profiles = VideoWriter.getProfiles()
```

Summary of installed VideoWriter profiles:

Name	Description
Archival	Video file compression with JPEG 2000 codec with lossless mode enabled
Grayscale AVI	An AVI file with Grayscale Video Data
Indexed AVI	An AVI file with Indexed Video Data
MPEG-4	A MPEG-4 file with H.264 Compression
Motion JPEG 2000	Video file compression with JPEG 2000 codec.
Motion JPEG AVI	An AVI file with Motion JPEG compression
Uncompressed AVI	An AVI file with uncompressed RGB24 video data

Find the index number for the 'Uncompressed AVI' profile.

```
uncompAVI = find(ismember({profiles.Name}, 'Uncompressed AVI'));
```

View the properties of the 'Uncompressed AVI' profile.

```
profiles(uncompAVI)
```

```
audiovideo.writer.ProfileInfo
```

```
ProfileInfo Properties:
```

```

Name: 'Uncompressed AVI'
Description: 'An AVI file with uncompressed RGB24 video data'
FileExtensions: {' .avi'}
ColorChannels: 3
FrameRate: 30
VideoBitsPerPixel: 24
VideoCompressionMethod: 'None'
VideoFormat: 'RGB24'
```

Get the file extensions associated with the profile.

```
ext = profiles(uncompAVI).FileExtensions
```

```
ext =
```

```
 '.avi'
```

## Output Arguments

### **profiles** — Supported profiles and video file formats

array of `audiovideo.writer.ProfileInfo` objects

Supported profiles and video file formats, returned as an array of `audiovideo.writer.ProfileInfo` objects, which have the following read-only properties.

Property	Description
Name	String profile name, such as 'Uncompressed AVI'.

<b>Property</b>	<b>Description</b>
Description	String description of the profile.
FileExtensions	Cell array of strings containing file extensions supported by the file format.
ColorChannels	Number of color channels in each output video frame.
CompressionRatio	Number greater than 1 that specifies the target ratio between the number of bytes in the input image and the number of bytes in the compressed image. Only applies to objects associated with Motion JPEG 2000 files. Default: 10.
FrameRate	Rate of playback for the video in frames per second. Default: 30.
LosslessCompression	Boolean value (logical true or false) that specifies whether to use reversible mode, so that the decompressed data is identical to the input data. When true, VideoWriter ignores values for CompressionRatio. Only applies to objects associated with Motion JPEG 2000 files.
MJ2BitDepth	Number of least-significant bits in the input image data, from 1 to 16. Applied only to objects associated with Motion JPEG 2000 files.
Quality	Number from 0 through 100. Higher values correspond to higher quality video and larger files. Only applies to objects associated with the MPEG-4 or Motion JPEG AVI profile. Default: 75.
VideoBitsPerPixel	Number of bits per pixel in each output video frame.
VideoCompressionMethod	String indicating the type of video compression, such as 'None' or 'Motion JPEG'.

Property	Description
VideoFormat	String indicating the MATLAB representation of the video format, such as 'RGB24'.

## See Also

VideoWriter

Introduced in R2010b

## open

Open file for writing video data

## Syntax

```
open(v)
```

## Description

`open(v)` opens the file associated with `v` for writing. When you open the file, all properties of the object become read only. `open` discards all existing contents of the file.

## Examples

### Open and Close Video File for Writing

Create a `VideoWriter` object to write a new Motion JPEG AVI file.

```
v = VideoWriter('newfile');
```

Open the file for writing.

```
open(v)
```

Write a 300-by-300 matrix of data to the file.

```
writeVideo(v,rand(300))
```

Close the file.

```
close(v)
```

## Input Arguments

**v** — Input `VideoWriter` object

`VideoWriter` object

Input `VideoWriter` object. Use `VideoWriter` to create the object.

### **See Also**

`close` | `VideoWriter` | `writeVideo`

**Introduced in R2010b**

## writeVideo

Write video data to file

### Syntax

```
writeVideo(v, img)
writeVideo(v, frame)
```

### Description

`writeVideo(v, img)` writes data from an array to the video file associated with `v`.

`writeVideo(v, frame)` writes one or more movie frames typically returned by the `getframe` function.

You must call `open(v)` before calling `writeVideo`.

### Examples

#### Write Image to Motion JPEG 2000 File

Write an RGB image to a Motion JPEG 2000 file with lossless compression.

Create an array containing data from the sample still image, `peppers.png`.

```
A = imread('peppers.png');
```

Create a `VideoWriter` object for a new video file. Use the 'Archival' profile to specify a Motion JPEG 2000 file with lossless compression.

```
v = VideoWriter('myFile', 'Archival');
```

Verify the type of video compression for the new file.

```
v.VideoCompressionMethod
```

```
ans =
```

Motion JPEG 2000

Open the video file for writing. Then, write the image data in `A` to the file.

```
open(v)
writeVideo(v,A)
```

Close the video file.

```
close(v)
```

### Write Indexed Image to AVI File

Read image and colormap data from the sample indexed image file, `corn.tif`.

```
[X,map] = imread('corn.tif');
```

Create a `VideoWriter` object for a new indexed AVI file.

```
v = VideoWriter('myIndexed.avi', 'Indexed AVI');
```

Assign the colormap data to the `Colormap` property of `v`.

```
v.Colormap = map;
```

Open the file for writing. After you open the file, you cannot change the properties of `v`.

```
open(v)
```

Write the image data in `X` to the video file. Then, close the file.

```
writeVideo(v,X)
close(v)
```

### Convert MPEG-4 to AVI File

Convert the example file, `xylophone.mp4`, to an uncompressed AVI file.

Create objects to read and write the video, and open the AVI file for writing.

```
reader = VideoReader('xylophone.mp4');
writer = VideoWriter('transcoded_xylophone.avi', ...
 'Uncompressed AVI');
```

```
writer.FrameRate = reader.FrameRate;
open(writer);
```

Read and write each frame.

```
while hasFrame(reader)
 img = readFrame(reader);
 writeVideo(writer, img);
end
```

```
close(writer);
```

## Create AVI File from Animation

Write a sequence of frames to a compressed AVI file named `peaks.avi`.

Prepare the new file.

```
v = VideoWriter('peaks.avi');
open(v);
```

Generate initial data and set axes and figure properties.

```
Z = peaks;
surf(Z);
axis tight manual
set(gca, 'nextplot', 'replacechildren');
```

Create a set of frames and write each frame to the file.

```
for k = 1:20
 surf(sin(2*pi*k/20)*Z, Z)
 frame = getframe;
 writeVideo(v, frame);
end
```

```
close(v);
```

## Input Arguments

### **v** — Input VideoWriter object

VideoWriter object

Input VideoWriter object. Use `VideoWriter` to create the object.

## **img** — Values representing grayscale or RGB color images

2-D array | 3-D array | 4-D array

Values representing grayscale or RGB color images, specified as a 2-D, 3-D, or 4-D array:

- For a single grayscale, monochrome, or indexed image, `img` must be two dimensional: height-by-width
- For a single truecolor (RGB) image, `img` is three dimensional: height-by-width-by-3.
- For a sequence of grayscale images, `img` is four dimensional: height-by-width-by-1-by-frames. The height and width must be consistent for all frames within a file.
- For a sequence of RGB images, `img` is four dimensional: height-by-width-by-3-by-frames. The height and width must be consistent for all frames within a file.

When creating AVI or MPEG-4 files:

- `img` is an array of `single`, `double`, or `uint8` values representing one or more grayscale or RGB color images, which `writeVideo` writes as one or more RGB video frames.
- Data of type `single` or `double` must be in the range `[0,1]`, except when writing indexed AVI files.

When creating Motion JPEG 2000 files:

- `img` is an array of `uint8`, `int8`, `uint16`, or `int16` values representing one or more monochrome or RGB color images.

Data Types: `single` | `double` | `int8` | `int16` | `uint8` | `uint16`

## **frame** — Frame data

1-by-1 structure array | 1-by-F array of structures

Frame data, specified as a 1-by-1 structure array representing a single frame, or a 1-by-F array of structures representing multiple frames. Each frame contains two fields: `cdata` and `colormap`. The `frame` array is typically returned by the `getframe` function.

If `colormap` is not empty, then each element of `cdata` should be a 2-D (height-by-width) array. The height and width must be consistent for all frames within a file.

`colormap` can contain a maximum of 256 entries. Each element of `colormap` must be in the range `[0,1]`.

When you create a `VideoWriter` object, the `profile` input and the size of `cdata` determine how `writeVideo` uses frame.

<b>profile of VideoWriter object</b>	<b>Size of each element of cdata</b>	<b>Behavior of writeVideo</b>
'Indexed AVI'	2-D (height-by-width)	Use frame as provided.
'Grayscale AVI'	2-D (height-by-width)	Use frame as provided. <code>colormap</code> should be empty.
All other profiles	2-D (height-by-width)	Construct RGB image frames using the <code>colormap</code> field
	3-D (height-by-width-by-3)	Ignore the <code>colormap</code> field. Construct RGB image frames using the <code>cdata</code> field

Data Types: `struct`

# view

Viewpoint specification

## Syntax

```
view(az,e1)
view([az,e1])
view([x,y,z])
view(2)
view(3)
view(ax,...)
[az,e1] = view
```

## Description

The position of the viewer (the viewpoint) determines the orientation of the axes. You specify the viewpoint in terms of azimuth and elevation, or by a point in three-dimensional space.

`view(az,e1)` and `view([az,e1])` set the viewing angle for a three-dimensional plot. The azimuth, `az`, is the horizontal rotation about the  $z$ -axis as measured in degrees from the negative  $y$ -axis. Positive values indicate counterclockwise rotation of the viewpoint. `e1` is the vertical elevation of the viewpoint in degrees. Positive values of elevation correspond to moving above the object; negative values correspond to moving below the object.

`view([x,y,z])` sets the view direction to the Cartesian coordinates  $x$ ,  $y$ , and  $z$ . The magnitude of  $(x,y,z)$  is ignored.

`view(2)` sets the default two-dimensional view, `az = 0`, `e1 = 90`.

`view(3)` sets the default three-dimensional view, `az = -37.5`, `e1 = 30`.

`view(ax,...)` uses axes `ax` instead of the current axes.

`[az,e1] = view` returns the current azimuth and elevation.

## Examples

View the object from directly overhead.

```
az = 0;
el = 90;
view(az, el);
```

Set the view along the  $y$ -axis, with the  $x$ -axis extending horizontally and the  $z$ -axis extending vertically in the figure.

```
view([0 0]);
```

Rotate the view about the  $z$ -axis by  $180^\circ$ .

```
az = 180;
el = 90;
view(az, el);
```

## More About

### Tips

Azimuth is a polar angle in the  $x$ - $y$  plane, with positive angles indicating counterclockwise rotation of the viewpoint. Elevation is the angle above (positive angle) or below (negative angle) the  $x$ - $y$  plane.

This diagram illustrates the coordinate system. The arrows indicate positive directions.

For more information, see `CameraPosition`, `CameraTarget`, `CameraViewAngle`, and `Projection`.

## viewmtx

View transformation matrices

### Syntax

```
viewmtx
T = viewmtx(az,e1)
T = viewmtx(az,e1,phi)
T = viewmtx(az,e1,phi,xc)
```

### Description

`viewmtx` computes a 4-by-4 orthographic or perspective transformation matrix that projects four-dimensional homogeneous vectors onto a two-dimensional view surface (e.g., your computer screen).

`T = viewmtx(az,e1)` returns an *orthographic* transformation matrix corresponding to azimuth `az` and elevation `e1`. `az` is the azimuth (i.e., horizontal rotation) of the viewpoint in degrees. `e1` is the elevation of the viewpoint in degrees.

`T = viewmtx(az,e1,phi)` returns a *perspective* transformation matrix. `phi` is the perspective viewing angle in degrees. `phi` is the subtended view angle of the normalized plot cube (in degrees) and controls the amount of perspective distortion.

Phi	Description
0 degrees	Orthographic projection
10 degrees	Similar to telephoto lens
25 degrees	Similar to normal lens
60 degrees	Similar to wide-angle lens

`T = viewmtx(az,e1,phi,xc)` returns the perspective transformation matrix using `xc` as the target point within the normalized plot cube (i.e., the camera is looking at the point `xc`). `xc` is the target point that is the center of the view. You specify the point as a

three-element vector,  $\mathbf{x}_C = [x_C, y_C, z_C]$ , in the interval  $[0,1]$ . The default value is  $\mathbf{x}_C = [0, 0, 0]$ .

A four-dimensional homogenous vector is formed by appending a 1 to the corresponding three-dimensional vector. For example,  $[x, y, z, 1]$  is the four-dimensional vector corresponding to the three-dimensional point  $[x, y, z]$ .

## Examples

### Compute Transformation Matrices

Determine the projected two-dimensional vector corresponding to the three-dimensional point  $(0.5, 0.0, -3.0)$  using the default view direction. Note that the point is a column vector.

```
A = viewmtx(-37.5,30);
x4d = [.5 0 -3 1]';
x2d = A*x4d;
x2d = x2d(1:2)
```

```
x2d =
```

```
 0.3967
 -2.4459
```

Create vectors that trace the edges of a unit cube.

```
x = [0 1 1 0 0 0 1 1 0 0 1 1 1 1 0 0];
y = [0 0 1 1 0 0 0 1 1 0 0 0 1 1 1 1];
z = [0 0 0 0 0 1 1 1 1 1 1 1 0 0 1 1 0];
```

Transform the points in these vectors to the screen, then plot the object.

```
A = viewmtx(-37.5,30);
[m,n] = size(x);
x4d = [x(:),y(:),z(:),ones(m*n,1)]';
x2d = A*x4d;
x2 = zeros(m,n); y2 = zeros(m,n);
x2(:) = x2d(1,:);
y2(:) = x2d(2,:);
```

```
plot(x2,y2)
```

Use a perspective transformation with a 25 degree viewing angle.

```
A = viewmtx(-37.5,30,25);
x4d = [.5 0 -3 1]';
x2d = A*x4d;
x2d = x2d(1:2)/x2d(4)
```

```
x2d =
```

```
0.1777
-1.8858
```

Transform the cube vectors to the screen and plot the object.

```
A = viewmtx(-37.5,30,25);
[m,n] = size(x);
x4d = [x(:),y(:),z(:),ones(m*n,1)]';
x2d = A*x4d;
x2 = zeros(m,n); y2 = zeros(m,n);
x2(:) = x2d(1,:)./x2d(4,:);
y2(:) = x2d(2,:)./x2d(4,:);
plot(x2,y2)
```

# visdiff

Compare two text files, MAT-Files, binary files, Zip files, or folders

## Syntax

```
visdiff('filename1', 'filename2')
visdiff('filename1', 'filename2', 'type')
```

## Description

`visdiff('filename1', 'filename2')` opens the Comparison Tool and presents the differences between the two files or folders. Either ensure that the two files or folders appear on the MATLAB path, or provide the full path for each file or folder. You can compare files or any combination of folders, zip files, Simulink manifests or models.

If you have Simulink Report Generator™ software, you can select a pair of Simulink models to compare XML text files generated from them. For information, see “Model Comparison”.

`visdiff('filename1', 'filename2', 'type')` opens the Comparison Tool and presents the differences between the two files using the specified comparison type. *type* can be 'text' or 'binary'. If you do not specify *type*, `visdiff` creates the default comparison type for your selected files. The *type* option does not apply when comparing folders.

If there are multiple comparison types available for your selections (e.g., text, binary, file list, or XML comparison), you can create a new comparison and choose a different comparison type.

- 1 In the Comparison Tool, click the New comparison button.

The dialog box Select Files or Folders for Comparison opens and shows your previous comparison selections in the drop-down lists.

- 2 Change the comparison type and click **Compare**.

## Examples

### Specifying Files or Folders to Compare

The `visdiff` function accepts fully qualified file names, relative file names, or names of files on the MATLAB path.

If the files you want to compare appear on the MATLAB path or in the current folder, you can specify the file names without the full path, for example:

```
visdiff('lengthofline.m','lengthofline2.m')
or
```

```
visdiff('lengthofline','lengthofline2')
```

If the files you want to compare are not on the path, either specify the full path to each file, or add the folders to the path.

For example, to specify the fully qualified file names to compare two example files:

```
visdiff(fullfile(matlabroot,'toolbox','matlab','demos','gatlin.mat'), ...
fullfile(matlabroot,'toolbox','matlab','demos','gatlin2.mat'))
```

Specify the full path to files as follows:

```
visdiff('C:\Work\comp\lengthofline.m', 'C:\Work\comp\lengthofline2.m')
```

You can specify paths to files relative to the current folder. For the preceding example, if the current folder is `WORK`, then the relative paths are:

```
visdiff('comp\lengthofline.m', 'comp\lengthofline2.m')
```

### Compare Two Text Files

To view a comparison of the two example files, `lengthofline.m` and `lengthofline2.m`:

```
visdiff(fullfile(matlabroot,'help','techdoc','matlab_env',...
'examples','lengthofline.m'), fullfile(matlabroot,'help',...
'techdoc','matlab_env','examples','lengthofline2.m'))
```

For information about using the report features, see “Comparing Text Files”.

---

**Note:** If the text files you compare are XML files, you see different results if you have MATLAB Report Generator installed. For details, see “Comparing Files and Folders”.

---

## Compare Two MAT-Files

To compare two example files:

```
visdiff(fullfile(matlabroot,'toolbox','matlab','demos','gatlin.mat'), ...
fullfile(matlabroot,'toolbox','matlab','demos','gatlin2.mat'))
```

For information about the report features, see “Comparing MAT-Files”.

## Compare Two Binary Files

The following example code adds a folder containing two MEX-files to the MATLAB path, and then compares the files:

```
addpath([matlabroot '\extern\examples\shrlib'])
visdiff('shrlibsample.mexw32', 'yprime.mexw32')
```

The Comparison Tool opens and indicates that the files are different, but does not provide details about the differences.

For more information on binary comparisons, see “Comparing Binary Files”.

## Compare Two Folders or Zip Files

You can perform file list comparisons for any combinations of folders and zip files. To view an example folder comparison and instructions for using the report features, see “Comparing Folders and Zip Files”.

## Compare Files and Specify Type

To compare two example text files and specify comparison type as binary:

```
visdiff(fullfile(matlabroot,'help','techdoc','matlab_env',...
'examples','lengthofline.m'), fullfile(matlabroot,'help',...
'techdoc','matlab_env','examples','lengthofline2.m'), 'binary')
```

If you do not specify type, `visdiff` creates the default comparison type for your selected files, in this case, text comparison. By changing to the binary comparison type you could examine differences such as end-of-line characters.

Similarly, when you compare XML files without specifying type, you get a hierarchical XML comparison report. If instead you want a text or binary comparison, you can specify "text" or "binary" comparison types to see more details. When you compare zip files, the default comparison type is a file list comparison, and you might want to specify a binary comparison instead.

## Alternatives

As an alternative to the `visdiff` function, compare files and folders using any of these interactive methods:

- From the Current Folder browser:
  - Select a file or folder. Right-click the file or folder, and select **Compare Against**.
  - For two files or subfolders in the same folder, select the files or folders. Then, right-click, and select **Compare Selected Files/Folders**.
- From the MATLAB desktop, on the **Home** tab, in the **File** section, click **Compare** and then select the files or folders to compare.
- If you have a file open in the Editor, on the **Editor** tab, in the **File** section, click **Compare**. Alternatively, under **Compare**, you can choose a file to compare against, or compare with the autosave version or the version on disk. See “Comparing Files with Autosave Version or Version on Disk”.

# volumebounds

Coordinate and color limits for volume data

## Syntax

```
lims = volumebounds(X,Y,Z,V)
lims = volumebounds(X,Y,Z,U,V,W)
lims = volumebounds(V)
lims = volumebounds(U,V,W)
```

## Description

`lims = volumebounds(X,Y,Z,V)` returns the x, y, z, and color limits of the current axes for scalar volume data. `lims` is returned as a vector:

```
[xmin xmax ymin ymax zmin zmax cmin cmax]
```

You can pass this vector to the `axis` command.

`lims = volumebounds(X,Y,Z,U,V,W)` returns the x, y, and z limits of the current axes for vector volume data. `lims` is returned as a vector:

```
[xmin xmax ymin ymax zmin zmax]
```

`lims = volumebounds(V)` and `lims = volumebounds(U,V,W)` assumes X, Y, and Z are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(V)`.

## Examples

This example uses `volumebounds` to set the axis and color limits for an isosurface generated by the `flow` function.

```
[x y z v] = flow;
```

```
p = patch(isosurface(x,y,z,v,-3));
isonormals(x,y,z,v,p)
daspect([1 1 1])
isocolors(x,y,z,flip1r(v),p)
shading interp
axis(volumebounds(x,y,z,v))
```

## See Also

# voronoi

Voronoi diagram

---

**Note:** Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `voronoi`.

---

---

**Note:** The behavior of `h = voronoi(...)` has changed. The new behavior returns a vector of two chart line handles; one representing the points and the other representing the voronoi edges.

---

## Syntax

```
voronoi(x,y)
voronoi(x,y,TRI)
voronoi(dt)
voronoi(AX,...)
voronoi(...,'LineStyle')
h = voronoi(...)
[vx,vy] = voronoi(...)
```

## Description

`voronoi(x,y)` plots the bounded cells of the Voronoi diagram for the points `x,y`. Lines-to-infinity are approximated with an arbitrarily distant endpoint.

`voronoi(x,y,TRI)` uses the triangulation `TRI` instead of computing internally.

`voronoi(dt)` uses the Delaunay triangulation `dt` instead of computing it.

`voronoi(AX,...)` plots into `AX` instead of `gca`.

`voronoi(...,'LineStyle')` plots the diagram with color and line style specified.

`h = voronoi(...)` returns `h`, which is a vector of two chart line handles. One represents the points and the other represents the voronoi edges.

`[vx,vy] = voronoi(...)` returns the finite vertices of the Voronoi edges in `vx` and `vy`.

---

**Note** For the topology of the Voronoi diagram, i.e., the vertices for each Voronoi cell, use `voronoin`.

`[v,c] = voronoin([x(:) y(:)])`

---

## Definitions

Consider a set of coplanar points  $P$ . For each point  $P_x$  in the set  $P$ , you can draw a boundary enclosing all the intermediate points lying closer to  $P_x$  than to other points in the set  $P$ . Such a boundary is called a *Voronoi polygon*, and the set of all Voronoi polygons for a given point set is called a *Voronoi diagram*.

## Visualization

Use one of these methods to plot a Voronoi diagram:

- If you provide no output argument, `voronoi` plots the diagram.
- To gain more control over color, line style, and other figure properties, use the syntax `[vx,vy] = voronoi(...)`. This syntax returns the vertices of the finite Voronoi edges, which you can then plot with the `plot` function.
- To fill the cells with color, use `voronoin` with `n = 2` to get the indices of each cell, and then use `patch` and other plot functions to generate the figure. Note that `patch` does not fill unbounded cells with color.

## Examples

### Voronoi Diagram Based on Points

This code uses the `voronoi` function to plot the Voronoi diagram for 10 randomly generated points.

```
x = gallery('uniformdata',[1 10],0);
y = gallery('uniformdata',[1 10],1);
voronoi(x,y)
```

### Voronoi Diagram Based on Vertices of Voronoi Edges

This code uses the vertices of the finite Voronoi edges to plot the Voronoi diagram for the same 10 points used in the previous example.

```
x = gallery('uniformdata',[1 10],0);
y = gallery('uniformdata',[1 10],1);
[vx,vy] = voronoi(x,y);
plot(x,y,'r+',vx,vy,'b-')
axis equal
```

Note that you can add the following code to get the figure shown in the previous example.

```
xlim([min(x) max(x)])
ylim([min(y) max(y)])
```

### Voronoi Diagram with Color

This code uses `voronoin` and `patch` to fill the bounded cells of the same Voronoi diagram with color.

```
x = gallery('uniformdata',[10 2],5);
[v,c] = voronoin(x);
for i = 1:length(c)
if all(c{i}~=1) % If at least one of the indices is 1,
 % then it is an open region and we can't
 % patch that.
patch(v(c{i},1),v(c{i},2),i); % use color i.
end
end
```

# voronoiDiagram

**Class:** DelaunayTri

(Not recommended) Voronoi diagram

---

**Note:** `voronoiDiagram(DelaunayTri)` is not recommended. Use `voronoiDiagram(delaunayTriangulation)` instead.

---

`DelaunayTri` is not recommended. Use `delaunayTriangulation` instead.

---

## Syntax

`[V, R] = voronoiDiagram(DT)`

## Description

`[V, R] = voronoiDiagram(DT)` returns the vertices `V` and regions `R` of the Voronoi diagram of the points `DT.X`. The region `R{i}` is a cell array of indices into `V` that represents the Voronoi vertices bounding the region. The Voronoi region associated with the `i`'th point, `DT.X(i)` is `R{i}`. For 2-D, vertices in `R{i}` are listed in adjacent order, i.e. connecting them will generate a closed polygon (Voronoi diagram). For 3-D the vertices in `R{i}` are listed in ascending order.

The Voronoi regions associated with points that lie on the convex hull of `DT.X` are unbounded. Bounding edges of these regions radiate to infinity. The vertex at infinity is represented by the first vertex in `V`.

## Input Arguments

`DT`                      Delaunay triangulation.

## Output Arguments

- V** `numv`-by-`ndim` matrix representing the coordinates of the Voronoi vertices, where `numv` is the number of vertices and `ndim` is the dimension of the space where the points reside.
- R** Vector cell array of length (`DR.X`), representing the Voronoi cell associated with each point.

## Definitions

The *Voronoi diagram* of a discrete set of points  $X$  decomposes the space around each point  $X(i)$  into a region of influence  $R\{i\}$ . Locations within the region are closer to point  $i$  than any other point. The region of influence is called the Voronoi region. The collection of all the Voronoi regions is the Voronoi diagram.

The *convex hull* of a set of points  $X$  is the smallest convex polygon (or polyhedron in higher dimensions) containing all of the points of  $X$ .

## Examples

Compute the Voronoi Diagram of a set of points:

```
X = [0.5 0
 0 0.5
 -0.5 -0.5
 -0.2 -0.1
 -0.1 0.1
 0.1 -0.1
 0.1 0.1]
dt = DelaunayTri(X)
[V,R] = voronoiDiagram(dt)
```

## See Also

[voronoi](#) | [delaunayTriangulation](#) | [voronoin](#) | [triangulation](#)

## voronoin

N-D Voronoi diagram

### Syntax

```
[V,C] = voronoin(X)
[V,C] = voronoin(X,options)
```

### Description

`[V,C] = voronoin(X)` returns Voronoi vertices **V** and the Voronoi cells **C** of the Voronoi diagram of **X**. **V** is a `numv-by-n` array of the `numv` Voronoi vertices in `n`-dimensional space, each row corresponds to a Voronoi vertex. **C** is a vector cell array where each element contains the indices into **V** of the vertices of the corresponding Voronoi cell. **X** is an `m-by-n` array, representing `m` `n`-dimensional points, where `n > 1` and `m >= n+1`.

The first row of **V** is a point at infinity. If any index in a cell of the cell array is 1, then the corresponding Voronoi cell contains the first point in **V**, a point at infinity. This means the Voronoi cell is unbounded.

`voronoin` uses `Qhull`.

`[V,C] = voronoin(X,options)` specifies a cell array of strings `options` to be used in `Qhull`. The default options are

- `{ 'Qbb' }` for 2- and 3-dimensional input
- `{ 'Qbb', 'Qx' }` for 4 and higher-dimensional input

If `options` is `[]`, the default options are used. If `code` is `{ '' }`, no options are used, not even the default. For more information on `Qhull` and its options, see <http://www.qhull.org>.

### Visualization

You can plot individual bounded cells of an `n`-dimensional Voronoi diagram. To do this, use `convhulln` to compute the vertices of the facets that make up the Voronoi cell. Then use `patch` and other plot functions to generate the figure.

## Examples

### Example 1

Let

```
x = [0.5 0
 0 0.5
 -0.5 -0.5
 -0.2 -0.1
 -0.1 0.1
 0.1 -0.1
 0.1 0.1]
```

then

```
[V,C] = voronoin(x)
```

V =

Inf	Inf
0.3833	0.3833
0.7000	-1.6500
0.2875	0.0000
-0.0000	0.2875
-0.0000	-0.0000
-0.0500	-0.5250
-0.0500	-0.0500
-1.7500	0.7500
-1.4500	0.6500

C =

```
[1x4 double]
[1x5 double]
[1x4 double]
[1x4 double]
[1x4 double]
[1x4 double]
[1x5 double]
[1x4 double]
```

Use a for loop to see the contents of the cell array C.

```
for i=1:length(C), disp(C{i}), end
```

```

 4 2 1 3
10 5 2 1 9
 9 1 3 7
10 8 7 9
10 5 6 8
 8 6 4 3 7
 6 4 2 5

```

In particular, the fifth Voronoi cell consists of 4 points:  $V(10, :)$ ,  $V(5, :)$ ,  $V(6, :)$ ,  $V(8, :)$ .

## Example 2

The following example illustrates the options input to `voronoin`. The commands

```
X = [-1 -1; 1 -1; 1 1; -1 1];
[V,C] = voronoin(X)
```

return an error message.

```
? qhull input error: can not scale last coordinate. Input is
cocircular
 or cospherical. Use option 'Qz' to add a point at infinity.
```

The error message indicates that you should add the option 'Qz'. The following command passes the option 'Qz', along with the default 'Qbb', to `voronoin`.

```
[V,C] = voronoin(X,{'Qbb','Qz'})
V =
```

```

 Inf Inf
 0 0
```

C =

```

[1x2 double]
[1x2 double]
[1x2 double]
[1x2 double]
```

## More About

### Algorithms

voronoi is based on Qhull [1]. For information about Qhull, see <http://www.qhull.org/>.

## References

**Introduced before R2006a**

# waitbar

Open or update wait bar dialog box

## Syntax

```
h = waitbar(x,'message')
waitbar(x,'message','CreateCancelBtn','button_callback')
waitbar(x,'message',property_name,property_value,...)
waitbar(x)
waitbar(x,h)
waitbar(x,h,'updated message')
```

## Description

A wait bar is a figure that displays what percentage of a calculation is complete as the calculation proceeds by progressively filling a bar with color from left to right.

`h = waitbar(x,'message')` displays a wait bar of fractional length `x`. The wait bar figure displays until the code that controls it closes it or the user clicks its Close Window button. Its (figure) handle is returned in `h`. The argument `x` must be between 0 and 1.

---

**Note** Wait bars are not modal figures (their `WindowStyle` is 'normal'). They often appear to be modal because the computational loops within which they are called prevent interaction with the Command Window until they terminate. For more information, see `WindowStyle` in Figure Properties.

---

`waitbar(x,'message','CreateCancelBtn','button_callback')` specifying `CreateCancelBtn` adds a **Cancel** button to the figure that executes the MATLAB commands specified in `button_callback` when the user clicks the **Cancel** button or the **Close Figure** button. `waitbar` sets both the **Cancel** button callback and the figure `CloseRequestFcn` to the string specified in `button_callback`.

`waitbar(x,'message',property_name,property_value,...)` optional arguments `property_name` and `property_value` enable you to set Figure Properties for the waitbar.

`waitbar(x)` subsequent calls to `waitbar(x)` extend the length of the bar to the new position `x`. Successive values of `x` normally increase. If they decrease, the wait bar runs in reverse.

`waitbar(x,h)` extends the length of the bar in the wait bar `h` to the new position `x`.

`waitbar(x,h,'updated message')` updates the message text in the `waitbar` figure, in addition to setting the fractional length to `x`.

## Examples

### Example 1 — Basic Wait Bar

Typically, you call `waitbar` repeatedly inside a `for` loop that performs a lengthy computation. For example:

```
h = waitbar(0,'Please wait...');
steps = 1000;
for step = 1:steps
 % computations take place here
 waitbar(step / steps)
end
close(h)
```

### Example 2 — Wait Bar with Dynamic Text and Cancel Button

Adding a **Cancel** button allows user to abort the computation. Clicking it sets a logical flag in the figure's application data (`appdata`). The function tests for that value within the main loop and exits the loop as soon as the flag has been set. The example iteratively approximates the value of  $\pi$ . At each step, the current value is encoded as a string and

displayed in the wait bar's message field. When the function finishes, it destroys the wait bar and returns the current estimate of  $\pi$  and the number of steps it ran.

Copy the following function to a code file and save it as `approxpi.m`. Execute it as follows, allowing it to run for 10,000 iterations.

```
[estimated_pi steps] = approxpi(10000)
```

You can click **Cancel** or close the window to abort the computation and return the current estimate of  $\pi$ .

```
function [valueofpi step] = approxpi(steps)
% Converge on pi in steps iterations, displaying waitbar.
% User can click Cancel or close button to exit the loop.
% Ten thousand steps yields error of about 0.001 percent.

h = waitbar(0,'1','Name','Approximating pi...',...
 'CreateCancelBtn',...
 'setappdata(gcf,'canceling',1)');
setappdata(h,'canceling',0)
% Approximate as $\pi^2/8 = 1 + 1/9 + 1/25 + 1/49 + \dots$
pisqover8 = 1;
denom = 3;
valueofpi = sqrt(8 * pisqover8);
for step = 1:steps
 % Check for Cancel button press
 if getappdata(h,'canceling')
 break
 end
 % Report current estimate in the waitbar's message field
 waitbar(step/steps,h,sprintf('%12.9f',valueofpi))
 % Update the estimate
 pisqover8 = pisqover8 + 1 / (denom * denom);
 denom = denom + 2;
 valueofpi = sqrt(8 * pisqover8);
end
delete(h) % DELETE the waitbar; don't try to CLOSE it.
The function sets the figure Name property to describe what is being
computed. In the for loop, calling waitbar sets the fractional progress
indicator and displays intermediate results. the code waitbar(i/
steps,h,sprintf('%12.9f',valueofpi)) sets the wait bar's message variable to
a string representation of the current estimate of π . Naturally, the extra computation
involved makes iterations last longer than they need to, but such feedback can be helpful
to users.
```

---

**Note:** You should call `delete` to remove a wait bar when you give it a `CloseRequestFcn`, as in the preceding code; calling `close` does not close it, and makes its Cancel and Close Window buttons unresponsive. This happens because the figure's `CloseRequestFcn` callback recursively calls itself. In such a situation you must forcibly remove the wait bar, for example like this:

```
set(groot, 'ShowHiddenHandles', 'on')
delete(get(groot, 'Children'))
```

However, as issuing these commands will delete all open figures—not just the wait bar—it is best never to use `close` in a `CloseRequestFcn` to close a window.

---

# waitfor

Block execution and wait for condition

## Syntax

```
waitfor(h)
waitfor(h,PropertyName)
waitfor(h,PropertyName,PropertyValue)
```

## Description

`waitfor(h)` blocks the caller from executing statements until the graphics object identified by `h` closes (is deleted). When object `h` no longer exists, `waitfor` returns, enabling execution to resume. If the object does not exist, `waitfor` returns immediately without processing any events.

`waitfor(h,PropertyName)` blocks the caller from executing until the value of `PropertyName` (any property of the graphics object `h`) changes or `h` closes (is deleted). If `PropertyName` is not a valid property for the object, MATLAB returns an error.

`waitfor(h,PropertyName,PropertyValue)` blocks the caller from executing until the value of `PropertyName` for the graphics object `h` changes to the specific value `PropertyValue` or `h` closes (is deleted). If the value of `PropertyName` is already `PropertyValue`, `waitfor` returns immediately without processing any events.

Here are some important characteristics of the `waitfor` function:

- The `waitfor` function prevents its caller from continuing, but callbacks that respond to various user actions (for example, pressing a mouse button) can still run.
- The `waitfor` function also blocks Simulink models from executing, but callbacks do still execute.
- The `waitfor` function can block nested function calls. For example, a callback that executes while the `waitfor` function is running can call `waitfor`.
- If a callback function of a UI component is currently executing the `waitfor` function, then that callback can be interrupted regardless of that component's `Interruptible` property value.

- If you type **Ctrl+C** in the Command Window while the `waitfor` function is executing, the executing program terminates. To avoid terminating, the program can call the `waitfor` function within a `try/catch` block that handles the exception that typing **Ctrl+C** generates.

## Examples

Create a plot and pause execution of the rest of the statements until you close the figure window:

```
f = warndlg('This is a warning.', 'A Warning Dialog');
disp('This prints immediately');
drawnow % Necessary to print the message
waitfor(f);
disp('This prints after you close the warning dialog');
```

Suspend execution until name of figure changes:

```
f = figure('Name', datestr(now));
h = uicontrol('String','Change Name',...
 'Position',[20 20 100 30],...
 'Callback', 'set(gcf, 'Name', datestr(now))');
disp('This prints immediately');
drawnow % Necessary to print the message
waitfor(f, 'Name');
disp('This prints after clicking the push button');
```

Display text object and wait for user to edit it:

```
figure;
textH = text(.5, .5, 'Edit me and click away');
set(textH,'Editing','on', 'BackgroundColor',[1 1 1]);
disp('This prints immediately. ');
drawnow
waitfor(textH,'Editing','off');
set(textH,'BackgroundColor',[1 1 0]);
disp('This prints after text editing is complete.');
```

If you close the figure while `waitfor` is executing, an error occurs because the code attempts to access handles of objects that no longer exist. You can handle the error by enclosing code starting with the call to `waitfor` in a `try/catch` block, as follows:

```
figure;
```

```
textH = text(.5, .5, 'Edit me and click away');
set(textH,'Editing','on', 'BackgroundColor',[1 1 1]);
disp('This prints immediately. ');
drawnow
% Use try/catch block to handle errors,
% such as deleting figure
try
 waitfor(textH,'Editing','off');
 set(textH,'BackgroundColor',[1 1 0]);
 disp('This prints after text editing is complete. ');
catch ME
 disp('This prints if figure is deleted:')
 disp(ME.message)
 % You can place other code to respond to the error here
end
```

The ME variable is a MATLAB Exception object that you can use to determine the type of error that occurred. For more information, see “Respond to an Exception”.

`drawnow` | `pause` | `keyboard` | `uiresume` | `uiwait` | `waitforbuttonpress`

**Introduced before R2006a**

## waitforbuttonpress

Wait for key press or mouse-button click

---

**Note:** The behavior of the `waitforbuttonpress` function changed in R2014b. The figure that is current when you call the `waitforbuttonpress` function is the only area in which users can press a key or click a mouse button to resume program execution.

---

### Syntax

`k = waitforbuttonpress`

### Description

`k = waitforbuttonpress` blocks the caller's execution stream until the function detects that the user has clicked a mouse button or pressed a key while the figure window is active. The figure that is current when you call the `waitforbuttonpress` function is the only area in which users can press a key or click a mouse button to resume program execution. The return argument, `k`, can have these values:

- 0 if it detects a mouse button click
- 1 if it detects a key press

If a `WindowButtonDownFcn` callback is defined for the figure, its callback is executed before `waitforbuttonpress` returns a value.

Only keys that generate characters cause the function to return. Pressing any of the following keys by itself does nothing: **Ctrl**, **Shift**, **Alt**, **Caps\_lock**, **Num\_lock**, **Scroll\_lock**.

These figure properties provide additional information about the user's interaction with the window: `CurrentCharacter`, `SelectionType`, and `CurrentPoint`.

You can interrupt the `waitforbuttonpress` function by typing **Ctrl+C**, but it returns an error unless your code calls it from within a `try/catch` block. The

`waitforbuttonpress` function errors if the user closes the figure by clicking the **X** (close box) unless your code calls the `waitforbuttonpress` function within a `try/catch` block.

## Examples

These statements display text in the Command Window when the user either clicks a mouse button or types a key in the figure window:

```
f = figure;
w = waitforbuttonpress;
if w == 0
 disp('Button click')
else
 disp('Key press')
end
```

## See Also

`dragrect` | `ginput` | `rbbox` | `waitfor`

**Introduced before R2006a**

## warndlg

Create warning dialog box

### Syntax

```
h = warndlg
h = warndlg(warningstring)
h = warndlg(warningstring,dlgname)
h = warndlg(warningstring,dlgname,createmode)
```

### Description

`h = warndlg` displays a dialog box named, Warning Dialog, containing the string, “This is the default warning string.” The `warndlg` function returns the handle of the dialog box in `h`. The warning dialog box disappears after the user clicks **OK**.

`h = warndlg(warningstring)` displays a dialog box entitled, Warning Dialog, containing the string specified by `warningstring`. The `warningstring` argument can be any valid string format – cell arrays are preferred.

To use multiple lines in your warning, define `warningstring` using either of the following:

- `sprintf` with newline characters separating the lines

```
warndlg(sprintf('Message line 1 \n Message line 2'))
```

- Cell arrays of strings

```
warndlg({'Message line 1';'Message line 2'})
```

`h = warndlg(warningstring,dlgname)` displays a dialog box with title `dlgname`.

`h = warndlg(warningstring,dlgname,createmode)` specifies whether the warning dialog box is modal or nonmodal. Optionally, it can also specify an interpreter for `warningstring` and `dlgname`. The `createmode` argument can be a string or a structure.

If *createmode* is a string, it must be one of the values shown in the following table.

createmode Value	Description
modal	Replaces the warning dialog box having the specified <b>Title</b> , that was last created or clicked on, with a modal warning dialog box as specified. All other warning dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.
nonmodal (default)	Creates a new nonmodal warning dialog box with the specified parameters. Existing warning dialog boxes with the same title are not deleted.
replace	Replaces the warning dialog box having the specified <b>Title</b> , that was last created or clicked on, with a nonmodal warning dialog box as specified. All other warning dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.

---

**Note:** A modal dialog box prevents the user from interacting with other windows before responding. To block MATLAB program execution as well, use the `uiwait` function.

Modal dialogs (created using `errordlg`, `msgbox`, or `warndlg`) replace any existing dialogs created with these functions that also have the same name.

For more information about modal dialog boxes, see `WindowStyle` in Figure Properties.

---

If `CreateMode` is a structure, it can have fields `WindowStyle` and `Interpreter`. `WindowStyle` must be one of the options shown in the table above. `Interpreter` is one of the strings `'tex'` or `'none'`. The default value for `Interpreter` is `'none'`.

## Examples

The statement

```
warndlg('Pressing OK will clear memory','!! Warning !!')
```

displays this dialog box:

## See Also

`dialog` | `errordlg` | `helpdlg` | `inputdlg` | `listdlg` | `msgbox` | `questdlg` | `figure` | `uiwait` | `uiresume` | `warning`

# warning

Display warning message

## Syntax

```
warning(msg)
warning(msg,A1,...,An)
warning(msgID, ___)
```

```
warning(state)
warning(state,msgID)
warning
```

```
warnStruct = warning
warning(warnStruct)
```

```
warning(state,mode)
warnStruct = warning(state,mode)
```

## Description

`warning(msg)` displays the warning message and sets the warning state for the `lastwarn` function. If `msg` is an empty string ( `' '` ), `warning` resets the warning state for `lastwarn`, but does not display any text.

`warning(msg,A1,...,An)` displays a message string that contains formatting conversion characters, such as those used with the MATLAB `sprintf` function. Each conversion character in `msg` is converted to one of the values `A1,...,An`.

`warning(msgID, ___ )` attaches a warning identifier to the warning message. You can include any of the input arguments in the previous syntaxes. The identifier enables you to distinguish warnings and to control what happens when MATLAB encounters the warnings.

`warning(state)` enables, disables, or displays the state of all warnings.

`warning(state,msgID)` acts on the state of a specified warning.

`warning` displays the state of all of the warnings. It is equivalent to `warning('query')`.

`warnStruct = warning` returns a structure or array of structures that contains information about which warnings are enabled and disabled. `warnStruct` includes an `identifier` field with a `msgID` or `'all'`, and a `state` field that indicates the state of the corresponding warning.

`warning(warnStruct)` sets the current warning settings as indicated in the structure array, `warnStruct`.

`warning(state,mode)` controls whether MATLAB displays the stack trace or additional information about the warning.

`warnStruct = warning(state,mode)` returns a structure with an `identifier` field containing the `mode` and a `state` field containing the current state of `mode`. If you pass the output structure, `warnStruct`, into the `warning` function, you set the state of the `mode`, not which warnings are enabled or disabled.

## Examples

### Issue Warning Message

Generate a warning that displays a message.

```
n = 7;
if ~ischar(n)
 warning('Input must be a string')
end
```

Warning: Input must be a string

Include information about `n` in the warning message.

```
if ~ischar(n)
 warning('Input must be a string, not a %s',class(n))
end
```

Warning: Input must be a string, not a double

Attach a message identifier to the warning message.

```
if ~ischar(n)
```

```
warning('MyComponent:incorrectType',...
 'Input must be a string, not a %s',class(n))
end
```

Warning: Input must be a string, not a double

### Set and Query Warning State

Disable all warnings.

```
warning('off')
```

Query the warnings.

```
warning
```

All warnings have the state 'off'.

Enable all warnings, disable the singular matrix warning, and query all warnings.

```
warning('on')
warning('off','MATLAB:singularMatrix')
warning
```

The default warning state is 'on'. Warnings not set to the default are

```
State Warning Identifier
```

```
off MATLAB:singularMatrix
```

Re-enable the singular matrix warning.

```
warning('on','MATLAB:singularMatrix')
```

### Save and Restore Warning Settings

Enable all warnings, and then disable the singular matrix warning.

```
warning('on')
warning('off','MATLAB:singularMatrix')
```

Save the current warning settings.

```
s = warning
```

```
s =
```

2x1 struct array with fields:

```
 identifier
 state
```

Examine the two structures.

```
s(1)
```

```
ans =
```

```
 identifier: 'all'
 state: 'on'
```

```
s(2)
```

```
ans =
```

```
 identifier: 'MATLAB:singularMatrix'
 state: 'off'
```

All warnings are enabled except for 'MATLAB:singularMatrix'.

Disable and query all warnings.

```
warning('off')
warning('query')
```

All warnings have the state 'off'.

Restore the saved warning state structure, and query the state.

```
warning(s)
warning('query')
```

The default warning state is 'on'. Warnings not set to the default are

```
State Warning Identifier
off MATLAB:singularMatrix
```

## Control Warning Verbosity

Ensure verbose and backtrace settings are the default values.

```
warning('off', 'verbose')
warning('on', 'backtrace')
```

Turn on all warnings, and remove a folder that does not exist on the MATLAB path.

```
warning('on')
rmpath('nosuchfolder')
```

```
Warning: "nosuchfolder" not found in path.
> In rmpath at 57
```

Enable verbosity to display an extended warning message.

```
warning('on','verbose')
rmpath('nosuchfolder')
```

```
Warning: "nosuchfolder" not found in path.
(Type "warning off MATLAB:rmpath:DirNotFound" to suppress this warning.)
```

```
> In rmpath at 57
```

Disable display of the stack trace.

```
warning('off','backtrace')
rmpath('nosuchfolder')
```

```
Warning: "nosuchfolder" not found in path.
(Type "warning off MATLAB:rmpath:DirNotFound" to suppress this warning.)
```

### Temporarily Disable Warning

Compute a singular matrix.

```
A = eye(2);
B = [3 6; 4 8];
C = B\A;
```

```
Warning: Matrix is singular to working precision.
```

Find the warning ID, save the current warning state, and disable the specific warning

```
[msgStr,msgId] = lastwarn;
warnStruct = warning('off',msgId);
C = B\A;
```

Restore previous warning state.

```
warning(warnStruct);
C = B\A;
```

Warning: Matrix is singular to working precision.

- “Issue Warnings and Errors”
- “Suppress Warnings”
- “Restore Warnings”
- “Change How Warnings Display”

## Input Arguments

### **msg** — Information about cause of warning

string

Information about the cause of the warning and how you might correct it, specified as a string. To format the string, use escape sequences, such as `\t` or `\n`. You also can use any format specifiers supported by the `sprintf` function, such as `%s` or `%d`. Specify values for the conversion specifiers via the `A1, . . . , An` input arguments. For more information, see “Formatting Strings”.

---

**Note:** You must specify more than one input argument with `warning` if you want MATLAB to convert special characters (such as `\t`, `\n`, `%s`, and `%d`) in the warning message string.

---

Example: `'Input must be a string.'`

### **A1, . . . , An** — Numeric or character arrays

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array. This input argument provides the values that correspond to and replace the conversion specifiers in `msg`.

### **msgID** — Identifier for warning

string | 'all' | 'last'

Identifier for the warning, specified as a string, `'all'`, or `'last'`. Use the warning identifier to help identify the source of the warning or to control a selected subset of the warnings in your program.

The message identifier includes a `component` and `mnemonic`. The identifier must always contain a colon and follows this simple format: `component:mnemonic`. The `component` and `mnemonic` fields must each begin with a letter. The remaining characters can be alphanumeric (A–Z, a–z, 0–9) and underscores. No whitespace characters can appear anywhere in `msgID`. For more information, see “Message Identifiers”.

When you set the `state` of a warning, the `msgID` can have a value of `'all'` or `'last'`. Use `'all'` to set the state of all warnings, and use `'last'` to set the state of the last issued warning.

Example: `'MATLAB:singularMatrix'`

Example: `'MATLAB:narginchk:notEnoughInputs'`

### **state** — Warning control indicator

`'on'` | `'off'` | `'query'`

Warning control indicator specified as `'on'`, `'off'`, or `'query'`. Use `'on'` or `'off'` to control whether MATLAB issues a warning. Use `'query'` to query the current state of the warning.

### **warnStruct** — Warning settings

structure | array of structures

Warning settings, specified as a structure or array of structures that contains information about which warnings are enabled and which are disabled. `warnStruct` includes an `identifier` field with a `msgID` or `'all'`, and `state` field indicating the state of the corresponding warning.

### **mode** — Verbosity and stack trace display settings

`'backtrace'` | `'verbose'`

Verbosity and the stack trace display of settings, specified by `'backtrace'` or `'verbose'`. By default, the state of verbosity is set to `'off'` and the state of stack trace display is set to `'on'`.

# waterfall

Waterfall plot

## Syntax

```
waterfall(Z)
waterfall(X,Y,Z)
waterfall(...,C)
waterfall(axes_handles,...)
h = waterfall(...)
```

## Description

The `waterfall` function draws a mesh similar to the `meshz` function, but it does not generate lines from the columns of the matrices. This produces a “waterfall” effect.

`waterfall(Z)` creates a waterfall plot using `x = 1:size(Z,2)` and `y = 1:size(Z,1)`. `Z` determines the color, so color is proportional to surface height.

`waterfall(X,Y,Z)` creates a waterfall plot using the values specified in `X`, `Y`, and `Z`. `Z` also determines the color, so color is proportional to the surface height. If `X` and `Y` are vectors, `X` corresponds to the columns of `Z`, and `Y` corresponds to the rows, where `length(x) = n`, `length(y) = m`, and `[m,n] = size(Z)`. `X` and `Y` are vectors or matrices that define the *x*- and *y*-coordinates of the plot. `Z` is a matrix that defines the *z*-coordinates of the plot (i.e., height above a plane). If `C` is omitted, color is proportional to `Z`.

`waterfall(...,C)` uses scaled color values to obtain colors from the current colormap. Color scaling is determined by the range of `C`, which must be the same size as `Z`.

MATLAB performs a linear transformation on **C** to obtain colors from the current colormap.

`waterfall(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = waterfall(...)` returns the handle of the patch graphics object used to draw the plot.

## Examples

### Create Waterfall Plot

Create a waterfall plot of the peaks function.

```
figure
[X,Y,Z] = peaks(30);
waterfall(X,Y,Z)
```

## More About

### Tips

For column-oriented data analysis, use `waterfall(Z')` or `waterfall(X',Y',Z')`.

### Algorithms

The range of  $X$ ,  $Y$ , and  $Z$ , or the current setting of the axes `XLim`, `YLim`, and `ZLim` properties, determines the range of the axes (also set by `axis`). The range of  $C$ , or the current setting of the axes `CLim` property, determines the color scaling (also set by `caxis`).

The `CData` property for the patch graphics objects specifies the color at every point along the edge of the patch, which determines the color of the lines.

The waterfall plot looks like a mesh surface; however, it is a patch graphics object. To create a surface plot similar to `waterfall`, use the `meshz` function and set the `MeshStyle` property of the surface to `'Row'`. For a discussion of parametric surfaces and related color properties, see `surf`.

**Introduced before R2006a**

## wavinfo

Information about WAVE (.wav) sound file

---

**Note:** `wavinfo` has been removed. Use `audioinfo` instead.

---

### Syntax

```
[m d] = wavinfo(filename)
```

### Description

[*m d*] = `wavinfo(filename)` returns information about the contents of the WAVE sound file specified by the string *filename*. Enclose the *filename* input in single quotes.

*m* is the string 'Sound (WAV) file', if *filename* is a WAVE file. Otherwise, it contains an empty string ('').

*d* is a string that reports the number of samples in the file and the number of channels of audio data. If *filename* is not a WAVE file, it contains the string 'Not a WAVE file'.

### See Also

`audioplayer` | `audiorecorder` | `audioread` | `audiowrite`

**Introduced before R2006a**

# wavread

Read WAVE (.wav) sound file

---

**Note:** `wavread` has been removed. Use `audioread` instead.

---

## Syntax

```
y = wavread(filename)
[y, Fs] = wavread(filename)
[y, Fs, nbits] = wavread(filename)
[y, Fs, nbits, opts] = wavread(filename)
[___] = wavread(filename, N)
[___] = wavread(filename, [N1 N2])
[___] = wavread(____, fmt)
siz = wavread(filename, 'size')
```

## Description

`y = wavread(filename)` loads a WAVE file specified by the string *filename*, returning the sampled data in *y*. If *filename* does not include an extension, `wavread` appends `.wav`.

`[y, Fs] = wavread(filename)` returns the sample rate (*Fs*) in Hertz used to encode the data in the file.

`[y, Fs, nbits] = wavread(filename)` returns the number of bits per sample (*nbits*).

`[y, Fs, nbits, opts] = wavread(filename)` returns a structure *opts* of additional information contained in the WAV file. The content of this structure differs from file to file. Typical structure fields include `opts.fmt` (audio format information) and `opts.info` (text that describes the title, author, etc.).

`[___] = wavread(filename, N)` returns only the first *N* samples from each channel in the file.

`[ ___ ] = wavread(filename, [N1 N2])` returns only samples *N1* through *N2* from each channel in the file.

`[ ___ ] = wavread( ___, fmt)` specifies the data format of *y* used to represent samples read from the file. *fmt* can be either of the following values, or a partial match (case-insensitive):

- 'double'            Double-precision normalized samples (default).
- 'native'            Samples in the native data type found in the file.

`siz = wavread(filename, 'size')` returns the size of the audio data contained in *filename* instead of the actual audio data, returning the vector `siz = [samples channels]`.

## Output Scaling

The range of values in *y* depends on the data format *fmt* specified. Some examples of output scaling based on typical bit-widths found in a WAV file are given below for both 'double' and 'native' formats.

### Native Formats

Number of Bits	MATLAB Data Type	Data Range
8	uint8 (unsigned integer)	$0 \leq y \leq 255$
16	int16 (signed integer)	$-32768 \leq y \leq +32767$
24	int32 (signed integer)	$-2^{23} \leq y \leq 2^{23}-1$
32	single (floating point)	$-1.0 \leq y < +1.0$

### Double Formats

Number of Bits	MATLAB Data Type	Data Range
N<32	double	$-1.0 \leq y < +1.0$
N=32	double	$-1.0 \leq y \leq +1.0$ Note: Values in <i>y</i> might exceed -1.0 or +1.0 for the case of N=32 bit data samples stored in the WAV file.

wavread supports multi-channel data, with up to 32 bits per sample.

wavread supports Pulse-code Modulation (PCM) data format only.

## Examples

Create a WAV file from the example file `handel.mat`, and read portions of the file back into MATLAB.

```
% Create WAV file in current folder.
load handel.mat

hfile = 'handel.wav';
wavwrite(y, Fs, hfile)
clear y Fs

% Read the data back into MATLAB, and listen to audio.
[y, Fs, nbits, readinfo] = wavread(hfile);
sound(y, Fs);

% Pause before next read and playback operation.
duration = numel(y) / Fs;
pause(duration + 2)

% Read and play only the first 2 seconds.
nsamples = 2 * Fs;
[y2, Fs] = wavread(hfile, nsamples);
sound(y2, Fs);
pause(4)

% Read and play the middle third of the file.
sizeinfo = wavread(hfile, 'size');

tot_samples = sizeinfo(1);
startpos = tot_samples / 3;
endpos = 2 * startpos;

[y3, Fs] = wavread(hfile, [startpos endpos]);
sound(y3, Fs);
```

## See Also

[mmfileinfo](#) | [audioinfo](#) | [audiowrite](#) | [audioread](#) | [audioplayer](#) | [audiorecorder](#) | [sound](#)

**Introduced before R2006a**

## wavwrite

Write WAVE (.wav) sound file

---

**Note:** wavwrite has been removed. Use audiowrite instead.

---

### Syntax

```
wavwrite(y, filename)
wavwrite(y, Fs, filename)
wavwrite(y, Fs, N, filename)
```

### Description

`wavwrite(y, filename)` writes the data stored in the variable `y` to a WAVE file called `filename`. The `filename` input is a string enclosed in single quotes. The data has a sample rate of 8000 Hz and is assumed to be 16-bit. Each column of the data represents a separate channel. Therefore, stereo data should be specified as a matrix with two columns.

`wavwrite(y, Fs, filename)` writes the data stored in the variable `y` to a WAVE file called `filename`. The data has a sample rate of `Fs` Hz and is assumed to be 16-bit.

`wavwrite(y, Fs, N, filename)` writes the data stored in the variable `y` to a WAVE file called `filename`. The data has a sample rate of `Fs` Hz and is `N`-bit, where `N` is 8, 16, 24, or 32.

### Input Data Ranges

The range of values in `y` depends on the number of bits specified by `N` and the data type of `y`. The following tables list the valid input ranges based on the value of `N` and the data type of `y`.

If `y` contains integer data:

N Bits	y Data Type	y Data Range	Output Format
8	uint8	$0 \leq y \leq 255$	uint8
16	int16	$-32768 \leq y \leq +32767$	int16
24	int32	$-2^{23} \leq y \leq 2^{23} - 1$	int32

If y contains floating-point data:

N Bits	y Data Type	y Data Range	Output Format
8	single or double	$-1.0 \leq y < +1.0$	uint8
16	single or double	$-1.0 \leq y < +1.0$	int16
24	single or double	$-1.0 \leq y < +1.0$	int32
32	single or double	$-1.0 \leq y \leq +1.0$	single

For floating point data where  $N < 32$ , amplitude values are clipped to the range  $-1.0 \leq y < +1.0$ .

---

**Note** 8-, 16-, and 24-bit files are type 1 integer pulse code modulation (PCM). 32-bit files are written as type 3 normalized floating point.

---

**Introduced before R2006a**

# web

Open Web page or file in browser

## Syntax

```
web
web(url)
web(url,opt)
web(url,opt1,...,optN)

stat = web(___)
[stat,h] = web(___)
[stat,h,url] = web(___)
```

## Description

`web` opens an empty MATLAB Web browser.

`web(url)` opens the page specified by `url` in the MATLAB Web browser. If multiple browsers are open, the page displays in the one that was most recently used.

`web(url,opt)` opens the page using the specified browser option, such as `'-new'` to create a new browser instance or `'-browser'` to use the system browser.

`web(url,opt1,...,optN)` opens the page using one or more browser options.

`stat = web( ___ )` returns the status of the operation: **0** if successful, **1** or **2** if unsuccessful. You can include any of the input arguments in previous syntaxes.

`[stat,h] = web( ___ )` returns a handle to a MATLAB Web browser that allows you to close it using the command `close(h)`. If you do not specify any inputs to the `web` function, such as `[stat,h] = web`, then the handle corresponds to the most recently used MATLAB Web browser.

`[stat,h,url] = web( ___ )` returns the URL of the current page in the MATLAB Web browser.

## Examples

### Web Page in MATLAB Web Browser

Open the MathWorks Web site home page.

```
url = 'http://www.mathworks.com';
web(url)
```

Open the page in a new instance of the browser that does not include a toolbar.

```
web(url, '-new', '-notoolbar')
```

### File in MATLAB Web Browser

View an HTML file that resides on your system.

Create an HTML file by publishing an example program file. Copy the program file to the current folder so that the code can run during the publishing process.

```
program = fullfile(matlabroot, 'help', 'techdoc', ...
 'matlab_env', 'examples', 'fourier_demo2.m');
copyfile(program);
htmlFile = publish('fourier_demo2.m');
```

View a file by specifying the file name.

```
web(htmlFile)
```

Alternatively, you can use the `file:///` URL scheme, as long as you include the full path. The `publish` function returns the path in the `htmlFile` output.

```
url = ['file:///', htmlFile];
web(url)
```

### Web Page in System Browser

Open the MathWorks Web site home page in the system browser.

```
url = 'http://www.mathworks.com';
web(url, '-browser')
```

### Email from System Browser

Send email from your system browser's default mail application using the `mailto:` URL scheme.

To run this example, replace the value for `email` with a valid email address.

```
email = 'myaddress@provider.ext';
url = ['mailto:',email];
web(url)
```

### Handle to MATLAB Web Browser

Open the MathWorks Web site home page, and then close the browser using its handle.

```
url = 'http://www.mathworks.com';
[stat,h] = web(url);
```

Close the browser window.

```
close(h)
```

### Text Displayed in MATLAB Web Browser

View formatted text using the `text://` URL scheme.

```
web('text://<html><h1>Hello World</h1></html>')
```

## Input Arguments

### **url** — Web page address or file location

string

Web page address or file location, specified as a string. File locations can include an absolute or relative path.

If `url` corresponds to a file in the installed product documentation, then the page displays in the MATLAB Help browser instead of the Web browser.

Example: 'http:\\www.mathworks.com'

Example: 'myfolder/myfile.html'

### **opt** — Browser option

'-browser' | '-new' | '-noaddressbox' | '-notoolbar'

Browser option, specified as one of the following strings. Options can appear in any order.

- '-browser' Opens the page in a system browser window instead of the MATLAB Web browser. On Microsoft Windows and Apple Macintosh platforms, the operating system determines the system Web browser. On other systems, the default is the Mozilla® Firefox® browser, but you can change the default using MATLAB Web preferences.
- '-new' Opens the page in a new MATLAB Web browser window. Does not apply to the system browser.
- '-noaddressbox' Opens the page in a browser that does not display the address box. Only applies to new instances of the MATLAB Web browser.
- '-notoolbar' Opens the page in a browser that does not display a toolbar or address box. Only applies to new instances of the MATLAB Web browser.

Example: '-new', '-noaddressbox'

## Output Arguments

### **stat** — Browser status

0 | 1 | 2

Browser status, returned as an integer with one of these values:

- 0 Found and launched system browser.
- 1 Could not find system browser.
- 2 Found, but could not launch system browser.

### **h** — Handle to most recent MATLAB Web browser

scalar

Handle to the most recent MATLAB Web browser, returned as a scalar instance of the associated Java class.

If you do not request the handle when you open the page, be aware that this handle might not correspond to your most recent use of the `web` function. Other MATLAB functionality also uses the `web` function, such as links to external sites from the Help browser.

**url** — Current page address

string

Current page address in the most recent MATLAB Web browser, returned as a string.

## More About

### Tips

- If you plan to deploy an application that calls the `web` function using the MATLAB Compiler product, then use the `'-browser'` option.
- If you are displaying Japanese streaming text in the MATLAB Web browser, specify a header that includes the `charset` attribute. For example:

```
web(['text://<html><head><meta http-equiv="content-type" ' ...
 'content="text/html; charset=utf-8"></head><body>TEXT</body></html>'])
```

- “Web Browsers and MATLAB”
- “Specify Proxy Server Settings for Connecting to the Internet”
- “Specify the System Browser for Linux Platforms”

# weboptions

Specify parameters for RESTful web service

## Syntax

```
options = weboptions
options = weboptions(Name,Value)
```

## Description

`options = weboptions` returns a default `weboptions` object to specify parameters for a request to a web service. A `weboptions` object can be an optional input argument to the `webread`, `websave`, and `webwrite` functions.

`options = weboptions(Name,Value)` specifies one or more properties of a `weboptions` object.

## Examples

### Default weboptions Object

Create a default `weboptions` object and display the default values for its properties.

```
options = weboptions
```

```
options =
```

```
weboptions with properties:
```

```
CharacterEncoding: 'auto'
UserAgent: 'MATLAB 8.6.0.238686 (R2015b)'
Timeout: 5
Username: ''
Password: ''
KeyName: ''
```

```

 KeyValue: ''
 ContentType: 'auto'
 ContentReader: []
 MediaType: 'application/x-www-form-urlencoded'
 RequestMethod: 'auto'
 ArrayFormat: 'csv'

```

## User Name and Password in weboptions Object

Set your web service user name and password in a `weboptions` object. You can use the object as an input argument to `webread`, `websave`, or `webwrite` when your web service requires authentication.

```
options = weboptions('Username','jdoe','Password','mypassword')
```

```
options =
```

```
weboptions with properties:
```

```

 CharacterEncoding: 'auto'
 UserAgent: 'MATLAB 8.6.0.238686 (R2015b)'
 Timeout: 5
 Username: 'jdoe'
 Password: '*****'
 KeyName: ''
 KeyValue: ''
 ContentType: 'auto'
 ContentReader: []
 MediaType: 'application/x-www-form-urlencoded'
 RequestMethod: 'auto'
 ArrayFormat: 'csv'

```

The password is obscured when you display the `weboptions` object. However, the object stores the password as plain text. You can retrieve the password from the `weboptions.Password` property.

```
options.Password
```

```
ans =
```

mypassword

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

Example: `weboptions('Timeout',60)` creates a `weboptions` object that sets the timeout connection duration to 60 seconds.

#### 'CharacterEncoding' — Character encoding

'auto' (default) | character array

Character encoding, specified as a character array. Common encodings include 'US-ASCII', 'UTF-8', 'latin1', 'Shift\_JS', and 'ISO-8859-1'.

#### 'UserAgent' — User agent identification

['MATLAB ' version] (default) | character array

User agent identification, specified as a character array indicating the client user agent.

#### 'Timeout' — Timeout connection duration

5 (default) | positive numeric scalar

Timeout connection duration in seconds, specified as a positive numeric scalar. Set to `Inf` to disable timeouts.

#### 'Username' — User identifier

' ' (default) | character array

User identifier, specified as a character array for basic HTTP authentication (no encryption).

#### 'Password' — User authentication password

' ' (default) | character array

User authentication password, specified as a character array for basic HTTP authentication (no encryption). If you display a `weboptions` object with the `Password`

property set, the value is displayed as a character array containing “\*”. However, the object stores the value of the `Password` property as plain text.

### 'KeyName' — Name of key

' ' (default) | character array

Name of a key, specified as a character array. `KeyName` is an additional name to add to the HTTP request header. For example, `KeyName` can be a web service API key name.

Example: `weboptions('KeyName', 'duration', 'KeyValue', 7)` creates a `weboptions` object that contains a key name, `duration`, defined by a web service.

### 'KeyValue' — Value of key

' ' (default) | character array | numeric | logical

Value of a key, specified as a character array, or a numeric or logical value to add to the HTTP request header. `KeyValue` is the value of a key specified by `KeyName`.

Example: `weboptions('KeyName', 'duration', 'KeyValue', 7)` creates a `weboptions` object that contains a key value, `7`, paired with a key name, `duration`.

### 'ContentType' — Content type

'auto' (default) | character array

Content type, specified as a character array. You can define the `ContentType` property of a `weboptions` object, and pass the object as an input argument to `webread`. Then `webread` returns data as that type of content. The table lists the valid content types.

ContentType Specifier	Output Type														
'auto' (default)	Output type automatically determined based on content type.														
'text'	Character array for content types: <table border="0" style="margin-left: 20px;"> <tr> <td>text/plain</td> <td>application/</td> </tr> <tr> <td>text/html</td> <td>javascript</td> </tr> <tr> <td>text/xml</td> <td>application/x-</td> </tr> <tr> <td>application/xml</td> <td>javascript</td> </tr> <tr> <td></td> <td>application/</td> </tr> <tr> <td></td> <td>x-www-form-</td> </tr> <tr> <td></td> <td>urlencoded</td> </tr> </table>	text/plain	application/	text/html	javascript	text/xml	application/x-	application/xml	javascript		application/		x-www-form-		urlencoded
text/plain	application/														
text/html	javascript														
text/xml	application/x-														
application/xml	javascript														
	application/														
	x-www-form-														
	urlencoded														

ContentType Specifier	Output Type
	If a web service returns a MATLAB file with a <code>.m</code> extension, the function returns its content as a character array.
'image'	<p>Numeric or logical matrix for <code>image/format</code> content. If the first output argument is an indexed image, the second output argument is the colormap, and the third output argument is the alpha channel.</p> <p>For supported image formats, see “Supported File Formats for Import and Export”.</p>
'audio'	<p>Numeric matrix for <code>audio/format</code> content with numeric scalar sampling rate as a second output argument.</p> <p>For supported audio formats, see “Supported File Formats for Import and Export”.</p>
'binary'	<code>uint8</code> column vector for binary content (that is, content not to be treated as type <code>char</code> ).
'table'	Scalar table object for spreadsheet and CSV ( <code>text/csv</code> ) content.
'json'	<code>char</code> , numeric, logical, structure, or cell array, for <code>application/json</code> content.
'xmlDOM'	Java Document Object Model (DOM) node for <code>text/xml</code> or <code>application/xml</code> content. If not specified, the function returns XML content as a character array.
'raw'	<code>char</code> column vector for <code>'text'</code> , <code>'xmlDOM'</code> , and <code>'json'</code> content. The function returns any other content type as a <code>uint8</code> column vector.

Example: `weboptions('ContentType', 'text')` creates a `weboptions` object that instructs `webread` to return text, JSON, or XML content as a character vector.

### 'ContentReader' — Content reader

[ ] (default) | function handle

Content reader, specified as a function handle. You can create a `weboptions` object with `ContentReader` specified, and pass the object as an input argument to `webread`. Then `webread` downloads data from a web service and reads the data with the function specified by the function handle. `webread` ignores `ContentType` when `ContentReader` is specified.

Example: `weboptions('ContentReader', @readtable)` creates a `weboptions` object that instructs `webread` to use `readtable` to read content as a table.

### 'MediaType' — Media type

'application/x-www-form-urlencoded' (default) | character array

Media type, specified as a character array. See Internet Media Types for a complete list of media types.

Example: `weboptions('MediaType', 'application/json')` creates a `weboptions` object that instructs `webwrite` to encode character array data as JSON to post it to a web service.

### 'RequestMethod' — HTTP request method

'auto' (default) | 'get' | 'post'

HTTP request method, specified as 'auto', 'get', or 'post'. `RequestMethod` can be set to 'get' to indicate the HTTP GET method, 'post' to indicate the HTTP POST method, or 'auto'.

- `webread` and `websave` use the HTTP GET method when the `RequestMethod` property of an input `weboptions` object is set to 'auto'.
- `webwrite` uses the HTTP POST method when the `RequestMethod` property of an input `weboptions` object is set to 'auto'.

Example: `weboptions('RequestMethod', 'post')` creates a `weboptions` object that instructs `webread`, `websave`, or `webwrite` to use the HTTP POST method of a web service.

### 'ArrayFormat' — Format to form-encode query or post values that represent multiple values

'csv' (default) | 'json' | 'repeating' | 'php'

Format to form-encode query or post values that represent multiple values, specified as 'csv', 'json', 'repeating', or 'php'. A query or post value contains multiple values if it is

- A numeric, logical, or `datetime` vector
- A character array with more than one row
- A cell vector, where each element is a numeric, logical, or `datetime` scalar or a character array with one row

No other data types or dimensions are supported.

This table shows form-encoded conversions for each format, for a query parameter named 'parameter' and a query value of [1 2 3]. The web service specifies the conversion to use.

ArrayFormat Specifier	Form-Encoded Conversion
'csv' (default)	parameter=1,2,3
'json'	parameter=[1,2,3]
'repeating'	parameter=1&parameter=2&parameter=3
'php'	parameter[]=1&parameter[]=2&parameter[]=3

To encode a scalar as a one-element array with the 'json' or 'php' specifiers, place the scalar in a one-element cell array.

Example: `weboptions('ArrayFormat','repeating')` creates a `weboptions` object that instructs `webread`, `websave`, or `webwrite` to form-encode any query or post value with multiple values as repeating query parameters.

## See Also

`webread` | `websave` | `webwrite`

**Introduced in R2014b**

# webread

Read content from RESTful web service

## Syntax

```
data = webread(url)
data = webread(url,
 QueryName1,QueryValue1,...,QueryNameN,QueryValueN)
data = webread(____,options)
```

```
[data,colormap,alpha] = webread(____)
```

```
[data,Fs] = webread(____)
```

## Description

`data = webread(url)` reads content from the web service specified by `url` and returns the content in `data`.

The web service provides a “RESTful API” on page 1-9603 that returns data formatted as an internet media type such as JSON, XML, image, or text.

`data = webread(url, QueryName1,QueryValue1,...,QueryNameN,QueryValueN)` appends query parameters to `url`, as specified by one or more pairs of name-value arguments. The web service defines the query parameters.

`data = webread( ____,options)` adds other HTTP request options, specified by the `weboptions` object `options`. You can use this syntax with any of the input arguments of the previous syntaxes.

To return data as a specific output type, specify the `ContentType` property of `options`.

To read content with a function, specify the `ContentReader` property of `options` as a handle to the function. `webread` downloads data from a web service and reads the data with the specified function:

- If you specify a handle to a function that returns multiple output arguments, `webread` returns all output arguments.
- If you specify a handle to a function that returns no output argument (such as `@implay` for video files), `webread` returns no output argument.

`webread` supports HTTP GET and POST methods. To send an HTTP POST request, specify the `RequestMethod` property of `options` as `'post'`. Many web services provide both GET and POST methods to request data.

`[data,colormap,alpha] = webread( ___ )` reads an image from the web service specified by `url` and returns the image in `data`. You can use the previous syntaxes to return the image only. Use this syntax to return the colormap and alpha channels associated with the image.

`webread` returns an image when the HTTP response has a `Content-Type` header field that specifies an image media type and if the image format is supported by `imread`. For supported image formats, see “Supported File Formats for Import and Export”.

`[data,Fs] = webread( ___ )` reads audio data from the web service specified by `url` and returns the audio data in `data`. You can use the previous syntaxes to return the audio data only. Use this syntax to return the sample rate of the audio data in hertz.

`webread` returns audio data when the HTTP response has a `Content-Type` header field that specifies an audio media type and if the audio format is supported by `audioread`. For supported audio formats, see “Supported File Formats for Import and Export”.

## Examples

### Read Image from Website

Read an image of Jupiter from the Hubble Heritage website and display it.

```
url = 'http://heritage.stsci.edu/2007/14/images/p0714aa.jpg';
rgb = webread(url);
whos rgb
```

Name	Size	Bytes	Class	Attributes
rgb	1000x800x3	2400000	uint8	

Resize and display the image.

```
rgb = imresize(rgb,0.6);
imshow(rgb)
```

Jupiter image courtesy of NASA, ESA, and the Hubble Heritage Team (STScI/AURA). (See Hubble Heritage Information Center for terms of use.)

## Read Data from Web Service API

Read temperature data for the USA from the World Bank Climate Data API. Plot temperatures from the years 1901 to 2012.

Read data from the World Bank. This API returns data as a JSON object.

```
api = 'http://climatedataapi.worldbank.org/climateweb/rest/v1/';
url = [api 'country/cru/tas/year/USA'];
S = webread(url)
```

```
S =
```

```
112x1 struct array with fields:
```

```
 year
 data
```

`webread` converts the JSON object to a structure array. Each structure contains the year and the average temperature in the USA for that year, in degrees Celsius.

Display the temperature for the first year.

```
S(1)
```

```
ans =
```

```
 year: 1901
 data: 6.6187
```

Plot the average temperatures. Concatenate `S.year` and `S.data` into arrays and plot them.

```
year = [S.year];
data = [S.data];
plot(year,data)
xlabel('Year');
ylabel('Temperature (Celsius)');
title('USA Average Temperatures')
axis tight
```

API and data courtesy of the World Bank: Climate Data API. (See World Bank: Climate Data API for more information about the API, and World Bank: Terms of Use for terms of use.)

### Specify Web Service Query Parameters

Search the File Exchange for files uploaded within the past 7 days that contain the word *Simulink*.

Specify the query parameters. `webread` appends web service query parameter names and values to the URL. The File Exchange web service defines the `term` and `duration` query parameters, not the `webread` function.

```
url = 'http://www.mathworks.com/matlabcentral/fileexchange/';
```

```
data = webread(url, 'term', 'simulink', 'duration', 7);
```

`webread` returns the HTML for the search result page as a character array.

## Specify Request Option

Specify an additional request option to read data from the World Bank Climate Data API to a character array.

Create a `weboptions` object and set its `ContentType` to `'text'`. The `webread` function converts the JSON object to a character array instead of a structure array. Display the beginning of the character array.

```
api = 'http://climatedataapi.worldbank.org/climateweb/rest/v1/';
url = [api 'country/cru/tas/year/USA'];
options = weboptions('ContentType','text');
data = webread(url,options);
data(1:62)
```

```
ans =
```

```
[{"year":1901,"data":6.6187487}, {"year":1902,"data":6.4643273}]
```

API and data courtesy of the World Bank: Climate Data API. (See World Bank: Climate Data API for more information about the API, and World Bank: Terms of Use for terms of use.)

## Read Data with POST Request

Send an HTTP POST request to search File Exchange for files uploaded within the past 7 days that contain the word *Simulink*.

```
url = 'http://www.mathworks.com/matlabcentral/fileexchange/';
options = weboptions('RequestMethod','post');
data = webread(url, 'term', 'simulink', 'duration', 7, options);
```

Many web services provide a POST method for requesting data in addition to GET.

## Specify Date and Time as Query Parameters

Read a Blue Marble: Next Generation image for December 2004 from the NASA Earth Observation (NEO) Web Mapping Service.

Specify the date of the requested image with a `datetime` object. Specify the `Format` property of `D` so that the format matches the format required by the web service.

```
url = 'http://neowms.sci.gsfc.nasa.gov/wms/wms';
D = datetime(2004,12,01,'Format','yyyy-MM-dd');
rgb = webread(url,'Time',D, ...
 'Service','WMS','Layers','BlueMarbleNG-TB','CRS','CRS:84', ...
 'Format','image/jpeg','Height',256,'Width',512, ...
 'BBOX','-180.0,-90.0,180.0,90.0','Version','1.3.0','Request','GetMap');
imshow(rgb)
```

`webread` converts `datetime` objects so that they can be values of web service query parameters. All the name-value pairs in the example provide query parameters specified by the NEO Web Mapping Service.

Blue Marble: Next Generation + Topography and Bathymetry image courtesy of NASA's Earth Observatory. Access to imagery and services provided by the NEO Web Mapping Service (WMS). (See NASA Earth Observations for credit and terms of use. See WMS 1.3.0 Capabilities for WMS query parameters.)

- “Download Data from Web Service”

- “Convert Data from Web Service”
- “Represent Dates and Times in MATLAB”

## Input Arguments

### **ur1 — URL to web service**

character array

URL to a web service, specified as a character array. The web service implements a RESTful interface. See “RESTful API” on page 1-9603 for more information.

Example: `webread('http://www.mathworks.com/matlabcentral')` reads the web page and returns its HTML as a character array.

### **QueryName1, QueryValue1, . . . , QueryNameN, QueryValueN — Web service query parameters**

name-value pairs

Web service query parameters, specified as one or more pairs of name-value arguments. A **QueryName** argument must specify the name of a query parameter. A **QueryValue** argument must be a character array or a numeric, logical, or **datetime** value that specifies the value of the query parameter. Numeric, logical, and **datetime** values can be in arrays. The web service defines name-value pairs that it accepts as part of a request.

When you specify **QueryValue** as a **datetime** object, you must specify its **Format** property so that it is consistent with the format required by the web service. If the **Format** property includes a time zone or offset, and the **datetime** object is not zoned, then `webread` specifies `'Local'` as the time zone.

When **QueryValue** contains multiple values in an array, you might need to specify the **ArrayFormat** property of a **weboptions** object to form-encode the array as specified by the web service.

Example: `webread('http://www.mathworks.com/matlabcentral/fileexchange/', 'term', 'webread')` retrieves a list of files uploaded to the File Exchange that contain the word `webread`.

### **options — Additional HTTP request options**

**weboptions** object

Additional HTTP request options, specified as a `weboptions` object.

You can specify the `ContentType` property of a `weboptions` object, and pass the object as an input argument to `webread`. Then `webread` returns `data` as that type of output. The table lists the valid content types you can specify in a `weboptions` object.

ContentType Specifier	Output Type
'auto' (default)	Output type automatically determined based on content type.
'text'	<p>Character array for content types:</p> <pre> text/plain      application/ text/html      javascript text/xml       application/x- application/xml javascript application/   application/ x-www-form-   x-www-form- urlencoded    urlencoded </pre> <p>If a web service returns a MATLAB file with a <code>.m</code> extension, the function returns its content as a character array.</p>
'image'	<p>Numeric or logical matrix for <code>image/format</code> content. If the first output argument is an indexed image, the second output argument is the colormap, and the third output argument is the alpha channel.</p> <p>For supported image formats, see “Supported File Formats for Import and Export”.</p>
'audio'	<p>Numeric matrix for <code>audio/format</code> content with numeric scalar sampling rate as a second output argument.</p> <p>For supported audio formats, see “Supported File Formats for Import and Export”.</p>

ContentType Specifier	Output Type
'binary'	uint8 column vector for binary content (that is, content not to be treated as type char).
'table'	Scalar table object for spreadsheet and CSV (text/csv) content.
'json'	char, numeric, logical, structure, or cell array, for application/json content.
'xmlDOM'	Java Document Object Model (DOM) node for text/xml or application/xml content. If not specified, the function returns XML content as a character array.
'raw'	char column vector for 'text', 'xmlDOM', and 'json' content. The function returns any other content type as a uint8 column vector.

See `weboptions` for all request options that are `weboptions` properties.

## Output Arguments

### **data** — Content from web service

scalar | array | structure | table

Content read from a web service, returned as a scalar, array, structure, or table.

### **colormap** — Colormap associated with indexed image

numeric array

Colormap associated with an indexed image, returned as a numeric array.

### **alpha** — Alpha channels associated with indexed image

numeric array

Alpha channels associated with an indexed image, returned as a numeric array.

### **Fs** — Sample rate of audio data in hertz

positive numeric scalar

Sample rate of audio data in hertz, returned as a positive numeric scalar.

## More About

### RESTful API

*REST* means *representational state transfer*, a common architectural style for web services. RESTful APIs or interfaces provide standard HTTP methods such as GET, PUT, POST, or DELETE.

### Tips

- The `webread` function supports only nonauthenticated and basic authentication types for use with your proxy server. To enable proxy support, run MATLAB with the Java JVM. To specify proxy server settings, see “Specify Proxy Server Settings for Connecting to the Internet”.
- For HTTPS connections, the `webread` function verifies that the certificate domain matches the host name of the web service. `webread` does not verify the certificate chain.
- For HTTP POST requests, the `webread` function supports only the `application/x-www-form-urlencoded` media type. To send a POST request with content of any other internet media type, use `webwrite`.

### Algorithms

JSON supports fewer data types than MATLAB. `webread` converts JSON data types to the MATLAB data types shown in the table.

`webread` converts JSON object field names to MATLAB structure field names.

JSON Data Type	MATLAB Data Type
Number	double
String	char array
Boolean	logical
Array, when all elements are of the same data type	Array
Array, when elements are of different data types	Cell array

<b>JSON Data Type</b>	<b>MATLAB Data Type</b>
Object. (In JSON, <i>object</i> means an unordered set of name-value pairs.)	Scalar structure
Array of objects, when all objects have the same set of field names	Structure array
Array of objects, when objects have different field names	Cell array of scalar structures

- Representational State Transfer
- JavaScript Object Notation (JSON)

### **See Also**

`datetime` | `weboptions` | `websave` | `webwrite`

**Introduced in R2014b**

# websave

Save content from RESTful web service to file

## Syntax

```
outfile = websave(filename, url)
outfile = websave(filename, url,
 QueryName1, QueryValue1, ..., QueryNameN, QueryValueN)
outfile = websave(____, options)
```

## Description

`outfile = websave(filename, url)` saves content from the web service specified by `url` and writes it to `filename`. The `websave` function returns the full filename path as `outfile`.

The web service provides a “RESTful API” on page 1-9609 that returns data formatted as an internet media type such as JSON, XML, image, or text.

`outfile = websave(filename, url, QueryName1, QueryValue1, ..., QueryNameN, QueryValueN)` appends query parameters to `url`, as specified by one or more pairs of name-value arguments. The web service defines the query parameters.

`outfile = websave( ____, options)` adds other HTTP request options, specified by the `weboptions` object `options`. You can use this syntax with any of the input arguments of the previous syntaxes.

`websave` supports HTTP GET and POST methods. To send an HTTP POST request, specify the `RequestMethod` property of `options` as `'post'`. Many web services provide both GET and POST methods to request data.

## Examples

### Save Image from Website

Save an image of Jupiter from the Hubble Heritage website.

```
url = 'http://heritage.stsci.edu/2007/14/images/p0714aa.jpg';
filename = 'jupiter_aurora.jpg';
outfilename = websave(filename,url)

outfilename =
```

```
C:\Libraries\Documents\jupiter_aurora.jpg
```

`websave` saves the image as a JPEG file, as specified by the Hubble web service, even when you give `filename` a different extension. (Jupiter image courtesy of NASA, ESA, and the Hubble Heritage Team (STScI/AURA). See Hubble Heritage Information Center for terms of use.)

## Save Search Results to File

Search File Exchange for files uploaded within the past 7 days that contain the word *Simulink* and display the results of the search.

```
url = 'http://www.mathworks.com/matlabcentral/fileexchange/';
filename = 'simulink_search.html';
outfilename = websave(filename,url,'term','simulink','duration',7)

outfilename =
```

```
C:\Libraries\Documents\simulink_search.html
```

Display the HTML file in a web browser.

```
web(outfilename)
```

## Save Data to File

Save sunspot data from the National Geophysical Data Center (NGDC) to an ASCII file. Use a `weboptions` object to set the timeout value to `Inf` so that the connection does not time out.

```
api = 'http://www.ngdc.noaa.gov/stp/space-weather/';
url = [api 'solar-data/solar-indices/sunspot-numbers/' ...
 'american/lists/list_aavso-arssn_yearly.txt'];
filename = 'sunspots_annual.txt';
options = weboptions('Timeout',Inf);
outfilename = websave(filename,url,options)

outfilename =
```

```
C:\Libraries\Documents\sunspots_annual.txt
```

Aggregated data and web service courtesy of the NGDC. Sunspot data courtesy of the American Association of Variable Star Observers (AAVSO), originally published in AAVSO Sunspot Counts: 1943-2013, AAVSO Solar Section (R. Howe, Chair). (See NGDC Privacy Policy, Disclaimer, and Copyright for NGDC terms of use, and AAVSO Solar Section for AAVSO terms of use.)

### Save Data with POST Request

Send an HTTP POST request to search File Exchange for files uploaded within the past 7 days that contain the word *Simulink*. Save the results of the search to an HTML file.

```
url = 'http://www.mathworks.com/matlabcentral/fileexchange/';
filename = 'simulink_search.html';
options = weboptions('RequestMethod','post');
outfilename = websave(filename,url,'term','simulink','duration',7,options);
```

Many web services provide a POST method for requesting data in addition to GET.

### Save Data for Specified Date and Time

Save the Blue Marble: Next Generation image for December 2004 from the NASA Earth Observation (NEO) Web Mapping Service.

Specify the date of the requested image with a `datetime` object. Specify the `Format` property of `D` so that the format matches the format required by the web service.

```
url = 'http://neowms.sci.gsfc.nasa.gov/wms/wms';
D = datetime(2004,12,01,'Format','yyyy-MM-dd');
filename = 'BlueMarble.jpg';
outfilename = websave(filename,url,'Time',D, ...
 'Service','WMS','Layers','BlueMarbleNG-TB','CRS','CRS:84', ...
 'Format','image/jpeg','Height',256,'Width',512, ...
 'BBOX','-180.0,-90.0,180.0,90.0','Version','1.3.0','Request','GetMap')

outfilename =
```

```
C:\Libraries\Documents\BlueMarble.jpg
```

`websave` converts `datetime` objects so that they can be values of web service query parameters. All the name-value pairs in the example provide query parameters specified by the NEO Web Mapping Service.

Blue Marble: Next Generation + Topography and Bathymetry image courtesy of NASA's Earth Observatory. Access to imagery and services provided by the NEO Web Mapping Service (WMS). (See NASA Earth Observations for credit and terms of use. See WMS 1.3.0 Capabilities for WMS query parameters.)

- “Download Web Page and Files”
- “Represent Dates and Times in MATLAB”

## Input Arguments

### **filename** — Name of file to save content to

character array

Name of file to save content to, specified as a character array. `webwrite` saves the content as is. `webwrite` ignores `options.ContentType` and `options.ContentReader`, even if these properties are set.

Example: `webwrite('matlabcentral.html','http://www.mathworks.com/matlabcentral')` reads the web page and saves its HTML to the file `matlabcentral.html`.

### **url** — URL to web service

character array

URL to a web service, specified as a character array. The web service implements a RESTful interface. See “RESTful API” on page 1-9609 for more information.

### **QueryName1, QueryValue1, . . . , QueryNameN, QueryValueN** — Web service query parameters

name-value pairs

Web service query parameters, specified as one or more pairs of name-value arguments. A `QueryName` argument must specify the name of a query parameter. A `QueryValue` argument must be a character array or a numeric, logical, or `datetime` value that specifies the value of the query parameter. Numeric, logical, and `datetime` values can be in arrays. The web service defines name-value pairs that it accepts as part of a request.

When you specify `QueryValue` as a `datetime` object, you must specify its `Format` property to be consistent with the format required by the web service. If the `Format`

property includes a time zone or offset, and the `datetime` object is not zoned, then `websave` specifies 'Local' as the time zone.

When `QueryValue` contains multiple values in an array, you might need to specify the `ArrayFormat` property of a `weboptions` object to form-encode the array as specified by the web service.

Example: `websave('webread_search.html','http://www.mathworks.com/matlabcentral/fileexchange/','term','simulink')` retrieves a list of files uploaded to the File Exchange that contain the word *simulink* and saves the search results to an HTML file.

### **options — Additional HTTP request options**

`weboptions` object

Additional HTTP request options, specified as a `weboptions` object. For all request options that are `weboptions` properties, see `weboptions`.

## **More About**

### **RESTful API**

*REST* means *representational state transfer*, a common architectural style for web services. RESTful APIs or interfaces provide standard HTTP methods such as GET, PUT, POST, or DELETE.

### **Tips**

- The `websave` function supports only nonauthenticated and basic authentication types for use with your proxy server. To enable proxy support, run MATLAB with the Java JVM. To specify proxy server settings, see “Specify Proxy Server Settings for Connecting to the Internet”.
- For HTTPS connections, the `websave` function verifies that the certificate domain matches the host name of the web service. `websave` does not verify the certificate chain.
- For HTTP POST requests, the `websave` function supports only the `application/x-www-form-urlencoded` media type. To send a POST request with content of any other internet media type, use `webwrite`.
- Representational State Transfer

- JavaScript Object Notation (JSON)

**See Also**

**Introduced in R2014b**

# webwrite

Write data to RESTful web service

## Syntax

```
response = webwrite(url,
PostName1,PostValue1,...,PostNameN,PostValueN)
response = webwrite(url,data)
response = webwrite(____,options)
```

## Description

`response = webwrite(url, PostName1,PostValue1,...,PostNameN,PostValueN)` writes content to the web service specified by `url` and returns `response`. The input arguments `PostName1,PostValue1,...,PostNameN,PostValueN` specify the content as name-value pairs. `webwrite` form-encodes the name-value pairs in the body of an HTTP POST request to the web service. The web service defines `response`.

The web service provides a “RESTful API” on page 1-9616 that returns data formatted as an internet media type such as JSON, XML, image, or text.

`response = webwrite(url,data)` writes content to the web service specified by `url` and returns `response`. The input argument `data` specifies the content as a form-encoded character array. `webwrite` puts `data` in the body of an HTTP POST request to the web service. The web service defines `response`.

`response = webwrite( ____,options)` adds other HTTP request options, specified by the `weboptions` object `options`. You can use this syntax with any of the input arguments of the previous syntaxes.

To write content as an internet media type other than a form-encoded character array ('application/x-www-form-urlencoded'), specify the `MediaType` property of `options`.

To request data with an HTTP POST request and read the response with a function, specify the `ContentReader` property of `options` as a handle to the function. If you

specify a handle to a function that returns multiple output arguments, `webwrite` returns all output arguments.

## Examples

### Write Data to Web Service

Write a number to a channel feed on the ThingSpeak server and read it back.

To run this code, create a ThingSpeak account. Call `webwrite` using the Write API key and Channel ID from your ThingSpeak account. The default field name is `'field1'`.

```
thingSpeakURL = 'http://api.thingspeak.com/';
thingSpeakWriteURL = [thingSpeakURL 'update'];
writeApiKey = 'Your Write API Key';
fieldName = 'field1';
fieldValue = 42;
response = webwrite(thingSpeakWriteURL, 'api_key', writeApiKey, fieldName, fieldValue)
```

If this call to `webwrite` is the first update to your ThingSpeak channel, `response` is 1.

Read back the number you wrote to your channel. ThingSpeak provides a different URL to get the last entry to your channel. Your Channel ID is part of the URL.

```
channelID = num2str(Your Channel ID);
thingSpeakReadURL = [thingSpeakURL 'channels/' channelID '/fields/' fieldName '/last'];
data = webread(thingSpeakReadURL, 'api_key', writeApiKey)

data =

42
```

### Write Form-Encoded Character Array

Write a number as a form-encoded character array to a channel feed on the ThingSpeak server and read it back.

To run this code, create a ThingSpeak account. Call `webwrite` using the Write API key and Channel ID from your ThingSpeak account. Encode your Write API Key and the number as a form-encoded character array. The default field name is `'field1'`.

```
thingSpeakURL = 'http://api.thingspeak.com/';
```

```

thingSpeakWriteURL = [thingSpeakURL 'update'];
writeApiKey = 'Your Write API Key';
data = 42;
data = num2str(data);
data = ['api_key=',writeApiKey,'&field1=',data];
response = webwrite(thingSpeakWriteURL,data)

```

If this call to `webwrite` is the first update to your ThingSpeak channel, response is 1.

Read back the number you wrote to your channel. ThingSpeak provides a different URL to get the last entry to your channel. Your Channel ID is part of the URL.

```

channelID = num2str(Your Channel ID);
thingSpeakReadURL = [thingSpeakURL 'channels/' channelID '/fields/field1/last'];
data = webread(thingSpeakReadURL,'api_key',writeApiKey)

```

```
data =
```

```
42
```

## Write JSON Object

Write a number as a JSON object to a channel feed on the ThingSpeak server and read the response as a JSON object.

To run this code, create a ThingSpeak account. Call `webwrite` using the Write API key and Channel ID from your ThingSpeak account. Create a structure where the fields are your Write API Key and the number. The default field name is `'field1'`. Specify the media type as `'application/json'`.

```

thingSpeakURL = 'http://api.thingspeak.com/update.json';
writeApiKey = 'Your Write API Key';
data = 42;
data = struct('api_key',writeApiKey,'field1',data);
options = weboptions('MediaType','application/json');
response = webwrite(thingSpeakURL,data,options)

```

```
response =
```

```

 channel_id: Your Channel ID
 field1: 42
 field2: []
 field3: []
 field4: []

```

```
 field5: []
 field6: []
 field7: []
 field8: []
 created_at: '2014-11-14T20:08:14Z'
 entry_id: 1
 status: []
 latitude: []
 longitude: []
 elevation: []
 location: []
```

As a response `webwrite` receives a JSON object that contains the number you wrote to your ThingSpeak channel. `webwrite` converts the JSON object and returns it as a structure in `response`.

## Specify Data and Time

Write a number and a specific date to a channel feed on the ThingSpeak server. Read the number and date back.

To run this code, create a ThingSpeak account. Call `webwrite` using the Write API key and Channel ID from your ThingSpeak account. Specify the date for the feed entry with a `datetime` object.

```
thingSpeakURL = 'http://api.thingspeak.com/';
thingSpeakWriteURL = [thingSpeakURL 'update'];
writeApiKey = 'Your Write API Key';
fieldName = 'field1';
fieldValue = 42;
D = datetime(2015,3,22,8,15,30,'Format','yyyy-MM-dd HH:mm:ss');
response = webwrite(thingSpeakWriteURL,'api_key',writeApiKey,fieldName,fieldValue,'create');
```

If this call to `webwrite` is the first update to your ThingSpeak channel, `response` is 1.

Read back the last entry to your channel. ThingSpeak provides a different URL to get the last entry to your channel. Append `last.json` to the URL to get the data as a JSON object. Your Channel ID is part of the URL.

```
channelID = num2str(Your Channel ID);
thingSpeakReadURL = [thingSpeakURL 'channels/' channelID '/fields/' fieldName '/last.json'];
data = webread(thingSpeakReadURL,'api_key',writeApiKey)

data =
```

```
created_at: '2015-03-22T08:15:30Z'
entry_id: 1
field1: '42'
```

The date in the `created_at` field matches the date specified in `D`.

- “Represent Dates and Times in MATLAB”

## Input Arguments

### **ur1** — URL to web service

character array

URL to a web service, specified as a character array. The web service implements a RESTful interface. See “RESTful API” on page 1-9616 for more information.

### **PostName1, PostValue1, ..., PostNameN, PostValueN** — Web service post parameters

name-value pairs

Web service post parameters, specified as one or more pairs of name-value arguments. A `PostName` argument must specify the name of a post parameter. A `PostValue` argument must be a character array or a numeric, logical, or `datetime` value that specifies the value of the post parameter. Numeric, logical, and `datetime` values can be in arrays. The web service defines name-value pairs that it accepts as part of a request. `webwrite` encodes the name-value pairs as a form-encoded character array in the body of an HTTP POST request and sets the content type to `application/x-www-form-urlencoded` by default.

When you specify `PostValue` as a `datetime` object, you must specify its `Format` property so that it is consistent with the format required by the web service. If the `Format` property includes a time zone or offset, and the `datetime` object is not zoned, then `webwrite` specifies `'Local'` as the time zone.

When a `PostValue` argument contains multiple values in an array, specify the `ArrayFormat` property of a `weboptions` object to form-encode the array as specified by the web service.

Example: `webwrite('http://www.mathworks.com/matlabcentral/fileexchange/', 'term', 'webwrite', 'duration', 7)` retrieves a list of files

uploaded to the File Exchange within the past 7 days that contain the word `webwrite`. The File Exchange web service defines the `term` and `duration` parameters.

## **data** — Data to write to web service

character array

Data to write to a web service, specified as a form-encoded character array. The web service implements a RESTful interface. `webwrite` puts `data` in the body of an HTTP POST request and sets the media type to `application/x-www-form-urlencoded` by default.

If `data` is not form-encoded, set the `MediaType` property of the `options` input argument to a different media type. See Internet Media Types for a complete list of media types.

Example: `webwrite('http://www.mathworks.com/matlabcentral/fileexchange/', 'term=webwrite&duration=7')` retrieves a list of files uploaded to the File Exchange within the past 7 days that contain the word `webwrite`. The File Exchange web service defines the `term` and `duration` parameters.

## **options** — Additional HTTP request options

`weboptions` object

Additional HTTP request options, specified as a `weboptions` object. See `weboptions` for all request options that are `weboptions` properties.

## Output Arguments

### **response** — Response from web service

scalar | array | structure | table

Response from a web service, returned as a scalar, array, structure, or table.

## More About

### RESTful API

*REST* means *representational state transfer*, a common architectural style for web services. RESTful APIs or interfaces provide standard HTTP methods such as GET, PUT, POST, or DELETE.

## Tips

- The `webwrite` function writes `PostName`, `PostValue` input arguments as form-encoded character arrays. If you also specify the `options` input argument, then its `MediaType` property must be `'application/x-www-form-urlencoded'`.
- The `webwrite` function supports only nonauthenticated and basic authentication types for use with your proxy server. To enable proxy support, run MATLAB with the Java JVM. To specify proxy server settings, see “Specify Proxy Server Settings for Connecting to the Internet”.
- For HTTPS connections, the `webwrite` function verifies that the certificate domain matches the host name of the web service. `webwrite` does not verify the certificate chain.
- `webwrite` cannot convert `datetime` objects to JSON, because JSON does not define a standard date format.
  - Representational State Transfer
  - JavaScript Object Notation (JSON)

## See Also

`datetime` | `weboptions` | `webread` | `websave`

**Introduced in R2015a**

## week

Week number

## Syntax

```
w = week(t)
w = week(t, weekType)
```

## Description

`w = week(t)` returns the week-of-year numbers of the datetime values in `t`. The `m` output is a double array the same size as `t` and contains integer values from 1 to 53.

`w = week(t, weekType)` returns the type of week number specified by `weekType`.

## Examples

### Find Week of Year Numbers of Dates

```
t = datetime(2013,05,31):calmonths(3):datetime(2014,06,15)
```

```
t =
```

```
 31-May-2013 31-Aug-2013 30-Nov-2013 28-Feb-2014 31-May-2014
```

```
w = week(t)
```

```
w =
```

```
 22 35 48 9 22
```

---

## Input Arguments

**t** — Input date and time`datetime` array

Input date and time, specified as a `datetime` array.

**weekType** — Type of week values`'weekofyear'` (default) | `'weekofmonth'`

Type of week values, specified as either `'weekofyear'` or `'weekofmonth'`.

- If `weekType` is `'weekofyear'`, then `month` returns the week-of-year number. Week 1 is the week in which January 1 falls, even if fewer than 4 days of that week fall in the same year.
- If `weekType` is `'weekofmonth'`, then `month` returns the week-of-month number. Week 1 in a month is defined as the week in which the first day of the month falls, even if fewer than 4 days of that week fall in the same month.

## See Also

`day` | `month` | `quarter` | `year`

**Introduced in R2014b**

# weekday

Day of week

## Syntax

```
DayNumber = weekday(D)
[DayNumber, DayName] = weekday(D)
[DayNumber, DayName] = weekday(D, DayForm)
[DayNumber, DayName] = weekday(D, language)
[DayNumber, DayName] = weekday(D, DayForm, language)
```

## Description

`DayNumber = weekday(D)` returns a number representing the day of the week for each element in `D`.

`[DayNumber, DayName] = weekday(D)` additionally returns abbreviated English names for the day of the week, in `DayName`.

`[DayNumber, DayName] = weekday(D, DayForm)` returns the name for the day of the week in the format specified by `DayForm`, in US English.

`[DayNumber, DayName] = weekday(D, language)` returns the abbreviated name for the day of the week in the language of the locale specified in `language`.

`[DayNumber, DayName] = weekday(D, DayForm, language)` returns the name for the day of the week in the specified format and in the language of the specified locale. You can specify `DayForm` and `language` in either order.

## Examples

### Return Day of Week of a Date String

Determine the day of the week of December 21, 2012.

```
D = '21-Dec-2012';
[DayNumber, DayName] = weekday(D)
```

```
DayNumber =
```

```
 6
```

```
DayName =
```

```
Fri
```

December 21, 2012 falls on a Friday.

### **Return Full Day Names of Multiple Date Numbers**

Return the full name of the day of the week for a vector of serial date numbers.

```
D = [734999;735015];
DayForm = 'long';
[DayNumber,DayName] = weekday(D,DayForm)
```

```
DayNumber =
```

```
 5
 7
```

```
DayName =
```

```
Thursday
Saturday
```

### **Return Full Day Names in Local Language**

Return day names in U.S. English using the language input argument.

```
D = 728647;
DayForm = 'long';
language = 'en_US';
[DayNumber, DayName] = weekday(D,DayForm,language)
```

```
DayNumber =
```

```
 2
```

```
DayName =
```

Monday

In U.S. English, the name of the day of the week is Monday.

Return day names in the language of the current locale.

```
language = 'local';
[DayNumber, DayName] = weekday(D,DayForm, language)
```

DayNumber =

2

DayName =

Lundi

In a French locale, the name of the day of the week is Lundi.

## Return Day of Week of a Date String in Custom Format

Determine the day of the week for a date specified in the format `mmm.dd.yyyy`. Call `datenum` inside of `weekday` to specify the format of the input date string.

```
[DayNumber, DayName] = weekday(datenum('Dec.21.2012', 'mmm.dd.yyyy'))
```

DayNumber =

6

DayName =

Fri

## Input Arguments

### D — Serial date numbers or date strings

vector | matrix | string | cell array of strings | character array

Serial date numbers or date strings. Date numbers can be specified as a vector or matrix. Date strings can be specified as a single string, a cell array of strings, or a character array. If D is a cell array of strings, it must be 1-by-n or n-by-1.

If `D` is a single date string, a cell array of date strings, or a character array of date strings, the date strings can be in one of the following formats.

Date String Format	Example
dd-mmm-yyyy	01-Mar-2000
mm/dd/yyyy	03/01/2000
yyyy-mm-dd	2000-03-01

For date strings in other formats, first convert them to serial date numbers using the `datenum` function, before passing them to `weekday`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `cell`

### **DayForm** — Format of output day names

'short' (default) | 'long'

Format of the output day names, specified as one of the following strings.

DayForm	Format of DayName Names	Example
'short'	Abbreviated name	Mon
'long'	Full name	Monday

### **language** — Output language of day names

'en\_US' (default) | 'local'

Output language of day names in `DayName`, specified as one of the following strings.

language	Description
'en_US'	US English
'local'	Language of the current locale

## Output Arguments

### **DayNumber** — Value representing day of week

array of integers in the range [1,7]

Value representing the day of the week, returned as an array of integers in the range [1, 7], where 1 represents Sunday, and 7 represents Saturday.

- If input `D` is a numeric array, then the size of `DayNumber` is equivalent to the size of `D`.
- If input `D` is a cell array of strings, then `DayNumber` is an `m`-by-1 vector, where `m` is equivalent to the length of `D`.

## **DayName — Name of day of week**

character array

Name of the day of the week, returned as a character array. The content of `DayName` depends on `DayForm`.

- If `DayForm` is 'short', then `DayName` contains an abbreviated name (for example, Tues).
- If `DayForm` is 'long', then `DayName` contains the full name of the weekday (for example, Tuesday).

`DayName` is `m`-by-`n`, where `m` is the number of serial date numbers or date strings in `D`.

## **See Also**

`datenum` | `datevec` | `eomday`

**Introduced before R2006a**

# what

List MATLAB files in folder

## Syntax

```
what
what folderName
s = what(folderName)
```

## Description

`what` lists the path for the current folder and all the MATLAB relevant files and folders found in the current folder. This list includes all files with MathWorks file extensions and all class and package folders. For more information, see “MathWorks File Extensions”.

`what folderName` lists path, file, and folder information for `folderName`. You do not need to specify the `@` or `+` symbol for class and package folders. For example, `what table` lists the MATLAB files and folders in `toolbox/matlab/datypes/@table`.

`s = what(folderName)` returns the results in a structure array.

## Examples

### List Path, File, and Folder Information

List the MATLAB files and folders in the `graph2d` folder. The location of this folders depends on your installation.

```
what graph2d
```

MATLAB Code files in folder `matlabroot\toolbox\matlab\graph2d`

## Find Supporting Files for Toolbox Package

Find the Control System Toolbox folders that contain MATLAB files.

```
s = what('control')
s =
 path: 'matlabroot\toolbox\control\control'
 m: {36x1 cell}
 mlapp: {0x1 cell}
 mat: {'ltiexamples.mat'}
 mex: {0x1 cell}
 mdl: {0x1 cell}
 slx: {3x1 cell}
 p: {0x1 cell}
 classes: {16x1 cell}
 packages: {'ltiblock'}
```

List the packages in the *matlabroot*\toolbox\control\control folder.

```
s.packages
ans =
 'ltiblock'
```

Find the supporting files for the `ltiblock` package.

```
s2 = what('ltiblock');
s2.m
ans =
 'Parametric.m'
```

## Input Arguments

**folderName** — Name of folder  
string

Name of folder, specified as a string.

It is not necessary to give the full path of the directory. Instead, you can specify a relative partial path. For example, `what strfun` and `what matlab/strfun` both list the MATLAB files in `toolbox/matlab/strfun`. For more information, see “Specify File Names”.

## Output Arguments

### **s** — List of path, files, and folders

structure array

List of path, files, and folders returned as a structure array with these fields.

Field	Description
<code>path</code>	Full path to folder
<code>m</code>	Cell array of MATLAB program file names
<code>mlapp</code>	Cell array of MLAPP-file names
<code>mat</code>	Cell array of MAT-file names
<code>mex</code>	Cell array of MEX-file names
<code>mdl</code>	Cell array of MDL-file names
<code>slx</code>	Cell array of SLX-file names
<code>p</code>	Cell array of P-file names
<code>classes</code>	Cell array of class folders
<code>packages</code>	Cell array of package folders

# which

Locate functions and files

## Syntax

```
which item
```

```
which fun1 in fun2
```

```
which ___ -all
```

```
str = which(item)
```

```
str = which(fun1, 'in', fun2)
```

```
str = which(___, '-all')
```

## Description

`which item` displays the full path for `item`.

- If `item` is a MATLAB function in an M or P file, or a Simulink model in an SLX or MDL file, then `which` displays the full path for the corresponding file. `item` must be on the MATLAB path.
- If `item` is a method in a loaded Java class, then `which` displays the package, class, and method name for that method.
- If `item` is a workspace variable, then `which` displays a message identifying `item` as a variable.
- If `item` is a file name including the extension, and it is in the current working folder or on the MATLAB path, then `which` displays the full path of `item`.

If `item` is an overloaded function or method, then `which item` returns only the path of the first function or method found.

`which fun1 in fun2` displays the path to function `fun1` that is called by file `fun2`. Use this syntax to determine whether a local function is being called instead of a function on the path. This syntax does not locate nested functions.

which \_\_\_ -all displays the paths to all items on the MATLAB path with the requested name. Such items include methods of instantiated classes. You can use -all with the input arguments of any of the previous syntaxes.

str = which(item) returns the full path for item in the string, str.

str = which(fun1, 'in', fun2) returns the path to function fun1 that is called by file fun2. Use this syntax to determine whether a local function is being called instead of a function on the path. This syntax does not locate nested functions.

str = which( \_\_\_, '-all') returns the results of which in the string or cell array of strings, str. You can use this syntax with any of the input arguments in the previous syntax group.

## Examples

### Locate MATLAB Function

Locate the pinv function.

```
which pinv
```

```
matlabroot\toolbox\matlab\matfun\pinv.m
```

pinv is in the matfun folder of MATLAB.

You also can use function syntax to return the path to a string, str. When using the function form of which, enclose all input strings in single quotes.

```
str = which('pinv');
```

### Locate Method in a Loaded Java Class

Create an instance of the Java class. This loads the class into MATLAB.

```
myDate = java.util.Date;
```

Locate the setMonth method.

```
which setMonth
```

```
setMonth is a Java method % java.util.Date method
```

### Locate Private Function

Find the `orthog` function in a private folder.

```
which private/orthog
```

```
matlabroot\toolbox\matlab\elmat\private\orthog.m % Private to elmat
```

MATLAB displays the path for `orthog.m` in the `/private` subfolder of `toolbox/matlab/elmat`.

### Determine if Local Function is Called

Determine which `parseargs` function is called by `area.m`.

```
which parseargs in area
```

```
matlabroot\toolbox\matlab\specgraph\area.m (parseargs) % Local function of area
```

You also can use function syntax to return the path to a string, `str`. When using the function form of `which`, enclose all input strings in single quotes.

```
str = which('parseargs', 'in', 'area');
```

### Locate Function Invoked with Given Input Arguments

Suppose you have a `matlab.io.MatFile` object that corresponds to the example MAT-file `'topography.mat'`:

```
matObj = matfile('topography.mat');
```

Display the path of the implementation of `who` that is invoked when called with the input argument (`matObj`).

```
which who(matObj)
```

```
matlabroot\toolbox\matlab\iofun\+matlab\+io\MatFile.m % matlab.io.MatFile method
```

Store the result to a string.

```
str = which('who(matObj)')
```

```
str =
matlabroot\toolbox\matlab\iofun\+matlab\+io\MatFile.m
```

If you do not specify the input argument (`matObj`), then `which` returns only the path of the first function or method found.

```
which who
```

```
built-in (matlabroot\toolbox\matlab\general\who)
```

## Locate All Items with Given Name

Display the paths to all items on the MATLAB path with the name `fopen`.

```
which fopen -all
```

```
built-in (matlabroot\toolbox\matlab\iofun\fopen)
matlabroot\toolbox\matlab\iofun\@serial\fopen.m % serial method
matlabroot\toolbox\shared\instrument\@icinterface\fopen.m % icinterface method
matlabroot\toolbox\instrument\instrument\@i2c\fopen.m % i2c method
```

## Return Path Names as Strings

Return the results of `which` in the string `str`.

You must use the function form of `which`, enclosing all arguments in parentheses and single quotes.

```
str = which('private/stradd', '-all');
whos str
```

Name	Size	Bytes	Class	Attributes
str	2x1	650	cell	

## Input Arguments

### **item** — Function or file to locate

string

Function or file to locate, specified as a string. When using the function form of `which`, enclose all input strings in single quotes. `item` can be in one of the following forms.

Form of the <code>item</code> Input	Path to Display
<i>fun</i>	Display full path for <code>fun</code> , which can be a MATLAB function, Simulink model, workspace variable, method

Form of the item Input	Path to Display
	<p>in a loaded Java class, or file name that includes the file extension.</p> <p>To display the path for a file that has no file extension, type <code>which file</code>. (The period following the filename is required). Use <code>exist</code> to check for the existence of files anywhere else.</p>
<code>/fun</code>	Limit the search to functions named <code>fun</code> that are on the search path. For example, <code>which /myfunction</code> displays the full path for function <code>myfunction.m</code> , but not built-in or JAVA functions with the same name.
<code>private/fun</code>	Limit the search to private functions named <code>fun</code> . For example, <code>which private/orthog</code> or <code>which('private/orthog')</code> displays the path for <code>orthog.m</code> in the <code>/private</code> subfolder of the parent folder.
<code>fun(a1,...,an)</code>	Display the path to the implementation of function <code>fun</code> which would be invoked if called with the input arguments <code>a1,...,an</code> . Use this syntax to query overloaded functions. See the Example, “Locate Function Invoked with Given Input Arguments” on page 1-9631.

### **fun1 – Function to locate**

string

Function to locate, specified as a string. `fun1` can be the name of a function, or it can be in the form `fun(a1,...,an)`. For more information about the form, `fun(a1,...,an)`, see “Locate Function Invoked with Given Input Arguments” on page 1-9631.

When using the function form of `which`, enclose all input strings in single quotes, for example, `which('myfun1','in','myfun2')`.

### **fun2 – Calling file**

string

Calling file, specified as a string. `fun2` can be the name of a file, or it can be in the form `fun(a1,...,an)`. For more information about the form, `fun(a1,...,an)`, see “Locate Function Invoked with Given Input Arguments” on page 1-9631.

When using the function form of `which`, enclose all input strings in single quotes, for example, `which('myfun1','in','myfun2')`.

## Output Arguments

### **str** — Function or file location

string | cell array of strings

Function or file location, returned as a string, or returned as a cell array of strings if you use `'-all'`.

- If `item` is a workspace variable, then `str` is the string `'variable'`.
- If `str` is a cell array of strings, then each row of `str` identifies a function. The functions are in order of precedence, unless they are shadowed. Among shadowed functions, you should not rely on the order of the functions in `str`. To determine if a function is shadowed, call `which` using command syntax. For example, `which test -all` displays the paths to all functions with the name `test`. Shadowed functions are indicated by the comment, `% Shadowed`.

## Limitations

- When the class is not loaded, `which` only finds methods if they are defined in separate files in an `@`-folder and are not in any packages.

## More About

### Tips

- For more information about how MATLAB uses scope and precedence when calling a function, see “Function Precedence Order”.

Introduced before R2006a

# while

Repeat execution of statements while condition is true

## Syntax

```
while expression
 statements
end
```

## Description

`while expression, statements, end` evaluates an expression, and repeats the execution of a group of statements in a loop while the expression is true. An expression is true when its result is nonempty and contains only nonzero elements (logical or real numeric). Otherwise, the expression is false.

## Examples

### Repeat Statements Until Expression Is False

Use a `while` loop to calculate `factorial(10)`.

```
n = 10;
f = n;
while n > 1
 n = n-1;
 f = f*n;
end
disp(['n! = ' num2str(f)])

n! = 3628800
```

### Skip to Next Loop Iteration

Count the number of lines of code in the file `magic.m`. Skip blank lines and comments using a `continue` statement. `continue` skips the remaining instructions in the `while` loop and begins the next iteration.

```
fid = fopen('magic.m','r');
count = 0;
while ~feof(fid)
 line = fgetl(fid);
 if isempty(line) || strcmp(line,'%') || ~ischar(line)
 continue
 end
 count = count + 1;
end
count
fclose(fid);
```

```
count =
```

```
 31
```

## Exit Loop Before Expression Is False

Sum a sequence of random numbers until the next random number is greater than an upper limit. Then, exit the loop using a `break` statement.

```
limit = 0.8;
s = 0;

while 1
 tmp = rand;
 if tmp > limit
 break
 end
 s = s + tmp;
end
```

## More About

### Expression

An expression can include relational operators (such as `<` or `==`) and logical operators (such as `&&`, `||`, or `~`). Use the logical operators **and** and **or** to create compound expressions. MATLAB evaluates compound expressions from left to right, adhering to operator precedence rules.

Within the conditional expression of a `while...end` block, logical operators `&` and `|` behave as short-circuit operators. This behavior is the same as `&&` and `||`, respectively. Since `&&` and `||` consistently short-circuit in conditional expressions and statements, it is good practice to use `&&` and `||` instead of `&` and `|` within the expression. For example,

```
x = 42;
while exist('myfunction.m','file') && (myfunction(x) >= pi)
 disp('Expressions are true')
 break
end
```

The first part of the expression evaluates to false. Therefore, MATLAB does not need to evaluate the second part of the expression, which would result in an undefined function error.

### Tips

- If you inadvertently create an infinite loop (that is, a loop that never ends on its own), stop execution of the loop by pressing **Ctrl+C**.
- If the conditional expression evaluates to a matrix, MATLAB evaluates the statements only if all elements in the matrix are true (nonzero). To execute statements if any element is true, wrap the expression in the `any` function.
- To programmatically exit the loop, use a `break` statement. To skip the rest of the instructions in the loop and begin the next iteration, use a `continue` statement.
- When nesting a number of `while` statements, each `while` statement requires an `end` keyword.
- “Relational Operators”

Introduced before R2006a

# whitebg

Change axes background color

## Syntax

```
whitebg
whitebg(fig)
whitebg(ColorSpec)
whitebg(fig, ColorSpec)
whitebg(fig, ColorSpec)
whitebg(fig)
```

## Description

`whitebg` complements the colors in the current figure.

`whitebg(fig)` complements colors in all figures specified in the vector `fig`.

`whitebg(ColorSpec)` and `whitebg(fig, ColorSpec)` change the color of the axes, which are children of the figure, to the color specified by `ColorSpec`. Without a figure specification, `whitebg` or `whitebg(ColorSpec)` affects the current figure and the root's default properties so subsequent plots and new figures use the new colors.

`whitebg(fig, ColorSpec)` sets the default axes background color of the figures in the vector `fig` to the color specified by `ColorSpec`. Other axes properties and the figure background color can change as well so that graphs maintain adequate contrast. `ColorSpec` can be a 1-by-3 RGB color or a color string such as 'white' or 'w'.

`whitebg(fig)` complements the colors of the objects in the specified figures. This syntax is typically used to toggle between black and white axes background colors, and is where `whitebg` gets its name. Include the root window handle (0) in `fig` to affect the default properties for new windows or for `clf reset`.

## Examples

Set the background color to blue-gray.

```
whitebg([0 .5 .6])
```

Set the background color to blue.

```
whitebg('blue')
```

## More About

### Tips

`whitebg` works best in cases where all the axes in the figure have the same background color.

`whitebg` changes the colors of the figure's children, with the exception of shaded surfaces. This ensures that all objects are visible against the new background color.

`whitebg` sets the default properties on the root such that all subsequent figures use the new background color.

**Introduced before R2006a**

## who

List variables in workspace

### Syntax

```
who
who(variables)
who(location)
who(variables,location)
c = who(variables,location)
```

### Description

`who` lists in alphabetical order all variables in the currently active workspace.

`who(variables)` lists only the specified variables.

`who(location)` lists variables in the specified location: `'global'` for the global workspace, or `'-file'` for a MAT-file. For MAT-files, you must also include the file name as an input.

`who(variables,location)` lists the specified variables in the specified location. The `location` input can appear before or after `variables`.

`c = who(variables,location)` stores the names of the variables in cell array `c`. Specifying `variables` and `location` is optional.

### Input Arguments

#### **variables**

Strings that specify the variables to list. Use one of these forms:

*var1, var2, ...*

List the specified variables.

Use the `'*'` wildcard to match patterns.

For example, `who('A*')` lists all variables that start with A.

'-regex', *expressions*

List variables whose names match the specified regular expressions.

**Default:** '\*' (all variables)

### location

String that indicates whether to list variables from the global workspace or from a file:

'global'

Global workspace.

'-file', *filename*

MAT-file. The *filename* input can include the full, relative, or partial path.

**Default:** '' (current workspace)

## Output Arguments

**c**

Cell array of strings that correspond to each variable name.

## Examples

Display information about variables in the current workspace whose names start with the letter **a**:

```
who a*
```

Show variables stored in MAT-file `durer.mat`:

```
who -file durer
```

This code returns:

Your variables are:

```
X caption map
```

Store the variable names from `durer.mat` in cell array `durerInfo`:

```
durerInfo = who('-file', 'durer');
```

Display the contents of cell array `durerInfo`:

```
for k=1:length(durerInfo)
 disp(durerInfo{k})
end
```

This code returns:

```
X
caption
map
```

Suppose that a file `mydata.mat` contains variables with names that start with `java` and end with `Array`. Display information about those variables:

```
whos -file mydata -regexp \<java.*Array\>
```

Call `who` within a nested function (`get_date`):

```
function who_demo
date_time = datestr(now);

[str pos] = textscan(date_time, '%s%s%s', ...
 1, 'delimiter', '- :');
get_date(str);

function get_date(d)
 day = d{1};
 mon = d{2};
 year = d{3};
 who
end
```

end

When you run `who_demo`, the `who` function displays the variables by function workspace (although the name of the function does not appear in the output):

Your variables are:

```
d mon ans pos
day year date_time str
```

## Alternatives

To view the variables in the workspace, use the Workspace browser. To view the contents of MAT-files, use the Details Panel of the Current Folder browser..

## More About

### Tips

- The `who` function displays the variable list unless you specify an output argument.
- When used within a nested function, the `who` function lists the variables in the workspaces of that function and all functions containing that function, grouped by workspace. This applies whether you call `who` from your function code or from the MATLAB debugger.

### See Also

`assignin` | `clear` | `dir` | `evalin` | `exist` | `inmem` | `load` | `save` | `what` | `whos` | `workspace`

**Introduced before R2006a**

# who

**Class:** matlab.io.MatFile

**Package:** matlab.io

Names of variables in MAT-file

## Syntax

```
varlist = who(matObj)
varlist = who(matObj,variables)
```

## Description

`varlist = who(matObj)` lists alphabetically all variables in the MAT-file associated with `matObj`. Optionally, returns the list in cell array `varlist`.

`varlist = who(matObj,variables)` lists the specified variables.

## Input Arguments

### **matObj**

Object created by the `matfile` function.

### **variables**

Names of variables in the MAT-file corresponding to `matObj`. Use one of these forms:

`var1, ..., varN`

Comma-separated list of variable name strings. Optionally, match patterns with the '\*' wildcard, such as `who(matobj, 'A*')`.

`'-regex', expressions`

Regular expression strings that describe variable names.

## Output Arguments

### **varlist**

Cell array of strings that correspond to each variable name.

## Examples

Display a list of variables in the example file `topography.mat`:

```
matObj = matfile('topography.mat');
who(matObj)
```

This code returns:

Your variables are:

```
topo topolegend topomap1 topomap2
```

## See Also

`whos` | `matfile`

## whos

List variables in workspace, with sizes and types

### Syntax

```
whos
whos(variables)
whos(location)
whos(variables,location)

S = whos(___)
```

### Description

`whos` displays in alphabetical order all variables in the currently active workspace, with information about their sizes and types.

`whos(variables)` displays only the specified variables.

`whos(location)` displays variables in the specified location.

`whos(variables,location)` displays the specified variables in the specified location. The `location` and `variables` inputs can appear in either order.

`S = whos( ___ )` stores information about the variables in structure array, `S`, using no input arguments, or any of the input arguments from the previous syntaxes.

### Examples

#### Display Information About Workspace Variables

Display information about variables in the current workspace whose names start with the letter `a`.

```
whos('a*')
```

#### Display Variables Stored in a MAT-File

Display all variables stored in the sample MAT-file, `durer.mat`.

```
whos('-file','durer.mat')
```

Name	Size	Bytes	Class	Attributes
X	648x509	2638656	double	
caption	2x28	112	char	
map	128x3	3072	double	

Show only variables in the MAT-file with names that end with `ion`.

```
whos('-file','durer.mat','-regexp','ion$')
```

Name	Size	Bytes	Class	Attributes
caption	2x28	112	char	

### Store Variable Information in a Structure Array

Store information about the variables in `durer.mat` in structure array `S`.

```
S = whos('-file','durer.mat');
```

Display the contents of `S`.

```
for k = 1:length(S)
 disp([' ' S(k).name ...
 ' ' mat2str(S(k).size) ...
 ' ' S(k).class]);
end
```

```
X [648 509] double
caption [2 28] char
map [128 3] double
```

### Create Function to Display Variable Attribute Information

In the Editor, create a function that creates variables with various persistent, global, sparse, and complex attributes, and then displays information about them.

```
function show_attributes
persistent p;
global g;
p = 1;
```

```
g = 2;
s = sparse(eye(5));
c = [4+5i 9-3i 7+6i];
whos
```

When you call the function, `show_attributes` displays the attributes.

```
show_attributes
```

Name	Size	Bytes	Class	Attributes
c	1x3	48	double	complex
g	1x1	8	double	global
p	1x1	8	double	persistent
s	5x5	128	double	sparse

### Call whos Within a Nested or Anonymous Function

Create a function, `whos_demo`, that contains a nested function, `get_date`. Call `whos` within the nested function.

```
function whos_demo
date_time = datestr(now);

C = strsplit(date_time,{'-',' '});
get_date(C);

 function get_date(d)
 day = d{1};
 mon = d{2};
 year = d{3};
 whos
 end

end
```

When you run the `whos_demo` function, `whos` displays the variables of the nested `get_date` function, and all functions that contain it, grouped by function workspace. This grouping applies whether you call `whos` from your function code or from the MATLAB debugger.

```
whos_demo
```

Name	Size	Bytes	Class	Attributes
------	------	-------	-------	------------

```

---- get_date -----
d 1x3 372 cell
day 1x2 4 char
mon 1x3 6 char
year 1x13 26 char

---- whos_demo -----
C 1x3 372 cell
ans 0x0 0 (unassigned)
date_time 1x20 40 char

```

When called within an anonymous function, variables in the anonymous function also display in a group, titled with the function signature

## Input Arguments

### **variables** — Variables to display

strings

Variables to display, specified as one or more strings in one of the following forms.

Form of Variables Input	Variable Names
<i>var1 ... varN</i>	List the named variables, specified as individual strings. Use the '*' wildcard to match patterns. For example, <code>whos('A*')</code> lists all variables in the workspace that start with A.
'-regex', <i>expr1 ... exprN</i>	List only the variables that match the regular expressions, specified as strings. For example, <code>whos('-regex','^Mon','^Tues')</code> lists only the variables in the workspace that begin with Mon or Tues.

### **location** — Location of variables

'global' | '-file',*filename*

Location of variables, specified as one of the following strings.

Value of location	Location of Variables
'global'	Global workspace.
'-file', <i>filename</i>	<p>MAT-file. The <i>filename</i> input can include the full, relative, or partial path. For example, <code>whos('-file', 'myFile.mat')</code> lists all variables in the MAT-file named <code>myFile.mat</code>.</p> <p><code>whos('-file', <i>filename</i>)</code> does not return the sizes of any MATLAB objects in file <i>filename</i>.</p>

## Output Arguments

### S — Information about variables

nested structure array

Information about variables, returned as a nested structure array that contains a scalar `struct` for each variable. Each scalar `struct` contains these fields.

Field	Description
<code>name</code>	Name of the variable.
<code>size</code>	Dimensions of the variable array.
<code>bytes</code>	Number of bytes allocated for the variable array.
<code>class</code>	Class of the variable. If the variable has no value, class is '(unassigned)'.
<code>global</code>	True if the variable is global; otherwise, false.
<code>sparse</code>	True if the variable is sparse; otherwise, false.
<code>complex</code>	True if the variable is complex; otherwise, false.
<code>nesting</code>	<p>Structure with these fields:</p> <ul style="list-style-type: none"> <li><code>function</code> — Name of the nested or outer function that defines the variable.</li> <li><code>level</code> — Nesting level of that function.</li> </ul>
<code>persistent</code>	True if the variable is persistent; otherwise, false.

## More About

### Tips

- You also can view the contents of MAT-files using the Details Panel of the Current Folder browser.

### Algorithms

whos returns the number of bytes each variable occupies in the workspace, not in a MAT-file. Version 7 MAT-files and later are compressed, so the number of bytes in the file is typically fewer than the number of bytes required in the workspace.

- “What Is the MATLAB Workspace?”

**Introduced before R2006a**

# whos

**Class:** matlab.io.MatFile

**Package:** matlab.io

Names, sizes, and types of variables in MAT-file

## Syntax

```
details = whos(matObj)
details = whos(matObj,variables)
```

## Description

`details = whos(matObj)` returns information about all variables in the MAT-file associated with `matObj`.

`details = whos(matObj,variables)` returns information about the specified variables.

## Input Arguments

### **matObj**

Object created by the `matfile` function.

### **variables**

Names of variables in the MAT-file corresponding to `matObj`. Use one of these forms:

`var1, ..., varN`

Comma-separated list of variable name strings. Optionally, match patterns with the '\*' wildcard, such as `whos(matobj, 'A*')`.

'-regex', expressions

Regular expression strings that describe variable names.

## Output Arguments

### details

Structure array with these fields (identical to the structure returned by the `whos` function):

<code>name</code>	Variable name
<code>size</code>	Dimensions of the variable
<code>bytes</code>	Number of bytes allocated for the array when you load the entire variable
<code>class</code>	Class (data type) of the variable
<code>global</code>	Whether the variable is global ( <code>true</code> or <code>false</code> )
<code>sparse</code>	Whether the variable is sparse
<code>complex</code>	Whether the variable is complex
<code>nesting</code>	Structure with these fields: <ul style="list-style-type: none"> <li>• <code>function</code> — Name of the nested or outer function that defines the variable</li> <li>• <code>level</code> — Nesting level</li> </ul>
<code>persistent</code>	Whether the variable is persistent

## Examples

Display a list of variables in the example file `topography.mat`:

```
matObj = matfile('topography.mat');
whos(matObj)
```

This code returns:

Name	Size	Bytes	Class	Attributes
<code>topo</code>	180x360	518400	double	
<code>topolegend</code>	1x3	24	double	
<code>topomap1</code>	64x3	1536	double	
<code>topomap2</code>	128x3	3072	double	

Without loading any data, find the size and number of dimensions of the variable `topo` in `topography.mat`:

```
matObj = matfile('topography.mat');
info = whos(matObj, 'topo');
sizeX = info.size
nDimsX = length(sizeX)
```

This code returns:

```
sizeX =
 180 360

nDimsX =
 2
```

## See Also

`size` | `matfile`

## width

Number of table variables

## Syntax

`W = width(T)`

## Description

`W = width(T)` returns the number of variables in table `T`.

`width(T)` is equivalent to `size(T,2)`.

## Examples

### Number of Variables in Table

Create a table, `T`.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
T = table(Age,Height,Weight,BloodPressure, 'RowNames',LastName)
```

`T =`

	Age	Height	Weight	BloodPressure	
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Find the number of variables in table T.

```
W = width(T)
```

```
W =
```

```
 4
```

T contains 4 variables; `width` does not count the row names.

The variable `BloodPressure` counts as one variable even though it contains two columns.

## Input Arguments

**T** — Input table

table

Input table, specified as a table.

Variables in a table can have multiple columns, but `width(T)` only counts the number of variables.

## See Also

`height` | `numel` | `size`

**Introduced in R2013b**

# wilkinson

Wilkinson's eigenvalue test matrix

## Syntax

```
W = wilkinson(n)
```

## Description

`W = wilkinson(n)` returns one of J. H. Wilkinson's eigenvalue test matrices. It is a symmetric, tridiagonal matrix with pairs of nearly, but not exactly, equal eigenvalues.

## Examples

```
wilkinson(7)
```

```
ans =
```

```
 3 1 0 0 0 0 0
 1 2 1 0 0 0 0
 0 1 1 1 0 0 0
 0 0 1 0 1 0 0
 0 0 0 1 1 1 0
 0 0 0 0 1 2 1
 0 0 0 0 0 1 3
```

The most frequently used case is `wilkinson(21)`. Its two largest eigenvalues are both about 10.746; they agree to 14, but not to 15, decimal places.

## See Also

`eig` | `gallery` | `pascal`

Introduced before R2006a

## winopen

Open file in appropriate application (Windows)

### Syntax

```
winopen(fileName)
```

### Description

`winopen(fileName)` opens `fileName` in the associated Microsoft Windows application. The application is associated with the extension in `fileName` in the Windows operating system. `filename` is a string enclosed in single quotes. `winopen` uses a Windows shell command, and performs the same action as double-clicking the file in the Windows Explorer program. That is, `winopen` calls the application associated the file extension to open the file. Use an absolute or relative path for `fileName`.

### Examples

Open the file `thesis.doc`, located in the current folder, in the Microsoft Word program:

```
winopen('thesis.doc')
```

Open `myresults.html` in the system Web browser:

```
winopen('D:/myfiles/myresults.html')
```

On Microsoft Windows platforms, open the current folder in the Windows Explorer tool:

```
winopen(cd)
```

To open a file on the MATLAB path, use `winopen` with `which`. For example, to open the `meshgrid` function in the Editor, use:

```
winopen(which('meshgrid'))
```

### See Also

`dos` | `open` | `web`

**Introduced before R2006a**

## winqueryreg

Item from Windows registry

### Syntax

```
valnames = winqueryreg('name', 'rootkey', 'subkey')
value = winqueryreg('rootkey', 'subkey', 'valname')
value = winqueryreg('rootkey', 'subkey')
```

### Description

`valnames = winqueryreg('name', 'rootkey', 'subkey')` returns all value names in `rootkey\subkey` of Microsoft Windows operating system registry to a cell array of strings. The first argument is the literal quoted string, 'name'.

`value = winqueryreg('rootkey', 'subkey', 'valname')` returns the value for value name `valname` in `rootkey\subkey`.

If the value retrieved from the registry is a string, `winqueryreg` returns a string. If the value is a 32-bit integer, `winqueryreg` returns the value as an integer of the MATLAB software type `int32`.

`value = winqueryreg('rootkey', 'subkey')` returns a value in `rootkey\subkey` that has no value name property.

---

**Note** The literal **name** argument and the **rootkey** argument are case-sensitive. The **subkey** and **valname** arguments are not.

---

## Examples

### Example 1

Get the value of CLSID for the MATLAB sample Microsoft COM control `mwsampctr1.2`:

```
winqueryreg 'HKEY_CLASSES_ROOT' 'mwsamp.mwsampctrl.2\clsid'
ans =
 {5771A80A-2294-4CAC-A75B-157DCDDD3653}
```

## Example 2

Get a list in variable `mousechar` for registry subkey `Mouse`, which is under subkey `Control Panel`, which is under root key `HKEY_CURRENT_USER`.

```
mousechar = winqueryreg('name', 'HKEY_CURRENT_USER', 'control panel\mouse');
```

For each name in the `mousechar` list, get its value from the registry and then display the name and its value:

```
for k = 1:length(mousechar)
 setting = winqueryreg('HKEY_CURRENT_USER', 'control panel\mouse', mousechar{k});
 str = sprintf('%s = %s', mousechar{k}, num2str(setting));
 disp(str)
end
```

```
ActiveWindowTracking = 0
DoubleClickHeight = 4
DoubleClickSpeed = 830
DoubleClickWidth = 4
MouseSpeed = 1
MouseThreshold1 = 6
MouseThreshold2 = 10
SnapToDefaultButton = 0
SwapMouseButton = 0
```

## More About

### Tips

This function works only for the following registry value types:

- strings (REG\_SZ)
- expanded strings (REG\_EXPAND\_SZ)
- 32-bit integer (REG\_DWORD)

**Introduced before R2006a**

## **workspace**

Open Workspace browser to manage workspace

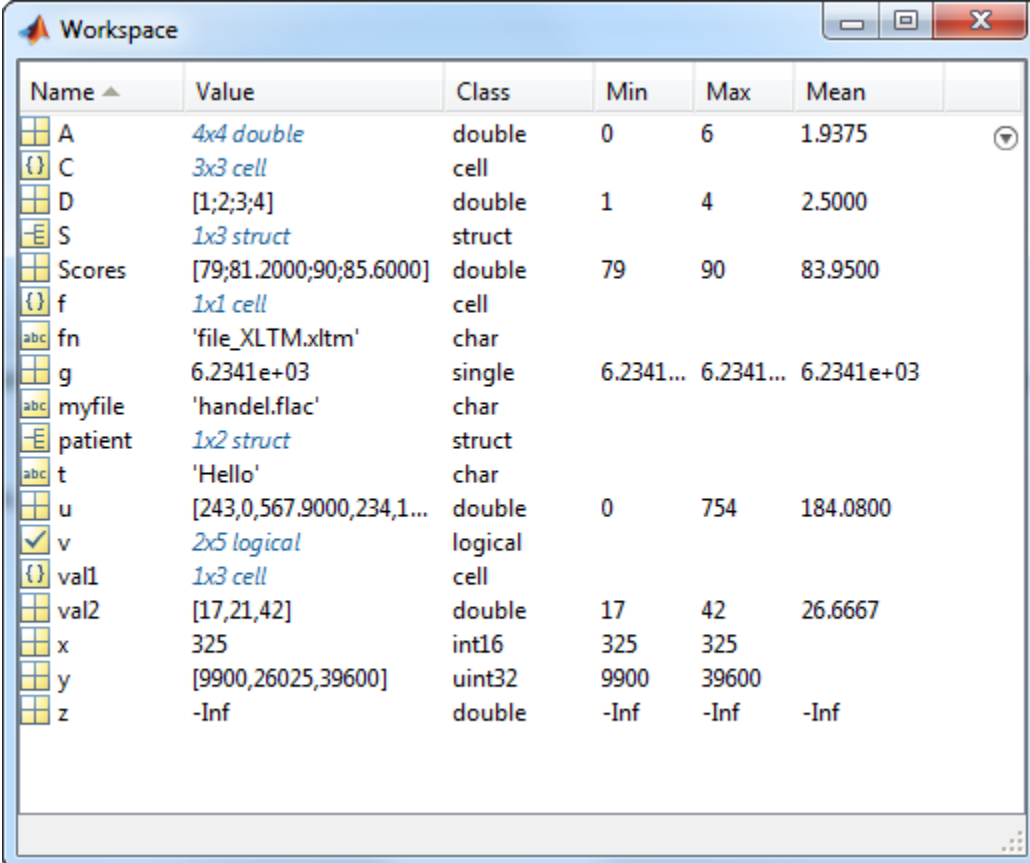

### **Syntax**

workspace

### **Description**

`workspace` displays the Workspace browser, a graphical user interface that allows you to view and manage the contents of the workspace in MATLAB. It provides a graphical representation of the `whos` display, and allows you to perform the equivalent of the `clear`, `load`, `open`, and `save` functions.

The Workspace browser also displays and automatically updates statistical calculations for each variable, which you can choose to show or hide.

Name ^	Value	Class	Min	Max	Mean
A	4x4 double	double	0	6	1.9375
C	3x3 cell	cell			
D	[1;2;3;4]	double	1	4	2.5000
S	1x3 struct	struct			
Scores	[79;81.2000;90;85.6000]	double	79	90	83.9500
f	1x1 cell	cell			
fn	'file_XLTM.xltn'	char			
g	6.2341e+03	single	6.2341...	6.2341...	6.2341e+03
myfile	'handel.flac'	char			
patient	1x2 struct	struct			
t	'Hello'	char			
u	[243,0,567.9000,234,1...	double	0	754	184.0800
v	2x5 logical	logical			
val1	1x3 cell	cell			
val2	[17,21,42]	double	17	42	26.6667
x	325	int16	325	325	
y	[9900,26025,39600]	uint32	9900	39600	
z	-Inf	double	-Inf	-Inf	-Inf

You can edit a value directly in the Workspace browser for small numeric and character arrays. To see and edit a graphical representation of larger variables and for other classes, double-click the variable in the Workspace browser. The variable displays in the Variables editor, where you can view the full contents and make changes.

## More About

- “What Is the MATLAB Workspace?”

openvar | who | filebrowser | commandhistory | commandwindow

**Introduced before R2006a**

## write

Write data to remote host over TCP/IP interface

## Syntax

```
write(t,data)
```

## Description

`write(t,data)` sends the N-dimensional matrix of data from `tcpclient` object `t` connected to the remote host. The function waits until the specified values are written to the remote host.

## Examples

### Read and Write uint8 Data

Create a TCP/IP object called `t`, connecting to a TCP/IP echo server, with Port of 7. This requires you to have an `echotcpip` server running on Port 7.

```
t = tcpclient('localhost', 7)
```

```
t =
```

```
tcpclient with properties:
```

```
Address: 'local host'
```

```
Port: 7
```

```
Timeout: 10
```

```
BytesAvailable: 0
```

The `write` function synchronously writes data to the remote host connected to the `tcpclient` object. First specify the data, then write the data. The function waits until the specified number of values is written to the remote host.

Assign 10 bytes of `uint8` data to the variable `data`.

```
data = uint8(1:10)
```

```
data =
```

```
 1 2 3 4 5 6 7 8 9 10
```

Check the data.

```
whos data
```

Name	Size	Bytes	Class	Attributes
data	1x10	10	uint8	

Write data to the echo server.

```
write(t, data)
```

Check that the data was written using the `BytesAvailable` property.

```
t.BytesAvailable
```

```
ans =
```

```
 10
```

Read the data from the server.

```
read(t)
```

```
ans =
```

```
 1 2 3 4 5 6 7 8 9 10
```

Close the connection between the TCP/IP client object and the remote host by clearing the object.

```
clear t
```

## Input Arguments

**data** — Data to write to the remote host

1xN matrix of numeric data

Data to write to the remote host, specified as a 1xN matrix of numeric data.

Example: `write(t, data)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## writetable

Write table to file

### Syntax

```
writetable(T)
writetable(T,filename)
writetable(____,Name,Value)
```

### Description

`writetable(T)` writes the table, `T`, to a comma delimited text file. The file name is the workspace variable name of the table, appended with the extension `.txt`. If `writetable` cannot construct the file name from the input table name, then it writes to the file `table.txt`.

Each column of each variable in `T` becomes a column in the output file. The variable names of `T` become column headings in the first line of the file.

`writetable(T,filename)` writes to a file with the name and extension specified by `filename`.

`writetable` determines the file format based on the specified extension. The extension must be one of the following:

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls`, `.xlsb`, `.xlsm`, or `.xlsx` for Excel spreadsheet files

`writetable( ____,Name,Value)` writes the table to a file with additional options specified by one or more `Name,Value` pair arguments and can include any of the input arguments in previous syntaxes.

For example, you can specify whether to write the variable names as column headings in the output file.

## Examples

### Write Table to Text File

Create a table.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
 {'NY';'CA';'MA'},[true;false;false])
```

T =

Var1	Var2		Var3	Var4
M	45	45	'NY'	true
F	41	32	'CA'	false
M	40	34	'MA'	false

Write the table to a comma delimited text file and display the file contents.

```
writetable(T)
```

writetable outputs a text file named T.txt.

```
type 'T.txt'
```

```
Var1,Var2_1,Var2_2,Var3,Var4
M,45,45,NY,1
F,41,32,CA,0
M,40,34,MA,0
```

writetable appends a unique suffix to the variable name, Var2, above the two columns of corresponding data.

### Write Table to Space-Delimited Text File

Create a table.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
 {'NY';'CA';'MA'},[true;false;false])
```

T =

Var1	Var2		Var3	Var4
_____	_____	_____	_____	_____
M	45	45	'NY'	true
F	41	32	'CA'	false
M	40	34	'MA'	false

Write the table to a space-delimited text file named `myData.txt` and display the file contents.

```
writetable(T,'myData.txt','Delimiter',' ')
type 'myData.txt'
```

```
Var1 Var2_1 Var2_2 Var3 Var4
M 45 45 NY 1
F 41 32 CA 0
M 40 34 MA 0
```

`writetable` appends a unique suffix to the variable name, `Var2`, above the two columns of corresponding data.

## Write Table to Text File Including Row Names

Create a table.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
T = table(Age,Height,Weight,BloodPressure,...
 'RowNames',LastName)
```

T =

	Age	Height	Weight	BloodPressure	
	_____	_____	_____	_____	_____
Smith	38	71	176	124	93

Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Write the table, `T`, to a comma delimited text file, called `myPatientData.dat`, and display the file contents.

```
writetable(T, 'myPatientData.dat', 'WriteRowNames', true)
type 'myPatientData.dat'
```

```
Row, Age, Height, Weight, BloodPressure_1, BloodPressure_2
Smith, 38, 71, 176, 124, 93
Johnson, 43, 69, 163, 109, 77
Williams, 38, 64, 131, 125, 83
Jones, 40, 67, 133, 117, 75
Brown, 49, 64, 119, 122, 80
```

The first column, which contains the row names, has the column heading, `Row`. This is the first dimension name for the table from the property `T.Properties.DimensionNames`.

### Write Foreign-Language Dates to Text File

Convert English dates in a table to German and write the table to file.

Create a table that contains a `datetime` array with dates in English. Create column vectors of numeric data to go with the dates.

```
D = datetime({'01-Jan-2014'; '01-Feb-2014'; '01-Mar-2014'});
D.Format = 'dd MMMM yyyy';
X1 = [20.2; 21.6; 20.7];
X2 = [100.5; 102.7; 99.8];
T = table(D, X1, X2)
```

`T =`

D	X1	X2
01 January 2014	20.2	100.5
01 February 2014	21.6	102.7
01 March 2014	20.7	99.8

Write the table to a text file. Specify German for the locale of the dates using the `DateLocale` name-value pair argument, and display the dates in the text file.

```
writetable(T,'myfile.txt','DateLocale','de_DE');
type myfile.txt
```

```
D,X1,X2
01 Januar 2014,20.2,100.5
01 Februar 2014,21.6,102.7
01 März 2014,20.7,99.8
```

### Write Quoted Strings to CSV File

Create a table.

```
T = table(['M';'F';'M'],[45;41;36],...
 {'New York, NY';'San Diego, CA';'Boston, MA'},[true;false;false])
```

T =

Var1	Var2	Var3	Var4
M	45	'New York, NY'	true
F	41	'San Diego, CA'	false
M	36	'Boston, MA'	false

Write the table to a comma-separated text file named `myData.csv` and view the file contents. Enclose strings in double quotation marks using the `'QuoteStrings'` name-value pair argument, to ensure that the commas in the third column are not treated as delimiters.

```
writetable(T,'myData.csv','Delimiter',' ','QuoteStrings',true)
type 'myData.csv'
```

```
Var1,Var2,Var3,Var4
"M",45,"New York, NY",1
"F",41,"San Diego, CA",0
"M",36,"Boston, MA",0
```

### Write Table to Specific Sheet and Range in Spreadsheet

Create a table.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
 {'NY';'CA';'MA'},[true;false;false])
```

T =

Var1	Var2	Var3	Var4
M	45	45	'NY'
F	41	32	'CA'
M	40	34	'MA'

Write the table to a spreadsheet named `myData.xls`. Include the data on the second sheet in the 5-by-5 region with corners at B2 and F6.

```
writetable(T, 'myData.xls', 'Sheet', 2, 'Range', 'B2:F6')
```

Excel fills the row of the spreadsheet from B6 to F6 with #N/A since the range specified is larger than the size of the input table T.

## Input Arguments

### T — Input data

table

Input data, specified as a table.

### filename — File name

string

File name, specified as a string. To write to a specific folder, specify the full path name. Otherwise, `writetable` writes to a file in the current folder. If `filename` includes the file extension, then `writetable` determines the file format from the extension. Otherwise, `writetable` creates a comma separated text file and appends the extension `.txt`. Alternatively, you can specify `filename` without the file's extension, and then include the `'FileType'` name-value pair arguments to indicate the type of file.

- If `filename` does not exist, then `writetable` creates the file.
- If `filename` is the name of an existing text file, then `writetable` overwrites the file.
- If `filename` is the name of an existing spreadsheet file, then `writetable` writes a table to the specified location, but does not overwrite any values outside that range.

Example: `'myData.xls'`

Example: `'C:\test\myData.txt'`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'WriteVariableNames', false` indicates that the variable names should not be included as the first row of the output file.

**'FileType' — Type of file**  
 'text' | 'spreadsheet'

Type of file, specified as the comma-separated pair consisting of `'FileType'` and the string `'text'` or `'spreadsheet'`.

The `'FileType'` name-value pair must be used with the `filename` input argument. You do not need to specify the `'FileType'` name-value pair argument if `writetable` can determine the file type from an extension in the `filename` input argument. `writetable` can determine the file type from these extensions:

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls`, `.xlsb`, `.xlsm`, or `.xlsx` for Excel spreadsheet files

Example: `writetable(T, 'mySpreadsheet', 'FileType', 'spreadsheet')`

**'WriteVariableNames' — Indicator for writing variable names as column headings**  
 true (default) | false | 1 | 0

Indicator for writing variable names as column headings, specified as the comma-separated pair consisting of `'WriteVariableNames'` and either `true`, `false`, `1`, or `0`.

Indicator	Behavior
true	<p><code>writetable</code> includes variable names as the column headings of the output. This is the default behavior.</p> <p>If both the <code>'WriteVariablesNames'</code> and <code>'WriteRowNames'</code> logical indicators are <code>true</code>, then <code>writetable</code> uses the first dimension name from the property <code>T.Properties.DimensionNames</code> as the column heading for the first column of the output.</p>

Indicator	Behavior
false	writetable does not include variable names in the output.

### 'WriteRowNames' — Indicator for writing row names in first column

false (default) | true | 0 | 1

Indicator for writing row names in first column, specified as the comma-separated pair consisting of 'WriteRowNames' and either false, true, 0, or 1.

Indicator	Behavior
false	writetable does not include the row names from T in the output. This is the default behavior.
true	writetable includes the row names from T as the first column of the output.  If both the 'WriteVariablesNames' and 'WriteRowNames' logical indicators are true, then writetable uses the first dimension name from the property T.Properties.DimensionNames as the column heading for the first column of the output.

### 'Delimiter' — Field delimiter character

string

Field delimiter character, specified as the comma-separated pair consisting of 'Delimiter' and one of the following strings:

Specifier	Field Delimiter
' , '	Comma. This is the default behavior.
' comma '	
' ' '	Space
' space '	
' \t '	Tab
' tab '	

Specifier	Field Delimiter
' ; '	Semicolon
' semi '	
'   '	Vertical bar
' bar '	

You can use the 'Delimiter' name-value pair only for delimited text files.

Example: 'Delimiter', 'space'

**'QuoteStrings' – Indicator for writing quoted strings**

false (default) | true | 0 | 1

Indicator for writing quoted strings, specified as the comma-separated pair consisting of 'QuoteStrings' and either false, true, 0, or 1. If 'QuoteStrings' is true, then writetable encloses strings in double quotation marks, and replaces any double-quote characters that appear as part of a string with two double-quote characters. For an example, see “Write Quoted Strings to CSV File” on page 1-9672.

You can use the 'QuoteStrings' name-value pair only with delimited text files.

**'DateLocale' – Locale for writing dates**

string

Locale for writing dates, specified as the comma-separated pair consisting of 'DateLocale' and a string. The string takes the form xx\_YY, where xx is a lowercase ISO 639-1 two-letter code indicating a language, and YY is an uppercase ISO 3166-1 alpha-2 code indicating a country. For a list of common values for the locale, see the Locale name-value pair argument for the datetime function.

When writing datetime values to the file, use DateLocale to specify the locale in which writetable should write month and day-of-week names and abbreviations.

Example: 'DateLocale', 'ja\_JP'

**'Sheet' – Worksheet to write to**

string containing worksheet name | positive integer indicating worksheet index

Worksheet to write to, specified as the comma-separated pair consisting of 'Sheet' and a string containing the worksheet name or a positive integer indicating the worksheet

index. The worksheet name string cannot contain a colon (:). To determine the names of sheets in a spreadsheet file, use `[status,sheets] = xlsfinfo(filename)`.

If the sheet does not exist, then `writetable` adds a new sheet at the end of the worksheet collection. If the sheet is an index larger than the number of worksheets, then `writetable` appends empty sheets until the number of worksheets in the workbook equals the sheet index. In either case, `writetable` generates a warning indicating that it has added a new worksheet.

You can use the 'Sheet' name-value pair only with spreadsheet files.

Example: 'Sheet',2

### 'Range' — Rectangular portion of worksheet to write to string

Rectangular portion of worksheet to write to, specified as the comma-separated pair consisting of 'Range' and a string in one of the following forms.

Form of the Value of Range	Description
'Corner1'	<p><i>Corner1</i> specifies the first cell of the region to write. <code>writetable</code> writes table T beginning at this cell.</p> <p><b>Example:</b> 'Range', 'D2'</p>
'Corner1:Corner2'	<p><i>Corner1</i> and <i>Corner2</i> are two opposing corners that define the region to write. For example, 'D2:H4' represents the 3-by-5 rectangular region between the two corners D2 and H4 on the worksheet. The 'Range' name-value pair argument is not case sensitive, and uses Excel A1 reference style (see Excel help).</p> <p>If the range you specify is larger than the size of the input table T, Excel software fills the remainder of the region with #N/A. If the range specified is smaller than the size of the input table T, then <code>writetable</code> writes only the subset that fits into the range.</p> <p><b>Example:</b> 'Range', 'D2:H4'</p>

The 'Range' name-value pair can only be used with Excel files.

## Limitations

- On Linux systems, `writetable` writes only to text files and does not write to spreadsheet files.

## More About

### Tips

- In the cases below, `writetable` creates a file that does not represent `T` exactly. Then, if you use `readtable` to read that file and create a new table, the result might not have the same format or contents as the original table. Save `T` as a MAT-file if you need to import it again as a table with the same data and organization.
  - `writetable` outputs numeric variables using `long g` format, and categorical or character variables as unquoted strings in text files.
  - For variables that have more than one column, `writetable` appends a unique identifier to the variable name to use as the column headings.
  - For output variables that have more than two dimensions, `writetable` outputs these variables as two dimensional where the trailing dimensions are collapsed. For example, `writetable` outputs a 4-by-3-by-2 variable as if its size were 4-by-6.
  - For variables with a `cell` data type, `writetable` outputs the contents of each cell as a single row, in multiple fields. If the contents are other than numeric, logical, character, or categorical, then `writetable` outputs a single empty field.

### Algorithms

Excel converts `Inf` values to `65535`. MATLAB converts `NaN` values to empty cells.

Introduced in R2013b

# write

**Class:** Tiff

Write entire image

## Syntax

```
write(tiffobj, imageData)
write(tiffobj, Y, Cb, Cr)
```

## Description

`write(tiffobj, imageData)` writes `imageData` to TIFF file associated with the Tiff object, `tiffobj`. The `write` method breaks the data into strips or tiles, depending on the value of the `RowsPerStrip` tag, or the `TileLength` and `TileWidth` tags.

`write(tiffobj, Y, Cb, Cr)` writes the YCbCr component data to the TIFF file. Use this syntax only for images with a YCbCr photometric interpretation.

## Examples

### Write Image Data

Write tags and image data to a new TIFF file.

Read sample data into an array, `imdata`. Create a Tiff object associated with a new file, `myfile.tif`, and open the file for writing.

```
imdata = imread('example.tif');
t = Tiff('myfile.tif', 'w');
```

Set tag values.

```
setTag(t, 'ImageLength', size(imdata, 1))
setTag(t, 'ImageWidth', size(imdata, 2))
setTag(t, 'Photometric', Tiff.Photometric.RGB)
```

```
setTag(t, 'BitsPerSample',8)
setTag(t, 'SamplesPerPixel',size(imdata,3))
setTag(t, 'TileWidth',128)
setTag(t, 'TileLength',128)
setTag(t, 'Compression',Tiff.Compression.JPEG)
setTag(t, 'PlanarConfiguration',Tiff.PlanarConfiguration.Chunky)
setTag(t, 'Software', 'MATLAB')
```

Write the image data to the TIFF file.

```
write(t,imdata)
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”

## See Also

Tiff.writeDirectory

# writeDirectory

**Class:** Tiff

Create new IFD and make it current IFD

## Syntax

```
writeDirectory(tiffobj)
```

## Description

`writeDirectory(tiffobj)` create a new image file directory (IFD) and makes it the current IFD. Tiff object methods operate on the current IFD. If you are creating a TIFF file that only contains one image, you do not need to use this method. With single-image TIFF files, just close the Tiff object to write data to the file.

## Examples

Open a TIFF file for modification and create a new IFD in the file. `writeDirectory` makes the newly created IFD the current IFD. Replace the name `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif', 'r+');
dnum = currentDirectory(t);
writeDirectory(t);
dnum = currentDirectory(t);
```

## References

This method corresponds to the `TIFFWriteDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

## See Also

[Tiff.write](#) | [Tiff.close](#)

# writeEncodedStrip

**Class:** Tiff

Write data to specified strip

## Syntax

```
writeEncodedStrip(tiffobj,stripNumber,imageData)
writeEncodedStrip(tiffobj,stripNumber,Y,Cb,Cr)
```

## Description

`writeEncodedStrip(tiffobj,stripNumber,imageData)` writes the data in `imageData` to the strip specified by `stripNumber`. Strip identification numbers are one-based. If `imageData` has fewer bytes than fit into a strip, `writeEncodedStrip` silently pads the strip. If `imageData` has more bytes than fit into a strip, `writeEncodedStrip` issues a warning and truncates the data. To determine the size of a strip, view the value of the `RowsPerStrip` tag.

`writeEncodedStrip(tiffobj,stripNumber,Y,Cb,Cr)` writes the YCbCr component data to the specified tile. You must set the `YCbCrSubSampling` tag.

## Examples

### Write Image Data to Strips

Open a Tiff object for writing and set tag values.

```
t = Tiff('myfile.tif','w');
setTag(t,'ImageLength',32)
setTag(t,'ImageWidth',32)
setTag(t,'Photometric',Tiff.Photometric.MinIsBlack)
setTag(t,'BitsPerSample',8)
setTag(t,'SamplesPerPixel',1)
setTag(t,'RowsPerStrip',16)
setTag(t,'PlanarConfiguration',Tiff.PlanarConfiguration.Chunky)
```

Write data to the first and second strips.

```
writeEncodedStrip(t,1,ones(16,32,'uint8'))
writeEncodedStrip(t,2,2*ones(16,32,'uint8'))
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

`Tiff.writeEncodedTile`

# writeEncodedTile

**Class:** Tiff

Write data to specified tile

## Syntax

```
writeEncodedTile(tiffobj, tileNumber, imageData)
writeEncodedTile(tiffobj, tileNumber, Y, Cb, Cr)
```

## Description

`writeEncodedTile(tiffobj, tileNumber, imageData)` writes the data in `imageData` to the tile specified by `tileNumber`. Tile identification numbers are one-based. If `imageData` has fewer bytes than fit into a tile, `writeEncodedTile` silently pads the tile. If `imageData` has more bytes than fit into a tile, `writeEncodedTile` issues a warning and truncates the data. To determine the size of a tile, view the value of the `tileLength` and `tileWidth` tags.

`writeEncodedTile(tiffobj, tileNumber, Y, Cb, Cr)` writes the YCbCr component data to the specified tile. You must set the `YCbCrSubSampling` tags.

## Examples

### Write Image Data to Tiles

Open a Tiff object for writing and set tag values.

```
t = Tiff('myfile.tif', 'w');
setTag(t, 'ImageLength', 32)
setTag(t, 'ImageWidth', 32)
setTag(t, 'Photometric', Tiff.Photometric.MinIsBlack)
setTag(t, 'BitsPerSample', 8)
setTag(t, 'SamplesPerPixel', 1)
setTag(t, 'TileWidth', 16)
setTag(t, 'TileLength', 16)
```

```
setTag(t, 'PlanarConfiguration', Tiff.PlanarConfiguration.Chunky)
```

Write data to four tiles.

```
writeEncodedTile(t, 1, ones(16, 16, 'uint8'))
writeEncodedTile(t, 2, 2*ones(16, 16, 'uint8'))
writeEncodedTile(t, 3, 3*ones(16, 16, 'uint8'))
writeEncodedTile(t, 4, 4*ones(16, 16, 'uint8'))
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## References

This method corresponds to the `TIFFWriteEncodedTile` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

## See Also

`Tiff.writeEncodedStrip`

## xlabel

Label x-axis

### Syntax

```
xlabel(str)
xlabel(str,Name,Value)
```

```
xlabel(ax, ___)
```

```
t = xlabel(___)
```

### Description

`xlabel(str)` labels the *x*-axis of the current axes with the text specified by `str`. Reissuing the `xlabel` command replaces the old label with the new label.

`xlabel(str,Name,Value)` specifies text properties for the label using one or more `Name,Value` pair arguments. For example, `'Color','blue'` creates a blue label.

`xlabel(ax, ___)` adds the label to the axes specified by `ax`, instead of the current axes. The option `ax` can precede any of the input argument combinations in the previous syntaxes.

`t = xlabel( ___)` returns the text object used as the *x*-axis label. Use `t` to make future modifications to the label after it is created.

### Examples

#### Label x-Axis

Display `Population` beneath the *x*-axis.

```
plot((1:10).^2)
xlabel('Population')
```

### Create Multiline x-Axis Label

Create a multiline label using a cell array of strings.

```
plot((1:10).^2)
xlabel({'Population', 'in thousands'})
```

### Include Greek Letters in x-Axis Label

Include Greek letters and other special characters in the label using TeX markup.

```
x = linspace(-2*pi,2*pi);
y = sin(x);
plot(x,y)
xlabel('-2\pi \leq x \leq 2\pi')
```

### Include Variable Value in x-Axis Label

Add a label with text and a variable value. Use the `num2str` function to convert the variable value to a string.

```
plot((1:10).^2)
year = 2014;
xlabel(['Population for Year ', num2str(year)])
```

### Include Superscript and Subscript in Axis Labels

Use the '^' and '\_' characters to include superscripts and subscripts in the axis labels. Use curly braces {} to modify more than one character.

```
t = linspace(0,1);
y = exp(t);
plot(t,y)
xlabel('t_{seconds}')
ylabel('e^t')
```

### Change x-Axis Label Font Size and Color

Use Name, Value pair arguments to set the font size, font weight, and text color properties of the x-axis label.

```
plot((1:10).^2)
xlabel('Population', 'FontSize', 12, 'FontWeight', 'bold', 'Color', 'r')
```

### Label x-Axis of Specific Subplot

Create a figure with two subplots. Label the x-axis of the top subplot.

```
ax1 = subplot(2,1,1);
plot((1:10).^2)
xlabel(ax1, 'Population')
```

```
ax2 = subplot(2,1,2);
plot((1:10).^3)
```

### Modify x-Axis Label After Creation

Label the  $x$ -axis and return the text object used as the label.

```
plot((1:10).^2)
t = xlabel('Population');
```

Use `t` to set text properties of the label after it has been created. For example, set the color of the label to red. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
t.Color = 'red';
```

- “Add Text to Graph Interactively”

## Input Arguments

### **str** — Axis label

character array | cell array | numeric value

Axis label, specified as a character array, cell array, or numeric value.

Example: 'my label'

Example: {'first line', 'second line'}

Example: 123

To include numeric variables with text in a label, use the `num2str` function. For example:

```
x = 42;
str = ['The value is ', num2str(x)];
```

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols use TeX markup. For a list of supported markup, see the `Interpreter` property.

To create multiline labels:

- Use a cell array, where each cell contains a line of text, such as `{'first line', 'second line'}`.
- Use a character array, where each row contains the same number of characters, such as `['abc'; 'ab ']`.
- Use `sprintf` to create a string with a new line character, such as `sprintf('first line \n second line')`.

Numeric labels are converted to text using `sprintf('%g', value)`. For example, 12345678 displays as 1.23457e+07.

---

**Note:** The words `default`, `factory`, and `remove` are reserved words that will not appear in a label when quoted as a normal string. To display any of these words individually, precede them with a backslash, such as `'\default'` or `'\remove'`.

---

## **ax — Axes object**

axes object

Axes object. If you do not specify an axes, then the `xlabel` function adds the label to the current axes.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Color','red','FontSize',12` specifies red, 12-point font.

The text properties listed here are only a subset. For a complete list, see Text Properties.

### 'FontSize' — Font size

11 (default) | scalar value greater than 0

Font size, specified as a scalar value greater than 0 in point units. One point equals 1/72 inch. To change the font units, use the `FontUnits` property.

Setting the font size properties for the associated axes also affects the label font size. The label font size updates to equal the axes font size times the label scale factor. The `FontSize` property of the axes contains the axes font size. The `LabelFontSizeMultiplier` property of the axes contains the label scale factor. By default, the axes font size is 10 points and the scale factor is 1.1, so the *x*-axis label font size is 11 points.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### 'FontWeight' — Thickness of text characters

'normal' (default) | 'bold'

Thickness of the text characters, specified as one of these values:

- 'normal' — Default weight as defined by the particular font
- 'bold' — Thicker character outlines than normal

MATLAB uses the `FontWeight` property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight still can result in the normal font weight.

---

**Note:** The 'light' and 'demi' font weight values have been removed. Use 'normal' instead.

---

### 'FontName' — Font name

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. The `'FixedWidth'` value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

**'Color' — Text color**

`[0.15 0.15 0.15]` (default) | RGB triplet | color string | `'none'`

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. If you set the color to `'none'`, then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
<code>'yellow'</code>	<code>'y'</code>	<code>[1 1 0]</code>
<code>'magenta'</code>	<code>'m'</code>	<code>[1 0 1]</code>
<code>'cyan'</code>	<code>'c'</code>	<code>[0 1 1]</code>
<code>'red'</code>	<code>'r'</code>	<code>[1 0 0]</code>
<code>'green'</code>	<code>'g'</code>	<code>[0 1 0]</code>
<code>'blue'</code>	<code>'b'</code>	<code>[0 0 1]</code>
<code>'white'</code>	<code>'w'</code>	<code>[1 1 1]</code>
<code>'black'</code>	<code>'k'</code>	<code>[0 0 0]</code>

Example: `'blue'`

Example: `[0 0 1]`

**'Interpreter' — Interpretation of text characters**

`'tex'` (default) | `'latex'` | `'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup.
- `'latex'` — Interpret text strings using LaTeX markup.

- 'none' — Display literal characters.

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers with the `Interpreter` property set to 'tex'. Modifiers remain in effect until the end of the string. Superscripts and subscripts are an exception because they only modify the next character or the text within the curly braces {}.

Modifier	Description	Example of String
<code>^{ }</code>	Superscript	<code>'text^{superscript}'</code>
<code>_{ }</code>	Subscript	<code>'text_{subscript}'</code>
<code>\bf</code>	Bold font	<code>'\bf text'</code>
<code>\it</code>	Italic font	<code>'\it text'</code>
<code>\sl</code>	Oblique font (usually the same as italic font)	<code>'\sl text'</code>
<code>\rm</code>	Normal font	<code>'\rm text'</code>
<code>\fontname{specifier}</code>	Font name — Set <code>specifier</code> as the name of a font family. You can use this in combination with other modifiers.	<code>'\fontname{Courier} text'</code>
<code>\fontsize{specifier}</code>	Font size — Set <code>specifier</code> as a numeric scalar value in point units to change the font size.	<code>'\fontsize{15} text'</code>
<code>\color{specifier}</code>	Font color — Set <code>specifier</code> as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue.	<code>'\color{magenta} text'</code>

Modifier	Description	Example of String
<code>\color[rgb]{specifier}</code>	Custom font color — Set specifier as a three-element RGB triplet.	<code>'\color[rgb]{0,0.5,0.5} text'</code>

This table lists the supported special characters with the Interpreter property set to 'tex'.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
<code>\alpha</code>	$\alpha$	<code>\upsilon</code>	$\upsilon$	<code>\sim</code>	$\sim$

<code>\wedge</code>	$\wedge$	<code>\varpi</code>	$\varpi$	<code>\emptyset</code>	$\emptyset$
<code>\rceil</code>	$\rceil$	<code>\rangle</code>	$\rangle$	<code>\mid</code>	$ $
<code>\vee</code>	$\vee$	<code>\langle</code>	$\langle$	<code>\copyright</code>	$\copyright$

## LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at <http://www.latex-project.org/>.

## Output Arguments

**t** — Text object  
text object

Text object used as the  $x$ -axis label. Use `t` to access and modify properties of the label after it has been created.

**Introduced before R2006a**

# matlab.wsd1.createWSDLCient

Create interface to SOAP-based web service

## Syntax

```
matlab.wsd1.createWSDLCient(wsd1URL)
matlab.wsd1.createWSDLCient(wsd1URL, folder)
matlab.wsd1.createWSDLCient(wsd1URL, folder, 'silent')

matlab.wsd1.createWSDLCient(____, options)

classname = matlab.wsd1.createWSDLCient(____, options)
```

## Description

`matlab.wsd1.createWSDLCient(wsd1URL)` creates an interface to a service based on a Web Services Description Language (WSDL) document specified by `wsd1URL`. This function creates a MATLAB class file for each Simple Object Access Protocol (SOAP) binding in the WSDL in the current folder. If necessary, the function creates additional support files. You can package and distribute these files to other users.

You must install the WSDL tools, Java JDK™ and Apache™ CXF software, then set the tool paths using the `matlab.wsd1.setWSDLToolPath` function.

You must have write permission for the current folder.

`matlab.wsd1.createWSDLCient(wsd1URL, folder)` creates the interface files in `folder`, which must be on the MATLAB path.

`matlab.wsd1.createWSDLCient(wsd1URL, folder, 'silent')` suppresses display of generated files and folders.

`matlab.wsd1.createWSDLCient( ____, options)` specifies additional information needed to access the WSDL document. You can use this syntax with any of the input arguments of the previous syntaxes.

`classname = matlab.wsd1.createWSDLCient( ____, options)` returns a handle to the created class. If multiple classes were created, the function returns a cell array of

handles. You can use this syntax with any of the input arguments of the previous syntaxes.

To get information on using the class, call the MATLAB `help` function on the class name.

## Examples

### Get Map Name from USGSImageryOnly\_MapServer Web Service

To run this example, install the WSDL tools and set the tool paths. `jdk` and `cxfl` are the paths to these tools on your system.

```
matlab.wsd1.setWSDLToolPath('JDK',jdk,'CXF',cxfl)
```

Create the class files.

```
url = ...
'http://basemap.nationalmap.gov/arcgis/services/USGSImageryOnly/MapServer?wsdl';
matlab.wsd1.createWSDLClient(url);
```

```
Created USGSImageryOnly_MapServer.
.\USGSImageryOnly_MapServer.m
.\+wsdl
```

In order to use `USGSImageryOnly_MapServer`, you must run `javaaddpath('.\+wsdl\mapserver`

Add the jar files to the Java path.

```
javaaddpath('.\+wsdl\mapserver.jar')
```

Create the service.

```
wsdl = USGSImageryOnly_MapServer;
```

Read help for the service and its functions.

```
help USGSImageryOnly_MapServer
```

```
USGSImageryOnly_MapServer A client to connect to the USGSImageryOnly_MapServer service
SERVICE = USGSImageryOnly_MapServer connects to http://basemap.nationalmap.gov/arcgis/services/USGSImageryOnly/MapServer
```

To communicate with the service, call a function on the `SERVICE`:

```
[...] = FUNCTION(SERVICE,arg,...)
```

See doc USGSImageryOnly\_MapServer for a list of functions.

Call one of the methods, for example `GetDefaultMapName` that returns the map name.

```
GetDefaultMapName(wsd1)
```

```
ans =
```

```
Layers
```

- “Set Up WSDL Tools”

## Input Arguments

### **wsd1URL** — WSDL URL or file path

string

WSDL URL or file path, specified as a string, that defines service methods, arguments, and transactions.

`wsd1URL` can be an `http` or `https` URL or a local path. `wsd1URL` cannot be a `file://` URL. On Microsoft Windows, UNC paths are not supported.

Example: 'http://www.mywebservice.com/servicename?WSDL'

### **folder** — Folder for generated files

string

Folder for generated files, specified as a string. If omitted or empty (' '), `matlab.wsd1.createWSDLCient` uses the current folder. You must have write permission for the folder. The function overwrites existing files with the same names as the generated files.

Example: 'c:\work'

### **options** — Additional options

`weboptions` object

Additional options, specified as a `weboptions` object, needed to access the WSDL document, such as `Username`, `Password`, and `Timeout`.

The additional options specified in `weboptions` do not apply to any other documents, such as other imported WSDL documents or schemas, that the primary WSDL document references. The options also do not apply to requests made to servers by the generated code.

Example: `'Username', 'john', 'Password', 'mypassword'`

## Limitations

- “Limitations to WSDL Document Support”

## More About

### Tips

- If you create WSDL files in multiple locations on your computer, avoid confusion by deleting the class files from duplicate locations, and then call `clear java`.

### See Also

`clear` | `createClassFromWsd1` | `matlab.wsd1.setWSDLToolPath` | `weboptions` | `webread`

**Introduced in R2014b**

# matlab.wsd1.setWSDLToolPath

Location of WSDL tools

## Syntax

```
matlab.wsd1.setWSDLToolPath(Name,Value)
```

```
paths = matlab.wsd1.setWSDLToolPath
```

## Description

`matlab.wsd1.setWSDLToolPath(Name,Value)` sets the paths to Java JDK and Apache CXF software. You must download these tools to use the `matlab.wsd1.createWSDLCClient` interface.

Specify values for both Name arguments 'JDK' and 'CXF' before calling `matlab.wsd1.createWSDLCClient`. The values are saved across sessions in your user preferences.

`paths = matlab.wsd1.setWSDLToolPath` displays paths to the JDK and CXF software.

## Examples

### Set Path to Tools

Set `jdk` and `cxf` to valid paths on your system. For example,

```
jdk = 'E:/Program Files/win64/jdk';
cxf = 'c:\apache-cxf-2.7.10'
matlab.wsd1.setWSDLToolPath('JDK',jdk,'CXF',cxf)
```

### Check If Tool Paths Are Set

```
p = matlab.wsd1.setWSDLToolPath;
if (isempty(p.JDK) || isempty(p.CXF))
 disp('Install the Java Development Kit (JDK) and Apache CXF programs.')
 disp('See the Set Up WSDL Tools example link at the end of this page.')
```

```
else
 disp('Paths set to:')
 matlab.wsd1.setWSDLToolPath
end
```

- “Set Up WSDL Tools”

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'CXF'`, `'C:\apache-cxf-2.7.10'`

#### **'JDK'** — Path to Java JDK software

string

Path to Java Development Kit (JDK) software, specified as a string. Download the software from <http://www.oracle.com/technetwork/java/javase/downloads> and choose the latest release of 7.

Example: `'E:/Program Files/win64/jdk'`

#### **'CXF'** — Path to Apache CXF software

string

Path to Apache CXF software, specified as a string. CXF is an open-source services framework. Download the software from <http://cxf.apache.org/download> and choose the latest release of 2.7.

Example: `'C:\apache-cxf-2.7.10'`

## Output Arguments

### **paths** — Tool paths

structure

Tool paths, returned as a structure with the fields:

**JDK — Path to Java JDK software**

string

Path to Java JDK software, specified as a string. If the value of `JDK` is empty, you cannot call `matlab.wsd1.createWSDLClient`.

**CXF — Path to Apache CXF software**

string

Path to Apache CXF software, specified as a string. If the value of `CXF` is empty, you cannot call `matlab.wsd1.createWSDLClient`.

## More About

- <http://www.oracle.com/technetwork/java/javase/downloads>
- <http://cxf.apache.org/download>

## See Also

`matlab.wsd1.createWSDLClient`

**Introduced in R2014b**

## year

Year number

## Syntax

```
y = year(t)
y = year(t,yearType)
```

## Description

`y = year(t)` returns the ISO year numbers for the datetime values in `t`. ISO year numbers include a year zero and represent years BCE using negative values. The `y` output is a `double` array the same size as `t`.

`y = year(t,yearType)` returns the type of year number specified by `yearType`.

The `year` function returns the year numbers of datetime values. To assign ISO year values to a datetime array, `t`, use `t.Year` and modify the `Year` property.

## Examples

### Extract Year Number from Dates

Extract the year numbers from an array of dates.

```
t = datetime(2010,05,31):calyears(1):datetime(2015,02,28)
```

```
t =
```

```
 31-May-2010 31-May-2011 31-May-2012 31-May-2013 31-May-2014
```

```
y = year(t)
```

```
y =
```

2010

2011

2012

2013

2014

## Input Arguments

### **t** — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

### **yearType** — Type of year values

'iso' (default) | 'gregorian'

Type of year values, specified as either 'iso' or 'gregorian'.

- If `yearType` is 'iso', then `year` returns the ISO year number, which includes a year zero and represents years BCE using negative values.
- If `yearType` is 'gregorian', then `year` returns the Gregorian year number, which is an unsigned integer. For example, the Gregorian year number for 5 CE and 5 BCE is 5 in both cases. Gregorian year numbers do not have a year zero.

## See Also

`datetime` Properties | `day` | `month` | `quarter` | `week` | `ymd`

**Introduced in R2014b**

## years

Duration in years

### Syntax

`Y = years(X)`

### Description

`Y = years(X)` returns an array of years equivalent to the values in `X`.

- If `X` is a numeric array, then `Y` is a **duration** array in units of fixed-length years. A fixed-length year is equal to 365.2425 days.
- If `X` is a **duration** array, then `Y` is a **double** array with each element equal to the number of fixed-length years in the corresponding element of `X`.

The `years` function converts between **duration** and **double** values. To display a duration in units of years, set its `Format` property to `'y'`.

### Examples

#### Create Duration Array of Fixed-Length Years

```
X = [1 3 5; 10 12 15]
```

```
X =
```

```
 1 3 5
 10 12 15
```

```
Y = years(X)
```

```
Y =
```

```

 1 yr 3 yrs 5 yrs
10 yrs 12 yrs 15 yrs

```

## Convert Durations to Numeric Array of Years

Find the difference between two arrays of dates. The output is a **duration** array.

```

t1 = datetime(2007:2010,10,1);
t2 = datetime(2014,05,1);
dt = t2 - t1

```

```

dt =

 57696:00:00 48912:00:00 40152:00:00 31392:00:00

```

Convert each duration in **dt** to a number of fixed-length years.

```

Y = years(dt)

```

```

Y =

 6.5819 5.5799 4.5805 3.5812

```

## Input Arguments

### X — Input array

numeric array | duration array | logical array

Input array, specified as a numeric array, duration array, or logical array.

## More About

### Tips

- `years` creates fixed-length years. To create an array of calendar years that account for leap days when used in calendar calculations, use the `calyears` function.

**See Also**  
calyears

**Introduced in R2014b**

# ylabel

Label y-axis

## Syntax

```
ylabel(str)
ylabel(str,Name,Value)
```

```
ylabel(ax, ___)
```

```
h = ylabel(___)
```

## Description

`ylabel(str)` labels the *y*-axis of the current axes with the string, `str`. Reissuing the `ylabel` command causes the new label to replace the old label. Labels appear beside the axis in a two-dimensional view and to the side or in front of the axis in a three-dimensional view.

`ylabel(str,Name,Value)` additionally specifies the text object properties using one or more `Name,Value` pair arguments.

`ylabel(ax, ___)` adds the label to the axes specified by `ax`. This syntax allows you to specify the axes to which to add a label. `ax` can precede any of the input argument combinations in the previous syntaxes.

`h = ylabel( ___)` returns the handle to the text object used as the *y*-axis label. The handle is useful when making future modifications to the label.

## Examples

### Label y-Axis with String

```
figure
```

```
plot((1:10).^2)
ylabel('Population')
```

MATLAB® displays Population beside the y-axis.

### Label y-Axis with Numeric Input

```
figure
plot((1:10).^2)
ylabel(123)
```

MATLAB® displays 123 beside the y-axis.

### Create Multiline Label

Create a multiline label using a multiline cell array.

```
figure
plot((1:10).^2)
ylabel({'2010'; 'Population'; 'in Years'})
```

### Include Superscript and Subscript in Axis Labels

Use the '^' and '\_' characters to include superscripts and subscripts in the axis labels. Use curly braces {} to modify more than one character.

```
t = linspace(0,1);
y = exp(t);
plot(t,y)
xlabel('t_{seconds}')
ylabel('e^t')
```

### Create y-Axis Label and Set Font Properties

Use Name, Value pairs to set the font size, font weight, and text color properties of the y-axis label.

```
figure
plot((1:10).^2)
ylabel('Population','FontSize',12,...
 'FontWeight','bold','Color','r')
```

'FontSize', 12 displays the label text in 12-point font. 'FontWeight', 'bold' makes the text bold. 'Color', 'r' sets the text color to red.

### Label y-Axis of Specific Axes

Create two subplots and return the axes handles, s(1) and s(2).

```
figure
s(1) = subplot(2,1,1);
plot((1:10).^2)
s(2) = subplot(2,1,2);
plot((1:10).^3)
```

Label the y-axis of the top plot by referring to its axes handle, `s(1)`.

```
ylabel(s(1), 'Population')
```

### Label y-Axis and Return Object Handle

Label the y-axis and return the handle to the text object used as the label.

```
plot((1:10).^2)
t = ylabel('Population');
```

Set the color of the label to red. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
t.Color = 'red';
```

- “Add Text to Graph Interactively”

## Input Arguments

### **str** — Axis label

character array | cell array | numeric value

Axis label, specified as a character array, cell array, or numeric value.

Example: 'my label'

Example: {'first line', 'second line'}

Example: 123

To include numeric variables with text in a label, use the `num2str` function. For example:

```
x = 42;
str = ['The value is ', num2str(x)];
```

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols use TeX markup. For a list of supported markup, see the `Interpreter` property.

To create multiline labels:

- Use a cell array, where each cell contains a line of text, such as `{'first line', 'second line'}`.
- Use a character array, where each row contains the same number of characters, such as `['abc'; 'ab ']`.
- Use `sprintf` to create a string with a new line character, such as `sprintf('first line \n second line')`.

Numeric labels are converted to text using `sprintf('%g', value)`. For example, 12345678 displays as 1.23457e+07.

---

**Note:** The words `default`, `factory`, and `remove` are reserved words that will not appear in a label when quoted as a normal string. To display any of these words individually, precede them with a backslash, such as `'\default'` or `'\remove'`.

---

## **ax** — Axes object

axes object

Axes object. If you do not specify an axes, then the `ylabel` function uses the current axes.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Color', 'red', 'FontSize', 12` specifies red, 12-point font.

In addition to the following, you can specify other text object properties using `Name, Value` pair arguments. See [Text Properties](#).

## **'FontSize' — Font size**

11 (default) | scalar value greater than 0

Font size, specified as a scalar value greater than 0 in point units. One point equals 1/72 inch. To change the font units, use the `FontUnits` property.

Setting the font size properties for the associated axes also affects the label font size. The label font size updates to equal the axes font size times the label scale factor. The `FontSize` property of the axes contains the axes font size. The `LabelFontSizeMultiplier` property of the axes contains the label scale factor. By default, the axes font size is 10 points and the scale factor is 1.1, so the y-axis label font size is 11 points.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **'FontWeight' — Thickness of text characters**

'normal' (default) | 'bold'

Thickness of the text characters, specified as one of these values:

- 'normal' — Default weight as defined by the particular font
- 'bold' — Thicker character outlines than normal

MATLAB uses the `FontWeight` property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight still can result in the normal font weight.

---

**Note:** The 'light' and 'demi' font weight values have been removed. Use 'normal' instead.

---

## **'FontName' — Font name**

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. The `'FixedWidth'` value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

### 'Color' — Text color

`[0.15 0.15 0.15]` (default) | RGB triplet | color string | `'none'`

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. If you set the color to `'none'`, then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
<code>'yellow'</code>	<code>'y'</code>	<code>[1 1 0]</code>
<code>'magenta'</code>	<code>'m'</code>	<code>[1 0 1]</code>
<code>'cyan'</code>	<code>'c'</code>	<code>[0 1 1]</code>
<code>'red'</code>	<code>'r'</code>	<code>[1 0 0]</code>
<code>'green'</code>	<code>'g'</code>	<code>[0 1 0]</code>
<code>'blue'</code>	<code>'b'</code>	<code>[0 0 1]</code>
<code>'white'</code>	<code>'w'</code>	<code>[1 1 1]</code>
<code>'black'</code>	<code>'k'</code>	<code>[0 0 0]</code>

Example: `'blue'`

Example: `[0 0 1]`

### 'Interpreter' — Interpretation of text characters

`'tex'` (default) | `'latex'` | `'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup.
- `'latex'` — Interpret text strings using LaTeX markup.

- 'none' — Display literal characters.

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers with the `Interpreter` property set to 'tex'. Modifiers remain in effect until the end of the string. Superscripts and subscripts are an exception because they only modify the next character or the text within the curly braces {}.

Modifier	Description	Example of String
<code>^{ }</code>	Superscript	'text <sup>{superscript}</sup> '
<code>_{ }</code>	Subscript	'text <sub>{subscript}</sub> '
<code>\bf</code>	Bold font	'\bf text'
<code>\it</code>	Italic font	'\it text'
<code>\sl</code>	Oblique font (usually the same as italic font)	'\sl text'
<code>\rm</code>	Normal font	'\rm text'
<code>\fontname{specifier}</code>	Font name — Set <code>specifier</code> as the name of a font family. You can use this in combination with other modifiers.	'\fontname{Courier} text'
<code>\fontsize{specifier}</code>	Font size — Set <code>specifier</code> as a numeric scalar value in point units to change the font size.	'\fontsize{15} text'
<code>\color{specifier}</code>	Font color — Set <code>specifier</code> as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue.	'\color{magenta} text'

Modifier	Description	Example of String
<code>\color[rgb]{specifier}</code>	Custom font color — Set specifier as a three-element RGB triplet.	<code>'\color[rgb]{0,0.5,0.5} text'</code>

This table lists the supported special characters with the Interpreter property set to 'tex'.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol

<code>\vee</code>	$\vee$	<code>\langle</code>	$\langle$	<code>\copyright</code>	$\copyright$

## LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at <http://www.latex-project.org/>.

## Output Arguments

**h** — Text object  
text object

Text object used as the  $y$ -axis label. Use `h` to access and modify properties of the label after its created.

## See Also

### Functions

`num2str` | `text` | `title` | `xlabel` | `ylabel`

### Properties

Text Properties

**Introduced before R2006a**

## **ymd**

Year, month, and day numbers of datetime

### **Syntax**

```
[y,m,d] = ymd(t)
```

### **Description**

`[y,m,d] = ymd(t)` returns the year, month, and day numbers of the datetime values in `t` as separate numeric arrays. The `y`, `m`, and `d` outputs are the same size as `t`, and contain integer values.

The `ymd` function is equivalent to calling the `year`, `month`, and `day` functions on the same datetime array.

### **Examples**

#### **Find Year, Month, and Day Numbers of Dates**

```
t = datetime(2013,05,31):calmonths(3):datetime(2014,06,15)
```

```
t =
```

```
 31-May-2013 31-Aug-2013 30-Nov-2013 28-Feb-2014 31-May-2014
```

```
[y,m,d] = ymd(t)
```

```
y =
```

```
 2013 2013 2013 2014 2014
```

```
m =
```

```
 5 8 11 2 5
d =
 31 31 30 28 31
```

`ymd` returns the year, month, and day values in separate arrays.

## Input Arguments

### **t** — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

## Output Arguments

### **y** — ISO year numbers

scalar | vector | matrix | multidimensional array

ISO year numbers, returned as a scalar, vector, matrix, or multidimensional array of integer values. ISO year numbers include a year zero and represent years BCE using negative values. `y` is of type `double` and is the same size as `t`.

### **m** — Month numbers

scalar | vector | matrix | multidimensional array

Month numbers, returned as a scalar, vector, matrix, or multidimensional array of integer values from 1 to 12. `m` is of type `double` and is the same size as `t`.

### **d** — Day of month numbers

scalar | vector | matrix | multidimensional array

Day of month numbers, returned as a scalar, vector, matrix, or multidimensional array of integer values from 1 to 28, 29, 30, or 31, depending on the month and year. `d` is of type `double` and is the same size as `t`.

**See Also**

day | hms | month | quarter | week | year

**Introduced in R2014b**

# yyymmdd

Convert MATLAB datetime to YYYYMMDD numeric value

## Syntax

```
d = yyymmdd(t)
```

## Description

`d = yyymmdd(t)` returns a **double** array containing integers whose digits represent the datetime values in `t`. For example, the date July 16, 2014 is converted to the integer 20140716. The conversion is performed this way:

```
d = 10000*year(t) + 100*month(t) + day(t)
```

## Examples

### Convert Datetime Array to YYYYMMDD Numeric Values

Create an array of YYYYMMDD numeric values that represent dates.

```
d = [20140628 20140701 20140704]
```

```
d =
```

```
 20140628 20140701 20140704
```

Convert the dates to datetime values.

```
t = datetime(d, 'ConvertFrom', 'yyymmdd')
```

```
t =
```

```
 28-Jun-2014 00:00:00 01-Jul-2014 00:00:00 04-Jul-2014 00:00:00
```

Convert the datetime values back to YYYYMMDD numeric values.

```
d2 = yyyymmdd(t)
```

```
d2 =
```

```
20140628 20140701 20140704
```

## Input Arguments

**t** — Input date and time

datetime array

Input date and time, specified as a `datetime` array.

## See Also

`datenum` | `datetime` | `exceltime` | `juliandate` | `posixtime`

**Introduced in R2014b**

# zlabel

Label z-axis

## Syntax

```
zlabel(str)
zlabel(str,Name,Value)
```

```
zlabel(ax, ___)
```

```
h = zlabel(___)
```

## Description

`zlabel(str)` labels the *z*-axis of the current axes with the string, `str`. Reissuing the `zlabel` command causes the new label to replace the old label.

`zlabel(str,Name,Value)` additionally specifies the text object properties using one or more `Name,Value` pair arguments.

`zlabel(ax, ___)` adds the label to the axes specified by `ax`. This syntax allows you to specify the axes to which to add a label. `ax` can precede any of the input argument combinations in the previous syntaxes.

`h = zlabel( ___)` returns the handle to the text object used as the *z*-axis label. The handle is useful when making future modifications to the label.

## Examples

### Label z-Axis with String

```
figure
surf(peaks)
zlabel('Height')
```

MATLAB® displays Height beside the z-axis.

**Label z-Axis with Numeric Input**

```
figure
surf(peaks)
zlabel(123)
```

MATLAB® displays 123 beside the z-axis.

### Create Multiline z-Axis Label

Create a multiline label using a multiline cell array.

```
figure
surf(peaks)
zlabel({'First Line'; 'Second Line'})
```

### Label z-Axis and Set Font Properties

Use Name, Value pairs to set the font size, font weight, and text color properties of the z-axis label.

```
figure
surf(peaks)
xlabel('Elevation','FontSize',12,...
 'FontWeight','bold','Color','r')
```

'FontSize', 12 displays the label text in 12-point font. 'FontWeight', 'bold' makes the text bold. 'Color', 'r' sets the text color to red.

### Label z-Axis of Specific Axes

Create two subplots and return the handles to the axes objects, `s(1)` and `s(2)`.

```
figure
s(1) = subplot(2,1,1);
surf(peaks(30))
s(2) = subplot(2,1,2);
surf(peaks(45))
```

Label the z-axis of each plot by referring to the axes handles, s(1) and s(2).

```
zlabel(s(1), 'Height1')
zlabel(s(2), 'Height2')
```

### Label z-Axis and Return Object Handle

Label the  $z$ -axis and return the text object used as the label.

```
surf(peaks)
t = zlabel('Population Change');
```

Set the color of the label to red. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
t.Color = 'red';
```

- “Add Text to Graph Interactively”

## Input Arguments

### **str** – Axis label

character array | cell array | numeric value

Axis label, specified as a character array, cell array, or numeric value.

Example: 'my label'

Example: {'first line', 'second line'}

Example: 123

To include numeric variables with text in a label, use the `num2str` function. For example:

```
x = 42;
str = ['The value is ', num2str(x)];
```

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols use TeX markup. For a list of supported markup, see the `Interpreter` property.

To create multiline labels:

- Use a cell array, where each cell contains a line of text, such as `{'first line', 'second line'}`.
- Use a character array, where each row contains the same number of characters, such as `['abc'; 'ab ']`.
- Use `sprintf` to create a string with a new line character, such as `sprintf('first line \n second line')`.

Numeric labels are converted to text using `sprintf('%g', value)`. For example, 12345678 displays as 1.23457e+07.

---

**Note:** The words `default`, `factory`, and `remove` are reserved words that will not appear in a label when quoted as a normal string. To display any of these words individually, precede them with a backslash, such as `'\default'` or `'\remove'`.

---

## **ax** — Axes object

axes object

Axes object. If you do not specify an axes, then the `zlabel` function uses the current axes.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Color', 'red', 'FontSize', 12` specifies red, 12-point font.

In addition to the following, you can specify other text object properties using `Name, Value` pair arguments. See [Text Properties](#).

### **'FontSize' — Font size**

11 (default) | scalar value greater than 0

Font size, specified as a scalar value greater than 0 in point units. One point equals 1/72 inch. To change the font units, use the `FontUnits` property.

Setting the font size properties for the associated axes also affects the label font size. The label font size updates to equal the axes font size times the label scale factor. The `FontSize` property of the axes contains the axes font size. The `LabelFontSizeMultiplier` property of the axes contains the label scale factor. By default, the axes font size is 10 points and the scale factor is 1.1, so the *z*-axis label font size is 11 points.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **'FontWeight' — Thickness of text characters**

'normal' (default) | 'bold'

Thickness of the text characters, specified as one of these values:

- 'normal' — Default weight as defined by the particular font
- 'bold' — Thicker character outlines than normal

MATLAB uses the `FontWeight` property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight still can result in the normal font weight.

---

**Note:** The 'light' and 'demi' font weight values have been removed. Use 'normal' instead.

---

### **'FontName' — Font name**

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. The `'FixedWidth'` value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

**'Color' — Text color**

`[0.15 0.15 0.15]` (default) | RGB triplet | color string | `'none'`

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. If you set the color to `'none'`, then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
<code>'yellow'</code>	<code>'y'</code>	<code>[1 1 0]</code>
<code>'magenta'</code>	<code>'m'</code>	<code>[1 0 1]</code>
<code>'cyan'</code>	<code>'c'</code>	<code>[0 1 1]</code>
<code>'red'</code>	<code>'r'</code>	<code>[1 0 0]</code>
<code>'green'</code>	<code>'g'</code>	<code>[0 1 0]</code>
<code>'blue'</code>	<code>'b'</code>	<code>[0 0 1]</code>
<code>'white'</code>	<code>'w'</code>	<code>[1 1 1]</code>
<code>'black'</code>	<code>'k'</code>	<code>[0 0 0]</code>

Example: `[0.5 0.6 0.7]`

Example: `'blue'`

**'Interpreter' — Interpretation of text characters**

`'tex'` (default) | `'latex'` | `'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup.
- `'latex'` — Interpret text strings using LaTeX markup.

- 'none' — Display literal characters.

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers with the `Interpreter` property set to 'tex'. Modifiers remain in effect until the end of the string. Superscripts and subscripts are an exception because they only modify the next character or the text within the curly braces {}.

Modifier	Description	Example of String
<code>^{ }</code>	Superscript	'text <sup>{superscript}</sup> '
<code>_{ }</code>	Subscript	'text <sub>{subscript}</sub> '
<code>\bf</code>	Bold font	'\bf text'
<code>\it</code>	Italic font	'\it text'
<code>\sl</code>	Oblique font (usually the same as italic font)	'\sl text'
<code>\rm</code>	Normal font	'\rm text'
<code>\fontname{specifier}</code>	Font name — Set <code>specifier</code> as the name of a font family. You can use this in combination with other modifiers.	'\fontname{Courier} text'
<code>\fontsize{specifier}</code>	Font size — Set <code>specifier</code> as a numeric scalar value in point units to change the font size.	'\fontsize{15} text'
<code>\color{specifier}</code>	Font color — Set <code>specifier</code> as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue.	'\color{magenta} text'

Modifier	Description	Example of String
<code>\color[rgb]{specifier}</code>	Custom font color — Set specifier as a three-element RGB triplet.	<code>'\color[rgb]{0,0.5,0.5} text'</code>

This table lists the supported special characters with the Interpreter property set to 'tex'.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol

## LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at <http://www.latex-project.org/>.

## Output Arguments

### **h** — Text object

text object

Text object used as the  $z$ -axis label. Use `h` to access and modify properties of the label after its created.

# xlim

Set or query  $x$ -axis limits

## Syntax

```
xlim(limits)
```

```
xlim auto
```

```
xlim manual
```

```
xl = xlim
```

```
m = xlim('mode')
```

```
___ = xlim(ax, ___)
```

## Description

`xlim(limits)` specifies the  $x$ -axis limits for the current axes. Specify `limits` as a two-element vector of the form `[xmin xmax]`, where `xmax` is a numeric value greater than `xmin`.

`xlim auto` lets the axes choose the  $x$ -axis limits. The axes chooses limits that span the range of the plotted data. This command sets the `XLimMode` property for the axes to `'auto'`.

`xlim manual` freezes the limits at the current values. Use this option if you want to retain the current limits when adding new data to the axes using the `hold on` command. This command sets the `XLimMode` property for the axes to `'manual'`.

`xl = xlim` returns a two-element vector containing the current limits.

`m = xlim('mode')` returns the current value of the limits mode, which is either `'auto'` or `'manual'`. By default, the mode is automatic unless you specify limits or set the mode to manual.

`___ = xlim(ax, ___)` uses the axes specified by `ax` instead of the current axes. The `ax` input argument can precede any of the input arguments in the previous syntaxes.

Use single quotes around input arguments that are character strings, for example, `xlim(ax, 'auto')` and `xlim(ax, 'manual')`. You can include any of the output arguments in the preceding syntaxes if the original syntax supports an output argument.

## Examples

### Set x-Axis Limits

Plot a line and set the *x*-axis limits to range from 0 to 5.

```
x = linspace(0,10);
y = sin(x);
plot(x,y)
xlim([0 5])
```

### Set x-Axis Limits for Specific Axes

Create a figure with two subplots and plot the same data in each subplot. Set the *x*-axis limits for the bottom subplot.

```
x = linspace(0,5,1000);
y = sin(100*x)./exp(x);
ax1 = subplot(2,1,1);
plot(x,y)
```

```
ax2 = subplot(2,1,2);
plot(x,y)
xlim(ax2,[0 1])
```

### Maintain Current x-Axis Limits

Use manual mode to maintain the current x-axis limits when you add more plots to the axes.

First, plot a line.

```
x = linspace(0,10);
y = sin(x);
plot(x,y);
```

Set the x-axis limits mode to manual so that the limits do not change. Use `hold on` to add a second plot to the axes.

```
xlim manual
hold on
plot(2*x,2*y)
hold off
```

The  $x$ -axis limits do not update to incorporate the new plot.

Switch back to automatically updated limits by resetting the mode to automatic.

```
xlim auto
```

### Return x-Axis Limits

Create a scatter plot of random data. Return the values of the *x*-axis limits.

```
x = randn(50,1);
y = randn(50,1);
scatter(x,y)
```

```
x1 = xlim
```

```
x1 =
```

```
 -3 4
```

## Input Arguments

**limits** — Minimum and maximum limits  
two-element vector

Minimum and maximum limits, specified as a two-element vector of the form [`xmin xmax`]. Specifying the *x*-axis limits sets the *x*-axis limits mode to manual. The `XLim` and `XLimMode` properties for the corresponding axes store the *x*-axis limits and the limits mode, respectively.

Changing the *x*-axis limits can cause other limits to change, unless their corresponding mode properties are set to manual.

Example: `[0 1]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **ax** — Axes object

axes object

Axes object. If you do not specify an axes, then `xlim` sets the limits for the current axes (`gca`).

## Output Arguments

### **x1** — Current limits

two-element vector

Current limits, returned as a two-element vector of the form [`xmin xmax`].

Querying the limits returns the `XLim` property value for the corresponding axes.

### **m** — Current limits mode

'auto' | 'manual'

Current limits mode, returned as one of these values:

- 'auto' — The limits automatically update to reflect changes in the data.
- 'manual' — The limits do not update to reflect changes in the data.

Querying the *x*-axis limits mode returns `XLimMode` property value for the corresponding axes.

## See Also

`axis` | `grid` | `hold` | `xlabel` | `ylim` | `zlim`

**Introduced before R2006a**

# ylim

Set or query *y*-axis limits

## Syntax

```
ylim(limits)
```

```
ylim auto
```

```
ylim manual
```

```
y1 = ylim
```

```
m = ylim('mode')
```

```
___ = ylim(ax, ___)
```

## Description

`ylim(limits)` sets the *y*-axis limits for the current axes. Specify `limits` as a two-element vector of the form `[ymin ymax]`, where `ymax` is a numeric value greater than `ymin`.

`ylim auto` lets the axes choose the *y*-axis limits. The axes chooses limits that span the range of the plotted data. This command sets the `YLimMode` property for the axes to `'auto'`.

`ylim manual` freezes the limits at the current values. Use this option if you want to retain the current limits when adding new data to the axes using the `hold on` command. This command sets the `YLimMode` property for the axes to `'manual'`.

`y1 = ylim` returns a two-element vector containing the current limits.

`m = ylim('mode')` returns the current value of the limits mode, which is either `'auto'` or `'manual'`. By default, the mode is automatic unless you specify limits or set the mode to manual.

`___ = ylim(ax, ___)` uses the axes specified by `ax` instead of the current axes. The `ax` input argument can precede any of the input arguments in the previous syntaxes.

Use single quotes around input arguments that are character strings, for example, `ylim(ax, 'auto')` and `ylim(ax, 'manual')`. You can include any of the output arguments in the preceding syntaxes if the original syntax supports an output argument.

## Examples

### Set y-Axis Limits

Plot a line and set the y-axis limits to range from -2 to 2.

```
x = linspace(0,10);
y = sin(x);
plot(x,y)
ylim([-2 2])
```

### Set y-Axis Limits for Specific Axes

Create a figure with two subplots and plot the same data in each subplot. Set the y-axis limits for the bottom subplot.

```
x = linspace(0,10,1000);
y = sin(10*x).*exp(.5*x);
ax1 = subplot(2,1,1);
plot(x,y)
```

```
ax2 = subplot(2,1,2);
plot(x,y)
ylim(ax2,[-10 10])
```

### Maintain Current y-Axis Limits

Use manual mode to maintain the current y-axis limits when you add more plots to the axes.

First, plot a line.

```
x = linspace(0,10);
y = sin(x);
plot(x,y)
```

Set the `y`-axis limits mode to manual so that the limits do not change. Use `hold on` to add a second plot to the axes.

```
ylim manual
hold on
y2 = 2*sin(x);
plot(x,y2)
hold off
```

The y-axis limits do not update to incorporate the new plot.

Switch back to automatically updated limits by resetting the mode to automatic.

```
ylim auto
```

### Return y-Axis Limits

Create a scatter plot of random data. Return the values of the y-axis limits.

```
x = randn(50,1);
y = randn(50,1);
scatter(x,y)
```

```
y1 = ylim
```

```
y1 =
```

```
 -2 3
```

## Input Arguments

**limits** — Minimum and maximum limits

two-element vector

Minimum and maximum limits, specified as a two-element vector of the form `[ymin ymax]`. Specifying the *y*-axis limits sets the *y*-axis limits mode to manual. The `YLim` and `YLimMode` properties for the corresponding axes store the *y*-axis limits and the limits mode, respectively.

Changing the *y*-axis limits can cause other limits to change, unless their corresponding mode properties are set to manual.

Example: `[0 1]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **ax** — Axes object

axes object

Axes object. If you do not specify an axes, then `ylim` sets the limits for the current axes (`gca`).

## Output Arguments

### **y1** — Current limits

two-element vector

Current limits, returned as a two-element vector of the form `[ymin ymax]`.

Querying the limits returns the `YLim` property value for the corresponding axes.

### **m** — Current limits mode

'auto' | 'manual'

Current limits mode, returned as one of these values:

- 'auto' — The limits update to reflect changes in the data.
- 'manual' — The limits do not update to reflect changes in the data.

Querying the *y*-axis limits mode returns `YLimMode` property value for the corresponding axes.

## See Also

`axis` | `grid` | `hold` | `xlim` | `ylabel` | `zlim`

**Introduced before R2006a**

# zlim

Set or query *z*-axis limits

## Syntax

```
zlim(limits)
```

```
zlim auto
```

```
zlim manual
```

```
zl = zlim
```

```
m = zlim('mode')
```

```
___ = zlim(ax, ___)
```

## Description

`zlim(limits)` sets the *z*-axis limits for the current axes. Specify `limits` as a two-element vector of the form `[zmin zmax]`, where `zmax` is a numeric value greater than `zmin`.

`zlim auto` lets the axes choose the *z*-axis limits. The axes chooses limits that span the range of the plotted data. This command sets the `ZLimMode` property for the axes to `'auto'`.

`zlim manual` freezes the limits at the current values. Use this option if you want to retain the current limits when adding new data to the axes using the `hold on` command. This command sets the `ZLimMode` property for the axes to `'manual'`.

`zl = zlim` returns a two-element vector containing the current limits.

`m = zlim('mode')` returns the current value of the limits mode, which is either `'auto'` or `'manual'`. By default, the mode is automatic unless you specify `limits` or set the mode to manual.

`___ = zlim(ax, ___)` uses the axes specified by `ax` instead of the current axes. The `ax` input argument can precede any of the input arguments in the previous syntaxes.

Use single quotes around input arguments that are character strings, for example, `zlim(ax, 'auto')` and `zlim(ax, 'manual')`. You can include any of the output arguments in the preceding syntaxes if the original syntax supports an output argument.

## Examples

### Set z-Axis Limits

Plot a surface and set the *z*-axis limits to range from -5 to 5.

```
[X,Y,Z] = peaks;
surf(X,Y,Z);
zlim([-5 5])
```

### Set z-Axis Limits for Specific Axes

Create a figure with two subplots and plot the same data in each subplot. Set the z-axis limits for the bottom subplot.

```
[X,Y,Z] = peaks;
ax1 = subplot(2,1,1);
surf(X,Y,Z)

ax2 = subplot(2,1,2);
surf(X,Y,Z)
zlim(ax2,[-5 5])
```

### Maintain Current z-Axis Limits

Use manual mode to maintain the current z-axis limits when you add more plots to the axes.

First, create a 3-D scatter plot.

```
theta = linspace(0,2*pi);
X = cos(theta);
Y = sin(theta);
Z = theta;
scatter3(X,Y,Z)
```

Set the z-axis limits mode to manual so that the limits do not change. Use `hold on` to add a second plot to the axes.

```
zlim manual
hold on
Znew = 5*theta;
scatter3(X,Y,Znew)
hold off
```

The z-axis limits do not update to incorporate the new plot.

Switch back to automatically updated limits by setting the mode to automatic.

```
zlim auto
```

### Return z-Axis Limits

Create a 3-D scatter plot of random data. Return the values of the z-axis limits.

```
x = randn(50,1);
y = randn(50,1);
z = randn(50,1);
scatter3(x,y,z)
```

```
z1 = zlim
```

```
z1 =
```

```
 -3 3
```

## Input Arguments

**limits** — Minimum and maximum limits  
two-element vector

Minimum and maximum limits, specified as a two-element vector of the form `[zmin zmax]`. Specifying the  $z$ -axis limits sets the  $z$ -axis limits mode to manual. The `ZLim` and `ZLimMode` properties for the corresponding axes store the  $z$ -axis limits and the limits mode, respectively.

Changing the  $z$ -axis limits can cause other limits to change, unless their corresponding mode properties are set to manual.

Example: `[0 1]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **ax** — Axes object

axes object

Axes object. If you do not specify an axes, then `zlim` sets the limits for the current axes (`gca`).

## Output Arguments

### **z1** — Current limits

two-element vector

Current limits, returned as a two-element vector of the form `[zmin zmax]`.

Querying the limits returns the `ZLim` property value for the corresponding axes.

### **m** — Current limits mode

'auto' | 'manual'

Current limits mode, returned as one of these values:

- 'auto' — The limits update to reflect changes in the data.
- 'manual' — The limits do not update to reflect changes in the data.

Querying the  $z$ -axis limits mode returns `ZLimMode` property value for the corresponding axes.

# xlsinfo

Determine if file contains Microsoft Excel spreadsheet

## Syntax

```
status = xlsinfo(filename)
[status,sheets] = xlsinfo(filename)
[status,sheets,xlFormat] = xlsinfo(filename)
```

## Description

`status = xlsinfo(filename)` indicates if `filename` is a file that the `xlsread` function can read.

`[status,sheets] = xlsinfo(filename)` additionally returns the name of each spreadsheet in the file.

`[status,sheets,xlFormat] = xlsinfo(filename)` also returns the format description that Excel returns for the file. On systems without Excel for Windows, `xlFormat` is an empty string, ''.

## Examples

### View Information About Spreadsheet File

Create a sample Excel file named `myExample.xlsx`.

```
values = {1, 2, 3 ; 4, 5, 'x' ; 7, 8, 9};
headers = {'First', 'Second', 'Third'};
xlswrite('myExample.xlsx', [headers; values]);
```

Call `xlsinfo` to get information about the file.

```
[status,sheets,xlFormat] = xlsinfo('myExample.xlsx')
status =
```

Microsoft Excel Spreadsheet

```
sheets =
 'Sheet1' 'Sheet2' 'Sheet3'
```

```
xlFormat =
```

```
xlOpenXMLWorkbook
```

**status** is a descriptive string indicating that the `xlsread` function can read the sample file.

## Input Arguments

**filename** — Name of file

string

Name of file, specified as a string.

Example: 'myFile.xlsx'

Data Types: char

## Output Arguments

**status** — Type of file

string

Type of file, returned as a string.

- If **filename** is a file that `xlsread` can read, then **status** is a descriptive string, such as 'Microsoft Excel Spreadsheet'.
- If **filename** is not a file that `xlsread` can read, then **status** is an empty string, ''.
- If MATLAB cannot find the file, then `xlsfinfo` returns an error.

**sheets** — Worksheet names

1-by-n cell array of strings

Worksheet names, returned as a 1-by- $n$  cell array of strings, where  $n$  is the number of worksheets in the file. Each cell contains the name of a worksheet. If `xlsread` cannot read a particular worksheet, the corresponding cell contains an error message.

If `xlsinfo` cannot read the file, then `sheets` contains an error message.

### **xlFormat** — File format description returned by Excel

string

File format description returned by Excel, returned as a string.

On Windows systems with Excel software, `xlFormat` is a nonempty string, such as one of the following.

'xlOpenXMLWorkbook'	Spreadsheet in XLSX format (Excel 2007 or later)
'xlWorkbookNormal' or 'xlExcel8'	Spreadsheet in XLS format (compatible with Excel 97-2003)
'xlCSV'	File in comma-separated value (CSV) format
'xlHtml' or 'xlWebArchive'	Spreadsheet exported to HTML format

On all other systems, `xlFormat` is an empty string, ''.

## Limitations

- `xlsinfo` supports only 7-bit ASCII characters.

## More About

### Tips

- If `xlsinfo` warns that it cannot start an ActiveX server, then the COM server, which is part of the typical Excel installation, is unavailable. In this case, consider reinstalling your Excel software. On systems with Excel for Windows, `xlsinfo` uses the COM server to obtain information.

`xlsread` | `xlswrite`

**Introduced before R2006a**

# xlsread

Read Microsoft Excel spreadsheet file

## Syntax

```
num = xlsread(filename)
num = xlsread(filename, sheet)
num = xlsread(filename, xlRange)
num = xlsread(filename, sheet, xlRange)
num = xlsread(filename, sheet, xlRange, 'basic')
[num, txt, raw] = xlsread(___)

___ = xlsread(filename, -1)

[num, txt, raw, custom] = xlsread(filename, sheet, xlRange, '', processFcn)
```

## Description

`num = xlsread(filename)` reads the first worksheet in the Microsoft Excel spreadsheet workbook named `filename` and returns the numeric data in a matrix.

`num = xlsread(filename, sheet)` reads the specified worksheet.

`num = xlsread(filename, xlRange)` reads from the specified range of the first worksheet in the workbook. Use Excel range syntax, such as `'A1:C3'`.

`num = xlsread(filename, sheet, xlRange)` reads from the specified worksheet and range.

`num = xlsread(filename, sheet, xlRange, 'basic')` reads data from the spreadsheet in `basic` import mode. If your computer does not have Excel for Windows, `xlsread` automatically operates in `basic` import mode, which supports XLS, XLSX, XLSM, XLTX, and XLTM files.

If you do not specify all the arguments, use empty strings as placeholders, for example, `num = xlsread(filename, '', '', 'basic')`.

`[num,txt,row] = xlsread( ___ )` additionally returns the text fields in cell array `txt`, and both numeric and text data in cell array `raw`, using any of the input arguments in the previous syntaxes.

`___ = xlsread(filename, -1)` opens an Excel window to interactively select data. Select the worksheet, drag and drop the mouse over the range you want, and click **OK**. This syntax is supported only on Windows computers with Microsoft Excel software installed.

`[num,txt,row,custom] = xlsread(filename, sheet, xlRange, '', processFcn)`, where `processFcn` is a function handle, reads from the spreadsheet, calls `processFcn` on the data, and returns the final results as numeric data in array `num`. The `xlsread` function returns the text fields in cell array `txt`, both the numeric and text data in cell array `raw`, and the second output from `processFcn` in array `custom`. The `xlsread` function does not change the data stored in the spreadsheet. This syntax is supported only on Windows computers with Excel software.

## Examples

### Read Worksheet Into Numeric Matrix

Create an Excel file named `myExample.xlsx`.

```
values = {1, 2, 3 ; 4, 5, 'x' ; 7, 8, 9};
headers = {'First', 'Second', 'Third'};
xlswrite('myExample.xlsx', [headers; values]);
```

Sheet1 of `myExample.xlsx` contains:

First	Second	Third
1	2	3
4	5	x
7	8	9

Read numeric data from the first worksheet.

```
filename = 'myExample.xlsx';
A = xlsread(filename)
```

```
A =
 1 2 3
 4 5 NaN
```

```
7 8 9
```

### Read Range of Cells

Read a specific range of data from the Excel file in the previous example.

```
filename = 'myExample.xlsx';
sheet = 1;
xlRange = 'B2:C3';

subsetA = xlsread(filename, sheet, xlRange)

subsetA =
 2 3
 5 NaN
```

### Read Column

Read the second column from the Excel file in the first example.

```
filename = 'myExample.xlsx';

columnB = xlsread(filename, 'B:B')

columnB =
 2
 5
 8
```

For better performance, include the row numbers in the range, such as 'B1:B3'.

### Request Numeric, Text, and Raw Data

Request the numeric data, text data, and combined data from the Excel file in the first example.

```
[num,txt,row] = xlsread('myExample.xlsx')

num =
 1 2 3
 4 5 NaN
 7 8 9

txt =
 'First' 'Second' 'Third'
 '' '' ''
```

```
 '' '' 'x'

raw =
 'First' 'Second' 'Third'
 [1] [2] [3]
 [4] [5] 'x'
 [7] [8] [9]
```

## Execute a Function on a Worksheet

In the Editor, create a function to process data from a worksheet. In this case, set values outside the range [0.2,0.8] to 0.2 or 0.8.

```
function [Data] = setMinMax(Data)

minval = 0.2;
maxval = 0.8;

for k = 1:Data.Count
 v = Data.Value{k};
 if v > maxval
 Data.Value{k} = maxval;
 elseif v < minval
 Data.Value{k} = minval;
 end
end
```

In the Command Window, add random data to `myExample.xlsx`.

```
A = rand(5);
xlswrite('myExample.xlsx',A,'MyData')
```

The worksheet named `MyData` contains values ranging from 0 to 1.

Read the data from the worksheet, and reset any values outside the range [0.2,0.8]. Specify the sheet name, but use '' as placeholders for the `xlRange` and 'basic' inputs.

```
trim = xlsread('myExample.xlsx','MyData','','',@setMinMax);
```

## Request Custom Output

Execute a function on a worksheet and display the custom index output.

In the Editor, modify the function `setMinMax` from the previous example to return the indices of the changed elements (custom output).

```

function [Data,indices] = setMinMax(Data)

minval = 0.2;
maxval = 0.8;
indices = [];

for k = 1:Data.Count
 v = Data.Value{k};
 if v > maxval
 Data.Value{k} = maxval;
 indices = [indices k];
 elseif v < minval
 Data.Value{k} = minval;
 indices = [indices k];
 end
end
end

```

Read the data from the worksheet `MyData`, and request the custom index output, `idx`.

```

[trim,txt,raw,idx] = xlsread('myExample.xlsx',...
 'MyData', '', '@setMinMax);

```

## Input Arguments

### **filename** — File name

string

File name, specified as a string. If you do not include an extension, `xlsread` searches for a file with the specified name and a supported Excel extension. `xlsread` can read data saved in files that are currently open in Excel for Windows.

Example: `'myFile.xlsx'`

Data Types: char

### **sheet** — Worksheet

string | positive integer

Worksheet, specified as one of the following:

- String that contains the worksheet name. The string cannot contain a colon (:). To determine the names of the sheets in a spreadsheet file, use `xlsfinfo`. For XLS files in `basic` mode, `sheet` is case sensitive.

- Positive integer that indicates the worksheet index. This option is not supported for XLS files in `basic` mode.

**x1Range — Rectangular range**

string

Rectangular range, specified as a string.

Specify `x1Range` using two opposing corners that define the region to read. For example, `'D2:H4'` represents the 3-by-5 rectangular region between the two corners `D2` and `H4` on the worksheet. The `x1Range` input is not case sensitive, and uses Excel A1 reference style (see Excel help).

Range selection is not supported when reading XLS files in `basic` mode. In this case, use `' '` in place of `x1Range`.

If you do not specify `sheet`, then `x1Range` must include both corners and a colon character, even for a single cell (such as `'D2:D2'`). Otherwise, `xlsread` interprets the input as a worksheet name (such as `'sales'` or `'D2'`).

If you specify `sheet`, then `x1Range`:

- Does not need to include a colon and opposite corner to describe a single cell.
- Can refer to a named range that you defined in the Excel file (see the Excel help).

When the specified `x1Range` overlaps merged cells:

- On Windows computers with Excel, `xlsread` expands the range to include all merged cells.
- On computers without Excel for Windows, `xlsread` returns data for the specified range only, with empty or NaN values for merged cells.

Data Types: char

**'basic' — Flag to request reading in basic mode**

literal string

Flag to request reading in `basic` mode, specified as the literal string, `'basic'`.

`basic` mode is the default for computers without Excel for Windows. In `basic` mode, `xlsread`:

- Reads XLS, XLSX, XLSM, XLTX, and XLTM files only.
- Does not support an `xlRange` input when reading XLS files. In this case, use `' '` in place of `xlRange`.
- Does not support function handle inputs.
- Imports all dates as Excel serial date numbers. Excel serial date numbers use a different reference date than MATLAB date numbers.

### **processFcn** — Handle to a custom function

function handle

Handle to a custom function. This argument is supported only on Windows computers with Excel software. `xlsread` reads from the spreadsheet, executes your function on a copy of the data, and returns the final results. `xlsread` does not change the data stored in the spreadsheet.

When `xlsread` calls the custom function, it passes a range interface from the Excel application to provide access to the data. The custom function must include this interface both as an input and output argument. (See “Execute a Function on a Worksheet” on page 1-9790)

Example: `@myFunction`

## Output Arguments

### **num** — Numeric data

matrix

Numeric data, returned as a matrix of `double` values. The array does not contain any information from header lines, or from outer rows or columns that contain nonnumeric data. Text data in inner spreadsheet rows and columns appear as `NaN` in the `num` output.

### **txt** — Text data

cell array

Text data, returned as a cell array. Numeric values in inner spreadsheet rows and columns appear as empty strings, `' '`, in `txt`.

For XLS files in `basic` import mode, the `txt` output contains empty strings, `' '`, in place of leading columns of numeric data that precede text data in the spreadsheet. In all other cases, `txt` does not contain these additional columns.

Undefined values (such as '#N/A') appear in the txt output as '#N/A', except for XLS files in `basic` mode.

**raw** — Numeric and text data

cell array

Numeric and text data from the worksheet, returned as a cell array.

On computers with Excel for Windows, undefined values (such as '#N/A') appear in the `raw` output as 'ActiveX\_VT\_ERROR:'. For XLSX, XLSM, XLTX, and XLTM files on other computers, undefined values appear as '#N/A'.

**custom** — Second output of the function corresponding to `processFcn`

defined by the function

Second output of the function corresponding to `processFcn`. The value and data type of `custom` are determined by the function.

## Limitations

- `xlsread` reads only 7-bit ASCII characters.
- `xlsread` does not support non-contiguous ranges.

## More About

### Algorithms

- `xlsread` imports formatted dates as strings (such as '10/31/96'), except in `basic` mode and on computers without Excel for Windows.
- “Import and Export Dates to Excel Files”
- “Create Function Handle”

### See Also

`importdata` | `readtable` | `uiimport` | `xlsinfo` | `xlswrite`

Introduced before R2006a

# xlswrite

Write Microsoft Excel spreadsheet file

## Syntax

```
xlswrite(filename,A)
xlswrite(filename,A, sheet)
xlswrite(filename,A,xlRange)
xlswrite(filename,A, sheet,xlRange)

status = xlswrite(___)
[status,message] = xlswrite(___)
```

## Description

`xlswrite(filename,A)` writes matrix `A` to the first worksheet in the Microsoft Excel spreadsheet workbook `filename` starting at cell `A1`.

`xlswrite(filename,A, sheet)` writes to the specified worksheet.

`xlswrite(filename,A,xlRange)` writes to the rectangular region specified by `xlRange` in the first worksheet of the workbook. Use Excel range syntax, such as `'A1:C3'`.

`xlswrite(filename,A, sheet,xlRange)` writes to the specified worksheet and range.

`status = xlswrite( ___ )` returns the status of the write operation, using any of the input arguments in previous syntaxes. When the operation is successful, status is 1. Otherwise, status is 0.

`[status,message] = xlswrite( ___ )` additionally returns any warning or error message generated by the write operation in structure `message`.

## Examples

### Write Vector to Spreadsheet

Write a 7-element vector to an Excel file.

```
filename = 'testdata.xlsx';
A = [12.7 5.02 -98 63.9 0 -.2 56];
xlswrite(filename,A)
```

## Write to Specific Sheet and Range in Spreadsheet

Write mixed text and numeric data to an Excel file starting at cell E1 of Sheet2.

```
filename = 'testdata.xlsx';
A = {'Time', 'Temperature'; 12,98; 13,99; 14,97};
sheet = 2;
xlRange = 'E1';
xlswrite(filename,A,sheet,xlRange)
```

## Input Arguments

### **filename** — File name

string

File name, specified as a string.

If **filename** does not exist, `xlswrite` creates a file, determining the format based on the specified extension. To create a file compatible with Excel 97-2003 software, specify an extension of `.xls`. To create files in Excel 2007 formats, specify an extension of `.xlsx`, `.xlsb`, or `.xlsm`. If you do not specify an extension, `xlswrite` uses the default, `.xls`.

Example: 'myFile.xlsx'

Example: 'C:\myFolder\myFile.xlsx'

### **A** — Input matrix

matrix

Input matrix, specified as a two-dimensional numeric or character array, or, if each cell contains a single element, a cell array.

If **A** is a cell array containing something other than a scalar numeric or a string, then `xlswrite` silently leaves the corresponding cell in the spreadsheet empty.

The maximum size of array **A** depends on the associated Excel version. For more information on Excel specifications and limits, see the Excel help.

Example: [10,2,45; -32,478,50]

Example: {92.0, 'Yes', 45.9, 'No'}

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | cell

### **sheet** — Worksheet name

string | positive integer

Worksheet name, specified as one of the following:

- String that contains the worksheet name. The string cannot contain a colon (:). To determine the names of the sheets in a spreadsheet file, use `xlsfinfo`.
- Positive integer that indicates the worksheet index.

If `sheet` does not exist, `xlswrite` adds a new sheet at the end of the worksheet collection. If `sheet` is an index larger than the number of worksheets, `xlswrite` appends empty sheets until the number of worksheets in the workbook equals `sheet`. In either case, `xlswrite` generates a warning indicating that it has added a new worksheet.

### **x1Range** — Rectangular range

string

Rectangular range, specified as a string.

Specify `x1Range` using two opposing corners that define the region to write. For example, 'D2:H4' represents the 3-by-5 rectangular region between the two corners D2 and H4 on the worksheet. The `x1Range` input is not case sensitive, and uses Excel A1 reference style (see Excel help). `xlswrite` does not recognize named ranges.

- If you do not specify `sheet`, then `x1Range` must include both corners and a colon character, even for a single cell (such as 'D2:D2'). Otherwise, `xlswrite` interprets the input as a worksheet name (such as 'D2').
- If you specify `sheet`, then `x1Range` can specify only the first cell (such as 'D2'). `xlswrite` writes input array `A` beginning at this cell.
- If `x1Range` is larger than the size of input array `A`, Excel software fills the remainder of the region with #N/A. If `x1Range` is smaller than the size of `A`, then `xlswrite` writes only the subset that fits into `x1Range` to the file.

## Output Arguments

### **status** — Status of the write operation

1 | 0

Status of the write operation, returned as either 1 (true) or 0 (false). When the write operation is successful, **status** is 1. Otherwise, **status** is 0.

### **message** — Error or warning generated during the write operation

structure array

Error or warning generated during the write operation, returned as a structure array containing two fields:

<b>message</b>	Text of the warning or error message, returned as a string.
<b>identifier</b>	Message identifier, returned as a string.

## Limitations

- If your computer does not have Excel for Windows, or if the COM server (part of the typical installation of Excel) is unavailable, then the `xlswrite` function:
  - Writes array **A** to a text file in comma-separated value (CSV) format. **A** must be a numeric matrix.
  - Ignores the `sheet` and `xlRange` arguments.

## More About

### Tips

- If your computer has Microsoft Office 2003 software, but you want to create a file in an Excel 2007 format, install the Office 2007 Compatibility Pack.
- Excel and MATLAB can store dates as strings (such as '10/31/96') or serial date numbers (such as 729329). If your array includes serial date numbers, convert the dates to strings using `datestr` before calling `xlswrite`. Alternatively, see “Import and Export Dates to Excel Files”.

- To write data to Excel files with custom formats (such as fonts or colors), access the Windows COM server directly using `actxserver` rather than `xlswrite`. For example, this MathWorks Support Answer uses `actxserver` to establish a connection between MATLAB and Excel, writes data to a worksheet, and specifies the colors of the cells.

### **Algorithms**

Excel converts `Inf` values to `65535`. MATLAB converts `NaN` values to empty cells.

### **See Also**

`writetable` | `xlsfinfo` | `xlsread`

**Introduced before R2006a**

## xmlread

Read XML document and return Document Object Model node

### Syntax

```
DOMnode = xmlread(filename)
```

### Description

`DOMnode = xmlread(filename)` reads the specified XML file and returns a Document Object Model node representing the document.

### Input Arguments

#### **filename**

String enclosed in single quotation marks that specifies the name of the local file or URL.

### Output Arguments

#### **DOMnode**

Document Object Model node, as defined by the World Wide Web consortium. For more information, see “What Is an XML Document Object Model (DOM)?”.

### Examples

The root element in an XML file sometimes includes an `xsi:noNamespaceSchemaLocation` attribute. The value of this attribute is the name of the preferred schema file. Call the `getAttribute` method to get this value:

```
xDoc = xmlread(fullfile(matlabroot,'toolbox',...
 'matlab','general','info.xml'));

xRoot = xDoc.getDocumentElement;
```

```
schema = char(xRoot.getAttribute('xsi:noNamespaceSchemaLocation'))
```

This code returns:

```
schema =
http://www.mathworks.com/namespace/info/v1/info.xsd
```

Create functions that parse data from an XML file into a MATLAB structure array with fields Name, Attributes, Data, and Children:

```
function theStruct = parseXML(filename)
% PARSEXML Convert XML file to a MATLAB structure.
try
 tree = xmlread(filename);
catch
 error('Failed to read XML file %s.',filename);
end

% Recurse over child nodes. This could run into problems
% with very deeply nested trees.
try
 theStruct = parseChildNodes(tree);
catch
 error('Unable to parse XML file %s.',filename);
end

% ----- Local function PARSECHILDNODES -----
function children = parseChildNodes(theNode)
% Recurse over node children.
children = [];
if theNode.hasChildNodes
 childNodes = theNode.getChildNodes;
 numChildNodes = childNodes.getLength;
 allocCell = cell(1, numChildNodes);

 children = struct(
 'Name', allocCell, 'Attributes', allocCell, ...
 'Data', allocCell, 'Children', allocCell);

 for count = 1:numChildNodes
 theChild = childNodes.item(count-1);
 children(count) = makeStructFromNode(theChild);
 end
end
end
```

```
% ----- Local function MAKESTRUCTFROMNODE -----
function nodeStruct = makeStructFromNode(theNode)
% Create structure of node info.

nodeStruct = struct(
 'Name', char(theNode.getNodeName), ...
 'Attributes', parseAttributes(theNode), ...
 'Data', '', ...
 'Children', parseChildNodes(theNode));

if any(strcmp(methods(theNode), 'getData'))
 nodeStruct.Data = char(theNode.getData);
else
 nodeStruct.Data = '';
end

% ----- Local function PARSEATTRIBUTES -----
function attributes = parseAttributes(theNode)
% Create attributes structure.

attributes = [];
if theNode.hasAttributes
 theAttributes = theNode.getAttributes;
 numAttributes = theAttributes.getLength;
 allocCell = cell(1, numAttributes);
 attributes = struct('Name', allocCell, 'Value', ...
 allocCell);

 for count = 1:numAttributes
 attrib = theAttributes.item(count-1);
 attributes(count).Name = char(attrib.getName);
 attributes(count).Value = char(attrib.getValue);
 end
end
end
```

## More About

### Tips

The display for a properly parsed document is [#document: null]. For example,

```
xDoc = xmlread('info.xml')
```

returns

xDoc =

[#document: null]

- “What Is an XML Document Object Model (DOM)?”
- “Example — Finding Text in an XML File”
- DOM Package Summary (methods and properties for nodes)

## **See Also**

xmlwrite | xslt

**Introduced before R2006a**

## xmlwrite

Write XML Document Object Model node

### Syntax

```
xmlwrite(filename,DOMnode)
str = xmlwrite(DOMnode)
```

### Description

`xmlwrite(filename,DOMnode)` writes the Document Object Model (DOM) node `DOMnode` to the file `filename`.

`str = xmlwrite(DOMnode)` serializes the DOM node to a string.

### Input Arguments

#### **filename**

String enclosed in single quotation marks that specifies the name of a local file or a URL.

#### **DOMnode**

Document Object Model node, as defined by the World Wide Web consortium. For more information, see “What Is an XML Document Object Model (DOM)?”

### Output Arguments

#### **str**

String that contains the serialized DOM node as it appears in an XML file.

### Examples

Create and view an XML document:

```
docNode = com.mathworks.xml.XMLUtils.createDocument...
 ('root_element')
docRootNode = docNode.getDocumentElement;
docRootNode.setAttribute('attr_name','attr_value');
for i=1:20
 thisElement = docNode.createElement('child_node');
 thisElement.appendChild...
 (docNode.createTextNode(sprintf('%i',i)));
 docRootNode.appendChild(thisElement);
end
docNode.appendChild(docNode.createComment('this is a comment'));

xmlFileName = [tempname, '.xml'];
xmlwrite(xmlFileName,docNode);
type(xmlFileName);
```

## xor

Logical exclusive-OR

### Syntax

`C = xor(A, B)`

### Description

`C = xor(A, B)` performs an exclusive OR operation on the corresponding elements of arrays `A` and `B`. The resulting element `C(i, j, ...)` is logical true (1) if `A(i, j, ...)` or `B(i, j, ...)`, but not both, is nonzero.

<b>A</b>	<b>B</b>	<b>C</b>
Zero	Zero	0
Zero	Nonzero	1
Nonzero	Zero	1
Nonzero	Nonzero	0

### Examples

Given `A = [0 0 pi eps]` and `B = [0 -2.4 0 1]`, then

```
C = xor(A,B)
```

```
C =
 0 1 1 0
```

To see where either `A` or `B` has a nonzero element and the other matrix does not,

```
spy(xor(A,B))
```

### More About

## xslt

Transform XML document using XSLT engine

### Syntax

```
result = xslt(source, style, dest)
[result,style] = xslt(___)
xslt(___ , '-web')
```

### Description

`result = xslt(source, style, dest)` transforms an XML document using a stylesheet and returns the resulting document's URL. The function uses these inputs, the first of which is required:

- `source` is the filename or URL of the source XML file. `source` can also specify a DOM node.
- `style` is the filename or URL of an XSL stylesheet.
- `dest` is the filename or URL of the desired output document. If `dest` is absent or empty, the function uses a temporary filename. If `dest` is `'-tostring'`, the function returns the output document as a MATLAB string.

`[result,style] = xslt( ___ )` returns a processed stylesheet appropriate for passing to subsequent XSLT calls as `style`. This prevents costly repeated processing of the stylesheet.

`xslt( ___ , '-web')` displays the resulting document in the Help Browser.

### Examples

This example converts the file `info.xml` using the stylesheet `info.xsl`, writing the output to the file `info.html`. It launches the resulting HTML file in the MATLAB Web Browser.

```
xslt('info.xml', 'info.xsl', 'info.html', '-web')
```

## More About

### Tips

MATLAB uses the Saxon XSLT processor, version 6.5.5, which supports XSLT 1.0 expressions. For more information, see <http://saxon.sourceforge.net/saxon6.5.5/>

For additional information on writing XSL stylesheets, see the World Wide Web Consortium (W3C<sup>®</sup>) web site, <http://www.w3.org/Style/XSL/>.

### See Also

`xmlread` | `xmlwrite`

**Introduced before R2006a**

## zeros

Create array of all zeros

### Syntax

```
X = zeros
X = zeros(n)
X = zeros(sz1, ..., szN)
X = zeros(sz)

X = zeros(____, typename)
X = zeros(____, 'like', p)
```

### Description

`X = zeros` returns the scalar 0.

`X = zeros(n)` returns an  $n$ -by- $n$  matrix of zeros.

`X = zeros(sz1, ..., szN)` returns an  $sz1$ -by-...-by- $szN$  array of zeros where  $sz1, \dots, szN$  indicate the size of each dimension. For example, `zeros(2,3)` returns a 2-by-3 matrix.

`X = zeros(sz)` returns an array of zeros where size vector `sz` defines `size(X)`. For example, `zeros([2 3])` returns a 2-by-3 matrix.

`X = zeros( ____, typename)` returns an array of zeros of data type `typename`. For example, `zeros('int8')` returns a scalar, 8-bit integer 0. You can use any of the input arguments in the previous syntaxes.

`X = zeros( ____, 'like', p)` returns an array of zeros like `p`; that is, of the same data type (class), sparsity, and complexity (real or complex) as `p`. You can specify `typename` or `'like'`, but not both.

## Examples

### Matrix of Zeros

Create a 4-by-4 matrix of zeros.

```
X = zeros(4)
```

```
X =
```

```

0 0 0 0
0 0 0 0
0 0 0 0
0 0 0 0
```

### 3-D Array of Zeros

Create a 2-by-3-by-4 array of zeros.

```
X = zeros(2,3,4);
size(X)
```

```
ans =
```

```

2 3 4
```

### Clone Size from Existing Array

Create an array of zeros that is the same size as an existing array.

```
A = [1 4; 2 5; 3 6];
sz = size(A);
X = zeros(sz)
```

```
X =
```

```

0 0
0 0
0 0
```

It is a common pattern to combine the previous two lines of code into a single line:

```
X = zeros(size(A));
```

### Specify Data Type of Zeros

Create a 1-by-3 vector of zeros whose elements are 32-bit unsigned integers.

```
X = zeros(1,3,'uint32')
X =
 0 0 0

class(X)
ans =
uint32
```

## Clone Complexity from Existing Array

Create a scalar 0 that is complex like an existing array instead of real valued.

First, create a complex vector.

```
p = [1+2i 3i];
```

Create a scalar 0 that is complex like p.

```
X = zeros('like',p)
```

```
X =
 0.0000 + 0.0000i
```

## Clone Sparsity from Existing Array

Create a 10-by-10 sparse matrix.

```
p = sparse(10,10,pi);
```

Create a 2-by-3 matrix of zeros that is sparse like p.

```
X = zeros(2,3,'like',p)
```

```
X =
All zero sparse: 2-by-3
```

## Clone Size and Data Type from Existing Array

Create a 2-by-3 array of 8-bit unsigned integers.

```
p = uint8([1 3 5 ; 2 4 6]);
```

Create an array of zeros that is the same size and data type as `p`.

```
X = zeros(size(p), 'like', p)
```

```
X =
```

```
 0 0 0
 0 0 0
```

```
class(X)
```

```
ans =
```

```
uint8
```

### Clone Distributed Array

If you have Parallel Computing Toolbox, create a 1000-by-1000 distributed array of zeros with underlying data type `int8`. For the `distributed` data type, the `'like'` syntax clones the underlying data type in addition to the primary data type.

```
p = zeros(1000, 'int8', 'distributed');
```

Create an array of zeros that is the same size, primary data type, and underlying data type as `p`.

```
X = zeros(size(p), 'like', p);
```

```
class(X)
```

```
ans =
```

```
distributed
```

```
classUnderlying(X)
```

```
ans =
```

```
int8
```

## Input Arguments

**n** — Size of square matrix

integer value

Size of square matrix, specified as an integer value.

- If `n` is 0, then `X` is an empty matrix.
- If `n` is negative, then it is treated as 0.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **`sz1, ..., szN` — Size of each dimension (as separate arguments)**

integer values

Size of each dimension, specified as separate arguments of integer values.

- If the size of any dimension is 0, then `X` is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- Beyond the second dimension, `zeros` ignores trailing dimensions with a size of 1. For example, `zeros([3, 1, 1, 1])` produces a 3-by-1 vector of zeros.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **`sz` — Size of each dimension (as a row vector)**

integer values

Size of each dimension, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension:

- If the size of any dimension is 0, then `X` is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- Beyond the second dimension, `zeros` ignores trailing dimensions with a size of 1. For example, `zeros([3, 1, 1, 1])` produces a 3-by-1 vector of zeros.

Example: `sz = [2, 3, 4]` creates a 2-by-3-by-4 array.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **`typename` — Data type (class) to create**

'double' (default) | 'single' | 'int8' | 'uint8' | ...

Data type (class) to create, specified as the string 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', 'uint64', or the name of another class that provides `zeros` support.

**p — Prototype of array to create**

numeric array

Prototype of array to create, specified as a numeric array.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 |  
uint32 | uint64

Complex Number Support: Yes

**Introduced before R2006a**

## zip

Compress files into zip file

### Syntax

```
zip(zipfile,files)
zip(zipfile,files,rootfolder)
entrynames = zip(zipfile,files,rootfolder)
```

### Description

`zip(zipfile,files)` creates a zip file with the name `zipfile` from the list of files and folders specified in `files`. Folders recursively include all of their content.

`zip(zipfile,files,rootfolder)` specifies the path for `files` relative to `rootfolder` instead of the current folder.

`entrynames = zip(zipfile,files,rootfolder)` returns a string cell array of the names of the files contained in `zipfile`. Specifying `rootfolder` is optional.

### Input Arguments

#### **zipfile**

String that specifies the name of the zip file. If `zipfile` has no extension, MATLAB appends the `.zip` extension.

If `files` includes relative paths, the zip file also contains relative paths. The zip file does not include absolute paths.

#### **files**

String or cell array of strings containing the list of files or folders to include in `zipfile`.

Individual files that are on the MATLAB path can be specified as partial path names. Otherwise an individual file can be specified relative to the current folder or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~username/`, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

### **rootfolder**

String that specifies the root of the paths for the files to zip.

Relative paths in the zip file reflect the relative paths in `files`, and do not include path information from `rootfolder`.

**Default:** current folder (`'.'`)

## **Output Arguments**

### **entrynames**

Cell array of strings that contain the paths to the files in `zipfile`. If `files` includes relative paths, `entrynames` also contains relative paths.

## **Examples**

### **Zip a File**

Create a zip file of the file `membrane.m`, which is in the MATLAB `general` folder. Save the zip file `tmwlogo.zip` in the current folder.

```
file = fullfile(matlabroot, 'toolbox', 'matlab', 'general', 'membrane.m');
zip('tmwlogo', file);
```

### **Zip Selected Files**

Suppose that your system has a folder named `d:/myfiles`. Zip the files `membrane.m` and `logo.m`, which are on the MATLAB search path, into a file named `tmwlogo.zip`.

```
myfile = fullfile('d:', 'myfiles', 'tmwlogo.zip');
zip(myfile, {'membrane.m', 'logo.m'});
```

Zip all `.m` and `.mat` files in the current folder to the file `backup.zip`.

```
zip('backup', {'*.m', '*.mat'});
```

## Zip a Folder

Suppose that your current folder contains a subfolder named `mywork`. Zip the contents of all subfolders of `mywork`, and store the relative paths in the zip file.

```
zip('myfiles.zip', 'mywork');
```

## Zip Between Folders

Suppose that you have files `thesis.doc` and `defense.ppt` in `d:/PhD`. Zip these files into `thesis.zip`, one level up from the current folder.

```
zip('../thesis.zip', {'thesis.doc', 'defense.ppt'}, 'd:/PhD');
```

## Create Zip Archive of Web Page

Create a zip archive of a Web page.

Locate the list of files at the MATLAB Central File Exchange uploaded within the past 7 days, that contain "Simulink."

```
filex = 'http://www.mathworks.com/matlabcentral/fileexchange/';
params = {'duration', '7', 'term', 'simulink'};
```

Save the Web content to a file.

```
urlwrite(filex, 'contains_simulink.html', 'get', params);
```

Create a zip archive of the retrieved Web page, using the `zip` function.

```
zip('simulink_matches.zip', 'contains_simulink.html');
```

`zip` creates a zip archive named `simulink_matches.zip` that contains the file, `contains_simulink.html`.

## Alternatives

To zip files in the Current Folder browser, select the files, right-click to open the context menu, and then select **Create Zip File**.

**Introduced before R2006a**

## zoom

Turn zooming on or off or magnify by factor

### Syntax

```
zoom on
zoom off
zoom out
zoom reset
zoom
zoom xon
zoom yon
zoom(factor)
zoom(fig, option)
h = zoom(figure_handle)
```

### Description

`zoom on` turns on interactive zooming. When interactive zooming is enabled in a figure, pressing a mouse button while your cursor is within an axes zooms into the point or out from the point beneath the mouse. Zooming changes the axes limits. When using `zoom` mode, you

- Zoom in by positioning the mouse cursor where you want the center of the plot to be and either
  - Press the mouse button or
  - Rotate the mouse scroll wheel away from you (upward).
- Zoom out by positioning the mouse cursor where you want the center of the plot to be and either
  - Simultaneously press **Shift** and the mouse button, or
  - Rotate the mouse scroll wheel toward you (downward).

Each mouse click or scroll wheel click zooms in or out by a factor of 2.

Clicking and dragging over an axes when zooming in is enabled draws a rubberband box. When you release the mouse button, the axes zoom in to the region enclosed by the rubberband box.

Double-clicking over an axes returns the axes to its initial zoom setting in both zoom-in and zoom-out modes.

`zoom off` turns interactive zooming off.

`zoom out` returns the plot to its initial zoom setting.

`zoom reset` remembers the current zoom setting as the initial zoom setting. Later calls to `zoom out`, or double-clicks when interactive `ZOOM` mode is enabled, will return to this zoom level.

`zoom` toggles the interactive zoom status between off and on (restoring the most recently used zoom tool).

`zoom xon` and `zoom yon` set `zoom on` for the  $x$ - and  $y$ -axis, respectively.

`zoom(factor)` zooms in or out by the specified zoom factor, without affecting the interactive zoom mode. Values greater than 1 zoom in by that amount, while numbers greater than 0 and less than 1 zoom out by  $1/\text{factor}$ .

`zoom(fig, option)` Any of the preceding options can be specified on a figure other than the current figure using this syntax.

`h = zoom(figure_handle)` returns a *zoom mode object* for the figure `figure_handle` for you to customize the mode's behavior.

## Using Zoom Mode Objects

You can access the following properties.

- *Enable* 'on' | 'off' — Specifies whether this figure mode is currently enabled on the figure
- *FigureHandle* <handle> — The associated figure handle, a read-only property that cannot be set
- *Motion* 'horizontal' | 'vertical' | 'both' — The type of zooming enabled for the figure

- *Direction* 'in' | 'out' — The direction of the zoom operation
- *RightClickAction* 'InverseZoom' | 'PostContextMenu' — The behavior of a right-click action

A value of 'InverseZoom' causes a right-click to zoom out. A value of 'PostContextMenu' displays a context menu. This setting persists between MATLAB sessions.

- *UIContextMenu* <handle> — Specifies a custom context menu to be displayed during a right-click action

This property is ignored if the *RightClickAction* property has been set to 'on'.

## Zoom Mode Callbacks

You can program the following callbacks for zoom mode operations.

- *ButtonDownFilter* <function\_handle> — Function to intercept *ButtonDown* events

The application can inhibit the zoom operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function [res] = myfunction(obj,event_obj)
% obj handle to the object clicked on
% event_obj struct for event data (empty in this release)
% res [output] a logical flag determines whether the zoom
% operation should take place(for 'res' set
% to 'false' or the 'ButtonDownFcn' property
% of the object should take precedence (when
% 'res' is 'true')
```

- *ActionPreCallback* <function\_handle> — Function to execute before zooming

Set this callback if you want to execute code when a zoom operation starts. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function myfunction(obj,event_obj)
% obj handle to the figure clicked on
% event_obj object containing struct of event data
```

The event data has the following field.

Axes	The handle of the axes that is being zoomed
------	---------------------------------------------

- **ActionPostCallback** <function\_handle> — Function to execute after zooming

Set this callback if you want to execute code when a zoom operation finishes. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function myfunction(obj,event_obj)
% obj handle to the figure clicked on
% event_obj object containing struct of event data
% (same as the event data of the
% 'ActionPreCallback' callback)
```

## Zoom Mode Utility Functions

The following functions in zoom mode query and set certain of its properties.

- **flags = isAllowAxesZoom(h,axes)** — Function querying permission to zoom axes

Calling the function `isAllowAxesZoom` on the zoom object, `h`, with a vector of axes handles, `axes`, as input returns a logical array of the same dimension as the axes handle vector, which indicates whether a zoom operation is permitted on the axes objects.

- **setAllowAxesZoom(h,axes,flag)** — Function to set permission to zoom axes

Calling the function `setAllowAxesZoom` on the zoom object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, either allows or disallows a zoom operation on the axes objects.

- **info = getAxesZoomMotion(h,axes)** — Function to get style of zoom operations

Calling the function `getAxesZoomMotion` on the zoom object, `H`, with a vector of axes handles, `axes`, as input returns a character cell array of the same dimension as the axes handle vector, which indicates the type of zoom operation for each axes. Possible values for the type of operation are 'horizontal', 'vertical', or 'both'.

- **setAxesZoomMotion(h,axes,style)** — Function to set style of zoom operations

Calling the function `setAxesZoomMotion` on the zoom object, `h`, with a vector of axes handles, `axes`, and a character array, `style`, sets the style of zooming on each axes.

## Examples

### Example 1 — Entering Zoom Mode

Plot a graph and turn on Zoom mode:

```
plot(1:10);
zoom on
% zoom in on the plot
```

### Example 2 — Constrained Zoom

Create zoom mode object and constrain to  $x$ -axis zooming:

```
plot(1:10);
h = zoom;
h.Motion = 'horizontal';
h.Enable = 'on';
% zoom in on the plot in the horizontal direction.
```

### Example 3 — Constrained Zoom in Subplots

Create four axes as subplots and set zoom style differently for each by setting a different property for each axes handle:

```
ax1 = subplot(2,2,1);
plot(1:10);
h = zoom;
ax2 = subplot(2,2,2);
plot(rand(3));
setAllowAxesZoom(h,ax2,false);
ax3 = subplot(2,2,3);
plot(peaks);
setAxesZoomMotion(h,ax3,'horizontal');
ax4 = subplot(2,2,4);
contour(peaks);
setAxesZoomMotion(h,ax4,'vertical');
```

```
% Zoom in on the plots.
```

## Example 4 — Coding a ButtonDown Callback

Create a `buttonDown` callback for zoom mode objects to trigger. Copy the following code to a new file, execute it, and observe zooming behavior:

```
function demo
% Allow a line to have its own 'ButtonDownFcn' callback.
hLine = plot(rand(1,10));
hLine.ButtonDownFcn = 'disp(''This executes'')';
hLine.Tag = 'DoNotIgnore';
h = zoom;
h.ButtonDownFilter = @mycallback;
h.Enable = 'on';
% mouse click on the line
%
function [flag] = mycallback(obj,event_obj)
% If the tag of the object is 'DoNotIgnore', then return true.
objTag = obj.Tag;
if strcmpi(objTag,'DoNotIgnore')
 flag = true;
else
 flag = false;
end
end
```

## Example 5 — Coding Pre- and Post-Callback Behavior

Create callbacks for pre- and post-`buttonDown` events for zoom mode objects to trigger. Copy the following code to a new file, execute it, and observe zoom behavior:

```
function demo
% Listen to zoom events
plot(1:10);
h = zoom;
h.ActionPreCallback = @myprecallback;
h.ActionPostCallback = @mypostcallback;
h.Enable = 'on';
%
function myprecallback(obj,evd)
disp('A zoom is about to occur.');
```

```
%
function mypostcallback(obj,evd)
```

```
newLim = evd.Axes.XLim;
msgbox(sprintf('The new X-Limits are [%.2f %.2f].',newLim));
```

## Example 6 — Creating a Context Menu for Zoom Mode

Coding a context menu that lets the user to switch to Pan mode by right-clicking:

```
figure
plot(magic(10))
hCMZ = uicontextmenu;
hZMenu = uimenu('Parent',hCMZ,'Label','Switch to pan',...
'Callback','pan(gcf,'on')');
hZoom = zoom(gcf);
hZoom.UIContextMenu = hCMZ;
zoom('on')
```

You cannot add items to the built-in zoom context menu, but you can replace it with your own.

## Alternatives

Use the Zoom tools  on the figure toolbar to zoom in or zoom out on a plot, or select **Zoom In** or **Zoom Out** from the figure's **Tools** menu. For details, see “Zooming in Graphs”.

## More About

### Tips

zoom changes the axes limits by a factor of 2 (in or out) each time you press the mouse button while the cursor is within an axes. You can also click and drag the mouse to define a zoom area, or double-click to return to the initial zoom level.

You can create a zoom mode object once and use it to customize the behavior of different axes, as Example 3 illustrates. You can also change its callback functions on the fly.

---

**Note:** Do not change figure callbacks within an interactive mode. While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change

any of the figure's callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a UI that updates a figure's callbacks, the UI should somehow keep track of which interactive mode is active, if any, before attempting to do this.

---

When you assign different zoom behaviors to different `subplot` axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse carries over to the linked axes, regardless of the behavior you previously set for the other axes.
