
Dates and time, returned as a `datetime` array. Each element includes a date and a time of day.

`t` has the following properties.

| Property | Description                                                                                 |
|----------|---------------------------------------------------------------------------------------------|
| Format   | Display format of the values in <code>t</code> , specified as a string                      |
| TimeZone | Time zone in which the values in <code>t</code> are interpreted, specified as a string      |
| Year     | Array containing the year number of each element in <code>t</code>                          |
| Month    | Array containing the month number of each element in <code>t</code>                         |
| Day      | Array containing the day of month number of each element in <code>t</code>                  |
| Hour     | Array containing the hour of each element in <code>t</code>                                 |
| Minute   | Array containing the minute of each element in <code>t</code>                               |
| Second   | Array containing the second, including a fractional part, of each element in <code>t</code> |

After you create a `datetime` array, `t`, you can access or change the value of any of its properties using dot notation. For example, to display the values of `t` in the format, 'yyyy-MM-dd', type:

```
t.Format = 'yyyy-MM-dd';
```

**Introduced in R2014b**

## datetime Properties

Assign date and time components and specify datetime display format

The `Format` property controls the display of `datetime` values. The other properties control the values of components such as years and months in the `datetime` array. Use dot notation to refer to a particular array and property:

```
t = datetime(2014,07,01,06,0,0);
t.Format = 'MMMM d, y';
```

### Properties

#### **Format** — Display format

'default' | 'defaultdate' | string

Display format, specified as a string of the letters A-Z and a-z, that correspond to the Unicode Locale Data Markup Language (LDML) standard for dates.

Example: 'eeee, MMMM d, yyyy HH:mm:ss' displays a date and time such as Saturday, April 5, 2014 21:41:06.

The following tables show the letters you can use to construct the value for `Format`. You can include nonletter characters such as a hyphen, space, colon, or any non-ASCII characters to separate the fields. To include the letters A-Z and a-z as literal characters in the format, enclose them with single quotes.

Example: 'uuuu-MM-dd' 'T' 'HH:mm:ss' displays a date and time, such as 2014-04-05T09:41:06.

The examples display the formatted output for the date, Saturday, April 5, 2014 at 9:41:06.12345 PM, in New York City.

## Date and Time Formats

Use these identifiers to specify the display formats of date and time fields.

| Letter Identifier | Description                                                        | Display |
|-------------------|--------------------------------------------------------------------|---------|
| G                 | Era                                                                | CE      |
| y                 | Year, with no leading zeros. See the Note that follows this table. | 2014    |

| Letter Identifier | Description                                                                                                                                                      | Display                                                               |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|
| yy                | Year, using last two digits. See the Note that follows this table.                                                                                               | 14                                                                    |
| yyy, yyyy ...     | Year, using at least the number of digits specified by the number of instances of 'y'                                                                            | For the year 2014, 'yyy' displays 2014, while 'yyyyy' displays 02014. |
| u, uu, ...        | ISO year. A single number designating the year. An ISO year value assigns positive values to CE years and negative values to BCE years, with 1 BCE being year 0. | 2014                                                                  |
| Q                 | Quarter, using one digit                                                                                                                                         | 2                                                                     |
| QQ                | Quarter, using two digits                                                                                                                                        | 02                                                                    |
| QQQ               | Quarter, abbreviated                                                                                                                                             | Q2                                                                    |
| QQQQ              | Quarter, full name                                                                                                                                               | 2nd quarter                                                           |
| M                 | Month, numerical using one or two digits                                                                                                                         | 4                                                                     |
| MM                | Month, numerical using two digits                                                                                                                                | 04                                                                    |
| MMM               | Month, abbreviated name                                                                                                                                          | Apr                                                                   |
| MMMM              | Month, full name                                                                                                                                                 | April                                                                 |
| MMMMM             | Month, capitalized first letter                                                                                                                                  | A                                                                     |
| W                 | Week of the month                                                                                                                                                | 1                                                                     |
| d                 | Day of the month, using one or two digits                                                                                                                        | 5                                                                     |
| dd                | Day of the month using two digits                                                                                                                                | 05                                                                    |
| D                 | Day of the year, using one, two or three digits                                                                                                                  | 95                                                                    |
| DD                | Day of the year using two digits                                                                                                                                 | 95                                                                    |
| DDD               | Day of the year using three digits                                                                                                                               | 095                                                                   |
| e                 | Day of the week, numerical using one or two digits.                                                                                                              | 7, where Sunday is the first day of the week.                         |

| H                        | Hour, 24-hour clock notation using one or two digits                                                        | 21                                      |
| HH                       | Hour, 24-hour clock notation using two digits                                                               | 21                                      |
| m                        | Minute, using one or two digits                                                                             | 41                                      |
| mm                       | Minute, using two digits                                                                                    | 41                                      |
| s                        | Second, using one or two digits                                                                             | 6                                       |
| ss                       | Second, using two digits                                                                                    | 06                                      |
| S, SS, ..., SSSSSSSS     | Fractional second, using the number of digits specified by the number of instances of 'S' (up to 9 digits). | 'SSS' truncates 6.12345 seconds to 123. |

---

**Note:** If you read a two-digit year number and specify the format as y or yy, then the pivot year determines the century to which the year belongs.

Use one or more u characters instead of y characters to represent the year when working with year numbers near zero.

Datetime values later than 144683 years CE or before 140743 BCE display only the year numbers, regardless of the specified **Format** value.

---

## Time Zone Offset Formats

Use these identifiers to specify the display format of the time zone offset. A time zone offset is the amount of time that a specific datetime is offset from UTC. This is different from a time zone, which comprises rules that determine the offsets that are used at specific times of the year. Include a time zone offset identifier in the display format for a datetime array when you want to ensure that the time components are displayed unambiguously.

| Letter Identifier | Description                                                                                                                                                | Display   |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| z                 | Abbreviated name of the time zone offset. If this value is not available, then the time zone offset uses the short UTC format, such as UTC-4.              | EDT       |
| Z                 | ISO 8601 basic format with hours, minutes, and optional seconds fields.                                                                                    | -0400     |
| ZZZZ              | Long UTC format.                                                                                                                                           | UTC-04:00 |
| ZZZZZ             | ISO 8601 extended format with hours, minutes, and optional seconds fields. A time offset of zero is displayed as the ISO 8601 UTC indicator "Z".           | -04:00    |
| x or X            | ISO 8601 basic format with hours field and optional minutes field. If you specify X, a time offset of zero is displayed as the ISO 8601 UTC indicator "Z". | -04       |
| xx or XX          | ISO 8601 basic format with hours and minutes fields. If you specify XX, a time offset of zero is displayed as the ISO 8601 UTC indicator "Z".              | -0400     |
| xxx or XXX        | ISO 8601 extended format with hours and minutes fields. If you specify XXX, a time offset of zero is displayed as the ISO 8601 UTC indicator "Z".          | -04:00    |

| Letter Identifier | Description                                                                                                                                                            | Display |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| xxxx or XXXX      | ISO 8601 basic format with hours, minutes, and optional seconds fields. If you specify XXXX, a time offset of zero is displayed as the ISO 8601 UTC indicator “Z”.     | -0400   |
| xxxxx or XXXXX    | ISO 8601 extended format with hours, minutes, and optional seconds fields. If you specify XXXXX, a time offset of zero is displayed as the ISO 8601 UTC indicator “Z”. | -04:00  |

**TimeZone** — Time zone

' ' (default) | string

Time zone, specified as one of the following strings:

- ' ', to create an “unzoned” `datetime` array that does not belong to a specific time zone.
- The name of a time zone region from the IANA Time Zone Database, for example, 'America/Los\_Angeles'. The name of a time zone region accounts for the current and historical rules for standard and daylight offsets from UTC that are observed in a geographic region.
- An ISO 8601 string of the form `+HH:mm` or `-HH:mm`, for example, '+01:00', to specify a time zone that is a fixed offset from UTC.
- 'UTC', to create a `datetime` array in Universal Coordinated Time.
- 'UTCLeapSeconds', to create a `datetime` array in Universal Coordinated Time that accounts for leap seconds.
- 'local', to create a `datetime` array in the system time zone. When you query the `TimeZone` property, the IANA string is returned.

This table lists some common names of time zone regions from the IANA Time Zone Database.

| Value of TimeZone     | UTC Offset | UTC DST Offset |
|-----------------------|------------|----------------|
| 'Africa/Johannesburg' | +02:00     | +02:00         |

| Value of TimeZone     | UTC Offset | UTC DST Offset |
|-----------------------|------------|----------------|
| 'America/Chicago'     | -06:00     | -05:00         |
| 'America/Denver'      | -07:00     | -06:00         |
| 'America/Los_Angeles' | -08:00     | -07:00         |
| 'America/New_York'    | -05:00     | -04:00         |
| 'America/Sao_Paulo'   | -03:00     | -02:00         |
| 'Asia/Hong_Kong'      | +08:00     | +08:00         |
| 'Asia/Kolkata'        | +05:30     | +05:30         |
| 'Asia/Tokyo'          | +09:00     | +09:00         |
| 'Australia/Sydney'    | +10:00     | +11:00         |
| 'Europe/London'       | +00:00     | +01:00         |
| 'Europe/Zurich'       | +01:00     | +02:00         |

You also can use the `timezones` function to display a list of IANA time zone names that the `datetime` function accepts.

Data Types: `char`

### **Year — Year number**

`scalar` | `vector` | `matrix` | `multidimensional array`

Year number of each value in the `datetime` array, specified as a scalar or a vector, matrix, or multidimensional array the same size and shape as the `datetime` array. Each year number is an integer value based on the ISO calendar. Years in the current era are positive and years in the previous era are zero or negative. For example, the year number of 1 BCE is 0.

If you set the `Year` property to a nonleap year for a `datetime` value that occurs on a leap day (February 29), then the `Day` and `Month` properties change to March 1.

### **Month — Month number**

`scalar` | `vector` | `matrix` | `multidimensional array`

Month number of each value in the `datetime` array, specified as a scalar or a vector, matrix, or multidimensional array the same size and shape as the `datetime` array. Each month number is an integer value from 1 to 12. If you set a value outside that range, then the `Year` property adjusts accordingly, and the `Month` property stays within the

range 1 to 12. For example, month 0 corresponds to month 12 of the previous year. For historical dates, the month number is based on the proleptic Gregorian calendar.

**Day — Day-of-month number**

scalar | vector | matrix | multidimensional array

Day-of-month number of each value in the `datetime` array, specified as a scalar or a vector, matrix, or multidimensional array the same size and shape as the `datetime` array. Each day-of-month number is an integer value from 1 to 28, 29, 30, or 31, depending on the month and year. If you set a value outside that range, then the `Month` and `Year` properties adjust accordingly, and the `Day` property stays within the appropriate range. For example, day 0 corresponds to the last day of the previous month. For historical dates, the day number is based on the proleptic Gregorian calendar.

**Hour — Hour number**

scalar | vector | matrix | multidimensional array

Hour number of each value in the `datetime` array, specified as a scalar or a vector, matrix, or multidimensional array the same size and shape as the `datetime` array. Each hour number is an integer value from 0 to 23. If you set a value outside that range, then the `Day`, `Month`, and `Year` properties adjust accordingly, and the `Hour` property stays within the appropriate range. For example, hour -1 corresponds to hour 23 of the previous day.

The following apply to `datetime` arrays with a specific time zone that follows daylight saving time:

- If you specify a value for the `Hour` property that would create a nonexistent datetime in the hour gap when daylight saving time begins, the value of the `Hour` property adjusts to the next hour.
- If you specify a value for the `Hour` property that would create an ambiguous datetime in the hour overlap when daylight saving time ends, then the datetime adjusts to the second of the two times (in standard time) with that hour.

**Minute — Minute number**

scalar | vector | matrix | multidimensional array

Minute number of each value in the `datetime` array, specified as a scalar or a vector, matrix, or multidimensional array the same size and shape as the `datetime` array. Each minute number is an integer value from 0 to 59. If you specify a value outside that range, then the `Hour`, `Day`, `Month`, and `Year` properties adjust accordingly, and the `Minute`

property stays within the appropriate range. For example, `minute -1` corresponds to minute 59 of the previous hour.

### **Second — Second**

scalar | vector | matrix | multidimensional array

Second of each value in the `datetime` array, specified as a scalar or a vector, matrix, or multidimensional array the same size and shape as the `datetime` array. Each second value is a floating-point value ordinarily ranging from 0 to less than 60. If you set a value outside that range, then the `Minute`, `Hour`, `Day`, `Month`, and `Year` properties adjust accordingly, and the `Second` property stays within the appropriate range. For example, `second -1` corresponds to second 59 of the previous minute.

A `datetime` array with a `TimeZone` value of `'UTCLeapSeconds'` has seconds ranging from 0 to less than 61. The values from 60 to 61 represent datetimes that occur during a leap second.

### **SystemTimeZone — System time zone setting**

string

This property is read only.

System time zone setting, specified as a string. This time zone setting is determined by the system on which MATLAB is running.

Example: `America/New_York`

### **See Also**

`datetime` | `timezones`

## datevec

Convert date and time to vector of components

The `datevec` function creates a numeric array whose values represent the date and time components of years, months, days, hours, minutes, and seconds. However, the best way to represent points in time is by using the `datetime` data type. The best way to represent elapsed time is by using the `duration` or `calendarDuration` data types.

### Syntax

`DateVector` = `datevec`(`t`)

`DateVector` = `datevec`(`DateNumber`)

`DateVector` = `datevec`(`DateString`)

`DateVector` = `datevec`(`DateString`,`formatIn`)

`DateVector` = `datevec`(`DateString`,`PivotYear`)

`DateVector` = `datevec`(`DateString`,`formatIn`,`PivotYear`)

[`Y`,`M`,`D`,`H`,`MN`,`S`] = `datevec`( \_\_\_ )

### Description

`DateVector` = `datevec`(`t`) converts the `datetime` values in `datetime` array `t` to date vectors. `datevec` returns an `m`-by-6 matrix where each row corresponds to a `datetime` value in `t`.

`DateVector` = `datevec`(`DateNumber`) converts one or more date numbers to date vectors. `datevec` returns an `m`-by-6 matrix containing `m` date vectors, where `m` is the total number of date numbers in `DateNumber`.

`DateVector` = `datevec`(`DateString`) converts date strings to date vectors. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

`DateVector` = `datevec`(`DateString`,`formatIn`) uses `formatIn` to interpret each date string.

`DateVector = datevec(DateString,PivotYear)` uses `PivotYear` to interpret date strings that specify the year as two characters. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

`DateVector = datevec(DateString,formatIn,PivotYear)` uses `formatIn` to interpret each date string, and `PivotYear` to interpret date strings that specify the year as two characters. You can specify `formatIn` and `PivotYear` in either order.

`[Y,M,D,H,MN,S] = datevec( ___ )` returns the components of the date vector as individual variables `Y`, `M`, `D`, `H`, `MN`, and `S` (year, month, day, hour, minutes and seconds). `datevec` returns milliseconds as a fractional part of the seconds (`S`) output.

## Examples

### Convert datetime Array to Date Vectors

```
format short g
```

```
t = [datetime('now');datetime('tomorrow')]
DateVector = datevec(t)
```

```
t =
```

```
24-Aug-2015 18:10:49
25-Aug-2015 00:00:00
```

```
DateVector =
```

```
2015 8 24 18 10 49.309
2015 8 25 0 0 0
```

### Convert Date Number to Date Vector

```
format short g
```

```
n = 733779.651;
datevec(n)
```

```
ans =
```

```
2009 1 6 15 37 26.4
```

## Convert Date String to Date Vector

```
DateString = '28.03.2005';
formatIn = 'dd.mm.yyyy';
datevec(DateString,formatIn)
```

```
ans =
```

```
2005 3 28 0 0 0
```

`datevec` returns a date vector for the date string with the format `'dd.mm.yyyy'`.

## Convert Multiple Date Strings to Date Vectors

Pass multiple date strings in a cell array. All input date strings must use the same format.

```
DateString = {'09/16/2007';'05/14/1996';'11/29/2010'};
formatIn = 'mm/dd/yyyy';
datevec(DateString,formatIn)
```

```
ans =
```

```
2007 9 16 0 0 0
1996 5 14 0 0 0
2010 11 29 0 0 0
```

## Convert Date with Milliseconds to Date Vector

```
datevec('11:21:02.647','HH:MM:SS.FFF')
```

```
ans =
```

```
1.0e+03 *
2.0150 0.0010 0.0010 0.0110 0.0210 0.0026
```

In the output date vector, milliseconds are a fractional part of the seconds field. The date string '11:21:02.647' does not contain enough information to convert to a full date vector. The days default to 1, months default to January, and years default to the current year.

### Convert Date String to Date Vector Using Pivot Year

Convert a date string to a date vector using the default pivot year.

```
DateString = '12-jun-17';
formatIn = 'dd-mmm-yy';
DateVector = datevec(DateString,formatIn)
```

```
DateVector =
 2017 6 12 0 0 0
```

Convert the same date string to a date vector using 1800 as the pivot year.

```
DateVector = datevec(DateString,formatIn,1800)
```

```
DateVector =
 1817 6 12 0 0 0
```

### Assign Elements of Returned Date Vector

Convert a date string to a date vector and return the components of the date vector.

```
[y, m, d, h, mn, s] = datevec('01.02.12','dd.mm.yy')
```

```
y =
 2012
```

```
m =
```

2

d =

1

h =

0

mn =

0

s =

0

## Input Arguments

### **t** — **datetime values**

scalar | vector | matrix | multidimensional array

**datetime** values, specified as a scalar, vector, matrix, or multidimensional **datetime** array.

### **DateNumber** — **Serial date number**

scalar | vector | multidimensional array

Serial date number, specified as a scalar, vector, or multidimensional array of positive double-precision numbers.

Example: 731878

Data Types: **double**

### **DateString** — **Date strings**

string | character array | 1-D cell array of strings

Date strings, specified as a character array where each row corresponds to one date string, or as a one dimensional cell array of strings. All of the date strings must have the same format.

Example: '24-Oct-2003 12:45:07'

Example: ['19-Sep-2013'; '20-Sep-2013'; '21-Sep-2013']

Example: {'15-Oct-2010' '20-Nov-2012'}

If the date string format is known, you should also specify `formatIn`. If you do not specify `formatIn`, `DateString` must be in one of the following formats.

| Date String Format     | Example              |
|------------------------|----------------------|
| 'dd-mmm-yyyy HH:MM:SS' | 01-Mar-2000 15:45:17 |
| 'dd-mmm-yyyy'          | 01-Mar-2000          |
| 'mm/dd/yyyy'           | 03/01/2000           |
| 'mm/dd/yy'             | 03/01/00             |
| 'mm/dd'                | 03/01                |
| 'mmm.dd,yyyy HH:MM:SS' | Mar.01,2000 15:45:17 |
| 'mmm.dd,yyyy'          | Mar.01,2000          |
| 'yyyy-mm-dd HH:MM:SS'  | 2000-03-01 15:45:17  |
| 'yyyy-mm-dd'           | 2000-03-01           |
| 'yyyy/mm/dd'           | 2000/03/01           |
| 'HH:MM:SS'             | 15:45:17             |
| 'HH:MM:SS PM'          | 3:45:17 PM           |
| 'HH:MM'                | 15:45                |
| 'HH:MM PM'             | 3:45 PM              |

---

**Note:** The symbolic identifiers describing date string formats are different from those that describe the display formats of `datetime` arrays.

---

Certain date string formats might not contain enough information to convert the date string. In those cases, hours, minutes, and seconds default to 0, days default to 1, months default to January, and years default to the current year. `datevec` and `datenum`

consider two-character date string years (e.g., '79') to fall within the 100-year range centered around the current year.

When you do not specify `formatIn`, note the following:

- For the formats that specify the month as two digits (mm), the month value must not be greater than 12.
- However, for the format 'mm/dd/yy', if the first entry in the date string is greater than 12 and the second entry is less than or equal to 12, then `datevec` considers the date string to be in 'yy/mm/dd' format.

### **formatIn — Format of the input date string**

string

Format of the input date string, specified as a string of symbolic identifiers.

The following table shows symbolic identifiers you can use to construct the `formatIn` string. You can include characters such as a hyphen, space, or colon to separate the fields.

---

**Note:** The symbolic identifiers describing date string formats are different from those that describe the display formats of `datetime` arrays.

---

| <b>Symbolic Identifier</b> | <b>Description</b>                        | <b>Example</b>  |
|----------------------------|-------------------------------------------|-----------------|
| yyyy                       | Year in full                              | 1990, 2002      |
| yy                         | Year in two digits                        | 90, 02          |
| QQ                         | Quarter year using letter Q and one digit | Q1              |
| mmmm                       | Month using full name                     | March, December |
| mmm                        | Month using first three letters           | Mar, Dec        |
| mm                         | Month in two digits                       | 03, 12          |
| m                          | Month using capitalized first letter      | M, D            |
| dddd                       | Day using full name                       | Monday, Tuesday |
| ddd                        | Day using first three letters             | Mon, Tue        |

| Symbolic Identifier | Description                                                                        | Example    |
|---------------------|------------------------------------------------------------------------------------|------------|
| dd                  | Day in two digits                                                                  | 05, 20     |
| d                   | Day using capitalized first letter                                                 | M, T       |
| HH                  | Hour in two digits<br>(no leading zeros when symbolic identifier AM or PM is used) | 05, 5 AM   |
| MM                  | Minute in two digits                                                               | 12, 02     |
| SS                  | Second in two digits                                                               | 07, 59     |
| FFF                 | Millisecond in three digits                                                        | 057        |
| AM or PM            | AM or PM inserted in date string                                                   | 3:45:02 PM |

The `formatIn` string must follow these guidelines:

- You cannot specify any field more than once. For example, you cannot use `'yy-mmm-dd-m'` because it has two month identifiers. The one exception to this is that you can combine one instance of `dd` with one instance of any of the other day identifiers. For example, `'dddd mmm dd yyyy'` is a valid input.
- When you use AM or PM, the HH field is also required.
- `datevec` does not accept formats that include `'QQ'`

### **PivotYear — Start year of 100-year date range**

present minus 50 years (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as an integer. Use a pivot year to interpret date strings that specify the year as two characters.

If `formatIn` contains the time of day, the pivot year is computed from the current time of the current day, month, and year. Otherwise it is computed from midnight of the current day, month, and year.

Example: 2000

Data Types: double

## Output Arguments

### **DateVector** — Date vectors

vector | matrix

Date vectors, returned as an  $m$ -by-6 matrix, where each row corresponds to one date vector, and  $m$  is the total number of input date numbers or date strings.

### **[Y,M,D,H,MN,S]** — Components of the date vector

scalar

Components of the date vector (year, month, day, hour, minute, and second), returned as individual scalar variables. Each variable is a scalar or a vector. Milliseconds are a fractional part of the seconds output. When converting a `datetime` array `t`, these components are equal to the values of the `Year`, `Month`, `Day`, `Hour`, `Minute`, and `Second` properties. For example, `Y = t.Year`.

## Limitations

- When computing date vectors, `datevec` sets month values less than 1 to 1. Day values, `D`, less than 1 are set to the last day of the previous month minus `|D|`. However, if  $0 \leq \text{DateNumber} < 1$ , then `datevec(DateNumber)` returns a date vector of the form `[0 0 0 H MN S]`, where `H`, `MN`, and `S` are hours, minutes, and seconds, respectively.

## More About

### Tips

- The vectorized calling syntax can offer significant performance improvement for large arrays.
- “Represent Dates and Times in MATLAB”

### See Also

`datenum` | `datestr` | `datetime`

**Introduced before R2006a**

## day

Day number or name

## Syntax

```
d = day(t)
d = day(t, dayType)
```

## Description

`d = day(t)` returns the day-of-month numbers for the datetime values in `t`. The `d` output contains integer values from 1 to 31, depending on the month and year.

`d = day(t, dayType)` returns the type of day number or name specified by `dayType`.

The `day` function returns the day numbers or names of datetime values. To assign day values to datetime array `t`, use `t.Day` and modify the `Day` property.

## Examples

### Extract Day Number from Dates

Extract the day of month numbers from an array of dates.

```
t = [datetime('yesterday');datetime('today');datetime('tomorrow')]
d = day(t)
```

```
t =
```

```
 23-Aug-2015
 24-Aug-2015
 25-Aug-2015
```

```
d =
```

```
23
24
25
```

## Determine Day of Week

Determine the day of the week for an arbitrary date, by specifying 'name' as the second input to the `day` function.

```
t = datetime(2014,05,16)
```

```
t =
```

```
16-May-2014
```

```
d = day(t, 'name')
```

```
d =
```

```
'Friday'
```

Alternatively, specify 'dayofweek' to return the day of the week as a number.

```
d = day(t, 'dayofweek')
```

```
d =
```

```
6
```

## Input Arguments

**t** — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

**dayType — Type of day values**`'dayofmonth'` (default) | `'dayofweek'` | `'dayofyear'` | `'name'` | `'shortname'`

Type of day values, specified as one of the following strings.

| Value of dayType          | Description                                                                                                                          |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <code>'dayofmonth'</code> | Day-of-month number, from 1 to 28, 29, 30, or 31. The range depends on the month.                                                    |
| <code>'dayofweek'</code>  | Day-of-week number, from 1 to 7, where day 1 of the week is Sunday.                                                                  |
| <code>'dayofyear'</code>  | Day-of-year number, from 1 to 365 or 366, depending on the year.                                                                     |
| <code>'name'</code>       | Full day names, for example, <b>Sunday</b> . For <b>NaT</b> datetime values, the day name is the empty string, <code>''</code> .     |
| <code>'shortname'</code>  | Abbreviated day names, for example, <b>Sun</b> . For <b>NaT</b> datetime values, the day name is the empty string, <code>''</code> . |

## Output Arguments

**d — Day number or name**`double` array | `cell` array of strings

Day number or name, returned as a numeric array of integers of type `double`, or a cell array of strings. `d` is the same size as `t`.

## See Also

# days

Duration in days

## Syntax

```
D = days(X)
```

## Description

`D = days(X)` returns an array of days equivalent to the values in `X`.

- If `X` is a numeric array, then `D` is a **duration** array in units of fixed-length days. A fixed-length day is equal to 24 hours.
- If `X` is a **duration** array, then `D` is a **double** array with each element equal to the number of fixed-length (24-hour) days in the corresponding element of `X`.

The `days` function converts between **duration** and **double** values. To display a duration in units of days, set its `Format` property to `'d'`.

## Examples

### Create Duration Array of Fixed-Length Days

```
X = magic(2);
D = days(X)
```

```
D =
```

```
 1 day 3 days
 4 days 2 days
```

Add each number of fixed-length days to the current date and time.

```
t = datetime('now') + D
```

t =

```
25-Aug-2015 17:52:51 27-Aug-2015 17:52:51
28-Aug-2015 17:52:51 26-Aug-2015 17:52:51
```

## Convert Durations to Numeric Array of Days

Create a duration array.

```
X = hours(23:20:95) + minutes(45)
```

X =

```
23.75 hrs 43.75 hrs 63.75 hrs 83.75 hrs
```

Convert each duration in X to a number of days.

```
D = days(X)
```

D =

```
0.9896 1.8229 2.6563 3.4896
```

## Input Arguments

### X — Input array

numeric array | duration array | logical array

Input array, specified as a numeric array, duration array, or logical array.

## More About

### Tips

- `days` creates fixed-length (24 hour) days. To create days that account for Daylight Saving Time shifts when used in calendar calculations, use the `caldays` function.

## **See Also**

caldays | duration

**Introduced in R2014b**

# dbclear

Clear breakpoints

## Syntax

```
dbclear all
dbclear in file ...
dbclear in file ... -completenames
dbclear if error ...
dbclear if warning ...
dbclear if naninf
dbclear if infnan
```

## Description

`dbclear all` removes all breakpoints in all MATLAB code files, as well as breakpoints set for errors, caught errors, caught error identifiers, warnings, warning identifiers, and `naninf/infnan`.

`dbclear in file ...` and `dbclear in file ... -completenames` formats are listed here:

| Format                                                | Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dbclear <b>in</b> file</code>                   | Removes all breakpoints in <code>file</code> . <code>file</code> must be the name of a MATLAB program file, and can include a MATLAB partial path.                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>dbclear <b>in</b> file - completenames</code>   | If the command includes the <code>-completenames</code> option, then <code>file</code> need not be on the path, as long as it is a fully qualified file name. (On Microsoft Windows platforms, this is a file name that begins with <code>\\</code> or with a drive letter followed by a colon. On UNIX platforms, this is a file name that begins with <code>/</code> or <code>~</code> .) <code>file</code> can include a <code>&gt;</code> to specify the path to a particular local function or to a nested function within a code file. |
| <code>dbclear <b>in</b> file <b>at</b> lineno</code>  | Removes the breakpoint set at line number <code>lineno</code> in <code>file</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>dbclear <b>in</b> file <b>at</b> lineno@</code> | Removes the breakpoint set in the anonymous function at line number <code>lineno</code> in <code>file</code> .                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Format                                   | Action                                                                                                                           |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>dbclear in file at lineno@n</code> | Removes the breakpoint set in the <code>n</code> th anonymous function at line number <code>lineno</code> in <code>file</code> . |
| <code>dbclear in file at locfun</code>   | Removes all breakpoints in local function <code>locfun</code> in <code>file</code> .                                             |

`dbclear if error` ... formats are listed here:

| Format                                          | Action                                                                                                                                                                                                                                                              |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dbclear if error</code>                   | Removes the breakpoints set using the <code>dbstop if error</code> and <code>dbstop if error identifier</code> statements.                                                                                                                                          |
| <code>dbclear if error identifier</code>        | Removes the breakpoint set using <code>dbstop if error identifier</code> for the specified <code>identifier</code> . Running this produces an error if <code>dbstop if error</code> or <code>dbstop if error all</code> is set.                                     |
| <code>dbclear if caught error</code>            | Removes the breakpoints set using the <code>dbstop if caught error</code> and <code>dbstop if caught error identifier</code> statements.                                                                                                                            |
| <code>dbclear if caught error identifier</code> | Removes the breakpoints set using the <code>dbstop if caught error identifier</code> statement for the specified <code>identifier</code> . Running this produces an error if <code>dbstop if caught error</code> or <code>dbstop if caught error all</code> is set. |

`dbclear if warning` ... formats are listed here:

|                                            |                                                                                                                                                                                                                                       |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dbclear if warning</code>            | Removes the breakpoints set using the <code>dbstop if warning</code> and <code>dbstop if warning identifier</code> statements.                                                                                                        |
| <code>dbclear if warning identifier</code> | Removes the breakpoint set using <code>dbstop if warning identifier</code> for the specified <code>identifier</code> . Running this produces an error if <code>dbstop if warning</code> or <code>dbstop if warning all</code> is set. |

`dbclear if naninf` removes the breakpoint set by `dbstop if naninf` or `dbstop if infnan`.

`dbclear if infnan` removes the breakpoint set by `dbstop if infnan` or `dbstop if naninf`.

## More About

### Tips

The **at** and **in** keywords are optional.

In the syntax, `file` can be a MATLAB program file, or the path to a function within a file. For example

```
dbclear in foo>myfun
```

clears the breakpoint at the `myfun` function in the file `foo.m`.

**Introduced before R2006a**

# dbcont

Resume execution

## Syntax

dbcont

## Description

dbcont resumes execution of a MATLAB code file from a breakpoint. Execution continues until another breakpoint is encountered, a pause condition is met, an error occurs, or MATLAB software returns to the base workspace prompt.

---

**Note** If you want to edit a file as a result of debugging, it is best to first quit debug mode and then edit and save changes to the file. If you edit a file while paused in debug mode, you can get unexpected results when you resume execution of the file and the results might not be reliable.

---

## See Also

dbclear | dbdown | dbquit | dbstack | dbstatus | dbstep | dbstop | dbtype | dbup

## Related Examples

- “Debug a MATLAB Program”

Introduced before R2006a

## dbdown

Reverse workspace shift performed by `dbup`, while in debug mode

### Syntax

```
dbdown
```

### Description

`dbdown` changes the current workspace context to the workspace of the called MATLAB code file when a breakpoint is encountered. You must have issued the `dbup` function at least once before you issue this function. `dbdown` is the opposite of `dbup`.

Multiple `dbdown` functions change the workspace context to each successively executed MATLAB code file on the stack until the current workspace context is the current breakpoint. It is not necessary, however, to move back to the current breakpoint to continue execution or to step to the next line.

### See Also

# dblquad

Numerically evaluate double integral over rectangle

## Compatibility

dblquad will be removed in a future release. Use `integral2` instead.

## Syntax

```
q = dblquad(fun,xmin,xmax,ymin,ymax)
q = dblquad(fun,xmin,xmax,ymin,ymax,tol)
q = dblquad(fun,xmin,xmax,ymin,ymax,tol,method)
```

## Description

`q = dblquad(fun,xmin,xmax,ymin,ymax)` calls the `quad` function to evaluate the double integral  $\text{fun}(x,y)$  over the rectangle  $x_{\min} \leq x \leq x_{\max}$ ,  $y_{\min} \leq y \leq y_{\max}$ . The input argument, `fun`, is a function handle that accepts a vector `x`, a scalar `y`, and returns a vector of integrand values.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = dblquad(fun,xmin,xmax,ymin,ymax,tol)` uses a tolerance `tol` instead of the default, which is `1.0e-6`.

`q = dblquad(fun,xmin,xmax,ymin,ymax,tol,method)` uses the quadrature function specified as `method`, instead of the default `quad`. Valid values for `method` are `@quad1` or the function handle of a user-defined quadrature method that has the same calling sequence as `quad` and `quad1`.

## Examples

Pass function handle `@integrnd` to `dblquad`:

```
Q = dblquad(@integrnd,pi,2*pi,0,pi);
```

where the function `integrnd.m` is:

```
function z = integrnd(x, y)
z = y*sin(x)+x*cos(y);
```

Pass anonymous function handle `F` to `dblquad`:

```
F = @(x,y)y*sin(x)+x*cos(y);
Q = dblquad(F,pi,2*pi,0,pi);
```

The `integrnd` function integrates  $y \sin(x) + x \cos(y)$  over the square  $\pi \leq x \leq 2\pi, 0 \leq y \leq \pi$ . Note that the integrand can be evaluated with a vector `x` and a scalar `y`.

Nonsquare regions can be handled by setting the integrand to zero outside of the region. For example, the volume of a hemisphere is:

```
dblquad(@(x,y)sqrt(max(1-(x.^2+y.^2),0)), -1, 1, -1, 1)
```

or

```
dblquad(@(x,y)sqrt(1-(x.^2+y.^2)).*(x.^2+y.^2<=1), -1, 1, -1, 1)
```

# dbmex

Enable MEX-file debugging (on UNIX platforms)

## Syntax

```
dbmex on
dbmex off
dbmex stop
```

## Description

`dbmex on` enables MEX-file debugging for UNIX platforms.

To use this option, first start MATLAB from a debugger by typing `matlab -Ddebugger`, where *debugger* is the name of the debugger program. Invoke `dbmex on` before calling your MEX-file. If you have already loaded the MEX-file, remove it from memory using the `clear` function.

`dbmex off` disables MEX-file debugging.

`dbmex stop` returns to the debugger prompt.

## More About

- “Debugging on Linux Platforms”

## See Also

`dbclean` | `dbcont` | `dbdown` | `dbquit` | `dbstack` | `dbstatus` | `dbstep` | `dbstop` | `dbtype` | `dbup`

**Introduced before R2006a**

## dbquit

Quit debug mode

### Syntax

```
dbquit
dbquit('all')
dbquit all
```

### Description

`dbquit` terminates debug mode. The Command Window then displays the standard prompt (`>>`). The file being processed is *not* completed and no results are returned. All breakpoints remain in effect, unless your file contains (and MATLAB has processed) one or more of the following commands: `clear all`, `clear function`, `clear classes`.

If you debug `file1` and step into `file2`, running `dbquit` terminates debugging for both files. However, if you debug `file3` and also debug `file4`, running `dbquit` terminates debugging for `file4`, but `file3` remains in debug mode until you run `dbquit` again.

`dbquit('all')` or the command form, `dbquit all`, ends debugging for all files at once.

### Examples

This example illustrates the use of `dbquit` relative to `dbquit('all')`. Set breakpoints in and run `file1` and `file2`:

```
>> dbstop in file1
>> dbstop in file2
>> file1
K>> file2
K>> dbstack
MATLAB software returns

K>> dbstack
 In file1 at 11
```

In file2 at 22

If you use the `dbquit` syntax

```
K>> dbquit
```

MATLAB ends debugging for `file2` but `file1` is still in debug mode as shown here

```
K>> dbstack
 in file1 at 11
```

Run `dbquit` again to exit debug mode for `file1`.

Alternatively, `dbquit('all')` ends debugging for both files at once:

```
K>> dbstack
 In file1 at 11
 In file2 at 22
dbquit('all')
dbstack
```

returns no result.

# dbstack

Function call stack

## Syntax

```
dbstack
dbstack(n)
dbstack(' -completenames ')
[ST,I] = dbstack(...)
```

## Description

`dbstack` displays the line numbers and file names of the function calls that led to the current breakpoint, listed in the order in which they were executed. The display lists the line number of the most recently executed function call (at which the current breakpoint occurred) first, followed by its calling function, which is followed by its calling function, and so on. This continues until the topmost MATLAB function is reached. Each line number is a hyperlink you can click to go directly to that line in the Editor. The notation `functionname>localfunctionname` is used to describe the location of the local function.

`dbstack(n)` omits the first `n` frames from the display. This is useful when issuing a `dbstack` from within an error handler, for example.

`dbstack(' -completenames ' )` outputs the “complete name“ (the absolute file name and the entire sequence of functions that nests the function in the stack frame) of each function in the stack.

Either none, one, or both `n` and `' -completenames '` can appear. If both appear, the order is irrelevant.

`[ST,I] = dbstack(...)` returns the stack trace information in an `m`-by-1 structure, `ST`, with the fields:

|                   |                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------|
| <code>file</code> | The file in which the function appears. This field is the empty string if there is no file. |
|-------------------|---------------------------------------------------------------------------------------------|

**name**           Function name within the file.  
**line**            Function line number.

The current workspace index is returned in **I**.

If you step past the end of a file, **dbstack** returns a negative line number value to identify that special case. For example, if the last line to be executed is line **15**, then the **dbstack** line number is **15** before you execute that line and **-15** afterwards.

## Examples

This example shows the information returned when you issue **dbstack** while debugging a MATLAB code file:

```
dbstack
```

```
In /usr/local/matlab/toolbox/matlab/cond.m at line 13
In test1.m at line 2
In test.m at line 3
```

This example shows the information returned when you issue **dbstack** while debugging **lengthofline.m** to get the complete name of the file, the function name, and line number in which the function appears:

```
[ST,I] = dbstack('-completenames')
ST =
 file: 'I:\MATLABFiles\myfiles\lengthofline.m'
 name: 'lengthofline'
 line: 28
I =
 1
```

## More About

### Tips

In addition to using **dbstack** while debugging, you can also use **dbstack** within a MATLAB code file outside the context of debugging. In this case, to get and analyze information about the current file stack. For example, to get the name of the calling file, use **dbstack** with an output argument within the file being called. For example:

```
st=dbstack;
```

**Introduced before R2006a**

# dbstatus

List all breakpoints

## Syntax

```
dbstatus
dbstatus file
dbstatus(' -completenames ')
s = dbstatus(...)
```

## Description

`dbstatus` lists all the breakpoints in effect including errors, caught errors, warnings, and `naninfs`.

`dbstatus file` displays a list of the line numbers for which breakpoints are set in the specified file, where `file` is a MATLAB code file function name or a MATLAB relative partial path. Each line number is a hyperlink you can click to go directly to that line in the Editor.

`dbstatus(' -completenames ' )` displays, for each breakpoint, the absolute file name and the sequence of functions that nest the function containing the breakpoint.

`s = dbstatus(...)` returns breakpoint information in an `m`-by-1 structure with the fields listed in the following table. Use this syntax to save breakpoint status and restore it at a later time using `dbstop(s)`—see `dbstop` for an example.

|                        |                                                                                                                                                                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>      | Function name.                                                                                                                                                                                                                                        |
| <code>file</code>      | Full path for file containing breakpoints.                                                                                                                                                                                                            |
| <code>line</code>      | Vector of breakpoint line numbers.                                                                                                                                                                                                                    |
| <code>anonymous</code> | Vector of integers representing the anonymous functions in the <code>line</code> field. For example, 2 means the second anonymous function in that line. A value of 0 means the breakpoint is at the start of the line, not in an anonymous function. |

|                         |                                                                                                                                                                              |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>expression</code> | Cell vector of breakpoint conditional expression strings corresponding to lines in the <code>line</code> field.                                                              |
| <code>cond</code>       | Condition string ('error', 'caught error', 'warning', or 'naninf').                                                                                                          |
| <code>identifier</code> | When <code>cond</code> is 'error', 'caught error', or 'warning', a cell vector of MATLAB message identifier strings for which the particular <code>cond</code> state is set. |

Use `dbstatus class/function`, `dbstatus private/function`, or `dbstatus class/private/function` to determine the status for methods, private functions, or private methods (for a class named `class`).

In all forms you can further qualify the function name with a local function name, as in `dbstatus function>localfunction`.

## More About

### Tips

In the syntax, `file` can be a file, or the path to a function within a file. For example

```
Breakpoint for foo>myfun is on line 9
```

means there is a breakpoint at the `myfun` local function, which is line 9 in the file `foo.m`.

# dbstep

Execute one or more lines from current breakpoint

## Syntax

```
dbstep
dbstep nlines
dbstep in
dbstep out
```

## Description

This function allows you to debug a MATLAB code file by following its execution from the current breakpoint. At a breakpoint, the **dbstep** function steps through execution of the current file one line at a time or at the rate specified by **nlines**.

**dbstep** executes the next executable line of the current file. **dbstep** steps over the current line, skipping any breakpoints set in functions called by that line.

**dbstep nlines** executes the specified number of executable lines.

**dbstep in** steps to the next executable line. If that line contains a call to another MATLAB code file function, execution will step to the first executable line of the called function. If there is no call to a MATLAB code file on that line, **dbstep in** is the same as **dbstep**.

**dbstep out** runs the rest of the function and stops just after leaving the function.

For all forms, MATLAB software also stops execution at any breakpoint it encounters.

---

**Note** If you want to edit a file as a result of debugging, it is best to first quit debug mode and then edit and save changes to the file. If you edit a file while paused in debug mode, you can get unexpected results when you resume execution of the file and the results might not be reliable.

---

## **Related Examples**

- “Debug a MATLAB Program”

**Introduced before R2006a**

# dbstop

Set breakpoints for debugging

## Syntax

```
dbstop in file
dbstop in file at location
dbstop in file if expression
dbstop in file at location if expression
```

```
dbstop if condition
```

```
dbstop(b)
```

## Description

`dbstop in file` sets a breakpoint at the first executable line in `file`. When you run `file`, MATLAB enters debug mode, pauses execution at the breakpoint and displays the line where it is paused.

`dbstop in file at location` sets a breakpoint at the specified location. MATLAB execution pauses immediately before that location, unless the location is an anonymous function. If the location is an anonymous function, then execution pauses just after the breakpoint.

`dbstop in file if expression` sets a conditional breakpoint at the first executable line of the file. Execution pauses only if `expression` evaluates to true (1).

`dbstop in file at location if expression` sets a conditional breakpoint at the specified location. Execution pauses at or just before that location only if the `expression` evaluates to true.

`dbstop if condition` pauses execution at the line that meets the specified condition, such as `error` or `naninf`. Unlike other breakpoints, you do not set this breakpoint at a specific line in a specific file. MATLAB stops at any line in any file when the specified condition occurs.

`dbstop(b)` restores breakpoints you previously saved to `b`. The files containing the saved breakpoints must be on the search path or in the current folder. MATLAB assigns breakpoints by line number, so the lines in the file must be the same as when you saved the breakpoints.

## Examples

### Stop at First Executable Line

Set a breakpoint and pause execution at the first executable line of a program.

Create a file, `buggy.m`, that contains these statements.

```
function z = buggy(x)
n = length(x);
z = (1:n)./x;
```

Issue the `dbstop` command and run `buggy`.

```
dbstop in buggy
buggy(1:5)
```

MATLAB displays the line where it pauses and enters debug mode.

```
2 n = length(x);
K>>
```

Type `dbquit` to exit debug mode.

### Stop at Function in File

Set a breakpoint in a program at the first executable line of a local function.

Create a file, `myfile.m`, that contains these statements

```
function n = myfile(x)
n = myfunction(x);

function y = myfunction(x)
y = x + 1;
```

Set a breakpoint at `myfunction`.

```
dbstop in myfile>myfunction
```

### Stop in File After $n$ Iterations of a Loop

Set a breakpoint in a program that causes MATLAB to pause after a certain number of iterations of a loop.

Create a file, `myprogram.m`, that contains these statements

```
x = ones(1,10);

for n = 1:10
x(n) = x(n) + 1;
end
```

Set a breakpoint to stop when  $n \geq 4$ , and run the code.

```
dbstop in myprogram at 4 if n>=4
myprogram
```

MATLAB pauses at line 4 after 3 iterations of the loop, when  $n = 4$ .

```
4 x(n) = x(n) + 1;
K>>
```

Type `dbquit` to exit debug mode.

### Stop if Error

Set a breakpoint and pause execution if a run-time error occurs.

Create a file, `buggy.m`, that requires an input vector.

```
function z = buggy(x)
n = length(x);
z = (1:n)./x;
```

Set an error breakpoint, and call `buggy` with a matrix input instead of a vector.

```
dbstop if error
buggy(magic(3))
```

A run-time error occurs, and MATLAB goes into debug mode, pausing at line 3 in `buggy.m`.

```
Error using ./
```

Matrix dimensions must agree.

```
Error in buggy at 3
z = (1:n)./x;
3 z = (1:n)./x;
```

Type `dbquit` to exit debug mode.

## Stop if NanInf

Set a breakpoint and pause execution if the code returns a NaN value.

Create a file, `buggy.m`, that requires an input vector.

```
function z = buggy(x)
n = length(x);
z = (1:n)./x;
```

Set a warning breakpoint, and call `buggy` with an input vector containing a 0 as one of its elements.

```
dbstop if naninf
buggy(0:2)
```

A division by zero error occurs, and MATLAB goes into debug mode, pausing at line 3 in `buggy.m`.

NaN/Inf breakpoint hit for buggy on line 3.

Type `dbquit` to exit debug mode.

## Restore Saved Breakpoints

Set, save, clear and then restore saved breakpoints.

Create a file, `buggy.m`, which contains these statements.

```
function z = buggy(x)
n = length(x);
z = (1:n)./x;
```

Set breakpoints from the Command Window.

```
dbstop at 2 in buggy
dbstop if error
```

Run `dbstatus`.

```
dbstatus
```

MATLAB describes the breakpoints you set.

```
Breakpoint for buggy is on line 2.
Stop if error.
```

Save the breakpoints to the structure, `b`, and then save `b` to the MAT-file, `buggybrkpts`. Use `b=dbstatus(' -completenames')` to save absolute paths and the breakpoint function nesting sequence.

```
b = dbstatus(' -completenames');
save buggybrkpts b
```

Clear all breakpoints.

```
dbclear all
```

Restore the breakpoints by loading the MAT-file.

```
load buggybrkpts
dbstop(b)
```

## Input Arguments

### **file** — File specification

string

File specification, specified as a string. The file specification can include a partial path, but must be in a folder on the search path or in the current folder.

Example: `myfile.m`

If the file specification includes the `-completenames` option, then the file need not be on the search path, as long as the file specification is a “fully qualified name” on page 1-2045.

Example: `c:\Program Files\MATLAB\myfile.m -completenames`

In addition, `file` can include a filemarker (`>`) to specify the path to a particular local function or to a nested function within the file.

Example: `myfile>myfunction`

If `file` is not a MATLAB code file (for instance, it is a built-in or MDL-file), then MATLAB issues a warning. MATLAB cannot stop *in* the file, so it pauses before executing the file.

### **location** — Location in file to set a breakpoint

line number | line number and anonymous function number | local function name

Location in file to set a breakpoint, specified as one of these options:

- Line number in `file` specified as a string. The default is 1.
- Line number in `file`, at the anonymous function number, specified as a string. For example, `1@2` specifies line number 1, at the second anonymous function. The default anonymous function number is 1.
- Name of a local function in `file`, specified as a string.

---

**Note:** When setting a breakpoint, you cannot specify `location` if `file` includes a filemarker. For example, the command `dbstop in myfile>myfilefunction at 5` is invalid.

---

### **expression** — Code that evaluates to scalar logical value 1 or 0

string

Code that evaluates (as if by `eval`) to a scalar logical value of 1 or 0, (true or false, respectively), specified as a string.

Example: `n >= 4`

### **condition** — Statement that causes execution to pause when that condition evaluates to true

error | caught error | warning | naninf | ...

Statement that causes execution to pause when that condition evaluates to true, specified as one of these options:

- **error** — Run-time error that occurs outside a `try/catch` block. You cannot resume execution after an uncaught run-time error.

If you want execution to pause only if a specific error occurs, specify the message id. For example:

- `dbstop if error` stops execution at the first run-time error that occurs outside a `try/catch` block.
- `dbstop if error MATLAB:ls:InputsMustBeStrings` pauses execution at the first run-time error outside a `try/catch` block that has a message ID of `MATLAB:ls:InputsMustBeStrings`.
- `caught error` — Run-time error that occurs within the `try` portion of a `try/catch` block. If you want execution to stop only if a specific error occurs, specify the message id.
- `warning` — Run-time warning occurs. If you want execution to pause only if a specific warning occurs, specify the message id.

This condition has no effect if you disable warnings with the `warning off all` command or if you disable warnings for the specified id. For more information about disabling warnings, see `warning`.

- `naninf` — The code returns an infinite value (`Inf`) or a value that is not a number (`NaN`) as a result of an operator, function call, or scalar assignment.

## **b** — List of breakpoints

structure array

List of breakpoints previously saved to a structure array using `b=dbstatus`.

# More About

## fully qualified name

A fully qualified name is an exact file name that is uniquely specified such that it cannot be mistaken for any other file on your system.

- Windows platforms — A file name that begins with two back slashes (`\\`) or with a drive letter followed by a colon (`:`).
- UNIX platforms — A file name that begins with a slash (`/`) or a tilde (`~`).

## Tips

- Before you begin debugging, make sure that your program is saved and that the program and any files it calls exist on your search path or in the current folder.

- To resume execution after a breakpoint pauses execution, use `dbcont` or `dbstep`. To exit debug mode, use `dbquit`.
- MATLAB can become unresponsive when it stops at a breakpoint while displaying a modal dialog box or figure created by your program. To exit debug mode and return to the MATLAB prompt (`>>`), use **Ctrl+C**.
- “Debug a MATLAB Program”

`dbclear` | `dbcont` | `dbdown` | `dbquit` | `dbstack` | `dbstatus` | `dbstep` | `dbtype` | `dbup`

**Introduced before R2006a**

# dbtype

List text file with line numbers

## Syntax

```
dbtype filename
dbtype filename start:end
```

## Description

The `dbtype` command is used to list a text file with line numbers, which is helpful when setting breakpoints in a MATLAB code file with `dbstop`.

`dbtype filename` displays the contents of the specified text file, with the line number preceding each line. `filename` must be the full path name of a file, or a MATLAB relative partial path.

`dbtype filename start:end` displays the portion of the file specified by a range of line numbers from `start` to `end`.

You cannot use `dbtype` for built-in functions.

## Examples

To see only the input and output arguments for a function, that is, the first line of the file, use the syntax

```
dbtype filename 1
```

For example,

```
dbtype addpath 1
```

returns

```
1 function oldpath = addpath(varargin)
```

**See Also**

dbclear | dbcont | dbdown | dbquit | dbstack | dbstatus | dbstep | dbstop |  
dbup

**Introduced before R2006a**

# dbup

Shift current workspace to workspace of caller, while in debug mode

## Syntax

```
dbup
```

## Description

This function allows you to examine the calling MATLAB code file to determine what caused the arguments to be passed to the called function.

dbup changes the current workspace context, while the user is in the debug mode, to the workspace of the calling file.

Multiple dbup functions change the workspace context to each previous calling file on the stack until the base workspace context is reached. (It is not necessary, however, to move back to the current breakpoint to continue execution or to step to the next line.)

## More About

### Tips

If you receive an error message such as the following, it means that the parent workspace is under construction so that the value of `x` is unavailable:

```
??? Reference to a called function result under construction x
```

- “Examine Values While Debugging”

## dde23

Solve delay differential equations (DDEs) with constant delays

### Syntax

```
sol = dde23(ddefun,lags,history,tspan)
sol = dde23(ddefun,lags,history,tspan,options)
```

### Arguments

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ddefun  | Function handle that evaluates the right side of the differential equations $y'(t) = f(t, y(t), y(t - \tau_1), \dots, y(t - \tau_k))$ . The function must have the form<br><br>$dydt = ddefun(t, y, Z)$<br><br>where $t$ corresponds to the current $t$ , $y$ is a column vector that approximates $y(t)$ , and $Z(:, j)$ approximates $y(t - \tau_j)$ for delay $\tau_j = lags(j)$ . The output is a column vector corresponding to $f(t, y(t), y(t - \tau_1), \dots, y(t - \tau_k))$ . |
| lags    | Vector of constant, positive delays $\tau_1, \dots, \tau_k$ .                                                                                                                                                                                                                                                                                                                                                                                                                            |
| history | Specify <b>history</b> in one of three ways: <ul style="list-style-type: none"><li>• A function of <math>t</math> such that <math>y = history(t)</math> returns the solution <math>y(t)</math> for <math>t \leq t_0</math> as a column vector</li><li>• A constant column vector, if <math>y(t)</math> is constant</li><li>• The solution <b>sol</b> from a previous integration, if this call continues that integration</li></ul>                                                      |
| tspan   | Interval of integration from $t_0=tspan(1)$ to $t_f=tspan(end)$ with $t_0 < t_f$ .                                                                                                                                                                                                                                                                                                                                                                                                       |
| options | Optional integration argument. A structure you create using the <b>dde23set</b> function. See <b>dde23set</b> for details.                                                                                                                                                                                                                                                                                                                                                               |

## Description

`sol = dde23(ddefun, lags, history, tspan)` integrates the system of DDEs

$$y'(t) = f(t, y(t), y(t - \tau_1), \dots, y(t - \tau_k))$$

on the interval  $[t_0, t_f]$ , where  $\tau_1, \dots, \tau_k$  are constant, positive delays and  $t_0, t_f$ . The input argument, `ddefun`, is a function handle.

“Parameterizing Functions” explains how to provide additional parameters to the function `ddefun`, if necessary.

`dde23` returns the solution as a structure `sol`. Use the auxiliary function `deval` and the output `sol` to evaluate the solution at specific points `tint` in the interval `tspan = [t0, tf]`.

`yint = deval(sol, tint)`

The structure `sol` returned by `dde23` has the following fields.

|                         |                                                                    |
|-------------------------|--------------------------------------------------------------------|
| <code>sol.x</code>      | Mesh selected by <code>dde23</code>                                |
| <code>sol.y</code>      | Approximation to $y(x)$ at the mesh points in <code>sol.x</code> . |
| <code>sol.yp</code>     | Approximation to $y'(x)$ at the mesh points in <code>sol.x</code>  |
| <code>sol.solver</code> | Solver name, 'dde23'                                               |

`sol = dde23(ddefun, lags, history, tspan, options)` solves as above with default integration properties replaced by values in `options`, an argument created with `ddeset`. See `ddeset` and “Types of DDEs” in the MATLAB documentation for details.

Commonly used options are scalar relative error tolerance '`RelTol`' (`1e-3` by default) and vector of absolute error tolerances '`AbsTol`' (all components are `1e-6` by default).

Use the '`Jumps`' option to solve problems with discontinuities in the history or solution. Set this option to a vector that contains the locations of discontinuities in the solution prior to `t0` (the history) or in coefficients of the equations at known values of  $t$  after `t0`.

Use the '`Events`' option to specify a function that `dde23` calls to find where functions  $g(t, y(t), y(t - \tau_1), \dots, y(t - \tau_k))$  vanish. This function must be of the form

```
[value, isterminal, direction] = events(t,y,Z)
```

and contain an event function for each event to be tested. For the  $k$ th event function in `events`:

- `value(k)` is the value of the  $k$ th event function.
- `isterminal(k) = 1` if you want the integration to terminate at a zero of this event function and 0 otherwise.
- `direction(k) = 0` if you want `dde23` to compute all zeros of this event function, +1 if only zeros where the event function increases, and -1 if only zeros where the event function decreases.

If you specify the 'Events' option and events are detected, the output structure `sol` also includes fields:

|                     |                                                                                                              |
|---------------------|--------------------------------------------------------------------------------------------------------------|
| <code>sol.xe</code> | Row vector of locations of all events, i.e., times when an event function vanished                           |
| <code>sol.ye</code> | Matrix whose columns are the solution values corresponding to times in <code>sol.xe</code>                   |
| <code>sol.ie</code> | Vector containing indices that specify which event occurred at the corresponding time in <code>sol.xe</code> |

## Examples

This example solves a DDE on the interval  $[0, 5]$  with lags 1 and 0.2. The function `ddex1de` computes the delay differential equations, and `ddex1hist` computes the history for  $t \leq 0$ .

---

**Note** The file, `ddex1.m`, contains the complete code for this example. To see the code in an editor, type `edit ddex1` at the command line. To run it, type `ddex1` at the command line.

---

```
sol = dde23(@ddex1de,[1, 0.2],@ddex1hist,[0, 5]);
```

This code evaluates the solution at 100 equally spaced points in the interval  $[0, 5]$ , then plots the result.

```
tint = linspace(0,5);
yint = deval(sol,tint);
plot(tint,yint);
```

ddex1 shows how you can code this problem using local functions. For more examples see ddex2.

## More About

### Algorithms

dde23 tracks discontinuities and integrates with the explicit Runge-Kutta (2,3) pair and interpolant of ode23. It uses iteration to take steps longer than the lags.

## ddeget

Extract properties from delay differential equations options structure

### Syntax

```
val = ddeget(options, 'name')
val = ddeget(options, 'name', default)
```

### Description

`val = ddeget(options, 'name')` extracts the value of the named property from the structure `options`, returning an empty matrix if the property value is not specified in `options`. It is sufficient to type only the leading characters that uniquely identify the property. Case is ignored for property names. `[]` is a valid `options` argument.

`val = ddeget(options, 'name', default)` extracts the named property as above, but returns `val = default` if the named property is not specified in `options`. For example,

```
val = ddeget(opts, 'RelTol', 1e-4);
```

returns `val = 1e-4` if the `RelTol` is not specified in `opts`.

# ddensd

Solve delay differential equations (DDEs) of neutral type

## Syntax

```
sol = ddensd(ddefun,dely,delyp,history,tspan)
sol = ddensd(ddefun,dely,delyp,history,tspan,options)
```

## Description

`sol = ddensd(ddefun,dely,delyp,history,tspan)` integrates a system of delay differential equations of neutral type, that has the form

$$y'(t) = f(t, y(t), y(dy_1), \dots, y(dy_p), y'(dyp_1), \dots, y'(dyp_q))$$

where

- $t$  is the independent variable representing time.
- $dy_i$  is any of  $p$  solution delays.
- $dyp_j$  is any of  $q$  derivative delays.

`sol = ddensd(ddefun,dely,delyp,history,tspan,options)` replaces default integration parameters with those specified in `options`, a structure created with the `ddeset` function.

## Examples

### Neutral DDE with Two Delays

Solve the following neutral DDE, presented by Paul, for  $0 \leq t \leq \pi$ :

$$y'(t) = 1 + y(t) - 2y(t/2)^2 - y'(t - \pi)$$

with history:  $y(t) = \cos(t)$  for  $t \leq 0$ .

Create a new program file in the editor. This file will contain a main function and four local functions.

Define the first-order DDE as a local function.

```
function yp = ddefun(t,y,ydel,ypdel)
 yp = 1 + y - 2*ydel^2 - ypdel;
end
```

Define the solution delay as a local function.

```
function dy = dely(t,y)
 dy = t/2;
end
```

Define the derivative delay as a local function.

```
function dyp = delyp(t,y)
 dyp = t-pi;
end
```

Define the solution history as a local function.

```
function y = history(t)
 y = cos(t);
end
```

Define the interval of integration and solve the DDE using the `ddensd` function. Add this code to the main function.

```
tspan = [0 pi];
sol = ddensd(@ddefun,@dely,@delyp,@history,tspan);
```

Evaluate the solution at 100 equally spaced points between 0 and  $\pi$ . Add this code to the main function.

```
tn = linspace(0,pi);
yn = deval(sol,tn);
```

Plot the results. Add this code to the main function.

```
plot(tn,yn);
xlim([0 pi]);
ylim([-1.2 1.2]);
```

```
xlabel('time t');
ylabel('solution y');
```

Run your program to calculate the solution and display the plot.

The file, `ddex4.m`, contains the complete code for this example. To see the code in an editor, type `edit ddex4` at the command line.

## Input Arguments

**ddexfun** — Derivative function  
function handle

Derivative function, specified as a function handle whose syntax is `yp = ddefun(t, y, ydel, ypdel)`. The arguments for `ddefun` are described in the table below.

| <b>ddefun Argument</b> | <b>Description</b>                                                                                                                                                                                                                                   |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t</code>         | A scalar value representing the current value of time, $t$ .                                                                                                                                                                                         |
| <code>y</code>         | A vector that represents $y(t)$ in Equation 1-1. The size of this vector is $n$ -by-1, where $n$ is the number of equations in the system you want to solve.                                                                                         |
| <code>ydel</code>      | A matrix whose columns, <code>ydel(:, i)</code> , represent $y(dy_i)$ . The size of this matrix is $n$ -by- $p$ , where $n$ is the number of equations in the system you want to solve, and $p$ is the number of $y(dy)$ terms in Equation 1-1.      |
| <code>ypdel</code>     | A matrix whose columns, <code>ypdel(:, j)</code> represent $y'(dy_p_j)$ . The size of this matrix is $n$ -by- $q$ , where $n$ is the number of equations in the system you want to solve, and $q$ is the number of $y'(dy_p)$ terms in Equation 1-1. |
| <code>yp</code>        | The result returned by <code>ddefun</code> . It is an $n$ -by-1 vector whose elements represent the right side of Equation 1-1.                                                                                                                      |

**dely — Solution delays**

function handle | vector

Solution delays, specified as a function handle, which returns  $dy_1, \dots, dy_p$  in Equation 1-1. Alternatively, you can pass constant delays in the form of a vector.

If you specify `dely` as a function handle, the syntax must be `dy = dely(t, y)`. The arguments for this function are described in the table below.

| <b>dely Argument</b> | <b>Description</b>                                                                                                                                                                                                                                                     |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t</code>       | A scalar value representing the current value of time, $t$ .                                                                                                                                                                                                           |
| <code>y</code>       | A vector that represents $y(t)$ in Equation 1-1. The size of this vector is $n$ -by-1, where $n$ is the number of equations in the system you want to solve.                                                                                                           |
| <code>dy</code>      | A vector returned by the <code>dely</code> function whose values are the solution delays, $dy_i$ , in Equation 1-1. The size of this vector is $p$ -by-1, where $p$ is the number of solution delays in the equation. Each element must be less than or equal to $t$ . |

If you want to specify constant solution delays having the form  $dy_i = t - \tau_i$ , then `dely` must be a vector, where `dely(i) =  $\tau_i$` . Each value in this vector must be greater than or equal to zero.

If  $dy$  is not present in the problem, set `dely` to `[ ]`.

Data Types: `function_handle` | `single` | `double`

### **delyp** — Derivative delays

`function handle` | `vector`

Derivative delays, specified as a function handle, which returns  $dyp_1, \dots, dyp_q$  in Equation 1-1. Alternatively, you can pass constant delays in the form of a vector.

If `delyp` is a function handle, its syntax must be `dyp = delyp(t,y)`. The arguments for this function are described in the table below.

| <b>delyp Argument</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t</code>        | A scalar value representing the current value of time, $t$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>y</code>        | A vector that represents $y(t)$ in Equation 1-1. The size of this vector is $n$ -by-1, where $n$ is the number of equations in the system you want to solve.                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>dyp</code>      | A vector returned by the <code>delyp</code> function whose values are the derivative delays, $dyp_j$ , in Equation 1-1. The size of this vector must be $q$ -by-1, where $q$ is the number of solution delays, $dyp_j$ , in the equation. Each element of <code>dyp</code> must be less than $t$ . There is one exception to this restriction: if you are solving an initial value DDE, the value of <code>dyp</code> can equal $t$ at $t = t_0$ . For more information, see “Initial Value Neutral Delay Differential Equations” on page 1-2061. |

If you want specify constant derivative delays having the form  $dyp_j = t - \tau_j$ , then `delyp` must be a vector, where `delyp(j) =  $\tau_j$` . Each value in this vector must be greater than zero. An exception to this restriction occurs when you solve initial value problems for DDEs of neutral type. In such cases, a value in `delyp` can equal zero at  $t = t_0$ . See “Initial Value Neutral Delay Differential Equations” on page 1-2061 for more information.

If  $dyp$  is not present in the problem, set `delyp` to `[ ]`.

Data Types: `function_handle` | `single` | `double`

### **history** — Solution history

`function handle` | `column vector` | `structure (sol, from previous integration)` | `1-by-2 cell array`

Solution history, specified as a function handle, column vector, `sol` structure (from a previous integration), or a cell array. This is the solution at  $t \leq t_0$ .

- If the history varies with time, specify the solution history as a function handle whose syntax is `y = history(t)`. This function returns an  $n$ -by-1 vector that approximates the solution,  $y(t)$ , for  $t \leq t_0$ . The length of this vector,  $n$ , is the number of equations in the system you want to solve.
- If  $y(t)$  is constant, you can specify `history` as an  $n$ -by-1 vector of the constant values.
- If you are calling `ddensd` to continue a previous integration to  $t_0$ , you can specify `history` as the output, `sol`, from the previous integration.
- If you are solving an initial value DDE, specify `history` as a cell array, `{y0, yp0}`. The first element, `y0`, is a column vector of initial values,  $y(t_0)$ . The second element, `yp0`, is a column vector whose elements are the initial derivatives,  $y'(t_0)$ . These vectors must be consistent, meaning that they satisfy Equation 1-1 at  $t_0$ . See “Initial Value Neutral Delay Differential Equations” on page 1-2061 for more information.

Data Types: `function_handle` | `single` | `double` | `struct` | `cell`

### **tspan** — Interval of integration

`1-by-2 vector`

Interval of integration, specified as the vector `[t0 tf]`. The first element, `t0`, is the initial value of  $t$ . The second element, `tf`, is the final value of  $t$ . The value of `t0` must be less than `tf`.

Data Types: `single` | `double`

### **options** — Optional integration parameters

`structure returned by ddeset`

Optional integration parameters, specified as a structure created and returned by the `ddeset` function. Some commonly used properties are: `'RelTol'`, `'AbsTol'`, and `'Events'`. See the `ddeset` reference page for more information about specifying options.

## Output Arguments

### sol — Solution

structure

Solution, returned as a structure containing the following fields.

|            |                                                 |
|------------|-------------------------------------------------|
| sol.x      | Mesh selected by <code>ddensd</code> .          |
| sol.y      | An approximation to $y(t)$ at the mesh points.  |
| sol.yp     | An approximation to $y'(t)$ at the mesh points. |
| sol.solver | A string identifying the solver, 'ddensd'.      |

You can pass `sol` to the `deval` function to evaluate the solution at specific points. For example, `y = deval(sol, 0.5*(sol.x(1) + sol.x(end)))` evaluates the solution at the midpoint of the interval of integration.

## More About

### Initial Value Neutral Delay Differential Equations

An initial value DDE has  $dy_i \geq t_0$  and  $dyp_j \geq t_0$ , for all  $i$  and  $j$ . At  $t = t_0$ , all delayed terms reduce to  $y(dy_i) = y(t_0)$  and  $y'(dyp_j) = y'(t_0)$ :

$$y'(t_0) = f(t_0, y(t_0), y(t_0), \dots, y(t_0), y'(t_0), \dots, y'(t_0))$$

For  $t > t_0$ , all derivative delays must satisfy  $dyp < t$ .

When you solve initial value neutral DDEs, you must supply  $y'(t_0)$  to `ddensd`. To do this, specify `history` as a cell array `{Y0, YP0}`. Here, `Y0` is the column vector of initial values,  $y(t_0)$ , and `YP0` is a column vector of initial derivatives,  $y'(t_0)$ . These vectors must be consistent, meaning that they satisfy Equation 1-2 at  $t_0$ .

|                      |                                                                                                                                    |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <code>tspan</code>   | Interval of integration from <code>t0=tspan(1)</code> to <code>tf=tspan(end)</code> with <code>t0 &lt; tf</code> .                 |
| <code>options</code> | Optional integration argument. A structure you create using the <code>ddeset</code> function. See <code>ddeset</code> for details. |

## Description

`sol = ddesd(ddefun,delays,history,tspan)` integrates the system of DDEs

$$y'(t) = f(t, y(t), y(d(1)), \dots, y(d(k)))$$

on the interval  $[t_0, t_f]$ , where delays  $d(j)$  can depend on both  $t$  and  $y(t)$ , and  $t_0 < t_f$ . Inputs `ddefun` and `delays` are function handles. See “Create Function Handle” for more information.

“Parameterizing Functions” explains how to provide additional parameters to the functions `ddefun`, `delays`, and `history`, if necessary.

`ddesd` returns the solution as a structure `sol`. Use the auxiliary function `deval` and the output `sol` to evaluate the solution at specific points `tint` in the interval `tspan = [t0,tf]`.

```
yint = deval(sol,tint)
```

The structure `sol` returned by `ddesd` has the following fields.

|                         |                                                                    |
|-------------------------|--------------------------------------------------------------------|
| <code>sol.x</code>      | Mesh selected by <code>ddesd</code>                                |
| <code>sol.y</code>      | Approximation to $y(x)$ at the mesh points in <code>sol.x</code> . |
| <code>sol.yp</code>     | Approximation to $y'(x)$ at the mesh points in <code>sol.x</code>  |
| <code>sol.solver</code> | Solver name, 'ddesd'                                               |

`sol = ddesd(ddefun,delays,history,tspan,options)` solves as above with default integration properties replaced by values in `options`, an argument created with `ddeset`. See `ddeset` and “Types of DDEs” in the MATLAB documentation for details.

Commonly used options are scalar relative error tolerance '`RelTol`' ( $1e-3$  by default) and vector of absolute error tolerances '`AbsTol`' (all components are  $1e-6$  by default).

Use the 'Events' option to specify a function that `ddesd` calls to find where functions  $g(t, y(t), y(d(1)), \dots, y(d(k)))$  vanish. This function must be of the form

```
[value, isterminal, direction] = events(t, y, Z)
```

and contain an event function for each event to be tested. For the  $k$ th event function in `events`:

- `value(k)` is the value of the  $k$ th event function.
- `isterminal(k) = 1` if you want the integration to terminate at a zero of this event function and 0 otherwise.
- `direction(k) = 0` if you want `ddesd` to compute all zeros of this event function, +1 if only zeros where the event function increases, and -1 if only zeros where the event function decreases.

If you specify the 'Events' option and events are detected, the output structure `sol` also includes fields:

|                     |                                                                                                              |
|---------------------|--------------------------------------------------------------------------------------------------------------|
| <code>sol.xe</code> | Row vector of locations of all events, i.e., times when an event function vanished                           |
| <code>sol.ye</code> | Matrix whose columns are the solution values corresponding to times in <code>sol.xe</code>                   |
| <code>sol.ie</code> | Vector containing indices that specify which event occurred at the corresponding time in <code>sol.xe</code> |

## Examples

The equation

```
sol = ddesd(@ddex1de, @ddex1delays, @ddex1hist, [0,5]);
```

solves a DDE on the interval  $[0, 5]$  with delays specified by the function `ddex1delays` and differential equations computed by `ddex1de`. The history is evaluated for  $t \leq 0$  by the function `ddex1hist`. The solution is evaluated at 100 equally spaced points in  $[0, 5]$ :

```
tint = linspace(0,5);
yint = deval(sol,tint);
```

and plotted with

```
plot(tint,yint);
```

This problem involves constant delays. The `delay` function has the form

```
function d = ddex1delays(t,y)
%DDEX1DELAYS Delays for using with DDEX1DE.
d = [t - 1
 t - 0.2];
```

The problem can also be solved with the syntax corresponding to constant delays

```
delays = [1, 0.2];
sol = ddesd(@ddex1de,delays,@ddex1hist,[0, 5]);
```

or using `dde23`:

```
sol = dde23(@ddex1de,delays,@ddex1hist,[0, 5]);
```

For more examples of solving delay differential equations see `ddex2` and `ddex3`.

`dde23` | `ddeget` | `ddensd` | `ddeset` | `deval`

# ddeset

Create or alter delay differential equations options structure

## Syntax

```
options = ddeset('name1',value1,'name2',value2,...)
options = ddeset(olddopts,'name1',value1,...)
options = ddeset(olddopts,newopts)
ddeset
```

## Description

`options = ddeset('name1',value1,'name2',value2,...)` creates an integrator options structure `options` in which the named properties have the specified values. Any unspecified properties have default values. It is sufficient to type only the leading characters that uniquely identify the property. `ddeset` ignores case for property names.

`options = ddeset(olddopts,'name1',value1,...)` alters an existing options structure `olddopts`. This overwrites any values in `olddopts` that are specified using name/value pairs and returns the modified structure as the output argument.

`options = ddeset(olddopts,newopts)` combines an existing options structure `olddopts` with a new options structure `newopts`. Any values set in `newopts` overwrite the corresponding values in `olddopts`.

`ddeset` with no input arguments displays all property names and their possible values, indicating defaults with braces {}.

You can use the function `ddeget` to query the `options` structure for the value of a specific property.

## DDE Properties

The following sections describe the properties that you can set using `ddeset`. There are several categories of properties:

- Error control

- Solver output
- Step size
- Event location
- Discontinuities

## Error Control Properties

At each step, the DDE solvers estimate an error  $e$ . The `dde23` function estimates the local truncation error, and the other solvers estimate the residual. In either case, this error must be less than or equal to the acceptable error, which is a function of the specified relative tolerance, `RelTol`, and the specified absolute tolerance, `AbSTol`.

$$|e(i)| * \max(\text{RelTol} * \text{abs}(y(i)), \text{AbSTol}(i))$$

For routine problems, the solvers deliver accuracy roughly equivalent to the accuracy you request. They deliver less accuracy for problems integrated over “long” intervals and problems that are moderately unstable. Difficult problems may require tighter tolerances than the default values. For relative accuracy, adjust `RelTol`. For the absolute error tolerance, the scaling of the solution components is important: if  $|y|$  is somewhat smaller than `AbSTol`, the solver is not constrained to obtain any correct digits in  $y$ . You might have to solve a problem more than once to discover the scale of solution components.

Roughly speaking, this means that you want `RelTol` correct digits in all solution components except those smaller than thresholds `AbSTol(i)`. Even if you are not interested in a component  $y(i)$  when it is small, you may have to specify `AbSTol(i)` small enough to get some correct digits in  $y(i)$  so that you can accurately compute more interesting components.

The following table describes the error control properties.

### DDE Error Control Properties

| Property            | Value                                    | Description                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>RelTol</code> | Positive scalar<br>{ <code>1e-3</code> } | A relative error tolerance that applies to all components of the solution vector $y$ . It is a measure of the error relative to the size of each solution component. Roughly, it controls the number of correct digits in all solution components except those smaller than thresholds <code>AbSTol(i)</code> . The default, <code>1e-3</code> , corresponds to 0.1% accuracy. |

| Property           | Value                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    |                                      | The estimated error in each integration step satisfies $ e(i)  \leq \max(\text{RelTol} \cdot \text{abs}(y(i)), \text{AbsTol}(i))$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>AbsTol</b>      | Positive scalar or vector $\{1e-6\}$ | <p>Absolute error tolerances that apply to the individual components of the solution vector. <b>AbsTol(i)</b> is a threshold below which the value of the <i>i</i>th solution component is unimportant. The absolute error tolerances determine the accuracy when the solution approaches zero. Even if you are not interested in a component <math>y(i)</math> when it is small, you may have to specify <b>AbsTol(i)</b> small enough to get some correct digits in <math>y(i)</math> so that you can accurately compute more interesting components.</p> <p>If <b>AbsTol</b> is a vector, the length of <b>AbsTol</b> must be the same as the length of the solution vector <math>y</math>. If <b>AbsTol</b> is a scalar, the value applies to all components of <math>y</math>.</p> |
| <b>NormControl</b> | on   {off}                           | Control error relative to norm of solution. Set this property on to request that the solvers control the error in each integration step with $\text{norm}(e) \leq \max(\text{RelTol} \cdot \text{norm}(y), \text{AbsTol})$ . By default, the solvers use a more stringent component-wise error control.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Solver Output Properties

You can use the solver output properties to control the output that the solvers generate.

### DDE Solver Output Properties

| Property         | Value                          | Description                                                                                                                                                                                                                                                                                                                                                         |
|------------------|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OutputFcn</b> | Function handle $\{@odeplot\}$ | <p>The output function is a function that the solver calls after every successful integration step. To specify an output function, set 'OutputFcn' to a function handle. For example,</p> <pre>options = ddeset('OutputFcn',... @myfun)</pre> <p>sets 'OutputFcn' to @myfun, a handle to the function myfun. See “Create Function Handle” for more information.</p> |

| Property | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|          |       | <p>The output function must be of the form</p> <pre>status = myfun(t,y,flag)</pre> <p>“Parameterizing Functions” explains how to provide additional parameters to <code>myfun</code>, if necessary.</p> <p>The solver calls the specified output function with the following flags. Note that the syntax of the call differs with the flag. The function must respond appropriately:</p> <ul style="list-style-type: none"> <li>• <code>init</code> — The solver calls <code>myfun(tspan,y0,'init')</code> before beginning the integration to allow the output function to initialize. <code>tspan</code> is the input argument to the solvers. <code>y0</code> is the initial value of the solution, either from <code>history(t0)</code> or specified in the <code>initialY</code> option.</li> <li>• <code>{none}</code> — The solver calls <code>status = myfun(t,y)</code> after each integration step on which output is requested. <code>t</code> contains points where output was generated during the step, and <code>y</code> is the numerical solution at the points in <code>t</code>. If <code>t</code> is a vector, the <code>i</code>th column of <code>y</code> corresponds to the <code>i</code>th element of <code>t</code>.</li> </ul> <p><code>myfun</code> must return a <code>status</code> output value of 0 or 1. If <code>status = 1</code>, the solver halts integration. You can use this mechanism, for instance, to implement a <b>Stop</b> button.</p> <ul style="list-style-type: none"> <li>• <code>done</code> — The solver calls <code>myfun([],[],'done')</code> when integration is complete to allow the output function to perform any cleanup chores.</li> </ul> <p>You can use these general purpose output functions or you can edit them to create your own. Type <code>help functionname</code> at the command line for more information.</p> <ul style="list-style-type: none"> <li>• <code>odeplot</code> – time series plotting (default when you call the solver with no output argument and you have not specified an output function)</li> <li>• <code>odephas2</code> – two-dimensional phase plane plotting</li> </ul> |

| Property               | Value                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        |                                      | <ul style="list-style-type: none"> <li>• <code>odephas3</code> – three-dimensional phase plane plotting</li> <li>• <code>odeprint</code> – print solution as the solver computes it</li> </ul>                                                                                                                                                                                                                                                                          |
| <code>OutputSel</code> | Vector of indices                    | <p>Vector of indices specifying which components of the solution vector the solvers pass to the output function. For example, if you want to use the <code>odeplot</code> output function, but you want to plot only the first and third components of the solution, you can do this using</p> <pre>options = ddeset... ('OutputFcn',@odeplot,... 'OutputSel',[1 3]);</pre> <p>By default, the solver passes all components of the solution to the output function.</p> |
| <code>Stats</code>     | <code>on</code>   <code>{off}</code> | <p>Specifies whether the solver should display statistics about its computations. By default, <code>Stats</code> is <code>off</code>. If it is <code>on</code>, after solving the problem the solver displays:</p> <ul style="list-style-type: none"> <li>• The number of successful steps</li> <li>• The number of failed attempts</li> <li>• The number of times the DDE function was called</li> </ul>                                                               |

## Step Size Properties

The step size properties let you specify the size of the first step the solver tries, potentially helping it to better recognize the scale of the problem. In addition, you can specify bounds on the sizes of subsequent time steps.

The following table describes the step size properties.

### DDE Step Size Properties

| Property                 | Value           | Description                                                                                                                                                                                                                                                                                                                              |
|--------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>InitialStep</code> | Positive scalar | Suggested initial step size. <code>InitialStep</code> sets an upper bound on the magnitude of the first step size the solver tries. If you do not set <code>InitialStep</code> , the solver bases the initial step size on the slope of the solution at the initial time <code>tspan(1)</code> . The initial step size is limited by the |

| Property             | Value                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      |                                                      | shortest delay. If the slope of all solution components is zero, the procedure might try a step size that is much too large. If you know this is happening or you want to be sure that the solver resolves important behavior at the start of the integration, help the code start by providing a suitable <code>InitialStep</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>MaxStep</code> | Positive scalar<br>{ $0.1 * \text{abs}(t_0 - t_f)$ } | Upper bound on solver step size. If the differential equation has periodic coefficients or solutions, it may be a good idea to set <code>MaxStep</code> to some fraction (such as 1/4) of the period. This guarantees that the solver does not enlarge the time step too much and step over a period of interest. Do <i>not</i> reduce <code>MaxStep</code> : <ul style="list-style-type: none"> <li>• When the solution does not appear to be accurate enough. Instead, reduce the relative error tolerance <code>RelTol</code>, and use the solution you just computed to determine appropriate values for the absolute error tolerance vector <code>AbsTol</code>. (See “Error Control Properties” on page 1-2068 for a description of the error tolerance properties.)</li> <li>• To make sure that the solver doesn't step over some behavior that occurs only once during the simulation interval. If you know the time at which the change occurs, break the simulation interval into two pieces and call the solver twice. If you do not know the time at which the change occurs, try reducing the error tolerances <code>RelTol</code> and <code>AbsTol</code>. Use <code>MaxStep</code> as a last resort.</li> </ul> |

## Event Location Property

In some DDE problems, the times of specific events are important. While solving a problem, the solvers can detect such events by locating transitions to, from, or through zeros of user-defined functions.

The following table describes the `Events` property.

### DDE Events Property

| String | Value           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Events | Function handle | <p>A function handle that includes one or more event functions. For <code>dde23</code> and <code>ddesd</code>, this function has the following syntax:</p> <pre>[value, isterminal, direction] = events(t,y,YDEL)</pre> <p>For <code>ddensd</code>, the syntax is:</p> <pre>[value, isterminal, direction] = events(t,y,YDEL,YPDEL)</pre> <p>The output arguments, <code>value</code>, <code>isterminal</code>, and <code>direction</code>, are vectors for which the <code>i</code>th element corresponds to the <code>i</code>th event function:</p> <ul style="list-style-type: none"> <li>• <code>value(i)</code> is the value of the <code>i</code>th event function.</li> <li>• <code>isterminal(i) = 1</code> if you want the integration to terminate at a zero of this event function, and <code>0</code> otherwise.</li> <li>• <code>direction(i) = 0</code> if you want the solver to locate all zeros (the default), <code>+1</code> if only zeros where the event function is increasing, and <code>-1</code> if only zeros where the event function is decreasing.</li> </ul> <p>If you specify an events function and events are detected, the solver returns three additional fields in the solution structure <code>sol</code>:</p> <ul style="list-style-type: none"> <li>• <code>sol.xe</code> is a row vector of times at which events occur.</li> <li>• <code>sol.ye</code> is a matrix whose columns are the solution values corresponding to times in <code>sol.xe</code>.</li> <li>• <code>sol.ie</code> is a vector containing indices that specify which event occurred at the corresponding time in <code>sol.xe</code>.</li> </ul> <p>For examples that use an event function while solving ordinary differential equation problems, see “Event Location” (<code>ballode</code>) and “Advanced Event Location” (<code>orbitode</code>), in the MATLAB Mathematics documentation.</p> |

## Discontinuity Properties

The solver functions can solve problems with discontinuities in the history or in the coefficients of the equations. The following properties enable you to provide these solvers with a different initial value, and, for `dde23`, locations of known discontinuities. For more information, see “Discontinuities in DDEs”.

The following table describes the discontinuity properties.

### DDE Discontinuity Properties

| String                | Value  | Description                                                                                                                                                                                                                      |
|-----------------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Jumps</code>    | Vector | Location of discontinuities. Points $t$ where the history or solution may have a jump discontinuity in a low-order derivative. This applies only to the <code>dde23</code> solver.                                               |
| <code>InitialY</code> | Vector | Initial value of solution. By default the initial value of the solution is the value returned by <code>history</code> at the initial point. Supply a different initial value as the value of the <code>InitialY</code> property. |

## Examples

To create an options structure that changes the relative error tolerance of the solver from the default value of  $1e-3$  to  $1e-4$ , enter

```
options = ddeSet('RelTol',1e-4);
```

To recover the value of 'RelTol' from `options`, enter

```
ddeget(options,'RelTol')
```

```
ans =
```

```
1.0000e-004
```

# deal

Distribute inputs to outputs

## Compatibility

Beginning with MATLAB Version 7.0 software, you can access the contents of cell arrays and structure fields without using the `deal` function. See Example 3, below.

## Syntax

```
[Y1, Y2, Y3, ...] = deal(X)
[Y1, Y2, Y3, ...] = deal(X1, X2, X3, ...)
[S.field] = deal(X)
[X{:}] = deal(A.field)
[Y1, Y2, Y3, ...] = deal(X{:})
[Y1, Y2, Y3, ...] = deal(S.field)
```

## Description

`[Y1, Y2, Y3, ...] = deal(X)` copies the single input to all the requested outputs. It is the same as `Y1 = X, Y2 = X, Y3 = X, ...`

`[Y1, Y2, Y3, ...] = deal(X1, X2, X3, ...)` is the same as `Y1 = X1; Y2 = X2; Y3 = X3; ...`

## Examples

### Example 1 — Assign Data From a Cell Array

Use `deal` to copy the contents of a 4-element cell array into four separate output variables.

```
C = {rand(3) ones(3,1) eye(3) zeros(3,1)};
[a,b,c,d] = deal(C{:})
```

```
a =
 0.9501 0.4860 0.4565
 0.2311 0.8913 0.0185
 0.6068 0.7621 0.8214
```

```
b =
 1
 1
 1
```

```
c =
 1 0 0
 0 1 0
 0 0 1
```

```
d =
 0
 0
 0
```

## Example 2 — Assign Data From Structure Fields

Use `deal` to obtain the contents of all the name fields in a structure array:

```
A.name = 'Pat'; A.number = 176554;
A(2).name = 'Tony'; A(2).number = 901325;
[name1,name2] = deal(A(:).name)
```

```
name1 =
 Pat
```

```
name2 =
 Tony
```

## Example 3 — Doing the Same Without deal

Beginning with MATLAB Version 7.0 software, you can, in most cases, access the contents of cell arrays and structure fields without using the `deal` function. The two commands shown below perform the same operation as those used in the previous two examples, except that these commands do not require `deal`.

```
[a,b,c,d] = C{:}
```

```
[name1,name2] = A(:).name
```

## More About

### Tips

`deal` is most useful when used with cell arrays and structures via comma-separated list expansion. Here are some useful constructions:

`[S.field] = deal(X)` sets all the fields with the name `field` in the structure array `S` to the value `X`. If `S` doesn't exist, use `[S(1:m).field] = deal(X)`.

`[X{:}] = deal(A.field)` copies the values of the field with name `field` to the cell array `X`. If `X` doesn't exist, use `[X{1:m}] = deal(A.field)`.

`[Y1, Y2, Y3, ...] = deal(X{:})` copies the contents of the cell array `X` to the separate variables `Y1, Y2, Y3, ...`

`[Y1, Y2, Y3, ...] = deal(S.field)` copies the contents of the fields with the name `field` to separate variables `Y1, Y2, Y3, ...`

# deblank

Strip trailing blanks from end of string

## Syntax

```
str = deblank(str)
c = deblank(c)
```

## Description

`str = deblank(str)` removes all trailing whitespace and null characters from the end of character string `str`. A whitespace is any character for which the `isspace` function returns logical 1 (`true`).

`c = deblank(c)` when `c` is a cell array of strings, applies `deblank` to each element of `c`.

The `deblank` function is useful for cleaning up the rows of a character array.

## Examples

### Example 1 – Removing Trailing Blanks From a String

Compose a string `str` that contains space, tab, and null characters:

```
NL = char(0); TAB = char(9);
str = [NL 32 TAB NL 'AB' 32 NL 'CD' NL 32 TAB NL 32];
```

Display all characters of the string between `|` symbols:

```
['|' str '|']
ans =
 | AB CD |
```

Remove trailing whitespace and null characters, and redisplay the string:

```
newstr = deblank(str);
```

```
['| ' newstr '| ']
ans =
 | AB CD|
```

## Example 2– Removing Trailing Blanks From a Cell Array of Strings

Create a 2-by-2 cell array in which each cell contains a word with trailing blanks:

```
A{1,1} = 'MATLAB '
A{1,2} = 'SIMULINK '
A{2,1} = 'Toolboxes '
A{2,2} = 'MathWorks '
A =
 'MATLAB ' 'SIMULINK '
 'Toolboxes ' 'MathWorks '
```

Remove the trailing blanks and redisplay the cell array:

```
A = deblank(A);

A
A =
 'MATLAB' 'SIMULINK'
 'Toolboxes' 'MathWorks'
```

# dec2base

Convert decimal to base N number in string

## Syntax

```
str = dec2base(d, base)
str = dec2base(d, base, n)
```

## Description

`str = dec2base(d, base)` converts the nonnegative integer `d` to the specified `base`. `d` must be a nonnegative integer smaller than  $2^{52}$ , and `base` must be an integer between 2 and 36. The returned argument `str` is a string.

`str = dec2base(d, base, n)` produces a representation with at least `n` digits.

## Examples

The expression `dec2base(23, 2)` converts  $23_{10}$  to base 2, returning the string `'10111'`.

## See Also

`base2dec`

Introduced before R2006a

## dec2bin

Convert decimal to binary number in string

### Syntax

```
str = dec2bin(d)
str = dec2bin(d,n)
```

### Description

`str = dec2bin(d)` returns the binary representation of `d` as a string. `d` must be a nonnegative integer. If `d` is greater than  $2^{52}$ , `dec2bin` might not return an exact representation of `d`.

`str = dec2bin(d,n)` produces a binary representation with at least `n` bits.

The output of `dec2bin` is independent of the endian settings of the computer you are using.

### Examples

Decimal 23 converts to binary 010111:

```
dec2bin(23)
ans =
 10111
```

### See Also

[bin2dec](#) | [dec2hex](#)

# dec2hex

Convert decimal to hexadecimal number in string

## Syntax

```
str = dec2hex(d)
str = dec2hex(d, n)
```

## Description

`str = dec2hex(d)` converts the decimal integer `d` to its hexadecimal representation stored in a MATLAB string. `d` must be a nonnegative integer. If `d` is an integer greater than  $2^{52}$ , `dec2hex` might not return an exact representation. MATLAB converts noninteger inputs, such as those of class `double` or `char`, to their integer equivalents before converting to hexadecimal.

`str = dec2hex(d, n)` produces a hexadecimal representation with at least `n` digits.

## Examples

To convert decimal 1023 to hexadecimal,

```
dec2hex(1023)
ans =
 3FF
```

```
dec2hex(1023, 6)
ans =
0003FF
```

Convert 2-by-5 array `A` to hexadecimal:

```
A = [3487, 125, 8997, 1433, 189; ...
 771, 84832, 118, 9366, 212];
```

```
A(:) dec2hex(A)
ans = ans =
```

|       |       |
|-------|-------|
| 3487  | 00D9F |
| 771   | 00303 |
| 125   | 0007D |
| 84832 | 14B60 |
| 8997  | 02325 |
| 118   | 00076 |
| 1433  | 00599 |
| 9366  | 02496 |
| 189   | 000BD |
| 212   | 000D4 |

## See Also

[dec2bin](#) | [format](#) | [hex2dec](#) | [hex2num](#)

# decic

Compute consistent initial conditions for ode15i

## Syntax

```
[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0)
[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0,options)
[y0mod,yp0mod,resnorm] =
decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0...)
```

## Description

`[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0)` uses the inputs `y0` and `yp0` as initial guesses for an iteration to find output values that satisfy the requirement  $f(t_0, y_{0mod}, y_{p0mod}) = 0$ , i.e., `y0mod` and `yp0mod` are consistent initial conditions. `odefun` is a function handle. The function `decic` changes as few components of the guesses as possible. You can specify that `decic` holds certain components fixed by setting `fixed_y0(i) = 1` if no change is permitted in the guess for `y0(i)` and 0 otherwise. `decic` interprets `fixed_y0 = []` as allowing changes in all entries. `fixed_yp0` is handled similarly.

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, if necessary.

You cannot fix more than `length(y0)` components. Depending on the problem, it may not be possible to fix this many. It also may not be possible to fix certain components of `y0` or `yp0`. It is recommended that you fix no more components than necessary.

`[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0,options)` computes as above with default tolerances for consistent initial conditions, `AbsTol` and `RelTol`, replaced by the values in `options`, a structure you create with the `odeset` function.

`[y0mod,yp0mod,resnorm] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0...)` returns the norm of

`odefun(t0, y0mod, yp0mod)` as `resnm`. If the norm seems unduly large, use `options` to decrease `RelTol` (`1e-3` by default).

## Examples

The files, `ihb1dae.m` and `iburgersode.m`, provide examples which use `decic` to solve implicit ODEs.

**Introduced before R2006a**

# deconv

Deconvolution and polynomial division

## Syntax

$$[q, r] = \text{deconv}(v, u)$$

## Description

$[q, r] = \text{deconv}(v, u)$  deconvolves vector  $u$  out of vector  $v$ , using long division. The quotient is returned in vector  $q$  and the remainder in vector  $r$  such that  $v = \text{conv}(u, q) + r$ .

If  $u$  and  $v$  are vectors of polynomial coefficients, convolving them is equivalent to multiplying the two polynomials, and deconvolution is polynomial division. The result of dividing  $v$  by  $u$  is quotient  $q$  and remainder  $r$ .

## Examples

If

$$u = [1 \quad 2 \quad 3 \quad 4]$$

$$v = [10 \quad 20 \quad 30]$$

the convolution is

$$c = \text{conv}(u, v)$$

$$c =$$

|    |    |     |     |     |     |
|----|----|-----|-----|-----|-----|
| 10 | 40 | 100 | 160 | 170 | 120 |
|----|----|-----|-----|-----|-----|

Use deconvolution to recover  $v$ :

$$[q, r] = \text{deconv}(c, u)$$

$$q =$$

|    |    |    |
|----|----|----|
| 10 | 20 | 30 |
|----|----|----|

$$r =$$

|   |   |   |   |   |   |
|---|---|---|---|---|---|
| 0 | 0 | 0 | 0 | 0 | 0 |
|---|---|---|---|---|---|

This gives a quotient equal to  $v$  and a zero remainder.

## **More About**

### **Algorithms**

`deconv` uses the `filter` primitive.

**Introduced before R2006a**

# deg2rad

Convert angle from degrees to radians

## Syntax

`R = deg2rad(D)`

## Description

`R = deg2rad(D)` converts angle units from degrees to radians for each element of `D`.

## Examples

### Right Angle in Radians

Convert a 90 degree angle into radians.

```
R = deg2rad(90)
```

```
R =
```

```
 1.5708
```

### Surface Distance

Specify the spherical distance between Munich and Bangalore in degrees and the mean radius of Earth in kilometers. Compute the distance (measured along the Earth's surface) between Munich and Bangalore, in kilometers.

```
D = 64.7;
radEarth = 6371;
R = deg2rad(D);
dist = radEarth*R
```

dist =

7.1943e+03

## Input Arguments

### **D** — Angle in degrees

scalar | vector | matrix | multidimensional array

Angle in degrees, specified as a scalar, vector, matrix, or multidimensional array. If **D** contains complex elements, **deg2rad** converts the real and imaginary parts separately.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **R** — Angle in radians

scalar | vector | matrix | multidimensional array

Angle in radians, returned as a scalar, vector, matrix, or multidimensional array. **R** is the same size as **D**.

## See Also

`rad2deg`

**Introduced in R2015b**

# del2

Discrete Laplacian

## Syntax

```
L = del2(U)
L = del2(U,h)
L = del2(U,h1,...,hN)
```

## Description

`L = del2(U)` returns a discrete approximation of Laplace's differential operator applied to `U` using the default spacing, `h = 1`, between all points.

`L = del2(U,h)` specifies a uniform, scalar spacing, `h`, between points in all dimensions of `U`.

`L = del2(U,h1,...,hN)` specifies the spacing, `h1,...,hN`, between points in each corresponding dimension of `U`. For each dimension, specify the spacing as a scalar or a vector of coordinates. The number of spacing inputs must equal the number of dimensions in `U`.

## Examples

### Second Derivative of Vector

Calculate the acceleration of an object from a vector of position data.

Create a vector of position data.

```
p = [1 3 6 10 16 18 29];
```

To find the acceleration of the object, use `del2` to calculate the second numerical derivative of `p`. Use the default spacing `h = 1` between data points.

```
L = 4*del2(p)
```

```
L =
```

```
 1 1 1 2 -4 9 22
```

Each value of L is an approximation of the instantaneous acceleration at that point.

## Second Derivative of Cosine Vector

Calculate the discrete 1-D Laplacian of a cosine vector.

Define the domain of the function.

```
x = linspace(-2*pi,2*pi);
```

This produces 100 evenly spaced points in the range  $-2\pi \leq x \leq 2\pi$ .

Create a vector of cosine values in this domain.

```
U = cos(x);
```

Calculate the Laplacian of U using `del2`. Use the domain vector `x` to define the 1-D coordinate of each point in U.

```
L = 4*del2(U,x);
```

Analytically, the Laplacian of this function is equal to  $\Delta U = -\cos(x)$ .

Plot the results.

```
plot(x,U,x,L)
legend('U(x)', 'L(x)', 'Location', 'Best')
```

The graph of U and L agrees with the analytic result for the Laplacian.

### Laplacian of Multivariate Function

Calculate and plot the discrete Laplacian of a multivariate function.

Define the x and y domain of the function.

```
[x,y] = meshgrid(-5:0.25:5, -5:0.25:5);
```

Define the function  $U(x, y) = \frac{1}{3}(x^4 + y^4)$  over this domain.

```
U = 1/3.*(x.^4+y.^4);
```

Calculate the Laplacian of this function using `del2`. The spacing between the points in `U` is equal in all directions, so you can specify a single spacing input, `h`.

```
h = 0.25;
L = 4*del2(U,h);
```

Analytically, the Laplacian of this function is equal to  $\Delta U(x,y) = 4x^2 + 4y^2$ .

Plot the discrete Laplacian, `L`.

```
figure
surf(x,y,L)
grid on
title('Plot of $\Delta U(x,y) = 4x^2 + 4y^2$ ', 'Interpreter', 'latex')
xlabel('x')
ylabel('y')
zlabel('z')
view(35,14)
```

The graph of  $L$  agrees with the analytic result for the Laplacian.

### Laplacian of Natural Logarithm Function

Calculate the discrete Laplacian of a natural logarithm function.

Define the  $x$  and  $y$  domain of the function on a grid of real numbers.

```
[x,y] = meshgrid(-5:5, -5:0.5:5);
```

Define the function  $U(x, y) = \frac{1}{2} \log(x^2 y)$  over this domain.

```
U = 0.5*log(x.^2.*y);
```

The logarithm is complex-valued when the argument  $y$  is negative.

Use `del2` to calculate the discrete Laplacian of this function. Specify the spacing between grid points in each direction.

```
hx = 1;
hy = 0.5;
L = 4*del2(U,hx,hy);
```

Analytically, the Laplacian is equal to  $\Delta U(x,y) = -(1/x^2 + 1/2y^2)$ . This function is not defined on the lines  $x = 0$  or  $y = 0$ .

Plot the real parts of  $U$  and  $L$  on the same graph.

```
figure
surf(x,y,real(L))
hold on
surf(x,y,real(U))
grid on
title('Plot of U(x,y) and $\Delta U(x,y)$ ','Interpreter','latex')
xlabel('x')
ylabel('y')
zlabel('z')
view(41,58)
```

The top surface is  $U$  and the bottom surface is  $L$ .

## Input Arguments

### **U** — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `single` | `double`

Complex Number Support: Yes

## **h** — Spacing in all dimensions

1 (default) | scalar

Spacing in all dimensions, specified as 1 (default), or a scalar.

Data Types: `single` | `double`

Complex Number Support: Yes

## **h1, . . . , hN** — Spacing in each dimension

scalars | vectors

Spacing in each dimension, specified as scalars or vectors. The number of spacing inputs must be equal to the number of dimensions in  $U$ . Each spacing input defines the spacing between points in the corresponding dimension of  $U$ :

- Use a scalar to specify a uniform spacing.
- Use a vector to specify a nonuniform spacing. The coordinate vector gives the position of each point and must have the same number of elements as the corresponding dimension of  $U$  (a one-to-one match of coordinates and points).

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **L** — Discrete Laplacian approximation

vector | matrix | multidimensional array

Discrete Laplacian approximation, returned as a vector, matrix, or multidimensional array.  $L$  is the same size as the input,  $U$ .

## More About

### Laplace's differential operator

If a matrix  $U$  is a function  $U(x,y)$  that is evaluated at the points of a square grid, then  $4*de12(U)$  is a finite difference approximation of Laplace's differential operator applied to  $U$ ,

$$L = \frac{\Delta U}{4} = \frac{1}{4} \left( \frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} \right).$$

For functions of more variables,  $U(x,y,z,\dots)$ , the discrete Laplacian `del2(U)` calculates second-derivatives in each dimension,

$$L = \frac{\Delta U}{2N} = \frac{1}{2N} \left( \frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} + \frac{\partial^2 U}{\partial z^2} + \dots \right),$$

where  $N$  is the number of dimensions in  $U$  and  $N \geq 2$ .

### Algorithms

If the input  $U$  is a matrix, the interior points of  $L$  are found by taking the difference between a point in  $U$  and the average of its four neighbors:

$$L_{ij} = \left[ \frac{(u_{i+1,j} + u_{i-1,j} + u_{i,j+1} + u_{i,j-1})}{4} - u_{i,j} \right].$$

Then, `del2` calculates the values on the edges of  $L$  by linearly extrapolating the second differences from the interior. This formula is extended for multidimensional  $U$ .

## DelaunayTri class

**Superclasses:** TriRep

(Not recommended) Delaunay triangulation in 2-D and 3-D

---

**Note:** DelaunayTri is not recommended. Use delaunayTriangulation instead.

---

### Description

DelaunayTri creates a Delaunay triangulation object from a set of points. You can incrementally modify the triangulation by adding or removing points. In 2-D triangulations you can impose edge constraints. You can perform topological and geometric queries, and compute the Voronoi diagram and convex hull.

### Definitions

The 2-D Delaunay triangulation of a set of points is the triangulation in which no point of the set is contained in the circumcircle for any triangle in the triangulation. The definition extends naturally to higher dimensions.

### Construction

.DelaunayTri (Not recommended) Construct Delaunay triangulation

### Methods

convexHull (Not recommended) Convex hull  
inOutStatus (Not recommended) Status of triangles in 2-D constrained Delaunay triangulation

---

# DelaunayTri

**Class:** DelaunayTri

(Not recommended) Construct Delaunay triangulation

---

**Note:** DelaunayTri is not recommended. Use delaunayTriangulation instead.

---

## Syntax

DT = DelaunayTri()  
DT = DelaunayTri(X)  
DT = DelaunayTri(x,y)  
DT = DelaunayTri(x,y,z)  
DT = DelaunayTri(..., C)

## Description

DT = DelaunayTri() creates an empty Delaunay triangulation.

DT = DelaunayTri(X), DT = DelaunayTri(x,y) and DT = DelaunayTri(x,y,z) create a Delaunay triangulation from a set of points. The points can be specified as an `mpts-by-ndim` matrix `X`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside, where `ndim` is 2 or 3. Alternatively, the points can be specified as column vectors `(x,y)` or `(x,y,z)` for 2-D and 3-D input.

DT = DelaunayTri(..., C) creates a constrained Delaunay triangulation. The edge constraints `C` are defined by an `numc-by-2` matrix, `numc` being the number of constrained edges. Each row of `C` defines a constrained edge in terms of its endpoint indices into the point set `X`. This feature is only supported for 2-D triangulations.

## Definitions

The 2-D Delaunay triangulation of a set of points is the triangulation in which no point of the set is contained in the circumcircle for any triangle in the triangulation. The definition extends naturally to higher dimensions.

## Examples

Compute the Delaunay triangulation of twenty random points located within a unit square.

```
x = rand(20,1);
y = rand(20,1);
dt = DelaunayTri(x,y)
triplot(dt);
```

For more examples, type `help demoDelaunayTri` at the MATLAB command-line prompt.

# delaunay

Delaunay triangulation

---

**Note:** Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `delaunay`.

---

## Syntax

```
TRI = delaunay(X,Y)
TRI = delaunay(X,Y,Z)
TRI = delaunay(X)
```

## Definitions

`delaunay` creates a Delaunay triangulation of a set of points in 2-D or 3-D space. A 2-D Delaunay triangulation ensures that the circumcircle associated with each triangle contains no other point in its interior. This definition extends naturally to higher dimensions.

— Delaunay triangle  
— Voronoi polygon

## Description

`TRI = delaunay(X,Y)` creates a 2-D Delaunay triangulation of the points (X,Y), where X and Y are column-vectors. `TRI` is a matrix representing the set of triangles that make up the triangulation. The matrix is of size `mtri-by-3`, where `mtri` is the number of triangles. Each row of `TRI` specifies a triangle defined by indices with respect to the points.

`TRI = delaunay(X,Y,Z)` creates a 3-D Delaunay triangulation of the points (X,Y,Z), where X, Y, and Z are column-vectors. `TRI` is a matrix representing the set of tetrahedra that make up the triangulation. The matrix is of size `mtri-by-4`, where `mtri` is the number of tetrahedra. Each row of `TRI` specifies a tetrahedron defined by indices with respect to the points.

`TRI = delaunay(X)` creates a 2-D or 3-D Delaunay triangulation from the point coordinates X. This variant supports the definition of points in matrix format. X is of size `mpts-by-ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside,  $2 \leq \text{ndim} \leq 3$ . The output triangulation is equivalent to that of the dedicated functions supporting the 2-input or 3-input calling syntax.

`delaunay` produces an isolated triangulation, useful for applications like plotting surfaces via the `trisurf` function. If you wish to query the triangulation; for example, to perform nearest neighbor, point location, or topology queries, use `delaunayTriangulation` instead.

## Visualization

Use one of these functions to plot the output of `delaunay`:

|                      |                                                                                                                                                                                                                                                                            |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>triplot</code> | Displays the triangles defined in the <code>m-by-3</code> matrix <code>TRI</code> .                                                                                                                                                                                        |
| <code>trisurf</code> | Displays each triangle defined in the <code>m-by-3</code> matrix <code>TRI</code> as a surface in 3-D space. To see a 2-D surface, you can supply a vector of some constant value for the third dimension. For example<br><br><code>trisurf(TRI,x,y,zeros(size(x)))</code> |
| <code>trimesh</code> | Displays each triangle defined in the <code>m-by-3</code> matrix <code>TRI</code> as a mesh in 3-D space. To see a 2-D surface, you can supply a vector of some constant value for the third dimension. For example,                                                       |

```
trimesh(TRI,x,y,zeros(size(x)))
```

produces almost the same result as `triplot`, except in 3-D space.

`tetramesh` Plots a triangulation composed of tetrahedra.

## Examples

### Plot Delaunay Triangulation

Plot the Delaunay triangulation of a large dataset.

```
load seamount
tri = delaunay(x,y);
trisurf(tri,x,y,z);
```

### See Also

[scatteredInterpolant](#) | [plot](#) | [triplot](#) | [delaunayTriangulation](#) | [trimesh](#) | [trisurf](#)

Introduced before R2006a

# delaunayn

N-D Delaunay triangulation

## Syntax

```
T = delaunayn(X)
T = delaunayn(X, options)
```

## Description

`T = delaunayn(X)` computes a set of simplices such that no data points of `X` are contained in any circumspheres of the simplices. The set of simplices forms the Delaunay triangulation. `X` is an `m`-by-`n` array representing `m` points in `n`-dimensional space. `T` is a `numt`-by-`(n+1)` array where each row contains the indices into `X` of the vertices of the corresponding simplex.

`T = delaunayn(X, options)` specifies a cell array of strings `options`. The default options are:

- `{ 'Qt', 'Qbb', 'Qc' }` for 2- and 3-dimensional input
- `{ 'Qt', 'Qbb', 'Qc', 'Qx' }` for 4 and higher-dimensional input

If `options` is `[]`, the default options used. If `options` is `{ '' }`, no options are used, not even the default.

## Visualization

Plotting the output of `delaunayn` depends of the value of `n`:

- For `n = 2`, use `triplot`, `trisurf`, or `trimesh` as you would for `delaunay`.
- For `n = 3`, use `tetramesh`.

For more control over the color of the facets, use `patch` to plot the output.

- You cannot plot `delaunayn` output for `n > 3`.

## Examples

### 3-D Delaunay Triangulation

This example generates an n-dimensional Delaunay triangulation, where  $n = 3$ .

```
d = [-1 1];
[x,y,z] = meshgrid(d,d,d); % A cube
x = [x(:);0];
y = [y(:);0];
z = [z(:);0];
% [x,y,z] are corners of a cube plus the center.
X = [x(:) y(:) z(:)];
Tes = delaunayn(X)
```

Tes =

|   |   |   |   |
|---|---|---|---|
| 4 | 3 | 9 | 1 |
| 4 | 9 | 2 | 1 |
| 7 | 9 | 3 | 1 |
| 7 | 5 | 9 | 1 |
| 7 | 9 | 4 | 3 |
| 7 | 8 | 4 | 9 |
| 6 | 2 | 9 | 1 |
| 6 | 9 | 5 | 1 |
| 6 | 4 | 9 | 2 |
| 6 | 4 | 8 | 9 |
| 6 | 9 | 7 | 5 |
| 6 | 8 | 7 | 9 |

You can use `tetramesh` to visualize the tetrahedrons that form the corresponding simplex. `camorbit` rotates the camera position to provide a meaningful view of the figure.

```
tetramesh(Tes,X);
camorbit(20,0)
```

Introduced before R2006a

# delaunayTriangulation class

**Superclasses:** triangulation

Delaunay triangulation in 2-D and 3-D

## Description

Use the `delaunayTriangulation` class to create a 2-D or 3-D triangulation from a set of points. When your points are in 2-D, you can specify edge constraints .

You can perform a variety of topological and geometric queries on a `delaunayTriangulation`, including any triangulation query. For example, locate a facet that contains a specific point, find the vertices of the convex hull, or compute the Voronoi Diagram.

## Construction

`DT = delaunayTriangulation(P)` creates a Delaunay triangulation from the points in `P`. Matrix `P` has 2 or 3 columns, depending on whether your points are in 2-D or 3-D space.

`DT = delaunayTriangulation(P,C)` specifies the edge constraints in matrix `C`. In this case, `P` specifies points in 2-D. Each row of `C` defines the start and end vertex IDs of a constrained edge.

`DT = delaunayTriangulation(x,y)` creates a 2-D Delaunay triangulation from the point coordinates in the column vectors, `x` and `y`.

`DT = delaunayTriangulation(x,y,C)` specifies the edge constraints in matrix `C`.

`DT = delaunayTriangulation(x,y,z)` creates a 3-D Delaunay triangulation from the point coordinates in the column vectors, `x`, `y`, and `z`.

`DT = delaunayTriangulation()` creates an empty Delaunay triangulation.

## Input Arguments

### **P**

Input points, specified as a matrix whose columns are the  $x$ ,  $y$ , (and possibly  $z$ ) coordinates of the triangulation points. The row numbers of **P** are the vertex IDs in the triangulation.

### **x**

$x$ -coordinates vector, specified as a column vector containing the  $x$ -coordinates of the triangulation points.

### **y**

$y$ -coordinates vector, specified as a column vector containing the  $y$ -coordinates of the triangulation points.

### **z**

$z$ -coordinates vector, specified as a column vector containing the  $z$ -coordinates of the triangulation points.

### **C**

Vertex IDs of constrained edges, specified as a 2-column matrix. Each row of **C** corresponds to a constrained edge and contains two IDs:

- $C(j, 1)$  is the ID of the vertex at the start of an edge.
- $C(j, 2)$  is the ID of the vertex at end of the edge.

You can specify edge constraints for 2-D triangulations only.

## Properties

### **Points**

Points in the triangulation, represented as a matrix containing the following information:

- Each row in **DT.Points** contains the coordinates of a vertex.
- Each row number of **DT.Points** is a vertex ID.

## **ConnectivityList**

Triangulation connectivity list, represented as a matrix. This matrix contains the following information:

- Each row represents a triangle or tetrahedron in the triangulation.
- Each row number of `DT.ConnectivityList` is a “Triangle or Tetrahedron ID” on page 1-2118.
- Each element is a vertex ID.

## **Constraints**

Constrained edges, represented as a two-column matrix of vertex IDs. Each row of `DT.Constraints` corresponds to a constrained edge and contains two IDs:

- `DT.Constraints(j,1)` is the ID of the vertex at the start of an edge.
- `DT.Constraints(j,2)` is the ID of the vertex at end of the edge.

`DT.Constraints` is an empty matrix when the triangulation has no constrained edges.

## **Methods**

|                             |                                                                           |
|-----------------------------|---------------------------------------------------------------------------|
| <code>convexHull</code>     | Convex hull                                                               |
| <code>isInterior</code>     | Test if triangle is in interior of 2-D constrained Delaunay triangulation |
| <code>voronoiDiagram</code> | Voronoi diagram                                                           |

## **Inherited Methods**

|                                     |                                                          |
|-------------------------------------|----------------------------------------------------------|

| vertexNormal      | Triangulation vertex normal                                         |

## Definitions

### Delaunay Triangulation

In a 2-D Delaunay triangulation, the circumcircle associated with each triangle does not contain any points in its interior. Similarly, a 3-D Delaunay triangulation does not have any points in the interior of the circumsphere associated with each tetrahedron. This definition extends to N-D, although `del aunayTriangulation` supports only 2-D and 3-D.

### Vertex ID

A row number of the matrix, `DT.Points`. Use this ID to refer a specific vertex in the triangulation.

## Triangle or Tetrahedron ID

A row number of the matrix, `DT.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### 2-D Delaunay Triangulation

Create a 2-D `delaunayTriangulation` for 30 random points.

```
P = gallery('uniformdata',[30 2],0);
DT = delaunayTriangulation(P)
```

```
DT =
```

```
 delaunayTriangulation with properties:
```

```
 Points: [30x2 double]
 ConnectivityList: [50x3 double]
 Constraints: []
```

Plot the triangulation.

```
figure
triplot(DT)
```

### 3-D Delaunay Triangulation

Create a 3-D delaunayTriangulation for 30 random points.

```
x = gallery('uniformdata',[30 1],0);
y = gallery('uniformdata',[30 1],1);
z = gallery('uniformdata',[30 1],2);
DT = delaunayTriangulation(x,y,z)
```

DT =

delaunayTriangulation with properties:

```
Points: [30x3 double]
ConnectivityList: [111x4 double]
Constraints: []
```

Plot the triangulation at 30% opacity with a light blue face color.

```
faceColor = [0.6875 0.8750 0.8984];
figure
tetramesh(DT, 'FaceColor', faceColor, 'FaceAlpha', 0.3);
```

## See Also

[delaunay](#) | [delaunayn](#) | [triangulation](#)

# convexHull

**Class:** delaunayTriangulation

Convex hull

## Syntax

```
K = convexHull(DT)
[K,v] = convexHull(DT)
```

## Description

`K = convexHull(DT)` returns the vertices of the convex hull.

`[K,v] = convexHull(DT)` also returns the area or volume bounded by the convex hull.

## Input Arguments

### DT

A Delaunay triangulation, see `delaunayTriangulation`.

## Output Arguments

### K

Convex hull vertices, returned as a matrix of vertex IDs. The shape of K depends on whether your triangulation is 2-D or 3-D:

- When DT is 2-D, K is a column vector containing the sequence of vertex IDs around the convex hull.
- When DT is 3-D, K is a triangulation connectivity list containing the triangles on the convex hull.

**v**

Area or volume bounded by the convex hull, returned as a scalar value.

## Definitions

### Vertex ID

A row number of the matrix, `DT.Points`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Convex Hull in 2-D Space

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[10,1],0);
y = gallery('uniformdata',[10,1],1);
DT = delaunayTriangulation(x,y);
```

Calculate the convex hull.

```
k = convexHull(DT)
```

```
k =
```

```
1
3
2
8
9
1
```

Plot the points and highlight the convex hull in red.

```
figure
```

```
plot(DT.Points(:,1),DT.Points(:,2), '.','markersize',10);
hold on
plot(DT.Points(k,1),DT.Points(k,2),'r')
hold off
```

### Convex Hull in 3-D Space

Use `convexHull` to calculate the convex hull of a set of random points within a unit cube.

Create a Delaunay triangulation from a set of random points.

```
P = gallery('uniformdata',[25,3],1);
```

```
DT = delaunayTriangulation(P);
```

Calculate the convex hull and the volume bounded by the convex hull.

```
[K,v] = convexHull(DT);
```

Examine the volume.

```
v
```

```
v =
```

```
0.3561
```

Plot the convex hull.

```
trisurf(K,DT.Points(:,1),DT.Points(:,2),DT.Points(:,3),...
 'FaceColor','cyan')
```

**See Also**

[convhull](#) | [convhulln](#) | [triangulation](#) | [voronoiDiagram](#)

## isInterior

**Class:** delaunayTriangulation

Test if triangle is in interior of 2-D constrained Delaunay triangulation

## Syntax

```
tf = isInterior(DT)
```

## Description

`tf = isInterior(DT)` returns an array of logical values that indicate whether the triangles in a constrained Delaunay triangulation are inside the bounded geometric domain. A triangle, `DT.ConnectivityList(j, :)`, is classified as inside the domain when `tf(j)` is `true`. Otherwise, the triangle is outside the domain.

## Input Arguments

**DT**

A 2-D delaunayTriangulation that has a set of constrained edges that define a bounded geometric domain.

## Output Arguments

**tf**

Logical values, returned as a column vector. Element `tf(j)` is `true` when the triangle whose ID is `j` is inside the domain of `DT`.

## Definitions

### Triangle ID

A row number of the matrix, `DT.ConnectivityList`. You use this ID to refer a specific triangle.

## Examples

### Find and Plot Triangles within a Boundary

Create a geometric domain whose shape is a square frame.

```
outerprofile = [-5 -5; -3 -5; -1 -5; 1 -5;
 3 -5; 5 -5; 5 -3; 5 -1;
 5 1; 5 3; 5 5; 3 5;
 1 5; -1 5; -3 5; -5 5;
 -5 3; -5 1; -5 -1; -5 -3];
```

```
innerprofile = outerprofile.*0.5;
profile = [outerprofile; innerprofile];
```

Define the edge constraints.

```
outercons = [(1:19)' (2:20)'; 20 1];
innercons = [(21:39)' (22:40)'; 40 21];
C = [outercons; innercons];
```

Create the constrained Delaunay triangulation.

```
DT = delaunayTriangulation(profile,C);
```

Plot the triangulation.

```
figure
subplot(1,2,1)
triplot(DT)

% Highlight the inner square in red.
hold on
plot(DT.Points(innercons',1),DT.Points(innercons',2),...
 '-r','LineWidth',2)
```

```
% Highlight the outer square in red and resize the |x| and |y| axes to make
% the plot square.
plot(DT.Points(outercons',1),DT.Points(outercons',2), ...
 '-r','LineWidth', 2)
axis equal

% Plot only the triangles that lie inside of the domain.
hold off
subplot(1,2,2)
inside = isInterior(DT);
triplot(DT.ConnectivityList(inside, :),DT.Points(:,1),DT.Points(:,2))

% Highlight the inner and outer squares in red.
hold on
plot(DT.Points(outercons',1),DT.Points(outercons',2), ...
 '-r','LineWidth', 2)
plot(DT.Points(innercons',1),DT.Points(innercons',2), ...
 '-r','LineWidth', 2)
axis equal
hold off
```

**See Also**  
triangulation

## voronoiDiagram

**Class:** delaunayTriangulation

Voronoi diagram

### Syntax

`[V,R] = voronoiDiagram(DT)`

### Description

`[V,R] = voronoiDiagram(DT)` returns the Voronoi vertices, `V`, and the Voronoi regions, `R`, of the points, `DT.Points`.

The *Voronoi diagram* of a set of points, such as `DT.Points`, decomposes the space around each point, `DT.Points(j,:)`, into a region of influence, `R{j}`. Locations within the region, `R{j}`, are closer to point `j` than any other point in `DT.Points`. The region of influence is called the *Voronoi region*. The collection of all the Voronoi regions is the Voronoi diagram.

The Voronoi regions associated with points that lie on the convex hull of `DT.Points` are unbounded. Bounding edges of these regions radiate to infinity. The vertex at infinity is represented by the first vertex in `V`.

### Input Arguments

**DT**

A Delaunay triangulation, see `delaunayTriangulation`.

### Output Arguments

**V**

Voronoi vertices, returned as a matrix. Each row of `V` contains the coordinates of a Voronoi vertex.

**R**

Voronoi regions, returned as a vector cell array the same length as `DT.Points`. The elements of `R` are row numbers of `V`. The coordinates of the Voronoi vertices bounding a region are `V(R{j}, :)`. The Voronoi region associated with the point `DT.Points(j)` is `R{j}`.

**Examples****Compute the Voronoi Diagram of a 2-D Triangulation**

Create a Delaunay triangulation from a set of points.

```
P = [0.5 0
 0 0.5
 -0.5 -0.5
 -0.2 -0.1
 -0.1 0.1
 0.1 -0.1
 0.1 0.1];
DT = delaunayTriangulation(P);
```

Calculate the Voronoi vertices and regions.

```
[V,R] = voronoiDiagram(DT);
```

Examine the connectivity of the Voronoi region associated with the third point in the triangulation.

```
R{3}
```

```
ans =
```

```
 1 10 7 4
```

Examine the coordinates of the Voronoi vertices bounding the region.

```
V(R{3}, :)
```

```
ans =
```

```
 Inf Inf
0.7000 -1.6500
```

-0.0500    -0.5250  
-1.7500    0.7500

The `Inf` values indicate that the region contains points on the convex hull.

# delete

Delete files or objects

## Syntax

```
delete('fileName1', 'filename2', ...)
delete fileName
delete(h)
delete(handle_array)
```

## Description

`delete('fileName1', 'filename2', ...)` deletes the files `fileName1`, `fileName2`, and so on, from the disk. `fileName` is a string and can be an absolute path or a path relative to the current folder. `fileName` also can include wildcards (\*).

`delete fileName` is the command syntax. Delete multiple files by appending filenames, separated by spaces. When filenames contain space characters, you must use the function form.

`delete(h)` deletes the graphics object `h`. If `h` an array, the function deletes all objects in the array. `h` can also contain the figure Number.

The function deletes objects without requesting verification, even if when the objects are figure windows.

`delete(handle_array)` is a method of the `handle` class. It removes from memory the handle objects referenced by `handle_array`.

When deleted, any references to the objects in `handle_array` become invalid. To remove the handle variables, use the `clear` function.

As `delete` does not ask for confirmation, to avoid accidentally losing files or graphics objects, be sure to specify accurately the items to delete. To move files to a different location when running `delete`, use the **General** preference for **Deleting files**, or the `recycle` function.

The `delete` function deletes files and graphics objects only. To delete folders, use `rmdir`.

## Examples

Delete all files with a `.mat` extension in the `/mytests/` folder:

```
delete('/mytests/*.mat')
```

Create a figure and an axes, and then delete the axes:

```
fig = figure;
ax = axes;
...
delete(ax)
```

The axes is deleted, but the figure remain. The axes variable `ax` remains in the workspace, but no longer refers to an object.

Use an array to delete all the line objects created by `plot`:

```
H = plot(magic(5));
```

Pass the array `H` to `delete`:

```
delete(H)
```

## More About

- “Specify File Names”

## See Also

`dir` | `rmdir` | `clear` | `recycle`

**Introduced before R2006a**

## delete (COM)

Remove COM control or server

### Syntax

```
delete(h)
```

### Description

`delete(h)` releases all interfaces derived from the specified COM server or control, and then deletes the server or control itself.

The `release` function, releases and invalidates an interface, but does not delete the server or control.

COM functions are available on Microsoft Windows systems only.

### See Also

`save (COM)` | `load (COM)` | `release` | `actxcontrol` | `actxserver`

**Introduced before R2006a**

## delete

**Class:** FTP

Remove file on FTP server

## Syntax

```
delete(ftpobj, filename)
```

## Description

`delete(ftpobj, filename)` removes the specified file from the current folder on the FTP server associated with `ftpobj`.

## Input Arguments

### **ftpobj**

FTP object created by `ftp`.

### **filename**

String enclosed in single quotation marks that specifies the name of the file to delete.

## Examples

Suppose that a hypothetical host, `ftp.testsite.com`, contains `myfile.m`. Connect to the server and delete the file:

```
ts = ftp('ftp.testsite.com');
delete(ts, 'myfile.m');
```

## See Also

`rmdir` | `ftp`

**Introduced before R2006a**

## delete (serial)

Remove serial port object from memory

### Syntax

```
delete(obj)
```

### Description

`delete(obj)` removes `obj` from memory, where `obj` is a serial port object or an array of serial port objects.

### Examples

This example creates the serial port object `s` on a Windows platform, connects `s` to the device, writes and reads text data, disconnects `s` from the device, removes `s` from memory using `delete`, and then removes `s` from the workspace using `clear`.

```
s = serial('COM1');
fopen(s)
fprintf(s, '*IDN?')
idn = fscanf(s);
fclose(s)
delete(s)
clear s
```

### More About

#### Tips

When you delete `obj`, it becomes an *invalid* object. Because you cannot connect an invalid serial port object to the device, you should remove it from the workspace with the `clear` command. If multiple references to `obj` exist in the workspace, then deleting one reference invalidates the remaining references.

If `obj` is connected to the device, it has a `Status` property value of `open`. If you issue `delete` while `obj` is connected, then the connection is automatically broken. You can also disconnect `obj` from the device with the `fclose` function.

### **See Also**

`clear` | `isvalid` | `fclose` | `Status`

**Introduced before R2006a**

## deleteproperty

Remove custom property from COM object

### Syntax

```
deleteproperty(h, 'name')
```

### Description

`deleteproperty(h, 'name')` deletes property specified in string, `name`, from custom properties belonging to object or interface, `h`.

You can only delete properties created with the `addproperty` function.

COM functions are available on Microsoft Windows systems only.

### Examples

This example removes a custom property from an instance of the MATLAB sample control.

- 1 Create an instance of the control.

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],f);
get(h)
```

```
Label: 'Label'
Radius: 20
```

- 2 Add a custom property named `Position` and assign a value:

```
addproperty(h, 'Position')
h.Position = [200 120];
get(h)
```

```
Label: 'Label'
Radius: 20
```

```
Position: [200 120]
```

- 3 Delete the custom property `Position`. MATLAB displays the original list of properties.

```
deleteproperty(h, 'Position')
get(h)
```

```
Label: 'Label'
Radius: 20
```

## See Also

[addproperty](#) | [set \(COM\)](#) | [get \(COM\)](#) | [inspect](#)

**Introduced before R2006a**

## delevent

Remove `tsdata.event` objects from `timeseries` object

### Syntax

```
ts = delevent(ts,event)
ts = delevent(ts,events)
ts = delevent(ts,event,n)
```

### Description

`ts = delevent(ts,event)` removes the `tsdata.event` object from the `ts.events` property, where `event` is an event name string.

`ts = delevent(ts,events)` removes the `tsdata.event` object from the `ts.events` property, where `events` is a cell array of event name strings.

`ts = delevent(ts,event,n)` removes the `n`th `tsdata.event` object from the `ts.events` property. `event` is the name of the `tsdata.event` object.

### Examples

The following example shows how to remove an event from a `timeseries` object:

- 1 Create a time series.  

```
ts = timeseries(rand(5,4))
```
- 2 Create an event object called 'test' such that the event occurs at time 3.  

```
e = tsdata.event('test',3)
```
- 3 Add the event object to the time series `ts`.  

```
ts = addevent(ts,e)
```
- 4 Remove the event object from the time series `ts`.  

```
ts = delevent(ts,'test')
```

## **See Also**

addevent | timeseries | tsdata.event

**Introduced before R2006a**

## delsamplefromcollection

Remove sample from `tscollection` object

### Syntax

```
tsc = delsamplefromcollection(tsc, 'Index', N)
tsc = delsamplefromcollection(tsc, 'Value', Time)
```

### Description

`tsc = delsamplefromcollection(tsc, 'Index', N)` deletes samples from the `tscollection` object `tsc`. `N` specifies the indices of the `tsc` time vector that correspond to the samples you want to delete.

`tsc = delsamplefromcollection(tsc, 'Value', Time)` deletes samples from the `tscollection` object `tsc`. `Time` specifies the time values that correspond to the samples you want to delete.

### See Also

`addsampletocollection` | `tscollection`

**Introduced before R2006a**

# demo

Access product examples in Help browser

## Syntax

```
demo
demo type
demo type name
```

## Description

`demo` displays the list of MATLAB examples in the Help browser.

`demo type` lists the examples for the specified product. Valid values for `type` are `matlab` or `simulink`.

`demo type name` lists the examples for products other than MATLAB or Simulink. Valid values for `type` include `matlab`, `simulink`, `toolbox`, or `blockset`.

## Examples

### MATLAB Examples

demo `matlab`

### Statistics and Machine Learning Toolbox Examples

demo `toolbox statistics`

### Communications System Toolbox Examples

demo `toolbox 'communications system'`

### Simulink Control Design Examples

demo `simulink 'simulink control design'`

## Input Arguments

### **type** — Product name or type

`matlab` (default) | `simulink` | `toolbox` | `blockset`

Product name or type, specified as one of these strings: `matlab`, `simulink`, `toolbox`, or `blockset`. For products other than MATLAB or Simulink, you must also specify a `name` input that corresponds to the product name.

### **name** — Product name other than MATLAB or Simulink

`string`

Product name other than MATLAB or Simulink, specified as a string. If `name` requires multiple words, enclose it in single quotes.

## More About

### Tips

- To access third-party and custom examples without using the `demo` command, open the Help browser and navigate to the documentation home page. Then, at the bottom of the page, click **Supplemental Software**.

## **See Also**

doc | echodemo | grabcode | help

**Introduced before R2006a**

## depdir

List dependent folders for function or P-file

---

**Note:** `depdir` has been removed. Use `matlab.codetools.requiredFilesAndProducts` instead. However, `matlab.codetools.requiredFilesAndProducts` returns the full path of a required file, including the file name.

---

### Syntax

```
list = depdir('file_name')
[list, prob_files, prob_sym, prob_strings] = depdir('file_name')
[...] = depdir('file_name1', 'file_name2',...)
```

### Description

The `depdir` function lists the folders of all the functions that a specified function or P-file needs to operate. This function is useful for finding all the folders that need to be included with a run-time application and for determining the run-time path.

`list = depdir('file_name')` creates a cell array of strings containing the folders of all the function and P-files that `file_name.m` or `file_name.p` uses. This includes the second-level files that are called directly by `file_name`, as well as the third-level files that are called by the second-level files, and so on.

`[list, prob_files, prob_sym, prob_strings] = depdir('file_name')` creates three additional cell arrays containing information about any problems with the `depdir` search. `prob_files` contains filenames that `depdir` was unable to parse. `prob_sym` contains symbols that `depdir` was unable to find. `prob_strings` contains callback strings that `depdir` was unable to parse.

`[...] = depdir('file_name1', 'file_name2',...)` performs the same operation for multiple files. The dependent folders of all files are listed together in the output cell arrays.

## Examples

```
list = depdir('mesh')
```

## See Also

`matlab.codetools.requiredFilesAndProducts`

**Introduced before R2006a**

## depfun

List dependencies of function or P-file

## Compatibility

depfun has been removed. Use `matlab.codetools.requiredFilesAndProducts` instead. However, `matlab.codetools.requiredFilesAndProducts` does not identify opaque classes, such as Java or COM classes. There is no replacement for this functionality.

## Syntax

```
list = depfun(fun)
[list,builtins] = depfun(fun)
[list,builtins,classes] = depfun(fun)
[list,builtins,classes,prob_files] = depfun(fun)
[list,builtins,classes,prob_files,~,eval_strings] = depfun(fun)
[list,builtins,classes,prob_files,~,eval_strings,called_from] =
depfun(fun)
[list,builtins,classes,prob_files,~,eval_strings,called_from,
opaque_classes] = depfun(fun)

___ = depfun(fun1,...,funN)

___ = depfun(___,option1,...,optionM)
```

## Description

`list = depfun(fun)` returns the paths of MATLAB program files that `fun` requires to run, where `fun` is a function, a P-file, or a figure file for a user interface. The output `list` includes second-level functions that `fun` calls directly, functions that the second-level functions call, and so on. The `depfun` function also displays a report in the Command Window.

---

**Note:**

- `depfun` does not always list all dependent files. For example, `depfun` does not list files hidden in callbacks or files whose names are constructed dynamically for evaluation.
  - The output list often includes extra files that are not called when the function is actually evaluated.
  - If `depfun` returns a parse error for any of the required functions, then the rest of the output of `depfun` might be incomplete. Correct the problematic files and invoke `depfun` again.
- 

`[list,builtins] = depfun(fun)` returns the built-in functions that `fun` requires.

`[list,builtins,classes] = depfun(fun)` returns the MATLAB classes that `fun` requires.

`[list,builtins,classes,prob_files] = depfun(fun)` returns the files that `depfun` cannot parse, find, or access. If there are problematic files (that is, if `prob_files` is not empty), then the rest of the output of `depfun` might be incomplete. Correct the problematic files, and then invoke `depfun` again.

`[list,builtins,classes,prob_files,~,eval_strings] = depfun(fun)` returns a list of files that contain calls to `eval` or related functions (`evalin`, `feval`, or `evalc`). These calls potentially use functions that are not in `list`.

The fifth output argument for `depfun` is not implemented, and returns an empty structure array. To request arguments later in the list, use the tilde symbol (`~`) as a placeholder. The tilde suppresses the creation of an extra, empty variable.

`[list,builtins,classes,prob_files,~,eval_strings,called_from] = depfun(fun)` returns a cell array of indices that maps each function in `list` to the set of functions that call it. That is, `list{called_from{k}}` returns the paths to the functions that call the function in `list{k}`.

`[list,builtins,classes,prob_files,~,eval_strings,called_from,opaque_classes] = depfun(fun)` returns the opaque classes that `fun` requires, such as Java or COM classes.

`___ = depfun(fun1,...,funN)` returns the functions required for multiple functions `fun1,...,funN`. You can request any of the outputs from the previous syntaxes.

`___ = depfun( ___,option1,...,optionM)` modifies the output as described by the specified options. For example, specify `'-toponly'` to list only the functions that `fun` calls directly. You can precede the options with one or more function names.

## Examples

### Identify Required Functions

Identify the MATLAB program files that `strtok.m` requires to run.

```
fun = 'strtok.m';
list = depfun(fun);
```

MATLAB displays a summary report in the Command Window and stores the list of files in variable `list`.

### Identify Top-Level Dependencies Only

List only the program files that `strtok.m` calls directly.

```
fun = 'strtok.m';
list = depfun(fun, '-toponly')
```

```
=====
depfun report summary:(top only)

-> trace list: 2 files (total)
 1 files (total arguments)
 0 files (arguments off MATLABPATH)
 0 files (argument duplicates on MATLABPATH)

Notes: 1. Use argument '-quiet' to not print this summary.
 2. Use arguments '-print','file' to produce a full
 report in file.
 3. Use argument '-all' to display all possible
 left hand side arguments in the report(s).
=====
```

```
list =

 'matlabroot\toolbox\matlab\strfun\strtok.m'
 'matlabroot\toolbox\matlab\strfun\@cell\strtok.m'
```

## Determine Which File Invokes Each Function

One of the functions that `strtok.m` depends upon is `num2cell`. Determine which file in the dependency list calls `num2cell`.

Identify the functions that `strtok.m` requires (`list`) and the files that invoke each of those functions (`called_from`).

```
fun = 'strtok.m';
[list,builtins,classes,prob_files,~,eval_strings,...
 called_from] = depfun(fun);
```

Find the index for `num2cell` within the dependency list.

```
num2cell_path = which('num2cell');
num2cell_index = find(ismember(list,num2cell_path))

num2cell_index =
 5
```

Identify the file that calls `num2cell`.

```
calls_num2cell = list{called_from{num2cell_index}}

calls_num2cell =
 matlabroot\toolbox\matlab\elmat\repmat.m
```

## Input Arguments

### **fun** — Function name

string | cell array of strings

Function name, specified as a string or a cell array of strings.

`fun` must be on the MATLAB path, as determined by the `which` function. If the path contains any relative folders, then files in those folders also will have a relative path in the output.

Example: `'plot.m'`

Example: `'plot.m','mesh.m'`

Example: {'plot.m', 'mesh.m'}

Data Types: char | cell

**option — Reporting option**

'-toponly' | '-verbose' | '-quiet' | '-print' | ...

Reporting option, specified as one of the following strings.

| Option             | Description                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| '-toponly'         | Identify only the files used directly by the specified function(s), <code>fun</code> .                                                                                                                             |
| '-verbose'         | Display additional internal messages.                                                                                                                                                                              |
| '-quiet'           | Display only error and warning messages, and not a summary report.                                                                                                                                                 |
| '-print', filename | Print a full report to the specified file.                                                                                                                                                                         |
| '-all'             | Display all outputs in the report, but return only the specified output arguments.                                                                                                                                 |
| '-expand'          | Include both indices and full paths in an exported report for the <code>call</code> or <code>called_from</code> list. Requires the '-print' option. This information does not appear in the Command Window report. |
| '-calltree'        | Replaces the <code>called_from</code> list with a list of functions that each file calls, as derived from the <code>called_from</code> list.                                                                       |

Example: '-print', 'myreport.txt'

Data Types: char

## Output Arguments

**list — Paths to required files**

cell array of strings

Paths to required files, returned as a cell array of strings.

**builtins — Required MATLAB built-in functions**

cell array of strings

Required MATLAB built-in functions, returned as a cell array of strings.

### **classes** — Required MATLAB classes

cell array of strings

Required MATLAB classes, returned as a cell array of strings.

### **prob\_files** — Files that depfun cannot parse or access

structure

Files that depfun cannot parse or access, returned as a structure with these fields:

- **name** — Path to the file
- **listindex** — Index of the file in `list`
- **errmsg** — Error message that describes the problem
- **errid** — Error identifier, if present

### **eval\_strings** — Files that call evaluation functions

cell array of strings

Files that call evaluation functions, returned as a cell array of strings.

### **called\_from** — Indices to files that call each function in `list`

cell array

Indices to files that call each function in `list`, returned as a cell array. Each element of the cell array is a numeric array of indices that correspond to elements in `list`. The `list` and `called_from` outputs have the same length.

### **opaque\_classes** — Paths to opaque classes

cell array of strings

Paths to opaque classes, such as Java or COM classes, returned as a cell array of strings.

Introduced before R2006a

## det

Matrix determinant

### Syntax

$d = \det(A)$

### Description

$d = \det(A)$  returns the determinant of square matrix A.

### Examples

#### Calculate Determinant of Matrix

Create a 3-by-3 square matrix, A.

$A = [1 \ -2 \ 4; \ -5 \ 2 \ 0; \ 1 \ 0 \ 3]$

A =

|    |    |   |
|----|----|---|
| 1  | -2 | 4 |
| -5 | 2  | 0 |
| 1  | 0  | 3 |

Calculate the determinant of A.

$d = \det(A)$

d =

-32

The determinant of A is -32.

#### Determine if Matrix Is Singular

Examine why the determinant is not an accurate measure of singularity.

Create a 10-by-10 matrix by multiplying an identity matrix, `eye(10)`, by a small number.

```
A = eye(10)*0.0001;
```

The matrix **A** has very small entries along the main diagonal. However, **A** is *not* singular, because it is a multiple of the identity matrix.

Calculate the determinant of **A**.

```
d = det(A)
```

```
d =
```

```
1.0000e-40
```

The determinant is extremely small. A tolerance test of the form `abs(det(A)) < tol` is likely to flag this matrix as singular. Although the determinant of the matrix is close to zero, **A** is actually not ill conditioned. Therefore, **A** is not close to being singular. The determinant of a matrix can be arbitrarily close to zero without conveying information about singularity.

To investigate if **A** is singular, use either the `cond` or `rcond` functions.

Calculate the condition number of **A**.

```
c = cond(A)
```

```
c =
```

```
1
```

The result confirms that **A** is not ill conditioned.

### **Compute Determinant of Inverse of Ill-Conditioned Matrix**

Examine how to calculate the determinant of the matrix inverse  $A^{-1}$ , for an ill-conditioned matrix **A**, without explicitly calculating  $A^{-1}$ .

Create a 10-by-10 Hilbert matrix, **A**.

```
A = hilb(10);
```

Find the condition number of **A**.

```
c = cond(A)
```

```
c =
```

```
1.6025e+13
```

The large condition number suggests that  $A$  is close to being singular, so calculating  $\text{inv}(A)$  might produce inaccurate results. Therefore, the inverse determinant calculation  $\text{det}(\text{inv}(A))$  is also inaccurate.

Calculate the determinant of the inverse of  $A$  by exploiting the fact that

$$\text{det}(A^{-1}) = \frac{1}{\text{det}(A)}.$$

```
d1 = 1/det(A)
```

```
d1 =
```

```
4.6202e+52
```

This method avoids computing the inverse of the matrix,  $A$ .

Calculate the determinant of the exact inverse of the Hilbert matrix,  $A$ , using `invhilb`. Compare the result to  $d1$  to find the relative error in  $d1$ .

```
d = det(invhilb(10));
relError = abs(d1-d)/abs(d)
```

```
relError =
```

```
1.1462e-04
```

The relative error in  $d1$  is reasonably small. Avoiding the explicit computation of the inverse of  $A$  minimizes it.

For comparison, also calculate the determinant of the inverse of  $A$  by explicitly calculating the inverse. Compare the result to  $d$  to see the relative error.

```
d2 = det(inv(A));
relError2 = abs(d2-d)/abs(d)
```

```
relError2 =
```

```
1.2427e+08
```

The relative error in the calculation of `d2` is many orders of magnitude larger than that of `d1`.

### Find Determinant of Singular Matrix

Examine a matrix that is exactly singular, but which has a large nonzero determinant. In theory, the determinant of any singular matrix is zero, but because of the nature of floating-point computation, this ideal is not always achievable.

Create a 13-by-13 diagonally dominant singular matrix, `A`.

```
A = diag([24 46 64 78 88 94 96 94 88 78 64 46 24]);
S = diag([-13 -24 -33 -40 -45 -48 -49 -48 -45 -40 -33 -24],1);
A = A + S + rot90(S,2)
```

`A =`

|     |     |     |     |     |     |     |     |     |     |     |     |     |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 24  | -13 | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| -24 | 46  | -24 | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| 0   | -33 | 64  | -33 | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| 0   | 0   | -40 | 78  | -40 | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| 0   | 0   | 0   | -45 | 88  | -45 | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| 0   | 0   | 0   | 0   | -48 | 94  | -48 | 0   | 0   | 0   | 0   | 0   | 0   |
| 0   | 0   | 0   | 0   | 0   | -49 | 96  | -49 | 0   | 0   | 0   | 0   | 0   |
| 0   | 0   | 0   | 0   | 0   | 0   | -48 | 94  | -48 | 0   | 0   | 0   | 0   |
| 0   | 0   | 0   | 0   | 0   | 0   | 0   | -45 | 88  | -45 | 0   | 0   | 0   |
| 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | -40 | 78  | -40 | 0   | 0   |
| 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | -33 | 64  | -33 | 0   |
| 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | -24 | 46  | -24 |
| 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | -13 | 24  |

`A` is singular because the rows are linearly dependent. For instance, `sum(A)` produces a vector of zeros.

Calculate the determinant of `A`.

```
d = det(A)
```

`d =`

```
1.059686712222177e+05
```

The determinant of `A` is quite large despite the fact that `A` is singular. In fact, the determinant of `A` should be exactly zero! The inaccuracy of `d` is due to an aggregation of

round-off errors in the MATLAB implementation of the LU decomposition, which `det` uses to calculate the determinant. This result demonstrates a few important aspects of calculating numeric determinants. See the “Limitations” on page 1-2160 section for more details.

## Input Arguments

### **A** — Input matrix

square numeric matrix

Input matrix, specified as a square numeric matrix.

Data Types: `single` | `double`

Complex Number Support: Yes

## Limitations

Avoid using `det` to examine if a matrix is singular because of the following limitations. Use `cond` or `rcond` instead.

| Limitation                                                                                                                        | Result                                                                                                                                                                                                     |
|-----------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The magnitude of the determinant is typically unrelated to the condition number of a matrix.                                      | The determinant of a matrix can be arbitrarily large or small without changing the condition number.                                                                                                       |
| <code>det</code> uses the LU decomposition to calculate the determinant, which is susceptible to floating-point round-off errors. | The determinant calculation is sometimes numerically unstable. For example, <code>det</code> can produce a large-magnitude determinant for a singular matrix, even though it should have a magnitude of 0. |

## More About

### Algorithms

`det` computes the determinant from the triangular factors obtained by Gaussian elimination with the `lu` function.

```
[L,U] = lu(X)
s = det(L) % This is always +1 or -1
det(X) = s*prod(diag(U))
```

## details

Display array details

## Syntax

`details(A)`

## Description

`details(A)` displays detailed information about the array, `A`.

When `A` is a MATLAB object array, `details` displays more information than the default display. This information includes:

- Fully qualified class name, including package names
- Link to class documentation
- Link to `handle` class documentation for classes that subclass `handle`
- List of all properties that have public get access
- List of property values if the array is scalar
- Link to list of public methods
- Link to list of events
- Link to list of all nonhidden superclasses

## Examples

### Display Object Details

Display object details for a class that overloads its own object display. The `details` function never calls overloaded display methods. Therefore, you can use this function to obtain information about the object array in all cases.

Suppose `POLYNOM` is a class that provides a specialized default display for polynomials. Use `details` to display information about the object.

Create an object using the polynomial coefficients:

```
pn = PolyNom([1,2,3,0,4])
```

The overloaded `disp` method displays the code for evaluating the polynomial:

```
pn =

x^4 + 2*x^3 + 3*x^2 + 4
```

Calling the `details` function provides information about the object:

```
details(pn)

PolyNom with properties:
 coef: [1 2 3 0 4]

Methods
```

## Input Arguments

### **A** — Input array

scalar or nonscalar array of any type

Input array, specified as a scalar or nonscalar array of any type. The `details` function displays detailed information about this array.

### See Also

`classdef` | `disp` | `display`

# detrend

Remove linear trends

## Syntax

```
y = detrend(x)
y = detrend(x, 'constant')
y = detrend(x, 'linear', bp)
```

## Description

`detrend` removes the mean value or linear trend from a vector or matrix, usually for FFT processing.

`y = detrend(x)` removes the best straight-line fit from vector `x` and returns it in `y`. If `x` is a matrix, `detrend` removes the trend from each column.

`y = detrend(x, 'constant')` removes the mean value from vector `x` or, if `x` is a matrix, from each column of the matrix.

`y = detrend(x, 'linear', bp)` removes a continuous, piecewise linear trend from vector `x` or, if `x` is a matrix, from each column of the matrix. Vector `bp` contains the indices of the breakpoints between adjacent linear segments. The breakpoint between two segments is defined as the data point that the two segments share.

`detrend(x, 'linear')`, with no breakpoint vector specified, is the same as `detrend(x)`.

## Examples

```
sig = [0 1 -2 1 0 1 -2 1 0]; % signal with no linear trend
trend = [0 1 2 3 4 3 2 1 0]; % two-segment linear trend
x = sig+trend; % signal with added trend
y = detrend(x,'linear',5) % breakpoint at 5th element

y =

 -0.0000
 1.0000
 -2.0000
 1.0000
 0.0000
 1.0000
 -2.0000
 1.0000
 -0.0000
```

Note that the breakpoint is specified to be the fifth element, which is the data point shared by the two segments.

## More About

### Algorithms

`detrend` computes the least-squares fit of a straight line (or composite line for piecewise linear trends) to the data and subtracts the resulting function from the data. To obtain the equation of the straight-line fit, use `polyfit`.

### See Also

`polyfit`

Introduced before R2006a

## deval

Evaluate solution of differential equation problem

### Syntax

```
sxint = deval(sol,xint)
sxint = deval(xint,sol)
sxint = deval(sol,xint,idx)
sxint = deval(xint,sol,idx)
[sxint, spxint] = deval(...)
```

### Description

`sxint = deval(sol,xint)` and `sxint = deval(xint,sol)` evaluate the solution of a differential equation problem. `sol` is a structure returned by one of these solvers:

- An initial value problem solver (`ode45`, `ode23`, `ode113`, `ode15s`, `ode23s`, `ode23t`, `ode23tb`, `ode15i`)
- A delay differential equations solver (`dde23`, `ddesd`, or `ddensd`),
- A boundary value problem solver (`bvp4c` or `bvp5c`).

`xint` is a point or a vector of points at which you want the solution. The elements of `xint` must be in the interval `[sol.x(1),sol.x(end)]`. For each `i`, `sxint(:,i)` is the solution at `xint(i)`.

`sxint = deval(sol,xint,idx)` and `sxint = deval(xint,sol,idx)` evaluate as above but return only the solution components with indices listed in the vector `idx`.

`[sxint, spxint] = deval(...)` also returns `spxint`, the value of the first derivative of the polynomial interpolating the solution.

---

**Note** For multipoint boundary value problems, the solution obtained by `bvp4c` or `bvp5c` might be discontinuous at the interfaces. For an interface point `xc`, `deval` returns the average of the limits from the left and right of `xc`. To get the limit values, set the `xint` argument of `deval` to be slightly smaller or slightly larger than `xc`.

---

## Examples

### Evaluate van der Pol Equation

This example solves the system  $y' = \text{vdp1}(t, y)$  using `ode45` and plots the first component of the solution.

Solve the system using `ode45`.

```
sol = ode45(@vdp1,[0 20],[2 0]);
```

Evaluate the first component of the solution at 100 points in the interval `[0, 20]`.

```
x = linspace(0,20,100);
y = deval(sol,x,1);
```

Plot the solution.

```
plot(x,y)
```

**Introduced before R2006a**

# diag

Create diagonal matrix or get diagonal elements of matrix

## Syntax

```
D = diag(v)
D = diag(v,k)
```

```
x = diag(A)
x = diag(A,k)
```

## Description

`D = diag(v)` returns a square diagonal matrix with the elements of vector `v` on the main diagonal.

`D = diag(v,k)` places the elements of vector `v` on the `k`th diagonal. `k=0` represents the main diagonal, `k>0` is above the main diagonal, and `k<0` is below the main diagonal.

`x = diag(A)` returns a column vector of the main diagonal elements of `A`.

`x = diag(A,k)` returns a column vector of the elements on the `k`th diagonal of `A`.

## Examples

### Create Diagonal Matrices

Create a 1-by-5 vector.

```
v = [2 1 -1 -2 -5];
```

Use `diag` to create a matrix with the elements of `v` on the main diagonal.

```
D = diag(v)
```

```
D =
```

```
2 0 0 0 0
0 1 0 0 0
0 0 -1 0 0
0 0 0 -2 0
0 0 0 0 -5
```

Create a matrix with the elements of `v` on the first super diagonal (`k=1`).

```
D1 = diag(v,1)
```

```
D1 =
```

```
0 2 0 0 0 0
0 0 1 0 0 0
0 0 0 -1 0 0
0 0 0 0 -2 0
0 0 0 0 0 -5
0 0 0 0 0 0
```

The result is a 6-by-6 matrix. When you specify a vector of length `n` as an input, `diag` returns a square matrix of size `n+abs(k)`.

### Get Diagonal Elements

Get the elements on the main diagonal of a random 6-by-6 matrix.

```
A = randi(10,6)
```

```
A =
```

```
9 3 10 8 7 8
10 6 5 10 8 1
2 10 9 7 8 3
10 10 2 1 4 1
7 2 5 9 7 1
1 10 10 10 2 9
```

```
x = diag(A)
```

```
x =
```

```
9
6
9
1
```

```

7
9

```

Get the elements on the first subdiagonal ( $k = -1$ ) of  $A$ . The result has one fewer element than the main diagonal.

```
x1 = diag(A, -1)
```

```
x1 =
```

```

0 0 0 0 7 0
0 0 0 0 0 9

```

## Input Arguments

### **v** — Diagonal elements

vector

Diagonal elements, specified as a vector. If  $v$  is a vector with  $N$  elements, then `diag(v, k)` is a square matrix of order  $N + \text{abs}(k)$ .

`diag([])` returns an empty matrix, `[]`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

Complex Number Support: Yes

**A — Input matrix**

matrix

Input matrix. `diag` returns an error if `ndims(A) > 2`.

`diag([])` returns an empty matrix, `[]`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

Complex Number Support: Yes

**k — Diagonal number**

integer

Diagonal number, specified as an integer. `k=0` represents the main diagonal, `k>0` is above the main diagonal, and `k<0` is below the main diagonal.

For an  $m$ -by- $n$  matrix,  $k$  is in the range  $(-m + 1) \leq k \leq (n - 1)$ .

**More About**

**Tips**

- The trace of a matrix is equal to `sum(diag(A))`.

## matlab.unittest.diagnostics

Summary of classes in MATLAB Diagnostics Interface

### Description

Use diagnostics to communicate relevant information in the event of a failure. To add a diagnostic message to a test case, use the `diagnostic` argument in any of the `matlab.unittest.qualifications` methods. The framework also displays diagnostic messages related to the nature of the qualification failure. The `matlab.unittest.diagnostics` package consists of the following classes:

|                                                                   |                                                                          |
|-------------------------------------------------------------------|--------------------------------------------------------------------------|
| <code>matlab.unittest.diagnostics.ConstraintDiagnostic</code>     | Diagnostics specific to <code>matlab.unittest</code> constraints         |
| <code>matlab.unittest.diagnostics.Diagnostic</code>               | Fundamental interface class for <code>matlab.unittest</code> diagnostics |
| <code>matlab.unittest.diagnostics.DisplayDiagnostic</code>        | Diagnostic using a value's displayed output                              |
| <code>matlab.unittest.diagnostics.FunctionHandleDiagnostic</code> | Diagnostic using a function's displayed output                           |
| <code>matlab.unittest.diagnostics.StringDiagnostic</code>         | Diagnostic using string                                                  |

The package contains the following event data classes:

|                                                                    |                                                              |

# matlab.unittest.diagnostics.ConstraintDiagnostic class

**Package:** matlab.unittest.diagnostics

**Superclasses:** matlab.unittest.diagnostics.Diagnostic

Diagnostics specific to matlab.unittest constraints

## Description

The `ConstraintDiagnostic` class provides various textual fields that are common to most constraints. These fields may be turned on or off depending on their applicability.

The `ConstraintDiagnostic` class is a helper class for displaying diagnostics when using constraints. The `ConstraintDiagnostic` class provides custom constraint authors a way to add a common look and feel to diagnostics produced by the `getDiagnosticFor` method of constraints.

Constraint diagnostics are displayed in the following order: Description, Conditions, Actual Value, and Expected Value.

## Properties

### ActVal

The actual value passed to the constraint for testing.

### ActValHeader

Header information for the actual value property, `ActVal`, specified as a string. The default header is 'Actual Value:'.

### Conditions

Formatted list of conditions, specified as a single string. Each condition starts on a new line and begins with an arrow ( --> ) delimiter. Conditions are added to the list using the `addCondition` and `addConditionsFrom` methods.

### ConditionsCount

Number of conditions in the condition list. This is a read-only property generated from the conditions list. The conditions list is defined in the `Conditions` property.

## **Description**

General diagnostic information, specified as a string.

## **DisplayActVal**

Indicator whether to display the actual value property, **ActVal**, specified as a boolean. By default, the actual value is not displayed and the value of this property is **false**.

## **DisplayConditions**

Indicator of whether to display the **Conditions** property, specified as a boolean. By default, the conditions are not displayed and the value of this property is **false**. Even if **DisplayConditions** is set to **true**, if there are no conditions on the conditions list, neither the conditions header or the conditions list are displayed.

## **DisplayDescription**

Indicator of whether to display the **Description** property, specified as a boolean. By default, the description is not displayed and the value of this property is **false**.

## **DisplayExpVal**

Indicator whether to display the expected value property, **ExpVal**, specified as a boolean. By default, the expected value is not displayed and the value of this property is **false**.

## **ExpVal**

If applicable, the expected value. This property can be turned off if the associated constraint does not contain an expected value.

## **ExpValHeader**

Header information for the expected value property, **ExpVal**, specified as a string. The default header is 'Expected Value:'.

## **Inherited Properties**

### **DiagnosticResult**

The **DiagnosticResult** property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the **diagnose** method.

## Methods

|                                       |                                                                                |
|---------------------------------------|--------------------------------------------------------------------------------|
| <code>addCondition</code>             | Add condition to condition list                                                |
| <code>addConditionsFrom</code>        | Add condition from another <code>ConstraintDiagnostic</code> to condition list |
| <code>getDisplayableString</code>     | Convert object to string for display                                           |
| <code>getPreDescriptionString</code>  | Returns text to be displayed prior to description                              |
| <code>getPostDescriptionString</code> | Returns text to be displayed following description                             |
| <code>getPostConditionString</code>   | Returns text to be displayed following conditions list                         |
| <code>getPostActValString</code>      | Returns text to be displayed following actual value                            |
| <code>getPostExpValString</code>      | Returns text to be displayed following expected value                          |

## Inherited Methods

|                       |                                               |
|-----------------------|-----------------------------------------------|
| <code>diagnose</code> | Execute diagnostic action                     |
| <code>join</code>     | Join multiple diagnostics into a single array |

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## See Also

## addCondition

**Class:** matlab.unittest.diagnostics.ConstraintDiagnostic

**Package:** matlab.unittest.diagnostics

Add condition to condition list

### Syntax

```
addCondition(diag, cond)
```

### Description

`addCondition(diag, cond)` adds the condition, `cond`, to the condition list. Add conditions to the condition list one at a time. When the condition list is displayed, each condition is preceded by an arrow (`- ->`) delimiter and indented.

### Input Arguments

#### **cond**

Condition, specified as a string containing information specific to the cause of the constraint failure or another `Diagnostic` instance, which acts as a “subdiagnostic”.

#### **diag**

`matlab.unittest.diagnostics.Diagnostic` instance.

### See Also

`addConditionsFrom`

# addConditionsFrom

**Class:** matlab.unittest.diagnostics.ConstraintDiagnostic

**Package:** matlab.unittest.diagnostics

Add condition from another `ConstraintDiagnostic` to condition list

## Syntax

```
addConditionsFrom(constDiag, otherConstDiag)
```

## Description

`addConditionsFrom(constDiag, otherConstDiag)` adds the conditions from the `ConstraintDiagnostic` instance, `constDiag`, to the condition list in the `Diagnostic` instance, `diag`. This is useful when a constraints composes another constraint, and needs to use the conditions produced in the diagnostics of the composed constraint.

## Input Arguments

### **constDiag**

Diagnostic to add conditions to, specified as a `matlab.unittest.diagnostics.ConstraintDiagnostic` instance

### **otherConstDiag**

Diagnostic to add conditions from, specified as a `matlab.unittest.diagnostics.ConstraintDiagnostic` instance

## Examples

### **Add Conditions from a Constraint**

```
% This demonstrates a constraint that composes another constraint
```

```
% and uses the addConditionsFrom method to utilize the conditions
% from the composed ConstraintDiagnostic.
classdef IsDouble < matlab.unittest.constraints.Constraint

 properties(Constant, GetAccess=private)
 DoubConst = matlab.unittest.constraints.IsInstanceOf(?double);
 end

 methods
 function tf = satisfiedBy(constraint, actual)
 tf = constraint.DoubConst.satisfiedBy(actual);
 end
 function diag = getDiagnosticFor(constraint, actual)
 diag = ConstraintDiagnostic;

 % Now add conditions from the IsInstanceOf
 % Diagnostic
 otherDiag = constraint.DoubConst.getDiagnosticFor(actual);
 diag.addConditionsFrom(otherDiag)

 % ...
 end
 end
end
```

## See Also

addCondition

# matlab.unittest.diagnostics.ConstraintDiagnostic.getDisplayableString

**Class:** matlab.unittest.diagnostics.ConstraintDiagnostic

**Package:** matlab.unittest.diagnostics

Convert object to string for display

## Syntax

```
str =
matlab.unittest.diagnostics.ConstraintDiagnostic.getDisplayableString(
value)
```

## Description

`str = matlab.unittest.diagnostics.ConstraintDiagnostic.getDisplayableString(value)` converts the object, `obj` to a string, `str` for display in a diagnostic result. This conversion determines if hotlinks should be included in the string and truncates large numeric or cell arrays.

## Input Arguments

### **value**

Object of arbitrary class

## getPreDescriptionString

**Class:** matlab.unittest.diagnostics.ConstraintDiagnostic

**Package:** matlab.unittest.diagnostics

Returns text to be displayed prior to description

### Syntax

```
str = getPreDescriptionString(constDiag)
```

### Description

`str = getPreDescriptionString(constDiag)` returns text to be displayed prior to the description. This method can be overridden to inject strings prior to displaying the `Description` property of the `ConstraintDiagnostic`. The location of this text is tied to the `Description` property. Its placement relative to other fields is not guaranteed.

### Input Arguments

**constDiag**

matlab.unittest.diagnostics.ConstraintDiagnostic instance.

### See Also

`ConstraintDiagnostic` | `getPostActValString` | `getPostConditionString` | `getPostDescriptionString` | `getPostExpValString`

# getPostDescriptionString

**Class:** matlab.unittest.diagnostics.ConstraintDiagnostic

**Package:** matlab.unittest.diagnostics

Returns text to be displayed following description

## Syntax

```
str = getPostDescriptionString(constDiag)
```

## Description

`str = getPostDescriptionString(constDiag)` returns text to be displayed following the description. This method can be overridden to inject strings subsequent to displaying the `Description` property of the `ConstraintDiagnostic`. The location of this text is tied to the `Description` property. Its placement relative to other fields is not guaranteed.

## Input Arguments

### **constDiag**

matlab.unittest.diagnostics.ConstraintDiagnostic instance.

## See Also

# getPostActValString

**Class:** matlab.unittest.diagnostics.ConstraintDiagnostic

**Package:** matlab.unittest.diagnostics

Returns text to be displayed following actual value

## Syntax

```
str = getPostActualValString(constDiag)
```

## Description

`str = getPostActualValString(constDiag)` returns text to be displayed following the actual value. This method can be overridden to inject strings subsequent to displaying the `ActVal` property of the `ConstraintDiagnostic`. The location of this text is tied to the `ActVal` property. Its placement relative to other fields is not guaranteed.

## Input Arguments

### **constDiag**

matlab.unittest.diagnostics.ConstraintDiagnostic instance.

## See Also

ConstraintDiagnostic | getPostConditionString | getPostDescriptionString | getPostExpValString | getPreDescriptionString

## getPostExpValString

**Class:** matlab.unittest.diagnostics.ConstraintDiagnostic

**Package:** matlab.unittest.diagnostics

Returns text to be displayed following expected value

### Syntax

```
str = getPostExpValString(constDiag)
```

### Description

`str = getPostExpValString(constDiag)` returns text to be displayed following the expected value. This method can be overridden to inject strings subsequent to displaying the `ExpVal` property of the `ConstraintDiagnostic`. The location of this text is tied to the `ExpVal` property. Its placement relative to other fields is not guaranteed.

### Input Arguments

**constDiag**

matlab.unittest.diagnostics.ConstraintDiagnostic instance.

# matlab.unittest.diagnostics.Diagnostic class

**Package:** matlab.unittest.diagnostics

Fundamental interface class for `matlab.unittest` diagnostics

## Description

The `Diagnostic` interface class is the means by which the `matlab.unittest` framework and its clients package diagnostic information. All diagnostics are derived from `Diagnostic`, whether they are user-supplied test diagnostics for an individual comparison or diagnostics associated with the `Constraint` used in the comparison.

Classes which derive from `Diagnostic` encode the diagnostic actions to be performed. They produce a diagnostic result that is displayed appropriately by the test running framework. In exchange for meeting this requirement, any `Diagnostic` implementation can be used directly with `matlab.unittest` qualifications. These qualifications execute the diagnostic action and store the result to be utilized by the test running framework.

As a convenience, the framework creates appropriate diagnostic instances for strings and function handles when they are user supplied test diagnostics. To retain good performance, these values are only converted into `Diagnostic` instances when a qualification failure occurs or when the test running framework is explicitly observing passing qualifications. The default test runner does not explicitly observe passing qualifications.

## Properties

### `DiagnosticResult`

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

## Methods

`diagnose`

Execute diagnostic action

join Join multiple diagnostics into a single array

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Use Diagnostic Result

```
import matlab.unittest.constraints.IsEqualTo

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase.forInteractiveUse;

% Create StringDiagnostic upon failure
testCase.verifyThat(1, IsEqualTo(2), 'User supplied Diagnostic')

% Create FunctionHandleDiagnostic upon failure
testCase.verifyThat(1, IsEqualTo(2), @() system('ps'))

% Usage of user defined Diagnostic upon failure (see definition below)
testCase.verifyThat(1, IsEqualTo(2), ProcessStatusDiagnostic...
 ('Could not close my third party application!'))

%%
% Diagnostic definition
%%
classdef ProcessStatusDiagnostic < matlab.unittest.diagnostics.Diagnostic
 % ProcessStatusDiagnostic - an example diagnostic
 %
 % Simple example to demonstrate how to create a custom
 % diagnostic.

 properties

 % HeaderText - user-supplied header to display
 HeaderText = '(No header supplied)';
 end
end
```

```

end

methods
function diag = ProcessStatusDiagnostic(header)
 % Constructor - construct a ProcessStatusDiagnostic
 %
 % The ProcessStatusDiagnostic constructor takes an
 % optional header to be displayed along with process
 % information.
 if (nargin >0)
 diag.HeaderText = header;
 end
end

function diagnose(diag)

 [status, processInfo] = system('ps');
 if (status ~= 0)
 processInfo = sprintf(...
 ['!!! Could not obtain status diagnostic information!!!'...
 ' [exit status code: %d]\n%s'], status, processInfo);
 end
 diag.DiagnosticResult = sprintf('%s\n%s', diag.HeaderText,...
 processInfo);
end
end

end % classdef

```

## See Also

[matlab.unittest.constraints.Constraint](#) | [FunctionHandleDiagnostic](#) |  
[matlab.unittest.diagnostics](#) | [StringDiagnostic](#)

## More About

- “Types of Qualifications”

## diagnose

**Class:** matlab.unittest.diagnostics.Diagnostic

**Package:** matlab.unittest.diagnostics

Execute diagnostic action

## Syntax

```
diagnose(diag)
```

## Description

`diagnose(diag)` executes diagnostic action for the `matlab.unittest.diagnostics.Diagnostic` instance, `diag`. The `diagnose` method is the means by which individual `Diagnostic` implementations can perform their respective diagnostic evaluations. Each concrete implementation is responsible for populating the `DiagnosticResult` property of the `Diagnostic` object. Typically, text printed to the Command Window during diagnostic evaluation is not considered part of the diagnostic result and is ignored by the testing framework.

## See Also

`Diagnostic`

# join

**Class:** matlab.unittest.diagnostics.Diagnostic

**Package:** matlab.unittest.diagnostics

Join multiple diagnostics into a single array

## Syntax

```
diagArray = join(diag1,...,diagN)
```

## Description

`diagArray = join(diag1,...,diagN)` joins multiple diagnostics, specified by `diag1` through `diagN`, into a single array, `diagArray`.

## Input Arguments

### **diag**

Diagnostic content, specified as an instance of a `Diagnostic` object, a string, a function handle, or an arbitrary type.

## Output Arguments

### **diagArray**

Array of joined diagnostic content.

- If `diagN` is an object that derives from `Diagnostic`, it is included in the array unmodified.
- If `diagN` is a `char`, it is formed into a `StringDiagnostic` and included in the array.
- If `diagN` is a `function_handle`, it is formed into a `FunctionHandleDiagnostic` and included in the array.
- If `diagN` is any other type, it is formed into a `DisplayDiagnostic` and included in the array.

## Alternatives

You can use array concatenation join diagnostics into an array if at least one of the values is a diagnostic. The `join` method prevents the need to have any `Diagnostics` in the array. Considering the following example.

```
arbitraryValue = 5;
testCase.verifyThat(false, IsTrue, ...
 ['should have been true', ...
 @() system('ps'), ...
 arbitraryValue, ...
 MyCustomDiagnostic]);
```

Since `MyCustomDiagnostic` is a `Diagnostic`, the other values are correctly converted to diagnostics as well.

## Examples

### Join Diagnostic Content

```
% The following example creates a diagnostic array of length 4,
% demonstrating standard Diagnostic conversions. Note:
% MyCustomDiagnostic is for example purposes and is not executable
% code.
```

```
import matlab.unittest.diagnostics.Diagnostic
import matlab.unittest.constraints.IsTrue

arbitraryValue = 5;
testCase.verifyThat(false, IsTrue, ...
 Diagnostic.join(...
 'should have been true', ...
 @() system('ps'), ...
 arbitraryValue, ...
 MyCustomDiagnostic))
```

### See Also

`matlab.mixin.Heterogeneous`

# matlab.unittest.diagnostics.DisplayDiagnostic class

**Package:** matlab.unittest.diagnostics

**Superclasses:** matlab.unittest.diagnostics.Diagnostic

Diagnostic using a value's displayed output

## Description

The `DisplayDiagnostic` class provides a diagnostic result that uses a value's displayed output. This output is the same text displayed using the `display` function. When the diagnostic information is accessible through a variable in the current workspace, the `DisplayDiagnostic` class is a means to provide quick diagnostic information.

## Construction

`DisplayDiagnostic(diagValue)` creates a new `DisplayDiagnostic` instance.

## Input Arguments

### **diagValue**

The value that the `Diagnostic` uses to generate diagnostic information.

The resulting diagnostic information is equivalent to displaying this value at the MATLAB command prompt. The result is packaged for consumption by the testing framework, which may or may not display the information at the command prompt.

## Properties

### **Value**

The value that the `Diagnostic` uses to generate diagnostic information, specified in the `diagValue` input argument. This property is read-only.

## Inherited Properties

### **DiagnosticResult**

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

## Methods

### Inherited Methods

|                       |                                               |
|-----------------------|-----------------------------------------------|
| <code>diagnose</code> | Execute diagnostic action                     |
| <code>join</code>     | Join multiple diagnostics into a single array |

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Create `DisplayDiagnostic` Object

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.diagnostics.DisplayDiagnostic
```

```
testCase = TestCase.forInteractiveUse;
```

Use a `DisplayDiagnostic` to display diagnostic information upon test failure.

```
testCase.verifyThat(1, IsEqualTo(2), DisplayDiagnostic(inputParser))
```

Interactive verification failed.

-----  
 Test Diagnostic:  
 -----

inputParser with properties:

```

 FunctionName: ''
 CaseSensitive: 0
 KeepUnmatched: 0
 PartialMatching: 1
 StructExpand: 1
 Parameters: {1x0 cell}
 Results: [1x1 struct]
 Unmatched: [1x1 struct]
 UsingDefaults: {1x0 cell}

```

-----  
 Framework Diagnostic:  
 -----

IsEqualTo failed.

--> NumericComparator failed.

--> The values are not equal using "isequaln".

--> Failure table:

| Actual | Expected | Error | RelativeError |
|--------|----------|-------|---------------|
| -----  | -----    | ----- | -----         |
| 1      | 2        | -1    | -0.5          |

Actual double:

1

Expected double:

2

In the test diagnostic section of the output, the output from `inputParser` object is the same as MATLAB displays at the command prompt.

## See Also

FunctionHandleDiagnostic | `matlab.unittest.diagnostics` | StringDiagnostic

**Introduced in R2013a**

# matlab.unittest.diagnostics.FunctionHandleDiagnostic class

**Package:** matlab.unittest.diagnostics

**Superclasses:** matlab.unittest.diagnostics.Diagnostic

Diagnostic using a function's displayed output

## Description

The `FunctionHandleDiagnostic` class provides a diagnostic result using a function's displayed output. This output is the same as the text displayed at the command prompt when MATLAB executes the function handle. When the diagnostic information is accessible through information displayed as output of the function handle, the `FunctionHandleDiagnostic` is a means to provide quick diagnostic information.

When using `matlab.unittest` qualifications, a function handle can be supplied directly as a test diagnostic. In this case, the testing framework automatically creates a `FunctionHandleDiagnostic` object.

## Construction

`FunctionHandleDiagnostic(fcnHandle)` creates a new `FunctionHandleDiagnostic` instance.

## Input Arguments

### **fcnHandle**

The function handle that the `Diagnostic` uses to generate diagnostic information.

The resulting diagnostic information is equivalent to output displayed at the MATLAB command prompt. The result is packaged for consumption by the testing framework, which may or may not display the information at the command prompt.

## Properties

### Fcn

The function handle that the `Diagnostic` uses to generate diagnostic information, specified in the `fcnHandle` input argument. This property is read-only.

## Inherited Properties

### DiagnosticResult

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

## Methods

### Inherited Methods

|                       |                                               |
|-----------------------|-----------------------------------------------|
| <code>diagnose</code> | Execute diagnostic action                     |
| <code>join</code>     | Join multiple diagnostics into a single array |

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Create FunctionHandleDiagnostic Object

Create a diagnostic result that displays the output of the `dir` function when a test fails.

Create a folder in your current working folder.

```
mkdir('subfolderInCurrentFolder')
```

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.diagnostics.FunctionHandleDiagnostic
```

```
testCase = TestCase.forInteractiveUse;
```

Use a `FunctionHandleDiagnostic` to display diagnostic information upon test failure.

```
testCase.verifyThat(1, IsEqualTo(2), FunctionHandleDiagnostic(@dir))
```

```
Interactive verification failed.
```

```

Test Diagnostic:

```

```
. .. subfolderInCurrentFolder
```

```

Framework Diagnostic:

```

```
IsEqualTo failed.
```

```
--> NumericComparator failed.
```

```
--> The values are not equal using "isequaln".
```

```
--> Failure table:
```

| Actual | Expected | Error | RelativeError |
|--------|----------|-------|---------------|
| 1      | 2        | -1    | -0.5          |

```
Actual double:
```

```
1
```

```
Expected double:
```

```
2
```

Upon test failure, the diagnostic displays the contents of the current working folder. In this example output, the folder only contains the subfolder `subfolderInCurrentFolder`.

Alternatively, the test framework can create a `FunctionHandleDiagnostic` object for you from a function handle input to the `verifyThat` qualification.

```
testCase.verifyThat(1, IsEqualTo(2), @dir)
```

```
Interactive verification failed.
```

```

Test Diagnostic:

```

```
. .. subfolderInCurrentFolder
```

```

Framework Diagnostic:

```

```
IsEqualTo failed.
```

```
--> NumericComparator failed.
```

```
--> The values are not equal using "isequaln".
```

```
--> Failure table:
```

| Actual | Expected | Error | RelativeError |
|--------|----------|-------|---------------|
| -----  | -----    | ----- | -----         |
| 1      | 2        | -1    | -0.5          |

```
Actual double:
```

```
1
```

```
Expected double:
```

```

**Introduced in R2013a**

# matlab.unittest.diagnostics.LoggedDiagnosticEventData class

**Package:** matlab.unittest.diagnostics

Event data for DiagnosticLogged event listeners

## Description

The `LoggedDiagnosticEventData` class holds event data for `DiagnosticLogged` event listeners. Invoking the `log` method within your tests triggers the `DiagnosticLogged` event listeners. Only the test framework constructs this class directly.

## Properties

### Verbosity

Verbosity level of the logged message, represented as a `matlab.unittest.Verbosity` enumeration

### Timestamp

Date and time of the call to the `log` method, represented as a `datetime` value

### Diagnostic

Diagnostic specified in the call to the `log` method, represented as a string, function handle, or instance of `matlab.unittest.diagnostics.Diagnostic`

### Stack

Function call stack leading up to the call to the `log` method, represented as a structure array

### DiagnosticResult

Logged diagnostic messages, represented as a cell array of strings

## See Also

matlab.unittest.TestCase.log | matlab.unittest.TestCase |

# matlab.unittest.diagnostics.StringDiagnostic class

**Package:** matlab.unittest.diagnostics

**Superclasses:** matlab.unittest.diagnostics.Diagnostic

Diagnostic using string

## Description

The `StringDiagnostic` class provides a diagnostic result that uses a string. When the diagnostic information is known at the time of construction, the `StringDiagnostic` is a means to provide quick diagnostic information.

When using `matlab.unittest` qualifications, a string can be supplied directly as a test diagnostic. In this case, the testing framework automatically creates a `StringDiagnostic` object.

## Construction

`StringDiagnostic(diagString)` creates a new `StringDiagnostic` instance.

## Input Arguments

**diagString**

The string that the `Diagnostic` uses to generate diagnostic information.

## Properties

### Inherited Properties

**DiagnosticResult**

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

## Methods

### Inherited Methods

|          |                                               |
|----------|-----------------------------------------------|
| diagnose | Execute diagnostic action                     |
| join     | Join multiple diagnostics into a single array |

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Create StringDiagnostic Object

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.diagnostics.StringDiagnostic
```

```
testCase = TestCase.forInteractiveUse;
```

Use a StringDiagnostic to display diagnostic information upon test failure.

```
testCase.verifyThat(1, IsEqualTo(2), ...
 StringDiagnostic('actual was supposed to be equal to expected'))
```

```
Interactive verification failed.
```

```

Test Diagnostic:

actual was supposed to be equal to expected
```

```

```

```
Framework Diagnostic:

IsEqualTo failed.
--> NumericComparator failed.
 --> The values are not equal using "isequaln".
 --> Failure table:
 Actual Expected Error RelativeError
 _____ _____ _____ _____
 1 2 -1 -0.5

Actual double:
 1
Expected double:
 2
```

Alternatively, the test framework can create a `StringDiagnostic` object for you from a string input to the `verifyThat` qualification.

```
testCase.verifyThat(1, IsEqualTo(2), ...
 'actual was supposed to be equal to expected')
```

Interactive verification failed.

```

Test Diagnostic:

actual was supposed to be equal to expected

Framework Diagnostic:

IsEqualTo failed.
--> NumericComparator failed.
 --> The values are not equal using "isequaln".
 --> Failure table:
 Actual Expected Error RelativeError
 _____ _____ _____ _____
 1 2 -1 -0.5

Actual double:
 1
Expected double:
 2
```

The testing framework only creates the `StringDiagnostic` object as needed, typically only in the event of a test failure.

`FunctionHandleDiagnostic` | `matlab.unittest.diagnostics`

**Introduced in R2013a**

## dialog

Create empty modal dialog box

### Syntax

```
d = dialog
d = dialog(Name,Value)
```

### Description

`d = dialog` creates an empty dialog box and returns `d`, a figure object. Use the `uicontrol` function to add user interface controls to a dialog.

`d = dialog(Name,Value)` specifies one or more figure property names and corresponding values. Use this syntax to override the default properties.

### Examples

#### Dialog Containing Text and a Button

Use the `uicontrol` function to add user interface controls to a dialog box. For instance, create a program file called `mydialog.m` that displays a dialog containing text and a button.

```
function mydialog
 d = dialog('Position',[300 300 250 150],'Name','My Dialog');

 txt = uicontrol('Parent',d,...
 'Style','text',...
 'Position',[20 80 210 40],...
 'String','Click the close button when you're done.');
```

```
 btn = uicontrol('Parent',d,...
 'Position',[85 20 70 25],...
 'String','Close',...
 'Callback','delete(gcf)');
```

```
end
```

Next, run the `mydialog` function from the Command Window.

```
mydialog
```

### Dialog That Returns Output

Use the `uiwait` function to return output based on user selections in the dialog box. For instance, create a program file called `choosedialog.m` to perform these tasks:

- Call the `dialog` function to create dialog with a specific size, location, and the title, “Select One”.
- Call the `uicontrol` function three times to add text, a pop-up menu, and a button, respectively.
- Define the function, `popup_callback`, to serve as the callback function for the button.
- Call the `uiwait` function to wait for the user to close the dialog before returning the output to the command line.

```
function choice = choosedialog

d = dialog('Position',[300 300 250 150], 'Name', 'Select One');
txt = uicontrol('Parent',d,...
 'Style','text',...
 'Position',[20 80 210 40],...
 'String','Select a color');

popup = uicontrol('Parent',d,...
 'Style','popup',...
```

```
 'Position',[75 70 100 25],...
 'String',{'Red';'Green';'Blue'},...
 'Callback',@popup_callback);

btn = uicontrol('Parent',d,...
 'Position',[89 20 70 25],...
 'String','Close',...
 'Callback','delete(gcf)');

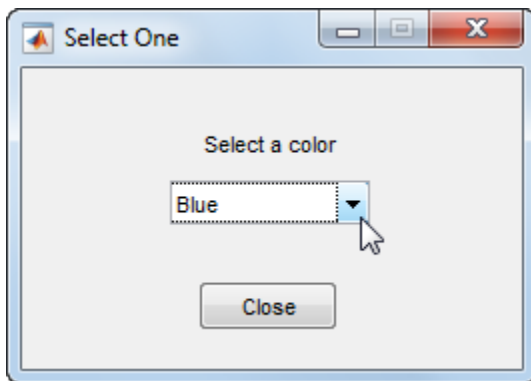

choice = 'Red';

% Wait for d to close before running to completion
uiwait(d);

function popup_callback(popup,callbackdata)
 idx = popup.Value;
 popup_items = popup.String;
 % This code uses dot notation to get properties.
 % Dot notation runs in R2014b and later.
 % For R2014a and earlier:
 % idx = get(popup,'Value');
 % popup_items = get(popup,'String');
 choice = char(popup_items(idx,:));
end
```

Run the `choosedialog` function from the Command Window. Then, select a color in the dialog.

```
color = choosedialog
```

choosedialog returns the last selected color when you close the dialog.

```
color =
```

```
Blue
```

---

**Note:** The `uiwait` function blocks the MATLAB thread. Although `uiwait` works well in a simple modal dialog, it is not recommended for use in more sophisticated applications.

---

## Input Arguments

### Name-Value Pair Arguments

Example: `'WindowStyle','normal'` sets the `WindowStyle` property to `'normal'`.

The properties listed here are only a subset. For a complete list, see [Figure Properties](#).

#### 'Position' — Location and size of window

```
[left bottom width height]
```

Location and size of window, specified as the vector, `[left bottom width height]`. This table describes the values in the `Position` vector. All values are in units specified by the `Units` property.

| Element | Description                                                                                                                                                         |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| left    | Distance from the left edge of the primary display to the inner left edge of the window. This value can be negative on systems that have more than one monitor.     |
| bottom  | Distance from the bottom edge of the primary display to the inner bottom edge of the window. This value can be negative on systems that have more than one monitor. |
| width   | Distance between the right and left inner edges of the window.                                                                                                      |
| height  | Distance between the top and bottom inner edges of the window.                                                                                                      |

---

**Note:**

- You cannot specify the `Position` property when the window is docked.
  - To place the full window, including the title bar, menu bar, tool bars, and outer edges, use the `OuterPosition` property.
  - The Windows operating system enforces a minimum figure window width. If you specify a width below that value, the figure will display at the Windows minimum width.
- 

Example: [230 250 570 510]

Data Types: double

### 'ButtonDownFcn' — Button-press callback function

function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

By default, MATLAB sets this command string to be the `ButtonDownFcn` callback for all dialogs. This command string makes the dialog box close when the user clicks the window.

```
'if isempty(allchild(gcf)), close(gcf), end'
```

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

### 'WindowStyle' — Window behavior

'modal' (default) | 'normal' | 'docked'

Window behavior, specified as one of the following:

- 'modal' — The window appears on top of all existing windows, making them inaccessible as long as the top window exists and remains modal. However, nothing prevents the display of subsequent windows after the modal window appears.

- 'normal' — The window is independent of other windows, and the other windows are accessible while the current window exists.
- 'docked' — The window appears in the desktop or a document window.

## Output Arguments

### **d** — Dialog window

figure object

Dialog window, returned as a figure object with these properties values set.

| Property          | Value                                          |
|-------------------|------------------------------------------------|
| ButtonDownFcn     | 'if isempty(allchild(gcbf)), close(gcbf), end' |
| Colormap          | []                                             |
| DockControls      | 'off'                                          |
| HandleVisibility  | 'callback'                                     |
| IntegerHandle     | 'off'                                          |
| InvertHardcopy    | 'off'                                          |
| MenuBar           | 'none'                                         |
| Number            | []                                             |
| NumberTitle       | 'off'                                          |
| PaperPositionMode | 'auto'                                         |
| Resize            | 'off'                                          |
| WindowStyle       | 'modal'                                        |

# diary

Save Command Window text to file

## Syntax

```
diary
diary('filename')
diary off
diary on
diary filename
```

## Description

The `diary` function creates a log of keyboard input and the resulting text output, with some exceptions (see “Tips” on page 1-2213 for details). The output of `diary` is an ASCII file, suitable for searching in, printing, inclusion in most reports and other documents. If you do not specify `filename`, the MATLAB software creates a file named `diary` in the current folder.

`diary` toggles `diary` mode on and off. To see the status of `diary`, type `get(0, 'Diary')`. MATLAB returns either `on` or `off` indicating the `diary` status.

`diary('filename')` writes a copy of all subsequent keyboard input and the resulting output (except it does not include graphics) to the named file, where `filename` is the full pathname or `filename` is in the current MATLAB folder. If the file already exists, output is appended to the end of the file. You cannot use a `filename` called `off` or `on`. To see the name of the `diary` file, use `get(0, 'DiaryFile')`.

`diary off` suspends the diary.

`diary on` resumes diary mode using the current filename, or the default filename `diary` if none has yet been specified.

`diary filename` is the unquoted form of the syntax.

## More About

### Tips

Because the output of `diary` is plain text, the file does not exactly mirror input and output from the Command Window:

- Output does not include graphics (figure windows).
- Syntax highlighting and font preferences are not preserved.
- Hidden components of Command Window output such as hyperlink information generated with `matlab:` are shown in plain text. For example, if you enter the following statement

```
str = sprintf('%s%s', ...
 '', ...
 'Generate magic square');
disp(str)
```

MATLAB displays

[Generate magic square](#)

However, the diary file, when viewed in a text editor, shows

```
str = sprintf('%s%s', ...
 '', ...
 'Generate magic square');
disp(str)
Generate magic square
```

If you view the output of `diary` in the Command Window, the Command Window interprets the `<a href ...>` statement and displays it as a hyperlink.

- Viewing the output of `diary` in a console window might produce different results compared to viewing `diary` output in the desktop Command Window. One example is using the `\r` option for the `fprintf` function; using the `\n` option might alleviate that problem.
- “Command History”

**Introduced before R2006a**

# diff

Differences and Approximate Derivatives

## Syntax

```
Y = diff(X)
Y = diff(X,n)
Y = diff(X,n,dim)
```

## Description

`Y = diff(X)` calculates differences between adjacent elements of `X` along the first array dimension whose size does not equal 1:

- If `X` is a vector of length `m`, then `Y = diff(X)` returns a vector of length `m-1`. The elements of `Y` are the differences between adjacent elements of `X`.

```
Y = [X(2)-X(1) X(3)-X(2) ... X(m)-X(m-1)]
```

- If `X` is a nonempty, nonvector `p`-by-`m` matrix, then `Y = diff(X)` returns a matrix of size `(p-1)`-by-`m`, whose elements are the differences between the rows of `X`.

```
Y = [X(2,:)-X(1,:); X(3,:)-X(2,:); ... X(p,:)-X(p-1,:)]
```

- If `X` is a 0-by-0 empty matrix, then `Y = diff(X)` returns a 0-by-0 empty matrix.

`Y = diff(X,n)` calculates the `n`th difference by applying the `diff(X)` operator recursively `n` times. In practice, this means `diff(X,2)` is the same as `diff(diff(X))`.

`Y = diff(X,n,dim)` is the `n`th difference calculated along the dimension specified by `dim`. The `dim` input is a positive integer scalar.

## Examples

### Differences Between Vector Elements

Create a vector, then compute the differences between the elements.

```
X = [1 1 2 3 5 8 13 21];
Y = diff(X)
```

```
Y =
```

```
 0 1 1 2 3 5 8
```

Note that Y has one fewer element than X.

## Differences Between Matrix Rows

Create a 3-by-3 matrix, then compute the first difference between the rows.

```
X = [1 1 1; 5 5 5; 25 25 25];
Y = diff(X)
```

```
Y =
```

```
 4 4 4
 20 20 20
```

The output Y is a 2-by-3 difference matrix.

## Multiple Differences

Create a vector and compute the second-order difference between the elements.

```
X = [0 5 15 30 50 75 105];
Y = diff(X,2)
```

```
Y =
```

```
 5 5 5 5 5
```

## Differences Between Matrix Columns

Create a 3-by-3 matrix, then compute the first-order difference between the columns.

```
X = [1 3 5; 7 11 13; 17 19 23];
Y = diff(X,1,2)
```

```
Y =
```

```
2 2
4 2
2 4
```

The output  $Y$  is a 3-by-2 difference matrix.

### Approximate Derivatives with `diff`

Use the `diff` function to approximate partial derivatives with the syntax  $Y = \text{diff}(f)/h$ , where  $f$  is a vector of function values evaluated over some domain,  $X$ , and  $h$  is an appropriate step size.

For example, the first derivative of  $\sin(x)$  with respect to  $x$  is  $\cos(x)$ , and the second derivative with respect to  $x$  is  $-\sin(x)$ . You can use `diff` to approximate these derivatives.

```
h = 0.001; % step size
X = -pi:h:pi; % domain
f = sin(X); % range
Y = diff(f)/h; % first derivative
Z = diff(Y)/h; % second derivative
plot(X(:,1:length(Y)),Y,'r',X,f,'b', X(:,1:length(Z)),Z,'k')
```

In this plot the blue line corresponds to the original function, `sin`. The red line corresponds to the calculated first derivative, `cos`, and the black line corresponds to the calculated second derivative, `-sin`.

### Differences Between Datetime Values

Create a sequence of equally-spaced datetime values, and find the time differences between them.

```
t1 = datetime('now');
t2 = t1 + minutes(5);
t = t1:minutes(1.5):t2
```

```

t =
Columns 1 through 3
 24-Aug-2015 17:52:41 24-Aug-2015 17:54:11 24-Aug-2015 17:55:41
Column 4
 24-Aug-2015 17:57:11

dt = diff(t)

dt =
 00:01:30 00:01:30 00:01:30

```

`diff` returns a duration array.

## Input Arguments

### **X** — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. *X* can be a numeric array, logical array, datetime array, or duration array.

Complex Number Support: Yes

### **n** — Difference order

positive integer scalar | []

Difference order, specified as a positive integer scalar or []. The default value of *n* is 1.

It is possible to specify *n* sufficiently large so that `dim` reduces to a single (`Size(X,dim) = 1`) dimension. When this happens, `diff` continues calculating along the next array dimension whose size does not equal 1. This process continues until a 0-by-0 empty matrix is returned.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional p-by-m input array, A:

- `diff(A,1,1)` works on successive elements in the columns of A and returns a (p-1)-by-m difference matrix.
- `diff(A,1,2)` works on successive elements in the rows of A and returns a p-by-(m-1) difference matrix.

A

`diff(A,1,1)`

`diff(A,1,2)`

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## Output Arguments

**Y** — Difference array

scalar | vector | matrix | multidimensional array

Difference array, returned as a scalar, vector, matrix, or multidimensional array. If X is a nonempty array, then the dimension of X acted on by `diff` is reduced in size by n in the output.

### See Also

cumsum | gradient | prod | sum

Introduced before R2006a

# diffuse

Calculate diffuse reflectance

## Syntax

```
R = diffuse(Nx,Ny,Nz,S)
```

## Description

`R = diffuse(Nx,Ny,Nz,S)` returns the reflectance of a surface with normal vector components `[Nx,Ny,Nz]`. `S` specifies the direction to the light source. You can specify these directions as three vectors `[x,y,z]` or two vectors `[Theta Phi]` (in spherical coordinates).

Lambert's Law:  $R = \cos(\text{PSI})$  where `PSI` is the angle between the surface normal and light source.

## See Also

`specular` | `surfl` | `surfnorm`

## indegree

In-degree of nodes

### Syntax

```
D = indegree(G)
D = indegree(G,nodeIDs)
```

### Description

`D = indegree(G)` returns a column vector containing the in-degree of each node in `G`.

`D = indegree(G,nodeIDs)` returns the in-degree of the nodes specified by `nodeIDs`.

### Examples

#### In-degree of All Graph Nodes

Create and plot a directed graph, and then compute the in-degree of every node in the graph. The in-degree of a node is equal to the number of edges with that node as the target.

```
s = [1 3 2 2 4 5 1 2];
t = [2 2 4 5 6 6 6 6];
G = digraph(s,t);
plot(G)
```

```
indeg = indegree(G)
```

```
indeg =
```

```
0
2
0
1
1
4
```

`indeg(j)` indicates the in-degree of node `j`.

### In-degree of Subset of Graph Nodes

Create and plot a directed graph with named nodes. Then compute the number of edges that have the 'a', 'b', and 'f' nodes as their target.

```
s = {'a' 'c' 'b' 'b' 'd' 'e' 'a' 'b'};
t = {'b' 'b' 'd' 'e' 'f' 'f' 'f' 'f'};
G = digraph(s,t);
plot(G)
```

```
nodeID = {'a' 'b' 'f'}';
```

```
indeg = indegree(G,nodeID)
```

```
indeg =
 0
 2
 4
```

`indeg(j)` indicates the in-degree of node `nodeID(j)`.

## Input Arguments

### **G** — Input graph

digraph object

Input graph, specified as a `digraph` object. Use the `digraph` function to create a directed graph object. For more information, see [Using digraph Objects](#).

Example: `G = digraph([1 2],[2 3])`

### **nodeIDs** — Node identifiers

scalar | vector | matrix | string | cell array of strings

Node identifiers, specified as a scalar node index, a vector or matrix of numeric node indices, a string node name, or a cell array of strings containing node names. You can refer to the nodes either by their numeric node index or by their node names.

## Output Arguments

### **D** — In-degree of nodes

array

In-degree of nodes, returned as a numeric array. `D` is a column vector unless you specify `nodeIDs`, in which case `D` has the same size as `nodeIDs`.

The in-degree of a graph node is equal to the number of predecessors, such that `indegree(G,ind) == length(predecessors(G,ind))`.

digraph | outdegree | predecessors

**Introduced in R2015b**

# isdag

Determine if graph is acyclic

## Syntax

```
tf = isdag(G)
```

## Description

`tf = isdag(G)` returns logical 1 (**true**) if **G** is a directed acyclic graph; otherwise, it returns logical 0 (**false**).

## Examples

### Determine if Directed Graph is Acyclic

Create and plot a directed graph, and then test the graph to determine if it is acyclic.

```
s = [1 1 2 2 3 3 4 4 4 5];
t = [2 3 4 5 6 7 8 9 10 4];
G = digraph(s,t)
```

```
G =
```

```
digraph with properties:
```

```
Edges: [10x1 table]
Nodes: [10x0 table]
```

```
plot(G)
```

```
tf = isdag(G)
```

```
tf =
```

```
1
```

## Input Arguments

**G** — Input graph  
digraph object

Input graph, specified as a `digraph` object. Use the `digraph` function to create a directed graph object. For more information, see [Using digraph Objects](#).

Example: `G = digraph([1 2],[2 3])`

## More About

### Directed Acyclic Graph (DAG)

A directed graph is acyclic if it contains no cycles. That is, starting at any node in the graph, no sequence of edges exists that can be followed to loop back to that starting node. As a result, directed acyclic graphs do not contain any self-loops.

- [Using digraph Objects](#)

## outdegree

Out-degree of nodes

### Syntax

```
D = outdegree(G)
D = outdegree(G,nodeIDs)
```

### Description

`D = outdegree(G)` returns a column vector containing the out-degree of each node in `G`.

`D = outdegree(G,nodeIDs)` returns the out-degree of the nodes specified by `nodeIDs`.

### Examples

#### Out-degree of All Graph Nodes

Create and plot a directed graph, and then compute the out-degree of every node in the graph. The out-degree of a node is equal to the number of edges with that node as the source.

```
s = [1 3 2 2 4 5 1 2];
t = [2 2 4 5 6 6 6 6];
G = digraph(s,t);
plot(G)
```

```
outdeg = outdegree(G)
```

```
outdeg =
```

```
2
3
1
1
1
0
```

$\text{outdeg}(j)$  indicates the out-degree of node  $j$ .

### Out-degree of Subset of Graph Nodes

Create and plot a directed graph with named nodes. Then compute the number of edges that have the 'a', 'b', and 'f' nodes as their source.

```
s = {'a' 'c' 'b' 'b' 'd' 'e' 'a' 'b'};
t = {'b' 'b' 'd' 'e' 'f' 'f' 'f' 'f'};
G = digraph(s,t);
plot(G)
```

```
nodeID = {'a' 'b' 'f'};
```

```
outdeg = outdegree(G,nodeID)
```

```
outdeg =
 2
 3
 0
```

`outdeg(j)` indicates the out-degree of node `nodeID(j)`.

## Input Arguments

### **G** — Input graph

digraph object

Input graph, specified as a `digraph` object. Use the `digraph` function to create a directed graph object. For more information, see [Using digraph Objects](#).

Example: `G = digraph([1 2],[2 3])`

### **nodeIDs** — Node identifiers

scalar | vector | matrix | string | cell array of strings

Node identifiers, specified as a scalar node index, a vector or matrix of numeric node indices, a string node name, or a cell array of strings containing node names. You can refer to the nodes either by their numeric node index or by their node names.

## Output Arguments

### **D** — Out-degree of nodes

array

Out-degree of nodes, returned as a numeric array. `D` is a column vector unless you specify `nodeIDs`, in which case `D` has the same size as `nodeIDs`.

The out-degree of a graph node is equal to the number of successors, such that `outdegree(G,ind) == length(successors(G,ind))`.

## **More About**

- Using digraph Objects

## **See Also**

digraph | indegree | successors

**Introduced in R2015b**

# predecessors

Node predecessors

## Syntax

```
preIDs = predecessors(G,nodeID)
```

## Description

`preIDs = predecessors(G,nodeID)` returns the predecessor nodes of the node in directed graph `G` specified by `nodeID`. The predecessor nodes form directed edges with `preIDs` as the source nodes, and `nodeID` as the target node.

## Examples

### Node Predecessors

Create and plot a directed graph and determine the predecessor nodes of node 'e'.

```
s = [1 1 1 2 2 3 3 7 8];
t = [2 3 4 5 6 7 8 5 5];
names = {'a' 'b' 'c' 'd' 'e' 'f' 'g' 'h'};
G = digraph(s,t,[],names);
plot(G)
```

```
preIDs = predecessors(G, 'e')
```

```
preIDs =
```

```
'b'
'g'
'h'
```

## Input Arguments

### **G** — Input graph

digraph object

Input graph, specified as a `digraph` object. Use the `digraph` function to create a directed graph object. For more information, see [Using digraph Objects](#).

Example: `G = digraph([1 2],[2 3])`

### **nodeID** — Node identifier

scalar | string

Node identifier, specified as a numeric scalar node index or a string node name.

Example: `preIDs = predecessors(G,3)` finds the predecessor nodes of node 3.

## Output Arguments

### **preIDs** — Predecessor node IDs

scalar | vector | cell array of strings

Predecessor node IDs, returned as a numeric scalar or column vector of node indices, or as a cell array of strings containing node names.

- If `nodeID` is a numeric node index, then `preIDs` contains numeric node indices.
- If `nodeID` is a node name, then `preIDs` contains node names.

## More About

## successors

Node successors

### Syntax

```
sucIDs = successors(G,nodeID)
```

### Description

`sucIDs = successors(G,nodeID)` returns the successor nodes of the node in directed graph `G` specified by `nodeID`. The successor nodes form directed edges with `nodeID` as the source node, and `sucIDs` as the target nodes.

### Examples

#### Node Successors

Create and plot a directed graph and determine the successor nodes of node 'a'.

```
s = [1 1 1 2 2 3 3 7 8];
t = [2 3 4 5 6 7 8 5 5];
names = {'a' 'b' 'c' 'd' 'e' 'f' 'g' 'h'};
G = digraph(s,t,[],names);
plot(G)
```

```
sucIDs = successors(G, 'a')
```

```
sucIDs =
```

```
'b'
'c'
'd'
```

## Input Arguments

### **G** — Input graph

digraph object

Input graph, specified as a `digraph` object. Use the `digraph` function to create a directed graph object. For more information, see [Using digraph Objects](#).

Example: `G = digraph([1 2],[2 3])`

### **nodeID** — Node identifier

scalar | string

Node identifier, specified as a numeric scalar node index or a string node name.

Example: `sucIDs = successors(G,3)` finds the successor nodes of node 3.

## Output Arguments

### **sucIDs** — Successor node IDs

scalar | vector | cell array of strings

Successor node IDs, returned as a numeric scalar or column vector of node indices, or as a cell array of strings containing node names.

- If `nodeID` is a numeric node index, then `sucIDs` contains numeric node indices.
- If `nodeID` is a node name, then `sucIDs` contains node names.

# toposort

Topological order of directed acyclic graph

## Syntax

```
n = toposort(G)
n = toposort(G, 'Order', algorithm)
[n, H] = toposort(___)
```

## Description

`n = toposort(G)` returns the topological order of the nodes in `G` such that  $i < j$  for every edge  $(n(i), n(j))$  in `G`. The directed graph `G` cannot have any cycles.

`n = toposort(G, 'Order', algorithm)` specifies the ordering algorithm. For example, `toposort(G, 'Order', 'stable')` uses a stable ordering algorithm based on the lexicographical order of the nodes.

`[n, H] = toposort( ___ )` additionally returns directed graph `H` whose nodes are in the given topological order. You can use any of the input argument combinations in previous syntaxes.

## Examples

### Topological Sort of Nodes

Create and plot a graph that represents a progression of university-level Mathematics courses. An edge between two courses signifies a course requirement.

```
A = [0 1 1 0 0 0 0
 0 0 0 1 0 0 0
 0 1 0 1 0 0 1
 0 0 0 0 1 1 0
 0 0 0 0 0 0 0]
```

```
 0 0 0 0 1 0 0
 0 0 0 0 1 0 0];
names = {'Calculus I', 'Linear Algebra', 'Calculus II', ...
 'Multivariate Calculus', 'Topology', ...
 'Differential Equations', 'Real Analysis'};
G = digraph(A, names);
plot(G)
```

Find the topological sorting of the courses to determine the proper order in which they should be completed.

```
N = toposort(G)
```

```
N =
 1 3 7 2 4 6 5
```

```
G.Nodes.Name(N, :)
```

```
ans =
 'Calculus I'
 'Calculus II'
 'Real Analysis'
 'Linear Algebra'
 'Multivariate Calculus'
 'Differential Equations'
 'Topology'
```

### Stable Topological Sort

Create a directed graph using a logical adjacency matrix, and then plot the graph.

```
rng default;
A = tril(sprand(10, 10, 0.3), -1)~=0;
G = digraph(A);
[~,G] = toposort(G);
plot(G)
```

Find the topological sorting of the graph nodes. Even though  $G$  is already in topological order, (1 2 3 4 5 6 7 8 9 10), `toposort` reorders the nodes.

```
toposort(G)
```

```
ans =
```

```
 2 1 4 10 9 8 5 7 3 6
```

Specify `Order` as `'stable'` to use the stable ordering algorithm, so that the sort orders the nodes with smaller indices first. Stable sort does not rearrange  $G$  if it is already in topological order.

```
toposort(G, 'Order', 'stable')
```

```
ans =
```

```
 1 2 3 4 5 6 7 8 9 10
```

## Input Arguments

### **G** — Input graph

digraph object

Input graph, specified as a **digraph** object. **G** must be a directed acyclic graph. Use **isdag** to confirm that **G** does not contain cycles.

Use **digraph** to create a directed graph. For more information, see [Using digraph Objects](#).

Example: `G = digraph([1 2],[2 3])`

### **algorithm** — Ordering algorithm

'fast' (default) | 'stable'

Ordering algorithm, specified as 'fast' or 'stable':

|                  |                                                                                                                                                                                                                                                                                                  |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'fast' (default) | <p>Based on a depth-first search. A node is added to the beginning of the list after considering all of its descendents.</p> <p>If <b>G</b> is already in topological order, this method might still reorder the nodes.</p>                                                                      |
| 'stable'         | <p>Based on lexicographical order. <math>n(1)</math> is the node with smallest index, <math>n(2)</math> the next smallest given <math>n(1)</math>, and so on.</p> <p>If <b>G</b> is in topological order then <b>H</b> is unchanged and <math>n</math> is <math>1:\text{numnodes}(G)</math>.</p> |

Example: `[n,H] = toposort(G,'Order','stable')`

Data Types: char

## Output Arguments

### **n** — Node indices

row vector

Node indices, returned as a row vector.

### **H** — Topologically sorted graph

digraph object

Topologically sorted graph, returned as a `digraph` object. `H` is the same graph as `G`, but has the nodes reordered according to `n`.

## More About

### Topological Order

The topological ordering of a directed graph is an ordering of the nodes in the graph such that each node appears before its successors (descendants).

Consider a directed graph whose nodes represent tasks and whose edges represent dependencies that certain tasks must be completed before others. For such a graph, the topological sorting of the graph nodes produces a valid sequence in which the tasks could be performed.

`digraph` | `isdag` | `reordernodes`

Introduced in R2015b

# transclosure

Transitive closure

## Syntax

```
H = transclosure(G)
```

## Description

`H = transclosure(G)` returns the transitive closure of graph `G` as a new graph, `H`. The nodes in `H` are the same as those in `G`, but `H` has additional edges. If there is a path from node `i` to node `j` in `G`, then there is an edge between node `i` and node `j` in `H`.

## Examples

### Transitive Closure of Graph

Create and plot a directed graph.

```
G = digraph([1 2 3 4 4 4 5 5 5 6 7 8],[2 3 5 1 3 6 6 7 8 9 9 9]);
plot(G)
```

Find the transitive closure of graph  $G$  and plot the resulting graph.  $H$  contains the same nodes as  $G$ , but has additional edges.

```
H = transclosure(G);
plot(H)
```

The transitive closure information in H can be used to answer reachability questions about the original graph, G.

Determine the nodes in G that can be reached from node 1. These nodes are the successors of node 1 in the transitive closure graph, H.

$N = \text{successors}(H, 1)$

$N =$

- 2
- 3
- 5

6  
7  
8  
9

## Input Arguments

### **G** — Input graph

digraph object

Input graph, specified as a `digraph` object. Use the `digraph` function to create a directed graph object. For more information, see [Using digraph Objects](#).

Example: `G = digraph([1 2],[2 3])`

## Output Arguments

### **H** — Transitive closure of G

digraph object

Transitive closure of G, returned as a `digraph` object. The table `G.Nodes` is copied to H, but any properties in `G.Edges` are dropped.

Use `successors(H,n)` to determine the nodes in G that are reachable from node n.

## More About

### Transitive Closure

The transitive closure of a graph describes the paths between the nodes. If there is a path from node *i* to node *j* in a graph, then an edge exists between node *i* and node *j* in the transitive closure of that graph. Thus, for a given node in the graph, the transitive closure turns any reachable node into a direct successor (descendent) of that node.

- [Using digraph Objects](#)

### See Also

`conncomp` | `digraph` | `predecessors` | `successors` | `transreduction`

**Introduced in R2015b**

## transreduction

Transitive reduction

### Syntax

```
H = transreduction(G)
```

### Description

`H = transreduction(G)` returns the transitive reduction of graph `G` as a new graph, `H`. The nodes in `H` are the same as those in `G`, but `H` has different edges. `H` contains the fewest number of edges such that if there is a path from node `i` to node `j` in `G`, then there is also a path from node `i` to node `j` in `H`.

### Examples

#### Transitive Reduction of Complete Graph

Create and plot a complete graph of order four.

```
G = digraph([1 1 1 2 2 2 3 3 3 4 4 4],[2 3 4 1 3 4 1 2 4 1 2 3]);
plot(G)
```

Find the transitive reduction and plot the resulting graph. Since the reachability in a complete graph is extensive, there are theoretically several possible transitive reductions, as any cycle through the four nodes is a candidate.

```
H = transreduction(G);
plot(H)
```

Two graphs with the same reachability also have the same transitive reduction. Therefore, any cycle of four nodes produces the same transitive reduction as H.

Create a directed graph that contains a different four node cycle: (1,3,4,2,1).

```
G1 = digraph([1 3 4 2],[3 4 2 1]);
plot(G1)
```

Find the transitive reduction of  $G_1$ . The cycle in  $G_1$  is reordered so that the transitive reductions  $H$  and  $H_1$  have the same cycle,  $(1,2,3,4,1)$ .

```
H1 = transreduction(G1);
plot(H1)
```

### Unique Transitive Reduction

Create and plot a directed acyclic graph.

```
s = [1 1 1 1 2 3 3 4];
t = [2 3 4 5 4 4 5 5];
G = digraph(s,t);
plot(G)
```

Confirm that  $G$  does not contain any cycles.

```
tf = isdag(G)
```

```
tf =
```

```
1
```

Find the transitive reduction of the graph. Since the graph does not contain cycles, the transitive reduction is unique and is a subgraph of  $G$ .

```
H = transreduction(G);
```

plot(H)

## Input Arguments

**G** — Input graph  
digraph object

Input graph, specified as a `digraph` object. Use the `digraph` function to create a directed graph object. For more information, see [Using digraph Objects](#).

Example: `G = digraph([1 2],[2 3])`

## Output Arguments

### **H — Transitive reduction of G**

digraph object

Transitive reduction of  $G$ , returned as a `digraph` object. The table `G.Nodes` is copied to `H`, but any properties in `G.Edges` are dropped. `H` might contain new edges not present in `G`.

`H` contains the fewest number of edges that still preserve the reachability of graph `G`. In other words, `transclosure(H)` is the same as `transclosure(G)`.

If `isdag(G)` is `true`, then `H` is unique and is a subgraph of `G`.

## More About

### Transitive Reduction

The transitive reduction of graph  $G$  is the graph with the fewest edges that still shares the same reachability as  $G$ . Therefore, of all the graphs that have the same transitive closure as  $G$ , the transitive reduction is the one with the fewest edges. If two directed graphs have the same transitive closure, they also have the same transitive reduction.

- Using digraph Objects

`conncomp` | `digraph` | `transclosure`

Introduced in R2015b

# digraph

Create directed graph

## Syntax

`G = digraph`

`G = digraph(A)`

`G = digraph(A,nodenames)`

`G = digraph(A, ____, 'OmitSelfLoops')`

`G = digraph(s,t)`

`G = digraph(s,t,weights)`

`G = digraph(s,t,weights,nodenames)`

`G = digraph(s,t,weights,num)`

`G = digraph(s,t, ____, 'OmitSelfLoops')`

`G = digraph(EdgeTable)`

`G = digraph(EdgeTable,NodeTable)`

`G = digraph(EdgeTable, ____, 'OmitSelfLoops')`

## Description

`G = digraph` creates an empty directed graph object, `G`, which has no nodes or edges.

`G = digraph(A)` creates a weighted directed graph using a square adjacency matrix, `A`. The location of each nonzero entry in `A` specifies an edge for the graph, and the weight of the edge is equal to the value of the entry. For example, if  $A(2,1) = 10$ , then `G` contains an edge from node 2 to node 1 with a weight of 10.

`G = digraph(A,nodenames)` additionally specifies node names using the cell array of strings, `nodenames`. The number of elements in `nodenames` must be equal to `size(A,1)`.

`G = digraph(A, ____, 'OmitSelfLoops')` ignores the diagonal elements of `A` and returns a graph without any self-loops. You must specify `A`, and optionally can specify `nodenames`.

`G = digraph(s,t)` specifies directed graph edges (`s,t`) in pairs to represent the source and target nodes. `s` and `t` can be numeric, strings, or cell arrays of strings with the same number of elements.

`G = digraph(s,t,weights)` also specifies edge weights with the array, `weights`.

`G = digraph(s,t,weights,nodenames)` additionally specifies all node names using the cell array of strings, `nodenames`. The `s` and `t` inputs cannot contain node names that are not in `nodenames`.

`G = digraph(s,t,weights,num)` specifies the number of nodes in the graph with the numeric scalar `num`.

`G = digraph(s,t, __, 'OmitSelfLoops')` does not add any self-loops to the graph. That is, any `k` that satisfies `s(k) == t(k)` is ignored. You must specify `s` and `t` and optionally can specify `weights`, `nodenames`, or `num`.

`G = digraph(EdgeTable)` uses the table, `EdgeTable`, to define the graph. The first variable in `EdgeTable` must be `EndNodes`, and it must be a two-column array defining the edge list of the graph. `EdgeTable` can contain any number of other table variables to define attributes of the graph edges.

`G = digraph(EdgeTable,NodeTable)` additionally uses the table, `NodeTable`, to define attributes of the graph nodes. `NodeTable` can contain any number of table variables to define attributes of the graph nodes.

`G = digraph(EdgeTable, __, 'OmitSelfLoops')` does not add self-loops to the graph. That is, any `k` that satisfies `EdgeTable.EndNodes(k,1) == EdgeTable.EndNodes(k,2)` is ignored. You must specify `EdgeTable` and optionally can specify `NodeTable`.

## Examples

### Adjacency Matrix Graph Construction

Create a symmetric adjacency matrix, `A`, that creates a complete directed graph of order 4. Use a logical adjacency matrix to create a graph without weights.

```
A = ones(4) - diag([1 1 1 1])
```

```
A =
```

```
0 1 1 1
1 0 1 1
1 1 0 1
1 1 1 0
```

`G = digraph(A~=0)`

`G =`

`digraph with properties:`

`Edges: [12x1 table]`

`Nodes: [4x0 table]`

View the edge list of the graph.

`G.Edges`

`ans =`

`EndNodes`

```

1 2
1 3
1 4
2 1
2 3
2 4
3 1
3 2
3 4
4 1
4 2
4 3
```

## Adjacency Matrix Construction with Node Names

Create an adjacency matrix.

```
A = magic(4);
A(A>10) = 0
```

```
A =
```

```

0 2 3 0
5 0 10 8
9 7 6 0
4 0 0 1
```

Create a graph with named nodes using the adjacency matrix. Specify 'OmitSelfLoops' to ignore the entries on the diagonal of A.

```
names = {'alpha' 'beta' 'gamma' 'delta'};
G = digraph(A,names,'OmitSelfLoops')
```

```
G =
```

```
digraph with properties:
```

```
Edges: [8x2 table]
Nodes: [4x1 table]
```

View the edge and node information.

**G.Edges**

```
ans =
```

| EndNodes |         | Weight |
|----------|---------|--------|
| -----    |         | -----  |
| 'alpha'  | 'beta'  | 2      |
| 'alpha'  | 'gamma' | 3      |
| 'beta'   | 'alpha' | 5      |
| 'beta'   | 'gamma' | 10     |
| 'beta'   | 'delta' | 8      |
| 'gamma'  | 'alpha' | 9      |
| 'gamma'  | 'beta'  | 7      |
| 'delta'  | 'alpha' | 4      |

## G.Nodes

```
ans =

 Name

 'alpha'
 'beta'
 'gamma'
 'delta'
```

## Edge List Graph Construction

Create and plot a cube graph using a list of the end nodes of each edge.

```
s = [1 1 1 2 2 3 3 4 5 5 6 7];
t = [2 4 8 3 7 4 6 5 6 8 7 8];
G = digraph(s,t)
```

```
G =

digraph with properties:

Edges: [12x1 table]
Nodes: [8x0 table]
```

```
plot(G, 'Layout', 'force')
```

### Edge List Graph Construction with Node Names and Edge Weights

Create and plot a cube graph using a list of the end nodes of each edge. Specify node names and edge weights as separate inputs.

```
s = [1 1 1 2 2 3 3 4 5 5 6 7];
t = [2 4 8 3 7 4 6 5 6 8 7 8];
weights = [10 10 1 10 1 10 1 1 12 12 12 12];
names = {'A' 'B' 'C' 'D' 'E' 'F' 'G' 'H'};
G = digraph(s,t,weights,names)
```

G =

digraph with properties:

Edges: [12x2 table]  
Nodes: [8x1 table]

```
plot(G, 'Layout', 'force', 'EdgeLabel', G.Edges.Weight)
```

## Edge List Construction with Extra Nodes

Create a weighted graph using a list of the end nodes of each edge. Specify that the graph should contain a total of 10 nodes.

```
s = [1 1 1 1 1];
```

```
t = [2 3 4 5 6];
weights = [5 5 5 6 9];
G = digraph(s,t,weights,10)
```

```
G =
```

```
digraph with properties:
```

```
Edges: [5x2 table]
Nodes: [10x0 table]
```

Plot the graph. The extra nodes are disconnected from the primary connected component.

```
plot(G)
```

### Add Nodes and Edges to Empty Graph

Create an empty digraph object, `G`.

```
G = digraph;
```

Add three nodes and three edges to the graph. The corresponding entries in `s` and `t` define the source and target nodes of the edges. `addedge` automatically adds the appropriate nodes to the graph if they are not already present.

```
s = [1 2 1];
t = [2 3 3];
G = addedge(G,s,t)
```

```
G =
 digraph with properties:
 Edges: [3x1 table]
 Nodes: [3x0 table]
```

View the edge list. Each row describes an edge in the graph.

### G.Edges

```
ans =
 EndNodes

 1 2
 1 3
 2 3
```

For the best performance, construct graphs all at once using a single call to `digraph`. Adding nodes or edges in a loop can be slow for large graphs.

### Graph Construction with Tables

Create an edge table that contains the variables `EndNodes`, `Weight`, and `Code`. Then create a node table that contains the variables `Name` and `Country`. The variables in each table specify properties of the graph nodes and edges.

```
s = [1 1 1 2 2 3];
t = [2 3 4 3 4 4];
weights = [6 6.5 7 11.5 12 17]';
code = {'1/44' '1/49' '1/33' '44/49' '44/33' '49/33'}';
EdgeTable = table([s' t'],weights,code, ...
 'VariableNames',{'EndNodes' 'Weight' 'Code'})
```

```
EdgeTable =
 EndNodes Weight Code
 _____ _____ _____
```

|   |   |      |         |
|---|---|------|---------|
| 1 | 2 | 6    | '1/44'  |
| 1 | 3 | 6.5  | '1/49'  |
| 1 | 4 | 7    | '1/33'  |
| 2 | 3 | 11.5 | '44/49' |
| 2 | 4 | 12   | '44/33' |
| 3 | 4 | 17   | '49/33' |

```
names = {'USA' 'GBR' 'DEU' 'FRA'}';
country_code = {'1' '44' '49' '33'}';
NodeTable = table(names, country_code, 'VariableNames', {'Name' 'Country'})
```

NodeTable =

| Name  | Country |
|-------|---------|
| 'USA' | '1'     |
| 'GBR' | '44'    |
| 'DEU' | '49'    |
| 'FRA' | '33'    |

Create a graph using the node and edge tables. Plot the graph using the country codes as node and edge labels.

```
G = digraph(EdgeTable, NodeTable);
plot(G, 'NodeLabel', G.Nodes.Country, 'EdgeLabel', G.Edges.Code)
```

- “Build Watts-Strogatz Small World Graph Model”
- “Use Page Rank Algorithm to Rank Websites”

## Input Arguments

**A** — Adjacency matrix  
matrix

Adjacency matrix, specified as a full or sparse, numeric matrix. The entries in **A** specify the network of connections (edges) between the nodes of the graph. The location of each

nonzero entry in **A** specifies an edge between two nodes. The value of that entry provides the edge weight. A logical adjacency matrix results in an unweighted graph.

Nonzero entries on the main diagonal of **A** specify *self-loops*, or nodes that are connected to themselves with an edge. Use the 'OmitSelfLoops' input option to ignore diagonal entries.

Example: **A** = [0 1 0; 0 0 0; 5 0 0] describes a graph with three nodes and two edges. The edge from node 1 to node 2 has a weight of 1, and the edge from node 3 to node 1 has a weight of 5.

Data Types: `single` | `double` | `logical`

### **nodenames** — Node names

cell array of strings

Node names, specified as a cell array of strings. **nodenames** must contain a nonempty, unique name for each node in the graph (its length must be equal to `numnodes(G)`).

Example: **G** = `digraph(A,{'n1','n2','n3'})` specifies three node names for a 3-by-3 adjacency matrix, **A**.

Data Types: `cell`

### **s, t** — Source and target node pairs

scalars | vectors | matrices | multidimensional arrays | strings | cell arrays of strings

Source and target node pairs, specified as scalars, vectors, matrices, multidimensional arrays, strings, or cell arrays of strings. `digraph` creates directed edges between the corresponding nodes in **s** and **t**, which must both be numeric, or both be strings or cell arrays of strings. In each case, **s** and **t** must have the same number of elements.

- If **s** and **t** are numeric, then they correspond to indices of graph nodes. Numeric node indices must be positive integers greater than or equal to 1.
- If **s** and **t** are strings or cell arrays of strings, then the strings specify names for the nodes. The **Nodes** property of the graph is a table containing a **Name** variable with the node names, `G.Nodes.Name`.
- **s** and **t** cannot specify duplicate edges. For directed graphs, `digraph([1 2],[2 1])` specifies two unique edges, but `digraph([1 1],[2 2])` specifies a duplicate edge with node 1 as the source and node 2 as the target.

Example: **G** = `digraph([1 2 3],[2 4 5])` creates a graph with five nodes and three edges.

Example: `G = digraph({'Boston' 'New York' 'Washington D.C.'},{'New York' 'New Jersey' 'Pittsburgh'})` creates a graph with five named nodes and three edges.

### **weights — Edge weights**

scalar | vector | matrix | multidimensional array

Edge weights, specified as a scalar, vector, matrix, or multidimensional array. `weights` can be a scalar or an array with the same number of elements as `s` and `t`.

`digraph` stores the edge weights as a `Weight` variable in the `G.Edges` property table. To add or change weights after creating a graph, you can modify the table variable directly, for example, `G.Edges.Weight = [25 50 75]'`.

Example: `G = digraph([1 2],[2 3],[100 200])` creates a graph with three nodes and two edges. The edges have weights of 100 and 200.

Data Types: `single` | `double`

### **num — Number of graph nodes**

positive scalar integer

Number of graph nodes, specified as a positive scalar integer. `num` must be greater than or equal to the largest elements in `s` and `t`.

Example: `G = digraph([1 2],[2 3],[ ],5)` creates a graph with three connected nodes and two isolated nodes.

### **EdgeTable — Table of edge information**

table

Table of edge information. The first variable in `EdgeTable` is required to be a two-column matrix called `EndNodes`, but you can have any number of other variables to describe attributes of the graph edges. For edge weights, use the variable `Weight`, since this table variable name is used by some graph functions. If there is a variable `Weight`, then it must be a numeric column vector. See `table` for more information on constructing a table.

After creating a graph, query the edge information table using `G.Edges`.

Example: `EdgeTable = table([1 2; 2 3; 3 5; 4 5],'VariableNames',{'EndNodes'})`

Data Types: `table`

**NodeTable — Table of node information**

table

Table of node information. **NodeTable** can contain any number of variables to describe attributes of the graph nodes. For node names, use the variable **Name**, since this variable name is used by some graph functions. If there is a variable **Name**, then it must be a column cell array of nonempty, unique strings. See **table** for more information on constructing a table.

After the graph is created, query the node information table using **G.Nodes**.

```
Example: NodeTable = table({'a'; 'b'; 'c'; 'd'}, 'VariableNames',
{'Name'})
```

Data Types: table

## Output Arguments

**G — Directed graph**

digraph object

Directed graph, returned as a **digraph** object. For more information, see [Using digraph Objects](#).

# Using digraph Objects

Graph with directed edges

## Description

`digraph` objects represent directed graphs, which have directional edges connecting the nodes. After you create a `digraph` object, you can learn more about the graph by using the object functions to perform queries against the object. For example, you can add or remove nodes or edges, determine the shortest path between two nodes, or locate a specific node or edge.

```
G = digraph([1 1], [2 3])
e = G.Edges
G = addedge(G,2,3)
G = addnode(G,4)
plot(G)
```

## Examples

### Create and Modify Digraph Object

Create a `digraph` object with three nodes and three edges. One edge is from node 1 to node 2, another is from node 1 to node 3, and the third is from node 2 to node 1.

```
G = digraph([1 1 2],[2 3 1])
```

```
G =
```

```
digraph with properties:
```

```
Edges: [3x1 table]
Nodes: [3x0 table]
```

View the edge table of the graph. For directed graphs, the first column indicates the source nodes of each edge, and the second column indicates the target nodes.

## G.Edges

ans =

EndNodes

| ----- |   |
|-------|---|
| 1     | 2 |
| 1     | 3 |
| 2     | 1 |

Add node names to the graph, then view the new node and edge tables. The source and target nodes of each edge are now expressed using their node names.

```
G.Nodes.Name = {'A' 'B' 'C'};
```

G.Nodes

ans =

Name

| ----- |
|-------|
| 'A'   |
| 'B'   |
| 'C'   |

## G.Edges

ans =

EndNodes

| ----- |     |
|-------|-----|
| 'A'   | 'B' |
| 'A'   | 'C' |
| 'B'   | 'A' |

You can add or modify extra variables in the **Nodes** and **Edges** tables to describe attributes of the graph nodes or edges. However, you cannot directly change the number

of nodes or edges in the graph by modifying these tables. Instead, use the `addedge`, `rmedge`, `addnode`, or `rmnode` functions to modify the number of nodes or edges in a graph.

For example, add an edge to the graph between nodes 2 and 3 and view the new edge list.

```
G = addedge(G,2,3)
```

```
G =
```

```
digraph with properties:
```

```
Edges: [4x1 table]
```

```
Nodes: [3x1 table]
```

```
G.Edges
```

```
ans =
```

```
EndNodes
```

| EndNodes |     |
|----------|-----|
| 'A'      | 'B' |
| 'A'      | 'C' |
| 'B'      | 'A' |
| 'B'      | 'C' |

## Properties

### Edges — Edges of graph

table

Edges of graph, returned as a table. By default this is an M-by-1 table, where M is the number of edges in the graph.

- To add new edge properties to the graph, create a new variable in the `Edges` table.
- To add or remove edges from the graph, use the `addedge` or `rmedge` object functions.

Example: `G.Edges` returns a table listing the edges in the graph

Example: `G.Edges.Weight` returns a numeric vector of the edge weights.

Example: `G.Edges.Weight = [10 20 30 55]'` specifies new edge weights for the graph.

Example: `G.Edges.NormWeight = G.Edges.Weight/sum(G.Edges.Weight)` adds a new edge property to the table containing the normalized weights of the edges.

Data Types: `table`

## **Nodes — Nodes of graph**

`table`

Nodes of graph, returned as a table. By default this is an empty N-by-0 table, where N is the number of nodes in the graph.

- To add new node properties to the graph, create a new variable in the **Nodes** table.
- To add or remove nodes from the graph, use the `addnode` or `rmnode` object functions.

Example: `G.Nodes` returns a table listing the node properties of the graph. This table is empty by default.

Example: `G.Nodes.Names = {'Montana', 'New York', 'Washington', 'California'}'` adds node names to the graph by adding the variable `Names` to the `Nodes` table.

Example: `G.Nodes.WiFi = logical([1 0 0 1 1])'` adds the variable `WiFi` to the `Nodes` table. This property specifies that certain airports have wireless internet coverage.

Data Types: `table`

## **Object Functions**

### **Access and Modify Nodes and Edges**

`addedge`  
`rmedge`  
`addnode`  
`rmnode`  
`findedge`  
`findnode`  
`numedges`

## **Introduced in R2015b**

# dir

List folder contents

## Syntax

```
dir
dir name
listing = dir(name)
```

## Description

`dir` returns a list of files and folders in the current folder.

`dir name` returns a list of files and folders that match the string `name`. When `name` is a folder, `dir` lists the contents of the folder. Specify `name` using absolute or relative path names. `name` can include wildcards (\*).

`listing = dir(name)` returns attributes about `name`.

## Examples

### View Contents of Folder

List the contents of a folder.

```
dir my_dir
```

### Find Files Matching Specified Name

List all files with a “.m” extension in the current folder that contain the term `my`.

```
dir *my*.m
```

### Find Information in the Return Structure

Return the folder listing of `my_dir` to the variable `MyDirInfo`.

```
MyDirInfo = dir('my_dir')
```

MATLAB returns the information in a structure array. If `my_dir` contains three files for example, the `dir` command returns this output.

```
MyDirInfo =
3x1 struct array with fields:
 name
 date
 bytes
 isdir
 datenum
```

Index into the structure to access a particular item.

```
MyDirInfo(3).name
```

```
ans =
 my_file.m
```

## Find Date File Was Modified

Get the serial date number for the date and time a file was last modified. Use the `datenum` field of the structure returned by the `dir` command.

```
MyFileInfo = dir('my_file.m');
FileDate = MyFileInfo.datenum
```

Do not use the `datenum` function to convert the string returned in the `date` field of the structure to a number. The results of the `datenum` function vary depending on the locale. Instead, use the `datenum` field.

## Input Arguments

### **name** — Name of file or folder

string

Name of file or folder, specified as a string.

The MATLAB `dir` function is consistent with the Microsoft Windows operating system `dir` command in that both support short file names generated by DOS.

## Output Arguments

### listing — File attributes

structure array

File attributes, returned as a n-by-1 structure array, where n is the number of files and folders returned by the `dir` command.

This table shows the fields in the structure.

| Field Name           | Description                                | Class                |
|----------------------|--------------------------------------------|----------------------|
| <code>name</code>    | File or folder name                        | <code>char</code>    |
| <code>date</code>    | Modification date timestamp                | <code>char</code>    |
| <code>bytes</code>   | Size of the file in bytes                  | <code>double</code>  |
| <code>isdir</code>   | 1 if name is a folder; 0 if name is a file | <code>logical</code> |
| <code>datenum</code> | Modification date as serial date number.   | <code>double</code>  |

## More About

### Tips

- To exclude invalid entries returned by the `dir` command, use the `cellfun` function.

```
MyDirInfo = dir;
MyDirInfo = MyDirInfo(~cellfun('isempty', {MyDirInfo.date}));
```

Invalid entries occur when you run `dir` with an output argument and the results include a nonexistent file or a file that `dir` cannot query for some other reason. In this case, `dir` returns the following default values.

```
date: ''
bytes: []
isdir: 0
datenum: []
```

The most common occurrence is on UNIX platforms when `dir` queries a file that is a symbolic link, pointing to a nonexistent target. A nonexistent target is a target that was moved, removed, or renamed.

- To obtain a list of available drives on Microsoft Windows platforms, use the DOS `net use` command in the Command Window.

```
dos('net use')
```

Or

```
[s,r] = dos('net use')
```

MATLAB returns the results to the character array `r`.

- “Specify File Names”

**Introduced before R2006a**

---

# dir

**Class:** FTP

View contents of folder on FTP server

## Syntax

```
dir(ftpobj)
dir(ftpobj, folder)
details = dir(ftpobj, folder)
```

## Description

`dir(ftpobj)` lists the files in current folder on the FTP server associated with `ftpobj`.

`dir(ftpobj, folder)` lists the files in the specified folder.

`details = dir(ftpobj, folder)` returns the results in a structure array that contains the name, modification date, and size of each file.

## Input Arguments

### **ftpobj**

FTP object created by `ftp`.

### **folder**

String enclosed in single quotation marks that specifies the target folder. To specify the folder above the current one, use `'..'`.

## Output Arguments

### **details**

`m`-by-1 structure array, where `m` is the number of files in the folder. Each element of the structure array contains the following fields:

| Field Name | Description                                                            | Data Type |
|------------|------------------------------------------------------------------------|-----------|
| name       | File name                                                              | char      |
| date       | Modification date timestamp                                            | char      |
| bytes      | Number of bytes allocated to the file                                  | double    |
| isdir      | If a folder, <code>isdir = 1</code> , otherwise <code>isdir = 0</code> | logical   |
| datenum    | Modification date as serial date number                                | char      |

## Examples

Connect to the National Geophysical Data Center (NGDC) FTP server and view the contents:

```
ngdc = ftp('ftp.ngdc.noaa.gov');
dir(ngdc)
```

This code returns:

```
D MSP Solid_Earth international wdc
INDEX.txt ftp.html ionosonde
README.txt geomag mgg
STP hazards pub
Snow_Ice index.html tmp
```

Continuing the previous example, save the folder contents to the structure `n`, close the connection, and view details about the `pub` subfolder:

```
n = dir(ngdc);
close(ngdc);

n(14)
```

This code returns:

```
ans =
```

```
name: 'pub'
bytes: 9
isdir: 1
date: '12-Dec-2014 21:22:00'
datenum: 7.3595e+05
```

FTP service courtesy of the NGDC. See NGDC Privacy Policy, Disclaimer, and Copyright for NGDC terms of service.

**Introduced before R2006a**

## discretize

Group numeric data into bins or categories

### Syntax

```
Y = discretize(X,edges)
```

```
Y = discretize(X,edges,values)
```

```
Y = discretize(X,edges,'categorical')
```

```
Y = discretize(X,edges,'categorical',categoryNames)
```

```
Y = discretize(___, 'IncludedEdge', side)
```

### Description

`Y = discretize(X,edges)` returns the indices of the bins that contain the elements of `X`. The  $j$ th bin contains element  $X(i)$  if  $\text{edges}(j) \leq X(i) < \text{edges}(j+1)$  for  $1 \leq j < N$ , where  $N$  is the number of bins and  $\text{length}(\text{edges}) = N+1$ . The last bin contains both edges such that  $\text{edges}(N) \leq X(i) \leq \text{edges}(N+1)$ .

`Y = discretize(X,edges,values)` returns the corresponding element in `values` rather than the bin number. For example, if  $X(1)$  is in bin 5, then  $Y(1)$  is `values(5)` rather than 5. `values` must be a vector with length equal to the number of bins.

`Y = discretize(X,edges,'categorical')` creates a categorical array where each bin is a category. The default category names are of the form “[A,B]” (or “[A,B]” for the last bin), where `A` and `B` are consecutive values from `edges`.

`Y = discretize(X,edges,'categorical',categoryNames)` names the categories in `Y` using the cell array of strings `categoryNames`. The length of `categoryNames` must be equal to the number of bins.

`Y = discretize(___, 'IncludedEdge', side)`, where `side` is 'right', specifies that each bin includes the right bin edge, except for the *first* bin which includes both edges. In this case, the  $j$ th bin contains an element  $X(i)$  if  $\text{edges}(j) < X(i) \leq \text{edges}(j+1)$ , where  $1 < j \leq N$  and  $N$  is the number of bins. The first bin includes the

left edge such that it contains  $\text{edges}(1) \leq X(i) \leq \text{edges}(2)$ . The default for `side` is `'left'`.

## Examples

### Group Data into Bins

Use `discretize` to group numeric values into discrete bins.

```
X = 1:2:21;
edges = primes(21);
Y = discretize(X,edges)
```

Y =

```
NaN 2 3 4 4 5 6 6 7 7 NaN
```

Since 1 and 21 fall outside the range of the bins, Y contains NaN values for those elements.

### Assign Bin Values

Use the right edge of each bin as the `values` input. The values of the elements in each bin are always less than the bin's value.

```
X = randi(100,1,10);
edges = 0:25:100;
values = edges(2:end);
Y = discretize(X,edges,values)
```

Y =

```
100 100 25 100 75 25 50 75 100 100
```

### Include Right Edge of Each Bin

Use the `'IncludedEdge'` input to specify that each bin should include its right edge (the first bin includes both edges). Compare the result to the default inclusion of left bin edges.

```
X = 1:2:11;
edges = [1 3 4 7 10 11];
Y = discretize(X,edges,'IncludedEdge','right')
```

```
Y =
```

```
 1 1 3 3 4 5
```

```
Z = discretize(X,edges)
```

```
Z =
```

```
 1 2 3 4 4 5
```

## Group Data into Categorical Array

Group normally distributed data into bins according to the distance from the mean, measured in standard deviations.

```
X = randn(1000,1);
edges = std(X)*(-3:3);
Y = discretize(X,edges, 'categorical', ...
 {'-3sigma', '-2sigma', '-sigma', 'sigma', '2sigma', '3sigma'});
```

Y contains undefined categorical values for the elements in X that are farther than 3 standard deviations from the mean.

Preview the values in Y.

```
Y(1:20)
```

```
ans =
```

```
sigma
2sigma
-3sigma
sigma
sigma
-2sigma
-sigma
```

```

sigma
<undefined>
3sigma
-2sigma
<undefined>
sigma
-sigma
sigma
-sigma
-sigma
2sigma
2sigma
2sigma

```

Confirm that approximately 68% of the data falls within one standard deviation of the mean.

```
nnz(Y=='-sigma' | Y=='sigma')/numel(Y)
```

```
ans =
```

```
0.6910
```

## Input Arguments

### **X** — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. X contains the data to be distributed into bins.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **edges** — Bin edges

vector

Bin edges, specified as a monotonically increasing numeric vector. Consecutive elements in **edges** form discrete bins, which **discretize** uses to partition the data in X. By

default, each bin includes the left bin edge, except for the last bin, which includes both bin edges.

**edges** must have at least two elements, since **edges(1)** is the left edge of the first bin, and **edges(end)** is the right edge of the last bin.

Example: `Y = discretize([1 3 5],[0 2 4 6])` distributes the values 1, 3, and 5 into three bins, which have edges [0,2), [2,4), and [4,6].

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

### **values** — Bin values

vector

Bin values, specified as a numeric vector. **values** must have the same length as the number of bins, `length(edges) - 1`. The elements in **values** replace the normal bin index in the output. That is, if `X(1)` falls into bin 2, then `discretize` returns `Y(1)` as `values(2)` rather than 2.

Example: `Y = discretize(randi(5,10,1),[1 1.5 3 5],diff([1 1.5 3 5]))` returns the widths of the bins, rather than indices ranging from 1 to 3.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Complex Number Support: Yes

### **categoryNames** — Categorical array category names

cell array of strings

Categorical array category names, specified as a cell array of strings. **categoryNames** must have length equal to the number of bins.

Example: `Y = discretize(randi(5,10,1),[1 1.5 3 5], 'categorical', {'A' 'B' 'C'})` distributes the data into three categories, A, B, and C.

Data Types: `cell`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `Y = discretize(X,edges,'IncludedEdge','right')`

### 'IncludedEdge' — Edges to include in each bin

'left' (default) | 'right'

Edges to include in each bin, specified as the comma-separated pair consisting of 'IncludedEdge' and the value 'left' or 'right'.

- If 'right', then each bin includes the right bin edge, except for the first bin, which includes both edges.
- The default value is 'left', so that each bin includes the left bin edge, except for the last bin, which includes both edges.

Example: `Y = discretize(randi(11,10,1),1:2:11,'IncludedEdge','right')` includes the right bin edge in each bin.

## Output Arguments

### Y — Bins

vector | matrix | multidimensional array | categorical array

Bins, returned as a numeric vector, matrix, multidimensional array, or categorical array. Y is the same size as X, and each element describes the bin placement for the corresponding element in X.

- Y contains NaN values for out-of-range elements in X (where  $X(i) < \text{edges}(1)$  or  $X(i) > \text{edges}(\text{end})$ ), or where X contains a NaN.
- If Y is a categorical array, then it contains undefined elements for out-of-range or NaN inputs.
- If values is a vector of an integer data type, then Y contains 0 for out-of-range or NaN inputs.

## More About

### Tips

- The behavior of `discretize` is similar to that of the `histcounts` function. Use `histcounts` to find the number of elements in each bin. On the other hand, use `discretize` to find which bin each element belongs to (without counting).

- “Replace Discouraged Instances of hist and histc”

**See Also**

categorical | histcounts | histogram

**Introduced in R2015a**

# disp

Display value of variable

## Syntax

```
disp(X)
```

## Description

`disp(X)` displays the value of variable `X` without printing the variable name. Another way to display a variable is to type its name, but this displays a leading “`X =`”, which is not always ideal.

If a variable contains an empty array, `disp` returns without displaying anything.

## Examples

### Display Variable Values

Create a numeric array and a string.

```
A = [15 150];
S = 'Hello World.';
```

Display the value of each variable.

```
disp(A)
```

```
15 150
```

```
disp(S)
```

```
Hello World.
```

### Display Matrix with Column Labels

Display a matrix and label the columns as `Corn`, `Oats`, and `Hay`.

```
X = rand(5,3);
disp(' Corn Oats Hay')
disp(X)
```

```
 Corn Oats Hay
0.8147 0.0975 0.1576
0.9058 0.2785 0.9706
0.1270 0.5469 0.9572
0.9134 0.9575 0.4854
0.6324 0.9649 0.8003
```

## Display Hyperlink in Command Window

Display a link to a Web page by including HTML hyperlink code as input to `disp`. For example, display a link to the MathWorks Web site.

```
X = 'MathWorks Web Site';
disp(X)
```

```
MathWorks Web Site
```

## Display Multiple Variables on Same Line

Here are three ways to display multiple variable values on the same line in the Command Window.

Concatenate multiple strings together using the `[]` operator. Convert any numeric values to characters using the `num2str` function. Use `disp` to display the string.

```
name = 'Alice';
age = 12;
X = [name, ' will be ', num2str(age), ' this year.'];
disp(X)
```

```
Alice will be 12 this year.
```

Use `sprintf` to create a string, and then display it with `disp`.

```
name = 'Alice';
age = 12;
X = sprintf('%s will be %d this year.', name, age);
disp(X)
```

```
Alice will be 12 this year.
```

Use `fprintf` to directly display the string without creating a variable. However, to terminate the display properly, you must end the string with the newline (`\n`) metacharacter.

```
name = 'Alice';
age = 12;
fprintf('%s will be %d this year.\n',name,age);
```

```
Alice will be 12 this year.
```

## Input Arguments

### **X** — Input array

array

Input array.

To display more than one array, you can use concatenation or the `sprintf` or `fprintf` functions as shown in the example, “Display Multiple Variables on Same Line” on page 1-2296.

### See Also

`format` | `fprintf` | `int2str` | `num2str` | `sprintf`

**Introduced before R2006a**

## disp (serial)

Serial port object summary information

### Syntax

```
obj
disp(obj)
```

### Description

`obj` or `disp(obj)` displays summary information for `obj`, a serial port object or an array of serial port objects.

### Examples

The following commands display summary information for the serial port object `s`. on a Windows platform

```
s = serial('COM1')
s.BaudRate = 300
s
```

### More About

#### Tips

In addition to the syntax shown above, you can display summary information for `obj` by excluding the semicolon when:

- Creating a serial port object
- Configuring property values using the dot notation

Use the display summary to quickly view the communication settings, communication state information, and information associated with read and write operations.

**Introduced before R2006a**

# display

Display text and numeric expressions

## Syntax

```
display(X)
display(X,DisplayName)
```

## Description

`display(X)` prints in input variable name and the value of `X`. MATLAB implicitly calls `display` after any variable or expression that is not terminated by a semicolon.

`display(X,DisplayName)` prints the specified character array and the value of `X` instead of the variable name.

To customize the display of objects, overload the `disp` function instead of the `display` function. `display` calls `disp`.

## Examples

### Display a Matrix

```
X = magic(3);
display(X)
```

X =

```
 8 1 6
 3 5 7
 4 9 2
```

### Specify Display Name

```
X = 1:10;
```

```
display(X.^2, 'X Squared')
```

```
X Squared =
```

```
 1 4 9 16 25 36 49 64 81 100
```

## Input Arguments

### **X** — Input value

variable | expression

Input value, specified as a variable or expression.

### **DisplayName** — Display name

character array

Display name, specified as a character array.

**Introduced before R2006a**

## dither

Convert image, increasing apparent color resolution by dithering

### Syntax

```
X = dither(RGB, map)
X = dither(RGB, map, Qm, Qe)
BW = dither(I)
```

### Description

`X = dither(RGB, map)` creates an indexed image approximation of the RGB image in the array `RGB` by dithering the colors in the colormap `map`. The colormap cannot have more than 65,536 colors.

`X = dither(RGB, map, Qm, Qe)` creates an indexed image from `RGB`, where `Qm` specifies the number of quantization bits to use along each color axis for the inverse color map, and `Qe` specifies the number of quantization bits to use for the color space error calculations. If `Qe < Qm`, dithering cannot be performed, and an undithered indexed image is returned in `X`. If you omit these parameters, `dither` uses the default values `Qm = 5, Qe = 8`.

`BW = dither(I)` converts the grayscale image in the matrix `I` to the binary (black and white) image `BW` by dithering.

### Class Support

`RGB` can be `uint8`, `uint16`, `single`, or `double`. `I` can be `uint8`, `uint16`, `int16`, `single`, or `double`. All other input arguments must be `double`. `BW` is `logical`. `X` is `uint8`, if it is an indexed image with 256 or fewer colors; otherwise, it is `uint16`.

## More About

### Algorithms

`dither` increases the apparent color resolution of an image by applying Floyd-Steinberg's error diffusion dither algorithm.

## divergence

Compute divergence of vector field

### Syntax

```
div = divergence(X,Y,Z,U,V,W)
div = divergence(U,V,W)
div = divergence(X,Y,U,V)
div = divergence(U,V)
```

### Description

`div = divergence(X,Y,Z,U,V,W)` computes the divergence of a 3-D vector field having vector components `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for the vector components `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements.

`div = divergence(U,V,W)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`div = divergence(X,Y,U,V)` computes the divergence of a 2-D vector field `U`, `V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`div = divergence(U,V)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[m,n] = size(U)`.

## Examples

This example displays the divergence of vector volume data as slice planes, using color to indicate divergence.

```
load wind
div = divergence(x,y,z,u,v,w);
h = slice(x,y,z,div,[90 134],59,0);
colormap jet
shading interp
daspect([1 1 1])
axis tight
camlight
set([h(1),h(2)], 'ambientstrength', .6)
```

# dlmread

Read ASCII-delimited file of numeric data into matrix

## Syntax

```
M = dlmread(filename)
M = dlmread(filename,delimiter)
M = dlmread(filename,delimiter,R1,C1)
M = dlmread(filename,delimiter,[R1 C1 R2 C2])
```

## Description

`M = dlmread(filename)` reads an ASCII-delimited numeric data file into matrix `M`. The `dlmread` function detects the delimiter from the file and treats repeated white spaces as a single delimiter.

`M = dlmread(filename,delimiter)` reads data from the file using the specified delimiter and treats repeated delimiter characters as separate delimiters.

`M = dlmread(filename,delimiter,R1,C1)` starts reading at row offset `R1` and column offset `C1`. For example, the offsets `R1=0`, `C1=0` specify the first value in the file.

To specify row and column offsets without specifying a delimiter, use an empty string as a placeholder, for example, `M = dlmread(filename, '',2,1)`.

`M = dlmread(filename,delimiter,[R1 C1 R2 C2])` reads only the range bounded by row offsets `R1` and `R2` and column offsets `C1` and `C2`. Another way to define the range is to use spreadsheet notation, such as `'A1..B7'` instead of `[0 0 6 1]`.

## Examples

### Read Entire Delimited File

Read the sample file, `count.dat`.

```
M = dlmread('count.dat')
```

M =

```
11 11 9
 7 13 11
14 17 20
11 13 9
43 51 69
38 46 76
61 132 186
75 135 180
38 88 115
28 36 55
12 12 14
18 27 30
18 19 29
17 15 18
19 36 48
32 47 10
42 65 92
57 66 151
44 55 90
114 145 257
35 58 68
11 12 15
13 9 15
10 9 7
```

`dlmread` detects the delimiter from the file and returns a matrix.

## Read File Containing Empty Delimited Fields

Write two matrices to a file, and then read the entire file using `dlmread`.

Export a matrix to a file named `myfile.txt`. Then, append an additional matrix to the file that is offset one row below the first.

```
X = magic(3);
dlmwrite('myfile.txt',[X*5 X/5], ' ')
dlmwrite('myfile.txt',X,'-append', ...
 'roffset',1,'delimiter',' ')
```

View the file contents.

```
type myfile.txt
```

```
40 5 30 1.6 0.2 1.2
15 25 35 0.6 1 1.4
20 45 10 0.8 1.8 0.4
```

```
8 1 6
3 5 7
4 9 2
```

Read the entire file using `dlmread`.

```
M = dlmread('myfile.txt')
```

```
M =
```

```
40.0000 5.0000 30.0000 1.6000 0.2000 1.2000
15.0000 25.0000 35.0000 0.6000 1.0000 1.4000
20.0000 45.0000 10.0000 0.8000 1.8000 0.4000
 8.0000 1.0000 6.0000 0 0 0
 3.0000 5.0000 7.0000 0 0 0
 4.0000 9.0000 2.0000 0 0 0
```

When `dlmread` imports a file containing nonrectangular data, it fills empty fields with zeros.

### Read Delimited File Starting At Specific Row and Column Offset

Create a file named `dlm1list.txt` that contains column headers and space-delimited values.

```
test max min direction
10 27.7 12.4 12
11 26.9 13.5 18
12 27.4 16.9 31
13 25.1 12.7 29
```

Read the numeric values in the file. Specify a space delimiter, a row offset of 1, and a column offset of 0.

```
filename = 'dlm1list.txt';
M = dlmread(filename, ' ',1,0)
```

```
M =

 10.0000 27.7000 12.4000 12.0000
 11.0000 26.9000 13.5000 18.0000
 12.0000 27.4000 16.9000 31.0000
 13.0000 25.1000 12.7000 29.0000
```

## Read Specific Range from Delimited File

Create a file named `dlm1ist.txt` that contains column headers and space-delimited values.

```
test max min direction
10 27.7 12.4 12
11 26.9 13.5 18
12 27.4 16.9 31
13 25.1 12.7 29
```

Read only the last two rows of numeric data from the file.

```
M = dlmread('dlm1ist.txt',' ', [3 0 4 3])
```

```
M =

 12.0000 27.4000 16.9000 31.0000
 13.0000 25.1000 12.7000 29.0000
```

## Input Arguments

### **filename** — File name

string

File name, specified as a string.

Example: `'myFile.dat'`

Data Types: char

### **delimiter** — Field delimiter character

string

Field delimiter character, specified as a string. Use `'\t'` to specify a tab delimiter.

Example: `','`

Example: ' '

**R1 — Starting row offset**

0 (default) | nonnegative integer

Starting row offset, specified as a nonnegative integer. The first row has an offset of 0.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**C1 — Starting column offset**

0 (default) | nonnegative integer

Starting column offset, specified as a nonnegative integer. The first column has an offset of 0.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**R2 — Ending row offset**

nonnegative integer

Ending row offset, specified as a nonnegative integer. The first row has an offset of 0.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**C2 — Ending column offset**

nonnegative integer

Ending column offset, specified as a nonnegative integer. The first column has an offset of 0.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## More About

### Tips

- Skip header rows or columns by specifying row and column offsets. All values in the file other than headers must be numeric.

## Algorithms

`dlmread` fills empty delimited fields with zero. When the `dlmread` function reads data files with lines that end with a nonspace delimiter, such as a semicolon, it returns a matrix, `M`, that has an additional last column of zeros.

`dlmread` imports any complex number as a whole into a complex numeric field. This table shows valid forms for a complex number.

| Form                                                             | Example  |
|------------------------------------------------------------------|----------|
| $\pm\langle\text{real}\rangle\pm\langle\text{imag}\rangle i   j$ | 5.7-3.1i |
| $\pm\langle\text{imag}\rangle i   j$                             | -7j      |

Embedded white space in a complex number is invalid and `dlmread` regards it as a field delimiter.

- “Ways to Import Text Files”

`dlmwrite` | `readtable` | `textscan` | `uiimport`

**Introduced before R2006a**

# dlmwrite

Write matrix to ASCII-delimited file

## Syntax

```
dlmwrite(filename,M)
dlmwrite(filename,M, '-append')

dlmwrite(____,Name,Value)

dlmwrite(filename,M,delimiter)
dlmwrite(filename,M,delimiter,row,col)
```

## Description

`dlmwrite(filename,M)` writes numeric data in array `M` to an ASCII format file, `filename`, using the default delimiter (,) to separate array elements. If the file, `filename`, already exists, `dlmwrite` overwrites the file.

`dlmwrite(filename,M, '-append')` appends the data to the end of the existing file, `filename`.

`dlmwrite( ____,Name,Value)` additionally specifies delimiter, newline character, offset, and precision options using one or more name-value pair arguments.

`dlmwrite(filename,M,delimiter)` writes array `M` to the file, `filename`, using the specified delimiter, `delimiter`, to separate array elements.

`dlmwrite(filename,M,delimiter,row,col)` writes the array starting at the specified row and column `row` and `col`, in the destination file. Empty elements separated by `delimiter` fill the leading rows and columns.

## Examples

### Write Comma-Separated Data

Create an array of sample data, `M`.

```
M = magic(3);
```

Write matrix M to a file, 'myFile.txt', using the default delimiter (,).

```
dlmwrite('myFile.txt',M)
```

View the data in the file.

```
type('myFile.txt')
```

```
8,1,6
3,5,7
4,9,2
```

## Write Tab-Delimited Data and Specify Precision

Create an array of sample data, M.

```
M = magic(3)*pi
```

```
M =
```

```
25.1327 3.1416 18.8496
 9.4248 15.7080 21.9911
12.5664 28.2743 6.2832
```

Write matrix M to a file, 'myFile.txt', delimited by the tab character and using a precision of 3 significant digits.

```
dlmwrite('myFile.txt',M,'delimiter','\t','precision',3)
```

View the data in the file.

```
type('myFile.txt')
```

```
25.1 3.14 18.8
9.42 15.7 22
12.6 28.3 6.28
```

## Write and Append Data to File

Create two arrays of sample numeric data.

```
M = magic(5);
N = magic(3);
```

Export matrix M to a file and use whitespace as the delimiter.

```
dlmwrite('myFile.txt',M,'delimiter',' ');
```

Append matrix N to the file, offset from the existing data by one row. Then, view the file.

```
dlmwrite('myFile.txt',N,'-append',...
'delimiter',' ','roffset',1)
type('myFile.txt')
```

```
17 24 1 8 15
23 5 7 14 16
4 6 13 20 22
10 12 19 21 3
11 18 25 2 9
```

```
8 1 6
3 5 7
4 9 2
```

Read the data in 'myFile.txt' using dlmread.

```
dlmread('myFile.txt')
```

```
ans =
```

```
 17 24 1 8 15
 23 5 7 14 16
 4 6 13 20 22
 10 12 19 21 3
 11 18 25 2 9
 8 1 6 0 0
 3 5 7 0 0
 4 9 2 0 0
```

When dlmread reads the two matrices from the file, it pads the smaller matrix with zeros.

### Write Data and Specify Precision As String

Create an array of sample numeric data.

```
M = magic(3);
```

Export matrix M to a file using a precision of 6 decimal places.

```
dlmwrite('myFile.txt',M,'precision','%.6f');
```

View the data in the file.

```
type('myFile.txt')
8.000000,1.000000,6.000000
3.000000,5.000000,7.000000
4.000000,9.000000,2.000000
```

## Input Arguments

### **filename** — Name of file to write

string

Name of file to write, specified as a string.

Example: 'myFile.txt'

Data Types: char

### **M** — Numeric data to write

matrix | cell array of numeric values

Numeric data to write, specified as a matrix or a cell array of numeric values with one value per cell.

Example: [1,2,3;4,5,6]

Example: {1,2,3;4,5,6}

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | cell

Complex Number Support: Yes

### **delimiter** — Delimiter to separate array elements

',' (default) | string

Delimiter to separate array elements, specified as a string containing a single character or control character. Use '\t' to produce tab-delimited files.

Example: ';'

Example: '\t'

Data Types: char

### **row** — Row offset

0 (default) | scalar

Row offset, specified as a scalar. The row offset indicates the number of rows to skip before writing the numeric data. `row` is zero-based, so that `row = 0` instructs MATLAB to begin writing in the first row of the destination file. Skipped rows are populated with the specified delimiter.

### **col** — Column offset

0 (default) | scalar

Column offset, specified as a scalar. The column offset indicates the number of columns to skip before writing the numeric data. `col` is zero-based, so that `col = 0` instructs MATLAB to begin writing in the first column of the destination file. Skipped columns are separated with the specified delimiter.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `dlmwrite('myFile.txt',M,'precision',4,'delimiter',' ')` writes the numeric values in array `M` with four significant digits and delimited using the whitespace character.

### **'delimiter'** — Delimiter to separate array elements

',' (default) | string

Delimiter to separate array elements, specified as the comma-separated pair consisting of `'delimiter'` and string containing a single character or control character. Use `'\t'` to produce tab-delimited files.

Example: `'delimiter',';'`

Example: `'delimiter','\t'`

Data Types: char

### **'rowoffset'** — Row offset

0 (default) | scalar

Row offset, specified as the comma-separated pair consisting of `'rowoffset'` and a scalar. The row offset indicates the number of rows to skip before writing the numeric data.

These rows are populated with the specified delimiter. When appending to an existing file, the new data is offset from the end of the existing data.

The row offset is zero-based, so that `'roffset',0` instructs MATLAB to begin writing in the first row of the destination file, which is the default. However, when appending to a file, `'roffset',0` instructs MATLAB to begin writing in the first row immediately following existing data.

Example: `'roffset',2`

**'coffset' — Column offset**

0 (default) | scalar

Column offset from the left side of the destination file, specified as the comma-separated pair consisting of `'coffset'` and a scalar. The column offset indicates the number of columns to skip before writing the numeric data. These columns are separated with the specified delimiter.

The column offset is zero-based, so that `'coffset',0` instructs MATLAB to begin writing in the first column of the destination file, which is the default.

Example: `'coffset',1`

**'precision' — Numeric precision**

5 (default) | scalar | C-style format string

Numeric precision to use in writing data to the file, specified as the comma-separated pair consisting of `'precision'` and a scalar or a C-style format string that begins with %, such as `'%10.5f'`. If the value of `precision` is a scalar, then it indicates the number of significant digits.

Example: `'precision',3`

Example: `'precision','%10.5f'`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char`

**'newline' — Line terminator**

`'pc'` | `'unix'`

Line terminator, specified as the comma-separated pair consisting of `'newline'` and either `'pc'` to use a carriage return/line feed (CR/LF), or `'unix'` to use a line feed (LF).

Example: `'newline','pc'`

## More About

### Tips

- `dlmwrite` writes a file that spreadsheet programs can read. Alternatively, if your system has Excel for Windows installed, you can create a spreadsheet using `xlswrite`.

### See Also

## dmperm

Dulmage-Mendelsohn decomposition

### Syntax

```
p = dmperm(A)
[p,q,r,s,cc,rr] = dmperm(A)
```

### Description

`p = dmperm(A)` finds a vector `p` such that `p(j) = i` if column `j` is matched to row `i`, or zero if column `j` is unmatched. If `A` is a square matrix with full structural rank, `p` is a maximum matching row permutation and `A(p, :)` has a zero-free diagonal. The structural rank of `A` is `sprank(A) = sum(p>0)`.

`[p,q,r,s,cc,rr] = dmperm(A)` where `A` need not be square or full structural rank, finds the Dulmage-Mendelsohn decomposition of `A`. `p` and `q` are row and column permutation vectors, respectively, such that `A(p,q)` has a block upper triangular form. `r` and `s` are index vectors indicating the block boundaries for the fine decomposition. `cc` and `rr` are vectors of length five indicating the block boundaries of the coarse decomposition.

`C = A(p,q)` is split into a 4-by-4 set of coarse blocks:

```
A11 A12 A13 A14
0 0 A23 A24
0 0 0 A34
0 0 0 A44
```

where `A12`, `A23`, and `A34` are square with zero-free diagonals. The columns of `A11` are the unmatched columns, and the rows of `A44` are the unmatched rows. Any of these blocks can be empty. In the coarse decomposition, the  $(i,j)$ th block is `C(rr(i):rr(i+1)-1,cc(j):cc(j+1)-1)`. For a linear system,

- `[A11 A12]` is the underdetermined part of the system—it is always rectangular and with more columns and rows, or 0-by-0,
- `A23` is the well-determined part of the system—it is always square, and

- $[A_{34} ; A_{44}]$  is the overdetermined part of the system—it is always rectangular with more rows than columns, or 0-by-0.

The structural rank of  $A$  is  $\text{sprank}(A) = nr(4) - 1$ , which is an upper bound on the numerical rank of  $A$ .  $\text{sprank}(A) = \text{rank}(\text{full}(\text{sprand}(A)))$  with probability 1 in exact arithmetic.

The  $A_{23}$  submatrix is further subdivided into block upper triangular form via the fine decomposition (the strongly connected components of  $A_{23}$ ). If  $A$  is square and structurally nonsingular,  $A_{23}$  is the entire matrix.

$C(r(i):r(i+1)-1, s(j):s(j+1)-1)$  is the  $(i, j)$ th block of the fine decomposition. The  $(1, 1)$  block is the rectangular block  $[A_{11} \ A_{12}]$ , unless this block is 0-by-0. The  $(b, b)$  block is the rectangular block  $[A_{34} ; A_{44}]$ , unless this block is 0-by-0, where  $b = \text{length}(r) - 1$ . All other blocks of the form  $C(r(i):r(i+1)-1, s(i):s(i+1)-1)$  are diagonal blocks of  $A_{23}$ , and are square with a zero-free diagonal.

## More About

### Tips

If  $A$  is a reducible matrix, the linear system  $Ax = b$  can be solved by permuting  $A$  to a block upper triangular form, with irreducible diagonal blocks, and then performing block backsubstitution. Only the diagonal blocks of the permuted matrix need to be factored, saving fill and arithmetic in the blocks above the diagonal.

In graph theoretic terms, `dmperm` finds a maximum-size matching in the bipartite graph of  $A$ , and the diagonal blocks of  $A(p, q)$  correspond to the strong Hall components of that graph. The output of `dmperm` can also be used to find the connected or strongly connected components of an undirected or directed graph. For more information see Pothen and Fan [1].

# doc

Reference page in Help browser

## Syntax

```
doc
doc name
```

## Description

`doc` opens the Help browser. If the Help browser is already open, but not visible, then `doc` brings it to the foreground and opens a new tab.

`doc name` displays documentation for the functionality specified by `name`, such as a function, class, or block.

- If there is a MathWorks reference page corresponding to `name`, then `doc` displays the page in the Help browser. The `doc` command does not display third-party or custom HTML documentation.
- If there is no reference page corresponding to `name`, then `doc` searches for help text in a file named `name.m`. When help text is available, `doc` displays it in the Help browser.
- If there is no reference page and no help text associated with `name`, then `doc` searches the documentation for `name` and displays the search results in the Help browser.

## Examples

### Function Reference Pages

Display the reference page for the `abs` function.

```
doc abs
```

Several products include different versions of `abs`. If your Help preferences support displaying documentation for those products, then the Help browser displays the

MATLAB `abs` reference page and a message with links to other versions of `abs`. This message appears at the top of the page.

## Class and Method Reference Pages

Display the reference page for the `handle` class.

```
doc handle
```

Display the reference page for the `findobj` method in the `handle` class.

```
doc handle.findobj
```

Display the reference page for the `Map` class in the `containers` package.

```
doc containers.Map
```

## Custom Class Pages

Display formatted help text for a custom class.

MATLAB includes a set of example files that show how to create a class, including a class file named `sads.m`. Add the example folder to the path, and request documentation for `sads`.

```
addpath(...
 fullfile(matlabroot, 'help', 'techdoc', 'matlab_env', ...
 'examples'))
doc sads
```

Display the help for the `steer` method of the `sads` class.

```
doc sads.steer
```

Because the help text follows MATLAB conventions, MATLAB formats the display in the browser.

## Input Arguments

**name** — Name of function, class, block, or other functionality

string

Name of a function, class, block, or other functionality, specified as a string. Alternatively, an operator symbol.

Some classes and other packaged items require that you specify the package name. Events, properties, and some methods require that you specify the class name. Separate the components of the name with periods, such as:

```
doc className.name
doc packageName.name
doc packageName.className.name
```

Methods for some classes are not accessible using the `doc` command; instead, use links on the class reference page.

## More About

### Tips

- To access third-party or custom documentation, open the Help browser and navigate to the documentation home page. Then, at the bottom of the page, click **Supplemental Software**.
- “Ways to Get Function Help”
- “Add Help for Your Program”
- “Display Custom Documentation”

## docsearch

Help browser search

### Syntax

```
docsearch
docsearch expression
```

### Description

`docsearch` opens the Help browser and displays the documentation home page. If the Help browser is already open, but not visible, then `docsearch` brings it to the foreground.

`docsearch expression` searches MathWorks documentation for pages with words that match the specified expression and highlights them. To clear highlighting, press the **Esc** key. The `docsearch` command does not search third-party or custom documentation.

### Examples

#### Single Words

Find all documentation pages that contain the word *plot*.

```
docsearch plot
```

#### Multiple Words

Find documentation pages with the words *plot* and *tools*.

```
docsearch plot tools
```

Expand the search to include variations of the word *plot*, such as *plotting* or *plots*, using a wildcard character.

```
docsearch plot* tools
```

Narrow the search to pages that include an exact phrase by enclosing the phrase in quotation marks.

```
docsearch "plot tools"
```

Find pages with either word, but not necessarily both words, using the **OR** operator.

```
docsearch plot OR tools
```

## Input Arguments

**expression** — Expression that defines search terms

string

Expression that defines search terms, specified as a string. Expressions can include:

- Quotation marks to specify exact phrases, such as "plot tools".
- Boolean operator keywords in uppercase (listed here in order of precedence): **NOT**, **OR**, **AND**.
- Asterisk (\*) wildcard characters, except at the beginning of a word or in an exact phrase. Searches require that at least two characters in the expression are *not* wildcard characters.

## More About

### Tips

- To access third-party or custom documentation, open the Help browser and navigate to the documentation home page. Then, at the bottom of the page, click **Supplemental Software**.
- “Search Syntax and Tips”

Introduced before R2006a

## dos

Execute DOS command and return output

### Syntax

```
status = dos(command)
[status,cmdout] = dos(command)
[status,cmdout] = dos(command, '-echo')
```

### Description

`status = dos(command)` executes the specified MS-DOS<sup>®</sup> command for Windows platforms, and waits for the command to finish execution before returning the exit status to the `status` variable.

`[status,cmdout] = dos(command)` also returns the output of the DOS command to `cmdout`. This syntax is most useful for DOS console commands that do not require user input, such as `dir`.

`[status,cmdout] = dos(command, '-echo')` also displays (echoes) the command output in the MATLAB Command Window. This syntax is most useful for DOS console commands that require user input and that run correctly in the MATLAB Command Window, such as `comp`.

### Examples

#### Save DOS Command Exit Status

Call a DOS command to create a folder named `mynew` and save the exit status to a variable.

```
command = 'mkdir mynew';
status = dos(command)

status =
```

```
0
```

The **status** of zero indicates that the mynew folder was created successfully.

### Open and Run a Windows UI Command

Open Microsoft Notepad and immediately return the exit status to MATLAB by appending an ampersand (&) to the **notepad** command.

```
status = dos('notepad &')
```

```
status =
```

```
0
```

The **status** of zero indicates that Notepad successfully started.

### Save Successful DOS Command Status and Output

Execute the DOS command, **dir**, and view the exit status and command output.

```
[status,cmdout] = dos('dir');
status, cmdout
```

```
status =
```

```
0
```

```
cmdout =
```

```
Volume in drive C is OSDisk
Volume Serial Number is XXX-XXXX
```

```
Directory of C:\my_MATLAB_files
```

```
04/10/2012 12:08 PM <DIR> .
04/10/2012 12:08 PM <DIR> ..
04/21/2011 09:24 AM 171 base.mat
02/08/2010 05:14 PM 73 baseball.dat
04/10/2012 12:08 PM 474 collatz.asv
04/10/2012 11:56 AM 480 collatz.m
.
.
.
```

When you call a valid DOS command, `status` indicates success and `cmdout` contains the command output.

## Save Unsuccessful DOS Command Status and Output

Attempt to execute a command called `foo`. Then, view the `status` and `results` output arguments.

```
[status,results] = dos('foo');
status, results
```

```
status =
```

```
1
```

```
results =
```

```
'foo' is not recognized as an internal or external command,
operable program or batch file.
```

When you call an invalid DOS command, `status` indicates failure and `results` contains the DOS error message.

## Display DOS Command Output in MATLAB Command Window

Display command output and prompts in the Command Window as the command executes, and also assign the command output to the `results` variable.

```
[status,results] = dos('comp', '-echo');
```

```
Name of first file to compare: collatz.m
collatz.m
Name of second file to compare: collatz.asv
collatz.asv
Option: /A
/A
Option:
```

```
Comparing collatz.m and collatz.asv...
Files compare OK
```

```
Compare more files (Y/N) ? N
N
```

&gt;&gt;

## Input Arguments

**command** — MS-DOS command  
string

MS-DOS command, specified as a string. The command can be a Windows UI program that opens a user interface, or a DOS console command that you typically run in a DOS command window. The command executes in a DOS shell, which might not be the shell from which you started MATLAB.

Example: 'dir'

## Output Arguments

**status** — Command exit status  
0 | nonzero integer

Command exit status, returned as either 0 or a nonzero integer. When the command is successful, **status** is 0. Otherwise, **status** is a nonzero integer.

- If **command** includes the ampersand character (&), then **status** is the exit status when **command** starts
- If **command** does not include the ampersand character (&), then **status** is the exit status upon **command** completion.

**cmdout** — Output of operating system command  
string

Output of the operating system command, returned as a string. The system shell might not properly represent non-Unicode characters.

## Limitations

- MATLAB converts characters to the encoding that your operating system shell accepts. Output from the **command** is converted to the MATLAB encoding to be

displayed in the command window. If you get unexpected results from the command, enter the `command` argument directly at the operating system prompt to see how the operating system treats your input.

- MS-DOS does not support UNC path names. Therefore, if the current folder uses a UNC path name, then running `dos` with a DOS `command` that relies on the current folder fails. MATLAB returns this error:

```
Error using dos
DOS commands may not be executed when the current directory is a UNC pathname
To work around this limitation, change the folder to a mapped drive before running
dos or a function that calls dos.
```

## More About

### Tips

- To execute the operating system command in the background, include the trailing character, `&`, in the `command` argument (for example, `'notepad &'`). The exit status is immediately returned to the `status` variable. This syntax is useful for console programs that require interactive user command input while they run, and that do not run correctly in the MATLAB Command Window.

---

**Note:** If `command` includes the trailing `&` character, then `cmdout` is empty.

---

Introduced before R2006a

# dot

Dot product

## Syntax

```
C = dot(A,B)
C = dot(A,B,dim)
```

## Description

`C = dot(A,B)` returns the scalar dot product of `A` and `B`.

- If `A` and `B` are vectors, then they must have the same length.
- If `A` and `B` are matrices or multidimensional arrays, then they must have the same size. In this case, the `dot` function treats `A` and `B` as collections of vectors. The function calculates the dot product of corresponding vectors along the first array dimension whose size does not equal 1.

`C = dot(A,B,dim)` evaluates the dot product of `A` and `B` along dimension, `dim`. The `dim` input is a positive integer scalar.

## Examples

### Dot Product of Real Vectors

Create two simple, three-element vectors.

```
A = [4 -1 2];
B = [2 -2 -1];
```

Calculate the dot product of `A` and `B`.

```
C = dot(A,B)
```

```
C =
```

8

The result is 8 since

$$C = A(1) * B(1) + A(2) * B(2) + A(3) * B(3)$$

$$C = 8 + 2 - 2.$$

## Dot Product of Complex Vectors

Create two complex vectors.

$$A = [1+i \ 1-i \ -1+i \ -1-i];$$

$$B = [3-4i \ 6-2i \ 1+2i \ 4+3i];$$

Calculate the dot product of A and B.

$$C = \text{dot}(A,B)$$

$$C =$$

$$1.0000 - 5.0000i$$

The result is a complex scalar since A and B are complex. In general, the dot product of two complex vectors is also complex. An exception is when you take the dot product of a complex vector with itself.

Find the inner product of A with itself.

$$D = \text{dot}(A,A)$$

$$D =$$

8

The result is a real scalar. The inner product of a vector with itself is related to the Euclidean length of the vector,  $\text{norm}(A)$ .

## Dot Product of Matrices

Create two matrices.

$$A = [1 \ 2 \ 3; 4 \ 5 \ 6; 7 \ 8 \ 9];$$

```
B = [9 8 7;6 5 4;3 2 1];
```

Find the dot product of A and B.

```
C = dot(A,B)
```

```
C =
```

```
 54 57 54
```

The result, **C**, contains three separate dot products. `dot` treats the columns of **A** and **B** as vectors and calculates the dot product of corresponding columns. So, for example, `C(1) = 54` is the dot product of `A(:,1)` with `B(:,1)`.

Find the dot product of A and B, treating the *rows* as vectors.

```
D = dot(A,B,2)
```

```
D =
```

```
 46
 73
 46
```

In this case, `D(1) = 46` is the dot product of `A(1,:)` with `B(1,:)`.

### Dot Product of Multidimensional Arrays

Create two multidimensional arrays.

```
A = cat(3,[1 1;1 1],[2 3;4 5],[6 7;8 9])
```

```
B = cat(3,[2 2;2 2],[10 11;12 13],[14 15; 16 17])
```

```
A(:, :, 1) =
```

```
 1 1
 1 1
```

```
A(:, :, 2) =
```

```
 2 3
 4 5
```

`A(:, :, 3) =`

```
 6 7
 8 9
```

`B(:, :, 1) =`

```
 2 2
 2 2
```

`B(:, :, 2) =`

```
 10 11
 12 13
```

`B(:, :, 3) =`

```
 14 15
 16 17
```

Calculate the dot product of **A** and **B** along the third dimension (`dim = 3`).

`C = dot(A,B,3)`

`C =`

```
 106 140
 178 220
```

The result, **C**, contains four separate dot products. The first dot product, `C(1,1) = 106`, is equal to the dot product of `A(1,1,:)` with `B(1,1,:)`.

## Input Arguments

**A, B** — Input arrays

numeric arrays

Input arrays, specified as numeric arrays.

Data Types: `single` | `double`

Complex Number Support: Yes

### **dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider two 2-D input arrays, A and B:

- `dot(A,B,1)` treats the columns of A and B as vectors and returns the dot products of corresponding columns.
- `dot(A,B,2)` treats the rows of A and B as vectors and returns the dot products of corresponding rows.

A

`dot(A,B,1)`

`dot(A,B,2)`

`dot` returns `conj(A) .* B` if `dim` is greater than `ndims(A)`.

## More About

### Scalar Dot Product

The scalar dot product of two real vectors of length  $n$  is equal to

$$\mathbf{u} \cdot \mathbf{v} = \sum_{i=1}^n u_i v_i = u_1 v_1 + u_2 v_2 + \dots + u_n v_n.$$

This relation is commutative for real vectors, such that `dot(u,v)` equals `dot(v,u)`. If the dot product is equal to zero, then  $u$  and  $v$  are perpendicular.

For complex vectors, the dot product involves a complex conjugate. This ensures that the inner product of any vector with itself is real and positive definite.

$$u \cdot v = \sum_{i=1}^n \bar{u}_i v_i.$$

Unlike the relation for real vectors, the complex relation is not commutative, so `dot(u,v)` equals `conj(dot(v,u))`.

## Algorithms

- When inputs `A` and `B` are real or complex vectors, the `dot` function treats them as column vectors and `dot(A,B)` is the same as `sum(conj(A).*B)`.
- When the inputs are matrices or multidimensional arrays, the `dim` argument determines which dimension the `sum` function operates on. In this case, `dot(A,B)` is the same as `sum(conj(A).*B,dim)`.

## See Also

`conj` | `cross` | `sum`

**Introduced before R2006a**

# double

Convert to double precision

## Syntax

```
double(x)
```

## Description

`double(x)` returns the double-precision value for `X`. If `X` is already a double-precision array, `double` has no effect.

## More About

### Tips

The `double` function can be overloaded for any object when it makes sense to convert it to a double-precision value.

- “Floating-Point Numbers”

### See Also

`cast` | `single` | `str2double` | `typecast`

**Introduced before R2006a**

## dragrect

Drag rectangles with mouse

### Syntax

```
[finalrect] = dragrect(initialrect)
[finalrect] = dragrect(initialrect,stepsize)
```

### Description

[finalrect] = dragrect(initialrect) tracks one or more rectangles anywhere on the screen. The n-by-4 matrix `initialrect` defines the rectangles. Each row of `initialrect` must contain the initial rectangle position as [left bottom width height] values. `dragrect` returns the final position of the rectangles in `finalrect`.

[finalrect] = dragrect(initialrect,stepsize) moves the rectangles in increments of `stepsize`. The lower left corner of the first rectangle is constrained to a grid of size equal to `stepsize` starting at the lower left corner of the figure, and all other rectangles maintain their original offset from the first rectangle.

[finalrect] = dragrect(...) returns the final positions of the rectangles when the mouse button is released. The default step size is 1.

### Examples

Drag a rectangle with dimensions of 50-by-100 pixels.

```
waitforbuttonpress
point1 = get(gcf,'CurrentPoint') % button down detected
rect = [point1(1,1) point1(1,2) 50 100]
[r2] = dragrect(rect)
```

## More About

### Pixels

Distances in pixels are independent of your system resolution on Windows and Macintosh systems:

- On Windows systems, a pixel is 1/96th of an inch.
- On Macintosh systems, a pixel is 1/72nd of an inch.

On Linux systems, the size of a pixel is determined by your system resolution.

### Tips

`dragrect` returns immediately if a mouse button is not currently pressed. Use `dragrect` in a `ButtonDownFcn`, or from the command line in conjunction with `waitforbuttonpress`, to ensure that the mouse button is down when `dragrect` is called. `dragrect` returns when you release the mouse button.

If the drag ends over a figure window, the positions of the rectangles are returned in that figure's coordinate system. If the drag ends over a part of the screen not contained within a figure window, the rectangles are returned in the coordinate system of the figure over which the drag began.

---

**Note:** You cannot use normalized figure units with `dragrect`.

---

`rbbox` | `waitforbuttonpress`

Introduced before R2006a

## drawnow

Update figures and process callbacks

### Syntax

```
drawnow
drawnow limitrate
drawnow nocallbacks
drawnow limitrate nocallbacks
```

```
drawnow update
drawnow expose
```

### Description

`drawnow` updates figures and processes any pending callbacks. Use this command if you modify graphics objects and want to see the updates on the screen immediately.

`drawnow limitrate` limits the number of updates to 20 frames per second. If it has been fewer than 50 milliseconds since the last update, or if the graphics renderer is busy with the previous change, then `drawnow` discards the new updates. Use this command if you are updating graphics objects in a loop and do not need to see every update on the screen. Skipping updates can create faster animations. Pending callbacks are processed, so you can interact with figures during animations.

`drawnow nocallbacks` defers callbacks, such as mouse clicks, until the next full `drawnow` command. Use this option if you want to prevent callbacks from interrupting your code. For more information, see “Actions Equivalent to `drawnow`” on page 1-2347.

`drawnow limitrate nocallbacks` limits the number of updates to 20 frames per second, skips updates if the renderer is busy, and defers callbacks.

`drawnow update` skips updates if the renderer is busy and defers callbacks.

---

**Note:** This syntax is not recommended. Use the `limitrate` option instead.

---

`drawnow` `expose` updates figures, but defers callbacks.

---

**Note:** This syntax is not recommended. Use the `nocallbacks` option instead.

---

## Examples

### Create Animation of Streaming Data

Create an animation of a line growing as it accumulates 2,000 data points. Use `drawnow` to display the changes on the screen after each iteration through the loop.

```
h = animatedline;
axis([0 4*pi -1 1])
x = linspace(0,4*pi,2000);

for k = 1:length(x)
 y = sin(x(k));
 addpoints(h,x(k),y);
 drawnow
end
```

### Skip Updates for Faster Animation

Create an animation of a line growing as it accumulates 10,000 points. Since there are 10,000 points, drawing each update on the screen is slow. Create a faster, smooth animation by limiting the number of updates using `drawnow limitrate`. Then, display the final updates on the screen by calling `drawnow` after the loop ends.

```
h = animatedline;
axis([0 4*pi -1 1])
x = linspace(0,4*pi,10000);

for k = 1:length(x)
 y = sin(x(k));
 addpoints(h,x(k),y);
end
drawnow
```

```
drawnow limitrate
end
drawnow
```

### Precompute Data, Then Create Animation

Compute all the data before the animation loop.

```
h = animatedline;
axis([0 4*pi -1 1])
x = linspace(0,4*pi,10000);
y = sin(x);
```

```
for k = 1:length(x)
 addpoints(h,x(k),y(k));
 drawnow limitrate
end
drawnow
```

If you have long computations, precomputing the data can improve performance. Precomputing minimizes the computation time by letting the computation run without

interruptions. Additionally, it helps ensure a smooth animation by focusing on only graphics code in the animation loop.

## More About

### Actions Equivalent to drawnow

These actions are equivalent to calling a full drawnow command:

- Returning to the MATLAB prompt.
- Using the `figure`, `getframe`, `input`, `pause`, and `keyboard` functions.
- Using functions that wait for user input, such as `waitforbuttonpress`, `waitfor`, or `ginput`.

### Tips

- The `nocallbacks` option always adds interrupting callbacks to the queue. If you want to discard interrupting callbacks, then use the `Interruptible` and `BusyAction` properties instead.

### See Also

`pause` | `refreshdata` | `waitfor`

Introduced before R2006a

## **dsearchn**

N-D nearest point search

### **Syntax**

```
k = dsearchn(X,T,XI)
k = dsearchn(X,T,XI,outval)
k = dsearchn(X,XI)
[k,d] = dsearchn(X,...)
```

### **Description**

`k = dsearchn(X,T,XI)` returns the indices `k` of the closest points in `X` for each point in `XI`. `X` is an `m`-by-`n` matrix representing `m` points in `n`-dimensional space. `XI` is a `p`-by-`n` matrix, representing `p` points in `n`-dimensional space. `T` is a `numt`-by-`n+1` matrix, a triangulation of the data `X` generated by `delaunayn`. The output `k` is a column vector of length `p`.

`k = dsearchn(X,T,XI,outval)` returns the indices `k` of the closest points in `X` for each point in `XI`, unless a point is outside the convex hull. If `XI(J,:)` is outside the convex hull, then `K(J)` is assigned `outval`, a scalar double. `Inf` is often used for `outval`. If `outval` is `[]`, then `k` is the same as in the case `k = dsearchn(X,T,XI)`.

`k = dsearchn(X,XI)` performs the search without using a triangulation. With large `X` and small `XI`, this approach is faster and uses much less memory.

`[k,d] = dsearchn(X,...)` also returns the distances `d` to the closest points. `d` is a column vector of length `p`.

### **More About**

#### **Algorithms**

`dsearchn` is based on Qhull [1]. For information about Qhull, see <http://www.qhull.org/>. For copyright information, see <http://www.qhull.org/COPYING.txt>.

## duration

Create duration array from numeric values

The `duration` function creates an array that represents elapsed time in units of fixed length, such as hours, minutes, and seconds. You also can create elapsed times in terms of fixed-length (24-hour) days and fixed-length (365.2425-day long) years.

### Syntax

`D = duration(H,MI,S)`

`D = duration(H,MI,S,MS)`

`D = duration(X)`

`D = duration( ____, 'Format', displayFormat)`

### Description

`D = duration(H,MI,S)` creates a duration array from numeric arrays containing the number of hours, minutes, and seconds specified by `H`, `MI`, and `S`, respectively.

`D = duration(H,MI,S,MS)` creates a duration array from numeric arrays containing the number of hours, minutes, second, and milliseconds specified by `H`, `MI`, `S`, and `MS`, respectively.

`D = duration(X)` creates a column vector of durations from a numeric matrix.

`D = duration( ____, 'Format', displayFormat)` additionally specifies the format in which `D` displays. You can use this syntax with any of the arguments from the previous syntaxes.

### Examples

#### Create Duration Array with Default Format

```
D = duration(1,30:33,0)
```

```
D =
 01:30:00 01:31:00 01:32:00 01:33:00
```

### Create Duration Array and Specify Format

Create a duration array from a matrix and display the values in units of fractional hours.

```
X = magic(3);
D = duration(X, 'Format', 'h')
```

```
D =
 8.0183 hrs
 3.0853 hrs
 4.1506 hrs
```

## Input Arguments

### H, MI, S — Hour, minute, and second arrays

scalar | vector | matrix | multidimensional array

Hour, minute, and second arrays specified as a scalar, vector, matrix or multidimensional array. These arrays must be the same size, or any one can be a scalar.

Example: 12, 45, 07.451

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### H, MI, S, MS — Hour, minute, second, and millisecond arrays

scalar | vector | matrix | multidimensional array

Hour, minute, second, and millisecond arrays, each specified as a scalar, vector, matrix or multidimensional array. The arrays must be the same size, or any one can be a scalar.

Example: 12, 45, 30, 35

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**X — Input matrix**

matrix

Input matrix, specified in the form [H,M,S].

Example: [1,30,0]

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**displayFormat — Display format of D**

'hh:mm:ss' (default) | string

Display format of D, the duration array, specified as a string. The displayFormat value does not change the duration values in D, only their display.

To display a duration as a single number that includes a fractional part (for example, 1.234 hours), specify one of the following strings.

| Value of displayFormat | Description                                                                        |
|------------------------|------------------------------------------------------------------------------------|
| 'y'                    | Number of exact fixed-length years. A fixed-length year is equal to 365.2425 days. |
| 'd'                    | Number of exact fixed-length days. A fixed-length day is equal to 24 hours.        |
| 'h'                    | Number of hours                                                                    |
| 'm'                    | Number of minutes                                                                  |
| 's'                    | Number of seconds                                                                  |

To display a duration in the form of a digital timer, specify one of the strings:

- 'dd:hh:mm:ss'
- 'hh:mm:ss'
- 'mm:ss'
- 'hh:mm'

In addition, you can display up to nine fractional second digits by appending up to nine S characters. For example, 'hh:mm:ss.SSS' displays the milliseconds of a duration value to three digits.

Data Types: char

## Output Arguments

### **D** — Output duration

duration array

Output duration, returned as a `duration` array.

You can change the display format of a duration by modifying the `Format` property. For example, to display the duration, `D`, as a number of minutes, type:

```
D.Format = 'm'
```

## dynamicprops

Abstract class used to derive handle class with dynamic properties

### Syntax

```
classdef myclass < dynamicprops
```

### Description

`classdef myclass < dynamicprops` makes *myclass* a subclass of the `dynamicprops` class, which is a subclass of the `handle` class.

Use the `dynamicprops` class to derive classes that can define dynamic properties (instance properties), which are associated with a specific objects, but have no effect on the objects class definition. Dynamic properties are useful for attaching temporary data to one or more objects.

### dynamicprops Methods

This class defines one method `addprop` and, as a subclass of the `handle` class, inherits all the `handle` class methods.

- `addprop` — adds the named property to the specified handle objects. See “Dynamic Properties — Adding Properties to an Instance” for more information.

### See Also

`handle`

# echo

Display statements during function execution

## Syntax

```
echo on
echo off
echo
echo fcnname on
echo fcnname off
echo fcnname
echo on all
echo off all
```

## Description

The **echo** command controls the display (or *echoing*) of statements in a function during their execution. Normally, statements in a function file are not displayed on the screen during execution. Command echoing is useful for debugging or for demonstrations, allowing the commands to be viewed as they execute.

The **echo** command behaves in a slightly different manner for script files and function files. For script files, the use of **echo** is simple; echoing can be either **on** or **off**, in which case any script used is affected.

**echo on** turns on the echoing of commands in all script files.

**echo off** turns off the echoing of commands in all script files.

**echo** toggles the echo state.

When you turn on echoing for a script or function file, each line in the file is displayed as it is executed. Since this results in inefficient execution, use **echo** only for debugging.

**echo *fcnname* on** turns on echoing of the named function file.

**echo *fcnname* off** turns off echoing of the named function file.

`echo fcname` toggles the echo state of the named function file.

`echo on all` sets echoing on for all function files.

`echo off all` sets echoing off for all function files.

## More About

### Tips

- To avoid confusing syntax, do not use `on` or `off` as a function name.

### See Also

`function`

**Introduced before R2006a**

# echodemo

Run example script step-by-step in Command Window

## Syntax

```
echodemo filename
echodemo(filename,index)
```

## Description

`echodemo filename` runs the script specified by `filename` step-by-step in the Command Window. The file must contain sections defined with two percent signs (%) to enable pausing after each step. At each step, you can click links in the Command Window to proceed or stop. If the Command Window is not large enough to show the links, scroll up to see them.

---

**Caution** If variables in your base workspace have the same name as variables that the example file creates, the example could overwrite your data. Preserve your data by saving it to a MAT-file before running the example.

---

`echodemo(filename,index)` starts with the section number specified by `index`. If the example relies on results of previous steps, using this syntax can produce errors or unexpected results.

## Examples

### Run Example Script in Command Window

Run the Loma Prieta Earthquake example.

```
echodemo quake
```

### Start Script from Specified Section

Start the Loma Prieta Earthquake example from the third section.

```
filename = 'quake';
index = 3;
echodemo(filename, index)
```

This code errors because the example requires variables created in earlier sections.

## Input Arguments

### **filename** — Script file name

string

Script file name, specified as a string.

When you use the function syntax for `echodemo` and specify its inputs within parentheses, enclose the `filename` input in single quotes.

### **index** — Section index

scalar integer

Section index, specified as a scalar integer.

The link text in the Command Window shows the current section number, `n`, and the total number of sections, `m`, as `n/m`.

## More About

### Tips

- Only use `echodemo` to display scripts, not functions. `echodemo` can run any script that you can execute, but only scripts with sections pause between steps.

# edgeAttachments

**Class:** TriRep

(Not recommended) Simplices attached to specified edges

---

**Note:** `edgeAttachments(TriRep)` is not recommended. Use `edgeAttachments(triangulation)` instead.

`TriRep` is not recommended. Use `triangulation` instead.

---

## Syntax

`SI = edgeAttachments(TR, V1, V2)`

`SI = edgeAttachments(TR, EDGE)`

## Description

`SI = edgeAttachments(TR, V1, V2)` returns the simplices `SI` attached to the edges specified by `(V1, V2)`. `(V1, V2)` represents the start and end vertices of the edges to be queried.

`SI = edgeAttachments(TR, EDGE)` specifies edges in matrix format.

## Input Arguments

|                     |                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>TR</code>     | Triangulation representation.                                                                                                                      |
| <code>V1, V2</code> | Column vectors of vertex indices into the array of points representing the vertex coordinates.                                                     |
| <code>EDGE</code>   | Matrix specifying edge start and end points. <code>EDGE</code> is of size <code>m-by-2</code> , <code>m</code> being the number of edges to query. |

## Output Arguments

**SI**            Vector cell array of indices into the triangulation matrix. **SI** is a cell array because the number of simplices associated with each edge can vary.

## Definitions

A simplex is a triangle/tetrahedron or higher dimensional equivalent.

## Examples

### Example 1

Load a 3-D triangulation to compute the tetrahedra attached to an edge.

```
load tetmesh
trep = TriRep(tet, X);
v1 = [15 21]';
v2 = [936 716]';
t1 = edgeAttachments(trep, v1, v2);
```

You can also specify the input as edges.

```
e = [v1 v2];
t2 = edgeAttachments(trep, e);
isequal(t1,t2);
```

### Example 2

Create a triangulation with `DelaunayTri`.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
dt = DelaunayTri(x,y);
```

Query the triangles attached to edge (1,5).

```
t = edgeAttachments(dt, 1,5);
```

```
t{:};
```

**See Also**

triangulation | edges | delaunayTriangulation

## edges

**Class:** TriRep

(Not recommended) Triangulation edges

---

**Note:** `edges(TriRep)` is not recommended. Use `edges(triangulation)` instead.

TriRep is not recommended. Use triangulation instead.

---

## Syntax

`E = edges(TR)`

## Description

`E = edges(TR)` returns the edges in the triangulation in an  $n$ -by-2 matrix.  $n$  is the number of edges. The vertices of the edges index into `TR.X`, the array of points representing the vertex coordinates.

## Input Arguments

TR      Triangulation representation.

## Output Arguments

E      Edge matrix.

## Examples

### Example 1

Load a 2-D triangulation.

```
load trimesh2d
trep = TriRep(tri, x,y);
```

Return all edges.

```
e = edges(trep);
```

### Example 2

Query a 2-D DelaunayTri-generated triangulation.

```
X = rand(10,2);
dt = DelaunayTri(X);
e = edges(dt);
```

### See Also

[triangulation](#) | [edgeAttachments](#) | [delaunayTriangulation](#)

## edit

Edit or create file

## Syntax

```
edit
edit file
edit file1 ... fileN
```

## Description

`edit` opens a new file called `Untitled` in the Editor. MATLAB does not automatically save `Untitled`.

`edit file` opens the specified file in the Editor. If `file` does not already exist, MATLAB asks if you want to create it. `file` can include a partial path, complete path, relative path, or no path. If `file` includes a partial path or no path, `edit` will look for the file on the search path. You must have write permission to the path to create `file`, otherwise, MATLAB ignores the argument.

You must specify the extension to open `.mat` and `.mdl` files. MATLAB cannot directly edit binary files, such as `.p` and `.mex` files.

`edit file1 ... fileN` opens each file, `file1 ... fileN`, in the Editor.

## Examples

### Open a New File

```
edit
```

A new file titled `Untitled` opens in the MATLAB Editor (or default editor). `Untitled` does not appear in your Current Folder.

### Create a New File

```
mkdir tests
edit tests/new_script.m
```

A dialog box appears, asking if you want to create `new_script.m`. If you select **Yes**, MATLAB creates and opens `tests/new_script.m`.

### Open Files

```
edit file1 file2 file3 file4
```

MATLAB sequentially creates and opens the files: `file1`, `file2`, `file3`, and `file4` in sequence.

## Input Arguments

### **file** — Name of file

string

Name of file, specified as a string. If `file` specifies a path that contains a nonexistent folder, MATLAB throws an error. Specify multiple files on the same line by separating filenames with a space.

If `file` is overloaded (that is, appears in multiple folders on the search path), then include a partial path to edit the correct page, such as

```
edit folderName/file
```

If you do not specify the extension, then `edit` opens a file with the specified name and a `.m` extension.

```
edit name
```

If the file is part of a class or package, then either specify the path and extension, or separate the components of the name with periods, such as:

```
edit className.name
edit packageName.name
edit packageName.className.name
edit packageName.name
```

Data Types: char

## More About

- “Change Default Editor”

**See Also**

open | type

**Introduced before R2006a**

# eig

Eigenvalues and eigenvectors

## Syntax

```
e = eig(A)
[V,D] = eig(A)
[V,D,W] = eig(A)

e = eig(A,B)
[V,D] = eig(A,B)
[V,D,W] = eig(A,B)

[___] = eig(A,balanceOption)
[___] = eig(A,B,algorithm)

[___] = eig(___,eigvalOption)
```

## Description

`e = eig(A)` returns a column vector containing the eigenvalues of square matrix  $A$ .

`[V,D] = eig(A)` returns diagonal matrix  $D$  of eigenvalues and matrix  $V$  whose columns are the corresponding right eigenvectors, so that  $A*V = V*D$ .

`[V,D,W] = eig(A)` also returns full matrix  $W$  whose columns are the corresponding left eigenvectors, so that  $W'*A = D*W'$ .

The eigenvalue problem is to determine the solution to the equation  $Av = \lambda v$ , where  $A$  is an  $n$ -by- $n$  matrix,  $v$  is a column vector of length  $n$ , and  $\lambda$  is a scalar. The values of  $\lambda$  that satisfy the equation are the eigenvalues. The corresponding values of  $v$  that satisfy the equation are the right eigenvectors. The left eigenvectors,  $w$ , satisfy the equation  $w'A = \lambda w'$ .

`e = eig(A,B)` returns a column vector containing the generalized eigenvalues of square matrices  $A$  and  $B$ .

`[V,D] = eig(A,B)` returns diagonal matrix  $D$  of generalized eigenvalues and full matrix  $V$  whose columns are the corresponding right eigenvectors, so that  $A*V = B*V*D$ .

`[V,D,W] = eig(A,B)` also returns full matrix  $W$  whose columns are the corresponding left eigenvectors, so that  $W'*A = D*W'*B$ .

The generalized eigenvalue problem is to determine the solution to the equation  $Av = \lambda Bv$ , where  $A$  and  $B$  are  $n$ -by- $n$  matrices,  $v$  is a column vector of length  $n$ , and  $\lambda$  is a scalar. The values of  $\lambda$  that satisfy the equation are the generalized eigenvalues. The corresponding values of  $v$  are the generalized right eigenvectors. The left eigenvectors,  $w$ , satisfy the equation  $w'A = \lambda w'B$ .

`[ ___ ] = eig(A,balanceOption)`, where `balanceOption` is `'nobalance'`, disables the preliminary balancing step in the algorithm. The default for `balanceOption` is `'balance'`, which enables balancing. The `eig` function can return any of the output arguments in previous syntaxes.

`[ ___ ] = eig(A,B,algorithm)`, where `algorithm` is `'chol'`, uses the Cholesky factorization of  $B$  to compute the generalized eigenvalues. The default for `algorithm` depends on the properties of  $A$  and  $B$ , but is generally `'qz'`, which uses the QZ algorithm.

If  $A$  is Hermitian and  $B$  is Hermitian positive definite, then the default for `algorithm` is `'chol'`.

`[ ___ ] = eig( ___,eigvalOption)` returns the eigenvalues in the form specified by `eigvalOption` using any of the input or output arguments in previous syntaxes. Specify `eigvalOption` as `'vector'` to return the eigenvalues in a column vector or as `'matrix'` to return the eigenvalues in a diagonal matrix.

## Examples

### Eigenvalues of Matrix

Use `gallery` to create a symmetric positive definite matrix.

```
A = gallery('lehmer',4)
```

```
A =
```

```

1.0000 0.5000 0.3333 0.2500
0.5000 1.0000 0.6667 0.5000
0.3333 0.6667 1.0000 0.7500
0.2500 0.5000 0.7500 1.0000

```

Calculate the eigenvalues of **A**. The result is a column vector.

```
e = eig(A)
```

```
e =
```

```

0.2078
0.4078
0.8482
2.5362

```

Alternatively, use `eigvalOption` to return the eigenvalues in a diagonal matrix.

```
D = eig(A, 'matrix')
```

```
D =
```

```

0.2078 0 0 0
0 0.4078 0 0
0 0 0.8482 0
0 0 0 2.5362

```

### Eigenvalues and Eigenvectors of Matrix

Use `gallery` to create a circulant matrix.

```
A = gallery('circul',3)
```

```
A =
```

```

1 2 3
3 1 2
2 3 1

```

Calculate the eigenvalues and right eigenvectors of **A**.

```
[V,D] = eig(A)
```

```
V =
```

```

-0.5774 + 0.0000i 0.2887 - 0.5000i 0.2887 + 0.5000i
-0.5774 + 0.0000i -0.5774 + 0.0000i -0.5774 + 0.0000i
-0.5774 + 0.0000i 0.2887 + 0.5000i 0.2887 - 0.5000i

```

D =

```

6.0000 + 0.0000i 0.0000 + 0.0000i 0.0000 + 0.0000i
0.0000 + 0.0000i -1.5000 + 0.8660i 0.0000 + 0.0000i
0.0000 + 0.0000i 0.0000 + 0.0000i -1.5000 - 0.8660i

```

Verify that the results satisfy  $A*V = V*D$ .

$A*V - V*D$

ans =

```

1.0e-14 *
-0.2665 + 0.0000i -0.0444 + 0.0222i -0.0444 - 0.0222i
0.0888 + 0.0000i 0.0111 + 0.0777i 0.0111 - 0.0777i
-0.0444 + 0.0000i -0.0111 + 0.0833i -0.0111 - 0.0833i

```

Ideally, the eigenvalue decomposition satisfies the relationship. Since `eig` performs the decomposition using floating-point computations, then  $A*V$  can, at best, approach  $V*D$ . In other words,  $A*V - V*D$  is close to, but not exactly, 0.

### Eigenvalues of a Matrix Whose Elements Differ Dramatically in Scale

```

A = [3.0 -2.0 -0.9 2*eps;
 -2.0 4.0 1.0 -eps;
 -eps/4 eps/2 -1.0 0;
 -0.5 -0.5 0.1 1.0];

```

Calculate the eigenvalues and right eigenvectors using the default (balancing) behavior.

`[VB,DB] = eig(A)`

VB =

```

0.6153 -0.4176 -0.0000 -0.1437
-0.7881 -0.3261 -0.0000 0.1264
-0.0000 -0.0000 -0.0000 -0.9196
0.0189 0.8481 1.0000 0.3432

```

DB =

```

5.5616 0 0 0
 0 1.4384 0 0
 0 0 1.0000 0
 0 0 0 -1.0000

```

Verify that the results satisfy  $A*VB = VB*DB$ .

$A*VB - VB*DB$

ans =

```

0.0000 0.0000 -0.0000 0.0000
 0 -0.0000 0.0000 -0.0000
0.0000 -0.0000 0.0000 0.0000
 0 0.0000 0.0000 0.6031

```

This result does not satisfy  $A*VB = VB*DB$ . Ideally, the eigenvalue decomposition satisfies this relationship. Since `eig` performs the decomposition using floating-point computations, then  $A*V$  can, at best, approach  $V*D$ . In other words,  $A*V - V*D$  is close to, but not exactly, 0.

Now, try calculating the eigenvalues and right eigenvectors without the balancing step.

$[VN, DN] = \text{eig}(A, 'nobalance')$

VN =

```

0.6153 -0.4176 -0.0000 -0.1528
-0.7881 -0.3261 0 0.1345
-0.0000 -0.0000 -0.0000 -0.9781
0.0189 0.8481 -1.0000 0.0443

```

DN =

```

5.5616 0 0 0
 0 1.4384 0 0
 0 0 1.0000 0
 0 0 0 -1.0000

```

Verify that the results satisfy  $A*VN = VN*DN$ .

$A*VN - VN*DN$

ans =

```
1.0e-14 *
-0.1776 -0.0111 -0.0559 -0.0167
 0.3553 0.1055 0.0336 -0.0194
 0.0017 0.0002 0.0007 0
 0.0264 -0.0222 0.0222 0.0097
```

$A*VN - VN*DN$  is much closer to 0, so the 'nobalance' option produces more accurate results in this case.

### Left Eigenvectors

Create a 3-by-3 matrix.

```
A = [1 7 3; 2 9 12; 5 22 7];
```

Calculate the right eigenvectors, V, the eigenvalues, D, and the left eigenvectors, W.

```
[V,D,W] = eig(A)
```

V =

```
-0.2610 -0.9734 0.1891
-0.5870 0.2281 -0.5816
-0.7663 -0.0198 0.7912
```

D =

```
25.5548 0 0
 0 -0.5789 0
 0 0 -7.9759
```

W =

```
-0.1791 -0.9587 -0.1881
-0.8127 0.0649 -0.7477
-0.5545 0.2768 0.6368
```

Verify that the results satisfy  $W' * A = D * W'$ .

```
W' * A - D * W'
```

```
ans =
```

```
1.0e-13 *
-0.0444 -0.1066 -0.0888
-0.0011 0.0442 0.0333
 0 0.0266 0.0178
```

Ideally, the eigenvalue decomposition satisfies the relationship. Since `eig` performs the decomposition using floating-point computations, then  $W' * A$  can, at best, approach  $D * W'$ . In other words,  $W' * A - D * W'$  is close to, but not exactly, 0.

### Eigenvalues of Nondiagonalizable (Defective) Matrix

Create a 3-by-3 matrix.

```
A = [3 1 0; 0 3 1; 0 0 3];
```

Calculate the eigenvalues and right eigenvectors of A.

```
[V,D] = eig(A)
```

```
V =
```

```
1.0000 -1.0000 1.0000
 0 0.0000 -0.0000
 0 0 0.0000
```

```
D =
```

```
3 0 0
0 3 0
0 0 3
```

A has repeated eigenvalues and the eigenvectors are not independent. This means that A is not diagonalizable and is, therefore, defective.

Verify that V and D satisfy the equation,  $A * V = V * D$ , even though A is defective.

```
A * V - V * D
```

```
ans =
```

```
1.0e-15 *
```

```

0 0.8882 -0.8882
0 0 0.0000
0 0 0

```

Ideally, the eigenvalue decomposition satisfies the relationship. Since `eig` performs the decomposition using floating-point computations, then  $A*V$  can, at best, approach  $V*D$ . In other words,  $A*V - V*D$  is close to, but not exactly, 0.

### Generalized Eigenvalues

Create two matrices, **A** and **B**, then solve the generalized eigenvalue problem for the eigenvalues and right eigenvectors of the pair (**A**,**B**).

```

A = [1/sqrt(2) 0; 0 1];
B = [0 1; -1/sqrt(2) 0];
[V,D]=eig(A,B)

```

V =

```

1.0000 + 0.0000i 1.0000 + 0.0000i
0.0000 - 0.7071i 0.0000 + 0.7071i

```

D =

```

0.0000 + 1.0000i 0.0000 + 0.0000i
0.0000 + 0.0000i 0.0000 - 1.0000i

```

Verify that the results satisfy  $A*V = B*V*D$ .

$A*V - B*V*D$

ans =

```

0 0
0 0

```

The residual error  $A*V - B*V*D$  is exactly zero.

### Generalized Eigenvalues Using QZ Algorithm for Badly Conditioned Matrices

Create a badly conditioned symmetric matrix containing values close to machine precision.

format long e

```
A = diag([10^-16, 10^-15])
```

```
A =
```

```
1.0000000000000000e-16 0
0 1.0000000000000000e-15
```

Calculate the generalized eigenvalues and a set of right eigenvectors using the default algorithm. In this case, the default algorithm is 'chol'.

```
[V1,D1] = eig(A,A)
```

```
V1 =
```

```
1.0000000000000000e+08 0
0 3.162277660168380e+07
```

```
D1 =
```

```
9.999999999999999e-01 0
0 1.0000000000000000e+00
```

Now, calculate the generalized eigenvalues and a set of right eigenvectors using the 'qz' algorithm.

```
[V2,D2] = eig(A,A, 'qz')
```

```
V2 =
```

```
1 0
0 1
```

```
D2 =
```

```
1 0
0 1
```

Check how well the 'chol' result satisfies  $A*V1 = A*V1*D1$ .

```
format short
```

```
A*V1 - A*V1*D1
```

```
ans =
```

```
1.0e-23 *
0.1654 0
0 -0.6617
```

Now, check how well the 'qz' result satisfies  $A*V2 = A*V2*D2$ .

```
A*V2 - A*V2*D2
```

```
ans =
```

```
0 0
0 0
```

When both matrices are symmetric, `eig` uses the 'chol' algorithm by default. In this case, the QZ algorithm returns more accurate results.

### Generalized Eigenvalues Where One Matrix is Singular

Create a 2-by-2 identity matrix, A, and a singular matrix, B.

```
A = eye(2);
B = [3 6; 4 8];
```

Try to calculate the generalized eigenvalues of the matrix,  $B^{-1}A$ .

```
[V,D] = eig(B\A)
```

```
Warning: Matrix is singular to working precision.
Error using eig
Input to EIG must not contain NaN or Inf.
```

Now calculate the generalized eigenvalues and right eigenvectors by passing both matrices to the `eig` function.

```
[V,D] = eig(A,B)
```

```
V =
```

```
-0.7500 -1.0000
-1.0000 0.5000
```

```
D =
```

```

0.0909 0
 0 Inf

```

It is better to pass both matrices separately, and let `eig` choose the best algorithm to solve the problem. In this case, `eig(A,B)` returned a set of eigenvectors and at least one real eigenvalue, even though `B` is not invertible.

Verify  $Av = \lambda Bv$  for the first eigenvalue and the first eigenvector.

```

eigval = D(1,1);
eigvec = V(:,1);
A*eigvec - eigval*B*eigvec

```

```
ans =
```

```

1.0e-15 *
0.1110
0.2220

```

Ideally, the eigenvalue decomposition satisfies the relationship. Since the decomposition is performed using floating-point computations, then `A*eigvec` can, at best, approach `eigval*B*eigvec`, as it does in this case.

## Input Arguments

### **A** — Input matrix

square matrix

Input matrix, specified as a real or complex square matrix.

Data Types: `double` | `single`

Complex Number Support: Yes

### **B** — Generalized eigenvalue problem input matrix

square matrix

Generalized eigenvalue problem input matrix, specified as a square matrix of real or complex values. `B` must be the same size as `A`.

Data Types: `double` | `single`

Complex Number Support: Yes

**balanceOption — Balance option**

'balance' (default) | 'nobalance'

Balance option, specified as one of two strings: 'balance', which enables a preliminary balancing step, or 'nobalance' which disables it. In most cases, the balancing step improves the conditioning of **A** to produce more accurate results. However, there are cases in which balancing produces incorrect results. Specify 'nobalance' when **A** contains values whose scale differs dramatically. For example, if **A** contains nonzero integers, as well as very small (near zero) values, then the balancing step might scale the small values to make them as significant as the integers and produce inaccurate results.

'balance' is the default behavior. For more information about balancing, see **balance**.

Data Types: char

**algorithm — Generalized eigenvalue algorithm**

'chol' | 'qz'

Generalized eigenvalue algorithm, specified as 'chol' or 'qz', which selects the algorithm to use for calculating the generalized eigenvalues of a pair.

| algorithm | Description                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------|
| 'chol'    | Computes the generalized eigenvalues of <b>A</b> and <b>B</b> using the Cholesky factorization of <b>B</b> .                             |
| 'qz'      | Uses the QZ algorithm, also known as the generalized Schur decomposition. This algorithm ignores the symmetry of <b>A</b> and <b>B</b> . |

In general, the two algorithms return the same result. The QZ algorithm can be more stable for certain problems, such as those involving badly conditioned matrices.

When you omit the **algorithm** argument, the **eig** function selects an algorithm based on the properties of **A** and **B**. It uses the 'chol' algorithm for symmetric (Hermitian) **A** and symmetric (Hermitian) positive definite **B**. Otherwise, it uses the 'qz' algorithm.

Regardless of the algorithm you specify, the **eig** function always uses the QZ algorithm when **A** or **B** are not symmetric.

**eigvalOption — Eigenvalue option**

'vector' | 'matrix'

Eigenvalue option, specified as 'vector' or 'matrix'. This option allows you to specify whether the eigenvalues are returned in a column vector or a diagonal matrix. The default behavior varies according to the number of outputs specified:

- If you specify one output, such as  $\mathbf{e} = \text{eig}(\mathbf{A})$ , then the eigenvalues are returned as a column vector by default.
- If you specify two or three outputs, such as  $[\mathbf{V}, \mathbf{D}] = \text{eig}(\mathbf{A})$ , then the eigenvalues are returned as a diagonal matrix,  $\mathbf{D}$ , by default.

Example:  $\mathbf{D} = \text{eig}(\mathbf{A}, \text{'matrix'})$  returns a diagonal matrix of eigenvalues with the one output syntax.

Data Types: char

## Output Arguments

**e — Eigenvalues (returned as vector)**

column vector

Eigenvalues, returned as a column vector containing the eigenvalues (or generalized eigenvalues of a pair) with multiplicity.

- When  $\mathbf{A}$  is real and symmetric or complex Hermitian, the values of  $\mathbf{e}$  that satisfy  $\mathbf{A}\mathbf{v} = \lambda\mathbf{v}$  are real.
- When  $\mathbf{A}$  is real and skew-symmetric or skew-Hermitian, the values of  $\mathbf{e}$  that satisfy  $\mathbf{A}\mathbf{v} = \lambda\mathbf{v}$  are purely imaginary or zero.

**V — Right eigenvectors**

square matrix

Right eigenvectors, returned as a square matrix whose columns are the right eigenvectors of  $\mathbf{A}$  or generalized right eigenvectors of the pair,  $(\mathbf{A}, \mathbf{B})$ . The form and normalization of  $\mathbf{V}$  depends on the combination of input arguments:

- $[\mathbf{V}, \mathbf{D}] = \text{eig}(\mathbf{A})$  returns matrix  $\mathbf{V}$ , whose columns are the right eigenvectors of  $\mathbf{A}$  such that  $\mathbf{A}*\mathbf{V} = \mathbf{V}*\mathbf{D}$ . The eigenvectors in  $\mathbf{V}$  are normalized so that the 2-norm of each is 1.

If  $A$  is real symmetric, then the right eigenvectors,  $V$ , are orthonormal.

- $[V,D] = \text{eig}(A, 'nobalance')$  also returns matrix  $V$ . However, the 2-norm of each eigenvector is not necessarily 1.
- $[V,D] = \text{eig}(A,B)$  and  $[V,D] = \text{eig}(A,B,algorithm)$  returns  $V$  as a matrix whose columns are the generalized right eigenvectors that satisfy  $A*V = B*V*D$ . The 2-norm of each eigenvector is not necessarily 1. In this case,  $D$  contains the generalized eigenvalues of the pair,  $(A,B)$ , along the main diagonal.

If  $A$  is symmetric and  $B$  is symmetric positive definite, then the eigenvectors in  $V$  are normalized so that the  $B$ -norm of each is 1.

### **D — Eigenvalues (returned as matrix)**

diagonal matrix

Eigenvalues, returned as a diagonal matrix with the eigenvalues of  $A$  on the main diagonal or the eigenvalues of the pair,  $(A,B)$ , with multiplicity, on the main diagonal.

- When  $A$  is real and symmetric or complex Hermitian, the values of  $D$  that satisfy  $Av = \lambda v$  are real.
- When  $A$  is real and skew-symmetric or skew-Hermitian, the values of  $D$  that satisfy  $Av = \lambda v$  are purely imaginary or zero.

### **W — Left eigenvectors**

square matrix

Left eigenvectors, returned as a square matrix whose columns are the left eigenvectors of  $A$  or generalized left eigenvectors of the pair,  $(A,B)$ . The form and normalization of  $W$  depends on the combination of input arguments:

- $[V,D,W] = \text{eig}(A)$  returns matrix  $W$ , whose columns are the left eigenvectors of  $A$  such that  $W'*A = D*W'$ . The eigenvectors in  $W$  are normalized so that the 2-norm of each is 1. If  $A$  is symmetric, then  $W$  is the same as  $V$ .
- $[V,D,W] = \text{eig}(A, 'nobalance')$  also returns matrix  $W$ . However, the 2-norm of each eigenvector is not necessarily 1.
- $[V,D,W] = \text{eig}(A,B)$  and  $[V,D,W] = \text{eig}(A,B,algorithm)$  returns  $W$  as a matrix whose columns are the generalized left eigenvectors that satisfy  $W'*A = D*W'*B$ . The 2-norm of each eigenvector is not necessarily 1. In this case,  $D$  contains the generalized eigenvalues of the pair,  $(A,B)$ , along the main diagonal.

If  $A$  and  $B$  are symmetric, then  $W$  is the same as  $V$ .

## More About

### Tips

- The `eig` function can calculate the eigenvalues of sparse matrices that are real and symmetric. To calculate the eigenvectors of a sparse matrix, or to calculate the eigenvalues of a sparse matrix that is not real and symmetric, use the `eigs` function.

### See Also

`balance` | `condeig` | `eigs` | `hess` | `qz` | `schur`

**Introduced before R2006a**

## eigs

Largest eigenvalues and eigenvectors of matrix

### Syntax

```
d = eigs(A)
[V,D] = eigs(A)
[V,D,flag] = eigs(A)
eigs(A,B)
eigs(A,k)
eigs(A,B,k)
eigs(A,k,sigma)
eigs(A,B,k,sigma)
eigs(A,K,sigma,opts)
eigs(A,B,k,sigma,opts)
eigs(Afun,n,...)
```

### Description

`d = eigs(A)` returns a vector of *A*'s six largest magnitude eigenvalues. *A* must be a square matrix. *A* should be large and sparse, though **eigs** will work on full matrices as well. See “Tips” on page 1-2390 below.

`[V,D] = eigs(A)` returns a diagonal matrix *D* of *A*'s six largest magnitude eigenvalues and a matrix *V* whose columns are the corresponding eigenvectors.

`[V,D,flag] = eigs(A)` also returns a convergence flag. If *flag* is 0 then all the eigenvalues converged; otherwise not all converged.

`eigs(A,B)` solves the generalized eigenvalue problem  $A*V == B*V*D$ . *B* must be the same size as *A*. `eigs(A,[ ],...)` indicates the standard eigenvalue problem  $A*V == V*D$ .

`eigs(A,k)` and `eigs(A,B,k)` return the *k* largest magnitude eigenvalues.

`eigs(A,k,sigma)` and `eigs(A,B,k,sigma)` return *k* eigenvalues based on *sigma*, which can take any of the following values:

|                                                                                              |                                                                                                                                                                     |
|----------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| scalar (real or complex, including 0)                                                        | The eigenvalues closest to $\sigma$ . If $A$ is a function, $Afun$ must return $Y = (A - \sigma * B) \backslash x$ (i.e., $Y = A \backslash x$ when $\sigma = 0$ ). |
| 'lm'                                                                                         | Largest magnitude (default).                                                                                                                                        |
| 'sm'                                                                                         | Smallest magnitude. Same as $\sigma = 0$ . If $A$ is a function, $Afun$ must return $Y = A \backslash x$ .                                                          |
| For real symmetric $A$ and symmetric positive-definite $B$ , the following are also options: |                                                                                                                                                                     |
| 'la'                                                                                         | Largest algebraic                                                                                                                                                   |
| 'sa'                                                                                         | Smallest algebraic                                                                                                                                                  |
| 'be'                                                                                         | Both ends (one more from high end if $k$ is odd)                                                                                                                    |
| For nonsymmetric and complex problems, the following are also options:                       |                                                                                                                                                                     |
| 'lr'                                                                                         | Largest real part                                                                                                                                                   |
| 'sr'                                                                                         | Smallest real part                                                                                                                                                  |
| 'li'                                                                                         | Largest imaginary part                                                                                                                                              |
| 'si'                                                                                         | Smallest imaginary part                                                                                                                                             |

**Note** The syntax `eigs(A,k,...)` is not valid when  $A$  is scalar. To pass a value for  $k$ , you must specify  $B$  as the second argument and  $k$  as the third (`eigs(A,B,k,...)`). If necessary, you can set  $B$  equal to `[]`, the default.

`eigs(A,K,sigma,opts)` and `eigs(A,B,k,sigma,opts)` specify an options structure. Default values are shown in brackets (`{}`).

| Parameter                | Description                                                                   | Values            |
|--------------------------|-------------------------------------------------------------------------------|-------------------|
| <code>opts.issym</code>  | 1 if $A$ or $A - \sigma * B$ represented by $Afun$ is symmetric, 0 otherwise. | [{0}   1]         |

| <code>opts.disp</code>  | Diagnostic information display level.                                                                                                                                                                                                       | [{0}   1   2]                                  |
| <code>opts.cholB</code> | 1 if $B$ is really its Cholesky factor $\text{chol}(B)$ , 0 otherwise.                                                                                                                                                                      | [{0}   1]                                      |
| <code>opts.permB</code> | Permutation vector $\text{permB}$ if sparse $B$ is really $\text{chol}(B(\text{permB}, \text{permB}))$ .                                                                                                                                    | [permB   {1:n}]                                |

`eigs(Afun, n, ...)` accepts a function handle, `Afun`, instead of the matrix  $A$ .

`y = Afun(x)` should return:

|                                 |                                                                                                                    |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------|
| $A*x$                           | if $\sigma$ is not specified, or is a string other than 'sm'                                                       |
| $A \backslash x$                | if $\sigma$ is 0 or 'sm'                                                                                           |
| $(A - \sigma * I) \backslash x$ | if $\sigma$ is a nonzero scalar (standard eigenvalue problem). $I$ is an identity matrix of the same size as $A$ . |
| $(A - \sigma * B) \backslash x$ | if $\sigma$ is a nonzero scalar (generalized eigenvalue problem)                                                   |

“Parameterizing Functions” explains how to provide additional parameters to the function `Afun`, if necessary.

The matrix  $A$ ,  $A - \sigma * I$  or  $A - \sigma * B$  represented by `Afun` is assumed to be real and nonsymmetric unless specified otherwise by `opts.isreal` and `opts.issym`. In all the `eigs` syntaxes, `eigs(A, ...)` can be replaced by `eigs(Afun, n, ...)`.

## Examples

### Smallest Eigenvalues of Sparse Matrix

```
A = delsq(numgrid('C',15));
d1 = eigs(A,5,'sm')
```

returns

```
d1 =
 0.5520
 0.4787
 0.3469
 0.2676
 0.1334
```

### Smallest Eigenvalues of Function-Generated Sparse Matrix

This example replaces the matrix `A` in example 1 with a handle to a function `dnRk`. The example is contained in file `run_eigs` that

- Calls `eigs` with the function handle `@dnRk` as its first argument.
- Contains `dnRk` as a nested function, so that all variables in `run_eigs` are available to `dnRk`.

The following shows the code for `run_eigs`:

```
function d2 = run_eigs
n = 139;
opts.issym = 1;
R = 'C';
k = 15;
d2 = eigs(@dnRk,n,5,'sm',opts);

 function y = dnRk(x)
 y = (delsq(numgrid(R,k))) \ x;
 end
end
```

## Largest Eigenvalue Pairs of Sparse Matrix

west0479 is a real-valued 479-by-479 sparse matrix with both real and complex pairs of conjugate eigenvalues. `eig` computes all 479 eigenvalues. `eigs` easily picks out the largest magnitude eigenvalues.

This plot shows the 8 largest magnitude eigenvalues of west0479 as computed by `eig` and `eigs`.

```
load west0479
d = eig(full(west0479));
d1m = eigs(west0479,8);
[dum,ind] = sort(abs(d));
plot(d1m, 'k+')
hold on
plot(d(ind(end-7:end)), 'ks')
hold off
legend('eigs(west0479,8)', 'eig(full(west0479))')
```

## Repeated Eigenvalues of Symmetric Positive Definite Sparse Matrix

`A = delsq(numgrid('C',30))` is a symmetric positive definite matrix of size 632 with eigenvalues reasonably well-distributed in the interval (0 8), but with 18 eigenvalues repeated at 4.

Use the `eig` function to compute all 632 eigenvalues, and the `eigs` function to compute the six largest and smallest magnitude eigenvalues.

```
A = delsq(numgrid('C',30));
d = sort(eig(full(A)));
d1m = eigs(A);
dsm = eigs(A,6,'sa');
```

Plot the results from `eig` and `eigs` for the six largest and smallest magnitude eigenvalues.

```
subplot(2,1,1)
plot(d1m, 'k+')
hold on
plot(d(end:-1:end-5), 'ks')
hold off
legend('eigs(A)', 'eig(full(A))')
xlim([0.5 6.5])
```

```
subplot(2,1,2)
plot(dsm, 'k+')
hold on
plot(d(1:6), 'ks')
hold off
legend('eigs(A,6, ''sa'')', 'eig(full(A))', 'Location', 'SouthEast')
xlim([0.5 6.5])
```

The repeated eigenvalue at 4 must be handled more carefully. The call `eigs(A,20,4.0)` to compute 20 eigenvalues near 4.0 tries to find eigenvalues of  $A - 4.0 \cdot I$ . This involves divisions of the form  $1 / (\lambda - 4.0)$ , where  $\lambda$  is an estimate of an eigenvalue of  $A$ . As  $\lambda$  gets closer to 4.0, `eigs` fails. We must use `sigma` near but not equal to 4 to find those eigenvalues.

```
sigma = 4 - 1e-6;
D = sort(eigs(A,20,sigma));
```

The plot below shows the 20 eigenvalues closest to 4 that were computed by `eig`, along with the 20 eigenvalues closest to  $4 - 1e-6$  that were computed by `eigs`.

```
figure(2)
plot(d(307:326), 'ks')
```

```
hold on
plot(D,'k+')
hold off
legend('eig(A)', 'eigs(A,20,sigma)')
title('18 Repeated Eigenvalues of A')
```

## More About

### Tips

- `d = eigs(A,k)` is not a substitute for  
`d = eig(full(A))`

```
d = sort(d)
d = d(end-k+1:end)
```

but is most appropriate for large sparse matrices. If the problem fits into memory, it may be quicker to use `eig(full(A))`.

- Unless you provide a start vector with `opts.v0`, the default start vector is generated by `rand`, possibly leading to different iterations each run, and perhaps even different convergence behavior. In order to control this, specify your start vector via `opts.v0`.
- `eigs` does not always return sorted eigenvalues and eigenvectors. Use `sort` to explicitly sort the output eigenvalues and eigenvectors in cases where their order is important.
- “Create Function Handle”

# ellipj

Jacobi elliptic functions

## Syntax

```
[SN,CN,DN] = ellipj(U,M)
[SN,CN,DN] = ellipj(U,M,tol)
```

## Description

`[SN,CN,DN] = ellipj(U,M)` returns the Jacobi elliptic functions `SN`, `CN`, and `DN` evaluated for corresponding elements of argument `U` and parameter `M`. Inputs `U` and `M` must be the same size, or either `U` or `M` must be scalar.

`[SN,CN,DN] = ellipj(U,M,tol)` computes the Jacobi elliptic functions to accuracy `tol`. The default value of `tol` is `eps`. Increase `tol` for a less accurate but more quickly computed answer.

## Examples

### Find the Jacobi Elliptic Functions

Find the Jacobi elliptic functions for `U = 0.5` and `M = 0.25`.

```
[s,c,d] = ellipj(0.5,0.25)
```

```
s =
 0.4751
c =
 0.8799
d =
 0.9714
```

### Plot the Jacobi Elliptic Functions

Plot the Jacobi elliptic functions for `-5 ≤ U ≤ 5` and `M = 0.7`.

```
M = 0.7;
U = -5:0.01:5;
[S,C,D] = ellipj(U,M);
plot(U,S,U,C,U,D);
legend('SN','CN','DN','Location','best')
grid on
title('Jacobi Elliptic Functions sn,cn,dn')
```

### Generate a Surface Plot of the Jacobi Elliptic sn Function

Generate a surface plot of the Jacobi elliptic sn function for the allowed range of M and  $-5 \leq U \leq 5$ .

```
[M,U] = meshgrid(0:0.1:1,-5:0.1:5);
```

```
S = ellipj(U,M);
surf(U,M,S)
xlabel('U')
ylabel('M')
zlabel('sn')
title('Surface Plot of Jacobi Elliptic Function sn')
```

### Faster Calculations of Jacobi Elliptic Integrals by Changing Tolerance

The default value of `tol` is `eps`. Find the run time with the default value for arbitrary `M` using `tic` and `toc`. Increase `tol` by a factor of 1000 and find the run time. Compare the run times.

```
tic
```

```
ellipj(0.253,0.937)
toc
tic
ellipj(0.253,0.937,eps*1000)
toc
```

```
ans =
```

```
 0.2479
```

```
Elapsed time is 0.044834 seconds.
```

```
ans =
```

```
 0.2479
```

```
Elapsed time is 0.003345 seconds.
```

ellipj runs significantly faster when tolerance is significantly increased.

## Input Arguments

### **U** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **U** is limited to real values. If **U** is nonscalar, **M** must be a scalar or a nonscalar of the same size as **U**.

Data Types: single | double

### **M** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. **M** can take values  $0 \leq m \leq 1$ . If **M** is a nonscalar, **U** must be a scalar or a nonscalar of the same size as **M**. Map other values of **M** into this range using the transformations described in [1], equations 16.10 and 16.11.

Data Types: single | double

### **tol** — Accuracy of result

eps (default) | nonnegative real number

Accuracy of result, specified as a nonnegative real number. The default value is `eps`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Output Arguments

### **SN — Jacobi elliptic function `sn`**

scalar | vector | matrix | multidimensional array

Jacobi elliptic function `sn`, returned as a scalar, vector, matrix, or multidimensional array.

### **CN — Jacobi elliptic function `cn`**

scalar | vector | matrix | multidimensional array

Jacobi elliptic function `cn`, returned as a scalar, vector, matrix, or multidimensional array.

### **DN — Jacobi elliptic function `dn`**

scalar | vector | matrix | multidimensional array

Jacobi elliptic function `dn`, returned as a scalar, vector, matrix, or multidimensional array.

## More About

### **Jacobi Elliptic Functions**

The Jacobi elliptic functions are defined in terms of the integral

$$u = \int_0^{\phi} \frac{d\theta}{\sqrt{1 - m \sin^2 \theta}}.$$

Then

$$\textit{sn}(u) = \sin \phi, \quad \textit{cn}(u) = \cos \phi, \quad \textit{dn}(u) = \sqrt{1 - m \sin^2 \phi}.$$

Some definitions of the elliptic functions use the elliptical modulus  $k$  or modular angle  $\alpha$  instead of the parameter  $m$ . They are related by

$$k^2 = m = \sin^2 \alpha.$$

The Jacobi elliptic functions obey many mathematical identities. For a good sample, see [1].

### Algorithms

`ellipj` computes the Jacobi elliptic functions using the method of the arithmetic-geometric mean of [1]. It starts with the triplet of numbers

$$a_0 = 1, b_0 = \sqrt{1-m}, c_0 = \sqrt{m}.$$

`ellipj` computes successive iterations using

$$a_i = \frac{1}{2}(a_{i-1} + b_{i-1})$$

$$b_i = (a_{i-1} b_{i-1})^{\frac{1}{2}}$$

$$c_i = \frac{1}{2}(a_{i-1} - b_{i-1}).$$

Next, it calculates the amplitudes in radians using

$$\sin(2\phi_{n-1} - \phi_n) = \frac{c_n}{a_n} \sin(\phi_n),$$

being careful to unwrap the phases correctly. The Jacobian elliptic functions are then simply

$$sn(u) = \sin \phi_0$$

$$cn(u) = \cos \phi_0$$

$$dn(u) = \sqrt{1 - m \cdot sn(u)^2}.$$

1.3506

## Plot Complete Elliptic Integrals of First and Second Kind

Plot the complete elliptic integrals of the first and second kind for the allowed range of M.

```
M = 0:0.01:1;
[K,E] = ellipke(M);
plot(M,K,M,E)
grid on
xlabel('M')
title('Complete Elliptic Integrals of First and Second Kind')
legend('First kind','Second kind')
```

### Faster Calculations of the Complete Elliptic Integrals by Changing the Tolerance

The default value of `tol` is `eps`. Find the runtime with the default value for arbitrary `M` using `tic` and `toc`. Increase `tol` by a factor of thousand and find the runtime. Compare the runtimes.

```
tic
ellipke(0.904561)
toc
tic
ellipke(0.904561,eps*1000)
toc
```

```
ans =
 2.6001
Elapsed time is 0.005189 seconds.
```

```
ans =
 2.6001
Elapsed time is 0.002095 seconds.
```

ellipke runs significantly faster when tolerance is significantly increased.

## Input Arguments

### **M** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. M is limited to values  $0 \leq m \leq 1$ .

Data Types: single | double

### **tol** — Accuracy of result

eps (default) | nonnegative real number

Accuracy of result, specified as a nonnegative real number. The default value is eps.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

## Output Arguments

### **K** — Complete elliptic integral of first kind

scalar | vector | matrix | multidimensional array

Complete elliptic integral of the first kind, returned as a scalar, vector, matrix, or multidimensional array.

### **E** — Complete elliptic integral of second kind

scalar | vector | matrix | multidimensional array

Complete elliptic integral of the second kind, returned as a scalar, vector, matrix, or multidimensional array.

## More About

### Complete Elliptic Integrals of the First and Second Kind

The complete elliptic integral of the first kind is

$$[K(m)] = \int_0^1 [(1-t^2)(1-mt^2)]^{-\frac{1}{2}} dt.$$

where  $m$  is the first argument of `ellipke`.

The complete elliptic integral of the second kind is

$$E(m) = \int_0^1 (1-t^2)^{-\frac{1}{2}} (1-mt^2)^{\frac{1}{2}} dt.$$

Some definitions of the elliptic functions use the elliptical modulus  $k$  or modular angle  $\alpha$  instead of the parameter  $m$ . They are related by

$$k^2 = m = \sin^2 \alpha.$$

## See Also

`ellipj`

Introduced before R2006a

# ellipsoid

Generate ellipsoid

## Syntax

```
[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr,n)
[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr)
ellipsoid(axes_handle,...)
ellipsoid(...)
```

## Description

`[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr,n)` generates a surface mesh described by three  $n+1$ -by- $n+1$  matrices, enabling `surf(x,y,z)` to plot an ellipsoid with center  $(xc,yc,zc)$  and semi-axis lengths  $(xr,yr,zr)$ .

`[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr)` uses  $n = 20$ .

`ellipsoid(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`ellipsoid(...)` with no output arguments plots the ellipsoid as a surface.

## Examples

### Surface Plot of Ellipsoid

Generate data for an ellipsoid with a center at  $(0,0,0)$  and semi-axis lengths  $(5.9,3.25,3.25)$ . Use `surf` to plot the ellipsoid.

```
[x, y, z] = ellipsoid(0,0,0,5.9,3.25,3.25,30);
figure
surf(x, y, z)
axis equal
```

## More About

### Algorithms

ellipsoid generates the data using the following equation:

$$\frac{(x - xc)^2}{xr^2} + \frac{(y - yc)^2}{yr^2} + \frac{(z - zc)^2}{zr^2} = 1$$

Note that `ellipsoid(0,0,0, .5, .5, .5)` is equivalent to a unit sphere.

## empty

Create empty array

### Syntax

```
A = ClassName.empty
A = ClassName.empty(n,m,p,...)
A = ClassName.empty([n,m,p,...])
```

### Description

Use `empty` to create empty arrays of the specified class, *ClassName*. Specify at least one dimension of the array as 0. MATLAB treats negative values as 0.

`A = ClassName.empty` returns an empty 0-by-0 array of the class of *ClassName*.

`A = ClassName.empty(n,m,p,...)` returns an empty rectangular array with the specified dimensions. At least one of the dimensions must be 0.

`A = ClassName.empty([n,m,p,...])` returns an empty rectangular array with the specified dimensions. At least one of the dimensions must be 0. This syntax is useful when using the values returned by the `size` function to define an empty array that is the same size as an existing empty array:

```
A = ClassName.empty(size(otherEmptyArray));
```

### Input Arguments

**n,m,p,...**

Dimensions of the empty array. At least one of the specified dimensions must be 0.

## Output Arguments

### A

An empty array of the specified dimensions and of the class used in the method invocation.

## Attributes

`empty` is a hidden, public, static method of all nonabstract MATLAB classes.

|        |        |
|--------|--------|
| Access | Public |
| Hidden | true   |
| Static | true   |

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

## Examples

Use `empty` to create a rectangular empty array of class `int16`:

```
A = int16.empty(5,0);
whos
 Name Size Bytes Class Attributes
 A 5x0 0 int16
```

Using the `empty` method of the `int16` class to produce an empty array in which some dimensions are not zero is simpler than using conversion and reshape operations:

```
A = int16([]);
A = reshape(A,5,0);
whos
 Name Size Bytes Class Attributes
 A 5x0 0 int16
```

Given the following definition for a class,

```

classdef ExEmpty
 properties
 Color = [1,0,0];
 end
 methods
 function obj = ExEmpty(c)
 if nargin > 0
 obj.Color = c;
 end
 end
 end
end
end

```

Create an empty array of class ExEmpty:

```

A = ExEmpty.empty;
whos

```

| Name | Size | Bytes | Class   | Attributes |
|------|------|-------|---------|------------|
| A    | 0x0  | 104   | ExEmpty |            |

One dimension of an empty array must be zero:

```

A5 = ExEmpty.empty(0,5);
whos

```

| Name | Size | Bytes | Class   | Attributes |
|------|------|-------|---------|------------|
| A5   | 0x5  | 104   | ExEmpty |            |

Empty object arrays follow array concatenation behavior:

```

B = [A,A5]
B =

```

0x5 ExEmpty array with properties:

```

 Color

```

You cannot index into an empty array:

```

A5(1)
Index exceeds matrix dimensions.

```

You can use the `isempty`, `size`, and `length` functions to identify empty object arrays:

```

isempty(A5)

```

```
ans =
 1
size(A5)
ans =
 0 5
length(A5)
ans =
 0
```

## Class of Empty Object Array

The `empty` method enables you to initialize arrays of a specific class:

```
C = char.empty(0,7)
```

```
C =
```

```
 Empty string: 0-by-7
```

```
class(C)
ans =
```

```
char
```

Initializing an array with empty brackets ([ ]):

```
a = [];
```

produces an array of class `double`:

```
class(a)
ans =
```

```
double
```

## See Also

| `isempty` | `size` | `length`

# enableNETfromNetworkDrive

Enable access to .NET commands from network drive

## Syntax

```
enableNETfromNetworkDrive
```

## Description

`enableNETfromNetworkDrive` adds an entry for the MATLAB interface to .NET module to the security policy on your machine. You must have administrative privileges to change your configuration.

## Compatibility

Use `enableNETfromNetworkDrive` for MATLAB releases R2012b or earlier, which support installed versions 2.0, 3.0, and 3.5 of the Microsoft .NET Framework.

## Related Examples

- [“Troubleshooting Security Policy Settings From Network Drives”](#)

**Introduced in R2009b**

## enableservice

Enable, disable, or report status of MATLAB Automation server

### Syntax

```
state = enableservice('AutomationServer',enable)
state = enableservice('AutomationServer')
```

### Description

`state = enableservice('AutomationServer',enable)` enables or disables the MATLAB Automation server. If `enable` is `true` (logical 1), `enableservice` converts an existing MATLAB session into an Automation server. If `enable` is `false` (logical 0), `enableservice` disables the MATLAB Automation server. `state` indicates the previous state of the Automation server. If `state = 1`, MATLAB was an Automation server. If `state = 0`, MATLAB was not an Automation server.

`state = enableservice('AutomationServer')` returns the current state of the Automation server. If `state` is logical 1 (`true`), MATLAB is an Automation server.

COM functions are available on Microsoft Windows systems only.

### Examples

Enable the Automation server in the current MATLAB session:

```
state = enableservice('AutomationServer',true);
```

Show the current state of the MATLAB session. MATLAB displays `true`:

```
state = enableservice('AutomationServer')
```

Enable the Automation server and show the previous state. MATLAB displays `true`. The previous state can be the same as the current state:

```
state = enableservice('AutomationServer',true)
```

To enable the Automation server every time you run MATLAB, see “Manually Create Automation Server”.

- “MATLAB COM Automation Server Interface”

## **See Also**

actxserver

**Introduced before R2006a**

## end

Terminate block of code, or indicate last array index

## Syntax

end

## Description

`end` terminates `for`, `while`, `switch`, `try`, `if`, and `parfor` statements. Without an `end` statement, `for`, `while`, `switch`, `try`, `if`, and `parfor` wait for further input. Each `end` is paired with the closest previous unpaired `for`, `while`, `switch`, `try`, `if`, or `parfor` and serves to delimit its scope.

`end` also marks the termination of a function, although in many cases it is optional. If your function contains one or more nested functions, then you must terminate every function in the file, whether nested or not, with `end`. This includes primary, nested, private, and local functions.

The `end` function also serves as the last index in an indexing expression. In that context, `end = (size(x,k))` when used as part of the  $k$ th index. Examples of this use are `X(3:end)` and `X(1,1:2:end-1)`. When using `end` to grow an array, as in `X(end+1)=5`, make sure `X` exists first.

You can overload the `end` statement for a user object by defining an `end` method for the object. The `end` method should have the calling sequence `end(obj,k,n)`, where `obj` is the user object, `k` is the index in the expression where the `end` syntax is used, and `n` is the total number of indices in the expression. For example, consider the expression

```
A(end-1,:)
```

The MATLAB software calls the `end` method defined for `A` using the syntax

```
end(A,1,2)
```

## Examples

This example shows `end` used with the `for` and `if` statements.

```
for k = 1:n
 if a(k) == 0
 a(k) = a(k) + 2;
 end
end
```

In this example, `end` is used in an indexing expression.

```
A = magic(5)
```

```
A =
```

```
 17 24 1 8 15
 23 5 7 14 16
 4 6 13 20 22
 10 12 19 21 3
 11 18 25 2 9
```

```
B = A(end,2:end)
```

```
B =
```

```
 18 25 2 9
```

## EndInvoke

Retrieve result of asynchronous call initiated by .NET System.Delegate BeginInvoke method

### Syntax

```
result = EndInvoke(asyncResult)
[res0, ..., resN] = EndInvoke(res0, ..., resN, asyncResult)
```

### Description

`result = EndInvoke(asyncResult)` retrieves result of asynchronous call initiated by `BeginInvoke` method.

`[res0, ..., resN] = EndInvoke(res0, ..., resN, asyncResult)` for methods with `out` and/or `ref` parameters.

### Input Arguments

#### **asyncResult**

.NET System.IAsyncResult object returned by `BeginInvoke`.

#### **res0, ..., resN**

For methods with `out` and/or `ref` parameters, results of the asynchronous call. The number of arguments is the sum of:

- Number of return values (0 or 1).
- Number of `out` and `ref` arguments.

### Output Arguments

#### **result**

Results of the asynchronous call.

**res0, ..., resN**

For methods with `out` and/or `ref` parameters, results of the asynchronous call,

## Examples

The following examples show how to call delegates with various input and output arguments. Each example contains:

- 1 The C# delegate signature. In order to execute the MATLAB code, build the delegate code into an assembly named `SignatureExamples` and load it into MATLAB. For information, see “Build a .NET Application for MATLAB Examples”.
- 2 An example MATLAB function to use with the delegate, which must exist on your path.
- 3 The `BeginInvoke` and `EndInvoke` signatures MATLAB creates. To display the signatures, create a delegate instance, `myDel`, and call the `methodsview` function.
- 4 Simple MATLAB example.

This example shows how to use a delegate that has no return value.

- 1 C# delegate:

```
public delegate void delint(Int32 arg);
```

- 2 MATLAB function to call:

```
% Display input argument
function dispfnc(A)
% A = number
['Input is ' num2str(A)]
end
```

- 3 MATLAB creates the following signatures. For `BeginInvoke`:

```
System.IAsyncResultRetVal
BeginInvoke (
 SignatureExamples.delint this,
 int32 scalar arg,
 System.AsyncCallback callback,
 System.Object object)
```

The `EndInvoke` signature:

```
EndInvoke (
 SignatureExamples.delint this,
 System.IAsyncResult result)
```

**4** Call `dispfnc`:

```
myDel = SignatureExamples.delint(@dispfnc);
asyncRes = myDel.BeginInvoke(6, [], []);
while asyncRes.IsCompleted ~= true
 pause(0.05); % Use pause() to let MATLAB process event
end
myDel.EndInvoke(asyncRes)
```

Input is 6

This example shows how to use a delegate with a return value. The delegate does not have `out` or `ref` parameters.

**1** C# delegate:

```
public delegate Int32 del2int(Int32 arg1, Int32 arg2);
```

**2** MATLAB function to call:

```
% Add input arguments
function res = addfnc(A, B)
% A and B are numbers
res = A + B;
end
```

**3** MATLAB creates the following signatures. For `BeginInvoke`:

```
System.IAsyncResultRetVal
BeginInvoke (
 SignatureExamples.del2int this,
 int32 scalar arg1,
 int32 scalar arg2,
 System.AsyncCallback callback,
 System.Object object)
```

The `EndInvoke` signature:

```
int32 scalarRetVal
EndInvoke (
 SignatureExamples.del2int this,
 System.IAsyncResult result)
```

**4** Call `addfnc`.

```

myDel = SignatureExamples.del2int(@addfnc);
asyncRes = myDel.BeginInvoke(6,8,[],[]);
while asyncRes.IsCompleted ~= true
 pause(0.05); % Use pause() to let MATLAB process event
end
result = myDel.EndInvoke(asyncRes)

result =
 14

```

This example shows how to use a delegate with a `ref` parameter, `refArg`, and no return value.

**1** C# delegate:

```
public delegate void delrefvoid(ref Double refArg);
```

**2** MATLAB maps the `ref` argument as both RHS and LHS arguments. MATLAB function to call.

```

% Increment input argument
function res = incfnc(A)
% A = number
res = A + 1;
end

```

**3** MATLAB creates the following signatures. For `BeginInvoke`:

```

[System.IAsyncResult RetVal,
double scalar refArg]
BeginInvoke (
 SignatureExamples.delrefvoid this,
 double scalar refArg,
 System.AsyncCallback callback,
 System.Object object)

```

The `EndInvoke` signature:

```

double scalar refArg
EndInvoke (
 SignatureExamples.delrefvoid this,
 double scalar refArg,
 System.IAsyncResult result)

```

**4** Call `incfnc`.

```
x = 6;
myDel = SignatureExamples.delrefvoid(@incfnc);
asyncRes = myDel.BeginInvoke(x,[],[]);
while asyncRes.IsCompleted ~= true
 pause(0.05); % Use pause() to let MATLAB process event
end
myRef = 0;
result = myDel.EndInvoke(myRef,asyncRes);
disp(['Increment of ' num2str(x) ' = ' num2str(result)]);

Increment of 6 = 7
```

This example shows how to use a delegate with an `out` parameter, `argOut`, and one return value.

**1** C# delegate:

```
public delegate Single deloutsingle(Single argIn, out Single argOut);
```

**2** MATLAB maps the `out` argument as a return value for a total of two return values. MATLAB function to call.

```
% Double input argument
function [res1,res2] = times2fnc(A)
res1 = A*2;
res2 = res1;
end
```

**3** MATLAB creates the following signatures. For `BeginInvoke`.

```
[System.IAsyncResult RetVal,
single scalar argOut]
 BeginInvoke (
 SignatureExamples.deloutsingle this,
 single scalar argIn,
 System.AsyncCallback callback,
 System.Object object)
```

The `EndInvoke` signature is:

```
[single scalar RetVal,
single scalar argOut]
 EndInvoke (
 SignatureExamples.deloutsingle this,
 System.IAsyncResult result)
```

#### 4 Call times2fnc.

```
myDel = SignatureExamples.deloutsingle(@times2fnc);
asyncRes = myDel.BeginInvoke(6,[],[]);
while asyncRes.IsCompleted ~= true
 pause(0.05); % Use pause() to let MATLAB process event
end
[a1,a2] = myDel.EndInvoke(asyncRes);
a1

a1 =
 12
```

## More About

### Tips

- If the delegate contains `out` or `ref` parameters, the signature for the `EndInvoke` method follows the MATLAB mapping rules. For information, see “Call Delegates With `out` and `ref` Type Arguments”.
- “Calling .NET Methods Asynchronously”
- MSDN Calling Synchronous Methods Asynchronously

### See Also

`BeginInvoke`

Introduced in R2011a

## eomday

Last day of month

### Syntax

E = eomday(Y,M)

### Description

E = eomday(Y,M) returns the last day of the year and month given by corresponding elements of the numeric arrays Y and M.

### Examples

Show the end of month for January through September for the year 1900:

```
eomday(1900, 1:9)
ans =
 31 28 31 30 31 30 31 31 30
```

Find the number of days during that period:

```
sum(eomday(1900, 1:9))
ans =
 273
```

Because 1996 is a leap year, the statement eomday(1996,2) returns 29. To show all the leap years in the twentieth century, try:

```
y = 1900:1999;
E = eomday(y, 2);
y(find(E == 29))

ans =
Columns 1 through 6
 1904 1908 1912 1916 1920 1924
```

Columns 7 through 12

|      |      |      |      |      |      |
|------|------|------|------|------|------|
| 1928 | 1932 | 1936 | 1940 | 1944 | 1948 |
|------|------|------|------|------|------|

Columns 13 through 18

|      |      |      |      |      |      |
|------|------|------|------|------|------|
| 1952 | 1956 | 1960 | 1964 | 1968 | 1972 |
|------|------|------|------|------|------|

Columns 19 through 24

|      |      |      |      |      |      |
|------|------|------|------|------|------|
| 1976 | 1980 | 1984 | 1988 | 1992 | 1996 |
|------|------|------|------|------|------|

## See Also

[datenum](#) | [datevec](#) | [weekday](#)

## enumeration

Display class enumeration members and names

### Syntax

```
enumeration ClassName
enumeration(obj)
m = enumeration(ClassName)
m = enumeration(obj)
[m,s] = enumeration(ClassName)
[m,s] = enumeration(obj)
```

### Description

`enumeration ClassName` displays the names of the enumeration members for the MATLAB class with the name `ClassName`.

`enumeration(obj)` displays the names of the enumeration members for the class of `obj`.

`m = enumeration(ClassName)` returns the enumeration members for the class in the column vector `m` of objects.

`m = enumeration(obj)` returns the enumeration members for the class of object, `obj`, in the column vector `m` of objects.

`[m,s] = enumeration(ClassName)` returns the names of the enumeration members in the cell array of strings `s`. The names in `s` correspond element-wise to the enumeration members in `m`.

`[m,s] = enumeration(obj)` returns the enumeration members for the class of object, `obj`, in the column vector `m` of objects.

## Input Arguments

### **ClassName**

The name of the enumeration class, in single quotes.

### **obj**

A instance of an enumeration class.

## Output Arguments

### **m**

Column vector of enumeration members.

### **s**

Cell array of strings containing the enumeration names.

## Examples

All examples use the following enumeration class.

```
classdef Boolean < logical
 enumeration
 No (0)
 Yes (1)
 Off (0)
 On (1)
 end
end
```

Display the names of the enumeration members for class **Boolean**:

```
enumeration Boolean
Enumerations for class Boolean:

 No
 Yes
```

Get the enumeration members for class `Boolean` in a column vector of objects:

```
members = enumeration('Boolean')
members =

 No
 Yes
```

Get all available enumeration members and their names:

```
[members, names] = enumeration('Boolean')
members =

 No
 Yes
 No
 Yes
```

```
names =

 'No'
 'Yes'
 'Off'
 'On'
```

## More About

### Tips

- An enumeration class that derives from a built-in class can specify more than one name for a given enumeration member.
- When you call the `enumeration` function with no output arguments, MATLAB displays only the first name for each enumeration member (as specified in the class definition). To see all available enumeration members and their names, use the two output arguments (for example, `[m, s] = enumeration(obj);`).

### See Also

`classdef`

## eps

Floating-point relative accuracy

### Syntax

```
d = eps
d = eps(x)
d = eps(datatype)
```

### Description

`d = eps` returns the distance from `1.0` to the next larger double-precision number, that is, `eps = 2-52`.

`d = eps(x)`, where `x` has data type `single` or `double`, returns the positive distance from `abs(x)` to the next larger floating-point number of the same precision as `x`. If `x` has type `duration`, then `eps(x)` returns the next larger `duration` value. The command `eps(1.0)` is equivalent to `eps`.

`d = eps(datatype)` returns `eps` according to the data type specified by `datatype`, which can be either `'double'` or `'single'`. The syntax `eps('double')` (default) is equivalent to `eps`, and `eps('single')` is equivalent to `eps(single(1.0))`.

### Examples

#### Accuracy in Double Precision

Display the distance from `1.0` to the next largest double-precision number.

```
d = eps
```

```
d =
```

```
2.2204e-16
```

`eps` is equivalent to `eps(1.0)` and `eps('double')`.

Compute `log2(eps)`.

```
d = log2(eps)
```

```
d =
```

```
-52
```

In base 2, `eps` is equal to  $2^{-52}$ .

Find the distance from `10.0` to the next largest double-precision number.

```
d = eps(10.0)
```

```
d =
```

```
1.7764e-15
```

## Accuracy in Single Precision

Display the distance from `1.0` to the next largest single-precision number.

```
d = eps('single')
```

```
d =
```

```
1.1921e-07
```

`eps('single')` is equivalent to `eps(single(1.0))`.

Compute `log2(eps('single'))`.

```
d = log2(eps('single'))
```

```
d =
```

```
-23
```

In base 2, single-precision `eps` is equal to  $2^{-23}$ .

Find the distance from the single-precision representation of 10.0 to the next largest single-precision number.

```
d = eps(single(10.0))
```

```
d =
```

```
9.5367e-07
```

## Input Arguments

### **x** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. `d` is the same size as `x`. For all `x`, `eps(x) = eps(-x) = eps(abs(x))`. If `x` is complex, `d` is the distance to the next larger floating-point number in magnitude. If `x` is `Inf` or `NaN`, then `eps(x)` returns `NaN`.

Data Types: `single` | `double` | `duration`

Complex Number Support: Yes

### **datatype** — Output data type

'double' (default) | 'single'

Output data type, specified as 'double' or 'single'.

- `eps('double')` is equivalent to `eps` and `eps(1.0)`.
- `eps('single')` is equivalent to `eps(single(1.0))` and `single(2-23)`.

Data Types: `char`

## More About

- Floating-Point Numbers

**See Also**

double | duration | intmax | realmax | realmin | single

**Introduced before R2006a**

## eq, ==

Determine equality

## Syntax

```
A == B
eq(A,B)
```

## Description

`A == B` returns a logical array with elements set to logical 1 (**true**) where arrays `A` and `B` are equal; otherwise, it returns logical 0 (**false**). The test compares both real and imaginary parts of numeric arrays. `eq` returns logical 0 (**false**) where `A` or `B` have NaN or undefined categorical elements.

`eq(A,B)` is an alternative way to execute `A == B`, but is rarely used. It enables operator overloading for classes.

## Examples

### Equality of Two Vectors

Create two vectors containing both real and imaginary numbers, then compare the vectors for equality.

```
A = [1+i 3 2 4+i];
B = [1 3+i 2 4+i];
A == B
```

```
ans =
```

```
0 0 1 1
```

The `eq` function tests both real and imaginary parts for equality, and returns logical 1 (`true`) only where both parts are equal.

## Find Characters in String

Create a character array.

```
M = 'masterpiece';
```

Test for the presence of a specific character using `==`.

```
M == 'e'
```

```
ans =
```

```
 0 0 0 0 1 0 0 0 1 0 1
```

The value of logical 1 (`true`) indicates the presence of the character 'e'.

## Find Values in Categorical Array

Create a categorical array with two values: 'heads' and 'tails'.

```
A = categorical({'heads' 'heads' 'tails'; 'tails' 'heads' 'tails'})
```

```
A =
```

```
 heads heads tails
 tails heads tails
```

Find all values in the 'heads' category.

```
A == 'heads'
```

```
ans =
```

```
 1 1 0
 0 1 0
```

A value of logical 1 (`true`) indicates a value in the category.

Compare the rows of A for equality.

```
A(1,:) == A(2,:)
```

```
ans =
```

```
 0 1 1
```

A value of logical 1 (`true`) indicates where the rows have equal category values.

### Compare Floating-Point Numbers

Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the `==` operator reflects.

Perform a few subtraction operations on a floating-point number and store the result in `C`.

```
C = 0.5-0.4-0.1
```

```
C =
```

```
-2.7756e-17
```

Intuitively, `C` should be equal to *exactly* 0. Its small value is due to the nature of floating-point arithmetic.

Compare `C` to 0 for equality.

```
C == 0
```

```
ans =
```

```
 0
```

Compare floating-point numbers using a tolerance, `tol`, instead of using `==`.

```
tol = eps(0.5);
abs(C-0) < tol
```

```
ans =
```

```
1
```

The two numbers, `C` and `0`, are closer to one another than two consecutive floating-point numbers. They are essentially equal.

## Compare Datetime Values

Compare the elements of two `datetime` arrays.

Create two `datetime` arrays in different time zones.

```
t1 = [2014,04,14,9,0,0;2014,04,14,10,0,0];
A = datetime(t1,'TimeZone','America/Los_Angeles');
A.Format = 'd-MMM-y HH:mm:ss Z'
```

```
A =
```

```
14-Apr-2014 09:00:00 -0700
14-Apr-2014 10:00:00 -0700
```

```
t2 = [2014,04,14,12,0,0;2014,04,14,12,30,0];
B = datetime(t2,'TimeZone','America/New_York');
B.Format = 'd-MMM-y HH:mm:ss Z'
```

```
B =
```

```
14-Apr-2014 12:00:00 -0400
14-Apr-2014 12:30:00 -0400
```

Check where elements in `A` and `B` are equal.

```
A==B
```

```
ans =
```

```
1
0
```

---

## Input Arguments

### A — Left array

numeric array | logical array | character array | categorical array | datetime array | duration array

Left array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

Complex Number Support: Yes

### B — Right array

numeric array | logical array | character array | categorical array | datetime array | duration array

Right array, specified as a numeric array, logical array, character array, or categorical array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

Complex Number Support: Yes

## More About

### Tips

- When comparing handle objects, use `==` to test whether objects have the same handle. Use `isequal` to determine if objects with different handles have equal property values.

### See Also

`ge` | `gt` | `le` | `lt` | `ne`

# erf

Error function

## Syntax

`erf(x)`

## Description

`erf(x)` returns the “Error Function” on page 1-2442 evaluated for each element of `x`.

## Examples

### Find Error Function

Find the error function of a value.

```
erf(0.76)
```

```
ans =
```

```
0.7175
```

Find the error function of the elements of a vector.

```
V = [-0.5 0 1 0.72];
erf(V)
```

```
ans =
```

```
-0.5205 0 0.8427 0.6914
```

Find the error function of the elements of a matrix.

```
M = [0.29 -0.11; 3.1 -2.9];
erf(M)
```

```
ans =
```

```
0.3183 -0.1236
1.0000 -1.0000
```

### Find Cumulative Distribution Function of Normal Distribution

The cumulative distribution function (CDF) of the normal, or Gaussian, distribution with standard deviation  $\sigma$  and mean  $\mu$  is

$$\Phi(x) = \frac{1}{2} \left( 1 + \operatorname{erf} \left( \frac{x - \mu}{\sigma\sqrt{2}} \right) \right).$$

Note that for increased computational accuracy, you can rewrite the formula in terms of `erfc`. For details, see “Tips”.

Plot the CDF of the normal distribution with  $\mu = 0$  and  $\sigma = 1$ .

```
x = -3:0.1:3;
y = (1/2)*(1+erf(x/sqrt(2)));
plot(x,y)
grid on
title('CDF of normal distribution with \mu = 0 and \sigma = 1')
xlabel('x')
ylabel('CDF')
```

### Calculate Solution of Heat Equation with Initial Condition

Where  $u(x, t)$  represents the temperature at position  $x$  and time  $t$ , the heat equation is

$$\frac{\partial u}{\partial t} = c \frac{\partial^2 u}{\partial x^2},$$

where  $c$  is a constant.

For a material with heat coefficient  $k$ , and for the initial condition  $u(x, 0) = a$  for  $x > b$  and  $u(x, 0) = 0$  elsewhere, the solution to the heat equation is

$$u(x, t) = \frac{a}{2} \left( \operatorname{erf} \left( \frac{x - b}{\sqrt{4kt}} \right) \right).$$

For  $k = 2$ ,  $a = 5$ , and  $b = 1$ , plot the solution of the heat equation at times  $t = 0.1$ ,  $5$ , and  $100$ .

```
x = -4:0.01:6;
t = [0.1 5 100];
a = 5;
k = 2;
b = 1;
figure(1)
hold on
for i = 1:3
 u(i,:) = (a/2)*(erf((x-b)/sqrt(4*k*t(i))));
 plot(x,u(i,:))
end
grid on
xlabel('x')
ylabel('Temperature')
legend('t = 0.1','t = 5','t = 100','Location','best')
title('Temperatures across material at t = 0.1, t = 5, and t = 100')
```

## Input Arguments

### **x** — Input

real number | vector of real numbers | matrix of real numbers | multidimensional array of real numbers

Input, specified as a real number, or a vector, matrix, or multidimensional array of real numbers.  $x$  cannot be sparse.

Data Types: `single` | `double`

## More About

### Error Function

The error function `erf` of  $x$  is

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt.$$

### Tips

- You can also find the standard normal probability distribution using the Statistics and Machine Learning Toolbox™ function `normcdf`. The relationship between the error function `erf` and `normcdf` is

$$\text{normcdf}(x) = \frac{1}{2} \left( 1 + \text{erf} \left( \frac{x}{\sqrt{2}} \right) \right).$$

- For expressions of the form  $1 - \text{erf}(x)$ , use the complementary error function `erfc` instead. This substitution maintains accuracy. When `erf(x)` is close to 1, then  $1 - \text{erf}(x)$  is a small number and might be rounded down to 0. Instead, replace  $1 - \text{erf}(x)$  with `erfc(x)`.

### See Also

`erfc` | `erfcinv` | `erfcx` | `erfinv`

**Introduced before R2006a**

# erfc

Complementary error function

## Syntax

`erfc(x)`

## Description

`erfc(x)` returns the “Complementary Error Function” on page 1-2446 evaluated for each element of `x`. Use the `erfc` function to replace `1 - erf(x)` for greater accuracy when `erf(x)` is close to 1.

## Examples

### Find Complementary Error Function

Find the complementary error function of a value.

```
erfc(0.35)
```

```
ans =
```

```
0.6206
```

Find the complementary error function of the elements of a vector.

```
V = [-0.5 0 1 0.72];
erfc(V)
```

```
ans =
```

1.5205    1.0000    0.1573    0.3086

Find the complementary error function of the elements of a matrix.

```
M = [0.29 -0.11; 3.1 -2.9];
erfc(M)
```

```
ans =
```

```
0.6817 1.1236
0.0000 2.0000
```

### Find Bit Error Rate of Binary Phase-Shift Keying

The bit error rate (BER) of binary phase-shift keying (BPSK), assuming additive white gaussian noise (AWGN), is

$$P_b = \frac{1}{2} \operatorname{erfc} \left( \sqrt{\frac{E_b}{N_0}} \right).$$

Plot the BER for BPSK for values of  $E_b/N_0$  from 0dB to 10dB.

```
EbNO_dB = 0:0.1:10;
EbNO = 10.^(EbNO_dB/10);
BER = 1/2.*erfc(sqrt(EbNO));
semilogy(EbNO_dB,BER)
grid on
ylabel('BER')
xlabel('E_b/N_0 (dB)')
title('Bit Error Rate for Binary Phase-Shift Keying')
```

### Avoid Roundoff Errors Using Complementary Error Function

You can use the complementary error function  $\text{erfc}$  in place of  $1 - \text{erf}(x)$  to avoid roundoff errors when  $\text{erf}(x)$  is close to 1.

Show how to avoid roundoff errors by calculating  $1 - \text{erf}(10)$  using  $\text{erfc}(10)$ . The original calculation returns 0 while  $\text{erfc}(10)$  returns the correct result.

```
1 - erf(10)
erfc(10)
```

ans =

0

ans =

2.0885e-45

## Input Arguments

### **x** — Input

real number | vector of real numbers | matrix of real numbers | multidimensional array of real numbers

Input, specified as a real number, or a vector, matrix, or multidimensional array of real numbers. **x** cannot be sparse.

Data Types: `single` | `double`

## More About

### Complementary Error Function

The complementary error function of  $x$  is defined as

$$\begin{aligned}\operatorname{erfc}(x) &= \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt \\ &= 1 - \operatorname{erf}(x).\end{aligned}$$

It is related to the error function as

$$\operatorname{erfc}(x) = 1 - \operatorname{erf}(x).$$

### Tips

- You can also find the standard normal probability distribution using the Statistics and Machine Learning Toolbox function `normcdf`. The relationship between the error function `erfc` and `normcdf` is

$$\text{normcdf}(x) = \left(\frac{1}{2}\right) \times \text{erfc}\left(\frac{-x}{\sqrt{2}}\right)$$

- For expressions of the form  $1 - \text{erfc}(x)$ , use the error function `erf` instead. This substitution maintains accuracy. When `erfc(x)` is close to 1, then  $1 - \text{erfc}(x)$  is a small number and might be rounded down to 0. Instead, replace  $1 - \text{erfc}(x)$  with `erf(x)`.
- For expressions of the form  $\exp(x^2) * \text{erfc}(x)$ , use the scaled complementary error function `erfcx` instead. This substitution maintains accuracy by avoiding roundoff errors for large values of  $x$ .

## erfcinv

Inverse complementary error function

### Syntax

```
erfcinv(x)
```

### Description

`erfcinv(x)` returns the value of the “Inverse Complementary Error Function” on page 1-2450 for each element of `x`. For inputs outside the interval `[0 2]`, `erfcinv` returns NaN. Use the `erfcinv` function to replace expressions containing `erfcinv(1-x)` for greater accuracy when `x` is close to 1.

### Examples

#### Find Inverse Complementary Error Function

```
erfcinv(0.3)
```

```
ans =
```

```
0.7329
```

Find the inverse complementary error function of the elements of a vector.

```
V = [-10 0 0.5 1.3 2 Inf];
erfcinv(V)
```

```
ans =
```

```
NaN Inf 0.4769 -0.2725 -Inf NaN
```

Find the inverse complementary error function of the elements of a matrix.

```
M = [0.1 1.2; 1 0.9];
erfcinv(M)
```

```
ans =
```

```
 1.1631 -0.1791
 0 0.0889
```

## Avoid Roundoff Errors Using Inverse Complementary Error Function

You can use the inverse complementary error function `erfcinv` in place of `erfinv(1-x)` to avoid roundoff errors when  $x$  is close to 0.

Show how to avoid roundoff by calculating `erfinv(1-x)` using `erfcinv(x)` for  $x = 1e-100$ . The original calculation returns `Inf` while `erfcinv(x)` returns the correct result.

```
x = 1e-100;
erfinv(1-x)
erfcinv(x)
```

```
ans =
```

```
 Inf
```

```
ans =
```

```
 15.0656
```

## Input Arguments

### **x** — Input

real number | vector of real numbers | matrix of real numbers | multidimensional array of real numbers

Input, specified as a real number, or a vector, matrix, or multidimensional array of real numbers.  $x$  cannot be sparse.

Data Types: `single` | `double`

## More About

### Inverse Complementary Error Function

The inverse complementary error function `erfcinv(x)` is defined as  $\text{erfcinv}(\text{erfc}(x)) = x$ .

### Tips

- You can also find the inverse standard normal probability distribution using the Statistics and Machine Learning Toolbox function `norminv`. The relationship between the inverse complementary error function `erfcinv` and `norminv` is

$$\text{norminv}(p) = (-\sqrt{2}) \times \text{erfcinv}(2p).$$

- For expressions of the form `erfcinv(1-x)`, use the inverse error function `erfinv` instead. This substitution maintains accuracy. When `x` is close to 1, then `1-x` is a small number and might be rounded down to 0. Instead, replace `erfcinv(1-x)` with `erfinv(x)`.

### See Also

# erfcx

Scaled complementary error function

## Syntax

`erfcx(x)`

## Description

`erfcx(x)` returns the value of the “Scaled Complementary Error Function” on page 1-2453 for each element of `x`. Use the `erfcx` function to replace expressions containing `exp(x^2)*erfc(x)` to avoid underflow or overflow errors.

## Examples

### Find Scaled Complementary Error Function

```
erfcx(5)
```

```
ans =
```

```
0.1107
```

Find the scaled complementary error function of the elements of a vector.

```
V = [-Inf -1 0 1 10 Inf];
erfcx(V)
```

```
ans =
```

```
Inf 5.0090 1.0000 0.4276 0.0561 0
```

Find the scaled complementary error function of the elements of a matrix.

```
M = [-0.5 15; 3.2 1];
erfcx(M)
```

```
ans =
```

```
 1.9524 0.0375
 0.1687 0.4276
```

## Avoid Roundoff Errors Using Scaled Complementary Error Function

You can use the scaled complementary error function `erfcx` in place of `exp(x^2)*erfc(x)` to avoid underflow or overflow errors.

Show how to avoid roundoff errors by calculating `exp(35^2)*erfc(35)` using `erfcx(35)`. The original calculation returns NaN while `erfcx(35)` returns the correct result.

```
x = 35;
exp(x^2)*erfc(x)
erfcx(x)
```

```
ans =
```

```
NaN
```

```
ans =
```

```
0.0161
```

## Input Arguments

### **x** — Input

real number | vector of real numbers | matrix of real numbers | multidimensional array of real numbers

Input, specified as a real number, or a vector, matrix, or multidimensional array of real numbers. `x` cannot be sparse.

Data Types: `single` | `double`

## More About

### Scaled Complementary Error Function

The scaled complementary error function `erfcx(x)` is defined as

$$\text{erfcx}(x) = e^{x^2} \text{erfc}(x).$$

For large  $X$ , `erfcx(X)` is approximately  $\left(\frac{1}{\sqrt{\pi}}\right)\frac{1}{x}$ .

### Tips

- For expressions of the form `exp(-x^2)*erfcx(x)`, use the complementary error function `erfc` instead. This substitution maintains accuracy by avoiding roundoff errors for large values of  $x$ .

### See Also

`erf` | `erfc` | `erfcinv` | `erfinv`

Introduced before R2006a

## **erfinv**

Inverse error function

### **Syntax**

```
erfinv(x)
```

### **Description**

`erfinv(x)` returns the “Inverse Error Function” on page 1-2459 evaluated for each element of `x`. For inputs outside the interval `[-1 1]`, `erfinv` returns `NaN`.

### **Examples**

#### **Find Inverse Error Function of Value**

```
erfinv(0.25)
```

```
ans =
```

```
0.2253
```

For inputs outside `[-1, 1]`, `erfinv` returns `NaN`. For `-1` and `1`, `erfinv` returns `-Inf` and `Inf`, respectively.

```
erfinv([-2 -1 1 2])
```

```
ans =
```

```
NaN -Inf Inf NaN
```

Find the inverse error function of the elements of a matrix.

```
M = [0 -0.5; 0.9 -0.2];
erfinv(M)
```

```
ans =
```

```
 0 -0.4769
 1.1631 -0.1791
```

### Plot the Inverse Error Function

Plot the inverse error function for  $-1 < x < 1$ .

```
x = -1:0.01:1;
y = erfinv(x);
plot(x,y)
grid on
xlabel('x')
ylabel('erfinv(x)')
title('Inverse Error Function for -1 < x < 1')
```

### Generate Gaussian Distributed Random Numbers

Generate Gaussian distributed random numbers using uniformly distributed random numbers. To convert a uniformly distributed random number  $x$  to a Gaussian distributed random number  $y$ , use the transform

$$y = \sqrt{2}\text{erf}^{-1}(x).$$

Note that because  $x$  has the form  $-1 + 2*\text{rand}(1,10000)$ , you can improve accuracy by using `erfcinv` instead of `erfinv`. For details, see “Tips”.

Generate 10,000 uniformly distributed random numbers on the interval  $[-1, 1]$ . Transform them into Gaussian distributed random numbers. Show that the numbers follow the form of the Gaussian distribution using a histogram plot.

```
rng('default')
x = -1 + 2*rand(1,10000);
y = sqrt(2)*erfinv(x);
h = histogram(y);
```

## Input Arguments

### **x** — Input

real number | vector of real numbers | matrix of real numbers | multidimensional array of real numbers

Input, specified as a real number, or a vector, matrix, or multidimensional array of real numbers. **x** cannot be sparse.

Data Types: `single` | `double`

## More About

### Inverse Error Function

The inverse error function `erfinv` is defined as the inverse of the error function, such that

$$\text{erfinv}(\text{erf}(x)) = x.$$

### Tips

- For expressions of the form `erfinv(1-x)`, use the complementary inverse error function `erfcinv` instead. This substitution maintains accuracy. When `x` is close to 1, then `1 - x` is a small number and may be rounded down to 0. Instead, replace `erfinv(1-x)` with `erfcinv(x)`.

## error

Throw error and display message

### Syntax

```
error(msg)
error(msg,A1,...,An)
error(msgID, ___)
error(errorStruct)
```

### Description

`error(msg)` throws an error and displays an error message.

`error(msg,A1,...,An)` displays an error message that contains formatting conversion characters, such as those used with the MATLAB `sprintf` function. Each conversion character in `msg` is converted to one of the values `A1,...,An`.

`error(msgID, ___ )` includes an error identifier on the exception. The identifier enables you to distinguish errors and to control what happens when MATLAB encounters the errors. You can include any of the input arguments in the previous syntaxes.

`error(errorStruct)` throws an error using the fields in a scalar structure.

### Examples

#### Throw Error

```
msg = 'Error occurred.';
error(msg)
```

```
Error occurred.
```

#### Throw Error with Formatted Message

Throw a formatted error message with a line break. You must specify more than one input argument with `error` if you want MATLAB to convert special characters (such as

\n) in the error message string. Include information about the class of variable `n` in the error message.

```
n = 7;
if ~ischar(n)
 error('Error. \nInput must be a char, not a %s.',class(n))
end
```

```
Error.
Input must be a char, not a double.
```

If you only use one input argument with `error`, then MATLAB does not convert `\n` to a line break.

```
if ~ischar(n)
 error('Error. \nInput must be a char.')
end
```

```
Error. \nInput must be a char.
```

Throw an error with an identifier.

```
if ~ischar(n)
 error('MyComponent:incorrectType',...
 'Error. \nInput must be a char, not a %s.',class(n))
end
```

```
Error.
Input must be a char, not a double.
```

Use the `MException.last` to view the last uncaught exception.

```
exception = MException.last
```

```
exception =
```

```
 MException with properties:
```

```
 identifier: 'MyComponent:incorrectType'
 message: 'Error.
Input must be a char, not a double.'
 cause: {0x1 cell}
```

```
stack: [0x1 struct]
```

### Throw Error Using Structure

Create structure with message and identifier fields. To keep the example simple, do not use the stack field.

```
errorStruct.message = 'Data file not found.';
errorStruct.identifier = 'MyFunction:fileNotFound';

errorStruct =

 message: 'Data file not found.'
 identifier: 'MyFunction:fileNotFound'
```

Throw the error.

```
error(errorStruct)

Data file not found.
```

- “Capture Information About Exceptions”

## Input Arguments

### **msg** — Information about error

string

Information about the error, specified as a string. This message displays as the error message. To format the string, use escape sequences, such as `\t` or `\n`. You also can use any format specifiers supported by the `sprintf` function, such as `%s` or `%d`. Specify values for the conversion specifiers via the `A1, . . . , An` input arguments. For more information, see “Formatting Strings”.

---

**Note:** You must specify more than one input argument with `error` if you want MATLAB to convert special characters (such as `\t`, `\n`, `%s`, and `%d`) in the error message string.

---

Example: 'File not found.'

### **msgID** — Identifier for error

string

Identifier for the error, specified as a string. Use the error identifier to help identify the source of the error or to control a selected subset of the errors in your program.

The error identifier includes a **component** and **mnemonic**. The identifier must always contain a colon and follows this simple format: **component:mnemonic**. The **component** and **mnemonic** fields must each begin with a letter. The remaining characters can be alphanumeric (A–Z, a–z, 0–9) and underscores. No whitespace characters can appear anywhere in **msgID**. For more information, see “Message Identifiers”.

Example: 'MATLAB:singularMatrix'

Example: 'MATLAB:narginchk:notEnoughInputs'

### **A1, . . . ,An — Numeric or character arrays**

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array. This input argument provides the values that correspond to and replace the conversion specifiers in **msg**.

### **errorStruct — Error reporting information**

scalar structure

Error reporting information, specified as a scalar structure. The structure must contain at least one of these fields.

|                   |                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>message</b>    | Error message string. For more information, see <b>msg</b> .                                                                                                                                                                                                                                                                                                                  |
| <b>identifier</b> | Error message identifier. For more information, see <b>msgID</b> .                                                                                                                                                                                                                                                                                                            |
| <b>stack</b>      | Stack field for the error. When <b>errorStruct</b> includes a <b>stack</b> field, <b>error</b> uses it to set the stack field of the error. When you specify <b>stack</b> , use the absolute file name and the entire sequence of functions that nests the function in the stack frame. This string is the same as the string returned by <b>dbstack(' -completenames')</b> . |

## More About

### Tips

- When you throw an error, MATLAB captures information about it and stores it in a data structure that is an object of the **MException** class. You can access information

in the exception object by using `try/catch`. Or, if your program terminates because of an exception and returns control to the Command Prompt, you can use `MException.last`.

- MATLAB does not cease execution of a program if an error occurs within a `try` block. In this case, MATLAB passes control to the `catch` block.
- If all inputs to `error` are empty, MATLAB does not throw an error.

## See Also

`MException` | `MException.last` | `assert` | `dbstack` | `errordlg` | `try` | `warning`

## errorbar

Plot error bars along curve

### Syntax

```
errorbar(Y,E)
errorbar(X,Y,E)
errorbar(X,Y,L,U)
errorbar(...,LineStyle)
errorbar(ax,...)
h = errorbar(...)
```

### Description

Error bars show the confidence intervals of data or the deviation along a curve.

`errorbar(Y,E)` plots  $Y$  and draws an error bar at each element of  $Y$ . The error bar is a distance of  $E(i)$  above and below the curve so that each bar is symmetric and  $2 \cdot E(i)$  long.

`errorbar(X,Y,E)` plots  $Y$  versus  $X$  with symmetric error bars  $2 \cdot E(i)$  long.  $X$ ,  $Y$ ,  $E$  must be the same size. When they are vectors, each error bar is a distance of  $E(i)$  above and below the point defined by  $(X(i), Y(i))$ . When they are matrices, each error bar is a distance of  $E(i, j)$  above and below the point defined by  $(X(i, j), Y(i, j))$ .

`errorbar(X,Y,L,U)` plots  $X$  versus  $Y$  with error bars  $L(i)+U(i)$  long specifying the lower and upper error bars.  $X$ ,  $Y$ ,  $L$ , and  $U$  must be the same size. When they are vectors, each error bar is a distance of  $L(i)$  below and  $U(i)$  above the point defined by  $(X(i), Y(i))$ . When they are matrices, each error bar is a distance of  $L(i, j)$  below and  $U(i, j)$  above the point defined by  $(X(i, j), Y(i, j))$ .

`errorbar(...,LineStyle)` uses the color and line style specified by the string 'LineStyle'. The color is applied to the data line and error bars. The linestyle and marker are applied to the data line only. See `linespec` for examples of styles.

`errorbar(ax,...)` plots into the axes specified by `ax` instead of the current axes.

`h = errorbar(...)` returns handles to the `errorbarseries` objects created. `errorbar` creates one object for vector input arguments and one object per column for matrix input arguments. See `Errorbar Series Properties` for more information.

When the arguments are all matrices, `errorbar` draws one line per matrix column. If `X` and `Y` are vectors, they specify one curve.

## Examples

### Symmetric Error Bars

Draw symmetric error bars that are two standard deviation units in length.

```
x = 0:pi/10:pi;
y = sin(x);
e = std(y)*ones(size(x));
```

```
figure
errorbar(x,y,e)
```

### Change Error Bar Marker and Color

Load the `count` data set to get the three-column matrix `count` that contains traffic volume for three street locations over the course of a day. Compute the mean of `count` for each row.

```
load count.dat;
y = mean(count,2);
```

Compute the standard deviation of `count` for each row and normalize by the number of elements in the sample by setting the second input argument to 1.

```
e = std(count,1,2);
```

Plot the computed average traffic volume,  $y$ , and the computed standard deviations,  $e$ , for the three street locations. Set the `LineStyle` to specify a red color, cross markers, and no line.

```
figure
errorbar(y,e,'rx')
```

### Properties

Errorbar Series Properties

**Introduced before R2006a**

## Errorbar Series Properties

Control errorbar series appearance and behavior

Errorbar series properties control the appearance and behavior of errorbar series object. By changing property values, you can modify certain aspects of the errorbar series.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = errorbar(...);
s = h.LineStyle;
h.LineStyle = ':';
```

If you are using an earlier release, use the `get` and `set` functions instead.

### Lines

#### LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                       |
|--------|------------------|--------------------------------------------------------------------------------------|
| '-'    | Solid line       |  |
| '--'   | Dashed line      |  |
| ':'    | Dotted line      |  |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                              |

#### LineWidth — Line width

0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

### Color — Line color

[0 0 0] (default) | RGB triplet | color string | 'none'

Line color, specified as an RGB triplet, a color string, or 'none'. The default RGB triplet value of [0 0 0] corresponds to black. If you specify the `Color` as 'none', then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

### AlignVertexCenters — Sharp vertical and horizontal lines

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a `GraphicsSmoothing` property set to 'on' and a `Renderer` property set to 'opengl', then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear

uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- `'off'` — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- `'on'` — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

---

**Note:** You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

---

## Markers

### Marker — Marker symbol

`'none'` (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the errorbar series object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

| String                                       | Marker Symbol                 |
|----------------------------------------------|-------------------------------|
| <code>'o'</code>                             | Circle                        |
| <code>'+'</code>                             | Plus sign                     |
| <code>'*'</code>                             | Asterisk                      |
| <code>'.'</code>                             | Point                         |
| <code>'x'</code>                             | Cross                         |
| <code>'square'</code> or <code>'s'</code>    | Square                        |
| <code>'diamond'</code> or <code>'d'</code>   | Diamond                       |
| <code>'^'</code>                             | Upward-pointing triangle      |
| <code>'v'</code>                             | Downward-pointing triangle    |
| <code>'&gt;'</code>                          | Right-pointing triangle       |
| <code>'&lt;'</code>                          | Left-pointing triangle        |
| <code>'pentagram'</code> or <code>'p'</code> | Five-pointed star (pentagram) |

| String            | Marker Symbol               |
|-------------------|-----------------------------|
| 'hexagram' or 'h' | Six-pointed star (hexagram) |
| 'none'            | No markers                  |

Example: '+'

Example: 'diamond'

### MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

### MarkerEdgeColor — Marker outline color

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the `Color` property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [ 1 1 0 ]   |
| 'magenta' | 'm'        | [ 1 0 1 ]   |
| 'cyan'    | 'c'        | [ 0 1 1 ]   |
| 'red'     | 'r'        | [ 1 0 0 ]   |
| 'green'   | 'g'        | [ 0 1 0 ]   |
| 'blue'    | 'b'        | [ 0 0 1 ]   |
| 'white'   | 'w'        | [ 1 1 1 ]   |
| 'black'   | 'k'        | [ 0 0 0 ]   |

Example: [0.5 0.5 0.5]

Example: 'blue'

### **MarkerFaceColor** — Marker fill color

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the Color property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: [0.3 0.2 0.1]

Example: 'green'

## **Data**

### **XData** — x values

[] (default) | vector

$x$  values, specified as a vector. The input argument `X` to the `errorbar` function sets the  $x$  values. If you do not specify `X`, then `errorbar` uses the indices of `YData` as the  $x$  values. `XData` and `YData` must have equal lengths.

Example: `1:10`

### **YData — y values**

`[]` (default) | vector

$y$  values, specified as a vector. The input argument `Y` to the `errorbar` function sets the  $y$  values. `XData` and `YData` must have equal lengths.

### **LData — Errorbar lengths below data points**

`[]` (default) | vector

Errorbar lengths below the data points, specified as a vector with length equal to `XData` and `YData`. Specify the values in data units.

Example: `1:10`

### **UData — Errorbar lengths above data points**

`[]` (default) | vector

Errorbar lengths above the data points, specified as a vector with length equal to `XData` and `YData`. Specify the values in data units.

Example: `1:10`

### **XDataSource — Variable linked to XData**

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'x'

## **YDataSource — Variable linked to YData**

' ' (default) | string containing MATLAB workspace variable name

Variable linked to **YData**, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the **YData**.

By default, there is no linked variable so the value is an empty string, ' '. If you link a variable, then MATLAB does not update the **YData** values immediately. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

Example: 'y'

## **LDataSource — Variable linked to LData**

' ' (default) | string containing MATLAB workspace variable

Variable linked to **LData**, specified as a string containing a MATLAB workspace variable. MATLAB evaluates the variable to generate the **LData**.

By default, there is no linked variable so the value is an empty string, ' '. If you change the variable for this property, then MATLAB does not update the **LData** values. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## **UDataSource — Variable linked to UData**

' ' (default) | string containing MATLAB workspace variable

Variable linked to **UData**, specified as a string containing a MATLAB workspace variable. MATLAB evaluates the variable to generate the **UData**.

By default, there is no linked variable so the value is an empty string, ''. If you change the variable for this property, then MATLAB does not update the `UData` values. To force an update of the data values, use the `refreshdata` function.

---

**Note:** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

### **XDataMode — Selection mode for XData**

'auto' (default) | 'manual'

Selection mode for `XData`, specified as one of these values:

- 'auto' — Use the indices of the values in `YData`.
- 'manual' — Use manually specified values. To specify the values, set the `XData` property or specify the input argument `X` to the plotting function.

## **Visibility**

### **Visible — State of visibility**

'on' (default) | 'off'

State of visibility, specified as one of these values:

- 'on' — Display the errorbar series.
- 'off' — Hide the errorbar series without deleting it. You still can access the properties of an invisible errorbar series object.

### **Clipping — Clipping of errorbar series object to axes limits**

'on' (default) | 'off'

Clipping of the errorbar series object to the axes limits, specified as one of these values:

- 'on' — Do not display parts of the errorbar series object that are outside the axes limits.
- 'off' — Display the entire errorbar series object, even if parts of it appear outside the axes limits. Parts of the errorbar series object might appear outside the axes

limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the errorbar series object so that it is larger than the original plot.

The `Clipping` property of the axes that contains the errorbar series object must be set to `'on'`, otherwise this property has no effect. For more information about the clipping behavior, see the `Clipping` property of the axes.

### **EraseMode — (removed) Technique to draw and erase objects**

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

---

**Note:** `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

---

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode`, `'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `COLOR` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Identifiers

### Type — Type of graphics object

'errorbar'

This property is read only.

Type of graphics object, returned as 'errorbar'. Use this property to find all objects of a given type within a plotting hierarchy, such as searching for the type using `findobj`.

### Tag — Tag to associate with errorbar series

' ' (default) | string

Tag to associate with the errorbar series, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: 'January Data'

Data Types: char

### UserData — Data to associate with errorbar series

[] (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the errorbar series object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: 1:100

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | table | cell

### DisplayName — Text used by legend

' ' (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the errorbar series.

Example: 'Text Description'

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `fprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where N is the number assigned to the errorbar series object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

### **Annotation — Legend icon display style**

Annotation object

This property is read only.

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the errorbar series from a legend.

- 1 Query the `Annotation` property to get the `Annotation` object.
- 2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
- 3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
  - `'on'` — Include the errorbar series object in the legend as one entry (default).
  - `'off'` — Do not include the errorbar series object in the legend.
  - `'children'` — Include only children of the errorbar series object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

## **Parent/Child**

### **Parent — Parent of errorbar series**

axes object | group object | transform object

Parent of errorbar series, specified as an axes, group, or transform object.

### **Children — Children of errorbar series**

empty `GraphicsPlaceholder` array

The errorbar series has no children. You cannot set this property.

### **HandleVisibility — Visibility of object handle**

'on' (default) | 'off' | 'callback'

Visibility of errorbar series object handle in the `Children` property of the parent, specified as one of these values:

- 'on' — The errorbar series object handle is always visible.
- 'off' — The errorbar series object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the `HandleVisibility` to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The errorbar series object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the errorbar series at the command-line, but allows callback functions to access it.

If the errorbar series object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to 'on' to list all object handles regardless of their `HandleVisibility` property setting.

## **Interactive Control**

### **ButtonDownFcn — Mouse-click callback**

' ' (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle

- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the errorbar series. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The errorbar series object — You can access properties of the errorbar series object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then this callback does not execute.

---

Example: `@myCallback`

Example: `{@myCallback, arg3}`

## **UIContextMenu — Context menu**

`uicontextmenu` object

Context menu, specified as a `uicontextmenu` object. Use this property to display a context menu when you right-click the errorbar series. Create the context menu using the `uicontextmenu` function.

---

**Note:** If the `PickableParts` property is set to 'none' or if the `HitTest` property is set to 'off', then the context menu does not appear.

---

## **Selected — Selection state**

'off' (default) | 'on'

Selection state, specified as one of these values:

- 'on' — Selected. If you click the errorbar series when in plot edit mode, then MATLAB sets its **Selected** property to 'on'. If the **SelectionHighlight** property also is set to 'on', then MATLAB displays selection handles around the errorbar series.
- 'off' — Not selected.

### **SelectionHighlight** — Display of selection handles when selected

'on' (default) | 'off'

Display of selection handles when selected, specified as one of these values:

- 'on' — Display selection handles when the **Selected** property is set to 'on'.
- 'off' — Never display selection handles, even when the **Selected** property is set to 'on'.

## **Callback Execution Control**

### **PickableParts** — Ability to capture mouse clicks

'visible' (default) | 'none'

Ability to capture mouse clicks, specified as one of these values:

- 'visible' — Can capture mouse clicks when visible. The **Visible** property must be set to 'on' and you must click a part of the errorbar series that has a defined color. You cannot click a part that has an associated color property set to 'none'. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The **HitTest** property determines if the errorbar series responds to the click or if an ancestor does.
- 'none' — Cannot capture mouse clicks. Clicking the errorbar series passes the click to the object below it in the current view of the figure window. The **HitTest** property of the errorbar series has no effect.

### **HitTest** — Response to captured mouse clicks

'on' (default) | 'off'

Response to captured mouse clicks, specified as one of these values:

- 'on' — Trigger the **ButtonDownFcn** callback of the errorbar series. If you have defined the **UIContextMenu** property, then invoke the context menu.

- 'off' — Trigger the callbacks for the nearest ancestor of the errorbar series that has a `HitTest` property set to 'on' and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

---

**Note:** The `PickableParts` property determines if the errorbar series object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

---

### **HitTestArea — (removed) Extents of clickable area for errorbar series**

'off' (default) | 'on'

---

**Note:** `HitTestArea` has been removed. Use `PickableParts` instead.

---

Extents of clickable area for errorbar series, specified as one of these values:

- 'off' — Click the errorbar series plot to select it. This is the default value.
- 'on' — Click anywhere within the extent of the errorbar series plot to select it, that is, anywhere within the rectangle that encloses the errorbar series plot.

Example: 'off'

### **Interruptible — Callback interruption**

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
  - The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.
-

If the `ButtonDownFcn` callback of the errorbar series is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

### **BusyAction — Callback queuing**

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

---

**Note:** There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

---

If the `ButtonDownFcn` callback of the errorbar series tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.

- 'cancel' — Discard the interrupting callback.

## Creation and Deletion Control

### **CreateFcn** — Creation callback

' ' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the errorbar series. Setting the `CreateFcn` property on an existing errorbar series has no effect. You must define a default value for this property, or define this property using a `Name, Value` pair during errorbar series creation. MATLAB executes the callback after creating the errorbar series and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The errorbar series object — You can access properties of the errorbar series object from within the callback function. You also can access the errorbar series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **DeleteFcn** — Deletion callback

' ' (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the errorbar series. MATLAB executes the callback before destroying the errorbar series so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The errorbar series object — You can access properties of the errorbar series object from within the callback function. You also can access the errorbar series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback, arg3}`

### **BeingDeleted** — Deletion status of errorbar series

'off' (default) | 'on'

This property is read only.

Deletion status of errorbar series, returned as 'on' or 'off'. MATLAB sets the `BeingDeleted` property to 'on' when the `delete` function of the errorbar series begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to 'on' until the errorbar series no longer exists.

Check the value of the `BeingDeleted` property to verify that the errorbar series is not about to be deleted before querying or modifying it.

# errordlg

Create error dialog box

## Syntax

```
h = errordlg
h = errordlg(errorstring)
h = errordlg(errorstring,dlgname)
h = errordlg(errorstring,dlgname,createmode)
```

## Description

`h = errordlg` creates and displays a dialog box entitled, Error Dialog, that contains the string, “This is the default error string.” The `errordlg` function returns the handle of the dialog box in `h`.

`h = errordlg(errorstring)` displays a dialog box entitled, Error Dialog, that contains the string, `errorstring`.

`h = errordlg(errorstring,dlgname)` displays a dialog box entitled, `dlgname`, that contains the string, `errorstring`.

`h = errordlg(errorstring,dlgname,createmode)` specifies whether the error dialog box is modal or nonmodal. Optionally, it can also specify an interpreter for `errorstring` and `dlgname`. The `createmode` argument can be a string or a structure.

If `createmode` is a string, it must be one of the values shown in the following table.

| createmode Value     | Description                                                                                                                                                                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'modal'              | Replaces the error dialog box having the specified <b>Title</b> , that was last created or clicked on, with a modal error dialog box as specified. All other error dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal. |
| 'nonmodal' (default) | Creates a new nonmodal error dialog box with the specified parameters. Existing error dialog boxes with the same title are not deleted.                                                                                                                                            |

| createmode Value | Description                                                                                                                                                                                                                                                                           |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'replace'        | Replaces the error dialog box having the specified <b>Title</b> , that was last created or clicked on, with a nonmodal error dialog box as specified. All other error dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal. |

---

**Note:** A modal dialog box prevents the user from interacting with other windows before responding. To block MATLAB program execution as well, use the `uiwait` function.

Modal dialogs (created using `errorDlg`, `msgbox`, or `warndlg`) replace any existing dialogs created with these functions that also have the same name.

For more information about modal dialog boxes, see `WindowState` in [Figure Properties](#).

---

If `CreateMode` is a structure, it can have fields `WindowState` and `Interpreter`. `WindowState` must be one of the options shown in the table above. `Interpreter` is one of the strings `'tex'` or `'none'`. The default value for `Interpreter` is `'none'`.

## Examples

This code,

```
errorDlg('File not found','File Error');
```

displays this dialog box:

This code,

```
mode = struct('WindowStyle','nonmodal',...
 'Interpreter','tex');
h = errordlg('Try this equation instead: f(x) = x^2',...
 'Equation Error', mode);
```

displays this dialog box:

## More About

### Tips

MATLAB sizes the dialog box to fit the string 'errorstring'. The error dialog box has an **OK** push button and remains on the screen until you press the **OK** button or the **Return** key. After pressing the button, the error dialog box disappears.

The appearance of the dialog box depends on the platform you use.

## etime

Time elapsed between date vectors

### Syntax

```
e = etime(t2,t1)
```

### Description

`e = etime(t2,t1)` returns the number of seconds between two date vectors or matrices of date vectors, `t1` and `t2`.

### Examples

#### Compute Elapsed Time

Compute the time elapsed between a specific time and the current time, to 0.01-second accuracy.

Define the initial date and time and convert to date vector form.

```
format shortg
str = 'March 28, 2012 11:51:00';
t1 = datevec(str, 'mmm dd, yyyy HH:MM:SS')
```

```
t1 =
```

```
 2012 3 28 11 51 0
```

Determine the current date and time.

```
t2 = clock
```

```
t2 =
```

2015

8

24

17

40

21.02

The `clock` function returns the current date and time as a date vector.

Use `etime` to compute the number of seconds between `t1` and `t2`.

```
e = etime(t2,t1)
```

```
e =
```

```
1.075e+08
```

## Input Arguments

### **t2, t1** — Date vectors

1-by-6 vector | m-by-6 matrix

Date vectors, specified as 1-by-6 vectors or m-by-6 matrices containing *m* full date vectors in the format: [Year Month Day Hour Minute Second].

Example: [2012 03 27 11 50 01]

Data Types: double

## More About

### Tips

- To time the duration of an event, use the `timeit` or `tic` and `toc` functions instead of `clock` and `etime`. The `clock` function is based on the system time, which can be adjusted periodically by the operating system, and thus might not be reliable in time comparison operations.

### Algorithms

`etime` does not account for the following:

- Leap seconds.

- Daylight savings time adjustments.
- Differences in time zones.

## **See Also**

`clock` | `cputime` | `now` | `tic` | `timeit` | `toc`

**Introduced before R2006a**

## etree

Elimination tree

### Syntax

```
p = etree(A)
p = etree(A, 'col')
p = etree(A, 'sym')
[p,q] = etree(...)
```

### Description

`p = etree(A)` returns an elimination tree for the square symmetric matrix whose upper triangle is that of `A`. `p(j)` is the parent of column `j` in the tree, or `0` if `j` is a root.

`p = etree(A, 'col')` returns the elimination tree of `A' * A`.

`p = etree(A, 'sym')` is the same as `p = etree(A)`.

`[p,q] = etree(...)` also returns a postorder permutation `q` of the tree.

### See Also

`treelayout` | `treepplot` | `etreeplot`

**Introduced before R2006a**

## etreeplot

Plot elimination tree

### Syntax

```
etreeplot(A)
etreeplot(A, nodeSpec, edgeSpec)
```

### Description

`etreeplot(A)` plots the elimination tree of  $A$  (or  $A+A'$ , if non-symmetric).

`etreeplot(A, nodeSpec, edgeSpec)` allows optional parameters `nodeSpec` and `edgeSpec` to set the node or edge color, marker, and linestyle. Use `' '` to omit one or both.

# eval

Execute MATLAB expression in text string

## Syntax

```
eval(expression)
[output1,...,outputN] = eval(expression)
```

## Description

`eval(expression)` evaluates the MATLAB code in the string `expression`. If you use `eval` within an anonymous function, nested function, or function that contains a nested function, the evaluated `expression` cannot create a variable.

`[output1,...,outputN] = eval(expression)` stores output from `expression` in the specified variables.

## Input Arguments

### **expression**

String that contains a valid MATLAB expression.

To include a numeric value in the expression, convert it to a string with `int2str`, `num2str`, or `sprintf`.

## Output Arguments

### **output1,...,outputN**

Outputs from the evaluated `expression`.

## Examples

### Variable Name Evaluation

Select a matrix to plot at runtime.

This example requires that you have a matrix in the current workspace. For example:

```
aMatrix = magic(5);
```

Interactively request the name of a matrix to plot, and call `eval` to use its value.

```
expression = input('Enter the name of a matrix: ', 's');
if (exist(expression, 'var'))
 mesh(eval(expression))
end
```

If you type `aMatrix` at the input prompt, this code creates a mesh plot of `magic(5)`.

## More About

### Tips

- Many common uses of the `eval` function are less efficient and are more difficult to read and debug than other MATLAB functions and language constructs. For more information, see “Alternatives to the `eval` Function”.
- Whenever possible, do not include output arguments within the input to the `eval` function, such as `eval(['output = ', expression])`. The preferred syntax,

```
output = eval(expression)
```

allows the MATLAB parser to perform stricter checks on your code, preventing untrapped errors and other unexpected behavior.

- “Alternatives to the `eval` Function”
- “Variables in Nested and Anonymous Functions”

`assignin` | `evalc` | `evalin` | `feval` | `try`

**Introduced before R2006a**

## **evalc**

Evaluate MATLAB expression with capture

### **Syntax**

```
T = evalc(expression)
[T,output1,...,outputN] = evalc(expression)
```

### **Description**

`T = evalc(expression)` is the same as `eval(expression)` except that anything that would normally be written to the command window, except for error messages, is captured and returned in the character array `T` (lines in `T` are separated by `\n` characters).

`[T,output1,...,outputN] = evalc(expression)` is the same as `[output1,...,outputN] = eval(expression)` except that any output is captured into `T`.

### **Input Arguments**

#### **expression**

String that contains a valid MATLAB expression.

To include a numeric value in the expression, convert it to a string with `int2str`, `num2str`, or `sprintf`.

### **Output Arguments**

#### **T**

Output normally written to the command window during the evaluation of `expression`, except for error messages, returned in a character array. The lines in `T` are separated by `\n` characters.

**output1, ..., outputN**

Outputs from the evaluated expression.

## More About

### Tips

When you are using `evalc`, functions `diary`, `more`, and `input` are disabled.

### See Also

`eval` | `evalin` | `assignin` | `more` | `feval` | `diary` | `input`

**Introduced before R2006a**

## evalin

Execute MATLAB expression in specified workspace

### Syntax

```
evalin(ws, expression)
[a1, a2, a3, ...] = evalin(ws, expression)
```

### Description

`evalin(ws, expression)` executes *expression*, a string containing any valid MATLAB expression using variables in the workspace *ws*. *ws* can have a value of 'base' or 'caller' to denote the MATLAB base workspace or the workspace of the caller function. You can construct *expression* by concatenating substrings and variables inside square brackets:

```
expression = [string1, int2str(var), string2,...]
```

`[a1, a2, a3, ...] = evalin(ws, expression)` executes *expression* and returns the results in the specified output variables. Using the `evalin` output argument list is recommended over including the output arguments in the expression string:

```
evalin(ws, '[a1, a2, a3, ...] = function(var)')
```

The above syntax avoids strict checking by the MATLAB parser and can produce untrapped errors and other unexpected behavior.

### Examples

This example extracts the value of the variable `var` in the MATLAB base workspace and captures the value in the local variable `v`:

```
v = evalin('base', 'var');
```

## Limitation

`evalin` cannot be used recursively to evaluate an expression. For example, a sequence of the form `evalin('caller', 'evalin(''caller'', ''x''))` doesn't work.

## More About

### Tips

The MATLAB base workspace is the workspace that is seen from the MATLAB command line (when not in the debugger). The caller workspace is the workspace of the function that called the currently running function. Note that the base and caller workspaces are equivalent in the context of a function that is invoked from the MATLAB command line.

`evalin('caller', expression)` finds only *variables* in the caller's workspace; it does not find *functions* in the caller. For this reason, you cannot use `evalin` to construct a handle to a function that is defined in the caller.

If you use `evalin('caller', expression)` in the MATLAB debugger after having changed your local workspace context with `dbup` or `dbdown`, MATLAB evaluates the expression in the context of the function that is one level up in the stack from your current workspace context.

`assignin` | `eval` | `evalc` | `feval` | `try`

**Introduced before R2006a**

## event.EventData

Base class for all data objects passed to event listeners

### Description

The `event.EventData` class defines the event data objects passed to listeners. When you trigger an event using the `notify` handle class method, MATLAB assigns values to the properties of the `event.EventData` object that is passed to the listener callback function (the event handler).

If you want to provide additional information to event listeners, you can do so by subclassing `event.EventData`. See “Define Event-Specific Data” for more information.

---

**Note:** Subclasses of `event.EventData` must set the class `ConstructOnLoad` attribute.

---

### Properties

The `event.EventData` class defines two properties and no methods:

- `EventName` — The name of the event described by this data object.
- `Source` — The source object whose class defines the event described by the data object.

### More About

- “Learn to Use Events and Listeners”
- “Class with Custom Event Data”

### See Also

`notify` | `event.PropertyEvent`

# event.listener

Class defining listener objects

## Syntax

```
lh = event.listener(Hobj, 'EventName', @CallbackFunction)
```

## Description

The `event.listener` class defines listener objects. Listener objects respond to the specified event and identify the callback function to invoke when the event is triggered.

`lh = event.listener(Hobj, 'EventName', @CallbackFunction)` creates an `event.listener` object, `lh`, for the event named in *EventName*, on the specified object, `Hobj`.

If `Hobj` is an array of object handles, the listener responds to the named event on any of the objects referenced in the array.

The listener callback function must accept at least two input arguments. For example,

```
function CallbackFunction(source, eventData)
 ...
end
```

where `source` is the object that is the source of the event and `eventData` is an `event.EventData` object.

The `event.listener` class is a handle class. The `event.listener` and the `event.proplistener` classes are part of the same heterogeneous hierarchy. Therefore, you can create arrays that contain objects of both classes. The class of an array containing both classes of objects is `event.listener`.

## Limiting Listener Lifecycle

Generally, you create a listener object using `addlistener`. However, you can call the `event.listener` constructor directly to create a listener. When you use the

`event.listener` constructor, the listener's lifecycle is not tied to the object(s) being listened to—once the listener object goes out of scope, the listener no longer exists. See “Control Listener Lifecycle” for more information on creating listener objects.

## Removing a Listener

If you call `delete(lh)` on the listener object, the listener ceases to exist, which means the event no longer causes the listener callback function to execute.

## Disabling a Listener

You can enable or disable a listener by setting the value of the listener's `Enabled` property (see Properties table below).

## More Information on Events and Listeners

See “Events” for more information and examples of how to use events and listeners.

## Properties

| Property  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Source    | Cell array of source objects                                                                                                                                                                                                                                                                                                                                                                                |
| EventName | Name of the event                                                                                                                                                                                                                                                                                                                                                                                           |
| Callback  | Function to execute when the event is triggered and the <code>Enabled</code> property is set to <code>true</code>                                                                                                                                                                                                                                                                                           |
| Enabled   | The callback executes when the event occurs if and only if <code>Enabled</code> is set to <code>true</code> (the default).                                                                                                                                                                                                                                                                                  |
| Recursive | When <code>false</code> (the default), this listener does not execute recursively. Therefore, if the callback triggers its own event, the listener does not execute again.<br><br>When <code>true</code> , the listener callback can cause the same event that triggered the callback. This scheme can lead to infinite recursion, which ends when the MATLAB recursion limit eventually triggers an error. |

Data for property events

### Description

The `event.PropertyEvent` class defines the data objects passed to listeners of the `meta.property` events:

- `PreGet`
- `PostGet`
- `PreSet`
- `PostSet`

`event.PropertyEvent` is a sealed subclass of `event.EventData` (i.e., you cannot subclass `event.PropertyEvent`).

### Properties

`event.PropertyEvent` inherits the first two properties from the `event.EventData`, and defines one new property:

- `EventName` — One of the four event names listed in the Description section
- `Source` — `meta.property` object that triggers the event
- `AffectedObject` — The object whose property is affected.

# event.proplistener

Define listener object for property events

## Syntax

```
lh =
event.proplistener(Hobj, Properties, 'PropEvent', @CallbackFunction)
```

## Description

```
lh =
event.proplistener(Hobj, Properties, 'PropEvent', @CallbackFunction)
```

creates a property listener object for one or more properties on the specified object.

- **Hobj** — handle of object whose property or properties are to be listened to. If **Hobj** is an array, the listener responds to the named event on all objects in the array.
- **Properties** — an object array or a cell array of `meta.property` object handles representing the properties to which you want to listen.
- **PropEvent** — must be one of the strings: `PreSet`, `PostSet`, `PreGet`, `PostGet`
- **@CallbackFunction** — function handle to the callback function that executes when the event occurs.

The `event.proplistener` class defines property event listener objects. It is a subclass of the `event.listener` class and adds one property to those defined by `event.listener`:

- **Object** — Cell array of objects whose property events are being listened to.

You can call the `event.proplistener` constructor instead of calling `addlistener` to create a property listener. However, when you do not use `addlistener`, the listener's lifecycle is not tied to the object(s) being listened to.

The `event.proplistener` class is a handle class. The `event.proplistener` and the `event.listener` classes are part of the same heterogeneous hierarchy. Therefore, you can create arrays that contain objects of both classes. The class of an array containing both classes of objects is `event.listener`.

See “Listen for Changes to Property Values”.

See “Get Information About Properties” for more information on using `meta.property` objects.

**Introduced in R2008a**

# eventlisteners

List event handler functions associated with COM object events

## Syntax

```
info = eventlisteners(h)
```

## Description

`info = eventlisteners(h)` lists the events and their event handler routines registered with COM object `h`. The function returns a cell array of strings `info`, with each row containing the name of a registered event and the handler routine for that event. If the object has no registered events, `eventlisteners` returns an empty cell array. You can register events either when you create the control, using `actxcontrol`, or at any time afterward, using `registerevent`.

COM functions are available on Microsoft Windows systems only.

## Examples

This example manages events for the MATLAB control, `mwsamp`.

```
f = figure('position',[100 200 200 200]);
% Create an mwsamp control and
% register the Click event
h = actxcontrol('mwsamp.mwsampctrl.2',...
 [0 0 200 200],f,{'Click' 'myclick'});
eventlisteners(h)

ans =
 'Click' 'myclick'
```

MATLAB displays the event name and its event handler, `myclick`.

Register two more events, `Db1Click` and `MouseDown`:

```
registerevent(h,{'Db1Click', 'my2click'; 'MouseDown' 'mymoused'})
```

```
eventlisteners(h)

ans =
 'Click' 'myclick'
 'Dblclick' 'my2click'
 'MouseDown' 'mymoused'
```

MATLAB displays all event names and handlers.

Unregister all events for the control:

```
unregisterallevents(h)
eventlisteners(h)

ans =
 {}
```

MATLAB displays an empty cell array, indicating the control has no registered events.

isevent | actxcontrol

**Introduced before R2006a**

## events

Event names

### Syntax

```
events('classname')
events(obj)
e = events(...)
```

### Description

`events('classname')` displays the names of the public events for the MATLAB class *classname*, including events inherited from superclasses.

`events(obj)` `obj` is a scalar or array of objects of a MATLAB class.

`e = events(...)` returns the event names in a cell array of strings.

An event is public when the value of its `ListenAccess` attribute is `public` and its `Hidden` attribute value is `false` (default values for both attributes). See “Event Attributes” for a complete list of attributes.

`events` is also a MATLAB class-definition keyword. See `classdef` for more information on class definition keywords.

### Examples

Get the names of the public events for the `handle` class:

```
events('handle')
Events for class handle:

 ObjectBeingDestroyed
```

### See Also

[properties](#) | [methods](#)

**Introduced before R2006a**

## events (COM)

List of events COM object can trigger

### Syntax

```
S = events(h)
```

### Description

`S = events(h)` returns structure array, `S`, containing all events, both registered and unregistered, known to the COM object, and the function prototype used when calling the event handler routine. For each array element, the structure field is the event name and the contents of that field is the function prototype for that event's handler.

COM functions are available on Microsoft Windows systems only.

## Examples

### List Control Events Example

Create an `mwsamp` control and list all events.

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],f);
events(h)

Click = void Click()
DblClick = void DblClick()
MouseDown = void MouseDown(int16 Button, int16 Shift,
 Variant x, Variant y)
Event_Args = void Event_Args(int16 typeshort, int32 typelong,
 double typedouble, string typestring, bool typebool)
```

Assign the output to a variable and get one field of the returned structure:

```
ev = events(h);
```

```
ev.MouseDown
```

```
ans =
void MouseDown(int16 Button, int16 Shift, Variant x, Variant y)
```

## List Workbook Events Example

Open a Microsoft Excel application and list all events for a Workbook object.

```
myApp = actxserver('Excel.Application');
wbs = myApp.Workbooks;
wb = Add(wbs);
events(wb)
```

The MATLAB software displays all events supported by the Workbook object.

# exceltime

Convert MATLAB datetime to Excel date number

## Syntax

```
e = exceltime(t)
e = exceltime(t,dateType)
```

## Description

`e = exceltime(t)` returns a double array containing Excel serial date numbers equivalent to the datetime values in `t`. Excel serial date numbers are the number of days and fractional days since 0-January-1900 00:00:00, and do not take into account time zone and leap seconds.

`e = exceltime(t,dateType)` returns the type of Excel serial date numbers specified by `dateType`. For example, you can convert datetime values to the number of days since 1-January-1904 00:00:00.

## Examples

### Convert Datetime Array to Excel Date Numbers

Create a datetime array. Then, convert the dates to the equivalent Excel® serial date numbers.

```
t = datetime('now') + calmonths(1:3)
```

```
t =
```

```
 24-Sep-2015 18:00:02 24-Oct-2015 18:00:02 24-Nov-2015 18:00:02
```

```
e = exceltime(t)
```

```
e =

1.0e+04 *

4.2272 4.2302 4.2333
```

## Input Arguments

### **t** — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

### **dateType** — Type of Excel serial date numbers

'1900' (default) | '1904'

Type of Excel serial date numbers, specified as either '1900' or '1904'.

- If `dateType` is '1900', then `exceltime` converts the `datetime` values in `t` to the equivalent the number of days and fractional days since 0-January-1900 00:00:00.
- If `dateType` is '1904', then `exceltime` converts the `datetime` values in `t` to the equivalent the number of days and fractional days since 1-January-1904 00:00:00.

`exceltime` does not account for time zone.

Example:

## Output Arguments

### **e** — Excel serial date numbers

scalar | vector | matrix | multidimensional array

Excel serial date numbers, returned as a scalar, vector, matrix, or multidimensional array of type `double`. Excel serial date numbers are not defined prior to their epoch (0-January-1900 or 1-January-1904). Excel serial date numbers treat 1900 as a leap year. Therefore, dates after February 28, 1900 are offset by one day relative to MATLAB serial date numbers, and there is a discontinuity of one day between February 28, 1900 and March 1, 1900.

`datenum` | `datetime` | `juliandate` | `posixtime` | `yyyymmdd`

**Introduced in R2014b**

## Execute

Execute MATLAB command in Automation server

## Syntax

### IDL Method Signature

```
BSTR Execute([in] BSTR command)
```

### Microsoft Visual Basic Client

```
Execute(command As String) As String
```

### MATLAB Client

```
result = Execute(h, 'command')
```

## Description

The `Execute` function executes the MATLAB statement specified by the string `command` in the MATLAB Automation server attached to handle `h`.

The server returns output from the command in the string, `result`. The `result` string also contains any MATLAB warning or error messages.

If you terminate the MATLAB command string with a semicolon and there are no warnings or error messages, `result` might be returned empty.

COM functions are available on Microsoft Windows systems only.

## Visual Basic .NET Examples

Create a 6-by-6 matrix in the MATLAB server, remove rows 4-6, and return the results to the client.

```
Dim Matlab As Object
Dim server_version As String
Matlab = CreateObject("matlab.application")
MatLab.PutWorkspaceData("A","base",rand(6))
Matlab.Execute("A(4:6,:) = [];")
Matlab.GetWorkspaceData("A","base",B)
```

## More About

### Tips

If you want to display output from `Execute` in the client window, specify an output variable, `result`.

If there is an error, the `Execute` function returns the MATLAB error message with the characters `???` prepended to the text.

### See Also

## exifread

Read EXIF information from JPEG and TIFF image files

### Syntax

---

**Note:** `exifread` has been removed. Use `imfinfo` instead.

---

```
output = exifread(filename)
```

### Description

`output = exifread(filename)` reads the Exchangeable Image File Format (EXIF) data from the file specified by the string `filename`. `filename` must specify a JPEG or TIFF image file. `output` is a structure containing metadata values about the image or images in `imagefile`.

---

**Note** `exifread` returns all EXIF tags and does not process them in any way.

---

EXIF is a standard used by digital camera manufacturers to store information in the image file, such as, the make and model of a camera, the time the picture was taken and digitized, the resolution of the image, exposure time, and focal length.

# exist

Check existence of variable, function, folder, or class

## Syntax

```
exist name
exist name kind
A = exist('name','kind')
```

## Description

`exist name` returns the status of `name`:

|   |                                                                                                                                                                                                                                                                                                                                   |
|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | <code>name</code> does not exist.                                                                                                                                                                                                                                                                                                 |
| 1 | <code>name</code> is a variable in the workspace.                                                                                                                                                                                                                                                                                 |
| 2 | One of the following is true: <ul style="list-style-type: none"> <li><code>name</code> exists on your MATLAB search path as a file with extension <code>.m</code>.</li> <li><code>name</code> is the name of an ordinary file on your MATLAB search path.</li> <li><code>name</code> is the full pathname to any file.</li> </ul> |
| 3 | <code>name</code> exists as a MEX-file on your MATLAB search path.                                                                                                                                                                                                                                                                |
| 4 | <code>name</code> exists as a Simulink model or library file on your MATLAB search path.                                                                                                                                                                                                                                          |
| 5 | <code>name</code> is a built-in MATLAB function.                                                                                                                                                                                                                                                                                  |
| 6 | <code>name</code> is a P-file on your MATLAB search path.                                                                                                                                                                                                                                                                         |
| 7 | <code>name</code> is a folder.                                                                                                                                                                                                                                                                                                    |
| 8 | <code>name</code> is a class. ( <code>exist</code> returns 0 for Java classes if you start MATLAB with the <code>-nojvm</code> option.)                                                                                                                                                                                           |

If `name` is a class, then `exist('name')` returns an 8. However, if `name` is a class file, then `exist('name')` returns a 2.

If a file or folder is not on the search path, then `name` must specify either a full pathname, a partial pathname relative to `MATLABPATH`, a partial pathname relative to your current folder, or the file or folder must reside in your current working folder.

If `name` specifies a filename, that filename may include an extension to preclude conflicting with other similar filenames. For example, `exist('file.ext')`.

`exist name kind` returns the status of `name` for the specified `kind`. If `name` of type `kind` does not exist, it returns 0. The `kind` argument may be one of the following:

|                      |                                     |
|----------------------|-------------------------------------|
| <code>builtin</code> | Checks only for built-in functions. |
| <code>class</code>   | Checks only for classes.            |
| <code>dir</code>     | Checks only for folders.            |
| <code>file</code>    | Checks only for files or folders.   |
| <code>var</code>     | Checks only for variables.          |

If you do not specify a `kind` argument, and `name` belongs to more than one of these categories, `exist` returns one value according to the order of evaluation shown in the table below. For example, if `name` matches both a folder and a file that defines a MATLAB function, `exist` returns 7, identifying it as a folder.

| Order of Evaluation | Return Value | Type of Entity  |
|---------------------|--------------|-----------------|
| 1                   | 1            | Variable        |
| 2                   | 5            | Built-in        |
| 3                   | 7            | Folder          |
| 4                   | 3            | MEX-file        |
| 5                   | 6            | P-file          |
| 6                   | 2            | MATLAB function |
| 7                   | 4            | SLX or MDL-file |
| 8                   | 8            | Class           |

`A = exist('name', 'kind')` is the function form of the syntax.

## Examples

### Check Existence of Workspace Variable

Create a variable named `|testresults`, and then check its existence in the workspace.

```
testresults = magic(5);
exist testresults var
```

```
ans =
 1
```

A variable named `testresults` exists in the workspace.

### Check if MATLAB Function is Built-In Function

Check whether the `plot` function is a built-in function or a file.

```
A = exist('plot')
```

```
A =
 5
```

This indicates that `plot` is a built-in MATLAB function.

## More About

### Tips

If `name` specifies a filename, MATLAB attempts to locate the file, examines the filename extension, and determines the value to return based on the extension alone. MATLAB does not examine the contents or internal structure of the file.

You can specify a partial path to a folder or file. A partial pathname is a pathname relative to the MATLAB path that contains only the trailing one or more components of the full pathname. For example, both of the following commands return `2`, identifying `mkdir.m` as a MATLAB function. The first uses a partial pathname:

```
exist('matlab/general/mkdir.m')
exist([matlabroot '/toolbox/matlab/general/mkdir.m'])
```

To check for the existence of more than one variable, use the `ismember` function. For example,

```
a = 5.83;
c = 'teststring';
ismember({'a','b','c'},who)
```

```
ans =
```

```
 1 0 1
```

**Introduced before R2006a**

## exit

Terminate MATLAB program (same as `quit`)

## Alternatives

As an alternative to the `exit` function, click the Close box in the MATLAB desktop.

## Syntax

```
exit
exit(code)
```

## Description

`exit` terminates the current session of MATLAB after running `finish.m`, if the file `finish.m` exists. It performs the same as `quit` and takes the same termination options, such as **force**. Call `exit` from the MATLAB command prompt. To interrupt a MATLAB command, see “Stop Execution”.

`exit(code)` returns exit code when calling a MATLAB command from the system command line.

## More About

- “Stop Execution”

## See Also

`quit` | `finish`

Introduced before R2006a

## exp

Exponential

## Syntax

$Y = \exp(X)$

## Description

$Y = \exp(X)$  returns the exponential  $e^x$  for each element in array  $X$ . For complex elements  $z = x + iy$ , it returns the complex exponential

$$e^z = e^x (\cos y + i \sin y).$$

Use `expm` to compute a matrix exponential.

## Examples

### Numeric Representation of e

Calculate the exponential of 1, which is Euler's number,  $e$ .

```
exp(1)
```

```
ans =
```

```
2.7183
```

### Euler's Identity

Euler's identity is the equality  $e^{i\pi} + 1 = 0$ .

Compute the value of  $e^{i\pi}$ .

```
Y = exp(1i*pi)
```

```
Y =
```

```
-1.0000 + 0.0000i
```

### Plot Exponential Function

Plot  $y = e^{x/2}$  for x values in the range  $[-2, 10]$ .

```
X = -2:0.5:10;
```

```
Y = exp(X/2);
```

```
plot(X,Y)
```

## Input Arguments

### **X** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

Complex Number Support: Yes

## Output Arguments

### **Y — Exponential values**

scalar | vector | matrix | multidimensional array

Exponential values, returned as a scalar, vector, matrix, or multidimensional array.

For real values of  $X$  in the interval  $(-\text{Inf}, \text{Inf})$ ,  $Y$  is in the interval  $(0, \text{Inf})$ . For complex values of  $X$ ,  $Y$  is complex. The data type of  $Y$  is the same as that of  $X$ .

### **See Also**

expint | expm | expm1 | log | log10 | mpower | power

**Introduced before R2006a**

## **expint**

Exponential integral

### **Syntax**

$Y = \text{expint}(X)$

### **Definitions**

The exponential integral computed by this function is defined as

$$E_1(x) = \int_x^{\infty} e^{-t} / t \, dt$$

Another common definition of the exponential integral function is the Cauchy principal value integral

$$\text{Ei}(x) = \int_{-\infty}^x e^t / t \, dt$$

which, for real positive  $x$ , is related to `expint` as

$$E_1(-x) = -\text{Ei}(x) - i\pi$$

### **Description**

$Y = \text{expint}(X)$  evaluates the exponential integral for each element of  $X$ .

### **References**

- [1] Abramowitz, M. and I. A. Stegun. *Handbook of Mathematical Functions*. Chapter 5, New York: Dover Publications, 1965.

**Introduced before R2006a**

## **expm**

Matrix exponential

### **Syntax**

`Y = expm(X)`

### **Description**

`Y = expm(X)` computes the matrix exponential of `X`. Although it is not computed this way, if `X` has a full set of eigenvectors `V` with corresponding eigenvalues `D`, then `[V,D] = eig(X)` and

$$\text{expm}(X) = V \cdot \text{diag}(\exp(\text{diag}(D))) / V$$

Use `exp` for the element-by-element exponential.

### **Examples**

#### **Compare Exponentials**

Compute and compare the exponential of `A` with the *matrix* exponential of `A`.

```
A = [1 1 0; 0 0 2; 0 0 -1];
exp(A)
```

```
ans =
```

```
 2.7183 2.7183 1.0000
 1.0000 1.0000 7.3891
 1.0000 1.0000 0.3679
```

```
expm(A)
```

```
ans =
```

|        |        |        |
|--------|--------|--------|
| 2.7183 | 1.7183 | 1.0862 |
| 0      | 1.0000 | 1.2642 |
| 0      | 0      | 0.3679 |

Notice that the diagonal elements of the two results are equal, which is true for any triangular matrix. The off-diagonal elements, including those below the diagonal, are different.

## Input Arguments

### **X** — Input matrix

square matrix

Input matrix, specified as a square matrix.

Data Types: `single` | `double`

Complex Number Support: Yes

## More About

### Algorithms

The algorithm `expm` uses is described in [1] and [2].

---

**Note** The files `expmdemo1.m`, `expmdemo2.m`, and `expmdemo3.m` illustrate the use of Padé approximation, Taylor series approximation, and eigenvalues and eigenvectors, respectively, to compute the matrix exponential. References [3] and [4] describe and compare many algorithms for computing a matrix exponential.

# expm1

Compute  $\exp(x)-1$  accurately for small values of  $x$

## Syntax

$y = \text{expm1}(x)$

## Description

$y = \text{expm1}(x)$  computes  $\exp(x) - 1$ , compensating for the roundoff in  $\exp(x)$ .

For small  $x$ ,  $\text{expm1}(x)$  is approximately  $x$ , whereas  $\exp(x) - 1$  can be zero.

## export2wsdlg

Create dialog box for exporting variables to workspace

### Syntax

```
export2wsdlg(cklabels,defaultvars,xitems)
export2wsdlg(cklabels,defaultvars,xitems,title)
export2wsdlg(cklabels,defaultvars,xitems,title,selected)
export2wsdlg(cklabels,defaultvars,xitems,title,selected,helpfunction)
export2wsdlg(cklabels,defaultvars,xitems,title,selected,helpfunction,function1)
hdialog = export2wsdlg(...)
[hdialog,ok_pressed] = export2wsdlg(...)
```

### Description

`export2wsdlg(cklabels,defaultvars,xitems)` creates a dialog with a series of check boxes and edit fields. `cklabels` is a cell array of labels for the check boxes. `defaultvars` is a cell array of strings that serve as a basis for variable names that appear in the edit fields. `xitems` is a cell array of the values to be stored in the variables. If there is only one item to export, `export2wsdlg` creates a text control instead of a check box.

---

**Note:** By default, the dialog box is modal. A modal dialog box prevents the user from interacting with other windows before responding.

---

`export2wsdlg(cklabels,defaultvars,xitems,title)` creates the dialog with `title` as its title.

`export2wsdlg(cklabels,defaultvars,xitems,title,selected)` creates the dialog allowing the user to control which check boxes are checked. `selected` is a logical array whose length is the same as `cklabels`. True indicates that the check box should initially be checked, false unchecked.

`export2wsdlg(cklabels,defaultvars,xitems,title,selected,helpfunction)` creates the dialog with a help button. `helpfunction` is a callback that displays help.

`export2wsdlg(cklabels,defaultvars,xitems,title,selected,helpfunction,functionlist)` creates a dialog that enables the user to pass in `functionlist`, a cell array of functions and optional arguments that calculate, then return the value to export. `functionlist` should be the same length as `cklabels`.

`hdialog = export2wsdlg(...)` returns the handle of the dialog.

`[hdialog,ok_pressed] = export2wsdlg(...)` sets `ok_pressed` to true if the OK button is pressed, or false otherwise. If two return arguments are requested, `hdialog` is `[]` and the function does not return until the dialog is closed.

The user can edit the text fields to modify the default variable names. If the same name appears in multiple edit fields, `export2wsdlg` creates a structure using that name. It then uses the `defaultvars` as field names for that structure.

The lengths of `cklabels`, `defaultvars`, `xitems` and `selected` must all be equal.

The strings in `defaultvars` must be unique.

## Examples

This example creates a dialog box that enables the user to save the variables `sumA` and/or `meanA` to the workspace. The dialog box title is `Save Sums to Workspace`.

```
A = randn(10,1);
checkLabels = {'Save sum of A to variable named:' ...
 'Save mean of A to variable named:'};
varNames = {'sumA','meanA'};
items = {sum(A),mean(A)};
export2wsdlg(checkLabels,varNames,items,...
 'Save Sums to Workspace');
```

## **exportsetupdlg**

Open figure Export Setup dialog box

### **Syntax**

```
exportsetupdlg(f)
exportsetupdlg
```

### **Description**

`exportsetupdlg(f)` displays the export settings dialog box. MATLAB applies your selections to the figure, `f`.

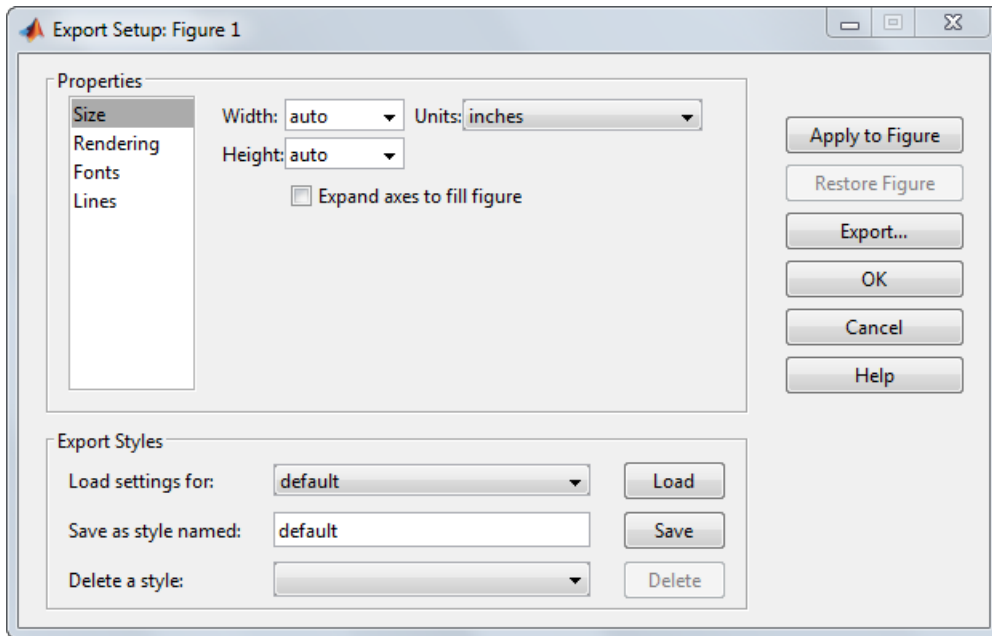

`exportsetupdlg` applies your selections to the current figure. If no figure exists, MATLAB creates a new figure.

### **Examples**

#### **Export Setting for a Figure**

Create a figure and display the Export Setup dialog.

```
f = figure;
exportsetupdlg(f);
```

## Input Arguments

### **f** — Target figure

figure object

Target figure, specified as a figure object.

Introduced in R2006b

## eye

Identity matrix

### Syntax

```
I = eye
```

```
I = eye(n)
```

```
I = eye(n,m)
```

```
I = eye(sz)
```

```
I = eye(classname)
```

```
I = eye(n,classname)
```

```
I = eye(n,m,classname)
```

```
I = eye(sz,classname)
```

```
I = eye('like',p)
```

```
I = eye(n,'like',p)
```

```
I = eye(n,m,'like',p)
```

```
I = eye(sz,'like',p)
```

### Description

`I = eye` returns the scalar, 1.

`I = eye(n)` returns an  $n$ -by- $n$  identity matrix with ones on the main diagonal and zeros elsewhere.

`I = eye(n,m)` returns an  $n$ -by- $m$  matrix with ones on the main diagonal and zeros elsewhere.

`I = eye(sz)` returns an array with ones on the main diagonal and zeros elsewhere. The size vector, `sz`, defines `size(I)`. For example, `eye([2,3])` returns a 2-by-3 array with ones on the main diagonal and zeros elsewhere.

`I = eye(classname)` returns a scalar, 1, where the string, `classname`, specifies the data type. For example, `eye('int8')` returns a scalar, 8-bit integer.

`I = eye(n,classname)` returns an  $n$ -by- $n$  identity matrix of data type `classname`.

`I = eye(n,m,classname)` returns an  $n$ -by- $m$  matrix of data type `classname` with ones on the main diagonal and zeros elsewhere.

`I = eye(sz,classname)` returns a matrix with ones on the main diagonal and zeros elsewhere. The size vector, `SZ`, defines `size(I)` and `classname` defines `class(I)`.

`I = eye('like',p)` returns a scalar, 1, with the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`I = eye(n,'like',p)` returns an  $n$ -by- $n$  identity matrix like `p`.

`I = eye(n,m,'like',p)` returns an  $n$ -by- $m$  matrix like `p`.

`I = eye(sz,'like',p)` returns a matrix like `p` where the size vector, `SZ`, defines `size(I)`.

## Examples

### Square Identity Matrix

Create a 4-by-4 identity matrix.

```
I = eye(4)
```

```
I =
```

```
 1 0 0 0
 0 1 0 0
 0 0 1 0
 0 0 0 1
```

### Rectangular Matrix

Create a 2-by-3 identity matrix.

```
I = eye(2,3)
```

```
I =
```

```
 1 0 0
```

```
0 1 0
```

## Identity Vector

Create a 3-by-1 identity vector.

```
sz = [3,1];
I = eye(sz)
```

```
I =
```

```
1
0
0
```

## Nondefault Numeric Data Type

Create a 3-by-3 identity matrix whose elements are 32-bit unsigned integers.

```
I = eye(3, 'uint32'),
class(I)
```

```
I =
```

```
1 0 0
0 1 0
0 0 1
```

```
ans =
```

```
uint32
```

## Complex Identity Matrix

Create a 2-by-2 identity matrix that is not real valued, but instead is complex like an existing array.

Define a complex vector.

```
p = [1+2i 3i];
```

Create an identity matrix that is complex like p.

```
I = eye(2, 'like', p)
```

```
I =
```

```
 1.0000 + 0.0000i 0.0000 + 0.0000i
 0.0000 + 0.0000i 1.0000 + 0.0000i
```

### Sparse Identity Matrix

Define a 5-by-5 sparse matrix.

```
p = sparse(5,5,pi);
```

Create a 5-by-5 identity matrix that is sparse like P.

```
I = eye(5, 'like', p)
```

```
I =
```

```
 (1,1) 1
 (2,2) 1
 (3,3) 1
 (4,4) 1
 (5,5) 1
```

### Size and Numeric Data Type Defined by Existing Array

Define a 2-by-2 matrix of single precision.

```
p = single([1 3 ; 2 4]);
```

Create an identity matrix that is the same size and data type as P.

```
I = eye(size(p), 'like', p),
class(I)
```

```
I =
```

```
 1 0
 0 1
```

```
ans =
```

single

## Input Arguments

### **n** — Size of first dimension of **I**

integer value

Size of first dimension of **I**, specified as an integer value.

- If **n** is the only integer input argument, then **I** is a square **n**-by-**n** identity matrix.
- If **n** is 0, then **I** is an empty matrix.
- If **n** is negative, then it is treated as 0.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **m** — Size of second dimension of **I**

integer value

Size of second dimension of **I**, specified as an integer value.

- If **m** is 0, then **I** is an empty matrix.
- If **m** is negative, then it is treated as 0.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### **sz** — Size of **I**

row vector of no more than two integer values

Size of **I**, specified as a row vector of no more than two integer values.

- If an element of **sz** is 0, then **I** is an empty matrix.
- If an element of **sz** is negative, then the element is treated as 0.

Example: **sz** = [2,3] defines **I** as a 2-by-3 matrix.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**classname — Output class**

'double' (default) | 'single' | 'int8' | 'uint8' | ...

Output class, specified as 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', or 'uint64'.

Data Types: char

**p — Prototype**

numeric variable

Prototype, specified as a numeric variable.

Data Types: double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Complex Number Support: Yes

## ezcontour

Easy-to-use contour plotter

### Syntax

```
ezcontour(fun)
ezcontour(fun, domain)
ezcontour(..., n)
ezcontour(axes_handle, ...)
h = ezcontour(...)
```

### Description

`ezcontour(fun)` plots the contour lines of `fun(x,y)` using the `contour` function. `fun` is plotted over the default domain:  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle for a MATLAB file function or an anonymous function (see “Create Function Handle” and “Anonymous Functions”) or a string (see Tips).

`ezcontour(fun, domain)` plots `fun(x,y)` over the specified domain. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]` (where  $\min < x < \max$ ,  $\min < y < \max$ ).

`ezcontour(..., n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezcontour(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezcontour(...)` returns the handle to a contour object in `h`.

`ezcontour` automatically adds a title and axis labels.

### Examples

#### Create Contour Plot of Mathematical Expression

This mathematical expression defines a function of two variables, `x` and `y`.

$$f(x, y) = 3(1 - x)^2 e^{-x^2 - (y+1)^2} - 10 \left( \frac{x}{5} - x^3 - y^5 \right) e^{-x^2 - y^2} - \frac{1}{3} e^{-(x+1)^2 - y^2}$$

The `ezcontour` function requires a function handle argument. Write this mathematical expression in MATLAB® syntax as an anonymous function with handle `f`. You can define an anonymous function in the command window without creating a separate file. For convenience, write the function on three lines.

```
f = @(x,y) 3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...
- 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...
- 1/3*exp(-(x+1).^2 - y.^2);
```

Pass the function handle, `f`, to `ezcontour`. Specify a domain from -3 to 3 in both the x-direction and y-direction and use a 49-by-49 computational grid.

```
ezcontour(f, [-3,3], 49)
```

In this particular case, the title string is too long to fit at the top of the graph so MATLAB® abbreviates the string.

## More About

### Tips

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezcontour`. For example, the MATLAB syntax for a contour plot of the expression

```
sqrt(x.^2 + y.^2)
```

is written as

```
ezcontour('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as `x.^2` in the string you pass to `ezcontour`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezcontour('u^2 - v^3', [0, 1], [3, 6])` plots the contour lines for  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

### Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezcontour`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezcontour(fh)
```

When using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezcontour` does not alter the syntax, as in the case with string inputs.

## Passing Additional Arguments

If your function has additional parameters, for example, `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then use an anonymous function to specify that parameter:

```
ezcontour(@(x,y)myfun(x,y,2))
```

## See Also

**Introduced before R2006a**

# ezcontourf

Easy-to-use filled contour plotter

## Syntax

```
ezcontourf(fun)
ezcontourf(fun, domain)
ezcontourf(..., n)
ezcontourf(axes_handle, ...)
h = ezcontourf(...)
```

## Description

`ezcontourf(fun)` plots the contour lines of `fun(x,y)` using the `contourf` function. `fun` is plotted over the default domain:  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle or a string (see Tips).

`ezcontourf(fun, domain)` plots `fun(x,y)` over the specified `domain`. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]`, where  $\min < x < \max$ ,  $\min < y < \max$ .

`ezcontourf(..., n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezcontourf(axes_handle, ...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = ezcontourf(...)` returns the handle to a contour object in `h`.

`ezcontourf` automatically adds a title and axis labels.

## Examples

### Create Filled Contour Plot of Mathematical Expression

This mathematical expression defines a function of two variables, `x` and `y`.

$$f(x, y) = 3(1 - x)^2 e^{-x^2 - (y+1)^2} - 10 \left( \frac{x}{5} - x^3 - y^5 \right) e^{-x^2 - y^2} - \frac{1}{3} e^{-(x+1)^2 - y^2}$$

The `ezcontourf` function requires a function handle argument. Write this mathematical expression in MATLAB® syntax as an anonymous function with handle `f`. You can define an anonymous function in the command window without creating a separate file. For convenience, write the function on three lines.

```
f = @(x,y) 3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...
- 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...
- 1/3*exp(-(x+1).^2 - y.^2);
```

Pass the function handle, `f`, to `ezcontourf`. Specify a domain from -3 to 3 in both the x-direction and y-direction and use a 49-by-49 computational grid.

```
ezcontourf(f, [-3,3], 49)
```

In this particular case, the title string is too long to fit at the top of the graph so MATLAB® abbreviates the string.

## More About

### Tips

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezcontourf`. For example, the MATLAB syntax for a filled contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezcontourf('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as `x.^2` in the string you pass to `ezcontourf`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezcontourf('u^2 - v^3', [0,1], [3,6])` plots the contour lines for  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

### Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezcontourf`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezcontourf(fh)
```

When using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezcontourf` does not alter the syntax, as in the case with string inputs.

## Passing Additional Arguments

If your function has additional parameters, for example, `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezcontourf(@(x,y)myfun(x,y,2))
```

- [Anonymous Functions](#)

## ezmesh

Easy-to-use 3-D mesh plotter

### Syntax

```
ezmesh(fun)
ezmesh(fun, domain)
ezmesh(funx, funy, funz)
ezmesh(funx, funy, funz, [smin, smax, tmin, tmax])
ezmesh(funx, funy, funz, [min, max])
ezmesh(..., n)
ezmesh(..., 'circ')
ezmesh(axes_handle, ...)
h = ezmesh(...)
```

### Description

`ezmesh(fun)` creates a graph of `fun(x, y)` using the `mesh` function. `fun` is plotted over the default domain:  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle or a string (see the Tips section).

`ezmesh(fun, domain)` plots `fun` over the specified `domain`. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]` (where  $\min < x < \max$ ,  $\min < y < \max$ ).

`ezmesh(funx, funy, funz)` plots the parametric surface `funx(s, t)`, `funy(s, t)`, and `funz(s, t)` over the square:  $-2\pi < s < 2\pi$ ,  $-2\pi < t < 2\pi$ .

`ezmesh(funx, funy, funz, [smin, smax, tmin, tmax])` or `ezmesh(funx, funy, funz, [min, max])` plots the parametric surface using the specified domain.

`ezmesh(..., n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezmesh(..., 'circ')` plots `fun` over a disk centered on the domain.

`ezmesh(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezmesh(...)` returns the handle to a surface object in `h`.

## Examples

### Mesh Plot of Mathematical Function

Create a mesh plot of the function  $f(x, y) = xe^{-x^2-y^2}$  over a 40-by-40 grid.

```
fh = @(x,y) x.*exp(-x.^2-y.^2);
ezmesh(fh,40)
```

Set the mesh lines to a uniform blue color by setting the colormap to a single color.

```
colormap([0 0 1])
```

## More About

### Tips

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezmesh`. For example, the MATLAB syntax for a mesh plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezmesh('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as  $x.^2$  in the string you pass to `ezmesh`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezmesh('u^2 - v^3', [0,1], [3,6])` plots  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

## Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezmesh`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezmesh(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezmesh` does not alter the syntax, as in the case with string inputs.

## Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezmesh(@(x,y)myfun(x,y,2))
```

- Anonymous Functions

## See Also

`ezmeshc` | `mesh`

Introduced before R2006a

## ezmeshc

Easy-to-use combination mesh/contour plotter

### Syntax

```
ezmeshc(fun)
ezmeshc(fun, domain)
ezmeshc(funx, funy, funz)
ezmeshc(funx, funy, funz, [smin, smax, tmin, tmax])
ezmeshc(funx, funy, funz, [min, max])
ezmeshc(..., n)
ezmeshc(..., 'circ')
ezmesh(axes_handle, ...)
h = ezmeshc(...)
```

### Description

`ezmeshc(fun)` creates a graph of  $\text{fun}(x, y)$  using the `meshc` function. `fun` is plotted over the default domain  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle or a string (see the Tips section).

`ezmeshc(fun, domain)` plots `fun` over the specified `domain`. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]` (where  $\text{min} < x < \text{max}$ ,  $\text{min} < y < \text{max}$ ).

`ezmeshc(funx, funy, funz)` plots the parametric surface  $\text{funx}(s, t)$ ,  $\text{funy}(s, t)$ , and  $\text{funz}(s, t)$  over the square:  $-2\pi < s < 2\pi$ ,  $-2\pi < t < 2\pi$ .

`ezmeshc(funx, funy, funz, [smin, smax, tmin, tmax])` or `ezmeshc(funx, funy, funz, [min, max])` plots the parametric surface using the specified domain.

`ezmeshc(..., n)` plots `fun` over the default domain using an  $n$ -by- $n$  grid. The default value for  $n$  is 60.

`ezmeshc(..., 'circ')` plots `fun` over a disk centered on the domain.

`ezmesh(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezmeshc(...)` returns the handle to a surface object in `h`.

## Examples

### Mesh and Contour Plot of Mathematical Function

Create a mesh/contour plot of the expression  $f(x, y) = \sqrt{x^2 + y^2}$  over the domain  $-5 < x < 5$  and  $-2\pi < y < 2\pi$  with a computational grid size of 35-by-35.

```
ezmeshc('sqrt(x^2 + y^2)', [-5,5, -2*pi, 2*pi], 35)
```

## More About

### Tips

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezmeshc`. For example, the MATLAB syntax for a mesh/contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezmeshc('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as  $x.^2$  in the string you pass to `ezmeshc`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezmeshc('u^2 - v^3', [0, 1], [3, 6])` plots  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

## Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezmeshc`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezmeshc(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezmeshc` does not alter the syntax, as in the case with string inputs.

## Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezmeshc(@(x,y)myfun(x,y,2))
```

- Anonymous Functions

## See Also

`ezmesh` | `ezsurf` | `meshc`

# ezplot

Easy-to-use function plotter

## Syntax

```
ezplot(fun)
ezplot(fun,[xmin,xmax])
ezplot(fun2)
ezplot(fun2,[xymin,xymax])
ezplot(fun2,[xmin,xmax,ymin,ymax])
ezplot(funx,funy)
ezplot(funx,funy,[tmin,tmax])
ezplot(...,fig)
ezplot(ax,...)
h = ezplot(...)
```

## Description

`ezplot(fun)` plots the expression  $\text{fun}(x)$  over the default domain  $-2\pi < x < 2\pi$ , where  $\text{fun}(x)$  is an explicit function of only  $x$ .

`fun` can be a function handle or a string.

`ezplot(fun,[xmin,xmax])` plots  $\text{fun}(x)$  over the domain:  $x_{\min} < x < x_{\max}$ .

For an implicit function, `fun2(x,y)`:

`ezplot(fun2)` plots  $\text{fun2}(x,y) = 0$  over the default domain  $-2\pi < x < 2\pi, -2\pi < y < 2\pi$ .

`ezplot(fun2,[xymin,xymax])` plots  $\text{fun2}(x,y) = 0$  over  $x_{\min} < x < x_{\max}$  and  $y_{\min} < y < y_{\max}$ .

`ezplot(fun2,[xmin,xmax,ymin,ymax])` plots  $\text{fun2}(x,y) = 0$  over  $x_{\min} < x < x_{\max}$  and  $y_{\min} < y < y_{\max}$ .

`ezplot(funx,funy)` plots the parametrically defined planar curve `funx(t)` and `funy(t)` over the default domain  $0 < t < 2\pi$ .

`ezplot(funx,funy,[tmin,tmax])` plots `funx(t)` and `funy(t)` over  $t_{\min} < t < t_{\max}$ .

`ezplot(...,fig)` plots into the figure window identified by `fig`. Use any of the input argument combinations in the previous syntaxes that include a domain. The domain options are `[xmin xmax]`, `[xymin xymax]`, `[xmin xmax ymin ymax]`, and `[tmin tmax]`.

`ezplot(ax,...)` plots into the axes `ax` instead of the current axes (`gca`).

`h = ezplot(...)` returns either a chart line or contour object.

## Examples

### Plot an Explicit Function

Plot the explicit function  $x^2$  over the domain  $[-2\pi, 2\pi]$ .

```
ezplot('x^2')
```

The default domain is  $[-2\pi, 2\pi]$ .

### Plot an Implicit Function

Plot the implicitly defined function  $x^2 - y^4 = 0$  over the domain  $[-2\pi, 2\pi]$ .

```
ezplot('x^2-y^4')
```

The default domain is  $[-2\pi, 2\pi]$ .

## More About

### Tips

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezplot`. For example, the MATLAB syntax for a plot of the expression

```
x.^2 - y.^2
```

which represents an implicitly defined function, is written as

```
ezplot('x^2 - y^2')
```

That is,  $x^2$  is interpreted as  $x.^2$  in the string you pass to `ezplot`.

## Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezplot`.

```
fh = @(x,y) x.^2 + y.^3 - 2*y - 1;
ezplot(fh)
axis equal
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezplot` does not alter the syntax, as in the case with string inputs.

## Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezplot(@(x,y)myfun(x,y,2))
```

- Anonymous Functions

# ezplot3

Easy-to-use 3-D parametric curve plotter

## Syntax

```
ezplot3(funx,funy,funz)
ezplot3(funx,funy,funz,[tmin,tmax])
ezplot3(...,'animate')
ezplot3(axes_handle,...)
h = ezplot3(...)
```

## Description

`ezplot3(funx,funy,funz)` plots the spatial curve  $\text{funx}(t)$ ,  $\text{funy}(t)$ , and  $\text{funz}(t)$  over the default domain  $0 < t < 2\pi$ .

`funx`, `funy`, and `funz` can be function handles or strings (see the Tips section).

`ezplot3(funx,funy,funz,[tmin,tmax])` plots the curve  $\text{funx}(t)$ ,  $\text{funy}(t)$ , and  $\text{funz}(t)$  over the domain  $t_{\min} < t < t_{\max}$ .

`ezplot3(...,'animate')` produces an animated trace of the spatial curve.

`ezplot3(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezplot3(...)` returns the handle to the plotted objects in `h`.

## Examples

### Plot a Parametric Curve

Plot this parametric curve over the domain  $[0, 6\pi]$ .

$$x = \sin(t), \quad y = \cos(t), \quad z = t$$

```
ezplot3('sin(t)', 'cos(t)', 't', [0,6*pi])
```

## More About

### Tips

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezplot3`. For example, the MATLAB syntax for a plot of the expression

```
 $x = s./2$, $y = 2.*s$, $z = s.^2$;
```

which represents a parametric function, is written as

```
ezplot3('s/2','2*s','s^2')
```

That is,  $s/2$  is interpreted as `s./2` in the string you pass to `ezplot3`.

## Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezplot3`.

```
fh1 = @(s) s./2; fh2 = @(s) 2.*s; fh3 = @(s) s.^2;
ezplot3(fh1,fh2,fh3)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezplot3` does not alter the syntax, as in the case with string inputs.

## Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfunkt`:

```
function s = myfunkt(t,k)
s = t.^k.*sin(t);
```

then you can use an anonymous function to specify that parameter:

```
ezplot3(@cos,@(t)myfunkt(t,1),@sqrt)
```

- Anonymous Functions

## See Also

`ezplot` | `ezpolar` | `plot3`

Introduced before R2006a

## ezpolar

Easy-to-use polar coordinate plotter

### Syntax

```
ezpolar(fun)
ezpolar(fun, [a,b])
ezpolar(axes_handle, ...)
h = ezpolar(...)
```

### Description

`ezpolar(fun)` plots the polar curve  $\rho = \text{fun}(\text{theta})$  over the default domain  $0 < \text{theta} < 2\pi$ .

`fun` can be a function handle or a string (see the Tips section).

`ezpolar(fun, [a,b])` plots `fun` for  $a < \text{theta} < b$ .

`ezpolar(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezpolar(...)` returns the handle to a line object in `h`.

### Examples

#### Polar Plot of Mathematical Function

Plot the function  $1 + \cos(t)$  over the domain  $[0, 2\pi]$ .

```
figure
ezpolar('1+cos(t)')
```

## More About

### Tips

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezpolar`. For example, the MATLAB syntax for a plot of the expression

```
t.^2.*cos(t)
```

which represents an implicitly defined function, is written as

```
ezpolar('t^2*cos(t)')
```

That is,  $t^2$  is interpreted as `t.^2` in the string you pass to `ezpolar`.

## Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezpolar`.

```
fh = @(t) t.^2.*cos(t);
ezpolar(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezpolar` does not alter the syntax, as in the case with string inputs.

## Passing Additional Arguments

If your function has additional parameters, for example `k1` and `k2` in `myfun`:

```
function s = myfun(t,k1,k2)
s = sin(k1*t).*cos(k2*t);
```

then you can use an anonymous function to specify the parameters:

```
ezpolar(@(t)myfun(t,2,3))
```

- Anonymous Functions

[ezplot](#) | [ezplot3](#) | [plot](#) | [plot3](#) | [polar](#)

**Introduced before R2006a**

# ezsurf

Easy-to-use 3-D colored surface plotter

## Syntax

```
ezsurf(fun)
ezsurf(fun, domain)
ezsurf(funx, funy, funz)
ezsurf(funx, funy, funz, [smin, smax, tmin, tmax])
ezsurf(funx, funy, funz, [min, max])
ezsurf(..., n)
ezsurf(..., 'circ')
ezsurf(axes_handle, ...)
h = ezsurf(...)
```

## Description

`ezsurf(fun)` creates a graph of `fun(x, y)` using the `surf` function. `fun` is plotted over the default domain:  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle or a string (see the Tips section).

`ezsurf(fun, domain)` plots `fun` over the specified `domain`. `domain` must be a vector. See the “Algorithms” on page 1-2581 section for details on vector inputs vs axes limit outputs.

`ezsurf(funx, funy, funz)` plots the parametric surface `funx(s, t)`, `funy(s, t)`, and `funz(s, t)` over the square:  $-2\pi < s < 2\pi$ ,  $-2\pi < t < 2\pi$ .

`ezsurf(funx, funy, funz, [smin, smax, tmin, tmax])` or `ezsurf(funx, funy, funz, [min, max])` plots the parametric surface using the specified domain.

`ezsurf(..., n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezsurf(..., 'circ')` plots `fun` over a disk centered on the domain.

`ezsurf(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezsurf(...)` returns the handle to a surface object in `h`.

## Examples

### Surface Plot of Mathematical Function

Plot the function  $f(x, y) = \text{real}(a \tan(x + iy))$  over the domain  $-2\pi < x < 2\pi$  and  $-2\pi < y < 2\pi$ . The `ezsurf` function does not plot points where the mathematical function is not defined. These points are set to NaN so that they do not plot.

```
figure
ezsurf('real(atan(x+i*y))')
```

Use `surf` to plot the same data without filtering discontinuities.

```
figure
[x,y] = meshgrid(linspace(-2*pi,2*pi,60));
z = real(atan(x+1i.*y));
surf(x,y,z)
```

## More About

### Tips

`ezsurf` and `ezsurfz` do not accept complex inputs.

## Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezsurf`. For example, the MATLAB syntax for a surface plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezsurf('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as `x.^2` in the string you pass to `ezsurf`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezsurf('u^2 - v^3', [0,1], [3,6])` plots  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

## Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezsurf`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezsurf(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezsurf` does not alter the syntax, as in the case with string inputs.

## Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k1,k2,k3)
z = x.*(y.^k1)./(x.^k2 + y.^k3);
```

then you can use an anonymous function to specify that parameter:

```
ezsurf(@(x,y)myfun(x,y,2,2,4))
```

## Algorithms

ezsurf determines the  $x$ - and  $y$ -axes limits in different ways depending on how you input the domain (if at all). In the following table,  $R$  is the vector  $[x_{\min}, x_{\max}, y_{\min}, y_{\max}]$  and  $v$  is the manually entered domain vector.

| Number of domain values specified: | Resulting domain vector:                                             |
|------------------------------------|----------------------------------------------------------------------|
| $v = [ ];$                         | $R = [-2*\pi, 2*\pi, -2*\pi, 2*\pi];$                                |
| $v = [ v(1) ];$                    | $R = \text{double}([-abs(v), abs(v), -abs(v), abs(v)]);$             |
| $v = [ v(1) v(2) ];$               | $R = \text{double}([v(1), v(2), v(1), v(2)]);$                       |
| $v = [ v(1) v(2) v(3) ];$          | $R = \text{double}([-v(1), v(2), -abs(v(3)), abs(v(3))]);$           |
| $v = [ v(1) v(2) v(3) v(4) ];$     | $R = \text{double}(v);$                                              |
| $v = [ v(1)..v(n) ];$<br>$n > 4$   | $R = \text{double}([-abs(v(1)), abs(v(1)), -abs(v(1)), abs(v(1))]);$ |

If you specify a single number in non-vector format (without square brackets,  $[ ]$ ), ezsurf interprets it as the  $n$ , the number of points desired between the axes  $\max$  and  $\min$  values.

By default, ezsurf uses 60 points between the  $\max$  and  $\min$  values of an axes. When the  $\min$  and  $\max$  values are the default values ( $R = [-2*\pi, 2*\pi, -2*\pi, 2*\pi];$ ), ezsurf ensures the 60 points fall within the non-complex range of the specified

equation. For example,  $\sqrt{1-x^2-y^2}$  is only real when  $x^2-y^2 \leq 1$ . The default graph of this function looks like this:

```
ezsurf('sqrt(1-x^2-y^2)')
```

You can see that there are 60 points between the minimum and maximum values for which  $\sqrt{1-x^2-y^2}$  has real values. However, when you specify the domain values to be the same as the default ( $R = [-2*\pi, 2*\pi, -2*\pi, 2*\pi];$ ), a different result appears:

```
ezsurf('sqrt(1-x^2-y^2)',[-2*pi 2*pi])
```

In this case, the graphic limits are the same, but `ezsurf` used 60 points between the user-defined limits instead of checking to see if all those points would have real answers.

- Anonymous Functions

## See Also

`ezmesh` | `ezsurf` | `surf`

Introduced before R2006a

## ezsurf

Easy-to-use combination surface/contour plotter

### Syntax

```
ezsurf(fun)
ezsurf(fun, domain)
ezsurf(funx, funy, funz)
ezsurf(funx, funy, funz, [smin, smax, tmin, tmax])
ezsurf(funx, funy, funz, [min, max])
ezsurf(..., n)
ezsurf(..., 'circ')
ezsurf(axes_handle, ...)
h = ezsurf(...)
```

### Description

`ezsurf(fun)` creates a graph of  $\text{fun}(x, y)$  using the `surf` function. The function `fun` is plotted over the default domain:  $-2\pi < x < 2\pi$ ,  $-2\pi < y < 2\pi$ .

`fun` can be a function handle or a string (see the Tips section).

`ezsurf(fun, domain)` plots `fun` over the specified domain. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]` (where  $\text{min} < x < \text{max}$ ,  $\text{min} < y < \text{max}$ ).

`ezsurf(funx, funy, funz)` plots the parametric surface  $\text{funx}(s, t)$ ,  $\text{funy}(s, t)$ , and  $\text{funz}(s, t)$  over the square:  $-2\pi < s < 2\pi$ ,  $-2\pi < t < 2\pi$ .

`ezsurf(funx, funy, funz, [smin, smax, tmin, tmax])` or `ezsurf(funx, funy, funz, [min, max])` plots the parametric surface using the specified domain.

`ezsurf(..., n)` plots  $f$  over the default domain using an  $n$ -by- $n$  grid. The default value for  $n$  is 60.

`ezsurf(..., 'circ')` plots  $f$  over a disk centered on the domain.

`ezsurf(axes_handle, ...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezsurf(...)` returns the handles to the graphics objects in `h`.

## Examples

### Surface and Contour Plot of Mathematical Function

Create a surface/contour plot of the expression  $f(x, y) = \sqrt{x^2 + y^2}$  over the domain  $-5 < x < 5$  and  $-2\pi < y < 2\pi$  with a computational grid size of 35-by-35.

```
ezsurf('sqrt(x^2 + y^2)', [-5,5, -2*pi,2*pi], 35)
```

## More About

### Tips

`ezsurf` and `ezsurfz` do not accept complex inputs.

### Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezsurfz`. For example, the MATLAB syntax for a surface/contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezsurf('sqrt(x^2 + y^2)')
```

That is,  $x^2$  is interpreted as  $x.^2$  in the string you pass to `ezsurf`.

If the function to be plotted is a function of the variables  $u$  and  $v$  (rather than  $x$  and  $y$ ), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezsurf('u^2 - v^3', [0,1], [3,6])` plots  $u^2 - v^3$  over  $0 < u < 1$ ,  $3 < v < 6$ .

## Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezsurf`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezsurf(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezsurf` does not alter the syntax, as in the case with string inputs.

## Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k1,k2,k3)
z = x.*(y.^k1)./(x.^k2 + y.^k3);
```

then you can use an anonymous function to specify that parameter:

```
ezsurf(@(x,y)myfun(x,y,2,2,4))
```

- Anonymous Functions

## faceNormals

**Class:** TriRep

(Not recommended) Unit normals to specified triangles

---

**Note:** `faceNormals(TriRep)` is not recommended. Use `faceNormal(triangulation)` instead.

`TriRep` is not recommended. Use triangulation instead.

---

## Syntax

`FN = faceNormals(TR, TI)`

## Description

`FN = faceNormals(TR, TI)` returns the unit normal vector to each of the specified triangles `TI`.

---

**Note:** This query is only applicable to triangular surface meshes.

---

## Input Arguments

`TR`            Triangulation representation.  
`TI`            Column vector of indices that index into the triangulation matrix `TR.Triangulation`.

## Output Arguments

`FN`            `m`-by-3 matrix. `m = length(TI)`, the number of triangles to be queried. Each row `FN(i, :)` represents the unit normal vector to triangle `TI(i)`.

If TI is not specified the unit normal information for the entire triangulation is returned, where the normal associated with triangle  $i$  is the  $i$ 'th row of FN.

## Examples

Triangulate a sample of random points on the surface of a sphere and use the `TriRep` to compute the normal to each triangle:

```
numpts = 100;
theta = rand(numpts,1)*2*pi;
phi = rand(numpts,1)*pi;
x = cos(theta).*sin(phi);
y = sin(theta).*sin(phi);
z = cos(phi);
dt = DelaunayTri(x,y,z);
[tri Xb] = freeBoundary(dt);
tr = TriRep(tri, Xb);
P = incenters(tr);
fn = faceNormals(tr);
trisurf(tri,Xb(:,1),Xb(:,2),Xb(:,3), ...
 'FaceColor', 'cyan', 'faceAlpha', 0.8);
axis equal;
hold on;
```

Display the result using a quiver plot:

```
quiver3(P(:,1),P(:,2),P(:,3), ...
 fn(:,1),fn(:,2),fn(:,3),0.5, 'color','r');
hold off;
```

**See Also**

[delaunayTriangulation](#) | [freeBoundary](#) | [triangulation](#)

# factor

Prime factors

## Syntax

```
f = factor(n)
```

## Description

`f = factor(n)` returns a row vector containing the prime factors of `n`. Vector `f` is of the same data type as `n`.

## Examples

### Prime Factors of Double Integer Value

```
f = factor(200)
```

```
f =
```

```
 2 2 2 5 5
```

Multiply the elements of `f` to reproduce the input value.

```
prod(f)
```

```
ans =
```

```
 200
```

### Prime Factors of Unsigned Integer Value

```
n = uint16(138);
```

```
f = factor(n)
```

```
f =
```

```
 2 3 23
```

Multiply the elements of `f` to reproduce `n`.

```
prod(f)
```

```
ans =
```

```
138
```

## Input Arguments

### **n** — Input value

real, nonnegative integer scalar

Input value, specified as a real, nonnegative integer scalar.

Example: 10

Example: `int16(64)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### See Also

`isprime` | `primes`

**Introduced before R2006a**

# factorial

Factorial of input

## Syntax

```
f = factorial(n)
```

## Description

`f = factorial(n)` returns the product of all positive integers less than or equal to `n`, where `n` is a nonnegative integer value. If `n` is an array, then `f` contains the factorial of each value of `n`. The data type and size of `f` is the same as that of `n`.

The factorial of `n` is commonly written in math notation using the exclamation point character as  $n!$ . Note that `n!` is not a valid MATLAB syntax for calculating the factorial of `n`.

## Examples

**10!**

```
f = factorial(10)
```

```
f =
```

```
3628800
```

**22!**

```
format long
```

```
f = factorial(22)
```

```
f =
```

```
1.124000727777608e+21
```

In this case, `f` is accurate up to 15 digits, `1.12400072777760e+21`, because double-precision numbers are only accurate up to 15 digits.

Reset the output format to the default.

format

## Factorial of Array Elements

```
n = [0 1 2; 3 4 5];
f = factorial(n)
```

f =

```
 1 1 2
 6 24 120
```

## Factorial of Unsigned Integer Values

```
n = uint64([5 10 15 20]);
f = factorial(n)
```

f =

```
 120 3628800 1307674368000 2432902008176640000
```

## Input Arguments

### n — Input values

scalar, vector, or array of real, nonnegative integer values

Input values, specified as a scalar, vector, or array of real, nonnegative integers.

Example: 5

Example: [0 1 2 3 4]

Example: int16([10 15 20])

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 |  
uint32 | uint64

## More About

### Tips

### Limitations

- For double-precision inputs, the result is exact when  $n$  is less than or equal to 21. Larger values of  $n$  produce a result that has the correct order of magnitude and is accurate for the first 15 digits. This is because double-precision numbers are only accurate up to 15 digits.
- For single-precision inputs, the result is exact when  $n$  is less than or equal to 13. Larger values of  $n$  produce a result that has the correct order of magnitude and is accurate for the first 8 digits. This is because single-precision numbers are only accurate up to 8 digits.

### Saturation

- The table below describes the saturation behavior of each data type when used with the `factorial` function. The values in the last column indicate the saturation point; that is, the first positive integer whose actual factorial is larger than the maximum representable value in the middle column. For `single` and `double`, all values larger than the maximum value are returned as `Inf`. For the integer data types, the saturation value is equal to the maximum value in the middle column.

| Data type           | Maximum Value                  | Factorial Saturation Threshold     |
|---------------------|--------------------------------|------------------------------------|
| <code>double</code> | <code>realmax</code>           | <code>factorial(171)</code>        |
| <code>single</code> | <code>realmax('single')</code> | <code>factorial(single(35))</code> |
| <code>uint64</code> | $2^{64}-1$                     | <code>factorial(uint64(21))</code> |
| <code>int64</code>  | $2^{63}-1$                     | <code>factorial(int64(21))</code>  |
| <code>uint32</code> | $2^{32}-1$                     | <code>factorial(uint32(13))</code> |
| <code>int32</code>  | $2^{31}-1$                     | <code>factorial(int32(13))</code>  |
| <code>uint16</code> | $2^{16}-1$                     | <code>factorial(uint16(9))</code>  |
| <code>int16</code>  | $2^{15}-1$                     | <code>factorial(int16(8))</code>   |
| <code>uint8</code>  | $2^8-1$                        | <code>factorial(uint8(6))</code>   |
| <code>int8</code>   | $2^7-1$                        | <code>factorial(int8(6))</code>    |

`prod`

Introduced before R2006a

## false

Logical 0 (false)

### Syntax

```
false
F = false(n)
F = false(sz)
F = false(sz1, ..., szN)
F = false(____, 'like', p)
```

### Description

`false` is shorthand for `logical(0)`.

`F = false(n)` is an `n`-by-`n` array of logical zeros.

`F = false(sz)` is an array of logical zeros where the size vector, `sz`, defines `size(F)`. For example, `false([2 3])` returns a 2-by-3 array of logical zeros.

`F = false(sz1, ..., szN)` is a `sz1`-by-...-by-`szN` array of logical zeros where `sz1, ..., szN` indicates the size of each dimension. For example, `false(2,3)` returns a 2-by-3 array of logical zeros.

`F = false( ____, 'like', p)` returns an array of logical zeros of the same sparsity as the logical variable `p` using any of the previous size syntaxes.

### Examples

#### Generate Square Matrix of Logical Zeros

Use `false` to generate a 3-by-3 square matrix of logical zeros.

```
A = false(3)
class(A)
```

```
A =
 0 0 0
 0 0 0
 0 0 0
ans =
logical
```

The result is of class `logical`.

### Generate Array of Logical Zeros with Arbitrary Dimensions

Use `false` to generate a 3-by-2-by-2 array of logical zeros.

```
false(3,2,2)
```

```
ans(:,:,1) =
 0 0
 0 0
 0 0
```

```
ans(:,:,2) =
 0 0
 0 0
 0 0
```

Alternatively, use a size vector to specify the size of the matrix.

```
false([3 2 2])
```

```
ans(:,:,1) =
 0 0
 0 0
 0 0
```

```
ans(:,:,2) =
 0 0
 0 0
 0 0
```

Note that specifying multiple vector inputs returns an error.

### Execute Logic Statement

`false` along with `true` can be used to execute logic statements.

Test the logical statement  $\sim(A \text{ and } B) \equiv (\sim A) \text{ or } (\sim B)$  for  $A = \text{logical false}$  and  $B = \text{logical true}$ .

```
~(false & true) == (~false) | (~true)
```

```
ans =
 1
```

The result is logical 1 (true), since the logical statements on both sides of the equation are equivalent. This logical statement is an instance of De Morgan's Law.

## Generate Logical Array of Selected Sparsity

Generate a logical array of the same data type and sparsity as the selected array.

```
A = logical(sparse(5,3));
whos A
F = false(4,'like',A);
whos F
```

|      |      |       |         |            |
|------|------|-------|---------|------------|
| Name | Size | Bytes | Class   | Attributes |
| A    | 5x3  | 41    | logical | sparse     |
| Name | Size | Bytes | Class   | Attributes |
| F    | 4x4  | 49    | logical | sparse     |

The output array  $F$  has the same `sparse` attribute as the specified array  $A$ .

## Input Arguments

### **n** — Size of square matrix

integer

Size of square matrix, specified as an integer.  $n$  sets the output array size to  $n$ -by- $n$ . For example, `false(3)` returns a 3-by-3 array of logical zeros.

- If  $n$  is 0, then  $F$  is an empty matrix.
- If  $n$  is negative, then it is treated as 0.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **sz** — Size vector

row vector of integers

Size vector, specified as a row vector of integers. For example, `false([2 3])` returns a 2-by-3 array of logical zeros.

- If the size of any dimension is 0, then `F` is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, `F`, does not include those dimensions.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **sz1, ..., szN — Size inputs**

comma-separated list of integers

Size inputs, specified by a comma-separated list of integers. For example, `false(2,3)` returns a 2-by-3 array of logical zeros.

- If the size of any dimension is 0, then `F` is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, `F`, does not include those dimensions.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **p — Prototype**

logical variable

Prototype, specified as a logical variable.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## **Output Arguments**

### **F — Output of logical zeros**

scalar | vector | matrix | N-D array

Output of logical zeros, returned as a scalar, vector, matrix, or N-D array.

Data Types: `logical`

## More About

### Tips

- `false(n)` is much faster and more memory efficient than `logical(zeros(n))`.
- “Class Support for Array-Creation Functions”

### See Also

`logical | true`

**Introduced before R2006a**

# fclose

Close one or all open files

## Syntax

```
fclose(fileID)
fclose('all')
status = fclose(...)
```

## Description

`fclose(fileID)` closes an open file. *fileID* is an integer file identifier obtained from `fopen`.

`fclose('all')` closes all open files.

`status = fclose(...)` returns a *status* of 0 when the close operation is successful. Otherwise, it returns -1.

## See Also

`ferror` | `fopen` | `frewind` | `fread` | `fwrite` | `fseek` | `ftell` | `feof` | `fscanf` | `fprintf`

**Introduced before R2006a**

## fclose (serial)

Disconnect serial port object from device

### Syntax

```
fclose(obj)
```

### Description

`fclose(obj)` disconnects `obj` from the device, where `obj` is a serial port object or an array of serial port objects.

### Examples

This example creates the serial port object `s` on a Windows platform, connects `s` to the device, writes and reads text data, and then disconnects `s` from the device using `fclose`.

```
s = serial('COM1');
fopen(s)
fprintf(s, '*IDN?')
idn = fscanf(s);
fclose(s)
```

At this point, the device is available to be connected to a serial port object. If you no longer need `s`, you should remove from memory with the `delete` function, and remove it from the workspace with the `clear` command.

### More About

#### Tips

If `obj` was successfully disconnected, then the `Status` property is configured to `closed` and the `RecordStatus` property is configured to `Off`. You can reconnect `obj` to the device using the `fopen` function.

An error is returned if you issue `fclose` while data is being written asynchronously. In this case, you should abort the write operation with the `stopasync` function, or wait for the write operation to complete.

**See Also**

`clear` | `fopen` | `stopasync` | `delete` | `RecordStatus` | `Status`

**Introduced before R2006a**

## feather

Plot velocity vectors

## Syntax

```
feather(U,V)
feather(Z)
feather(...,LineStyle)
feather(axes_handle,...)
h = feather(...)
```

## Description

A feather plot displays vectors emanating from equally spaced points along a horizontal axis. You express the vector components relative to the origin of the respective vector.

`feather(U,V)` displays the vectors specified by `U` and `V`, where `U` contains the  $x$  components as relative coordinates, and `V` contains the  $y$  components as relative coordinates.

`feather(Z)` displays the vectors specified by the complex numbers in `Z`. This is equivalent to `feather(real(Z), imag(Z))`.

`feather(...,LineStyle)` draws a feather plot using the line type, marker symbol, and color specified by `LineStyle`.

`feather(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = feather(...)` returns the handles to line objects in `h`.

## Examples

### Create Feather Plot

Define `theta` as values between  $-2\pi$  and  $2\pi$ . Define `r` as a vector the same size as `theta`.

```
theta = -pi/2:pi/16:pi/2;
r = 2*ones(size(theta));
```

Create a feather plot showing the direction of `theta`. Since `feather` uses Cartesian coordinates, convert `theta` and `r` to Cartesian coordinates using `pol2cart`.

```
[u,v] = pol2cart(theta,r);
feather(u,v)
```

**See Also**

**Introduced before R2006a**

# featureEdges

**Class:** TriRep

(Not recommended) Sharp edges of surface triangulation

---

**Note:** `featureEdges(TriRep)` is not recommended. Use `featureEdges(triangulation)` instead.

TriRep is not recommended. Use triangulation instead.

---

## Syntax

```
FE = featureEdges(TR, filterangle)
```

## Description

`FE = featureEdges(TR, filterangle)` returns an edge matrix FE. This method is typically used to extract the sharp edges in the surface mesh for the purpose of display. Edges that are shared by only one triangle and edges that are shared by more than two triangles are considered to be feature edges by default.

---

**Note:** This query is only applicable to triangular surface meshes.

---

## Input Arguments

|             |                                                                                                                                                                                                                                    |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TR          | Triangulation representation.                                                                                                                                                                                                      |
| filterangle | The threshold angle in radians. Must be in the range $(0, \pi)$ . <code>featureEdges</code> will return adjacent triangles that have a dihedral angle that deviates from $\pi$ by an angle greater than <code>filterangle</code> . |

## Output Arguments

**FE** Edges of the triangulation. **FE** is of size  $m$ -by-2 where  $m$  is the number of computed feature edges in the mesh. The vertices of the edges index into the array of points representing the vertex coordinates, **TR.X**.

## Examples

Create a surface triangulation:

```
x = [0 0 0 0 0 3 3 3 3 3 3 6 6 6 6 6 9 9 9 9 9 9]';
y = [0 2 4 6 8 0 1 3 5 7 8 0 2 4 6 8 0 1 3 5 7 8]';
dt = DelaunayTri(x,y);
tri = dt(:,:);
```

Elevate the 2-D mesh to create a surface:

```
z = [0 0 0 0 0 2 2 2 2 2 2 0 0 0 0 0 0 0 0 0 0 0]';
subplot(1,2,1);
trisurf(tri,x,y,z, 'FaceColor', 'cyan');
axis equal;
% TRISURF display of surface mesh
% showing mesh edges
```

Compute the feature edges using a filter angle of  $\pi/6$ :

```
tr = TriRep(tri, x,y,z);
fe = featureEdges(tr,pi/6)';
subplot(1,2,2);
trisurf(tr, 'FaceColor', 'cyan', 'EdgeColor','none', ...
 'FaceAlpha', 0.8); axis equal;
```

Add the feature edges to the plot:

```
hold on;
plot3(x(fe), y(fe), z(fe), 'k', 'LineWidth',1.5);
hold off;
% TRISURF display of surface mesh
% suppressing mesh edges
% and showing feature edges
```

**See Also**

[delaunayTriangulation](#) | [edges](#) | [triangulation](#)

## feof

Test for end-of-file

### Syntax

```
status = feof(fileID)
```

### Description

`status = feof(fileID)` returns 1 if a previous operation set the end-of-file indicator for the specified file. Otherwise, `feof` returns 0. *fileID* is an integer file identifier obtained from `fopen`.

Opening an empty file does *not* set the end-of-file indicator. Read operations, and the `fseek` and `frewind` functions, move the file position indicator.

### Examples

Read `bench.dat`, which contains MATLAB benchmark data, one character at a time:

```
fid = fopen('bench.dat');

k = 0;
while ~feof(fid)
 curr = fscanf(fid, '%c', 1);
 if ~isempty(curr)
 k = k+1;
 benchstr(k) = curr;
 end
end

fclose(fid);
```

### More About

- “Testing for End of File (EOF)”

**See Also**

fclose | ferror | fopen | frewind | fseek | ftell

**Introduced before R2006a**

## **ferror**

Information about file I/O errors

### **Syntax**

```
message = ferror(fileID)
[message, errnum] = ferror(fileID)
[...] = ferror(fileID, 'clear')
```

### **Description**

*message* = ferror(*fileID*) returns the error message for the most recent file I/O operation on the specified file. If the operation was successful, *message* is an empty string. *fileID* is an integer file identifier obtained from `fopen`, or an identifier reserved for standard input (0), standard output (1), or standard error (2).

[*message*, *errnum*] = ferror(*fileID*) returns the error number. If the most recent file I/O operation was successful, *errnum* is 0. Negative error numbers correspond to MATLAB error messages. Positive error numbers correspond to C library error messages for your system.

[...] = ferror(*fileID*, 'clear') clears the error indicator for the specified file.

### **See Also**

`fclose` | `fopen` | `fseek` | `ftell` | `feof` | `fscanf` | `fprintf` | `fread` | `fwrite`

# feval

Evaluate function

## Syntax

```
[y1,...,yN] = feval(fun,x1,...,xM)
```

## Description

`[y1,...,yN] = feval(fun,x1,...,xM)` evaluates a function using its name or its handle, and using the input arguments `x1,...,xM`.

The `feval` function follows same scoping and precedence rules as calling a function handle directly. For more information, see “Create Function Handle”.

## Examples

### Evaluate Function Using Function Name String

Round the value of `pi` to the nearest integer using the name of the function.

```
fun = 'round';
x1 = pi;
y = feval(fun,x1)
```

```
y =

 3
```

Round the value of `pi` to two digits to the right of the decimal point.

```
x2 = 2;
y = feval(fun,x1,x2)
```

```
y =
 3.1400
```

## Input Arguments

### **fun** — Function to evaluate

function name | function handle

Function to evaluate, specified as a function name or a handle to a function. The function accepts  $M$  input arguments, and returns  $N$  output arguments. To specify `fun` as a function name, do not include path information.

Invoking `feval` with a function handle is equivalent to invoking the function handle directly.

Example: `fun = 'cos'`

Example: `fun = @sin`

### **x1, ..., xM** — Inputs to evaluated function

depends on function

Inputs to the evaluated function. The types of the inputs depend on the function, `fun`.

## Output Arguments

### **y1, ..., yN** — Outputs from evaluated function

depends on function

Outputs from evaluated function. The types of the outputs depend on the function, `fun`.

## More About

### Tips

- If you have a function handle, it is not necessary to use `feval` because you can invoke the function handle directly. The results of the following statements are equivalent.

```
fh = @eig;
[V,D] = fh(A)
```

```
[V,D] = feval(@eig,A)
```

- To evaluate a nested or local function using `feval`, use a function handle instead of the function name. For more information, see “Call Local Functions Using Function Handles”.
- “Create Function Handle”

## See Also

`assignin` | `builtin` | `eval` | `evalin` | `functions`

**Introduced before R2006a**

## fewerbins

Decrease number of histogram bins

### Syntax

```
N = fewerbins(h)
N = fewerbins(h,direction)
```

### Description

`N = fewerbins(h)` decreases the number of bins in histogram `h` by 10% (rounded down to the nearest integer) and returns the new number of bins.

For bivariate histograms, this decreases the bin count in both the  $x$  and  $y$  directions.

`N = fewerbins(h,direction)`, where `h` must be a `histogram2` object, only decreases the number of bins in the dimension specified by `direction`. The `direction` option can be `'x'`, `'y'`, or `'both'`. The default value is `'both'`.

### Examples

#### Decrease Number of Histogram Bins

Plot a histogram of 1,000 random numbers and return a handle to the histogram object.

```
x = randn(1000,1);
h = histogram(x)
```

```
h =
```

```
 Histogram with properties:
```

```
 Data: [1000x1 double]
 Values: [1x23 double]
 NumBins: 23
 BinEdges: [1x24 double]
 BinWidth: 0.3000
```

```
BinLimits: [-3.3000 3.6000]
Normalization: 'count'
FaceColor: 'auto'
EdgeColor: [0 0 0]
```

Use GET to show all properties

Use `fewerbins` to decrease the number of bins in the histogram.

```
fewerbins(h);
fewerbins(h)
```

```
ans =
 18
```

## Input Arguments

### **h** — Input histogram

histogram object | histogram2 object

Input histogram, specified as a `histogram` or `histogram2` object. For more information, see [Using histogram Objects](#) or [Using histogram2 Objects](#).

h cannot be a categorical histogram.

**direction** — Direction to decrease number of bins

'both' (default) | 'x' | 'y'

Direction to decrease the number of bins, specified as 'x', 'y', or 'both'. Specify 'x' or 'y' to only decrease the number of bins in that direction while leaving the number of bins in the other direction constant.

## Output Arguments

**N** — Number of bins

scalar | vector

Number of bins, returned as a scalar or vector. N is the new number of bins for the histogram after increase. For bivariate histogram plots, N is a two-element vector, [nx ny].

## Feval (COM)

Evaluate MATLAB function in Automation server

### Syntax

#### IDL Method Signature

```
HRESULT Feval([in] BSTR functionname, [in] long numout,
[out] VARIANT* result, [in, optional] VARIANT arg1, arg2, ...)
```

#### Microsoft Visual Basic Client

```
Feval(String functionname, long numout,
arg1, arg2, ...) As Object
```

#### MATLAB Client

```
result = Feval(h, 'functionname', numout, arg1, arg2, ...)
```

### Description

`result = Feval(h, 'functionname', numout, arg1, arg2, ...)` executes the MATLAB function specified by the string `functionname` in the Automation server attached to handle `h`. The function name is case-sensitive.

COM functions are available on Microsoft Windows systems only.

Indicate the number of outputs to be returned by the function in a 1-by-1 double array, `numout`. The server returns output from the function in the cell array, `result`.

You can specify as many as 32 input arguments to be passed to the function. These arguments follow `numout` in the `Feval` argument list. The following table shows ways to pass an argument.

| Passing Mechanism           | Description                                                                                                                                                                                                                                                  |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pass the value itself       | To pass any numeric or string value, specify the value in the <code>Feval</code> argument list:<br><br><pre>a = Feval(h, 'sin', 1, -pi:0.01:pi);</pre>                                                                                                       |
| Pass a client variable      | To pass an argument assigned to a variable in the client, specify the variable name alone:<br><br><pre>x = -pi:0.01:pi; a = Feval(h, 'sin', 1, x);</pre>                                                                                                     |
| Reference a server variable | To reference a variable defined in the server, specify the variable name followed by an equals (=) sign:<br><br><pre>PutWorkspaceData(h, 'x', 'base', -pi:0.01:pi); a = Feval(h, 'sin', 1, 'x=');</pre> <p>MATLAB does not reassign the server variable.</p> |

## Visual Basic .NET Examples

### Passing Arguments

This example shows how to pass arguments using `Feval` to execute MATLAB commands on a MATLAB Automation server from a Visual Basic® .NET client.

- Pass two strings to the MATLAB function `strcat` on the server:

```
Dim Matlab As Object
Dim out As Object
out = Nothing
Matlab = CreateObject("matlab.application")
Matlab.Feval("strcat", 1, out, "hello", " world")
```

- Define `clistr` locally and pass this variable:

```
Dim clistr As String
clistr = " world"
Matlab.Feval("strcat", 1, out, "hello", clistr)
```

- Pass the name of a variable defined on the server:

```
Matlab.PutCharArray("srvstr","base"," world")
Matlab.Feval("strcat",1,out,"hello","srvstr=")
```

## Defining Feval Return Values

`Feval` returns data from the evaluated function in a cell array. The cell array has one row for every return value. You control the number of return values using the `numout` argument.

```
Dim Matlab As Object
Dim out As Object
Matlab = CreateObject("matlab.application")
Matlab.Feval("fileparts",3,out,"d:\work\ConsoleApp.cpp")
```

## Creating Server Variables

Use variables defined in the client, `rows` and `cols`, to modify a server variable, `A`.

- Create a matrix, `A`, in the server.

```
Dim Matlab As Object
Dim server_version As String
Matlab = CreateObject("matlab.application")
Matlab.PutWorkspaceData("A","base",rand(6))
```

- Reshape `A`.

```
rows = 6
cols = 3
Matlab.Feval("reshape",0,"A=",rows,cols)
```

MATLAB interprets `A` in the expression `'A='` as a server variable name.

- The `reshape` function does not modify variable `A`.

```
Matlab.GetWorkspaceData("A","base",B)
```

`A` is unchanged.

- To get the result of the `reshape` function, use the `numout` argument to assign the value to `C`.

```
Matlab.Feval("reshape",1,"A=",rows,cols,C)
```

## More About

### Tips

To display the output from `Feval` in the client window, assign a return value.

## **fft**

Fast Fourier transform

### **Syntax**

$Y = \text{fft}(X)$

$Y = \text{fft}(X, n)$

$Y = \text{fft}(X, n, \text{dim})$

### **Description**

$Y = \text{fft}(X)$  computes the discrete Fourier transform (DFT) of  $X$  using a fast Fourier transform (FFT) algorithm.

- If  $X$  is a vector, then  $\text{fft}(X)$  returns the Fourier transform of the vector.
- If  $X$  is a matrix, then  $\text{fft}(X)$  treats the columns of  $X$  as vectors and returns the Fourier transform of each column.
- If  $X$  is a multidimensional array, then  $\text{fft}(X)$  treats the values along the first array dimension whose size does not equal 1 as vectors and returns the Fourier transform of each vector.

$Y = \text{fft}(X, n)$  returns the  $n$ -point DFT. If no value is specified,  $Y$  is the same size as  $X$ .

- If  $X$  is a vector and the length of  $X$  is less than  $n$ , then  $X$  is padded with trailing zeros to length  $n$ .
- If  $X$  is a vector and the length of  $X$  is greater than  $n$ , then  $X$  is truncated to length  $n$ .
- If  $X$  is a matrix, then each column is treated as in the vector case.
- If  $X$  is a multidimensional array, then the first array dimension whose size does not equal 1 is treated as in the vector case.

$Y = \text{fft}(X, n, \text{dim})$  returns the Fourier transform along the dimension  $\text{dim}$ . For example, if  $X$  is a matrix, then  $\text{fft}(X, n, 2)$  returns the  $n$ -point Fourier transform of each row.

## Examples

### Noisy Signal

Use Fourier transforms to find the frequency components of a signal buried in noise.

Specify the parameters of a signal with a sampling frequency of 1 kHz and a signal duration of 1 second.

```
Fs = 1000; % Sampling frequency
T = 1/Fs; % Sampling period
L = 1000; % Length of signal
t = (0:L-1)*T; % Time vector
```

Form a signal containing a 50 Hz sinusoid of amplitude 0.7 and a 120 Hz sinusoid of amplitude 1.

```
S = 0.7*sin(2*pi*50*t) + sin(2*pi*120*t);
```

Corrupt the signal with zero-mean white noise with a variance of 4.

```
X = S + 2*randn(size(t));
```

Plot the noisy signal in the time domain. It is difficult to identify the frequency components by looking at the signal  $X(t)$ .

```
plot(1000*t(1:50),X(1:50))
title('Signal Corrupted with Zero-Mean Random Noise')
xlabel('t (milliseconds)')
ylabel('X(t)')
```

Compute the Fourier transform of the signal.

```
Y = fft(X);
```

Compute the two-sided spectrum **P2**. Then compute the single-sided spectrum **P1** based on **P2** and the even-valued signal length **L**.

```
P2 = abs(Y/L);
P1 = P2(1:L/2+1);
P1(2:end-1) = 2*P1(2:end-1);
```

Define the frequency domain **f** and plot the single-sided amplitude spectrum **P1**. The amplitudes are not exactly at 0.7 and 1, as expected, because of the added noise. On average, longer signals produce better frequency approximations.

```
f = Fs*(0:(L/2))/L;
plot(f,P1)
title('Single-Sided Amplitude Spectrum of X(t)')
xlabel('f (Hz)')
ylabel('|P1(f)|')
```

Now, take the Fourier transform of the original, uncorrupted signal and retrieve the exact amplitudes, 0.7 and 1.0.

```
Y = fft(S);
P2 = abs(Y/L);
P1 = P2(1:L/2+1);
P1(2:end-1) = 2*P1(2:end-1);
```

```
plot(f,P1)
title('Single-Sided Amplitude Spectrum of S(t)')
xlabel('f (Hz)')
ylabel('|P1(f)|')
```

## Gaussian Pulse

Convert a Gaussian pulse from the time domain to the frequency domain.

Define signal parameters and a Gaussian pulse, X.

```
Fs = 100; % Sampling frequency
t = -0.5:1/Fs:0.5; % Time vector
L = length(t); % Signal length
```

```
X = 1/(4*sqrt(2*pi*0.01))*(exp(-t.^2/(2*0.01)));
```

Plot the pulse in the time domain.

```
plot(t,X)
title('Gaussian Pulse in Time Domain')
xlabel('Time (t)')
ylabel('X(t)')
```

To use the `fft` function to convert the signal to the frequency domain, first identify a new input length that is the next power of 2 from the original signal length. This will pad the signal `X` with trailing zeros in order to improve the performance of `fft`.

```
n = 2^nextpow2(L);
```

Convert the Gaussian pulse to the frequency domain.

```
Y = fft(X,n);
```

Define the frequency domain and plot the unique frequencies.

```
f = Fs*(0:(n/2))/n;
P = abs(Y/n);
```

```
plot(f,P(1:n/2+1))
title('Gaussian Pulse in Frequency Domain')
xlabel('Frequency (f)')
ylabel('|P(f)|')
```

### Cosine Waves

Compare cosine waves in the time domain and the frequency domain.

Specify the parameters of a signal with a sampling frequency of 1kHz and a signal duration of 1 second.

```
Fs = 1000; % Sampling frequency
T = 1/Fs; % Sampling period
L = 1000; % Length of signal
t = (0:L-1)*T; % Time vector
```

Create a matrix where each row represents a cosine wave with scaled frequency. The result,  $X$ , is a 3-by-1000 matrix. The first row has a wave frequency of 50, the second row has a wave frequency of 150, and the third row has a wave frequency of 300.

```
x1 = cos(2*pi*50*t); % First row wave
x2 = cos(2*pi*150*t); % Second row wave
x3 = cos(2*pi*300*t); % Third row wave
```

```
X = [x1; x2; x3];
```

Plot the first 100 entries from each row of  $X$  in a single figure in order and compare their frequencies.

```
for i = 1:3
 subplot(3,1,i)
 plot(t(1:100),X(i,1:100))
 title(['Row ',num2str(i),' in the Time Domain'])
end
```

For algorithm performance purposes, `fft` allows you to pad the input with trailing zeros. In this case, pad each row of `X` with zeros so that the length of each row is the next higher power of 2 from the current length. Define the new length using the `nextpow2` function.

```
n = 2^nextpow2(L);
```

Specify the `dim` argument to use `fft` along the rows of `X`, that is, for each signal.

```
dim = 2;
```

Compute the Fourier transform of the signals.

```
Y = fft(X,n,dim);
```

Calculate the double-sided spectrum and single-sided spectrum of each signal.

```
P2 = abs(Y/n);
P1 = P2(:,1:n/2+1);
P1(:,2:end-1) = 2*P1(:,2:end-1);
```

In the frequency domain, plot the single-sided amplitude spectrum for each row in a single figure.

```
for i=1:3
 subplot(3,1,i)
 plot(0:(Fs/n):(Fs/2-Fs/n),P1(i,1:n/2))
 title(['Row ',num2str(i), ' in the Frequency Domain'])
end
```

## Input Arguments

### **X** — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Input arrays of 8-bit or 16-bit unsigned integers are cast to **double** prior to computing the Fourier transform.

If  $X$  is an empty 0-by-0 matrix, then `fft(X)` returns an empty 0-by-0 matrix.

Data Types: `double` | `single` | `uint8` | `uint16`  
Complex Number Support: Yes

**n — Transform length**

`[]` (default) | nonnegative integer scalar

Transform length, specified as `[]` or a nonnegative integer scalar. Specifying a positive integer scalar for the transform length can increase the performance of `fft`. The length is typically specified as a power of 2 or a value that can be factored into a product of small prime numbers. If `n` is less than the length of the signal, then `fft` ignores the remaining signal values past the `n`th entry and returns the truncated result. If `n` is 0, then `fft` returns an empty matrix.

Example: `n = 2^nextpow2(size(X,1))`

Data Types: `double` | `single` | `uint8` | `uint16`

**dim — Dimension to operate along**

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

- `fft(X,[],1)` operates along the columns of `X` and returns the Fourier transform of each column.

- `fft(X,[],2)` operates along the rows of `X` and returns the Fourier transform of each row.

`fft(X,[],2)`

If `dim` is greater than `ndims(X)`, then `fft(X,[],dim)` returns `X`. When `n` is specified, `fft(X,n,dim)` pads or truncates `X` to length `n` along dimension `dim`.

Data Types: `double` | `single` | `uint8` | `uint16`

## Output Arguments

### **Y** — Frequency domain representation

vector | matrix | multidimensional array

Frequency domain representation returned as a vector, matrix, or multidimensional array.

If `X` is of type `single`, then `fft` natively computes in single precision, and `Y` is also of type `single`. Otherwise, `Y` is returned as a type `double`.

The size of `Y` is as follows:

- For `Y = fft(X)` or `Y = fft(X,[],dim)`, the size of `Y` is equal to the size of `X`.
- For `Y = fft(X,n,dim)`, the value of `size(Y,dim)` is equal to `n`, while the size of all other dimensions remains as in `X`.

If `X` is real, then `Y` is conjugate symmetric, and the number of unique points in `Y` is `ceil((n+1)/2)`.

## More About

### Discrete Fourier Transform of Vector

$Y = \text{fft}(X)$  and  $X = \text{ifft}(Y)$  implement the Fourier transform and inverse Fourier transform, respectively. For  $X$  and  $Y$  of length  $n$ , these transforms are defined as follows:

$$Y(k) = \sum_{j=1}^n X(j) W_n^{(j-1)(k-1)}$$
$$X(j) = \frac{1}{n} \sum_{k=1}^n Y(k) W_n^{-(j-1)(k-1)},$$

where

$$W_n = e^{(-2\pi i)/n}$$

is one of  $n$  roots of unity.

### Tips

- The execution time for `fft` depends on the length of the transform. The time is fastest for powers of two and almost as fast for lengths that have only small prime factors. The time is typically several times slower for lengths that are prime, or which have large prime factors.
- For most values of  $n$ , real-input DFTs require roughly half the computation time of complex-input DFTs. However, when  $n$  has large prime factors, there is little or no speed difference.
- You can potentially increase the speed of `fft` using the utility function, `fftw`. This function controls the optimization of the algorithm used to compute an FFT of a particular size and dimension.

### Algorithms

The FFT functions (`fft`, `fft2`, `fftn`, `ifft`, `ifft2`, `ifftn`) are based on a library called FFTW [1] [2].

- “Discrete Fourier Transform (DFT)”
- “Fast Fourier Transform (FFT)”

**Introduced before R2006a**

## fft2

2-D fast Fourier transform

### Syntax

```
Y = fft2(X)
Y = fft2(X,m,n)
```

### Description

`Y = fft2(X)` returns the two-dimensional discrete Fourier transform (DFT) of `X`. The DFT is computed with a fast Fourier transform (FFT) algorithm. The result, `Y`, is the same size as `X`.

If the dimensionality of `X` is greater than 2, the `fft2` function returns the 2-D DFT for each higher dimensional slice of `X`. For example, if `size(X) = [100 100 3]`, then `fft2` computes the DFT of `X(:,:,1)`, `X(:,:,2)` and `X(:,:,3)`.

`Y = fft2(X,m,n)` truncates `X`, or pads `X` with zeros to create an `m`-by-`n` array before doing the transform. The result is `m`-by-`n`.

### Data Type Support

`fft2` supports inputs of data types `double` and `single`. If you call `fft2` with the syntax `y = fft2(X, ...)`, the output `y` has the same data type as the input `X`.

### More About

#### Algorithms

`fft2(X)` can be simply computed as

```
fft(fft(X).').'
```

This computes the one-dimensional DFT of each column  $X$ , then of each row of the result. The execution time for `fft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `fft2` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

---

### See Also

`fft` | `fftn` | `fftw` | `fftshift` | `ifft2`

**Introduced before R2006a**

## **fftn**

N-D fast Fourier transform

### **Syntax**

```
Y = fftn(X)
Y = fftn(X,siz)
```

### **Description**

`Y = fftn(X)` returns the discrete Fourier transform (DFT) of `X`, computed with a multidimensional fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`Y = fftn(X,siz)` pads `X` with zeros, or truncates `X`, to create a multidimensional array of size `siz` before performing the transform. The size of the result `Y` is `siz`.

### **Data Type Support**

`fftn` supports inputs of data types `double` and `single`. If you call `fftn` with the syntax `y = fftn(X, ...)`, the output `y` has the same data type as the input `X`.

### **More About**

#### **Algorithms**

`fftn(X)` is equivalent to

```
Y = X;
for p = 1:length(size(X))
 Y = fft(Y,[],p);
end
```

This computes in-place the one-dimensional fast Fourier transform along each dimension of `X`. The execution time for `fft` depends on the length of the transform. It is fastest

for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

---

**Note** You might be able to increase the speed of `fftn` using the utility function `fftw`, which controls the optimization of the algorithm used to compute an FFT of a particular size and dimension.

---

### See Also

`fft` | `fft2` | `fftw` | `ifftn`

**Introduced before R2006a**

## fftshift

Shift zero-frequency component to center of spectrum

### Syntax

```
Y = fftshift(X)
Y = fftshift(X,dim)
```

### Description

`Y = fftshift(X)` rearranges the outputs of `fft`, `fft2`, and `fftn` by moving the zero-frequency component to the center of the array. It is useful for visualizing a Fourier transform with the zero-frequency component in the middle of the spectrum.

For vectors, `fftshift(X)` swaps the left and right halves of `X`. For matrices, `fftshift(X)` swaps the first quadrant with the third and the second quadrant with the fourth.

For higher-dimensional arrays, `fftshift(X)` swaps “half-spaces” of `X` along each dimension.

`Y = fftshift(X,dim)` applies the `fftshift` operation along the dimension `dim`.

For dim = 1:

For dim = 2:

---

**Note:** `ifftshift` will undo the results of `fftshift`. If the matrix `X` contains an odd number of elements, `ifftshift(fftshift(X))` must be done to obtain the original `X`. Simply performing `fftshift(X)` twice will not produce `X`.

---

## Examples

For any matrix `X`

```
Y = fft2(X)
```

has `Y(1,1) = sum(sum(X))`; the zero-frequency component of the signal is in the upper-left corner of the two-dimensional FFT. For

```
Z = fftshift(Y)
```

this zero-frequency component is near the center of the matrix.

The difference between `fftshift` and `ifftshift` is important for input sequences of odd-length.

```
N = 5;
X = 0:N-1;
Y = fftshift(fftshift(X));
Z = ifftshift(fftshift(X));
```

Notice that `Z` is a correct replica of `X`, but `Y` is not.

```
isequal(X,Y),isequal(X,Z)
```

# fftw

Interface to FFTW library run-time algorithm tuning control

## Syntax

```
fftw('planner', method)
method = fftw('planner')
str = fftw('dwisdom')
str = fftw('swisdom')
fftw('dwisdom', str)
fftw('swisdom', str)
```

## Description

`fftw` enables you to optimize the speed of the MATLAB FFT functions `fft`, `ifft`, `fft2`, `ifft2`, `fftn`, and `ifftn`. You can use `fftw` to set options for a tuning algorithm that experimentally determines the fastest algorithm for computing an FFT of a particular size and dimension at run time. MATLAB software records the optimal algorithm in an internal data base and uses it to compute FFTs of the same size throughout the current session. The tuning algorithm is part of the FFTW library that MATLAB software uses to compute FFTs.

`fftw('planner', method)` sets the method by which the tuning algorithm searches for a good FFT algorithm when the dimension of the FFT is not a power of 2. You can specify `method` to be one of the following. The default method is `estimate`:

- 'estimate'
- 'measure'
- 'patient'
- 'exhaustive'
- 'hybrid'

When you call `fftw('planner', method)`, the next time you call one of the FFT functions, such as `fft`, the tuning algorithm uses the specified method to optimize the

FFT computation. Because the tuning involves trying different algorithms, the first time you call an FFT function, it might run more slowly than if you did not call `fftw`. However, subsequent calls to any of the FFT functions, for a problem of the same size, often run more quickly than they would without using `fftw`.

---

**Note** The FFT functions only use the optimal FFT algorithm during the current MATLAB session. “Reusing Optimal FFT Algorithms” on page 1-2650 explains how to reuse the optimal algorithm in a future MATLAB session.

---

If you set the method to `'estimate'`, the FFTW library does not use run-time tuning to select the algorithms. The resulting algorithms might not be optimal.

If you set the method to `'measure'`, the FFTW library experiments with many different algorithms to compute an FFT of a given size and chooses the fastest. Setting the method to `'patient'` or `'exhaustive'` has a similar result, but the library experiments with even more algorithms so that the tuning takes longer the first time you call an FFT function. However, subsequent calls to FFT functions are faster than with `'measure'`.

If you set `'planner'` to `'hybrid'`, MATLAB software

- Sets method to `'measure'` method for FFT dimensions 8192 or smaller.
- Sets method to `'estimate'` for FFT dimensions greater than 8192.

`method = fftw('planner')` returns the current planner method.

`str = fftw('dwisdom')` returns the information in the FFTW library's internal double-precision database as a string. The string can be saved and then later reused in a subsequent MATLAB session using the next syntax.

`str = fftw('swisdom')` returns the information in the FFTW library's internal single-precision database as a string.

`fftw('dwisdom', str)` loads `fftw` wisdom represented by the string `str` into the FFTW library's internal double-precision wisdom database. `fftw('dwisdom', '')` or `fftw('dwisdom', [])` clears the internal wisdom database.

`fftw('swisdom', str)` loads `fftw` wisdom represented by the string `str` into the FFTW library's internal single-precision wisdom database. `fftw('swisdom', '')` or `fftw('swisdom', [])` clears the internal wisdom database.

**Note on large powers of 2** For FFT dimensions that are powers of 2, between  $2^{14}$  and  $2^{22}$ , MATLAB software uses special preloaded information in its internal database to optimize the FFT computation. No tuning is performed when the dimension of the FFT is a power of 2, unless you clear the database using the command `fftw('wisdom', [])`.

For more information about the FFTW library, see <http://www.fftw.org>.

## Examples

### Comparison of Speed for Different Planner Methods

The following example illustrates the run times for different settings of `planner`. The example first creates some data and applies `fft` to it using the default method, `estimate`.

```
t=0:.001:5;
x = sin(2*pi*50*t)+sin(2*pi*120*t);
y = x + 2*randn(size(t));

tic; Y = fft(y,1458); toc
Elapsed time is 0.000521 seconds.
```

If you execute the commands

```
tic; Y = fft(y,1458); toc
Elapsed time is 0.000151 seconds.
```

a second time, MATLAB software reports the elapsed time as essentially 0. To measure the elapsed time more accurately, you can execute the command `Y = fft(y,1458)` 1000 times in a loop.

```
tic; for k=1:1000
Y = fft(y,1458);
end; toc
Elapsed time is 0.056532 seconds.
```

This tells you that it takes on order of 1/10000 of a second to execute `fft(y, 1458)` a single time.

For comparison, set `planner` to `patient`. Since this `planner` explores possible algorithms more thoroughly than `hybrid`, the first time you run `fft`, it takes longer to compute the results.

```
fftw('planner','patient')
tic;Y = fft(y,1458);toc
Elapsed time is 0.100637 seconds.
```

However, the next time you call `fft`, it runs at approximately the same speed as before you ran the method `patient`.

```
tic;for k=1:1000
Y=fft(y,1458);
end;toc
Elapsed time is 0.057209 seconds.
```

## Reusing Optimal FFT Algorithms

In order to use the optimized FFT algorithm in a future MATLAB session, first save the “wisdom” using the command

```
str = fftw('wisdom')
```

You can save `str` for a future session using the command

```
save str
```

The next time you open a MATLAB session, load `str` using the command

```
load str
```

and then reload the “wisdom” into the FFTW database using the command

```
fftw('wisdom', str)
```

## fgetl

Read line from file, removing newline characters

### Syntax

```
tline = fgetl(fileID)
```

### Description

*tline* = fgetl(*fileID*) returns the next line of the specified file, removing the newline characters. *fileID* is an integer file identifier obtained from fopen. *tline* is a text string unless the line contains only the end-of-file marker. In this case, *tline* is the numeric value -1.

fgetl reads characters using the encoding scheme associated with the file. To specify the encoding scheme, use fopen.

### Examples

Read and display the file fgetl.m one line at a time:

```
fid = fopen('fgetl.m');

tline = fgetl(fid);
while ischar(tline)
 disp(tline)
 tline = fgetl(fid);
end

fclose(fid);
```

Compare these results to the fgets example, which replaces the calls to fgetl with fgets.

### More About

- “Testing for EOF with fgetl and fgets”

**See Also**

fclose | feof | ferror | fgets | fopen | fprintf | fread | fscanf | fwrite

**Introduced before R2006a**

## fgetl (serial)

Read line of ASCII text from device and discard terminator

### Syntax

```
tline = fgetl(obj)
[tline,count] = fgetl(obj)
[tline,count,msg] = fgetl(obj)
```

### Description

`tline = fgetl(obj)` reads one line of ASCII text from the device connected to the serial port object, `obj`, and returns the data to `tline`. This returned data does not include the terminator with the text line. To include the terminator, use `fgets`.

`[tline,count] = fgetl(obj)` returns the number of values read to `count`, including the terminator.

`[tline,count,msg] = fgetl(obj)` returns a warning message to `msg` if the read operation was unsuccessful.

### Examples

On a Windows platform, create the serial port object `s`, connect `s` to a Tektronix® TDS 210 oscilloscope, and write the `RS232?` command with the `fprintf` function. `RS232?` instructs the scope to return serial port communications settings.

```
s = serial('COM1');
fopen(s)
fprintf(s, 'RS232?')
```

Because the default value for the `ReadAsyncMode` property is `CONTINUOUS`, data is automatically returned to the input buffer.

```
s.BytesAvailable
```

```
ans =
 17
```

Use `fgetl` to read the data returned from the previous write operation, and discard the terminator.

```
settings = fgetl(s)
```

```
settings =
9600;0;0;NONE;LF
```

```
length(settings)
```

```
ans =
 16
```

Disconnect `s` from the scope, and remove `s` from memory and the workspace.

```
fclose(s)
delete(s)
clear s
```

## More About

### Tips

Before you can read text from the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read – including the terminator – each time `fgetl` is issued.

---

**Note:** You cannot use ASCII values larger than 127 characters. The function is limited to 127 binary characters.

---

## Rules for Completing a Read Operation with `fgetl`

A read operation with `fgetl` blocks access to the MATLAB command line until:

- The terminator specified by the `Terminator` property is reached.
- The time specified by the `Timeout` property passes.
- The input buffer is filled.

---

**Note:** You cannot use ASCII values larger than 127 characters. The function is limited to 127 binary characters.

---

## **fgets**

Read line from file, keeping newline characters

### **Syntax**

```
tline = fgets(fileID)
tline = fgets(fileID, nchar)
```

### **Description**

*tline* = fgets(*fileID*) reads the next line of the specified file, including the newline characters. *fileID* is an integer file identifier obtained from fopen. *tline* is a text string unless the line contains only the end-of-file marker. In this case, *tline* is the numeric value -1. fgets reads characters using the encoding scheme associated with the file. To specify the encoding scheme, use fopen.

*tline* = fgets(*fileID*, *nchar*) returns at most *nchar* characters of the next line. *tline* does not include any characters after the newline characters or the end-of-file marker.

### **Examples**

Read and display the file `fgets.m`. Because fgets keeps newline characters and disp adds a newline character, this code displays the file with double-spacing:

```
fid = fopen('fgets.m');

tline = fgets(fid);
while ischar(tline)
 disp(tline)
 tline = fgets(fid);
end

fclose(fid);
```

Compare these results to the `fgetl` example, which replaces the calls to fgets with fgetl.

## More About

## **fgets (serial)**

Read line of text from device and include terminator

### **Syntax**

```
tline = fgets(obj)
[tline,count] = fgets(obj)
[tline,count,msg] = fgets(obj)
```

### **Description**

`tline = fgets(obj)` reads one line of text from the device connected to the serial port object, `obj`, and returns the data to `tline`. This returned data includes the terminator with the text line. To exclude the terminator, use `fgetl`.

`[tline,count] = fgets(obj)` returns the number of values read to `count`, including the terminator.

`[tline,count,msg] = fgets(obj)` returns a warning message to `msg` if the read operation was unsuccessful.

### **Examples**

Create the serial port object `s`, connect `s` to a Tektronix TDS 210 oscilloscope, and write the `RS232?` command with the `fprintf` function. `RS232?` instructs the scope to return serial port communications settings.

```
s = serial('COM1');
fopen(s)
fprintf(s, 'RS232?')
```

Because the default value for the `ReadAsyncMode` property is `CONTINUOUS`, data is automatically returned to the input buffer.

```
s.BytesAvailable
ans =
 17
```

Use `fgets` to read the data returned from the previous write operation, and include the terminator.

```
settings = fgets(s)
```

```
settings =
9600;0;0;NONE;LF
```

```
length(settings)
```

```
ans =
 17
```

Disconnect `s` from the scope, and remove `s` from memory and the workspace.

```
fclose(s)
delete(s)
clear s
```

# fieldnames

Field names of structure, or public fields of object

## Syntax

```
names = fieldnames(s)
names = fieldnames(obj)
names = fieldnames(obj, '-full')
```

## Description

`names = fieldnames(s)` returns a cell array of strings containing the names of the fields in structure `s`.

`names = fieldnames(obj)` returns a cell array of strings containing the names of the public properties of `obj`. MATLAB objects can overload `fieldnames` and define their own behavior.

`names = fieldnames(obj, '-full')` returns a cell array of strings containing the name, type, attributes, and inheritance of the properties of `obj`. Only supported for COM or Java objects.

## Examples

### Structure Fields

Create a structure array and view its fields.

```
s(1,1).name = 'alice';
s(1,1).ID = 0;
s(2,1).name = 'gertrude';
s(2,1).ID = 1;

names = fieldnames(s)
```

```
names =
 'name'
 'ID'
```

## Java Object Properties

Create a Java® object and view its public properties.

```
obj = java.lang.Integer(0);
names = fieldnames(obj)
```

```
names =
 'MIN_VALUE'
 'MAX_VALUE'
 'TYPE'
 'SIZE'
```

# figure

Create figure window

## Syntax

```
figure
figure('PropertyName',propertyvalue,...)
figure(h)
h = figure(...)
```

## Properties

For a list of properties, see [Figure Properties](#).

## Description

`figure` creates a new figure window using default property values. This new figure window becomes the current figure, and it displays on top of all other figures on the screen. The title of the figure is an integer value that is not already used by an existing figure. MATLAB saves this integer value in the figure's `Number` property.

`figure('PropertyName',propertyvalue,...)` creates a new figure window using specific property values. For a list of available properties, see [Figure Properties](#). MATLAB uses default values for any properties that you do not explicitly define as arguments.

`figure(h)` does one of the following:

- If `h` is the handle or the `Number` property value of an existing figure, then `figure(h)` makes that existing figure the current figure, makes it visible, and moves it on top of all other figures on the screen. The current figure is the target for graphics output.
- If `h` is not the handle and is not the `Number` property value of an existing figure, but is an integer, then `figure(h)` creates a figure object and assigns its `Number` property the value `h`.

- If `h` is not the handle to a figure and is not a positive integer, then MATLAB returns an error.

`h = figure(...)` returns the handle to the figure object.

## Examples

### Specifying Figure Size and Screen Location

To create a figure window that is one quarter the size of your screen and is positioned in the upper left corner, use the root object's `ScreenSize` property to determine the size. The `ScreenSize` property value is a four-element vector: [`left bottom width height`].

```
scrsz = get(groot,'ScreenSize');
figure('Position',[1 scrsz(4)/2 scrsz(3)/2 scrsz(4)/2])
```

To position the full figure window including the menu bar, title bar, tool bars, and outer edges, use the `OuterPosition` property in the same manner.

### Specifying the Figure Window Title

You can add your own title to a figure by setting the `Name` property and turning off the `NumberTitle` property:

```
figure('Name','Simulation Plot Window','NumberTitle','off')
```

## Setting Default Properties

You can set default figure properties only on the `groot` level.

```
set(groot,'DefaultFigureProperty',PropertyValue...)
```

where *Property* is the name of the figure property and `PropertyValue` is the value you are specifying. Use `set` and `get` to access figure properties.

## More About

### Tips

Use dot notation to query or modify a particular figure's property. For example, `f.Units = 'inches'` sets the `Units` property of figure `f` to inches.

Figures can be docked in the desktop. The `DockControls` property determines whether you can dock the figure.

### Making a Figure Current

The current figure is the target for graphics output. There are two ways to make a figure `h` the current figure.

- Make the figure `h` current, visible, and displayed on top of other figures:  
`figure(h);`
- Make the figure `h` current, but do not change its visibility or stacking with respect to other figures:

```
set(groot, 'CurrentFigure', h);
```

**Introduced before R2006a**

## Figure Properties

Control figure window appearance and behavior

Figures are windows that contain graphics or user interface components. Figure properties control the appearance and behavior of a particular instance of a figure. To modify aspects of a figure, change property values.

Starting in R2014b, you can use dot notation to query and set properties.

```
fig = figure;
u = fig.Units;
fig.Units = 'inches';
```

If you are using an earlier release, use the `get` and `set` functions instead.

## Figure Appearance

### Color — Figure window background color

RGB triplet | short name | long name | 'none'

The figure window background color, specified as an RGB triplet, a predefined color name string, or 'none'. If you specify 'none', the figure background color appears black on screen, but if you print it, the background prints as though the figure window is transparent.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'white'   | 'w'        | [ 1 1 1 ]   |
| 'black'   | 'k'        | [ 0 0 0 ]   |

Data Types: double | char

### DockControls — Interactive figure docking

'on' (default) | 'off'

Interactive figure docking, specified as one of the following:

- 'on' — Figure can be docked in the MATLAB desktop. The **Desktop > Dock Figure** menu item and the Dock Figure button  in the menu bar are enabled.
- 'off' — MATLAB disables the **Desktop > Dock Figure** menu item and does not display the figure dock button.

You cannot set the DockControls property to 'off' if the WindowStyle is set to 'docked'.

### MenuBar — Figure menu bar display

'figure' (default) | 'none'

Figure menu bar display, specified as 'figure' or 'none'. The MenuBar property enables you to display or hide the default menus at the top of a figure window. Specify 'figure' to display the menu bar. Specify 'none' to hide it.

This property affects only default menus, and does not affect menus defined with the uimenu command.

Menu bars do not appear in figures whose WindowStyle property is set to 'Modal'. If a figure containing uimenu children is changed to 'Modal', the uimenu children still exist in the Children property of the figure. However, the uimenu do not display while WindowStyle is set to 'Modal'.

---

**Note:** If you do not want to display the default menus in the figure, then set this property to 'none' when you create the figure.

---

### Name — Figure window title

' ' (default) | string

Figure window title, specified as a string. The `Name` property specifies the title that the figure window displays. By default, the figure title displays as `Figure 1`, `Figure 2`, and so on. When you set this property to a string, the figure title becomes `Figure:n string`. If you want only the `Name` value to display, set `IntegerHandle` or `NumberTitle` to `'off'`.

Example: `'Results'`

### **NumberTitle — Figure window title number**

`'on'` (default) | `'off'`

Figure window title number, specified as `'on'` or `'off'`. The `NumberTitle` property determines whether MATLAB includes the string `Figure n` in the title bar, where `n` is the figure `Number` property value.

If you set `IntegerHandle` to `'off'`, then a number does not display in the figure window title, regardless of the `NumberTitle` property setting.

### **ToolBar — Figure toolbar display**

`'auto'` (default) | `'figure'` | `'none'`

Figure toolbar display, specified as one of the following:

- `'auto'` — Uses the same value as the `MenuBar` property.
- `'figure'` — Toolbar displays.
- `'none'` — Toolbar does not display.

This property affects only the default toolbar. It does not affect other toolbars such as, the Camera Toolbar or Plot Edit Toolbar. Selecting **Figure Toolbar** from the figure **View** menu sets this property to `'figure'`.

Toolbars do not appear in figures whose `WindowStyle` property is set to `'Modal'`. If a figure containing a toolbar is changed to `'Modal'`, the tool bar children still exist in the `Children` property of the figure. However, the toolbar does not display while `WindowStyle` is set to `'Modal'`.

---

**Note:** If you want to hide the default tool bar, then set this property to `'none'` when you create the figure.

---

### **Visible — Figure visibility**

`'on'` (default) | `'off'`

Figure visibility, specified as `'on'` or `'off'`. The `Visible` property determines whether the figure displays on the screen. If the `Visible` property of a figure is set to `'off'`, the entire figure is invisible, but you can still specify and access its properties.

Changing the size of an invisible figure triggers the `SizeChangedFcn` callback when the figure becomes visible.

---

**Note** Changing the `Visible` property of a figure does *not* change the `Visible` property of its child components even though hiding the figure prevents its children from displaying.

---

### **Clipping — Clipping of child components to figure**

`'on'` (default) | `'off'`

This property has no effect on figures.

## **Axes and Plot Appearance**

### **GraphicsSmoothing — Axes graphics smoothing**

`'on'` (default) | `'off'`

Axes graphics smoothing, specified as `'on'` or `'off'`. Smoothing reduces the appearance of jagged lines in an axes graphic. MATLAB applies a smoothing technique to an axes graphic (and the axes rulers) if `GraphicsSmoothing` is set to `'on'`, and either of these conditions is true:

- The `Renderer` property is set to `'painters'`.
- The `Renderer` property is set to `'opengl'` and your hardware card supports OpenGL.

If your axes graphic contains mostly vertical or horizontal lines, consider setting the `GraphicsSmoothing` property to `'on'` and the line or lines `AlignVertexCenters` property to `'on'`. The smoothing technique sacrifices some sharpness for smoothness, which might be particularly noticeable in such graphics.

---

**Note:** Graphics smoothing has no affect on text. MATLAB smooths text regardless of the value of the `GraphicsSmoothing` property.

---

**Renderer — Rendering method used for screen display and printing**`'opengl'` (default) | `'painters'`

Rendering method used for screen display and printing, specified as one of these values:

- `'opengl'` — OpenGL renderer. This option enables MATLAB to access graphics hardware if it is available on your system. The OpenGL renderer displays objects sorted in front to back order, as seen on the monitor. Lines always draw in front of faces when at the same location on the plane of the monitor.
- `'painters'` — Painters renderer. This option works well for axes in a 2-D view. In 2-D, the Painters renderer sorts graphics objects by child order (order specified). In 3-D, the Painters renderer sorts objects in front to back order. However, it might not correctly draw intersecting polygons in 3-D.

---

**Note:** The `'zbuffer'` option has been removed. Use `'opengl'` or `'painters'` instead.

---

## OpenGL Hardware and Software Implementations

OpenGL is available on all computers that run MATLAB since a software version of OpenGL is built-into MATLAB. However, if you have graphics hardware that supports a hardware-accelerated version of OpenGL, then MATLAB automatically uses the hardware-accelerated version to increase performance.

In some cases, MATLAB automatically uses software OpenGL even if a hardware version is available. For example, MATLAB uses the software version if it detects graphics hardware with known driver issues or detects that you are using a virtual machine or remote desktop on Windows.

MATLAB issues a warning if it cannot find a usable OpenGL library.

## Software OpenGL Selection

To switch from hardware to software OpenGL, do the following:

- On Linux systems, start MATLAB with the command `matlab -softwareopengl`.
- On Windows systems, execute the command `opengl software` in MATLAB or start MATLAB with the command `matlab -softwareopengl`.

- On Macintosh systems, software OpenGL is not supported.

The following software versions are available:

- On Linux systems, MATLAB uses the software implementation of OpenGL that is included in the MATLAB distribution.
- On Windows, OpenGL is available as part of the operating system. If you experience problems with OpenGL, contact your graphics driver vendor to obtain the latest qualified version of OpenGL.
- On Macintosh systems, software OpenGL is not available.

## Determine OpenGL Library Version

To determine the version and vendor of the OpenGL library that MATLAB is using on your system, type the following command at the MATLAB prompt:

```
opengl info
```

The returned information contains a line that indicates if MATLAB is using software OpenGL (`Software = true`) or hardware-accelerated OpenGL (`Software = false`).

This command also returns a string of extensions to the OpenGL specification that are available with the particular library MATLAB is using. Include this information if you report a bug.

Be aware that issuing the `opengl info` command causes MATLAB to initialize OpenGL.

## XServer Connection Lost

When using Linux, if there is a break in the connection to the XServer, MATLAB can crash with a segmentation violation. If this happens, ensure that the system has the latest XServer installed.

On a Linux system, you also can try upgrading the OpenGL driver or starting MATLAB with software OpenGL using this command:

```
matlab -softwareopengl
```

**RendererMode — Renderer selection**

'auto' (default) | 'manual'

Renderer selection, specified as:

- 'auto' — MATLAB selects the rendering method for printing and screen display based on the size and complexity of the graphics objects in the figure.
- 'manual' — MATLAB uses the renderer specified with the `Renderer` property.

MATLAB sets the `RendererMode` property to 'manual' if you explicitly set the `Renderer` property to 'painters' or 'opengl'.

## Color and Transparency Mapping

**Alphamap — Transparency map for axes content of figure**

array of 64 values from 0 to 1 (default) | array of finite alpha values from 0 to 1

Transparency map for axes content of figure, specified as an array of finite alpha values that progress linearly from 0 to 1. The size of the array can be  $m$ -by-1 or 1-by- $m$ . MATLAB accesses alpha values by their row number. For example, an index of 1 specifies the first alpha value, an index of 2 specifies the second alpha value, and so on. Alphamaps can be any length.

Alphamaps affect the rendering of objects created with the `surface`, `image`, and `patch` functions, but do not affect other graphics objects.

**Colormap — Color map for axes content of figure**

parula (default) |  $m$ -by-3 array of RGB triplets

Color map for axes content of a figure, specified as an  $m$ -by-3 array of RGB (red, green, blue) triplets that define  $m$  individual colors. MATLAB accesses these colors by their row number. For example, an index of 1 specifies the first RGB triplet, an index of 2 specifies the second RGB triplet, and so on.

Colormaps affect the rendering of objects created with the `surface`, `image`, and `patch` functions, but generally do not affect other graphics objects.

Colormaps can be any length, but must be three columns wide.

Example: `[1 0 1; 0 0 1; 1 1 0]`

## Location and Size

### Position — Location and size of figure's drawable area

[left bottom width height]

Location and size of figure's drawable area, specified as the vector, [left bottom width height]. The drawable area is the inner area of the window, excluding the title bar, menu bar, and tool bars. This table describes each element in the **Position** vector.

| Element | Description                                                                                                                                                                |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| left    | Distance from the left edge of the primary display to the inner left edge of the figure window. This value can be negative on systems that have more than one monitor.     |
| bottom  | Distance from the bottom edge of the primary display to the inner bottom edge of the figure window. This value can be negative on systems that have more than one monitor. |
| width   | Distance between the right and left inner edges of the figure.                                                                                                             |
| height  | Distance between the top and bottom inner edges of the figure.                                                                                                             |

All measurements are in units specified by the **Units** property.

You cannot specify the figure **Position** property when the figure is docked.

To place the full window, including the title bar, menu bar, tool bars, and outer edges, use the **OuterPosition** property.

---

**Note:** The Windows operating system enforces a minimum figure window width. If you specify a width below that value, the figure will display at the Windows minimum width.

---

Example: [230 250 570 510]

Data Types: double

### OuterPosition — Location and size of figure's outer bounds

[left bottom width height]

Location and size of outer bounds, specified as the vector, [left bottom width height]. This table describes each element in the vector.

| Element | Description                                                                                                                                                                |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| left    | Distance from the left edge of the primary display to the outer left edge of the figure window. This value can be negative on systems that have more than one monitor.     |
| bottom  | Distance from the bottom edge of the primary display to the outer bottom edge of the figure window. This value can be negative on systems that have more than one monitor. |
| width   | Distance between the right and left outer edges of the figure.                                                                                                             |
| height  | Distance between the top and bottom outer edges of the figure.                                                                                                             |

All measurements are in units specified by the `Units` property.

If you attempt to set the `OuterPosition` property when the figure is docked, this warning displays:

```
Warning: Cannot set OuterPosition while
WindowStyle is 'docked'
```

---

**Note:** On Microsoft Windows systems, figure windows are always at least 104 pixels wide, regardless of the value of the `OuterPosition` property.

---

Example: [230 250 570 510]

Data Types: double

### **Units — Units of measurement**

'pixels' (default) | 'normalized' | 'inches' | 'centimeters' | 'points' | 'characters'

Units of measurement, specified one of the values from this table.

| Units Value        | Description |
|--------------------|-------------|
| 'pixels' (default) | Pixels.     |

| Units Value   | Description                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <p>Starting in R2015b, distances in pixels are independent of your system resolution on Windows and Macintosh systems:</p> <ul style="list-style-type: none"> <li>• On Windows systems, a pixel is 1/96th of an inch.</li> <li>• On Macintosh systems, a pixel is 1/72nd of an inch.</li> </ul> <p>On Linux systems, the size of a pixel is determined by your system resolution.</p> |
| 'normalized'  | These units are normalized with respect to the parent container. The lower-left corner of the container maps to (0,0) and the upper-right corner maps to (1,1).                                                                                                                                                                                                                       |
| 'inches'      | Inches.                                                                                                                                                                                                                                                                                                                                                                               |
| 'centimeters' | Centimeters.                                                                                                                                                                                                                                                                                                                                                                          |
| 'points'      | Points. One point equals 1/72nd of an inch.                                                                                                                                                                                                                                                                                                                                           |
| 'characters'  | <p>These units are based on the default system font character size.</p> <ul style="list-style-type: none"> <li>• Character width = width of the letter x.</li> <li>• Character height = distance between the baselines of two lines of text.</li> </ul>                                                                                                                               |

MATLAB measures all units from the lower left corner of the parent object.

This property affects the **Position** property. If you change the units, then it is good practice to return it to its default value after completing your computation to prevent affecting other functions that assume **Units** is the default value.

The order in which you specify the **Units** and **Position** properties has these effects:

- If you specify the **Units** before the **Position** property, then MATLAB sets **Position** using the units you specify.

- If you specify the `Units` property after the `Position` property, MATLAB sets the position using the default `Units`. Then, MATLAB converts the `Position` value to the equivalent value in units you specify.

### **Resize — Window resize mode**

'on' (default) | 'off'

Window resize mode, specified as:

- 'on' — Users can resize the figure window.
- 'off' — Users cannot resize the figure window. The figure window does not display any resizing controls.

### **SizeChangedFcn — Window resize callback function**

' ' (default) | function handle | cell array | string

Callback function that executes when the figure size changes, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

Define this callback function when you want to customize a UI layout beyond what the `Position` and `Units` properties provide.

The `SizeChangedFcn` callback executes under these circumstances:

- The figure becomes visible for the first time.
- The figure is visible while its drawable area changes. The drawable area is the area inside the outer bounds of the figure.
- The figure becomes visible for the first time after its drawable area changes. This situation occurs when the drawable area changes while the figure is invisible, and then it becomes visible later.

These are some of the important characteristics of the `SizeChangedFcn` callback and some recommended best practices:

- Consider delaying the display of the figure until after all the variables that the figure's `SizeChangedFcn` uses are defined. This practice can prevent the figure's

SizeChangedFcn callback from returning an error. To delay the display of the figure, set its `Visible` property to `'off'`. Then, set the `Visible` property to `'on'` after you define the variables that your `SizeChangedFcn` callback uses.

- Use the `gcbo` function in your `SizeChangedFcn` code to get the figure object that the user is resizing.

## Example: Uicontrol That has Constant Height

Use the `SizeChangedFcn` callback to constrain the size of UI components. For instance, create a program file called `sbar.m` that contains the following code.

If you are using R2014b or later, use dot notation to set and query properties:

```
function sbar(src,callbackdata)
 u = findobj(gcbo,'Tag','StatusBar');
 fig = gcbo;
 old_units = fig.Units;
 fig.Units = 'pixels';
 sbar_units = u.Units;
 u.Units = 'pixels';
 figpos = fig.Position;
 upos = [1 figpos(4) - 20 figpos(3) 20];
 u.Position = upos;
 u.Units = sbar_units;
 fig.Units = old_units;
 u.Visible = 'on';
end
```

If you are using R2014a or an earlier release, use this code instead.

```
function sbar(src,callbackdata)
 u = findobj(gcbo,'Tag','StatusBar');
 fig = gcbo;
 old_units = get(fig,'Units');
 set(fig,'Units','pixels');
 sbar_units = get(u,'Units');
 set(u,'Units','pixels');
 figpos = get(fig,'Position');
 upos = [1 figpos(4) - 20 figpos(3) 20];
 set(u,'Position',upos);
 set(u,'Units',sbar_units);
 set(fig,'Units',old_units);
```

```
 set(u, 'Visible', 'on');
end
```

After saving `sbar.m`, run this code in the Command Window:

```
f = figure('Visible', 'off', 'SizeChangedFcn', @sbar);
u = uicontrol('Style', 'edit', 'Tag', 'StatusBar');
f.Visible = 'on';
% For R2014a and earlier: set(f, 'Visible', 'on');
```

The `sbar` function maintains a 20-pixel `uicontrol` height and sets the `uicontrol` width equal to the width of the figure. Notice the use of the `findobj` function to retrieve the `uicontrol` object. This function also calls the `gcb0` function to access the figure object.

Data Types: `function_handle` | `cell` | `char`

### **ResizeFcn — Figure resize callback function**

' ' (default) | function handle | cell array | string

Callback function that executes when the figure size changes, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

---

**Note:** Use of the `ResizeFcn` property is not recommended. It might be removed in a future release. Use `SizeChangedFcn` instead.

---

Data Types: `function_handle` | `cell` | `char`

## **Multiple Plots**

### **NextPlot — Directive on how to add next plot**

'add' (default) | 'new' | 'replace' | 'replacechildren'

Directive on how to add next plot, specified as 'add', 'new', 'replace', or 'replacechildren'.

This table describes the effects of each value.

| Property Value    | Effect                                                                                                                                                                     |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'new'             | Creates a new figure and uses it as the current figure.                                                                                                                    |
| 'add'             | Adds new graphics objects without clearing or resetting the current figure.                                                                                                |
| 'replacechildren' | Removes all axes objects who are not hidden before adding new objects. Does not reset figure properties.<br><br>Equivalent to using the <code>clf</code> command.          |
| 'replace'         | Removes all axes objects and resets figure properties to their defaults before adding new graphics objects.<br><br>Equivalent to using the <code>clf reset</code> command. |

Consider using the `newplot` function to handle the `NextPlot` property. For more information, see the axes `NextPlot` property and “Prepare Figures and Axes for Graphs”.

## Interactive Control

### Selected — Selection status of figure

'off' (default) | 'on'

---

**Note:** The behavior of the `Selected` property changed in R2014b, and it is not recommended. It no longer has any effect on figures. This property might be removed in a future release.

---

### SelectionHighlight — Ability of figure to highlight when user selects it

'on' (default) | 'off'

---

**Note:** Use of the figure `SelectionHighlight` property is not recommended. This property might be removed in a future release.

---

This property has no effect on figures.

## Callback Execution Control

### **Interruptible** — Callback interruption

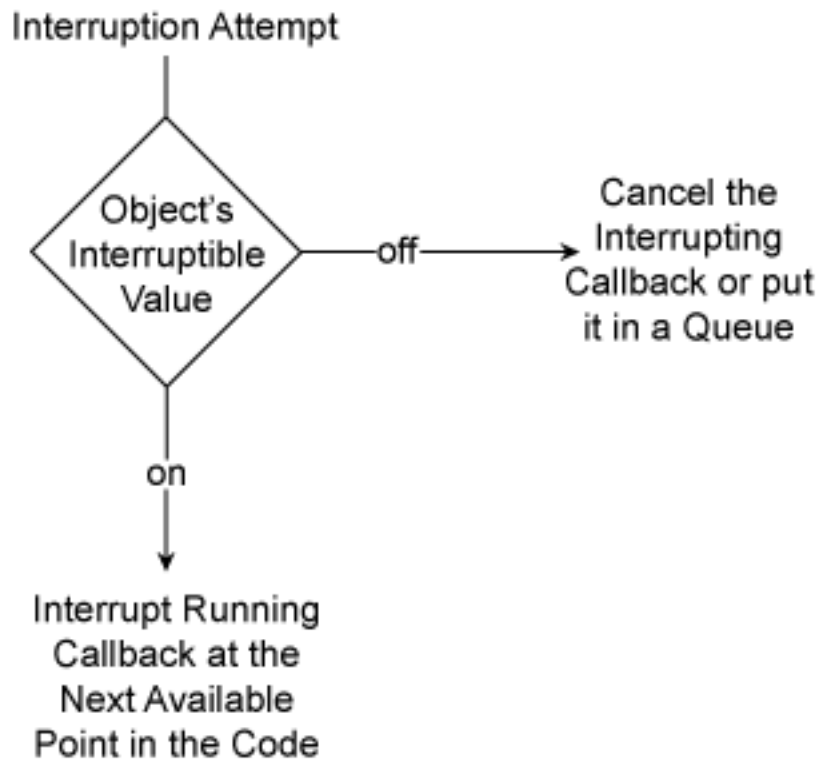

'on' (default) | 'off'

Callback interruption, specified as 'on' or 'off'. The `Interruptible` property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The `Interruptible` property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put into a queue.

If a figure callback is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- 'on' — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
- If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.

- If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

---

**Note:** Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a `DeleteFcn`, `CloseRequestFcn`, or `SizeChangedFcn` callback, then the interruption occurs regardless of the `Interruptible` property value.
  - If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the `Interruptible` property value.
  - MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.
- 

See “Interrupt Callback Execution” for an example that shows how the `Interruptible` and `BusyAction` properties affect the behavior of a program.

### **BusyAction — Callback queuing**

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' (default) or 'cancel'. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- 'cancel' — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The `Interruptible` property of the object whose callback is running determines if interruption is allowed. If `Interruptible` is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The `BusyAction` property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the `BusyAction` and `Interruptible` properties affect the behavior of a program.

### **HitTest — Ability to become current object**

'on' (default) | 'off'

Ability to become current object, specified as 'on' or 'off':

- Setting the value to 'on' allows the figure to become the current object when the user clicks on it. A value of 'on' also allows the figure `CurrentObject` property and the `gco` function to report the figure as the current object.
- Setting the value to 'off' sets the figure `CurrentObject` property to an empty `GraphicsPlaceholder` array when the user clicks on the figure.

## **Keyboard Control**

### **CurrentCharacter — Last key pressed in figure**

' ' (default) | 1-character string

The last key pressed in the figure, returned as a 1-character string. Use the `CurrentCharacter` property to obtain user input.

Example: 't'

### **KeyPressFcn — Key-press callback function**

' ' (default) | function handle | cell array | string

The callback function that executes when a user presses a key, specified as one of these values:

- Function handle

- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback function executes when the figure window has focus and the user presses a key. If you do not define a function for this property, MATLAB passes key presses to the Command Window. Repeated key presses retain the focus of the figure, and the function executes with each key press. If the user presses multiple keys at approximately the same time, MATLAB detects the key press for the last key pressed.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

| Property  | Contents                                                                                                                                                                                                                                                  |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Character | The character that displays as a result of pressing the key or keys. The character can be empty or unprintable.                                                                                                                                           |
| Modifier  | A cell array containing the names of one or more modifier keys that are being pressed (such as , <b>control</b> , <b>alt</b> , <b>shift</b> ). On Macintosh computers, the cell array contains 'command' when the <b>command</b> modifier key is pressed. |
| Key       | The key being pressed, identified by the (lowercase) label on the key, or a descriptive string.                                                                                                                                                           |
| Source    | The object that has focus when the user presses the key.                                                                                                                                                                                                  |
| Eventname | The action that caused the callback function to execute.                                                                                                                                                                                                  |

Pressing modifier keys affects the callback data in the following ways:

- Modifier keys can affect the **Character** property, but do not change the **Key** property.
- Certain keys, and keys modified with **Ctrl**, put unprintable characters in the **Character** property.
- **Ctrl**, **Alt**, **Shift**, and several other keys, do not generate **Character** property data.

You also can query the `CurrentCharacter` property of the figure to determine which character the user pressed.

Example: `@myfun`

Example: `{@myfun,x}`

### KeyReleaseFcn — Key-release callback function

' ' (default) | function handle | cell array | string

Key press callback function, specified as one of these values

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback function executes when the figure object has focus and the user releases a key.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

| Property  | Description                                                                                      | Examples:  |            |           |           |
|-----------|--------------------------------------------------------------------------------------------------|------------|------------|-----------|-----------|
|           |                                                                                                  | a          | =          | Shift     | Shift-a   |
| Character | Character interpretation of the key that was released.                                           | 'a'        | '='        | ' '       | 'A'       |
| Modifier  | Current modifier, such as 'control', or an empty cell array if there is no modifier              | {1x0 cell} | {1x0 cell} | {'shift'} | {'shift'} |
| Key       | The key being released, identified by the (lowercase) label on the key, or a descriptive string. | 'a'        | 'equal'    | 'shift'   | 'a'       |

| Property  | Description                                              | Examples: |         |          |               |
|-----------|----------------------------------------------------------|-----------|---------|----------|---------------|
|           |                                                          | a         | =       | Shift    | Shift-a       |
| Source    | The object that has focus when the user presses the key. | figure    | figure  | figure   | figure        |
| Eventname | The action that caused the callback function to execute. | 'KeyRel   | 'KeyRe] | 'KeyRele | 'KeyRelease ' |

Pressing modifier keys affects the callback data in the following ways:

- Modifier keys can affect the `Character` property, but do not change the `Key` property.
- Certain keys, and keys modified with `Ctrl`, put unprintable characters in the `Character` property.
- `Ctrl`, `Alt`, `Shift`, and several other keys, do not generate `Character` property data.

You also can query the `CurrentCharacter` property of the figure to determine which character the user pressed.

Example: `@myfun`

Example: `{@myfun,x}`

### **WindowKeyPressFcn — Key-press callback function for the figure window**

' ' (default) | function handle | cell array | string

Key-press callback function for the figure window, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback executes whenever a key press occurs while either the figure window or any of its children has focus.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to

the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

| Property  | Contents                                                                                                                                                                                                                         |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Character | The character displayed as a result of pressing the key. The character which can be empty or unprintable                                                                                                                         |
| Modifier  | A cell array containing the names of one or more modifier keys being pressed (such as <b>control</b> , <b>alt</b> , <b>shift</b> ). On Macintosh computers, it contains 'command' when pressing the <b>command</b> modifier key. |
| Key       | The key being pressed, identified by the (lowercase) label on the key, or a descriptive string.                                                                                                                                  |
| Source    | The object that has focus when the user presses the key.                                                                                                                                                                         |
| Eventname | The action that caused the callback function to execute.                                                                                                                                                                         |

Example: @myfun

Example: {@myfun,x}

### WindowKeyReleaseFcn — Key-release callback function for the figure window

' ' (default) | function handle | cell array | string

Key-release callback function for the figure window, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback executes whenever a key release occurs while the figure window or any of its children has focus.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to

the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

| Property  | Contents                                                                                                                                                                                                                           |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Character | The character displayed as a result of the releasing the key or keys. The character which can be empty or unprintable.                                                                                                             |
| Modifier  | A cell array containing the names of one or more modifier keys being released (such as <b>control</b> , <b>alt</b> , <b>shift</b> ). On Macintosh computers, it contains 'command' when releasing the <b>command</b> modifier key. |
| Key       | The key being released, identified by the (lowercase) label on the key, or a descriptive string.                                                                                                                                   |
| Source    | The object that has focus when the user releases the key.                                                                                                                                                                          |
| Eventname | The action that caused the callback function to execute.                                                                                                                                                                           |

Example: @myfun

Example: {@myfun,x}

## Mouse Control

### **ButtonDownFcn** — Button-press callback function

' ' (default) | function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback executes whenever the user clicks a mouse button while the pointer is in the figure window, but not over a child object such as a uicontrol, uipanel, axes, or axes child.

See the figure's `SelectionType` property to determine whether modifier keys are also pressed.

### **CurrentPoint** — Location of mouse pointer

two-element vector

Location of mouse pointer, returned as a two-element vector. The `CurrentPoint` property contains the coordinates  $(x, y)$  of the mouse pointer, measured from the lower left corner of the figure (in units determined by the `Units` property).

The coordinates indicate the location of the last mouse click, unless there is a `WindowButtonMotionFcn` callback defined for the figure. If the `WindowButtonMotionFcn` callback is defined, then the coordinates indicate the last location of the mouse pointer.

---

**Note:** If you use the values returned by the `CurrentPoint` property to plot points, the coordinate values might contain rounding error.

---

## **CurrentPoint and Cursor Motion**

MATLAB updates `CurrentPoint` before executing callback functions defined for the figure `WindowButtonMotionFcn` and `WindowButtonUpFcn` properties. This enables you to query `CurrentPoint` from these callback functions. It behaves like this:

- If you define a callback function for the `WindowButtonMotionFcn` property or the `WindowButtonUpFcn` property, then MATLAB updates the `CurrentPoint` property only when the user presses the mouse button within the figure window.
- If you define a callback function for the `WindowButtonMotionFcn` property, then MATLAB updates the `CurrentPoint` property just before executing the callback. The `WindowButtonMotionFcn` property executes only within the figure window, unless the user presses the mouse button within the figure and *keeps the mouse button down* while moving the pointer around the screen. In this case, the function executes (and MATLAB updates the `CurrentPoint` property) anywhere on the screen until the user releases the mouse button.
- If you define a callback function for the `WindowButtonUpFcn` property, then MATLAB updates the `CurrentPoint` property just before executing the callback. The `WindowButtonUpFcn` callback executes only while the pointer is within the

figure window, unless the user presses the mouse button within the window and *releases the mouse button* anywhere on the screen. In this case, the function executes, preceded by an update of the `CurrentPoint` property value.

- If you add a `uicontrol` or `uitable` component to the figure, then MATLAB updates the `CurrentPoint` property when the user right-clicks the component, or when they left-click the component while the `Enable` property of that component is `'off'` or `'inactive'`.

In some situations (such as when the `WindowButtonMotionFcn` callback takes a long time to execute and the user moves the pointer very rapidly), the `CurrentPoint` property might not reflect the actual location of the pointer, but rather the location at the time when the `WindowButtonMotionFcn` callback began execution.

The root `PointerLocation` property contains the location of the pointer updated synchronously with pointer movement. However, the location is measured with respect to the screen, not a figure window.

**SelectionType — Mouse selection type**

`'normal'` (default) | `'extend'` | `'alt'` | `'open'`

Mouse selection type, returned as `'normal'`, `'extend'`, `'alt'`, or `'open'`. MATLAB maintains this property to provide information about the last mouse-button press that occurred within the figure window. This information indicates the type of selection made. Selection types are actions that MATLAB generally associates with particular responses from the user interface software (for example, single-clicking a graphics object places it in move or resize mode; double-clicking a file name opens it, and so on).

The value of this property depends on the type of mouse click and the user's operating system.

| Selection Type        | Microsoft Windows                                                                                                  | Linux                                                                                                                                                    | Mac                                                                                                                                                       |
|-----------------------|--------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'normal'</code> | Click left mouse button.                                                                                           | Click left mouse button.                                                                                                                                 | Click left mouse button.                                                                                                                                  |
| <code>'extend'</code> | Either of the following: <ul style="list-style-type: none"> <li>• <b>Shift</b>-click left mouse button.</li> </ul> | Either of the following: <ul style="list-style-type: none"> <li>• <b>Shift</b>-click left mouse button.</li> <li>• Click middle mouse button.</li> </ul> | Any one of the following: <ul style="list-style-type: none"> <li>• <b>Shift</b>-click left mouse button.</li> <li>• Click middle mouse button.</li> </ul> |

| Selection Type | Microsoft Windows                                                                          | Linux                                                                | Mac                                                                                        |
|----------------|--------------------------------------------------------------------------------------------|----------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
|                | <ul style="list-style-type: none"> <li>Click both left and right mouse buttons.</li> </ul> |                                                                      | <ul style="list-style-type: none"> <li>Click both left and right mouse buttons.</li> </ul> |
| 'alt'          | <b>Control</b> -click left mouse button or click right mouse button.                       | <b>Control</b> -click left mouse button or click right mouse button. | <b>Control</b> -click left mouse button or click right mouse button.                       |
| 'open'         | Double-click any mouse button.                                                             | Double-click any mouse button.                                       | Double-click any mouse button.                                                             |

---

**Note:** For a list box (uicontrol), the second click of a double-click sets the `SelectionType` property to 'open'.

---

### WindowButtonDownFcn — Button press callback function

' ' (default) | function handle | cell array | string

Button press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback function executes whenever a user clicks a mouse button while the pointer is in the figure window. See the `WindowButtonMotionFcn` property for an example.

---

**Note:** When using a two-button or three-button mouse on Macintosh systems, right-button and middle-button presses are not always reported. This happens *only* when a new figure window appears under the mouse cursor and the user clicks the mouse without first moving the mouse. In this circumstance, for the `WindowButtonDownFcn` callback to work, the user needs to do one of the following:

- Move the mouse after the figure is created, and then click any mouse button.

- Press **Shift** or **Ctrl** while clicking the left mouse button to perform the Extend and Alternate selection types.

Pressing the left mouse button (or single mouse button) works without having to take either of the above actions.

---

For information on how callbacks interact, see the `Interruptible` and `BusyAction` properties.

Example: `@myfun`

Example: `{@myfun,x}`

### **WindowButtonMotionFcn** — Mouse-motion callback function

' ' (default) | function handle | cell array | string

Mouse-motion callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback function executes whenever the user moves the pointer within the figure window.

---

**Note:** On some systems, the `WindowButtonMotionFcn` callback executes when MATLAB creates a figure, even though there has been no mouse motion within the figure.

---

Your callback functions might need to update the display by calling the `drawnow` or `pause` function, which causes MATLAB to process all callbacks in the queue. Processing the callback queue can cause your callback function to be reentered. Design your code to handle reentrancy and do not depend on global variables that might change state during reentrance.

For information on how callbacks interact, see the `Interruptible` and `BusyAction` properties.

## Example: Coding Window Button Callback Functions

This example shows how to code all three window button callback functions so that the user can draw lines using mouse motions.

Copy and save the following code to a file on a writable folder on your system. Then, run the code. Click the left mouse button in the axes and move the cursor. Left-click to define the line end point. Right-click to end drawing mode.

```
function window_motion_test
figure('WindowButtonDownFcn',@wbdcdb)
ah = axes('SortMethod','childorder');
axis ([1 10 1 10])
title('Click and drag')
 function wbdcdb(src,callbackdata)
 seltype = src.SelectionType;
 % This code uses dot notation to set properties
 % Dot notation runs in R2014b and later.
 % For R2014a and earlier: seltype = get(src,'SelectionType');
 if strcmp(seltype,'normal')
 src.Pointer = 'circle';
 cp = ah.CurrentPoint;
 % For R2014a and earlier:
 % set(src,'Pointer','circle');
 % cp = get(ah,'CurrentPoint');
 xinit = cp(1,1);
 yinit = cp(1,2);
 hl = line('XData',xinit,'YData',yinit,...
 'Marker','p','color','b');
 src.WindowButtonMotionFcn = @wbmcb;
 src.WindowButtonUpFcn = @wbucb;
 % For R2014a and earlier:
 % set(src,'WindowButtonMotionFcn',@wbmcb);
 % set(src,'WindowButtonUpFcn',@wbucb);
 end

 function wbmcb(src,callbackdata)
 cp = ah.CurrentPoint;
 % For R2014a and earlier:
```

```
% cp = get(ah,'CurrentPoint');
xdat = [xinit,cp(1,1)];
ydat = [yinit,cp(1,2)];
hl.XData = xdat;
hl.YData = ydat;
% For R2014a and earlier:
% set(hl,'XData',xdat);
% set(hl,'YData',ydat);
drawnow
end

function wbucl(src,callbackdata)
 last_seltype = src.SelectionType;
 % For R2014a and earlier:
 % last_seltype = get(src,'SelectionType');
 if strcmp(last_seltype,'alt')
 src.Pointer = 'arrow';
 src.WindowButtonMotionFcn = '';
 src.WindowButtonUpFcn = '';
 % For R2014a and earlier:
 % set(src,'Pointer','arrow');
 % set(src,'WindowButtonMotionFcn','');
 % set(src,'WindowButtonUpFcn','');
 else
 return
 end
end
end
end
```

### **WindowButtonUpFcn — Button-release callback function**

'' (default) | function handle | cell array | string

Button-release callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback function executes whenever a user releases a mouse button.

The button-up callback is associated with the figure window in which a previous button-down action occurred. Therefore, the pointer need not be in the figure window when the user releases the button to generate the button-up callback.

If the callback functions defined by the `WindowButtonDownFcn` or `WindowButtonMotionFcn` properties contain `drawnow` commands or call other functions that contain `drawnow` commands and the `Interruptible` property is set to `'off'`, then the `WindowButtonUpFcn` callback might not be called. You can prevent this situation by setting the `Interruptible` property to `'on'`.

Your callback functions might need to update the display by calling the `drawnow` or `pause` function, which causes MATLAB to process all callbacks in the queue. Processing the queue can cause your callback function to be reentered. For example, a `drawnow` command in the `WindowButtonUpFcn` callback might result in the `WindowButtonUpFcn` callback being called again before the first call has finished. Design your code to handle reentrancy and do not depend on global variables that might change state during reentrance.

You can use the `Interruptible` and `BusyAction` figure properties to control how callbacks interact.

Example: `@myfun`

Example: `{@myfun,x}`

### **WindowScrollWheelFcn — Mouse-scroll-wheel callback**

`''` (default) | function handle | cell array | string

Mouse-scroll-wheel callback, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback executes when the user moves the mouse-scroll-wheel while the figure has focus. MATLAB executes the callback with each single mouse-scroll-wheel click.

Be aware that it is possible for another object to capture the mouse-scroll-wheel movement from MATLAB. For example, if the figure contains Java or ActiveX control objects that are listening for mouse-scroll-wheel movements, then these objects can capture the activity and prevent the `WindowScrollWheelFcn` callback from executing.

## WindowScrollWheelFcn Callback Data

When the callback is a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

| Property                          | Contents                                                                                                                                                                                                                                                |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>VerticalScrollCount</code>  | A positive or negative integer that indicates the number of mouse-scroll-wheel clicks. Positive values indicate clicks of the wheel scrolled in the down direction. Negative values indicate clicks of the wheel scrolled in the up direction.          |
| <code>VerticalScrollAmount</code> | The current system setting for the number of lines that are scrolled for each click of the scroll wheel. If the mouse property setting for scrolling is set to <code>One screen at a time</code> , the <code>VerticalScrollAmount</code> property is 1. |

## Effects on Other Properties

The `WindowScrollWheelFcn` property value has the following effects on these properties:

- `CurrentObject` property — The `WindowScrollWheelFcn` property has no effect on the `CurrentObject` property.
- `CurrentPoint` property — If there is no callback defined for the `WindowScrollWheelFcn` property, then MATLAB does not update the `CurrentPoint` property as the user turns the scroll wheel. However, if there is a callback defined for the `WindowScrollWheelFcn` property, then MATLAB updates the `CurrentPoint` property just before executing the callback. This enables you to determine the point at which the mouse scrolling occurred.

- SelectionType property — The WindowScrollWheelFcn property has no effect on the SelectionType property.

## Values Returned by VerticalScrollCount

When a user moves the mouse scroll wheel by one click, MATLAB increments the count by +/- 1, depending on the direction of the scroll (scroll down being positive). When MATLAB calls the WindowScrollWheelFcn callback, the counter resets. In most cases, this means that the absolute value of the returned value is 1. However, if the WindowScrollWheelFcn callback takes a long enough time to return or the user spins the scroll wheel very fast, or both, then the returned value can have an absolute value greater than one.

The actual value returned by VerticalScrollCount property is the algebraic sum of all mouse-scroll-wheel clicks that occurred since last processed. This enables your callback to respond correctly to the user action.

## Example: Code WindowScrollWheelFcn Callback

This example creates a graph and enables users to use the mouse scroll wheel to change the range over which MATLAB evaluates a mathematical function. In addition, it updates the graph to reflect the new limits as the user turns the scroll wheel.

Copy and save the function to a writable folder on your system. Then, run the code. Mouse over the figure and scroll your mouse wheel.

```
function scroll_wheel
% Illustrates how to use WindowScrollWheelFcn property
%
f = figure('WindowScrollWheelFcn',@figScroll,'Name','Scroll Wheel Demo');
x = [0:.1:40];
y = 4.*cos(x)./(x+2);
a = axes;
h = plot(x,y);
title('Rotate the scroll wheel')
function figScroll(src,callbackdata)
 if callbackdata.VerticalScrollCount > 0
 xd = h.XData;
 % This code uses dot notation to set properties
 % Dot notation runs in R2014b and later.
 % For R2014a and earlier: xd = get(h,'XData');
 inc = xd(end)/20;
```

```
 x = [0:.1:xd(end)+inc];
 re_eval(x)
 elseif callbackdata.VerticalScrollCount < 0
 xd = h.XData;
 % For R2014a and earlier: xd = get(h,'XData');
 inc = xd(end)/20;
 x = [0:.1:xd(end)-inc+.1]; % Don't let xd = 0;
 re_eval(x)
 end
end

function re_eval(x)
 y = 4.*cos(x)./(x+2);
 h.YData = y;
 h.XData = x;
 a.XLim = [0 x(end)];
 % For R2014a and earlier:
 % set(h,'YData',y);
 % set(h,'XData',x);
 % set(a,'XLim',[0 x(end)]);
 drawnow
end
end
```

### **UIContextMenu** — Figure context menu

empty GraphicsPlaceholder array (default) | uicontextmenu object

Figure context menu, specified as a uicontextmenu object. Use this property to display a context menu when the user right-clicks on the figure. Create the context menu using the uicontextmenu function.

## **Window Control**

### **CloseRequestFcn** — Figure close request callback function

' ' (default) | function handle | cell array | string

Figure close request callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback executes whenever a user attempts to close a figure window. You can, for example, display a dialog box to ask a user to confirm or cancel the close operation or to prevent users from closing a figure that contains a UI.

The basic mechanism is:

- 1 A user issues the `close` or `close all` command from the command line, closes the figure from the computer window manager menu, or closes the figure by quitting MATLAB.
- 2 The close operation executes the function defined by the figure `CloseRequestFcn` property. The default function is `closereq`.

The `closereq` function unconditionally deletes the current figure, destroying the window. The `closereq` function takes advantage of the fact that the `close` command makes each figure specified as an argument the current figure before calling its respective close request function.

The `closereq` function honors the `ShowHiddenHandles` property setting during figure deletion and does not delete hidden figures.

Unless the close request function calls the `delete` or `close` function, MATLAB never closes the figure. (You can call `delete(f)` from the command line if you have created a window with a nondestructive close request function.)

## Example: Code `CloseRequestFcn` to Display Dialog Box

This example shows how to code the close request function to display a question dialog box asking the user to confirm the close operation. Save the code to a writable folder on your system.

```
function my_closereq(src,callbackdata)
% Close request function
% to display a question dialog box
 selection = questdlg('Close This Figure?',...
 'Close Request Function',...
 'Yes','No','Yes');
 switch selection,
 case 'Yes',
 delete(gcf)
 case 'No'
 return
```

```
end
end
```

Now, create a figure specifying `my_closereq` for the `CloseRequestFcn`:

```
figure('CloseRequestFcn',@my_closereq)
```

Close the figure window and the question dialog box displays.

## **WindowStyle — Figure window behavior**

'normal' (default) | 'modal' | 'docked'

Figure window behavior, specified as one of the following:

- 'normal' — The figure window is independent of other windows, and the other windows are accessible while the figure is displaying.
- 'modal' — The figure displays on top of all existing figure windows, making them inaccessible as long as the top figure exists and remains modal. However, any new figures created after a modal figure will display.

When multiple modal windows exist, the most recently created window keeps focus and stays above all other windows until it becomes invisible, or is returned to a normal window style, or is deleted. At that time, focus reverts to the window that last had focus.

- 'docked' — The figure displays in the desktop or a document window. When the `WindowStyle` property is set to 'docked', you cannot set the `DockControls` property to 'off'.

---

**Note:** These are some important characteristics of the `WindowStyle` property and some recommended best practices:

- When you create UI windows, always specify the `WindowStyle` property. If you also want to set the `Resize`, `Position`, or `OuterPosition` properties of the figure, then set the `WindowStyle` property first.
- You can change the `WindowStyle` property of a figure at any time, including when the figure is visible and contains children. However on some systems, setting this property might cause the figure to flash or disappear and reappear, depending on the system's implementation of normal and modal windows. For best visual results, set the `WindowStyle` property at creation time or when the figure is invisible.

- Calling `reset` on a figure does not change the value of the `WindowStyle` property.
- 

## Modal Window Style Behavior

When `WindowStyle` is set to `'modal'`, the figure window traps all keyboard and mouse actions over all MATLAB windows as long as the windows are visible. Windows belonging to applications other than MATLAB are unaffected.

Typing **Ctrl+C** when a modal figure has focus causes that figure to revert to a `'normal'` `WindowStyle` property setting. This allows the user to type at the command line.

Figures with the `WindowStyle` property set to `'modal'` and the `Visible` property set to `'off'` do not behave modally until MATLAB makes them visible. Therefore, you can hide a modal window for later reuse, instead of destroying it.

Modal figures do not display `uimenu` children, built-in menus, or toolbars. But, it is not an error to create `uimenu`s in a modal figure or to change the `WindowStyle` property setting to `'modal'` on a figure with `uimenu` children. The `uimenu` objects exist and the figure retains them. If you reset the figure's `WindowStyle` property to `'normal'`, the `uimenu`s display.

## Creation and Deletion Control

### **BeingDeleted** — Deletion status of figure

`'off'` (default) | `'on'`

This property is read only.

Deletion status of figure, returned as `'on'` or `'off'`. MATLAB sets the `BeingDeleted` property to `'on'` when the `delete` function of the figure begins execution (see the `DeleteFcn` property). The `BeingDeleted` property remains set to `'on'` until the figure no longer exists.

Check the value of the `BeingDeleted` property to verify that the figure is not about to be deleted before querying or modifying it.

### **CreateFcn** — Figure creation function

function handle | cell array | string

Figure creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This property specifies a callback function to execute when MATLAB creates the figure. MATLAB initializes all figure property values before executing the `CreateFcn` callback. If you do not specify the `CreateFcn` property, then MATLAB executes a default creation function.

Use the `gcb0` function in your `CreateFcn` code to get the handle to the figure that is being created.

Setting the `CreateFcn` property on an existing figure has no effect.

---

**Note:** Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. Copying the figure object causes the `CreateFcn` callback to execute repeatedly.

---

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

### **DeleteFcn** — Figure deletion function

function handle | cell array | string

Figure deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The `DeleteFcn` property specifies a callback function to execute when MATLAB deletes the figure (for example, when the end user deletes the figure). MATLAB executes the `DeleteFcn` callback before destroying the properties of the figure. If you do not specify the `DeleteFcn` property, then MATLAB executes a default deletion function.

Use the `gcb0` function in your `DeleteFcn` code to get the handle to the figure that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

## Identifiers

### **CurrentAxes** — Target axes in current figure

axes object

Target axes in the current figure, specified as an axes object. MATLAB sets this property to the figure's current axes object. In all figures for which axes children exist, there is always a current axes. The current axes does not have to be the topmost axes, and setting an axes to be the current axes does not restack it above all other axes. If a figure contains no axes, the `get(gcf, 'CurrentAxes')` command returns an empty array.

Query the `CurrentAxes` property to get the current axes object without forcing the creation of an axes if one does not exist.

### **CurrentObject** — Most recently selected component in figure

object

Most recently selected component in the Figure, specified as an object. MATLAB sets the `CurrentObject` property to the last object the user clicked. This object is the front-most object in the view. You can use this property to determine which object a user has selected.

An object's `HitTest` property controls whether that object can become the `CurrentObject`.

Clicking an object whose `HandleVisibility` property is `off` (such as axis labels and title) causes the `CurrentObject` property to be set to empty. To avoid returning an

empty value when users click a hidden object, set `HitTest` property of the hidden object to `'off'`.

Moving the cursor over objects does not update the `CurrentObject`. Users must click objects to update this property. See the `CurrentPoint` property for related information.

If you are looking for a quick way to access the current object, consider using the `gco` command.

**FileName — FIG-file name**

string

FIG-file name, specified as a string. GUIDE uses this property to store the name of the UI layout file that it saves. If you are not working in GUIDE, then the `FileName` property is empty.

Example: `'myguifile.fig'`

**IntegerHandle — Ability to assign figure number**

`'on'` (default) | `'off'`

Ability to assign figure number, specified as `'on'` or `'off'`.

If you set the `IntegerHandle` property to `'on'`, MATLAB finds the lowest integer value not used by an existing figure and sets the `Number` property to that value. If you delete a figure, MATLAB can reuse the number on a new figure window.

If you set the `IntegerHandle` property to `'off'`, MATLAB does not assign an integer value to the figure and sets the `Number` property to an empty array (`[]`).

**Number — Figure number**

integer | `[]`

This property is read only.

Figure number, returned as an integer or empty array. You can refer to a figure using this value. For example, `figure(2)` makes the figure with a `Number` property value of 2 the current figure.

If the `IntegerHandle` property is set to `'off'`, `Number` is an empty array.

If `IntegerHandle` is `'on'`, the `Number` property value is an integer value. If a figure is deleted, MATLAB reuses that figure's number for the next figure window created.

Example: 3

### **Type — Type of Figure object**

'figure'

This property is read only.

Type of Figure object, returned as the string, 'figure'. Use this property to find all objects of a given type within a plotting hierarchy.

### **Tag — Figure identifier**

' ' (default) | string

Figure identifier, specified as a string. You can specify a unique **Tag** value to serve as an identifier for the figure. When you need access to the figure elsewhere in your code, you can use the `findobj` function to search for the figure based on the **Tag** value.

Example: 'Plotting Figure'

### **UserData — Data to associate with the figure object**

empty array (default) | array

Data to associate with the figure object, specified as any array. Specifying **UserData** can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: [1 2 3]

Example: 'April 21'

Example: struct('value1',[1 2 3],'value2','April 21')

Example: {[1 2 3],'April 21'}

## **Parent/Child**

### **Parent — Figure parent**

root object

Figure parent, returned as a root object.

### **Children — Children of figure**

empty `GraphicsPlaceholder` array (default) | 1-D array of objects

Children of the figure, returned as an empty `GraphicsPlaceholder` or a 1-D array of objects.

You cannot add or remove children using the `Children` property of the figure. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the front-to-back order (stacking order) of the components on the screen.

To add a child to this list, set the `Parent` property of the child component to be the figure object.

Objects with the `HandleVisibility` property set to `'off'` do not list in the `Children` property. For more information, see the `HandleVisibility` property description.

### **HandleVisibility – Visibility of figure handle**

`'on'` (default) | `'callback'` | `'off'`

Visibility of figure handle, specified as `'on'`, `'callback'`, or `'off'`.

This property determines whether a figure is in its parent's (the root's) list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into, or deleting a figure that contains only user interface components (such as a dialog box).

If an object is not in its parent's list of children, functions that find objects by searching the object hierarchy or querying properties cannot return that object. Such functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When the `HandleVisibility` property value is restricted using the `'callback'` or `'off'` settings, the object does not appear in the parent object `Children` property, figures do not appear in the root `CurrentFigure` property, objects do not appear in the root `CallbackObject` property or in the figure `CurrentObject` property, and axes do not appear in their parent `CurrentAxes` property.

Set the root `ShowHiddenHandles` property to `'on'` to make all objects visible, regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

## **Pointers**

### **Pointer – Pointer symbol**

`'arrow'` (default) | string

Pointer symbol, specified as a string. Valid strings are listed in the following table. By convention, each symbol commonly indicates a particular usage. However, MATLAB does not enforce rules for the use of any symbols. The appearance of the symbol that displays for a given string is operating-system dependent.

| Typical Usage Indicated                                   | Symbol String     |
|-----------------------------------------------------------|-------------------|
| Editing location in text                                  | 'ibeam'           |
| Point on a graphics object                                | 'crosshair'       |
| Point anywhere in the figure                              | 'arrow'           |
| Busy system                                               | 'watch'           |
| Resizing an object from a top-left or bottom-right corner | 'topl' or 'botr'  |
| Resizing an object from a top-right or bottom-left corner | 'topr' or 'botl'  |
| A hot spot                                                | 'circle'          |
| A point                                                   | 'cross'           |
| Moving an object                                          | 'fleur'           |
| Resizing an object from the left side                     | 'left'            |
| Resizing an object from the right side                    | 'right'           |
| Resizing an object from the top or bottom                 | 'top' or 'bottom' |
| Clickable icon                                            | 'hand'            |

---

**Note:** The 'fullcrosshair' option was removed in R2014b.

---

Setting `Pointer` property to 'custom' enables you to define your own pointer symbol. See the `PointerShapeCData` property for more information.

### **PointerShapeCData** — Pointer shape

16-by-16 matrix

Pointer shape MATLAB uses when the `Pointer` property is set to 'custom', specified as a 16-by-16 matrix. The matrix defines a 16-by-16 pixel pointer using the following values:

- 1 — Color pixel black.
- 2 — Color pixel white.
- NaN — Make pixel transparent, such that underlying screen shows through

Element (1,1) of the `PointerShapeCData` matrix corresponds to the upper-left corner of the pointer. Setting the `Pointer` property to one of the predefined pointer symbols does not change the value of the `PointerShapeCData`. Computer systems supporting 32-by-32 pixel pointers fill only one quarter of the available pixmap.

### **PointerShapeHotSpot — Active area of pointer**

[1 1] — upper-left corner (default) | two-element vector

Active area of pointer, specified as a two-element vector. The vector specifies the row and column indices in the `PointerShapeCData` matrix defining the pixel indicating the pointer location. The `CurrentPoint` property and the root object's `PointerLocation` property specify the location.

## **Printing and Saving**

### **PaperPosition — Figure size and location on page when printing or saving**

four-element vector of the form [left bottom width height]

Figure size and location on page when printing or saving, specified as a four-element vector of the form [left bottom width height].

- Print to a printer — The `left` and `bottom` values specify the distance from the lower left corner of the page to the lower left corner of the figure. The `width` and `height` values define the dimensions of the figure.
- Save to a paged format (PDF and PostScript® formats) — The `left` and `bottom` values specify the distance from the lower left corner of the page to the lower left corner of the figure. The `width` and `height` values define the dimensions of the figure.
- Save to a nonpaged format (image formats) — The `width` and `height` values define the dimensions of the figure. Image formats ignore the `left` and `bottom` values.

---

**Note:** If the width and height values are too large, then the figure might not reach the specified size. If the figure does not reach the specified size, then UI components on the figure, such as uicontrols or a uitable, might not save or print as expected.

---

The `PaperUnits` property determines the units of measurement of the `PaperPosition` values. Consider setting the `PaperUnits` property to `'normalized'`. This setting enables MATLAB to automatically size the figure to occupy the same relative amount of the printed page, regardless of the page size.

Example: `[.25 .25 8 6]`

### **PaperPositionMode** — Directive to use displayed figure size when printing or saving

`'manual'` (default) | `'auto'`

Directive to use displayed figure size when printing or saving, specified as one of these values:

- `'auto'` — Printed or saved figure size matches the displayed figure size. The `width` and `height` values of the `PaperPosition` property equal the figure size on the display. The `left` and `bottom` values center the figure. If the figure size changes on the display, the `PaperPosition` property automatically updates to the appropriate size and location values.
- `'manual'` — Printed or saved figure size might not match the displayed figure size. Use this option if you want to print or save the figure using a size that differs from the display, or if you do not want the figure centered on the printed or saved page. Set the `PaperPosition` property to the desired size and location. If the figure size changes on the display, the `PaperPosition` property does not automatically update.

To generate output that has the same size and resolution (DPI) as the displayed figure, set the `PaperPositionMode` property of the figure to `'auto'` and save the figure using `print` with the `-r0` option. The `-r0` option ensures that the output resolution is the same as the display resolution. If the resolutions are different, then the generated output size matches the displayed figure size in measured units (inches, centimeters, points), but not in pixels. For example, if the display resolution is 100 DPI, then a 4-by-5 inch figure is 400-by-500 pixels. If the output resolution is 200 DPI, then the printed or saved figure is the same size in inches, but 800-by-1000 pixels.

### **InvertHardcopy** — Figure background color when printing or saving

`'on'` (default) | `'off'`

Figure background color when saving or printing, specified as one of these values:

- `'on'` — Change the figure background and axes background colors to white.
- `'off'` — Use the same colors as the colors on the display. To change the figure background color on the display, use the `Color` property of the figure. To change the axes background color, use the `Color` property of the axes.

**PaperType — Standard page sizes**

'usletter' | 'uslegal' | 'tabloid' | 'a0' | 'a1' | 'a2' | 'a3' | ...

Standard page sizes when printing the figure or saving it to a paged format (PDF and PostScript formats), specified as one of the values in this table. Specifying the PaperType property sets the PaperSize property to the corresponding page size.

| Value      | Page Size (Width x Height)                 |
|------------|--------------------------------------------|
| 'usletter' | 8.5-by-11 in (default in US)               |
| 'uslegal'  | 8.5-by-14 in                               |
| 'tabloid'  | 11-by-17 in                                |
| 'a0'       | 84.1-by-118.9 cm                           |
| 'a1'       | 59.4-by-84.1 cm                            |
| 'a2'       | 42-by-59.4 cm                              |
| 'a3'       | 29.7-by-42 cm                              |
| 'a4'       | 21-by-29.7 cm (default in Europe and Asia) |
| 'a5'       | 14.8-by-21 cm                              |
| 'b0'       | 102.9-by-145.6 cm                          |
| 'b1'       | 72.8-by-102.8 cm                           |
| 'b2'       | 51.4-by-72.8 cm                            |
| 'b3'       | 36.4-by-51.4 cm                            |
| 'b4'       | 25.7-by-36.4 cm                            |
| 'b5'       | 18.2-by-25.7 cm                            |
| 'arch-a'   | 9-by-12 in                                 |
| 'arch-b'   | 12-by-18 in                                |
| 'arch-c'   | 18-by-24 in                                |
| 'arch-d'   | 24-by-36 in                                |
| 'arch-e'   | 36-by-48 in                                |
| 'a'        | 8.5-by-11 in                               |
| 'b'        | 11-by-17 in                                |
| 'c'        | 17-by-22 in                                |

| Value    | Page Size (Width x Height)                                                                                                                     |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 'd'      | 22-by-34 in                                                                                                                                    |
| 'e'      | 34-by-43 in                                                                                                                                    |
| 'custom' | Custom page size. Specifying a non-standard page size using the <code>PaperSize</code> property sets <code>PaperPosition</code> to this value. |

### **PaperSize — Custom page size**

two-element vector of the form `[width height]`

Custom page size when printing the figure or saving it to a paged format (PDF and PostScript formats), specified as a two-element vector of the form `[width height]`. In the United States, the default value is `[8.5 11]`. In Europe and Asia, the default value is `[21 29.7]`.

---

**Note:** If you are saving the figure to a file, the `PaperSize` property only affects PDF and PostScript file formats. Other file formats ignore this property. Use the `PaperPosition` property to control the size of the saved figure.

---

The `PaperUnits` property determines the units of measurement for the `PaperSize` property. You cannot set the `PaperSize` property if the `PaperUnits` property is set to `'normalized'`. Attempting to do so results in an error.

Specifying the `PaperSize` property sets the `PaperType` property to the corresponding type, if one exists, or to `'custom'` otherwise.

### **PaperOrientation — Orientation of page**

`'portrait'` (default) | `'landscape'`

Orientation of page when printing figure or saving it to a paged format (PDF and PostScript formats), specified as one of these values:

- `'portrait'` — Orient the longest page dimension vertically.
- `'landscape'` — Orient the longest page dimension horizontally.

See the `orient` function for more information.

### **PaperUnits — Units used for PaperSize and PaperPosition**

`'inches'` | `'centimeters'` | `'normalized'` | `'points'`

Units used for `PaperSize` and `PaperPosition`, specified as one of these values:

- `'inches'` — Value in inches. This is the default when the locale is the United States.
- `'normalized'` — Normalized units. The lower left corner of the page maps to `(0,0)` and the upper right corner maps to `(1,1)`.
- `'centimeters'` — Value in centimeters. This is the default when the locale is Europe or Asia.
- `'points'` — Value in points. One point equals  $1/72$  of an inch.

---

**Note:** If you change the value of the `PaperUnits` property, it is good practice to return the property to its original value after completing your computation so as not to affect other functions that assume the `PaperUnits` property has not changed.

---

# figurepalette

Show or hide **Figure Palette**

## Syntax

```
figurepalette('show')
figurepalette('hide')
figurepalette
figurepalette(figure_handle,...)
```

## Description

`figurepalette('show')` displays the palette on the current figure.

`figurepalette('hide')` hides the palette on the current figure.

`figurepalette` toggles the visibility of the palette on the current figure. You can also use `figurepalette('toggle')` instead for the same functionality.

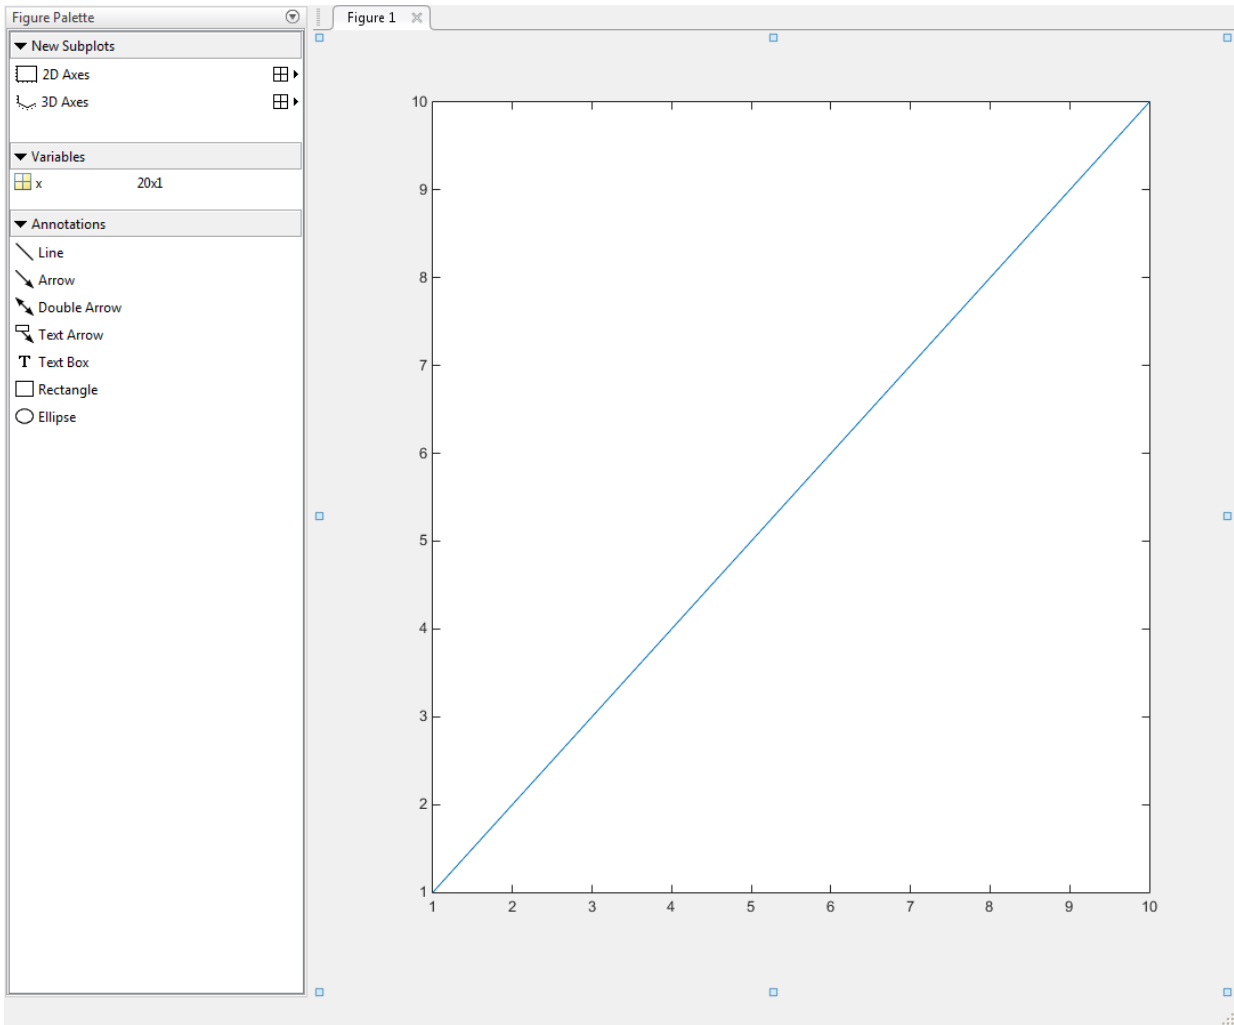

`figurepalette(figure_handle,...)` shows or hides the palette on the figure specified by `figure_handle`.

## Examples

### Open Figure Palette

Plot a line and open the figure palette.

```
plot(1:10)
figurepalette('show')
```

## Alternatives

To collectively enable the plot tools, use the larger icon  on the figure toolbar. To collectively disable the plot tools, use the smaller icon . Open or close the **Figure Palette** tool from the figure's **View** menu.

## More About

### Tips

If you call `figurepalette` in a MATLAB program and subsequent lines depend on the Figure Palette being fully initialized, follow it by `drawnow` to ensure complete initialization.

**Introduced before R2006a**

## fileattrib

Set or get attributes of file or folder

### Syntax

```
fileattrib
```

```
fileattrib(name)
```

```
fileattrib(name,attribs)
```

```
fileattrib(name,attribs,users)
```

```
fileattrib(name,attribs,users,'s')
```

```
[status,message,messageid] = fileattrib(name,attribs, ___)
```

```
[status,message] = fileattrib(name)
```

### Description

fileattrib gets attribute values for the current folder, using the following structure, where **Name** is always a string containing the current folder name. For the other fields, a value of 0 indicates that the attribute is off, 1 indicates that the attribute is on, and NaN indicates that the attribute does not apply:

Name

archive

system

hidden

directory

UserRead

UserWrite

UserExecute

GroupRead

GroupWrite

GroupExecute

OtherRead

OtherWrite

OtherExecute

fileattrib(name) gets the attribute values for the named file or folder.

`fileattrib(name,attribs)` sets the specified attributes for the named file or folder.

`fileattrib(name,attribs,users)` sets the file or folder attributes for the specified subset of users.

`fileattrib(name,attribs,users,'s')` sets the specified attributes for the specified users for the contents of the named folder.

`[status,message,messageid] = fileattrib(name,attribs,___)` sets the specified file attributes and gets the function status:

- If `status` is 0, then `message` is the error message, and `messageid` is the error message identifier.
- If `status` is 1, then `message` is a structure containing the attributes of the named file or folder, and `messageid` is an empty string.

`[status,message] = fileattrib(name)` gets `status` and the last *successfully* set attribute structure values for the named file or folder and returns the structure to `message`. (`status` is always 1.)

## Examples

### View Current Folder Attributes

View attributes of the current folder, assuming the current folder is `C:\my_MATLAB_files`.

```
fileattrib
```

```
ans =
```

```
 Name: 'C:\my_MATLAB_files'
 archive: 0
 system: 0
 hidden: 0
 directory: 1
 UserRead: 1
 UserWrite: 1
 UserExecute: 1
 GroupRead: NaN
 GroupWrite: NaN
 GroupExecute: NaN
```

```
OtherRead: NaN
OtherWrite: NaN
OtherExecute: NaN
```

The attributes indicate that you have read, write, and execute permissions for the current folder.

## View File Attributes

View attributes of file `collatz.m`.

```
fileattrib('collatz.m')
```

```
ans =
```

```
 Name: 'C:\my_MATLAB_files\collatz.m'
 archive: 1
 system: 0
 hidden: 0
 directory: 0
 UserRead: 1
 UserWrite: 0
 UserExecute: 1
 GroupRead: NaN
 GroupWrite: NaN
 GroupExecute: NaN
 OtherRead: NaN
 OtherWrite: NaN
 OtherExecute: NaN
```

The attributes indicate that the specified item is a file. You can read and execute the file, but cannot update it. The file is archived.

## View Folder Attributes on a Windows System

View attributes for the folder `C:\my_MATLAB_files\doc`.

```
fileattrib('C:\my_MATLAB_files\doc')
```

```
ans =
```

```
 Name: 'C:\my_MATLAB_files\doc'
 archive: 0
 system: 0
 hidden: 0
```

```

 directory: 1
 UserRead: 1
 UserWrite: 1
 UserExecute: 1
 GroupRead: NaN
 GroupWrite: NaN
 GroupExecute: NaN
 OtherRead: NaN
 OtherWrite: NaN
 OtherExecute: NaN

```

The attributes indicate that you have read, write, and execute permissions for the specified folder.

### View Folder Attributes on a UNIX System

View attributes for the folder `/public` on a UNIX system.

```
fileattrib('/public')
```

```
ans =
```

```

 Name: '/public'
 archive: NaN
 system: NaN
 hidden: NaN
 directory: 1
 UserRead: 1
 UserWrite: 1
 UserExecute: 1
 GroupRead: 1
 GroupWrite: 0
 GroupExecute: 1
 OtherRead: 1
 OtherWrite: 0
 OtherExecute: 1

```

The attributes indicate that you have read, write, and execute permissions for the specified folder. In addition, users in your UNIX group and all others have read and execute permissions for the specified folder, but not write permissions.

### Set File Attributes

Make `myfile.m` writeable.

```
fileattrib('myfile.m','+w')
```

## Set File Attributes for Specific Users on UNIX

Make the folder `/home/work/results` a read-only folder for *all users* on UNIX platforms.

```
fileattrib('/home/work/results','-w','a')
```

The minus (-) preceding the write attribute, w, removes the write status.

## Set Attributes for Folder and Its Contents

On Windows platforms, make the folder `D:\work\results` and all its contents read only and hidden.

```
fileattrib('D:\work\results','+h -w','','s')
```

Because a value for the `users` argument is not applicable on Windows systems, the argument is an empty string. The `s` argument applies the hidden and read-only attributes to the contents of the folder.

## Get Attributes Structure for a Folder

Get the attributes for the folder `results` and return them to a structure:

```
[stat, struc] = fileattrib('results')
```

```
stat =
 1
```

```
struc =
 Name: 'D:\work\results'
 archive: 0
 system: 0
 hidden: 0
 directory: 1
 UserRead: 1
 UserWrite: 1
 UserExecute: 1
 GroupRead: NaN
 GroupWrite: NaN
 GroupExecute: NaN
 OtherRead: NaN
```

```
OtherWrite: NaN
OtherExecute: NaN
```

The operation is successful as indicated by the status, `stat`, value of 1. The structure, `struc`, contains the file attributes.

Access the name attribute value in the structure. MATLAB returns the path for results.

```
struc.Name
```

```
ans =
D:\work\results
```

### Get Attributes Structure for Multiple Files

Get the attributes for all files in the current folder with names that begin with `new`.

```
[stat,struc] = fileattrib('new*')
```

```
stat =
 1
```

```
mess =
1x3 struct array with fields:
```

```
 Name
 archive
 system
 hidden
 directory
 UserRead
 UserWrite
 UserExecute
 GroupRead
 GroupWrite
 GroupExecute
 OtherRead
 OtherWrite
 OtherExecute
```

The results indicate there are three matching files.

View the file names.

```
struc.Name
```

```
ans =
D:\work\results\newname.m
```

```
ans =
D:\work\results\newone.m
```

```
ans =
D:\work\results\newtest.m
```

View just the second file name.

```
struct(2).Name
```

```
ans =
D:\work\results\newname.m
```

## Successfully Set Attributes for a File and Get Messages

Show output that results when an attempt to set file attributes is successful.

```
[status,message,messageid] = fileattrib('C:/my_MATLAB_files/doc',...
'+h -w', '', 's')
```

```
status =
```

```
1
```

```
message =
```

```
''
```

```
messageid =
```

```
''
```

The `status` value of 1 indicates the set operation was successful; therefore, no error message or `messageid` is returned.

## Unsuccessfully Set Attributes for a File and Get Messages

Show output that results when an attempt to set file attributes is unsuccessful.

```
[status,message,messageid] = fileattrib('C:/my_MATLAB_files\doc',...
'+h w-', ' ', 's')
```

```
status =
```

```
0
```

```
message =
```

```
Illegal file mode characters on the current platform.
```

```
messageid =
```

```
MATLAB:FILEATTRIB:ModeSyntaxError
```

The **status** value of 0 indicates the set operation was unsuccessful. The minus sign incorrectly appears after **w**, instead of before it.

## Input Arguments

### **name** — File or folder name

string

The absolute or relative path for a folder or file, specified as a string. To specify all names beginning with certain characters, add the wildcard character, **\***.

Example: `fileattrib('myfile.m')`

### **attribs** — File or folder attribute values

'a' | 'h' | 's' | 'w' | 'x'

File or folder attribute values, specified as a space delimited string. Use the plus (+) qualifier before an attribute to set it, and the minus (-) qualifier before an attribute to clear it.

| attribvalue | Description                                |
|-------------|--------------------------------------------|
| 'a'         | Archive (Microsoft Windows platform only). |
| 'h'         | Hidden file (Windows platform only).       |

| attribvalue | Description                                                                                                                                                                                                                                                                         |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 's'         | System file (Windows platform only).                                                                                                                                                                                                                                                |
| 'w'         | Write access (Windows and UNIX platforms). Results differ by platform and application. For example, even though <code>fileattrib</code> disables the “write” privilege for a folder, making it read only, files in the folder could be writable for some platforms or applications. |
| 'x'         | Executable (UNIX platform only).                                                                                                                                                                                                                                                    |

Example: `fileattrib('myfile.m', '+w -h')`

**users — Subset of users**

'a' | 'g' | 'o' | 'u' | ''

Subset of users (on UNIX platforms only), specified as a string. For all platforms other than UNIX, specify the `users` argument as an empty string, `''`. This value is not returned by `fileattrib` get operations.

| Value for UNIX Users | Description                 |
|----------------------|-----------------------------|
| 'a'                  | All users on UNIX platforms |
| 'g'                  | Group of users              |
| 'o'                  | All other users             |
| 'u'                  | Current user                |

Example: `fileattrib('D:/work/results', '-w', 'a')`

## Output Arguments

**status — Indication of whether attempt to set attribute was successful**

0 | 1

If attempt to set attribute was unsuccessful, `status` is 0. Otherwise, `status` is 1.

**message — Attribute structure or error message**

string | structure array

Attribute structure or error message, depending on whether you are setting or getting attributes and `status`.

| Getting or Setting Attributes | Status | Message contents                                |
|-------------------------------|--------|-------------------------------------------------|
| Setting                       | 0      | Error message                                   |
| Setting                       | 1      | Empty string                                    |
| Getting                       | 1      | Structure containing file attributes and values |

When you are getting file attributes, the structure contains these fields and possible values.

| Field name   | Possible Values                               |
|--------------|-----------------------------------------------|
| Name         | String containing name of file or folder      |
| archive      | 0 (not set), 1 (set), or NaN (not applicable) |
| system       | 0, 1, or NaN                                  |
| hidden       | 0, 1, or NaN                                  |
| directory    | 0, 1, or NaN                                  |
| UserRead     | 0, 1, or NaN                                  |
| UserWrite    | 0, 1, or NaN                                  |
| UserExecute  | 0, 1, or NaN                                  |
| GroupRead    | 0, 1, or NaN                                  |
| GroupWrite   | 0, 1, or NaN                                  |
| GroupExecute | 0, 1, or NaN                                  |
| OtherRead    | 0, 1, or NaN                                  |
| OtherWrite   | 0, 1, or NaN                                  |
| OtherExecute | 0, 1, or NaN                                  |

#### **messageid** – Error message identifier

string

Error message identifier when the attempt to set attribute is unsuccessful (`status` is 0), returned as a string. If `status` is 1, then `messageid` is an empty string.

## More About

### Tips

- `fileattrib` is like the DOS `attrib` command, or the UNIX `chmod` command. <sup>1</sup>

### See Also

`cd` | `copyfile` | `delete` | `dir` | `ls` | `mkdir` | `movefile` | `rmdir`

**Introduced before R2006a**

---

1. UNIX is a registered trademark of The Open Group in the United States and other countries.

# filebrowser

Open Current Folder browser, or select it if already open

## Syntax

```
filebrowser
```

## Description

`filebrowser` opens the Current Folder browser, or if it is already open, makes it the selected tool.

## More About

- “Manage Files and Folders”

## See Also

```
cd | copyfile | ls | mkdir | fileattrib | movefile | pwd | rmdir |
commandhistory | workspace | commandwindow
```

**Introduced before R2006a**

## filemarker

Character to separate file name and internal function name

### Syntax

M = filemarker

### Description

M = filemarker returns the character that separates a file and a within-file function name.

### Examples

On the Microsoft Windows platform, for example, filemarker returns the '>' character:

```
filemarker
```

```
ans =
>
```

You can use the following command on any platform to get the help text for the local function `validateSizes` defined in `imwrite.m`:

```
helptext = help(['imwrite' filemarker 'validateSizes'])
```

```
helptext =
How many bytes does each element occupy in memory?
```

You can use the `filemarker` character to indicate a location within a MATLAB program file where you want to set a breakpoint, for example. On all platforms, if you need to distinguish between two nested functions with the same name, use the forward slash (/) character to indicate the path to a particular instance of a function.

For instance, suppose `myfile.m` contains the following code:

```
function x = A(p1, p2)
```

```
...
function y = B(p3)
 ...
end
function m = C(p4)
 ...
end
end

function z = C(p5)
...
function y = D(p6)
 ...
end
end
```

To indicate that you want to set a breakpoint at **function y** nested within **function x**, use the following command on the Windows platform:

```
dbstop myfile>x/y
```

To indicate that you want to set a breakpoint at **function m** nested within **function x** use the following command on the Windows platform:

```
dbstop myfile>m
```

In the first case, you specify **x/y** because **myfile.m** contains two nested functions named **y**. In the second case, there is no need to specify **x/m** because there is only one function **m** within **myfile.m**.

## See Also

filesep

Introduced in R2006a

## fileparts

Parts of file name and path

### Syntax

```
[pathstr,name,ext] = fileparts(filename)
```

### Description

[pathstr,name,ext] = fileparts(filename) returns the path name, file name, and extension for the specified file. The file does not have to exist. `filename` is a string enclosed in single quotes. The returned `ext` field contains a dot (.) before the file extension.

### Input Arguments

#### **filename**

String containing a name of a file or folder, which can include a path and file extension. The function interprets all characters following the right-most delimiter as a file name plus extension.

### Output Arguments

#### **pathstr**

String containing the part of `filename` interpreted as a path name

#### **name**

String containing the name of the file without any extension

#### **ext**

String containing the file extension only, beginning with a period (.)

## Examples

Return the pieces of a file specification string to the separate string outputs `pathstr`, `name`, and `ext`. The full file specification is:

```
file = 'H:\user4\matlab\myfile.txt';
[pathstr,name,ext] = fileparts(file)
```

```
pathstr =
H:\user4\matlab
```

```
name =
myfile
```

```
ext =
.txt
```

Query parts of a user `.cshrc` file:

```
[pathstr,name,ext] = fileparts('/home/jsmith/.cshrc')
```

```
pathstr =
/home/jsmith
```

```
name =
Empty string: 1-by-0
```

```
ext =
.cshrc
```

`fileparts` interprets the entire file name as an extension because it begins with a period.

## Alternatives

Use `uigetfile` to interactively select and return a file name and path, or `uigetdir` to interactively select and return a path name. If you call `fileparts` with the output of `uigetfile`, you can parse out the file name and extension.

## More About

### Path Name

The full or partial path to a destination folder location, always the initial portion of the filename string. Path names end with a slash character and, where appropriate, can begin with a drive letter. Windows paths use backward slashes (\). UNIX and Macintosh paths use forward slashes (/).

### Tips

- `fileparts` only parses file names. It does not verify that a file or a folder exists.
- You can reconstruct the file from the parts using:

```
fullfile(pathstr,[name ext])
```

- On Microsoft Windows systems, you can use either forward (/) or back (\) slashes as path delimiters, even within the same string. On UNIX and Macintosh systems, use only / as a delimiter. You can use the `filesep` function to insert the correct separator character for the platform on which your code executes:

```
sep = filesep;
file = ['H:' sep 'user4' sep 'matlab' sep 'myfile.txt'];

file =
H:\user4\matlab\myfile.txt
```

- If the input consists of a folder name only, be sure that the right-most character is a delimiter (/ or \). Otherwise, `fileparts` parses the trailing portion of `filename` as the name of a file and returns it in `name` instead of in `pathstr`.

# fileread

Read contents of file into string

## Syntax

```
text = fileread(filename)
```

## Description

`text = fileread(filename)` returns the contents of the file *filename* as a MATLAB string.

## Examples

Read and search the file `Contents.m` in the MATLAB `iofun` directory for the reference to `fileread`:

```
% find the correct directory and file
io_contents = ...
 fullfile(matlabroot,'toolbox','matlab','iofun','Contents.m');

% read the file
filetext = fileread(io_contents);

% search for the line of code that includes 'fileread'
% each line is separated by a newline ('\n')

expr = '[^\n]*fileread[^\n]*';
fileread_info = regexp(filetext,expr,'match');
```

## See Also

## filesep

File separator for current platform

### Syntax

```
f = filesep
```

### Description

`f = filesep` returns the platform-specific file separator character. The file separator is the character that separates individual folder and file names in a path string.

### Examples

Create a path to the `iofun` folder on a Microsoft Windows platform:

```
iofun_dir = ['toolbox' filesep 'matlab' filesep 'iofun']
```

```
iofun_dir =
 toolbox\matlab\iofun
```

Create a path to `iofun` on a UNIX<sup>2</sup> platform.

```
iodir = ['toolbox' filesep 'matlab' filesep 'iofun']
```

```
iodir =
 toolbox/matlab/iofun
```

### See Also

# fill

Filled 2-D polygons

## Syntax

```
fill(X,Y,C)
fill(X,Y,ColorSpec)
fill(X1,Y1,C1,X2,Y2,C2,...)
fill(...,'PropertyName',PropertyValue)
h = fill(...)
```

## Description

The `fill` function creates colored polygons.

`fill(X,Y,C)` creates filled polygons from the data in `X` and `Y` with vertex color specified by `C`. `C` is a vector or matrix used as an index into the colormap. If `C` is a row vector, `length(C)` must equal `size(X,2)` and `size(Y,2)`; if `C` is a column vector, `length(C)` must equal `size(X,1)` and `size(Y,1)`. If necessary, `fill` closes the polygon by connecting the last vertex to the first.

`fill(X,Y,ColorSpec)` fills two-dimensional polygons specified by `X` and `Y` with the color specified by `ColorSpec`.

`fill(X1,Y1,C1,X2,Y2,C2,...)` specifies multiple two-dimensional filled areas.

`fill(...,'PropertyName',PropertyValue)` allows you to specify property names and values for a patch graphics object.

`h = fill(...)` returns a vector of handles to patch graphics objects, one handle per patch object.

## Examples

### Create Red Octagon

Define the data.

```
t = (1/16:1/8:1)'*2*pi;
x = cos(t);
y = sin(t);
```

Create a red octagon using the `fill` function.

```
fill(x,y,'r')
axis square
```

## More About

### Tips

If `X` or `Y` is a matrix, and the other is a column vector with the same number of elements as rows in the matrix, `fill` replicates the column vector argument to produce a matrix of the required size. `fill` forms a vertex from corresponding elements in `X` and `Y` and creates one polygon from the data in each column.

If `X` or `Y` contains one or more NaN values, then `fill` does not fill the polygons.

The type of color shading depends on how you specify color in the argument list. If you specify color using `ColorSpec`, `fill` generates flat-shaded polygons by setting the patch object's `FaceColor` property to the corresponding RGB triplet.

If you specify color using `C`, `fill` scales the elements of `C` by the values specified by the axes property `CLim`. After scaling `C`, `C` indexes the current colormap.

If `C` is a row vector, `fill` generates flat-shaded polygons where each element determines the color of the polygon defined by the respective column of the `X` and `Y` matrices. Each patch object's `FaceColor` property is set to `'flat'`. Each row element becomes the `CData` property value for the  $n$ th patch object, where  $n$  is the corresponding column in `X` or `Y`.

If `C` is a column vector or a matrix, `fill` uses a linear interpolation of the vertex colors to generate polygons with interpolated colors. It sets the patch graphics object `FaceColor` property to `'interp'` and the elements in one column become the `CData` property value for the respective patch object. If `C` is a column vector, `fill` replicates the column vector to produce the required sized matrix.

# fill3

Filled 3-D polygons

## Syntax

```
fill3(X,Y,Z,C)
fill3(X,Y,Z,ColorSpec)
fill3(X1,Y1,Z1,C1,X2,Y2,Z2,C2,...)
fill3(...,'PropertyName',PropertyValue)
h = fill3(...)
```

## Description

The `fill3` function creates flat-shaded and Gouraud-shaded polygons.

`fill3(X,Y,Z,C)` fills three-dimensional polygons. `X`, `Y`, and `Z` triplets specify the polygon vertices. If `X`, `Y`, or `Z` is a matrix, `fill3` creates  $n$  polygons, where  $n$  is the number of columns in the matrix. `fill3` closes the polygons by connecting the last vertex to the first when necessary.

`C` specifies color, where `C` is a vector or matrix of indices into the current colormap. If `C` is a row vector, `length(C)` must equal `size(X,2)` and `size(Y,2)`; if `C` is a column vector, `length(C)` must equal `size(X,1)` and `size(Y,1)`.

`fill3(X,Y,Z,ColorSpec)` fills three-dimensional polygons defined by `X`, `Y`, and `Z` with color specified by `ColorSpec`.

`fill3(X1,Y1,Z1,C1,X2,Y2,Z2,C2,...)` specifies multiple filled three-dimensional areas.

`fill3(..., 'PropertyName', PropertyValue)` allows you to set values for specific patch properties.

`h = fill3(...)` returns a vector of handles to patch graphics objects, one handle per patch.

## Examples

### Create Filled 3-D Polygon

Create four triangles with interpolated colors.

```
X = [0 1 1 2; 1 1 2 2; 0 0 1 1];
Y = [1 1 1 1; 1 0 1 0; 0 0 0 0];
Z = [1 1 1 1; 1 0 1 0; 0 0 0 0];
C = [0.5000 1.0000 1.0000 0.5000;
 1.0000 0.5000 0.5000 0.1667;
 0.3330 0.3330 0.5000 0.5000];
```

```
figure
fill3(X,Y,Z,C)
```

## More About

### Algorithms

If  $X$ ,  $Y$ , and  $Z$  are matrices of the same size, `fill3` forms a vertex from the corresponding elements of  $X$ ,  $Y$ , and  $Z$  (all from the same matrix location), and creates one polygon from the data in each column.

If  $X$ ,  $Y$ , or  $Z$  is a matrix, `fill3` replicates any column vector argument to produce matrices of the required size.

If you specify color using `ColorSpec`, `fill3` generates flat-shaded polygons and sets the patch object `FaceColor` property to an RGB triplet.

If you specify color using `C`, `fill3` scales the elements of `CLim` by the axes property `CLim`, which specifies the color axis scaling parameters, before indexing the current colormap.

If `C` is a row vector, `fill3` generates flat-shaded polygons and sets the `FaceColor` property of the patch objects to `'flat'`. Each element becomes the `CData` property value for the respective patch object.

If `C` is a column vector or a matrix, `fill3` generates polygons with interpolated colors and sets the patch object `FaceColor` property to `'interp'`. `fill3` uses a linear interpolation of the vertex colormap indices when generating polygons with interpolated colors. The elements in one column become the `CData` property value for the respective patch object. If `C` is a column vector, `fill3` replicates the column vector to produce the required sized matrix.

# filter

1-D digital filter

## Syntax

```
y = filter(b,a,x)
y = filter(b,a,x,zi)
y = filter(b,a,x,zi,dim)
[y,zf] = filter(___)
```

## Description

`y = filter(b,a,x)` filters the input data, `x`, using a rational transfer function defined by the numerator and denominator coefficients `b` and `a`, respectively.

If `a(1)` is not equal to 1, then `filter` normalizes the filter coefficients by `a(1)`. Therefore, `a(1)` must be nonzero.

- If `x` is a vector, then `filter` returns the filtered data as a vector of the same size as `x`.
- If `x` is a matrix, then `filter` acts along the first dimension and returns the filtered data for each column.
- If `x` is a multidimensional array, then `filter` acts along the first array dimension whose size does not equal 1.

`y = filter(b,a,x,zi)` uses initial conditions, `zi`, for the filter delays. The length of `zi` must equal `max(length(a),length(b))-1`.

`y = filter(b,a,x,zi,dim)` acts along dimension `dim`. For example, if `x` is a matrix, then `filter(b,a,x,zi,2)` returns the filtered data for each row.

`[y,zf] = filter( ___ )` also returns the final conditions, `zf`, of the filter delays, using any of the previous syntax arguments.

## Examples

### Moving-Average Filter of Vector Data

Find the moving-average of a vector without using a `for` loop.

Create a 1-by-100 row vector of sinusoidal input data corrupted by random noise. Initialize the random number generator to make the output of `rand` repeatable.

```
t = linspace(-pi,pi,100);
rng default
x = sin(t) + 0.25*rand(size(t));
```

A moving-average filter is represented by the following difference equation,

$$y(n) = \frac{1}{windowSize} (x(n) + x(n-1) + \dots + x(n - (windowSize - 1))).$$

Define the numerator coefficients of the rational transfer function. Use a window size of 5.

```
windowSize = 5;
b = (1/windowSize)*ones(1,windowSize)

b =
 0.2000 0.2000 0.2000 0.2000 0.2000
```

Define the denominator coefficients of the rational transfer function.

```
a = 1;
```

Find the moving-average of the data with a window size of 5.

```
y = filter(b,a,x);
y(1) is equivalent to 0.2*x(1).
y(2) is equivalent to 0.2*(x(1)+x(2)).
```

---

...

$y(5)$  is equivalent to  $0.2 * (\text{sum}(x(1:5)) = \text{mean}(x(1:5)))$ .

$y(6)$  is equivalent to  $\text{mean}(x(2:6))$ .

...

$y(100)$  is equivalent to  $\text{mean}(x(96:100))$ .

Compare the original data and the filtered data using an overlaid plot.

```
plot(t,x)
hold on
plot(t,y)
```

```
grid on
legend('Input Data', 'Filtered Data', 'Location', 'NorthWest')
title('Plot of Input and Filtered Data')
```

### Apply Rational Transfer Function to Matrix

Filter the rows or columns of a matrix with the following rational transfer function,

$$H(z) = \frac{b(1)}{a(1) + a(2)z^{-1}} = \frac{1}{1 - 0.2z^{-1}}.$$

Create a 15-by-2 matrix of random input data. Initialize the random number generator to make the output of rand repeatable.

```
rng default
x = rand(15,2)
```

```
x =

 0.8147 0.1419
 0.9058 0.4218
 0.1270 0.9157
 0.9134 0.7922
 0.6324 0.9595
 0.0975 0.6557
 0.2785 0.0357
 0.5469 0.8491
 0.9575 0.9340
 0.9649 0.6787
 0.1576 0.7577
 0.9706 0.7431
 0.9572 0.3922
 0.4854 0.6555
 0.8003 0.1712
```

Define the numerator and denominator coefficients for the rational transfer function.

```
b = 1;
a = [1 -0.2];
```

Apply the transfer function along the first dimension (default) and return the 1-D digital filter of each column.

```
y = filter(b,a,x)
```

```
y =

 0.8147 0.1419
 1.0687 0.4501
 0.3407 1.0058
 0.9815 0.9934
 0.8287 1.1582
 0.2633 0.8874
 0.3312 0.2132
 0.6131 0.8918
 1.0801 1.1123
 1.1809 0.9012
 0.3938 0.9380
 1.0494 0.9307
 1.1670 0.5784
```

```
0.7188 0.7712
0.9440 0.3254
```

Compare the original data and the filtered data using an overlaid plot for each column.

Plot the first column of input and filtered data.

```
t = 0:length(x)-1;

plot(t,x(:,1))
hold on
plot(t,y(:,1))

grid on
legend('Input Data','Filtered Data','Location','BestOutside')
title('Plot of Input and Filtered Data from Column 1')
```

Plot the second column of input and filtered data.

```
figure
```

```
plot(t,x(:,2))
```

```
hold on
```

```
plot(t,y(:,2))
```

```
grid on
```

```
legend('Input Data','Filtered Data','Location','BestOutside')
```

```
title('Plot of Input and Filtered Data from Column 2')
```

Alternatively, you can filter the rows of a matrix by specifying `dim = 2`.

Consider the 2-by-15 matrix, `x'`, whose rows contain the data to filter.

Filter the matrix along the second dimension. Use the default initial conditions for filter delays.

```
dim = 2;
y2 = filter(b,a,x',[],dim)
```

```
y2 =
```

```
Columns 1 through 7
```

```

0.8147 1.0687 0.3407 0.9815 0.8287 0.2633 0.3312
0.1419 0.4501 1.0058 0.9934 1.1582 0.8874 0.2132

```

Columns 8 through 14

```

0.6131 1.0801 1.1809 0.3938 1.0494 1.1670 0.7188
0.8918 1.1123 0.9012 0.9380 0.9307 0.5784 0.7712

```

Column 15

```

0.9440
0.3254

```

$y_2$  is the transpose of  $y$  from above.

### Filter Data in Sections

Use initial and final conditions for filter delays to filter data in sections, especially if memory limitations are a consideration.

Generate a large random data sequence and split it into two segments,  $x_1$  and  $x_2$ .

```
x = randn(10000,1);
```

```
x1 = x(1:5000);
```

```
x2 = x(5001:end);
```

The whole sequence,  $x$ , is the vertical concatenation of  $x_1$  and  $x_2$ .

Define the numerator and denominator coefficients for the rational transfer function,

$$H(z) = \frac{b(1) + b(2)z^{-1}}{a(1) + a(2)z^{-1}} = \frac{2 + 3z^{-1}}{1 + 0.2z^{-1}}.$$

```
b = [2,3];
```

```
a = [1,0.2];
```

Filter the subsequences  $x_1$  and  $x_2$  one at a time. Output the final conditions from filtering  $x_1$  to store the internal status of the filter at the end of the first segment.

```
[y1,zf] = filter(b,a,x1);
```

Use the final conditions from filtering `x1` as initial conditions to filter the second segment, `x2`.

```
y2 = filter(b,a,x2,zf);
```

`y1` is the filtered data from `x1`, and `y2` is the filtered data from `x2`. The entire filtered sequence is the vertical concatenation of `y1` and `y2`.

Filter the entire sequence simultaneously for comparison.

```
y = filter(b,a,x);
```

```
isequal(y,[y1;y2])
```

```
ans =
```

```
1
```

## Input Arguments

### **b** — Numerator coefficients of rational transfer function

vector

Numerator coefficients of the rational transfer function, specified as a vector.

Data Types: `double` | `single`

Complex Number Support: Yes

### **a** — Denominator coefficients of rational transfer function

vector

Denominator coefficients of the rational transfer function, specified as a vector.

Data Types: `double` | `single`

Complex Number Support: Yes

### **x** — Input data

vector | matrix | multidimensional array

Input data, specified as a vector, matrix, or multidimensional array.

Data Types: `double` | `single`

Complex Number Support: Yes

### **zi** — Initial conditions for filter delays

[ ] (default) | vector | matrix | multidimensional array

Initial conditions for filter delays, specified as a vector, matrix, or multidimensional array.

- If **zi** is a vector, then its length must be  $\max(\text{length}(a), \text{length}(b)) - 1$ .
- If **zi** is a matrix or multidimensional array, then the size of the leading dimension must be  $\max(\text{length}(a), \text{length}(b)) - 1$ . The size of each remaining dimension must match the size of the corresponding dimension of **x**.

The default value, specified by [ ], initializes all filter delays to zero.

Data Types: `double` | `single`

Complex Number Support: Yes

### **dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, **x**.

- If **dim** = 1, then `filter(b,a,x,zi,1)` works along the rows of **x** and returns the filter applied to each column.

- If **dim** = 2, then `filter(b,a,zi,2)` works along the columns of **x** and returns the filter applied to each row.

If `dim` is greater than `ndims(x)`, then `filter` returns `x`.

Data Types: `double` | `single`

## Output Arguments

### **y** — Filtered data

vector | matrix | multidimensional array

Filtered data, returned as a vector, matrix, or multidimensional array of the same size as the input data, `x`.

### **zf** — Final conditions for filter delays

vector | matrix | multidimensional array

Final conditions for filter delays, returned as a vector, matrix, or multidimensional array.

- If `x` is a vector, then `zf` is a column vector of length `max(length(a), length(b)) - 1`.
- If `x` is a matrix or multidimensional array, then `zf` is an array of column vectors of length `max(length(a), length(b)) - 1`, such that the number of columns in `zf` is equivalent to the number of columns in `x`.

## More About

### Rational Transfer Function

The input-output description of the `filter` operation on a vector in the Z-transform domain is a rational transfer function. A rational transfer function is of the form,

$$Y(z) = \frac{b(1) + b(2)z^{-1} + \dots + b(n_b + 1)z^{-n_b}}{1 + a(2)z^{-1} + \dots + a(n_a + 1)z^{-n_a}} X(z),$$

which handles both FIR and IIR filters [1].  $n_a$  is the feedback filter order, and  $n_b$  is the feedforward filter order.

You also can express the rational transfer function as the following difference equation,

$$\begin{aligned} \alpha(1)y(n) &= b(1)x(n) + b(2)x(n - 1) + \dots + b(n_b + 1)x(n - n_b) \\ &\quad - a(2)y(n - 1) - \dots - a(n_a + 1)y(n - n_a). \end{aligned}$$

Furthermore, you can represent the rational transfer function using its direct form II transposed implementation, as in the following diagram. Due to normalization, assume  $a(1) = 1$ .

The operation of **filter** at sample  $m$  is given by the time domain difference equations

$$\begin{aligned} y(m) &= b(1)x(m) + z_1(m - 1) \\ z_1(m) &= b(2)x(m) + z_2(m - 1) - a(2)y(m) \\ \vdots &= \quad \vdots \quad \quad \quad \quad \quad \vdots \\ z_{n-2}(m) &= b(n - 1)x(m) + z_{n-1}(m - 1) - a(n - 1)y(m) \\ z_{n-1}(m) &= b(n)x(m) - a(n)y(m). \end{aligned}$$

**Tips**

- If you have the Signal Processing Toolbox™, you can design a filter, **d**, using **designfilt**. Then, you can use **Y = filter(d,X)** to filter your data.
- “Filtering Data”

# filter2

2-D digital filter

## Syntax

```
Y = filter2(h,X)
Y = filter2(h,X,shape)
```

## Description

`Y = filter2(h,X)` filters the data in `X` with the two-dimensional FIR filter in the matrix `h`. It computes the result, `Y`, using two-dimensional correlation, and returns the central part of the correlation that is the same size as `X`.

`Y = filter2(h,X,shape)` returns the part of `Y` specified by the `shape` parameter. `shape` is a string with one of these values:

- 'full' Returns the full two-dimensional correlation. In this case, `Y` is larger than `X`.
- 'same' (default) Returns the central part of the correlation. In this case, `Y` is the same size as `X`.
- 'valid' Returns only those parts of the correlation that are computed without zero-padded edges. In this case, `Y` is smaller than `X`.

## More About

### Tips

Two-dimensional correlation is equivalent to two-dimensional convolution with the filter matrix rotated 180 degrees. See the Algorithm section for more information about how `filter2` performs linear filtering.

### Algorithms

Given a matrix `X` and a two-dimensional FIR filter `h`, `filter2` rotates your filter matrix 180 degrees to create a convolution kernel. It then calls `conv2`, the two-dimensional convolution function, to implement the filtering operation.

`filter2` uses `conv2` to compute the full two-dimensional convolution of the FIR filter with the input matrix. By default, `filter2` then extracts the central part of the convolution that is the same size as the input matrix, and returns this as the result. If the `shape` parameter specifies an alternate part of the convolution for the result, `filter2` returns the appropriate part.

# find

Find indices and values of nonzero elements

## Syntax

```
k = find(X)
k = find(X,n)
k = find(X,n,direction)

[row,col] = find(___)
[row,col,v] = find(___)
```

## Description

`k = find(X)` returns a vector containing the linear indices of each nonzero element in array `X`.

- If `X` is a vector, then `find` returns a vector with the same orientation as `X`.
- If `X` is a multidimensional array, then `find` returns a column vector of the linear indices of the result.
- If `X` contains no nonzero elements or is empty, then `find` returns an empty array.

`k = find(X,n)` returns the first `n` indices corresponding to the nonzero elements in `X`.

`k = find(X,n,direction)`, where `direction` is `'last'`, finds the last `n` nonzero elements in `X`. The default for `direction` is `'first'`, which finds the first `n` nonzero elements.

`[row,col] = find( ___ )` returns the row and column subscripts of each nonzero element in array `X` using any of the input arguments in previous syntaxes.

`[row,col,v] = find( ___ )` also returns vector `v`, which contains the nonzero elements of `X`.

## Examples

### Zero and Nonzero Elements in Matrix

Find the nonzero elements in a 3-by-3 matrix.

```
X = [1 0 2; 0 1 1; 0 0 4]
```

```
X =
```

```
 1 0 2
 0 1 1
 0 0 4
```

```
k = find(X)
```

```
k =
```

```
 1
 5
 7
 8
 9
```

Use the logical not operator on X to locate the zeros.

```
k2 = find(~X)
```

```
k2 =
```

```
 2
 3
 4
 6
```

### Elements Satisfying a Condition

Find the first five elements that are less than 10 in a 4-by-4 magic square matrix.

```
X = magic(4)
```

```
X =
```

```
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

```
k = find(X<10,5)
```

```
k =
```

```
 2
 3
 4
 5
 7
```

View the corresponding elements of X.

```
X(k)
```

```
ans =
```

```
 5
 9
 4
 2
 7
```

### Elements Equal to Specific Values

To find a specific integer value, use the `==` operator. For instance, find the element equal to 13 in a 1-by-10 vector of odd integers.

```
x = 1:2:20
```

```
x =
```

```
 1 3 5 7 9 11 13 15 17 19
```

```
k = find(x==13)
```

```
k =
```

```
7
```

To find a noninteger value, use a tolerance value based on your data. Otherwise, the result is sometimes an empty matrix due to floating-point roundoff error.

```
y = 0:0.1:1
```

```
y =
```

```
Columns 1 through 7
```

```
0 0.1000 0.2000 0.3000 0.4000 0.5000 0.6000
```

```
Columns 8 through 11
```

```
0.7000 0.8000 0.9000 1.0000
```

```
k = find(y==0.3)
```

```
k =
```

```
Empty matrix: 1-by-0
```

```
k = find(abs(y-0.3) < 0.001)
```

```
k =
```

```
4
```

## Last Several Nonzero Elements

Create a 6-by-6 magic square matrix with all of the odd-indexed elements equal to zero.

```
X = magic(6);
X(1:2:end) = 0
```

```
X =
```

```

0 0 0 0 0 0
3 32 7 21 23 25
0 0 0 0 0 0
8 28 33 17 10 15
0 0 0 0 0 0
4 36 29 13 18 11
```

Locate the *last* four nonzeros.

```
k = find(X,4,'last')
```

```
k =
```

```

30
32
34
36
```

### Elements Satisfying Multiple Conditions

Find the first three elements in a 4-by-4 matrix that are greater than 0 and less than 10. Specify two outputs to return the row and column subscripts to the elements.

```
X = [18 3 1 11; 8 10 11 3; 9 14 6 1; 4 3 15 21]
```

```
X =
```

```

18 3 1 11
 8 10 11 3
 9 14 6 1
 4 3 15 21
```

```
[row,col] = find(X>0 & X<10,3)
```

```
row =
```

```
2
3
4
```

```
col =
```

```
1
1
1
```

The first instance is  $X(2, 1)$ , which is 8.

### **Subscripts and Values for Nonzero Elements**

Find the nonzero elements in a 3-by-3 matrix. Specify three outputs to return the row subscripts, column subscripts, and element values.

```
X = [3 2 0; -5 0 7; 0 0 1]
```

```
X =
```

```
3 2 0
-5 0 7
0 0 1
```

```
[row,col,v] = find(X)
```

```
row =
```

```
1
2
1
2
3
```

```
col =
```

```

1
1
2
3
3

```

v =

```

3
-5
2
7
1

```

### Subscripts of Multidimensional Array

Find the nonzero elements in a 4-by-2-by-3 array. Specify two outputs, `row` and `col`, to return the row and column subscripts of the nonzero elements. When the input is a multidimensional array ( $N > 2$ ), `find` returns `col` as a linear index over the  $N-1$  trailing dimensions of `X`.

```

X = zeros(4,2,3);
X([1 12 19 21]) = 1

```

X(:, :, 1) =

```

1 0
0 0
0 0
0 0

```

X(:, :, 2) =

```

0 0
0 0
0 0
1 0

```

X(:, :, 3) =

```
0 1
0 0
1 0
0 0
```

```
[row,col] = find(X)
```

```
row =
```

```
1
4
3
1
```

```
col =
```

```
1
3
5
6
```

- “Find Array Elements That Meet a Condition”

## Input Arguments

### **X** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. If X is an empty array or has no nonzero elements, then k is an empty array.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

Complex Number Support: Yes

### **n** — Number of nonzeros to find

positive integer scalar

Number of nonzeros to find, specified as a positive integer scalar. By default, `find(X,n)` looks for the first `n` nonzero elements in `X`.

**direction — Search direction**

'first' (default) | 'last'

Search direction, specified as the string 'first' or 'last'. Look for the *last* `n` nonzero elements in `X` using `find(X,n,'last')`.

## Output Arguments

**k — Indices to nonzero elements**

vector

Indices to nonzero elements, returned as a vector. If `X` is a row vector, then `k` is also a row vector. Otherwise, `k` is a column vector. `k` is an empty array when `X` is an empty array or has no nonzero elements.

You can return the nonzero values in `X` using `X(k)`.

**row — Row subscripts**

vector

Row subscripts, returned as a vector. Together, `row` and `col` specify the `X(row,col)` subscripts corresponding to the nonzero elements in `X`.

**col — Column subscripts**

vector

Column subscripts, returned as a vector. Together, `row` and `col` specify the `X(row,col)` subscripts corresponding to the nonzero elements in `X`.

If `X` is a multidimensional array with `N > 2`, then `col` is a linear index over the `N-1` trailing dimensions of `X`. This preserves the relation `X(row(i),col(i)) == v(i)`.

**v — Nonzero elements of X**

vector

Nonzero elements of `X`, returned as a vector.

## More About

### Linear Indices

A linear index allows use of a single subscript to index into an array, such as `A(k)`. MATLAB treats the array as a single column vector with each column appended to the bottom of the previous column. Thus, linear indexing numbers the elements in the columns from top to bottom, left to right.

For example, consider a 3-by-3 matrix. You can reference the `A(2,2)` element with `A(5)`, and the `A(2,3)` element with `A(8)`. The linear index changes depending on the size of the array; `A(5)` returns a differently located element for a 3-by-3 matrix than it does for a 4-by-4 matrix.

The `sub2ind` and `ind2sub` functions are useful in converting between subscripts and linear indices.

### Tips

- To find array elements that meet a condition, use `find` in conjunction with a relational expression. For example, `find(X<5)` returns the linear indices to the elements in `X` that are less than 5.
- To directly find the elements in `X` that satisfy the condition `X<5`, use `X(X<5)`. Avoid function calls like `X(find(X<5))`, which unnecessarily use `find` on a logical matrix.
- When you execute `find` with a relational operation like `X>1`, it is important to remember that the result of the relational operation is a logical matrix of ones and zeros. For example, the command `[row,col,v] = find(X>1)` returns a column vector of logical 1 (`true`) values for `v`.
- The row and column subscripts, `row` and `col`, are related to the linear indices in `k` by `k = sub2ind(size(X),row,col)`.

## findall

Find all graphics objects

### Syntax

```
object_handles = findall(handle_list)
object_handles = findall(handle_list, 'property', 'value', ...)
```

### Description

`object_handles = findall(handle_list)` returns the handles, including hidden handles, of all objects in the hierarchy under the objects identified in `handle_list`.

`object_handles = findall(handle_list, 'property', 'value', ...)` returns the handles of all objects in the hierarchy under the objects identified in `handle_list` that have the specified properties set to the specified values.

### Examples

```
plot(1:10)
xlabel xlab
a = findall(gcf)
b = findobj(gcf)
c = findall(b, 'Type', 'text')
% returns the xlabel handle twice
d = findobj(b, 'Type', 'text')
% can't find the xlabel handle
```

### More About

#### Tips

`findall` is similar to `findobj`, except that it finds objects even if their `HandleVisibility` is set to `off`.

## **See Also**

allchild | findobj

**Introduced before R2006a**

## **findfigs**

Find visible offscreen figures

### **Syntax**

```
findfigs
```

### **Description**

`findfigs` finds all visible figure windows whose display area is off the screen and positions them on the screen.

A window appears to the MATLAB software to be offscreen when its display area (the area not covered by the window's title bar, menu bar, and toolbar) does not appear on the screen.

This function is useful when you are bringing an application from a larger monitor to a smaller one (or one with lower resolution). Windows visible on the larger monitor may appear offscreen on a smaller monitor. Using `findfigs` ensures that all windows appear on the screen.

**Introduced before R2006a**

# findgroups

Find groups and return group numbers

## Syntax

```
G = findgroups(A)
G = findgroups(A1,...,AN)

[G,ID] = findgroups(A)
[G,ID1,...,IDN] = findgroups(A1,...,AN)

G = findgroups(T)
[G,TID] = findgroups(T)
```

## Description

`G = findgroups(A)` returns `G`, a vector of group numbers created from the grouping variable `A`. The output argument `G` contains integer values from 1 to `N`, indicating `N` distinct groups for the `N` unique values in `A`. For example, if `A` is `{'b','a','a','b'}`, then `findgroups` returns `G` as `[2 1 1 2]`. You can use `G` to split groups of data out of other variables. Use `G` as an input argument to `splitapply` in the “Split-Apply-Combine Workflow” on page 1-2781.

`findgroups` treats empty strings and `NaN`, `NaN`, and undefined categorical values in `A` as missing values and returns `NaN` as the corresponding elements of `G`.

`G = findgroups(A1,...,AN)` creates group numbers from `A1,...,AN`. The `findgroups` function defines groups as the unique combinations of values across `A1,...,AN`. For example, if `A1` is `{'a','a','b','b'}` and `A2` is `[0 1 0 0]`, then `findgroups(A1,A2)` returns `G` as `[1 2 3 3]`, because the combination `'b' 0` occurs twice.

`[G,ID] = findgroups(A)` also returns the unique values for each group in `ID`. For example, if `A` is `{'b','a','a','b'}`, then `findgroups` returns `G` as `[2 1 1 2]` and `ID` as `{'a','b'}`. The arguments `A` and `ID` are the same data type, but need not be the same size.

`[G, ID1, ..., IDN] = findgroups(A1, ..., AN)` also returns the unique values for each group across `ID1, ..., IDN`. The values across `ID1, ..., IDN` define the groups. For example, if `A1` is `{'a', 'a', 'b', 'b'}` and `A2` is `[0 1 0 0]`, then `findgroups(A1, A2)` returns `G` as `[1 2 3 3]`, and `ID1` and `ID2` as `{'a', 'a', 'b'}` and `[0 1 0]`.

`G = findgroups(T)` returns `G`, a vector of group numbers created from the variables in table `T`. The `findgroups` function treats all the variables in `T` as grouping variables.

`[G, TID] = findgroups(T)` also returns `TID`, a table that contains the unique values for each group. `TID` contains the unique combinations of values across the variables of `T`. The variables in `T` and `TID` have the same names, but the tables need not have the same number of rows.

## Examples

### Use Group Numbers to Split Data

Use group numbers to split patient height measurements into groups by gender. Then calculate the mean height for each group.

Load patient heights and genders from the data file `patients.mat`.

```
load patients
whos Gender Height
```

| Name   | Size  | Bytes | Class  | Attributes |
|--------|-------|-------|--------|------------|
| Gender | 100x1 | 12212 | cell   |            |
| Height | 100x1 | 800   | double |            |

Specify groups by gender with `findgroups`.

```
G = findgroups(Gender);
```

Compare the first five elements of `Gender` and `G`. Where `Gender` contains `'Female'`, `G` contains 1. Where `Gender` contains `'Male'`, `G` contains 2.

```
Gender(1:5)
```

```
ans =
```

```
'Male'
'Male'
'Female'
'Female'
'Female'
```

```
G(1:5)
```

```
ans =
```

```
2
2
1
1
1
```

Split the `Height` variable into two groups of heights using `G`. Apply the `mean` function. The groups contain the mean heights of female and male patients, respectively.

```
splitapply(@mean,Height,G)
```

```
ans =
```

```
65.1509
69.2340
```

### Use Two Grouping Variables to Split Data

Calculate mean blood pressures for groups of patients from measurements grouped by gender and status as a smoker.

Load blood pressure readings, gender, and smoking data for patients from the data file `patients.mat`.

```
load patients
whos Systolic Diastolic Gender Smoker
```

| Name      | Size  | Bytes | Class  | Attributes |
|-----------|-------|-------|--------|------------|
| Diastolic | 100x1 | 800   | double |            |
| Gender    | 100x1 | 12212 | cell   |            |

```
Smoker 100x1 100 logical
Systolic 100x1 800 double
```

Specify groups using gender and smoking information about the patients. **G** contains integers from one to four because there are four possible combinations of values from **Smoker** and **Gender**.

```
G = findgroups(Smoker,Gender);
G(1:10)
```

```
ans =
```

```
4
2
1
1
1
1
3
2
2
1
```

Calculate the mean blood pressure for each group.

```
meanSystolic = splitapply(@mean,Systolic,G);
meanDiastolic = splitapply(@mean,Diastolic,G);
mBP = [meanSystolic,meanDiastolic]
```

```
mBP =
```

```
119.4250 79.0500
119.3462 79.8846
129.0000 89.2308
129.5714 90.3333
```

## Use Unique Group Values in Output Table

Calculate the median heights for groups of patients, and display the results in a table. To define the groups of patients, use the additional output argument from **findgroups**.

Load patient heights and genders from the data file `patients.mat`.

```
load patients
whos Gender Height
```

| Name   | Size  | Bytes | Class  | Attributes |
|--------|-------|-------|--------|------------|
| Gender | 100x1 | 12212 | cell   |            |
| Height | 100x1 | 800   | double |            |

Specify groups by gender with `findgroups`. The values in the output argument `gender` define the groups that `findgroups` finds in the grouping variable.

```
[G,gender] = findgroups(Gender);
```

Calculate the median heights. Create a table that contains the median heights.

```
medianHeight = splitapply(@median,Height,G);
T = table(gender,medianHeight)
```

T =

| gender   | medianHeight |
|----------|--------------|
| 'Female' | 65           |
| 'Male'   | 69           |

### Use Unique Values from Two Grouping Variables

Calculate mean blood pressures for groups of patients, and display the results in a table. To define the groups of patients, use the additional output arguments from `findgroups`.

Load blood pressure readings, gender, and smoking data for 100 patients from the data file `patients.mat`.

```
load patients
whos Systolic Diastolic Gender Smoker
```

| Name      | Size  | Bytes | Class  | Attributes |
|-----------|-------|-------|--------|------------|
| Diastolic | 100x1 | 800   | double |            |

```
Gender 100x1 12212 cell
Smoker 100x1 100 logical
Systolic 100x1 800 double
```

Specify groups using gender and smoking information about the patients. Calculate mean blood pressure for each group. The values across the output arguments `gender` and `smoker` define the groups that `findgroups` finds in the grouping variables.

```
[G,gender,smoker] = findgroups(Gender,Smoker);
meanSystolic = splitapply(@mean,Systolic,G);
meanDiastolic = splitapply(@mean,Diastolic,G);
```

Create a table with the mean blood pressure for each group of patients.

```
T = table(gender,smoker,meanSystolic,meanDiastolic)
```

```
T =
```

| gender   | smoker | meanSystolic | meanDiastolic |
|----------|--------|--------------|---------------|
| 'Female' | false  | 119.43       | 79.05         |
| 'Female' | true   | 129          | 89.231        |
| 'Male'   | false  | 119.35       | 79.885        |
| 'Male'   | true   | 129.57       | 90.333        |

## Group by Table Variables

Calculate mean blood pressures for patients using grouping variables that are in a table.

Load gender and smoking data for 100 patients into a table.

```
load patients
T = table(Gender,Smoker);
T(1:5,:)
```

```
ans =
```

| Gender | Smoker |
|--------|--------|
|--------|--------|

```
'Male' true
'Male' false
'Female' false
'Female' false
'Female' false
```

Specify groups of patients using the `Gender` and `Smoker` variables in `T`.

```
G = findgroups(T);
```

Calculate mean blood pressures from the data variables `Systolic` and `Diastolic`.

```
meanSystolic = splitapply(@mean,Systolic,G);
meanDiastolic = splitapply(@mean,Diastolic,G);
mBP = [meanSystolic,meanDiastolic]
```

```
mBP =
```

```
119.4250 79.0500
129.0000 89.2308
119.3462 79.8846
129.5714 90.3333
```

### Group from Table and Create Output Table

Create a table of mean blood pressures for patients grouped by gender and status as a smoker or nonsmoker.

Load gender and smoking data for patients into a table.

```
load patients
T = table(Gender,Smoker);
```

Specify groups of patients using the `Gender` and `Smoker` variables in `T`. The output table `TID` identifies the groups.

```
[G,TID] = findgroups(T);
TID
```

```
TID =
```

| Gender   | Smoker |
|----------|--------|
| 'Female' | false  |
| 'Female' | true   |
| 'Male'   | false  |
| 'Male'   | true   |

Calculate mean blood pressures from the data variables `Systolic` and `Diastolic`. Append mean blood pressures to `TID`.

```
TID.meanSystolic = splitapply(@mean,Systolic,G);
TID.meanDiastolic = splitapply(@mean,Diastolic,G)
```

TID =

| Gender   | Smoker | meanSystolic | meanDiastolic |
|----------|--------|--------------|---------------|
| 'Female' | false  | 119.43       | 79.05         |
| 'Female' | true   | 129          | 89.231        |
| 'Male'   | false  | 119.35       | 79.885        |
| 'Male'   | true   | 129.57       | 90.333        |

- “Split Table Data Variables and Apply Functions”
- “Split Data into Groups and Calculate Statistics”
- “Calculations on Tables”

## Input Arguments

### A — Grouping variable

vector | cell array of strings

Grouping variable, specified as a vector or a cell array of strings. The unique values in `A` identify groups.

If `A` is a vector, it can be numeric or of data type `categorical`, `datetime`, `duration`, or `logical`.

**T — Grouping variables**

table

Grouping variables, specified as a table. `findgroups` treats each table variable as a separate grouping variable.

## Output Arguments

**G — Group numbers**

vector of positive integers

Group numbers, returned as a vector of positive integers. For  $N$  groups identified in the grouping variables, every integer between 1 and  $N$  specifies a group. `G` contains `NaN` where any grouping variable contains an empty string or a `NaN`, `NaT`, or undefined categorical value.

- If the grouping variables are vectors, then `G` and the grouping variables all are the same size.
- If the grouping variables are in a table, the length of `G` is equal to the number of rows of the table.

**ID — Unique values that identify each group**

vector of unique values | cell array of strings

The unique values that identify each group, returned as a vector or cell array of strings. `ID` is of the same data type as `A`, but need not be the same size.

**TID — Table of unique values that identify each group**

table

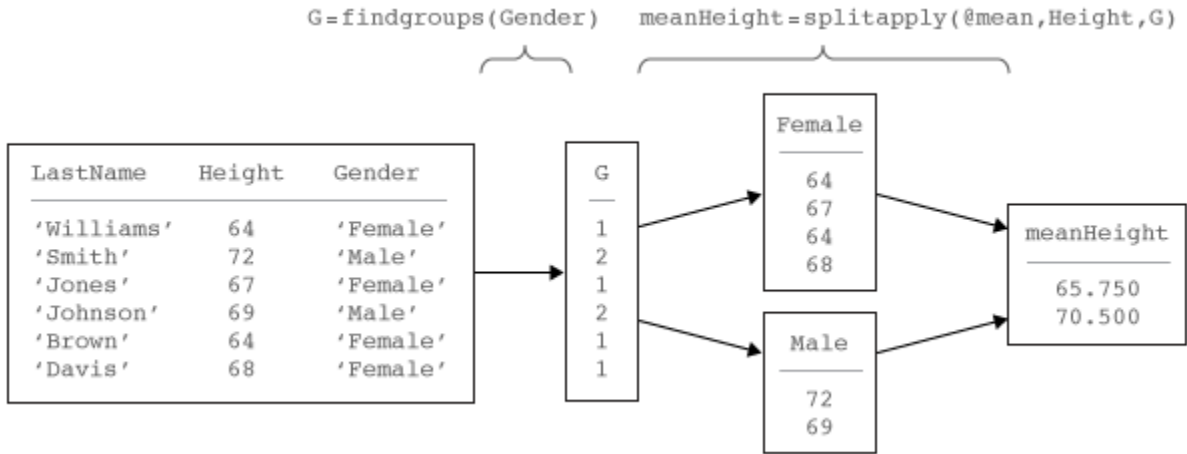

The unique values that identify each group, returned as a table. The variables in `TID` and `T` have the same names. However, `TID` and `T` need not have the same numbers of rows.

## More About

**Split-Apply-Combine Workflow**

The *Split-Apply-Combine* workflow is common in data analysis. In this workflow, the analyst splits the data into groups, applies a function to each group, and combines

the results. The diagram shows a typical example of the workflow and the parts of the workflow implemented by `findgroups` and `splitapply`.

- “Grouping Variables To Split Data”

`arrayfun` | `ismember` | `rowfun` | `splitapply` | `unique` | `varfun`

Introduced in R2015b

# findobj

Locate graphics objects with specific properties

## Syntax

```
findobj
h = findobj
h = findobj('PropertyName',PropertyValue,...)
h = findobj('PropertyName',PropertyValue,'-logicaloperator',
PropertyName',PropertyValue,...)
h = findobj('-regexp','PropertyName','regexp',...)
h = findobj('-property','PropertyName')
h = findobj(objhandles,...)
h = findobj(objhandles,'-depth',d,...)
h = findobj(objhandles,'flat','PropertyName',PropertyValue,...)
```

## Description

`findobj` returns handles of the root object and all its descendants without assigning the result to a variable.

`h = findobj` returns handles of the root object and all its descendants.

`h = findobj('PropertyName',PropertyValue,...)` returns handles of all graphics objects having the property *PropertyName*, set to the value *PropertyValue*. You can specify more than one property/value pair, in which case, `findobj` returns only those objects having all specified values.

`h = findobj('PropertyName',PropertyValue,'-logicaloperator',  
PropertyName',PropertyValue,...)` applies the logical operator to the property value matching. Possible values for *-logicaloperator* are:

- `-and`
- `-or`
- `-xor`
- `-not`

For more information on logical operators, see “Logical Operations”.

`h = findobj(' -regexp', 'PropertyName', 'regexp', ...)` matches objects using regular expressions as if the value of you passed the property `PropertyName` to the `regexp` function as

```
regexp(PropertyValue, 'regexp')
```

If a match occurs, `findobj` returns the object handle. See the `regexp` function for information on how the MATLAB software uses regular expressions.

`h = findobj(' -property', 'PropertyName')` finds all objects having the specified property.

`h = findobj(objhandles, ...)` restricts the search to objects listed in `objhandles` and their descendants.

`h = findobj(objhandles, ' -depth', d, ...)` specifies the depth of the search. The depth argument `d` controls how many levels under the handles in `objhandles` MATLAB traverses. Specify `d` as `inf` to get the default behavior of all levels. Specify `d` as `0` to get the same behavior as using the `flat` argument.

`h = findobj(objhandles, 'flat', 'PropertyName', PropertyValue, ...)` restricts the search to those objects listed in `objhandles` and does not search descendants.

`findobj` returns an error if a handle refers to a nonexistent graphics object.

`findobj` correctly matches any legal property value. For example,

```
findobj('Color', 'r')
```

finds all objects having a `Color` property set to `red`, `r`, or `[1 0 0]`.

When a graphics object is a descendant of more than one object identified in `objhandles`, MATLAB searches the object each time `findobj` encounters its handle. Therefore, implicit references to a graphics object can result in multiple returns of its handle.

To find handle objects that meet specified conditions, use `findobj`.

## Examples

Find all line objects in the current axes:

```
h = findobj(gca,'Type','line')
```

Find all objects having a **Label** set to 'foo' and a **String** set to 'bar':

```
h = findobj('Label','foo','-and','String','bar');
```

Find all objects whose **String** is not 'foo' and is not 'bar':

```
h = findobj('-not','String','foo','-not','String','bar');
```

Find all objects having a **String** set to 'foo' and a **Tag** set to 'button one' and whose **Color** is not 'red' or 'blue':

```
h = findobj('String','foo','-and','Tag','button one',...
 '-and','-not',{'Color','red','-or','Color','blue'})
```

Find all objects for which you have assigned a value to the **Tag** property (that is, the value is not the empty string ''):

```
h = findobj('-regexp','Tag','[^'']')
```

Find all children of the current figure that have their **BackgroundColor** property set to a certain shade of gray ([.7 .7 .7]). This statement also searches the current figure for the matching property value pair.

```
h = findobj(gcf,'-depth',1,'BackgroundColor',[.7 .7 .7])
```

## See Also

**Introduced before R2006a**

## findstr

Find string within another, longer string

---

**Note:** `findstr` is not recommended. Use `strfind` instead.

---

### Syntax

```
k = findstr(str1, str2)
```

### Description

`k = findstr(str1, str2)` searches the longer of the two input strings for any occurrences of the shorter string, returning the starting index of each such occurrence in the double array `k`. If no occurrences are found, then `findstr` returns the empty array, `[]`.

The search performed by `findstr` is case sensitive. Any leading and trailing blanks in either input string are explicitly included in the comparison.

Unlike the `strfind` function, the order of the input arguments to `findstr` is not important. This can be useful if you are not certain which of the two input strings is the longer one.

### Examples

```
s = 'Find the starting indices of the shorter string.';
```

```
findstr(s, 'the')
ans =
 6 30
```

```
findstr('the', s)
ans =
```

6 30

# finish

Termination file for MATLAB program

## Description

When the MATLAB program quits, it runs a script called `finish.m`, if the script exists and is on the search path MATLAB uses or in the current folder. `finish.m` is a file you create that instructs MATLAB to perform any final tasks before terminating. For example, you can save the data in your workspace to a MAT-file.

`finish.m` is invoked whenever you do one of the following:

- Click the Close box  in the MATLAB desktop on Microsoft Windows platforms or the equivalent on UNIX platforms
- Type `quit` or `exit` at the command prompt

## Examples

Two sample termination files are provided with MATLAB in `matlabroot/toolbox/local`.

- `finishesav.m` — Saves the workspace to a MAT-file when MATLAB quits.
- `finishdlg.m` — Displays a dialog box allowing you to cancel quitting and saves the workspace. See also the “Confirmation Dialogs Preferences” and the option for exiting MATLAB.

To create a termination file, make a copy of one of these sample files and change the name to `finish.m`. Make sure that the file is on the MATLAB path. You can modify the file to include any operations you want the termination file to perform.

## More About

### Tips

When using Handle Graphics features in `finish.m`, use `uiwait`, `waitfor`, or `drawnow` so that figures are visible.

- “Exit MATLAB”

## fitsdisp

Display FITS metadata

### Syntax

```
fitsdisp(filename)
fitsdisp(filename,Name,Value)
```

### Description

`fitsdisp(filename)` displays metadata for all the Header/Data Units (HDUs) found in the FITS file specified by `filename`.

`fitsdisp(filename,Name,Value)` displays metadata for all the Header/Data Units (HDUs) found in the FITS file with additional options specified by one or more `Name,Value` pair arguments.

### Input Arguments

#### **filename**

Text string specifying the name of an existing FITS file.

**Default:**

#### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

#### **'Index'**

Positive scalar value or vector specifying the HDUs.

**Default:****'Mode'**

One of the following strings:

- `standard` – Display standard keywords
- `min` – Display only HDU types and sizes
- `full` – Display all HDU keywords

**Default:** `standard`

## Examples

Display metadata in the 2nd HDU in the FITS file.

```
fitsdisp('tst0012.fits', 'Index', 2);
```

Display the metadata in the 1st, 3rd, and 5th HDUs in a file.

```
fitsdisp('tst0012.fits', 'Index', [1 3 5]);
```

Display all metadata in the 5th HDU in a file

```
fitsdisp('tst0012.fits', 'Index', 5, 'Mode', 'full');
```

## fitsinfo

Information about FITS file

### Syntax

```
info = fitsinfo(filename)
```

### Description

`info = fitsinfo(filename)` returns the structure, `info`, with fields that contain information about the contents of a Flexible Image Transport System (FITS) file. `filename` is a string enclosed in single quotes that specifies the name of the FITS file.

The `info` structure contains the following fields, listed in the order they appear in the structure. In addition, the `info` structure can also contain information about any number of optional file components, called *extensions* in FITS terminology. For more information, see “FITS File Extensions” on page 1-2793.

| Field Name  | Description                                                 | Return Type           |
|-------------|-------------------------------------------------------------|-----------------------|
| Filename    | Name of the file                                            | String                |
| FileModDate | File modification date                                      | String                |
| FileSize    | Size of the file in bytes                                   | double                |
| Contents    | List of extensions in the file in the order that they occur | Cell array of strings |
| PrimaryData | Information about the primary data in the FITS file         | Structure array       |

### PrimaryData

The `PrimaryData` field is a structure that describes the primary data in the file. The following table lists the fields in the order they appear in the structure.

| Field Name | Description           | Return Type |
|------------|-----------------------|-------------|
| DataType   | Precision of the data | String      |

| Field Name       | Description                                                                                                                                                                                                                          | Return Type           |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Size             | Size of each dimension. The number of rows correspond to the value of the NAXIS2 keyword, while the number of columns correspond to the value of the NAXIS1 keyword. Any further dimensions correspond to NAXIS3, NAXIS4, and so on. | double array          |
| DataSize         | Size of the primary data in bytes                                                                                                                                                                                                    | double                |
| MissingDataValue | Value used to represent undefined data                                                                                                                                                                                               | double                |
| Intercept        | Value, used with <b>Slope</b> , to calculate actual pixel values from the array pixel values, using the equation:<br>$\text{actual\_value} = \text{Slope} * \text{array\_value} + \text{Intercept}$                                  | double                |
| Slope            | Value, used with <b>Intercept</b> , to calculate actual pixel values from the array pixel values, using the equation:<br>$\text{actual\_value} = \text{Slope} * \text{array\_value} + \text{Intercept}$                              | double                |
| Offset           | Number of bytes from beginning of the file to the location of the first data value                                                                                                                                                   | double                |
| Keywords         | A number-of-keywords-by-3 cell array containing keywords, values, and comments of the header in each column                                                                                                                          | Cell array of strings |

## FITS File Extensions

A FITS file can also include optional extensions. If the file contains any of these extensions, the `info` structure can contain these additional fields.

- `AsciiTable` — Numeric information in tabular format, stored as ASCII characters
- `BinaryTable` — Numeric information in tabular format, stored in binary representation
- `Image` — A multidimensional array of pixels

- Unknown — Nonstandard extension

## AsciiTable Extension

The `AsciiTable` structure contains the following fields, listed in the order they appear in the structure.

| Field Name                    | Description                                                                                                                                                                                                                                    | Return Type           |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| <code>Rows</code>             | Number of rows in the table                                                                                                                                                                                                                    | double                |
| <code>RowSize</code>          | Number of characters in each row                                                                                                                                                                                                               | double                |
| <code>NFields</code>          | Number of fields in each row                                                                                                                                                                                                                   | double array          |
| <code>FieldFormat</code>      | A 1-by- <code>NFields</code> cell containing formats in which each field is encoded. The formats are FORTRAN-77 format codes.                                                                                                                  | Cell array of strings |
| <code>FieldPrecision</code>   | A 1-by- <code>NFields</code> cell containing precision of the data in each field                                                                                                                                                               | Cell array of strings |
| <code>FieldWidth</code>       | A 1-by- <code>NFields</code> array containing the number of characters in each field                                                                                                                                                           | double array          |
| <code>FieldPos</code>         | A 1-by- <code>NFields</code> array of numbers representing the starting column for each field                                                                                                                                                  | double array          |
| <code>DataSize</code>         | Size of the data in the table in bytes                                                                                                                                                                                                         | double                |
| <code>MissingDataValue</code> | A 1-by- <code>NFields</code> array of numbers used to represent undefined data in each field                                                                                                                                                   | Cell array of strings |
| <code>Intercept</code>        | A 1-by- <code>NFields</code> array of numbers used along with <code>Slope</code> to calculate actual data values from the array data values using the equation: $\text{actual\_value} = \text{Slope} * \text{array\_value} + \text{Intercept}$ | double array          |
| <code>Slope</code>            | A 1-by- <code>NFields</code> array of numbers used with <code>Intercept</code> to calculate true data values from the array data values using the equation: $\text{actual\_value} = \text{Slope} * \text{array\_value} + \text{Intercept}$     | double array          |

| Field Name | Description                                                                                                     | Return Type           |
|------------|-----------------------------------------------------------------------------------------------------------------|-----------------------|
| Offset     | Number of bytes from beginning of the file to the location of the first data value in the table                 | double                |
| Keywords   | A number-of-keywords-by-3 cell array containing all the Keywords, Values and Comments in the ASCII table header | Cell array of strings |

## BinaryTable Extension

The `BinaryTable` structure contains the following fields, listed in the order they appear in the structure.

| Field Name       | Description                                                                                                                                    | Return Type           |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Rows             | Number of rows in the table                                                                                                                    | double                |
| RowSize          | Number of bytes in each row                                                                                                                    | double                |
| NFields          | Number of fields in each row                                                                                                                   | double                |
| FieldFormat      | A 1-by-NFields cell array containing the data type of the data in each field. The data type is represented by a FITS binary table format code. | Cell array of strings |
| FieldPrecision   | A 1-by-NFields cell containing precision of the data in each field                                                                             | Cell array of strings |
| FieldSize        | A 1-by-NFields array, where each element contains the number of values in the Nth field                                                        | double array          |
| DataSize         | Size of the data in the Binary Table, in bytes. Includes any data past the main table.                                                         | double                |
| MissingDataValue | An 1-by-NFields array of numbers used to represent undefined data in each field                                                                | Cell array of double  |
| Intercept        | A 1-by-NFields array of numbers used along with Slope to calculate actual data values from the array data values                               | double array          |

| Field Name      | Description                                                                                                                                                                         | Return Type           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
|                 | using the equation: $actual\_value = slope * array\_value + Intercept$                                                                                                              |                       |
| Slope           | A 1-by-NFields array of numbers used with Intercept to calculate true data values from the array data values using the equation: $actual\_value = Slope * array\_value + Intercept$ | double array          |
| Offset          | Number of bytes from beginning of the file to the location of the first data value                                                                                                  | double                |
| ExtensionSize   | Size of any data past the main table, in bytes                                                                                                                                      | double                |
| ExtensionOffset | Number of bytes from the beginning of the file to any data past the main table                                                                                                      | double                |
| Keywords        | A number-of-keywords-by-3 cell array containing all the Keywords, values, and comments in the Binary Table header                                                                   | Cell array of strings |

## Image Extension

The Image structure contains the following fields, listed in the order they appear in the structure.

| Field Name | Description                                                                                                                                                                                                                          | Return Type  |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| DataType   | Precision of the data                                                                                                                                                                                                                | String       |
| Size       | Size of each dimension. The number of rows correspond to the value of the NAXIS2 keyword, while the number of columns correspond to the value of the NAXIS1 keyword. Any further dimensions correspond to NAXIS3, NAXIS4, and so on. | double array |
| DataSize   | Size of the data in the Image extension in bytes                                                                                                                                                                                     | double       |
| Offset     | Number of bytes from the beginning of the file to the first data value                                                                                                                                                               | double       |

| Field Name       | Description                                                                                                                                                                                  | Return Type           |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| MissingDataValue | Value used to represent undefined data                                                                                                                                                       | double                |
| Intercept        | Value, used with Slope, to calculate actual pixel values from the array pixel values, using the equation: $\text{actual\_value} = \text{Slope} * \text{array\_value} + \text{Intercept}$     | double                |
| Slope            | Value, used with Intercept, to calculate actual pixel values from the array pixel values, using the equation: $\text{actual\_value} = \text{Slope} * \text{array\_value} + \text{Intercept}$ | double                |
| Keywords         | A number-of-keywords-by-3 cell array containing all the Keywords, values, and comments in the Binary Table header                                                                            | Cell array of strings |

## Unknown Structure

The Unknown structure contains the following fields, listed in the order they appear in the structure.

| Field Name       | Description                                                                                                                                                                            | Return Type  |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|
| DataType         | Precision of the data                                                                                                                                                                  | String       |
| Size             | Sizes of each dimension                                                                                                                                                                | double array |
| DataSize         | Size of the data in nonstandard extensions, in bytes                                                                                                                                   | double       |
| Offset           | Number of bytes from beginning of the file to the first data value                                                                                                                     | double       |
| MissingDataValue | Representation of undefined data                                                                                                                                                       | double       |
| Intercept        | Value, used with Slope, to calculate actual data values from the array data values, using the equation: $\text{actual\_value} = \text{Slope} * \text{array\_value} + \text{Intercept}$ | double       |

| Field Name | Description                                                                                                                                                    | Return Type           |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Slope      | Value, used with Intercept, to calculate actual data values from the array data values, using the equation: $actual\_value = Slope * array\_value + Intercept$ | double                |
| Keywords   | A number-of-keywords-by-3 cell array containing all the Keywords, values, and comments in the Binary Table header                                              | Cell array of strings |

## Examples

### Get Information About FITS File

Use `fitsinfo` to obtain information about the FITS file `tst0012.fits`. In addition to its primary data, the file also contains an example of the extensions `BinaryTable`, `Unknown`, `Image`, and `AsciiTable`.

```
S = fitsinfo('tst0012.fits')
```

```
S =
 Filename: 'matlabroot\toolbox\matlab\demos\tst0012.fits'
 FileModDate: '12-Mar-2001 18:37:46'
 FileSize: 109440
 Contents: {'Primary' 'Binary Table' 'Unknown'
'Image' 'ASCII Table'}
 PrimaryData: [1x1 struct]
 BinaryTable: [1x1 struct]
 Unknown: [1x1 struct]
 Image: [1x1 struct]
 AsciiTable: [1x1 struct]
```

View the `PrimaryData` field.

```
S.PrimaryData
```

```
ans =
 DataType: 'single'
 Size: [109 102]
 DataSize: 44472
```

```

MissingDataValue: []
 Intercept: 0
 Slope: 1
 Offset: 2880
 Keywords: {25x3 cell}

```

The `PrimaryData` field describes the data in the file. For example, the `Size` field indicates the data is a 109-by-102 matrix.

View the `AsciiTable` field.

`S.Asciitable`

```

ans =
 Rows: 53
 RowSize: 59
 NFields: 8
 FieldFormat: {'A9' 'F6.2' 'I3' 'E10.4' 'D20.15' 'A5' 'A1' 'I4'}
 FieldPrecision: {1x8 cell}
 FieldWidth: [9 6.2000 3 10.4000 20.1500 5 1 4]
 FieldPos: [1 11 18 22 33 54 54 55]
 DataSize: 3127
MissingDataValue: {'*' '-----' ' ' '*' [] '*' '*' '*' ''}
 Intercept: [0 0 -70.2000 0 0 0 0 0]
 Slope: [1 1 2.1000 1 1 1 1 1]
 Offset: 103680
 Keywords: {65x3 cell}

```

The `AsciiTable` field describes the `AsciiTable` extension. For example, using the `FieldWidth` and `FieldPos` fields you can determine the length and location of each field within a row.

## fitsread

Read data from FITS file

### Syntax

```
data = fitsread(filename)
data = fitsread(filename,extname)
data = fitsread(filename,extname,index)
data = fitsread(filename,Name,Value)
```

### Description

`data = fitsread(filename)` reads the primary data of the Flexible Image Transport System (FITS) file specified by the text string `filename`. The function replaces undefined data values with NaN and scales numeric data by the slope and intercept values, always returning double precision values.

`data = fitsread(filename,extname)` reads data from the FITS file extension specified by `extname`.

`data = fitsread(filename,extname,index)` reads data from the FITS file extension specified by `extname`. If there is more than one of the specified extensions in the file, `index` specifies the one to read.

`data = fitsread(filename,Name,Value)` reads data from the FITS file with additional options specified by one or more `Name, Value` pair arguments.

### Input Arguments

#### **filename**

Text string specifying the name of a FITS file.

#### **Default:**

**extname**

One of the following text strings specifying the name of a data array or extension in the FITS file. To determine the contents of a FITS, view the **Contents** field of the structure returned by `fitsinfo`.

**Data Arrays or Extensions**

| <b>Extname</b> | <b>Description</b>                                                                              |
|----------------|-------------------------------------------------------------------------------------------------|
| 'primary'      | Read data from the primary data array.                                                          |
| 'asciitable'   | Read data from the ASCII Table extension. The return value, <b>data</b> , is a 1-D cell array.  |
| 'binarytable'  | Read data from the Binary Table extension. The return value, <b>data</b> , is a 1-D cell array. |
| 'image'        | Read data from the Image extension.                                                             |
| 'unknown'      | Read data from the Unknown extension.                                                           |

**Default:**

**index**

Numeric value specifying which extension to read, if more than one exists in the file.

**Default:**

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'info'**

`info` structure returned by `fitsinfo` specifying the location of data to read.

---

**Note:** Using the `info` structure returned by `fitsinfo` to specify the location of data in a FITS file can significantly improve performance, especially when reading multiple images from the file.

---

**Default:****'PixelRegion'**

Cell array {`rows`, `cols`, ...} specifying the boundaries of a subimage region to read from the file. Each dimension (`rows`, `cols`) is a vector of 1-based indices given either as `START`, [`START STOP`], or [`START INCREMENT STOP`]. This parameter is valid only for primary or image extensions.

**Default:****'raw'**

Specifies that `fitsread` should not scale the data read from the file or replace undefined values with NaN. Data read from the file is the same class as it is stored in the file.

**Default:****'TableColumns'**

Vector of 1-based indices specifying the columns to read from the ASCII or Binary table extension. This vector should contain unique and valid indices into the table data specified in increasing order. This parameter is valid only for ASCII or Binary extensions.

**Default:****'TableRows'**

Vector of 1-based indices specifying the rows to read from the ASCII or Binary table extension. This vector should contain unique and valid indices into the table data specified in increasing order. This parameter is valid only for ASCII or Binary extensions.

**Default:**

## Output Arguments

**data**

Data returned from the FITS file.

## Examples

Read primary data from FITS file

```
data = fitsread('tst0012.fits');
```

| Name | Size    | Bytes | Class  | Attributes |
|------|---------|-------|--------|------------|
| data | 109x102 | 88944 | double |            |

Inspect available extensions, read 'image' extension using the `extname` option.

```
info = fitsinfo('tst0012.fits');
% List of contents, includes any extensions if present.
disp(info.Contents);
imageData = fitsread('tst0012.fits','image');
```

Subsample the fifth plane of 'image' extension by 2.

```
info = fitsinfo('tst0012.fits');
rowend = info.Image.Size(1);
colend = info.Image.Size(2);
primaryData = fitsread('tst0012.fits','image',...
 'Info', info,...
 'PixelRegion',[1 2 rowend], [1 2 colend], 5);
```

Read every other row from an ASCII table.

```
info = fitsinfo('tst0012.fits');
rowend = info.Asciitable.Rows;
tableData = fitsread('tst0012.fits','asciitable',...
 'Info',info,...
 'TableRows',[1:2:rowend]);
```

Read all data for the first, second and fifth columns of the Binary table.

```
info = fitsinfo('tst0012.fits');
rowend = info.BinaryTable.Rows;
tableData = fitsread('tst0012.fits','binarytable',...
 'Info',info,...
 'TableColumns',[1 2 5]);
```

## More About

### **extension**

A FITS file contains primary data and can optionally contain any number of optional components, called *extensions* in FITS terminology.

### **See Also**

# fitswrite

Write image to FITS file

## Syntax

```
fitswrite(imagedata,filename)
fitswrite(imagedata,filename,Name,Value)
```

## Description

`fitswrite(imagedata,filename)` writes `imagedata` to the FITS file specified by `filename`. If `filename` does not exist, `fitswrite` creates the file as a simple FITS file. If `filename` exists, `fitswrite` overwrites the file or appends the image to the end of the file, depending on the value of the `writemode` argument.

`fitswrite(imagedata,filename,Name,Value)` writes `imagedata` to the FITS file specified by `filename` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **imagedata**

Image array.

**Default:**

### **filename**

Text string specifying the name of an existing FITS file or the name you want to assign to a new FITS file.

**Default:**

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### 'WriteMode'

One of these strings:

- `overwrite`
- `append`

**Default:** `overwrite`

### 'Compression'

One of these strings:

- `none`
- `gzip`
- `rice`
- `hcompress`
- `plio`

**Default:** `none`

## Examples

Create a FITS file containing the red channel of an RGB image.

```
X = imread('ngc6543a.jpg');
R = X(:,:,1);
fitswrite(R,'myfile.fits');
fitsdisp('myfile.fits');
```

Create a FITS file with three images constructed from the channels of an RGB image.

```
X = imread('ngc6543a.jpg');
```

```
R = X(:,:,1); G = X(:,:,2); B = X(:,:,3);
fitswrite(R,'myfile.fits');
fitswrite(G,'myfile.fits','writemode','append');
fitswrite(B,'myfile.fits','writemode','append');
fitsdisp('myfile.fits');
```

## **fix**

Round toward zero

## **Syntax**

`Y = fix(X)`

## **Description**

`Y = fix(X)` rounds each element of `X` to the nearest integer toward zero. For positive `X`, the behavior of `fix` is the same as `floor`. For negative `X`, the behavior of `fix` is the same as `ceil`.

## **Examples**

### **Round Matrix Elements Toward Zero**

```
X = [-1.9 -3.4; 1.6 2.5; -4.5 4.5]
```

```
X =
```

```
-1.9000 -3.4000
 1.6000 2.5000
-4.5000 4.5000
```

```
Y = fix(X)
```

```
Y =
```

```
-1 -3
 1 2
-4 4
```

### Round Complex Numbers Toward Zero

```
X = [1.4+2.3i 3.1-2.2i -5.3+10.9i]
```

```
X =
```

```
1.4000 + 2.3000i 3.1000 - 2.2000i -5.3000 +10.9000i
```

```
Y = fix(X)
```

```
Y =
```

```
1.0000 + 2.0000i 3.0000 - 2.0000i -5.0000 +10.0000i
```

## Input Arguments

### **X** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. For complex **X**, **fix** treats the real and imaginary parts independently.

**fix** converts logical and **char** elements of **X** into **double** values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `logical`

Complex Number Support: Yes

# matlab.unittest.fixtures

Summary of classes in MATLAB Fixtures Interface

## Description

Fixtures ease creation of setup and teardown code. The `matlab.unittest.fixtures` package consists of the following customized MATLAB fixtures.

|                                                                |                                                |
|----------------------------------------------------------------|------------------------------------------------|
| <code>matlab.unittest.fixtures.CurrentFolderFixture</code>     | Fixture for changing current working folder    |
| <code>matlab.unittest.fixtures.Fixture</code>                  | Interface class for test fixtures              |
| <code>matlab.unittest.fixtures.PathFixture</code>              | Fixture for adding a folder to the MATLAB path |
| <code>matlab.unittest.fixtures.SuppresseWarningsFixture</code> | Fixture to suppress display of warnings        |
| <code>matlab.unittest.fixtures.TemporaryFolderFixture</code>   | Fixture for creating a temporary folder        |

## matlab.unittest.fixtures.CurrentFolderFixture class

**Package:** matlab.unittest.fixtures

Fixture for changing current working folder

### Description

The `CurrentFolderFixture` class provides a fixture for changing the current working folder. When the test framework sets up the fixture, it changes the working folder. When the test framework tears down the fixture, it restores the working folder to its previous state.

### Construction

`matlab.unittest.fixtures.CurrentFolderFixture(folder)` constructs a fixture for changing the current working folder to `folder`.

### Input Arguments

**folder** — Folder to make the current working folder  
string

Folder to make the current working folder, specified as a string. MATLAB throws an error if `folder` does not exist.

### Properties

**Folder**

Folder to make the current working folder, specified as a string in the `folder` input argument.

### Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Create Fixture to Change Current Working Folder

Create the following `changeFolderFixtureTest` class definition on your MATLAB path. This example assumes that the subfolder `helperFiles` exists in your working folder. Create the `changeToFolder` in your working folder if it does not exist.

The `test1` function includes a call to `pwd` to demonstrate the current path changed to the `helperFiles` folder.

```
classdef changeFolderFixtureTest < matlab.unittest.TestCase
 methods(Test)
 function test1(testCase)
 import matlab.unittest.fixtures.CurrentFolderFixture

 changeToFolder = 'helperFiles';
 testCase.applyFixture(CurrentFolderFixture ...
 (changeToFolder));
 pwd
 end
 end
end
```

At the command prompt, run the test. For the purposes of this example, call `pwd` before and after `run` to show the fixture was properly torn down and the path returned to the pre-test state.

```
currentFolderBeforeTest = pwd
run(changeFolderFixtureTest);
currentFolderAfterTest = pwd

currentFolderBeforeTest =

H:\Documents\doc_examples

Running changeFolderFixtureTest

ans =

H:\Documents\doc_examples\helperFiles

.
Done changeFolderFixtureTest
```

currentFolderAfterTest =  
H:\Documents\doc\_examples

# matlab.unittest.fixtures.Fixture class

**Package:** matlab.unittest.fixtures

Interface class for test fixtures

## Description

The `Fixture` interface class is the means by which test authors create custom fixtures. Fixtures configure the environment state required for tests.

Classes deriving from the `Fixture` interface must implement the `setup` method. This method executes the changes to the environment. A fixture should restore the environment to its initial state when it is torn down. To restore the environment, use the `addTeardown` method in the `setup` method or implement the fixture's `teardown` method.

Subclasses can set the `SetupDescription` and `TeardownDescription` properties in their constructors to provide descriptions for the actions performed by the `setup` and `teardown` methods. The testing framework can display these descriptions when setting up and tearing down the fixture.

A class that derives from `Fixture` must implement the `isCompatible` method if its constructor accepts any input arguments or is otherwise configurable. `Fixture` subclasses use this method to define a notion of interchangeability of fixtures. Two `matlab.unittest.fixtures` instances of the same class are considered to be interchangeable if the `isCompatible` method returns `true`. The `TestRunner` uses the result of `isCompatible` to determine whether two fixture instances of the same class correspond to the same shared test fixture state.

## Properties

### SetupDescription

Description of fixture setup actions, specified as a string. The `SetupDescription` property describes the actions the fixture performs when the testing framework invokes the fixture's `setup` method.

## TeardownDescription

Description of fixture teardown actions, specified as a string. The `TeardownDescription` property describes the actions the fixture performs when the testing framework invokes the fixture's `teardown` method.

## Methods

|                           |                                                                 |
|---------------------------|-----------------------------------------------------------------|
| <code>log</code>          | Record diagnostic information                                   |
| <code>setup</code>        | Set up fixture                                                  |

## Related Examples

- “Create Basic Custom Fixture”
- “Create Advanced Custom Fixture”

## log

**Class:** `matlab.unittest.fixtures.Fixture`

**Package:** `matlab.unittest.fixtures`

Record diagnostic information

## Syntax

`log(f,diagnostic)`

`log(f,v,diagnostic)`

## Description

`log(f,diagnostic)` logs the supplied diagnostic. The `log` method provides a means for tests to log information during fixture setup and teardown routines. The testing framework displays logged messages only if you configure it to do so by adding an appropriate plugin, such as the `matlab.unittest.plugins.LoggingPlugin`.

`log(f,v,diagnostic)` logs the diagnostic at the specified verbosity level, `v`.

## Input Arguments

**f** — Instance of fixture

`matlab.unittest.fixtures.Fixture` instance

Instance of fixture, specified as a `matlab.unittest.fixtures.Fixture`.

**diagnostic** — Diagnostic information to display upon a failure

string | function handle | `matlab.unittest.diagnostics.Diagnostic` instance

Diagnostic information to display upon a failure, specified as a string, function handle, or `matlab.unittest.diagnostics.Diagnostic` instance.

**v** — Verbosity level

2 (default) | 1 | 3 | 4 | `matlab.unittest.Verbosity` enumeration

Verbosity level, specified as an integer value between 1 and 4 or a `matlab.unittest.Verbosity` enumeration object. The default verbosity level for diagnostic messages is `Concise`. Integer values correspond to the members of the `matlab.unittest.Verbosity` enumeration.

| Numeric Representation | Corresponding Enumeration Member               | Verbosity Description              |
|------------------------|------------------------------------------------|------------------------------------|
| 1                      | <code>matlab.unittest.Verbosity.Terse</code>   | Minimal amount of information      |
| 2                      | <code>matlab.unittest.Verbosity.Concise</code> | Typical amount of information      |
| 3                      | <code>matlab.unittest.Verbosity.Detail</code>  | Supplemental amount of information |
| 4                      | <code>matlab.unittest.Verbosity.Verbose</code> | Surplus of information             |

## Examples

### Log Diagnostic Information

In a file, `FormatHexFixture.m`, in your current working folder, create the following fixture.

```
classdef FormatHexFixture < matlab.unittest.fixtures.Fixture
 properties (Access=private)
 OriginalFormat
 end
 methods
 function setup(fixture)
 fixture.OriginalFormat = get(0,'Format');
 fixture.log(['The previous format setting was ',...
 fixture.OriginalFormat])
 log(fixture,'Setting Format')
 set(0,'Format','hex')
 log(fixture,3,'Format Set')
 end
 function teardown(fixture)
 log(fixture,'Resetting Format')
 set(0,'Format',fixture.OriginalFormat)
 log(fixture,3,'Original Format Restored')
 end
 end
end
```

```
end
end
```

In a file, `SampleTest.m`, in your current working folder, create the following test class.

```
classdef SampleTest < matlab.unittest.TestCase
 methods (Test)
 function test1(testCase)
 testCase.applyFixture(FormatHexFixture);
 actStr = getColumnForDisplay([1;2;3], 'Small Integers');
 expStr = ['Small Integers '
 '3ff0000000000000'
 '4000000000000000'
 '4008000000000000'];
 testCase.verifyEqual(actStr, expStr)
 end
 end
end

function str = getColumnForDisplay(values, title)
 elements = cell(numel(values)+1, 1);
 elements{1} = title;
 for idx = 1:numel(values)
 elements{idx+1} = displayNumber(values(idx));
 end
 str = char(elements);
end

function str = displayNumber(n)
 str = strtrim(evalc('disp(n);'));
end
```

Run the test.

```
result = run(SampleTest);
```

```
Running SampleTest
.
Done SampleTest

```

None of the logged messages are displayed because the default test runner has a verbosity level of 1 (**Terse**) and the default log message is at level 2 (**Concise**).

Create a test runner to report the diagnostics at levels 1, 2, and 3 and rerun the test.

```
import matlab.unittest.TestRunner
import matlab.unittest.plugins.LoggingPlugin

ts = matlab.unittest.TestSuite.fromClass(?SampleTest);
runner = TestRunner.withNoPlugins;
p = LoggingPlugin.withVerbosity(3);
runner.addPlugin(p);

results = runner.run(ts);

[Concise] Diagnostic logged (2014-04-23T13:17:35): The previous format setting was sh
[Concise] Diagnostic logged (2014-04-23T13:17:35): Setting Format
[Detailed] Diagnostic logged (2014-04-23T13:17:35): Format Set
[Concise] Diagnostic logged (2014-04-23T13:17:35): Resetting Format
[Detailed] Diagnostic logged (2014-04-23T13:17:35): Original Format Restored
```

**Introduced in R2014b**

## setup

**Class:** `matlab.unittest.fixtures.Fixture`

**Package:** `matlab.unittest.fixtures`

Set up fixture

## Syntax

`setup(f)`

## Description

`setup(f)` sets up a fixture by performing the defined environment modifications. Classes deriving from the `Fixture` interface must implement the `setup` method. This method executes the changes to the environment. A fixture should restore the environment to its initial state when it is torn down. To restore the environment, use the `addTeardown` method in the `setup` method or implement the fixture's `teardown` method.

## Input Arguments

**f**

`matlab.unittest.fixtures.Fixture` instance

## See Also

`matlab.unittest.fixtures.Fixture` | `matlab.unittest.fixtures.Fixture.teardown` | `matlab.unittest.fixtures.Fixture.addTeardown`

## Related Examples

- “Create Basic Custom Fixture”
- “Create Advanced Custom Fixture”

# teardown

**Class:** `matlab.unittest.fixtures.Fixture`

**Package:** `matlab.unittest.fixtures`

Tear down fixture

## Syntax

`teardown(f)`

## Description

`teardown(f)` tears down a fixture by performing the defined actions to restore the environment to the initial state.

## Input Arguments

**f**

`matlab.unittest.fixtures.Fixture` instance

## Alternatives

Instead of defining a `teardown` method, you can define teardown actions within the `setup` method by implementing the `addTeardown` method.

## See Also

`matlab.unittest.fixtures.Fixture` | `matlab.unittest.fixtures.Fixture.addTeardown` | `matlab.unittest.fixtures.Fixture.setup`

## Related Examples

- “Create Advanced Custom Fixture”

# addTeardown

**Class:** matlab.unittest.fixtures.Fixture

**Package:** matlab.unittest.fixtures

Dynamically add teardown routine

## Syntax

```
addTeardown(f,tearDownFcn)
```

```
addTeardown(f,tearDownFcn,arg1,...,argN)
```

## Description

`addTeardown(f,tearDownFcn)` adds the `tearDownFcn` function handle that defines fixture teardown code to the `Fixture` instance. The teardown code is executed in the reverse order to which it is added. This is known as LIFO (or Last-In-First-Out).

`addTeardown(f,tearDownFcn,arg1,...,argN)` provides input arguments to the `tearDownFcn`.

## Input Arguments

**f**

matlab.unittest.fixtures.Fixture instance

**tearDownFcn**

Function that defines the fixture teardown code, specified as a function handle.

**arg1,...,argN**

Input arguments required by `tearDownFcn`, specified by any type. The argument type is specified by the `tearDownFcn` function argument list.

## Alternatives

Instead of defining teardown actions within the setup method by implementing the `addTeardown` method, you can implement the `teardown` method.

## See Also

`matlab.unittest.fixtures.Fixture` | `matlab.unittest.fixtures.Fixture.teardown` | `matlab.unittest.fixtures.Fixture.setup`

## Related Examples

# isCompatible

**Class:** matlab.unittest.fixtures.Fixture

**Package:** matlab.unittest.fixtures

Determine if two fixtures of the same class are interchangeable

## Syntax

```
TF = isCompatible(f1, f2)
```

## Description

`TF = isCompatible(f1, f2)` determines if two fixtures of the same class are interchangeable. The `isCompatible` method returns either logical 1 (`true`) or logical 0 (`false`).

A class that derives from `Fixture` must implement the `isCompatible` method if its constructor accepts any input arguments or is otherwise configurable. `Fixture` subclasses use this method to define a notion of interchangeability of fixtures. Two `matlab.unittest.fixtures` instances of the same class are considered to be interchangeable if the `isCompatible` method returns `true`. The `TestRunner` uses the result of `isCompatible` to determine whether two fixture instances of the same class correspond to the same shared test fixture state. The test framework always calls the `isCompatible` method with two fixture instances of the same class, so the fixture author does not need to implement code to handle the case where the second fixture is a different fixtures class.

## Input Arguments

**f**

matlab.unittest.fixtures.Fixture instance

## Attributes

Access

Protected

# matlab.unittest.fixtures.PathFixture class

**Package:** matlab.unittest.fixtures

Fixture for adding a folder to the MATLAB path

## Description

The `PathFixture` class provides a fixture for adding a folder to the MATLAB path. When the test framework sets up the fixture, it adds the specified folder to the path. When the test framework tears down the fixture, it restores the MATLAB path to its previous state.

## Construction

`matlab.unittest.fixtures.PathFixture(folder)` constructs a fixture for adding a folder to the MATLAB path. When the test framework sets up the fixture, it adds `folder` to the path. When it tears down the fixture, it restores the MATLAB path to its previous state.

## Input Arguments

**folder** — Folder to add to the MATLAB path  
string

Folder to add to the MATLAB path, specified as a string. MATLAB throws an error if `folder` does not exist.

## Properties

### Folder

Folder to add to the MATLAB path, specified as a string in the `folder` input argument.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Add Directory to MATLAB Path for Testing

Create the following `addPathFixtureTest` class definition on your MATLAB path. This example assumes that the subfolder, `helperFiles`, exists in your working folder. If it does not, define `addFolder` to be a directory that exists within your current folder.

```
classdef addPathFixtureTest < matlab.unittest.TestCase
 methods(Test)
 function test1(testCase)
 import matlab.unittest.fixtures.PathFixture

 addFolder = 'helperFiles';
 f = testCase.applyFixture(PathFixture(addFolder));
 disp(['Added to path: ' f.Folder])
 end
 end
end
```

At the command prompt, run the test.

```
run(addPathFixtureTest);
```

```
Running addPathFixtureTest
Added to path: H:\Documents\doc_examples\helperFiles
.
Done addPathFixtureTest
```

After the tests finish running, the framework removes the folder from the path.

### Add Directory to Path Using Shared Test Fixture

Create the following `sharedAddPathFixtureTest` class definition on your MATLAB path. This example assumes that the subfolder, `helperFiles`, exists in your working folder.

```
classdef (SharedTestFixtures={ ...
 matlab.unittest.fixtures.PathFixture('helperFiles')}) ...
 sharedAddPathFixtureTest < matlab.unittest.TestCase
 methods(Test)
 function test1(testCase)
 f = testCase.getSharedTestFixtures;
```

```
 disp(['Added to path: ' f.Folder])
 end
end
end
```

At the command prompt, run the test.

```
run(sharedAddPathFixtureTest);
```

```
Setting up PathFixture
Done setting up PathFixture: Added 'H:\Documents\doc_examples\helperFiles' to the path.
```

```
Running sharedAddPathFixtureTest
Added to path: H:\Documents\doc_examples\helperFiles
.
Done sharedAddPathFixtureTest
```

```
Tearing down PathFixture
Done tearing down PathFixture: Restored the path to its original state.
```

After the tests finish running, the framework removes the folder from the path.

# matlab.unittest.fixtures.SuppresseWarningsFixture class

**Package:** matlab.unittest.fixtures

Fixture to suppress display of warnings

## Description

The `SuppresseWarningsFixture` class provides a fixture to suppress the display of warnings. When set up, `SuppresseWarningsFixture` disables one ore more specified warnings. When torn down, the fixture restores the states of warnings to their previous values.

## Construction

`matlab.unittest.fixtures.SuppresseWarningsFixture(warnIDs)` constructs a fixture to suppress the display of one or more warnings.

## Input Arguments

**warnIDs** — Identifier for warnings disabled when the fixture is set up

string | cell array of strings

Warning identifiers for the warnings to be suppressed, specified as a string or cell array of strings.

## Properties

### Warnings

Warning identifiers describing warnings to suppress specified as a cell array of strings in the warnings input argument.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Create Fixture to Suppress Warnings

Suppress the warning that occurs when you try to remove a folder from the search path that is not on the search path.

Remove the folder, `folderthatisonpath` from your path, assuming it does not exist.

```
rmpath('folderthatisonpath')
```

```
Warning: "folderthatisonpath" not found in path.
> In rmpath at 58
```

A warning appears because `rmpath` cannot find the folder.

Suppress the warning during testing by creating the following `suppressWarningsTest` class definition on your MATLAB path.

```
classdef suppressWarningsTest < matlab.unittest.TestCase
 methods(Test)
 function test1(testCase)
 import matlab.unittest.fixtures.SuppresseWarningsFixture

 testCase.applyFixture(...
 SuppresseWarningsFixture('MATLAB:rmpath:DirNotFound'));

 % would otherwise cause warning
 rmpath('folderthatisonpath')
 end
 end
end
```

At the command prompt, run the test. For the purposes of this example, call `rmpath` before and after running the test to show the warning is not suppressed outside execution of the test.

```
rmpath('folderthatisnotonpath')
run(suppressWarningsTest);
rmpath('folderthatisnotonpath')
```

```
Warning: "folderthatisnotonpath" not found in path.
> In rmpath at 58
Running suppressWarningsTest
.
Done suppressWarningsTest
```

---

```
Warning: "folderthatisnotonpath" not found in path.
> In rmpath at 58
```

Note that the call to `rmpath` within `suppressWarningsTest` does not result in a warning.

## See Also

`matlab.unittest.TestCase.applyFixture` | `matlab.unittest.fixtures` | `warning`

# matlab.unittest.fixtures.TemporaryFolderFixture class

**Package:** matlab.unittest.fixtures

Fixture for creating a temporary folder

## Description

The `matlab.unittest.fixtures.TemporaryFolderFixture` provides a fixture to create a temporary folder. When the testing framework sets up the fixture, it creates the temporary folder. When it tears down the fixture, it deletes the folder and all its contents. Before it deletes the folder, the fixture clears from memory the definitions of any MATLAB-files, P-files, and MEX-files that are defined in the temporary folder.

## Construction

`matlab.unittest.fixtures.TemporaryFolderFixture` constructs a fixture for creating a temporary folder.

`matlab.unittest.fixtures.TemporaryFolderFixture(Name, Value)` constructs a fixture for creating a temporary folder with additional options specified by one or more `Name, Value` pair arguments.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'PreservingOnFailure'** — Preservation state of temporary folder and contents after test failure

false (default) | true

Indicator of whether the temporary folder and its contents are preserved in the event of a test failure, specified as `false` or `true` (logical 0 or 1). This property is `false` by default. You can specify it as `true` during fixture construction.

Data Types: `logical`

**'WithSuffix'** — Suffix for temporary folder name

string (default)

Suffix for temporary folder name, specified as a string.

## Properties

### Folder

Absolute path of the folder created by the fixture, specified as a string.

### PreserveOnFailure

Indicator of whether the temporary folder and its contents are preserved in the event of a test failure. This property is `logical(0)` or `logical(1)`. It is `logical(0)` by default but is set to `logical(1)` if the `'PreservingOnFailure'` input value is set to `true` during fixture construction.

### Suffix

Suffix used for temporary folder, specified as a string in the `Name, Value` pair argument, `'WithSuffix'`.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Examples

### Create Temporary Folder Fixture

Create the following `tempFolderFixtureTest` class definition on your MATLAB path.

```
classdef tempFolderFixtureTest < matlab.unittest.TestCase
 methods(Test)
```

```

function test1(testCase)
 import matlab.unittest.fixtures.TemporaryFolderFixture

 tempFolder = testCase.applyFixture(TemporaryFolderFixture);

 disp(['The temporary folder: ' tempFolder.Folder])
end
end
end

```

At the command prompt, run the test.

```

run(tempFolderFixtureTest);

Running tempFolderFixtureTest
The temporary folder: C:\Temp\tpfb1ae2cf_c9de_4de3_9557_00d52bfc1b2
.
Done tempFolderFixtureTest

```

The name of the temporary folder varies.

### Create Temporary Folder Fixture Persisting Through Test Failure

Create the following `anotherTempFolderFixtureTest` class definition on your MATLAB path. For the purposes of this example, the `test1` function contains an assertion that causes test failure.

```

classdef anotherTempFolderFixtureTest < matlab.unittest.TestCase
 methods(Test)
 function test1(testCase)
 import matlab.unittest.fixtures.TemporaryFolderFixture

 testCase.applyFixture(TemporaryFolderFixture(...
 'PreservingOnFailure',true,'WithSuffix','TestData'));

 % Failed assertion, perserved temporary folder
 testCase.assertEqual(1,2)
 end
 end
end
end

```

At the command prompt, run the test.

```
run(anotherTempFolderFixtureTest);
```

```

Running anotherTempFolderFixtureTest

=====
Assertion failed in anotherTempFolderFixtureTest/test1 and it did not run to completion.

Framework Diagnostic:

assertEqual failed.
--> The values are not equal using "isequaln".
--> Failure table:

```

```

**Introduced in R2013b**

# flintmax

Largest consecutive integer in floating-point format

## Syntax

```
f = flintmax
f = flintmax(precision)
```

## Description

`f = flintmax` returns the largest consecutive integer in IEEE® double precision, which is  $2^{53}$ . Above this value, double-precision format does not have integer precision, and not all integers can be represented exactly.

`f = flintmax(precision)` returns the largest consecutive integer in IEEE single or double precision. `flintmax` returns `single(2^24)` for single precision and  $2^{53}$  for double precision.

## Examples

### Double Precision

Return the largest consecutive integer in IEEE double precision.

```
format long e
f = flintmax

f =

 9.007199254740992e+15
```

This is  $2^{53}$ .

### Single Precision

Return the largest consecutive integer in IEEE single precision.

```
f = flintmax('single')
```

```
f =
```

```
16777216
```

This is `single(2^24)`.

Check the class of `f`.

```
class(f)
```

```
ans =
```

```
single
```

### Limit of Integer Single Precision

Above the value returned by `flintmax('single')`, not all integers can be represented exactly with single precision.

Return the largest consecutive integer in IEEE single precision.

```
f = flintmax('single')
```

```
f =
```

```
16777216
```

This is `single(2^24)`.

Add 1 to the value returned from `flintmax`.

```
f1 = f + 1
```

```
f1 =
```

```
16777216
```

`f1` is the same as `f`.

```
isequal(f,f1)
```

```
ans =
```

```
1
```

Add 2 to the value returned from `flintmax`.

```
f2 = f + 2
```

```
f2 =
```

```
 16777218
```

16777218 is represented exactly in single precision while 16777217 is not.

## Input Arguments

**precision** — Floating-point precision type

'double' (default) | 'single'

Floating-point precision type, specified as 'double' or 'single'.

Data Types: char

## Output Arguments

**f** — Largest consecutive integer in floating-point format

scalar constant

Largest consecutive integer in floating-point format returned as a scalar constant. This constant is  $2^{53}$  for double precision and `single(224)` for single precision.

## More About

- “Floating-Point Numbers”

## See Also

`eps` | `format` | `intmax` | `realmax`

Introduced in R2013a

## flip

Flip order of elements

### Syntax

```
B = flip(A)
B = flip(A,dim)
```

### Description

`B = flip(A)` returns array `B` the same size as `A`, but with the order of the elements reversed. The dimension that is reordered in `B` depends on the shape of `A`:

- If `A` is vector, then `flip(A)` reverses the order of the elements along the length of the vector.
- If `A` is a matrix, then `flip(A)` reverses the elements in each column.
- If `A` is an N-D array, then `flip(A)` operates on the first dimension of `A` in which the size value is not 1.

`B = flip(A, dim)` reverses the order of the elements in `A` along dimension `dim`. For example, if `A` is a matrix, then `flip(A,1)` reverses the elements in each column, and `flip(A,2)` reverses the elements in each row.

### Examples

#### Flip String of Characters

```
A = 'no word, no bond, row on.';
B = flip(A)
```

```
B =
```

```
.no wor ,dnob on ,drow on
```

#### Flip Column Vector

```
A = [1;2;3];
```

```
B = flip(A)
```

```
B =
```

```
 3
 2
 1
```

### Flip Matrix

Create a diagonal matrix, A.

```
A = diag([100 200 300])
```

```
A =
```

```
 100 0 0
 0 200 0
 0 0 300
```

Flip A without specifying the `dim` argument.

```
B = flip(A)
```

```
B =
```

```
 0 0 300
 0 200 0
 100 0 0
```

Now, flip A along the second dimension.

```
B = flip(A,2)
```

```
B =
```

```
 0 0 100
 0 200 0
 300 0 0
```

### Flip N-D Array

Create a 1-by-3-by-2 array.

```
A = zeros(1,3,2);
```

```
A(:,:,1) = [1 2 3];
A(:,:,2) = [4 5 6];
A
```

```
A(:,:,1) =
 1 2 3
```

```
A(:,:,2) =
 4 5 6
```

Flip A without specifying the `dim` argument.

```
B = flip(A)
```

```
B(:,:,1) =
 3 2 1
```

```
B(:,:,2) =
 6 5 4
```

Now, flip A along the third dimension.

```
B = flip(A,3)
```

```
B(:,:,1) =
 4 5 6
```

```
B(:,:,2) =
 1 2 3
```

## Flip Cell Array

Create a 3-by-2 cell array.

```
A = {'foo',1000; 999,true; 'aaa','bbb'}
```

```
A =
```

```
'foo' [1000]
[999] [1]
'aaa' 'bbb'
```

Flip **A** without specifying the `dim` argument.

```
B = flip(A)
```

```
B =
```

```
'aaa' 'bbb'
[999] [1]
'foo' [1000]
```

Now, flip **A** along the second dimension.

```
B = flip(A,2)
```

```
B =
```

```
[1000] 'foo'
[1] [999]
'bbb' 'aaa'
```

## Input Arguments

### **A** — Input array

vector | matrix | array | cell array | table

Input array, specified as a vector, matrix, array, cell array, or table.

Example: [1 2 3 4]

Example: ['abcde']

Example: [1 2; 3 4]

Example: {'abcde', [1 2 3]}

Example: table(rand(1,5),rand(1,5))

### **dim** — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

The following illustration shows the difference between `dim=1` and `dim=2` when `A` is a matrix.

|   |   |   |
|---|---|---|
| 1 | 2 | 3 |
| 4 | 5 | 6 |

A

|   |   |   |
|---|---|---|
| 4 | 5 | 6 |
| 1 | 2 | 3 |

`flip(A,1)`

|   |   |   |
|---|---|---|
| 3 | 2 | 1 |
| 6 | 5 | 4 |

`flip(A,2)`

Introduced in R2013b

# flipdim

(Not recommended) Flip array along specified dimension

## Compatibility

flipdim is not recommended. Use flip instead.

## Syntax

```
B = flipdim(A,dim)
```

## Description

B = flipdim(A,dim) returns A with dimension dim flipped.

When the value of dim is 1, the array is flipped row-wise down. When dim is 2, the array is flipped columnwise left to right. flipdim(A,1) is the same as flipud(A), and flipdim(A,2) is the same as fliplr(A).

## Examples

flipdim(A,1) where

A =

```
1 4
2 5
3 6
```

produces

```
3 6
2 5
```

1 4

**Introduced before R2006a**

# fliplr

Flip array left to right

## Syntax

```
B = fliplr(A)
```

## Description

`B = fliplr(A)` returns `A` with its columns flipped in the left-right direction (that is, about a vertical axis).

If `A` is a row vector, then `fliplr(A)` returns a vector of the same length with the order of its elements reversed. If `A` is a column vector, then `fliplr(A)` simply returns `A`. For multidimensional arrays, `fliplr` operates on the planes formed by the first and second dimensions.

## Examples

### Flip Row Vector

Create a row vector.

```
A = 1:10
```

```
A =
```

```
 1 2 3 4 5 6 7 8 9 10
```

Use `fliplr` to flip the elements of `A` in the horizontal direction.

```
B = fliplr(A)
```

```
B =
```

```
 10 9 8 7 6 5 4 3 2 1
```

The order of the elements in B is reversed compared to A.

## Flip Cell Array of Strings

Create a 3-by-3 cell array of strings.

```
A = {'a' 'b' 'c'; 'd' 'e' 'f'; 'g' 'h' 'i'}
```

A =

```
 'a' 'b' 'c'
 'd' 'e' 'f'
 'g' 'h' 'i'
```

Change the order of the columns in the horizontal direction by using `fliplr`.

```
B = fliplr(A)
```

B =

```
 'c' 'b' 'a'
 'f' 'e' 'd'
 'i' 'h' 'g'
```

The order of the first and third columns of A is switched in B, while the second column remains unchanged.

## Flip Multidimensional Array

Create a multidimensional array.

```
A = cat(3, [1 2; 3 4], [5 6; 7 8])
```

A(:,:,1) =

```
 1 2
 3 4
```

A(:,:,2) =

```
 5 6
 7 8
```

A is an array of size 2-by-2-by-2.

Flip the elements on each page of **A** in the horizontal direction.

```
B = fliplr(A)
```

```
B(:,:,1) =
```

```
 2 1
 4 3
```

```
B(:,:,2) =
```

```
 6 5
 8 7
```

The result, **B**, is the same size as **A**, but the horizontal order of the elements is flipped. The operation flips the elements on each page independently.

## Input Arguments

### **A** — Input array

vector | matrix | array | cell array | categorical array | table

Input array, specified as a vector, matrix, array, cell array, categorical array, or table of any data type.

Complex Number Support: Yes

## More About

### Tips

- `fliplr(A)` is equivalent to `flip(A,2)`.
- Use the `flipud` function to flip arrays in the vertical direction (that is, about a horizontal axis).
- The `flip` function can flip arrays in any direction.

### See Also

`flip` | `flipud` | `rot90`

**Introduced before R2006a**

# flipud

Flip array up to down

## Syntax

```
B = flipud(A)
```

## Description

`B = flipud(A)` returns `A` with its rows flipped in the up-down direction (that is, about a horizontal axis).

If `A` is a column vector, then `flipud(A)` returns a vector of the same length with the order of its elements reversed. If `A` is a row vector, then `flipud(A)` simply returns `A`. For multidimensional arrays, `flipud` operates on the planes formed by the first and second dimensions.

## Examples

### Flip Column Vector

Create a column vector.

```
A=(1:10)'
```

```
A =
```

```
1
2
3
4
5
6
7
8
9
10
```

Use `flipud` to flip the elements of `A` in the vertical direction.

```
B = flipud(A)
```

```
B =
```

```
10
9
8
7
6
5
4
3
2
1
```

The order of the elements in `B` is reversed compared to `A`.

## Flip Cell Array of Strings

Create a 3-by-3 cell array of strings.

```
A = {'a' 'b' 'c'; 'd' 'e' 'f'; 'g' 'h' 'i'}
```

```
A =
```

```
'a' 'b' 'c'
'd' 'e' 'f'
'g' 'h' 'i'
```

Change the order of the rows in the vertical direction by using `flipud`.

```
B = flipud(A)
```

```
B =
```

```
'g' 'h' 'i'
'd' 'e' 'f'
'a' 'b' 'c'
```

The order of the first and third rows of `A` is switched in `B`, while the second row remains unchanged.

## Flip Multidimensional Array

Create a multidimensional array.

```
A = cat(3, [1 2; 3 4], [5 6; 7 8])
```

```
A(:,:,1) =
```

```
 1 2
 3 4
```

```
A(:,:,2) =
```

```
 5 6
 7 8
```

A is an array of size 2-by-2-by-2.

Flip the elements on each page of A in the vertical direction.

```
B = flipud(A)
```

```
B(:,:,1) =
```

```
 3 4
 1 2
```

```
B(:,:,2) =
```

```
 7 8
 5 6
```

The result, B, is the same size as A, but the vertical order of the elements is flipped. The operation flips the elements on each page independently.

## Input Arguments

### A — Input array

vector | matrix | array | cell array | categorical array | table

Input array, specified as a vector, matrix, array, cell array, categorical array, or table of any data type.

Complex Number Support: Yes

## More About

### Tips

- `flipud(A)` is equivalent to `flip(A,1)`.
- Use the `fliplr` function to flip arrays in the horizontal direction (that is, about a vertical axis).
- The `flip` function can flip arrays in any direction.

# floor

Round toward negative infinity

## Syntax

`Y = floor(X)`

`Y = floor(t)`

`Y = floor(t,unit)`

## Description

`Y = floor(X)` rounds each element of `X` to the nearest integer less than or equal to that element.

`Y = floor(t)` rounds each element of the `duration` array `t` to the nearest number of seconds less than or equal to that element.

`Y = floor(t,unit)` rounds each element of `t` to the nearest number of the specified unit of time less than or equal to that element.

## Examples

### Round Matrix Elements Toward Negative Infinity

```
X = [-1.9 -0.2 3.4; 5.6 7.0 2.4+3.6i];
Y = floor(X)
```

Y =

```
-2.0000 + 0.0000i -1.0000 + 0.0000i 3.0000 + 0.0000i
5.0000 + 0.0000i 7.0000 + 0.0000i 2.0000 + 3.0000i
```

### Round Duration Values Toward Negative Infinity

Round each value in a `duration` array to the nearest number of seconds less than or equal to that value.

```
t = hours(8) + minutes(29:31) + seconds(1.23);
t.Format = 'hh:mm:ss.SS'
```

```
t =
```

```
08:29:01.23 08:30:01.23 08:31:01.23
```

```
Y1 = floor(t)
```

```
Y1 =
```

```
08:29:01.00 08:30:01.00 08:31:01.00
```

Round each value in `t` to the nearest number of hours less than or equal to that value.

```
Y2 = floor(t, 'hours')
```

```
Y2 =
```

```
08:00:00.00 08:00:00.00 08:00:00.00
```

## Input Arguments

### **X** — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. For complex `X`, `floor` treats the real and imaginary parts independently.

`floor` converts logical and `char` elements of `X` into `double` values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `logical`

Complex Number Support: Yes

### **t** — Input duration

duration array

Input duration, specified as a `duration` array.

**unit** – Unit of time

'seconds' (default) | 'minutes' | 'hours' | 'days' | 'years'

Unit of time, specified as 'seconds', 'minutes', 'hours', 'days', or 'years'. A duration of 1 year is equal to exactly 365.2425 24-hour days.

**Introduced before R2006a**

## flow

Simple function of three variables

### Syntax

```
v = flow
v = flow(n)
v = flow(x,y,z)
[x,y,z,v] = flow(...)
```

### Description

`flow`, a function of three variables, generates fluid-flow data that is useful for demonstrating `slice`, `interp3`, and other functions that visualize scalar volume data.

`v = flow` produces a 25-by-50-by-25 array.

`v = flow(n)` produces a n-by-2n-by-n array.

`v = flow(x,y,z)` evaluates the speed profile at the points `x`, `y`, and `z`.

`[x,y,z,v] = flow(...)` returns the coordinates as well as the volume data.

# fminbnd

Find minimum of single-variable function on fixed interval

## Syntax

```
x = fminbnd(fun,x1,x2)
x = fminbnd(fun,x1,x2,options)
x = fminbnd(problem)
[x,fval] = fminbnd(...)
[x,fval,exitflag] = fminbnd(...)
[x,fval,exitflag,output] = fminbnd(...)
```

## Description

fminbnd finds the minimum of a function of one variable within a fixed interval.

`x = fminbnd(fun,x1,x2)` returns a value `x` that is a local minimizer of the function that is described in `fun` in the interval `x1 < x < x2`. `fun` is a function handle; see “Function Handles”.

“Parameterizing Functions” in the MATLAB Mathematics documentation, explains how to pass additional parameters to your objective function `fun`.

`x = fminbnd(fun,x1,x2,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `fminbnd` uses these `options` structure fields:

|                    |                                                                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Display</b>     | Level of display. 'off' or 'none' displays no output; 'iter' displays output at each iteration; 'final' displays just the final output; 'notify' (default) displays output only if the function does not converge. See “Iterative Display” in MATLAB Mathematics for more information. |
| <b>FunValCheck</b> | Check whether objective function values are valid. 'on' displays an error when the objective function returns a value that is complex or NaN. The default 'off' displays no error.                                                                                                     |

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>MaxFunEvals</code> | Maximum number of function evaluations allowed, a positive integer. The default is 500.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>MaxIter</code>     | Maximum number of iterations allowed, a positive integer. The default is 500.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>OutputFcn</code>   | User-defined function that is called at each iteration. The default is none ( <code>[]</code> ). See “Output Functions” in MATLAB Mathematics for more information.                                                                                                                                                                                                                                                                                                                                                          |
| <code>PlotFcns</code>    | Plots various measures of progress while the algorithm executes, select from predefined plots or write your own. Pass a function handle or a cell array of function handles. The default is none ( <code>[]</code> ). <ul style="list-style-type: none"><li>• <code>@optimplotx</code> plots the current point</li><li>• <code>@optimplotfval</code> plots the function value</li><li>• <code>@optimplotfunccount</code> plots the function count</li></ul> See “Plot Functions” in MATLAB Mathematics for more information. |
| <code>TolX</code>        | Termination tolerance on <code>x</code> , a positive scalar. The default is <code>1e-4</code> .                                                                                                                                                                                                                                                                                                                                                                                                                              |

`x = fminbnd(problem)` finds the minimum for `problem`, where `problem` is a structure with the following fields:

|                        |                                                       |
|------------------------|-------------------------------------------------------|
| <code>objective</code> | Objective function                                    |
| <code>x1</code>        | Left endpoint                                         |
| <code>x2</code>        | Right endpoint                                        |
| <code>solver</code>    | <code>'fminbnd'</code>                                |
| <code>options</code>   | Options structure created using <code>optimset</code> |

`[x,fval] = fminbnd(...)` returns the value of the objective function computed in `fun` at `x`.

`[x,fval,exitflag] = fminbnd(...)` returns a value `exitflag` that describes the exit condition of `fminbnd`:

1                    `fminbnd` converged to a solution `x` based on `options.TolX`.

- 0 Maximum number of function evaluations or iterations was reached.
- 1 Algorithm was terminated by the output function.
- 2 Bounds are inconsistent ( $x_1 > x_2$ ).

`[x,fval,exitflag,output] = fminbnd(...)` returns a structure `output` that contains information about the optimization in the following fields:

|                         |                                                               |
|-------------------------|---------------------------------------------------------------|
| <code>algorithm</code>  | <code>'golden section search, parabolic interpolation'</code> |
| <code>funcCount</code>  | Number of function evaluations                                |
| <code>iterations</code> | Number of iterations                                          |
| <code>message</code>    | Exit message                                                  |

## Arguments

`fun` is the function to be minimized. `fun` accepts a scalar `x` and returns a scalar `f`, the objective function evaluated at `x`. The function `fun` can be specified as a function handle for a function file

```
x = fminbnd(@myfun,x1,x2);
```

where `myfun.m` is a function file such as

```
function f = myfun(x)
f = ... % Compute function value at x.
```

or as a function handle for an anonymous function:

```
x = fminbnd(@(x) sin(x*x),x1,x2);
```

Other arguments are described in the syntax descriptions above.

## Examples

`x = fminbnd(@cos,3,4)` computes  $\pi$  to a few decimal places and gives a message on termination.

```
[x,fval,exitflag] = ...
```

```
fminbnd(@cos,3,4,optimset('TolX',1e-12,'Display','off'))
```

computes  $\pi$  to about 12 decimal places, suppresses output, returns the function value at  $x$ , and returns an `exitflag` of 1.

The argument `fun` can also be a function handle for an anonymous function. For example, to find the minimum of the function  $f(x) = x^3 - 2x - 5$  on the interval  $(0, 2)$ , create an anonymous function `f`

```
f = @(x)x.^3-2*x-5;
```

Then invoke `fminbnd` with

```
x = fminbnd(f, 0, 2)
```

The result is

```
x =
 0.8165
```

The value of the function at the minimum is

```
y = f(x)

y =
 -6.0887
```

If `fun` is parameterized, you can use anonymous functions to capture the problem-dependent parameters. For example, suppose you want to minimize the objective function `myfun` defined by the following function file:

```
function f = myfun(x,a)
f = (x - a)^2;
```

Note that `myfun` has an extra parameter `a`, so you cannot pass it directly to `fminbnd`. To optimize for a specific value of `a`, such as `a = 1.5`.

**1** Assign the value to `a`.

```
a = 1.5; % define parameter first
```

**2** Call `fminbnd` with a one-argument anonymous function that captures that value of `a` and calls `myfun` with two arguments:

```
x = fminbnd(@(x) myfun(x,a),0,1)
```

## Limitations

The function to be minimized must be continuous. `fminbnd` may only give local solutions.

`fminbnd` often exhibits slow convergence when the solution is on a boundary of the interval.

`fminbnd` only handles real variables.

## More About

### Algorithms

`fminbnd` is a function file. Its algorithm is based on golden section search and parabolic interpolation. Unless the left endpoint  $x_1$  is very close to the right endpoint  $x_2$ , `fminbnd` never evaluates `fun` at the endpoints, so `fun` need only be defined for  $x$  in the interval  $x_1 < x < x_2$ .

If the minimum actually occurs at  $x_1$  or  $x_2$ , `fminbnd` returns a point `x` in the interior of the interval  $(x_1, x_2)$  that is close to the minimizer. In this case, the distance of `x` from the minimizer is no more than  $2 * (\text{To1X} + 3 * \text{abs}(x) * \text{sqrt}(\text{eps}))$ . See [1] or [2] for details about the algorithm.

# fminsearch

Find minimum of unconstrained multivariable function using derivative-free method

## Syntax

```
x = fminsearch(fun,x0)
x = fminsearch(fun,x0,options)
x = fminsearch(problem)
[x,fval] = fminsearch(...)
[x,fval,exitflag] = fminsearch(...)
[x,fval,exitflag,output] = fminsearch(...)
```

## Description

`fminsearch` finds the minimum of a scalar function of several variables, starting at an initial estimate. This is generally referred to as *unconstrained nonlinear optimization*.

`x = fminsearch(fun,x0)` starts at the point `x0` and returns a value `x` that is a local minimizer of the function described in `fun`. `x0` can be a scalar, vector, or matrix. `fun` is a function handle; see “Function Handles”.

“Parameterizing Functions” in the MATLAB Mathematics documentation explains how to pass additional parameters to your objective function `fun`. See also “Example 2” on page 1-2870 and “Example 3” on page 1-2871 below.

`x = fminsearch(fun,x0,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `fminsearch` uses these `options` structure fields:

### Display

Level of display. 'off' displays no output; 'iter' displays output at each iteration; 'final' displays just the final output; 'notify' (default) displays output only if the function does not converge. See “Iterative Display” in MATLAB Mathematics for more information.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FunValCheck | Check whether objective function values are valid. 'on' displays an error when the objective function returns a value that is <b>complex</b> or <b>NaN</b> . 'off' (the default) displays no error.                                                                                                                                                                                                                                                                     |
| MaxFunEvals | Maximum number of function evaluations allowed, a positive integer. The default is $200 \times \text{numberOfVariables}$ .                                                                                                                                                                                                                                                                                                                                              |
| MaxIter     | Maximum number of iterations allowed, a positive integer. The default value is $200 \times \text{numberOfVariables}$ .                                                                                                                                                                                                                                                                                                                                                  |
| OutputFcn   | Specify one or more user-defined functions that an optimization function calls at each iteration, either as a function handle or as a cell array of function handles. The default is none ([ ]). See "Output Functions" in MATLAB Mathematics for more information.                                                                                                                                                                                                     |
| PlotFcns    | Plots various measures of progress while the algorithm executes, select from predefined plots or write your own. Pass a function handle or a cell array of function handles. The default is none ([ ]). <ul style="list-style-type: none"><li>• @optimplotx plots the current point</li><li>• @optimplotfval plots the function value</li><li>• @optimplotfunccount plots the function count</li></ul> See "Plot Functions" in MATLAB Mathematics for more information. |
| TolFun      | Termination tolerance on the function value, a positive scalar. The default is $1e-4$ .                                                                                                                                                                                                                                                                                                                                                                                 |
| TolX        | Termination tolerance on x, a positive scalar. The default value is $1e-4$ .                                                                                                                                                                                                                                                                                                                                                                                            |

`x = fminsearch(problem)` finds the minimum for `problem`, where `problem` is a structure with the following fields:

|           |                                                       |
|-----------|-------------------------------------------------------|
| objective | Objective function                                    |
| x0        | Initial point for x                                   |
| solver    | 'fminsearch'                                          |
| options   | Options structure created using <code>optimset</code> |

`[x,fval] = fminsearch(...)` returns in `fval` the value of the objective function `fun` at the solution `x`.

`[x,fval,exitflag] = fminsearch(...)` returns a value `exitflag` that describes the exit condition of `fminsearch`:

|    |                                                                   |
|----|-------------------------------------------------------------------|
| 1  | <code>fminsearch</code> converged to a solution <code>x</code> .  |
| 0  | Maximum number of function evaluations or iterations was reached. |
| -1 | Algorithm was terminated by the output function.                  |

`[x,fval,exitflag,output] = fminsearch(...)` returns a structure `output` that contains information about the optimization in the following fields:

|                         |                                     |
|-------------------------|-------------------------------------|
| <code>algorithm</code>  | 'Nelder-Mead simplex direct search' |
| <code>funcCount</code>  | Number of function evaluations      |
| <code>iterations</code> | Number of iterations                |
| <code>message</code>    | Exit message                        |

## Arguments

`fun` is the function to be minimized. It accepts an input `x` and returns a scalar `f`, the objective function evaluated at `x`. The function `fun` can be specified as a function handle for a function file

```
x = fminsearch(@myfun, x0)
```

where `myfun` is a function file such as

```
function f = myfun(x)
f = ... % Compute function value at x
```

or as a function handle for an anonymous function, such as

```
x = fminsearch(@(x)sin(x^2), x0);
```

Other arguments are described in the syntax descriptions above.

## Examples

### Example 1

The Rosenbrock banana function is a classic test example for multidimensional minimization:

$$f(x) = 100(x_2 - x_1^2)^2 + (1 - x_1)^2.$$

The minimum is at  $(1, 1)$  and has the value 0. The traditional starting point is  $(-1.2, 1)$ . The anonymous function shown here defines the function and returns a function handle called `banana`:

```
banana = @(x) 100*(x(2) - x(1)^2)^2 + (1 - x(1))^2;
```

Pass the function handle to `fminsearch`:

```
[x, fval] = fminsearch(banana, [-1.2, 1])
```

This produces

```
x =
```

```
1.0000 1.0000
```

```
fval =
```

```
8.1777e-010
```

This indicates that the minimizer was found to at least four decimal places with a value near zero.

### Example 2

If `fun` is parameterized, you can use anonymous functions to capture the problem-dependent parameters. For example, suppose you want to minimize the objective function `myfun` defined by the following function file:

```
function f = myfun(x,a)
f = x(1)^2 + a*x(2)^2;
```

Note that `myfun` has an extra parameter `a`, so you cannot pass it directly to `fminsearch`. To optimize for a specific value of `a`, such as `a = 1.5`.

1 Assign the value to `a`.

```
a = 1.5; % define parameter first
```

2 Call `fminsearch` with a one-argument anonymous function that captures that value of `a` and calls `myfun` with two arguments:

```
x = fminsearch(@(x) myfun(x,a), [0,1])
```

### Example 3

You can modify the first example by adding a parameter  $a$  to the second term of the banana function:

$$f(x) = 100(x_2 - x_1^2)^2 + (a - x_1)^2.$$

This changes the location of the minimum to the point  $[a, a^2]$ . To minimize this function for a specific value of `a`, for example `a = sqrt(2)`, create a one-argument anonymous function that captures the value of `a`.

```
a = sqrt(2);
banana = @(x) 100*(x(2) - x(1)^2)^2 + (a - x(1))^2;
```

Then the statement

```
[x,fval] = fminsearch(banana, [-1.2, 1], ...
 optimset('TolX',1e-8));
```

seeks the minimum  $[\text{sqrt}(2), 2]$  to an accuracy higher than the default on `x`.

### Limitations

`fminsearch` can often handle discontinuity, particularly if it does not occur near the solution. `fminsearch` may only give local solutions.

`fminsearch` only minimizes over the real numbers, that is, `x` must only consist of real numbers and  $f(x)$  must only return real numbers. When `x` has complex variables, they must be split into real and imaginary parts.

## More About

### Algorithms

fminsearch uses the simplex search method of Lagarias et al. [1]. This is a direct search method that does not use numerical or analytic gradients.

If  $n$  is the length of  $x$ , a simplex in  $n$ -dimensional space is characterized by the  $n+1$  distinct vectors that are its vertices. In two-space, a simplex is a triangle; in three-space, it is a pyramid. At each step of the search, a new point in or near the current simplex is generated. The function value at the new point is compared with the function's values at the vertices of the simplex and, usually, one of the vertices is replaced by the new point, giving a new simplex. This step is repeated until the diameter of the simplex is less than the specified tolerance.

For more information, see “fminsearch Algorithm”.

**Introduced before R2006a**

# fopen

Open file, or obtain information about open files

## Syntax

```
fileID = fopen(filename)
fileID = fopen(filename,permission)
fileID = fopen(filename,permission,machinefmt,encodingIn)
[fileID,errmsg] = fopen(___)

fIDs = fopen('all')

filename = fopen(fileID)
[filename,permission,machinefmt,encodingOut] = fopen(fileID)
```

## Description

`fileID = fopen(filename)` opens the file, `filename`, for binary read access, and returns an integer file identifier equal to or greater than 3. MATLAB reserves file identifiers 0, 1, and 2 for standard input, standard output (the screen), and standard error, respectively.

If `fopen` cannot open the file, then `fileID` is -1.

`fileID = fopen(filename,permission)` opens the file with the type of access specified by `permission`.

`fileID = fopen(filename,permission,machinefmt,encodingIn)` additionally specifies the order for reading or writing bytes or bits in the file using the `machinefmt` argument. The optional `encodingIn` argument specifies the character encoding scheme associated with the file.

`[fileID,errmsg] = fopen( ___ )` additionally returns a system-dependent error message if `fopen` fails to open the file. Otherwise, `errmsg` is an empty string. You can use this syntax with any of the input arguments of the previous syntaxes.

`fIDs = fopen('all')` returns a row vector containing the file identifiers of all open files. The identifiers reserved for standard input, output, and error are not included. The number of elements in the vector is equal to the number of open files.

`filename = fopen(fileID)` returns the file name that a previous call to `fopen` used when it opened the file specified by `fileID`. The output `filename` is resolved to the full path. The `fopen` function does not read information from the file to determine the output value.

`[filename,permission,machinefmt,encodingOut] = fopen(fileID)` additionally returns the permission, machine format, and encoding that a previous call to `fopen` used when it opened the specified file. If the file was opened in binary mode, `permission` includes the letter 'b'. The `encodingOut` output is a standard encoding scheme name. `fopen` does not read information from the file to determine these output values. An invalid `fileID` returns empty strings for all output arguments.

## Examples

### Open File and Pass Identifier to File I/O Function

Open a file and pass the file identifier to the `fgetl` function to read data.

Open the file, `airfoil.m`, and obtain the file identifier.

```
fileID = fopen('airfoil.m');
```

Pass the `fileID` to the `fgetl` function to read one line from the file. Then, close the file.

```
tline = fgetl(fileID);
fclose(fileID)
```

### Request Name of File to Open

Create a prompt to request the name of a file to open. If `fopen` cannot open the file, display the relevant error message.

```
fileID = -1;
errmsg = '';
while fileID < 0
 disp(errmsg);
 filename = input('Open file: ', 's');
 [fileID,errmsg] = fopen(filename);
```

end

### Open File for Writing and Specify Access Type, Writing Order, Character Encoding

Open a file to write to a file using the Shift-JIS character encoding.

```
fileID = fopen('japanese_out.txt','w','n','Shift_JIS');
```

The 'w' input specifies write access, the 'n' input specifies native byte ordering, and 'Shift\_JIS' specifies the character encoding scheme.

### Get Information About Open Files

Suppose you previously opened a file using fopen.

```
fileID = fopen('airfoil.m');
```

Get the file identifiers of all open files.

```
fIDs = fopen('all')
```

```
fIDs =
```

```
3
```

Get the file name and character encoding for the open file. Use ~ in place of output arguments you want to omit.

```
[filename,~,~,encoding] = fopen(3)
```

```
filename =
```

```
matlabroot\toolbox\matlab\demos\airfoil.m
```

```
encoding =
```

```
windows-1252
```

The output shown here is representative. Your results might differ.

## Input Arguments

**filename** — Name of file to open

string

Name of the file to open, including the file extension, specified as a string. If the file is not in the current folder, `filename` must include a full or a relative path.

On UNIX systems, if `filename` begins with `'~/ '` or `'~username/ '`, the `fopen` function expands the path to the current or specified user's home directory, respectively.

- If you open a file with read access and the file is not in the current folder, then `fopen` searches along the MATLAB search path.
- If you open a file with write or append access and the file is not in the current folder, then `fopen` creates a file in the current directory.

Example: `'myFile.txt'`

Data Types: `char`

### **permission — File access type**

`'r'` (default) | `'w'` | `'a'` | `'r+'` | `'w+'` | `'a+'` | `'A'` | `'W'` | ...

File access type, specified as a string. You can open a file in binary mode or in text mode. On UNIX systems, both translation modes have the same effect. To open a file in binary mode, specify one of the following strings.

|                   |                                                                                      |
|-------------------|--------------------------------------------------------------------------------------|
| <code>'r'</code>  | Open file for reading.                                                               |
| <code>'w'</code>  | Open or create new file for writing. Discard existing contents, if any.              |
| <code>'a'</code>  | Open or create new file for writing. Append data to the end of the file.             |
| <code>'r+'</code> | Open file for reading and writing.                                                   |
| <code>'w+'</code> | Open or create new file for reading and writing. Discard existing contents, if any.  |
| <code>'a+'</code> | Open or create new file for reading and writing. Append data to the end of the file. |
| <code>'A'</code>  | Open file for appending without automatic flushing of the current output buffer.     |
| <code>'W'</code>  | Open file for writing without automatic flushing of the current output buffer.       |

To open files in text mode, attach the letter `'t'` to the `permission` argument, such as `'rt'` or `'wt+'`.

On Windows systems, in text mode:

- Read operations that encounter a carriage return followed by a newline character ('`\r\n`') remove the carriage return from the input.
- Write operations insert a carriage return before any newline character in the output.

Open or create a new file in text mode if you want to write to it in MATLAB and then open it in Microsoft Notepad, or any text editor that does not recognize '`\n`' as a newline sequence. When writing to the file, end each line with '`\r\n`'. For an example, see `fprintf`. Otherwise, open files in binary mode for better performance.

To read and write to the same file:

- Open the file with a value for `permission` that includes a plus sign, '+ '.
- Call `fseek` or `frewind` between read and write operations. For example, do not call `fread` followed by `fwrite`, or `fwrite` followed by `fread`, unless you call `fseek` or `frewind` between them.

### **machinefmt — Order for reading or writing bytes or bits**

'n' (default) | 'b' | 'l' | 's' | 'a' | ...

Order for reading or writing bytes or bits in the file, specified as one of the following strings.

|                      |                                               |
|----------------------|-----------------------------------------------|
| 'n' or 'native'      | Your system byte ordering (default)           |
| 'b' or 'ieee-be'     | Big-endian ordering                           |
| 'l' or 'ieee-le'     | Little-endian ordering                        |
| 's' or 'ieee-be.164' | Big-endian ordering, 64-bit long data type    |
| 'a' or 'ieee-le.164' | Little-endian ordering, 64-bit long data type |

By default, all currently supported platforms use little-endian ordering for new files. Existing binary files can use either big-endian or little-endian ordering.

### **encodingIn — Character encoding**

'UTF-8' | 'ISO-8859-1' | 'windows-1251' | 'windows-1252' | ...

Character encoding to use for subsequent read and write operations, including `fscanf`, `fprintf`, `fgetl`, `fgets`, `fread`, and `fwrite`, specified as a string. The string must contain a standard character encoding scheme name such as the following.

|        |              |               |
|--------|--------------|---------------|
| 'Big5' | 'ISO-8859-1' | 'windows-847' |
|--------|--------------|---------------|

|              |               |                |
|--------------|---------------|----------------|
| 'Big5-HKSCS' | 'ISO-8859-2'  | 'windows-949'  |
| 'CP949'      | 'ISO-8859-3'  | 'windows-1250' |
| 'EUC-KR'     | 'ISO-8859-4'  | 'windows-1251' |
| 'EUC-JP'     | 'ISO-8859-5'  | 'windows-1252' |
| 'EUC-TW'     | 'ISO-8859-6'  | 'windows-1253' |
| 'GB18030'    | 'ISO-8859-7'  | 'windows-1254' |
| 'GB2312'     | 'ISO-8859-8'  | 'windows-1255' |
| 'GBK'        | 'ISO-8859-9'  | 'windows-1256' |
| 'IBM866'     | 'ISO-8859-11' | 'windows-1257' |
| 'KOI8-R'     | 'ISO-8859-13' | 'windows-1258' |
| 'KOI8-U'     | 'ISO-8859-15' | 'US-ASCII'     |
|              | 'Macintosh'   | 'UTF-8'        |
|              | 'Shift_JIS'   |                |

The default encoding is system-dependent.

If you specify a value for encoding that is not in the list of supported values, MATLAB issues a warning. Specifying other encoding names sometimes (but not always) produces correct results.

Data Types: char

### **fileID** — File identifier of an open file

integer

File identifier of an open file, specified as an integer.

Data Types: double

## **More About**

### **Tips**

- In most cases, it is not necessary to open a file in text mode. MATLAB import functions, all UNIX applications, and Microsoft Word and WordPad recognize '\n' as a newline indicator.

**See Also**

fclose | feof | ferror | fprintf | fread | frewind | fscanf | fseek | ftell |  
fwrite

**Introduced before R2006a**

## fopen (serial)

Connect serial port object to device

### Syntax

```
fopen(obj)
```

### Description

fopen(obj) connects the serial port object, obj to the device.

### Examples

This example creates the serial port object **s**, connects **s** to the device using **fopen**, writes and reads text data, and then disconnects **s** from the device. This example works on a Windows platform.

```
s = serial('COM1');
fopen(s)
fprintf(s, '*IDN?')
idn = fscanf(s);
fclose(s)
```

### More About

#### Tips

Before you can perform a read or write operation, **obj** must be connected to the device with the **fopen** function. When **obj** is connected to the device:

- Data remaining in the input buffer or the output buffer is flushed.
- The **Status** property is set to **open**.
- The **BytesAvailable**, **ValuesReceived**, **ValuesSent**, and **BytesToOutput** properties are set to 0.

An error is returned if you attempt to perform a read or write operation while `obj` is not connected to the device. You can connect only one serial port object to a given device.

Some properties are read-only while the serial port object is open (connected), and must be configured before using `fopen`. Examples include `InputBufferSize` and `OutputBufferSize`. Refer to the property reference pages to determine which properties have this constraint.

The values for some properties are verified only after `obj` is connected to the device. If any of these properties are incorrectly configured, then an error is returned when `fopen` is issued and `obj` is not connected to the device. Properties of this type include `BaudRate`, and are associated with device settings.

**Introduced before R2006a**

## for

Execute statements specified number of times

### Syntax

```
for index = values
 statements
end
```

### Description

for *index* = *values*, *statements*, end executes a group of statements in a loop for a specified number of times. *values* has one of the following forms:

- *initVal:endVal* — Increment the *index* variable from *initVal* to *endVal* by 1, and repeat execution of *statements* until *index* is greater than *endVal*.
- *initVal:step:endVal* — Increment *index* by the value *step* on each iteration, or decrements *index* when *step* is negative.
- *valArray* — Create a column vector, *index*, from subsequent columns of array *valArray* on each iteration. For example, on the first iteration, *index* = *valArray*(:,1). The loop executes a maximum of *n* times, where *n* is the number of columns of *valArray*, given by `numel(valArray,1,:)`. The input *valArray* can be of any MATLAB data type, including a string, cell array, or struct.

### Examples

#### Assign Matrix Values

Create a Hilbert matrix of order 10.

```
s = 10;
H = zeros(s);

for c = 1:s
 for r = 1:s
```

```
 H(r,c) = 1/(r+c-1);
 end
end
```

### Decrement Values

Step by increments of -0.2, and display the values.

```
for v = 1.0:-0.2:0.0
 disp(v)
end
```

```
1
0.8000
0.6000
0.4000
0.2000
0
```

### Execute Statements for Specified Values

```
for v = [1 5 8 17]
 disp(v)
end
```

```
1
5
8
17
```

### Repeat Statements for Each Matrix Column

```
for I = eye(4,3)
 disp('Current unit vector:')
 disp(I)
```

`end`

Current unit vector:

```
1
0
0
0
```

Current unit vector:

```
0
1
0
0
```

Current unit vector:

```
0
0
1
0
```

## More About

### Tips

- To programmatically exit the loop, use a `break` statement. To skip the rest of the instructions in the loop and begin the next iteration, use a `continue` statement.
- Avoid assigning a value to the *index* variable within the loop statements. The `for` statement overrides any changes made to *index* within the loop.
- To iterate over the values of a single column vector, first transpose it to create a row vector.

Introduced before R2006a

# format

Set Command Window output display format

## Syntax

```
format style
format
```

## Description

`format style` changes the output display format in the Command Window to the format specified by `style`.

`format`, by itself, resets the output format to the default, which is the short, fixed-decimal format for floating-point notation and loose line spacing for all output lines.

Numeric formats affect only how numbers appear in Command Window output, not how MATLAB computes or saves them.

## Examples

### Long Format

Set the output format to the long fixed-decimal format and display the value of `pi`.

```
format long
pi
```

```
ans =
```

```
3.141592653589793
```

### Reset Format to Default

Set the output format to the short engineering format with compact line spacing, and then reset the format to the default.

```
format shortEng
format compact
x = rand(3)

x =
 814.7237e-003 913.3759e-003 278.4982e-003
 905.7919e-003 632.3592e-003 546.8815e-003
 126.9868e-003 97.5404e-003 957.5068e-003
```

```
format
x
```

```
x =

 0.8147 0.9134 0.2785
 0.9058 0.6324 0.5469
 0.1270 0.0975 0.9575
```

## Hexadecimal Format

Display the maximum values for integers and real numbers in hexadecimal format.

```
format hex
intmax('uint64')
```

```
ans =

 ffffffffffffffffff
```

```
realmax
```

```
ans =

 7fefffffffffffffff
```

## Short and Long Engineering Notation

Display the difference between shortEng and longEng formats.

Set the output format to shortEng.

```
format shortEng
```

Create a variable and increase its value by a multiple of 10 each time through a `for` loop.

```
A = 5.123456789;
for k = 1:10
 disp(A)
 A = A*10;
end
```

```
5.1235e+000
51.2346e+000
512.3457e+000
5.1235e+003
51.2346e+003
512.3457e+003
5.1235e+006
51.2346e+006
512.3457e+006
5.1235e+009
```

The values display with 4 digits after the decimal point and an exponent that is a multiple of 3.

Set the output format to the long engineering format and view the same values.

```
format longEng
```

```
A = 5.123456789;
for k = 1:10
 disp(A)
 A = A*10;
end
```

```
5.12345678900000e+000
```

```
51.2345678900000e+000
512.3456789000000e+000
5.123456789000000e+003
51.2345678900000e+003
512.3456789000000e+003
5.123456789000000e+006
51.2345678900000e+006
512.3456789000000e+006
5.123456789000000e+009
```

The values display with 15 digits and an exponent that is a multiple of 3.

## Large Data Range Format

Use the `shortG` format when some of the values in an array are short numbers and some have large exponents. The `shortG` format picks whichever of `short` or `shortE` has the most compact display.

Create a variable and display output in the `short` format, which is the default.

```
x = [25 56 255 9876899999];
format short
x

x =

 1.0e+09 *
 0.0000 0.0000 0.0000 9.8769
```

Set the format to `shortG` and redisplay the values.

```
format shortG
```

```
x
```

```
x =
```

```
 25 56 255 9.8769e+09
```

### Get Current Format

Get the current numeric format.

```
f = get(0, 'Format')
```

```
f =
```

```
shortG
```

Get the current line spacing, which can be set to `loose` or `compact`.

```
S = get(0, 'FormatSpacing')
```

```
S =
```

```
loose
```

- “Format Output in Command Window”

## Input Arguments

### **style** — Output display format

`short` (default) | `long` | `shortE` | `longE` | ...

Output display format, specified by a string from the tables below.

## Numeric Format

These styles control the output display format for numeric variables.

| Style                           | Result                                                             | Example |
|---------------------------------|--------------------------------------------------------------------|---------|
| <code>short</code><br>(default) | Short, fixed-decimal format with 4 digits after the decimal point. | 3.1416  |

| Style    | Result                                                                                                                                                     | Example               |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| long     | Long, fixed-decimal format with 15 digits after the decimal point for <b>double</b> values, and 7 digits after the decimal point for <b>single</b> values. | 3.141592653589793     |
| shortE   | Short scientific notation with 4 digits after the decimal point.                                                                                           | 3.1416e+00            |
| longE    | Long scientific notation with 15 digits after the decimal point for <b>double</b> values, and 7 digits after the decimal point for <b>single</b> values.   | 3.141592653589793e+00 |
| shortG   | <b>short</b> or <b>shortE</b> , whichever is more compact.                                                                                                 | 3.1416                |
| longG    | <b>long</b> or <b>longE</b> , whichever is more compact.                                                                                                   | 3.14159265358979      |
| shortEng | Short engineering notation (exponent is a multiple of 3) with 4 digits after the decimal point.                                                            | 3.1416e+000           |
| longEng  | Long engineering notation (exponent is a multiple of 3) with 15 significant digits.                                                                        | 3.14159265358979e+000 |
| +        | Positive/Negative format with +, -, and blank characters displayed for positive, negative, and zero elements.                                              | +                     |
| bank     | Currency format with 2 digits after the decimal point.                                                                                                     | 3.14                  |
| hex      | Hexadecimal representation of a binary double-precision number.                                                                                            | 400921fb54442d18      |
| rat      | Ratio of small integers.                                                                                                                                   | 355/113               |

## Line Spacing Format

| Style   | Result                                                              | Example                           |
|---------|---------------------------------------------------------------------|-----------------------------------|
| compact | Suppress excess blank lines to show more output on a single screen. | theta = pi/2<br>theta =<br>1.5708 |

| Style | Result                                        | Example                           |
|-------|-----------------------------------------------|-----------------------------------|
| loose | Add blank lines to make output more readable. | theta = pi/2<br>theta =<br>1.5708 |

## More About

### Tips

- The specified format applies only to the current MATLAB session. To maintain a format across sessions, choose a **Numeric format** or **Numeric display** option in the Command Window Preferences.
- You can insert a space between `short` or `long` and the presentation type, for instance, `format short E`.
- MATLAB always displays integer data types to the appropriate number of digits for the data type. For example, MATLAB uses 3 digits to display `int8` data types (for instance, `-128:127`). Setting the output format to `short` or `long` does not affect the display of integer-type variables.
- Integer-valued, floating-point numbers with a maximum of 9 digits do not display in scientific notation.
- If you are displaying a matrix with a wide range of values, consider using `shortG`. See “Large Data Range Format” on page 1-2888.

Introduced before R2006a

# fplot

Plot function between specified limits

## Syntax

```
fplot(fun,limits)
fplot(fun,limits,LineStyle)
fplot(fun,limits,tol)
fplot(fun,limits,tol,LineStyle)
fplot(fun,limits,n)
fplot(fun,lims,...)
fplot(axes_handle,...)
[X,Y] = fplot(fun,limits,...)
```

## Description

`fplot` plots a function between specified limits. The function must be of the form  $y = f(x)$ , where  $x$  is a vector whose range specifies the limits, and  $y$  is a vector the same size as  $x$  and contains the function's value at the points in  $x$  (see the first example). If the function returns more than one value for a given  $x$ , then  $y$  is a matrix whose columns contain each component of  $f(x)$  (see the second example).

`fplot(fun,limits)` plots `fun` between the limits specified by `limits`. `limits` is a vector specifying the  $x$ -axis limits (`[xmin xmax]`), or the  $x$ - and  $y$ -axes limits, (`[xmin xmax ymin ymax]`).

`fun` must be

- The name of a function
- A string with variable  $x$  that may be passed to `eval`, such as `'sin(x)'`, `'diric(x,10)'`, or `'[sin(x),cos(x)]'`
- A function handle

The function  $f(x)$  must return a row vector for each element of vector  $x$ . For example, if  $f(x)$  returns `[f1(x), f2(x), f3(x)]` then for input `[x1;x2]` the function should return the matrix

```
f1(x1) f2(x1) f3(x1)
f1(x2) f2(x2) f3(x2)
```

`fplot(fun,limits,LineStyle)` plots `fun` using the line specification `LineStyle`.

`fplot(fun,limits,tol)` plots `fun` using the relative error tolerance `tol` (the default is  $2e-3$ , i.e., 0.2 percent accuracy).

`fplot(fun,limits,tol,LineStyle)` plots `fun` using the relative error tolerance `tol` and a line specification that determines line type, marker symbol, and color. See `LineStyle` for more information.

`fplot(fun,limits,n)` with `n >= 1` plots the function with a minimum of `n+1` points. The default `n` is 1. The maximum step size is restricted to be  $(1/n) * (xmax - xmin)$ .

`fplot(fun,lims,...)` accepts combinations of the optional arguments `tol`, `n`, and `LineStyle`, in any order.

`fplot(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`[X,Y] = fplot(fun,limits,...)` returns the abscissas and ordinates for `fun` in `X` and `Y`. No plot is drawn on the screen; however, you can plot the function using `plot(X,Y)`.

## Examples

### MATLAB® Function Handle

Plot the hyperbolic tangent function from -2 to 2 using the MATLAB® function `tanh`.

```
fh = @tanh;
fplot(fh,[-2,2])
```

## Function Handle Created From Anonymous Function

Create a function handle from an anonymous function. Plot the function from 0.01 to 0.1.

```
sn = @(x) sin(1./x);
fplot(sn,[0.01,0.1])
```

## Function Handle Created From Custom Function File

Create a file named `myfun.m` that contains the following code.

```
function Y = myfun(x)
Y(:,1) = 200*sin(x(:))./x(:);
Y(:,2) = x(:).^2;
```

Then, create a function handle pointing to `myfun`.

```
fh = @myfun;
```

Plot the function from -20 to 20.

```
fplot(fh,[-20 20])
```

## More About

### Tips

`fplot` uses adaptive step control to produce a representative graph, concentrating its evaluation in regions where the function's rate of change is the greatest.

# fprintf

Write data to text file

## Syntax

```
fprintf(fileID,formatSpec,A1,...,An)
fprintf(formatSpec,A1,...,An)
```

```
nbytes = fprintf(___)
```

## Description

`fprintf(fileID,formatSpec,A1,...,An)` applies the `formatSpec` to all elements of arrays `A1,...,An` in column order, and writes the data to a text file. `fprintf` uses the encoding scheme specified in the call to `fopen`.

`fprintf(formatSpec,A1,...,An)` formats data and displays the results on the screen.

`nbytes = fprintf( ___ )` returns the number of bytes that `fprintf` writes, using any of the input arguments in the preceding syntaxes.

## Examples

### Print Literal Text and Array Values

Print multiple numeric values and literal text to the screen.

```
A1 = [9.9, 9900];
A2 = [8.8, 7.7 ; ...
 8800, 7700];
formatSpec = 'X is %4.2f meters or %8.3f mm\n';
fprintf(formatSpec,A1,A2)
```

```
X is 9.90 meters or 9900.000 mm
X is 8.80 meters or 8800.000 mm
X is 7.70 meters or 7700.000 mm
```

`%4.2f` in the `formatSpec` input specifies that the first value in each line of output is a floating-point number with a field width of four digits, including two digits after the decimal point. `%8.3f` in the `formatSpec` input specifies that the second value in each line of output is a floating-point number with a field width of eight digits, including three digits after the decimal point. `\n` is a control character that starts a new line.

## Print Double-Precision Values as Integers

Explicitly convert double-precision values with fractions to integer values.

```
a = [1.02 3.04 5.06];
fprintf('%d\n', round(a));
```

```
1
3
5
```

`%d` in the `formatSpec` input prints each value in the vector, `round(a)`, as a signed integer. `\n` is a control character that starts a new line.

## Write Tabular Data to Text File

Write a short table of the exponential function to a text file called `exp.txt`.

```
x = 0:.1:1;
A = [x; exp(x)];

fileID = fopen('exp.txt','w');
fprintf(fileID, '%6s %12s\n', 'x', 'exp(x)');
fprintf(fileID, '%6.2f %12.8f\n', A);
fclose(fileID);
```

The first call to `fprintf` prints header text `x` and `exp(x)`, and the second call prints the values from variable `A`.

If you plan to read the file with Microsoft Notepad, use `\r\n` instead of `\n` to move to a new line. For example, replace the calls to `fprintf` with the following:

```
fprintf(fileID, '%6s %12s\r\n', 'x', 'exp(x)');
fprintf(fileID, '%6.2f %12.8f\r\n', A);
```

MATLAB import functions, all UNIX applications, and Microsoft Word and WordPad recognize `\n` as a newline indicator.

View the contents of the file with the `type` command.

```
type exp.txt
```

```

 x exp(x)
0.00 1.00000000
0.10 1.10517092
0.20 1.22140276
0.30 1.34985881
0.40 1.49182470
0.50 1.64872127
0.60 1.82211880
0.70 2.01375271
0.80 2.22554093
0.90 2.45960311
1.00 2.71828183

```

### Get Number of Bytes Written to File

Write data to a file and return the number of bytes written.

Write an array of data, `A`, to a file and get the number of bytes that `fprintf` writes.

```

A = magic(4);

fileID = fopen('myfile.txt','w');
nbytes = fprintf(fileID,'%5d %5d %5d %5d\n',A)

```

```
nbytes =
```

```
96
```

The `fprintf` function wrote 96 bytes to the file.

Close the file.

```
fclose(fileID);
```

View the contents of the file with the `type` command.

```
type('myfile.txt')
```

```

16 5 9 4
 2 11 7 14

```

```
 3 10 6 15
 13 8 12 1
```

## Display Hyperlinks in Command Window

Display a hyperlink (The MathWorks Web Site) on the screen.

```
url = 'http://www.mathworks.com';
sitename = 'The MathWorks Web Site';

fprintf('%s\n',url,sitename)
```

`%s` in the `formatSpec` input indicates that the values of the variables `url` and `sitename`, should be printed as strings.

- “Export Cell Array to Text File”
- “Append To or Overwrite Existing Text Files”

## Input Arguments

### **fileID** — File identifier

1 (default) | 2 | scalar

File identifier, specified as one of the following:

- A file identifier obtained from `fopen`.
- 1 for standard output (the screen).
- 2 for standard error.

Data Types: `double`

### **formatSpec** — Format of output fields

string containing formatting operators

Format of the output fields, specified as a string containing formatting operators. `formatSpec` also can include ordinary text and special characters.

### Formatting Operator

A formatting operator starts with a percent sign, `%`, and ends with a conversion character. The conversion character is required. Optionally, you can specify identifier,

flags, field width, precision, and subtype operators between % and the conversion character. (Spaces are invalid between operators and are shown here only for readability).

### Conversion Character

This table shows conversion characters to format numeric and character data as strings.

| Value Type            | Conversion | Details                                                                                                                             |
|-----------------------|------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Integer, signed       | %d or %i   | Base 10                                                                                                                             |
| Integer, unsigned     | %u         | Base 10                                                                                                                             |
|                       | %o         | Base 8 (octal)                                                                                                                      |
|                       | %x         | Base 16 (hexadecimal), lowercase letters a–f                                                                                        |
|                       | %X         | Same as %x, uppercase letters A–F                                                                                                   |
| Floating-point number | %f         | Fixed-point notation (Use a precision operator to specify the number of digits after the decimal point.)                            |
|                       | %e         | Exponential notation, such as 3.141593e+00 (Use a precision operator to specify the number of digits after the decimal point.)      |
|                       | %E         | Same as %e, but uppercase, such as 3.141593E+00 (Use a precision operator to specify the number of digits after the decimal point.) |
|                       | %g         | The more compact of %e or %f, with no trailing zeros (Use a precision operator to specify the number of significant digits.)        |

| Value Type | Conversion | Details                                                                                                                      |
|------------|------------|------------------------------------------------------------------------------------------------------------------------------|
|            | %G         | The more compact of %E or %f, with no trailing zeros (Use a precision operator to specify the number of significant digits.) |
| Characters | %C         | Single character                                                                                                             |
|            | %S         | String of characters                                                                                                         |

**Optional Operators**

The optional identifier, flags, field width, precision, and subtype operators further define the format of the output string.

- **Identifier**

Order for processing values from the input list. Use the syntax *n*\$, where *n* represents the position of the value in the input list.

**Example:** '%3\$s %2\$s %1\$s %2\$s' prints inputs 'A', 'B', 'C' as follows: C B A B.

- **Flags**

|     |                                                                                                                                                                                                                                                                                                                   |
|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| '-' | Left-justify.<br><b>Example:</b> %-5.2f                                                                                                                                                                                                                                                                           |
| '+' | Always print a sign character (+ or -) for any value.<br><b>Example:</b> %+5.2f                                                                                                                                                                                                                                   |
| ' ' | Insert a space before the value.<br><b>Example:</b> % 5.2f                                                                                                                                                                                                                                                        |
| '0' | Pad to field width with zeros before the value.<br><b>Example:</b> %05.2f                                                                                                                                                                                                                                         |
| '#' | Modify selected numeric conversions: <ul style="list-style-type: none"> <li>• For %o, %x, or %X, print 0, 0x, or 0X prefix.</li> <li>• For %f, %e, or %E, print decimal point even when precision is 0.</li> <li>• For %g or %G, do not remove trailing zeros or decimal point.</li> </ul> <b>Example:</b> %#5.0f |

- **Field Width**

Minimum number of characters to print. The field width operator can be a number, or an asterisk (\*) to refer to an argument in the input list.

**Example:** The input list ('%12d', intmax) is equivalent to ('%\*d', 12, intmax).

The function pads to field width with spaces before the value unless otherwise specified by flags.

- **Precision**

|                   |                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------|
| For %f, %e, or %E | Number of digits to the right of the decimal point<br><b>Example:</b> '%.4f' prints pi as '3.1416' |
| For %g or %G      | Number of significant digits<br><b>Example:</b> '%.4g' prints pi as ' 3.142'                       |

The precision operator can be a number, or an asterisk (\*) to refer to an argument in the input list.

**Example:** The input list ('%6.4f', pi) is equivalent to ('%\*.4f', 6, 4, pi).

---

**Note:** If you specify a precision operator for floating-point values that exceeds the precision of the input numeric data type, the results might not match the input values to the precision you specified. The result depends on your computer hardware and operating system.

---

- **Subtypes**

Certain conversion characters can support a subtype. The subtype operator immediately precedes the conversion character. This table shows the conversions that can use subtypes.

| Input Value Type      | Subtype and Conversion Character | Output Value Type                                                                                          |
|-----------------------|----------------------------------|------------------------------------------------------------------------------------------------------------|
| Floating-point number | %bx or %bX<br>%bo<br>%bu         | Double-precision hexadecimal, octal, or decimal value<br><b>Example:</b> %bx prints pi as 400921fb54442d18 |

| Input Value Type | Subtype and Conversion Character       | Output Value Type                                                                                  |
|------------------|----------------------------------------|----------------------------------------------------------------------------------------------------|
|                  | %tx or %tX<br>%to<br>%tu               | Single-precision hexadecimal, octal, or decimal value<br><b>Example:</b> %tx prints pi as 40490fdb |
| Integer          | %ld or %li<br>%lo<br>%lu<br>%lX or %lX | 64-bit value                                                                                       |
| Integer          | %hd or %hi<br>%ho<br>%hu<br>%hX or %hX | 16-bit value                                                                                       |

**Text Before or After Formatting Operators**

formatSpec can also include additional text before a percent sign, %, or after a conversion character. The text can be:

- Ordinary text to print.
- Special characters that you cannot enter as ordinary text. This table shows how to represent special characters in formatSpec.

| Special Character     | Representation |
|-----------------------|----------------|
| Single quotation mark | ' '            |
| Percent character     | %%             |
| Backslash             | \\             |
| Alarm                 | \a             |
| Backspace             | \b             |
| Form feed             | \f             |
| New line              | \n             |
| Carriage return       | \r             |
| Horizontal tab        | \t             |

| Special Character                                       | Representation |
|---------------------------------------------------------|----------------|
| Vertical tab                                            | \v             |
| Character whose ASCII code is the hexadecimal number, N | \xN            |
| Character whose ASCII code is the octal number, N       | \N             |

### Notable Behavior of Conversions with Formatting Operators

- Numeric conversions print only the real component of complex numbers.
- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses %e.

**Example:** '%s' converts pi to 3.141593e+00.

- If you apply a string conversion (%s) to integer values, MATLAB converts values that correspond to valid character codes to characters.

**Example:** '%s' converts [65 66 67] to ABC.

### A1, ..., An — Numeric or character arrays

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

## Output Arguments

### nbytes — Number of bytes

scalar

Number of bytes that fprintf writes, returned as a scalar. When writing to a file, nbytes is determined by the character encoding. When printing data to the screen, nbytes is the number of characters displayed on the screen.

## More About

### Tips

- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

# fprintf (serial)

Write text to device

## Syntax

```
fprintf(obj, 'cmd')
fprintf(obj, 'format', 'cmd')
fprintf(obj, 'cmd', 'mode')
fprintf(obj, 'format', 'cmd', 'mode')
```

## Description

`fprintf(obj, 'cmd')` writes the string `cmd` to the device connected to the serial port object, `obj`. The default format is `%s\n`. The write operation is synchronous and blocks the command line until execution completes.

`fprintf(obj, 'format', 'cmd')` writes the string using the format specified by `format`.

`fprintf(obj, 'cmd', 'mode')` writes the string with command-line access specified by `mode`. `mode` specifies if `cmd` is written synchronously or asynchronously.

`fprintf(obj, 'format', 'cmd', 'mode')` writes the string using the specified format. `format` is a C language conversion specification.

You need an open connection from the serial port object, `obj`, to the device before performing read or write operations.

Use the `fopen` function to open a connection to the device. When `obj` has an open connection to the device, it has a `Status` property value of `open`. Refer to “Troubleshooting Common Errors” for `fprintf` errors.

To understand the use of `fprintf` refer to “Completing a Write Operation with `fprintf`” and “Rules for Writing the Terminator”.

## Input Arguments

### format

ANSI C conversion specification includes these conversion characters.

| Specifier | Description                                                              |
|-----------|--------------------------------------------------------------------------|
| %c        | Single character                                                         |
| %d or %i  | Decimal notation (signed)                                                |
| %e        | Exponential notation (using lowercase <b>e</b> as in <b>3.1415e+00</b> ) |
| %E        | Exponential notation (using uppercase <b>E</b> as in <b>3.1415E+00</b> ) |
| %f        | Fixed-point notation                                                     |
| %g        | The more compact of %e or %f. Insignificant zeros do not print.          |
| %G        | Same as %g, but using uppercase <b>E</b>                                 |
| %o        | Octal notation (unsigned)                                                |
| %s        | String of characters                                                     |
| %u        | Decimal notation (unsigned)                                              |
| %x        | Hexadecimal notation (using lowercase letters <b>a–f</b> )               |
| %X        | Hexadecimal notation (using uppercase letters <b>A–F</b> )               |

### mode

Specifies whether the string `cmd` is written synchronously or asynchronously:

- **sync**: `cmd` is written synchronously and the command line is blocked.
- **async**: `cmd` is written asynchronously and the command line is not blocked.

If *mode* is not specified, the write operation is synchronous.

If you specify asynchronous *mode*, when the write operation occurs:

- The `BytesToOutput` property value continuously updates to reflect the number of bytes in the output buffer.
- The MATLAB file callback function specified for the `OutputEmptyFcn` property is executed when the output buffer is empty.

Use the `TransferStatus` property to determine whether an asynchronous write operation is in progress.

For more information on synchronous and asynchronous write operations, see [Controlling Access to the MATLAB Command Line](#).

## Examples

Create a serial port object `s` and connect it to a Tektronix TDS 210 oscilloscope. Write the `RS232?` command with `fprintf`. `RS232?` instructs the scope to return serial port communications settings. This example works on a Windows platform.

```
s = serial('COM1');
fopen(s)
fprintf(s, 'RS232?')
```

Specify a format for the data that does not include the terminator, or configure the terminator to empty.

```
s = serial('COM1');
fopen(s)
fprintf(s, '%s', 'RS232?')
```

The default format for `fprintf` is `%s\n`. Therefore, the terminator specified by the `Terminator` property is automatically written. However, in some cases you might want to suppress writing the terminator.

Specify an array of formats and commands:

```
s = serial('COM1');
fopen(s)
fprintf(s, ['ch:%d scale:%d'], [1 20e-3], 'sync');
```

## frame2im

Return image data associated with movie frame

### Syntax

```
[X,Map] = frame2im(F)
```

### Description

`[X,Map] = frame2im(F)` returns the indexed image data `X` and associated colormap `Map` from the single movie frame `F`. The output `Map` is a three-column matrix where each row of the matrix is an RGB triplet value that defines one color of the colormap. If the frame contains true-color data, then `Map` is empty. The functions `getframe` and `im2frame` create a movie frame.

### Examples

#### Convert Movie Frame to Image Data

Create a surface plot.

```
surf(peaks)
```

Use `getframe` to capture the plot as a movie frame. Then, convert the captured movie frame to image data.

```
F = getframe;
[X,map] = frame2im(F);
```

## fread

Read data from binary file

### Syntax

```
A = fread(fileID)
A = fread(fileID,sizeA)
A = fread(fileID,sizeA,precision)
A = fread(fileID,sizeA,precision,skip)
A = fread(fileID,sizeA,precision,skip,machinefmt)
[A,count] = fread(___)
```

### Description

`A = fread(fileID)` reads data from an open binary file into column vector `A` and positions the file pointer at the end-of-file marker. The binary file is indicated by the file identifier, `fileID`. Use `fopen` to open the file and obtain the `fileID` value. When you finish reading, close the file by calling `fclose(fileID)`.

`A = fread(fileID,sizeA)` reads file data into an array, `A`, with dimensions, `sizeA`, and positions the file pointer after the last value read. `fread` populates `A` in column order.

`A = fread(fileID,sizeA,precision)` interprets values in the file according to the form and size described by `precision`. The `sizeA` argument is optional.

`A = fread(fileID,sizeA,precision,skip)` skips the number of bytes or bits specified by `skip` after reading each value in the file. The `sizeA` argument is optional.

`A = fread(fileID,sizeA,precision,skip,machinefmt)` additionally specifies the order for reading bytes or bits in the file. The `sizeA` and `skip` arguments are optional.

`[A,count] = fread( ___ )` additionally returns the number of characters that `fread` reads into `A`. You can use this syntax with any of the input arguments of the previous syntaxes.

## Examples

### Read Entire File of uint8 Data

Write a nine-element vector to a sample file, `nine.bin`.

```
fileID = fopen('nine.bin','w');
fwrite(fileID,[1:9]);
fclose(fileID);
```

Read all the data in the file into a vector of class `double`. By default, `fread` reads a file 1 byte at a time, interprets each byte as an 8-bit unsigned integer (`uint8`), and returns a `double` array.

```
fileID = fopen('nine.bin');
A = fread(fileID)
```

A =

```
1
2
3
4
5
6
7
8
9
```

`fread` returns a column vector, with one element for each byte in the file.

View information about A.

whos A

| Name | Size | Bytes | Class  | Attributes |
|------|------|-------|--------|------------|
| A    | 9x1  | 72    | double |            |

Close the file.

```
fclose(fileID);
```

### **Read Entire File of Double-Precision Data**

Create a file named `doubledata.bin`, containing nine double-precision values.

```
fileID = fopen('doubledata.bin','w');
fwrite(fileID,magic(3),'double');
fclose(fileID);
```

Open the file, `doubledata.bin`, and read the data in the file into a 3-by-3 array, `A`. Specify that the source data is class `double`.

```
fileID = fopen('doubledata.bin');
A = fread(fileID,[3 3],'double')
```

A =

```
 8 1 6
 3 5 7
 4 9 2
```

Close the file.

```
fclose(fileID);
```

### **Read Text File**

Read the contents of the file, `fread.m`. Transpose the output array, `A` so that it is a row vector.

```
fileID = fopen('fread.m');
A = fread(fileID,'*char');
fclose(fileID);
```

`fread` returns the character array, `A`.

### **Read Selected Rows or Columns from File**

Create a file named `nine.bin`, containing the values from 1 to 9. Write the data as `uint16` values.

```
fileID = fopen('nine.bin','w');
fwrite(fileID,[1:9],'uint16');
```

```
fclose(fileID);
```

Read the first six values into a 3-by-2 array. Specify that the source data is class `uint16`.

```
fileID = fopen('nine.bin');
A = fread(fileID,[3,2],'uint16')
```

A =

```
 1 4
 2 5
 3 6
```

`fread` returns an array populated column-wise with the first six values from the file, `nine.bin`.

Return to the beginning of the file.

```
frewind(fileID)
```

Read two values at a time, and skip one value before reading the next values. Specify this format using the `precision` value, `'2*uint16'`. Because the data is class `uint16`, one value is represented by 2 bytes. Therefore, specify the `skip` argument as 2.

```
precision = '2*uint16';
skip = 2;
B = fread(fileID,[2,3],precision,skip)
```

B =

```
 1 4 7
 2 5 8
```

`fread` returns a 2-by-3 array populated column-wise with the values from `nine.bin`.

Close the file.

```
fclose(fileID);
```

### Read Digits of Binary Coded Decimal Values

Create a file with binary coded decimal (BCD) values.

```
str = ['AB'; 'CD'; 'EF'; 'FA'];

fileID = fopen('bcd.bin','w');
fwrite(fileID,hex2dec(str),'ubit8');
fclose(fileID);
```

Read 1 byte at a time.

```
fileID = fopen('bcd.bin');
onebyte = fread(fileID,4,'*ubit8');
```

Display the BCD values.

```
disp(dec2hex(onebyte))
```

```
AB
CD
EF
FA
```

Return to the beginning of the file using `frewind`. If you read 4 bits at a time on a little-endian system, your results appear in the wrong order.

```
frewind(fileID)

err = fread(fileID,8,'*ubit4');
disp(dec2hex(err))
```

```
B
A
D
C
F
E
A
F
```

Return to the beginning of the file using `frewind`. Read the data 4 bits at a time as before, but specify a big-endian ordering to display the correct results.

```
frewind(fileID)

correct = fread(fileID,8,'*ubit4','ieee-be');
disp(dec2hex(correct))
```

```
A
B
C
D
E
F
F
A
```

Close the file.

```
fclose(fileID);
```

## Input Arguments

### **fileID** — File identifier

integer

File identifier of an open binary file, specified as an integer. Before reading a file with `fread`, you must use `fopen` to open the file and obtain the `fileID`.

Data Types: double

### **sizeA** — Dimensions of output array

Inf (default) | integer | two-element row vector

Dimensions of the output array, `A`, specified as `Inf`, an integer, or a two-element row vector.

| Form of the <code>sizeA</code> Input | Dimensions of the output array, <code>A</code>                                                                                         |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>Inf</code>                     | Column vector, with each element containing a value in the file.                                                                       |
| <code>n</code>                       | Column vector with <code>n</code> elements.                                                                                            |
| <code>[m, n]</code>                  | <code>m</code> -by- <code>n</code> matrix, filled in column order. <code>n</code> can be <code>Inf</code> , but <code>m</code> cannot. |

### **precision** — Class and size of values to read

'uint8=>double' (default) | string

Class and size in bits of the values to read, specified as a string in one of the following forms. Optionally the input specifies the class of the output matrix, A.

| Form of the precision Input                      | Description                                                                                                                                                                                                                                                     |
|--------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>source</i>                                    | Input values are of the class specified by <i>source</i> . Output matrix A is class double. Example: 'int16'                                                                                                                                                    |
| <i>source=&gt;output</i>                         | Input values are of the class specified by <i>source</i> . The class of the output matrix, A, is specified by <i>output</i> . Example: 'int8=>char'                                                                                                             |
| * <i>source</i>                                  | The input values and the output matrix, A, are of the class specified by <i>source</i> . For <i>bitn</i> or <i>ubitn</i> precisions, the output has the smallest class that can contain the input. Example: '*ubit18'<br>This is equivalent to 'ubit18=>uint32' |
| <i>N*source</i> or<br><i>N*source=&gt;output</i> | Read <i>N</i> values before skipping the number of bytes specified by the <i>skip</i> argument. Example: '4*int8'                                                                                                                                               |

The following table shows possible values for *source* and *output*.

| Value Type         | Precision     | Bits (Bytes)       |
|--------------------|---------------|--------------------|
| Integers, unsigned | uint          | 32 (4)             |
|                    | uint8         | 8 (1)              |
|                    | uint16        | 16 (2)             |
|                    | uint32        | 32 (4)             |
|                    | uint64        | 64 (8)             |
|                    | uchar         | 8 (1)              |
|                    | unsigned char | 8 (1)              |
|                    | ushort        | 16 (2)             |
|                    | ulong         | 32 (4)             |
|                    | ubitn         | $1 \leq n \leq 64$ |

| Value Type             | Precision    | Bits (Bytes)                                                                                    |
|------------------------|--------------|-------------------------------------------------------------------------------------------------|
| Integers, signed       | int          | 32 (4)                                                                                          |
|                        | int8         | 8 (1)                                                                                           |
|                        | int16        | 16 (2)                                                                                          |
|                        | int32        | 32 (4)                                                                                          |
|                        | int64        | 64 (8)                                                                                          |
|                        | integer*1    | 8 (1)                                                                                           |
|                        | integer*2    | 16 (2)                                                                                          |
|                        | integer*4    | 32 (4)                                                                                          |
|                        | integer*8    | 64 (8)                                                                                          |
|                        | schar        | 8 (1)                                                                                           |
|                        | signed char  | 8 (1)                                                                                           |
|                        | short        | 16 (2)                                                                                          |
|                        | long         | 32 (4)                                                                                          |
|                        | bit <i>n</i> | $1 \leq n \leq 64$                                                                              |
| Floating-point numbers | single       | 32 (4)                                                                                          |
|                        | double       | 64 (8)                                                                                          |
|                        | float        | 32 (4)                                                                                          |
|                        | float32      | 32 (4)                                                                                          |
|                        | float64      | 64 (8)                                                                                          |
|                        | real*4       | 32 (4)                                                                                          |
|                        | real*8       | 64 (8)                                                                                          |
|                        | Characters   | char*1                                                                                          |
| char                   |              | Depends on the encoding scheme associated with the file. Set encoding with <code>fopen</code> . |

For most values of *source*, if `fread` reaches the end of the file before reading a complete value, it does not return a result for the final value. However, if *source* is `bitn` or `ubitn`, then `fread` returns a partial result for the final value.

---

**Note:** To preserve NaN and Inf values in MATLAB, read and write data of class `double` or `single`.

---

**skip** — Number of bytes to skip

0 (default) | scalar

Number of bytes to skip after reading each value, specified as a scalar. If you specify a precision of `bitn` or `ubitn`, specify `skip` in bits.

Use the `skip` argument to read data from noncontiguous fields in fixed-length records.

**machinefmt** — Order for reading bytes

'n' (default) | 'b' | 'l' | 's' | 'a' | ...

Order for reading bytes in the file, specified as one of the strings in the table that follows. For `bitn` and `ubitn` precisions, `machinefmt` specifies the order for reading bits within a byte, but the order for reading bytes remains your system byte ordering.

|                      |                                               |
|----------------------|-----------------------------------------------|
| 'n' or 'native'      | Your system byte ordering (default)           |
| 'b' or 'ieee-be'     | Big-endian ordering                           |
| 'l' or 'ieee-le'     | Little-endian ordering                        |
| 's' or 'ieee-be.164' | Big-endian ordering, 64-bit long data type    |
| 'a' or 'ieee-le.164' | Little-endian ordering, 64-bit long data type |

By default, all currently supported platforms use little-endian ordering for new files. Existing binary files can use either big-endian or little-endian ordering.

## Output Arguments

**A** — File data

column vector | matrix

File data, returned as a column vector. If you specified the `sizeA` argument, then `A` is a matrix of the specified size. Data in `A` is class `double` unless you specify a different class in the `precision` argument.

**count** — Number of characters read

scalar

Number of characters read, returned as a scalar value.

## fread (serial)

Read binary data from device

### Syntax

```
A = fread(obj)
A = fread(obj,size,'precision')
[A,count] = fread(...)
[A,count,msg] = fread(...)
```

### Description

`A = fread(obj)` and `A = fread(obj,size)` read binary data from the device connected to the serial port object, `obj`, and returns the data to `A`. The maximum number of values to read is specified by `size`. If `size` is not specified, the maximum number of values to read is determined by the object's `InputBufferSize` property. Valid options for `size` are:

|                    |                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>     | Read at most <code>n</code> values into a column vector.                                                                     |
| <code>[m,n]</code> | Read at most <code>m</code> -by- <code>n</code> values filling an <code>m</code> -by- <code>n</code> matrix in column order. |

`size` cannot be `inf`, and an error is returned if the specified number of values cannot be stored in the input buffer. You specify the size, in bytes, of the input buffer with the `InputBufferSize` property. A value is defined as a byte multiplied by the *precision* (see below).

`A = fread(obj,size,'precision')` reads binary data with precision specified by *precision*.

*precision* controls the number of bits read for each value and the interpretation of those bits as integer, floating-point, or character values. If *precision* is not specified, `uchar` (an 8-bit unsigned character) is used. By default, numeric values are returned in double-precision arrays. The supported values for *precision* are listed below in Tips.

`[A,count] = fread(...)` returns the number of values read to `count`.

[A,count,msg] = fread(...) returns a warning message to msg if the read operation was unsuccessful.

## More About

### Tips

Before you can read data from the device, it must be connected to obj with the fopen function. A connected serial port object has a Status property value of open. An error is returned if you attempt to perform a read operation while obj is not connected to the device.

If msg is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The ValuesReceived property value is increased by the number of values read, each time fread is issued.

### Rules for Completing a Binary Read Operation

A read operation with fread blocks access to the MATLAB command line until:

- The specified number of values are read.
- The time specified by the Timeout property passes.

---

**Note** The Terminator property is not used for binary read operations.

---

### Supported Precisions

The supported values for *precision* are listed below.

| Data Type | Precision | Interpretation                     |
|-----------|-----------|------------------------------------|
| Character | uchar     | 8-bit unsigned character           |
|           | schar     | 8-bit signed character             |
|           | char      | 8-bit signed or unsigned character |
| Integer   | int8      | 8-bit integer                      |

| <b>Data Type</b> | <b>Precision</b> | <b>Interpretation</b>          |
|------------------|------------------|--------------------------------|
|                  | int16            | 16-bit integer                 |
|                  | int32            | 32-bit integer                 |
|                  | uint8            | 8-bit unsigned integer         |
|                  | uint16           | 16-bit unsigned integer        |
|                  | uint32           | 32-bit unsigned integer        |
|                  | short            | 16-bit integer                 |
|                  | int              | 32-bit integer                 |
|                  | long             | 32- or 64-bit integer          |
|                  | ushort           | 16-bit unsigned integer        |
|                  | uint             | 32-bit unsigned integer        |
|                  | ulong            | 32- or 64-bit unsigned integer |
| Floating-point   | single           | 32-bit floating point          |
|                  | float32          | 32-bit floating point          |
|                  | float            | 32-bit floating point          |
|                  | double           | 64-bit floating point          |
|                  | float64          | 64-bit floating point          |

# freeBoundary

**Class:** TriRep

(Not recommended) Facets referenced by only one simplex

---

**Note:** `freeBoundary(TriRep)` is not recommended. Use `freeBoundary(triangulation)` instead.

`TriRep` is not recommended. Use `triangulation` instead.

---

## Syntax

`FF = freeBoundary(TR)`  
`[FF XF] = freeBoundary(TR)`

## Description

`FF = freeBoundary(TR)` returns a matrix `FF` that represents the free boundary facets of the triangulation. A facet is on the free boundary if it is referenced by only one simplex (triangle/tetrahedron, etc). `FF` is of size `m`-by-`n`, where `m` is the number of boundary facets and `n` is the number of vertices per facet. The vertices of the facets index into the array of points representing the vertex coordinates `TR.X`. The array `FF` could be empty as in the case of a triangular mesh representing the surface of a sphere.

`[FF XF] = freeBoundary(TR)` returns a matrix of free boundary facets

## Input Arguments

`TR`            Triangulation representation.

## Output Arguments

`FF`            `FF` that has vertices defined in terms of a compact array of coordinates `XF`.

**XF**            XF is of size `m-by-ndim` where `m` is the number of free facets, and `ndim` is the dimension of the space where the triangulation resides

## Definitions

A *simplex* is a triangle/tetrahedron or higher-dimensional equivalent. A *facet* is an edge of a triangle or a face of a tetrahedron.

## Examples

### Example 1

Use `TriRep` to compute the boundary triangulation of an imported triangulation.

Load a 3-D triangulation:

```
load tetmesh;
trep = TriRep(tet, X);
```

Compute the boundary triangulation:

```
[tri xf] = freeBoundary(trep);
```

Plot the boundary triangulation:

```
trisurf(tri, xf(:,1),xf(:,2),xf(:,3), ...
 'FaceColor','cyan', 'FaceAlpha', 0.8);
```

## Example 2

Perform a direct query of a 2-D triangulation created with `DelaunayTri`.

Plot the mesh:

```
x = rand(20,1);
y = rand(20,1);
dt = DelaunayTri(x,y);
fe = freeBoundary(dt)';
triplot(dt);
hold on;
```

Display the free boundary edges in red:

```
plot(x(fe), y(fe), '-r', 'LineWidth',2) ;
hold off;
```

In this instance the free edges correspond to the convex hull of  $(x, y)$ .

# freqspace

Frequency spacing for frequency response

## Syntax

```
[f1,f2] = freqspace(n)
[f1,f2] = freqspace([m n])
[x1,y1] = freqspace(...,'meshgrid')
f = freqspace(N)
f = freqspace(N,'whole')
```

## Description

`freqspace` returns the implied frequency range for equally spaced frequency responses. `freqspace` is useful when creating desired frequency responses for various one- and two-dimensional applications.

`[f1,f2] = freqspace(n)` returns the two-dimensional frequency vectors `f1` and `f2` for an `n`-by-`n` matrix.

For `n` odd, both `f1` and `f2` are `[-n+1:2:n-1]/n`.

For `n` even, both `f1` and `f2` are `[-n:2:n-2]/n`.

`[f1,f2] = freqspace([m n])` returns the two-dimensional frequency vectors `f1` and `f2` for an `m`-by-`n` matrix.

`[x1,y1] = freqspace(...,'meshgrid')` is equivalent to

```
[f1,f2] = freqspace(...);
[x1,y1] = meshgrid(f1,f2);
```

`f = freqspace(N)` returns the one-dimensional frequency vector `f` assuming `N` evenly spaced points around the unit circle. For `N` even or odd, `f` is `(0:2/N:1)`. For `N` even, `freqspace` therefore returns  $(N+2)/2$  points. For `N` odd, it returns  $(N+1)/2$  points.

`f = freqspace(N,'whole')` returns `N` evenly spaced points around the whole unit circle. In this case, `f` is `0:2/N:2*(N-1)/N`.

# frewind

Move file position indicator to beginning of open file

## Syntax

```
frewind(fileID)
```

## Description

`frewind(fileID)` sets the file position indicator to the beginning of a file. *fileID* is an integer file identifier obtained from `fopen`.

If the file is on a tape device and the rewind operation fails, `frewind` does not return an error message.

## Alternatives

`frewind(fileID)` is equivalent to:

```
fseek(fileID, 0, 'bof');
```

# fscanf

Read data from text file

## Syntax

```
A = fscanf(fileID,formatSpec)
A = fscanf(fileID,formatSpec,sizeA)
[A,count] = fscanf(___)
```

## Description

`A = fscanf(fileID,formatSpec)` reads data from an open text file into column vector `A` and interprets values in the file according to the format specified by `formatSpec`. The `fscanf` function reapplies the format throughout the entire file and positions the file pointer at the end-of-file marker. If `fscanf` cannot match `formatSpec` to the data, it reads only the portion that matches and stops processing.

The text file is indicated by the file identifier, `fileID`. Use `fopen` to open the file, specify the character encoding, and obtain the `fileID` value. When you finish reading, close the file by calling `fclose(fileID)`.

`A = fscanf(fileID,formatSpec,sizeA)` reads file data into an array, `A`, with dimensions, `sizeA`, and positions the file pointer after the last value read. `fscanf` populates `A` in column order.

`[A,count] = fscanf( ___ )` additionally returns the number of fields that `fscanf` reads into `A`. For numeric data, this is the number of values read. You can use this syntax with any of the input arguments of the previous syntaxes.

## Examples

### Read File Contents into Column Vector

Create a sample text file that contains floating-point numbers.

```
x = 100*rand(8,1);
```

```
fileID = fopen('nums1.txt','w');
fprintf(fileID,'%4.4f\n',x);
fclose(fileID);
```

View the contents of the file.

```
type nums1.txt
```

```
81.4724
90.5792
12.6987
91.3376
63.2359
9.7540
27.8498
54.6882
```

Open the file for reading, and obtain the file identifier, `fileID`.

```
fileID = fopen('nums1.txt','r');
```

Define the format of the data to read. Use the string, `'%f'`, to specify floating-point numbers.

```
formatSpec = '%f';
```

Read the file data, filling output array, `A`, in column order. `fscanf` reapplies the format, `formatSpec`, throughout the file.

```
A = fscanf(fileID,formatSpec)
```

```
A =
```

```
81.4724
90.5792
12.6987
91.3376
63.2359
9.7540
27.8498
54.6882
```

`A` is a column vector containing data from the file.

Close the file.

```
fclose(fileID);
```

## Read File Contents into Array

Create a sample text file that contains integers and floating-point numbers.

```
x = 1:1:5;
y = [x;rand(1,5)];
fileID = fopen('nums2.txt','w');
fprintf(fileID,'%d %4.4f\n',y);
fclose(fileID);
```

View the contents of the file.

```
type nums2.txt
```

```
1 0.8147
2 0.9058
3 0.1270
4 0.9134
5 0.6324
```

Open the file for reading, and obtain the file identifier, `fileID`.

```
fileID = fopen('nums2.txt','r');
```

Define the format of the data to read and the shape of the output array.

```
formatSpec = '%d %f';
sizeA = [2 Inf];
```

Read the file data, filling output array, `A`, in column order. `fscanf` reuses the format, `formatSpec`, throughout the file.

```
A = fscanf(fileID,formatSpec,sizeA)
fclose(fileID);
```

```
A =
```

```
 1.0000 2.0000 3.0000 4.0000 5.0000
 0.8147 0.9058 0.1270 0.9134 0.6324
```

Transpose the array so that A matches the orientation of the data in the file.

```
A = A'
```

```
A =
```

```
1.0000 0.8147
2.0000 0.9058
3.0000 0.1270
4.0000 0.9134
5.0000 0.6324
```

### Skip Specific Characters in File

Skip specific characters in a sample file, and return only numeric data.

Create a sample text file containing temperature values.

```
str = '78°C 72°C 64°C 66°C 49°C';
fileID = fopen('temperature.dat','w');
fprintf(fileID,'%s',str);
fclose(fileID);
```

Read the numbers in the file, skipping the text, °C. Also return the number of values that fscanff reads. The extended ASCII code 176 represents the degree sign.

```
fileID = fopen('temperature.dat','r');
degrees = char(176);
[A,count] = fscanff(fileID, ['%d' degrees 'C'])
fclose(fileID);
```

```
A =
```

```
78
72
64
66
49
```

```
count =
```

```
5
```

A is a vector containing the numeric values in the file. `count` indicates that `fscanf` read five values.

## Input Arguments

### **fileID** – File identifier

integer

File identifier of an open text file, specified as an integer. Before reading a file with `fscanf`, you must use `fopen` to open the file and obtain the `fileID`.

Data Types: `double`

### **formatSpec** – Format of data fields

string

Format of the data fields in the file, specified as a string of one or more conversion specifiers. When `fscanf` reads a file, it attempts to match the data to the `formatSpec` string.

### Numeric Fields

This table lists available conversion specifiers for numeric inputs. `fscanf` converts values to their decimal (base 10) representation.

| Numeric Field Type | Conversion Specifier                 | Details                                                                                                                                                                                                                                                                                                                 |
|--------------------|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Integer, signed    | <code>%d</code>                      | Base 10                                                                                                                                                                                                                                                                                                                 |
|                    | <code>%i</code>                      | The values in the file determine the base: <ul style="list-style-type: none"> <li>The default is base 10.</li> <li>If the initial digits are <code>0x</code> or <code>0X</code>, then the values are hexadecimal (base 16).</li> <li>If the initial digit is <code>0</code>, then values are octal (base 8).</li> </ul> |
|                    | <code>%ld</code> or <code>%li</code> | 64-bit values, base 10, 8, or 16                                                                                                                                                                                                                                                                                        |
| Integer, unsigned  | <code>%u</code>                      | Base 10                                                                                                                                                                                                                                                                                                                 |
|                    | <code>%o</code>                      | Base 8 (octal)                                                                                                                                                                                                                                                                                                          |

| Numeric Field Type    | Conversion Specifier | Details                                                                                               |
|-----------------------|----------------------|-------------------------------------------------------------------------------------------------------|

|                       | %lu, %lo, %lx        | 64-bit values, base 10, 8, or 16                                                                      |
| Floating-point number | %f                   | Floating-point fields can contain any of the following (not case sensitive): Inf, -Inf, NaN, or -NaN. |
|                       | %e                   |                                                                                                       |
|                       | %g                   |                                                                                                       |

### Character Fields

This table lists available conversion specifiers for character inputs.

| Character Field Type    | Conversion Specifier | Description                                                                                                                                  |
|-------------------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Characters              | %s                   | Read a string until <code>fscanf</code> encounters white space.                                                                              |
|                         | %c                   | Read any single character, including white space.<br>To read multiple characters at a time, specify field width.                             |
| Pattern-matching string | %[ . . . ]           | Read only characters in the brackets up to the first nonmatching character or white space.<br><br>Example: %[mus] reads 'summer ' as 'summ'. |

If `formatSpec` contains a combination of numeric and character specifiers, then `fscanf` converts each character to its numeric equivalent. This conversion occurs even when the format explicitly skips all numeric values (for example, `formatSpec` is '%\*d %s').

### Optional Operators

- Fields and Characters to Ignore

`fscanf` reads all numeric values and characters in your file in sequence, unless you tell it to ignore a particular field or a portion of a field. To skip fields, insert an asterisk (\*) after the percent sign (%). For example, to skip integers, specify `%*d`.

- Field Width

To specify the maximum number of digits or text characters to read at a time, insert a number after the percent character. For example, `%10c` reads up to 10 characters at a time, including white space. `%4f` reads up to 4 digits at a time, including the decimal point.

- Literal Text to Ignore

`fscanf` ignores specified text appended to the `formatSpec` string.

Example: `Level%u` reads 'Level11' as 1.

Example: `%uStep` reads '2Step' as 2.

### **sizeA — Dimensions of output array**

`Inf` (default) | integer | two-element row vector

Dimensions of the output array, `A`, specified as `Inf`, an integer, or a two-element row vector.

| Form of the <code>sizeA</code> Input | Description                                                                                                                                                                                                                           |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Inf</code>                     | Read to the end of the file.<br>For numeric data, the output, <code>A</code> , is a column vector.<br>For text data, <code>A</code> is a string.                                                                                      |
| <code>n</code>                       | Read at most <code>n</code> numeric values or character fields.<br>For numeric data, the output, <code>A</code> , is a column vector.<br>For text data, <code>A</code> , is a string.                                                 |
| <code>[m, n]</code>                  | Read at most <code>m*n</code> numeric values or character fields.<br><code>n</code> can be <code>Inf</code> , but <code>m</code> cannot. The output, <code>A</code> , is <code>m</code> -by- <code>n</code> , filled in column order. |

## Output Arguments

### **A — File data**

column vector | matrix | string | character array

File data, returned as a column vector, matrix, string, or character array. The class and size of `A` depend on the `formatSpec` input:

- If `formatSpec` contains only numeric specifiers, then `A` is numeric. If you specify the `sizeA` argument, then `A` is a matrix of the specified size. Otherwise, `A` is a column vector. If the input contains fewer than `sizeA` values, then `fscanf` pads `A` with zeros.
  - If `formatSpec` contains only 64-bit signed integer specifiers, then `A` is of class `int64`.
  - If `formatSpec` contains only 64-bit unsigned integer specifiers, then `A` is of class `uint64`.
  - Otherwise, `A` is of class `double`.
- If `formatSpec` contains only character or string specifiers (`%C` or `%s`), then `A` is a character array. If you specify `sizeA` and the input contains fewer characters, then `fscanf` pads `A` with `char(0)`.
- If `formatSpec` contains a combination of numeric and character specifiers, then `A` is numeric, of class `double`, and `fscanf` converts each text characters to its numeric equivalent. This occurs even when `formatSpec` explicitly skips all numeric fields (for example, `formatSpec` is `'%*d %s'`).
- If MATLAB cannot match the file data to `formatSpec`, then `A` can be numeric or a character array. The class of `A` depends on the values that `fscanf` reads before it stops processing.

**count — Number of characters read**

scalar

Number of characters read, returned as a scalar value.

## More About

### Tips

- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

### Algorithms

MATLAB reads characters using the encoding scheme associated with the file. You specify the encoding when you open the file using the `fopen` function.

- “Reading Data in a Formatted Pattern”
- “Opening Files with Different Character Encodings”

**See Also**

**Introduced before R2006a**

## fscanf (serial)

Read ASCII data from device, and format as text

### Syntax

```
A = fscanf(obj)
A = fscanf(obj, 'format')
A = fscanf(obj, 'format', size)
[A, count] = fscanf(...)
[A, count, msg] = fscanf(...)
```

### Description

`A = fscanf(obj)` reads ASCII data from the device connected to the serial port object, `obj`, and returns it to `A`. The data is converted to text using the `%c` format. For binary data, use `fread`.

`A = fscanf(obj, 'format')` reads data and converts it according to *format*. *format* is a C language conversion specification. Conversion specifications involve the `%` character and the conversion characters `d`, `i`, `o`, `u`, `x`, `X`, `f`, `e`, `E`, `g`, `G`, `c`, and `s`. Refer to the `sscanf` file I/O format specifications or a C manual for more information.

`A = fscanf(obj, 'format', size)` reads the number of values specified by `size`. Valid options for `size` are:

|                    |                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------|
| <code>n</code>     | Read at most <code>n</code> values into a column vector.                                                                     |
| <code>[m,n]</code> | Read at most <code>m</code> -by- <code>n</code> values filling an <code>m</code> -by- <code>n</code> matrix in column order. |

`size` cannot be `inf`, and an error is returned if the specified number of values cannot be stored in the input buffer. If `size` is not of the form `[m,n]`, and a character conversion is specified, then `A` is returned as a row vector. You specify the size, in bytes, of the input buffer with the `InputBufferSize` property. An ASCII value is one byte.

`[A, count] = fscanf(...)` returns the number of values read to `count`.

`[A, count, msg] = fscanf(...)` returns a warning message to `msg` if the read operation did not complete successfully.

## Examples

Create the serial port object `s` and connect `s` to a Tektronix TDS 210 oscilloscope, which is displaying sine wave. This example works on a Windows platform.

```
s = serial('COM1');
fopen(s)
```

Use the `fprintf` function to configure the scope to measure the peak-to-peak voltage of the sine wave, return the measurement type, and return the peak-to-peak voltage.

```
fprintf(s, 'MEASUREMENT:IMMED:TYPE PK2PK')
fprintf(s, 'MEASUREMENT:IMMED:TYPE?')
fprintf(s, 'MEASUREMENT:IMMED:VALUE?')
```

Because the default value for the `ReadAsyncMode` property is `continuous`, data associated with the two query commands is automatically returned to the input buffer.

```
s.BytesAvailable
```

```
ans =
 21
```

Use `fscanf` to read the measurement type. The operation will complete when the first terminator is read.

```
meas = fscanf(s)
```

```
meas =
PK2PK
```

Use `fscanf` to read the peak-to-peak voltage as a floating-point number, and exclude the terminator.

```
pk2pk = fscanf(s, '%e', 14)
```

```
pk2pk =
 2.0200
```

Disconnect `s` from the scope, and remove `s` from memory and the workspace.

```
fclose(s)
delete(s)
clear s
```

## More About

### Tips

Before you can read data from the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read – including the terminator – each time `fscanf` is issued.

### Rules for Completing a Read Operation with fscanf

A read operation with `fscanf` blocks access to the MATLAB command line until:

- The terminator specified by the `Terminator` property is read.
- The time specified by the `Timeout` property passes.
- The number of values specified by `size` is read.
- The input buffer is filled (unless `size` is specified)

### See Also

**Introduced before R2006a**

## **fseek**

Move to specified position in file

### **Syntax**

```
fseek(fileID, offset, origin)
status = fseek(fileID, offset, origin)
```

### **Description**

`fseek(fileID, offset, origin)` sets the file position indicator *offset* bytes from *origin* in the specified file.

`status = fseek(fileID, offset, origin)` returns 0 when the operation is successful. Otherwise, it returns -1.

### **Input Arguments**

#### **fileID**

Integer file identifier obtained from `fopen`.

#### **offset**

Number of bytes to move from `origin`. Can be positive, negative, or zero. The *n* bytes of a given file are in positions 0 through *n* - 1.

#### **origin**

Starting location in the file:

|             |                          |
|-------------|--------------------------|
| 'bof' or -1 | Beginning of file        |
| 'cof' or 0  | Current position in file |

|            |             |
|------------|-------------|
| 'eof' or 1 | End of file |
|------------|-------------|

## Examples

Copy 5 bytes from the file `test1.dat`, starting at the tenth byte, and append to the end of `test2.dat`:

```
% Create files test1.dat and test2.dat
% Each character uses 8 bits (1 byte)

fid1 = fopen('test1.dat', 'w+');
fwrite(fid1, 'ABCDEFGHIJKLMNOPQRSTUVWXYZ');

fid2 = fopen('test2.dat', 'w+');
fwrite(fid2, 'Second File');

% Seek to the 10th byte ('J'), read 5
fseek(fid1, 9, 'bof');
A = fread(fid1, 5, 'uint8=>char');
fclose(fid1);

% Append to test2.dat
fseek(fid2, 0, 'eof');
fwrite(fid2, A);
fclose(fid2);
```

## Alternatives

To move to the beginning of a file, call

```
frewind(fileID)
```

This call is identical to

```
fseek(fileID, 0, 'bof')
```

## More About

- “Reading Portions of a File”

fprintf

**Introduced before R2006a**

# ftell

Position in open file

## Syntax

```
position = ftell(fileID)
```

## Description

*position* = ftell(*fileID*) returns the current position in the specified file. *position* is a zero-based integer that indicates the number of bytes from the beginning of the file. If the query is unsuccessful, *position* is -1. *fileID* is an integer file identifier obtained from fopen.

**Introduced before R2006a**

## FTP class

Connect to FTP server

### Description

Connect to an FTP server by calling the `ftp` function, which creates an FTP object. Perform file operations using methods on the FTP object, such as `mput` and `mget`. When you finish accessing the server, call the `close` method to close the connection.

### Construction

`f = ftp(host, username, password)` connects to the FTP server `host` and creates FTP object `f`. If the host supports anonymous connections, you can use the `host` argument alone. To specify an alternate port, separate it from `host` with a colon (`:`).

### Input Arguments

#### **host**

String enclosed in single quotation marks that specifies the FTP server.

#### **username**

String enclosed in single quotation marks that specifies your user name for the FTP server.

#### **password**

String enclosed in single quotation marks that specifies your password for the FTP server. Because FTP is not a secure protocol, others can see your user name and password.

### Methods

`ascii`

Set FTP transfer type to ASCII

|        |                                             |
|--------|---------------------------------------------|
| binary | Set FTP transfer type to binary             |
| cd     | Change or view current folder on FTP server |
| close  | Close connection to FTP server              |
| delete | Remove file on FTP server                   |
| dir    | View contents of folder on FTP server       |
| mget   | Download files from FTP server              |
| mkdir  | Create folder on FTP server                 |
| mput   | Upload file or folder to FTP server         |
| rename | Rename file on FTP server                   |
| rmdir  | Remove folder on FTP server                 |

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

Connect to an FTP server and display the FTP object. Replace `ftp.testsite.com` with the URL for an actual FTP site.

```
ts = ftp('ftp.testsite.com');
disp(ts)
```

Connect to port 34. If you specify a port that the FTP server does not support, then `ftp` returns an error.

```
ts = ftp('ftp.testsite.com:34')
```

Modify the following code to connect to a host that requires a password:

```
ts = ftp('ftp.testsite.com', 'myname', 'mypassword')
```

## **Algorithms**

The `ftp` function is based on code from the Apache Jakarta Project.

## **Limitations**

The `ftp` function does not support proxy server settings.

## **See Also**

`urlwrite`

**Introduced before R2006a**

# full

Convert sparse matrix to full matrix

## Syntax

```
A = full(S)
```

## Description

`A = full(S)` converts a sparse matrix `S` to full storage organization, such that `issparse(A)` returns logical 0 (`false`). If `S` is a full matrix, then `A` is identical to `S`.

## Examples

Here is an example of a sparse matrix with a density of about two-thirds. `sparse(S)` and `full(S)` require about the same number of bytes of storage.

```
S = sparse(double(rand(200,200) < 2/3));
A = full(S);
whos
```

| Name | Size    | Bytes  | Class  | Attributes |
|------|---------|--------|--------|------------|
| A    | 200x200 | 320000 | double |            |
| S    | 200x200 | 429624 | double | sparse     |

## More About

### Tips

If `X` is an `m`-by-`n` matrix with `nz` nonzero elements then `full(X)` requires space to store `m*n` elements. On the other hand, `sparse(X)` requires space to store `nz` elements and `(nz+n+1)` integers.

The density of a matrix (`nnz(X)/numel(X)`) determines whether or not it is more efficient to store the matrix as sparse or full. The exact crossover point depends on the

matrix class as well as the platform. For example, in 32-bit MATLAB, a double sparse matrix with less than about 2/3 density will require less space than the same matrix in full storage. In 64-bit MATLAB, however, double matrices with less than half of their elements nonzero are more efficient to store as sparse matrices.

## **See Also**

`issparse` | `sparse`

**Introduced before R2006a**

# fullfile

Build full file name from parts

## Syntax

```
f = fullfile(filepart1,...,filepartN)
```

## Description

`f = fullfile(filepart1,...,filepartN)` builds a full file specification, `f`, from the folders and file names specified. `fullfile` inserts platform-dependent file separators where necessary, and does not add a trailing file separator. The output of `fullfile` is conceptually equivalent to

```
f = [filepart1 filesep filepart2 filesep ... filesep filepartN]
```

## Examples

### Create a Full File Name

```
f = fullfile('myfolder','mysubfolder','myfile.m')
```

```
f =
myfolder\mysubfolder\myfile.m
```

`fullfile` returns a string containing the full path to the file. On Windows platforms, the file separator character is a backslash, `\`. On other platforms, the file separator might be a different character.

### Create Paths to Multiple Files

```
f = fullfile(toolboxdir('matlab'),'iofun',{'filesep.m';'fullfile.m'});
```

`fullfile` returns a cell array containing a path to the file `filesep.m`, and a path to the file `fullfile.m`.

### Create a Path to a Folder

```
f = fullfile(matlabroot,'toolbox','matlab',filesep);
```

fullfile does not trim a leading or trailing filesep.

## Input Arguments

### **filepart1, ..., filepartN** — Folder and file names

strings | cell arrays of strings

Folder and file names, specified as strings and cell arrays of strings. Any nonscalar cell arrays must be of the same size.

Example: 'folder1', 'folder2', 'myfile.m'

Example: {'folder1'; 'folder2'}, {'subfolder1'; 'subfolder2'}, 'myfile.m'

### **See Also**

fileparts | filesep | genpath | path | pathsep

**Introduced before R2006a**

# func2str

Construct string from function handle

## Syntax

```
str = func2str(fh)
```

## Description

`str = func2str(fh)` constructs a string, `str`, that contains the name of the function associated with the function handle, `fh`. If `fh` is associated with an anonymous function, `func2str` returns a string that represents the anonymous function.

## Examples

### Convert Function Handle to String

Create function handles for both the `COS` function and for an anonymous function, and then convert them to strings.

```
fh = @cos;
str = func2str(fh)
```

```
str =
```

```
cos
```

```
fh = @(x,y)sqrt(x.^2+y.^2);
str = func2str(fh);
```

```
disp(['Anonymous function: ' str])
```

```
Anonymous function: @(x,y)sqrt(x.^2+y.^2)
```

### Display Function Handle String Programmatically

Create a function that evaluates a function handle for a single input.

Create the following function in a file, `evaluateHandle.m`, in your working folder.

```
% Copyright 2015 The MathWorks, Inc.

function evaluateHandle(fh,x)

y = fh(x);
str = func2str(fh);

disp('For input value: ')
disp(x)
disp(['The function ' str ' evaluates to:'])
disp(y)

end
```

Use a function handle to evaluate the `sin` function at  $\pi/2$ .

```
fh = @sin;
x = pi/2;
evaluateHandle(fh,x)

For input value:
 1.5708

The function sin evaluates to:
 1
```

Use a function handle to evaluate  $x^2 + 7$  for the specified matrix, `A`.

```
fh = @(x) x.^2+7;
A = [1 2;0 1];
evaluateHandle(fh,A)

For input value:
 1 2
 0 1

The function @(x)x.^2+7 evaluates to:
 8 11
 7 8
```

## Input Arguments

**fh** — Handle to convert to string  
function handle

Handle to convert to a string, specified as a function handle.

## More About

### Tips

- You lose variables stored in the function handle when you convert it to a string using `func2str`, and then back to a handle using `str2func`.
- “Create Function Handle”

### See Also

`functions` | `str2func`

**Introduced before R2006a**

## function

Declare function name, inputs, and outputs

### Syntax

```
function [y1,...,yN] = myfun(x1,...,xM)
```

### Description

`function [y1,...,yN] = myfun(x1,...,xM)` declares a function named `myfun` that accepts inputs `x1,...,xM` and returns outputs `y1,...,yN`. This declaration statement must be the first executable line of the function.

Save the function code in a text file with a `.m` extension. The name of the file should match the name of the first function in the file. Valid function names begin with an alphabetic character, and can contain letters, numbers, or underscores.

Files can include multiple local functions or nested functions. Use the `end` keyword to indicate the end of each function in a file if:

- Any function in the file contains a nested function
- Any local function in the file uses the `end` keyword

Otherwise, the `end` keyword is optional.

## Examples

### Function with One Output

Define a function in a file named `average.m` that accepts an input vector, calculates the average of the values, and returns a single result.

```
function y = average(x)
if ~isvector(x)
 error('Input must be a vector')
end
```

```
y = sum(x)/length(x);
end
```

Call the function from the command line.

```
z = 1:99;
average(z)
```

```
ans =
 50
```

### Function with Multiple Outputs

Define a function in a file named `stat.m` that returns the mean and standard deviation of an input vector.

```
function [m,s] = stat(x)
n = length(x);
m = sum(x)/n;
s = sqrt(sum((x-m).^2/n));
end
```

Call the function from the command line.

```
values = [12.7, 45.4, 98.9, 26.6, 53.1];
[ave,stdev] = stat(values)
```

```
ave =
 47.3400
stdev =
 29.4124
```

### Multiple Functions in a File

Define two functions in a file named `stat2.m`, where the first function calls the second.

```
function [m,s] = stat2(x)
n = length(x);
m = avg(x,n);
s = sqrt(sum((x-m).^2/n));
end
```

```
function m = avg(x,n)
m = sum(x)/n;
end
```

Function `avg` is a *local function*. Local functions are only available to other functions within the same file.

Call function `stat2` from the command line.

```
values = [12.7, 45.4, 98.9, 26.6, 53.1];
[ave,stdev] = stat2(values)
```

```
ave =
 47.3400
stdev =
 29.4124
```

# functions

Information about function handle

## Syntax

```
s = functions(fh)
```

## Description

`s = functions(fh)` returns information about a function handle. This information includes the function name, type, and file name.

Use the `functions` function for querying and debugging purposes only.

---

**Note:** Do not use `functions` programmatically because its behavior could change in subsequent MATLAB releases.

---

## Examples

### Display Information About Named Function Handle

Create a function handle and display its information.

```
fh = @cos;
s = functions(fh)
```

```
s =
```

```
function: 'cos'
type: 'simple'
file: ''
```

### Display Information About Anonymous Function Handle

Create a function handle to an anonymous function. Display its information and values of required variables.

Create a handle to the function  $x^2 + y$ , and invoke the function using the handle.

```
y = 7;
fh = @(x)x.^2+y;
z = fh(2)
```

```
z =

 11
```

Display information about the function handle.

```
s = functions(fh)
s =

 function: '@(x)x.^2+y'
 type: 'anonymous'
 file: ''
 workspace: {[1x1 struct]}
 within_file_path: '__base_function'
```

The function handle contains the required value of  $y$ .

```
s.workspace{1}
ans =

 y: 7
```

## Display Information About Nested and Local Function Handle

Create a function that returns handles to local and nested functions. Display their information.

Create the following function in a file, `functionsExample.m`, in your working folder. The function returns handles to a nested and local function.

```
function [hNest,hLocal] = functionsExample(v)

hNest = @nestFunction;
hLocal = @localFunction;

 function y = nestFunction(x)
 y = x + v;
 end
```

```
end
```

```
function y = localFunction(z)
y = z + 1;
end
```

Invoke the function.

```
[hNest,hLocal] = functionsExample(13)
```

```
hNest =
```

```
 @functionsExample/nestFunction
```

```
hLocal =
```

```
 @localFunction
```

Display information about the handle to the nested function.

```
s1 = functions(hNest)
```

```
s1 =
```

```
 function: 'functionsExample/nestFunction'
 type: 'nested'
 file: 'C:\work\functionsExample.m'
 workspace: {[1x1 struct]}
```

Display information about the handle to the local function.

```
s2 = functions(hLocal)
```

```
s2 =
```

```
 function: 'localFunction'
 type: 'scopedfunction'
 file: 'C:\work\functionsExample.m'
 parentage: {'localFunction' 'functionsExample'}
```

## Input Arguments

**fh** — Handle to query

function handle

Handle to query, specified as a function handle.

## Output Arguments

### **s** — Information about function handle

structure

Information about a function handle, returned as a structure. The structure contains the following fields.

| Field Name            | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>function</code> | Function name. If the function associated with the handle is a nested function, the function name takes the form <i>main_function/nested_function</i> .                                                                                                                                                                                                                                                                                                            |
| <code>type</code>     | Function type. For example 'simple', 'nested', 'scopedfunction', or 'anonymous'.                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>file</code>     | Full path to the function with the file extension. <ul style="list-style-type: none"><li>• If the function is a local or nested function, then <code>file</code> is the full path to the main function.</li><li>• If the function is built-in MATLAB function or an anonymous function, then <code>file</code> is an empty character array ('').</li><li>• If you load a saved function handle, then <code>file</code> is an empty character array ('').</li></ul> |

The structure has additional fields depending on the type of function associated with the handle. For example, a local function has a `parentage` field, and an anonymous function has a `workspace` field. Use the information in `s` for querying and debugging purposes only.

**Introduced before R2006a**

## functiontests

Create array of tests from handles to local functions

### Syntax

```
tests = functiontests(f)
```

### Description

`tests = functiontests(f)` creates an array of tests, `tests`, from a cell array of handles to local functions, `f`. To apply defined setup and teardown functions, include their function handles in `f`.

Local test functions must include 'test' at the beginning or end of the function name. `functiontests` must be called from within a test file.

### Examples

#### Create Test Array

Create the file `exampleTest.m` in your MATLAB path. In the main function, create a test array. Use local functions to define setup, teardown, and two function tests. Your file should look like this.

```
function tests = exampleTest
tests = functiontests(localfunctions);

function setup(testCase)
function teardown(testCase)
function exampleOneTest(testCase)
function testExampleTwo(testCase)
```

From the command line, call the `exampleTest` function.

```
tests = exampleTest
```

```
tests =
 1x2 Test array with properties:
 Name
 Parameterization
 SharedTestFixtures
 Tags
Tests Include:
 0 Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.
```

Access the test suite to verify the names of the two function tests.

```
tests.Name
```

```
ans =
```

```
exampleTest/exampleOneTest
```

```
ans =
```

```
exampleTest/testExampleTwo
```

- “Write Function-Based Unit Tests”
- “Write Simple Test Case Using Functions”
- “Write Test Using Setup and Teardown Functions”

## Input Arguments

### **f** — Handles to local test functions

cell array of function handles

Handles to local test functions, specified as a cell array. Use `f=localfunctions` in your working file to automatically generate a cell array of function handles for that file. If you want explicit test enumeration, construct `f` by listing individual functions. `f` must include any setup or teardown functions necessary for your test.

Example: `f = localfunctions;`

Example: `f = {@setup,@exampleOneTest,@teardown};`

# funm

Evaluate general matrix function

## Syntax

```
F = funm(A,fun)
F = funm(A,fun,options)
F = funm(A,fun,options,p1,p2,...)
[F,exitflag] = funm(...)
[F,exitflag,output] = funm(...)
```

## Description

$F = \text{funm}(A, \text{fun})$  evaluates the user-defined function `fun` at the square matrix argument `A`.  $F = \text{fun}(x, k)$  must accept a vector `x` and an integer `k`, and return a vector `f` of the same size of `x`, where  $f(i)$  is the  $k$ th derivative of the function `fun` evaluated at  $x(i)$ . The function represented by `fun` must have a Taylor series with an infinite radius of convergence, except for `fun = @log`, which is treated as a special case.

You can also use `funm` to evaluate the special functions listed in the following table at the matrix `A`.

| Function          | Syntax for Evaluating Function at Matrix A |
|-------------------|--------------------------------------------|
| <code>exp</code>  | <code>funm(A, @exp)</code>                 |
| <code>log</code>  | <code>funm(A, @log)</code>                 |
| <code>sin</code>  | <code>funm(A, @sin)</code>                 |
| <code>cos</code>  | <code>funm(A, @cos)</code>                 |
| <code>sinh</code> | <code>funm(A, @sinh)</code>                |
| <code>cosh</code> | <code>funm(A, @cosh)</code>                |

For matrix square roots, use `sqrtm(A)` instead. For matrix exponentials, which of `expm(A)` or `funm(A, @exp)` is the more accurate depends on the matrix `A`.

The function represented by `fun` must have a Taylor series with an infinite radius of convergence. The exception is `@log`, which is treated as a special case. “Parameterizing

Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`F = funm(A, fun, options)` sets the algorithm's parameters to the values in the structure `options`.

The following table lists the fields of `options`.

| Field                         | Description                                                                                                 | Values                                                                                                                                                                       |
|-------------------------------|-------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>options.Display</code>  | Level of display                                                                                            | 'off' (default), 'on', 'verbose'                                                                                                                                             |
| <code>options.TolBlk</code>   | Tolerance for blocking Schur form                                                                           | Positive scalar. The default is 0.1.                                                                                                                                         |
| <code>options.TolTay</code>   | Termination tolerance for evaluating the Taylor series of diagonal blocks                                   | Positive scalar. The default is <code>eps</code> .                                                                                                                           |
| <code>options.MaxTerms</code> | Maximum number of Taylor series terms                                                                       | Positive integer. The default is 250.                                                                                                                                        |
| <code>options.MaxSqrt</code>  | When computing a logarithm, maximum number of square roots computed in inverse scaling and squaring method. | Positive integer. The default is 100.                                                                                                                                        |
| <code>options.Ord</code>      | Specifies the ordering of the Schur form <code>T</code> .                                                   | A vector of length <code>length(A)</code> . <code>options.Ord(i)</code> is the index of the block into which <code>T(i,i)</code> is placed. The default is <code>[]</code> . |

`F = funm(A, fun, options, p1, p2, ...)` passes extra inputs `p1, p2, ...` to the function.

`[F, exitflag] = funm(...)` returns a scalar `exitflag` that describes the exit condition of `funm`. `exitflag` can have the following values:

- 0 — The algorithm was successful.
- 1 — One or more Taylor series evaluations did not converge, or, in the case of a logarithm, too many square roots are needed. However, the computed value of `F` might still be accurate.

`[F,exitflag,output] = funm(...)` returns a structure `output` with the following fields:

| Field                     | Description                                                                                                                                                                                                                          |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>output.terms</code> | Vector for which <code>output.terms(i)</code> is the number of Taylor series terms used when evaluating the <i>i</i> th block, or, in the case of the logarithm, the number of square roots of matrices of dimension greater than 2. |
| <code>output.ind</code>   | Cell array for which the <code>(i,j)</code> block of the reordered Schur factor <code>T</code> is <code>T(output.ind{i}, output.ind{j})</code> .                                                                                     |
| <code>output.ord</code>   | Ordering of the Schur form, as passed to <code>ordschur</code>                                                                                                                                                                       |
| <code>output.T</code>     | Reordered Schur form                                                                                                                                                                                                                 |

If the Schur form is diagonal then `output = struct('terms',ones(n,1),'ind',{1:n})`.

## Examples

### Example 1

The following command computes the matrix sine of the 3-by-3 magic matrix.

```
F=funm(magic(3), @sin)
```

F =

```
-0.3850 1.0191 0.0162
 0.6179 0.2168 -0.1844
 0.4173 -0.5856 0.8185
```

### Example 2

The statements

```
S = funm(X,@sin);
C = funm(X,@cos);
```

produce the same results to within roundoff error as

```
E = expm(i*X);
C = real(E);
S = imag(E);
```

In either case, the results satisfy  $S^*S + C^*C = I$ , where  $I = \text{eye}(\text{size}(X))$ .

## Example 3

To compute the function  $\exp(x) + \cos(x)$  at  $A$  with one call to `funm`, use

```
F = funm(A,@fun_expcos)
```

where `fun_expcos` is the following function.

```
function f = fun_expcos(x, k)
% Return kth derivative of exp + cos at X.
 g = mod(ceil(k/2),2);
 if mod(k,2)
 f = exp(x) + sin(x)*(-1)^g;
 else
 f = exp(x) + cos(x)*(-1)^g;
 end
```

## More About

### Algorithms

The algorithm `funm` uses is described in [1].

- “Create Function Handle”

## **fwrite**

Write data to binary file

### **Syntax**

```
fwrite(fileID,A)
fwrite(fileID,A,precision)
fwrite(fileID,A,precision,skip)
fwrite(fileID,A,precision,skip,machinefmt)
```

```
count = fwrite(___)
```

### **Description**

`fwrite(fileID,A)` write the elements of array `A` as 8-bit unsigned integers to a binary file in column order. The binary file is indicated by the file identifier, `fileID`. Use `fopen` to open the file and obtain the `fileID` value. When you finish reading, close the file by calling `fclose(fileID)`.

`fwrite(fileID,A,precision)` writes the values in `A` in the form and size described by `precision`.

`fwrite(fileID,A,precision,skip)` skips the number of bytes or bits specified by `skip` before writing each value.

`fwrite(fileID,A,precision,skip,machinefmt)` additionally specifies the order for writing bytes or bits to the file. The `skip` argument is optional.

`count = fwrite( ___ )` returns the number of elements of `A` that `fwrite` successfully writes to the file. You can use this syntax with any of the input arguments of the previous syntaxes.

## Examples

### Write uint8 Data to Binary File

Open a file named `nine.bin` for writing. Specify write access using `'w'` in the call to `fopen`.

```
fileID = fopen('nine.bin','w');
```

`fopen` returns a file identifier, `fileID`.

Write the integers from 1 to 9 as 8-bit unsigned integers.

```
fwrite(fileID,[1:9]);
```

Close the file.

```
fclose(fileID);
```

### Write 4-byte Integers to Binary File

Open a file named `magic5.bin` for writing.

```
fileID = fopen('magic5.bin','w');
```

Write the 25 elements of the 5-by-5 magic square. Use the `precision` argument, `'integer*4'`, to write 4-byte integers.

```
fwrite(fileID,magic(5),'integer*4');
```

Close the file.

```
fclose(fileID);
```

### Append Data to Binary File

Write a binary file containing the elements of the 4-by-4 magic square, stored as double-precision floating-point numbers.

```
fileID = fopen('magic4.bin','w');
fwrite(fileID,magic(4),'double');
fclose(fileID);
```

Open the file, `magic4.bin`, with write-access that enables appending to the file. Specify the file-access type, `'a'`, in the call to `fopen`.

```
fileID = fopen('magic4.bin','a');
```

Append a 4-by-4 matrix of zeros to the file. Then, close the file.

```
fwrite(fileID,zeros(4),'double');
fclose(fileID);
```

### Write Binary File with Big-Endian Byte Ordering

Write random double-precision numbers to a file named `myfile.bin` for use on a big-endian system. Specify a `machinefmt` value of `'ieee-be'` in the call to `fwrite`, to indicate big-endian byte ordering.

```
fileID = fopen('myfile.bin','w');
fwrite(fileID,rand(4),'double','ieee-be');
fclose(fileID);
```

- “Write and Read Complex Numbers”

## Input Arguments

### **fileID** — File identifier

integer | 1 | 2

File identifier, specified as an integer obtained from `fopen`, 1 for standard output (the screen), or 2 for standard error.

### **A** — Data to write

numeric array | character array

Data to write, specified as a numeric or character array.

Example: `[1,2,3;4,5,6]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

Complex Number Support: Yes

### **precision** — Class and size of values to write

`uint8` (default) | `string`

Class and size in bits of the values to write, specified as one of the following strings in the Precision column.

| Value Type             | Precision     | Bits (Bytes)       |
|------------------------|---------------|--------------------|
| Integers, unsigned     | uint          | 32 (4)             |
|                        | uint8         | 8 (1)              |
|                        | uint16        | 16 (2)             |
|                        | uint32        | 32 (4)             |
|                        | uint64        | 64 (8)             |
|                        | uchar         | 8 (1)              |
|                        | unsigned char | 8 (1)              |
|                        | ushort        | 16 (2)             |
|                        | ulong         | 32 (4)             |
|                        | ubit <i>n</i> | $1 \leq n \leq 64$ |
| Integers, signed       | int           | 32 (4)             |
|                        | int8          | 8 (1)              |
|                        | int16         | 16 (2)             |
|                        | int32         | 32 (4)             |
|                        | int64         | 64 (8)             |
|                        | integer*1     | 8 (1)              |
|                        | integer*2     | 16 (2)             |
|                        | integer*4     | 32 (4)             |
|                        | integer*8     | 64 (8)             |
|                        | schar         | 8 (1)              |
|                        | signed char   | 8 (1)              |
|                        | short         | 16 (2)             |
|                        | long          | 32 (4)             |
|                        | bit <i>n</i>  | $1 \leq n \leq 64$ |
| Floating-point numbers | single        | 32 (4)             |
|                        | double        | 64 (8)             |

| Value Type | Precision | Bits (Bytes)                                                                                    |
|------------|-----------|-------------------------------------------------------------------------------------------------|
|            | float     | 32 (4)                                                                                          |
|            | float32   | 32 (4)                                                                                          |
|            | float64   | 64 (8)                                                                                          |
|            | real*4    | 32 (4)                                                                                          |
|            | real*8    | 64 (8)                                                                                          |
| Characters | char*1    | 8 (1)                                                                                           |
|            | char      | Depends on the encoding scheme associated with the file. Set encoding with <code>fopen</code> . |

If you specify a precision of `bitn` or `ubitn`, then `fwrite` saturates for all values outside the range.

---

**Note:** To preserve NaN and Inf values in MATLAB, read and write data of class `double` or `single`.

---

**skip — Number of bytes to skip**

0 (default) | scalar

Number of bytes to skip before writing each value, specified as a scalar. If you specify a precision of `bitn` or `ubitn`, specify `skip` in bits.

Use the `skip` argument to insert data into noncontiguous fields in fixed-length records.

**machinefmt — Order for writing bytes**

'n' (default) | 'b' | 'l' | 's' | 'a'

Order for writing bytes within the file, specified as one of the strings in the table that follows. For `bitn` and `ubitn` precisions, `machinefmt` specifies the order for writing bits within a byte, but the order for writing bytes remains your system byte ordering.

|                  |                                     |
|------------------|-------------------------------------|
| 'n' or 'native'  | Your system byte ordering (default) |
| 'b' or 'ieee-be' | Big-endian ordering                 |
| 'l' or 'ieee-le' | Little-endian ordering              |

|                      |                                               |
|----------------------|-----------------------------------------------|
| 's' or 'ieee-be.l64' | Big-endian ordering, 64-bit long data type    |
| 'a' or 'ieee-le.l64' | Little-endian ordering, 64-bit long data type |

By default, all currently supported platforms use little-endian ordering for new files. Existing binary files can use either big-endian or little-endian ordering.

## **fwrite (serial)**

Write binary data to device

### **Syntax**

```
fwrite(obj,A)
fwrite(obj,A,'precision')
fwrite(obj,A,'mode')
fwrite(obj,A,'precision','mode')
```

### **Description**

`fwrite(obj,A)` writes the binary data `A` to the device connected to the serial port object, `obj`.

`fwrite(obj,A,'precision')` writes binary data with precision specified by `precision`.

`precision` controls the number of bits written for each value and the interpretation of those bits as integer, floating-point, or character values. If `precision` is not specified, `uchar` (an 8-bit unsigned character) is used. The supported values for `precision` are listed in Tips.

`fwrite(obj,A,'mode')` writes binary data with command-line access specified by `mode`. If `mode` is `sync`, `A` is written synchronously and the command line is blocked. If `mode` is `async`, `A` is written asynchronously and the command line is not blocked. If `mode` is not specified, the write operation is synchronous.

`fwrite(obj,A,'precision','mode')` writes binary data with precision specified by `precision` and command-line access specified by `mode`.

### **More About**

#### **Tips**

Before you can write data to the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error

is returned if you attempt to perform a write operation while `obj` is not connected to the device.

The `ValuesSent` property value is increased by the number of values written each time `fwrite` is issued.

An error occurs if the output buffer cannot hold all the data to be written. You can specify the size of the output buffer with the `OutputBufferSize` property.

If you set the `FlowControl` property to `hardware` on a serial object, and a hardware connection is not detected, `fwrite` returns an error message. This occurs if a device is not connected, or a connected device is not asserting that it is ready to receive data. Check the remote device status and flow control settings to see if hardware flow control is causing errors in MATLAB.

---

**Note:** If you want to check to see if the device is asserting that it is ready to receive data, set the `FlowControl` to `none`. Once you connect to the device, check the `PinStatus` structure for `ClearToSend`. If `ClearToSend` is `off`, there is a problem on the remote device side. If `ClearToSend` is `on`, there is a hardware `FlowControl` device prepared to receive data and you can execute `fwrite`.

---

## Synchronous Versus Asynchronous Write Operations

By default, data is written to the device synchronously and the command line is blocked until the operation completes. You can perform an asynchronous write by configuring the `mode` input argument to be `async`. For asynchronous writes:

- The `BytesToOutput` property value is continuously updated to reflect the number of bytes in the output buffer.
- The callback function specified for the `OutputEmptyFcn` property is executed when the output buffer is empty.

You can determine whether an asynchronous write operation is in progress with the `TransferStatus` property.

Synchronous and asynchronous write operations are discussed in more detail in *Writing Data*.

## Rules for Completing a Write Operation with `fwrite`

A binary write operation using `fwrite` completes when:

- The specified data is written.
- The time specified by the `Timeout` property passes.

---

**Note** The `Terminator` property is not used with binary write operations.

---

## Supported Precisions

The following table shows the supported values for *precision*.

| Data Type      | Precision            | Interpretation                     |
|----------------|----------------------|------------------------------------|
| Character      | <code>uchar</code>   | 8-bit unsigned character           |
|                | <code>schar</code>   | 8-bit signed character             |
|                | <code>char</code>    | 8-bit signed or unsigned character |
| Integer        | <code>int8</code>    | 8-bit integer                      |
|                | <code>int16</code>   | 16-bit integer                     |
|                | <code>int32</code>   | 32-bit integer                     |
|                | <code>uint8</code>   | 8-bit unsigned integer             |
|                | <code>uint16</code>  | 16-bit unsigned integer            |
|                | <code>uint32</code>  | 32-bit unsigned integer            |
|                | <code>short</code>   | 16-bit integer                     |
|                | <code>int</code>     | 32-bit integer                     |
|                | <code>long</code>    | 32- or 64-bit integer              |
|                | <code>ushort</code>  | 16-bit unsigned integer            |
|                | <code>uint</code>    | 32-bit unsigned integer            |
|                | <code>ulong</code>   | 32- or 64-bit unsigned integer     |
| Floating-point | <code>single</code>  | 32-bit floating point              |
|                | <code>float32</code> | 32-bit floating point              |
|                | <code>float</code>   | 32-bit floating point              |

---

| Data Type | Precision | Interpretation        |
|-----------|-----------|-----------------------|
|           | double    | 64-bit floating point |
|           | float64   | 64-bit floating point |

## fzero

Root of nonlinear function

### Syntax

```
x = fzero(fun,x0)
x = fzero(fun,x0,options)

x = fzero(problem)

[x,fval,exitflag,output] = fzero(___)
```

### Description

`x = fzero(fun,x0)` tries to find a point `x` where `fun(x) = 0`. This solution is where `fun(x)` changes sign—`fzero` cannot find a root of a function such as `x^2`.

`x = fzero(fun,x0,options)` uses `options` to modify the solution process.

`x = fzero(problem)` solves a root-finding problem specified by `problem`.

`[x,fval,exitflag,output] = fzero( ___ )` returns `fun(x)` in the `fval` output, `exitflag` encoding the reason `fzero` stopped, and an output structure containing information on the solution process.

### Examples

#### Root Starting From One Point

Calculate  $\pi$  by finding the zero of the sine function near 3.

```
fun = @sin; % function
x0 = 3; % initial point
x = fzero(fun,x0)
```

```
x =
 3.1416
```

### Root Starting From an Interval

Find the zero of cosine between 1 and 2.

```
fun = @cos; % function
x0 = [1 2]; % initial interval
x = fzero(fun,x0)
```

```
x =
 1.5708
```

Note that  $\cos(1)$  and  $\cos(2)$  differ in sign.

### Root of a Function Defined by a File

Find a zero of the function  $f(x) = x^3 - 2x - 5$ .

First, write a file called `f.m`.

```
function y = f(x)
y = x.^3 - 2*x - 5;
```

Save `f.m` on your MATLAB path.

Find the zero of  $f(x)$  near 2.

```
fun = @f; % function
x0 = 2; % initial point
z = fzero(fun,x0)
```

```
z =
 2.0946
```

Since  $f(x)$  is a polynomial, you can find the same real zero, and a complex conjugate pair of zeros, using the `roots` command.

```
roots([1 0 -2 -5])
```

```
ans =
 2.0946
 -1.0473 + 1.1359i
 -1.0473 - 1.1359i
```

## Root of Function with Extra Parameter

Find the root of a function that has an extra parameter.

```
myfun = @(x,c) cos(c*x); % parameterized function
c = 2; % parameter
fun = @(x) myfun(x,c); % function of x alone
x = fzero(fun,0.1)
```

```
x =

 0.7854
```

## Nondefault Options

Plot the solution process by setting some plot functions.

Define the function and initial point.

```
fun = @(x)sin(cosh(x));
x0 = 1;
```

Examine the solution process by setting options that include plot functions.

```
options = optimset('PlotFcns',{@optimplotx,@optimplotfval});
```

Run `fzero` including options.

```
x = fzero(fun,x0,options)
```

```
x =

 1.8115
```

### Solve Problem Structure

Solve a problem that is defined by a problem structure.

Define a structure that encodes a root-finding problem.

```
problem.objective = @(x)sin(cosh(x));
problem.x0 = 1;
problem.solver = 'fzero'; % a required part of the structure
problem.options = optimset(@fzero); % default options
```

Solve the problem.

```
x = fzero(problem)
```

```
x =

 1.8115
```

### More Information from Solution

Find the point where  $\exp(-\exp(-x)) = x$ , and display information about the solution process.

```
fun = @(x) exp(-exp(-x)) - x; % function
x0 = [0 1]; % initial interval
options = optimset('Display','iter'); % show iterations
[x fval exitflag output] = fzero(fun,x0,options)
```

| Func-count | x        | f(x)         | Procedure     |
|------------|----------|--------------|---------------|
| 2          | 1        | -0.307799    | initial       |
| 3          | 0.544459 | 0.0153522    | interpolation |
| 4          | 0.566101 | 0.00070708   | interpolation |
| 5          | 0.567143 | -1.40255e-08 | interpolation |
| 6          | 0.567143 | 1.50013e-12  | interpolation |
| 7          | 0.567143 | 0            | interpolation |

```
Zero found in the interval [0, 1]
```

```
x =

 0.5671
```

```
fval =

 0
```

```
exitflag =

 1
```

```
output =

 intervaliterations: 0
```

```

iterations: 5
funcCount: 7
algorithm: 'bisection, interpolation'
message: 'Zero found in the interval [0, 1]'

```

$fval = 0$  means  $\text{fun}(x) = 0$ , as desired.

- “Roots of Scalar Functions”
- “Parameterizing Functions”

## Input Arguments

### **fun** — Function to solve

function handle

Function to solve, specified as a handle to a scalar-valued function. **fun** accepts a scalar  $x$  and returns a scalar  $\text{fun}(x)$ .

**fzero** solves  $\text{fun}(x) = 0$ . To solve an equation  $\text{fun}(x) = c(x)$ , instead solve  $\text{fun2}(x) = \text{fun}(x) - c(x) = 0$ .

To include extra parameters in your function, see the example “Root of Function with Extra Parameter” on page 1-2986 and the section “Parameterizing Functions”.

Example: `@sin`

Example: `@myFunction`

Example: `@(x)(x-a)^5 - 3*x + a - 1`

Data Types: `function_handle`

### **x0** — Initial value

scalar | 2-element vector

Initial value, specified as a real scalar or a 2-element real vector.

- Scalar — **fzero** begins at  $x0$  and tries to locate a point  $x1$  where  $\text{fun}(x1)$  has the opposite sign of  $\text{fun}(x0)$ . Then **fzero** iteratively shrinks the interval where **fun** changes sign to reach a solution.
- 2-element vector — **fzero** checks that  $\text{fun}(x0(1))$  and  $\text{fun}(x0(2))$  have opposite signs, and errors if they do not. It then iteratively shrinks the interval where **fun**

changes sign to reach a solution. An interval `x0` must be finite; it cannot contain  $\pm\text{Inf}$ .

---

**Tip** Calling `fzero` with an interval (`x0` with two elements) is often faster than calling it with a scalar `x0`.

---

Example: 3

Example: [2,17]

Data Types: double

### **options** — Options for solution process

structure, typically created using `optimset`

Options for solution process, specified as a structure. Create or modify the `options` structure using `optimset`. `fzero` uses these `options` structure fields.

|                    |                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Display</b>     | Level of display: <ul style="list-style-type: none"><li>• 'off' displays no output.</li><li>• 'iter' displays output at each iteration.</li><li>• 'final' displays just the final output.</li><li>• 'notify' (default) displays output only if the function does not converge.</li></ul>      |
| <b>FunValCheck</b> | Check whether objective function values are valid. <ul style="list-style-type: none"><li>• 'on' displays an error when the objective function returns a value that is <code>complex</code>, <code>Inf</code>, or <code>NaN</code>.</li><li>• The default, 'off', displays no error.</li></ul> |
| <b>OutputFcn</b>   | Specify one or more user-defined functions that an optimization function calls at each iteration, either as a function handle or as a cell array of function handles. The default is none ( <code>[]</code> ). See “Output Functions”.                                                        |
| <b>PlotFcns</b>    | Plot various measures of progress while the algorithm executes. Select from predefined plots or write your own. Pass a function handle or a cell array of function handles. The default is none ( <code>[]</code> ).                                                                          |

- `@optimplotx` plots the current point.
- `@optimplotfval` plots the function value.

For information on writing a custom plot function, see “Plot Functions”.

**TolX** Termination tolerance on  $x$ , a positive scalar. The default is `eps`,  $2.2204e-16$ .

Example: `options = optimset('FunValCheck','on')`

Data Types: `struct`

### **problem** — Root-finding problem

structure

Root-finding problem, specified as a structure with all of the following fields.

|                  |                                                                  |
|------------------|------------------------------------------------------------------|
| <b>objective</b> | Objective function                                               |
| <b>x0</b>        | Initial point for $x$ , real scalar or 2-element vector          |
| <b>solver</b>    | 'fzero'                                                          |
| <b>options</b>   | Options structure, typically created using <code>optimset</code> |

For an example, see “Solve Problem Structure” on page 1-2987.

Data Types: `struct`

## Output Arguments

### **x** — Location of root or sign change

real scalar

Location of root or sign change, returned as a scalar.

### **fval** — Function value at $x$

real scalar

Function value at  $x$ , returned as a scalar.

### **exitflag** — Integer encoding the exit condition

integer

Integer encoding the exit condition, meaning the reason `fzero` stopped its iterations.

- 1 Function converged to a solution  $x$ .
- 1 Algorithm was terminated by the output function or plot function.
- 3 NaN or Inf function value was encountered while searching for an interval containing a sign change.
- 4 Complex function value was encountered while searching for an interval containing a sign change.
- 5 Algorithm might have converged to a singular point.
- 6 `fzero` did not detect a sign change.

## **output — Information about root-finding process**

structure

Information about root-finding process, returned as a structure. The fields of the structure are:

|                                 |                                                                  |
|---------------------------------|------------------------------------------------------------------|
| <code>intervaliterations</code> | Number of iterations taken to find an interval containing a root |
| <code>iterations</code>         | Number of zero-finding iterations                                |
| <code>funcCount</code>          | Number of function evaluations                                   |
| <code>algorithm</code>          | 'bisection, interpolation'                                       |
| <code>message</code>            | Exit message                                                     |

## **More About**

### **Algorithms**

The `fzero` command is a function file. The algorithm, created by T. Dekker, uses a combination of bisection, secant, and inverse quadratic interpolation methods. An Algol 60 version, with some improvements, is given in [1]. A Fortran version, upon which `fzero` is based, is in [2].

## **matlab.unittest.FunctionTestCase class**

**Package:** matlab.unittest

**Superclasses:** matlab.unittest.TestCase

TestCase used for function-based tests

### **Description**

The `FunctionTestCase` class is a subclass of `TestCase` that allows function-based tests to use qualification functions in the `matlab.unittest.qualifications` package. For each test function, MATLAB creates an instance of the `FunctionTestCase` class and passes it to the test function.

The `functiontests` function constructs `FunctionTestCase` instances, so there is no need for test authors to construct this class directly.

**Introduced in R2013b**

# gallery

Test matrices

## Syntax

```
[A,B,C,...] = gallery(matname,P1,P2,...)
[A,B,C,...] = gallery(matname,P1,P2,...,classname)
gallery(3)
gallery(5)
```

## Description

`[A,B,C,...] = gallery(matname,P1,P2,...)` returns the test matrices specified by the quoted string `matname`. The `matname` input is the name of a matrix family selected from the table below. `P1,P2,...` are input parameters required by the individual matrix family. The number of optional parameters `P1,P2,...` used in the calling syntax varies from matrix to matrix. The exact calling syntaxes are detailed in the individual matrix descriptions below.

`[A,B,C,...] = gallery(matname,P1,P2,...,classname)` produces a matrix of class `classname`. The `classname` input is a quoted string that must be either `'single'` or `'double'` (unless `matname` is `'integerdata'`, in which case `'int8'`, `'int16'`, `'int32'`, `'uint8'`, `'uint16'`, and `'uint32'` are also allowed). If `classname` is not specified, then the class of the matrix is determined from those arguments among `P1,P2,...` that do not specify dimensions or select an option. If any of these arguments is of class `single` then the matrix is `single`; otherwise the matrix is `double`.

`gallery(3)` is a badly conditioned 3-by-3 matrix and `gallery(5)` is an interesting eigenvalue problem.

The gallery holds over fifty different test matrix functions useful for testing algorithms and other purposes.

### binomial — Multiple of involutory matrix

`A = gallery('binomial',n)` returns an  $n$ -by- $n$  matrix, with integer entries such that  $A^2 = 2^{(n-1)} \cdot \text{eye}(n)$ .

Thus,  $B = A^{2^{(1-n)/2}}$  is involutory, that is,  $B^2 = \text{eye}(n)$ .

### **cauchy — Cauchy matrix**

`C = gallery('cauchy',x,y)` returns an  $n$ -by- $n$  matrix,  $C(i,j) = 1/(x(i)+y(j))$ . Arguments  $x$  and  $y$  are vectors of length  $n$ . If you pass in scalars for  $x$  and  $y$ , they are interpreted as vectors  $1:x$  and  $1:y$ .

`C = gallery('cauchy',x)` returns the same as above with  $y = x$ . That is, the command returns  $C(i,j) = 1/(x(i)+x(j))$ .

Explicit formulas are known for the inverse and determinant of a Cauchy matrix. The determinant  $\det(C)$  is nonzero if  $x$  and  $y$  both have distinct elements.  $C$  is totally positive if  $0 < x(1) < \dots < x(n)$  and  $0 < y(1) < \dots < y(n)$ .

### **chebspec — Chebyshev spectral differentiation matrix**

`C = gallery('chebspec',n,switch)` returns a Chebyshev spectral differentiation matrix of order  $n$ . Argument `switch` is a variable that determines the character of the output matrix. By default, `switch = 0`.

For `switch = 0` (“no boundary conditions”),  $C$  is nilpotent ( $C^n = 0$ ) and has the null vector `ones(n,1)`. The matrix  $C$  is similar to a Jordan block of size  $n$  with eigenvalue zero.

For `switch = 1`,  $C$  is nonsingular and well-conditioned, and its eigenvalues have negative real parts.

The eigenvector matrix of the Chebyshev spectral differentiation matrix is ill-conditioned.

### **chebvand — Vandermonde-like matrix for the Chebyshev polynomials**

`C = gallery('chebvand',p)` produces the (primal) Chebyshev Vandermonde matrix based on the vector of points  $p$ , which define where the Chebyshev polynomial is calculated.

`C = gallery('chebvand',m,p)` where  $m$  is scalar, produces a rectangular version of the above, with  $m$  rows.

If  $\mathbf{p}$  is a vector, then  $C(i,j) = T_{i-1}(p(j))$  where  $T_{i-1}$  is the Chebyshev polynomial of degree  $i-1$ . If  $\mathbf{p}$  is a scalar, then  $\mathbf{p}$  equally spaced points on the interval  $[0, 1]$  are used to calculate  $\mathbf{C}$ .

## chow — Singular Toeplitz lower Hessenberg matrix

$\mathbf{A} = \text{gallery}('chow', n, \alpha, \delta)$  returns  $\mathbf{A}$  such that

$\mathbf{A} = \mathbf{H}(\alpha) + \delta \cdot \text{eye}(n)$ , where  $H_{i,j}(\alpha) = \alpha^{(i-j+1)}$  and argument  $n$  is the order of the Chow matrix. Default value for scalars  $\alpha$  and  $\delta$  are 1 and 0, respectively.

$\mathbf{H}(\alpha)$  has  $p = \text{floor}(n/2)$  eigenvalues that are equal to zero. The rest of the eigenvalues are equal to  $4 \cdot \alpha \cdot \cos(k \cdot \pi / (n+2))^2$ ,  $k=1:n-p$ .

## circul — Circulant matrix

$\mathbf{C} = \text{gallery}('circul', \mathbf{v})$  returns the circulant matrix whose first row is the vector  $\mathbf{v}$ .

A circulant matrix has the property that each row is obtained from the previous one by cyclically permuting the entries one step forward. It is a special Toeplitz matrix in which the diagonals “wrap around.”

If  $\mathbf{v}$  is a scalar, then  $\mathbf{C} = \text{gallery}('circul', 1:\mathbf{v})$ .

The eigensystem of  $\mathbf{C}$  ( $n$ -by- $n$ ) is known explicitly: If  $t$  is an  $n$ th root of unity, then the inner product of  $\mathbf{v}$  and  $\mathbf{w} = [1 \ t \ t^2 \ \dots \ t^{(n-1)}]$  is an eigenvalue of  $\mathbf{C}$  and  $\mathbf{w}(n:-1:1)$  is an eigenvector.

## clement — Tridiagonal matrix with zero diagonal entries

$\mathbf{A} = \text{gallery}('clement', n, k)$  returns an  $n$ -by- $n$  tridiagonal matrix with zeros on its main diagonal and known eigenvalues. It is singular if  $n$  is odd. About 64 percent of the entries of the inverse are zero. The eigenvalues include plus and minus the numbers  $n-1$ ,  $n-3$ ,  $n-5$ ,  $\dots$ , (1 or 0).

For  $k=0$  (the default),  $\mathbf{A}$  is nonsymmetric. For  $k=1$ ,  $\mathbf{A}$  is symmetric.

$\text{gallery}('clement', n, 1)$  is diagonally similar to  $\text{gallery}('clement', n)$ .

For odd  $N = 2 \cdot M + 1$ ,  $M+1$  of the singular values are the integers  $\text{sqrt}((2 \cdot M + 1)^2 - (2 \cdot K + 1)^2)$ ,  $K = 0:M$ .

---

**Note:** Similar properties hold for `gallery('tridiag',x,y,z)` where  $y = \text{zeros}(n, 1)$ . The eigenvalues still come in plus/minus pairs but they are not known explicitly.

---

### **compar — Comparison matrices**

`A = gallery('compar',A,1)` returns `A` with each diagonal element replaced by its absolute value, and each off-diagonal element replaced by minus the absolute value of the largest element in absolute value in its row. However, if `A` is triangular `compar(A,1)` is too.

`gallery('compar',A)` is `diag(B) - tril(B,-1) - triu(B,1)`, where  $B = \text{abs}(A)$ . `compar(A)` is often denoted by  $M(A)$  in the literature.

`gallery('compar',A,0)` is the same as `gallery('compar',A)`.

### **condex — Counter-examples to matrix condition number estimators**

`A = gallery('condex',n,k,theta)` returns a “counter-example” matrix to a condition estimator. It has order  $n$  and scalar parameter `theta` (default 100).

The matrix, its natural size, and the estimator to which it applies are specified by `k`:

|                    |            |                                                                                                      |
|--------------------|------------|------------------------------------------------------------------------------------------------------|
| <code>k = 1</code> | 4-by-4     | LINPACK                                                                                              |
| <code>k = 2</code> | 3-by-3     | LINPACK                                                                                              |
| <code>k = 3</code> | arbitrary  | LINPACK ( <code>rcond</code> ) (independent of <code>theta</code> )                                  |
| <code>k = 4</code> | $n \geq 4$ | LAPACK ( <code>RCOND</code> ) (default). It is the inverse of this matrix that is a counter-example. |

If  $n$  is not equal to the natural size of the matrix, then the matrix is padded out with an identity matrix to order  $n$ .

### **cycol — Matrix whose columns repeat cyclically**

`A = gallery('cycol',[m n],k)` returns an  $m$ -by- $n$  matrix with cyclically repeating columns, where one “cycle” consists of `randn(m,k)`. Thus, the rank of matrix `A` cannot exceed `k`, and `k` must be a scalar.

Argument  $k$  defaults to  $\text{round}(n/4)$ , and need not evenly divide  $n$ .

$A = \text{gallery}('cycol', n, k)$ , where  $n$  is a scalar, is the same as  $\text{gallery}('cycol', [n \ n], k)$ .

### **dorr — Diagonally dominant, ill-conditioned, tridiagonal matrix**

$[c, d, e] = \text{gallery}('dorr', n, \theta)$  returns the vectors defining an  $n$ -by- $n$ , row diagonally dominant, tridiagonal matrix that is ill-conditioned for small nonnegative values of  $\theta$ . The default value of  $\theta$  is 0.01. The Dorr matrix itself is the same as  $\text{gallery}('tridiag', c, d, e)$ .

$A = \text{gallery}('dorr', n, \theta)$  returns the matrix itself, rather than the defining vectors.

### **dramadah — Matrix of zeros and ones whose inverse has large integer entries**

$A = \text{gallery}('dramadah', n, k)$  returns an  $n$ -by- $n$  matrix of 0's and 1's for which  $\mu(A) = \text{norm}(\text{inv}(A), 'fro')$  is relatively large, although not necessarily maximal. An anti-Hadamard matrix  $A$  is a matrix with elements 0 or 1 for which  $\mu(A)$  is maximal.

$n$  and  $k$  must both be scalars. Argument  $k$  determines the character of the output matrix:

|         |                                                                                                                                                                                                     |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $k = 1$ | Default. $A$ is Toeplitz, with $\text{abs}(\det(A)) = 1$ , and $\mu(A) > c(1.75)^n$ , where $c$ is a constant. The inverse of $A$ has integer entries.                                              |
| $k = 2$ | $A$ is upper triangular and Toeplitz. The inverse of $A$ has integer entries.                                                                                                                       |
| $k = 3$ | $A$ has maximal determinant among lower Hessenberg (0,1) matrices. $\det(A) =$ the $n$ th Fibonacci number. $A$ is Toeplitz. The eigenvalues have an interesting distribution in the complex plane. |

### **fiedler — Symmetric matrix**

$A = \text{gallery}('fiedler', c)$ , where  $c$  is a length  $n$  vector, returns the  $n$ -by- $n$  symmetric matrix with elements  $\text{abs}(n(i) - n(j))$ . For scalar  $c$ ,  
 $A = \text{gallery}('fiedler', 1:c)$ .

Matrix  $A$  has a dominant positive eigenvalue and all the other eigenvalues are negative.

Explicit formulas for  $\text{inv}(A)$  and  $\text{det}(A)$  are given in [Todd, J., *Basic Numerical Mathematics*, Vol. 2: Numerical Algebra, Birkhauser, Basel, and Academic Press, New York, 1977, p. 159] and attributed to Fiedler. These indicate that  $\text{inv}(A)$  is tridiagonal except for nonzero  $(1, n)$  and  $(n, 1)$  elements.

### **forsythe — Perturbed Jordan block**

$A = \text{gallery}('forsythe', n, \alpha, \lambda)$  returns the  $n$ -by- $n$  matrix equal to the Jordan block with eigenvalue  $\lambda$ , excepting that  $A(n, 1) = \alpha$ . The default values of scalars  $\alpha$  and  $\lambda$  are  $\text{sqrt}(\text{eps})$  and  $0$ , respectively.

The characteristic polynomial of  $A$  is given by:

$$\text{det}(A - t \cdot I) = (\lambda - t)^n - \alpha \cdot (-1)^n.$$

### **frank — Matrix with ill-conditioned eigenvalues**

$F = \text{gallery}('frank', n, k)$  returns the Frank matrix of order  $n$ . It is upper Hessenberg with determinant 1. If  $k = 1$ , the elements are reflected about the anti-diagonal  $(1, n) - (n, 1)$ . The eigenvalues of  $F$  may be obtained in terms of the zeros of the Hermite polynomials. They are positive and occur in reciprocal pairs; thus if  $n$  is odd, 1 is an eigenvalue.  $F$  has  $\text{floor}(n/2)$  ill-conditioned eigenvalues — the smaller ones.

### **gcdmat — Greatest common divisor matrix**

$A = \text{gallery}('gcdmat', n)$  returns the  $n$ -by- $n$  matrix with  $(i, j)$  entry  $\text{gcd}(i, j)$ . Matrix  $A$  is symmetric positive definite, and  $A.^r$  is symmetric positive semidefinite for all nonnegative  $r$ .

### **gearmat — Gear matrix**

$A = \text{gallery}('gearmat', n, i, j)$  returns the  $n$ -by- $n$  matrix with ones on the sub- and super-diagonals,  $\text{sign}(i)$  in the  $(1, \text{abs}(i))$  position,  $\text{sign}(j)$  in the  $(n, n+1-\text{abs}(j))$  position, and zeros everywhere else. Arguments  $i$  and  $j$  default to  $n$  and  $-n$ , respectively.

Matrix  $A$  is singular, can have double and triple eigenvalues, and can be defective.

All eigenvalues are of the form  $2 \cdot \cos(a)$  and the eigenvectors are of the form  $[\sin(w+a), \sin(w+2a), \dots, \sin(w+n \cdot a)]$ , where  $a$  and  $w$  are given in Gear, C. W., "A

Simple Set of Test Matrices for Eigenvalue Programs," *Math. Comp.*, Vol. 23 (1969), pp. 119-125.

## grcar — Toeplitz matrix with sensitive eigenvalues

`A = gallery('grcar', n, k)` returns an  $n$ -by- $n$  Toeplitz matrix with  $-1$ s on the subdiagonal,  $1$ s on the diagonal, and  $k$  superdiagonals of  $1$ s. The default is  $k = 3$ . The eigenvalues are sensitive.

## hanowa — Matrix whose eigenvalues lie on a vertical line in the complex plane

`A = gallery('hanowa', n, d)` returns an  $n$ -by- $n$  block 2-by-2 matrix of the form:

```
[d*eye(m) -diag(1:m)
diag(1:m) d*eye(m)]
```

Argument  $n$  is an even integer  $n=2*m$ . Matrix  $A$  has complex eigenvalues of the form  $d \pm k*i$ , for  $1 \leq k \leq m$ . The default value of  $d$  is  $-1$ .

## house — Householder matrix

`[v, beta, s] = gallery('house', x, k)` takes  $x$ , an  $n$ -element column vector, and returns  $V$  and  $\beta$  such that  $H*x = s*e1$ . In this expression,  $e1$  is the first column of  $\text{eye}(n)$ ,  $\text{abs}(s) = \text{norm}(x)$ , and  $H = \text{eye}(n) - \beta*v*v'$  is a Householder matrix.

$k$  determines the sign of  $s$ :

|         |                                                 |
|---------|-------------------------------------------------|
| $k = 0$ | $\text{sign}(s) = -\text{sign}(x(1))$ (default) |
| $k = 1$ | $\text{sign}(s) = \text{sign}(x(1))$            |
| $k = 2$ | $\text{sign}(s) = 1$ ( $x$ must be real)        |

If  $x$  is complex, then  $\text{sign}(x) = x./\text{abs}(x)$  when  $x$  is nonzero.

If  $x = 0$ , or if  $x = \alpha*e1$  ( $\alpha \geq 0$ ) and either  $k = 1$  or  $k = 2$ , then  $V = 0$ ,  $\beta = 1$ , and  $s = x(1)$ . In this case,  $H$  is the identity matrix, which is not strictly a Householder matrix.

`[v, beta] = gallery('house', x)` takes `x`, a scalar or `n`-element column vector, and returns `v` and `beta` such that `eye(n,n) - beta*v*v'` is a Householder matrix. A Householder matrix `H` satisfies the relationship

$$H*x = -\text{sign}(x(1))*\text{norm}(x)*e1$$

where `e1` is the first column of `eye(n,n)`. Note that if `x` is complex, then `sign(x)exp(i*arg(x))` (which equals `x./abs(x)` when `x` is nonzero).

If `x = 0`, then `v = 0` and `beta = 1`.

## **integerdata — Array of arbitrary data from uniform distribution on specified range of integers**

`A = gallery('integerdata', imax, [m,n,...], j)` returns an `m`-by-`n`-by-... array `A` whose values are a sample from the uniform distribution on the integers `1:imax`. `j` must be an integer value in the interval `[0, 2^32-1]`. Calling `gallery('integerdata', ...)` with different values of `J` will return different arrays. Repeated calls to `gallery('integerdata', ...)` with the same `imax`, size vector and `j` inputs will always return the same array.

In any call to `gallery('integerdata', ...)` you can substitute individual inputs `m,n,...` for the size vector input `[m,n,...]`. For example, `gallery('integerdata', 7, [1,2,3,4], 5)` is equivalent to `gallery('integerdata', 7, 1, 2, 3, 4, 5)`.

`A = gallery('integerdata', [imin imax], [m,n,...], j)` returns an `m`-by-`n`-by-... array `A` whose values are a sample from the uniform distribution on the integers `imin:imax`.

`[A,B,...] = gallery('integerdata', [imin imax], [m,n,...], j)` returns multiple `m`-by-`n`-by-... arrays `A, B, ...`, containing different values.

`A = gallery('integerdata', [imin imax], [m,n,...], j, classname)` produces an array of class `classname`. `classname` must be `'uint8'`, `'uint16'`, `'uint32'`, `'int8'`, `'int16'`, `'int32'`, `'single'` or `'double'`.

## **invhess — Inverse of an upper Hessenberg matrix**

`A = gallery('invhess', x, y)`, where `x` is a length `n` vector and `y` is a length `n-1` vector, returns the matrix whose lower triangle agrees with that of `ones(n,1)*x'` and whose strict upper triangle agrees with that of `[1 y]*ones(1,n)`.

The matrix is nonsingular if  $x(1) \neq 0$  and  $x(i+1) \neq y(i)$  for all  $i$ , and its inverse is an upper Hessenberg matrix. Argument  $y$  defaults to  $-x(1:n-1)$ .

If  $x$  is a scalar, `invhess(x)` is the same as `invhess(1:x)`.

## **invol — Involutory matrix**

`A = gallery('invol',n)` returns an  $n$ -by- $n$  involutory ( $A^*A = \text{eye}(n)$ ) and ill-conditioned matrix. It is a diagonally scaled version of `hilb(n)`.

$B = (\text{eye}(n) - A) / 2$  and  $B = (\text{eye}(n) + A) / 2$  are idempotent ( $B^*B = B$ ).

## **ipjfact — Hankel matrix with factorial elements**

`[A,d] = gallery('ipjfact',n,k)` returns  $A$ , an  $n$ -by- $n$  Hankel matrix, and  $d$ , the determinant of  $A$ , which is known explicitly. If  $k = 0$  (the default), then the elements of  $A$  are  $A(i,j) = (i+j)!$ . If  $k = 1$ , then the elements of  $A$  are  $A(i,j) = 1 / (i+j)$ .

Note that the inverse of  $A$  is also known explicitly.

## **jordbloc — Jordan block**

`A = gallery('jordbloc',n,lambda)` returns the  $n$ -by- $n$  Jordan block with eigenvalue  $\lambda$ . The default value for  $\lambda$  is 1.

## **kahan — Upper trapezoidal matrix**

`A = gallery('kahan',n,theta,pert)` returns an upper trapezoidal matrix that has interesting properties regarding estimation of condition and rank.

If  $n$  is a two-element vector, then  $A$  is  $n(1)$ -by- $n(2)$ ; otherwise,  $A$  is  $n$ -by- $n$ . The useful range of  $\theta$  is  $0 < \theta < \pi$ , with a default value of 1.2.

To ensure that the QR factorization with column pivoting does not interchange columns in the presence of rounding errors, the diagonal is perturbed by `pert*eps*diag([n:-1:1])`. The default `pert` is 25, which ensures no interchanges for `gallery('kahan',n)` up to at least  $n = 90$  in IEEE arithmetic.

## **kms — Kac-Murdock-Szego Toeplitz matrix**

`A = gallery('kms',n,rho)` returns the  $n$ -by- $n$  Kac-Murdock-Szego Toeplitz matrix such that  $A(i,j) = \rho^{(\text{abs}(i-j))}$ , for real  $\rho$ .

For complex  $\rho$ , the same formula holds except that elements below the diagonal are conjugated.  $\rho$  defaults to 0.5.

The KMS matrix  $A$  has these properties:

- An LDL' factorization with  $L = \text{inv}(\text{gallery('triu',n,-rho,1)})'$ , and  $D(i,i) = (1 - \text{abs}(\rho)^2) * \text{eye}(n)$ , except  $D(1,1) = 1$ .
- Positive definite if and only if  $0 < \text{abs}(\rho) < 1$ .
- The inverse  $\text{inv}(A)$  is tridiagonal.

## **krylov — Krylov matrix**

`B = gallery('krylov',A,x,j)` returns the Krylov matrix

$[x, Ax, A^2x, \dots, A^{(j-1)}x]$

where  $A$  is an  $n$ -by- $n$  matrix and  $x$  is a length  $n$  vector. The defaults are  $x = \text{ones}(n,1)$ , and  $j = n$ .

`B = gallery('krylov',n)` is the same as `gallery('krylov',randn(n))`.

## **lauchli — Rectangular matrix**

`A = gallery('lauchli',n,mu)` returns the  $(n+1)$ -by- $n$  matrix

$[\text{ones}(1,n); \mu * \text{eye}(n)]$

The Lauchli matrix is a well-known example in least squares and other problems that indicates the dangers of forming  $A' * A$ . Argument  $\mu$  defaults to  $\text{sqrt}(\text{eps})$ .

## **lehmer — Symmetric positive definite matrix**

`A = gallery('lehmer',n)` returns the symmetric positive definite  $n$ -by- $n$  matrix such that  $A(i,j) = i/j$  for  $j \geq i$ .

The Lehmer matrix  $A$  has these properties:

- $A$  is totally nonnegative.
- The inverse  $\text{inv}(A)$  is tridiagonal and explicitly known.
- The order  $n \leq \text{cond}(A) \leq 4*n*n$ .

## leslie — Matrix of birth numbers and survival rates

$L = \text{gallery}('leslie', a, b)$  is the  $n$ -by- $n$  matrix from the Leslie population model with average birth numbers  $a(1:n)$  and survival rates  $b(1:n-1)$ . It is zero, apart from the first row (which contains the  $a(i)$ ) and the first subdiagonal (which contains the  $b(i)$ ). For a valid model, the  $a(i)$  are nonnegative and the  $b(i)$  are positive and bounded by 1, i.e.,  $0 < b(i) \leq 1$ .

$L = \text{gallery}('leslie', n)$  generates the Leslie matrix with  $a = \text{ones}(n, 1)$ ,  $b = \text{ones}(n-1, 1)$ .

## lesp — Tridiagonal matrix with real, sensitive eigenvalues

$A = \text{gallery}('lesp', n)$  returns an  $n$ -by- $n$  matrix whose eigenvalues are real and smoothly distributed in the interval approximately  $[-2*N-3.5, -4.5]$ .

The sensitivities of the eigenvalues increase exponentially as the eigenvalues grow more negative. The matrix is similar to the symmetric tridiagonal matrix with the same diagonal entries and with off-diagonal entries 1, via a similarity transformation with  $D = \text{diag}(1!, 2!, \dots, n!)$ .

## lotkin — Lotkin matrix

$A = \text{gallery}('lotkin', n)$  returns the Hilbert matrix with its first row altered to all ones. The Lotkin matrix  $A$  is nonsymmetric, ill-conditioned, and has many negative eigenvalues of small magnitude. Its inverse has integer entries and is known explicitly.

## minij — Symmetric positive definite matrix

$A = \text{gallery}('minij', n)$  returns the  $n$ -by- $n$  symmetric positive definite matrix with  $A(i, j) = \min(i, j)$ .

The `minij` matrix has these properties:

- The inverse `inv(A)` is tridiagonal and equal to -1 times the second difference matrix, except its  $(n,n)$  element is 1.
- Givens' matrix, `2*A-ones(size(A))`, has tridiagonal inverse and eigenvalues  $0.5*\sec((2*r-1)*\pi/(4*n))^2$ , where  $r=1:n$ .
- $(n+1)*\text{ones}(\text{size}(A))-A$  has elements that are  $\max(i,j)$  and a tridiagonal inverse.

### **moler — Symmetric positive definite matrix**

`A = gallery('moler',n,alpha)` returns the symmetric positive definite  $n$ -by- $n$  matrix  $U^*U$ , where  $U = \text{gallery}('triw',n,alpha)$ .

For the default  $\alpha = -1$ ,  $A(i,j) = \min(i,j) - 2$ , and  $A(i,i) = i$ . One of the eigenvalues of  $A$  is small.

### **neumann — Singular matrix from the discrete Neumann problem (sparse)**

`C = gallery('neumann',n)` returns the sparse  $n$ -by- $n$  singular, row diagonally dominant matrix resulting from discretizing the Neumann problem with the usual five-point operator on a regular mesh. Argument  $n$  is a perfect square integer  $n = m^2$  or a two-element vector.  $C$  is sparse and has a one-dimensional null space with null vector `ones(n,1)`.

### **normaldata — Array of arbitrary data from standard normal distribution**

`A = gallery('normaldata',[m,n,...],j)` returns an  $m$ -by- $n$ -by-... array  $A$ . The values of  $A$  are a random sample from the standard normal distribution.  $j$  must be an integer value in the interval  $[0, 2^{32}-1]$ . Calling `gallery('normaldata',...)` with different values of  $j$  will return different arrays. Repeated calls to `gallery('normaldata',...)` with the same size vector and  $j$  inputs will always return the same array.

In any call to `gallery('normaldata',...)` you can substitute individual inputs  $m,n,...$  for the size vector input  $[m,n,...]$ . For example, `gallery('normaldata',[1,2,3,4],5)` is equivalent to `gallery('normaldata',1,2,3,4,5)`.

`[A,B,...] = gallery('normaldata',[m,n,...],j)` returns multiple m-by-n-by-... arrays A, B, ..., containing different values.

`A = gallery('normaldata',[m,n,...],j,classname)` produces a matrix of class `classname`. `classname` must be either `'single'` or `'double'`.

Generate the arbitrary 6-by-4 matrix of data from the standard normal distribution  $N(0, 1)$  corresponding to `j = 2`:

```
x = gallery('normaldata', [6, 4], 2);
```

Generate the arbitrary 1-by-2-by-3 single array of data from the standard normal distribution  $N(0, 1)$  corresponding to `j = 17`:

```
y = gallery('normaldata', 1, 2, 3, 17, 'single');
```

## orthog — Orthogonal and nearly orthogonal matrices

`Q = gallery('orthog',n,k)` returns the `k`th type of matrix of order `n`, where `k > 0` selects exactly orthogonal matrices, and `k < 0` selects diagonal scalings of orthogonal matrices. Available types are:

|                    |                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>k = 1</code> | $Q(i,j) = \sqrt{2/(n+1)} * \sin(i*j*\pi/(n+1))$ <p>Symmetric eigenvector matrix for second difference matrix. This is the default.</p>                                                           |
| <code>k = 2</code> | $Q(i,j) = 2/(\sqrt{2*n+1}) * \sin(2*i*j*\pi/(2*n+1))$ <p>Symmetric.</p>                                                                                                                          |
| <code>k = 3</code> | $Q(r,s) = \exp(2*\pi*i*(r-1)*(s-1)/n) / \sqrt{n}$ <p>Unitary, the Fourier matrix. <math>Q^4</math> is the identity. This is essentially the same matrix as <code>fft(eye(n))/sqrt(n)!</code></p> |
| <code>k = 4</code> | <p>Helmert matrix: a permutation of a lower Hessenberg matrix, whose first row is <code>ones(1:n)/sqrt(n)</code>.</p>                                                                            |
| <code>k = 5</code> | $Q(i,j) = \sin(2*\pi*(i-1)*(j-1)/n) + \cos(2*\pi*(i-1)*(j-1)/n)$ <p>Symmetric matrix arising in the Hartley transform.</p>                                                                       |

|          |                                                                                                                  |
|----------|------------------------------------------------------------------------------------------------------------------|
| $k = 6$  | $Q(i, j) = \sqrt{2/n} * \cos((i-1/2)*(j-1/2)*\pi/n)$<br>Symmetric matrix arising as a discrete cosine transform. |
| $k = -1$ | $Q(i, j) = \cos((i-1)*(j-1)*\pi/(n-1))$<br>Chebyshev Vandermonde-like matrix, based on extrema of $T(n-1)$ .     |
| $k = -2$ | $Q(i, j) = \cos((i-1)*(j-1/2)*\pi/n)$<br>Chebyshev Vandermonde-like matrix, based on zeros of $T(n)$ .           |

### **parter — Toeplitz matrix with singular values near pi**

$C = \text{gallery}('parter', n)$  returns the matrix  $C$  such that  $C(i, j) = 1/(i-j+0.5)$ .

$C$  is a Cauchy matrix and a Toeplitz matrix. Most of the singular values of  $C$  are very close to  $\pi$ .

### **pei — Pei matrix**

$A = \text{gallery}('pei', n, \alpha)$ , where  $\alpha$  is a scalar, returns the symmetric matrix  $\alpha * \text{eye}(n) + \text{ones}(n)$ . The default for  $\alpha$  is 1. The matrix is singular for  $\alpha$  equal to either 0 or  $-n$ .

### **poisson — Block tridiagonal matrix from Poisson's equation (sparse)**

$A = \text{gallery}('poisson', n)$  returns the block tridiagonal (sparse) matrix of order  $n^2$  resulting from discretizing Poisson's equation with the 5-point operator on an  $n$ -by- $n$  mesh.

### **prolate — Symmetric, ill-conditioned Toeplitz matrix**

$A = \text{gallery}('prolate', n, w)$  returns the  $n$ -by- $n$  prolate matrix with parameter  $w$ . It is a symmetric Toeplitz matrix.

If  $0 < w < 0.5$  then  $A$  is positive definite

- The eigenvalues of  $A$  are distinct, lie in  $(0, 1)$ , and tend to cluster around 0 and 1.
- The default value of  $w$  is 0.25.

## randcolu — Random matrix with normalized cols and specified singular values

`A = gallery('randcolu',n)` is a random  $n$ -by- $n$  matrix with columns of unit 2-norm, with random singular values whose squares are from a uniform distribution.

`A'*A` is a correlation matrix of the form produced by `gallery('randcorr',n)`.

`gallery('randcolu',x)` where  $x$  is an  $n$ -vector ( $n > 1$ ), produces a random  $n$ -by- $n$  matrix having singular values given by the vector  $x$ . The vector  $x$  must have nonnegative elements whose sum of squares is  $n$ .

`gallery('randcolu',x,m)` where  $m \geq n$ , produces an  $m$ -by- $n$  matrix.

`gallery('randcolu',x,m,k)` provides a further option:

|                    |                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>k = 0</code> | <code>diag(x)</code> is initially subjected to a random two-sided orthogonal transformation, and then a sequence of Givens rotations is applied (default). |
| <code>k = 1</code> | The initial transformation is omitted. This is much faster, but the resulting matrix may have zero entries.                                                |

For more information, see [4].

## randcorr — Random correlation matrix with specified eigenvalues

`gallery('randcorr',n)` is a random  $n$ -by- $n$  correlation matrix with random eigenvalues from a uniform distribution. A correlation matrix is a symmetric positive semidefinite matrix with 1s on the diagonal (see `corrcoef`).

`gallery('randcorr',x)` produces a random correlation matrix having eigenvalues given by the vector  $x$ , where `length(x) > 1`. The vector  $x$  must have nonnegative elements summing to `length(x)`.

`gallery('randcorr',x,k)` provides a further option:

|                    |                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>k = 0</code> | The diagonal matrix of eigenvalues is initially subjected to a random orthogonal similarity transformation, and then a sequence of Givens rotations is applied (default). |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                    |                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------|
| <code>k = 1</code> | The initial transformation is omitted. This is much faster, but the resulting matrix may have some zero entries. |
|--------------------|------------------------------------------------------------------------------------------------------------------|

For more information, see [3] and [4].

### **randhess — Random, orthogonal upper Hessenberg matrix**

`H = gallery('randhess', n)` returns an  $n$ -by- $n$  real, random, orthogonal upper Hessenberg matrix.

`H = gallery('randhess', x)` if  $x$  is an arbitrary, real, length  $n$  vector with  $n > 1$ , constructs  $H$  nonrandomly using the elements of  $x$  as parameters.

Matrix  $H$  is constructed via a product of  $n-1$  Givens rotations.

### **randjorth — Random J-orthogonal matrix**

`A = gallery('randjorth', n)`, for a positive integer  $n$ , produces a random  $n$ -by- $n$   $J$ -orthogonal matrix  $A$ , where

- `J = blkdiag(eye(ceil(n/2)), -eye(floor(n/2)))`
- `cond(A) = sqrt(1/eps)`

$J$ -orthogonality means that  $A^*J^*A = J$ . Such matrices are sometimes called *hyperbolic*.

`A = gallery('randjorth', n, m)`, for positive integers  $n$  and  $m$ , produces a random  $(n+m)$ -by- $(n+m)$   $J$ -orthogonal matrix  $A$ , where

- `J = blkdiag(eye(n), -eye(m))`
- `cond(A) = sqrt(1/eps)`

`A = gallery('randjorth', n, m, c, symm, method)`

uses the following optional input arguments:

- `c` — Specifies `cond(A)` to be the scalar `c`.
- `symm` — Enforces symmetry if the scalar `symm` is nonzero.
- `method` — calls `qr` to perform the underlying orthogonal transformations if the scalar `method` is nonzero. A call to `qr` is much faster than the default method for large dimensions

## **rando — Random matrix composed of elements -1, 0 or 1**

`A = gallery('rando', n, k)` returns a random  $n$ -by- $n$  matrix with elements from one of the following discrete distributions:

|                    |                                                                 |
|--------------------|-----------------------------------------------------------------|
| <code>k = 1</code> | <code>A(i, j) = 0 or 1</code> with equal probability (default). |
| <code>k = 2</code> | <code>A(i, j) = -1 or 1</code> with equal probability.          |
| <code>k = 3</code> | <code>A(i, j) = -1, 0 or 1</code> with equal probability.       |

Argument `n` may be a two-element vector, in which case the matrix is  $n(1)$ -by- $n(2)$ .

## **randsvd — Random matrix with preassigned singular values**

`A = gallery('randsvd', n, kappa, mode, kl, ku)` returns a banded (multidiagonal) random matrix of order  $n$  with  $\text{cond}(A) = \text{kappa}$  and singular values from the distribution `mode`. If `n` is a two-element vector, `A` is  $n(1)$ -by- $n(2)$ .

Arguments `kl` and `ku` specify the number of lower and upper off-diagonals, respectively, in `A`. If they are omitted, a full matrix is produced. If only `kl` is present, `ku` defaults to `kl`.

Distribution `mode` can be:

|     |                                                                                                                                                                                                                                                                              |
|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | One large singular value.                                                                                                                                                                                                                                                    |
| 2   | One small singular value.                                                                                                                                                                                                                                                    |
| 3   | Geometrically distributed singular values (default).                                                                                                                                                                                                                         |
| 4   | Arithmetically distributed singular values.                                                                                                                                                                                                                                  |
| 5   | Random singular values with uniformly distributed logarithm.                                                                                                                                                                                                                 |
| < 0 | If <code>mode</code> is -1, -2, -3, -4, or -5, then <code>randsvd</code> treats <code>mode</code> as <code>abs(mode)</code> , except that in the original matrix of singular values the order of the diagonal entries is reversed: small to large instead of large to small. |

Condition number `kappa` defaults to `sqrt(1/eps)`. In the special case where `kappa < 0`, `A` is a random, full, symmetric, positive definite matrix with  $\text{cond}(A) = -\text{kappa}$  and eigenvalues distributed according to `mode`. Arguments `kl` and `ku`, if present, are ignored.

`A = gallery('randsvd', n, kappa, mode, kl, ku, method)` specifies how the computations are carried out. `method = 0` is the default, while `method = 1` uses an

alternative method that is much faster for large dimensions, even though it uses more flops.

## **redheff — Redheffer's matrix of 1s and 0s**

`A = gallery('redheff', n)` returns an  $n$ -by- $n$  matrix of 0's and 1's defined by  $A(i, j) = 1$ , if  $j = 1$  or if  $i$  divides  $j$ , and  $A(i, j) = 0$  otherwise.

The Redheffer matrix has these properties:

- $(n - \text{floor}(\log_2(n))) - 1$  eigenvalues equal to 1
- A real eigenvalue (the spectral radius) approximately  $\sqrt{n}$
- A negative eigenvalue approximately  $-\sqrt{n}$
- The remaining eigenvalues are provably “small.”
- The Riemann hypothesis is true if and only if  $\det(A) = O(n^{1/2+\varepsilon})$  for every  $\varepsilon > 0$ .

Barrett and Jarvis conjecture that “the small eigenvalues all lie inside the unit circle  $\text{abs}(Z) = 1$ ,” and a proof of this conjecture, together with a proof that some eigenvalue tends to zero as  $n$  tends to infinity, would yield a new proof of the prime number theorem.

## **riemann — Matrix associated with the Riemann hypothesis**

`A = gallery('riemann', n)` returns an  $n$ -by- $n$  matrix for which the Riemann hypothesis is true if and only if

$$\det(A) = O(n!n^{-1/2+\varepsilon})$$

for every  $\varepsilon > 0$ .

The Riemann matrix is defined by:

$$A = B(2:n+1, 2:n+1)$$

where  $B(i, j) = i - 1$  if  $i$  divides  $j$ , and  $B(i, j) = -1$  otherwise.

The Riemann matrix has these properties:

- Each eigenvalue  $e(i)$  satisfies  $\text{abs}(e(i)) \leq m - 1/m$ , where  $m = n + 1$ .
- $i \leq e(i) \leq i + 1$  with at most  $m - \sqrt{m}$  exceptions.

- All integers in the interval  $(m/3, m/2]$  are eigenvalues.

### **ris — Symmetric Hankel matrix**

`A = gallery('ris', n)` returns a symmetric  $n$ -by- $n$  Hankel matrix with elements

$$A(i, j) = 0.5 / (n - i - j + 1.5)$$

The eigenvalues of `A` cluster around  $\pi/2$  and  $-\pi/2$ . This matrix was invented by F.N. Ris.

### **sampling — Nonsymmetric matrix with ill-conditioned integer eigenvalues.**

`A = gallery('sampling', x)`, where `x` is an  $n$ -vector, is the  $n$ -by- $n$  matrix with  $A(i, j) = X(i) / (X(i) - X(j))$  for  $i \neq j$  and  $A(j, j)$  the sum of the off-diagonal elements in column  $j$ . `A` has eigenvalues  $0:n-1$ . For the eigenvalues  $0$  and  $n-1$ , corresponding eigenvectors are `X` and `ones(n, 1)`, respectively.

The eigenvalues are ill-conditioned. `A` has the property that  $A(i, j) + A(j, i) = 1$  for  $i \neq j$ .

Explicit formulas are available for the left eigenvectors of `A`. For scalar  $n$ , `sampling(n)` is the same as `sampling(1:n)`. A special case of this matrix arises in sampling theory.

### **smoke — Complex matrix with a 'smoke ring' pseudospectrum**

`A = gallery('smoke', n)` returns an  $n$ -by- $n$  matrix with 1's on the superdiagonal, 1 in the  $(n, 1)$  position, and powers of roots of unity along the diagonal.

`A = gallery('smoke', n, 1)` returns the same except that element  $A(n, 1)$  is zero.

The eigenvalues of `gallery('smoke', n, 1)` are the  $n$ th roots of unity; those of `gallery('smoke', n)` are the  $n$ th roots of unity times  $2^{(1/n)}$ .

### **toepdd — Symmetric positive definite Toeplitz matrix**

`A = gallery('toepdd', n, m, w, theta)` returns an  $n$ -by- $n$  symmetric, positive semi-definite (SPD) Toeplitz matrix composed of the sum of  $m$  rank 2 (or, for certain `theta`, rank 1) SPD Toeplitz matrices. Specifically,

$$T = w(1)*T(theta(1)) + \dots + w(m)*T(theta(m))$$

where  $T(\theta(k))$  has  $(i, j)$  element  $\cos(2\pi\theta(k)(i-j))$ .

By default:  $m = n, w = \text{rand}(m, 1)$ , and  $\theta = \text{rand}(m, 1)$ .

### **toeppen — Pentadiagonal Toeplitz matrix (sparse)**

$P = \text{gallery}('toeppen', n, a, b, c, d, e)$  returns the  $n$ -by- $n$  sparse, pentadiagonal Toeplitz matrix with the diagonals:  $P(3, 1) = a, P(2, 1) = b, P(1, 1) = c, P(1, 2) = d$ , and  $P(1, 3) = e$ , where  $a, b, c, d$ , and  $e$  are scalars.

By default,  $(a, b, c, d, e) = (1, -10, 0, 10, 1)$ , yielding a matrix of Rutishauser. This matrix has eigenvalues lying approximately on the line segment  $2\cos(2\pi t) + 20i\sin(\pi t)$ .

### **tridiag — Tridiagonal matrix (sparse)**

$A = \text{gallery}('tridiag', c, d, e)$  returns the tridiagonal matrix with subdiagonal  $c$ , diagonal  $d$ , and superdiagonal  $e$ . Vectors  $c$  and  $e$  must have  $\text{length}(d) - 1$ .

$A = \text{gallery}('tridiag', n, c, d, e)$ , where  $c, d$ , and  $e$  are all scalars, yields the Toeplitz tridiagonal matrix of order  $n$  with subdiagonal elements  $c$ , diagonal elements  $d$ , and superdiagonal elements  $e$ . This matrix has eigenvalues

$$d + 2\sqrt{c \cdot e} \cos(k\pi / (n+1))$$

where  $k = 1:n$ . (see [1].)

$A = \text{gallery}('tridiag', n)$  is the same as  $A = \text{gallery}('tridiag', n, -1, 2, -1)$ , which is a symmetric positive definite M-matrix (the negative of the second difference matrix).

### **triw — Upper triangular matrix discussed by Wilkinson and others**

$A = \text{gallery}('triw', n, \alpha, k)$  returns the upper triangular matrix with ones on the diagonal and  $\alpha$ s on the first  $k \geq 0$  superdiagonals.

Order  $n$  may be a 2-element vector, in which case the matrix is  $n(1)$ -by- $n(2)$  and upper trapezoidal.

Ostrowski ["On the Spectrum of a One-parametric Family of Matrices," *J. Reine Angew. Math.*, 1954] shows that

```
cond(gallery('triw',n,2)) = cot(pi/(4*n))^2,
```

and, for large  $\text{abs}(\alpha)$ ,  $\text{cond}(\text{gallery}('triw',n,\alpha))$  is approximately  $\text{abs}(\alpha)^n \sin(\pi/(4*n-2))$ .

Adding  $-2^{(2-n)}$  to the  $(n,1)$  element makes  $\text{triw}(n)$  singular, as does adding  $-2^{(1-n)}$  to all the elements in the first column.

## **uniformdata — Array of arbitrary data from standard uniform distribution**

$A = \text{gallery}('uniformdata', [m,n,\dots], j)$  returns an  $m$ -by- $n$ -by-... array  $A$ . The values of  $A$  are a random sample from the standard uniform distribution.  $j$  must be an integer value in the interval  $[0, 2^{32}-1]$ . Calling  $\text{gallery}('uniformdata', \dots)$  with different values of  $j$  will return different arrays. Repeated calls to  $\text{gallery}('uniformdata', \dots)$  with the same size vector and  $j$  inputs will always return the same array.

In any call to  $\text{gallery}('uniformdata', \dots)$  you can substitute individual inputs  $m,n,\dots$  for the size vector input  $[m,n,\dots]$ . For example,  $\text{gallery}('uniformdata', [1,2,3,4],5)$  is equivalent to  $\text{gallery}('uniformdata', 1,2,3,4,5)$ .

$[A,B,\dots] = \text{gallery}('uniformdata', [m,n,\dots], j)$  returns multiple  $m$ -by- $n$ -by-... arrays  $A, B, \dots$ , containing different values.

$A = \text{gallery}('uniformdata', [m,n,\dots], j, \text{classname})$  produces a matrix of class  $\text{classname}$ .  $\text{classname}$  must be either 'single' or 'double'.

Generate the arbitrary 6-by-4 matrix of data from the uniform distribution on  $[0, 1]$  corresponding to  $j = 2$ .

```
x = gallery('uniformdata', [6, 4], 2);
```

Generate the arbitrary 1-by-2-by-3 single array of data from the uniform distribution on  $[0, 1]$  corresponding to  $j = 17$ .

```
y = gallery('uniformdata', 1, 2, 3, 17, 'single');
```

## **wathen — Finite element matrix (sparse, random entries)**

$A = \text{gallery}('wathen', nx, ny)$  returns a sparse, random,  $n$ -by- $n$  finite element matrix where  $n = 3*nx*ny + 2*nx + 2*ny + 1$ .

Matrix A is precisely the “consistent mass matrix” for a regular  $n_x$ -by- $n_y$  grid of 8-node (serendipity) elements in two dimensions. A is symmetric, positive definite for any (positive) values of the “density,”  $\rho(n_x, n_y)$ , which is chosen randomly in this routine.

`A = gallery('wathen', nx, ny, 1)` returns a diagonally scaled matrix such that  
 $0.25 \leq \text{eig}(\text{inv}(D)*A) \leq 4.5$

where  $D = \text{diag}(\text{diag}(A))$  for any positive integers  $n_x$  and  $n_y$  and any densities  $\rho(n_x, n_y)$ .

### wilk — Various matrices devised or discussed by Wilkinson

`gallery('wilk', n)` returns a different matrix or linear system depending on the value of  $n$ .

|          |                                                                               |
|----------|-------------------------------------------------------------------------------|
| $n = 3$  | Upper triangular system $Ux=b$ illustrating inaccurate solution.              |
| $n = 4$  | Lower triangular system $Lx=b$ , ill-conditioned.                             |
| $n = 5$  | <code>hilb(6)(1:5, 2:6)*1.8144</code> . A symmetric positive definite matrix. |
| $n = 21$ | W21+, a tridiagonal matrix. eigenvalue problem. For more detail, see [2].     |

## gamma

Gamma function

## Syntax

`Y = gamma(X)`

## Definitions

The gamma function is defined by the integral:

$$\Gamma(x) = \int_0^{\infty} e^{-t} t^{x-1} dt$$

The gamma function interpolates the factorial function. For integer  $n$ :

`gamma(n+1) = n! = prod(1:n)`

## Description

`Y = gamma(X)` returns the gamma function at the elements of  $X$ .  $X$  must be real.

## More About

### Algorithms

The computation of `gamma` is based on algorithms outlined in [1]. Several different minimax rational approximations are used depending upon the value of  $A$ .

## gammainc

Incomplete gamma function

### Syntax

```
Y = gammainc(X,A)
Y = gammainc(X,A,tail)
Y = gammainc(X,A,'scaledlower')
Y = gammainc(X,A,'scaledupper')
```

### Definitions

The incomplete gamma function is

$$\text{gammainc}(x,a) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt$$

where  $\Gamma(a)$  is the gamma function, `gamma(a)`.

For any  $A \geq 0$ , `gammainc(X,A)` approaches 1 as  $X$  approaches infinity. For small  $X$  and  $A$ , `gammainc(X,A)` is approximately equal to  $X^A$ , so `gammainc(0,0) = 1`.

### Description

`Y = gammainc(X,A)` returns the incomplete gamma function of corresponding elements of  $X$  and  $A$ . The elements of  $A$  must be nonnegative. Furthermore,  $X$  and  $A$  must be real and the same size (or either can be scalar).

`Y = gammainc(X,A,tail)` specifies the tail of the incomplete gamma function. The choices for `tail` are 'lower' (the default) and 'upper'. The upper incomplete gamma function is defined as:

$$\text{gammainc}(x,a,'upper') = \frac{1}{\Gamma(a)} \int_x^\infty t^{a-1} e^{-t} dt$$

When the upper tail value is close to 0, the 'upper' option provides a way to compute that value more accurately than by subtracting the lower tail value from 1.

`Y = gammainc(X,A,'scaledlower')` and `Y = gammainc(X,A,'scaledupper')` return the incomplete gamma function, scaled by

$$\Gamma(\alpha + 1) \left( \frac{e^x}{x^\alpha} \right).$$

These functions are unbounded above, but are useful for values of `X` and `A` where `gammainc(X,A,'lower')` or `gammainc(X,A,'upper')` underflow to zero.

---

**Note:** When `X` is negative, `Y` can be inaccurate for `abs(X) > A+1`. This applies to all syntaxes.

---

`gamma` | `gammaincinv` | `psi` | `gamma1n`

**Introduced before R2006a**

## gammaincinv

Inverse incomplete gamma function

### Syntax

```
x = gammaincinv(y,a)
x = gammaincinv(y,a,tail)
```

### Description

`x = gammaincinv(y,a)` evaluates the inverse incomplete gamma function for corresponding elements of `y` and `a`, such that `y = gammainc(x,a)`. The elements of `y` must be in the closed interval `[0,1]`, and those of `a` must be nonnegative. `y` and `a` must be real and the same size (or either can be a scalar).

`x = gammaincinv(y,a,tail)` specifies the tail of the incomplete gamma function. Choices are `'lower'` (the default) to use the integral from 0 to `x`, or `'upper'` to use the integral from `x` to infinity.

These two choices are related as:

$$\text{gammaincinv}(y,a,'upper') = \text{gammaincinv}(1-y,a,'lower').$$

When `y` is close to 0, the `'upper'` option provides a way to compute `x` more accurately than by subtracting `y` from 1.

### Definitions

The lower incomplete gamma function is defined as:

$$\text{gammainc}(x,a) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt$$

where  $\Gamma(a)$  is the gamma function, `gamma(a)`. The upper incomplete gamma function is defined as:

$$\text{gammainc}(x, a, 'upper') = \frac{1}{\Gamma(a)} \int_x^{\infty} t^{a-1} e^{-t} dt$$

`gammaincinv` computes the inverse of the incomplete gamma function with respect to the integration limit `x` using Newton's method.

For any `a > 0`, as `y` approaches 1, `gammaincinv(y, a)` approaches infinity. For small `x` and `a`, `gammainc(x, a) ≅ xa`, so `gammaincinv(1, 0) = 0`.

## **gammaln**

Logarithm of gamma function

### **Syntax**

`Y = gammaln(A)`

### **Description**

`Y = gammaln(A)` returns the logarithm of the gamma function,  $\text{gammaln}(A) = \log(\text{gamma}(A))$ . Input `A` must be nonnegative and real. The `gammaln` command avoids the underflow and overflow that may occur if it is computed directly using  $\log(\text{gamma}(A))$ .

## gca

Current axes handle

## Syntax

```
ax = gca
```

## Description

`ax = gca` returns the handle to the current axes for the current figure. If an axes does not exist, then `gca` creates an axes and returns its handle. You can use the axes handle to query and modify axes properties. For more information, see [Axes Properties](#).

## Examples

### Specify Properties for Current Axes

Plot a sine wave.

```
x = linspace(0,10);
y = sin(4*x);
plot(x,y)
```

Set the font size, tick direction, tick length, and y-axis limits for the current axes. Use `gca` to refer to the current axes.

**Note:** Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead, such as `set(ax, 'FontSize', 12)`.

```
ax = gca; % current axes
ax.FontSize = 12;
ax.TickDir = 'out';
ax.TickLength = [0.02 0.02];
ax.YLim = [-2 2];
```

## More About

### Current Axes

The current axes is the target for graphics output. It is the axes in which graphics commands such as `plot`, `text`, and `surf` draw their results. It is typically the last axes created or the last axes clicked with the mouse. Changing the current figure also changes the current axes.

User interaction can change the current axes. If you need to access a specific axes, store the axes handle in your program code when you create the axes and use this handle instead of `gca`.

## Tips

- To get the handle of the current axes without forcing the creation of an axes if one does not exist, query the figure `CurrentAxes` property.

```
fig = gcf;
ax = fig.CurrentAxes;
MATLAB returns ax as an empty array if there is no current axes.
```

- Set axes properties after plotting since some plotting functions reset axes properties.

# **gcbf**

Handle of figure containing object whose callback is executing

## **Syntax**

```
fig = gcbf
```

## **Description**

`fig = gcbf` returns the handle of the figure that contains the object whose callback is currently executing. This object can be the figure itself, in which case, `gcbf` returns the figure's handle.

When no callback is executing, `gcbf` returns the empty matrix, `[]`.

The value returned by `gcbf` is identical to the `figure` output argument returned by `gcbo`.

## **See Also**

`gcbo` | `gco` | `gcf` | `gca`

**Introduced before R2006a**

## gcbo

Handle of object whose callback is executing

### Syntax

```
h = gcbo
[h,figure] = gcbo
```

### Description

`h = gcbo` returns the handle of the graphics object whose callback is executing.

`[h,figure] = gcbo` returns the handle of the current callback object and the handle of the figure containing this object.

### More About

#### Tips

The MATLAB software stores the handle of the object whose callback is executing in the root `CallbackObject` property. If a callback interrupts another callback, MATLAB replaces the `CallbackObject` value with the handle of the object whose callback is interrupting. When that callback completes, MATLAB restores the handle of the object whose callback was interrupted.

The root `CallbackObject` property is read only, so its value is always valid at any time during callback execution. The root `CurrentFigure` property, and the figure `CurrentAxes` and `CurrentObject` properties (returned by `gcf`, `gca`, and `gco`, respectively) are user settable, so they can change during the execution of a callback, especially if that callback is interrupted by another callback. Therefore, those functions are not reliable indicators of which object's callback is executing.

When you write callback routines for the `CreateFcn` and `DeleteFcn` of any object and the figure `ResizeFcn`, you must use `gcbo` since those callbacks do not update the root's `CurrentFigure` property, or the figure's `CurrentObject` or `CurrentAxes` properties; they only update the root's `CallbackObject` property.

When no callbacks are executing, `gcbo` returns `[]` (an empty matrix).

## gcd

Greatest common divisor

### Syntax

```
G = gcd(A,B)
[G,U,V] = gcd(A,B)
```

### Description

`G = gcd(A,B)` returns the greatest common divisors of the elements of `A` and `B`. The elements in `G` are always nonnegative, and `gcd(0,0)` returns `0`. This syntax supports inputs of any numeric type.

`[G,U,V] = gcd(A,B)` also returns the Bézout coefficients, `U` and `V`, which satisfy:  $A \cdot U + B \cdot V = G$ . The Bézout coefficients are useful for solving Diophantine equations. This syntax supports double, single, and signed integer inputs.

### Examples

#### Greatest Common Divisors of Double Values

```
A = [-5 17; 10 0];
B = [-15 3; 100 0];
G = gcd(A,B)
```

```
G =
```

```
 5 1
 10 0
```

`gcd` returns positive values, even when the inputs are negative.

#### Greatest Common Divisors of Unsigned Integers

```
A = uint16([255 511 15]);
B = uint16([15 127 1023]);
```

$$G = \gcd(A, B)$$

$$G =$$

$$15 \quad 1 \quad 3$$

### Solution to Diophantine Equation

Solve the Diophantine equation,  $30x + 56y = 8$  for  $x$  and  $y$ .

Find the greatest common divisor and a pair of Bézout coefficients for 30 and 56.

$$[g, u, v] = \gcd(30, 56)$$

$$g =$$

$$2$$

$$u =$$

$$-13$$

$$v =$$

$$7$$

$u$  and  $v$  satisfy the Bézout's identity,  $(30*u) + (56*v) = g$ .

Rewrite Bézout's identity so that it looks more like the original equation. Do this by multiplying by 4. Use `==` to verify that both sides of the equation are equal.

$$(30*u*4) + (56*v*4) == g*4$$

$$\text{ans} =$$

$$1$$

Calculate the values of  $x$  and  $y$  that solve the problem.

$$x = u*4$$

$$y = v*4$$

$$x =$$

$$-52$$

y =

28

## Input Arguments

### **A, B — Input values**

scalars, vectors, or arrays of real integer values

Input values, specified as scalars, vectors, or arrays of real integer values. **A** and **B** can be any numeric type, and they can be of different types within certain limitations:

- If **A** or **B** is of type `single`, then the other can be of type `single` or `double`.
- If **A** or **B** belongs to an integer class, then the other must belong to the same class or it must be a `double` scalar value.

**A** and **B** must be the same size or one must be a scalar.

Example: `[20 -3 13],[10 6 7]`

Example: `int16([100 -30 200]),int16([20 15 9])`

Example: `int16([100 -30 200]),20`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

## Output Arguments

### **G — Greatest common divisor**

real, nonnegative integer values

Greatest common divisor, returned as an array of real nonnegative integer values. **G** is the same size as **A** and **B**, and the values in **G** are always real and nonnegative. **G** is returned as the same type as **A** and **B**. If **A** and **B** are of different types, then **G** is returned as the `nondouble` type.

### **U, V — Bézout coefficients**

real integer values

Bézout coefficients, returned as arrays of real integer values that satisfy the equation,  $A \cdot U + B \cdot V = G$ . The data type of  $U$  and  $V$  is the same type as that of  $A$  and  $B$ . If  $A$  and  $B$  are of different types, then  $U$  and  $V$  are returned as the nondouble type.

## More About

### Algorithms

$g = \text{gcd}(A, B)$  is calculated using the Euclidian algorithm.[1]

$[g, u, v] = \text{gcd}(A, B)$  is calculated using the extended Euclidian algorithm.[1]

lcm

Introduced before R2006a

## **gcf**

Current figure handle

### **Syntax**

```
fig = gcf
```

### **Description**

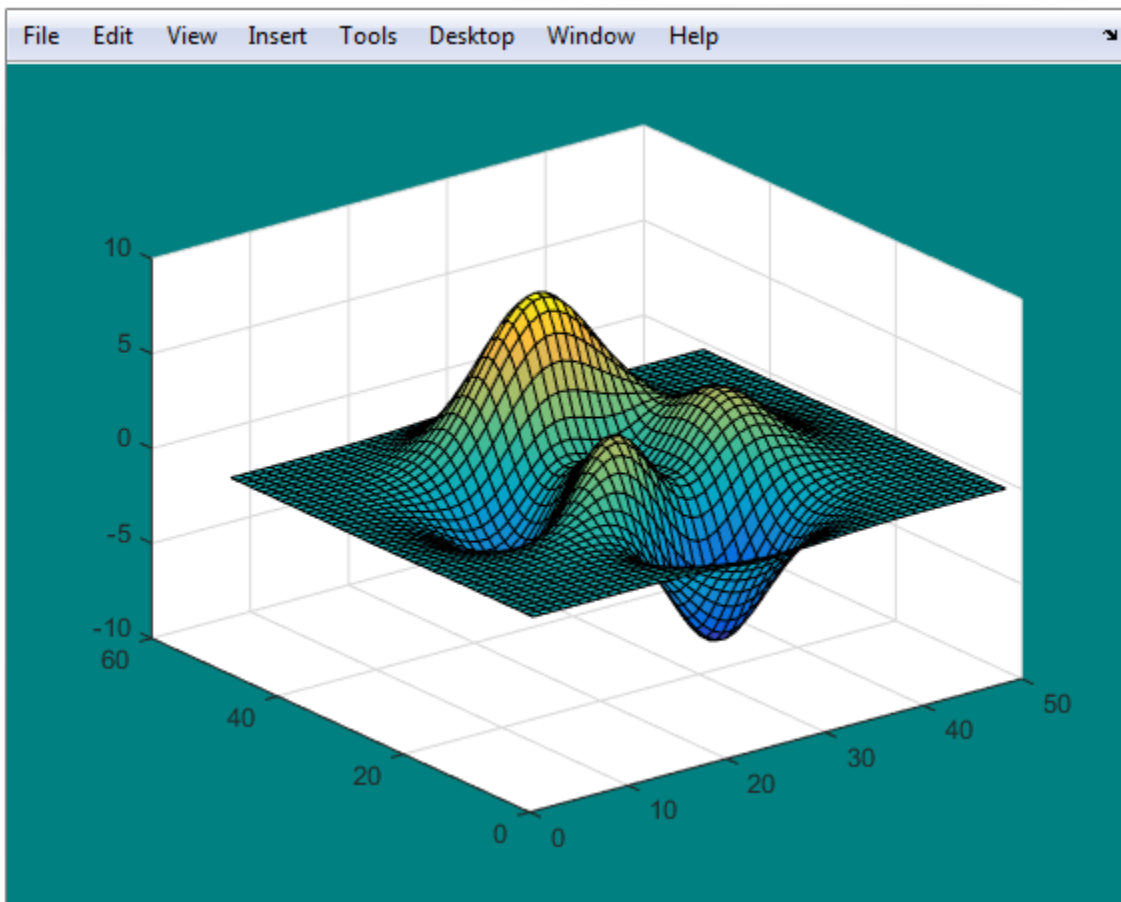

`fig = gcf` returns the current figure handle. If a figure does not exist, then `gcf` creates a figure and returns its handle. You can use the figure handle to query and modify figure properties. For more information, see [Figure Properties](#).

### **Examples**

#### **Specify Properties for Current Figure**

Set the background color and remove the toolbar for the current figure. Use the `gcf` command to get the current figure handle.

```
surf(peaks)
fig = gcf; % current figure handle
fig.Color = [0 0.5 0.5];
fig.ToolBar = 'none';
```

## More About

### Current Figure

The current figure is the target for graphics output. It is the figure window in which graphics commands such as `plot`, `title`, and `surf` draw their results. It is typically the last figure created or the last figure clicked with the mouse.

User interaction can change the current figure. If you need to access a specific figure, store the figure handle in your program code when you create the figure and use this handle instead of `gcf`.

## Tips

- To get the handle of the current figure without forcing the creation of a figure if one does not exist, query the `CurrentFigure` property on the root object.

```
fig = get(groot, 'CurrentFigure');
MATLAB returns fig as an empty array if there is no current figure.
```

## gcmr

Get current mapreducer configuration

### Syntax

```
mr = gcmr
mr = gcmr('nocreate')
```

### Description

`mr = gcmr` returns an object representing the current global execution environment for `mapreduce`.

- If no global execution environment exists, then `gcmr` calls `mapreducer` to set the global execution environment to be the default.
- If a global execution environment currently exists, then `gcmr` returns the last visible MapReducer object created.

When you create a MapReducer object using `mapreducer`, the object sets the global execution environment. The global execution environment persists even if the object representing it is later deleted.

- If the global execution environment is deleted or invalid, then `gcmr` returns the next visible MapReducer object available. For example, `delete(gcmr)` deletes the current global execution environment.

The `gcmr` function defines the global execution environment for `mapreduce`, and is most likely used with Parallel Computing Toolbox, MATLAB Distributed Computing Server™, or MATLAB Compiler™.

If you do not specify a configuration to use in your call to `mapreduce`, then by default `mapreduce` uses the configuration returned (or generated) by `gcmr`.

`mr = gcmr('nocreate')` returns the current global execution environment for `mapreduce`, if one already exists. If no global execution environment exists, then `gcmr` returns `[]`.

## More About

### Tips

- If you have Parallel Computing Toolbox, see the `mapreducer` function reference page for related information.
- If you have MATLAB Compiler, see the `mapreducer` function reference page for related information.
- “Speed Up and Deploy MapReduce Using Other Products”

`mapreduce` | `mapreducer`

**Introduced in R2014b**

## gco

Handle of current object

## Syntax

```
h = gco
h = gco(figure_handle)
```

## Description

`h = gco` returns the handle of the current object.

`h = gco(figure_handle)` returns the handle of the current object in the figure specified by `figure_handle`.

## More About

### Tips

The current object is the last object clicked or selected via keyboard interaction, excluding `uimenu`s. If the mouse click did not occur over a figure child object, the figure becomes the current object. The MATLAB software stores the handle of the current object in the figure's `CurrentObject` property.

An object can become the current object as a result of pressing the space bar to invoke a callback in a dialog when a `uicontrol` in that dialog has focus (usually the result of using the **Tab** key to change focus).

The `CurrentObject` of the `CurrentFigure` does not always indicate the object whose callback is being executed. Interruptions of callbacks by other callbacks can change the `CurrentObject` or even the `CurrentFigure`. Some callbacks, such as `CreateFcn` and `DeleteFcn`, and `uimenu Callback`, intentionally do not update `CurrentFigure` or `CurrentObject`.

`gcb0` provides the only completely reliable way to retrieve the handle to the object whose callback is executing, at any point in the `callback` function, regardless of the type of callback or of any previous interruptions.

**Introduced before R2006a**

## ge, >=

Determine greater than or equal to

## Syntax

```
A >= B
ge(A,B)
```

## Description

A >= B returns a logical array with elements set to logical 1 (true) where A is greater than or equal to B; otherwise, it returns logical 0 (false).

The test compares only the real part of numeric arrays. **ge** returns logical 0 (false) where A or B have NaN or undefined categorical elements.

**ge(A,B)** is an alternate way to execute A >= B, but is rarely used. It enables operator overloading for classes.

## Examples

### Test Vector Elements

Find which vector elements are greater than or equal to a given value.

Create a numeric vector.

```
A = [1 12 18 7 9 11 2 15];
```

Test the vector for elements that are greater than or equal to 11.

```
A >= 11
```

```
ans =
```

```
0 1 1 0 0 1 0 1
```

The result is a vector with values of logical 1 (true) where the elements of A satisfy the expression.

Use the vector of logical values as an index to view the values in A that are greater than or equal to 11.

```
A(A >= 11)
```

```
ans =
```

```
 12 18 11 15
```

The result is a subset of the elements in A.

## Replace Elements of Matrix

Create a matrix.

```
A = magic(4)
```

```
A =
```

```
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

Replace all values greater than or equal to 9 with the value 10.

```
A(A >= 9) = 10
```

```
A =
```

```
 10 2 3 10
 5 10 10 8
 10 7 6 10
 4 10 10 1
```

The result is a new matrix whose largest element is 10.

## Compare Values in Categorical Array

Create an ordinal categorical array.

```
A = categorical({'large' 'medium' 'small'; 'medium' ...
```

```
'small' 'large'}},{'small' 'medium' 'large'},'Ordinal',1)
```

```
A =
```

```
 large medium small
 medium small large
```

The array has three categories: 'small', 'medium', and 'large'.

Find all values greater than or equal to the category 'medium'.

```
A >= 'medium'
```

```
ans =
```

```
 1 1 0
 1 0 1
```

A value of logical 1 (`true`) indicates a value greater than or equal to the category 'medium'.

Compare the rows of A.

```
A(1,:) >= A(2,:)
```

```
ans =
```

```
 1 1 0
```

The function returns logical 1 (`true`) where the first row has a category value greater than or equal to the second row.

### Test Complex Numbers

Create a vector of complex numbers.

```
A = [1+i 2-2i 1+3i 1-2i 5-i];
```

Find the values that are greater than or equal to 2.

```
A(A >= 2)
```

```
ans =
```

```
2.0000 - 2.0000i 5.0000 - 1.0000i
```

`ge` compares only the real part of the elements in `A`.

Use `abs` to find which elements are outside a radius of 2 from the origin.

```
A(abs(A) >= 2)
```

```
ans =
```

```
2.0000 - 2.0000i 1.0000 + 3.0000i 1.0000 - 2.0000i 5.0000 - 1.0000i
```

The result has more elements since `abs` accounts for the imaginary part of the numbers.

## Test Duration Values

Create a `duration` array.

```
d = hours(21:25) + minutes(75)
```

```
d =
```

```
22.25 hrs 23.25 hrs 24.25 hrs 25.25 hrs 26.25 hrs
```

Test the array for elements that are greater than or equal to one standard day.

```
d >= 1
```

```
ans =
```

```
0 0 1 1 1
```

## Input Arguments

### A — Left array

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Left array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

### **B — Right array**

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Right array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

## **More About**

### **Tips**

- Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the `>=` operator reflects. For more information, see “Avoiding Common Problems with Floating-Point Arithmetic”.
- “Ordinal Categorical Arrays”

# genpath

Generate path string

## Syntax

```
p = genpath
p = genpath(folderName)
```

## Description

`p = genpath` returns a path string, `p`, that includes all the folders and subfolders below `matlabroot/toolbox`, including empty subfolders.

`p = genpath(folderName)` returns a path string that includes `folderName` and multiple levels of subfolders below `folderName`. The path string does not include folders named `private`, folders that begin with the `@` character (class folders), folders that begin with the `+` character (package folders), or subfolders within any of these.

## Examples

### Add Folder and Subfolders to Search Path

Use `genpath` in conjunction with `addpath` to add a folder and its subfolders to the search path.

Generate a path that includes `matlabroot/toolbox/images/colspaces` and all folders below it.

```
folderName = fullfile(matlabroot, 'toolbox', 'images', 'colspaces');
p = genpath(folderName);
```

Add the folder and its subfolders to the search path.

addpath(p)

## Input Arguments

**folderName** — Folder name

string

Folder name, specified as a string.

Example: 'c:/matlab/myfiles'

## More About

- “What Is the MATLAB Search Path?”

addpath | path | rmpath

**Introduced before R2006a**

## genvarname

Construct valid variable name from string

---

**Note:** `genvarname` will be removed in a future release. Use `matlab.lang.makeValidName` and `matlab.lang.makeUniqueStrings` instead.

---

### Syntax

```
varname = genvarname(str)
varname = genvarname(str, exclusions)
```

### Description

`varname = genvarname(str)` constructs a string `varname` that is similar to or the same as the `str` input, and can be used as a valid variable name. `str` can be a single character array or a cell array of strings. If `str` is a cell array of strings, `genvarname` returns a cell array of strings in `varname`. The strings in a cell array returned by `genvarname` are guaranteed to be different from each other.

`varname = genvarname(str, exclusions)` returns a valid variable name that is different from any name listed in the `exclusions` input. The `exclusions` input can be a single character array or a cell array of strings. Specify the function `who` in the `exclusions` character array to create a variable name that will be unique in the current MATLAB workspace (see “Example 4” on page 1-3053, below).

---

**Note** `genvarname` returns a string that can be used as a variable name. It does not create a variable in the MATLAB workspace. You cannot, therefore, assign a value to the output of `genvarname`.

---

## Examples

### Example 1

Create four similar variable name strings that do not conflict with each other:

```
v = genvarname({'A', 'A', 'A', 'A'})
v =
 'A' 'A1' 'A2' 'A3'
```

### Example 2

Read a column header `hdr` from worksheet `trial2` in Excel spreadsheet `myproj_apr23`:

```
[data hdr] = xlsread('myproj_apr23.xls', 'trial2');
```

Make a variable name from the text of the column header that will not conflict with other names:

```
v = genvarname(['Column ' hdr{1,3}]);
```

Assign data taken from the spreadsheet to the variable in the MATLAB workspace:

```
eval([v '= data(1:7, 3);']);
```

### Example 3

Collect readings from an instrument once every minute over the period of an hour into different fields of a structure. Simulate instrument readings using a random number. `genvarname` not only generates unique fieldname strings, but also creates the structure and fields in the MATLAB workspace:

```
for k = 1:60
 record.(genvarname(['reading' datestr(clock, 'HHMMSS')))) = rand(1);
 pause(60)
end
```

After the program ends, display the recorded data from the workspace:

```
record
```

```

record =

 reading092610: 0.6541
 reading092710: 0.6892
 reading092811: 0.7482
 reading092911: 0.4505
 reading093011: 0.0838
 .
 .
 .

```

## Example 4

Generate variable names that are unique in the MATLAB workspace by putting the output from the `who` function in the `exclusions` list.

```

for k = 1:5
 t = clock;
 pause(uint8(rand * 10));
 v = genvarname('time_elapsed', who);
 eval([v ' = etime(clock,t)'])
end

```

As this code runs, you can see that the variables created by `genvarname` are unique in the workspace:

```

time_elapsed =
 5.0070
time_elapsed1 =
 2.0030
time_elapsed2 =
 7.0010
time_elapsed3 =
 8.0010
time_elapsed4 =
 3.0040

```

After the program completes, use the `who` function to view the workspace variables:

```

who

k time_elapsed time_elapsed2 time_elapsed4
t time_elapsed1 time_elapsed3 v

```

## Example 5

If you try to make a variable name from a MATLAB keyword, `genvarname` creates a variable name string that capitalizes the keyword and precedes it with the letter `x`:

```
v = genvarname('global')
v =
 xGlobal
```

## Example 6

If you enter a string that is longer than the value returned by the `namelengthmax` function, `genvarname` truncates the resulting variable name string:

```
namelengthmax
ans =
 63

vstr = genvarname(sprintf('%s%s', ...
 'This name truncates because it contains ', ...
 'more than the maximum number of characters'))
vstr =
 ThisNameTruncatesBecauseItContainsMoreThanTheMaximumNumberOfCha
```

## More About

### Tips

A valid MATLAB variable name is a character string of letters, digits, and underscores, such that the first character is a letter, and the length of the string is less than or equal to the value returned by the `namelengthmax` function. Any string that exceeds `namelengthmax` is truncated in the `varname` output. See “Example 6” on page 1-3054, below.

The variable name returned by `genvarname` is not guaranteed to be different from other variable names currently in the MATLAB workspace unless you use the `exclusions` input in the manner shown in “Example 4” on page 1-3053, below.

If you use `genvarname` to generate a field name for a structure, MATLAB does create a variable for the structure and field in the MATLAB workspace. See “Example 3” on page 1-3052, below.

If the `str` input contains any whitespace characters, `genvarname` removes them and capitalizes the next alphabetic character in `str`. If `str` contains any nonalphanumeric characters, `genvarname` translates these characters into their hexadecimal value.

## get

Query graphics object properties

### Syntax

```
v = get(h)
v = get(h,propertyName)
v = get(h,propertyArray)
v = get(h,'default')
v = get(h,defaultTypeProperty)
v = get(groot,'factory')
v = get(groot,factoryTypeProperty)
```

### Description

---

**Note:** Do not use the `get` function on Java objects as it will cause a memory leak. For more information, see “Accessing Private and Public Data”

---

`v = get(h)` returns all properties and property values for the graphics object identified by `h`. `v` is a structure whose field names are the property names and whose values are the corresponding property values. `h` can be a single object or an  $m$ -by- $n$  array of objects. If `h` is a single object and you do not specify an output argument, then MATLAB displays the information on the screen.

`v = get(h,propertyName)` returns the value for the specific property, `propertyName`. Use single quotes around the property name, for example, `get(h,'Color')`. If you do not specify an output argument, then MATLAB displays the information on the screen.

`v = get(h,propertyArray)` returns an  $m$ -by- $n$  cell array, where  $m$  is equal to `length(h)` and  $n$  is equal to the number of property names contained in `propertyArray`.

`v = get(h,'default')` returns all default values currently defined on object `h` in a structure array. The field names are the object property names and the field values are

the corresponding property values. If you do not specify an output argument, MATLAB displays the information on the screen.

`v = get(h,defaultTypeProperty)` returns the current default value for a specific property. The argument `defaultTypeProperty` is the word `default` concatenated with the object type (e.g., `Figure`) and the property name (e.g., `Color`) in single quotes. For example, `get(groot, 'defaultFigureColor')`.

`v = get(groot, 'factory')` returns the factory-defined values of all user-settable properties in a structure array. The field names are the object property names and the field values are the corresponding property values. If you do not specify an output argument, MATLAB displays the information on the screen.

`v = get(groot, factoryTypeProperty)` returns the factory-defined value for a specific property. The argument `factoryTypeProperty` is the word `factory` concatenated with the object type (e.g., `Figure`) and the property name (e.g., `Color`) in single quotes. For example, `get(groot, 'factoryFigureColor')`.

## Examples

### List All Property Values for Specific Object

Create a line plot and return the chart line object as `p`. List all the properties of the line and the current property values.

```
p = plot(1:10);
get(p)

AlignVertexCenters: 'off'
Annotation: [1x1 matlab.graphics.eventdata.Annotation]

```

## Query Specific Property of Specific Object

Create a line plot and return the chart line object as `p`. Use `get` to return the current value of the `LineWidth` property.

```
p = plot(1:10);
get(p, 'LineWidth')
```

```
ans =
 0.5000
```

## Query Set of Properties for Specific Object

Create a line plot with circle markers and return the chart line object as `p`. Use `get` to return the current values of the `LineWidth`, `Marker`, and `MarkerSize` properties for the object.

```
p = plot(1:10, 'ro-');
```

```
props = {'LineWidth', 'Marker', 'MarkerSize'};
get(p, props)

ans =

 [0.5000] 'o' [6]
```

## Query Default Property Value on Root

Return the default value of the `LineWidth` property defined on the root for all line graphics objects.

```
get(groot, 'DefaultLineLineWidth')

ans =

 0.5000
```

## More About

- “Graphics Object Properties”

## See Also

`findobj` | `gca` | `gcf` | `gco` | `set`

**Introduced before R2006a**

## get

Query property values for audioplayer object

### Syntax

```
Value = get(obj,Name)
Values = get(obj,{Name1,...,NameN})
Values = get(obj)
get(obj)
```

### Description

*Value* = `get(obj,Name)` returns the value of the specified property for object *obj*.

*Values* = `get(obj,{Name1,...,NameN})` returns the values of the specified properties in a 1-by-*N* cell array.

*Values* = `get(obj)` returns a scalar structure that contains the values of all properties of *obj*. Each field name corresponds to a property name.

`get(obj)` displays all property names and their current values.

### Examples

Create an audioplayer object from the example file `handel.mat` and query the object properties:

```
load handel.mat;
handelObj = audioplayer(y, Fs);

% Display all properties.
get(handelObj)

% Display only the SampleRate property.
get(handelObj, 'SampleRate')
```

---

```
% Create a cell array that contains
% values for two properties.
info = get(handelObj, {'BitsPerSample', 'NumberOfChannels'});
```

## Alternatives

To access a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, find the value of the `TotalSamples` property for an object named `handelObj` (as created in the Example):

```
numSamples = handelObj.TotalSamples;
```

This command is exactly equivalent to:

```
numSamples = get(handelObj, 'TotalSamples');
```

## See Also

`audioplayer` | `set`

## get

Query property values for audiorecorder object

### Syntax

```
Value = get(obj,Name)
Values = get(obj,{Name1,...,NameN})
Values = get(obj)
get(obj)
```

### Description

*Value* = `get(obj,Name)` returns the value of the specified property for object *obj*.

*Values* = `get(obj,{Name1,...,NameN})` returns the values of the specified properties in a 1-by-*N* cell array.

*Values* = `get(obj)` returns a scalar structure that contains the values of all properties of *obj*. Each field name corresponds to a property name.

`get(obj)` displays all property names and their current values.

### Examples

Create an audiorecorder object and query the object properties:

```
recorderObj = audiorecorder;

% Display all properties.
get(recorderObj)

% Display only the SampleRate property.
get(recorderObj, 'SampleRate')

% Create a cell array that contains
% values for two properties.
```

```
info = get(recorderObj, {'BitsPerSample', 'NumberOfChannels'});
```

## Alternatives

To access a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, find the value of the `TotalSamples` property for an object named `recorderObj` (as created in the Example):

```
numSamples = recorderObj.TotalSamples;
```

This command is exactly equivalent to:

```
numSamples = get(recorderObj, 'TotalSamples');
```

## See Also

[audiorecorder](#) | [set](#)

## get (COM)

Get property value from interface, or display properties

### Syntax

```
V = get(h)
V = get(h, 'name')
```

### Description

`V = get(h)` returns a list of all properties and their values for the object or interface, `h`.

If `V` is empty, either there are no properties in the object, or MATLAB cannot read the object type library. Refer to the COM vendors documentation.

`V = get(h, 'name')` returns value of property specified in string, `name`.

COM functions are available on Microsoft Windows systems only.

### Examples

Create a COM server running Microsoft Excel software:

```
e = actxserver('Excel.Application');
```

Retrieve a single property value.

```
e.Path
```

```
ans =
C:\Program Files\MSOffice\OFFICE11
```

MATLAB displays the path to your program.

List of all properties for the `CommandBars` interface.

```
c = CommandBars.get(e)
```

MATLAB displays information for your version of Excel.

## More About

### Tips

The meaning and type of the return value is dependent upon the specific property being retrieved. The object documentation describes the specific meaning of the return value. MATLAB might convert the data type of the return value. For a description of how MATLAB converts COM data types, see “Handle COM Data in MATLAB”.

`set (COM)` | `inspect` | `isprop` | `addproperty` | `deleteproperty`

**Introduced before R2006a**

## get (RandStream)

Random stream properties

### Class

@RandStream

### Syntax

```
get(s)
P = get(s)
P = get(s, 'PropertyName')
```

### Description

get(s) prints the list of properties for the random stream s.

P = get(s) returns all properties of s in a scalar structure.

P = get(s, 'PropertyName') returns the property 'PropertyName'.

### See Also

RandStream | set (RandStream)

# get (serial)

Serial port object properties

## Syntax

```
get(obj)
out = get(obj)
out = get(obj, 'PropertyName')
```

## Description

`get(obj)` returns all property names and their current values to the command line for the serial port object, `obj`.

`out = get(obj)` returns the structure `out` where each field name is the name of a property of `obj`, and each field contains the value of that property.

`out = get(obj, 'PropertyName')` returns the value `out` of the property specified by *PropertyName* for `obj`. If *PropertyName* is replaced by a 1-by-n or n-by-1 cell array of strings containing property names, then `get` returns a 1-by-n cell array of values to `out`. If `obj` is an array of serial port objects, then `out` will be a m-by-n cell array of property values where m is equal to the length of `obj` and n is equal to the number of properties specified.

## Examples

This example illustrates some of the ways you can use `get` to return property values for the serial port object `s` on a Windows platform.

```
s = serial('COM1');
out1 = get(s);
out2 = get(s,{'BaudRate','DataBits'});
s.Parity

ans =
none
```

## More About

### Tips

Refer to [Displaying Property Names and Property Values](#) for a list of serial port object properties that you can return with `get`.

When you specify a property name, you can do so without regard to case. For example, if `s` is a serial port object, then these commands are equivalent.

```
out = s.BaudRate;
out = s.baudrate;
```

### See Also

`set`

**Introduced before R2006a**

## get (tscollection)

Query tscollection object property values

### Syntax

```
value = get(tsc, 'PropertyName')
```

### Description

`value = get(tsc, 'PropertyName')` returns the value of the specified property of the `tscollection` object `tsc`. The following syntax is equivalent:

```
value = tsc.PropertyName
```

`get(tsc)` displays all properties and values of the `tscollection` object `tsc`.

### See Also

`set (tscollection)` | `timeseries`

**Introduced before R2006a**

## getabstime (tscollection)

Extract date-string time vector into cell array

### Syntax

```
getabstime(tsc)
```

### Description

`getabstime(tsc)` extracts the time vector from the `tscollection` object `tsc` as a cell array of date strings. To define the time vector relative to a calendar date, set the `TimeInfo.StartDate` property of the time-series collection. When the `TimeInfo.StartDate` format is a valid `datestr` format, the output strings from `getabstime` have the same format.

### Examples

- 1 Create a `tscollection` object.

```
tsc = tscollection(timeseries([3 6 8 0 10]));
```

- 2 Set the `StartDate` property.

```
tsc.TimeInfo.StartDate = '10/27/2005 07:05:36';
```

- 3 Extract a vector of absolute time values.

```
getabstime(tsc)
```

```
ans =
```

```
'27-Oct-2005 07:05:36'
'27-Oct-2005 07:05:37'
'27-Oct-2005 07:05:38'
'27-Oct-2005 07:05:39'
'27-Oct-2005 07:05:40'
```

- 4 Change the date-string format of the time vector.

```
tsc.TimeInfo.Format = 'mm/dd/yy';
```

- 5 Extract the time vector with the new date-string format.

```
getabstime(tsc)
```

```
ans =
```

```
 '10/27/05'
```

```
 '10/27/05'
```

```
 '10/27/05'
```

```
 '10/27/05'
```

```
 '10/27/05'
```

## getappdata

Retrieve application-defined data

Use this function to retrieve data stored using the `setappdata` function. Both of these functions provide a convenient way to share data between callbacks or between separate UIs.

### Syntax

```
val = getappdata(obj,name)
vals = getappdata(obj)
```

### Description

`val = getappdata(obj,name)` returns a value stored in the graphics object, `obj`. The name identifier, `name`, uniquely identifies the value to retrieve.

`vals = getappdata(obj)` returns all values stored in the graphics object with their name identifiers.

### Examples

#### Store and Retrieve Date and Time

Create a figure window.

```
f = figure;
```

Get the current date and time as separate variables.

```
dt = fix(clock);
currdate = dt(1:3);
currtime = dt(4:6);
```

Store `currdate` and `currtime` using the `setappdata` function.

```
setappdata(f, 'todaysdate',currdate);
```

```
setappdata(f, 'presenttime', currttime);
```

Retrieve the date information.

```
getappdata(f, 'todaysdate')
```

```
ans =
```

```
 2014 12 23
```

Retrieve all data associated with figure f.

```
getappdata(f)
```

```
ans =
```

```
 todaysdate: [2014 12 23]
 presenttime: [16 51 5]
```

## Input Arguments

**obj** — Graphics object containing the value

figure | uipanel | uibuttongroup | uicontrol | ...

Graphics object containing the value, specified as any graphics object (except an ActiveX component). This is the same graphics object passed to `setappdata` during the storage operation.

**name** — Name identifier

string

Name identifier, specified as a `string` value. This is the same name identifier passed to `setappdata` during the storage operation.

Data Types: char

## Output Arguments

**va1** — Stored value

any MATLAB data type

Stored value, returned as the same value and data type that was originally stored.

**vals** — All values stored in the graphics object with name identifiers  
structure

All values stored in the graphics object with name identifiers, returned as a structure. Each field in the structure corresponds to a stored value. The field names of the structure correspond to the name identifiers assigned when each value was stored.

## More About

- “Share Data Among Callbacks”

## See Also

`guidata` | `isappdata` | `rmapdata` | `setappdata`

# getaudiodata

Store recorded audio signal in numeric array

## Syntax

```
y = getaudiodata(recorder)
y = getaudiodata(recorder, dataType)
```

## Description

`y = getaudiodata(recorder)` returns recorded audio data associated with audiorecorder object `recorder` to double array `y`.

`y = getaudiodata(recorder, dataType)` converts the signal data to the specified data type: 'double', 'single', 'int16', 'int8', or 'uint8'.

## Output Arguments

**y**

Audio signal data `y` contains the same number of columns as the number of channels in the recording: one for mono, two for stereo. The range of values depends on the data type, as shown in the following table.

| Data Type | Sample Value Range |
|-----------|--------------------|
| int8      | -128 to 127        |
| uint8     | 0 to 255           |
| int16     | -32768 to 32767    |
| single    | -1 to 1            |
| double    | -1 to 1            |

## Examples

Collect a sample of your speech with a microphone, and plot the signal data:

```
% Record your voice for 5 seconds.
recObj = audiorecorder;
disp('Start speaking.')
recordblocking(recObj, 5);
disp('End of Recording. ');

% Play back the recording.
play(recObj);

% Store data in double-precision array.
myRecording = getaudiodata(recObj);

% Plot the waveform.
plot(myRecording);
```

## See Also

audiorecorder

## How To

- “Characteristics of Audio Files”
- “Record Audio”

# GetCharArray

Character array from Automation server

## Syntax

### IDL Method Signature

```
HRESULT GetCharArray([in] BSTR varName, [in] BSTR Workspace,
 [out, retval] BSTR *mlString)
```

### Microsoft Visual Basic Client

```
GetCharArray(varname As String, workspace As String) As String
```

### MATLAB Client

```
str = GetCharArray(h, 'varname', 'workspace')
```

## Description

`str = GetCharArray(h, 'varname', 'workspace')` gets the character array stored in `varname` from the specified *workspace* of the server attached to handle `h` and returns it in `str`. The values for *workspace* are `base` or `global`.

## Examples

This example uses a Visual Basic .NET client.

- 1 Create the Visual Basic application. Use the `MsgBox` command to control flow between MATLAB and the application.

```
Dim Matlab As Object
Dim S As String
Matlab = CreateObject("matlab.application")
```

```
MsgBox("In MATLAB, type" & vbCrLf _
 & "str='new string';")
```

- 2 Open the MATLAB window, then type:

```
str='new string';
```

- 3 Click **Ok**.

Try

```
S = Matlab.GetCharArray("str", "base")
MsgBox("str = " & S)
Catch ex As Exception
 MsgBox("You did not set 'str' in MATLAB")
End Try
```

The Visual Basic MsgBox displays what you typed in MATLAB.

## See Also

[PutCharArray](#) | [GetWorkspaceData](#) | [GetVariable](#)

**Introduced before R2006a**

# getenv

Environment variable

## Syntax

```
getenv 'name'
N = getenv('name')
```

## Description

`getenv 'name'` searches the underlying operating system environment list for a string of the form `name=value`, where `name` is the input string. If found, MATLAB returns the string `value`. If the specified name cannot be found, an empty matrix is returned.

On UNIX platforms, the shell you use to start MATLAB determines the operating system environment. For example, starting MATLAB on a Mac platform from the Applications folder creates a different shell environment from starting MATLAB from Terminal.

`N = getenv('name')` returns `value` to the variable `N`.

## Examples

```
os = getenv('OS')
```

```
os =
Windows_NT
```

## See Also

[setenv](#) | [computer](#) | [pwd](#) | [ver](#) | [path](#)

Introduced before R2006a

# getfield

Field of structure array

## Syntax

```
value = getfield(struct, 'field')
value = getfield(struct, {sIndx1, ..., sIndxM}, 'field',
{fIndx1, ..., fIndxN})
```

## Description

`value = getfield(struct, 'field')`, where `struct` is a 1-by-1 structure, returns the contents of the specified field, equivalent to `value = struct.field`. Pass field references as strings.

`value = getfield(struct, {sIndx1, ..., sIndxM}, 'field', {fIndx1, ..., fIndxN})` returns the contents of the specified field, equivalent to `value = struct(sIndx1, ..., sIndxM).field(fIndx1, ..., fIndxN)`. The `getfield` function supports multiple sets of `field` and `fIndx` inputs, and all `Indx` inputs are optional. If structure `struct` or any of the fields is a nonscalar structure, and you do not specify an `Indx`, the `getfield` function returns the values associated with the first index. If you specify a single colon operator for an `fIndx` input, enclose it in single quotation marks: `' : '`.

## Examples

The `what` function returns a structure array that describes the MATLAB files in the current folder. Find the files with the `.m` extension:

```
files = getfield(what, 'm');
```

To perform the same task by indexing requires that you create a temporary variable:

```
templist = what;
files = templist.m;
```

Find values within a structure that contains nested fields:

```
level = 5;
semester = 'Fall';
subject = 'Math';
student = 'John_Doe';
fieldnames = {semester subject student};

% Add data to a structure named grades.
grades(level).(semester).(subject).(student)(10,21:30) = ...
 [85, 89, 76, 93, 85, 91, 68, 84, 95, 73];

% Retrieve the data added.
getfield(grades, {level}, fieldnames{:}, {10,21:30})
```

Using the structure defined in the previous example, find all values in the tenth row of the specified field:

```
getfield(grades, {level}, fieldnames{:}, {10,':'})
```

## More About

### Tips

- For most cases, retrieve data from a structure array by indexing rather than using the `getfield` function. For more information, see “Access Data in a Structure Array” and “Generate Field Names from Variables”.
- Call `getfield` to simplify references to structure arrays with nested fields, or to avoid creating unnecessary temporary variables, as shown in the Examples section.
- “Generate Field Names from Variables”
- “Access Data in a Structure Array”

### See Also

`setfield` | `fieldnames` | `isfield` | `orderfields` | `rmfield`

Introduced before R2006a

## getframe

Capture axes or figure as movie frame

### Compatibility

Starting in R2015b, if you are using a high-resolution system, then the size of the `cdata` array in output `F` might be larger than in previous releases or on other systems. Also, the number of elements in `cdata` might not match the size in pixels reported by either the `Position` property of the figure or axes, or the `rect` input argument. For more information, see “DPI-Aware Behavior in MATLAB”.

### Syntax

```
F = getframe
F = getframe(ax)
F = getframe(fig)
F = getframe(___,rect)
```

### Description

`F = getframe` captures the current axes as it appears on the screen as a movie frame. `F` is a structure containing the image data. `getframe` captures the axes at the same size that it appears on the screen. It does not capture tick labels or other content outside the axes outline.

`F = getframe(ax)` captures the axes identified by `ax` instead of the current axes.

`F = getframe(fig)` captures the figure identified by `fig`. Specify a figure if you want to capture the entire interior of the figure window, including the axes title, labels, and tick marks. The captured movie frame does not include the figure menu and tool bars.

`F = getframe( ___,rect)` captures the area within the rectangle defined by `rect`. Specify `rect` as a four-element vector of the form `[left bottom width height]`. Use this option with either the `ax` or `fig` input arguments in the previous syntaxes.

## Examples

### Capture Contents of Current Axes

Create a plot of random data. Capture the axes and return the image data. `getframe` captures the interior of the axes and the axes outline. It does not capture content that extends beyond the axes outline.

```
plot(rand(5))
F = getframe;
```

F is a structure with the field `cdata` that contains the captured image data.

Display the captured image data using `imshow`.

```
figure
imshow(F.cdata)
```

### Capture Contents of Figure

Create a surface plot. Capture the interior of the figure window, excluding the menu and tool bars.

```
surf(peaks)
F = getframe(gcf);
```

F is a structure with the field `cdata` that contains the captured image data.

Display the captured image data using `imshow`.

```
figure
imshow(F.cdata)
```

### Specify Rectangular Region to Capture

Capture the interior of an axes plus a margin of 30 pixels in each direction. The added margin is necessary to include the tick labels in the capture frame. Depending on the size of the tick labels, the margin might need to be adjusted.

Create a plot of random data.

```
plot(rand(5))
```

Change the axes units to pixels and return the current axes position. The third and fourth elements of the position vector specify the axes width and height in pixels.

```
drawnow
ax = gca;
ax.Units = 'pixels';
pos = ax.Position

pos =
 73.8000 47.2000 434.0000 342.3000
```

Create a four-element vector, `rect`, that defines a rectangular area covering the axes plus the desired margin. The first two elements of `rect` specify the lower left corner of

the rectangle relative to the lower left corner of the axes. The last two elements of `rect` specify the width and height of the rectangle. Reset the axes units to the default value of `'normalized'`.

```
marg = 30;
rect = [-marg, -marg, pos(3)+2*marg, pos(4)+2*marg];
F = getframe(gca,rect);
ax.Units = 'normalized';
```

Display the captured image data using `imshow`.

```
figure
imshow(F.cdata)
```

### Calculate Region to Include Title and Labels

Calculate a margin around the axes so that the captured image data includes the title, axis labels, and tick labels.

Create a plot with a title and an  $x$ -axis label.

```
plot(rand(5))
xlabel('x values')
title('Plot of Random Data')
```

Change the axes units to pixels and store the `Position` and `TightInset` property values for the axes. The `TightInset` property is a four-element vector of the form `[left bottom right top]`. The values are the margins used around the axes for the tick values and text labels.

```
drawnow
ax = gca;
ax.Units = 'pixels';
pos = ax.Position;
ti = ax.TightInset;
```

Create a four-element vector, `rect`, that defines a rectangular area covering the axes plus the automatically calculated margin. The first two elements of `rect` specify the

lower left corner of the rectangle relative to the lower left corner of the axes. The last two elements of `rect` specify the width and height of the rectangle.

```
rect = [-ti(1), -ti(2), pos(3)+ti(1)+ti(3), pos(4)+ti(2)+ti(4)];
F = getframe(ax,rect);
```

Display the captured image data using `imshow`.

```
figure
imshow(F.cdata)
```

### Capture Specific Subplot Axes

Create a figure with two subplots. In the upper subplot, plot a blue line. In the lower subplot, plot a red line.

```
ax1 = subplot(2,1,1);
plot(1:10, 'b')
ax2 = subplot(2,1,2);
plot(1:10, 'r')
```

Capture the contents of the lower subplot. `getframe` captures the interior and border of the subplot. It does not capture tick values or labels that extend beyond the outline of the subplot.

```
F = getframe(ax2);
```

Display the captured image data using `imshow`.

```
figure
imshow(F.cdata)
```

## Record Frames and Play Movie

Record frames of the `peaks` function vibrating by using `getframe` in a loop. Preallocate an array to store the movie frames.

```
Z = peaks;
surf(Z)
axis tight manual
ax = gca;
ax.NextPlot = 'replaceChildren';

loops = 40;
F(loops) = struct('cdata',[],'colormap',[]);
for j = 1:loops
 X = sin(j*pi/10)*Z;
 surf(X,Z)
 drawnow
 F(j) = getframe(gcf);
end
```

Playback the movie two times.

```
fig = figure;
```

```
movie(fig,F,2)
```

## Input Arguments

### **ax** — Axes to capture

axes object

Axes to capture, specified as an axes object. Use this option if you want to capture an axes that is not the current axes.

`getframe` captures the content within the smallest rectangle that encloses the axes outline. If you want to capture all the tick values and labels, then use the `fig` input argument instead.

```
Example: F = getframe(ax);
```

### **fig** — Figure to capture

figure object

Figure to capture, specified as a figure object. Use `gcf` to capture the current figure.

```
Example: F = getframe(gcf);
```

### **rect** — Rectangular area to capture

four-element vector of the form `[left bottom width height]`

Rectangular area to capture, specified as a four-element vector of the form `[left bottom width height]` in pixels. The `left` and `bottom` elements define the position of the lower left corner of the rectangle. The position is relative to the figure or axes that is specified as the first input argument to `getframe`. The `width` and `height` elements define the dimensions of the rectangle.

Specify a rectangle that is fully contained within the figure window.

```
Example: F = getframe(gcf,[0 0 560 420]);
```

## Output Arguments

### **F** — Movie frame

structure

Movie frame, returned as a structure with two fields:

- `cdata` — The image data stored as an array of `uint8` values. The size of the image data array depends on your screen resolution.
- `colormap` — The colormap. On true color systems, this field is empty.

---

**Note:** These are some important considerations about the size of `cdata`:

- Starting in R2015b, if you are using a high-resolution system, then the size of `cdata` might be larger than in previous releases or on other systems.
  - If you query the size of the region that `getframe` captures (either the figure, the axes, or the region specified by `rect`), the size in pixels might not match the number of elements in `cdata`. This difference is because the number of elements in `cdata` depends on your screen resolution (and operating system settings), but pixels in MATLAB might not correspond to the actual pixels on your screen.
- 

## More About

### Pixels

Distances in pixels are independent of your system resolution on Windows and Macintosh systems:

- On Windows systems, a pixel is 1/96th of an inch.
- On Macintosh systems, a pixel is 1/72nd of an inch.

On Linux systems, the size of a pixel is determined by your system resolution.

### Tips

- For the fastest performance when using `getframe`, make sure that the figure is visible on the screen. If the figure is not visible, `getframe` can still capture the figure, but performance can be slower.
- For more control over the resolution of the image data, use the `print` function instead. The `cdata` output argument with `print` returns the image data. The `resolution` input argument controls the resolution of the image.

**Introduced before R2006a**

# GetFullMatrix

Matrix from Automation server workspace

## Syntax

### IDL Method Signature

```
GetFullMatrix([in] BSTR varname, [in] BSTR workspace,
 [in, out] SAFEARRAY(double) *pr, [in, out] SAFEARRAY(double) *pi)
```

### Microsoft Visual Basic Client

```
GetFullMatrix(varname As String, workspace As String,
 [out] XReal As Double, [out] XImag As Double)
```

### MATLAB Client

```
[xreal ximag] = GetFullMatrix(h, 'varname', 'workspace', zreal, zimag)
```

## Description

[xreal ximag] = GetFullMatrix(h, 'varname', 'workspace', zreal, zimag) gets matrix stored in variable *varname* from the specified *workspace* of the server attached to handle *h*. The function returns the real part in *xreal* and the imaginary part in *ximag*. The values for *workspace* are *base* or *global*.

The *zreal* and *zimag* arguments are matrices of the same size as the real and imaginary matrices (*xreal* and *ximag*) returned from the server. The *zreal* and *zimag* matrices are commonly set to zero.

Use `GetFullMatrix` for values of type `double` only. Use `GetVariable` or `GetWorkspaceData` for other types.

For VBScript clients, use the `GetWorkspaceData` and `PutWorkspaceData` functions to pass numeric data to and from the MATLAB workspace. These functions use the

variant data type instead of the `safearray` data type used by `GetFullMatrix` and `PutFullMatrix`. VBScript does not support `safearray`.

## Examples

This example uses a Visual Basic .NET client to read data from a MATLAB Automation server:

- 1 Create the Visual Basic application. To control flow between MATLAB and the application, use the `MsgBox` command.

```
Dim MatLab As Object
Dim Result As String
Dim XReal(4, 4) As Double
Dim XImag(4, 4) As Double
Dim i, j As Integer

MatLab = CreateObject("matlab.application")
Result = MatLab.Execute("M = rand(5);")
MsgBox("In MATLAB, type" & vbCrLf _
 & "M(3,4)")
```

- 2 Open the MATLAB window and type:

```
M(3,4)
```

- 3 Click **Ok**.

- 4 In the Visual Basic application:

```
MatLab.GetFullMatrix("M", "base", XReal, XImag)
i = 2 %0-based array
j = 3

MsgBox("XReal(" & i + 1 & ", " & j + 1 & ")" & _
 " = " & XReal(i, j))
```

- 5 To close and terminate MATLAB, click **Ok**.

## getnext

Get next value from ValueIterator

## Syntax

```
X = getnext(ValIter)
```

## Description

`X = getnext(ValIter)` returns the next available value in `ValIter`. Use the `hasnext` function to confirm availability of values in `ValIter` before calling `getnext`.

## Examples

### Get Values from ValueIterator in Reduce Function

Use the `hasnext` and `getnext` functions in a `while` loop within the reduce function to iteratively get values from the `ValueIterator` object. For example,

```
function MeanDistReduceFun(sumLenKey, sumLenIter, outKVStore)
 sumLen = [0 0];
 while hasNext(sumLenIter)
 sumLen = sumLen + getnext(sumLenIter);
 end
 add(outKVStore, 'Mean', sumLen(1)/sumLen(2));
end
```

Always call `hasnext` before `getnext` to confirm availability of a value. `mapreduce` returns an error if you call `getnext` with no remaining values in the `ValueIterator` object.

## Input Arguments

**ValIter** — Intermediate value iterator

ValueIterator object

Intermediate value iterator, specified as a `ValueIterator` object. The `mapreduce` function automatically creates this object during execution. The second input to the reduce function specifies the variable name for the `ValueIterator` object, which is the variable name to use with the `hasnext` and `getnext` functions.

For more information, see [Using ValueIterator Objects](#).

## More About

- [Using ValueIterator Objects](#)
- [“Build Effective Algorithms with MapReduce”](#)

## See Also

`hasnext` | `mapreduce`

**Introduced in R2014b**

## getpixelposition

Get component position in pixels

### Syntax

```
position = getpixelposition(handle)
position = getpixelposition(handle,recursive)
```

### Description

`position = getpixelposition(handle)` gets the position, in pixels, of the component specified by `handle`. MATLAB returns the `position` as a four-element vector that specifies the location and size of the component: [distance from left, distance from bottom, width, height].

`position = getpixelposition(handle,recursive)` gets the position as above. If `recursive` is true, the returned position is relative to the parent figure of `handle`.

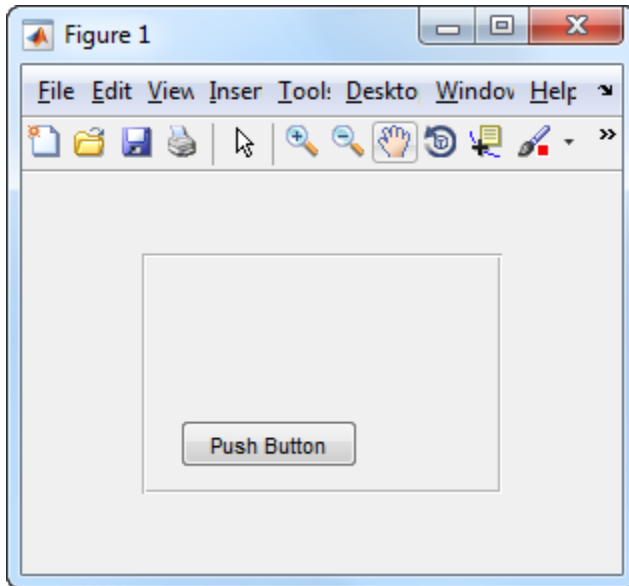

Use the `getpixelposition` function only to obtain coordinates for children of figures and container components (uipanel, or uibuttongroups). Results are not reliable for children of axes or other Handle Graphics objects.

### Examples

This example creates a push button within a panel, and then retrieves its position, in pixels, relative to the *panel*.

```
f = figure('Position',[300 300 300 200]);
p = uipanel('Position',[.2 .2 .6 .6]);
h1 = uicontrol(p,'Style','PushButton',...
 'Units','Normalized',...
 'String','Push Button',...
 'Position',[.1 .1 .5 .2]);
drawnow;
pos1 = getpixelposition(h1)
```

```
pos1 =
 18.6000 12.6000 88.0000 23.2000
```

The following statement retrieves the position of the push button, in pixels, relative to the *figure*.

```
pos1 = getpixelposition(h1,true)
pos1 =
 78.6000 52.6000 88.0000 23.2000
```

## More About

### Pixels

Distances in pixels are independent of your system resolution on Windows and Macintosh systems:

- On Windows systems, a pixel is 1/96th of an inch.
- On Macintosh systems, a pixel is 1/72nd of an inch.

On Linux systems, the size of a pixel is determined by your system resolution.

## **See Also**

`setpixelposition` | `uicontrol` | `uipanel`

# getpoints

Return points that define animated line

## Syntax

```
[x,y] = getpoints(h)
[x,y,z] = getpoints(h)
```

## Description

`[x,y] = getpoints(h)` returns the  $x$  and  $y$  coordinates for the points that define the animated line specified by `h`. Create an animated line with the `animatedline` function. For more information on line animations, see [Using Animated Line Objects](#).

`[x,y,z] = getpoints(h)` returns the coordinates for the 3-D animated line specified by `h`. If the line does not have any  $z$  values, then `getpoints` returns `z` as a vector of zeros the same length as `x` and `y`.

## Examples

### Return Points from Animated Line

Create an animated line with 10 points. Then, return the points stored in the animated line.

```
h = animatedline(1:10,1:10);
```

```
[x,y] = getpoints(h)
```

```
x =
```

```
1 2 3 4 5 6 7 8 9 10
```

```
y =
```

```
1 2 3 4 5 6 7 8 9 10
```

## Input Arguments

### **h** — Animated line object

animated line object

Animated line object. Create an animated line object using the `animatedline` function.

## Output Arguments

### **x** — x values

vector

x values that define the animated line, returned as vector.

### **y** — y values

vector

y values that define the animated line, returned as vector.

### **z** — z values

vector

z values that define the 3-D animated line, returned as vector.

# getpref

Preference

## Syntax

```
getpref('group','pref')
getpref('group','pref',default)
getpref('group',{'pref1','pref2',... 'prefn'})
getpref('group',{'pref1',... 'prefn'},{default1,...defaultn})
getpref('group')
getpref
```

## Description

`getpref('group','pref')` returns the value for the preference specified by `group` and `pref`. It is an error to get a preference that does not exist.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g. `'ApplicationOnePrefs'`. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`getpref('group','pref',default)` returns the current value if the preference specified by `group` and `pref` exists. Otherwise creates the preference with the specified default value and returns that value.

`getpref('group',{'pref1','pref2',... 'prefn'})` returns a cell array containing the values for the preferences specified by `group` and the cell array of preference names. The return value is the same size as the input cell array. It is an error if any of the preferences do not exist.

`getpref('group',{'pref1',... 'prefn'},{default1,...defaultn})` returns a cell array with the current values of the preferences specified by `group` and the cell array of preference names. Any preference that does not exist is created with the specified default value and returned.

`getpref('group')` returns the names and values of all preferences in the group as a structure.

getpref returns all groups and preferences as a structure.

---

**Note** Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

---

## Examples

### Get the Value of an Existing Preference

```
addpref('mytoolbox','version','1.0')
getpref('mytoolbox','version')
```

```
ans =
 1.0
```

### Create a Preference Using Specified Default Value

```
setpref('mytoolbox','version','1.0')
rmpref('mytoolbox','version')
getpref('mytoolbox','version','1.0');
getpref('mytoolbox','version')
```

```
ans =
 1.0
```

The first call to `getpref` adds the `'version'` preference and sets its value to the default value, `1.0`. The second call to `getpref` verifies that the preference exists, and that its value is `1.0`.

### See Also

`addpref` | `ispref` | `rmpref` | `setpref` | `uigetpref` | `uisetpref`

**Introduced before R2006a**

## getsampleusingtime (tscollection)

Extract data samples into new `tscollection` object

### Syntax

```
tsc2 = getsampleusingtime(tsc1,Time)
tsc2 = getsampleusingtime(tsc1,StartTime,EndTime)
```

### Description

`tsc2 = getsampleusingtime(tsc1,Time)` returns a new `tscollection` `tsc2` with a single sample corresponding to `Time` in `tsc1`.

`tsc2 = getsampleusingtime(tsc1,StartTime,EndTime)` returns a new `tscollection` `tsc2` with samples between the times `StartTime` and `EndTime` in `tsc1`.

### More About

#### Tips

When the time vector in `ts1` is numeric, `StartTime` and `EndTime` must also be numeric. When the times in `ts1` are date strings and the `StartTime` and `EndTime` values are numeric, then the `StartTime` and `EndTime` values are treated as `datenum` values.

#### See Also

`tscollection`

**Introduced before R2006a**

# getTag

**Class:** Tiff

Value of specified tag

## Syntax

```
tagValue = getTag(tagId)
```

## Description

`tagValue = getTag(tagId)` retrieves the value of the TIFF tag specified by `tagId`. You can specify `tagId` as a character string ('ImageWidth') or using the numeric tag identifier defined by the TIFF specification (256). To see a list of all the tags with their numeric identifiers, view the value of the Tiff object `TagID` property. Use the `TagID` property to specify the value of a tag. For example, `Tiff.TagID.ImageWidth` is equivalent to the tag's numeric identifier.

## Examples

### Get Value of Tag

Open a Tiff object and get the value of a tag. Specify the tag by name.

```
t = Tiff('example.tif', 'r');
tagval = t.getTag('ImageWidth')
```

```
tagval =
```

```
 600
```

Alternatively, specify the tag by numeric identifier.

```
tagval1 = t.getTag(256)
```

```
tagval1 =
```

600

Another way to specify the numeric identifier is to use the `TagID` property.

```
tagval2 = t.getTag(Tiff.TagID.ImageWidth)
```

```
tagval2 =
```

600

Close the `Tiff` object.

```
t.close();
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## References

This method corresponds to the `TIFFGetField` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTiff - TIFF Library and Utilities](#).

## See Also

`Tiff.setTag`

# Tiff.getTagNames

**Class:** Tiff

List of recognized TIFF tags

## Syntax

```
tagNames = Tiff.getTagNames()
```

## Description

`tagNames = Tiff.getTagNames()` returns a cell array of TIFF tags recognized by the Tiff object.

## Examples

Retrieve a list of TIFF tags recognized by the Tiff object.

```
Tiff.getTagNames
```

```
ans =
```

```
 'SubFileType'
 'ImageWidth'
 'ImageLength'
 'BitsPerSample'
 'Compression'
 'Photometric'
 'Thresholding'
 'FillOrder'
 'DocumentName'
 'ImageDescription'
 .
 .
 .
```

## See Also

## gettimeseriesnames

Cell array of names of `timeseries` objects in `tscollection` object

### Syntax

```
names = gettimeseriesnames(tsc)
```

### Description

`names = gettimeseriesnames(tsc)` returns names of `timeseries` objects in a `tscollection` object `tsc`. `names` is a cell array of strings.

### Examples

- 1 Create `timeseries` objects `a` and `b`.

```
a = timeseries(rand(1000,1), 'name', 'position');
b = timeseries(rand(1000,1), 'name', 'response');
```

- 2 Create a `tscollection` object that includes these two time series.

```
tsc = tscollection({a,b});
```

- 3 Get the names of the `timeseries` objects in `tsc`.

```
names = gettimeseriesnames(tsc)
```

```
names =
```

```
 'position' 'response'
```

### See Also

`timeseries` | `tscollection`

# gettsafterevent

New `timeseries` object with samples occurring at or after event

## Syntax

```
ts1 = gettsafterevent(ts,event)
ts1 = gettsafterevent(ts,event,n)
```

## Description

`ts1 = gettsafterevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring at and after an event in `ts`, where `event` can be either a `tsdata.event` object or a string. When `event` is a `tsdata.event` object, the time defined by `event` is used. When `event` is a string, the first `tsdata.event` object in the `Events` property of the time series `ts` that matches the event name specifies the time.

`ts1 = gettsafterevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples at and after an event in `ts`, where `n` is the number of the event occurrence with a matching event name.

## More About

### Tips

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

# gettsafterevent

New `timeseries` object with samples occurring after event

## Syntax

```
ts1 = gettsafterevent(ts,event)
ts1 = ttsafterevent(ts,event,n)
```

## Description

`ts1 = gettsafterevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring after an event in `ts`, where `event` can be either a `tsdata.event` object or a string. When `event` is a `tsdata.event` object, the time defined by `event` is used. When `event` is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = ttsafterevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring after an event in time series `ts`, where `n` is the number of the event occurrence with a matching event name.

## More About

### Tips

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

## gettsatevent

New `timeseries` object with samples occurring at event

### Syntax

```
ts1 = gettsatevent(ts,event)
ts1 = gettsatevent(ts,event,n)
```

### Description

`ts1 = gettsatevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring at an event in `ts`, where `event` can be either a `tsdata.event` object or a string. When `event` is a `tsdata.event` object, the time defined by `event` is used. When `event` is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsatevent(ts,event,n)` returns a new time series `ts1` with samples occurring at an event in time series `ts`, where `n` is the number of the event occurrence with a matching event name.

### More About

#### Tips

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in the `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

# gettsbeforeatevent

New `timeseries` object with samples occurring before or at event

## Syntax

```
ts1 = gettsbeforeatevent(ts,event)
ts1 = gettsbeforeatevent(ts,event,n)
```

## Description

`ts1 = gettsbeforeatevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring at and before an event in `ts`, where `event` can be either a `tsdata.event` object or a string. When `event` is a `tsdata.event` object, the time defined by `event` is used. When `event` is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsbeforeatevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring at and before an event in time series `ts`, where `n` is the number of the event occurrence with a matching event name.

## More About

### Tips

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

## gettsbeforeevent

New `timeseries` object with samples occurring before event

### Syntax

```
ts1 = gettsbeforeevent(ts,event)
ts1 = gettsbeforeevent(ts,event,n)
```

### Description

`ts1 = gettsbeforeevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring before an event in `ts`, where `event` can be either a `tsdata.event` object or a string. When `event` is a `tsdata.event` object, the time defined by `event` is used. When `event` is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsbeforeevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring before an event in `ts`, where `n` is the number of the event occurrence with a matching event name.

### More About

#### Tips

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

## gettsbetweenevents

New `timeseries` object with samples occurring between events

### Syntax

```
ts1 = gettsbetweenevents(ts,event1,event2)
ts1 = gettsbetweenevents(ts,event1,event2,n1,n2)
```

### Description

`ts1 = gettsbetweenevents(ts,event1,event2)` returns a new `timeseries` object `ts1` with samples occurring between events in `ts`, where `event1` and `event2` can be either a `tsdata.event` object or a string. When `event1` and `event2` are `tsdata.event` objects, the time defined by the events is used. When `event1` and `event2` are strings, the first `tsdata.event` object in the `Events` property of `ts` that matches the event names specifies the time.

`ts1 = gettsbetweenevents(ts,event1,event2,n1,n2)` returns a new `timeseries` object `ts1` with samples occurring between events in `ts`, where `n1` and `n2` are the `n`th occurrences of the events with matching event names.

### More About

#### Tips

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

#### See Also

# GetVariable

Data from variable in Automation server workspace

## Syntax

### IDL Method Signature

```
HRESULT GetVariable([in] BSTR varname, [in] BSTR workspace,
 [out, retval] VARIANT* pdata)
```

### Microsoft Visual Basic Client

```
GetVariable(varname As String, workspace As String) As Object
```

### MATLAB Client

```
D = GetVariable(h, 'varname', 'workspace')
```

## Description

`D = GetVariable(h, 'varname', 'workspace')` gets data stored in variable `varname` from the specified `workspace` of the server attached to handle `h` and returns it in output argument `D`. The values for `workspace` are `base` or `global`.

Do *not* use `GetVariable` on sparse arrays, structures, or function handles.

If your scripting language requires a result be returned explicitly, use the `GetVariable` function in place of `GetWorkspaceData`, `GetFullMatrix`, or `GetCharArray`.

## Examples

This example uses a Visual Basic .NET client to read data from a MATLAB Automation server:

```
Dim Matlab As Object
```

```
Dim Result As String
Dim C2 As Variant
Matlab = CreateObject("matlab.application")
Result = Matlab.Execute("C1 = {25.72, 'hello', rand(4)};")
C2 = Matlab.GetVariable("C1", "base")
MsgBox("Second item in cell array: " & C2(0, 1))
```

## See Also

[GetWorkspaceData](#) | [GetFullMatrix](#) | [GetCharArray](#) | [Execute](#)

**Introduced before R2006a**

## Tiff.getVersion

**Class:** Tiff

LibTIFF library version

### Syntax

```
versionString = Tiff.getVersion()
```

### Description

`versionString = Tiff.getVersion()` returns the version number and other information about the LibTIFF library.

### Examples

Display version of LibTIFF library:

```
Tiff.getVersion
```

```
ans =
```

```
LIBTIFF, Version 3.9.5
```

```
Copyright (c) 1988-1996 Sam Leffler
```

```
Copyright (c) 1991-1996 Silicon Graphics, Inc.
```

### References

This method corresponds to the `TIFFGetVersion` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

# GetWorkspaceData

Data from Automation server workspace

## Syntax

### IDL Method Signature

```
HRESULT GetWorkspaceData([in] BSTR varname, [in] BSTR workspace,
 [out] VARIANT* pdata)
```

### Microsoft Visual Basic Client

```
GetWorkspaceData(varname As String, workspace As String) As Object
```

### MATLAB Client

```
D = GetWorkspaceData(h, 'varname', 'workspace')
```

## Description

`D = GetWorkspaceData(h, 'varname', 'workspace')` gets data stored in variable `varname` from the specified `workspace` of the server attached to handle `h` and returns it in output argument `D`. The values for `workspace` are `base` or `global`.

Use `GetWorkspaceData` instead of `GetFullMatrix` and `GetCharArray` to get numeric and character array data, respectively. Do *not* use `GetWorkspaceData` on sparse arrays, structures, or function handles.

For VBScript clients, use the `GetWorkspaceData` and `PutWorkspaceData` functions to pass numeric data to and from the MATLAB workspace. These functions use the variant data type instead of the `safearray` data type used by `GetFullMatrix` and `PutFullMatrix`. VBScript does not support `safearray`.

## Examples

This example uses a Visual Basic .NET client to read data from a MATLAB Automation server:

```
Dim Matlab As Object
Dim C2 As Variant
Dim Result As String
Matlab = CreateObject("matlab.application")
Result = MatLab.Execute("C1 = {25.72, 'hello', rand(4)};")
MsgBox("In MATLAB, type" & vbCrLf & "C1")
Matlab.GetWorkspaceData("C1", "base", C2)
MsgBox("second value of C1 = " & C2(0, 1))
```

## See Also

**Introduced before R2006a**

# ginput

Graphical input from mouse or cursor

## Syntax

```
[x,y] = ginput(n)
[x,y] = ginput
[x,y,button] = ginput(...)
```

## Description

`ginput` raises crosshairs in the current axes to for you to identify points in the figure, positioning the cursor with the mouse. The figure must have focus before `ginput` can receive input. If it has no axes, one is created upon the first click or keypress.

`[x,y] = ginput(n)` enables you to identify `n` points from the current axes and returns their  $x$ - and  $y$ -coordinates in the `x` and `y` column vectors. Press the **Return** key to terminate the input before entering `n` points. Specify `n` as a positive integer.

`[x,y] = ginput` gathers an unlimited number of points until you press the **Return** key.

`[x,y,button] = ginput(...)` returns the  $x$ -coordinates, the  $y$ -coordinates, and the button or key designation. `button` is a vector of integers indicating which mouse buttons you pressed (1 for left, 2 for middle, 3 for right), or ASCII numbers indicating which keys on the keyboard you pressed.

Clicking an axes makes that axes the current axes. Even if you set the current axes before calling `ginput`, whichever axes you click becomes the current axes and `ginput` returns points relative to that axes. If you select points from multiple axes, the results returned are relative to the coordinate system of the axes they come from.

---

**Note:** MATLAB returns errors such as the following if you start MATLAB with the `-noFigureWindows` or `-nodisplay` flag and then run `ginput`:

Error using ginput (line 31)  
Terminal mode is no longer supported

---

## Definitions

Coordinates returned by `ginput` are scaled to the `XLim` and `YLim` bounds of the axes you click (data units). Setting the axes or figure `Units` property has no effect on the output from `ginput`. You can click anywhere within the figure canvas to obtain coordinates. If you click outside the axes limits, `ginput` extrapolates coordinate values so they are still relative to the axes origin.

The figure `CurrentPoint` property, by contrast, is always returned in figure `Units`, irrespective of axes `Units` or limits.

## Examples

Pick 4 two-dimensional points from the figure window.

```
[x,y] = ginput(4)
```

Position the cursor with the mouse. Enter data points by pressing a mouse button or a key on the keyboard. To terminate input before entering 4 points, press the **Return** key.

```
x =
 0.2362
 0.5749
 0.5680
 0.2707
```

```
y =
 0.6711
 0.6769
 0.4313
 0.4401
```

```
plot(x,y)
```

In this example, `plot` rescaled the axes  $x$ -limits and  $y$ -limits from  $[0 \ 1]$  and  $[0 \ 1]$  to  $[0.20 \ 0.65]$  and  $[0.40 \ 0.75]$ . The rescaling occurred because the axes `XLimMode` and `YLimMode` are set to `'auto'` (the default). Consider setting `XLimMode` and `YLimMode` to `'manual'` if you want to maintain consistency when you gather results from `ginput` and plot them together.

`gtext`

Introduced before R2006a

# global

Declare variables as global

## Syntax

```
global var1 ... varN
```

## Description

`global var1 ... varN` declares variables `var1 ... varN` as global in scope.

Ordinarily, each MATLAB function has its own local variables, which are separate from those of other functions and from those of the base workspace. However, if several functions all declare a particular variable name as `global`, then they all share a single copy of that variable. Any change of value to that variable, in any function, is visible to all the functions that declare it as global.

If the global variable does not exist the first time you issue the `global` statement, it is initialized to an empty 0x0 matrix.

If a variable with the same name as the global variable already exists in the current workspace, MATLAB issues a warning and changes the value of that variable and its scope to match the global variable.

## Examples

### Share Global Variable Between Functions

Create a function in your current working folder that sets the value of a global variable.

```
function setGlobalx(val)
global x
x = val;
```

Create a function in your current working folder that returns the value of a global variable. These two functions have separate function workspaces, but they both can access the global variable.

```
function r = getGlobalx
global x
r = x;
```

Set the value of the global variable, `x`, and obtain it from a different workspace.

```
setGlobalx(1138)
r = getGlobalx

r =
```

```
1138
```

### Share Global Variable Between Function and Command Line

Assign a value to the global variable using the function that you defined in the previous example.

```
clear all
setGlobalx(42)
```

Display the value of the global variable, `x`. Even though the variable is global, it is not accessible at the command line.

```
x
```

```
Undefined function or variable 'x'.
```

Declare `x` as a global variable at the command line, and display its value.

```
global x
x
```

```
x =
```

```
42
```

Change the value of `x` and use the function that you defined in the previous example to return the global value from a different workspace.

```
x = 1701;
r = getGlobalx
```

```
r =
```

1701

## More About

### Tips

- To clear a global variable from all workspaces, use `clear global variable`.
- To clear a global variable from the current workspace but not other workspaces, use `clear variable`.

## gmres

Generalized minimum residual method (with restarts)

### Syntax

```
x = gmres(A,b)
gmres(A,b,restart)
gmres(A,b,restart,tol)
gmres(A,b,restart,tol,maxit)
gmres(A,b,restart,tol,maxit,M)
gmres(A,b,restart,tol,maxit,M1,M2)
gmres(A,b,restart,tol,maxit,M1,M2,x0)
[x,flag] = gmres(A,b,...)
[x,flag,relres] = gmres(A,b,...)
[x,flag,relres,iter] = gmres(A,b,...)
[x,flag,relres,iter,resvec] = gmres(A,b,...)
```

### Description

`x = gmres(A,b)` attempts to solve the system of linear equations  $A^*x = b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and should be large and sparse. The column vector  $b$  must have length  $n$ .  $A$  can be a function handle, `afun`, such that `afun(x)` returns  $A^*x$ . For this syntax, `gmres` does not restart; the maximum number of iterations is  $\min(n, 10)$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `gmres` converges, a message to that effect is displayed. If `gmres` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A^*x) / \text{norm}(b)$  and the iteration number at which the method stopped or failed.

`gmres(A,b,restart)` restarts the method every `restart` inner iterations. The maximum number of outer iterations is  $\min(n/\text{restart}, 10)$ . The maximum number

of total iterations is `restart*min(n/restart,10)`. If `restart` is `n` or `[]`, then `gmres` does not restart and the maximum number of total iterations is `min(n,10)`.

`gmres(A,b,restart,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `gmres` uses the default, `1e-6`.

`gmres(A,b,restart,tol,maxit)` specifies the maximum number of outer iterations, i.e., the total number of iterations does not exceed `restart*maxit`. If `maxit` is `[]` then `gmres` uses the default, `min(n/restart,10)`. If `restart` is `n` or `[]`, then the maximum number of total iterations is `maxit` (instead of `restart*maxit`).

`gmres(A,b,restart,tol,maxit,M)` and `gmres(A,b,restart,tol,maxit,M1,M2)` use preconditioner `M` or `M = M1*M2` and effectively solve the system `inv(M)*A*x = inv(M)*b` for `x`. If `M` is `[]` then `gmres` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns `M\x`.

`gmres(A,b,restart,tol,maxit,M1,M2,x0)` specifies the first initial guess. If `x0` is `[]`, then `gmres` uses the default, an all-zero vector.

`[x,flag] = gmres(A,b,...)` also returns a convergence flag:

|                       |                                                                                                                    |
|-----------------------|--------------------------------------------------------------------------------------------------------------------|
| <code>flag = 0</code> | <code>gmres</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> outer iterations. |
| <code>flag = 1</code> | <code>gmres</code> iterated <code>maxit</code> times but did not converge.                                         |
| <code>flag = 2</code> | Preconditioner <code>M</code> was ill-conditioned.                                                                 |
| <code>flag = 3</code> | <code>gmres</code> stagnated. (Two consecutive iterates were the same.)                                            |

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = gmres(A,b,...)` also returns the relative residual norm `(b-A*x)/norm(b)`. If `flag` is 0, `relres <= tol`. The third output, `relres`, is the relative residual of the preconditioned system.

`[x,flag,relres,iter] = gmres(A,b,...)` also returns both the outer and inner iteration numbers at which `x` was computed, where `0 <= iter(1) <= maxit` and `0 <= iter(2) <= restart`.

`[x,flag,relres,iter,resvec] = gmres(A,b,...)` also returns a vector of the residual norms at each inner iteration. These are the residual norms for the preconditioned system.

## Examples

### Using gmres with a Matrix Input

```
A = gallery('wilk',21);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M1 = diag([10:-1:1 1 1:10]);

x = gmres(A,b,10,tol,maxit,M1);
```

displays the following message:

```
gmres(10) converged at outer iteration 2 (inner iteration 9) to
a solution with relative residual 3.3e-013
```

### Using gmres with a Function Handle

This example replaces the matrix `A` in the previous example with a handle to a matrix-vector product function `afun`, and the preconditioner `M1` with a handle to a backsolve function `mfun`. The example is contained in a function `run_gmres` that

- Calls `gmres` with the function handle `@afun` as its first argument.
- Contains `afun` and `mfun` as nested functions, so that all variables in `run_gmres` are available to `afun` and `mfun`.

The following shows the code for `run_gmres`:

```
function x1 = run_gmres
n = 21;
b = afun(ones(n,1));
tol = 1e-12; maxit = 15;
x1 = gmres(@afun,b,10,tol,maxit,@mfun);
```

```
function y = afun(x)
 y = [0; x(1:n-1)] + ...
 [((n-1)/2:-1:0)'; (1:(n-1)/2)'].*x + ...
 [x(2:n); 0];
end

function y = mfun(r)
 y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
end
end
```

When you enter

```
x1 = run_gmres;
```

MATLAB software displays the message

```
gmres(10) converged at outer iteration 2 (inner iteration 10)
to a solution with relative residual 1.1e-013.
```

## Using a Preconditioner without Restart

This example demonstrates the use of a preconditioner without restarting `gmres`.

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12;
maxit = 20;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
[x0,f10,rr0,it0,rv0] = gmres(A,b,[],tol,maxit);
```

`f10` is 1 because `gmres` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. The best approximate solution that `gmres` returns is the last one (as indicated by `it0(2) = 20`). MATLAB stores the residual history in `rv0`.

Plot the behavior of gmres.

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

The plot shows that the solution converges slowly. A preconditioner may improve the outcome.

Use `ilu` to form the preconditioner, since `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the 'udiag' option.

Note MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

As indicated by the error message, try again with a reduced drop tolerance.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,f11,rr1,it1,rv1] = gmres(A,b,[],tol,maxit,L,U);
```

f11 is 0 because gmres drives the relative residual to  $9.5436e-14$  (the value of rr1). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of it1(2)) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output, rv1(1), is  $\text{norm}(M \setminus b)$ , where  $M = L * U$ . The output, rv1(7), is  $\text{norm}(U \setminus (L \setminus (b - A * x1)))$ .

Follow the progress of gmres by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:it1(2),rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

## Using a Preconditioner with Restart

This example demonstrates the use of a preconditioner with restarted gmres.

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Construct an incomplete LU preconditioner as in the previous example.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
```

The benefit to using restarted `gmres` is to limit the amount of memory required to execute the method. Without restart, `gmres` requires `maxit` vectors of storage to keep the basis of the Krylov subspace. Also, `gmres` must orthogonalize against all of the previous vectors at each step. Restarting limits the amount of workspace used and the amount of work done per outer iteration. Note that even though preconditioned `gmres` converged in six iterations above, the algorithm allowed for as many as twenty basis vectors and therefore, allocated all of that space up front.

Execute `gmres(3)`, `gmres(4)`, and `gmres(5)`

```
tol = 1e-12;
maxit = 20;
re3 = 3;
[x3,f13,rr3,it3,rv3] = gmres(A,b,re3,tol,maxit,L,U);
re4 = 4;
[x4,f14,rr4,it4,rv4] = gmres(A,b,re4,tol,maxit,L,U);
re5 = 5;
[x5,f15,rr5,it5,rv5] = gmres(A,b,re5,tol,maxit,L,U);
```

`f13`, `f14`, and `f15` are all 0 because in each case restarted `gmres` drives the relative residual to less than the prescribed tolerance of  $1e-12$ .

The following plots show the convergence histories of each restarted `gmres` method. `gmres(3)` converges at outer iteration 5, inner iteration 3 (`it3 = [5, 3]`) which would be the same as outer iteration 6, inner iteration 0, hence the marking of 6 on the final tick mark.

```
figure
semilogy(1:1/3:6,rv3/norm(b),'-o');
h1 = gca;
h1.XTick = [1:1/3:6];
h1.XTickLabel = ['1'; ' '; ' '; '2'; ' '; ' '; '3'; ' '; ' '; '4'; ' '; ' '; '5'; ' '; ' '; '6'];
title('gmres(3)');
xlabel('Iteration number');
ylabel('Relative residual');
```

```
figure
semilogy(1:1/4:3,rv4/norm(b),'-o');
h2 = gca;
h2.XTick = [1:1/4:3];
h2.XTickLabel = ['1'; ' '; ' '; '2'; ' '; ' '; '3'];
```

```
title('gmres(4)')
xlabel('Iteration number');
ylabel('Relative residual');

figure
semilogy(1:1/5:2.8,rv5/norm(b),'-o');
h3 = gca;
h3.XTick = [1:1/5:2.8];
h3.XTickLabel = ['1'; ' '; ' '; ' '; ' '; '2'; ' '; ' '; ' '; ' '];
title('gmres(5)')
xlabel('Iteration number');
ylabel('Relative residual');
```

# gobjects

Initialize array for graphics objects

## Syntax

```
H = gobjects(n)
H = gobjects(s1, ..., sn)
H = gobjects(v)

H = gobjects
H = gobjects(0)
```

## Description

`H = gobjects(n)` returns an  $n$ -by- $n$  graphics object array. Use the `gobjects` function instead of the `ones` or `zeros` functions to preallocate an array to store graphics objects.

`H = gobjects(s1, ..., sn)` returns an  $s1$ -by-...-by- $sn$  graphics object array, where the list of integers  $s1, \dots, sn$  defines the dimensions of the array. For example, `gobjects(2,3)` returns a 2-by-3 array.

`H = gobjects(v)` returns a graphics object array where the elements of the row vector,  $v$ , define the dimensions of the array. For example, `gobjects([2,3,4])` returns a 2-by-3-by-4 array.

`H = gobjects` returns a 1-by-1 graphics object array.

`H = gobjects(0)` returns an empty graphics object array.

## Examples

### Specify Array Dimensions

Preallocate a 4-by-1 array to store graphics handles.

```
H = gobjects(4,1)
```

```
H =
```

```
4x1 GraphicsPlaceholder array:
```

```
GraphicsPlaceholder
GraphicsPlaceholder
GraphicsPlaceholder
GraphicsPlaceholder
```

## Specify Array Dimensions with Size of Existing Array

Create an array to store graphics handles using the size of an existing array.

Define A as a 3-by-4 array.

```
A = [1,2,3,2; 4,5,6,6; 7,8,9,7];
```

Create an array of graphics handles using the size of A.

```
v = size(A);
H = gobjects(v);
```

The dimensions of the graphics handle array are the same as the dimensions of A.

```
isequal(size(H),size(A))
```

```
ans =
```

```
1
```

## Return Empty Handle Array

Use the `gobjects` function to return an empty array.

```
H = gobjects(0)
```

```
H =
```

```
0x0 empty GraphicsPlaceholder array.
```

## Input Arguments

### **n** — defines n-by-n array

integer value

Size of the object array, specified as an integer value. Negative integers are treated as 0. The array has dimensions n-by-n.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **s1, . . . , sn** — Size of each array dimension

two or more integer values

Size of each array dimension, specified as a list of two or more integer values. Negative integers are treated as 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **v** — Size of each array dimension

row vector of integer values

Size of each array dimension, specified as a row vector of integer values. Negative integers are treated as 0.

Example: `[2,4,6,7]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### **0** — Define an empty array

one or more dimensions equal to 0

Define an empty array by specifying one or more dimension equal to 0

## Output Arguments

### **H** — Initialized graphics object array

graphics object array of specified size

Initialized graphics object array of type `GraphicsPlaceholder`. Use this array to contain any type of graphics object.

## **More About**

- “Graphics Arrays”

**Introduced in R2013a**

# gplot

Plot nodes and links representing adjacency matrix

## Syntax

```
gplot(A,Coordinates)
gplot(A,Coordinates,LineSpec)
```

## Description

The `gplot` function graphs a set of coordinates using an adjacency matrix.

`gplot(A,Coordinates)` plots a graph of the nodes defined in `Coordinates` according to the  $n$ -by- $n$  adjacency matrix `A`, where  $n$  is the number of nodes. `Coordinates` is an  $n$ -by-2 matrix, where  $n$  is the number of nodes and each coordinate pair represents one node.

`gplot(A,Coordinates,LineSpec)` plots the nodes using the line type, marker symbol, and color specified by `LineSpec`.

## Examples

### Plot Graph of Nodes Using Asterisks

Plot half of a "Bucky ball" carbon molecule, placing asterisks at each node.

```
k = 1:30;
[B,XY] = bucky;
gplot(B(k,k),XY(k,:), '-*')
axis square
```

## More About

### Tips

For two-dimensional data, `Coordinates(i,:) = [x(i) y(i)]` denotes node `i`, and `Coordinates(j,:) = [x(j) y(j)]` denotes node `j`. If node `i` and node `j` are connected, `A(i,j)` or `A(j,i)` is nonzero; otherwise, `A(i,j)` and `A(j,i)` are zero.

### See Also

`LineSpec` | `sparse` | `spy`

## grabcode

Extract MATLAB code from file published to HTML

### Syntax

```
grabcode('name.html')
grabcode('urlname')
codeString = grabcode('name.html')
```

### Description

`grabcode('name.html')` copies MATLAB code from the file `name.html` and pastes it into an untitled document in the Editor. Use `grabcode` to get MATLAB code from published files when the source code is not readily available. The file `name.html` was created by publishing `name.m`, a MATLAB code file containing cells. The MATLAB code from `name.m` is included at the end of `name.html` as HTML comments.

`grabcode('urlname')` copies MATLAB code from the `urlname` location and pastes it into an untitled document in the Editor.

`codeString = grabcode('name.html')` gets MATLAB code from the file `name.html` and assigns it the variable `codeString`.

### Examples

This example illustrates how to use `grabcode` to get MATLAB code from an existing HTML file:

```
% Copy sine_wave_f.html and the images it includes
% from the MATLAB examples directory to your
% current folder:

copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
 'examples','sine_wave_f.html'), 'my_sine_wave.html')

copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
```

```
'examples','sine_wave_f_01.png'), 'sine_wave_f_01.png')
copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
'examples','sine_wave_f_02.png'), 'sine_wave_f_02.png')

% If you want to view the file, double-click my_sine_wave.html
% in your current folder.

% Extract the MATLAB code from sine_wave_f.html:
code = grabcode('my_sine_wave.html')

MATLAB returns:

code =

%% Plot Sine Wave
% Calculate and plot a sine wave.

%% Calculate and Plot Sine Wave
% Calculate and plot |y = sin(x)|.

function sine_wave_f(x)

y = sin(x);
plot(x,y)

%% Modify Plot Properties

title('Sine Wave', 'FontWeight','bold')
xlabel('x')
ylabel('sin(x)')
set(gca, 'Color', 'w')
set(gcf, 'MenuBar', 'none')
```

# gradient

Numerical gradient

## Syntax

```
FX = gradient(F)
[FX,FY] = gradient(F)
[FX,FY,FZ,...] = gradient(F)
[...] = gradient(F,h)
[...] = gradient(F,h1,h2,...)
```

## Definitions

The *gradient* of a function of two variables,  $F(x,y)$ , is defined as

$$\nabla F = \frac{\partial F}{\partial x} \hat{i} + \frac{\partial F}{\partial y} \hat{j}$$

and can be thought of as a collection of vectors pointing in the direction of increasing values of  $F$ . In MATLAB software, numerical gradients (differences) can be computed for functions with any number of variables. For a function of  $N$  variables,  $F(x,y,z, \dots)$ ,

$$\nabla F = \frac{\partial F}{\partial x} \hat{i} + \frac{\partial F}{\partial y} \hat{j} + \frac{\partial F}{\partial z} \hat{k} + \dots$$

## Description

`FX = gradient(F)`, where  $F$  is a vector, returns the one-dimensional numerical gradient of  $F$ . Here  $FX$  corresponds to  $\partial F / \partial x$ , the differences in  $x$  (horizontal) direction.

`[FX,FY] = gradient(F)`, where  $F$  is a matrix, returns the  $x$  and  $y$  components of the two-dimensional numerical gradient.  $FX$  corresponds to  $\partial F / \partial x$ , the differences in  $x$  (horizontal) direction.  $FY$  corresponds to  $\partial F / \partial y$ , the differences in the  $y$  (vertical) direction. The spacing between points in each direction is assumed to be one.

`[FX,FY,FZ,...] = gradient(F)`, where  $F$  has  $N$  dimensions, returns the  $N$  components of the gradient of  $F$ . There are two ways to control the spacing between values in  $F$ :

- A single spacing value,  $h$ , specifies the spacing between points in every direction.
- $N$  spacing values ( $h_1, h_2, \dots$ ) specifies the spacing for each dimension of  $F$ . Scalar spacing parameters specify a constant spacing for each dimension. Vector parameters specify the coordinates of the values along corresponding dimensions of  $F$ . In this case, the length of the vector must match the size of the corresponding dimension.

---

**Note** The first output  $FX$  is always the gradient along the 2nd dimension of  $F$ , going across columns. The second output  $FY$  is always the gradient along the 1st dimension of  $F$ , going across rows. For the third output  $FZ$  and the outputs that follow, the  $N$ th output is the gradient along the  $N$ th dimension of  $F$ .

---

`[...] = gradient(F,h)`, where  $h$  is a scalar, uses  $h$  as the spacing between points in each direction.

`[...] = gradient(F,h1,h2,...)` with  $N$  spacing parameters specifies the spacing for each dimension of  $F$ .

## Examples

### Contour Plot of Vector Field

Calculate the 2-D gradient of  $xe^{-x^2-y^2}$  on a grid.

```
v = -2:0.2:2;
[x,y] = meshgrid(v);
z = x .* exp(-x.^2 - y.^2);
[px,py] = gradient(z,.2,.2);
```

Plot the contour lines and vectors in the same figure.

```
contour(v,v,z)
hold on
quiver(v,v,px,py)
hold off
```

## Specify Dimensional Spacing of Points

Create a 3-D array.

```
F(:,:,1) = magic(3);
F(:,:,2) = pascal(3);
```

The command,

```
gradient(F)
```

takes  $dx = dy = dz = 1$ . However, the command,

```
[PX,PY,PZ] = gradient(F,0.2,0.1,0.2)
```

takes  $dx = 0.2$ ,  $dy = 0.1$ , and  $dz = 0.2$ .

## More About

### Algorithms

`gradient` calculates the *central difference* for interior data points. For example, consider a matrix with unit-spaced data,  $A$ , that has horizontal gradient  $G = \text{gradient}(A)$ . The interior gradient values,  $G(:, j)$ , are:

$$G(:, j) = 0.5 * (A(:, j+1) - A(:, j-1));$$

where  $j$  varies between 2 and  $N-1$ , where  $N$  is `size(A,2)`.

The gradient values along the edges of the matrix are calculated with *single-sided differences*, so that

$$\begin{aligned} G(:, 1) &= A(:, 2) - A(:, 1); \\ G(:, N) &= A(:, N) - A(:, N-1); \end{aligned}$$

If the point spacing is specified, then the differences are scaled appropriately. If two or more outputs are specified, `gradient` also calculates differences along other dimensions in a similar manner. Unlike the `diff` function, `gradient` returns an array with the same number of elements as the input.

Introduced before R2006a

## addedge

Add new edge to graph

### Syntax

```
H = addedge(G,s,t)
H = addedge(G,s,t,w)
H = addedge(G,EdgeTable)
```

### Description

`H = addedge(G,s,t)` adds an edge to graph `G` between nodes `s` and `t`. The edge between `s` and `t` cannot already exist in `G`. If a node specified by `s` or `t` is not present in `G`, then that node is added as well. The new graph, `H`, is equivalent to `G`, but includes the new edge and any required new nodes.

`H = addedge(G,s,t,w)` also specifies weights, `w`, for the edges between `s` and `t`.

`H = addedge(G,EdgeTable)` adds edges with attributes specified by the table, `EdgeTable`. The `EdgeTable` input must be able to be concatenated with `G.Edges`.

### Examples

#### Add Edges to Graph

Add two new edges to an existing graph. Since one of the new edges references a node that does not exist, `addedge` automatically adds the required fourth node to the graph.

```
G = graph([1 2],[2 3])
```

```
G =
```

```
graph with properties:
```

```
Edges: [2x1 table]
Nodes: [3x0 table]
```

```
G = addedge(G,[2 1],[4 3])
```

```
G =
```

```
graph with properties:
```

```
Edges: [4x1 table]
```

```
Nodes: [4x0 table]
```

### Add Weighted Edges to Graph

Create a directed graph with weighted edges.

```
G = digraph({'A' 'B' 'C'}, {'D' 'C' 'D'}, [10 20 45])
```

```
G =
```

```
digraph with properties:
```

```
Edges: [3x2 table]
```

```
Nodes: [4x1 table]
```

Add three new weighted edges to the graph. `addedge` also automatically adds any required new nodes to the graph.

```
G = addedge(G, {'A' 'D' 'E'}, {'E' 'B' 'D'}, [5 30 5])
```

```
G =
```

```
digraph with properties:
```

```
Edges: [6x2 table]
```

```
Nodes: [5x1 table]
```

### Add Edges with Attributes to Graph

Create a graph whose edges have the attributes `Weight` and `Power`. Use an edge table to create the graph.

```
EdgeTable = table([1 2; 2 3; 2 4; 2 5; 5 6; 5 7; 5 8], ...
 {'on', 'off', 'off', 'on', 'on', 'on', 'off'}', [10 20 20 10 10 10 20] ', ...
 'VariableNames', {'EndNodes', 'Power', 'Weight'});
G = graph(EdgeTable)
```

G =

graph with properties:

Edges: [7x3 table]  
Nodes: [8x0 table]

Add two new edges to the graph by creating a smaller table that can be concatenated to `G.Edges`. Note that this smaller table must use the same order of variables as `G.Edges`.

```
NewEdges = table([5 9; 3 6], {'on' 'off'}', [10 20] ', ...
 'VariableNames', {'EndNodes', 'Power', 'Weight'});
G = addedge(G, NewEdges)
```

G =

graph with properties:

Edges: [9x3 table]  
Nodes: [9x0 table]

View the new edge list of the graph, which includes the added edges.

`G.Edges`

ans =

|   | EndNodes | Power | Weight |
|---|----------|-------|--------|
| 1 | 2        | 'on'  | 10     |
| 2 | 3        | 'off' | 20     |
| 2 | 4        | 'off' | 20     |
| 2 | 5        | 'on'  | 10     |
| 3 | 6        | 'off' | 20     |

|   |   |       |    |
|---|---|-------|----|
| 5 | 6 | 'on'  | 10 |
| 5 | 7 | 'on'  | 10 |
| 5 | 8 | 'off' | 20 |
| 5 | 9 | 'on'  | 10 |

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a **graph** or **digraph** object. Use the **graph** function to create an undirected graph or the **digraph** function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

### **s, t** — Node pairs (as separate arguments)

scalars | vectors | strings | cell arrays of strings

Node pairs, specified as separate arguments of scalars, vectors, strings, or cell arrays of strings. Similarly located elements in **s** and **t** specify the source and target nodes for an edge in the graph.

Example: `G = addedge(G, [1 2], [3 4])` adds two edges to the graph: one from node 1 to node 3, and one from node 2 to node 4.

Example: `G = addedge(G, {'a' 'a'; 'b' 'c'}, {'b' 'c'; 'c' 'e'})` adds four edges to the graph, the first of which goes from 'a' to 'b'.

### **w** — Edge weights

scalar | vector | matrix

Edge weights, specified as a scalar, vector, or matrix.

- If **w** is a scalar or row vector, then it is scalar expanded to specify a weight for each edge in **s** and **t**.
- If **w** is a column vector, then it must have the same length as **s(:)** and **t(:)**.
- If **w** is a matrix, it must have the same number of rows as **s(:)** and **t(:)**.

Example: `G = addedge(G, [2 2], [4 5], [1 100]')` adds two edges with weights of 1 and 100.

Data Types: `single` | `double`

Complex Number Support: Yes

## **EdgeTable** — Edge attributes

table

Edge attributes, specified as a table. **EdgeTable** must be able to be concatenated with **G.Edges**:

- The first variable in **EdgeTable** must be **EndNodes**.
- For weighted graphs, **EdgeTable** must also contain a variable **Weight**.
- If the graph has other edge attributes, then **EdgeTable** must contain all of the same variables as **G.Edges** to ensure compatibility.
- The order of variables in **EdgeTable** must be the same as that of **G.Edges**.

Data Types: `table`

## **Output Arguments**

### **H** — Output graph

graph object | digraph object

Output graph, returned as a graph or digraph object.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

## **More About**

- “Directed and Undirected Graphs”
- “Modify Nodes and Edges of Existing Graph”
- “Add Graph Node Names, Edge Weights, and Other Attributes”

## **See Also**

`addnode` | `digraph` | `graph` | `numedges` | `rmedge`

**Introduced in R2015b**

## addnode

Add new node to graph

### Syntax

```
H = addnode(G,nodeIDs)
H = addnode(G,numNodes)
H = addnode(G,NodeProps)
```

### Description

`H = addnode(G,nodeIDs)` adds the nodes specified by `nodeIDs` to graph `G`. The node names in `nodeIDs` must not refer to nodes already present in `G`.

`H = addnode(G,numNodes)` adds a number of new nodes to `G` equal to `numNodes`. If `G` contains nodes with names, then the new nodes are assigned sequential names indicating their row placement in `G.Nodes.Name`. For example, 'Node5' is located at `G.Nodes.Name(5)`.

`H = addnode(G,NodeProps)` adds new nodes to `G` with the node properties in `NodeProps`. One node is added for each row in `NodeProps`. The `NodeProps` table must be able to be concatenated to `G.Nodes`, so that the result is `H.Nodes = [G.Nodes; NodeProps]`.

### Examples

#### Add Nodes to Graph

Add two nodes to a graph that does not have node names.

```
G = graph([1 2 3],[2 3 4])
```

```
G =
```

```
graph with properties:
```

```
Edges: [3x1 table]
Nodes: [4x0 table]
```

```
G = addnode(G,2)
```

```
G =
```

```
graph with properties:
```

```
Edges: [3x1 table]
Nodes: [6x0 table]
```

Add node names to the graph, and then add five additional new nodes. The auto-generated names for the new nodes indicate their placement in `G.Nodes.Name`.

```
G.Nodes.Name = {'A' 'B' 'C' 'D' 'E' 'F'}
```

```
G =
```

```
graph with properties:
```

```
Edges: [3x1 table]
Nodes: [6x1 table]
```

```
G = addnode(G,5);
```

```
G.Nodes
```

```
ans =
```

```
 Name

'A'
'B'
'C'
'D'
'E'
'F'
'Node7'
'Node8'
```

```
'Node9'
'Node10'
'Node11'
```

## Add Named Nodes to Graph

Create a directed graph with named nodes, and then add two named nodes to the graph.

```
G = digraph({'A' 'B' 'C'},{'D' 'C' 'D'})
```

```
G =
```

```
digraph with properties:
```

```
Edges: [3x1 table]
Nodes: [4x1 table]
```

```
G = addnode(G,{'E' 'F'})
```

```
G =
```

```
digraph with properties:
```

```
Edges: [3x1 table]
Nodes: [6x1 table]
```

If the graph does not already have node names, then adding named nodes to the graph automatically generates names for the other nodes.

Create a directed graph without node names, and then add two named nodes to the graph.

```
H = digraph([1 2 3],[4 3 4])
```

```
H =
```

```
digraph with properties:
```

```
Edges: [3x1 table]
```

```
Nodes: [4x0 table]
```

```
H = addnode(H,{'E','F'});
H.Nodes
```

```
ans =
```

```
 Name

 'Node1'
 'Node2'
 'Node3'
 'Node4'
 'E'
 'F'
```

### Add Nodes with Attributes to Graph

Create a graph whose nodes represent airports.

```
G = graph({'JFK' 'LAX'}, {'LAX' 'DEN'})
```

```
G =
```

```
graph with properties:
```

```
Edges: [2x1 table]
Nodes: [3x1 table]
```

Add a node attribute to indicate whether each airport has free WIFI.

```
G.Nodes.WIFI = [false true true]';
G.Nodes
```

```
ans =
```

```
 Name WIFI

```

```
'JFK' false
'LAX' true
'DEN' true
```

Add two new nodes to the graph by creating a table, `NodeProps`, containing the node name and WIFI status of each new node. Use `addnode` to concatenate `NodeProps` to `G.Nodes`.

```
NodeProps = table({'ATL' 'ANC'}, [false true], ...
 'VariableNames', {'Name' 'WIFI'});
G = addnode(G, NodeProps);
```

View the modified node table.

`G.Nodes`

ans =

| Name  | WIFI  |
|-------|-------|
| 'JFK' | false |
| 'LAX' | true  |
| 'DEN' | true  |
| 'ATL' | false |
| 'ANC' | true  |

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a `graph` or `digraph` object. Use the `graph` function to create an undirected graph or the `digraph` function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

**nodeIDs — Node names**

string | cell array of strings

Node names, specified as a string or cell array of strings.

Data Types: char | cell

**numNodes — Number of nodes to add**

nonnegative numeric scalar

Number of nodes to add, specified as a nonnegative numeric scalar.

**NodeProps — Node attributes**

table

Node attributes, specified as a table.

Data Types: table

## Output Arguments

**H — Output graph**

graph object | digraph object

Output graph, returned as a graph or digraph object.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

## More About

- “Directed and Undirected Graphs”
- “Modify Nodes and Edges of Existing Graph”
- “Add Graph Node Names, Edge Weights, and Other Attributes”

addedge | graph | numnodes | rmnode

**Introduced in R2015b**

# adjacency

Graph adjacency matrix

## Syntax

A = adjacency(G)

## Description

A = adjacency(G) returns the sparse adjacency matrix for graph G. If (i, j) is an edge in G, then  $A(i, j) = 1$ . Otherwise,  $A(i, j) = 0$ .

## Examples

### Adjacency Matrix of Graph

Create a directed graph using an edge list, and then find the equivalent adjacency matrix representation of the graph. The adjacency matrix is returned as a sparse matrix.

```
s = [1 1 1 2 2 3];
t = [2 3 4 5 6 7];
G = digraph(s,t)
```

G =

digraph with properties:

```
Edges: [6x1 table]
Nodes: [7x0 table]
```

A = adjacency(G)

A =

```
(1,2) 1
(1,3) 1
(1,4) 1
(2,5) 1
(2,6) 1
(3,7) 1
```

### Adjacency Matrix of Weighted Graph

Create an undirected graph using an upper triangular adjacency matrix. When constructing a graph with an adjacency matrix, the nonzero values in the matrix correspond to edge weights.

```
A = [0 5 3 0; 0 0 1 2; 0 0 0 11; 0 0 0 0]
```

```
A =
```

```
 0 5 3 0
 0 0 1 2
 0 0 0 11
 0 0 0 0
```

```
G = graph(A, 'upper')
```

```
G =
```

```
graph with properties:
```

```
Edges: [5x2 table]
Nodes: [4x0 table]
```

```
G.Edges
```

```
ans =
```

```
EndNodes Weight

```

```
1 2 5
1 3 3
2 3 1
2 4 2
3 4 11
```

Use `adjacency` to return the adjacency matrix of the graph. Regardless of the form of adjacency matrix used to construct the graph, the `adjacency` function always returns a symmetric and sparse adjacency matrix containing only 1s and 0s.

```
B = adjacency(G)
```

```
B =
```

```
(2,1) 1
(3,1) 1
(1,2) 1
(3,2) 1
(4,2) 1
(1,3) 1
(2,3) 1
(4,3) 1
(2,4) 1
(3,4) 1
```

## Reconstruct Weighted Adjacency Matrix

Create a weighted graph.

```
G = digraph([1 1 1 2],[2 3 4 4],[5 6 7 8])
```

```
G =
```

```
digraph with properties:
```

```
Edges: [4x2 table]
Nodes: [4x0 table]
```

Find the adjacency matrix of the graph.

```
A = adjacency(G)
```

```
A =
```

```
(1,2) 1
(1,3) 1
(1,4) 1
(2,4) 1
```

This form of the adjacency matrix does not include the edge weights in the graph.

Use the `sparse` function to construct a weighted adjacency matrix representation of the graph.

```
nn = numnodes(G);
[s,t] = findedge(G);
A = sparse(s,t,G.Edges.Weight,nn,nn)
```

```
A =
```

```
(1,2) 5
(1,3) 6
(1,4) 7
(2,4) 8
```

Preview a full storage version of the matrix.

```
full(A)
```

```
ans =
```

```
 0 5 6 7
 0 0 0 8
 0 0 0 0
 0 0 0 0
```

This reconstruction of the weighted adjacency matrix also can be accomplished with undirected graphs. In that case, the procedure is similar, but has one final step:

```
A = A + A.' - diag(diag(A));
```

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a **graph** or **digraph** object. Use the **graph** function to create an undirected graph or the **digraph** function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

## Output Arguments

### **A** — Adjacency matrix

sparse matrix

Adjacency matrix, returned as a sparse matrix. The size of **A** is `numnodes(G)`-by-`numnodes(G)`.

**Introduced in R2015b**

# bfsearch

Breadth-first graph search

## Syntax

```
v = bfsearch(G,s)
T = bfsearch(G,s,events)
T = bfsearch(____, 'Restart', true)
```

## Description

`v = bfsearch(G,s)` applies breadth-first search to graph `G` starting at node `s`. The result is a vector of node IDs in order of their discovery.

`T = bfsearch(G,s,events)` customizes the output of the breadth-first search by flagging one or more search events. For example, `T = bfsearch(G,s,'allevents')` returns a table containing all flagged events, and `X = bfsearch(G,s,'edgetonew')` returns a matrix or cell array of edges.

`T = bfsearch( ____, 'Restart', true)` restarts the search if no new nodes are reachable from the discovered nodes. You can use any of the input argument combinations in previous syntaxes. This option ensures that the breadth-first search reaches all nodes and edges in the graph, even if they are not reachable from the starting node, `s`.

## Examples

### Perform Breadth-First Graph Search

Create and plot a graph.

```
s = [1 1 1 1 2 2 2 2 2 2 2 2 2 2 2 15 15 15 15 15];
t = [3 5 4 2 14 6 11 12 13 10 7 9 8 15 16 17 19 18 20];
G = graph(s,t);
plot(G)
```

Perform a breadth-first search of the graph starting at node 2. The result indicates the order of node discovery.

```
v = bfssearch(G,2)
```

```
v =
```

- 2
- 1
- 6
- 7
- 8
- 9

10  
11  
12  
13  
14  
15  
3  
4  
5  
16  
17  
18  
19  
20

### **Breadth-First Graph Search with All Events**

Create and plot a directed graph.

```
s = [1 1 1 2 3 3 3 4 6];
t = [2 4 5 5 6 7 4 1 4];
G = digraph(s,t);
plot(G)
```

Perform a breadth-first search on the graph starting at node 1. Specify 'allevents' to return a table containing all of the events in the algorithm.

```
T = bfssearch(G,1,'allevents')
```

T =

| Event        | Node | Edge |     |
|--------------|------|------|-----|
| startnode    | 1    | NaN  | NaN |
| discovernode | 1    | NaN  | NaN |
| edgetonew    | NaN  | 1    | 2   |

|                  |     |     |     |
|------------------|-----|-----|-----|
| discovernode     | 2   | NaN | NaN |
| edgetonew        | NaN | 1   | 4   |
| discovernode     | 4   | NaN | NaN |
| edgetonew        | NaN | 1   | 5   |
| discovernode     | 5   | NaN | NaN |
| finishnode       | 1   | NaN | NaN |
| edgetodiscovered | NaN | 2   | 5   |
| finishnode       | 2   | NaN | NaN |
| edgetofinished   | NaN | 4   | 1   |
| finishnode       | 4   | NaN | NaN |
| finishnode       | 5   | NaN | NaN |

To follow the steps in the algorithm, read the events in the table from top to bottom. For example:

- 1 The algorithm begins at node 1
- 2 An edge is discovered between node 1 and node 2
- 3 Node 2 is discovered
- 4 and so on...

### Breadth-First Graph Search with Multiple Components

Perform a breadth-first search of a graph with multiple components, and then highlight the graph nodes and edges based on the search results.

Create and plot a directed graph. This graph has two weakly connected components.

```
s = [1 1 2 2 2 3 4 7 8 8 8 8];
t = [3 4 7 5 6 2 6 2 9 10 11 12];
G = digraph(s,t);
p = plot(G, 'Layout', 'layered');
```

```
c = conncomp(G, 'Type', 'weak')
```

```
c =
```

```
1 1 1 1 1 1 1 2 2 2 2 2
```

Perform a breadth-first search of the graph starting at node 2, and flag the 'edgetonew', 'edgetofinished', and 'startnode' events. Specify Restart as true to make the search restart whenever there are remaining nodes that cannot be reached.

```
events = {'edgetonew', 'edgetofinished', 'startnode'};
```

```
T = bfsearch(G,2,events, 'Restart', true)
```

```
T =
```

| Event          | Node | Edge | Edge |
|----------------|------|------|------|
| startnode      | 2    | NaN  | NaN  |
| edgetonew      | NaN  | 2    | 5    |
| edgetonew      | NaN  | 2    | 6    |
| edgetonew      | NaN  | 2    | 7    |
| edgetofinished | NaN  | 7    | 2    |
| startnode      | 1    | NaN  | NaN  |
| edgetonew      | NaN  | 1    | 3    |
| edgetonew      | NaN  | 1    | 4    |
| edgetofinished | NaN  | 3    | 2    |
| edgetofinished | NaN  | 4    | 6    |
| startnode      | 8    | NaN  | NaN  |
| edgetonew      | NaN  | 8    | 9    |
| edgetonew      | NaN  | 8    | 10   |
| edgetonew      | NaN  | 8    | 11   |
| edgetonew      | NaN  | 8    | 12   |

When `Restart` is true, the `'startnode'` event returns information about where and when the algorithm restarts the search.

Highlight the graph based on event:

- Color the starting nodes red.
- Green edges are for `'edgetonew'`
- Black edges are for `'edgetofinished'`

```
edgenew = T.Edge(T.Event == 'edgetonew',:);
edgefin = T.Edge(T.Event == 'edgetofinished',:);

highlight(p,edgenew(:,1),edgenew(:,2), 'EdgeColor', 'g')
highlight(p,edgefin(:,1),edgefin(:,2), 'EdgeColor', 'k')
highlight(p,T.Node(~isnan(T.Node)), 'NodeColor', 'r')
```

### Determine if Graph is Bipartite

Use breadth-first search to determine that a graph is bipartite, and return the relevant partitions. A bipartite graph is a graph that has nodes you can divide into two sets, A and B, with each edge in the graph connecting a node in A to a node in B.

Create and plot a directed graph.

```
s = [1 1 1 1 2 2 4 5 6 7 8];
t = [2 3 6 8 5 10 6 6 10 3 10];
g = digraph(s,t);
plot(g);
```

Use a breath-first search on the graph to determine if it is bipartite, and if so, return the relevant partitions.

```

events = {'edgetonew', 'edgetodiscovered', 'edgetofinished'};
T = bfsearch(g, 1, events, 'Restart', true);
partitions = false(1, numnodes(g));
is_bipart = true;

for ii=1:size(T, 1)
 if T.Event(ii) == 'edgetonew'
 partitions(T.Edge(ii, 2)) = ~partitions(T.Edge(ii, 1));
 else
 if partitions(T.Edge(ii, 1)) == partitions(T.Edge(ii, 2))
 is_bipart = false;
 end
 end
end

```

```
 break;
 end
 end
 end
```

```
is_bipart
```

```
is_bipart =
```

```
 1
```

Since `g` is bipartite, the `partitions` variable contains the information about which partition each node belongs to.

Plot the bipartite graph with the 'layered' layout, using the `partitions` variable to specify the source nodes that appear in the first layer.

```
partitions
```

```
partitions =
```

```
 0 1 1 0 0 1 0 1 0 0
```

```
plot(g, 'Layout', 'layered', 'Source', find(partitions));
```

- “Visualize Breadth-First and Depth-First Search”

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a `graph` or `digraph` object. Use the `graph` function to create an undirected graph or the `digraph` function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

**s — Starting node**

nonnegative scalar integer | string

Starting node, specified as either a nonnegative scalar integer between 1 and `numnodes(G)`, or a string containing a node name.

Example: `bfsearch(G,1)`

**events — Flagged search events**

'discovernode' (default) | 'startnode' | 'finishnode' | 'edgetonew' | 'edgetodiscovered' | 'edgetofinished' | 'allevents' | cell array

Flagged search events, specified as one of the options in the following table.

- To flag single events, use the flag names.
- To flag a subset of events, put two or more flag names into a cell array.
- To flag all events, use 'allevents'.

---

**Note:** Depending on the value of `events`, the output of `bfsearch` varies. See the last column in the following table for information about the output returned by each option.

---

| Value of events          | Description                                                                                                                                               | Output                                                                                                                                                                                                                                                                         |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'discovernode' (default) | A new node has been discovered.                                                                                                                           | Return a vector of node IDs: <ul style="list-style-type: none"> <li>• If <code>s</code> is a numeric node index, then the vector contains numeric node indices.</li> <li>• If <code>s</code> is a node name, then the vector is a cell array containing node names.</li> </ul> |
| 'finishnode'             | All outgoing edges from the node have been visited.                                                                                                       |                                                                                                                                                                                                                                                                                |
| 'startnode'              | This flag indicates the starting node in the search.<br><br>If 'Restart' is true, then 'startnode' flags the starting node each time the search restarts. |                                                                                                                                                                                                                                                                                |
| 'edgetonew'              | Edge connects to an undiscovered node.                                                                                                                    | Return a matrix or cell array of size N-by-2 that specifies                                                                                                                                                                                                                    |

| Value of events    | Description                                    | Output                                                                                                                                                                                                                                         |
|--------------------|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'edgetodiscovered' | Edge connects to a previously discovered node. | the end nodes of edges in the graph:                                                                                                                                                                                                           |
| 'edgetofinished'   | Edge connects to a finished node.              | <ul style="list-style-type: none"><li>• If <math>s</math> is a numeric node index, then the matrix contains numeric node indices.</li><li>• If <math>s</math> is a node name, then the matrix is a cell array containing node names.</li></ul> |

| Value of events | Description                                                                            | Output                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cell array      | Specify two or more flags in a cell array to only flag those events during the search. | Return a table, <code>T</code> , which contains the variables <code>T.Event</code> , <code>T.Node</code> , and <code>T.Edge</code> :                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 'allevents'     | All events are flagged.                                                                | <ul style="list-style-type: none"> <li>• <code>T.Event</code> is a categorical vector containing the flags in order of their occurrence.</li> <li>• <code>T.Node</code> contains the node ID of the corresponding node for the events 'discovernode', 'finishnode', and 'startnode'.</li> <li>• <code>T.Edge</code> contains the corresponding edge for the events 'edgetonew', 'edgetodiscovered', and 'edgetofinished'.</li> <li>• Unused elements of <code>T.Node</code> and <code>T.Edge</code> are set to NaN.</li> <li>• If <code>s</code> is a numeric node index, then <code>T.Node</code> and <code>T.Edge</code> contain numeric node indices.</li> <li>• If <code>s</code> is a node name, then <code>T.Node</code> and <code>T.Edge</code> are cell arrays containing node names.</li> </ul> |

Example: `v = bfsearch(G,3)` begins the search at the third node and returns a vector, `v`, containing the nodes in order of discovery. This is the same as `v = bfsearch(G,3, 'discovernode')`.

Example: `X = bfsearch(G, 'A', 'edgetonew')` begins at the node named 'A' and returns a cell array of strings, X, indicating each of the edges that connects to an undiscovered node during the search.

Example: `T = bfsearch(G,s,{'discovernode','finishnode'})` returns a table, T, but only flags when new nodes are discovered or when a node is marked finished.

Example: `T = bfsearch(G,s,'allevents')` flags all search events and returns a table, T.

Data Types: char | cell

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

Example: `v = bfsearch(G,s,'Restart',true)`

### 'Restart' — Toggle to restart search

false (default) | true

Toggle to restart search, specified as **false** (default) or **true**. This option is useful if the graph contains nodes that are unreachable from the starting node. If 'Restart' is **true**, then the search restarts whenever undiscovered nodes remain that are unreachable from the discovered nodes. The new start node is the node with smallest index that is still undiscovered. The restarting process repeats until **bfsearch** discovers all nodes.

'Restart' is **false** by default, so that the search only visits nodes that are reachable from the starting node.

When 'Restart' is **true**, the 'discovernode' and 'finishnode' events occur once for each node in the graph. Also, each edge in the graph is flagged once by 'edgetonew', 'edgetodiscovered', or 'edgetofinished'. The edges flagged by 'edgetonew' form one or more trees.

Example: `T = bfsearch(graph([1 3],[2 4]),1,'Restart',true)` searches both of the connected components in the graph.

Data Types: logical

## Output Arguments

### **v** — Node IDs

numeric column vector | cell vector of strings

Node IDs, returned in one of the following formats:

- If you use a numeric node ID to specify the starting node, **s**, then **v** is a numeric column vector of node indices.
- If **s** is a string containing a node name, then **v** is a cell vector of strings containing node names.

The node IDs in **v** reflect the order of discovery by the breadth-first graph search.

### **T** — Search results

table | vector | matrix | cell array of node names

Search results, returned in one of the following formats:

- If **events** is not specified or is 'discovernode', 'finishnode', or 'startnode', then **T** is a vector of node IDs similar to **v**.
- If **events** is 'edgetonew', 'edgetodiscovered', or 'edgetofinished', then **T** is a matrix or cell array of strings of size **N**-by-2 indicating the source and target nodes for each relevant edge.
- If **events** is a cell array of search events or 'allevents', then **T** is a table containing the flagged search events. The table contains the search event flags in **T.Event**, relevant node IDs in **T.Node**, and relevant edges in **T.Edge**.

In all cases:

- The order of the elements or rows of **T** indicates their order of occurrence during the search.
- If you specify **s** as a numeric node ID, then **T** also refers to nodes using their numeric IDs.
- If you specify **s** as a node name string, then **T** also refers to nodes using their string names.

## More About

### Tips

- `dfsearch` and `bfsearch` treat undirected graphs the same as directed graphs. An undirected edge between nodes `s` and `t` is treated like two directed edges, one from `s` to `t` and one from `t` to `s`.

### Algorithms

The Breadth-First search algorithm begins at the starting node, `s`, and inspects all of its neighboring nodes in order of their node index. Then for each of those neighbors, it visits their unvisited neighbors in order. The algorithm continues until all nodes that are reachable from the starting node have been visited.

In pseudo-code, the algorithm can be written as:

```
Event discovernode(S)
NodeList = {S}
```

```
WHILE NodeList is not empty
```

```
 C = NodeList{1}
 Remove first element from NodeList
```

```
 FOR node N from successors of node C
```

```
 Event edgetonew(C,N), edgetodiscovered(C,N) or edgetofinished(C,N) depending on the
```

```
 IF event was edgetonew
```

```
 Event discovernode(N)
```

```
 Append N to the end of NodeList
```

```
 END
```

```
 END
```

```
 Event finish(C)
```

```
END
```

`bfsearch` can return flags to describe the different events in the algorithm, such as when a new node is discovered or when all of the outgoing edges of a node have been visited. The event flags are listed here.

| Event Flag     | Event Description               |
|----------------|---------------------------------|
| 'discovernode' | A new node has been discovered. |

| Event Flag         | Event Description                                    |
|--------------------|------------------------------------------------------|
| 'finishnode'       | All outgoing edges from the node have been visited.  |
| 'startnode'        | This flag indicates the starting node in the search. |
| 'edgetonew'        | Edge connects to an undiscovered node                |
| 'edgetodiscovered' | Edge connects to a previously discovered node        |
| 'edgetofinished'   | Edge connects to a finished node                     |

For more information, see the input argument description for **events**.

---

**Note:** In cases where the input graph contains nodes that are unreachable from the starting node, the 'Restart' option provides a way to make the search visit every node in the graph. In that case, the 'startnode' event indicates the starting node each time the search restarts.

**Introduced in R2015b**

## conncomp

Connected graph components

### Syntax

```
bins = conncomp(G)
bins = conncomp(G,Name,Value)
```

### Description

`bins = conncomp(G)` returns the connected components of graph `G` as `bins`. The bin numbers indicate which component each node in the graph belongs to.

- If `G` is an undirected graph, then two nodes belong to the same component if there is a path connecting them.
- If `G` is a directed graph, then two nodes belong to the same strong component only if there is a path connecting them in both directions.

`bins = conncomp(G,Name,Value)` uses additional options specified by one or more Name-Value pair arguments. For example, `conncomp(G, 'OutputForm', 'cell')` returns a cell array to describe the connected components.

### Examples

#### Find Graph Components

Create and plot an undirected graph with three connected components. Use `conncomp` to determine which component each node belongs to.

```
G = graph([1 1 4],[2 3 5],[1 1 1],6);
plot(G)
```

```
bins = conncomp(G)
```

```
bins =
```

```
 1 1 1 2 2 3
```

### Strong and Weak Graph Components

Create and plot a directed graph, and then compute the strongly connected components and weakly connected components. Weakly connected components ignore the direction of connecting edges.

```
s = [1 2 2 3 3 3 4 5 5 5 8 8];
```

```
t = [2 3 4 1 4 5 5 3 6 7 9 10];
G = digraph(s,t);
plot(G,'Layout','layered')
```

```
str_bins = conncomp(G)
```

```
str_bins =
```

```
 4 4 4 4 4 6 5 1 3 2
```

```
weak_bins = conncomp(G,'Type','weak')
```

```
weak_bins =
 1 1 1 1 1 1 1 2 2 2
```

## Input Arguments

### G — Input graph

graph object | digraph object

Input graph, specified as either a **graph** or **digraph** object. Use the **graph** function to create an undirected graph or the **digraph** function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `bins = conncomp(G, 'OutputForm', 'cell')`

### 'OutputForm' — Type of output

'vector' (default) | 'cell'

Type of output, specified as the comma-separated pair consisting of 'OutputForm' and either 'vector' or 'cell'.

| Option             | Output                                                                                                                  |
|--------------------|-------------------------------------------------------------------------------------------------------------------------|
| 'vector' (default) | <b>bins</b> is a numeric vector indicating which connected component each node belongs to.                              |
| 'cell'             | <b>bins</b> is a cell array, and <b>bins{j}</b> contains the node IDs for all nodes that belong to component <b>j</b> . |

**'Type' — Type of connected components**

'strong' (default) | 'weak'

**Note:** The 'Type' option is supported only for directed graphs created using `digraph`.

Type of connected components, specified as the comma-separated pair consisting of 'Type' and either 'strong' (default) or 'weak'.

| Option             | Result                                                                                                              |
|--------------------|---------------------------------------------------------------------------------------------------------------------|
| 'strong' (default) | Two nodes belong to the same connected component only if there is a path connecting them in <i>both</i> directions. |
| 'weak'             | Two nodes belong to the same connected component if there is a path connecting them, ignoring edge directions.      |

Example: `bins = conncomp(G, 'Type', 'weak')` computes the weakly connected components of directed graph G.

## Output Arguments

**bins — Connected components**

vector | cell array

Connected components, returned as a vector or cell array. The bin numbers assign each node in the graph to a connected component:

- If `OutputForm` is 'vector' (default), then `bins` is a numeric vector indicating which connected component (bin) each node belongs to.
- If `OutputForm` is 'cell', then `bins` is a cell array, with `bins{j}` containing the node IDs for all nodes that belong to component `j`.

## More About

### Weakly Connected Components

Two nodes belong to the same weakly connected component if there is a path connecting them (ignoring edge direction). There are no edges between two weakly connected components.

The concepts of strong and weak components apply only to directed graphs, as they are equivalent for undirected graphs.

### Strongly Connected Components

Two nodes belong to the same strongly connected component if there are paths connecting them in both directions. There can be edges between two strongly connected components, but these connecting edges are never part of a cycle.

The bin numbers of strongly connected components are such that any edge connecting two components points from the component of smaller bin number to the component with a larger bin number.

The concepts of strong and weak components apply only to directed graphs, as they are equivalent for undirected graphs.

# degree

Degree of graph nodes

## Syntax

```
D = degree(G)
D = degree(G,nodeIDs)
```

## Description

`D = degree(G)` returns the degree of each node in graph `G`. The degree is the number of edges connected to each node.

`D = degree(G,nodeIDs)` returns the degree of the nodes specified by `nodeIDs`.

## Examples

### Degree of All Graph Nodes

Create and plot a graph, and then use `degree` to find the degree of each node in the graph.

```
s = [1 1 1 4 4 6 6 6];
t = [2 3 4 5 6 7 8 9];
G = graph(s,t);
plot(G)
```

deg = degree(G)

deg =

- 3
- 1
- 1
- 3
- 1
- 4
- 1
- 1
- 1

$\text{deg}(j)$  indicates the degree of node  $j$ .

### Degree of Subset of Graph Nodes

Create and plot a graph, and then find the degree of the first, third, and fifth nodes.

```
s = {'a' 'a' 'a' 'd' 'd' 'f' 'f' 'f'};
t = {'b' 'c' 'd' 'e' 'f' 'g' 'h' 'i'};
G = graph(s,t);
plot(G)
```

```
nodeIDs = {'a' 'c' 'e'};
deg = degree(G,nodeIDs)
```

```
deg =
 3
 1
 1
```

`deg(j)` indicates the degree of node `nodeIDs(j)`.

## Input Arguments

### **G** — Input graph

graph object

Input graph, specified as a `graph` object. Use the `graph` function to create an undirected graph object. For more information, see [Using graph Objects](#).

Example: `G = graph(1,2)`

### **nodeIDs** — Node identifiers

scalar | vector | matrix | string | cell array of strings

Node identifiers, specified as a scalar node index, a vector or matrix of numeric node indices, a string node name, or a cell array of strings containing node names. You can refer to the nodes either by their numeric node index or by their node names.

Example: `D = degree(G, [3 4])`

Example: `D = degree(G, {'LAX', 'ALB'})`

## Output Arguments

### **D** — Degree of nodes

array

Degree of nodes, returned as a numeric array. `D` is a column vector unless you specify `nodeIDs`, in which case `D` has the same size as `nodeIDs`.

A node that is connected to itself by an edge (a self-loop) is listed as its own neighbor twice, and the self-loop adds 2 to the total degree of the node.

# dfsearch

Depth-first graph search

## Syntax

```
v = dfsearch(G,s)
T = dfsearch(G,s,events)
T = dfsearch(____, 'Restart', true)
```

## Description

`v = dfsearch(G,s)` applies depth-first search to graph `G` starting at node `s`. The result is a vector of node IDs in order of their discovery.

`T = dfsearch(G,s,events)` customizes the output of the depth-first search by flagging one or more search events. For example, `T = dfsearch(G,s,'allevents')` returns a table containing all flagged events, and `X = dfsearch(G,s,'edgetonew')` returns a matrix or cell array of edges.

`T = dfsearch( ____, 'Restart', true)` restarts the search if no new nodes are reachable from the discovered nodes. You can use any of the input argument combinations in previous syntaxes. This option ensures that the depth-first search reaches all nodes and edges in the graph, even if they are not reachable from the starting node, `s`.

## Examples

### Perform Depth-First Graph Search

Create and plot a graph.

```
s = [1 1 1 1 2 2 2 2 2 2 2 2 2 2 15 15 15 15 15];
t = [3 5 4 2 14 6 11 12 13 10 7 9 8 15 16 17 19 18 20];
G = graph(s,t);
plot(G)
```

Perform a depth-first search of the graph starting at node 17. The result indicates the order of node discovery.

```
v = dfsearch(G, 17)
```

```
v =
```

```
17
15
2
1
3
4
```

5  
6  
7  
8  
9  
10  
11  
12  
13  
14  
16  
18  
19  
20

## Depth-First Graph Search with All Events

Create and plot a directed graph.

```
A = [0 1 0 1 1 0 0;
 0 0 0 0 0 0 0;
 0 0 0 1 0 1 1;
 0 0 0 0 0 1 0;
 0 0 0 0 0 0 0;
 0 0 0 0 0 0 0;
 0 0 0 0 0 0 0];
G = digraph(A);
plot(G)
```

Perform a depth-first search on the graph starting at node 3. Specify 'allevents' to return a table containing all of the events in the algorithm.

```
T = dfsearch(G,3,'allevents')
```

T =

| Event        | Node | Edge |     |
|--------------|------|------|-----|
| startnode    | 3    | NaN  | NaN |
| discovernode | 3    | NaN  | NaN |
| edgetonew    | NaN  | 3    | 4   |

|                |     |     |     |
|----------------|-----|-----|-----|
| discovernode   | 4   | NaN | NaN |
| edgetonew      | NaN | 4   | 6   |
| discovernode   | 6   | NaN | NaN |
| finishnode     | 6   | NaN | NaN |
| finishnode     | 4   | NaN | NaN |
| edgetofinished | NaN | 3   | 6   |
| edgetonew      | NaN | 3   | 7   |
| discovernode   | 7   | NaN | NaN |
| finishnode     | 7   | NaN | NaN |
| finishnode     | 3   | NaN | NaN |

To follow the steps in the algorithm, read the events in the table from top to bottom. For example:

- 1 The algorithm begins at node 3
- 2 An edge is discovered between node 3 and node 4
- 3 Node 4 is discovered
- 4 and so on...

## Depth-First Graph Search with Multiple Components

Perform a depth-first search of a graph with multiple components, and then highlight the graph nodes and edges based on the search results.

Create and plot a directed graph. This graph has two weakly connected components.

```
s = [1 1 2 2 2 3 4 7 8 8 8 8];
t = [3 4 7 5 6 2 6 2 9 10 11 12];
G = digraph(s,t);
p = plot(G, 'Layout', 'layered');
```

```
c = conncomp(G, 'Type', 'weak')
```

```
c =
```

```
1 1 1 1 1 1 1 2 2 2 2 2
```

Perform a depth-first search of the graph starting at node 4, and flag the 'edgetonew', 'edgetodiscovered', 'edgetofinished', and 'startnode' events. Specify Restart as true to make the search restart whenever there are remaining nodes that cannot be reached.

```
events = {'edgetonew', 'edgetodiscovered', 'edgetofinished', 'startnode'};
```

```
T = dfsearch(G,4,events, 'Restart', true)
```

```
T =
```

| Event            | Node | Edge | Edge |
|------------------|------|------|------|
| startnode        | 4    | NaN  | NaN  |
| edgetonew        | NaN  | 4    | 6    |
| startnode        | 1    | NaN  | NaN  |
| edgetonew        | NaN  | 1    | 3    |
| edgetonew        | NaN  | 3    | 2    |
| edgetonew        | NaN  | 2    | 5    |
| edgetofinished   | NaN  | 2    | 6    |
| edgetonew        | NaN  | 2    | 7    |
| edgetodiscovered | NaN  | 7    | 2    |
| edgetofinished   | NaN  | 1    | 4    |
| startnode        | 8    | NaN  | NaN  |
| edgetonew        | NaN  | 8    | 9    |
| edgetonew        | NaN  | 8    | 10   |
| edgetonew        | NaN  | 8    | 11   |
| edgetonew        | NaN  | 8    | 12   |

When `Restart` is `true`, the `'startnode'` event returns information about where and when the algorithm restarts the search.

Highlight the graph based on event:

- Color the starting nodes red.
- Green edges are for `'edgetonew'`
- Black edges are for `'edgetofinished'`
- Magenta edges are for `'edgetodiscovered'`

```
edgenew = T.Edge(T.Event == 'edgetonew',:);
edgefin = T.Edge(T.Event == 'edgetofinished',:);
edgedis = T.Edge(T.Event == 'edgetodiscovered',:);

highlight(p,edgedis(:,1),edgedis(:,2),'EdgeColor','m')
highlight(p,edgenew(:,1),edgenew(:,2),'EdgeColor','g')
highlight(p,edgefin(:,1),edgefin(:,2),'EdgeColor','k')
highlight(p,T.Node(~isnan(T.Node)),'NodeColor','r')
```

### Remove Cycles from Graph

Make a directed graph acyclic by reverting some of its edges.

Create and plot a directed graph.

```
s = [1 2 3 3 3 3 4 5 6 7 8 9 9 9 10];
t = [7 6 1 5 6 8 2 4 4 3 7 1 6 8 2];
g = digraph(s,t);
plot(g, 'Layout', 'force')
```

Perform a depth-first search on the graph, flagging the 'edgetodiscovered' event. This event corresponds to edges that complete a cycle.

```
e = dfsearch(g, 1, 'edgetodiscovered', 'Restart', true)
```

```
e =
```

```

3 1
6 4
8 7
```

Reverse the direction of the edges, so that they no longer complete a cycle. This removes all cycles from the graph. Use `isdag` to confirm that the graph is acyclic.

```
gnew = rmedge(g, e(:, 1), e(:, 2));
gnew = addedge(gnew, e(:, 2), e(:, 1));
isdag(gnew)
```

```
ans =
```

```
1
```

```
plot(gnew, 'Layout', 'force');
```

- “Visualize Breadth-First and Depth-First Search”

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a `graph` or `digraph` object. Use the `graph` function to create an undirected graph or the `digraph` function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

### **s** — Starting node

nonnegative scalar integer | string

Starting node, specified as either a nonnegative scalar integer between 1 and `numnodes(G)`, or a string containing a node name.

Example: `dfsearch(G,1)`

### **events** — Flagged search events

'discovernode' (default) | 'startnode' | 'finishnode' | 'edgetonew' | 'edgetodiscovered' | 'edgetofinished' | 'allevents' | cell array

Flagged search events, specified as one of the options in the following table.

- To flag single events, use the flag names.
- To flag a subset of events, put two or more flag names into a cell array.
- To flag all events, use 'allevents'.

---

**Note:** Depending on the value of `events`, the output of `dfsearch` varies. See the last column in the following table for information about the output returned by each option.

---

| Value of events          | Description                                                                                                                                               | Output                                                                                                                                                                                                                                                                         |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'discovernode' (default) | A new node has been discovered.                                                                                                                           | Return a vector of node IDs: <ul style="list-style-type: none"> <li>• If <code>s</code> is a numeric node index, then the vector contains numeric node indices.</li> <li>• If <code>s</code> is a node name, then the vector is a cell array containing node names.</li> </ul> |
| 'finishnode'             | All outgoing edges from the node have been visited.                                                                                                       |                                                                                                                                                                                                                                                                                |
| 'startnode'              | This flag indicates the starting node in the search.<br><br>If 'Restart' is true, then 'startnode' flags the starting node each time the search restarts. |                                                                                                                                                                                                                                                                                |
| 'edgetonew'              | Edge connects to an undiscovered node.                                                                                                                    | Return a matrix or cell array of size N-by-2 that specifies                                                                                                                                                                                                                    |

| <b>Value of events</b> | <b>Description</b>                             | <b>Output</b>                                                                                                                                                                                                                      |
|------------------------|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'edgetodiscovered'     | Edge connects to a previously discovered node. | the end nodes of edges in the graph:                                                                                                                                                                                               |
| 'edgetofinished'       | Edge connects to a finished node.              | <ul style="list-style-type: none"><li>• If <b>s</b> is a numeric node index, then the matrix contains numeric node indices.</li><li>• If <b>s</b> is a node name, then the matrix is a cell array containing node names.</li></ul> |

| Value of events | Description                                                                            | Output                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cell array      | Specify two or more flags in a cell array to only flag those events during the search. | Return a table, <code>T</code> , which contains the variables <code>T.Event</code> , <code>T.Node</code> , and <code>T.Edge</code> :                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 'allevents'     | All events are flagged.                                                                | <ul style="list-style-type: none"> <li>• <code>T.Event</code> is a categorical vector containing the flags in order of their occurrence.</li> <li>• <code>T.Node</code> contains the node ID of the corresponding node for the events 'discovernode', 'finishnode', and 'startnode'.</li> <li>• <code>T.Edge</code> contains the corresponding edge for the events 'edgetonew', 'edgetodiscovered', and 'edgetofinished'.</li> <li>• Unused elements of <code>T.Node</code> and <code>T.Edge</code> are set to NaN.</li> <li>• If <code>s</code> is a numeric node index, then <code>T.Node</code> and <code>T.Edge</code> contain numeric node indices.</li> <li>• If <code>s</code> is a node name, then <code>T.Node</code> and <code>T.Edge</code> are cell arrays containing node names.</li> </ul> |

Example: `v = dfsearch(G,3)` begins the search at the third node and returns a vector, `v`, containing the nodes in order of discovery. This is the same as `v = dfsearch(G,3, 'discovernode')`.

Example: `X = dfsearch(G, 'A', 'edgetonew')` begins at the node named 'A' and returns a cell array of strings, X, indicating each of the edges that connects to an undiscovered node during the search.

Example: `T = dfsearch(G,s,{'discovernode','finishnode'})` returns a table, T, but only flags when new nodes are discovered or when a node is marked finished.

Example: `T = dfsearch(G,s,'allevents')` flags all search events and returns a table, T.

Data Types: char | cell

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

Example: `v = dfsearch(G,s,'Restart',true)`

### 'Restart' — Toggle to restart search

false (default) | true

Toggle to restart search, specified as **false** (default) or **true**. This option is useful if the graph contains nodes that are unreachable from the starting node. If 'Restart' is **true**, then the search restarts whenever undiscovered nodes remain that are unreachable from the discovered nodes. The new start node is the node with smallest index that is still undiscovered. The restarting process repeats until `dfsearch` discovers all nodes.

'Restart' is **false** by default, so that the search only visits nodes that are reachable from the starting node.

When 'Restart' is **true**, the 'discovernode' and 'finishnode' events occur once for each node in the graph. Also, each edge in the graph is flagged once by 'edgetonew', 'edgetodiscovered', or 'edgetofinished'. The edges flagged by 'edgetonew' form one or more trees.

Example: `T = dfsearch(graph([1 3],[2 4]),1,'Restart',true)` searches both of the connected components in the graph.

Data Types: logical

## Output Arguments

### **v** — Node IDs

numeric column vector | cell vector of strings

Node IDs, returned in one of the following formats:

- If you use a numeric node ID to specify the starting node, **s**, then **v** is a numeric column vector of node indices.
- If **s** is a string containing a node name, then **v** is a cell vector of strings containing node names.

The node IDs in **v** reflect the order of discovery by the depth-first graph search.

### **T** — Search results

table | vector | matrix | cell array of node names

Search results, returned in one of the following formats:

- If **events** is not specified or is 'discovernode', 'finishnode', or 'startnode', then **T** is a vector of node IDs similar to **v**.
- If **events** is 'edgetonew', 'edgetodiscovered', or 'edgetofinished', then **T** is a matrix or cell array of strings of size N-by-2 indicating the source and target nodes for each relevant edge.
- If **events** is a cell array of search events or 'allevents', then **T** is a table containing the flagged search events. The table contains the search event flags in **T.Event**, relevant node IDs in **T.Node**, and relevant edges in **T.Edge**.

In all cases:

- The order of the elements or rows of **T** indicates their order of occurrence during the search.
- If you specify **s** as a numeric node ID, then **T** also refers to nodes using their numeric IDs.
- If you specify **s** as a node name string, then **T** also refers to nodes using their string names.

## More About

### Tips

- `dfsearch` and `bfsearch` treat undirected graphs the same as directed graphs. An undirected edge between nodes `s` and `t` is treated like two directed edges, one from `s` to `t` and one from `t` to `s`.

### Algorithms

The Depth-First search algorithm begins at the starting node, `s`, and inspects the neighbor of `s` that has the smallest node index. Then for that neighbor, it inspects the next undiscovered neighbor with the lowest index. This continues until the search encounters a node whose neighbors have all been visited. At that point, the search backtracks along the path to the nearest previously discovered node that has an undiscovered neighbor. This process continues until all nodes that are reachable from the starting node have been visited.

In pseudo-code, the (recursive) algorithm can be written as:

```
function DFS(C)
 Event discovernode(C)
 FOR node N from successors of node C
 Event edgetonew(C,N), edgetodiscovered(C,N) or edgetofinished(C,N) depending on the
 IF event was edgetonew
 Call DFS(N)
 END
 END
 Event finish(C)
END
```

`dfsearch` can return flags to describe the different events in the algorithm, such as when a new node is discovered or when all of the outgoing edges of a node have been visited. The event flags are listed here.

| Event Flag     | Event Description               |
|----------------|---------------------------------|
| 'discovernode' | A new node has been discovered. |

---

| Event Flag         | Event Description                                    |
|--------------------|------------------------------------------------------|
| 'finishnode'       | All outgoing edges from the node have been visited.  |
| 'startnode'        | This flag indicates the starting node in the search. |
| 'edgetonew'        | Edge connects to an undiscovered node                |
| 'edgetodiscovered' | Edge connects to a previously discovered node        |
| 'edgetofinished'   | Edge connects to a finished node                     |

For more information, see the input argument description for **events**.

---

**Note:** In cases where the input graph contains nodes that are unreachable from the starting node, the 'Restart' option provides a way to make the search visit every node in the graph. In that case, the 'startnode' event indicates the starting node each time the search restarts.

## distances

Shortest path distances of all node pairs

### Syntax

```
d = distances(G)
d = distances(G,s)
d = distances(G,s,t)
d = distances(____, 'Method', algorithm)
```

### Description

`d = distances(G)` returns a matrix, `d`, where `d(i, j)` is the length of the shortest path between node `i` and node `j`. If the graph is weighted (that is, `G.Edges` contains a variable `Weight`), then those weights are used as the distances along the edges in the graph. Otherwise, all edge distances are taken to be 1.

`d = distances(G,s)` restricts the source nodes to the nodes defined by `s`, such that `d(i, j)` is the distance from node `s(i)` to node `j`.

`d = distances(G,s,t)` additionally restricts the target nodes to the nodes defined by `t`, such that `d(i, j)` is the distance from node `s(i)` to node `t(j)`.

`d = distances( ____, 'Method', algorithm)` optionally specifies the algorithm to use in computing the shortest path using any of the input arguments in previous syntaxes. For example, if `G` is a weighted graph, then `distances(G, 'Method', 'unweighted')` ignores the edge weights in `G` and instead treats all edge weights as 1.

### Examples

#### Shortest Path Distance for All Node Pairs

Create and plot a graph.

```
s = [1 1 1 2 5 5 5 8 9 9];
t = [2 3 4 5 6 7 8 9 10 11];
G = graph(s,t);
plot(G)
```

Calculate the shortest path distance between all node pairs in the graph. Since the graph edges do not have weights, all edge distances are taken to be 1.

`d = distances(G)`

`d =`

|   |   |   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|---|---|
| 0 | 1 | 1 | 1 | 2 | 3 | 3 | 3 | 4 | 5 | 5 |
| 1 | 0 | 2 | 2 | 1 | 2 | 2 | 2 | 3 | 4 | 4 |
| 1 | 2 | 0 | 2 | 3 | 4 | 4 | 4 | 5 | 6 | 6 |
| 1 | 2 | 2 | 0 | 3 | 4 | 4 | 4 | 5 | 6 | 6 |
| 2 | 1 | 3 | 3 | 0 | 1 | 1 | 1 | 2 | 3 | 3 |
| 3 | 2 | 4 | 4 | 1 | 0 | 2 | 2 | 3 | 4 | 4 |

|   |   |   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|---|---|
| 3 | 2 | 4 | 4 | 1 | 2 | 0 | 2 | 3 | 4 | 4 |
| 3 | 2 | 4 | 4 | 1 | 2 | 2 | 0 | 1 | 2 | 2 |
| 4 | 3 | 5 | 5 | 2 | 3 | 3 | 1 | 0 | 1 | 1 |
| 5 | 4 | 6 | 6 | 3 | 4 | 4 | 2 | 1 | 0 | 2 |
| 5 | 4 | 6 | 6 | 3 | 4 | 4 | 2 | 1 | 2 | 0 |

$d$  is symmetric because  $G$  is an undirected graph. In general  $d(i, j)$  is the length of the shortest path between node  $i$  and node  $j$ , and for undirected graphs this is equivalent to  $d(j, i)$ .

For example, find the length of the shortest path between node 1 and node 10.

$d(1, 10)$

ans =

5

## Shortest Path Distances from Specified Sources

Create and plot a graph.

```
s = [1 1 1 1 2 2 3 4 4 5 6];
t = [2 3 4 5 3 6 6 5 7 7 7];
G = graph(s,t);
plot(G)
```

Find the shortest path distances from node 1, node 2, and node 3 to all other nodes in the graph.

```
d = distances(G,[1 2 3])
```

d =

|   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|
| 0 | 1 | 1 | 1 | 1 | 2 | 2 |
| 1 | 0 | 1 | 2 | 2 | 1 | 2 |
| 1 | 1 | 0 | 2 | 2 | 1 | 2 |

Use `d` to find the shortest path distance from node 1 to node 7.

```
d(1,7)
```

```
ans =
```

```
2
```

## Shortest Path Distances to Specified Targets

Create and plot a graph.

```
s = [1 1 1 2 2 3 3 4 5 5 6 7 8 8 10 11];
t = [2 3 10 4 12 5 4 6 6 7 9 8 9 11 11 12];
G = graph(s,t);
plot(G)
```

Find the shortest path distances from nodes 5 and 7 to nodes 2 and 3.

```
sources = [5 7];
targets = [2 3];
d = distances(G,sources,targets)
```

d =

```
3 1
4 2
```

Use `d` to find the shortest path distance between node 7 and node 3. In this case, `d(i, j)` is the distance from node `sources(i)` to node `targets(j)`.

```
d(2,2)
```

```
ans =
```

```
2
```

## Ignore Edge Weights

Create and plot a directed graph with weighted edges.

```
s = [1 1 1 2 5 3 6 4 7 8 8 8];
t = [2 3 4 5 3 6 4 7 2 6 7 5];
weights = [100 10 10 10 10 20 10 30 50 10 70 10];
G = digraph(s,t,weights);
plot(G, 'EdgeLabel', G.Edges.Weight)
```

Find the shortest path distance between all pairs of graph nodes.

`d = distances(G)`

`d =`

|     |     |     |     |     |     |    |     |
|-----|-----|-----|-----|-----|-----|----|-----|
| 0   | 90  | 10  | 10  | 100 | 30  | 40 | Inf |
| Inf | 0   | 20  | 50  | 10  | 40  | 80 | Inf |
| Inf | 110 | 0   | 30  | 120 | 20  | 60 | Inf |
| Inf | 80  | 100 | 0   | 90  | 120 | 30 | Inf |
| Inf | 120 | 10  | 40  | 0   | 30  | 70 | Inf |
| Inf | 90  | 110 | 10  | 100 | 0   | 40 | Inf |
| Inf | 50  | 70  | 100 | 60  | 90  | 0  | Inf |

```
Inf 100 20 20 10 10 50 0
```

Since  $G$  is a directed graph,  $d$  is not symmetric, and  $d(i, j)$  corresponds to the distance between nodes  $i$  and  $j$ . The `Inf` values in  $d$  correspond to nodes that are unreachable. For example, since node 1 has no predecessors, it is not possible to reach node 1 from any other node in the graph. So the first column of  $d$  contains many `Inf` values to reflect that node 1 is unreachable.

By default, `distances` uses the edge weights to compute the distances. Specify 'Method' as 'unweighted' to ignore the edge weights and treat all edge distances as 1.

```
d1 = distances(G, 'Method', 'unweighted')
```

```
d1 =
```

```
 0 1 1 1 2 2 2 Inf
 Inf 0 2 4 1 3 5 Inf
 Inf 4 0 2 5 1 3 Inf
 Inf 2 4 0 3 5 1 Inf
 Inf 5 1 3 0 2 4 Inf
 Inf 3 5 1 4 0 2 Inf
 Inf 1 3 5 2 4 0 Inf
 Inf 2 2 2 1 1 1 0
```

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a `graph` or `digraph` object. Use the `graph` function to create an undirected graph or the `digraph` function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

```
Example: G = graph(1,2)
```

```
Example: G = digraph([1 2],[2 3])
```

### **s** — Source nodes

'all' (default) | vector | cell array of strings

Source nodes, specified as 'all', a vector of node indices, or a cell array of strings containing node names.

Example: `distances(G,[1 2])`

Example: `distances(G,'all',[1 3 5])`

### **t** — Target nodes

'all' (default) | vector | cell array of strings

Target nodes, specified as 'all', a vector of node indices, or a cell array of strings containing node names.

Example: `distances(G,[1 2])`

Example: `distances(G,'all',[1 3 5])`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `d = distances(G,'Method','unweighted')`

### **'Method'** — Shortest path algorithm

'auto' (default) | 'unweighted' | 'positive' | 'mixed'

Shortest path algorithm, specified as the comma-separated pair consisting of 'Method' and one of the options in the table.

| <b>Option</b>    | <b>Description</b>                                                                                                                                                                                                                                                                                             |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'auto' (default) | <p>The 'auto' option automatically selects the algorithm:</p> <ul style="list-style-type: none"> <li>'unweighted' is used for graph and digraph inputs with no edge weights.</li> <li>'positive' is used for all graph inputs that have edge weights, and requires the weights to be positive. This</li> </ul> |

| Option                     | Description                                                                                                                                                                                                                                                 |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            | option is also used for <b>digraph</b> inputs with positive edge weights. <ul style="list-style-type: none"><li>'mixed' is used for <b>digraph</b> inputs whose edge weights contain some negative values. The graph cannot have negative cycles.</li></ul> |
| 'unweighted'               | Breadth-First computation that treats all edge weights as 1.                                                                                                                                                                                                |
| 'positive'                 | Dijkstra algorithm that requires all edge weights to be positive.                                                                                                                                                                                           |
| 'mixed' (only for digraph) | Bellman-Ford algorithm for directed graphs that requires the graph to have no negative cycles.<br><br>While 'mixed' is slower than 'positive' for the same problem, 'mixed' is more versatile as it allows some edge weights to be negative.                |

---

**Note:** For most graphs, 'unweighted' is the fastest algorithm, followed by 'positive', and 'mixed'.

---

Example: `distances(G,s,t,'Method','unweighted')`

## Output Arguments

### **d** — Shortest path distances between node pairs

matrix

Shortest path distances between node pairs, returned as a matrix. The size of **d** is (# source nodes)-by-(# target nodes). A value of **Inf** indicates a path that does not exist.

## More About

### Tips

- The `shortestpath`, `shortestpathtree`, and `distances` functions do not support undirected graphs with negative edge weights, or more generally any graph containing a negative cycle, for these reasons:
  - A *negative cycle* is a path that leads from a node back to itself, with the sum of the edge weights on the path being negative. If a negative cycle is on a path between two nodes, then no shortest path exists between the nodes, since a shorter path can always be found by traversing the negative cycle.
  - A single negative edge weight in an undirected graph creates a negative cycle.

**Introduced in R2015b**

# findedge

Locate edge in graph

## Syntax

```
idxOut = findedge(G,s,t)
[sOut,tOut] = findedge(G)
[sOut,tOut] = findedge(G,idx)
```

## Description

`idxOut = findedge(G,s,t)` returns the numeric edge indices, `idxOut`, for the edges specified by the source and target node pairs `s` and `t`. The edge indices correspond to the rows `G.Edges.Edge(idxOut,:)` in the `G.Edges` table of the graph. An edge index of 0 indicates an edge that is not in the graph.

`[sOut,tOut] = findedge(G)` returns the source and target node IDs, `sOut` and `tOut`, for all of the edges in graph `G`.

`[sOut,tOut] = findedge(G,idx)` finds the source and target nodes of the edges specified by `idx`.

## Examples

### Locate Edges with Specified End Nodes

Create a graph, and then determine the edge index for the (1,2) and (3,5) edges.

```
s = [1 1 2 2 2 3 3 3];
t = [2 3 3 4 5 6 7 5];
G = graph(s,t)
```

G =

graph with properties:

```
Edges: [8x1 table]
Nodes: [7x0 table]
```

```
idxOut = findedge(G,[1 3],[2 5])
```

```
idxOut =
```

```
1
6
```

idxOut contains the row index into `G.Edges.EndNodes` for each specified edge.

### End Nodes of All Graph Edges

Create a graph, and then determine the end nodes of all edges in the graph.

```
s = {'a' 'a' 'b' 'b' 'c' 'c'};
t = {'b' 'c' 'd' 'e' 'f' 'g'};
G = graph(s,t)
```

```
G =
```

```
graph with properties:
```

```
Edges: [6x1 table]
Nodes: [7x1 table]
```

```
[sOut,tOut] = findedge(G)
```

```
sOut =
```

```
1
1
2
2
3
3
```

```
tOut =
```

```
2
3
4
5
6
7
```

## Locate Edges with Specified Edge Indices

Create a graph, and then determine the end nodes for the edges whose indices are 3 and 7.

```
s = [1 1 1 1 2 2 3 3 4 4];
t = [2 3 4 5 6 7 8 9 10 11];
G = digraph(s,t)
```

```
G =
```

```
digraph with properties:
```

```
Edges: [10x1 table]
Nodes: [11x0 table]
```

```
[sOut,tOut] = findedge(G,[3 7])
```

```
sOut =
```

```
1
3
```

```
tOut =
```

```
4
8
```

## Determine Weight of Specified Edge

Create a graph.

```
s = [1 1 2 3];
t = [2 3 3 4];
weights = [10 20 30 40];
G = graph(s,t,weights)
```

```
G =
```

```
graph with properties:
```

```
Edges: [4x2 table]
Nodes: [4x0 table]
```

Find the weight of the (1,3) edge, using `findedge` to retrieve the index.

```
G.Edges.Weight(findedge(G,1,3))
```

```
ans =
```

```
20
```

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a `graph` or `digraph` object. Use the `graph` function to create an undirected graph or the `digraph` function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

### **s, t** — Node pairs

scalars | vectors | strings | cell arrays of strings

Node pairs, specified as scalars, vectors, strings, or cell arrays of strings. Similarly located elements in `s` and `t` specify the source and target nodes that form edges in the graph.

Example: `G = findedge(G,[1 2],[3 4])`

Example: `G = findedge(G,{'a' 'a'; 'b' 'c'},{'b' 'c'; 'c' 'e'})`

## **idx** — Edge indices

scalar | vector

Edge indices, specified as a scalar or vector of positive integers. The edge index corresponds to a row in the `G.Edges` table of the graph, `G.Edges(idx,:)`.

## Output Arguments

### **idxOut** — Edge indices

scalar | vector

Edge indices, returned as a scalar or vector of nonnegative integers. The edge indices correspond to rows in the `G.Edges` table of the graph, `G.Edges(idxOut,:)`. An edge index of 0 indicates an edge that is not in the graph.

### **sOut, tOut** — Node IDs

scalars | vectors

Node IDs, returned as separate scalars or vectors of positive integers. Similarly located elements in `sOut` and `tOut` specify the source and target nodes that form the edges `G.Edges(idx,:)`.

## See Also

`digraph` | `findnode` | `graph` | `numedges`

Introduced in R2015b

# findnode

Locate node in graph

## Syntax

```
k = findnode(G,nodeID)
```

## Description

`k = findnode(G,nodeID)` returns the numeric node ID, `k`, of the node in graph `G` whose name is `nodeID`. The numeric node ID is zero if the node is not in the graph.

## Examples

### Determine Index of Named Node

Create a graph, and then determine the numeric node index for the nodes named 'AB' and 'BC'.

```
s = {'AA' 'AA' 'AA' 'AB' 'AC' 'BB'};
t = {'BA' 'BB' 'BC' 'BA' 'AB' 'BC'};
G = graph(s,t)
```

G =

```
graph with properties:
```

```
Edges: [6x1 table]
```

```
Nodes: [6x1 table]
```

```
k = findnode(G,{'AB' 'BC'})
```

k =

```
5
```

4

`k` contains the row index into `G.Nodes.Name` for each specified node.

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a `graph` or `digraph` object. Use the `graph` function to create an undirected graph or the `digraph` function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

### **nodeID** — Node names

string | cell array of strings

Node names, specified as a string or cell array of strings.

Example: `k = findnode(G, 'Chicago')` returns the numeric node ID for the node in graph `G` with the name, `'Chicago'`.

Data Types: char | cell

## Output Arguments

### **k** — Numeric node IDs

scalar | column vector

Numeric node IDs, returned as a scalar or column vector. The values of `k` are indices into `G.Nodes.Name`, which is a cell array of strings containing the node names.

## More About

## incidence

Graph incidence matrix

### Syntax

```
I = incidence(G)
```

### Description

`I = incidence(G)` returns the sparse incidence matrix for graph `G`. If `s` and `t` are the node IDs of the source and target nodes of the `j`th edge in `G`, then  $I(s, j) = -1$  and  $I(t, j) = 1$ . That is, each column of `I` indicates the source and target nodes for a single edge in `G`.

### Examples

#### Graph Incidence Matrix

Create a graph using an edge list, and then calculate the graph incidence matrix.

```
s = [1 1 1 1 1];
t = [2 3 4 5 6];
G = graph(s,t);
I = incidence(G)
```

I =

|       |    |
|-------|----|
| (1,1) | -1 |
| (2,1) | 1  |
| (1,2) | -1 |
| (3,2) | 1  |
| (1,3) | -1 |
| (4,3) | 1  |
| (1,4) | -1 |
| (5,4) | 1  |
| (1,5) | -1 |
| (6,5) | 1  |

Each column in  $I$  contains two nonzero entries, which indicate the end nodes of a single edge in  $G$ .

Calculate the graph Laplacian matrix,  $L$ , and confirm the relation  $L = I \cdot I'$  for undirected graphs.

```
L = laplacian(G);
L - I*I'
```

```
ans =
```

```
All zero sparse: 6-by-6
```

### Incidence Matrix of Directed Graph

Create a directed graph using an edge list, and then calculate the incidence matrix.

```
s = [1 2 1 3 2 3 3 3];
t = [2 1 3 1 3 4 5 6];
G = digraph(s,t)
```

```
G =
```

```
digraph with properties:
```

```
Edges: [8x1 table]
Nodes: [6x0 table]
```

```
I = incidence(G)
```

```
I =
```

```
(1,1) -1
(2,1) 1
(1,2) -1
(3,2) 1
(1,3) 1
(2,3) -1
(2,4) -1
(3,4) 1
(1,5) 1
```

|       |    |
|-------|----|
| (3,5) | -1 |
| (3,6) | -1 |
| (4,6) | 1  |
| (3,7) | -1 |
| (5,7) | 1  |
| (3,8) | -1 |
| (6,8) | 1  |

Each column in **I** represents the source and target nodes of a single edge in **G**.

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a **graph** or **digraph** object. Use the **graph** function to create an undirected graph or the **digraph** function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

## Output Arguments

### **I** — Incidence matrix

sparse matrix

Incidence matrix, returned as a sparse matrix. The size of **I** is `numnodes(G)`-by-`numedges(G)`. The graph incidence matrix is undefined for graphs with self-loops.

## More About

### Tips

- The incidence function calculates the variety of incidence matrix commonly known as a *signed* or *oriented* incidence matrix. The signed incidence matrix of an undirected graph, **I**, is related to the graph Laplacian matrix, **L**, such that  $L == I * I'$ .

# laplacian

Graph Laplacian matrix

## Syntax

```
L = laplacian(G)
```

## Description

`L = laplacian(G)` returns the graph Laplacian matrix, `L`. Each diagonal entry, `L(j, j)`, is given by the degree of node `j`, `degree(G, j)`. The off-diagonal entries of `L` represent the edges in `G` such that `L(i, j) = L(j, i) = -1` if there is an edge between nodes `i` and `j`; otherwise, `L(i, j) = L(j, i) = 0`.

## Examples

### Graph Laplacian Matrix

Create a graph using an edge list, and then calculate the graph Laplacian matrix.

```
s = [1 1 1 1 1];
t = [2 3 4 5 6];
G = graph(s,t);
L = laplacian(G)
```

```
L =
```

```
(1,1) 5
(2,1) -1
(3,1) -1
(4,1) -1
(5,1) -1
(6,1) -1
(1,2) -1
(2,2) 1
(1,3) -1
```

```
(3,3) 1
(1,4) -1
(4,4) 1
(1,5) -1
(5,5) 1
(1,6) -1
(6,6) 1
```

The diagonal elements of  $L$  indicate the degree of the nodes, such that  $L(j, j)$  is the degree of node  $j$ .

Calculate the graph incidence matrix,  $I$ , and confirm the relation  $L = I * I'$ .

```
I = incidence(G);
L = I*I'
```

```
ans =
```

```
All zero sparse: 6-by-6
```

## Input Arguments

### **G** — Input graph

graph object

Input graph, specified as a **graph** object. Use the **graph** function to create an undirected graph object. For more information, see Using graph Objects.

Example: `G = graph(1,2)`

## Output Arguments

### **L** — Laplacian matrix

matrix

Laplacian matrix.  $L$  is a square, symmetric, sparse matrix of size `numnodes(G)`-by-`numnodes(G)`. The graph Laplacian matrix is undefined for graphs with self-loops.

**See Also**

adjacency | graph | incidence

# maxflow

Maximum flow in graph

## Syntax

```
mf = maxflow(G,s,t)
mf = maxflow(G,s,t,algorithm)
[mf,GF] = maxflow(____)
[mf,GF,cs,ct] = maxflow(____)
```

## Description

`mf = maxflow(G,s,t)` returns the maximum flow between nodes `s` and `t`. If graph `G` is unweighted (that is, `G.Edges` does not contain the variable `Weight`), then `maxflow` treats all graph edges as having a weight equal to 1.

`mf = maxflow(G,s,t,algorithm)` specifies the maximum flow algorithm to use. This syntax is only available if `G` is a directed graph.

`[mf,GF] = maxflow(____)` also returns a directed graph object, `GF`, using any of the input arguments in previous syntaxes. `GF` is formed using only the edges in `G` that have nonzero flow values.

`[mf,GF,cs,ct] = maxflow(____)` additionally returns the source and target node IDs, `cs` and `ct`, representing the minimum cut associated with the maximum flow.

## Examples

### Maximum Flow in Graph

Create and plot a weighted graph. The weighted edges represent flow capacities.

```
s = [1 1 2 2 3 4 4 4 5 5];
t = [2 3 3 4 5 3 5 6 4 6];
weights = [0.77 0.44 0.67 0.75 0.89 0.90 2 0.76 1 1];
G = digraph(s,t,weights);
```

```
plot(G, 'EdgeLabel',G.Edges.Weight, 'Layout', 'layered');
```

Determine the maximum flow from node 1 to node 6.

```
mf = maxflow(G,1,6)
```

mf =

1.2100

### Maximum Flow with Specified Algorithm

Create and plot a graph. The weighted edges represent flow capacities.

```

s = [1 1 2 2 3 3 4];
t = [2 3 3 4 4 5 5];
weights = [10 6 15 5 10 3 8];
G = digraph(s,t,weights);
H = plot(G, 'EdgeLabel',G.Edges.Weight);

```

Find the maximum flow value between node 1 and node 5. Specify 'augmentpath' to use the Ford-Fulkerson algorithm, and use two outputs to return a graph of the nonzero flows.

```
[mf,GF] = maxflow(G,1,5,'augmentpath')
```

```
mf =
```

```
 11
```

```
GF =
```

```
digraph with properties:
```

```
Edges: [6x2 table]
```

```
Nodes: [5x0 table]
```

Highlight and label the graph of nonzero flows.

```
H.EdgeLabel = {};
highlight(H,GF,'EdgeColor','r','LineWidth',2);
st = GF.Edges.EndNodes;
labeledge(H,st(:,1),st(:,2),GF.Edges.Weight);
```

### Minimum Cut Computation

Create and plot a weighted graph. The edge weights represent flow capacities.

```
s = [1 1 2 3 3 4 4 5 5];
t = [2 3 3 2 5 5 6 4 6];
weights = [0.77 0.44 0.67 0.69 0.73 2 0.78 1 1];
G = digraph(s,t,weights);
plot(G,'EdgeLabel',G.Edges.Weight,'Layout','layered')
```

Find the maximum flow and minimum cut of the graph.

```
[mf,~,cs,ct] = maxflow(G,1,6)
```

```
mf =
```

```
0.7300
```

```
cs =
```

```
1
2
```

---

3

ct =

4

5

6

Plot the minimum cut, using the `cs` nodes as sources and the `ct` nodes as sinks. Highlight the `cs` nodes as red and the `ct` nodes as green. Note that the weight of the edge that connects these two sets of nodes is equal to the maximum flow.

```
H = plot(G, 'Layout', 'layered', 'Sources', cs, 'Sinks', ct, ...
 'EdgeLabel', G.Edges.Weight);
highlight(H, cs, 'NodeColor', 'red')
highlight(H, ct, 'NodeColor', 'green')
```

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a **graph** or **digraph** object. Use the **graph** function to create an undirected graph or the **digraph** function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

**s, t — Node pair (as separate arguments)**

scalars | strings

Node pair, specified as separate arguments of scalar node indices or string node names.

Example: `mf = maxflow(G, 'A', 'B')`

Example: `mf = maxflow(G, 1, 10)`

Data Types: double | char

**algorithm — Maximum flow algorithm**

'searchtrees' (default) | 'augmentpath' | 'pushrelabel'

Maximum flow algorithm, specified as one of the entries in the table.

---

**Note:** You can only specify nondefault `algorithm` options with a directed graph.

---

| Option                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'searchtrees' (default) | Uses the Boykov-Kolmogorov algorithm. Computes the maximum flow by constructing two search trees associated with nodes <code>s</code> and <code>t</code> .                                                                                                                                                                                                                                                                                                                                                            |
| 'augmentpath'           | Uses the Ford-Fulkerson algorithm. Computes the maximum flow iteratively by finding an augmenting path in a residual directed graph.<br><br>The directed graph cannot have any parallel edges of opposite direction between the same two nodes, unless the weight of one of those edges is zero. So if the graph contains edge <code>[ i j ]</code> , then it can contain the reverse edge <code>[ j i ]</code> only if the weight of <code>[ i j ]</code> is zero and/or the weight of <code>[ j i ]</code> is zero. |
| 'pushrelabel'           | Computes the maximum flow by pushing a node's excess flow to its neighbors and then relabeling the node.                                                                                                                                                                                                                                                                                                                                                                                                              |

| Option | Description                                                                                                                                                                                                                                                                                                          |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        | The directed graph cannot have any parallel edges of opposite direction between the same two nodes, unless the weight of one of those edges is zero. So if the graph contains edge [ i j ], then it can contain the reverse edge [ j i ] only if the weight of [ i j ] is zero and/or the weight of [ j i ] is zero. |

Example: `mf = maxflow(G, 'A', 'D', 'augmentpath')`

## Output Arguments

### **mf** — Maximum flow

scalar

Maximum flow, returned as a scalar.

### **GF** — Directed graph of flows

digraph object

Directed graph of flows, returned as a `digraph` object. **GF** contains the same nodes as **G**, but only contains those edges of **G** that have a nonzero flow.

### **cs** — Minimum cut source node IDs

scalar | vector | string | cell array of strings

Minimum cut source node IDs, returned as a scalar node index, vector of node indices, string node name, or cell array of node names.

- If **s** and **t** specify numeric node indices, then **cs** and **ct** also contain node indices.
- If **s** and **t** specify node names, then **cs** and **ct** also contain node names.

### **ct** — Minimum cut target node IDs

scalar | vector | string | cell array of strings

Minimum cut target node IDs, returned as a scalar node index, vector of node indices, string node name, or cell array of node names.

- If `s` and `t` specify numeric node indices, then `cs` and `ct` also contain node indices.
- If `s` and `t` specify node names, then `cs` and `ct` also contain node names.

## More About

### Maximum Flow

In the context of maximum flow, the edges in a graph are considered to have a *capacity* as represented by the edge weight. The capacity of an edge is the amount of flow that can pass through that edge. Therefore, the maximum flow between two nodes in a graph maximizes the amount of flow passing from the source node, `s`, to the target node, `t`, based on the capacities of the connecting edges.

### Minimum Cut

A minimum cut partitions the directed graph nodes into two sets, `cs` and `ct`, such that the sum of the weights of all edges connecting `cs` and `ct` (weight of the cut) is minimized. The weight of the minimum cut is equal to the maximum flow value, `mf`.

The entries in `cs` and `ct` indicate the nodes of `G` associated with nodes `s` and `t`, respectively. `cs` and `ct` satisfy `numel(cs) + numel(ct) = numnodes(G)`.

## minspantree

Minimum spanning tree of graph

### Syntax

```
T = minspantree(G)
T = minspantree(G,Name,Value)
[T,pred] = minspantree(____)
```

### Description

`T = minspantree(G)` returns the minimum spanning tree, `T`, for graph `G`.

`T = minspantree(G,Name,Value)` uses additional options specified by one or more Name-Value pair arguments. For example, `minspantree(G, 'Method', 'sparse')` uses Kruskal's algorithm for calculating the minimum spanning tree.

`[T,pred] = minspantree(____)` also returns a vector of predecessor nodes, `pred`, using any of the input arguments in previous syntaxes.

### Examples

#### Minimum Spanning Tree of Cube Graph

Create and plot a cube graph with weighted edges.

```
s = [1 1 1 2 5 3 6 4 7 8 8 8];
t = [2 3 4 5 3 6 4 7 2 6 7 5];
weights = [100 10 10 10 10 20 10 30 50 10 70 10];
G = graph(s,t,weights);
p = plot(G, 'EdgeLabel',G.Edges.Weight);
```

Calculate and plot the minimum spanning tree of the graph on top of the graph.  $T$  contains the same nodes as  $G$ , but a subset of the edges.

```
[T,pred] = minspantree(G);
highlight(p,T)
```

### Minimum Spanning Forest from Specified Root Node

Create and plot a graph that has multiple components.

```
s = {'a' 'a' 'a' 'b' 'b' 'c' 'e' 'e' 'f' 'f' 'f' 'f' 'g' 'g'};
t = {'b' 'c' 'd' 'c' 'd' 'd' 'f' 'g' 'g' 'h' 'i' 'j' 'i' 'j'};
G = graph(s,t);
p = plot(G,'Layout','layered');
```

Find the minimum spanning forest for the graph, starting at node *i*. Highlight the resulting forest in the plot. The graph node names are carried over into the minimum spanning tree graph.

```
[T,pred] = minspantree(G,'Type','forest','Root',findnode(G,'i'));
highlight(p,T)
```

Use the vector of predecessor nodes, `pred`, to create a directed version of the minimum spanning forest. All of the edges in this tree are directed away from the root nodes in each component (nodes `i` and `a`).

```
rootedTree = digraph(pred(pred~=0), find(pred~=0), [], G.Nodes.Name);
plot(rootedTree)
```

## Input Arguments

### **G** — Input graph

graph object

Input graph, specified as a **graph** object. Use the **graph** function to create an undirected graph object. For more information, see [Using graph Objects](#).

Example: `G = graph(1,2)`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[T, pred] = minspantree(G, 'Method', 'sparse')`

### 'Method' — Minimum spanning tree algorithm

'dense' (default) | 'sparse'

Minimum spanning tree algorithm, specified as the comma-separated pair consisting of 'Method' and one of the options in the table.

| Option            | Description                                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| 'dense' (default) | Prim's algorithm. This algorithm starts at the root node and adds edges to the tree while traversing the graph.                     |
| 'sparse'          | Kruskal's algorithm. This algorithm sorts all of the edges by weight, and then adds them to the tree if they do not create a cycle. |

### 'Root' — Root node

1 (default) | positive scalar node index | string node name

Root node, specified as the comma-separated pair consisting of 'Root' and a positive scalar node index or string node name. The default root node is 1.

- If 'Method' is 'dense' (default), then the root node is the starting node.
- If 'Method' is 'sparse', then the root node is used only to compute `pred`, the vector of predecessor nodes.

### 'Type' — Type of minimum spanning tree

'tree' (default) | 'forest'

Type of minimum spanning tree, specified as the comma-separated pair consisting of 'Type' and one of the options in the table.

| Option   | Description                                                                                                                                                       |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'tree'   | Only a single tree is returned. The tree contains the root node.                                                                                                  |
| 'forest' | A forest of minimum spanning trees is returned. In other words, specify 'forest' to calculate the minimum spanning tree of all connected components in the graph. |

## Output Arguments

### **T** — Minimum spanning tree

graph object

Minimum spanning tree, returned as a graph object.

### **pred** — Predecessor nodes

vector

Predecessor nodes, returned as a vector of node indices. `pred(I)` is the node index of the predecessor of node `I`. By convention, `pred(rootNode) = 0`. If `Type` is 'tree', then `pred(I) = NaN` for all nodes `I` that are not in the same component as the root node.

`pred` specifies a directed version of the minimum spanning tree, with all edges directed away from the root node.

## More About

### Minimum Spanning Tree

For connected graphs, a spanning tree is a subgraph that connects every node in the graph, but contains no cycles. There can be many spanning trees for any given graph. By assigning a weight to each edge, the different spanning trees are assigned a number for the total weight of their edges. The minimum spanning tree is then the spanning tree whose edges have the least total weight.

For graphs with equal edge weights, all spanning trees are minimum spanning trees, since traversing  $n$  nodes requires  $n - 1$  edges.

**Introduced in R2015b**

# neighbors

Neighbors of graph node

## Syntax

```
N = neighbors(G,nodeID)
```

## Description

`N = neighbors(G,nodeID)` returns the node IDs of all nodes connected by an edge to the node specified by `nodeID`.

## Examples

### Neighboring Graph Nodes

Create and plot a graph, and then determine the neighbors of node 10.

```
G = graph(bucky);
plot(G)
```

`N = neighbors(G,10)`

`N =`

```

6
9
12

```

## Input Arguments

### **G** — Input graph

graph object

Input graph, specified as a **graph** object. Use the **graph** function to create an undirected graph object. For more information, see Using graph Objects.

Example: `G = graph(1,2)`

### **nodeID** — Node identifier

scalar | string

Node identifier, specified as a scalar node index or string node name.

Example: `N = neighbors(G,3)`

Example: `N = neighbors(G,'A')`

## Output Arguments

### **N** — Neighboring nodes

column vector

Neighboring nodes, returned as a column vector of node indices. A node that is connected to itself by an edge (a self-loop) is listed as its own neighbor twice, and the self-loop adds 2 to the total degree of the node.

## More About

- Using graph Objects

### See Also

degree | graph

Introduced in R2015b

## numedges

Number of edges in graph

### Syntax

```
N = numedges(G)
```

### Description

`N = numedges(G)` returns the number of edges in graph `G`.

### Examples

#### Number of Graph Edges

Use the `bucky` adjacency matrix to create a directed graph, and then determine how many edges the graph contains.

```
G = digraph(bucky)
```

```
G =
```

```
digraph with properties:
```

```
Edges: [180x2 table]
```

```
Nodes: [60x0 table]
```

```
N = numedges(G)
```

```
N =
```

```
180
```

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a `graph` or `digraph` object. Use the `graph` function to create an undirected graph or the `digraph` function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

## Output Arguments

### **N** — Number of edges

scalar

Number of edges, returned as a scalar.

### See Also

`addedge` | `graph` | `numnodes` | `rmedge`

**Introduced in R2015b**

## numnodes

Number of nodes in graph

### Syntax

```
N = numnodes(G)
```

### Description

`N = numnodes(G)` returns the number of nodes in graph `G`.

### Examples

#### Number of Graph Nodes

Use the `bucky` adjacency matrix to create a directed graph, and then determine how many nodes the graph contains.

```
G = digraph(bucky)
```

```
G =
```

```
digraph with properties:
```

```
Edges: [180x2 table]
```

```
Nodes: [60x0 table]
```

```
N = numnodes(G)
```

```
N =
```

```
60
```

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a `graph` or `digraph` object. Use the `graph` function to create an undirected graph or the `digraph` function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

## Output Arguments

### **N** — Number of nodes

scalar

Number of nodes, returned as a scalar.

### See Also

`addnode` | `graph` | `numedges` | `rmnode`

**Introduced in R2015b**

# highlight

Highlight nodes and edges in plotted graph

## Syntax

```
highlight(H,nodeIDs)
highlight(H,G)
highlight(H,s,t)
highlight(____,Name,Value)
```

## Description

`highlight(H,nodeIDs)` highlights the nodes specified by `nodeIDs` by increasing the sizes of their markers.

`highlight(H,G)` highlights the nodes and edges of graph `G` by increasing their node marker size and edge line width, respectively. `G` must have the same nodes and a subset of the edges of the underlying graph of `H`. Isolated nodes with degree 0 are not highlighted.

`highlight(H,s,t)` highlights the edges specified by the source and target node pairs in `s` and `t` by increasing their edge line widths.

`highlight( ____,Name,Value)` uses additional options specified by one or more Name-Value pair arguments using any of the input argument combinations in previous syntaxes. For example, `highlight(H,nodes,'NodeColor','g')` highlights a subset of nodes by changing their color to green, instead of increasing their marker size.

## Examples

### Highlight Graph Nodes

Create and plot a graph. Return a handle to the `GraphPlot` object, `h`.

```
s = 1;
```

```
t = 2:6;
G = graph(s,t);
h = plot(G, 'Layout', 'force')
```

```
h =
```

```
GraphPlot with properties:
```

```
 NodeColor: [0 0.4470 0.7410]
 MarkerSize: 4
 Marker: 'o'
 EdgeColor: [0 0.4470 0.7410]
 LineWidth: 0.5000
 LineStyle: '-'
 NodeLabel: {'1' '2' '3' '4' '5' '6'}
 EdgeLabel: {}
 XData: [5.2608e-04 0.0482 1.7124 1.0121 -1.6822 -1.0911]
 YData: [-2.9904e-04 1.7887 0.5056 -1.4785 0.5981 -1.4136]
```

```
Use GET to show all properties
```

Highlight nodes 1 and 3 by increasing their marker size.

```
highlight(h,[1 3])
```

Highlight nodes 1 and 3 by changing their color.

```
highlight(h,[1 3], 'NodeColor', 'g')
```

### Highlight Minimum Spanning Tree of Graph

Create and plot a graph. Return a handle to the `GraphPlot` object, `h`.

```
s = [1 1 1 1 1 1 2 3 4 5 6 7 7 7 7 8 9 10 11 8 6];
t = [2 3 4 5 6 7 3 4 5 6 2 8 9 10 11 10 10 10 11 8 1 11];
G = graph(s,t);
h = plot(G)
```

`h =`

`GraphPlot` with properties:

```
NodeColor: [0 0.4470 0.7410]
MarkerSize: 4
Marker: 'o'
EdgeColor: [0 0.4470 0.7410]
LineWidth: 0.5000
LineStyle: '-'
NodeLabel: {'1' '2' '3' '4' '5' '6' '7' '8' '9' '10' '11'}
EdgeLabel: {}
XData: [1x11 double]
YData: [1x11 double]
```

Use GET to show all properties

Calculate the minimum spanning tree of the graph. Highlight the minimum spanning tree subgraph in the plot by increasing the line width and changing the color of the edges in the tree.

```
[T,p] = minspantree(G);
highlight(h,T,'EdgeColor','r','LineWidth',1.5)
```

### Highlight Shortest Path

Create and plot a graph. Return a handle to the GraphPlot object, h.

```
n = 10;
A = delsq(numgrid('L',n+2));
```

```
G = graph(A, 'OmitSelfLoops');
G.Edges.Weight = ones(numedges(G),1);
h = plot(G);
```

Highlight the shortest path between nodes 74 and 21 by changing the color of the nodes and edges along the path to green.

```
path = shortestpath(G,74,21);
highlight(h,path, 'NodeColor', 'g', 'EdgeColor', 'g')
```

### Highlight Node Neighbors

Create a graph representing a square grid with a side of 8 nodes. Plot the graph and return a handle to the `GraphPlot` object, `p`.

```
n = 8;
A = delsq(numgrid('S',n+2));
G = graph(A,'OmitSelfLoops');
p = plot(G);
```

Find the neighbors of node 36.

```
n36 = neighbors(G,36)
```

```
n36 =
```

```
28
35
37
44
```

Use `highlight` to change the color of node 36 to green, and the color of its neighbors and their connecting edges to red.

```
highlight(p,36,'NodeColor',[0 0.75 0])
highlight(p,n36,'NodeColor','red')
highlight(p,36,n36,'EdgeColor','red')
```

### Highlight Path of Maximum Flow

Create and plot a directed graph. Return a handle to the `GraphPlot` object, `h`.

```
G = digraph(bucky);
h = plot(G);
```

Compute the maximum flow between nodes 1 and 56. Specify two outputs to `maxflow` to return a directed graph of the nonzero flows, `GF`.

```
[mf,GF] = maxflow(G,1,56)
```

```
mf =
```

```
3
```

```
GF =
```

```
digraph with properties:
```

```
Edges: [28x2 table]
Nodes: [60x0 table]
```

Use `highlight` to change the color of the edges that contain nonzero flow values. Also change the color of source node 1 and target node 56 to green.

```
highlight(h,GF,'EdgeColor',[0.9 0.3 0.1],'NodeColor',[0.9 0.3 0.1])
highlight(h,[1 56],'NodeColor','g')
```

## Input Arguments

### H — Input graph plot

GraphPlot object

Input graph plot, specified as a GraphPlot object. Use the `graph` or `digraph` functions to create a graph, and then use `plot` with an output argument to return a GraphPlot object.

For more information, see [Using GraphPlot Objects](#).

Example: `H = plot(G)`

**nodeIDs — Nodes to highlight**

vector | node name | cell array of strings

Nodes to highlight, specified as a vector of node indices, a node name, or a cell array of strings containing node names.

**G — Graph to highlight**

graph object | digraph object

Graph to highlight, specified as a **graph** or **digraph** object. **G** must have the same nodes and a subset of the edges of the underlying graph of **H**. Isolated nodes with degree 0 are not highlighted.

**s, t — Edges to highlight (as separate arguments)**

scalars | vectors | strings | cell arrays of strings

Edges to highlight, specified as separate arguments that indicate the end nodes of the edges as scalar node indices, vectors of node indices, string node names, or cell arrays of strings containing node names.

Example: `highlight(H, [1 2], [3 3])` highlights the graph edges (1,3) and (2,3).

Example: `highlight(H, 'a', 'b')` highlights the edge ('a', 'b').

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `highlight(H, nodes, 'NodeColor', 'y')`

**'EdgeColor' — Edge color**

[0 0.4470 0.7410] (default) | RGB triplet or color string

Edge color, specified as the comma-separated pair consisting of **'EdgeColor'** and an RGB triplet or color string.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: `plot(G, 'EdgeColor', 'r')` creates a graph plot with red edges.

### 'LineStyle' — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as the comma-separated pair consisting of 'LineStyle' and one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                       |
|--------|------------------|--------------------------------------------------------------------------------------|
| '-'    | Solid line       |   |
| '--'   | Dashed line      |  |
| ':'    | Dotted line      |  |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                              |

### 'LineWidth' — Edge line width

0.5 (default) | positive value

Edge line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in point units.

Example: 0.75

**'Marker' – Node marker symbol**

'o' (default) | marker string

Node marker symbol, specified as the comma-separated pair consisting of 'Marker' and one of the marker strings listed in this table. The default is to use circular markers for the graph nodes.

| String             | Marker Symbol                 |
|--------------------|-------------------------------|
| 'o'                | Circle                        |
| '+'                | Plus sign                     |
| '*'                | Asterisk                      |
| '.'                | Point                         |
| 'x'                | Cross                         |
| 'square' or 's'    | Square                        |
| 'diamond' or 'd'   | Diamond                       |
| '^'                | Upward-pointing triangle      |
| 'v'                | Downward-pointing triangle    |
| '>'                | Right-pointing triangle       |
| '<'                | Left-pointing triangle        |
| 'pentagram' or 'p' | Five-pointed star (pentagram) |
| 'hexagram' or 'h'  | Six-pointed star (hexagram)   |
| 'none'             | No markers                    |

Example: '+'

Example: 'diamond'

**'MarkerSize' – Node marker size**

positive value

Node marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a positive value in point units. The default marker size is 4 for graphs with 100 or fewer nodes, and 2 for graphs with more than 100 nodes.

Example: 10

**'NodeColor' — Node color**

[0 0.4470 0.7410] (default) | RGB triplet or color string

Node color, specified as the comma-separated pair consisting of `'NodeColor'` and an RGB triplet or color string.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range  $[0, 1]$ , for example,  $[0.4 \ 0.6 \ 0.7]$ . This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: `plot(G, 'NodeColor', 'k')` creates a graph plot with black nodes.

## More About

- Using GraphPlot Objects
- “Graph Plotting and Customization”

## See Also

`labeledge` | `labelnode` | `layout` | `plot`

Introduced in R2015b

# labeledge

Label graph edges

## Syntax

```
labeledge(H,s,t,Labels)
labeledge(H,idx,Labels)
```

## Description

`labeledge(H,s,t,Labels)` labels the edges specified by `(s,t)` pairs with the strings contained in `Labels`. The lengths of `s`, `t`, and `Labels` must be equal, or `Labels` can be scalar.

`labeledge(H,idx,Labels)` specifies the edges to label using their edge indices. The edge indices are positive integers corresponding to the row number of the edge in the edge list of the graph, `G.Edges`.

## Examples

### Label Graph Edge Weight

Create and plot a graph.

```
s = [1 1 1 2 2];
t = [2 3 4 2 5];
G = graph(s,t);
h = plot(G);
```

Label the edge weights using `labeledge`.

```
weights = [5 10 15 10 10];
labeledge(h,1:numedges(G),weights)
```

## Add Text Labels to Graph Edges

Create and plot a graph.

```
s = [1 1 2 2 3];
t = [2 3 3 4 4];
G = graph(s,t);
h = plot(G);
```

Add text labels to three of the five graph edges.

```
labelText = {'ABC' 'DEF' 'GHI'};
labeledge(h,[1 1 2],[2 3 3],labelText)
```

## Input Arguments

### **H** — Input graph plot

GraphPlot object

Input graph plot, specified as a GraphPlot object. Use the `graph` or `digraph` functions to create a graph, and then use `plot` with an output argument to return a GraphPlot object.

For more information, see [Using GraphPlot Objects](#).

Example: `H = plot(G)`

**s, t — Edges to label (as separate arguments)**

scalars | vectors | strings | cell arrays of strings

Edges to label, specified as separate arguments that indicate the end nodes of the edges as scalar node indices, vectors of node indices, string node names, or cell arrays of strings containing node names.

Example: `labeledge(H,[1 2 2],[2 3 4],{'label1' 'label2' 'label3'})`

Example: `labeledge(H,{'a' 'b' 'b'},{'b' 'c' 'd'},{'label1' 'label2' 'label3'})`

**idx — Edge indices**

scalar | vector

Edge indices, specified as scalar or vector of positive integers. The edge indices correspond to rows in the table `H.Edges`, such that `H.Edges(idx,:)` returns the end nodes of the edge. The maximum value for `idx` is `numedges(H)`. The number of indices in `idx` must be the same as the number of values in `Labels`.

Example: `labeledge(H,[1 3 5 7],{'label1' 'label2' 'label3' 'label4'})`

**Labels — Edge labels**

string | cell array of strings

Edge labels, specified as a single string or a cell array of strings.

- If `Labels` is a single string, then `labeledge` uses that label for each specified edge.
- If `Labels` is a cell array, then it must contain a label for each specified edge.

Data Types: `char` | `cell`

**More About**

- Using GraphPlot Objects
- “Graph Plotting and Customization”

**See Also**

`highlight` | `labelnode` | `layout` | `plot`

Introduced in R2015b

## labelnode

Label graph nodes

### Syntax

`labelnode(H,nodeIDs,Labels)`

### Description

`labelnode(H,nodeIDs,Labels)` labels the nodes specified by `nodeIDs` with the strings contained in `Labels`. The lengths of `nodeIDs` and `Labels` must be equal, or `Labels` can be scalar.

### Examples

#### Label Graph Nodes

Create and plot a graph.

```
s = [1 1 2 2 3 4 5 5];
t = [2 3 3 4 4 5 1 2];
G = digraph(s,t);
h = plot(G);
```

The `plot` function automatically labels the graph nodes with their node indices (or with their node names, if available). Use text labels for some of the graph nodes instead.

```
labelnode(h,[1 2],{'source' 'target'})
```

Label node 3 and node 4 as 'A'. Since the node labels do not change the underlying graph,  $G$ , the labels can contain duplicate names (the official node names in  $G$  must always be unique).

```
labelnode(h, [3 4], 'A')
```

## Input Arguments

### **H** — Input graph plot

GraphPlot object

Input graph plot, specified as a GraphPlot object. Use the `graph` or `digraph` functions to create a graph, and then use `plot` with an output argument to return a GraphPlot object.

For more information, see [Using GraphPlot Objects](#).

Example: `H = plot(G)`

**nodeIDs — Nodes to label**

vector | node name | cell array of strings

Nodes to label, specified as a vector of node indices, a node name, or a cell array of strings containing node names.

**Labels — Node labels**

string | cell array of strings

Node labels, specified as a single string or a cell array of strings.

- If **Labels** is a single string, then **labelnode** uses that label for each node specified by **nodeIDs**.
- If **Labels** is a cell array, then it must contain a label for each node specified by **nodeIDs**.

Data Types: char | cell

## See Also

highlight | labeledge | layout | plot

**Introduced in R2015b**

# layout

Change layout of graph plot

## Syntax

```
layout(H)
layout(H,method)
layout(H,method,Name,Value)
```

## Description

`layout(H)` changes the layout of graph plot `H` by using an automatic choice of layout method based on the structure of the graph. The `layout` function modifies the `XData` and `YData` properties of `H`.

`layout(H,method)` optionally specifies the layout method. `method` can be `'circle'`, `'force'`, `'layered'`, or `'subspace'`.

`layout(H,method,Name,Value)` uses additional options specified by one or more Name-Value pair arguments. For example, `layout(H,'force','Iterations',N)` specifies the number of iterations to use in computing the force layout, and `layout(H,'layered','Sources',S)` uses a layered layout with source nodes `S` included in the first layer.

## Examples

### Graph Layout Based on Structure

Create and plot a graph using the `'force'` layout.

```
s = [1 1 1 1 1 6 6 6 6 6];
t = [2 3 4 5 6 7 8 9 10 11];
G = graph(s,t);
h = plot(G,'Layout','force');
```

Change the layout to be the default that `plot` determines based on the structure and properties of the graph. The result is the same as using `plot(G)`.

`layout(h)`

### Change Layout of Graph

Create and plot a graph using the 'layered' layout.

```
s = [1 1 1 2 2 3 3 4 5 5 6 7];
t = [2 4 5 3 6 4 7 8 6 8 7 8];
G = graph(s,t);
h = plot(G, 'Layout', 'layered');
```

Change the layout of the graph to use the 'subspace' method.

```
layout(h, 'subspace')
```

### Refine Layout Method of Graph

Create and plot a graph using the 'layered' layout method.

```
s = [1 1 1 2 3 3 3 4 4];
t = [2 4 5 6 2 4 7 8 1];
G = digraph(s,t);
h = plot(G,'Layout','layered');
```

Use the `layout` function to refine the hierarchical layout by specifying source nodes and a horizontal orientation.

```
layout(h, 'layered', 'Direction', 'right', 'Sources', [1 4])
```

## Input Arguments

### H — Input graph plot

GraphPlot object

Input graph plot, specified as a GraphPlot object. Use the `graph` or `digraph` functions to create a graph, and then use `plot` with an output argument to return a GraphPlot object.

For more information, see [Using GraphPlot Objects](#).

Example: `H = plot(G)`

**method — Layout method**

'auto' (default) | 'circle' | 'force' | 'layered' | 'subspace'

Layout method, specified as one of the options in the table. The table also lists compatible Name-Value pairs to further refine each layout method.

| Option           | Description                                                                                                                                                                                                                                  | Name-Value Pairs                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|
| 'auto' (default) | Automatic choice of layout method based on the structure of the graph.                                                                                                                                                                       | —                                                     |
| 'circle'         | Circular layout. Places the graph nodes on a circle centered at the origin with radius 1.                                                                                                                                                    | —                                                     |
| 'force'          | Force-directed layout. Uses attractive forces between adjacent nodes and repulsive forces between distant nodes.                                                                                                                             | 'Iterations'<br>'XStart' and 'Ystart'                 |
| 'layered'        | Layered layout. Places the graph nodes into a set of layers, revealing hierarchical structure. By default the layers progress downwards (the arrows of a directed acyclic graph point down).                                                 | 'Direction'<br>'Sources'<br>'Sinks'<br>'AssignLayers' |
| 'subspace'       | Subspace embedding layout. Plots the graph nodes in a high-dimensional embedded subspace, and then projects the positions back into 2-D. By default the subspace dimension is either 100 or the total number of nodes, whichever is smaller. | 'Dimension'                                           |

Example: `layout(H, 'layered')`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `layout(H,'subspace','Dimension',200)`

## Force

### 'Iterations' — Number of force-directed layout iterations

100 (default) | positive scalar integer

Number of force-directed layout iterations, specified as the comma-separated pair consisting of 'Iterations' and a positive scalar integer.

This option is available only when `method` is 'force'.

Example: `layout(H,'force','Iterations',250)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### 'XStart' — Starting x-coordinates for nodes

vector

Starting x-coordinates for nodes, specified as the comma-separated pair consisting of 'XStart' and a vector of node coordinates. Use this option together with 'YStart' to specify the starting  $x$  and  $y$  node coordinates before iterations of the force-directed algorithm change the node positions.

This option is available only when `method` is 'force'.

Example: `layout(H,'force','XStart',x,'YStart',y)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### 'YStart' — Starting y-coordinates for nodes

vector

Starting y-coordinates for nodes, specified as the comma-separated pair consisting of 'YStart' and a vector of node coordinates. Use this option together with 'XStart'

to specify the starting  $x$  and  $y$  node coordinates before iterations of the force-directed algorithm change the node positions.

This option is available only when `method` is `'force'`.

Example: `layout(H, 'force', 'XStart', x, 'YStart', y)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Layered

### 'Direction' — Direction of layers

`'down'` (default) | `'up'` | `'left'` | `'right'`

Direction of layers, specified as the comma-separated pair consisting of `'Direction'` and either `'down'`, `'up'`, `'left'` or `'right'`. For directed acyclic (DAG) graphs, the arrows point in the indicated direction.

This option is available only when `method` is `'layered'`.

Example: `layout(H, 'layered', 'Direction', 'up')`

### 'Sources' — Nodes to include in the first layer

`vector` | `cell array`

Nodes to include in first the layer, specified as the comma-separated pair consisting of `'Sources'` and either a vector of node indices or a cell array of strings containing node names.

This option is available only when `method` is `'layered'`.

Example: `layout(H, 'layered', 'Sources', [1 3 5])`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `cell`

### 'Sinks' — Nodes to include in the last layer

`vector` | `cell array`

Nodes to include in the last layer, specified as the comma-separated pair consisting of `'Sinks'` and either a vector of node indices or a cell array of strings containing node names.

This option is available only when `method` is `'layered'`.

Example: `layout(H, 'layered', 'Sinks', [2 4 6])`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `cell`

### 'AssignLayers' — Layer assignment method

`'auto'` (default) | `'asap'` | `'alap'`

Layer assignment method, specified as the comma-separated pair consisting of `'AssignLayers'` and one of the options in this table.

| Option                        | Description                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>'auto'</code> (default) | Node assignment uses either <code>'asap'</code> or <code>'alap'</code> , whichever is more compact.                                               |
| <code>'asap'</code>           | As soon as possible. Each node is assigned to the first possible layer, given the constraint that all its predecessors must be in earlier layers. |
| <code>'alap'</code>           | As late as possible. Each node is assigned to the last possible layer, given the constraint that all its successors must be in later layers.      |

This option is available only when `method` is `'layered'`.

Example: `layout(H, 'layered', 'AssignLayers', 'alap')`

## Subspace

### 'Dimension' — Dimension of embedded subspace

positive scalar integer greater than or equal to 2

Dimension of embedded subspace, specified as the comma-separated pair consisting of `'Dimension'` and a positive scalar integer greater than or equal to 2 but less than the number of nodes. The default value is `min([100, numnodes(G)])`.

This option is available only when `method` is `'subspace'`.

Example: `layout(H, 'subspace', 'Dimension', d)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## More About

### Tips

- Use the `Layout` Name-Value pair to change the layout of a graph when you plot it. For example, `plot(G, 'Layout', 'circle')` plots the graph `G` with a circular layout.
- When using the `'force'` layout method, a best practice is to use more iterations with the algorithm instead of using `XStart` and `YStart` to restart the algorithm using previous outputs. The result of executing the algorithm with 100 iterations is different in comparison to executing 50 iterations, and then restarting the algorithm from the ending positions to execute 50 more iterations.

Introduced in R2015b

# plot (graph)

Graph plot

## Syntax

```
plot(G)
plot(G,LineStyle)
plot(____,Name,Value)
plot(ax, ____)
h = plot(____)
```

## Description

`plot(G)` plots the nodes and edges in graph `G`.

`plot(G,LineStyle)` sets the line style, marker symbol, and color. For example, `plot(G, '-or')` uses red circles for the nodes and red lines for the edges.

`plot( ____,Name,Value)` uses additional options specified by one or more Name-Value pair arguments using any of the input argument combinations in previous syntaxes. For example, `plot(G, 'Layout', 'circle')` plots a circular ring layout of the graph, and `plot(G, 'XData', X, 'YData', Y)` specifies the  $(X, Y)$  coordinates of the graph nodes.

`plot(ax, ____)` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option, `ax`, can precede any of the input argument combinations in previous syntaxes.

`h = plot( ____)` returns a `GraphPlot` object. Use this object to inspect and adjust the properties of the plotted graph.

## Examples

### Plot Graph

Create a graph using a sparse adjacency matrix, and then plot the graph.

```
n = 10;
A = delsq(numgrid('L',n+2));
G = graph(A, 'OmitSelfLoops')
```

```
G =
```

```
graph with properties:
```

```
Edges: [130x2 table]
Nodes: [75x0 table]
```

```
plot(G)
```

### Plot Graph Using Line Specifier

Create and plot a graph. Specify the LineSpec input to change the Marker, NodeColor, and/or LineStyle of the graph plot.

```
G = graph(bucky);
plot(G, '-.dr', 'NodeLabel', {})
```

### Plot Graph with Specified Layout

Create a directed graph, and then plot the graph using the 'force' layout.

```
G = digraph(1,2:5);
G = addedge(G,2,6:15);
G = addedge(G,15,16:20)
```

```
G =
```

```
digraph with properties:
```

```
Edges: [19x1 table]
```

Nodes: [20x0 table]

```
plot(G, 'Layout', 'force')
```

### Custom Graph Node Coordinates

Create a weighted graph.

```
s = [1 1 1 1 1 2 2 7 7 9 3 3 1 4 10 8 4 5 6 8];
t = [2 3 4 5 7 6 7 5 9 6 6 10 10 10 11 11 8 8 11 9];
weights = [1 1 1 1 3 3 2 4 1 6 2 8 8 9 3 2 10 12 15 16];
G = graph(s,t,weights)
```

G =

graph with properties:

Edges: [20x2 table]

Nodes: [11x0 table]

Plot the graph using custom coordinates for the nodes. The x-coordinates are specified using `XData`, and the y-coordinates are specified using `YData`. Use `EdgeLabel` to label the edges using the edge weights.

```
x = [0 0.5 -0.5 -0.5 0.5 0 1.5 0 2 -1.5 -2];
y = [0 0.5 0.5 -0.5 -0.5 2 0 -2 0 0 0];
plot(G, 'XData',x, 'YData',y, 'EdgeLabel',G.Edges.Weight)
```

### Edge Line Width Proportional to Edge Weight

Create a weighted graph.

```
s = [1 1 1 1 2 2 3 4 4 5 6];
t = [2 3 4 5 3 6 6 5 7 7 7];
weights = [50 10 20 80 90 90 30 20 100 40 60];
G = graph(s,t,weights)
```

G =

graph with properties:

Edges: [11x2 table]

Nodes: [7x0 table]

Plot the graph, labeling the edges with their weights, and making the width of the edges proportional to their weights. Use a rescaled version of the edge weights to determine the width of each edge, such that the widest line has a width of 5.

```
LWidths = 5*G.Edges.Weight/max(G.Edges.Weight);
plot(G,'EdgeLabel',G.Edges.Weight,'LineWidth',LWidths)
```

## Label Graph Nodes and Edges

Create a directed graph, and then plot the graph with custom labels for the nodes and edges.

```
s = [1 1 1 2 2 3 3 4 4 5 6 7];
t = [2 3 4 5 6 5 7 6 7 8 8 8];
G = digraph(s,t)
```

```
G =
```

```
digraph with properties:
```

```
Edges: [12x1 table]
Nodes: [8x0 table]
```

```
eLabels = {'x' 'y' 'z' 'y' 'z' 'x' 'z' 'x' 'y' 'z' 'y' 'x'};
nLabels = {'{0}', '{x}', '{y}', '{z}', '{x,y}', '{x,z}', '{y,z}', '{x,y,z}'};
plot(G, 'Layout', 'force', 'EdgeLabel', eLabels, 'NodeLabel', nLabels)
```

### Adjust GraphPlot Properties

Create and plot a directed graph. Specify an output argument to `plot` to return a handle to the `GraphPlot` object.

```
s = [1 1 1 2 2 3 3 4 5 5 6 7 7 8 8 9 10 11];
t = [2 3 10 4 12 4 5 6 6 7 9 8 10 9 11 12 11 12];
G = digraph(s,t)
```

G =

digraph with properties:

```
Edges: [18x1 table]
Nodes: [12x0 table]
```

```
p = plot(G)
```

```
p =
```

```
GraphPlot with properties:
```

```
NodeColor: [0 0.4470 0.7410]
MarkerSize: 4
Marker: 'o'
EdgeColor: [0 0.4470 0.7410]
LineWidth: 0.5000
LineStyle: '-'
NodeLabel: {1x12 cell}
EdgeLabel: {}
XData: [2.5000 1.5000 2.5000 2 3 2 3 3 2.5000 4 3.5000 2.5000]
YData: [7 6 6 5 5 4 4 3 2 3 2 1]
```

```
Use GET to show all properties
```

Change the color and marker of the nodes.

```
p.Marker = 's';
p.NodeColor = 'r';
```

Increase the size of the nodes.

```
p.MarkerSize = 7;
```

Change the line style of the edges.

```
p.LineStyle = '-.-';
```

Change the  $x$  and  $y$  coordinates of the nodes.

```
p.XData = [2 4 1.5 3.5 1 3 1 2.1 3 2 3.1 4];
p.YData = [3 3 3.5 3.5 4 4 2 2 2 1 1 1];
```

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a **graph** or **digraph** object. Use the **graph** function to create an undirected graph or the **digraph** function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

**LineStyleSpec — Line style, marker symbol, and color**

string

Line style, marker symbol, and color, specified as a string. The elements of the string can appear in any order, and you can omit one or more options from the string specifier. If you omit the line style, then the plot shows solid lines for the graph edges.

Example: ' - - o r ' uses red circle node markers and red dashed lines as edges.

Example: ' r \* ' uses red asterisk node markers and solid red lines as edges.

| Specifier | Line Style           |
|-----------|----------------------|
| -         | Solid line (default) |
| - -       | Dashed line          |
| :         | Dotted line          |
| - .       | Dash-dot line        |

| Specifier | Marker                     |
|-----------|----------------------------|
| o         | Circle                     |
| +         | Plus sign                  |
| *         | Asterisk                   |
| .         | Point                      |
| x         | Cross                      |
| s         | Square                     |
| d         | Diamond                    |
| ^         | Upward-pointing triangle   |
| v         | Downward-pointing triangle |
| >         | Right-pointing triangle    |
| <         | Left-pointing triangle     |
| p         | Pentagram                  |
| h         | Hexagram                   |

| Specifier | Color  |
|-----------|--------|
| y         | yellow |

| Specifier | Color   |
|-----------|---------|
| m         | magenta |
| c         | cyan    |
| r         | red     |
| g         | green   |
| b         | blue    |
| w         | white   |
| k         | black   |

**ax — Axes object**

object

Axes object. If you do not specify an axes object, then `plot` uses the current axes (`gca`).

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `p = plot(G, 'EdgeColor', 'r', 'NodeColor', 'k', 'LineStyle', '--')`

The graph properties listed here are only a subset. For a complete list, see [GraphPlot Properties](#).

**'ArrowSize' — Arrow size**

positive value

---

**Note:** `ArrowSize` only affects the display of directed graphs created using `digraph`.

---

Arrow size, specified as the comma-separated pair consisting of `'ArrowSize'` and a positive value in point units. The default value of `ArrowSize` is 7 for graphs with 100 or fewer nodes, and 4 for graphs with more than 100 nodes.

Example: 15

**'EdgeAlpha' — Transparency of graph edges**

0.5 (default) | scalar value between 0 and 1 inclusive

Transparency of graph edges, specified as the comma-separated pair consisting of 'EdgeAlpha' and a scalar value between 0 and 1 inclusive. A value of 1 means fully opaque and 0 means completely transparent (invisible).

Example: 0.25

**'EdgeCData' — Color data of edge lines**

vector

Color data of edge lines, specified as the comma-separated pair consisting of 'EdgeCData' and a vector with length equal to the number of edges in the graph. The values in `EdgeCData` map linearly to the colors in the current colormap, resulting in different colors for each edge in the plotted graph.

**'EdgeColor' — Edge color**

[0 0.4470 0.7410] (default) | RGB triplet or color string | 'flat' | 'none'

Edge color, specified as the comma-separated pair consisting of 'EdgeColor' and one of these values:

- 'none' — Edges are not drawn.
- 'flat' — Color of each edge depends on the value of `EdgeCData`.
- RGB triplet or a color string — Edges use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: `plot(G, 'EdgeColor', 'r')` creates a graph plot with red edges.

**'EdgeLabel' – Edge labels**

{ } (default) | vector | cell array of strings

Edge labels, specified as the comma-separated pair consisting of 'EdgeLabel' and a numeric vector or cell array of strings. The length of `EdgeLabel` must be equal to the number of edges in the graph. By default `EdgeLabel` is an empty cell array (no edge labels are displayed).

Example: { 'A', 'B', 'C' }

Example: [1 2 3]

Example: `plot(G, 'EdgeLabel', G.Edges.Weight)` labels the graph edges with their weights.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | cell

**'Layout' – Graph layout method**

'auto' (default) | 'circle' | 'force' | 'layered' | 'subspace'

Graph layout method, specified as the comma-separated pair consisting of 'Layout' and one of the options in the table. The table also lists compatible Name-Value pairs to further refine each layout method. See the `layout` reference page for more information on these layout-specific Name-Value pairs.

| Option           | Description                                                                               | Name-Value Pairs |
|------------------|-------------------------------------------------------------------------------------------|------------------|
| 'auto' (default) | Automatic choice of layout method based on the structure of the graph.                    | —                |
| 'circle'         | Circular layout. Places the graph nodes on a circle centered at the origin with radius 1. | —                |

| Option     | Description                                                                                                                                                                                                                                       | Name-Value Pairs                                      |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|
| 'force'    | Force-directed layout. Uses attractive forces between adjacent nodes and repulsive forces between distant nodes.                                                                                                                                  | 'Iterations'<br>'XStart' and 'Ystart'                 |
| 'layered'  | Layered node layout. Places the graph nodes into a set of layers, revealing hierarchical structure. By default the layers progress downwards (the arrows of a directed acyclic graph point down).                                                 | 'Direction'<br>'Sources'<br>'Sinks'<br>'AssignLayers' |
| 'subspace' | Subspace embedding node layout. Plots the graph nodes in a high-dimensional embedded subspace, and then projects the positions back into 2-D. By default the subspace dimension is either 100 or the total number of nodes, whichever is smaller. | 'Dimension'                                           |

Example: `plot(G, 'Layout', 'force', 'Iterations', 10)`

Example: `plot(G, 'Layout', 'subspace', 'Dimension', 50)`

Example: `plot(G, 'Layout', 'layered')`

### 'LineStyle' — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as the comma-separated pair consisting of 'LineStyle' and one of the line style strings listed in this table.

| String | Line Style | Resulting Line                                                                       |
|--------|------------|--------------------------------------------------------------------------------------|
| '-'    | Solid line |  |

| String  | Line Style       | Resulting Line                                                                     |
|---------|------------------|------------------------------------------------------------------------------------|
| ' - - ' | Dashed line      |  |
| ' : '   | Dotted line      |  |
| ' - . ' | Dash-dotted line |  |
| 'none'  | No line          | No line                                                                            |

**'LineWidth' — Edge line width**

0.5 (default) | positive value

Edge line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in point units.

Example: 0.75

**'Marker' — Node marker symbol**

'o' (default) | marker string

Node marker symbol, specified as the comma-separated pair consisting of 'Marker' and one of the marker strings listed in this table. The default is to use circular markers for the graph nodes.

| String           | Marker Symbol              |
|------------------|----------------------------|
| 'o'              | Circle                     |
| '+'              | Plus sign                  |
| '*'              | Asterisk                   |
| '.'              | Point                      |
| 'x'              | Cross                      |
| 'square' or 's'  | Square                     |
| 'diamond' or 'd' | Diamond                    |
| '^'              | Upward-pointing triangle   |
| 'v'              | Downward-pointing triangle |
| '>'              | Right-pointing triangle    |
| '<'              | Left-pointing triangle     |

| String             | Marker Symbol                 |
|--------------------|-------------------------------|
| 'pentagram' or 'p' | Five-pointed star (pentagram) |
| 'hexagram' or 'h'  | Six-pointed star (hexagram)   |
| 'none'             | No markers                    |

Example: '+'

Example: 'diamond'

### 'MarkerSize' — Node marker size

positive value

Node marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a positive value in point units. The default value of `MarkerSize` is 4 for graphs with 100 or fewer nodes, and 2 for graphs with more than 100 nodes.

Example: 10

### 'NodeCData' — Color data of node markers

vector

Color data of node markers, specified as the comma-separated pair consisting of 'NodeCData' and a vector with length equal to the number of nodes in the graph. The values in `NodeCData` map linearly to the colors in the current colormap, resulting in different colors for each node in the plotted graph.

### 'NodeColor' — Node color

[0 0.4470 0.7410] (default) | RGB triplet or color string | 'flat' | 'none'

Node color, specified as the comma-separated pair consisting of 'NodeColor' and one of these values:

- 'none' — Nodes are not drawn.
- 'flat' — Color of each node depends on the value of `NodeCData`.
- RGB triplet or a color string — Nodes use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: `plot(G, 'NodeColor', 'k')` creates a graph plot with black nodes.

### 'NodeLabel' — Node labels

node IDs (default) | vector | cell array of strings

Node labels, specified as the comma-separated pair consisting of 'NodeLabel' and a numeric vector or cell array of strings. The length of NodeLabel must be equal to the number of nodes in the graph. By default NodeLabel is a cell array containing the node IDs for the graph nodes:

- For nodes without names (that is, `G.Nodes` does not contain a `Name` variable), the node labels are the values `unique(G.Edges.EndNodes)` contained in a cell array.
- For named nodes, the node labels are `G.Nodes.Name`.

Example: {'A', 'B', 'C'}

Example: [1 2 3]

Example: `plot(G, 'NodeLabel', G.Nodes.Name)` labels the nodes with their names.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | cell

### 'XData' — x-coordinate of nodes

vector

---

**Note:** XData and YData must be specified together so that each node has a valid (x,y) coordinate.

---

---

x-coordinate of nodes, specified as the comma-separated pair consisting of 'XData' and a vector with length equal to the number of nodes in the graph.

**'YData' — y-coordinate of nodes**

vector

---

**Note:** XData and YData must be specified together so that each node has a valid  $(x,y)$  coordinate.

---

y-coordinate of nodes, specified as the comma-separated pair consisting of 'YData' and a vector with length equal to the number of nodes in the graph.

## Output Arguments

**h — Graph plot**

GraphPlot object

Graph plot, returned as an object. For more information, see Using GraphPlot Objects.

**Introduced in R2015b**

## **rmedge**

Remove edge from graph

### **Syntax**

```
H = rmedge(G,s,t)
H = rmedge(G,idx)
```

### **Description**

`H = rmedge(G,s,t)` removes the edges specified by the node pairs `s` and `t` from graph `G`.

`H = rmedge(G,idx)` specifies which edges to remove with edge indices `idx`. The edge indices are row numbers in the `G.Edges` table.

### **Examples**

#### **Remove Edges with Specified End Nodes**

Create and plot a graph.

```
s = [1 1 1 2 2 3 3 4 5 5 6 7];
t = [2 4 5 3 6 4 7 8 6 8 7 8];
G = graph(s,t);
plot(G)
```

Remove several edges from the graph and plot the result.

```
G = rmedge(G,[1 2 3 4],[5 6 7 8]);
plot(G)
```

## Remove Edge with Specified Index

Create a graph and view the edge list.

```
s = {'BOS' 'NYC' 'NYC' 'NYC' 'LAX'};
t = {'NYC' 'LAX' 'DEN' 'LAS' 'DCA'};
G = digraph(s,t);
G.Edges
```

ans =

EndNodes

---

```
'BOS' 'NYC'
'NYC' 'LAX'
'NYC' 'DEN'
'NYC' 'LAS'
'LAX' 'DCA'
```

Remove the edge between nodes 'NYC' and 'DEN' using the edge index.

```
G = rmedge(G,3);
G.Edges
```

```
ans =
```

```
 EndNodes

' BOS' ' NYC'
' NYC' ' LAX'
' NYC' ' LAS'
' LAX' ' DCA'
```

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a **graph** or **digraph** object. Use the **graph** function to create an undirected graph or the **digraph** function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

### **s, t** — Node pairs (as separate arguments)

scalars | vectors | strings | cell arrays of strings

Node pairs, specified as separate arguments of scalars, vectors, strings, or cell arrays of strings. Similarly located elements in **s** and **t** specify the source and target nodes for an edge in the graph.

Example: `G = rmedge(G, 1, 2)` removes the edge between node 1 and node 2 from graph G.

Example: `G = rmedge(G, {'a' 'b'}, {'d' 'c'})` removes two edges from graph G, the first of which is between node 'a' and node 'd'.

## **idx** — Edge indices

scalar | vector

Edge indices, specified as a scalar or vector. The edge indices are nonnegative integers that are row numbers in the `G.Edges` table.

Example: `G = rmedge(G, [1 3 5])` removes the first, third, and fifth edges (rows) from `G.Edges`.

## Output Arguments

### **H** — Output graph

graph object | digraph object

Output graph, returned as a graph or digraph object.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

# rmnode

Remove node from graph

## Syntax

```
H = rmnode(G,nodeIDs)
```

## Description

`H = rmnode(G,nodeIDs)` removes the nodes specified by `nodeIDs` from graph `G`. Any edges incident upon the nodes in `nodeIDs` are also removed. `rmnode` refreshes the numbering of the nodes in `H`.

## Examples

### Remove Node from Graph

Create and plot a graph.

```
s = [1 1 1 2 2 3];
t = [2 3 4 3 4 4];
G = graph(s,t);
plot(G)
```

Remove node 1 from the graph and plot the result. The nodes in the new graph are automatically renumbered.

```
G = rmnode(G,1);
plot(G)
```

### Remove Several Named Nodes from Graph

Create and plot a graph with named nodes.

```
s = [1 1 1 1 2 2 3 3 3 5 5];
t = [2 3 4 6 1 5 4 5 6 4 6];
names = {'New York' 'Los Angeles' 'Washington D.C.' 'Pittsburgh' ...
 'Denver' 'Austin'};
G = digraph(s,t,[],names);
plot(G)
```

Remove the nodes 'New York' and 'Pittsburgh' from the graph, then replot the result.

```
G = rmnode(G,{'New York' 'Pittsburgh'});
plot(G, 'Layout', 'force')
```

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a **graph** or **digraph** object. Use the **graph** function to create an undirected graph or the **digraph** function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

**nodeIDs — Node identifiers**

scalar | vector | matrix | string | cell array of strings

Node identifiers, specified as a scalar, vector, matrix, string, or cell array of strings.

Example: `G = rmnode(G, [1 2])` removes node 1 and node 2 from graph G.

## Output Arguments

**H — Output graph**

graph object | digraph object

Output graph, returned as a graph or digraph object.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

**Introduced in R2015b**

# reordernodes

Reorder graph nodes

## Syntax

```
H = reordernodes(G,order)
[H,idx] = reordernodes(G,order)
```

## Description

`H = reordernodes(G,order)` reorders the nodes in graph `G` according to `order`. This reordering corresponds to a symmetric permutation of the adjacency matrix of `G`.

`[H,idx] = reordernodes(G,order)` also returns the permutation vector for the edge indices, `idx`. For example, if `G.Edges` has a variable `Weight`, then `H.Edges.Weight == G.Edges.Weight(idx)`.

## Examples

### Reorder Graph Nodes

Create and plot a graph.

```
s = [1 1 1 2 5 3 6 4 7 8 8 8];
t = [2 3 4 5 3 6 4 7 2 6 7 5];
G = graph(s,t);
plot(G)
```

Reorder the graph nodes using a permutation vector.

```
order = [7 2 3 4 8 1 5 6];
G = reordernodes(G,order);
plot(G)
```

### Reorder Graph Nodes by Degree

Create and plot a weighted graph.

```
s = [1 1 1 2 2 2 2 3 4];
t = [3 4 2 3 4 5 6 5 6];
weights = [6 7 6 3 2 8 7 1 1];
G = digraph(s,t,weights);
plot(G, 'EdgeLabel', G.Edges.Weight)
```

Reorder the graph nodes based on the out-degree, such that node 1 has the largest out-degree.

```
[~,order] = sort(outdegree(G), 'descend')
```

order =

- 2
- 1
- 3
- 4
- 5
- 6

```
[H,idx] = reordernodes(G,order);
plot(H,'EdgeLabel',H.Edges.Weight)
```

`idx` describes the permutation of the rows in `G.Edges`. Confirm this correspondence using the `Weight` variable.

```
isequal(H.Edges.Weight, G.Edges.Weight(idx))
```

```
ans =
```

```
1
```

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a **graph** or **digraph** object. Use the **graph** function to create an undirected graph or the **digraph** function to create a directed graph.

For more information, see Using graph Objects or Using digraph Objects.

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

### **order** — Node order

vector of indices | cell array of node names

Node order, specified as a vector of indices or cell array of node names. **order** specifies a symmetric permutation of the adjacency matrix of **G**. If  $A = \text{adjacency}(G)$ , then  $A(\text{order}, \text{order})$  produces  $\text{adjacency}(H)$ .

Example: `H = reordernodes(G,[3 1 2])`

## Output Arguments

### **H** — Output graph

graph object | digraph object

Output graph, returned as a **graph** or **digraph** object. **H** contains the same **Nodes** and **Edges** properties as **G**, but with the rows of **H.Nodes** and **H.Edges** permuted:

- **H.Nodes** is the same as **G.Nodes(order, :)**.
- **H.Edges** is similar to **G.Edges(idx, :)**, except that the nodes are renumbered.

### **idx** — Permutation vector of edge indices

vector

Permutation vector of edge indices, returned as a vector. The values in **idx** describe the permutation of the rows in **G.Edges**.

## **See Also**

addnode | digraph | findnode | graph | rmnode | subgraph

**Introduced in R2015b**

## shortestpath

Shortest path between two single nodes

### Syntax

```
path = shortestpath(G,s,t)
path = shortestpath(G,s,t,'Method',algorithm)
[path,d] = shortestpath(___)
```

### Description

`path = shortestpath(G,s,t)` computes the shortest path starting at source node `s` and ending at target node `t`. If the graph is weighted (that is, `G.Edges` contains a variable `Weight`), then those weights are used as the distances along the edges in the graph. Otherwise, all edge distances are taken to be 1.

`path = shortestpath(G,s,t,'Method',algorithm)` optionally specifies the algorithm to use in computing the shortest path. For example, if `G` is a weighted graph, then `shortestpath(G,s,t,'Method','unweighted')` ignores the edge weights in `G` and instead treats all edge weights as 1.

`[path,d] = shortestpath( ___ )` additionally returns the length of the shortest path, `d`, using any of the input arguments in previous syntaxes.

### Examples

#### Shortest Path Between Specified Nodes

Create and plot a directed graph.

```
s = [1 1 2 3 3 4 4 6 6 7 8 7 5];
t = [2 3 4 4 5 5 6 1 8 1 3 2 8];
G = digraph(s,t);
plot(G)
```

Calculate the shortest path between nodes 7 and 8.

```
path = shortestpath(G,7,8)
```

```
path =
```

```
 7 1 3 5 8
```

### Shortest Path in Weighted Graph

Create and plot a graph with weighted edges.

```
s = [1 1 1 2 2 6 6 7 7 3 3 9 9 4 4 11 11 8];
```

```
t = [2 3 4 5 6 7 8 5 8 9 10 5 10 11 12 10 12 12];
weights = [10 10 10 10 10 10 1 1 1 1 1 1 1 1 1 1 1 1];
G = graph(s,t,weights);
plot(G,'EdgeLabel',G.Edges.Weight)
```

Find the shortest path between nodes 3 and 8, and specify two outputs to also return the length of the path.

```
[path,d] = shortestpath(G,3,8)
```

```
path =
```

```
3 9 5 7 8
```

```
d =
```

```
4
```

Since the edges in the center of the graph have large weights, the shortest path between nodes 3 and 8 goes around the boundary of the graph where the edge weights are smallest. This path has a total length of 4.

### Shortest Path Ignoring Edge Weights

Create and plot a graph with weighted edges, using custom node coordinates.

```
s = [1 1 1 1 1 2 2 7 7 9 3 3 1 4 10 8 4 5 6 8];
t = [2 3 4 5 7 6 7 5 9 6 6 10 10 10 11 11 8 8 11 9];
weights = [1 1 1 1 3 3 2 4 1 6 2 8 8 9 3 2 10 12 15 16];
G = graph(s,t,weights);

x = [0 0.5 -0.5 -0.5 0.5 0 1.5 0 2 -1.5 -2];
y = [0 0.5 0.5 -0.5 -0.5 2 0 -2 0 0 0];
p = plot(G, 'XData',x, 'YData',y, 'EdgeLabel',G.Edges.Weight);
```

Find the shortest path between nodes 6 and 8 based on the graph edge weights. Highlight this path in green.

```
[path1,d] = shortestpath(G,6,8)
```

```
path1 =
```

```
6 3 1 4 8
```

```
d =
```

```
14
```

```
highlight(p,path1,'EdgeColor','g')
```

Specify Method as `unweighted` to ignore the edge weights, instead treating all edges as if they had a weight of 1. This method produces a different path between the nodes, one that previously had too large of a path length to be the shortest path. Highlight this path in red.

```
[path2,d] = shortestpath(G,6,8,'Method','unweighted')
```

```
path2 =
```

```
6 9 8
```

```
d =
```

```
2
```

```
highlight(p,path2,'EdgeColor','r')
```

## Input Arguments

**G** — Input graph

graph object | digraph object

Input graph, specified as either a `graph` or `digraph` object. Use the `graph` function to create an undirected graph or the `digraph` function to create a directed graph.

For more information, see `Using graph Objects` or `Using digraph Objects`.

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

### **s** — Source node ID

numeric node index | string node name

Source node ID, specified as either a numeric node index or a string node name.

Example: `shortestpath(G,2,5)` computes the shortest path between node 2 and node 5.

Example: `shortestpath(G,'node1','node2')` computes the shortest path between the named nodes `node1` and `node2`.

### **t** — Target node ID

numeric node index | string node name

Target node ID, specified as either a numeric node index or a string node name.

Example: `shortestpath(G,2,5)` computes the shortest path between node 2 and node 5.

Example: `shortestpath(G,'node1','node2')` computes the shortest path between the named nodes `node1` and `node2`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `path = shortestpath(G,s,t,'Method','acyclic')`

### **'Method'** — Shortest path algorithm

'auto' (default) | 'unweighted' | 'positive' | 'mixed' | 'acyclic'

Shortest path algorithm, specified as the comma-separated pair consisting of `'Method'` and one of the options in the table.

| Option                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'auto' (default)             | <p>The 'auto' option automatically selects the algorithm:</p> <ul style="list-style-type: none"> <li>• 'unweighted' is used for graph and digraph inputs with no edge weights.</li> <li>• 'positive' is used for all graph inputs that have edge weights, and requires the weights to be positive. This option is also used for digraph inputs with positive edge weights.</li> <li>• 'mixed' is used for digraph inputs whose edge weights contain some negative values. The graph cannot have negative cycles.</li> </ul> |
| 'unweighted'                 | Breadth-First computation that treats all edge weights as 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 'positive'                   | Dijkstra algorithm that requires all edge weights to be positive.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 'mixed' (only for digraph)   | <p>Bellman-Ford algorithm for directed graphs that requires the graph to have no negative cycles.</p> <p>While 'mixed' is slower than 'positive' for the same problem, 'mixed' is more versatile as it allows some edge weights to be negative.</p>                                                                                                                                                                                                                                                                         |
| 'acyclic' (only for digraph) | <p>Algorithm designed to improve performance for directed, acyclic graphs (DAGs) with weighted edges.</p> <p>Use <code>isdag</code> to confirm if a directed graph is acyclic.</p>                                                                                                                                                                                                                                                                                                                                          |

---

**Note:** For most graphs, 'unweighted' is the fastest algorithm, followed by 'acyclic', 'positive', and 'mixed'.

---

Example: `shortestpath(G,s,t,'Method','acyclic')`

## Output Arguments

### **path** — Shortest path between nodes

vector of node indices | cell array of strings

Shortest path between nodes, returned as a vector of node indices if **s** and **t** are numeric, or as a cell array of node names if **s** and **t** are strings. **path** is empty, {}, if there is no path between the nodes.

If there are multiple shortest paths between **s** and **t**, then **path** contains only one of the paths. The path that is returned can change depending on which algorithm **Method** specifies.

### **d** — Shortest path distance

scalar

Shortest path distance, returned as a numeric scalar. **d** is the summation of the edge weights between consecutive nodes in **path**. If there is no path between the nodes, then **d** is `Inf`.

## More About

### Tips

- The `shortestpath`, `shortestpathtree`, and `distances` functions do not support undirected graphs with negative edge weights, or more generally any graph containing a negative cycle, for these reasons:
  - A *negative cycle* is a path that leads from a node back to itself, with the sum of the edge weights on the path being negative. If a negative cycle is on a path between two nodes, then no shortest path exists between the nodes, since a shorter path can always be found by traversing the negative cycle.
  - A single negative edge weight in an undirected graph creates a negative cycle.

**Introduced in R2015b**

# shortestpathtree

Shortest path tree from node

## Syntax

```
tree = shortestpathtree(G,s)
tree = shortestpathtree(G,s,t)
tree = shortestpathtree(____,Name,Value)
[tree,D] = shortestpathtree(____)
```

## Description

`tree = shortestpathtree(G,s)` returns a directed graph, `tree`, that contains the tree of shortest paths from source node `s` to all other nodes in the graph. If the graph is weighted (that is, `G.Edges` contains a variable `Weight`), then those weights are used as the distances along the edges in the graph. Otherwise, all edge distances are taken to be 1.

`tree = shortestpathtree(G,s,t)` computes the tree of shortest paths between multiple source or target nodes:

- `s` can be a single source node, and `t` can specify multiple target nodes.
- `s` can specify several source nodes, and `t` can specify a single target node.

`tree = shortestpathtree( ____,Name,Value)` uses additional options specified by one or more Name-Value pair arguments, using any of the input argument combinations in previous syntaxes. For example, `shortestpathtree(G,s,'OutputForm','vector')` returns a numeric vector that describes the shortest path tree.

`[tree,D] = shortestpathtree( ____ )` additionally returns the shortest path distance between nodes in the tree.

## Examples

### Shortest Paths from Specified Source Node

Find the shortest paths from a source node to each of the other reachable nodes in a graph, and plot the results.

Create a directed graph.

```
s = [1 1 2 3 3 4 4 6 6 7 8 7 5];
t = [2 3 4 4 5 5 6 1 8 1 3 2 8];
G = digraph(s,t)
```

G =

digraph with properties:

```
Edges: [13x1 table]
Nodes: [8x0 table]
```

Calculate the shortest paths from node 1 to each of the other reachable nodes in the graph. Then, plot the resulting tree on top of the graph.

```
tree = shortestpathtree(G,1);
p = plot(G);
highlight(p,tree,'EdgeColor','r')
```

Since there is no path from node 1 to node 7, node 7 is disconnected from the tree.

### Shortest Paths to Specified Target Node

Find the shortest paths from each node in a graph to a target node, and plot the results.

Create and plot a graph.

```
s = [1 1 1 1 1 1 1 2 2 7 7 7 7 9 9 3 3 1 6 4 8 10 6 8 4 5];
t = [2 3 4 5 6 8 7 6 7 5 6 8 9 6 8 6 10 10 10 10 10 10 11 11 11 8 8];
G = graph(s,t);
x = [0 0.5 -0.5 -0.5 0.5 0 1.5 0 2 -1.5 -2];
y = [0 0.5 0.5 -0.5 -0.5 2 0 -2 0 0 0];
plot(G, 'XData',x, 'YData',y)
```

Find the shortest paths from each node in the graph to node 10. Plot the resulting tree.

```
tree = shortestpathtree(G, 'all', 10);
plot(tree)
```

### Subset of Shortest Paths with Specified Source Node

Find the shortest paths and path lengths from a single source node to several target nodes.

Create and plot a graph.

```
G = digraph(bucky);
plot(G)
```

Find the shortest paths from node 23 to several other nodes. Specify `OutputForm` as `cell` to return the shortest paths in a cell array. Specify two outputs to also return the shortest path distances.

```
target = [1 5 13 32 44];
[tree,D] = shortestpathtree(G,23,target,'OutputForm','cell')
```

```
tree =
```

```

[1x6 double]
[1x5 double]
[1x8 double]
[1x6 double]
```

```
[1x6 double]

D =
 5 4 7 5 5
```

`tree{j}` is the shortest path from node 23 to node `target(j)` with length `D(j)`.

Find the path and path length from node 21 to node 5.

```
path = tree{2}

path =
 23 22 21 4 5

path_length = D(2)

path_length =
 4
```

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a **graph** or **digraph** object. Use the **graph** function to create an undirected graph or the **digraph** function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

### **s** — Source node(s)

scalar | vector | string | cell array of strings | 'all'

Source node(s), specified as a single node with a scalar node index or string node name, as multiple nodes with a numeric vector or cell array of strings, or as all nodes in the graph with 'all'.

- When used alone, **s** must specify a single source node.
- When used together with **t**, the **s** and **t** inputs must satisfy:
  - **s** can be a single source node, and **t** can specify multiple target nodes.
  - **s** can specify several source nodes, and **t** can specify a single target node.

Example: `shortestpathtree(G, 'a')`

Example: `shortestpathtree(G, [1 2 3], 8)`

### **t** — Target node(s)

'all' (default) | scalar | vector | cell array of strings

Target node(s), specified as a single node with a scalar node index, as multiple nodes with a numeric vector or cell array of strings, or as all nodes in the graph with 'all'.

The **s** and **t** inputs must satisfy:

- **s** can be a single source node, and **t** can specify multiple target nodes.
- **s** can specify several source nodes, and **t** can specify a single target node.

Example: `shortestpathtree(G, [1 2 3], 8)`

Example: `shortestpathtree(G, {'a', 'b', 'c'}, {'f'})`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `[tree, D] =`

`shortestpathtree(G, s, t, 'Method', 'unweighted', 'OutputForm', 'vector')`

### **'OutputForm'** — Format of output

'tree' (default) | 'cell' | 'vector'

Format of output, specified as the comma-separated pair consisting of 'OutputForm' and one of the options in the table.

| Option           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'tree' (default) | <code>tree</code> is a directed graph representing the shortest path tree.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 'cell'           | <code>tree</code> is a cell array, and <code>tree{k}</code> contains the path from <code>s</code> to <code>t(k)</code> or from <code>s(k)</code> to <code>t</code> . If there is no path between the nodes, then <code>tree{k}</code> is empty.<br><br>If <code>s</code> and <code>t</code> are string node names, then <code>tree{k}</code> is a cell array of strings. Otherwise, <code>tree{k}</code> is a numeric vector.                                                                                                                                                                                                                                                 |
| 'vector'         | <code>tree</code> is a vector that describes the tree: <ul style="list-style-type: none"> <li>• If <code>s</code> contains a single source node, then <code>tree(k)</code> is the ID of the node that precedes node <code>k</code> on the path from <code>s</code> to <code>k</code>. By convention, <code>tree(s) = 0</code>.</li> <li>• If <code>s</code> contains multiple source nodes, then <code>tree(k)</code> is the ID of the node that succeeds node <code>k</code> on the path from <code>k</code> to <code>t</code>. By convention, <code>tree(t) = 0</code>.</li> </ul> In each case <code>tree(k)</code> is NaN if node <code>k</code> is not part of the tree. |

Example: `shortestpathtree(G,s,'OutputForm','vector')`

#### 'Method' — Shortest path algorithm

'auto' (default) | 'unweighted' | 'positive' | 'mixed' | 'acyclic'

Shortest path algorithm, specified as the comma-separated pair consisting of 'Method' and one of the options in the table.

| Option           | Description                                            |
|------------------|--------------------------------------------------------|
| 'auto' (default) | The 'auto' option automatically selects the algorithm: |

| Option                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              | <ul style="list-style-type: none"> <li>• 'unweighted' is used for graph and digraph inputs with no edge weights.</li> <li>• 'positive' is used for all graph inputs that have edge weights, and requires the weights to be positive. This option is also used for digraph inputs with positive edge weights.</li> <li>• 'mixed' is used for digraph inputs whose edge weights contain some negative values. The graph cannot have negative cycles.</li> </ul> |
| 'unweighted'                 | Breadth-First computation that treats all edge weights as 1.                                                                                                                                                                                                                                                                                                                                                                                                  |
| 'positive'                   | Dijkstra algorithm that requires all edge weights to be positive.                                                                                                                                                                                                                                                                                                                                                                                             |
| 'mixed' (only for digraph)   | <p>Bellman-Ford algorithm for directed graphs that requires the graph to have no negative cycles.</p> <p>While 'mixed' is slower than 'positive' for the same problem, 'mixed' is more versatile as it allows some edge weights to be negative.</p>                                                                                                                                                                                                           |
| 'acyclic' (only for digraph) | <p>Algorithm designed to improve performance for directed, acyclic graphs (DAGs) with weighted edges.</p> <p>Use <code>isdag</code> to confirm if a directed graph is acyclic.</p>                                                                                                                                                                                                                                                                            |

---

**Note:** For most graphs, 'unweighted' is the fastest algorithm, followed by 'acyclic', 'positive', and 'mixed'.

---

Example: `shortestpath(G,s,t,'Method','acyclic')`

## Output Arguments

### **tree** — Shortest path tree

digraph object

Shortest path tree, returned as a **digraph** object. Use the **highlight** function to visualize the shortest path tree on top of a plot of the graph, or use **plot(tree)** to visualize the shortest path tree on its own.

If there are multiple shortest paths between two nodes, then **tree** contains only one of the paths. The path that is returned can change depending on which algorithm is specified by **Method**. The **tree** output is a graph with zero edges if there are no paths connecting any of the specified nodes.

### **D** — Distance between source and target nodes

vector

Distance between source and target nodes, returned as a vector. A value of **Inf** indicates there is no path between two nodes.

## More About

### Tips

- The **shortestpath**, **shortestpathtree**, and **distances** functions do not support undirected graphs with negative edge weights, or more generally any graph containing a negative cycle, for these reasons:
  - A *negative cycle* is a path that leads from a node back to itself, with the sum of the edge weights on the path being negative. If a negative cycle is on a path between two nodes, then no shortest path exists between the nodes, since a shorter path can always be found by traversing the negative cycle.
  - A single negative edge weight in an undirected graph creates a negative cycle.

Introduced in R2015b

# subgraph

Extract subgraph

## Syntax

`H = subgraph(G,nodeIDs)`

## Description

`H = subgraph(G,nodeIDs)` returns a subgraph of `G` that contains only the nodes specified by `nodeIDs`.

## Examples

### Extract Subgraph

Create and plot a graph.

```
s = [1 1 1 1 2 2 2 2 2 2 2 2 2 2 2 15 15 15 15 15];
t = [3 5 4 2 14 6 11 12 13 10 7 9 8 15 16 17 19 18 20];
G = graph(s,t);
plot(G,'Layout','force')
```

Extract a subgraph from  $G$  by specifying which nodes to include. The node numbering in the subgraph is reset.

```
idx = [2 15 16 17 18 19 20 1 3 4 5];
H = subgraph(G,idx);
plot(H,'Layout','force')
```

### Subgraph with Node and Edge Properties

Create and plot a weighted graph with named nodes.

```
s = [1 1 1 2 2 2 8 8 8 8];
t = [2 3 4 5 6 7 9 10 11 12];
weights = [10 30 40 80 60 60 20 30 90 80];
names = {'A' 'B' 'C' 'D' 'E' 'F' 'G' 'H' 'I' 'J' 'K' 'L'};
G = graph(s,t,weights,names);
plot(G, 'EdgeLabel', G.Edges.Weight)
```

Extract a subgraph that contains node 'B' and all of its neighbors. `subgraph` preserves the node names and edge weights. However, the numeric node IDs in H are renumbered compared to G.

```
N = neighbors(G, 'B');
H = subgraph(G, ['B'; N]);
plot(H, 'EdgeLabel', H.Edges.Weight)
```

## Input Arguments

### **G** — Input graph

graph object | digraph object

Input graph, specified as either a **graph** or **digraph** object. Use the **graph** function to create an undirected graph or the **digraph** function to create a directed graph.

For more information, see [Using graph Objects](#) or [Using digraph Objects](#).

Example: `G = graph(1,2)`

Example: `G = digraph([1 2],[2 3])`

**nodeIDs — Node IDs**

vector of indices | cell array of node names

Node IDs, specified as a vector of indices, or cell array of node names. **nodeIDs** selects a subset of the nodes in **G** to generate the subgraph, **H**.

Example: `H = subgraph(G, [1 2 5])`

Example: `H = subgraph(G, {'A' 'B' 'E'})`

## Output Arguments

**H — Subgraph**

graph object | digraph object

Subgraph, returned as a **graph** or **digraph** object. **H** contains only the nodes that were selected with **nodeIDs**. Other nodes in **G** (and the edges connecting to those nodes) are discarded. The node properties and edge properties of the nodes and edges referred to by **nodeIDs** are carried over from **G** into **H**.

See Using graph Objects or Using digraph Objects for more information about graph objects.

**Introduced in R2015b**

# graph

Create undirected graph

## Syntax

`G = graph`

`G = graph(A)`

`G = graph(A,nodenames)`

`G = graph(A, ____, type)`

`G = graph(A, ____, 'OmitSelfLoops')`

`G = graph(s,t)`

`G = graph(s,t,weights)`

`G = graph(s,t,weights,nodenames)`

`G = graph(s,t,weights,num)`

`G = graph(s,t, ____, 'OmitSelfLoops')`

`G = graph(EdgeTable)`

`G = graph(EdgeTable,NodeTable)`

`G = graph(EdgeTable, ____, 'OmitSelfLoops')`

## Description

`G = graph` creates an empty undirected graph object, `G`, which has no nodes or edges.

`G = graph(A)` creates a weighted graph using a square, symmetric adjacency matrix, `A`. The location of each nonzero entry in `A` specifies an edge for the graph, and the weight of the edge is equal to the value of the entry. For example, if  $A(2,1) = 10$ , then `G` contains an edge between node 2 and node 1 with a weight of 10.

`G = graph(A,nodenames)` additionally specifies node names using the cell array of strings, `nodenames`. The number of elements in `nodenames` must be equal to `size(A,1)`.

`G = graph(A, ____, type)` specifies a triangle of the adjacency matrix to use in constructing the graph. You must specify `A` and optionally can specify `nodenames`. To use

only the upper or lower triangle of **A** to construct the graph, **type** can be either 'upper' or 'lower'.

**G** = **graph**(**A**, \_\_\_\_, 'OmitSelfLoops') ignores the diagonal elements of **A** and returns a graph without any self-loops. You can use any of the input arguments in previous syntaxes.

**G** = **graph**(**s**,**t**) specifies graph edges (**s**,**t**) in node pairs. **s** and **t** can be numeric, strings, or cell arrays of strings with the same number of elements.

**G** = **graph**(**s**,**t**,**weights**) also specifies edge weights with the array, **weights**.

**G** = **graph**(**s**,**t**,**weights**,**nodenames**) additionally specifies all node names using the cell array of strings, **nodenames**. The **s** and **t** inputs cannot contain node names that are not in **nodenames**.

**G** = **graph**(**s**,**t**,**weights**,**num**) specifies the number of nodes in the graph with the numeric scalar **num**.

**G** = **graph**(**s**,**t**, \_\_\_\_, 'OmitSelfLoops') does not add any self-loops to the graph. That is, any **k** that satisfies **s**(**k**) == **t**(**k**) is ignored. You must specify **s** and **t** and optionally can specify **weights**, **nodenames**, or **num**.

**G** = **graph**(**EdgeTable**) uses the table, **EdgeTable**, to define the graph. The first variable in **EdgeTable** must be **EndNodes**, and it must be a two-column array defining the edge list of the graph. **EdgeTable** can contain any number of other table variables to define attributes of the graph edges.

**G** = **graph**(**EdgeTable**,**NodeTable**) additionally uses the table, **NodeTable**, to define attributes of the graph nodes. **NodeTable** can contain any number of table variables to define attributes of the graph nodes.

**G** = **graph**(**EdgeTable**, \_\_\_\_, 'OmitSelfLoops') does not add self-loops to the graph. That is, any **k** that satisfies **EdgeTable.EndNodes**(**k**,1) == **EdgeTable.EndNodes**(**k**,2) is ignored. You must specify **EdgeTable** and optionally can specify **NodeTable**.

## Examples

### Adjacency Matrix Graph Construction

Create a symmetric adjacency matrix, **A**, that creates a complete graph of order 4. Use a logical adjacency matrix to create a graph without weights.

```
A = ones(4) - diag([1 1 1 1])
```

```
A =
```

```
 0 1 1 1
 1 0 1 1
 1 1 0 1
 1 1 1 0
```

```
G = graph(A~=0)
```

```
G =
```

```
graph with properties:
```

```
Edges: [6x1 table]
Nodes: [4x0 table]
```

View the edge list of the graph.

```
G.Edges
```

```
ans =
```

```
EndNodes

 1 2
 1 3
 1 4
 2 3
 2 4
```

3 4

### Adjacency Matrix Construction with Node Names

Create an upper triangular adjacency matrix.

```
A = triu(magic(4))
```

A =

```

16 2 3 13
 0 11 10 8
 0 0 6 12
 0 0 0 1

```

Create a graph with named nodes using the adjacency matrix. Specify 'OmitSelfLoops' to ignore the entries on the diagonal of A, and specify type as 'upper' to indicate that A is upper-triangular.

```
names = {'alpha' 'beta' 'gamma' 'delta'};
G = graph(A, names, 'upper', 'OmitSelfLoops')
```

G =

graph with properties:

```
Edges: [6x2 table]
Nodes: [4x1 table]
```

View the edge and node information.

G.Edges

ans =

| EndNodes | Weight |
|----------|--------|
| -----    | -----  |

```
'alpha' 'beta' 2
'alpha' 'gamma' 3
'alpha' 'delta' 13
'beta' 'gamma' 10
'beta' 'delta' 8
'gamma' 'delta' 12
```

## G.Nodes

```
ans =
```

```
 Name

'alpha'
'beta'
'gamma'
'delta'
```

## Edge List Graph Construction

Create and plot a cube graph using a list of the end nodes of each edge.

```
s = [1 1 1 2 2 3 3 4 5 5 6 7];
t = [2 4 8 3 7 4 6 5 6 8 7 8];
G = graph(s,t)
```

```
G =
```

```
graph with properties:
```

```
Edges: [12x1 table]
Nodes: [8x0 table]
```

```
plot(G)
```

### Edge List Graph Construction with Node Names and Edge Weights

Create and plot a cube graph using a list of the end nodes of each edge. Specify node names and edge weights as separate inputs.

```
s = [1 1 1 2 2 3 3 4 5 5 6 7];
t = [2 4 8 3 7 4 6 5 6 8 7 8];
weights = [10 10 1 10 1 10 1 1 12 12 12 12];
names = {'A' 'B' 'C' 'D' 'E' 'F' 'G' 'H'};
G = graph(s,t,weights,names)
```

G =

graph with properties:

Edges: [12x2 table]

Nodes: [8x1 table]

```
plot(G, 'EdgeLabel', G.Edges.Weight)
```

### Edge List Construction with Extra Nodes

Create a weighted graph using a list of the end nodes of each edge. Specify that the graph should contain a total of 10 nodes.

```
s = [1 1 1 1 1];
```

```
t = [2 3 4 5 6];
weights = [5 5 5 6 9];
G = graph(s,t,weights,10)
```

```
G =
```

```
graph with properties:
```

```
Edges: [5x2 table]
Nodes: [10x0 table]
```

Plot the graph. The extra nodes are disconnected from the primary connected component.

```
plot(G)
```

## Add Nodes and Edges to Empty Graph

Create an empty graph object, *G*.

```
G = graph;
```

Add three nodes and three edges to the graph. The corresponding entries in *s* and *t* define the end nodes of the graph edges. `addedge` automatically adds the appropriate nodes to the graph if they are not already present.

```
s = [1 2 1];
t = [2 3 3];
G = addedge(G,s,t)
```

```
G =
graph with properties:
 Edges: [3x1 table]
 Nodes: [3x0 table]
```

View the edge list. Each row describes an edge in the graph.

### G.Edges

```
ans =
 EndNodes

 1 2
 1 3
 2 3
```

For the best performance, construct graphs all at once using a single call to `graph`. Adding nodes or edges in a loop can be slow for large graphs.

### Graph Construction with Tables

Create an edge table that contains the variables `EndNodes`, `Weight`, and `Code`. Then create a node table that contains the variables `Name` and `Country`. The variables in each table specify properties of the graph nodes and edges.

```
s = [1 1 1 2 3];
t = [2 3 4 3 4];
weights = [6 6.5 7 11.5 17]';
code = {'1/44' '1/49' '1/33' '44/49' '49/33'}';
EdgeTable = table([s' t'],weights,code, ...
 'VariableNames',{'EndNodes' 'Weight' 'Code'})
```

```
EdgeTable =
 EndNodes Weight Code
 _____ _____ _____
```

|   |   |      |         |
|---|---|------|---------|
| 1 | 2 | 6    | '1/44'  |
| 1 | 3 | 6.5  | '1/49'  |
| 1 | 4 | 7    | '1/33'  |
| 2 | 3 | 11.5 | '44/49' |
| 3 | 4 | 17   | '49/33' |

```
names = {'USA' 'GBR' 'DEU' 'FRA'}';
country_code = {'1' '44' '49' '33'}';
NodeTable = table(names,country_code,'VariableNames',{'Name' 'Country'})
```

NodeTable =

| Name  | Country |
|-------|---------|
| 'USA' | '1'     |
| 'GBR' | '44'    |
| 'DEU' | '49'    |
| 'FRA' | '33'    |

Create a graph using the node and edge tables. Plot the graph using the country codes as node and edge labels.

```
G = graph(EdgeTable,NodeTable);
plot(G,'NodeLabel',G.Nodes.Country,'EdgeLabel',G.Edges.Code)
```

- “Build Watts-Strogatz Small World Graph Model”
- “Use Page Rank Algorithm to Rank Websites”

## Input Arguments

**A** — Adjacency matrix  
matrix

Adjacency matrix, specified as a full or sparse, numeric matrix. The entries in **A** specify the network of connections (edges) between the nodes of the graph. The location of each nonzero entry in **A** specifies an edge between two nodes. The value of that entry provides the edge weight. A logical adjacency matrix results in an unweighted graph.

Nonzero entries on the main diagonal of **A** specify *self-loops*, or nodes that are connected to themselves with an edge. Use the `'OmitSelfLoops'` input option to ignore diagonal entries.

**A** must be symmetric unless the `type` input is specified. Use `issymmetric` to confirm matrix symmetry. For triangular adjacency matrices, specify `type` to use only the upper or lower triangle.

Example: `A = [0 1 5; 1 0 0; 5 0 0]` describes a graph with three nodes and two edges. The edge between node 1 and node 2 has a weight of 1, and the edge between node 1 and node 3 has a weight of 5.

Data Types: `single` | `double` | `logical`

### **nodenames** — Node names

cell array of strings

Node names, specified as a cell array of strings. **nodenames** must contain a nonempty, unique name for each node in the graph (its length must be equal to `numnodes(G)`).

Example: `G = graph(A, {'n1', 'n2', 'n3'})` specifies three node names for a 3-by-3 adjacency matrix, **A**.

Data Types: `cell`

### **type** — Type of adjacency matrix

`'upper'` | `'lower'`

Type of adjacency matrix, specified as either `'upper'` or `'lower'`.

Example: `G = graph(A, 'upper')` uses only the upper triangle of **A** to construct the graph, **G**.

### **s, t** — Node pairs

scalars | vectors | matrices | multidimensional arrays | strings | cell arrays of strings

Node pairs, specified as scalars, vectors, matrices, multidimensional arrays, strings, or cell arrays of strings. `graph` creates edges between the corresponding nodes in **s** and **t**, which must both be numeric, or both be strings or cell arrays of strings. In each case, **s** and **t** must have the same number of elements.

- If **s** and **t** are numeric, then they correspond to indices of graph nodes. Numeric node indices must be positive integers greater than or equal to 1.

- If **s** and **t** are strings or cell arrays of strings, then the strings specify names for the nodes. The **Nodes** property of the graph is a table containing a **Name** variable with the node names, **G.Nodes.Name**.
- **s** and **t** cannot specify duplicate edges. For undirected graphs, `graph([1 2],[2 1])` and `graph([1 1],[2 2])` both specify a duplicate edge between node 1 and node 2.

Example: `G = graph([1 2 3],[2 4 5])` creates a graph with five nodes and three edges.

Example: `G = graph({'Boston' 'New York' 'Washington D.C.'},{'New York' 'New Jersey' 'Pittsburgh'})` creates a graph with five named nodes and three edges.

### **weights** — Edge weights

scalar | vector | matrix | multidimensional array

Edge weights, specified as a scalar, vector, matrix, or multidimensional array. **weights** can be a scalar or an array with the same number of elements as **s** and **t**.

`graph` stores the edge weights as a **Weight** variable in the **G.Edges** property table. To add or change weights after creating a graph, you can modify the table variable directly, for example, `G.Edges.Weight = [25 50 75]`.

Example: `G = graph([1 2],[2 3],[100 200])` creates a graph with three nodes and two edges. The edges have weights of 100 and 200.

Data Types: `single` | `double`

### **num** — Number of graph nodes

positive scalar integer

Number of graph nodes, specified as a positive scalar integer. **num** must be greater than or equal to the largest elements in **s** and **t**.

Example: `G = graph([1 2],[2 3],[],5)` creates a graph with three connected nodes and two isolated nodes.

### **EdgeTable** — Table of edge information

table

Table of edge information. The first variable in **EdgeTable** is required to be a two-column matrix called **EndNodes**, but you can have any number of other variables to

describe attributes of the graph edges. For edge weights, use the variable `Weight`, since this table variable name is used by some graph functions. If there is a variable `Weight`, then it must be a numeric column vector. See `table` for more information on constructing a table.

After creating a graph, query the edge information table using `G.Edges`.

```
Example: EdgeTable = table([1 2; 2 3; 3 5; 4 5], 'VariableNames',
{'EndNodes'})
```

Data Types: `table`

## **NodeTable — Table of node information**

`table`

Table of node information. `NodeTable` can contain any number of variables to describe attributes of the graph nodes. For node names, use the variable `Name`, since this variable name is used by some graph functions. If there is a variable `Name`, then it must be a column cell array of nonempty, unique strings. See `table` for more information on constructing a table.

After the graph is created, query the node information table using `G.Nodes`.

```
Example: NodeTable = table({'a'; 'b'; 'c'; 'd'}, 'VariableNames',
{'Name'})
```

Data Types: `table`

## **Output Arguments**

### **G — Undirected graph**

graph object

Undirected graph, returned as a graph object. For more information, see `Using graph Objects`.

## **More About**

- `Using graph Objects`

digraph

**Introduced in R2015b**

## Using graph Objects

Graph with undirected edges

### Description

graph objects represent undirected graphs, which have direction-less edges connecting the nodes. After you create a graph object, you can learn more about the graph by using object functions to perform queries against the object. For example, you can add or remove nodes or edges, determine the shortest path between two nodes, or locate a specific node or edge.

```
G = graph([1 1], [2 3]);
e = G.Edges
G = addedge(G,2,3)
G = addnode(G,4)
plot(G)
```

### Examples

#### Create and Modify Graph Object

Create a graph object with three nodes and two edges. One edge is between node 1 and node 2, and the other edge is between node 1 and node 3.

```
G = graph([1 1],[2 3])
```

```
G =
```

```
graph with properties:
```

```
Edges: [2x1 table]
Nodes: [3x0 table]
```

View the edge table of the graph.

```
G.Edges
```

```
ans =
```

```
EndNodes
```

```

1 2
1 3
```

Add node names to the graph, and then view the new node and edge tables. The end nodes of each edge are now expressed using their node names.

```
G.Nodes.Name = {'A' 'B' 'C'}';
```

```
G.Nodes
```

```
ans =
```

```
Name
```

```

'A'
'B'
'C'
```

```
G.Edges
```

```
ans =
```

```
EndNodes
```

```

'A' 'B'
'A' 'C'
```

You can add or modify extra variables in the **Nodes** and **Edges** tables to describe attributes of the graph nodes or edges. However, you cannot directly change the number of nodes or edges in the graph by modifying these tables. Instead, use the **addedge**, **rmedge**, **addnode**, or **rmnode** functions to modify the number of nodes or edges in a graph.

For example, add an edge to the graph between nodes 2 and 3 and view the new edge list.

```
G = addedge(G,2,3)
```

```
G =
```

```
graph with properties:
```

```
Edges: [3x1 table]
```

```
Nodes: [3x1 table]
```

```
G.Edges
```

```
ans =
```

```
EndNodes
```

| EndNodes |     |
|----------|-----|
| 'A'      | 'B' |
| 'A'      | 'C' |
| 'B'      | 'C' |

## Properties

### Edges — Edges of graph

table

Edges of graph, returned as a table. By default this is an M-by-1 table, where M is the number of edges in the graph.

- To add new edge properties to the graph, create a new variable in the `Edges` table.
- To add or remove edges from the graph, use the `addege` or `rmedge` object functions.

Example: `G.Edges` returns a table listing the edges in the graph

Example: `G.Edges.Weight` returns a numeric vector of the edge weights.

Example: `G.Edges.Weight = [10 20 30 55]'` specifies new edge weights for the graph.

Example: `G.Edges.NormWeight = G.Edges.Weight/sum(G.Edges.Weight)` adds a new edge property to the table containing the normalized weights of the edges.

Data Types: table

## Nodes — Nodes of graph

table

Nodes of graph, returned as a table. By default this is an empty N-by-0 table, where N is the number of nodes in the graph.

- To add new node properties to the graph, create a new variable in the **Nodes** table.
- To add or remove nodes from the graph, use the **addnode** or **rmnode** object functions.

Example: `G.Nodes` returns a table listing the node properties of the graph. This table is empty by default.

Example: `G.Nodes.Names = {'Montana', 'New York', 'Washington', 'California'}` adds node names to the graph by adding the variable `Names` to the `Nodes` table.

Example: `G.Nodes.WiFi = logical([1 0 0 1 1])` adds the variable `WiFi` to the `Nodes` table. This property specifies that certain airports have wireless internet coverage.

Data Types: table

## Object Functions

### Access and Modify Nodes and Edges

|                           |                          |
|---------------------------|--------------------------|
| <code>addedge</code>      | Add new edge to graph    |
| <code>rmedge</code>       | Remove edge from graph   |
| <code>addnode</code>      | Add new node to graph    |
| <code>rmnode</code>       | Remove node from graph   |
| <code>findedge</code>     | Locate edge in graph     |
| <code>findnode</code>     | Locate node in graph     |
| <code>numedges</code>     | Number of edges in graph |
| <code>numnodes</code>     | Number of nodes in graph |
| <code>reordernodes</code> | Reorder graph nodes      |
| <code>subgraph</code>     | Extract subgraph         |

### Search and Structure

|                       |                            |
|-----------------------|----------------------------|
| <code>bfsearch</code> | Breadth-first graph search |
| <code>dfsearch</code> | Depth-first graph search   |

|                              |                                           |
|------------------------------|-------------------------------------------|
| conncomp                     | Connected graph components                |
| maxflow                      | Maximum flow in graph                     |
| minspantree                  | Minimum spanning tree of graph            |
| <b>Shortest Path</b>         |                                           |
| shortestpath                 | Shortest path between two single nodes    |
| shortestpathtree             | Shortest path tree from node              |
| distances                    | Shortest path distances of all node pairs |
| <b>Matrix Representation</b> |                                           |
| adjacency                    | Graph adjacency matrix                    |
| incidence                    | Graph incidence matrix                    |
| laplacian                    | Graph Laplacian matrix                    |
| <b>Node Information</b>      |                                           |
| degree                       | Degree of graph nodes                     |
| neighbors                    | Neighbors of graph node                   |
| <b>Visualization</b>         |                                           |
| plot                         | Graph plot                                |

## Create Object

Use the `graph` function to create an undirected graph object.

For directed graphs, use the `digraph` function.

## See Also

`digraph` | `graph`

# Using GraphPlot Objects

Graph plot for directed and undirected graphs

## Description

Graph plots are the primary way to visualize graphs and networks created using the `graph` and `digraph` functions. After you create a `GraphPlot` object, you can modify aspects of the plot by changing its property values. This is particularly useful for modifying the display of the graph nodes or edges.

## Examples

### Adjust Properties of GraphPlot Object

Create a `GraphPlot` object, and then show how to adjust the properties of the object to affect the output display.

Create and plot a graph.

```
s = [1 1 1 1 1 1 1 9 9 9 9 9 9];
t = [2 3 4 5 6 7 8 2 3 4 5 6 7 8];
G = graph(s,t);
h = plot(G)
```

h =

GraphPlot with properties:

```
NodeColor: [0 0.4470 0.7410]
MarkerSize: 4
Marker: 'o'
EdgeColor: [0 0.4470 0.7410]
LineWidth: 0.5000
LineStyle: '-'
NodeLabel: {'1' '2' '3' '4' '5' '6' '7' '8' '9'}
EdgeLabel: {}
```

```
XData: [1x9 double]
YData: [1x9 double]
```

Use GET to show all properties

Use custom node coordinates for the graph nodes.

```
h.XData = [0 -3 -2 -1 0 1 2 3 0];
h.YData = [2 0 0 0 0 0 0 0 -2];
```

Make the graph nodes red.

```
h.NodeColor = 'r';
```

Use dashed lines for the graph edges.

```
h.LineStyle = '- -';
```

Increase the size of the nodes.

```
h.MarkerSize = 8;
```

### Saving and Loading GraphPlot Objects

Use the `savefig` function to save a graph plot figure.

```
s = [1 1 1 2 2 3 3 4 5 5 6 7];
t = [2 4 5 3 6 4 7 8 6 8 7 8];
G = graph(s,t);
h = plot(G);
savefig('cubegraph.fig');
clear all
close all
```

Use `openfig` to load the graph plot figure back into MATLAB. `openfig` also returns a handle to the figure, `y`.

```
y = openfig('cubegraph.fig');
```

Use the `findobj` function to locate the correct object handle using one of the property values. Using `findobj` allows you to continue manipulating the original `GraphPlot` object used to generate the figure.

```
h = findobj('Marker','o')
```

```
h =
```

```
GraphPlot with properties:
```

```
NodeColor: [0 0.4470 0.7410]
```

```

MarkerSize: 4
 Marker: 'o'
EdgeColor: [0 0.4470 0.7410]
LineWidth: 0.5000
LineStyle: '-'
NodeLabel: {'1' '2' '3' '4' '5' '6' '7' '8'}
EdgeLabel: {}
 XData: [-1.0037 -1.7654 0.2498 0.9369 -0.2498 -0.9369 1.0037 1.7654]
 YData: [1.8212 0.0069 -0.4533 1.4963 0.4533 -1.4963 -1.8212 -0.0069]

```

Use GET to show all properties

## Properties

GraphPlot Properties

Control graph plot appearance and behavior

## Object Functions

layout

Change layout of graph plot

highlight

Highlight nodes and edges in plotted graph

labelnode

Label graph nodes

labeledge

Label graph edges

## Create Object

To create a GraphPlot object, specify an output argument with the plot function. For example:

```

G = graph([1 1 1 1 5 5 5 5],[2 3 4 5 6 7 8 9]);
h = plot(G)

```

**Introduced in R2015b**

# GraphPlot Properties

Control graph plot appearance and behavior

GraphPlot properties control the appearance and behavior of plotted graphs. By changing property values, you can modify aspects of the graph display. Use dot notation to refer to a particular object and property:

```
G = graph([1 1 1 1 5 5 5 5],[2 3 4 5 6 7 8 9]);
h = plot(G);
c = h.EdgeColor;
h.EdgeColor = 'k';
```

## Graph Edges

### **ArrowSize** — Arrow size

positive value

---

**Note:** ArrowSize affects only the display of directed graphs created using digraph.

---

Arrow size, specified as a positive value in point units. The default value of ArrowSize is 7 for graphs with 100 or fewer nodes, and 4 for graphs with more than 100 nodes.

Example: 15

### **EdgeAlpha** — Transparency of graph edges

0.5 (default) | scalar value between 0 and 1 inclusive

Transparency of graph edges, specified as a scalar value between 0 and 1 inclusive. A value of 1 means fully opaque and 0 means completely transparent (invisible).

Example: 0.25

### **EdgeCData** — Color data of edge lines

vector

Color data of edge lines, specified as a vector with length equal to the number of edges in the graph. The values in EdgeCData map linearly to the colors in the current colormap, resulting in different colors for each edge in the plotted graph.

**EdgeColor** — Edge color`[0 0.4470 0.7410]` (default) | RGB triplet or color string | 'flat' | 'none'

Edge color, specified as one of these values:

- 'none' — Edges are not drawn.
- 'flat' — Color of each edge depends on the value of `EdgeCData`.
- RGB triplet or a color string — Edges use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: `plot(G, 'EdgeColor', 'r')` creates a graph plot with red edges.

**EdgeLabel1** — Edge labels`{}` (default) | vector | cell array of strings

Edge labels, specified as a numeric vector or cell array of strings. The length of `EdgeLabel1` must be equal to the number of edges in the graph. By default `EdgeLabel1` is an empty cell array (no edge labels are displayed).

Example: `{'A', 'B', 'C'}`

Example: `[1 2 3]`

Example: `plot(G, 'EdgeLabels', G.Edges.Weight)` labels the graph edges with their weights.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `cell`

### EdgeLabelMode — Selection mode for edge labels

'manual' (default) | 'auto'

Selection mode for edge labels, specified as 'manual' (default) or 'auto'. Specify `EdgeLabelMode` as 'auto' to populate `EdgeLabel` with the edge weights in `G.Edges.Weight` (if available), or the edge indices `G.Edges(k,:)` (if no weights are available). Specifying `EdgeLabelMode` as 'manual' does not change the values in `EdgeLabel`.

### LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

| String | Line Style       | Resulting Line                                                                       |
|--------|------------------|--------------------------------------------------------------------------------------|
| '-'    | Solid line       |    |
| '--'   | Dashed line      |    |
| ':'    | Dotted line      |  |
| '-.'   | Dash-dotted line |  |
| 'none' | No line          | No line                                                                              |

### LineWidth — Edge line width

0.5 (default) | positive value

Edge line width, specified as a positive value in point units.

Example: 0.75

## Graph Nodes

### Marker — Node marker symbol

'o' (default) | marker string

Node marker symbol, specified as one of the marker strings listed in this table. The default is to use circular markers for the graph nodes.

| String             | Marker Symbol                 |
|--------------------|-------------------------------|
| 'o'                | Circle                        |
| '+'                | Plus sign                     |
| '*'                | Asterisk                      |
| '.'                | Point                         |
| 'x'                | Cross                         |
| 'square' or 's'    | Square                        |
| 'diamond' or 'd'   | Diamond                       |
| '^'                | Upward-pointing triangle      |
| 'v'                | Downward-pointing triangle    |
| '>'                | Right-pointing triangle       |
| '<'                | Left-pointing triangle        |
| 'pentagram' or 'p' | Five-pointed star (pentagram) |
| 'hexagram' or 'h'  | Six-pointed star (hexagram)   |
| 'none'             | No markers                    |

Example: '+'

Example: 'diamond'

**MarkerSize** — Node marker size

positive value

Node marker size, specified as a positive value in point units. The default value of MarkerSize is 4 for graphs with 100 or fewer nodes, and 2 for graphs with more than 100 nodes.

Example: 10

**NodeCData** — Color data of node markers

vector

Color data of node markers, specified as a vector with length equal to the number of nodes in the graph. The values in `NodeCData` map linearly to the colors in the current colormap, resulting in different colors for each node in the plotted graph.

### **NodeColor** — Node color

[0 0.4470 0.7410] (default) | RGB triplet or color string | 'flat' | 'none'

Node color, specified as one of these values:

- 'none' — Nodes are not drawn.
- 'flat' — Color of each node depends on the value of `NodeCData`.
- RGB triplet or a color string — Nodes use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: `plot(G, 'NodeColor', 'k')` creates a graph plot with black nodes.

### **NodeLabel** — Node labels

node IDs (default) | vector | cell array of strings

Node labels, specified as a numeric vector or cell array of strings. The length of `NodeLabel` must be equal to the number of nodes in the graph. By default `NodeLabel` is a cell array containing the node IDs for the graph nodes:

- For nodes without names (that is, `G.Nodes` does not contain a `Name` variable), the node labels are the values `unique(G.Edges.EndNodes)` contained in a cell array.
- For named nodes, the node labels are `G.Nodes.Name`.

Example: {'A', 'B', 'C'}

Example: [1 2 3]

Example: `plot(G, 'NodeLabels', G.Nodes.Name)` labels the nodes with their names.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `cell`

### **NodeLabelMode — Selection mode for node labels**

'auto' (default) | 'manual'

Selection mode for node labels, specified as 'auto' (default) or 'manual'. Specify `NodeLabelMode` as 'auto' to populate `NodeLabel` with the node IDs for the graph nodes (numeric node indices or string node names). Specifying `NodeLabelMode` as 'manual' does not change the values in `NodeLabel`.

### **XData — x-coordinate of nodes**

vector

---

**Note:** Specify `XData` and `YData` together so that each node has a valid  $(x,y)$  coordinate.

---

x-coordinate of nodes, specified as a vector with length equal to the number of nodes in the graph.

### **YData — y-coordinate of nodes**

vector

---

**Note:** Specify `XData` and `YData` together so that each node has a valid  $(x,y)$  coordinate.

---

y-coordinate of nodes, specified as a vector with length equal to the number of nodes in the graph.

## Visibility

### Visible — State of visibility

'on' (default) | 'off'

State of visibility, specified as one of these values:

- 'on' — Display the GraphPlot.
- 'off' — Hide the GraphPlot without deleting it. You still can access the properties of an invisible GraphPlot object.

## Parent/Child

### Parent — Parent of GraphPlot

axes object | group object | transform object

Parent of GraphPlot, specified as an axes, group, or transform object.

### Children — Children of GraphPlot

empty GraphicsPlaceholder array

The GraphPlot has no children. You cannot set this property.

### HandleVisibility — Visibility of object handle

'on' (default) | 'off' | 'callback'

Visibility of GraphPlot object handle in the Children property of the parent, specified as one of these values:

- 'on' — The GraphPlot object handle is always visible.
- 'off' — The GraphPlot object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to 'off' to temporarily hide the handle during the execution of that function.
- 'callback' — The GraphPlot object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the GraphPlot at the command-line, but allows callback functions to access it.

If the GraphPlot object is not listed in the Children property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle

properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root `ShowHiddenHandles` property to `'on'` to list all object handles regardless of their `HandleVisibility` property setting.

# matlab.graphics.Graphics class

**Package:** matlab.graphics

Common base class for graphics objects

## Description

The `matlab.graphics.Graphics` class is the base class of all graphics objects. Because graphics objects are part of a heterogeneous hierarchy, you can create arrays of mixed classes (for example, an array can contain lines, surfaces, axes, and other graphics objects).

The class of an array of mixed objects is `matlab.graphics.Graphics` because this class is common to all graphics object.

## Attributes

# matlab.graphics.GraphicsPlaceholder class

**Package:** matlab.graphics

**Superclasses:** matlab.graphics.Graphics

Default graphics object

## Description

The `matlab.graphics.GraphicsPlaceholder` class defines the default graphics object. Instances of this class appear as:

- Elements of pre-allocated arrays created with `gobjects`.
- Unassigned array element placeholders
- Graphics object properties that hold object handles, but are set to empty values
- Empty values returned by functions that return object handles (for example, `findobj`).

## **graymon**

Set default figure properties for grayscale monitors

### **Syntax**

graymon

### **Description**

graymon sets defaults for graphics properties to produce more legible displays for grayscale monitors.

### **See Also**

axes | figure

**Introduced before R2006a**

# grid

Display or hide axes grid lines

## Syntax

```
grid on
grid off
grid
```

```
grid minor
```

```
grid(ax, ___)
```

## Description

`grid on` displays the major grid lines for the current axes. Major grid lines extend from each tick mark.

`grid off` removes all grid lines from the current axes.

`grid` toggles the visibility of the major grid lines.

`grid minor` toggles the visibility of the minor grid lines. Minor grid lines lie between the tick marks.

`grid(ax, ___)` uses the axes defined by `ax` instead of the current axes (`gca`). Specify `ax` as a scalar axes object. You can specify an axes with any of the input arguments in the previous syntaxes. Use single quotes around input arguments that are character strings, for example, `grid(ax, 'on')`, `grid(ax, 'off')`, and `grid(ax, 'minor')`.

## Examples

### Display Grid Lines

Display the grid lines for a sine plot.

```
x = linspace(0,10);
y = sin(x);
plot(x,y)
grid on
```

## Remove Grid Lines

Create a surface plot and remove the grid lines.

```
[X,Y,Z] = peaks;
surf(X,Y,Z)
grid off
```

### Display Major and Minor Grid Lines

Display the major and minor grid lines for a sine plot.

```
x = linspace(0,10);
y = sin(x);
plot(x,y)
grid on
grid minor
```

By default, major grid lines use a solid line style and align with the tick marks. Minor grid lines use a dotted line style and lie between the tick marks.

### Display Grid Lines on Specific Axes

Create a figure with two subplots and plot a sine wave in each one.

```
x = linspace(0,10);
y = sin(x);
ax1 = subplot(2,1,1);
plot(x,y)
```

```
y2 = sin(3*x);
ax2 = subplot(2,1,2);
```

```
plot(x,y2)
```

Display the grid lines on the upper subplot.

```
grid(ax1, 'on')
```

## More About

### Tips

- Some axes properties affect the appearance of the grid lines. By changing property values, you can modify the appearance. This table lists a subset of axes properties related to the grid.

| Axes Property       | Description                                                         |
|---------------------|---------------------------------------------------------------------|
| XTick, YTick, ZTick | Location of tick marks and major grid lines for each axis direction |

| <b>Axes Property</b>               | <b>Description</b>                                         |
|------------------------------------|------------------------------------------------------------|
| XGrid, YGrid, ZGrid                | Display of major grid lines for each axis direction        |
| XMinorGrid, YMinorGrid, ZMinorGrid | Display of minor grid lines for each axis direction        |
| LineWidth                          | Line width of grid lines, axes box outline, and tick marks |
| GridLineStyle                      | Major grid line style                                      |
| MinorGridLineStyle                 | Minor grid line style                                      |
| GridColor                          | Major grid line color                                      |
| MinorGridColor                     | Minor grid line color                                      |
| GridAlpha                          | Major grid line transparency                               |
| MinorGridAlpha                     | Minor grid line transparency                               |
| Layer                              | Location of grid lines with respect to the plotted data    |

For a full list, see Axes Properties.

- To turn on or off grid lines for each axis direction separately, you must set the axes properties individually. The `grid` function controls all major and minor grid lines together, setting the corresponding axes properties to either 'on' or 'off'.

## griddata

Interpolate scattered data

---

**Note:** Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `griddata`.

In a future release, the following syntaxes will be removed:

```
[Xq,Yq,Vq] = griddata(x,y,v,xq,yq)
[Xq,Yq,Vq] = griddata(x,y,v,xq,yq, method)
```

In addition, `griddata` will not accept any input vectors of mixed orientation in a future release. To specify a grid of query points, construct a full grid with `ndgrid` or `meshgrid` before calling `griddata`.

---

## Syntax

```
vq = griddata(x,y,v,xq,yq)
vq = griddata(x,y,z,v,xq,yq,zq)
vq = griddata(____,method)
```

## Description

`vq = griddata(x,y,v,xq,yq)` fits a surface of the form  $v = f(x,y)$  to the scattered data in the vectors  $(x,y,v)$ . The `griddata` function interpolates the surface at the query points specified by  $(xq,yq)$  and returns the interpolated values, `vq`. The surface always passes through the data points defined by `x` and `y`.

`vq = griddata(x,y,z,v,xq,yq,zq)` fits a hypersurface of the form  $v = f(x,y,z)$ .

`vq = griddata( ____,method)` uses a specified interpolation method to compute `vq` using any of the input arguments in the previous syntaxes.

## Input Arguments

### **x**

Vector specifying the  $x$ - coordinates of the sample points.

### **y**

Vector specifying the  $y$ - coordinates of the sample points.

### **z**

Vector specifying the  $z$ - coordinates of the sample points.

### **v**

Vector of sample values that correspond to the sample coordinates  $x$ ,  $y$  (and  $z$  for 3-D interpolation).

### **xq**

Vector or array that specifies  $x$ - coordinates of the query points to be evaluated.  $xq$  must be the same size as  $yq$  (and  $zq$  for 3-D interpolation).

- Specify an array if you want to pass a grid of query points. Use `ndgrid` or `meshgrid` to construct the array.
- Specify a vector if you want to pass a collection of scattered points.

### **yq**

Vector or array that specifies  $y$ - coordinates of the query points to be evaluated.  $yq$  must be the same size as  $xq$  (and  $zq$  for 3-D interpolation).

- Specify an array if you want to pass a grid of query points. Use `ndgrid` or `meshgrid` to construct the array.
- Specify a vector if you want to pass a collection of scattered points.

### **zq**

Vector or array that specifies  $z$ - coordinates of the query points to be evaluated.  $zq$  must be the same size as  $xq$  and  $yq$ .

- Specify an array if you want to pass a grid of query points. Use `ndgrid` or `meshgrid` to construct the array.

- Specify a vector if you want to pass a collection of scattered points.

**method**

Keyword that specifies the interpolation method. Use one of the following:

| method string | Description                                                                                                                                                                              | Continuity                    |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| 'nearest'     | Triangulation-based nearest neighbor interpolation supporting 2-D and 3-D interpolation.                                                                                                 | Discontinuous                 |
| 'linear'      | Triangulation-based linear interpolation (default) supporting 2-D and 3-D interpolation                                                                                                  | $C^0$                         |
| 'natural'     | Triangulation-based natural neighbor interpolation supporting 2-D and 3-D interpolation. This method is an efficient tradeoff between linear and cubic.                                  | $C^1$ except at sample points |
| 'cubic'       | Triangulation-based cubic interpolation supporting 2-D interpolation only                                                                                                                | $C^2$                         |
| 'v4'          | Biharmonic spline interpolation (MATLAB 4 <code>griddata</code> method) supporting 2-D interpolation only. Unlike the other methods, this interpolation is not based on a triangulation. | $C^2$                         |

## Output Arguments

**vq**

The interpolated values at the query points.

- For 2-D interpolation, where `xq` and `yq` specify an  $m$ -by- $n$  grid of query points, `vq` is an  $m$ -by- $n$  array.
- For 3-D interpolation, where `xq`, `yq`, and `zq` specify an  $m$ -by- $n$ -by- $p$  grid of query points, `vq` is an  $m$ -by- $n$ -by- $p$  array.
- If `xq`, `yq`, (and `zq` for 3-D interpolation) are vectors that specify scattered points, `vq` is a vector of the same length.

## Examples

### Interpolate Scattered Data Over a Uniform Grid

Sample a function at 200 random points between -2.5 and 2.5.

```
xy = -2.5 + 5*gallery('uniformdata',[200 2],0);
x = xy(:,1);
y = xy(:,2);
v = x.*exp(-x.^2-y.^2);
```

$x$ ,  $y$ , and  $v$  are vectors containing scattered (nonuniform) sample points and data.

Define a regular grid and interpolate the scattered data over the grid.

```
[xq,yq] = meshgrid(-2:.2:2, -2:.2:2);
vq = griddata(x,y,v,xq,yq);
```

Plot the gridded data as a mesh and the scattered data as dots.

```
figure
mesh(xq,yq,vq);
hold on
plot3(x,y,v, 'o');

h = gca;
h.XLim = [-2.7 2.7];
h.YLim = [-2.7 2.7];
```

### Interpolate 3-D Data Set Over a Grid in the x-y Plane

Sample a function at 5000 random points between -1 and 1. Initialize the random number generator to make the output of `randn` repeatable.

```
rng default
x = 2*rand(5000,1) - 1;
y = 2*rand(5000,1) - 1;
z = 2*rand(5000,1) - 1;
v = x.^2 + y.^2 + z.^2;
```

`x`, `y`, and `z` are now vectors containing nonuniformly sampled data.

Define a regular grid with points in the range `[-0.8, 0.8]`.

```
d = -0.8:0.05:0.8;
[xq,yq,zq] = meshgrid(d,d,0);
```

Interpolate the scattered data over a rectangular region at  $z=0$ . Then, plot the results.

```
vq = griddata(x,y,z,v,xq,yq,zq);
surf(xq,yq,vq);
```

```
h = gca;
h.XTick = [-1 -0.5 0 0.5 1];
h.YTick = [-1 -0.5 0 0.5 1];
```

**Introduced before R2006a**

# griddatan

Data gridding and hypersurface fitting (dimension  $\geq 2$ )

## Syntax

```
yi = griddatan(x,y,xi)
yi = griddatan(x,y,xi,method)
yi = griddatan(x,y,xi,method,options)
```

## Description

`yi = griddatan(x,y,xi)` fits a hyper-surface of the form  $y = f(x)$  to the data in the (usually) nonuniformly-spaced vectors  $(x, y)$ . `griddatan` interpolates this hyper-surface at the points specified by `xi` to produce `yi`. `xi` can be nonuniform.

`X` is of dimension  $m$ -by- $n$ , representing  $m$  points in  $n$ -dimensional space. `y` is of dimension  $m$ -by-1, representing  $m$  values of the hyper-surface  $f(X)$ . `xi` is a vector of size  $p$ -by- $n$ , representing  $p$  points in the  $n$ -dimensional space whose surface value is to be fitted. `yi` is a vector of length  $p$  approximating the values  $f(xi)$ . The hypersurface always goes through the data points  $(X,y)$ . `xi` is usually a uniform grid (as produced by `meshgrid`).

`yi = griddatan(x,y,xi,method)` defines the type of surface fit to the data, where 'method' is one of:

| method string | Description                                         | Continuity    |
|---------------|-----------------------------------------------------|---------------|
| 'linear'      | Triangulation-based linear interpolation (default). | $C^0$         |
| 'nearest'     | Nearest neighbor interpolation.                     | Discontinuous |

All the methods are based on a Delaunay triangulation of the data.

If `method` is `[]`, the default 'linear' method is used.

`yi = griddatan(x,y,xi,method,options)` specifies a cell array of strings `options` to be used in Qhull via `delaunayn`.

If `options` is `[]`, the default options are used. If `options` is `{ '' }`, no options are used, not even the default.

## Examples

### Fit a Hypersurface

```
X = 2*gallery('uniformdata',[5000 3],0)-1;
Y = sum(X.^2,2);
d = -0.8:0.05:0.8;
[y0,x0,z0] = ndgrid(d,d,d);
XI = [x0(:) y0(:) z0(:)];
YI = griddatan(X,Y,XI);
```

Since it is difficult to visualize 4-D data sets, use `isosurface` at 0.8:

```
YI = reshape(YI, size(x0));
figure
p = patch(isosurface(x0,y0,z0,YI,0.8));
isonormals(x0,y0,z0,YI,p)

p.FaceColor = 'blue';
p.EdgeColor = 'none';

view(3)
axis equal
camlight
lighting phong
```

# griddedInterpolant class

Gridded data interpolation

---

**Note:** The behavior of `griddedInterpolant` has changed. All interpolation methods now support extrapolation by default. Set `F.ExtrapolationMethod` to `'none'` to preserve the pre-R2013a behavior when `F.Method` is `'linear'`, `'cubic'` or `'nearest'`. Before R2013a, evaluation returned NaN values at query points outside the domain when `F.Method` was set to `'linear'`, `'cubic'` or `'nearest'`.

---

## Description

Use `griddedInterpolant` to perform interpolation on a 1-D, 2-D, 3-D, or N-D “Gridded Data” on page 1-3457 set. For example, you can pass a set of  $(x, y)$  points and values,  $v$ , to `griddedInterpolant`, and it returns a surface of the form  $v = F(x, y)$ . This surface always passes through the sample values at the point locations. You can evaluate this surface at any query point,  $(xq, yq)$ , to produce an interpolated value,  $vq$ .

Use `griddedInterpolant` to create the “Interpolant” on page 1-3456,  $F$ . Then you can evaluate  $F$  at specific points using any of the following syntaxes:

- $Vq = F(Xq)$  evaluates  $F$  at a set of query points in matrix  $Xq$ . The points in  $Xq$  are scattered, and each row of  $Xq$  contains the coordinates of a query point.
- $Vq = F(xq1, xq2, \dots, xqn)$  specifies the query locations,  $xq1, xq2, \dots, xqn$ , as column vectors of length  $m$  representing  $m$  points scattered in  $n$ -dimensional space.
- $Vq = F(Xq1, Xq2, \dots, Xqn)$  specifies the query locations as  $n$   $n$ -dimensional arrays,  $Xq1, Xq2, \dots, Xqn$ , of equal size which define a “Full Grid” on page 1-3457 of points.
- $Vq = F(\{xgq1, xgq2, \dots, xgqn\})$  specifies the query locations as “Grid Vectors” on page 1-3457. Use this syntax to conserve memory when you want to query a large grid of points.

## Construction

`F = griddedInterpolant(x,v)` creates a 1-D interpolant from a vector of sample points, `x`, and corresponding values, `v`.

`F = griddedInterpolant(X1,X2,...,Xn,V)` creates a 2-D, 3-D, or N-D interpolant using a “Full Grid” on page 1-3457 of sample points passed as a set of `n`-dimensional arrays, `X1,X2,...,Xn`. The `V` array contains the sample values associated with the point locations in `X1,X2,...,Xn`. Each of the arrays, `X1,X2,...,Xn` must be the same size as `V`.

`F = griddedInterpolant(V)` uses the default grid to create the interpolant. When you use this syntax, `griddedInterpolant` defines the grid as set of points whose spacing is 1 and range is `[1, size(V,i)]` in the `i`th dimension. Use this syntax when you want to conserve memory and are not concerned about the absolute distances between points.

`F = griddedInterpolant({xg1,xg2,...,xgn},V)` specifies `n` “Grid Vectors” on page 1-3457 to describe an `n`-dimensional grid of sample points. Use this syntax when you want to use a specific grid and also conserve memory.

`F = griddedInterpolant( ____, Method)` specifies a string that describes an interpolation method: 'linear', 'nearest', 'next', 'previous', 'pchip', 'cubic', or 'spline'. You can specify `Method` as the last input argument in any of the first four syntaxes.

`F = griddedInterpolant( ____, Method, ExtrapolationMethod)` specifies both the interpolation and extrapolation methods as strings. `griddedInterpolant` uses `ExtrapolationMethod` to estimate the value when your query points fall outside the domain of your sample points. Specify `Method` and `ExtrapolationMethod` together as the last two input arguments in any of the first four syntaxes.

## Input Arguments

**x**

Sample points vector, specified as a vector of input coordinates the same size as `v`.

**v**

Sample values vector, specified as a vector of input values the same size as `x`.

**X1, X2, . . . , Xn**

Sample points in “Full Grid” on page 1-3457 form, specified as a set of n-dimensional arrays. You can create the arrays, X1, X2, . . . , Xn, using the `ndgrid` function. These arrays are all the same size, and each one is the same size as V.

**{xg1, xg2, . . . , xgn}**

Sample points in grid vector form, specified as a cell array of grid vectors. These vectors must specify a grid that is the same size as V. In other words, `size(V) = [length(xg1) length(xg2) . . . length(xgn)]`. Use this form as an alternative to the full grid to save memory when your grid is very large.

**V**

Sample values, specified as an array. The elements of V are the values that correspond to the sample points. The size of V must be the size of the full grid of sample points.

- If you specify the sample points as a full grid consisting of N-D arrays, then V must be the same size as any one of: X1, X2, . . . , Xn.
- If you specify the sample points as grid vectors, then `size(V) = [length(xg1) length(xg2) . . . length(xgn)]`.

**Method**

Interpolation method, specified as a string from the table below.

| Method             | Description                                                                                                                                     | Continuity    | Comments                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'linear' (default) | The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. | $C^0$         | <ul style="list-style-type: none"> <li>• Requires at least 2 grid points in each dimension.</li> <li>• Requires more memory than 'nearest'.</li> </ul>       |
| 'nearest'          | Nearest neighbor interpolation. The interpolated value at a query point is the value at the nearest sample grid point.                          | Discontinuous | <ul style="list-style-type: none"> <li>• Requires 2 grid points in each dimension.</li> <li>• Fastest computation with modest memory requirements</li> </ul> |
| 'next'             | Next neighbor interpolation (for 1-D only). The interpolated                                                                                    | Discontinuous | <ul style="list-style-type: none"> <li>• Requires at least 2 points.</li> </ul>                                                                              |

| Method     | Description                                                                                                                                                                                                                    | Continuity    | Comments                                                                                                                                                                                                                                                                            |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | value at a query point is the value at the next sample grid point.                                                                                                                                                             |               | <ul style="list-style-type: none"> <li>• Same memory requirements and computation time as 'nearest'.</li> </ul>                                                                                                                                                                     |
| 'previous' | Previous neighbor interpolation (for 1-D only). The interpolated value at a query point is the value at the previous sample grid point.                                                                                        | Discontinuous | <ul style="list-style-type: none"> <li>• Requires at least 2 points.</li> <li>• Same memory requirements and computation time as 'nearest'.</li> </ul>                                                                                                                              |
| 'pchip'    | Shape-preserving piecewise cubic interpolation (for 1-D only). The interpolated value at a query point is based on a shape-preserving piecewise cubic interpolation of the values at neighboring grid points.                  | $C^1$         | <ul style="list-style-type: none"> <li>• Requires at least 4 points.</li> <li>• Requires more memory and computation time than 'linear'.</li> </ul>                                                                                                                                 |
| 'cubic'    | The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic convolution.                            | $C^1$         | <ul style="list-style-type: none"> <li>• Grid must have uniform spacing, though the spacing in each dimension does not have to be the same.</li> <li>• Requires at least 4 points in each dimension.</li> <li>• Requires more memory and computation time than 'linear'.</li> </ul> |
| 'spline'   | The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic spline using not-a-knot end conditions. | $C^2$         | <ul style="list-style-type: none"> <li>• Requires 4 points in each dimension.</li> <li>• Requires more memory and computation time than 'cubic'.</li> </ul>                                                                                                                         |

**ExtrapolationMethod**

Extrapolation method, specified as any of the `Method` choices: 'linear', 'nearest', 'next', 'previous', 'pchip', 'cubic', or 'spline'. In addition, you can specify 'none' if you want queries outside the domain of your grid return NaN values.

If you omit `ExtrapolationMethod`, the default value is the string you specify for `Method`. If you omit both the `Method` and `ExtrapolationMethod` arguments, both default to 'linear'.

## Properties

**GridVectors**

Cell array containing grid vectors, {`xg1`, `xg2`, ..., `xgn`}. These vectors specify the grid points (locations) for the values in `F.Values`.

**Values**

Array of values associated with the grid points in `F.GridVectors`.

**Method**

A string specifying the name of a method used to interpolate the data. `Method` is one of the strings: 'linear', 'nearest', 'next', 'previous', 'pchip', 'cubic', or 'spline'. The default value is 'linear'.

**ExtrapolationMethod**

A string specifying the name of a method used to extrapolate the data. `ExtrapolationMethod` is one of the strings: 'linear', 'nearest', 'next', 'previous', 'pchip', 'cubic', 'spline', or 'none'. A value of 'none' indicates that extrapolation is disabled. The default value is the value of `F.Method`.

## Definitions

**Interpolant**

Interpolating function that you can evaluate at query locations.

## Gridded Data

A set of points that are axis-aligned and ordered.

## Scattered Data

A set of points that have no structure among their relative locations.

## Full Grid

A grid represented as a set of arrays. For example, you can create a full grid using `ndgrid`.

## Grid Vectors

A set of vectors that serve as a compact representation of a grid in `ndgrid` format. For example, `[X,Y] = ndgrid(xg,yg)` returns a full grid in the matrices `X` and `Y`. You can represent the same grid using the grid vectors, `xg` and `yg`.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Indexing

Index-based editing of the properties of `F` are not supported. Instead, wholly replace the `GridVectors` or `Values` arrays as necessary. See “Interpolation with the `griddedInterpolant` Class” in the [MATLAB Mathematics documentation](#) for more information.

## Examples

### 2-D Interpolation Over Finer Grid

Interpolate coarsely sampled data using a full grid with spacing of 0.5.

Define the sample points as a full grid with range [1, 10] in both dimensions.

```
[X,Y] = ndgrid(1:10,1:10);
```

Sample  $f(x, y) = x^2 + y^2$  at the grid points.

```
V = X.^2 + Y.^2;
```

Create the interpolant, specifying cubic interpolation.

```
F = griddedInterpolant(X,Y,V, 'cubic');
```

Define a full grid of query points with 0.5 spacing and evaluate the interpolant at those points. Then plot the result.

```
[Xq,Yq] = ndgrid(1:0.5:10,1:0.5:10);
Vq = F(Xq,Yq);
mesh(Xq,Yq,Vq);
```

### 1-D Extrapolation

Compare results of querying the interpolant outside the domain of  $F$  using the 'pchip' and 'nearest' extrapolation methods.

Create the interpolant and specify 'pchip' as the interpolation method.

```
x = [1 2 3 4 5];
v = [12 16 31 10 6];
F = griddedInterpolant(x,v,'pchip')
```

F =

griddedInterpolant with properties:

```
GridVectors: {[1 2 3 4 5]}
Values: [12 16 31 10 6]
Method: 'pchip'
ExtrapolationMethod: 'pchip'
```

Query the interpolant, and include points outside the domain of F.

```
xq = 0:0.1:6;
vq = F(xq);
figure
plot(x,v,'o',xq,vq,'-b');
legend('v','vq')
```

Query the interpolant at the same points again, using the nearest neighbor extrapolation method.

```
F.ExtrapolationMethod = 'nearest';
figure
vq = F(xq);
plot(x,v,'o',xq,vq,'-b');
legend ('v','vq')
```

## **How To**

- Class Attributes
- Property Attributes
- “Interpolating Gridded Data”

# groot

Graphics root object

## Syntax

```
groot
r = groot
```

## Description

`groot` refers to the graphics root object. Use `groot` to access root properties. For a list of properties, see [Root Properties](#).

`r = groot` stores the graphics root object handle. To set root properties using dot notation, you must store the handle first.

## Examples

### View Root Property Values

View a list of graphics root properties and their current values.

```
get(groot)

 CallbackObject: []
 Children: []
 CurrentFigure: []
FixedWidthFontName: 'Courier New'
 HandleVisibility: 'on'
 MonitorPositions: [2x4 double]
 Parent: []
 PointerLocation: [2957 348]
 ScreenDepth: 32
ScreenPixelsPerInch: 96
 ScreenSize: [1 1 1920 1200]
 ShowHiddenHandles: 'off'
```

```
Tag: ''
Type: 'root'
Units: 'pixels'
UserData: []
```

## Set Root Property Values

Set graphics root property values by storing the object handle and using dot notation.

```
r = groot;
r.ShowHiddenHandles = 'on';
```

## More About

### Tips

- Use the graphics root object to set default values on the root level for other types of objects. For example, set the default colormap for all future figures to the `summer` colormap.

```
set(groot, 'DefaultFigureColormap', summer)
```

To restore a property to its original MATLAB default, use the `'remove'` keyword.

```
set(groot, 'DefaultFigureColormap', 'remove')
```

For more information on setting default values, see “Default Property Values”.

# gsvd

Generalized singular value decomposition

## Syntax

```
[U,V,X,C,S] = gsvd(A,B)
sigma = gsvd(A,B)
```

## Description

`[U,V,X,C,S] = gsvd(A,B)` returns unitary matrices  $U$  and  $V$ , a (usually) square matrix  $X$ , and nonnegative diagonal matrices  $C$  and  $S$  so that

$$\begin{aligned} A &= U * C * X' \\ B &= V * S * X' \\ C' * C + S' * S &= I \end{aligned}$$

$A$  and  $B$  must have the same number of columns, but may have different numbers of rows. If  $A$  is  $m$ -by- $p$  and  $B$  is  $n$ -by- $p$ , then  $U$  is  $m$ -by- $m$ ,  $V$  is  $n$ -by- $n$  and  $X$  is  $p$ -by- $q$  where  $q = \min(m+n, p)$ .

`sigma = gsvd(A,B)` returns the vector of generalized singular values, `sqrt(diag(C' * C) ./ diag(S' * S))`.

The nonzero elements of  $S$  are always on its main diagonal. If  $m \geq p$  the nonzero elements of  $C$  are also on its main diagonal. But if  $m < p$ , the nonzero diagonal of  $C$  is `diag(C, p-m)`. This allows the diagonal elements to be ordered so that the generalized singular values are nondecreasing.

`gsvd(A,B,0)`, with three input arguments and either  $m$  or  $n \geq p$ , produces the “economy-sized” decomposition where the resulting  $U$  and  $V$  have at most  $p$  columns, and  $C$  and  $S$  have at most  $p$  rows. The generalized singular values are `diag(C) ./ diag(S)`.

When  $B$  is square and nonsingular, the generalized singular values, `gsvd(A,B)`, are equal to the ordinary singular values, `svd(A/B)`, but they are sorted in the opposite order. Their reciprocals are `gsvd(B,A)`.

In this formulation of the `gsvd`, no assumptions are made about the individual ranks of `A` or `B`. The matrix `X` has full rank if and only if the matrix `[A;B]` has full rank. In fact, `svd(X)` and `cond(X)` are equal to `svd([A;B])` and `cond([A;B])`. Other formulations, eg. G. Golub and C. Van Loan [1], require that `null(A)` and `null(B)` do not overlap and replace `X` by `inv(X)` or `inv(X')`.

Note, however, that when `null(A)` and `null(B)` do overlap, the nonzero elements of `C` and `S` are not uniquely determined.

## Examples

### Example 1

The matrices have at least as many rows as columns.

```
A = reshape(1:15,5,3)
```

```
B = magic(3)
```

```
A =
```

```
 1 6 11
 2 7 12
 3 8 13
 4 9 14
 5 10 15
```

```
B =
```

```
 8 1 6
 3 5 7
 4 9 2
```

The statement

```
[U,V,X,C,S] = gsvd(A,B)
```

produces a 5-by-5 orthogonal `U`, a 3-by-3 orthogonal `V`, a 3-by-3 nonsingular `X`,

```
X =
```

```
 2.8284 -9.3761 -6.9346
 -5.6569 -8.3071 -18.3301
 2.8284 -7.2381 -29.7256
```

and

```
C =
```

```
 0.0000 0 0
```

$$S = \begin{bmatrix} 0 & 0.3155 & 0 \\ 0 & 0 & 0.9807 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1.0000 & 0 & 0 \\ 0 & 0.9489 & 0 \\ 0 & 0 & 0.1957 \end{bmatrix}$$

Since  $A$  is rank deficient, the first diagonal element of  $C$  is zero.

The economy sized decomposition,

$$[U, V, X, C, S] = \text{gsvd}(A, B, 0)$$

produces a 5-by-3 matrix  $U$  and a 3-by-3 matrix  $C$ .

$$U = \begin{bmatrix} 0.5700 & -0.6457 & -0.4279 \\ -0.7455 & -0.3296 & -0.4375 \\ -0.1702 & -0.0135 & -0.4470 \\ 0.2966 & 0.3026 & -0.4566 \\ 0.0490 & 0.6187 & -0.4661 \end{bmatrix}$$

$$C = \begin{bmatrix} 0.0000 & 0 & 0 \\ 0 & 0.3155 & 0 \\ 0 & 0 & 0.9807 \end{bmatrix}$$

The other three matrices,  $V$ ,  $X$ , and  $S$  are the same as those obtained with the full decomposition.

The generalized singular values are the ratios of the diagonal elements of  $C$  and  $S$ .

$$\begin{aligned} \text{sigma} &= \text{gsvd}(A, B) \\ \text{sigma} &= \\ &0.0000 \\ &0.3325 \\ &5.0123 \end{aligned}$$

These values are a reordering of the ordinary singular values

$$\begin{aligned} \text{svd}(A/B) \\ \text{ans} &= \\ &5.0123 \\ &0.3325 \end{aligned}$$

0.0000

## Example 2

The matrices have at least as many columns as rows.

```
A = reshape(1:15,3,5)
```

```
B = magic(5)
```

A =

|   |   |   |    |    |
|---|---|---|----|----|
| 1 | 4 | 7 | 10 | 13 |
| 2 | 5 | 8 | 11 | 14 |
| 3 | 6 | 9 | 12 | 15 |

B =

|    |    |    |    |    |
|----|----|----|----|----|
| 17 | 24 | 1  | 8  | 15 |
| 23 | 5  | 7  | 14 | 16 |
| 4  | 6  | 13 | 20 | 22 |
| 10 | 12 | 19 | 21 | 3  |
| 11 | 18 | 25 | 2  | 9  |

The statement

```
[U,V,X,C,S] = gsvd(A,B)
```

produces a 3-by-3 orthogonal U, a 5-by-5 orthogonal V, a 5-by-5 nonsingular X and

C =

|   |   |        |        |        |
|---|---|--------|--------|--------|
| 0 | 0 | 0.0000 | 0      | 0      |
| 0 | 0 | 0      | 0.0439 | 0      |
| 0 | 0 | 0      | 0      | 0.7432 |

S =

|        |        |        |        |        |
|--------|--------|--------|--------|--------|
| 1.0000 | 0      | 0      | 0      | 0      |
| 0      | 1.0000 | 0      | 0      | 0      |
| 0      | 0      | 1.0000 | 0      | 0      |
| 0      | 0      | 0      | 0.9990 | 0      |
| 0      | 0      | 0      | 0      | 0.6690 |

In this situation, the nonzero diagonal of C is  $\text{diag}(C, 2)$ . The generalized singular values include three zeros.

```
sigma = gsvd(A,B)
sigma =
```

```
 0
 0
0.0000
0.0439
1.1109
```

Reversing the roles of A and B reciprocates these values, producing two infinities.

```
gsvd(B,A)
ans =
```

```
1.0e+16 *
0.0000
0.0000
8.8252
 Inf
 Inf
```

## Diagnostics

The only warning or error message produced by `gsvd` itself occurs when the two input arguments do not have the same number of columns.

## More About

### Algorithms

The generalized singular value decomposition uses the C-S decomposition described in [1], as well as the built-in `svd` and `qr` functions. The C-S decomposition is implemented in a local function in the `gsvd` program file.

## gt, >

Determine greater than

### Syntax

```
A > B
gt(A,B)
```

### Description

`A > B` returns a logical array with elements set to logical 1 (true) where A is greater than B; otherwise, it returns logical 0 (false).

The test compares only the real part of numeric arrays. `gt` returns logical 0 (false) where A or B have NaN or undefined categorical elements.

`gt(A,B)` is an alternate way to execute `A > B`, but is rarely used. It enables operator overloading for classes.

### Examples

#### Test Vector Elements

Determine if vector elements are greater than a given value.

Create a numeric vector.

```
A = [1 12 18 7 9 11 2 15];
```

Test the vector for elements that are greater than 10.

```
A > 10
```

```
ans =
```

```
0 1 1 0 0 1 0 1
```

The result is a vector with values of logical 1 (true) where the elements of A satisfy the expression.

Use the vector of logical values as an index to view the values in A that are greater than 10.

```
A(A > 10)
```

```
ans =
```

```
 12 18 11 15
```

The result is a subset of the elements in A.

## Replace Elements of Matrix

Create a matrix.

```
A = magic(4)
```

```
A =
```

```
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

Replace all values greater than 9 with the value 10.

```
A(A > 9) = 10
```

```
A =
```

```
 10 2 3 10
 5 10 10 8
 9 7 6 10
 4 10 10 1
```

The result is a new matrix whose largest element is 10.

## Compare Values in Categorical Array

Create an ordinal categorical array.

```
A = categorical({'large' 'medium' 'small'; 'medium' ...
```

```
'small' 'large'}},{'small' 'medium' 'large'},'Ordinal',1)
```

```
A =
```

```
 large medium small
 medium small large
```

The array has three categories: 'small', 'medium', and 'large'.

Find all values greater than the category 'medium'.

```
A > 'medium'
```

```
ans =
```

```
 1 0 0
 0 0 1
```

A value of logical 1 (`true`) indicates a value greater than the category 'medium'.

Compare the rows of A.

```
A(1,:) > A(2,:)
```

```
ans =
```

```
 1 1 0
```

The function returns logical 1 (`true`) where the first row has a category value greater than the second row.

### Test Complex Numbers

Create a vector of complex numbers.

```
A = [1+i 2-2i 1+3i 1-2i 5-i];
```

Find the values that are greater than 2.

```
A(A > 2)
```

```
ans =
```

```
5.0000 - 1.0000i
```

`gt` compares only the real part of the elements in A.

Use `abs` to find which elements are outside a radius of 2 from the origin.

```
A(abs(A) > 2)
```

```
ans =
```

```
2.0000 - 2.0000i 1.0000 + 3.0000i 1.0000 - 2.0000i 5.0000 - 1.0000i
```

The result has more elements since `abs` accounts for the imaginary part of the numbers.

## Compare Dates

Create a vector of dates.

```
A = datetime([2014,05,01;2014,05,31])
```

```
A =
```

```
01-May-2014
31-May-2014
```

Find the dates that occur after May 10, 2014.

```
A(A > '2014-05-10')
```

```
ans =
```

```
31-May-2014
```

## Input Arguments

### A — Left array

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Left array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical

arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

### **B — Right array**

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Right array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

## gtext

Add text to figure using mouse

### Syntax

```
gtext(str)
gtext(str,Name,Value)

t = gtext(___)
```

### Description

`gtext(str)` inserts the text, `str`, at the location you select with the mouse. When you hover over the figure window, the pointer becomes a crosshair. `gtext` is waiting for you to select a location. Move the pointer to the location you want and either click the figure or press any key, except **Enter**.

`gtext(str,Name,Value)` specifies text properties using one or more name-value pair arguments. For example, `'FontSize',14` specifies a 14-point font.

`t = gtext( ___ )` returns an array of text objects created by `gtext`. Use `t` to modify properties of the text objects after they are created. For a list of properties and descriptions, see [Text Properties](#). You can return an output argument using any of the arguments from the previous syntaxes.

### Examples

#### Add Text to Figure Using Mouse

Create a simple line plot and use `gtext` to add text to the figure using the mouse.

```
plot(1:10)
gtext('My Plot')
```

Click the figure to place the text at the selected location.

## Specify Font Size and Color

Create a simple line plot and add text to the figure using the mouse. Use a red, 14-point font.

```
plot(1:10)
gtext('My Plot', 'Color', 'red', 'FontSize', 14)
```

Click the figure where you want to display the text.

### Modify Text After Creation

Create a simple line plot and add text to the figure using the mouse. Return the text object created, `t`.

```
plot(1:10)
t = gtext('My Plot')
```

Click the figure to place the text and create the text object.

t =

Text (My Plot) with properties:

```
String: 'My Plot'
FontSize: 10
FontWeight: 'normal'
FontName: 'Helvetica'
Color: [0 0 0]
HorizontalAlignment: 'left'
Position: [4.3906 5.3950 0]
Units: 'data'
```

Show all properties

Use `t` to change the font size and color of the text by setting text properties. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the `set` function instead.

```
t.Color = 'red';
t.FontSize = 14;
```

- “Add Text to Specific Points on Graph”

## Input Arguments

**str** — Text to display

character string | cell array of strings | character array with multiple rows

Text to display, specified in one of these forms:

- Character string — Display the text with one click, for example:

```
gtext('my text')
```

- Cell array of strings — Display one row of the array with each click. For example, this code displays `first` with the first click and `second` with the second click.

```
gtext({'first';'second'})
```

To display multiline text, specify more than one string per row.

```
gtext({'first','new line';'second','new line'})
```

- Character array with multiple rows — Display one row of the array with each click. Each row must contain the same number of characters, for example:

```
gtext(['one';'two'])
```

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols, use TeX markup. For a list of supported markup, see the `Interpreter` property.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `text(.5,.5,'my text','FontSize',14,'Color','red')`

The properties listed here are only a subset. For a full list, see `Text Properties`.

---

**Note:** You cannot specify the `Position` text property as a name-value pair during text creation. `gtext` ignores the specified value.

---

### 'FontSize' — Font size

10 (default) | scalar value greater than zero

Font size, specified as a scalar value greater than zero in point units. One point equals 1/72 inch. To change the font units, use the `FontUnits` property.

Example: 12

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

### 'FontWeight' — Thickness of text characters

'normal' (default) | 'bold'

Thickness of the text characters, specified as one of these values:

- 'normal' — Default weight as defined by the particular font
- 'bold' — Thicker character outlines than normal

MATLAB uses the `FontWeight` property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight still can result in the normal font weight.

---

**Note:** The 'light' and 'demi' font weight values have been removed. Use 'normal' instead.

---

### 'FontName' — Font name

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. The 'FixedWidth' value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: 'Cambria'

### 'Color' — Text color

[0 0 0] (default) | RGB triplet | color string | 'none'

Text color, specified as a three-element RGB triplet, a color string, or 'none'. The default color is black with an RGB triplet value of [0 0 0]. If you set the color to 'none', then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0, 1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

| Long Name | Short Name | RGB Triplet |
|-----------|------------|-------------|
| 'yellow'  | 'y'        | [1 1 0]     |
| 'magenta' | 'm'        | [1 0 1]     |
| 'cyan'    | 'c'        | [0 1 1]     |
| 'red'     | 'r'        | [1 0 0]     |
| 'green'   | 'g'        | [0 1 0]     |
| 'blue'    | 'b'        | [0 0 1]     |
| 'white'   | 'w'        | [1 1 1]     |
| 'black'   | 'k'        | [0 0 0]     |

Example: 'blue'

Example: [0 0 1]

**'HorizontalAlignment'** — Horizontal alignment of text with respect to position point  
'left' (default) | 'center' | 'right'

Horizontal alignment of the text with respect to the x value in the `Position` property, specified as one of the values in this table. The vertical line indicates where the x value lies in relation to the text.

| Value            | Result                                                                              |
|------------------|-------------------------------------------------------------------------------------|
| 'left' (default) |  |
| 'center'         |  |
| 'right'          |  |

**'Interpreter' — Interpretation of text characters**`'tex'` (default) | `'latex'` | `'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup.
- `'latex'` — Interpret text strings using LaTeX markup.
- `'none'` — Display literal characters.

## TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers with the `Interpreter` property set to `'tex'`. Modifiers remain in effect until the end of the string. Superscripts and subscripts are an exception because they only modify the next character or the text within the curly braces `{}`.

| Modifier                          | Description                                                                                                          | Example of String                      |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------|----------------------------------------|
| <code>^{ }</code>                 | Superscript                                                                                                          | <code>'text^{superscript}'</code>      |
| <code>_{ }</code>                 | Subscript                                                                                                            | <code>'text_{subscript}'</code>        |
| <code>\bf</code>                  | Bold font                                                                                                            | <code>'\bf text'</code>                |
| <code>\it</code>                  | Italic font                                                                                                          | <code>'\it text'</code>                |
| <code>\sl</code>                  | Oblique font (usually the same as italic font)                                                                       | <code>'\sl text'</code>                |
| <code>\rm</code>                  | Normal font                                                                                                          | <code>'\rm text'</code>                |
| <code>\fontname{specifier}</code> | Font name — Set <b>specifier</b> as the name of a font family. You can use this in combination with other modifiers. | <code>'\fontname{Courier} text'</code> |
| <code>\fontsize{specifier}</code> | Font size — Set <b>specifier</b> as a numeric scalar value                                                           | <code>'\fontsize{15} text'</code>      |

| Modifier                            | Description                                                                                                                                | Example of String                            |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|
|                                     | in point units to change the font size.                                                                                                    |                                              |
| <code>\color{specifier}</code>      | Font color — Set specifier as one of these colors: red, green, yellow, magenta, blue, black, white, gray, darkGreen, orange, or lightBlue. | ' <code>\color{magenta} text</code> '        |
| <code>\color[rgb]{specifier}</code> | Custom font color — Set specifier as a three-element RGB triplet.                                                                          | ' <code>\color[rgb]{0,0.5,0.5} text</code> ' |

This table lists the supported special characters with the Interpreter property set to 'tex'.

| Character Sequence     | Symbol      | Character Sequence    | Symbol     | Character Sequence                | Symbol            |
|------------------------|-------------|-----------------------|------------|-----------------------------------|-------------------|
| <code>\alpha</code>    | $\alpha$    | <code>\upsilon</code> | $\upsilon$ | <code>\sim</code>                 | $\sim$            |
| <code>\angle</code>    | $\angle$    | <code>\phi</code>     | $\Phi$     | <code>\leq</code>                 | $\leq$            |

## LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to 'latex'. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at <http://www.latex-project.org/>.

# guidata

Store or retrieve UI data

## Syntax

```
guidata(object_handle,data)
data = guidata(object_handle)
```

## Description

`guidata(object_handle,data)` stores the variable `data` with the object specified by `object_handle`. If `object_handle` is not a figure, then the object's parent figure is used. `data` can be any MATLAB variable, but is typically a structure, which enables you to add new fields as required.

`guidata` can manage only one variable at any time. Subsequent calls to `guidata(object_handle,data)` overwrite the previously stored `data`.

---

**GUIDE Uses guidata** GUIDE uses `guidata` to store and maintain the `handles` structure. In a GUIDE code file, do not overwrite the `handles` structure or your program will no longer work. If you need to store other data, you can do so by adding new fields to the `handles` structure.

---

`data = guidata(object_handle)` returns previously stored data, or an empty matrix if nothing is stored.

To change the data managed by `guidata`:

- 1 Get a copy of the data with the command `data = guidata(object_handle)`.
- 2 Make the desired changes to `data`.
- 3 Save the changed version of `data` with the command `guidata(object_handle,data)`.

`guidata` provides application developers with a convenient interface to a figure's application data:

- You do not need to create and maintain a hard-coded property name for the application data throughout your source code.
- You can access the data from within a local function callback routine using the component's handle (which is returned by `gcb0`), without needing to find the figure's handle.

If you are not using GUIDE, `guidata` is particularly useful in conjunction with `guihandles`, which creates a structure containing the all of the components in a UI.

## Examples

This example calls `guidata` to save a structure containing a figure's application data from within the initialization section of the application code file. The first section shows how to do this within a programmatic UI. The second section shows how the code differs when you use GUIDE to create a template code file. GUIDE provides a `handles` structure as an argument to all local function callbacks, so you do not need to call `guidata` to obtain it. You do, however, need to call `guidata` to save changes you make to the structure.

### Using guidata in a Programmatic UI

Calling the `guihandles` function creates the structure into which your code places additional data. It contains all handles used by the figure at the time it is called, generating field names based on each object's `Tag` property.

```
% Create figure
figure_handle = figure('Toolbar','none');
% create structure of handles
myhandles = guihandles(figure_handle);
% Add some additional data as a new field called numberOfErrors
myhandles.numberOfErrors = 0;
% Save the structure
guidata(figure_handle,myhandles)
```

You can recall the data from within a local callback function, modify it, and then replace the structure in the figure:

```
function My_Callback()
% ...
% Get the structure using guidata in the local function
myhandles = guidata(gcb0);
% Modify the value of your counter
myhandles.numberOfErrors = myhandles.numberOfErrors + 1;
```

```
% Save the change you made to the structure
guidata(gcbo,myhandles)
```

## Using guidata in GUIDE

If you use GUIDE, you do not need to call `guihandles` to create a structure. You can add your own data to the `handles` structure. For example, this code adds the field, `numberOfErrors`, to the structure:

```
% --- Executes just before simple_gui_tab is made visible.
function my_GUIDE_GUI_OpeningFcn(hObject, eventdata, handles, varargin)
% This function has no output args, see OutputFcn.
% hObject handle to figure
% eventdata reserved - to be defined in a future version of MATLAB
% handles structure with handles and user data (see GUIDATA)
% varargin command line arguments to simple_gui_tab (see VARARGIN)
% ...
```

```
% add some additional data as a new field called numberOfErrors
handles.numberOfErrors = 0;
% Save the change you made to the structure
guidata(hObject,handles)
```

Notice that you use the input argument `hObject` in place of `gcbo` to refer to the object whose callback is executing.

Suppose you needed to access the `numberOfErrors` field in a push button callback. Your callback code now looks something like this:

```
% --- Executes on button press in pushbutton1.
function my_GUIDE_GUI_pushbutton1_Callback(hObject, eventdata, handles)
% hObject handle to pushbutton1 (see GCBO)
% eventdata reserved - to be defined in a future version of MATLAB
% handles structure with handles and user data (see GUIDATA)
% ...
```

```
% No need to call guidata to obtain a structure;
% it is provided by GUIDE via the handles argument
handles.numberOfErrors = handles.numberOfErrors + 1;
% save the changes to the structure
guidata(hObject,handles)
```

## guide

Open GUIDE

### Syntax

```
guide
guide('filename.fig')
guide('fullpath')
guide(HandleList)
```

### Description

`guide` launches GUIDE, a UI design environment.

`guide` opens the GUIDE Quick Start dialog where you can choose to open a previously created or create a new one using one of the provided templates.

`guide('filename.fig')` opens the FIG-file named `filename.fig` for editing if it is on the MATLAB path.

`guide('fullpath')` opens the FIG-file at `fullpath` even if it is not on the MATLAB path.

`guide(HandleList)` opens the content of each of the figures in `HandleList` in a separate copy of the GUIDE design environment.

# guihandles

Create structure of handles

## Syntax

```
handles = guihandles(object_handle)
handles = guihandles
```

## Description

`handles = guihandles(object_handle)` returns a structure containing the handles of the objects in a figure, using the value of their `Tag` properties as the field names, with the following caveats:

- Objects are excluded if their `Tag` properties are empty, or are not legal variable names.
- If several objects have the same `Tag`, that field in the structure contains a vector of handles.
- Objects with hidden handles are included in the structure.

`handles = guihandles` returns a structure of handles for the current figure.

# gunzip

Uncompress GNU zip files

## Syntax

```
gunzip(files)
gunzip(files,outputdir)
gunzip(url, ...)
filenames = gunzip(...)
```

## Description

`gunzip(files)` uncompresses GNU zip files from the list of files specified in `files`. Directories recursively `gunzip` all of their content. The output files have the same name, excluding the extension `.gz`, and are written to the same directory as the input files.

`files` is a string or cell array of strings containing a list of files or directories. Individual files that are on the MATLAB path can be specified as partial path names. Otherwise, an individual file can be specified relative to the current directory or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~username/`, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

`gunzip(files,outputdir)` writes the gunzipped file into the directory `outputdir`. If `outputdir` does not exist, MATLAB creates it.

`gunzip(url, ...)` extracts the GNU zip contents from an Internet universal resource locator (URL). The URL must include the protocol type (for example, `'http://'`). MATLAB downloads the URL to the temp directory, and then deletes it.

`filenames = gunzip(...)` gunzips the files and returns the relative path names of the gunzipped files in the string cell array `filenames`.

## Examples

To `gunzip` all `.gz` files in the current directory, type:

```
gunzip('*.*gz');
```

To `gunzip` Cleve Moler's “Numerical Computing with MATLAB” examples to the output directory `ncm`, type:

```
url = 'http://www.mathworks.com/moler/ncm.tar.gz';
gunzip(url, 'ncm')
untar('ncm/ncm.tar', 'ncm')
```

## **gzip**

Compress files into GNU zip files

### **Syntax**

```
gzip(files)
gzip(files,outputdir)
filenames = gzip(...)
```

### **Description**

`gzip(files)` creates GNU zip files from the list of files specified in `files`. Directories recursively `gzip` all their contents. Each output gzipped file is written to the same directory as the input file and with the file extension `.gz`.

`files` is a string or cell array of strings containing a list of files or directories to `gzip`. Individual files that are on the MATLAB path can be specified as partial path names. Otherwise, an individual file can be specified relative to the current directory or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~username/`, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

`gzip(files,outputdir)` writes the gzipped files into the directory `outputdir`. If `outputdir` does not exist, MATLAB creates it.

`filenames = gzip(...)` gzips the files and returns the relative path names of all gzipped files in the string cell array `filenames`.

### **Examples**

To `gzip` all `.m` and `.mat` files in the current directory and store the results in the directory `archive`, type:

```
gzip({'*.m', '*.mat'}, 'archive');
```

**See Also**

## h5create

Create HDF5 data set

### Syntax

```
h5create(filename,datasetname,size,Name,Value)
```

### Description

`h5create(filename,datasetname,size,Name,Value)` creates an HDF5 data set in the file specified by `filename`.

### Input Arguments

#### **filename**

Text string specifying the name of an HDF5 file. If `filename` does not already exist, `h5create` creates it, with additional options specified by one or more `Name,Value` pair arguments.

#### **Default:**

#### **datasetname**

Text string specifying the name of the data set you want to create. If `datasetname` is a full path name, `h5create` creates all intermediate groups, if they don't already exist.

#### **Default:**

#### **size**

Array specifying the extents of the dataset. To specify an unlimited extent, set the corresponding element of `size` to `Inf`.

#### **Default:**

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### 'Datatype'

Any of the following MATLAB datatypes.

|        |        |        |        |       |
|--------|--------|--------|--------|-------|
| double | uint64 | uint32 | uint16 | uint8 |
| single | int64  | int32  | int16  | int8  |

**Default:** double

### 'ChunkSize'

Defines chunking layout.

**Default:** Not chunked

### 'Deflate'

Defines gzip compression level (0-9).

**Default:** 0

### 'FillValue'

Defines the fill value for numeric data sets.

**Default:**

### 'Fletcher32'

Turns on the Fletcher32 checksum filter.

**Default:** false

### 'Shuffle'

Turns on the Shuffle filter.

Default: false

## Examples

### Create Fixed-Size Data Set

Create a fixed-size 100-by-200 data set.

```
h5create('myfile.h5', '/myDataset1', [100 200])
h5disp('myfile.h5')
```

```
HDF5 myfile.h5
Group '/'
 Dataset 'myDataset1'
 Size: 100x200
 MaxSize: 100x200
 Datatype: H5T_IEEE_F64LE (double)
 ChunkSize: []
 Filters: none
 FillValue: 0.000000
```

### Create Data Set with Compression

Create a single-precision 1000-by-2000 data set with a chunk size of 50-by-80. Apply the highest level of compression.

```
h5create('myfile.h5', '/myDataset2', [1000 2000], 'Datatype', 'single', ...
 'ChunkSize', [50 80], 'Deflate', 9)
h5disp('myfile.h5')
```

```
HDF5 myfile.h5
Group '/'
 Dataset 'myDataset2'
 Size: 1000x2000
 MaxSize: 1000x2000
 Datatype: H5T_IEEE_F32LE (single)
 ChunkSize: 50x80
 Filters: deflate(9)
 FillValue: 0.000000
```

### Create Data Set with Unlimited Dimension

Create a two-dimensional data set that is unlimited along the second extent.

```
h5create('myfile.h5', '/myDataset3', [200 Inf], 'ChunkSize', [20 20])
h5disp('myfile.h5')
```

```
HDF5 myfile.h5
Group '/'
 Dataset 'myDataset3'
 Size: 200x0
 MaxSize: 200xInf
 Datatype: H5T_IEEE_F64LE (double)
 ChunkSize: 20x20
 Filters: none
 FillValue: 0.000000
```

## h5disp

Display contents of HDF5 file

### Syntax

```
h5disp(filename)
h5disp(filename,location)
h5disp(filename,location,mode)
```

### Description

`h5disp(filename)` displays the structure (metadata) of the entire HDF5 file, `filename`.

`h5disp(filename,location)` displays the metadata for the specified location.

`h5disp(filename,location,mode)` displays the file metadata according to the value of `mode`.

### Input Arguments

#### **filename**

Text string specifying the name of an HDF5 file.

#### **Default:**

#### **location**

Text string specifying the full path to a location in an HDF5 file. To display the metadata for the entire file, specify `'/'` as the value of `location`. If `location` is a group, `h5disp` displays all objects below the group.

#### **Default:**

**mode**

Either of the following text strings.

| Value  | Description                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------------|
| min    | Minimal, display only group and data set names.                                                                     |
| simple | Display data set metadata and attribute values, if the attribute is an integer, floating point, or a scalar string. |

**Default:** simple

## Examples

Display the entire contents of an HDF5 file.

```
h5disp('example.h5')
```

Display metadata for one data set in an HDF5 file.

```
h5disp('example.h5', '/g4/world');
```

## See Also

h5info

**Introduced in R2011a**

## h5info

Return information about HDF5 file

### Syntax

```
info = h5info(filename)
info = h5info(filename,location)
```

### Description

`info = h5info(filename)` returns information about the entire HDF5 file, specified by `filename`.

`info = h5info(filename,location)` returns information about the group, data set, or named datatype specified by `location` in the HDF5 file, `filename`.

### Input Arguments

#### **filename**

Text string specifying the name of an HDF5 file.

**Default:**

#### **location**

Text string specifying the location of a group, data set, or named datatype in an HDF5 file.

**Default:**

## Output Arguments

### info

A structure containing information about the HDF5 file. The set of fields in the structure depends on the `location` parameter. The first field is always 'Filename'. Other fields that might be present in the `info` structure are as follows.

| Location Type    | Field      | Description                                                                                    |
|------------------|------------|------------------------------------------------------------------------------------------------|
| Files and Groups | Name       | Text string specifying name of the group. If you specify only a file name, this value is '/ '. |
|                  | Groups     | Array of structures describing subgroups.                                                      |
|                  | Datasets   | Array of structures describing data sets.                                                      |
|                  | Datatypes  | Array of structures describing named datatypes.                                                |
|                  | Links      | Array of structures describing soft, external, user-defined, and certain hard links.           |
|                  | Attributes | Array of structures describing group attributes.                                               |
|                  | Data sets  | Name                                                                                           |
| Datatype         |            | Structure describing the datatype.                                                             |
| Dataspace        |            | Structure describing the size of the dataset.                                                  |
| ChunkSize        |            | Extents of the data set's chunk size, if defined.                                              |
| FillValue        |            | Data set's fill value, if defined.                                                             |
| Filter           |            | Array of structures describing any defined filters such as compression.                        |

| Location Type   | Field      | Description                                             |
|-----------------|------------|---------------------------------------------------------|
|                 | Attributes | Array of structures describing data set attributes.     |
| Named Datatypes |            |                                                         |
|                 | Name       | Text string specifying the name of the datatype object. |
|                 | Class      | HDF5 class of the named datatype.                       |
|                 | Type       | Text string or struct further describing the datatype.  |
|                 | Size       | Size of the named datatype in bytes.                    |

## Examples

Return all information.

```
info = h5info('example.h5');
```

Return information about a group and all data sets contained within the group.

```
info = h5info('example.h5', '/g4');
```

Return information about a specific dataset.

```
info = h5info('example.h5', '/g4/time');
```

## See Also

`h5disp`

# h5read

Read data from HDF5 data set

## Syntax

```
data = h5read(filename,datasetname)
data = h5read(filename,datasetname,start,count)
data = h5read(filename,datasetname,start,count,stride)
```

## Description

`data = h5read(filename,datasetname)` retrieves all of the data from the HDF5 data set `datasetname` in the file `filename`.

`data = h5read(filename,datasetname,start,count)` reads a subset of data from the data set `datasetname`. `start` is the one-based index of the first element to be read. `count` defines how many elements to read along each dimension. If a particular element of `count` is `Inf`, `h5read` reads data until the end of the corresponding dimension.

`data = h5read(filename,datasetname,start,count,stride)` reads a subset of data, where `stride` specifies the interelement spacing along each data set extent.

## Input Arguments

### **filename**

Text string specifying the name of an HDF5 file.

### **Default:**

### **datasetname**

Text string specifying the name of a data set in an HDF5 file.

### **Default:**

**start**

Numeric index value specifying the place to start reading data in the dataset in an HDF5 file. Indices are 1-based.

**Default:****count**

Numeric value specifying the amount of data to read.

**Default:****stride**

Numeric value specifying the interval spacing during the read operation. For example, a spacing of 2 indicates reading every other value.

**Default:**

## Output Arguments

**data**

Data read from the data set.

## Examples

**Read Entire Data Set**

Read an entire data set from the sample file, `example.h5`.

```
h5disp('example.h5', '/g4/lat')
```

```
HDF5 example.h5
Dataset 'lat'
 Size: 19
 MaxSize: 19
 Datatype: H5T_IEEE_F64LE (double)
 ChunkSize: []
 Filters: none
```

```
FillValue: 0.000000
Attributes:
 'units': 'degrees_north'
 'CLASS': 'DIMENSION_SCALE'
 'NAME': 'lat'
```

```
data = h5read('example.h5', '/g4/lat')
```

```
data =
```

```
-90
-80
-70
-60
-50
-40
-30
-20
-10
 0
 10
 20
 30
 40
 50
 60
 70
 80
 90
```

### Read Subset of a Data Set

Read the first 5-by-3 subset of a data set.

```
h5disp('example.h5', '/g4/world')
```

```
HDF5 example.h5
Dataset 'world'
 Size: 36x19
 MaxSize: 36x19
 Datatype: H5T_IEEE_F64LE (double)
 ChunkSize: []
 Filters: none
```

```
FillValue: 0.000000
data = h5read('example.h5', '/g4/world', [1 1], [5 3])

data =

 0 0 0
 0 0 0
 0 0 0
 0 0 0
 0 0 0
```

## Read Data Set of References

Read a data set of references to other data sets.

```
h5disp('example.h5', '/g3/reference')

HDF5 example.h5
Dataset 'reference'
 Size: 2
 MaxSize: 2
 Datatype: H5T_REFERENCE
 ChunkSize: []
 Filters: none
 FillValue: H5T_REFERENCE

data = h5read('example.h5', '/g3/reference')

data =

 [2x1 int32]
 [2x1 single]
```

**Introduced in R2011a**

# h5readatt

Read attribute from HDF5 file

## Syntax

```
attval = h5readatt(filename,location,attr)
```

## Description

`attval = h5readatt(filename,location,attr)` retrieves the value for the named attribute `attr` from the given `location` in the HDF5 file `filename`.

## Input Arguments

### **filename**

Text string specifying the name of an HDF5 file.

### **Default:**

### **location**

Text string specifying the full path of the attribute in an HDF5 file. `location` can refer to either a group or a data set.

### **Default:**

### **attr**

Text string specifying the name of an attribute in an HDF5 file.

### **Default:**

## Output Arguments

### **attval**

Value of the attribute.

## Examples

### Read Group Attribute

```
attval = h5readatt('example.h5', '/', 'attr2')
```

```
attval =
```

```
 0 2
 1 3
```

### Read Data Set Attribute

Read the `units` attribute.

```
attval = h5readatt('example.h5', '/g4/lon', 'units')
```

```
attval =
```

```
degrees_east
```

- “Using the High-Level HDF5 Functions to Import Data”

`h5writeatt` | `h5info`

**Introduced in R2011a**

# h5write

Write to HDF5 data set

## Syntax

```
h5write(filename,datasetname,data)
h5write(filename,datasetname,data,start,count)
h5write(filename,datasetname,data,start,count,stride)
```

## Description

`h5write(filename,datasetname,data)` writes `data` to an entire data set, `datasetname`, in the HDF5 file, `filename`.

`h5write(filename,datasetname,data,start,count)` writes a subset of the data to a data set, `datasetname`, in the HDF5 file, `filename`. `start` is a one-based index value that specifies the first element to be written. `count` specifies the number of elements to write along each dimension. `h5write` extends an extendable data set along any unlimited dimensions, if necessary.

`h5write(filename,datasetname,data,start,count,stride)` writes a hyperslab of data, where `stride` specifies the inter-element spacing along each dimension.

## Input Arguments

### **filename**

Text string specifying the name of an HDF5 file.

### **Default:**

### **datasetname**

Text string specifying the name of a data set in the HDF5 file.

### **Default:**

**data**

Data to be written to the HDF5 file. You can specify only floating-point and integer data sets.

**Default:****start**

Numeric index value specifying where in the data set to start writing to the file.

**Default:****count**

Numeric value specifying how much data to write to the file.

**Default:****stride**

Numeric value specifying the interelement spacing of data to write to the file.

**Default:** Vector of ones.

## Examples

**Write to Entire Data Set**

Write random values to a data set named DS1.

```
h5create('myfile.h5', '/DS1', [10 20])
mydata = rand(10,20);
h5write('myfile.h5', '/DS1', mydata)
```

Display the contents of the file.

```
h5disp('myfile.h5')
```

```
HDF5 myfile.h5
Group '/'
```

```

Dataset 'DS1'
 Size: 10x20
 MaxSize: 10x20
 Datatype: H5T_IEEE_F64LE (double)
 ChunkSize: []
 Filters: none
 FillValue: 0.000000

```

### Write to Block of Data Set

Write a hyperslab of data to the last 5-by-7 block of a data set.

```

h5create('myfile.h5', '/DS2', [10 20])
mydata = rand(5,7);
h5write('myfile.h5', '/DS2', mydata, [6 14], [5 7])

```

### Append Data to Unlimited Data Set

```

h5create('myfile.h5', '/DS3', [20 Inf], 'ChunkSize', [5 5]);
for j = 1:10
 data = j*ones(20,1);
 start = [1 j];
 count = [20 1];
 h5write('myfile.h5', '/DS3', data, start, count);
end
h5disp('myfile.h5');

```

```

HDF5 myfile.h5
Group '/'
 Dataset 'DS3'
 Size: 20x10
 MaxSize: 20xInf
 Datatype: H5T_IEEE_F64LE (double)
 ChunkSize: 5x5
 Filters: none
 FillValue: 0.000000

```

- “Exporting to HDF5 Files”

## Limitations

- `h5write` supports only floating point and integer data sets. To write to string data sets, you must use the H5D package.

## **More About**

### **Hyperslab**

A hyperslab is a collection of points in a data space. The points can be contiguous or form a regular pattern of points or blocks in a data space.

### **See Also**

`h5read` | `h5create` | `h5writeatt` | `h5disp` | `H5D.create` | `H5D.write`

**Introduced in R2011a**

# h5writeatt

Write HDF5 attribute

## Syntax

```
h5writeatt(filename,location,attname,attvalue)
```

## Description

`h5writeatt(filename,location,attname,attvalue)` writes the attribute named `attname` with the value `attvalue` to the HDF5 file `filename`. The parent object `location` can be either a group or variable. `location` is the complete path name of the group or variable to which you want to associate the attribute.

## Input Arguments

### **filename**

Text string specifying the name of an HDF5 file.

### **Default:**

### **location**

Text string specifying the full path identifying a group or variable in an HDF5 file.

### **Default:**

### **attname**

Text string specifying the name of an attribute in an HDF5 file. If the attribute does not exist, `h5writeatt` creates the attribute with the name specified.

If the specified attribute already exists but does not have a datatype or dataspace consistent with `attvalue`, `h5writeatt` deletes the attribute and recreates it. String attributes are created with a scalar dataspace.

**Default:**

**attvalue**

Value to be written to the attribute in an HDF5 file.

**Default:**

## Examples

Create a root group attribute whose value is the current time.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
h5writeatt('myfile.h5','/','creation_date',datestr(now));
```

Create a double-precision data set attribute.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
attData = [0 1 2 3];
h5writeatt('myfile.h5','/g4/world','attr',attData);
h5disp('myfile.h5','/g4/world');
```

## See Also

# H5.close

Close HDF5 library

## Syntax

```
H5.close()
```

## Description

`H5.close()` closes the HDF5 library.

## See Also

`H5.open`

## **H5.garbage\_collect**

Free unused memory in HDF5 library

### **Syntax**

```
H5.garbage_collect()
```

### **Description**

`H5.garbage_collect()` frees unused memory in the HDF5 library.

## H5.get\_libversion

Version of HDF5 library

### Syntax

```
[majnum,minnum,relnum] = H5.get_libversion()
```

### Description

[majnum,minnum,relnum] = H5.get\_libversion() returns the version of the HDF5 library in use.

## **H5.open**

Open HDF5 library

### **Syntax**

`H5.open()`

### **Description**

`H5.open()` opens the HDF5 library.

### **See Also**

`H5.close`

## H5.set\_free\_list\_limits

Set size limits on free lists

### Syntax

```
H5.set_free_list_limits(reg_global_lim,reg_list_lim,arr_global_lim,arr_list_li
```

### Description

H5.set\_free\_list\_limits(reg\_global\_lim,reg\_list\_lim,arr\_global\_lim,arr\_list\_li  
sets size limits on all types of free lists.

## **H5A.close**

Close specified attribute

### **Syntax**

```
H5A.close(attr_id)
```

### **Description**

`H5A.close(attr_id)` terminates access to the attribute specified by `attr_id`, releasing the identifier.

### **See Also**

`H5A.open`

# H5A.create

Create attribute

## Syntax

```
attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id)
attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id,aapl_id)
```

## Description

`attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id)` creates the attribute name that is attached to the object specified by `loc_id`. `loc_id` is a group, dataset, or named datatype identifier. The datatype and dataspace identifiers of the attribute, `type_id` and `space_id`, respectively, are created with the H5T and H5S interfaces. The attribute property list, `acpl_id`, is currently unused and should be set to 'H5P\_DEFAULT'. This interface corresponds to the 1.6.x version of H5Acreate.

`attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id,aapl_id)` creates the attribute with the additional attribute access property list identifier `aapl_id`. `aapl_id` should currently be set to 'H5P\_DEFAULT'. This interface corresponds to the 1.8.x version of H5Acreate.

## Examples

```
acpl_id = H5P.create('H5P_ATTRIBUTE_CREATE');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
space_id = H5S.create('H5S_SCALAR');
fid = H5F.create('myfile.h5');
attr_id = H5A.create(fid,'my_attr',type_id,space_id,acpl_id);
H5A.close(attr_id);
H5F.close(fid);
```

## See Also

[H5A.close](#) | [H5P.create](#)

## H5A.delete

Delete attribute

### Syntax

```
H5A.delete(loc_id,name)
```

### Description

`H5A.delete(loc_id,name)` removes the attribute specified by `name` from the dataset, group, or named datatype specified by `loc_id`.

### Examples

Delete a root group attribute.

```
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'example.h5');
copyfile(srcFile, 'myfile.h5');
fileattrib('myfile.h5', '+w');
fid = H5F.open('myfile.h5', 'H5F_ACC_RDWR', 'H5P_DEFAULT');
gid = H5G.open(fid, '/');
H5A.delete(gid, 'attr1');
H5G.close(gid);
H5F.close(fid);
```

# H5A.get\_info

Information about attribute

## Syntax

```
info = H5A.get_info(attr_id)
```

## Description

`info = H5A.get_info(attr_id)` returns information about an attribute specified by `attr_id`.

## Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/');
attr_id = H5A.open(gid, 'attr1');
info = H5A.get_info(attr_id);
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

## See Also

H5A.open

## H5A.get\_name

Attribute name

### Syntax

```
attr_name = H5A.get_name(attr_id)
```

### Description

`attr_name = H5A.get_name(attr_id)` returns the name of the attribute specified by `attr_id`.

### Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/g1/g1.1');
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_INC';
attr_id = H5A.open_by_idx(gid, 'dset1.1.1', idx_type, order, 0);
name = H5A.get_name(attr_id);
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

### See Also

`H5A.open_by_idx`

# H5A.get\_space

Copy of attribute data space

## Syntax

```
dspace_id = H5A.get_space(attr_id)
```

## Description

`dspace_id = H5A.get_space(attr_id)` returns a copy of the data space for the attribute specified by `attr_id`.

## Examples

Retrieve the dimensions of an attribute data space.

```
fid = H5F.open('example.h5');
attr_id = H5A.open(fid, 'attr2');
space = H5A.get_space(attr_id);
[~, dims] = H5S.get_simple_extent_dims(space);
H5A.close(attr_id);
H5F.close(fid);
```

## See Also

[H5A.open](#) | [H5S.close](#)

## H5A.get\_type

Copy of attribute data type

### Syntax

```
type_id = H5A.get_type(attr_id)
```

### Description

`type_id = H5A.get_type(attr_id)` returns a copy of the data type for the attribute specified by `attr_id`.

### Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/');
attr_id = H5A.open(gid, 'attr1');
type_id = H5A.get_type(attr_id);
H5T.close(type_id);
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

### See Also

[H5A.open](#) | [H5T.close](#)

## H5A.iterate

Execute function for attributes attached to object

### Syntax

```
[status,idx_stop,cdata_out] =
H5A.iterate(obj_id,idx_type,order,idx_start,iter_func,cdata_in)
H5A.iterate(loc_id,attr_idx,iterator_func)
```

### Description

```
[status,idx_stop,cdata_out] =
H5A.iterate(obj_id,idx_type,order,idx_start,iter_func,cdata_in)
```

executes the specified function `iter_func` for each attribute connected to an object. `obj_id` identifies the object to which attributes are attached. `idx_type` is the type of index and valid values include the following.

|                      |                                          |
|----------------------|------------------------------------------|
| 'H5_INDEX_NAME'      | An alpha-numeric index by attribute name |
| 'H5_INDEX_CRT_ORDER' | An index by creation order               |

`order` specifies the index traversal order. Valid values include the following.

|                  |                                          |
|------------------|------------------------------------------|
| 'H5_ITER_INC'    | Iteration from beginning to end          |
| 'H5_ITER_DEC'    | Iteration from end to beginning          |
| 'H5_ITER_NATIVE' | Iteration in the fastest available order |

`idx_start` specifies the starting point of the iteration. `idx_stop` returns the point at which iteration was stopped. This allows an interrupted iteration to be resumed.

The callback function, `iter_func`, must have the following signature:

```
[status,cdata_out] = iter_func(obj_id,attr_name,info,cdata_in)
```

`cdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func cdata_in` parameter. The `cdata_out` of an iteration step

forms the `cdata_in` for the next iteration step. Then, the final `cdata_out` at the end of the iteration is returned to the caller as `cdata_out`. This form of `H5A.iterate` corresponds to the `H5Aiterate2` function in the HDF5 C API.

`status` value returned by `iter_func` is interpreted as follows.

|          |                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------|
| zero     | Continues with the iteration or returns zero status value to the caller if all members have been processed |
| positive | Stops the iteration and returns the positive status value to the caller                                    |
| negative | Stops the iteration and throws an error indicating failure                                                 |

`H5A.iterate(loc_id,attr_idx,iterator_func)` executes the specified function for each attribute of the group, dataset, or named datatype specified by `loc_id`. The `attr_idx` argument specifies where the iteration begins. `iterator_func` must be a function handle.

The iterator function must have the following signature:

```
status = iterator_func(loc_id,attr_name)
```

`loc_id` still specifies the group, dataset, or named data type passed into `H5A.iterate`, and `attr_name` specifies the current attribute. This form of `H5A.iterate` corresponds to `H5Aiterate1` function in the HDF5 C API.

# H5A.open

Open attribute

## Syntax

```
attr_id = H5A.open(obj_id,attr_name)
attr_id = H5A.open(obj_id,attr_name,aapl_id)
```

## Description

`attr_id = H5A.open(obj_id,attr_name)` opens an attribute for an object specified by a parent object identifier and attribute name.

`attr_id = H5A.open(obj_id,attr_name,aapl_id)` opens an attribute with an attribute access property list identifier, `aapl_id`. The only currently valid value for `aapl_id` is 'H5P\_DEFAULT'.

## Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/');
attr_id = H5A.open(gid, 'attr1');
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

## See Also

[H5A.close](#) | [H5A.open\\_by\\_idx](#) | [H5A.open\\_by\\_name](#)

## H5A.open\_by\_idx

Open attribute specified by index

### Syntax

```
attr_id = H5A.open_by_idx(loc_id, obj_name, idx_type, order, n)
attr_id =
H5A.open_by_idx(loc_id, obj_name, idx_type, order, n, aapl_id, lapl_id)
```

### Description

`attr_id = H5A.open_by_idx(loc_id, obj_name, idx_type, order, n)` opens an existing attribute at index `n` attached to an object specified by its location, `loc_id`, and name, `obj_name`.

`idx_type` is the type of index and valid values include the following.

|                      |                                          |
|----------------------|------------------------------------------|
| 'H5_INDEX_NAME'      | An alpha-numeric index by attribute name |
| 'H5_INDEX_CRT_ORDER' | An index by creation order               |

`order` specifies the index traversal order. Valid values include the following.

|                  |                                          |
|------------------|------------------------------------------|
| 'H5_ITER_INC'    | Iteration from beginning to end          |
| 'H5_ITER_DEC'    | Iteration from end to beginning          |
| 'H5_ITER_NATIVE' | Iteration in the fastest available order |

`attr_id = H5A.open_by_idx(loc_id, obj_name, idx_type, order, n, aapl_id, lapl_id)` opens an attribute with attribute access property list, `aapl_id`, and link access property list, `lapl_id`. The `aapl_id` argument must currently be specified as 'H5P\_DEFAULT'. Also, `lapl_id` can be specified by 'H5P\_DEFAULT'.

### Examples

Loop through a set of dataset attributes in reverse alphabetical order.

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/g1/g1.1');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
info = H5O.get_info(dset_id);
for idx = 0:info.num_attrs-1
 attr_id = H5A.open_by_idx(gid, 'dset1.1.1', 'H5_INDEX_NAME', 'H5_ITER_DEC', idx);
 fprintf('attribute name: %s\n', H5A.get_name(attr_id));
 H5A.close(attr_id);
end
H5G.close(gid);
H5F.close(fid);
```

## See Also

[H5A.close](#) | [H5A.open](#) | [H5A.open\\_by\\_name](#)

## H5A.open\_by\_name

Open attribute specified by name

### Syntax

```
attr_id = H5A.open_by_name(loc_id,obj_name,attr_name)
attr_id =
H5A.open_by_name(loc_id,obj_name,attr_name,aapl_id,lapl_id)
```

### Description

`attr_id = H5A.open_by_name(loc_id,obj_name,attr_name)` opens an existing attribute `attr_name` attached to an object specified by its location `loc_id` and name `obj_name`.

`attr_id = H5A.open_by_name(loc_id,obj_name,attr_name,aapl_id,lapl_id)` opens an existing attribute with the attribute access property list `aapl_id` and link access property list `lapl_id`. `aapl_id` must be specified as 'H5P\_DEFAULT'. `lapl_id` may also be specified by 'H5P\_DEFAULT'.

### Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g1/g1.1');
attr_id = H5A.open_by_name(gid,'dset1.1.1','attr1');
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

### See Also

[H5A.close](#) | [H5A.open](#) | [H5A.open\\_by\\_idx](#)

# H5A.read

Read attribute

## Syntax

```
attr = H5A.read(attr_id)
attr = H5A.read(attr_id, mem_type_id)
```

## Description

`attr = H5A.read(attr_id)` reads the attribute specified by `attr_id`. MATLAB will determine the appropriate memory datatype.

`attr = H5A.read(attr_id, mem_type_id)` reads the attribute specified by `attr_id`. `mem_type_id` specifies the attribute's memory datatype and should usually be given as `'H5ML_DEFAULT'`, which specifies that MATLAB will determine the appropriate memory datatype.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. If the HDF5 library reports the attribute size as 3-by-4-by-5, then the corresponding MATLAB array size is 5-by-4-by-3. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

## Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/');
attr_id = H5A.open(gid, 'attr1');
data = H5A.read(attr_id);
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

**See Also**

H5A.open | H5A.write

# H5A.write

Write attribute

## Syntax

```
H5A.write(attr_id,type_id,buf)
```

## Description

`H5A.write(attr_id,type_id,buf)` writes the data in `buf` into the attribute specified by `attr_id`. `type_id` specifies the attribute's memory datatype. The memory datatype should be `'H5ML_DEFAULT'`, which specifies that MATLAB should determine the appropriate memory datatype.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. If the MATLAB array size is 5-by-4-by-3, then the HDF5 library should be reporting the attribute size as 3-by-4-by-5. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

## Examples

Write a scalar double precision attribute.

```
acpl = H5P.create('H5P_ATTRIBUTE_CREATE');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
space_id = H5S.create('H5S_SCALAR');
fid = H5F.create('myfile.h5');
attr_id = H5A.create(fid,'my_attr',type_id,space_id,acpl);
H5A.write(attr_id,'H5ML_DEFAULT',10.0)
H5A.close(attr_id);
H5F.close(fid);
H5T.close(type_id);
```

## See Also

H5A.read

## H5D.close

Close dataset

### Syntax

```
H5D.close(dataset_id)
```

### Description

`H5D.close(dataset_id)` ends access to a dataset specified by `dataset_id` and releases resources used by it.

### See Also

`H5D.create` | `H5D.open`

## H5D.create

Create new dataset

### Syntax

```
dataset_id = H5D.create(loc_id,name,type_id,space_id,plist_id)
dataset_id =
H5D.create(loc_id,name,type_id,space_id,lcpl_id,dcpl_id,dapl_id)
```

### Description

`dataset_id = H5D.create(loc_id,name,type_id,space_id,plist_id)` creates the data set specified by `name` in the file or in the group specified by `loc_id`. `type_id` and `space_id` identify the datatype and dataspace, respectively. `plist_id` identifies the dataset creation property list. This interface corresponds to the `H5Dcreate1` function in the HDF5 library C 1.6 API.

```
dataset_id =
H5D.create(loc_id,name,type_id,space_id,lcpl_id,dcpl_id,dapl_id)
```

creates the data set with three distinct property lists:

|                      |                                |
|----------------------|--------------------------------|
| <code>lcpl_id</code> | link creation property list    |
| <code>dcpl_id</code> | dataset creation property list |
| <code>dapl_id</code> | dataset access property list   |

This interface corresponds to the `H5Dcreate` function in the HDF5 library C 1.8 API.

### Examples

Create a 10x5 double precision dataset with default property list settings.

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [10 5];
h5_dims = fliplr(dims);
```

```
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = 'H5P_DEFAULT';
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5S.close(space_id);
H5T.close(type_id);
H5D.close(dset_id);
H5F.close(fid);
h5disp('myfile.h5');
```

Create a 6x3 fixed length string dataset. Each string will have a length of 4 characters.

```
fid = H5F.create('myfile_strings.h5');
type_id = H5T.copy('H5T_C_S1');
H5T.set_size(type_id,4);
dims = [6 3];
h5_dims = flip1r(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = 'H5P_DEFAULT';
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5S.close(space_id);
H5T.close(type_id);
H5D.close(dset_id);
H5F.close(fid);
h5disp('myfile_strings.h5');
```

## See Also

[H5D.close](#) | [H5S.close](#) | [H5S.create\\_simple](#) | [H5T.copy](#)

## H5D.get\_access\_plist

Copy of dataset access property list

### Syntax

```
plist_id = H5D.get_access_plist(dataset_id)
```

### Description

`plist_id = H5D.get_access_plist(dataset_id)` returns a copy of the dataset access property list used to open the specified dataset.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
dapl = H5D.get_access_plist(dset_id);
H5P.close(dapl);
H5D.close(dset_id);
H5F.close(fid);
```

### See Also

`H5D.get_create_plist` | `H5P.close`

## H5D.get\_create\_plist

Copy of dataset creation property list

### Syntax

```
plist_id = H5D.get_create_plist(dataset_id)
```

### Description

`plist_id = H5D.get_create_plist(dataset_id)` returns the identifier to a copy of the dataset creation property list for the dataset specified by `dataset_id`.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
dcpl = H5D.get_create_plist(dset_id);
H5P.close(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

### See Also

`H5D.get_access_plist` | `H5P.close`

## H5D.get\_offset

Location of dataset in file

### Syntax

```
offset = H5D.get_offset(dataset_id)
```

### Description

`offset = H5D.get_offset(dataset_id)` returns the location in the file of the dataset specified by `dataset_id`. The location is expressed as an offset, in bytes, from the beginning of the file.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
offset = H5D.get_offset(dset_id);
H5D.close(dset_id);
H5F.close(fid);
```

## H5D.get\_space

Copy of dataset data space

### Syntax

```
dspace_id = H5D.get_space(dataset_id)
```

### Description

`dspace_id = H5D.get_space(dataset_id)` returns an identifier for a copy of the data space for a dataset.

### Examples

Retrieve the dimensions of an attribute data space.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
space = H5D.get_space(dset_id);
[~,dims] = H5S.get_simple_extent_dims(space);
H5S.close(space);
H5D.close(dset_id);
H5F.close(fid);
```

### See Also

`H5D.open` | `H5S.close`

# H5D.get\_space\_status

Determine if space is allocated

## Syntax

```
status = H5D.get_space_status(dataset_id)
```

## Description

`status = H5D.get_space_status(dataset_id)` determines whether space has been allocated for the dataset specified by `dataset_id`.

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
status = H5D.get_space_status(dset_id);
switch(status)
 case H5ML.get_constant_value('H5D_SPACE_STATUS_NOT_ALLOCATED')
 fprintf('Not allocated.\n');
 case H5ML.get_constant_value('H5D_SPACE_STATUS_ALLOCATED')
 fprintf('Allocated.\n');
 case H5ML.get_constant_value('H5D_SPACE_STATUS_PART_ALLOCATED')
 fprintf('Part allocated.\n');
end
H5D.close(dset_id);
H5F.close(fid);
```

## See Also

`H5D.get_space`

## H5D.get\_storage\_size

Determine required storage size

### Syntax

```
dataset_size = H5D.get_storage_size(dataset_id)
```

### Description

`dataset_size = H5D.get_storage_size(dataset_id)` returns the amount of storage that is required for the dataset specified by `dataset_id`.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
dataset_size = H5D.get_storage_size(dset_id);
H5D.close(dset_id);
H5F.close(fid);
```

# H5D.get\_type

Copy of datatype

## Syntax

```
type_id = H5D.get_type(dataset_id)
```

## Description

`type_id = H5D.get_type(dataset_id)` returns an identifier for a copy of the data type for the dataset specified by `dataset_id`.

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
type_id = H5D.get_type(dset_id);
H5T.close(type_id);
H5D.close(dset_id);
H5F.close(fid);
```

## See Also

`H5T.close`

## H5D.open

Open specified dataset

### Syntax

```
dataset_id = H5D.open(loc_id,name)
dataset_id = H5D.open(loc_id,name,dapl_id)
```

### Description

`dataset_id = H5D.open(loc_id,name)` opens the dataset specified by `name` in the file or group specified by `loc_id`.

`dataset_id = H5D.open(loc_id,name,dapl_id)` opens the dataset specified by `name` in the file or group specified by `loc_id`. The dataset access property list, `dapl_id`, provides information regarding access to the dataset.

### Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g2');
dset_id = H5D.open(gid,'dset2.2');
H5D.close(dset_id);
H5F.close(fid);
```

### See Also

`H5D.close`

# H5D.read

Read data from HDF5 dataset

## Syntax

```
data = H5D.read(dataset_id)
data =
H5D.read(dataset_id,mem_type_id,mem_space_id,file_space_id,dxpl)
```

## Description

`data = H5D.read(dataset_id)` reads the entire dataset specified by `dataset_id`.

`data = H5D.read(dataset_id,mem_type_id,mem_space_id,file_space_id,dxpl)` reads the dataset specified by `dataset_id`. The `mem_type_id` input specifies the memory data type and should usually be `'H5ML_DEFAULT'` to allow MATLAB to determine the appropriate value. `mem_space_id` describes how the data is to be arranged in memory and should usually be `'H5S_ALL'`. The `file_space_id` input describes how the data is to be selected from the file. It also can be given as `'H5S_ALL'`, but this results in the entire dataset being read into memory. `dxpl` is the dataset transfer property list identifier and should usually be `'H5P_DEFAULT'`.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

## Examples

Read an entire dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
data = H5D.read(dset_id);
```

```
H5D.close(dset_id);
H5F.close(fid);
```

Read the 2x3 hyperslab starting in the 4th row and 5th column of the example dataset.

```
plist = 'H5P_DEFAULT';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g1/g1.1/dset1.1.1');
dims = fliplr([2 3]);
mem_space_id = H5S.create_simple(2,dims,[]);
file_space_id = H5D.get_space(dset_id);
offset = fliplr([3 4]);
block = fliplr([2 3]);
H5S.select_hyperslab(file_space_id, 'H5S_SELECT_SET', offset, [], [], block);
data = H5D.read(dset_id, 'H5ML_DEFAULT', mem_space_id, file_space_id, plist);
H5D.close(dset_id);
H5F.close(fid);
```

## See Also

H5D.open | H5D.write | H5S.create\_simple

## H5D.set\_extent

Change size of dataset dimensions

### Syntax

```
H5D.set_extent(dset_id,h5_extents)
```

### Description

`H5D.set_extent(dset_id,h5_extents)` changes the dimensions of the dataset `dset_id` to the sizes specified in `h5_extents`.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_extents` parameter assumes C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

### Examples

Extend an unlimited one-dimensional dataset from a length of 10 to a length of 20.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
dset_id = H5D.open(fid,'/g4/time');
H5D.set_extent(dset_id,20);
H5D.close(dset_id);
H5F.close(fid);
```

## H5D.vlen\_get\_buf\_size

Determine variable length storage requirements

### Syntax

```
size = H5D.vlen_get_buf_size(dataset_id,type_id,space_id)
```

### Description

`size = H5D.vlen_get_buf_size(dataset_id,type_id,space_id)` determines the number of bytes required to store the VL data from the dataset, using the `space_id` for the selection in the dataset on disk and the `type_id` for the memory representation of the VL data in memory.

## H5D.write

Write data to HDF5 dataset

### Syntax

```
H5D.write(dataset_id,mem_type_id,mem_space_id,file_space_id,plist_id,buf)
```

### Description

`H5D.write(dataset_id,mem_type_id,mem_space_id,file_space_id,plist_id,buf)` writes the dataset specified by `dataset_id` from the application memory buffer `buf` into the file. `plist_id` specifies the data transfer properties. `mem_type_id` identifies the memory datatype of the dataset. `mem_space_id` and `file_space_id` define the part of the dataset to write. The memory datatype should usually be `'H5ML_DEFAULT'`, which specifies that MATLAB should determine the appropriate memory datatype.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

### Examples

Write to the entire 36-by-19 `/g4/world` example dataset.

```
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'example.h5');
copyfile(srcFile, 'myfile.h5');
fileattrib('myfile.h5', '+w');
plist = 'H5P_DEFAULT';
fid = H5F.open('myfile.h5', 'H5F_ACC_RDWR', plist);
dset_id = H5D.open(fid, '/g4/world');
dims = [36 19];
data = rand(dims);
H5D.write(dset_id, 'H5ML_DEFAULT', 'H5S_ALL', 'H5S_ALL', plist, data);
H5D.close(dset_id);
H5F.close(fid);
```

Write to the entire two-element /g3/VLstring dataset.

```
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'example.h5');
copyfile(srcFile, 'myfile.h5');
fileattrib('myfile.h5', '+w');
h5disp('myfile.h5', '/g3/VLstring');
plist = 'H5P_DEFAULT';
fid = H5F.open('myfile.h5', 'H5F_ACC_RDWR', plist);
dset_id = H5D.open(fid, '/g3/VLstring');
data = {'dogs'; 'dogs and cats'};
H5D.write(dset_id, 'H5ML_DEFAULT', 'H5S_ALL', 'H5S_ALL', plist, data);
H5D.close(dset_id);
H5F.close(fid);
data_out = h5read('myfile.h5', '/g3/VLstring');
```

Write a 10-by-5 block of data to the location starting at row index 15 and column index 5 of the same dataset. Recall that indexing is zero-based.

```
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'example.h5');
copyfile(srcFile, 'myfile.h5');
fileattrib('myfile.h5', '+w');
plist = 'H5P_DEFAULT';
fid = H5F.open('myfile.h5', 'H5F_ACC_RDWR', plist);
dset_id = H5D.open(fid, '/g4/world');
start = [15 5];
h5_start = fliplr(start);
block = [10 5];
h5_block = fliplr(block);
mem_space_id = H5S.create_simple(2, h5_block, []);
file_space_id = H5D.get_space(dset_id);
H5S.select_hyperslab(file_space_id, 'H5S_SELECT_SET', h5_start, [], [], h5_block);
data = rand(block);
H5D.write(dset_id, 'H5ML_DEFAULT', mem_space_id, file_space_id, plist, data);
H5D.close(dset_id);
H5F.close(fid);
```

## See Also

H5D.read

# H5DS.attach\_scale

Attach dimension scale to specific dataset dimension

## Syntax

```
H5DS.attach_scale(dataset_id,dimscale_id,idx)
```

## Description

H5DS.attach\_scale(dataset\_id,dimscale\_id,idx) attaches a dimension scale `dimscale_id` to dimension `idx` of the dataset `dataset_id`.

---

**Note:** The ordering of the dimension scale indices are the same as the HDF5 library C API.

---

## Examples

Add the 'lon' and 'lat' dimension scales to the 'world' dataset.

```
plist = 'H5P_DEFAULT';
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
world_dset_id = H5D.open(fid,'/g4/world',plist);
lat_dset_id = H5D.open(fid,'/g4/lat',plist);
lon_dset_id = H5D.open(fid,'/g4/lon',plist);
H5DS.attach_scale(world_dset_id,lat_dset_id,0);
H5DS.attach_scale(world_dset_id,lon_dset_id,1);
H5D.close(lat_dset_id);
H5D.close(lon_dset_id);
H5D.close(world_dset_id);
H5F.close(fid);
```

## See Also

H5DS.detach\_scale

## H5DS.detach\_scale

Detach dimension scale from specific dataset dimension

### Syntax

```
H5DS.detach_scale(dataset_id,dimscale_id,idx)
```

### Description

H5DS.detach\_scale(dataset\_id,dimscale\_id,idx) detaches dimension scale `dimscale_id` from dimension `idx` of the dataset `dataset_id`.

---

**Note:** The ordering of the dimension scale indices are the same as the HDF5 library C API.

---

### See Also

H5DS.attach\_scale

# H5DS.get\_label

Retrieve label from specific dataset dimension

## Syntax

```
label = H5DS.get_label(dataset_id, idx)
```

## Description

`label = H5DS.get_label(dataset_id, idx)` retrieves the label for dimension `idx` of the dataset `dataset_id`.

---

**Note:** The ordering of the dimension scale indices are the same as the HDF5 library C API.

---

## Examples

```
fid = H5F.open('example.h5');
world_dset_id = H5D.open(fid, '/g4/world');
label = H5DS.get_label(world_dset_id, 0);
H5D.close(world_dset_id);
H5F.close(fid);
```

## See Also

`H5DS.set_label`

## H5DS.get\_num\_scales

Number of scales attached to dataset dimension

### Syntax

```
num_scales = H5DS.get_num_scales(dataset_id, idx)
```

### Description

`num_scales = H5DS.get_num_scales(dataset_id, idx)` determines the number of dimension scales that are attached to dimension `idx` of the dataset `dataset_id`.

### Examples

```
fid = H5F.open('example.h5');
world_dset_id = H5D.open(fid, '/g4/world');
num_scales = H5DS.get_num_scales(world_dset_id, 0);
H5D.close(world_dset_id);
H5F.close(fid);
```

# H5DS.get\_scale\_name

Name of dimension scale

## Syntax

```
name = H5DS.get_scale_name(dimscale_id)
```

## Description

`name = H5DS.get_scale_name(dimscale_id)` retrieves the name of the dimension scale `dimscale_id`.

## Examples

```
fid = H5F.open('example.h5');
lat_dset_id = H5D.open(fid, '/g4/lat');
scale_name = H5DS.get_scale_name(lat_dset_id);
H5D.close(lat_dset_id);
H5F.close(fid);
```

## See Also

`H5DS.set_scale`

## H5DS.is\_scale

Determine if dataset is a dimension scale

### Syntax

```
bool = H5DS.is_scale(dataset_id)
```

### Description

`bool = H5DS.is_scale(dataset_id)` determines whether the dataset `dataset_id` is a dimension scale.

### Examples

```
fid = H5F.open('example.h5');
lat_dset_id = H5D.open(fid, '/g4/lat');
if H5DS.is_scale(lat_dset_id)
 fprintf('/g4/lat is a dimension scale.\n');
else
 fprintf('/g4/lat is not a dimension scale.\n');
end
H5D.close(lat_dset_id);
H5F.close(fid);
```

## H5DS.iterate\_scales

Iterate on scales attached to dataset dimension

### Syntax

```
[status,idx_out,opdata_out] =
H5DS.iterate_scales(dset_id,dim,idx_in,iter_func,opdata_in)
```

### Description

[status,idx\_out,opdata\_out] = H5DS.iterate\_scales(dset\_id,dim,idx\_in,iter\_func,opdata\_in) iterates over the scales attached to dimension `dim` of the dataset `dset_id` to perform a common operation whose function handle is `iter_func`.

`idx_in` specifies the starting point of the iteration. `idx_out` returns the point at which iteration was stopped. This allows an interrupted iteration to be resumed. If `idx_in` is `[]`, then the iterator starts at the first member.

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] =
iter_func(dset_id,dim,dimscale_id,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`dimscale_id` specifies the current dimension scale dataset identifier and `dim` is the associated dimension.

status value returned by `iter_func` is interpreted as follows:

|      |                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------|
| zero | Continues with the iteration or returns zero status value to the caller if all members have been processed |
|------|------------------------------------------------------------------------------------------------------------|

|          |                                                                         |
|----------|-------------------------------------------------------------------------|
| positive | Stops the iteration and returns the positive status value to the caller |
| negative | Stops the iteration and throws an error indicating failure              |

# H5DS.set\_label

Set label for dataset dimension

## Syntax

```
H5DS.set_label(dataset_id,idx,label)
```

## Description

H5DS.set\_label(dataset\_id,idx,label) sets a label for dimension idx of the dataset dataset\_id.

---

**Note:** The ordering of the dimension scale indices are the same as the HDF5 library C API.

---

## Examples

```
plist = 'H5P_DEFAULT';
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
world_dset_id = H5D.open(fid,'/g4/world',plist);
H5DS.set_label(world_dset_id,0,'latitude');
H5DS.set_label(world_dset_id,1,'longitude');
H5D.close(world_dset_id);
H5F.close(fid);
```

## See Also

H5DS.get\_label

## H5DS.set\_scale

Convert dataset to dimension scale

### Syntax

```
H5DS.set_scale(dataset_id,dim_name)
```

### Description

H5DS.set\_scale(dataset\_id,dim\_name) converts the dataset, dataset\_id, to a dimension scale with name dim\_name.

### Examples

Create a dimension scale with name 'xdim'. The dataset has the name, 'x'.

```
fid = H5F.create('myfile.h5');
space_id = H5S.create_simple(1,10,10);
dtype = 'H5T_NATIVE_INT';
dcpl = 'H5P_DEFAULT';
dset_id = H5D.create(fid,'x',dtype,space_id,dcpl);
H5DS.set_scale(dset_id,'xdim');
H5S.close(space_id);
H5D.close(dset_id);
H5F.close(fid);
```

### See Also

H5DS.get\_scale\_name

## **H5E.clear**

Clear error stack

### **Syntax**

```
H5E.clear()
```

### **Description**

`H5E.clear()` clears the error stack for the current thread.

## **H5E.get\_major**

Description of major error number

### **Syntax**

```
err_string = H5E.get_major(major_number)
```

### **Description**

`err_string = H5E.get_major(major_number)` returns a character string describing an error specified by the major error number, `major_number`.

The HDF5 group has deprecated the use of this function.

### **See Also**

`H5E.get_minor`

## H5E.get\_minor

Description of minor error number

### Syntax

```
err_string = H5E.get_minor(minor_number)
```

### Description

`err_string = H5E.get_minor(minor_number)` returns a character string describing an error specified by the minor error number, `minor_number`.

The HDF5 group has deprecated the use of this function.

### See Also

`H5E.get_major`

## H5E.walk

Walk error stack

### Syntax

```
H5E.walk(direction, func)
```

### Description

`H5E.walk(direction, func)` walks the error stack for the current thread and calls the specified function for each error along the way. `func` is a function handle. `direction` specifies how the error stack is traversed and can be given by one of the following strings or the numeric equivalent.

```
'H5E_WALK_UPWARD'
```

```
'H5E_WALK_DOWNWARD'
```

The specified function must have the following signature:

```
status = func(n, error_struct)
```

where `n` is the indexed position of the error in the stack and `error_struct` is a structure with the following fields:

|                        |                                      |
|------------------------|--------------------------------------|
| <code>maj_num</code>   | Major error number                   |
| <code>min_num</code>   | Minor error number                   |
| <code>func_name</code> | Function in which the error occurred |
| <code>file_name</code> | File in which the error occurred     |
| <code>line</code>      | Line in file where error occurs      |
| <code>desc</code>      | Optional supplied description        |

This function corresponds to the `H5Ewalk1` function in the HDF5 library C API.

### See Also

`H5ML.get_constant_value`

# H5F.close

Close HDF5 file

## Syntax

```
H5F.close(file_id)
```

## Description

`H5F.close(file_id)` terminates access to HDF5 file identified by `file_id`, flushing all data to storage.

## See Also

`H5F.open`

## H5F.create

Create HDF5 file

### Syntax

```
file_id = H5F.create(filename)
file_id = H5F.create(name, flags, fcpl_id, fapl_id)
```

### Description

`file_id = H5F.create(filename)` creates the file specified by `filename` with default library properties if the file does not already exist.

`file_id = H5F.create(name, flags, fcpl_id, fapl_id)` creates the file specified by `name`. `flags` specifies whether to truncate the file, if it already exists, or to fail if the file already exists. `flags` can be specified by one of the following strings or the numeric equivalent:

|                 |                                              |
|-----------------|----------------------------------------------|
| 'H5F_ACC_TRUNC' | overwrite any existing file by the same name |
| 'H5F_ACC_EXCL'  | do not overwrite an existing file            |

`fcpl_id` is the file creation property list identifier. `fapl_id` is the file access property list identifier. A value of 'H5P\_DEFAULT' for either property list indicates that the library should use default values for the appropriate property list.

### Examples

Create an HDF5 file called 'myfile.h5'.

```
fid = H5F.create('myfile.h5');
H5F.close(fid);
```

Create an HDF5 file called 'myfile.h5', overwriting any existing file by the same name. Default file access and file creation properties shall apply.

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcpl, fapl);
H5F.close(fid);
```

## See Also

[H5F.close](#) | [H5ML.get\\_constant\\_value](#) | [H5P.create](#)

## H5F.flush

Flush buffers to disk

### Syntax

```
H5F.flush(object_id,scope)
```

### Description

`H5F.flush(object_id,scope)` causes all buffers associated with a file to be immediately flushed to disk without removing the data from the cache. `object_id` can be any object associated with the file, including the file itself, a dataset, a group, an attribute, or a named data type. `scope` specifies whether the scope of the flushing action is global or local. `scope` may be one of the following strings:

```
'H5F_SCOPE_GLOBAL'
```

```
'H5F_SCOPE_LOCAL'
```

# H5F.get\_access\_plist

File access property list

## Syntax

```
fapl_id = H5F.get_access_plist(file_id)
```

## Description

`fapl_id = H5F.get_access_plist(file_id)` returns the file access property list identifier of the file specified by `file_id`.

## Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
H5P.close(fapl);
H5F.close(fid);
```

## See Also

`H5F.get_create_plist`

## H5F.get\_create\_plist

File creation property list

### Syntax

```
fcpl_id = H5F.get_create_plist(file_id)
```

### Description

`fcpl_id = H5F.get_create_plist(file_id)` returns a file creation property list identifier identifying the creation properties used to create the file specified by `file_id`.

### Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
H5P.close(fcpl);
H5F.close(fid);
```

### See Also

H5F.get\_access\_plist

# H5F.get\_filesize

Size of HDF5 file

## Syntax

```
size = H5F.get_filesize(file_id)
```

## Description

`size = H5F.get_filesize(file_id)` returns the size of the HDF5 file specified by `file_id`.

## **H5F.get\_freespace**

Amount of free space in file

### **Syntax**

```
free_space = H5F.get_freespace(file_id)
```

### **Description**

`free_space = H5F.get_freespace(file_id)` returns the amount of space that is unused by any objects in the file specified by `file_id`.

# H5F.get\_info

Global information about file

## Syntax

```
file_info = H5F.get_info(obj_id)
```

## Description

`file_info = H5F.get_info(obj_id)` returns global information for the file associated with the object identifier `obj_id`. For details about the fields of the `file_info` structure, please refer to the HDF5 documentation.

## Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, 'g2');
info = H5F.get_info(gid);
H5G.close(gid);
H5F.close(fid);
```

## H5F.get\_mdc\_config

Metadata cache configuration

### Syntax

```
config_struct = H5F.get_mdc_config(file_id)
```

### Description

`config_struct = H5F.get_mdc_config(file_id)` returns the current metadata cache configuration for the target file.

### Examples

```
fid = H5F.open('example.h5');
config = H5F.get_mdc_config(fid);
H5F.close(fid);
```

### See Also

`H5F.set_mdc_config`

# H5F.get\_mdc\_hit\_rate

Metadata cache hit-rate

## Syntax

```
hitRate = H5F.get_mdc_hit_rate(file_id)
```

## Description

`hitRate = H5F.get_mdc_hit_rate(file_id)` queries the metadata cache of the target file to obtain its hit-rate since the last time hit-rate statistics were reset. If the cache has not been accessed since the last time the hit-rate statistics were reset, the hit-rate is defined to be 0.0. The hit-rate is calculated as

$$(\text{cache hits} / (\text{cache hits} + \text{cache misses}))$$

## Examples

```
fid = H5F.open('example.h5');
hit_rate = H5F.get_mdc_hit_rate(fid);
H5F.close(fid);
```

## See Also

`H5F.get_mdc_config`

## H5F.get\_mdc\_size

Metadata cache size data

### Syntax

```
[max_sz,min_clean_sz,cursz,num_cur_entries] =
H5F.get_mdc_size(fileId)
```

### Description

```
[max_sz,min_clean_sz,cursz,num_cur_entries] =
H5F.get_mdc_size(fileId)
```

 queries the metadata cache of the target file to obtain current metadata cache size information.

### Examples

```
fid = H5F.open('example.h5');
[maxsz,minsz,cursz,nent] = H5F.get_mdc_size(fid);
H5F.close(fid);
```

### See Also

H5F.get\_mdc\_config

# H5F.get\_name

Name of HDF5 file

## Syntax

```
name = H5F.get_name(obj_id)
```

## Description

`name = H5F.get_name(obj_id)` returns the name of the file to which the object `obj_id` belongs. The object can be a group, dataset, attribute, or named data type.

## Examples

```
fid = H5F.open('example.h5');
name = H5F.get_name(fid);
H5F.close(fid);
```

## See Also

[H5A.get\\_name](#) | [H5I.get\\_name](#)

## H5F.get\_obj\_count

Number of open objects in HDF5 file

### Syntax

```
obj_count = H5F.get_obj_count(file_id, types)
```

### Description

`obj_count = H5F.get_obj_count(file_id, types)` returns the number of open object identifiers for the file specified by `file_id` for the specified type. `types` can be one of the following strings.

```
'H5F_OBJ_FILE '
'H5F_OBJ_DATASET '
'H5F_OBJ_GROUP '
'H5F_OBJ_DATATYPE '
'H5F_OBJ_ATTR '
'H5F_OBJ_ALL '
'H5F_OBJ_LOCAL '
```

### Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/g2');
obj_count = H5F.get_obj_count(fid, 'H5F_OBJ_GROUP');
H5G.close(gid);
H5F.close(fid);
```

### See Also

`H5F.get_obj_ids`

# H5F.get\_obj\_ids

List of open HDF5 file objects

## Syntax

```
[num_obj_ids,obj_id_list] = H5F.get_obj_ids(file_id,types,max_objs)
```

## Description

[num\_obj\_ids,obj\_id\_list] = H5F.get\_obj\_ids(file\_id,types,max\_objs) returns a list of all open identifiers for HDF5 objects of the type specified by `types` in the file specified by `file_id`. The `max_objs` input specifies the maximum number of object identifiers to return. `num_obj_ids` is the total number of objects in the list. `types` can be one of the following strings.

```
'H5F_OBJ_FILE '
'H5F_OBJ_DATASET '
'H5F_OBJ_GROUP '
'H5F_OBJ_DATATYPE '
'H5F_OBJ_ATTR '
'H5F_OBJ_ALL '
'H5F_OBJ_LOCAL '
```

## Examples

```
fid = H5F.open('example.h5');
gid1 = H5G.open(fid,'/g1');
gid2 = H5G.open(fid,'/g2');
gid3 = H5G.open(fid,'/g3');
gid4 = H5G.open(fid,'/g4');
[num_obj_ids,objs] = H5F.get_obj_ids(fid,'H5F_OBJ_GROUP',3);
H5G.close(gid1);
H5G.close(gid2);
```

```
H5G.close(gid3);
H5G.close(gid4);
H5F.close(fid);
```

**See Also**

H5F.get\_obj\_count

## H5F.is\_hdf5

Determine if file is HDF5

### Syntax

```
value = H5F.is_hdf5(name)
```

### Description

`value = H5F.is_hdf5(name)` returns a positive number if the file specified by `name` is in the HDF5 format, and zero if it is not. A negative return value indicates failure.

### Examples

```
value = H5F.is_hdf5('example.tif');
if value > 0
 fprintf('example.tif is an HDF5 file\n');
else
 fprintf('example.tif is not an HDF5 file\n');
end
```

## H5F.mount

Mount HDF5 file onto specified location

### Syntax

```
H5F.mount(loc_id,name,child_id,plist_id)
```

### Description

`H5F.mount(loc_id,name,child_id,plist_id)` mounts the file specified by `child_id` onto the group specified by `loc_id` and `name`, using the mount properties specified by `plist_id`.

### Examples

Mount one file with a dataset onto a group in a second file and access the dataset via the second file.

```
plist = 'H5P_DEFAULT';
fid2 = H5F.create('file2.h5','H5F_ACC_TRUNC',plist,plist);
gid2 = H5G.create(fid2,'g2',plist,plist,plist);
fid1 = H5F.create('file1.h5','H5F_ACC_TRUNC','H5P_DEFAULT',...
 'H5P_DEFAULT');
space_id = H5S.create('H5S_SCALAR');
dset_id = H5D.create(fid1,'DS1','H5T_NATIVE_DOUBLE',space_id,plist);
H5S.close(space_id);
H5D.close(dset_id);
H5F.mount(fid2,'g2',fid1,plist);
dset_id1 = H5D.open(fid1,'/g2/DS1',plist);
H5D.close(dset_id1);
H5F.unmount(fid1,'g2');
H5G.close(gid2);
H5F.close(fid1);
H5F.close(fid2);
```

`H5F.unmount`

# H5F.open

Open HDF5 file

## Syntax

```
file_id = H5F.open(filename)
file_id = H5F.open(name, flags, fapl_id)
```

## Description

`file_id = H5F.open(filename)` opens the file specified by `filename` for read-only access and returns the file identifier, `file_id`.

`file_id = H5F.open(name, flags, fapl_id)` opens the file specified by `name`, returning the file identifier, `file_id`. `flags` specifies file access flags and can be specified by one of the following strings or their numeric equivalents:

|                  |                 |
|------------------|-----------------|
| 'H5F_ACC_RDWR'   | read-write mode |
| 'H5F_ACC_RDONLY' | read-only mode  |

The file access property list, `fapl_id`, may be specified as 'H5P\_DEFAULT', in which case the default I/O settings are used.

## Examples

Open a file in read-only mode with default file access properties.

```
fid = H5F.open('example.h5');
H5F.close(fid);
```

Open a file in read-write mode.

```
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'example.h5');
copyfile(srcFile, 'myfile.h5');
fileattrib('myfile.h5', '+w');
fid = H5F.open('myfile.h5', 'H5F_ACC_RDWR', 'H5P_DEFAULT');
```

```
H5F.close(fid);
```

**See Also**

H5F.close | H5ML.get\_constant\_value

# H5F.reopen

Reopen HDF5 file

## Syntax

```
new_file_id = H5F.reopen(file_id)
```

## Description

`new_file_id = H5F.reopen(file_id)` returns a new file identifier for the already open HDF5 file specified by `file_id`.

## See Also

`H5F.open`

## H5F.set\_mdc\_config

Configure HDF5 file metadata cache

### Syntax

```
H5F.set_mdc_config(fileId,config)
```

### Description

`H5F.set_mdc_config(fileId,config)` attempts to configure the file's metadata cache according to the supplied configuration structure. Before using this function, you should retrieve the current configuration using `H5F.get_mdc_config`.

### See Also

`H5F.get_mdc_config`

# H5F.unmount

Unmount file or group from mount point

## Syntax

```
H5F.unmount(loc_id, name)
```

## Description

`H5F.unmount(loc_id, name)` disassociates the file or group specified by `loc_id` from the mount point specified by `name`. `loc_id` can be a file or group identifier.

## See Also

`H5F.mount`

## H5G.close

Close group

### Syntax

```
H5G.close(group_id)
```

### Description

`H5G.close(group_id)` releases resources used by the group specified by `group_id`. `group_id` was returned by either `H5G.create` or `H5G.open`.

### See Also

`H5G.create` | `H5G.open`

# H5G.create

Create group

## Syntax

```
group_id = H5G.create(loc_id,name,size_hint)
group_id = H5G.create(loc_id,name,lcpl_id,gcpl_id,gapl_id)
```

## Description

`group_id = H5G.create(loc_id,name,size_hint)` creates a new group with the name specified by `name` at the location specified by `loc_id`. `loc_id` can be a file or group identifier. `size_hint` specifies the number of bytes to reserve for the names that will appear in the group. This interface corresponds to the 1.6 version of `H5Gcreate`.

`group_id = H5G.create(loc_id,name,lcpl_id,gcpl_id,gapl_id)` creates a new group with link creation, group creation, and group access property lists `lcpl_id`, `gcpl_id`, and `gapl_id`. This interface corresponds to the 1.8 version of `H5Gcreate`.

## Examples

Create an HDF5 file 'myfile.h5' with a group 'my\_group' with default property list settings.

```
fid = H5F.create('myfile.h5');
plist = 'H5P_DEFAULT';
gid = H5G.create(fid,'my_group',plist,plist,plist);
H5G.close(gid);
H5F.close(fid);
```

## See Also

[H5G.close](#) | [H5G.open](#)

## H5G.get\_info

Information about group

### Syntax

```
info = H5G.get_info(group_id)
```

### Description

`info = H5G.get_info(group_id)` retrieves information about the group specified by `group_id`.

### Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/g2');
info = H5G.get_info(gid);
H5G.close(gid);
H5F.close(fid);
```

### See Also

[H5G.create](#) | [H5G.open](#)

# H5G.open

Open specified group

## Syntax

```
group_id = H5G.open(loc_id,name)
group_id = H5G.open(loc_id,name,gapl_id)
```

## Description

`group_id = H5G.open(loc_id,name)` opens the group specified by `name` at the location specified by `loc_id`. `loc_id` is a file or group identifier. This interface corresponds to the 1.6 version of `H5Gopen`.

`group_id = H5G.open(loc_id,name,gapl_id)` opens the group with an additional group access property list, `gapl_id`. This interface corresponds to the 1.8 version of `H5Gopen`.

## Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/g2');
H5G.close(gid);
H5F.close(fid);
```

## See Also

[H5G.close](#) | [H5P.create](#)

## H5I.dec\_ref

Decrement reference count

### Syntax

```
ref_count = H5I.dec_ref(obj_id)
```

### Description

`ref_count = H5I.dec_ref(obj_id)` decrements the reference count of the object identified by `obj_id` and returns the new count.

### See Also

[H5I.get\\_ref](#) | [H5I.inc\\_ref](#)

# H5I.get\_file\_id

File identifier for specified object

## Syntax

```
file_id = H5I.get_file_id(obj_id)
```

## Description

`file_id = H5I.get_file_id(obj_id)` returns the identifier of the file associated with the object referenced by `obj_id`.

## Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/g4');
fid2 = H5I.get_file_id(gid);
name = H5F.get_name(fid2);
fprintf('The filename is %s.\n', name);
H5G.close(gid);
H5F.close(fid);
H5F.close(fid2);
```

## H5I.get\_name

Name of object

### Syntax

```
name = H5I.get_name(obj_id)
```

### Description

`name = H5I.get_name(obj_id)` returns the name of the object specified by `obj_id`. If no name is attached to the object, the empty string is returned.

### Examples

Display the names of all the objects in the `/g3` group in the example file by alphabetical order.

```
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_INC';
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/g3');
info = H5G.get_info(gid);
for j = 1:info.nlinks
 obj_id = H5O.open_by_idx(fid, 'g3', idx_type, order, j-1, 'H5P_DEFAULT');
 name = H5I.get_name(obj_id);
 fprintf('Object %d: '%s'.\n', j-1, name);
 H5O.close(obj_id);
end
H5G.close(gid);
H5F.close(fid);
```

### See Also

[H5A.get\\_name](#) | [H5F.get\\_name](#)

## H5I.get\_ref

Reference count of object

### Syntax

```
refcount = H5I.get_ref(obj_id)
```

### Description

`refcount = H5I.get_ref(obj_id)` returns the reference count of the object specified by `obj_id`.

### See Also

[H5I.dec\\_ref](#) | [H5I.inc\\_ref](#)

## H5I.get\_type

Type of object

### Syntax

```
obj_type = H5I.get_type(obj_id)
```

### Description

`obj_type = H5I.get_type(obj_id)` returns the type of the object specified by `obj_id`. `obj_type` corresponds to one of the following enumerated values.

```
H5I_FILE
H5I_GROUP
H5I_DATATYPE
H5I_DATASPACE
H5I_DATASET
H5I_ATTR
H5I_BADID
```

### Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/g3');
dset_id = H5D.open(fid, '/g4/world');
[~,objs] = H5F.get_obj_ids(fid, 'H5F_OBJ_ALL', 3);
for j = 1:numel(objs)
 name = H5I.get_name(objs(j));
 fprintf('object '%s': ==> ', name);
 type = H5I.get_type(objs(j));
 switch(type)
 case H5ML.get_constant_value('H5I_FILE')
 fprintf('FILE identifier.\n');
```

```
 case H5ML.get_constant_value('H5I_GROUP')
 fprintf('GROUP identifier.\n');
 case H5ML.get_constant_value('H5I_DATASET')
 fprintf('DATASET identifier.\n');
 otherwise
 fprintf('unknown identifier type.\n');
end
end
H5G.close(gid);
H5F.close(fid);
```

## See Also

H5ML.get\_constant\_value

## **H5I.inc\_ref**

Increment reference count of specified object

### **Syntax**

```
ref_count = H5I.inc_ref(obj_id)
```

### **Description**

`ref_count = H5I.inc_ref(obj_id)` increments the reference count of the object specified by `obj_id` and returns the new count.

### **See Also**

`H5I.dec_ref` | `H5I.get_ref`

## H5I.is\_valid

Determine if specified identifier is valid

### Syntax

```
tf = H5I.is_valid(obj_id)
```

### Description

`tf = H5I.is_valid(obj_id)` determines whether the identifier `obj_id` is valid.

### Examples

```
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.close(fapl);
if H5I.is_valid(fapl);
 fprintf('File access property list is valid.\n');
else
 fprintf('File access property list is not valid.\n');
end
```

## H5L.copy

Copy link from source location to destination location

### Syntax

```
H5L.copy(src_loc_id,src_name,dest_loc_id,dest_name,lcpl_id,lapl_id)
```

### Description

`H5L.copy(src_loc_id,src_name,dest_loc_id,dest_name,lcpl_id,lapl_id)` copies the link specified by `src_name` from the file or group specified by `src_loc_id` to the destination `dest_loc_id`. The new copy of the link is created with the name `dest_name`.

`dest_loc_id` must refer to either the current file or a group in the current file. If `dest_loc_id` is the file identifier, the copy is placed in the file's root group.

The new link is created with the creation and access property lists specified by `lcpl_id` and `lapl_id`.

### Examples

```
plist_id = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',plist_id,plist_id);
g1 = H5G.create(fid,'g1',plist_id);
g2 = H5G.create(fid,'g2',plist_id);
g11 = H5G.create(g1,'g3',plist_id);
H5L.copy(g1,'g3',g2,'g4',plist_id,plist_id);
```

# H5L.create\_external

Create soft link to external object

## Syntax

```
H5L.create_external(filename,objname,link_loc_id,link_name,lcpl_id,lapl_id)
```

## Description

`H5L.create_external(filename,objname,link_loc_id,link_name,lcpl_id,lapl_id)` creates a soft link to an object in a different file. `filename` identifies the target file containing the target object. `obj_name` specifies the path to the target object within that file. `obj_name` must start at the target file's root group but is not interpreted until lookup time.

`link_loc_id` and `link_name` specify the location and name, respectively, of the new link. `link_name` is interpreted relative to `link_loc_id`.

`lcpl_id` and `lapl_id` are the link creation and access property lists associated with the new link.

## Examples

```
plist_id = 'H5P_DEFAULT';
fid1 = H5F.create('myfile1.h5');
g1 = H5G.create(fid1,'g1',plist_id,plist_id,plist_id);
H5G.close(g1);
H5F.close(fid1);
fid2 = H5F.create('myfile2.h5');
H5L.create_external('myfile1.h5','g1',fid2,'g2',plist_id,plist_id);
```

## H5L.create\_hard

Create hard link

### Syntax

```
H5L.create_hard(obj_loc_id,obj_name,link_loc_id,link_name,lcpl_id,lapl_id)
```

### Description

`H5L.create_hard(obj_loc_id,obj_name,link_loc_id,link_name,lcpl_id,lapl_id)` creates a new hard link to a pre-existing object in an HDF5 file. The new link may be one of many that point to that object. `obj_loc_id` and `obj_name` specify the location and name, respectively, of the target object, i.e., the object to which the new hard link points.

`link_loc_id` and `link_name` specify the location and name, respectively, of the new link. `link_name` is interpreted relative to `link_loc_id`.

`lcpl_id` and `lapl_id` are the link creation and access property lists associated with the new link.

### Examples

```
fid = H5F.create('myfile.h5');
gid1 = H5G.create(fid, '/g1',0);
gid2 = H5G.create(gid1, 'g2',0);
gid3 = H5G.create(gid2, 'g3',0);
lcpl = 'H5P_DEFAULT';
lapl = 'H5P_DEFAULT';
H5L.create_hard(gid2, 'g3',gid1, 'g4',lcpl,lapl);
H5G.close(gid3);
H5G.close(gid2);
H5G.close(gid1);
H5F.close(fid);
```

### See Also

`H5L.create_soft`

# H5L.create\_soft

Create soft link

## Syntax

```
H5L.create_soft(target_path,link_loc_id,link_name,lcpl_id,lapl_id)
```

## Description

`H5L.create_soft(target_path,link_loc_id,link_name,lcpl_id,lapl_id)` creates a new soft link to an object in an HDF5 file. The new link may be one of many that point to that object. `target_path` specifies the path to the target object, i.e., the object that the new soft link points to. `target_path` can be anything and is interpreted at lookup time. This `target_path` may be absolute in the file or relative to `link_loc_id`.

`link_loc_id` and `link_name` specify the location and name, respectively, of the new link. `link_name` is interpreted relative to `link_loc_id`.

`lcpl_id` and `lapl_id` are the link creation and access property lists associated with the new link.

## Examples

```
plist_id = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5');
gid1 = H5G.create(fid, '/g1', 0);
gid3 = H5G.create(gid1, 'g3', 0);
gid2 = H5G.create(fid, '/g2', 0);
lcpl = 'H5P_DEFAULT';
lapl = 'H5P_DEFAULT';
H5L.create_soft('/g1/g3', gid2, 'g4', lcpl, lapl);
H5G.close(gid3);
H5G.close(gid2);
H5G.close(gid1);
H5F.close(fid);
```

**See Also**

H5L.create\_hard

# H5L.delete

Remove link

## Syntax

```
H5L.delete(loc_id,name,lapl_id)
```

## Description

`H5L.delete(loc_id,name,lapl_id)` removes the link specified by name from the location `loc_id`. `lapl_id` is a link access property list identifier.

## Examples

Remove the only link to the `'/g3'` group in `example.h5`.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
H5L.delete(fid,'g3','H5P_DEFAULT');
H5F.close(fid);
```

## See Also

`H5L.move`

## H5L.exists

Determine if link exists

### Syntax

```
bool = H5L.exists(loc_id,name,lapl_id)
```

### Description

`bool = H5L.exists(loc_id,name,lapl_id)` checks if a link specified by the pairing of an object id and name exists within a group. `lapl_id` is a link access property list identifier.

### Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g1/g1.2/g1.2.1');
if H5L.exists(gid,'slink','H5P_DEFAULT')
 fprintf('link exists\n');
else
 fprintf('link does not exist\n');
end
```

# H5L.get\_info

Information about link

## Syntax

```
linkStruct = H5L.get_info(location_id, link_name, lapl_id)
```

## Description

`linkStruct = H5L.get_info(location_id, link_name, lapl_id)` returns information about a link.

A file or group identifier, `location_id`, specifies the location of the link. `link_name`, interpreted relative to `link_id`, specifies the link being queried.

## Examples

```
fid = H5F.open('example.h5');
info = H5L.get_info(fid, 'g3', 'H5P_DEFAULT');
H5F.close(fid);
```

## H5L.get\_name\_by\_idx

Information about link specified by index

### Syntax

```
name =
H5L.get_name_by_idx(loc_id,group_name,idx_type,order,n,lapl_id)
```

### Description

```
name =
H5L.get_name_by_idx(loc_id,group_name,idx_type,order,n,lapl_id)
```

retrieves information about a link at index `n`, present in group `group_name`, at location `loc_id`. The `lapl_id` input specifies the link access property list for querying the group.

`idx_type` is the type of index and valid values include the following.

|                      |                             |
|----------------------|-----------------------------|
| 'H5_INDEX_NAME'      | Alpha-numeric index on name |
| 'H5_INDEX_CRT_ORDER' | Index on creation order     |

`order` specifies the index traversal order. Valid values include the following.

|                  |                                          |
|------------------|------------------------------------------|
| 'H5_ITER_INC'    | Iteration from beginning to end          |
| 'H5_ITER_DEC'    | Iteration from end to beginning          |
| 'H5_ITER_NATIVE' | Iteration in the fastest available order |

### Examples

```
fid = H5F.open('example.h5');
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_DEC';
lapl_id = 'H5P_DEFAULT';
name = H5L.get_name_by_idx(fid,'g3',idx_type,order,0,lapl_id);
H5F.close(fid);
```

# H5L.get\_val

Value of symbolic link

## Syntax

```
linkval = H5L.get_val(link_loc_id,link_name,lapl_id)
```

## Description

`linkval = H5L.get_val(link_loc_id,link_name,lapl_id)` returns the value of a symbolic link.

`link_loc_id` is a file or group identifier. `link_name` identifies a symbolic link and is defined relative to `link_loc_id`. Symbolic links include soft and external links and some user-defined links.

In the case of soft links, `linkval` is a cell array containing the path to which the link points.

In the case of external links, `linkval` is a cell array consisting of the name of the target file and the object name.

This function corresponds to the `H5L.get_val` and `H5Lunpack_elink_val` functions in the HDF5 1.8 C API.

## Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g1/g1.2/g1.2.1');
linkval = H5L.get_val(gid,'slink','H5P_DEFAULT');
H5G.close(gid);
H5F.close(fid);
```

## H5L.iterate

Iterate over links

### Syntax

```
[status,idx_out,opdata_out] =
H5L.iterate(group_id,index_type,order,idx_in,iter_func,opdata_in)
```

### Description

```
[status,idx_out,opdata_out] =
H5L.iterate(group_id,index_type,order,idx_in,iter_func,opdata_in)
```

iterates through the links in a group, specified by `group_id`, to perform a common function whose function handle is `iter_func`. `H5L.iterate` does not recursively follow links into subgroups of the specified group.

`index_type` and `order` establish the iteration. `index_type` specifies the index to be used. If the links have not been indexed by the index type, they will first be sorted by that index then the iteration will begin. If the links have been so indexed, the sorting step will be unnecessary, so the iteration may begin more quickly. Valid values include the following:

|                      |                             |
|----------------------|-----------------------------|
| 'H5_INDEX_NAME'      | Alpha-numeric index on name |
| 'H5_INDEX_CRT_ORDER' | Index on creation order     |

`order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following:

|                  |                         |
|------------------|-------------------------|
| 'H5_ITER_INC'    | Increasing order        |
| 'H5_ITER_DEC'    | Decreasing order        |
| 'H5_ITER_NATIVE' | Fastest available order |

`idx_in` specifies the starting point of the iteration. `idx_out` returns the point at which iteration was stopped. This allows an interrupted iteration to be resumed.

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] = iter_func(group_id,name,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`status` value returned by `iter_func` is interpreted as follows:

|          |                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------|
| zero     | Continues with the iteration or returns zero status value to the caller if all members have been processed |
| positive | Stops the iteration and returns the positive status value to the caller                                    |
| negative | Stops the iteration and throws an error indicating failure                                                 |

## H5L.iterate\_by\_name

Iterate through links in group specified by name

### Syntax

```
[status,idx_out,opdata_out] =
H5L.iterate_by_name(loc_id,group_name,index_type,order,idx_in,iter_func,opdata_out)
```

### Description

```
[status,idx_out,opdata_out] =
H5L.iterate_by_name(loc_id,group_name,index_type,order,idx_in,iter_func,opdata_out)
```

iterates through the links in a group to perform a common function whose function handle is `iter_func`. The starting point of the iteration is pairing of a specified by the location id and a relative group name. `H5L.iterate_by_name` does not recursively follow links into subgroups of the specified group. A link access property list, `lapl_id`, may affect the outcome depending upon the type of link being traversed.

`index_type` and `order` establish the iteration. `index_type` specifies the index to be used. If the links have not been indexed by the index type, they will first be sorted by that index then the iteration will begin. If the links have been so indexed, the sorting step will be unnecessary, so the iteration may begin more quickly. Valid values include the following:

|                      |                             |
|----------------------|-----------------------------|
| 'H5_INDEX_NAME'      | Alpha-numeric index on name |
| 'H5_INDEX_CRT_ORDER' | Index on creation order     |

`order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following:

|                  |                         |
|------------------|-------------------------|
| 'H5_ITER_INC'    | Increasing order        |
| 'H5_ITER_DEC'    | Decreasing order        |
| 'H5_ITER_NATIVE' | Fastest available order |

`idx_in` specifies the starting point of the iteration. `idx_out` returns the point at which iteration was stopped. This allows an interrupted iteration to be resumed.

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] = iter_func(group_id,name,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`status` value returned by `iter_func` is interpreted as follows:

|          |                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------|
| zero     | Continues with the iteration or returns zero status value to the caller if all members have been processed |
| positive | Stops the iteration and returns the positive status value to the caller                                    |
| negative | Stops the iteration and throws an error indicating failure                                                 |

## H5L.move

Rename link

### Syntax

```
H5L.move(src_loc_id,src_name,dest_loc_id,dest_name,lcpl_id,lapl_id)
```

### Description

`H5L.move(src_loc_id,src_name,dest_loc_id,dest_name,lcpl_id,lapl_id)` renames a link within an HDF5 file. The original link, `src_name`, is removed from the group graph and the new link, `dest_name`, is inserted; this change is accomplished as an atomic operation.

`src_loc_id` and `src_name` identify the existing link. `src_loc_id` is either a file or group identifier; `src_name` is the path to the link and is interpreted relative to `src_loc_id`.

`dest_loc_id` and `dest_name` identify the new link. `dest_loc_id` is either a file or group identifier; `dest_name` is the path to the link and is interpreted relative to `dest_loc_id`.

`lcpl_id` and `lapl_id` are the link creation and link access property lists, respectively, associated with the new link, `dest_name`.

### Examples

Rename the `'/g2'` group to `'/g2/g3'`.

```
srcFile = fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'example.h5');
copyfile(srcFile, 'myfile.h5');
fileattrib('myfile.h5', '+w');
fid = H5F.open('myfile.h5', 'H5F_ACC_RDWR', 'H5P_DEFAULT');
g2id = H5G.open(fid, 'g2');
H5L.move(fid, 'g3', g2id, 'g3', 'H5P_DEFAULT', 'H5P_DEFAULT');
H5G.close(g2id);
```

```
H5F.close(fid);
```

### **See Also**

H5L.delete

## H5L.visit

Recursively iterate through links in group specified by group identifier

### Syntax

```
[status opdata_out] =
H5L.visit(group_id, index_type, order, iter_func, opdata_in)
```

### Description

```
[status opdata_out] =
H5L.visit(group_id, index_type, order, iter_func, opdata_in) recursively
iterates through all links in and below a group, specified by group_id, to perform a
common function whose function handle is iter_func.
```

`index_type` and `order` establish the iteration. `index_type` specifies the index to be used. If the links have not been indexed by the index type, they are first sorted by that index, and then the iteration will begin. If the links have been so indexed, the sorting step is unnecessary, so the iteration can begin more quickly. Valid values include the following.

|                      |                             |
|----------------------|-----------------------------|
| 'H5_INDEX_NAME'      | Alpha-numeric index on name |
| 'H5_INDEX_CRT_ORDER' | Index on creation order     |

Note that the index type passed in `index_type` is a best effort setting. If the application passes in a value indicating iteration in creation order and a group is encountered that was not tracked in creation order, that group will be iterated over in alpha-numeric order by name, or name order. (Name order is the native order used by the HDF5 Library and is always available.)

`order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following.

|               |                  |
|---------------|------------------|
| 'H5_ITER_INC' | Increasing order |
| 'H5_ITER_DEC' | Decreasing order |

'H5\_ITER\_NATIVE' Fastest available order

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] = iter_func(group_id,name,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`status` value returned by `iter_func` is interpreted as follows.

|          |                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------|
| zero     | Continues with the iteration or returns zero status value to the caller if all members have been processed |
| positive | Stops the iteration and returns the positive status value to the caller                                    |
| negative | Stops the iteration and throws an error indicating failure                                                 |

## H5L.visit\_by\_name

Recursively iterate through links in group specified by location and group name

### Syntax

```
[status,opdata_out] =
H5L.visit_by_name(loc_id,group_name,index_type,order,iter_func,opdata_in,lapl_id)
```

### Description

```
[status,opdata_out] =
H5L.visit_by_name(loc_id,group_name,index_type,order,iter_func,opdata_in,lapl_id)
```

recursively iterates through all links in and below a group to perform a common function whose function handle is `iter_func`. The starting point of the iteration is specified by the pairing of a location id and a relative group name. A link access property list, `lapl_id`, may affect the outcome depending upon the type of link being traversed.

`index_type` and `order` establish the iteration. `index_type` specifies the index to be used. If the links have not been indexed by the index type, they are first sorted by that index, and then the iteration will begin. If the links have been so indexed, the sorting step is unnecessary, so the iteration can begin more quickly. Valid values include the following.

|                      |                             |
|----------------------|-----------------------------|
| 'H5_INDEX_NAME'      | Alpha-numeric index on name |
| 'H5_INDEX_CRT_ORDER' | Index on creation order     |

Note that the index type passed in `index_type` is a best effort setting. If the application passes in a value indicating iteration in creation order and a group is encountered that was not tracked in creation order, that group will be iterated over in alpha-numeric order by name, or name order. (Name order is the native order used by the HDF5 Library and is always available.)

`order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following.

|               |                  |
|---------------|------------------|
| 'H5_ITER_INC' | Increasing order |
|---------------|------------------|

|                  |                         |
|------------------|-------------------------|
| 'H5_ITER_DEC'    | Decreasing order        |
| 'H5_ITER_NATIVE' | Fastest available order |

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] = iter_func(group_id,name,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`status` value returned by `iter_func` is interpreted as follows.

|          |                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------|
| zero     | Continues with the iteration or returns zero status value to the caller if all members have been processed |
| positive | Stops the iteration and returns the positive status value to the caller                                    |
| negative | Stops the iteration and throws an error indicating failure                                                 |

## H5ML.compare\_values

Numerically compare two HDF5 values

### Syntax

```
bEqual = H5ML.compare_values(value1,value2)
```

### Description

`bEqual = H5ML.compare_values(value1,value2)` compares two values, where either or both values may be represented as a string. The values are compared numerically.

Function parameters:

|                     |                                                             |
|---------------------|-------------------------------------------------------------|
| <code>bEqual</code> | A logical value indicating whether the two values are equal |
| <code>value1</code> | The first value to be compared                              |
| <code>value2</code> | The second value to be compared                             |

### Examples

```
val = H5ML.get_constant_value('H5T_NATIVE_INT');
H5ML.compare_values(val,'H5T_NATIVE_INT')
```

## H5ML.get\_constant\_names

Constants known by HDF5 library

### Syntax

```
names = H5ML.get_constant_names()
```

### Description

`names = H5ML.get_constant_names()` returns a list of known library constants, definitions, and enumerations. When these strings are supplied as actual parameters to HDF5 functions, they are automatically be converted to the appropriate numeric value.

Function parameters.

|                    |                                     |
|--------------------|-------------------------------------|
| <code>names</code> | An alphabetized cell array of names |
|--------------------|-------------------------------------|

## H5ML.get\_constant\_value

Value corresponding to a string

### Syntax

```
value = H5ML.get_constant_value(constant)
```

### Description

`value = H5ML.get_constant_value(constant)` returns the value corresponding to a given string. The string should correspond to an enumeration (for example, 'H5\_ENUM\_T') or a predefined identifier (for example, 'H5T\_NATIVE\_INT'). Since the value corresponding to a given string is not guaranteed to remain the same, it is almost always preferable to use the `H5ML.compare_values()` function instead.

Function parameters:

|                       |                                                                   |
|-----------------------|-------------------------------------------------------------------|
| <code>value</code>    | The value corresponding to the supplied string                    |
| <code>constant</code> | A string that corresponds to a HDF5 enumeration or defined value. |

### Examples

```
a = H5ML.get_constant_value('H5T_NATIVE_INT');
```

## H5ML.get\_function\_names

Functions provided by HDF5 library

### Syntax

```
names = H5ML.get_function_names()
```

### Description

`names = H5ML.get_function_names()` returns a list of supported library functions.

Function parameters:

|                    |                                     |
|--------------------|-------------------------------------|
| <code>names</code> | An alphabetized cell array of names |
|--------------------|-------------------------------------|

## H5ML.get\_mem\_datatype

Data type for dataset ID

### Syntax

```
DTYPE_ID = H5ML.get_mem_datatype(LOCATION_ID)
```

### Description

`DTYPE_ID = H5ML.get_mem_datatype(LOCATION_ID)` returns the ID of an HDF5 memory datatype for the dataset or attribute identified by `LOCATION_ID`. This HDF5 memory datatype is the default used by `H5D.read` or `H5D.write` when you specify `'H5ML_DEFAULT'` as a value of the memory data type parameter.

The identifier returned by `H5ML.get_mem_datatype` should eventually be closed by calling `H5T.close` to release resources.

### Examples

```
file_id = H5F.open('example.h5', 'H5F_ACC_RDONLY', 'H5P_DEFAULT');
dset_id = H5D.open(file_id, '/g1/g1.1/dset1.1.1');
datatype_id = H5ML.get_mem_datatype(dset_id)
H5T.close(datatype_id);
H5D.close(dset_id);
H5F.close(file_id);
```

# H5ML.hoffset

Determine the offset of a field within a structure

---

**Note:** H5ML.hoffset is not recommended. Use H5T instead.

---

## Syntax

## Description

This function is used to determine the offset (in bytes) of a structure, `H5T.insert(file_type, 'a', offset(1), dtype(1));`, within a field. It is used when constructing an HDF5 COMPOUND type. It is designed to correspond to the HDF5 HOFFSET macro. For more details about the operation of the HOFFSET macro, please consult the HDF5 documentation.

Function parameters:

|                        |                                                       |
|------------------------|-------------------------------------------------------|
| <code>offset</code>    | The byte offset of the field within the structure.    |
| <code>structure</code> | The structure which contains the specified fieldname. |
| <code>fieldname</code> | The field for which the offset is determined.         |

## Examples

This function is deprecated. It can only be used in workflows that do not include a field that is itself an HDF5 COMPOUND or of variable length. To handle these cases, the offsets should be computed directly. For example, in the case above, a file dataspace for such a compound could be created with:

```
dtype(1) = H5T.copy('H5T_NATIVE_INT');
```

```
dtype(2) = H5T.copy('H5T_NATIVE_DOUBLE');
dtype(3) = H5T.copy('H5T_NATIVE_FLOAT');

for j = 1:3, sz(j,1) = H5T.get_size(dtype(j)); end

% The first offset would always be zero and the size of the last
% field does not matter.
offset(1) = 0;
offset(2:3) = cumsum(sz(1:2));

file_type = H5T.create('H5T_COMPOUND',sum(sz));

H5T.insert(file_type,'a', offset(1), dtype(1));
H5T.insert(file_type,'b', offset(2), dtype(2));
H5T.insert(file_type,'c', offset(3), dtype(3));
```

**See Also**

H5T.get\_size

# H5ML.sizeof

Return the size (in bytes) of a variable as stored on disk

---

**Note:** `H5ML.sizeof` is not recommended. Use `H5T` instead.

---

## Syntax

## Description

This function is used to determine the size (in bytes) of a structure or other (simple) variable. It is designed to correspond to the C `sizeof()` operator as it is used during the creation of HDF5 datatypes, especially the HDF5 COMPOUND type.

Function parameters:

|                   |                                                                    |
|-------------------|--------------------------------------------------------------------|
| <code>size</code> | The size (in bytes) of the variable as it would be stored on disk. |
| <code>arg</code>  | The variable for which the size is being sought.                   |

## Examples

This function is deprecated. It can only be used in workflows that do not include a field that is itself an HDF5 COMPOUND or of variable length. To handle these cases, the offsets should be computed directly. For example, in the case above, a file dataspace for such a compound could be created with:

```
dtype(1) = H5T.copy('H5T_NATIVE_INT');
dtype(2) = H5T.copy('H5T_NATIVE_DOUBLE');
dtype(3) = H5T.copy('H5T_NATIVE_FLOAT');

for j = 1:3, sz(j,1) = H5T.get_size(dtype(j)); end
```

```
% The first offset would always be zero and the size of the last
% field does not matter.
offset(1) = 0;
offset(2:3) = cumsum(sz(1:2));

file_type = H5T.create('H5T_COMPOUND',sum(sz));

H5T.insert(file_type,'a', offset(1), dtype(1));
H5T.insert(file_type,'b', offset(2), dtype(2));
H5T.insert(file_type,'c', offset(3), dtype(3));
```

## See Also

H5T.get\_size

# H5O.close

Close object

## Syntax

```
H5O.close(obj_id)
```

## Description

`H5O.close(obj_id)` closes the object specified by `obj_id`. `obj_id` cannot be a dataspace, attribute, property list, or file.

## H5O.copy

Copy object from source location to destination location

### Syntax

```
H5O.copy(src_loc_id,src_name,dst_loc_id,dst_name,ocpypl_id,lcpl_id)
```

### Description

`H5O.copy(src_loc_id,src_name,dst_loc_id,dst_name,ocpypl_id,lcpl_id)` copies the group, dataset or named datatype specified by `src_name` from the file or group specified by `src_loc_id` to the destination location `dst_loc_id`.

The destination location, as specified in `dst_loc_id`, may be a group in the current file or a location in a different file. If `dst_loc_id` is a file identifier, the copy will be placed in that file's root group.

The new copy will be created with the name `dst_name`. `dst_name` must not pre-exist in the destination location. If `dst_name` already exists at the location `dst_loc_id`, the operation will fail.

The new copy of the object is created with the object creation property and link creation property lists `ocpypl_id` and `lcpl_id`, respectively.

### Examples

Copy the group `'/g3'` and all its datasets to a new group `'/g3.5'`.

```
srcFile = [matlabroot '/toolbox/matlab/demos/example.h5'];
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
ocpl = H5P.create('H5P_OBJECT_COPY');
lcpl = H5P.create('H5P_LINK_CREATE');
H5P.set_create_intermediate_group(lcpl,true);
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
gid = H5G.open(fid,'/');
```

```
H5O.copy(gid, 'g3', gid, 'g3.5', ocpl, lcpl);
H5G.close(gid);
H5P.close(ocpl);
H5P.close(lcpl);
H5F.close(fid);
```

## H5O.get\_comment

Get comment for object specified by object identifier

### Syntax

```
comment = H5O.get_comment(obj_id)
```

### Description

`comment = H5O.get_comment(obj_id)` retrieves the comment for the object specified by `obj_id`.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, 'g4/world');
comment = H5O.get_comment(dset_id);
H5D.close(dset_id);
H5F.close(fid);
```

### See Also

[H5O.get\\_comment\\_by\\_name](#) | [H5O.set\\_comment](#) | [H5O.set\\_comment\\_by\\_name](#)

## H5O.get\_comment\_by\_name

Get comment for object specified by location and object name

### Syntax

```
comment = H5O.get_comment_by_name(loc_id,name,lapl_id)
```

### Description

`comment = H5O.get_comment_by_name(loc_id,name,lapl_id)` retrieves a comment where a location id and name together specify the object. A link access property list can affect the outcome if a link is traversed to access the object.

### Examples

```
fid = H5F.open('example.h5','H5F_ACC_RDONLY','H5P_DEFAULT');
comment = H5O.get_comment_by_name(fid,'g4/world','H5P_DEFAULT');
H5F.close(fid);
```

### See Also

[H5O.get\\_comment](#) | [H5O.set\\_comment](#) | [H5O.set\\_comment\\_by\\_name](#)

## H5O.get\_info

Object metadata

### Syntax

```
info = H5O.get_info(obj_id)
```

### Description

`info = H5O.get_info(obj_id)` retrieves the metadata for an object specified by `obj_id`. For details about the object metadata, please refer to the HDF5 documentation.

### Examples

Determine the number of attributes for a dataset.

```
fid = H5F.open('example.h5', 'H5F_ACC_RDONLY', 'H5P_DEFAULT');
dsetId = H5D.open(fid, '/g1/g1.1/dset1.1.1');
info = H5O.get_info(dsetId);
info.num_attrs
```

Determine the type of objects in the root group.

```
plist = 'H5P_DEFAULT';
fid = H5F.open('example.h5');
gid = H5G.open(fid, '/');
root_info = H5G.get_info(gid);
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_DEC';
for j = 0:root_info.nlinks-1
 obj_id = H5O.open_by_idx(fid, '/', idx_type, order, j, plist);
 obj_info = H5O.get_info(obj_id);
 switch(obj_info.type)
 case H5ML.get_constant_value('H5G_LINK')
 fprintf('Object #%d is a link.\n', j);
 case H5ML.get_constant_value('H5G_GROUP')
 fprintf('Object #%d is a group.\n', j);
```

```
 case H5ML.get_constant_value('H5G_DATASET')
 fprintf('Object #%d is a dataset.\n',j);
 case H5ML.get_constant_value('H5G_TYPE')
 fprintf('Object #%d is a named datatype.\n',j);
 end
 H5O.close(obj_id);
end
H5G.close(gid);
H5F.close(fid);
```

## See Also

[H5D.open](#) | [H5F.open](#) | [H5G.open](#) | [H5T.open](#)

## H5O.link

Create hard link to specified object

### Syntax

```
H5O.link(obj_id,new_loc_id,new_link_name,lcpl_id,lapl_id)
```

### Description

`H5O.link(obj_id,new_loc_id,new_link_name,lcpl_id,lapl_id)` creates a hard link to an object, where `new_loc_id` and `new_link_name` specify the location. `lcpl_id` and `lapl_id` are the link creation and access property lists associated with the new link.

`H5O.link` is designed to add additional structure to an existing file so that, for example, an object can be shared among multiple groups.

### Examples

Create a hard link from group `'/g2'` to the dataset `'/g1/ds1'`.

```
plist_id = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',plist_id,plist_id);
gid1 = H5G.create(fid,'/g1',plist_id);
space_id = H5S.create_simple(1,10,[]);
ds1 = H5D.create(gid1,'ds1','H5T_NATIVE_INT',space_id,plist_id);
gid2 = H5G.create(fid,'/g2',plist_id);
H5O.link(ds1,gid2,'ds2',plist_id,plist_id);
H5D.close(ds1);
H5S.close(space_id);
H5G.close(gid2); H5G.close(gid1);
H5F.close(fid);
```

# H5O.open

Open specified object

## Syntax

```
obj_id = H5O.open(loc_id, relname, lapl_id)
```

## Description

`obj_id = H5O.open(loc_id, relname, lapl_id)` opens an object specified by location identifier and relative path name. `lapl_id` is the link access property list associated with the link pointing to the object. If default link access properties are appropriate, this can be passed in as `'H5P_DEFAULT'`.

## Examples

```
fid = H5F.open('example.h5');
obj_id = H5O.open(fid, 'g3', 'H5P_DEFAULT');
H5O.close(obj_id);
H5F.close(fid);
```

## See Also

[H5O.close](#) | [H5O.open\\_by\\_idx](#)

## H5O.open\_by\_idx

Open object specified by index

### Syntax

```
obj_id = H5O.open_by_idx(loc_id, group_name, idx_type, order, n,
lapl_id)
```

### Description

`obj_id = H5O.open_by_idx(loc_id, group_name, idx_type, order, n, lapl_id)` opens the `n`-th object in the group specified by `loc_id` and `group_name`. `loc_id` specifies a file or group. `group_name` specifies the group relative to `loc_id` in which the object can be found.

Two parameters are used to establish the iteration: `index_type` and `order`. `index_type` specifies the type of index by which objects are ordered. Valid values include the following:

|                      |                             |
|----------------------|-----------------------------|
| 'H5_INDEX_NAME'      | Alpha-numeric index on name |
| 'H5_INDEX_CRT_ORDER' | Index on creation order     |

`order` specifies the order in which the links are to be referenced for the purposes of this function. Valid values include the following:

|                  |                         |
|------------------|-------------------------|
| 'H5_ITER_INC'    | Increasing order        |
| 'H5_ITER_DEC'    | Decreasing order        |
| 'H5_ITER_NATIVE' | Fastest available order |

`n` specifies the zero-based position of the object within the index. `lapl_id` specifies the link access property list to be used in accessing the object.

### Examples

```
fid = H5F.open('example.h5');
```

```
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_DEC';
obj_id = H5O.open_by_idx(fid, 'g3', idx_type, order, 0, 'H5P_DEFAULT');
H5O.close(obj_id);
H5F.close(fid);
```

[H5O.close](#) | [H5O.open](#)

## H5O.set\_comment

Set comment for object specified by object identifier

### Syntax

```
H5O.set_comment(obj_id,comment)
```

### Description

`H5O.set_comment(obj_id,comment)` sets a comment for the object specified by `obj_id`.

### Examples

```
plist = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', plist, plist);
gid = H5G.create(fid, '/g1', plist);
H5O.set_comment(gid, 'This is a group comment.');
```

### See Also

`H5O.get_comment` | `H5O.get_comment_by_name` | `H5O.set_comment_by_name`

## H5O.set\_comment\_by\_name

Set comment for object specified by location and object name

### Syntax

```
H5O.set_comment_by_name(loc_id,rel_name,comment,lapl_id)
```

### Description

`H5O.set_comment_by_name(loc_id,rel_name,comment,lapl_id)` sets a comment for an object specified by a location ID and a relative name. `lapl_id` is a link access property list identifier that can affect the outcome if links are traversed.

### Examples

```
plist = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', plist, plist);
gid = H5G.create(fid, '/g1', plist);
H5O.set_comment_by_name(fid, 'g1', 'This is a group comment.', plist);
H5G.close(gid);
H5F.close(fid);
```

## H5O.visit

Visit objects specified by object identifier

### Syntax

```
[status,opdata_out] =
H5O.visit(obj_id,index_type,order,iter_func,opdata_in)
```

### Description

[status,opdata\_out] =  
H5O.visit(obj\_id,index\_type,order,iter\_func,opdata\_in) is a recursive iteration function to visit the object `object_id` and, if `object_id` is a group, all objects in and below it in an HDF5 file. This provides a mechanism for an application to perform a common set of operations across all of those objects or a dynamically selected subset.

If `object_id` is a group identifier, that group serves as the root of a recursive iteration. If `object_id` is a file identifier, that file's root group serves as the root of the recursive iteration. If `object_id` is any other type of object, such as a dataset or named data type, there is no iteration.

Two parameters are used to establish the iteration: `index_type` and `order`. The `index_type` parameter specifies the index used. If the links in a group have not been indexed by the index type, they are first sorted by that index, and then the iteration will begin. If the links have been so indexed, the sorting step is unnecessary, so the iteration can begin more quickly. Valid values include the following.

|                      |                             |
|----------------------|-----------------------------|
| 'H5_INDEX_NAME'      | Alpha-numeric index on name |
| 'H5_INDEX_CRT_ORDER' | Index on creation order     |

Note that the index type passed in `index_type` is a best effort setting. If the application passes in a value indicating iteration in creation order and a group is encountered that was not tracked in creation order, that group will be iterated over in alpha-numeric order by name, or name order. (Name order is the native order used by the HDF5 Library and is always available.) `order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following.

---

|                  |                         |
|------------------|-------------------------|
| 'H5_ITER_INC'    | Increasing order        |
| 'H5_ITER_DEC'    | Decreasing order        |
| 'H5_ITER_NATIVE' | Fastest available order |

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] = iter_func(group_id,name,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`status` value returned by `iter_func` is interpreted as follows.

|          |                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------|
| zero     | Continues with the iteration or returns zero status value to the caller if all members have been processed |
| positive | Stops the iteration and returns the positive status value to the caller                                    |
| negative | Stops the iteration and throws an error indicating failure                                                 |

## See Also

H5O.visit\_by\_name

## H5O.visit\_by\_name

Visit objects specified by location and object name

### Syntax

```
[status,opdata_out] =
H5O.visit_by_name(loc_id,obj_name,index_type,order,iter_func,opdata_in,lapl_id)
```

### Description

```
[status,opdata_out] =
H5O.visit_by_name(loc_id,obj_name,index_type,order,iter_func,opdata_in,lapl_id)
```

specifies the object by the pairing of the location identifier and object name. `loc_id` specifies a file or an object in a file and `obj_name` specifies an object in the file with either an absolute name or relative to `loc_id`. A link access property list can affect the outcome if links are involved.

Two parameters are used to establish the iteration: `index_type` and `order`. The `index_type` parameter specifies the index to be used. If the links in a group have not been indexed by the index type, they are first sorted by that index, and then the iteration will begin; if the links have been so indexed, the sorting step is unnecessary, so the iteration can begin more quickly. Valid values include the following.

|                      |                             |
|----------------------|-----------------------------|
| 'H5_INDEX_NAME'      | Alpha-numeric index on name |
| 'H5_INDEX_CRT_ORDER' | Index on creation order     |

Note that the index type passed in `index_type` is a best effort setting. If the application passes in a value indicating iteration in creation order and a group is encountered that was not tracked in creation order, that group will be iterated over in alpha-numeric order by name, or name order. (Name order is the native order used by the HDF5 Library and is always available.) `order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following.

|               |                  |
|---------------|------------------|
| 'H5_ITER_INC' | Increasing order |
| 'H5_ITER_DEC' | Decreasing order |

'H5\_ITER\_NATIVE'                      Fastest available order

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] = iter_func(group_id,name,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`lapl_id` is a link access property list. When default link access properties are acceptable, 'H5P\_DEFAULT' can be used.

`status` value returned by `iter_func` is interpreted as follows.

|          |                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------|
| zero     | Continues with the iteration or returns zero status value to the caller if all members have been processed |
| positive | Stops the iteration and returns the positive status value to the caller                                    |
| negative | Stops the iteration and throws an error indicating failure                                                 |

H5O.visit

## **H5P.close**

Close property list

### **Syntax**

```
H5P.close(plist_id)
```

### **Description**

H5P.close(plist\_id) terminates access to the property list specified by `plist_id`.

### **See Also**

H5P.create

# H5P.copy

Copy of property list

## Syntax

```
plist_copy = H5P.copy(plist_id)
```

## Description

`plist_copy = H5P.copy(plist_id)` returns a copy of the property list specified by `plist_id`.

## Examples

Make a copy of the file creation property list for 'example.h5'.

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
fcpl2 = H5P.copy(fcpl);
```

## H5P.create

Create new property list

### Syntax

```
plist = H5P.create(class_id)
```

### Description

`plist = H5P.create(class_id)` creates a new property list as an instance of the property list class specified by `class_id`. The `class_id` input can be one of the following strings or the corresponding constant value.

```
'H5P_ATTRIBUTE_CREATE '
'H5P_DATASET_ACCESS '
'H5P_DATASET_CREATE '
'H5P_DATASET_XFER '
'H5P_DATATYPE_CREATE '
'H5P_DATATYPE_ACCESS '
'H5P_FILE_MOUNT '
'H5P_FILE_CREATE '
'H5P_FILE_ACCESS '
'H5P_GROUP_CREATE '
'H5P_GROUP_ACCESS '
'H5P_LINK_CREATE '
'H5P_LINK_ACCESS '
'H5P_OBJECT_COPY '
'H5P_OBJECT_CREATE '
'H5P_STRING_CREATE '
```

`class_id` can also be an instance of a property list class.

## Examples

```
fapl = H5P.create('H5P_FILE_ACCESS');
fid = H5F.open('example.h5', 'H5F_ACC_RDONLY', fapl);
```

## See Also

[H5ML.get\\_constant\\_value](#) | [H5P.close](#) | [H5P.get\\_class](#)

## H5P.get\_class

Property list class

### Syntax

```
plist_class = H5P.get_class(plist_id)
```

### Description

`plist_class = H5P.get_class(plist_id)` returns the property list class for the property list specified by `plist_id`.

### Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
pclass = H5P.get_class(fcpl);
name = H5P.get_class_name(pclass);
```

### See Also

`H5P.get_class_name`

## H5P.close\_class

Close property list class

### Syntax

```
H5P.close_class(class)
```

### Description

H5P.close\_class(class) closes the property list class specified by pclass\_id.

## H5P.equal

Determine equality of property lists

### Syntax

```
value = H5P.equal(plist1_id, plist2_id)
```

### Description

`value = H5P.equal(plist1_id, plist2_id)` returns a positive number if the two property lists specified are equal, and zero if they are not. A negative value indicates failure.

### Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
fcpl = H5F.get_create_plist(fid);
if H5P.equal(fapl,fcpl)
 fprintf('property lists are equal\n');
else
 fprintf('property lists are not equal\n');
end
```

## H5P.exist

Determine if specified property exists in property list

### Syntax

```
value = H5P.exist(prop_id, name)
```

### Description

`value = H5P.exist(prop_id, name)` returns a positive value if the property specified by the text string `name` exists within the property list or class specified by `prop_id`.

### Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
if H5P.exist(fapl, 'sieve_buf_size')
 fprintf('sieve buffer size property exists\n');
else
 fprintf('sieve buffer size property does not exist\n');
end
```

## H5P.get

Value of specified property in property list

### Syntax

```
value = H5P.get(plist_id, name)
```

### Description

`value = H5P.get(plist_id, name)` retrieves a copy of the value of the property specified by the text string `name` in the property list specified by `plist_id`. The `H5P.get` function returns the property as an array of `uint8` values. You might need to cast the value to an appropriate data type to get a meaningful result.

### Examples

```
plist = H5P.create('H5P_FILE_ACCESS');
val = H5P.get(plist, 'rdcc_w0');
rdcc_w0 = typecast(val, 'double');
```

It is recommended to use alternative functions like `H5P.get_chunk`, `H5P.get_layout`, `H5P.get_size` etc., where available, to get values for the common property names.

### See Also

[H5P.set](#) | [typecast](#)

## H5P.get\_class\_name

Name of property list class

### Syntax

```
classname = H5P.get_class_name(pclass_id)
```

### Description

`classname = H5P.get_class_name(pclass_id)` retrieves the name of the generic property list class. `classname` is a text string. If no class is found, the empty string is returned.

### Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
pclass = H5P.get_class(fcpl);
name = H5P.get_class_name(pclass);
```

### See Also

[H5P.get\\_class](#)

## H5P.get\_class\_parent

Identifier for parent class

### Syntax

```
pclass_obj_id = H5P.get_class_parent(pclass_id)
```

### Description

`pclass_obj_id = H5P.get_class_parent(pclass_id)` returns an identifier to the parent class object of the property class specified by `pclass_id`.

### Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
fcpl_class = H5P.get_class(fcpl);
parent_class = H5P.get_class_parent(fcpl_class);
name = H5P.get_class_name(parent_class);
```

### See Also

`H5P.get_class` | `H5P.get_class_name`

## H5P.get\_nprops

Query number of properties in property list or class

### Syntax

```
nprops = H5P.get_nprops(id)
```

### Description

`nprops = H5P.get_nprops(id)` returns the number of properties in the property list or class specified by `id`.

### Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
nprops = H5P.get_nprops(fcpl);
```

## H5P.get\_size

Query size of property value in bytes

### Syntax

```
sz = H5P.get_size(id,name)
```

### Description

`sz = H5P.get_size(id,name)` returns the size, in bytes, of the property specified by the text string `name` in the property list or property class specified by `id`.

### Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
sz = H5P.get_size(fapl, 'sieve_buf_size');
```

## H5P.isa\_class

Determine if property list is member of class

### Syntax

```
output = H5P.isa_class(plist_id, pclass_id)
```

### Description

`output = H5P.isa_class(plist_id, pclass_id)` returns a positive number if the property list specified by `plist_id` is a member of the class specified by `pclass_id`, zero if it is not, and a negative value to indicate an error.

### Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
if H5P.isa_class(fcpl, 'H5P_FILE_ACCESS')
 fprintf('fcpl is a file access property list\n');
else
 fprintf('fcpl is not a file access property list\n');
end
```

### See Also

`H5P.get_class`

## H5P.iterate

Iterate over properties in property list

### Syntax

```
[output,idx_out] = H5P.iterate(id,idx_in,iter_func)
```

### Description

[output,idx\_out] = H5P.iterate(id,idx\_in,iter\_func) executes the operation `iter_func` on each property in the property object specified in `id`. The `id` input can be a property list or a property class. `idx_in` specifies the index of the next property to be processed. `output` is the value returned by the last call to `iter_func`. `idx_out` is the index of the last property processed. `iter_func` is a function handle.

The iterator function must have the following signature:

```
status = iter_func(id,prop_name)
```

`id` still identifies the property object passed into `H5P.iterate`, but `name` identifies the name of the current property.

## H5P.set

Set property list value

### Syntax

```
H5P.set(plist_id,name,value)
```

### Description

`H5P.set(plist_id,name,value)` sets the value of the property specified by the text string `name` in the property list specified by `plist_id` to the value specified in `value`. The datatype of `value` must be `uint8`.

### Examples

```
plist = H5P.create('H5P_FILE_ACCESS');
H5P.set(plist, 'rdcc_w0', typecast(0.8, 'uint8'));
```

It is recommended to use alternative functions like `H5P.set_chunk`, `H5P.set_layout`, `H5P.set_size`, etc., where available, to set values for the common property names.

### See Also

`typecast`

## H5P.get\_btree\_ratios

B-tree split ratios

### Syntax

```
[left,middle,right] = H5P.get_btree_ratios(plist_id)
```

### Description

[left,middle,right] = H5P.get\_btree\_ratios(plist\_id) returns the B-tree split ratios for the dataset transfer property list specified by `plist_id`. The `left` output specifies the B-tree split ratio for left-most nodes. `right` corresponds to the right-most nodes and lone nodes, and `middle` corresponds to all other nodes.

### Examples

```
dxpl = H5P.create('H5P_DATASET_XFER');
[left,middle,right] = H5P.get_btree_ratios(dxpl);
```

### See Also

H5P.set\_btree\_ratios

# H5P.get\_chunk\_cache

Raw data chunk cache parameters

## Syntax

```
[rdcc_nslots,rdcc_nbytes,rdcc_w0] = H5P.get_chunk_cache(dapl_id)
```

## Description

```
[rdcc_nslots,rdcc_nbytes,rdcc_w0] = H5P.get_chunk_cache(dapl_id)
```

retrieves the number of chunk slots in the raw data chunk cache hash table (`rdcc_nslots`), the maximum possible number of bytes in the raw data chunk cache (`rdcc_nbytes`), and the preemption policy value (`rdcc_w0`) on a dataset access property list.

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/vlen3D');
dap1 = H5D.get_access_plist(dset_id);
[rrdcc_nslots,rdcc_nbytes,rdcc_w0] = H5P.get_chunk_cache(dapl);
H5P.close(dapl);
H5D.close(dset_id);
H5F.close(fid);
```

## See Also

H5P.set\_chunk\_cache

## H5P.get\_dxpl\_multi

Data access property lists for multiple files

---

**Note:** H5P.get\_dxpl\_multi has been removed.

---

### Syntax

```
memb_dxpl = H5P.get_dxpl_multi(dxpl_id)
```

### Description

memb\_dxpl = H5P.get\_dxpl\_multi(dxpl\_id) returns an array of data access property lists for the multifile data transfer property list specified by dxpl\_id.

## H5P.get\_edc\_check

Determine if error detection is enabled

### Syntax

```
check = H5P.get_edc_check(plist_id)
```

### Description

`check = H5P.get_edc_check(plist_id)` queries the dataset transfer property list, specified by `plist_id`, to determine whether error detection is enabled for data read operations. Returns either `H5Z_ENABLE_EDC` or `H5Z_DISABLE_EDC`.

### Examples

```
dxpl = H5P.create('H5P_DATASET_XFER');
check = H5P.get_edc_check(dxpl);
switch(check)
 case H5ML.get_constant_value('H5Z_ENABLE_EDC')
 fprintf('error detection enabled\n');
 case H5ML.get_constant_value('H5Z_DISABLE_EDC')
 fprintf('error detection disabled\n');
end
```

### See Also

`H5P.set_edc_check`

## H5P.get\_hyper\_vector\_size

Number of I/O vectors

### Syntax

```
sz = H5P.get_hyper_vector_size(dxpl_id)
```

### Description

`sz = H5P.get_hyper_vector_size(dxpl_id)` returns the number of I/O vectors to be read/written in hyperslab I/O.

### Examples

```
dxpl = H5P.create('H5P_DATASET_XFER');
sz = H5P.get_hyper_vector_size(dxpl);
```

### See Also

`H5P.set_hyper_vector_size`

## H5P.set\_btree\_ratios

Set B-tree split ratios for dataset transfer

### Syntax

```
H5P.set_btree_ratios(plist_id, left, middle, right)
```

### Description

`H5P.set_btree_ratios(plist_id, left, middle, right)` sets the B-tree split ratios for the dataset transfer property list specified by `plist_id`. The `left` argument specifies the B-tree split ratio for left-most nodes. `right` specifies the B-tree split ratio for right-most nodes and lone nodes. `middle` specifies the B-tree split ratio for all other nodes.

### Examples

```
dxpl = H5P.create('H5P_DATASET_XFER');
H5P.set_btree_ratios(dxpl, 0.2, 0.6, 0.95);
```

### See Also

`H5P.get_btree_ratios`

## H5P.set\_chunk\_cache

Set raw data chunk cache parameters

### Syntax

```
H5P.set_chunk_cache(dapl_id, rdcc_nslots, rdcc_nbytes, rdcc_w0)
```

### Description

`H5P.set_chunk_cache(dapl_id, rdcc_nslots, rdcc_nbytes, rdcc_w0)` sets the number of elements (`rdcc_nslots`), the total number of bytes (`rdcc_nbytes`), and the preemption policy value (`rdcc_w0`) in the raw data chunk cache.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/v1en3D');
dap1 = H5D.get_access_plist(dset_id);
H5P.set_chunk_cache(dap1, 500, 1e6, 0.7);
H5P.close(dap1);
H5D.close(dset_id);
H5F.close(fid);
```

### See Also

`H5P.get_chunk_cache`

## H5P.set\_dxpl\_multi

Set data transfer property list for multifile driver

---

**Note:** H5P.set\_dxpl\_multi has been removed.

---

### Syntax

```
H5P.set_dxpl_multi(dxpl_id, memb_dxpl)
```

### Description

H5P.set\_dxpl\_multi(dxpl\_id, memb\_dxpl) sets the data transfer property list dxpl\_id to use the multifile driver. memb\_dxpl is an array of data access property lists.

## H5P.set\_edc\_check

Enable error detection for dataset transfer

### Syntax

```
H5P.set_edc_check(plist_id,check)
```

### Description

`H5P.set_edc_check(plist_id,check)` sets the dataset transfer property list specified by `plist_id` to enable or disable error detection when reading data. `check` can have the value `H5Z_ENABLE_EDC` or `H5Z_DISABLE_EDC`.

### Examples

Disable error detection for a default dataset transfer property list.

```
dxpl = H5P.create('H5P_DATASET_XFER');
H5P.set_edc_check(dxpl, 'H5Z_DISABLE_EDC');
```

### See Also

`H5P.get_edc_check`

## H5P.set\_hyper\_vector\_size

Set number of I/O vectors for hyperslab I/O

### Syntax

```
H5P.set_hyper_vector_size(dxpl_id,size)
```

### Description

`H5P.set_hyper_vector_size(dxpl_id,size)` sets the number of I/O vectors to be accumulated in memory before being issued to the lower levels of the HDF5 library for reading or writing the actual data. `dxpl_id` is a dataset transfer property list identifier. `size` specifies the number of I/O vectors to accumulate in memory for I/O operations.

### Examples

```
dxpl = H5P.create('H5P_DATASET_XFER');
H5P.set_hyper_vector_size(dxpl,2048);
```

### See Also

`H5P.get_hyper_vector_size`

## H5P.all\_filters\_avail

Determine availability of all filters

### Syntax

```
value = H5P.all_filters_avail(dcpl_id)
```

### Description

`value = H5P.all_filters_avail(dcpl_id)` returns a positive value if all of the filters set in the dataset creation property list `dcpl_id` are currently available, and zero if they are not. A negative value indicates failure.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/float');
dcpl = H5D.get_create_plist(dset_id);
if H5P.all_filters_avail(dcpl)
 fprintf('all filters available\n');
else
 fprintf('all filters not available\n');
end
H5P.close(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

### See Also

H5P.set\_filter

# H5P.fill\_value\_defined

Determine if fill value is defined

## Syntax

```
fvstatus = H5P.fill_value_defined(plist_id)
```

## Description

`fvstatus = H5P.fill_value_defined(plist_id)` determines whether a fill value is defined in the dataset creation property list `plist_id`. The `fvstatus` output can have any of the following values: `H5D_FILL_VALUE_UNDEFINED`, `H5D_FILL_VALUE_DEFAULT`, or `H5D_FILL_VALUE_USER_DEFINED`.

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/float');
dcpl = H5D.get_create_plist(dset_id);
fvstatus = H5P.fill_value_defined(dcpl);
switch(fvstatus)
 case H5ML.get_constant_value('H5D_FILL_VALUE_UNDEFINED')
 fprintf('fill value undefined\n');
 case H5ML.get_constant_value('H5D_FILL_VALUE_DEFAULT')
 fprintf('fill value set to default\n');
 case H5ML.get_constant_value('H5D_FILL_VALUE_USER_DEFINED')
 fprintf('fill value is user defined\n');
end
```

## See Also

[H5P.get\\_fill\\_value](#) | [H5P.set\\_fill\\_value](#)

## H5P.get\_alloc\_time

Return timing of storage space allocation

### Syntax

```
alloc_time = H5P.get_alloc_time(plist_id)
```

### Description

`alloc_time = H5P.get_alloc_time(plist_id)` retrieves the timing for storage space allocation from the dataset creation property list specified by `plist_id`. The `alloc_time` output can have any of the following values: `H5D_ALLOC_TIME_DEFAULT`, `H5D_ALLOC_TIME_EARLY`, `H5D_ALLOC_TIME_INCR`, or `H5D_ALLOC_TIME_LATE`.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
alloc_time = H5P.get_alloc_time(dcpl);
switch(alloc_time)
 case H5ML.get_constant_value('H5D_ALLOC_TIME_DEFAULT')
 fprintf('allocation time is default\n');
 case H5ML.get_constant_value('H5D_ALLOC_TIME_EARLY')
 fprintf('allocation time is dataset creation time\n');
 case H5ML.get_constant_value('H5D_ALLOC_TIME_INCR')
 fprintf('allocation time is incremental\n');
 case H5ML.get_constant_value('H5D_ALLOC_TIME_LATE')
 fprintf('allocation time is when data is first written\n');
end
```

# H5P.get\_chunk

Return size of chunks

## Syntax

```
[rank,h5_chunk_dims] = H5P.get_chunk(plist_id)
```

## Description

[rank,h5\_chunk\_dims] = H5P.get\_chunk(plist\_id) retrieves the size of chunks for the raw data of a chunked layout dataset for the dataset creation property list specified by `plist_id`.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_chunk_dims` parameter assumes C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g4/time');
dcpl = H5D.get_create_plist(dset_id);
[rank,chunk_dims] = H5P.get_chunk(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

## See Also

H5P.set\_chunk

## H5P.get\_external

Return information about external file

### Syntax

```
[name,offset,size] = H5P.get_external(plist_id,idx)
```

### Description

[name,offset,size] = H5P.get\_external(plist\_id,idx) returns information about the external file specified by the dataset creation property list `plist_id`. The `idx` specifies the external file index, which is a number from zero to N-1, where N is the value returned by H5P.get\_external\_count. The `name` output returns the name of the external file (limited by 2048 characters). The `offset` output returns the location in bytes, from the beginning of the external file, where the data starts. The `size` output returns the size of the external data.

### See Also

H5P.get\_external\_count

## H5P.get\_external\_count

Return count of external files

### Syntax

```
num_files = H5P.get_external_count(plist_id)
```

### Description

`num_files = H5P.get_external_count(plist_id)` returns the number of external files for the dataset creation property list, `plist_id`.

### See Also

`H5P.get_external`

## H5P.get\_fill\_time

Return time when fill values are written to dataset

### Syntax

```
fill_time = H5P.get_fill_time(plist_id)
```

### Description

`fill_time = H5P.get_fill_time(plist_id)` returns the time when fill values are written to the dataset specified by the dataset creation property list `plist_id`. The `fill_time` output is one of the following values: `H5D_FILL_TIME_IFSET`, `H5D_FILL_TIME_ALLOC`, or `H5D_FILL_TIME_NEVER`.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
fill_time = H5P.get_fill_time(dcpl);
switch(fill_time)
 case H5ML.get_constant_value('H5D_FILL_TIME_IFSET')
 fprintf('upon allocation if and only if fill value set by user\n');
 case H5ML.get_constant_value('H5D_FILL_TIME_ALLOC')
 fprintf('written when storage space is allocated\n');
 case H5ML.get_constant_value('H5D_FILL_TIME_NEVER')
 fprintf('fill values are never written\n');
end
```

### See Also

[H5P.get\\_fill\\_time](#) | [H5P.set\\_fill\\_value](#)

## H5P.get\_fill\_value

Return dataset fill value

### Syntax

```
value = H5P.get_fill_value(plist_id,type_id)
```

### Description

`value = H5P.get_fill_value(plist_id,type_id)` returns the dataset fill value defined in the dataset creation property list `plist_id`. The `type_id` input specifies the datatype of the returned fill value.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
type_id = H5T.copy('H5T_NATIVE_INT');
fill_value = H5P.get_fill_value(dcpl,type_id);
```

### See Also

[H5P.get\\_fill\\_time](#) | [H5P.set\\_fill\\_time](#) | [H5P.set\\_fill\\_value](#)

## H5P.get\_filter

Return information about filter in pipeline

### Syntax

```
[filter,flags,cd_values,name] = H5P.get_filter(plist_id,index)
[filter,flags,cd_values,name,filter_config] =
H5P.get_filter(plist_id,index)
```

### Description

[filter,flags,cd\_values,name] = H5P.get\_filter(plist\_id,index) returns information about the filter, specified by its filter index, in the filter pipeline, specified by the property list with which it is associated. This interface corresponds to the 1.6 version of H5Pget\_filter in the HDF5 library.

[filter,flags,cd\_values,name,filter\_config] = H5P.get\_filter(plist\_id,index) returns information about the filter, specified by its filter index, in the filter pipeline, specified by the property list with which it is associated. It also returns information about the filter. Consult the HDF5 documentation for H5Zget\_filter\_info for information about filter\_config. This interface corresponds to the 1.8 version of H5Pget\_filter in the HDF5 library.

### See Also

H5P.get\_filter\_by\_id | H5P.get\_nfilters | H5P.modify\_filter |  
H5P.remove\_filter

## H5P.get\_filter\_by\_id

Return information about specified filter

### Syntax

```
[flags,cd_values,name,filter_config] =
H5P.get_filter_by_id(plist_id,idx)
```

### Description

```
[flags,cd_values,name,filter_config] =
H5P.get_filter_by_id(plist_id,idx) returns information about the filter
specified by the filter id, idx.
```

### See Also

H5P.get\_filter | H5P.get\_nfilters | H5P.modify\_filter |  
H5P.remove\_filter

## H5P.get\_layout

Determine layout of raw data for dataset

### Syntax

```
layout = H5P.get_layout(dcp1)
```

### Description

`layout = H5P.get_layout(dcp1)` returns the layout of the raw data for the dataset specified by the dataset creation property list, `dcp1`. Possible values are: `H5D_COMPACT`, `H5D_CONTIGUOUS`, or `H5D_CHUNKED`.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
dcp1 = H5D.get_create_plist(dset_id);
layout = H5P.get_layout(dcp1);
switch(layout)
 case H5ML.get_constant_value('H5D_COMPACT')
 fprintf('layout is compact\n');
 case H5ML.get_constant_value('H5D_CONTIGUOUS')
 fprintf('layout is contiguous\n');
 case H5ML.get_constant_value('H5D_CHUNKED')
 fprintf('layout is chunked\n');
end
```

### See Also

`H5P.set_layout`

## H5P.get\_nfilters

Return number of filters in pipeline

### Syntax

```
num_filters = H5P.get_nfilters(plist_id)
```

### Description

`num_filters = H5P.get_nfilters(plist_id)` returns the number of filters defined in the filter pipeline associated with the dataset creation property list, `plist_id`.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g4/world');
dcpl = H5D.get_create_plist(dset_id);
num_filters = H5P.get_nfilters(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

### See Also

[H5P.get\\_filter](#) | [H5P.get\\_filter\\_by\\_id](#) | [H5P.modify\\_filter](#) | [H5P.remove\\_filter](#)

## H5P.modify\_filter

Modify filter in pipeline

### Syntax

```
H5P.modify_filter(plist_id,filter_id,flags,cd_values)
```

### Description

`H5P.modify_filter(plist_id,filter_id,flags,cd_values)` modifies the specified filter in the filter pipeline. `plist_id` is a property list identifier. `flags` is a bit vector specifying certain general properties of the filter. `cd_values` specifies auxiliary data for the filter.

### See Also

`H5P.get_filter` | `H5P.get_filter_by_id` | `H5P.get_nfilters` |  
`H5P.remove_filter`

## H5P.remove\_filter

Remove filter from property list

### Syntax

```
H5P.remove_filter(plist_id,filter)
```

### Description

H5P.remove\_filter(plist\_id,filter) removes the specified filter from the filter pipeline. plist\_id is the dataset creation property list identifier.

### See Also

H5P.get\_filter | H5P.get\_filter\_by\_id | H5P.get\_nfilters |  
H5P.modify\_filter

## H5P.set\_alloc\_time

Set timing for storage space allocation

### Syntax

```
H5P.set_alloc_time(plist_id,alloc_time)
```

### Description

`H5P.set_alloc_time(plist_id,alloc_time)` sets the timing for the allocation of storage space for a dataset's raw data. `plist_id` is a dataset creation property list. `alloc_time` can have any of the following values: `H5D_ALLOC_TIME_DEFAULT`, `H5D_ALLOC_TIME_EARLY`, `H5D_ALLOC_TIME_INC`, or `H5D_ALLOC_TIME_LATE`.

### Examples

Create a 1000x500 double precision dataset with late allocation time.

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [1000 500];
h5_dims = flip1r(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
alloc_time = H5ML.get_constant_value('H5D_ALLOC_TIME_LATE');
H5P.set_alloc_time(dcpl,alloc_time);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

### See Also

`H5P.get_alloc_time`

# H5P.set\_chunk

Set chunk size

## Syntax

```
H5P.set_chunk(plist_id,h5_chunk_dims)
```

## Description

`H5P.set_chunk(plist_id,h5_chunk_dims)` sets the size of the chunks used to store a chunked layout dataset. `plist_id` is a dataset creation property list identifier. `h5_chunk_dims` is an array specifying the size, in dataset elements, of each chunk.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_chunk_dims` parameter assumes C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

## Examples

Create a two dimensional double precision dataset that has an initial size of [512 1024], but is also unlimited in both dimensions and has a chunk size of [512 1024].

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
unlimited = H5ML.get_constant_value('H5S_UNLIMITED');
dims = [512 1024];
h5_dims = flip1r(dims);
h5_maxdims = [unlimited unlimited];
space_id = H5S.create_simple(2,[1024 512],h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
chunk_dims = [512 1024];
h5_chunk_dims = flip1r(chunk_dims);
H5P.set_chunk(dcpl,h5_chunk_dims);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
```

```
H5D.close(dset_id);
H5F.close(fid);
```

**See Also**

H5P.get\_chunk

## H5P.set\_deflate

Set compression method and compression level

### Syntax

```
H5P.set_deflate(plist_id,level)
```

### Description

`H5P.set_deflate(plist_id,level)` sets the compression method for the dataset creation property list specified by `plist_id` to `H5D_COMPRESS_DEFLATE`. `level` specifies the compression level as a value from 0 and 9, inclusive. Lower values results in less compression.

### Examples

Create a two dimensional double precision dataset that has an initial size of [512 1024], but is also unlimited in both dimensions and has a chunk size of [512 1024] and a compression level of 5.

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
unlimited = H5ML.get_constant_value('H5S_UNLIMITED');
dims = [512 1024];
h5_dims = fliplr(dims);
h5_maxdims = [unlimited unlimited];
space_id = H5S.create_simple(2,[1024 512],h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
chunk_dims = [512 1024];
h5_chunk_dims = fliplr(chunk_dims);
H5P.set_chunk(dcpl,h5_chunk_dims);
H5P.set_deflate(dcpl,5);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

## H5P.set\_external

Add additional file to external file list

### Syntax

```
H5P.set_external(plist_id,name,offset,nbytes)
```

### Description

`H5P.set_external(plist_id,name,offset,nbytes)` adds the external file specified by `name` to the list of external files in the dataset creation property list, `plist_id`. The `offset` argument specifies the location, in bytes, where the data starts relative to the beginning of the file. `nbytes` is the number of bytes reserved in the file for the data. `nbytes` may also be given as `'H5F_UNLIMITED'`, in which case the external file may be of unlimited size.

### Examples

Create a dataset with an unlimited size external file.

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 50];
h5_dims = fliplr(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
H5P.set_external(dcpl,'myexternalfile.dat',0,'H5F_UNLIMITED');
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
data = rand(dims);
dxpl = 'H5P_DEFAULT';
H5D.write(dset_id,'H5ML_DEFAULT','H5S_ALL','H5S_ALL',dxpl,data);
H5D.close(dset_id);
H5F.close(fid);
```

### See Also

## H5P.set\_fill\_time

Set time when fill values are written to dataset

### Syntax

```
H5P.set_fill_time(plist_id,fill_time)
```

### Description

`H5P.set_fill_time(plist_id,fill_time)` sets the timing for writing fill values to a dataset in the dataset creation property list `plist_id`. The timing can be specified by one of the following values: `H5D_FILL_TIME_IFSET`, `H5D_FILL_TIME_ALLOC`, or `H5D_FILL_TIME_NEVER`.

### Examples

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 50];
h5_dims = fliplr(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
fill_time = H5ML.get_constant_value('H5D_FILL_TIME_ALLOC');
H5P.set_fill_time(dcpl,fill_time);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

### See Also

[H5P.get\\_fill\\_time](#) | [H5P.get\\_fill\\_value](#) | [H5P.set\\_fill\\_value](#)

## H5P.set\_fill\_value

Set fill value for dataset creation property list

### Syntax

```
H5P.set_fill_value(plist_id,type_id,value)
```

### Description

`H5P.set_fill_value(plist_id,type_id,value)` sets the fill value for a the dataset creation property list specified by `plist_id`. The `value` argument specifies the fill value. `type_id` specifies the datatype of the fill value. Setting `value` to an empty array indicates that the fill value is to be undefined.

### Examples

Create a double precision dataset with a fill value of -999.

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 50];
h5_dims = flip1r(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
fill_time = H5ML.get_constant_value('H5D_FILL_TIME_ALLOC');
H5P.set_fill_time(dcpl,fill_time);
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
H5P.set_fill_value(dcpl,type_id,-999);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

## H5P.set\_filter

Add filter to filter pipeline

### Syntax

```
H5P.set_filter(plist_id,filter,flags,cd_values)
```

### Description

`H5P.set_filter(plist_id,filter,flags,cd_values)` adds the specified filter and corresponding properties to the end of an output filter pipeline. `plist_id` is a property list identifier. `filter` is a filter identifier and should correspond to one of the following values:

H5P\_FILTER\_DEFLATE

H5P\_FILTER\_SHUFFLE

H5P\_FILTER\_FLETCHER32

`flags` is a bit vector specifying properties of the filter. `cd_values` is an array that contains auxiliary data for the filter.

### See Also

`H5P.set_deflate` | `H5P.set_fletcher32` | `H5P.set_shuffle`

## H5P.set\_fletcher32

Set Fletcher32 checksum filter in dataset creation

### Syntax

```
H5P.set_fletcher32(plist_id)
```

### Description

`H5P.set_fletcher32(plist_id)` sets the Fletcher32 checksum filter in the dataset creation property list specified by `plist_id`. The dataset creation property list must also have chunking enabled.

### Examples

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,dims,[]);
dcpl = H5P.create('H5P_DATASET_CREATE');
chunk_dims = [10 20];
h5_chunk_dims = fliplr(chunk_dims);
H5P.set_chunk(dcpl,h5_chunk_dims);
H5P.set_fletcher32(dcpl);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

### See Also

# H5P.set\_layout

Set type of storage for dataset

## Syntax

```
H5P.set_layout(dcpl,layout)
```

## Description

`H5P.set_layout(dcpl,layout)` sets the type of storage used to store the raw data for the dataset creation property list, `dcpl`. The `layout` argument specifies the type of storage layout for raw data: `H5D_COMPACT`, `H5D_CONTIGUOUS`, or `H5D_CHUNKED`.

## Examples

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,dims,[]);
dcpl = H5P.create('H5P_DATASET_CREATE');
layout = H5ML.get_constant_value('H5D_CONTIGUOUS');
H5P.set_layout(dcpl,layout);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

## **H5P.set\_nbit**

Set N-Bit filter

### **Syntax**

```
H5P.set_nbit(plist_id)
```

### **Description**

`H5P.set_nbit(plist_id)` sets the N-Bit filter, `H5Z_FILTER_NBIT`, in the dataset creation property list `plist_id`.

# H5P.set\_scaleoffset

Set Scale-Offset filter

## Syntax

```
H5P.set_scaleoffset(plistId, scaleType, scaleFactor)
```

## Description

`H5P.set_scaleoffset(plistId, scaleType, scaleFactor)` sets the Scale-Offset filter, `H5Z_FILTER_SCALEOFFSET`, for a dataset. For integer data types, the parameter `scaleType` should be set to the enumerated value `H5Z_SO_INT`. For floating-point data types, the `scaleType` should be the enumerated value `H5Z_SO_FLOAT_DSCALE`. Chunking must already be enabled on the dataset creation property list.

## See Also

`H5P.set_chunk`

## H5P.set\_shuffle

Set shuffle filter

### Syntax

```
H5P.set_shuffle(plist_id)
```

### Description

`H5P.set_shuffle(plist_id)` sets the shuffle filter, `H5Z_FILTER_SHUFFLE`, in the dataset creation property list `plist_id`. Compression must be enabled on the dataset creation property list in order to use the shuffle filter, and best results are usually obtained when the shuffle filter is set immediately prior to setting the deflate filter.

### Examples

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,dims,[]);
dcpl = H5P.create('H5P_DATASET_CREATE');
chunk_dims = [10 20];
h5_chunk_dims = fliplr(chunk_dims);
H5P.set_chunk(dcpl,h5_chunk_dims);
H5P.set_shuffle(dcpl);
H5P.set_deflate(dcpl,5);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

### See Also

`H5P.set_deflate`

# H5P.get\_alignment

Retrieve alignment properties

## Syntax

```
[threshold,alignment] = H5P.get_alignment(plist_id)
```

## Description

`[threshold,alignment] = H5P.get_alignment(plist_id)` retrieves the current settings for alignment properties from the file access property list specified by `plist_id`.

## Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
[threshold,alignment] = H5P.get_alignment(fapl);
H5P.close(fapl);
H5F.close(fid);
```

## H5P.get\_driver

Low-level file driver

### Syntax

```
driver_id = H5P.get_driver(plist_id)
```

### Description

`driver_id = H5P.get_driver(plist_id)` returns the identifier of the low-level file driver associated with the file access property list or data transfer property list specified by `plist_id`. See HDF5 documentation for a list of valid return values.

### Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
driver_id = H5P.get_driver(fapl);
if (driver_id == H5ML.get_constant_value('H5FD_SEC2'))
 fprintf('File driver is H5FD_SEC2.\n');
end
H5P.close(fapl);
H5F.close(fid);
```

### See Also

`H5ML.get_constant_value`

## H5P.get\_family\_offset

Offset for family file driver

### Syntax

```
offset = H5P.get_family_offset(fapl_id)
```

### Description

`offset = H5P.get_family_offset(fapl_id)` retrieves the value of `offset` from the file access property list, `fapl_id`. `offset` is the offset of the data in the HDF5 file that is stored on disk in the selected member file in a family of files.

### See Also

`H5P.set_family_offset`

## H5P.get\_fapl\_core

Information about core file driver properties

### Syntax

```
[increment,backing_store] = H5P.get_fapl_core(fapl_id)
```

### Description

[increment,backing\_store] = H5P.get\_fapl\_core(fapl\_id) queries the H5FD\_CORE driver properties as set by H5P.set\_fapl\_core. The fapl\_id argument specifies a file access property list. The return value increment specifies the size, in bytes, of memory increments. backing\_store is a Boolean flag indicating whether to write the file contents to disk when the file is closed.

### See Also

H5P.set\_fapl\_core

# H5P.get\_fapl\_family

File access property list information

## Syntax

```
[memb_size,memb_fapl_id] = H5P.get_fapl_family(fapl_id)
```

## Description

[memb\_size,memb\_fapl\_id] = H5P.get\_fapl\_family(fapl\_id) returns the size in bytes of each file member and the identifier of the file access property list for use with the family driver specified by fapl\_id.

## See Also

H5P.set\_fapl\_family

## H5P.get\_fapl\_multi

Information about multifile access property list

### Syntax

```
[memb_map,memb_fapl,memb_name,memb_addr,relax] =
H5P.get_fapl_multi(fapl_id)
```

### Description

```
[memb_map,memb_fapl,memb_name,memb_addr,relax] =
H5P.get_fapl_multi(fapl_id)
```

returns information about the multifile access property list specified by `fapl_id`. The `memb_map` output maps memory usage types to other memory usage types. `memb_fapl` is a property list for each memory usage type. `memb_name` is the name generator for names of member files. `relax` is a Boolean value that, when non-zero, allows read-only access to incomplete file sets.

### See Also

H5P.set\_fapl\_multi

# H5P.get\_fclose\_degree

File close degree

## Syntax

```
degree = H5P.get_fclose_degree(fapl_id)
```

## Description

`degree = H5P.get_fclose_degree(fapl_id)` returns the current setting of the file close degree property `fc_degree` in the file access property list specified by `fapl_id`. Possible return values are: `H5F_CLOSE_DEFAULT`, `H5F_CLOSE_WEAK`, `H5F_CLOSE_SEMI`, or `H5F_CLOSE_STRONG`.

## Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
degree = H5P.get_fclose_degree(fapl);
switch(degree)
 case H5ML.get_constant_value('H5F_CLOSE_DEFAULT')
 fprintf('file close degree is default\n');
 case H5ML.get_constant_value('H5F_CLOSE_WEAK')
 fprintf('file close degree is weak\n');
 case H5ML.get_constant_value('H5F_CLOSE_SEMI')
 fprintf('close degree is semi\n');
 case H5ML.get_constant_value('H5F_CLOSE_STRONG')
 fprintf('close degree is strong\n');
end
H5P.close(fapl);
H5F.close(fid);
```

## See Also

`H5P.set_fclose_degree`

## H5P.get\_libver\_bounds

Library version bounds settings

### Syntax

```
[low,high] = H5P.get_libver_bounds(fapl_id)
```

### Description

[low,high] = H5P.get\_libver\_bounds(fapl\_id) gets bounds on library version bounds settings that control the format versions used when creating objects in the file with access property list fapl\_id.

### Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
[low,high] = H5P.get_libver_bounds(fapl);
```

### See Also

H5F.get\_access\_plist | H5P.set\_libver\_bounds

# H5P.get\_gc\_references

Garbage collection references setting

## Syntax

```
gc_ref = H5P.get_gc_references(fapl_id)
```

## Description

`gc_ref = H5P.get_gc_references(fapl_id)` returns the current setting for the garbage collection references property from the file access property list specified by `fapl_id`. If `gc_ref` is 1, garbage collection is on; if 0, garbage collection is off.

## Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
gc_ref = H5P.get_gc_references(fapl);
H5P.close(fapl);
H5F.close(fid);
```

## See Also

`H5P.set_gc_references`

## H5P.get\_mdc\_config

Metadata cache configuration

### Syntax

```
config_struct = H5P.get_mdc_config(plist_id)
```

### Description

`config_struct = H5P.get_mdc_config(plist_id)` returns the current metadata cache configuration from the indicated file access property list.

### Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
config = H5P.get_mdc_config(fapl);
H5P.close(fapl);
H5F.close(fid);
```

### See Also

`H5P.set_mdc_config`

# H5P.get\_meta\_block\_size

Metadata block size setting

## Syntax

```
sz = H5P.get_meta_block_size(fapl_id)
```

## Description

`sz = H5P.get_meta_block_size(fapl_id)` returns the current minimum size, in bytes, of new metadata block allocations.

## Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
sz = H5P.get_meta_block_size(fapl);
H5P.close(fapl);
H5F.close(fid);
```

## See Also

`H5P.set_meta_block_size`

## **H5P.get\_multi\_type**

Type of data property for MULTI driver

### **Syntax**

```
type = H5P.get_multi_type(fapl_id)
```

### **Description**

`type = H5P.get_multi_type(fapl_id)` returns the type of data setting from the file access or data transfer property list, `fapl_id`.

This function should only be used with an HDF5 file written as a set of files with the MULTI file driver.

### **See Also**

`H5P.set_multi_type`

## H5P.get\_sieve\_buf\_size

Maximum data sieve buffer size

### Syntax

```
sz = H5P.get_sieve_buf_size(fapl_id)
```

### Description

`sz = H5P.get_sieve_buf_size(fapl_id)` returns the current maximum size of the data sieve buffer.

### Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
sz = H5P.get_sieve_buf_size(fapl);
H5P.close(fapl);
H5F.close(fid);
```

### See Also

`H5P.set_sieve_buf_size`

## H5P.get\_small\_data\_block\_size

Small data block size setting

### Syntax

```
sz = H5P.get_small_data_block_size(fapl_id)
```

### Description

`sz = H5P.get_small_data_block_size(fapl_id)` returns the current setting for the size of the small data block. `fapl_id` is a file access property list identifier.

### Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
sz = H5P.get_small_data_block_size(fapl);
H5P.close(fapl);
H5F.close(fid);
```

### See Also

`H5P.set_small_data_block_size`

# H5P.set\_alignment

Set alignment properties for file access property list

## Syntax

```
H5P.set_alignment(fapl_id, threshold, alignment)
```

## Description

`H5P.set_alignment(fapl_id, threshold, alignment)` sets the alignment properties of the file access property list specified by `fapl_id` so that any file object greater than or equal in size to `threshold` (in bytes) is aligned on an address which is a multiple of `alignment`.

In most cases the default values of `threshold` and `alignment` result in the best performance.

## See Also

`H5P.get_alignment`

## **H5P.set\_family\_offset**

Set offset property for family of files

### **Syntax**

```
H5P.set_family_offset(fapl_id,offset)
```

### **Description**

`H5P.set_family_offset(fapl_id,offset)` sets `offset` property in the file access property list specified by `fapl_id` for low-level access to a file in a family of files. `offset` identifies a user-determined location from the beginning of the HDF5 file in bytes.

### **See Also**

`H5P.get_family_offset`

## H5P.set\_fapl\_core

Modify file access to use H5FD\_CORE driver

### Syntax

```
H5P.set_fapl_core(fapl_id,increment,backing_store)
```

### Description

`H5P.set_fapl_core(fapl_id,increment,backing_store)` modifies the file access property list to use the H5FD\_CORE driver. `increment` specifies the increment by which allocated memory is to be increased each time more memory is required. `backing_store` is a Boolean flag that, when non-zero, indicates the file contents should be written to disk when the file is closed.

### Examples

Create a file image in memory only.

```
plist = 'H5P_DEFAULT';
ndatasets = 20;
block_size = 1024*1024;
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_fapl_core(fapl,2^16,false);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',plist,fapl);
space_id = H5S.create_simple(1, block_size, []);
type_id = H5T.copy('H5T_IEEE_F64LE');
data = zeros(block_size,1);
for j = 1:ndatasets
 dsname = sprintf('dset%02d', j);
 fprintf('Writing dataset %s...\n',dsname);
 dsid = H5D.create(fid,dsname,type_id,space_id,'H5P_DEFAULT');
 H5D.write(dsid,'H5ML_DEFAULT',space_id,space_id,plist,data);
 H5D.close(dsid);
end
H5P.close(fapl);
H5S.close(space_id);
```

```
H5T.close(type_id);
H5F.close(fid);
dir('myfile.h5');
```

## **See Also**

H5P.get\_fapl\_core

# H5P.set\_fapl\_family

Set file access to use family driver

## Syntax

```
H5P.set_fapl_family(fapl_id,memb_size,memb_fapl_id)
```

## Description

`H5P.set_fapl_family(fapl_id,memb_size,memb_fapl_id)` sets the file access property list, specified by `fapl_id`, to use the family driver. `memb_size` is the size in bytes of each file member. `memb_fapl_id` is the identifier of the file access property list to be used for each family member.

## Examples

```
plist = 'H5P_DEFAULT';
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_fapl_family(fapl, 8192, plist);
fid = H5F.create('family%d.h5', 'H5F_ACC_TRUNC', 'H5P_DEFAULT', fapl);
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [50 25];
h5_dims = flipr(dims);
space_id = H5S.create_simple(2, h5_dims, []);
dset_id = H5D.create(fid, 'DS', type_id, space_id, plist);
data = reshape(1:prod(dims), dims);
H5D.write(dset_id, 'H5ML_DEFAULT', 'H5S_ALL', 'H5S_ALL', plist, data);
H5P.close(fapl);
H5T.close(type_id);
H5S.close(space_id);
H5D.close(dset_id);
dir('*h5');
h5disp('family%d.h5');
```

## See Also

`H5P.get_fapl_family`

## H5P.set\_fapl\_log

Set use of logging driver

### Syntax

```
H5P.set_fapl_log(fapl_id, logfile, flags, buf_size)
```

### Description

`H5P.set_fapl_log(fapl_id, logfile, flags, buf_size)` modifies the file access property list, `fapl_id`, to use the logging driver `H5FD_LOG`. `logfile` is the name of the file in which the logging entries are to be recorded. `flags` is a bit mask that specifies the types of activity to log. See the HDF5 documentation for a list of available flag settings. `buf_size` specifies the size of the logging buffer.

## H5P.set\_fapl\_multi

Set use of multifile driver

### Syntax

```
H5P.set_fapl_multi(fapl_id,relax)
```

```
H5P.set_fapl_multi(fapl_id,memb_map,memb_fapl,memb_name,memb_addr,relax)
```

### Description

`H5P.set_fapl_multi(fapl_id,relax)` sets the file access property list, `fapl_id`, to access HDF5 files created with the multi-driver with default values provided by the HDF5 library. `relax` is a Boolean value that allows read-only access to incomplete file sets when set to 1.

`H5P.set_fapl_multi(fapl_id,memb_map,memb_fapl,memb_name,memb_addr,relax)` sets the file access property list to use the multifile driver. `memb_map` maps memory usage types to other memory usage types. `memb_fapl` contains a property list for each memory usage type. `memb_name` is a name generator for names of member files. `memb_addr` specifies the offsets within the virtual address space at which each type of data storage begins.

### See Also

`H5P.get_fapl_multi`

## H5P.set\_fapl\_sec2

Set file access for sec2 driver

### Syntax

```
H5P.set_fapl_sec2(fapl_id)
```

### Description

`H5P.set_fapl_sec2(fapl_id)` modifies the file access property list, `fapl_id`, to use the `H5FD_SEC2` driver.

### Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_fapl_sec2(fapl);
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcpl, fapl);
H5F.close(fid);
```

## H5P.set\_fapl\_split

Set file access for emulation of split file driver

### Syntax

```
H5P.set_fapl_split(fapl_id,meta_ext,meta_plist_id,raw_ext,raw_plist_id)
```

### Description

`H5P.set_fapl_split(fapl_id,meta_ext,meta_plist_id,raw_ext,raw_plist_id)` is a compatibility function that enables the multi-file driver to emulate the split driver from HDF5 Releases 1.0 and 1.2. `meta_ext` is a text string that specifies the metadata filename extension. `meta_plist_id` is a file access property list identifier for the metadata file. `raw_ext` is a text string that specifies the raw data filename extension. `raw_plist_id` is the file access property list identifier for the raw data file.

## H5P.set\_fapl\_stdio

Set file access for standard I/O driver

### Syntax

```
H5P.set_fapl_stdio(fapl_id)
```

### Description

`H5P.set_fapl_stdio(fapl_id)` modifies the file access property list, `fapl_id`, to use the standard I/O driver, `H5FD_STDIO`.

### Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_fapl_stdio(fapl);
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcpl, fapl);
H5F.close(fid);
```

# H5P.set\_fclose\_degree

Set file access for file close degree

## Syntax

```
H5P.set_fclose_degree(fapl_id,degree)
```

## Description

`H5P.set_fclose_degree(fapl_id,degree)` sets the file close degree property in the file access property list, `fapl_id`, to the value specified by `degree`. The `degree` argument can have any of the following values:

```
'H5F_CLOSE_WEAK'
'H5F_CLOSE_SEMI'
'H5F_CLOSE_STRONG'
'H5F_CLOSE_DEFAULT'
```

## Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_fclose_degree(fapl,'H5F_CLOSE_STRONG');
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

## See Also

`H5P.get_fclose_degree`

## H5P.set\_gc\_references

Set garbage collection references flag

### Syntax

```
H5P.set_gc_references(fapl_id,gc_ref)
```

### Description

`H5P.set_gc_references(fapl_id,gc_ref)` sets the flag for garbage collecting references for the file specified by the file access property list identifier, `fapl_id`. The `gc_ref` argument is a flag setting reference garbage collection to on (1) or off (0).

### Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_gc_references(fapl,1);
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcpl, fapl);
H5F.close(fid);
```

### See Also

`H5P.get_gc_references`

# H5P.set\_libver\_bounds

Set library version bounds for objects

## Syntax

```
H5P.set_libver_bounds(fapl_id,low,high)
```

## Description

`H5P.set_libver_bounds(fapl_id,low,high)` sets bounds on library versions, and indirectly format versions, to be used when creating objects in the file with access property list `fapl_id`. The `low` argument must be set to either of `'H5F_LIBVER_EARLIEST'`, `'H5F_LIBVER_18'` or `'H5F_LIBVER_LATEST'`. The `high` argument must be set to `'H5F_LIBVER_18'` or `'H5F_LIBVER_LATEST'`.

## Examples

Create an HDF5 file where objects are created using the latest available format for each object.

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_libver_bounds(fapl,'H5F_LIBVER_LATEST','H5F_LIBVER_LATEST');
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
```

## See Also

## **H5P.set\_mdc\_config**

Set initial metadata cache configuration

### **Syntax**

```
H5P.set_mdc_config(plist_id,config_struct)
```

### **Description**

`H5P.set_mdc_config(plist_id,config_struct)` sets the initial metadata cache configuration in the indicated file access property list to the supplied values. Before using this function, you should retrieve the current configuration using `H5P.get_mdc_config`.

Many of the fields in the structure, `config_struct`, are intended to be used only in close consultation with the HDF5 Group itself.

### **See Also**

`H5P.get_mdc_config`

# H5P.set\_meta\_block\_size

Set minimum metadata block size

## Syntax

```
H5P.set_meta_block_size(fapl_id,size)
```

## Description

`H5P.set_meta_block_size(fapl_id,size)` sets the minimum metadata block size for the file access property list specified by `fapl_id`. The `size` argument specifies minimum size, in bytes, of metadata block allocations.

## Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_meta_block_size(fapl,4096);
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcpl, fapl);
H5F.close(fid);
```

## See Also

`H5P.get_meta_block_size`

## **H5P.set\_multi\_type**

Specify type of data accessed with MULTI driver

### **Syntax**

```
H5P.set_multi_type(fapl_id,type)
```

### **Description**

`H5P.set_multi_type(fapl_id,type)` sets the type of data property in the file access or data transfer property list `fapl_id`. The `type` argument can have any of the following values: `H5FD_MEM_SUPER`, `H5FD_MEM_BTREE`, `H5FD_MEM_DRAW`, `H5FD_MEM_GHEAP`, `H5FD_MEM_LHEAP`, or `H5FD_MEM_OHDR`.

### **See Also**

`H5P.get_multi_type`

## H5P.set\_sieve\_buf\_size

Set maximum size of data sieve buffer

### Syntax

```
H5P.set_sieve_buf_size(fapl_id,buffer_size)
```

### Description

`H5P.set_sieve_buf_size(fapl_id,buffer_size)` sets `buffer_size`, the maximum size in bytes of the data sieve buffer, which is used by file drivers that are capable of using data sieving. `fapl_id` is a file access property list identifier.

### Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_sieve_buf_size(fapl,131072);
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcpl, fapl);
H5F.close(fid);
```

### See Also

`H5P.get_sieve_buf_size`

## H5P.set\_small\_data\_block\_size

Set size of block reserved for small data

### Syntax

```
H5P.set_small_data_block_size(fapl_id,size)
```

### Description

`H5P.set_small_data_block_size(fapl_id,size)` sets the maximum size, in bytes, of a contiguous block reserved for small data. `fapl_id` is a file access property list identifier.

### Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_small_data_block_size(fapl,4096);
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcpl, fapl);
H5F.close(fid);
```

### See Also

`H5P.get_small_data_block_size`

## H5P.get\_istore\_k

Return 1/2 rank of indexed storage B-tree

### Syntax

```
ik = H5P.get_istore_k(plist_id)
```

### Description

`ik = H5P.get_istore_k(plist_id)` returns the chunked storage B-tree 1/2 rank of the file creation property list specified by `plist_id`.

### Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
ik = H5P.get_istore_k(fcpl);
H5P.close(fcpl);
H5F.close(fid);
```

### See Also

[H5P.set\\_istore\\_k](#)

## H5P.get\_sizes

Return size of offsets and lengths

### Syntax

```
[sizeof_addr,sizeof_size] = H5P.get_sizes(fcpl)
```

### Description

[sizeof\_addr,sizeof\_size] = H5P.get\_sizes(fcpl) returns the size of the offsets and lengths used in an HDF5 file. fcpl specifies a file creation property list.

### Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
[soaddr, sosize] = H5P.get_sizes(fcpl);
H5P.close(fcpl);
H5F.close(fid);
```

### See Also

H5P.set\_sizes

## H5P.get\_sym\_k

Return size of B-tree 1/2 rank and leaf node 1/2 size

### Syntax

```
[ik,lk] = H5P.get_sym_k(plist_id)
```

### Description

[ik,lk] = H5P.get\_sym\_k(plist\_id) returns the size of the symbol table B-tree 1/2 rank, ik, and the symbol table leaf node 1/2 size, lk. The plist\_id argument is a file creation property list identifier.

### Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
[ik, lk] = H5P.get_sym_k(fcpl);
H5P.close(fcpl);
H5F.close(fid);
```

### See Also

H5P.set\_sym\_k

## H5P.get\_userblock

Return size of user block

### Syntax

```
sz = H5P.get_userblock(plist_id)
```

### Description

`sz = H5P.get_userblock(plist_id)` returns the size of a user block in a file creation property list. `plist_id` is a property list identifier.

### Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
sz = H5P.get_userblock(fcpl);
H5P.close(fcpl);
H5F.close(fid);
```

### See Also

`H5P.set_userblock`

## H5P.get\_version

Return version information for file creation property list

### Syntax

```
[superblock, freelist, stab, shhdr] = H5P.get_version(fcpl)
```

### Description

[superblock, freelist, stab, shhdr] = H5P.get\_version(fcpl) returns the version of the super block, the global freelist, the symbol table, and the shared object header. Retrieving this information requires the file creation property list.

### Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
[super, freelist, stab, shhdr] = H5P.get_version(fcpl);
H5P.close(fcpl);
H5F.close(fid);
```

## H5P.set\_istore\_k

Set size of parameter for indexing chunked datasets

### Syntax

```
H5P.set_istore_k(plist_id, ik)
```

### Description

`H5P.set_istore_k(plist_id, ik)` sets the size of the parameter used to control the B-trees for indexing chunked datasets for the file creation property list specified by `plist_id`. The `ik` argument is one half the rank of a tree that stores chunked raw data.

### Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_istore_k(fcpl, 64);
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcpl, fapl);
H5F.close(fid);
```

### See Also

`H5P.get_istore_k`

## H5P.set\_sizes

Set byte size of offsets and lengths

### Syntax

```
H5P.set_sizes(plist_id, sizeof_addr, sizeof_size)
```

### Description

H5P.set\_sizes(plist\_id, sizeof\_addr, sizeof\_size) sets the byte size of the offsets and lengths used to address objects in an HDF5 file. `plist_id` is a file creation property list.

### See Also

H5P.get\_sizes

## H5P.set\_sym\_k

Set size of parameters used to control symbol table nodes

### Syntax

```
H5P.set_sym_k(plist_id, ik, lk)
```

### Description

`H5P.set_sym_k(plist_id, ik, lk)` sets the size of parameters used to control the symbol table nodes for the file access property list, `plist_id`. The `ik` argument is one half the rank of a tree that stores a symbol table for a group. `lk` is one half of the number of symbols that can be stored in a symbol table node.

### Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_sym_k(fcpl, 32, 8);
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcpl, fapl);
H5F.close(fid);
```

### See Also

`H5P.get_sym_k`

# H5P.set\_userblock

Set user block size

## Syntax

```
H5P.set_userblock(plist_id,size)
```

## Description

`H5P.set_userblock(plist_id,size)` sets the user block size of the file creation property list, `plist_id`.

## Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_userblock(fcpl,4096);
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', fcpl, fapl);
H5F.close(fid);
```

## See Also

`H5P.get_userblock`

## H5P.get\_attr\_creation\_order

Return tracking order and indexing settings

### Syntax

```
crt_order_flags = H5P.get_attr_creation_order(ocpl_id)
```

### Description

`crt_order_flags = H5P.get_attr_creation_order(ocpl_id)` retrieves tracking and indexing settings for attribute creation order. If `crt_order_flags` is zero, then the attribute creation order is neither tracked or indexed. Otherwise the creation order flags should be one of the following constant values:

H5P\_CRT\_ORDER\_TRACKED

H5P\_CRT\_ORDER\_INDEXED

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
flags = H5P.get_attr_creation_order(dcpl);
switch (flags)
 case 0
 fprintf('neither tracked nor indexed\n');
 case H5ML.get_constant_value('H5P_CRT_ORDER_TRACKED')
 fprintf('tracked\n');
 case H5ML.get_constant_value('H5P_CRT_ORDER_INDEXED')
 fprintf('indexed\n');
end
H5P.close(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

## See Also

H5ML.get\_constant\_value | H5P.set\_attr\_creation\_order

## H5P.get\_attr\_phase\_change

Retrieve attribute phase change thresholds

### Syntax

```
[max_compact,min_dense] = H5P.get_attr_phase_change(ocpl_id)
```

### Description

[max\_compact,min\_dense] = H5P.get\_attr\_phase\_change(ocpl\_id) retrieves attribute phase change thresholds for the dataset or group with creation property list ocpl\_id.

max\_compact is the maximum number of attributes to be stored in compact storage (default is 8).

min\_dense is the minimum number of attributes to be stored in dense storage (default is 6).

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
[max_compact,min_dense] = H5P.get_attr_phase_change(dcpl);
H5P.close(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

### See Also

H5P.set\_attr\_phase\_change

# H5P.get\_copy\_object

Return properties to be used when object is copied

## Syntax

```
copy_options = H5P.get_copy_object(ocpl_id)
```

## Description

`copy_options = H5P.get_copy_object(ocpl_id)` retrieves the properties currently specified in the object copy property list `ocpl_id`, which will be invoked when a new copy is made of an existing object.

## Examples

```
ocpl = H5P.create('H5P_OBJECT_COPY');
options = H5P.get_copy_object(ocpl);
```

## See Also

`H5P.set_copy_object`

## H5P.set\_attr\_creation\_order

Set tracking of attribute creation order

### Syntax

```
H5P.set_attr_creation_order(gcplId,crt_order_flags)
```

### Description

`H5P.set_attr_creation_order(gcplId,crt_order_flags)` sets tracking and indexing of attribute creation order. The creation order flags should be either `H5P_CRT_ORDER_TRACKED` or a bitwise-or of `H5P_CRT_ORDER_TRACKED` and `H5P_CRT_ORDER_INDEXED`.

The default behavior is that attribute creation order is neither tracked nor indexed.

### Examples

```
dcpl = H5P.create('H5P_DATASET_CREATE');
order = H5ML.get_constant_value('H5P_CRT_ORDER_TRACKED');
H5P.set_attr_creation_order(dcpl,order);
```

### See Also

`bitor` | `H5ML.get_constant_value` | `H5P.get_attr_creation_order`

## H5P.set\_attr\_phase\_change

Set attribute storage phase change thresholds

### Syntax

```
H5P.set_attr_phase_change(ocpl_id,max_compact,min_dense)
```

### Description

`H5P.set_attr_phase_change(ocpl_id,max_compact,min_dense)` sets attribute storage phase change thresholds for the group or dataset with creation order property list `ocpl_id`.

`max_compact` is the maximum number of attributes to be stored in compact storage (default is 8).

`min_dense` is the minimum number of attributes to be stored in dense storage (default is 6).

### See Also

`H5P.get_attr_phase_change`

## H5P.set\_copy\_object

Set properties to be used when objects are copied

### Syntax

```
H5P.set_copy_object(ocp_plist_id,copy_options)
```

### Description

`H5P.set_copy_object(ocp_plist_id,copy_options)` sets the properties in the object copy property list `ocp_plist_id` that will be invoked when a new copy is made of an existing object. `ocp_plist_id` is the object copy property list and specifies the properties governing the copying of the object.

Several flags, described below, are available for inclusion in the object copy property list:

|                                              |                                                                                                                              |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <code>H50_COPY_SHALLOW_HIERARCHY_FLAG</code> | Copy only immediate members of a group. Default behavior, without flag: Recursively copy all objects below the group.        |
| <code>H50_COPY_EXPAND_SOFT_LINK_FLAG</code>  | Expand soft links into new objects. Default behavior, without flag: Keep soft links as they are.                             |
| <code>H50_COPY_EXPAND_EXT_LINK_FLAG</code>   | Expand external link into new objects. Default behavior, without flag: Keep external links as they are.                      |
| <code>H50_COPY_EXPAND_REFERENCE_FLAG</code>  | Copy objects that are pointed to by references. Default behavior, without flag: Update only the values of object references. |
| <code>H50_COPY_WITHOUT_ATTR_FLAG</code>      | Copy object without copying attributes. Default behavior, without flag: Copy object along with all its attributes.           |

### Examples

```
ocp_plist_id = H5P.create ('H5P_OBJECT_COPY');
```

```
option1 = H5ML.get_constant_value('H5O_COPY_EXPAND_SOFT_LINK_FLAG');
option2 = H5ML.get_constant_value('H5O_COPY_EXPAND_REFERENCE_FLAG');
copy_options = bitor(option1,option2);
H5P.set_copy_object(ocp_plist_id, copy_options);
```

## H5P.get\_create\_intermediate\_group

Determine creation of intermediate groups

### Syntax

```
bool = H5P.get_create_intermediate_group(lcpl_id)
```

### Description

`bool = H5P.get_create_intermediate_group(lcpl_id)` determines whether the link creation property list `lcpl_id` is set to enable creating missing intermediate groups.

### Examples

```
lcpl = H5P.create('H5P_LINK_CREATE');
if H5P.get_create_intermediate_group(lcpl)
 fprintf('set to enable creating intermediate groups\n');
else
 fprintf('not set to enable creating intermediate groups\n');
end
```

### See Also

`H5P.set_create_intermediate_group`

# H5P.get\_link\_creation\_order

Query if link creation order is tracked

## Syntax

```
crt_order_flags = H5P.get_link_creation_order(gcpl_id)
```

## Description

`crt_order_flags = H5P.get_link_creation_order(gcpl_id)` queries whether link creation order is tracked or indexed in a group with creation property list identifier `gcpl_id`. The creation order flags should be one of the following constant values:

H5P\_CRT\_ORDER\_TRACKED

H5P\_CRT\_ORDER\_INDEXED

## Examples

```
tracked = H5ML.get_constant_value('H5P_CRT_ORDER_TRACKED');
indexed = H5ML.get_constant_value('H5P_CRT_ORDER_INDEXED');
gcpl = H5P.create('H5P_GROUP_CREATE');
order = H5P.get_link_creation_order(gcpl);
if bitand(order,tracked)
 fprintf('order is tracked\n');
end
if bitand(order,indexed)
 fprintf('order is indexed\n');
end
```

## See Also

`bitand` | `H5ML.get_constant_value` | `H5P.set_link_creation_order`

## H5P.get\_link\_phase\_change

Query settings for conversion between groups

### Syntax

```
[max_compact,min_dense] = H5P.get_link_phase_change(gcpl_id)
```

### Description

[max\_compact,min\_dense] = H5P.get\_link\_phase\_change(gcpl\_id) retrieves the settings for conversion between compact and dense groups.

max\_compact is the maximum number of links to store as header messages in the group header before converting the group to the dense format. Groups that are in the compact format and exceed this number of links are automatically converted to the dense format.

min\_dense is the minimum number of links to store in the dense format. Groups which are in dense format and in which the number of links falls below this number are automatically converted back to the compact format.

### Examples

```
gcpl = H5P.create('H5P_GROUP_CREATE');
[max_compact, min_dense] = H5P.get_link_phase_change(gcpl);
```

### See Also

H5P.set\_link\_phase\_change

# H5P.set\_create\_intermediate\_group

Set creation of intermediate groups

## Syntax

```
H5P.set_create_intermediate_group(lcpl_id, flag)
```

## Description

`H5P.set_create_intermediate_group(lcpl_id, flag)` specifies in the link creation property list `lcpl_id` whether to create missing intermediate groups.

## Examples

Enable the creation of intermediate groups.

```
fid = H5F.create('myfile.h5');
lcpl = H5P.create('H5P_LINK_CREATE');
H5P.set_create_intermediate_group(lcpl, 1);
gid = H5G.create(fid, '/a/b/c/d', lcpl, 'H5P_DEFAULT', 'H5P_DEFAULT');
H5G.close(gid);
H5F.close(fid);
```

## See Also

`H5P.get_create_intermediate_group`

## H5P.set\_link\_creation\_order

Set creation order tracking and indexing

### Syntax

```
H5P.set_link_creation_order(gcplId,crt_order_flags)
```

### Description

`H5P.set_link_creation_order(gcplId,crt_order_flags)` sets creation order tracking and indexing for links in the group with group creation property list `gcpl_id`.

The creation order flags should be one of the following constant values:

`H5P_CRT_ORDER_TRACKED`

`H5P_CRT_ORDER_INDEXED`

If only `H5P_CRT_ORDER_TRACKED` is set, HDF5 will track link creation order in any group created with the group creation property list `gcpl_id`. If both `H5P_CRT_ORDER_TRACKED` and `H5P_CRT_ORDER_INDEXED` are set, HDF5 will track link creation order in the group and index links on that property.

### Examples

```
tracked = H5ML.get_constant_value('H5P_CRT_ORDER_TRACKED');
indexed = H5ML.get_constant_value('H5P_CRT_ORDER_INDEXED');
order = bitor(tracked,indexed);
gcpl = H5P.create('H5P_GROUP_CREATE');
H5P.set_link_creation_order(gcpl,order);
```

### See Also

`H5ML.get_constant_value` | `H5P.get_link_creation_order`

# H5P.set\_link\_phase\_change

Set parameters for group conversion

## Syntax

```
H5P.set_link_phase_change(gcpl_id,max_compact,min_dense)
```

## Description

`H5P.set_link_phase_change(gcpl_id,max_compact,min_dense)` sets the parameters for conversion between compact and dense groups.

`max_compact` is the maximum number of links to store as header messages in the group header before converting the group to the dense format. Groups that are in the compact format and exceed this number of links are automatically converted to the dense format.

`min_dense` is the minimum number of links to store in the dense format. Groups which are in dense format and in which the number of links falls below this number are automatically converted back to the compact format.

## Examples

```
gcpl = H5P.create('H5P_GROUP_CREATE');
H5P.set_link_phase_change(gcpl,10,8);
```

## See Also

`H5P.get_link_phase_change`

## H5P.get\_char\_encoding

Return character encoding

### Syntax

```
encoding = H5P.get_char_encoding(propertyList)
```

### Description

`encoding = H5P.get_char_encoding(propertyList)` retrieves the character encoding used to encode strings or object names that are created with the property list `propertyList`. The values returned correspond to either `H5T_CSET_ASCII` or `H5T_CSET_UTF8`.

### See Also

`H5ML.get_constant_value` | `H5P.set_char_encoding`

## H5P.set\_char\_encoding

Set character encoding used to encode strings

### Syntax

```
H5P.set_char_encoding(propList,encoding)
```

### Description

`H5P.set_char_encoding(propList,encoding)` sets the character encoding used to encode strings or object names that are created with the property list `propList`. The values of `encoding` should either be `H5T_CSET_ASCII` or `H5T_CSET_UTF8`.

### See Also

`H5ML.get_constant_value` | `H5P.get_char_encoding`

## H5R.create

Create reference

### Syntax

```
ref = H5R.create(loc_id,name,ref_type,space_id)
```

### Description

`ref = H5R.create(loc_id,name,ref_type,space_id)` creates the reference, `ref`, of the type specified in `ref_type`, pointing to the object specified by name located at `loc_id`. The `ref_type` argument can be either `'H5R_OBJECT'`, or `'H5R_DATASET_REGION'`. The `space_id` argument should be `-1`, if `ref_type` is `'H5R_OBJECT'`.

### Examples

Create a double-precision dataset and a reference dataset.

```
fid = H5F.create('myfile.h5');
type1_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [10 5];
h5_dims = flip1r(dims);
h5_maxdims = h5_dims;
space1_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = 'H5P_DEFAULT';
dset1_id = H5D.create(fid,'my_double',type1_id,space1_id,dcpl);
type2_id = 'H5T_STD_REF_OBJ';
space2_id = H5S.create('H5S_SCALAR');
dset2_id = H5D.create(fid,'my_ref',type2_id,space2_id,dcpl);
ref_data = H5R.create(fid,'my_double','H5R_OBJECT',-1);
dxpl = 'H5P_DEFAULT';
H5D.write(dset2_id,'H5ML_DEFAULT','H5S_ALL','H5S_ALL',dxpl,ref_data);
H5D.close(dset1_id);
H5D.close(dset2_id);
H5F.close(fid);
```

**See Also**

H5D.create

## H5R.dereference

Open object specified by reference

### Syntax

```
output = H5R.dereference(dataset,ref_type,ref)
```

### Description

`output = H5R.dereference(dataset,ref_type,ref)` returns an identifier to the object specified by `ref` in the dataset specified by `dataset`.

### Examples

```
plist = 'H5P_DEFAULT';
space = 'H5S_ALL';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/reference');
ref_data = H5D.read(dset_id, 'H5T_STD_REF_OBJ', space, space, plist);
deref_dset_id = H5R.dereference(dset_id, 'H5R_OBJECT', ref_data(:,1));
H5D.close(dset_id);
H5D.close(deref_dset_id);
H5F.close(fid);
```

### See Also

[H5I.get\\_name](#) | [H5R.create](#)

# H5R.get\_name

Name of referenced object

## Syntax

```
name = H5R.get_name(loc_id,ref_type,ref)
```

## Description

`name = H5R.get_name(loc_id,ref_type,ref)` retrieves the name for the object identified by `ref`. The `loc_id` argument is the identifier for the dataset containing the reference or for the group containing that dataset. `ref_type` specifies the type of the reference `ref`. Valid values for `ref_type` are 'H5R\_OBJECT' or 'H5R\_DATASET\_REGION'.

## Examples

```
plist = 'H5P_DEFAULT';
space = 'H5S_ALL';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/reference');
ref_data = H5D.read(dset_id, 'H5T_STD_REF_OBJ', space, space, plist);
name = H5R.get_name(dset_id, 'H5R_OBJECT', ref_data(:,1));
H5D.close(dset_id);
H5F.close(fid);
```

## See Also

H5I.get\_name

## H5R.get\_obj\_type

Type of referenced object

### Syntax

```
obj_type = H5R.get_obj_type(id,ref_type,ref)
```

### Description

`obj_type = H5R.get_obj_type(id,ref_type,ref)` returns the type of object that an object reference points to. Valid values for `ref_type` are: `H5R_OBJECT` or `H5R_DATASET_REGION`. Valid return values correspond to the following values.

|                           |                             |
|---------------------------|-----------------------------|
| 'H5O_TYPE_GROUP'          | Object is a group.          |
| 'H5O_TYPE_DATASET'        | Object is a dataset.        |
| 'H5O_TYPE_NAMED_DATATYPE' | Object is a named datatype. |

This function corresponds to the 1.8 interface version of `H5Rget_obj_type` in the HDF5 library C API.

### Examples

```
plist = 'H5P_DEFAULT';
space = 'H5S_ALL';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/reference');
ref_data = H5D.read(dset_id, 'H5T_STD_REF_OBJ', space, space, plist);
obj_type = H5R.get_obj_type(fid, 'H5R_OBJECT', ref_data(:,1));
switch(obj_type)
 case H5ML.get_constant_value('H5O_TYPE_GROUP')
 fprintf('group\n');
 case H5ML.get_constant_value('H5O_TYPE_DATASET')
 fprintf('dataset\n');
 case H5ML.get_constant_value('H5O_TYPE_NAMED_DATATYPE')
 fprintf('named datatype\n');
```

```
end
H5D.close(dset_id);
H5F.close(fid);
```

### **See Also**

H5ML.get\_constant\_value

## H5R.get\_region

Copy of data space of specified region

### Syntax

```
space_id = H5R.get_region(dataset,ref_type,ref)
```

### Description

`space_id = H5R.get_region(dataset,ref_type,ref)` returns a data space with the specified region selected. `dataset` is used to identify the file containing the referenced region and can be any identifier for any object in the file.

### Examples

```
space = 'H5S_ALL';
plist = 'H5P_DEFAULT';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/region_reference');
ref_data = H5D.read(dset_id, 'H5T_STD_REF_DSETREG', space, space, plist);
space_id = H5R.get_region(fid, 'H5R_DATASET_REGION', ref_data(:,1));
H5S.close(space_id);
H5D.close(dset_id);
H5F.close(fid);
```

# H5S.copy

Create copy of data space

## Syntax

```
output = H5S.copy(space_id)
```

## Description

`output = H5S.copy(space_id)` creates a new data space, which is an exact copy of the dataspace identified by `space_id`. The `output` argument is a data space identifier.

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g2/dset2.1');
space1_id = H5D.get_space(dset_id);
space2_id = H5S.copy(space1_id);
[~,dims1] = H5S.get_simple_extent_dims(space1_id)
[~,dims2] = H5S.get_simple_extent_dims(space2_id)
```

## H5S.create

Create new data space

### Syntax

```
space_id = H5S.create(space_type)
```

### Description

`space_id = H5S.create(space_type)` creates a new dataspace of the type specified by `space_type`, which can be specified by one of the following strings.

'H5S\_SCALAR'

'H5S\_SIMPLE'

'H5S\_NULL'

`space_id` is the identifier for the new dataspace.

### Examples

Create a scalar dataspace.

```
space_id = H5S.create('H5S_SCALAR');
numpoints = H5S.get_simple_extent_npoints(space_id);
```

### See Also

`H5S.get_simple_extent_npoints`

## H5S.close

Close data space

### Syntax

```
H5S.close(space_id)
```

### Description

H5S.close(space\_id) releases and terminates access to a data space. space\_id is a data space identifier.

### See Also

H5A.get\_space | H5D.get\_space

## H5S.create\_simple

Create new simple data space

### Syntax

```
space_id = H5S.create_simple(rank,h5_dims,h5_maxdims)
```

### Description

`space_id = H5S.create_simple(rank,h5_dims,h5_maxdims)` creates a new simple data space and opens it for access. `rank` is the number of dimensions used in the data space. `h5_dims` is an array specifying the size of each dimension of the dataset. `h5_maxdims` is an array specifying the upper limit on the size of each dimension. `space_id` is a data space identifier.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_dims` and `h5_maxdims` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

### Examples

Create a data space for a dataset with 10 rows and 5 columns.

```
dims = [10 5];
h5_dims = fliplr(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
```

Create a data space for a dataset with 10 rows and 5 columns such that the dataset is extendible along the column dimension.

```
dims = [10 5];
h5_dims = fliplr(dims);
maxdims = [10 H5ML.get_constant_value('H5S_UNLIMITED')];
```

```
h5_maxdims = fliplr(maxdims);
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
```

**See Also**

[H5ML.get\\_constant\\_value](#) | [H5S.close](#) | [H5S.create](#)

## H5S.extent\_copy

Copy extent from source to destination data space

### Syntax

```
H5S.extent_copy(dst_id,src_id)
```

### Description

H5S.extent\_copy(dst\_id,src\_id) copies the extent from the source data space, src\_id, to the destination data space, dst\_id.

### Examples

```
space_id1 = H5S.create('H5S_SIMPLE');
dims = [100 200];
h5_dims = fliplr(dims);
maxdims = [100 H5ML.get_constant_value('H5S_UNLIMITED')];
h5_maxdims = fliplr(maxdims);
H5S.set_extent_simple(space_id1,2,h5_dims,h5_maxdims);
space_id2 = H5S.create('H5S_SIMPLE');
H5S.extent_copy(space_id2,space_id1);
```

### See Also

H5S.create | H5S.get\_simple\_extent\_dims | H5S.set\_extent\_simple

# H5S.get\_select\_bounds

Bounding box of data space selection

## Syntax

```
[start,finish] = H5S.get_select_bounds(space_id)
```

## Description

[start,finish] = H5S.get\_select\_bounds(space\_id) returns the coordinates of the bounding box containing the current selection. `start` contains the starting coordinates of the bounding box and `finish` contains the coordinates of the diagonally opposite corner.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_start`, `h5_stride`, `h5_count` and `h5_block` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

## Examples

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([10 20]); block = fliplr([20 30]);
H5S.select_hyperslab(space_id, 'H5S_SELECT_SET', start,[],[],block);
start = fliplr([30 40]); block = fliplr([20 30]);
H5S.select_hyperslab(space_id, 'H5S_SELECT_OR', start,[],[],block);
[start, finish] = H5S.get_select_bounds(space_id);
matlab_start = fliplr(start);
matlab_finish = fliplr(finish);
```

## See Also

H5S.create\_simple | H5S.select\_hyperslab

## H5S.get\_select\_elem\_npoints

Number of element points in selection

### Syntax

```
numpoints = H5S.get_select_elem_npoints(space_id)
```

### Description

`numpoints = H5S.get_select_elem_npoints(space_id)` returns the number of element points in the current data space selection.

### Examples

Select the corner points of a data space.

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
coords = [0 0; 0 199; 99 0; 99 199];
coords = fliplr(coords);
coords = coords';
H5S.select_elements(space_id, 'H5S_SELECT_SET', coords)
numpoints = H5S.get_select_elem_npoints(space_id);
```

### See Also

`H5S.select_elements`

# H5S.get\_select\_elem\_pointlist

Element points in data space selection

## Syntax

```
points =
H5S.get_select_elem_pointlist(space_id,startpoint,numpoints)
```

## Description

```
points =
H5S.get_select_elem_pointlist(space_id,startpoint,numpoints)
```

returns the list of element points in the current data space selection. `startpoint` specifies the element point to start with and `numpoints` specifies the total number of points.

`points` is a two-dimensional array of 0-based values specifying the coordinates of the elements. If `m` is the rank of the dataspace, then `points` will have size `[m x numpoints]`.

---

**Note:** The ordering of the coordinate points is the same as the HDF5 library C API.

---

## Examples

Determine the first two points in the current selection.

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
coords = [0 0; 0 199; 99 0; 99 199];
coords = fliplr(coords);
coords = coords';
H5S.select_elements(space_id,'H5S_SELECT_SET',coords);
points = H5S.get_select_elem_pointlist(space_id,0,2);
```

## H5S.get\_select\_hyper\_blocklist

List of hyperslab blocks

### Syntax

```
blocklist =
H5S.get_select_hyper_blocklist(space_id,startblock,numblocks)
```

### Description

`blocklist = H5S.get_select_hyper_blocklist(space_id,startblock,numblocks)` returns a list of the hyperslab blocks currently selected. `space_id` is a dataspace identifier. `startblock` specifies the block to start with and `numblocks` specifies the number of hyperslab blocks to retrieve.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_start`, `h5_stride`, `h5_count` and `h5_block` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

### Examples

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([10 20]); block = fliplr([20 25]);
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],[],block);
start = fliplr([20 30]); block = fliplr([20 25]);
H5S.select_hyperslab(space_id,'H5S_SELECT_NOTB',start,[],[],block);
numblocks = H5S.get_select_hyper_nblocks(space_id);
for j = 1:numblocks
 hblocks{j} = H5S.get_select_hyper_blocklist(space_id,j-1,1);
end
```

## **See Also**

H5S.get\_select\_hyper\_nblocks | H5S.select\_hyperslab

## H5S.get\_select\_hyper\_nblocks

Number of hyperslab blocks

### Syntax

```
num_blocks = H5S.get_select_hyper_nblocks(space_id)
```

### Description

`num_blocks = H5S.get_select_hyper_nblocks(space_id)` returns the number of hyperslab blocks in the current data space selection.

### Examples

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([10 20]); block = fliplr([20 25]);
H5S.select_hyperslab(space_id, 'H5S_SELECT_SET', start, [], [], block);
start = fliplr([20 30]); block = fliplr([20 25]);
H5S.select_hyperslab(space_id, 'H5S_SELECT_NOTB', start, [], [], block);
nblocks = H5S.get_select_hyper_nblocks(space_id);
```

### See Also

`H5S.get_select_hyper_blocklist` | `H5S.select_hyperslab`

## H5S.get\_select\_npoints

Number of elements in data space selection

### Syntax

```
num_points = H5S.get_select_npoints(space_id)
```

### Description

`num_points = H5S.get_select_npoints(space_id)` returns the number of elements in the current data space selection.

### Examples

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
op = 'H5S_SELECT_SET';
start = fliplr([10 20]); block = fliplr([20 30]);
H5S.select_hyperslab(space_id, 'H5S_SELECT_SET', start, [], [], block);
n = H5S.get_select_npoints(space_id);
```

### See Also

`H5S.create_simple` | `H5S.select_hyperslab`

## H5S.get\_select\_type

Type of data space selection

### Syntax

```
sel_type = H5S.get_select_type(space_id)
```

### Description

`sel_type = H5S.get_select_type(space_id)` returns the data space selection type. Valid return values correspond to the following enumerated constants:

```
H5S_SEL_NONE
H5S_SEL_POINTS
H5S_SEL_HYPERSLABS
H5S_SEL_ALL
```

### Examples

```
dims = [100 200];
h5_dims = flip1r(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = flip1r([10 20]); block = flip1r([20 30]);
H5S.select_hyperslab(space_id, 'H5S_SELECT_SET', start, [], [], block);
sel_type = H5S.get_select_type(space_id);
switch(sel_type)
 case H5ML.get_constant_value('H5S_SEL_NONE')
 fprintf('no selection\n');
 case H5ML.get_constant_value('H5S_SEL_POINTS');
 fprintf('point selection\n');
 case H5ML.get_constant_value('H5S_SEL_HYPERSLABS');
 fprintf('hyperslab selection\n');
end
```

## **See Also**

H5ML.get\_constant\_value | H5S.select\_elements | H5S.select\_hyperslab

## H5S.get\_simple\_extent\_dims

Data space size and maximum size

### Syntax

```
[numdims,h5_dims,h5_maxdims] = H5S.get_simple_extent_dims(space_id)
```

### Description

`[numdims,h5_dims,h5_maxdims] = H5S.get_simple_extent_dims(space_id)` returns the number of dimensions in the data space, the size of each dimension, and the maximum size of each dimension.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_dims` and `h5_maxdims` assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g2/dset2.2');
space_id = H5D.get_space(dset_id);
[ndims,h5_dims] = H5S.get_simple_extent_dims(space_id);
matlab_dims = fliplr(h5_dims);
```

## H5S.get\_simple\_extent\_ndims

Data space rank

### Syntax

```
output = H5S.get_simple_extent_ndims(space_id)
```

### Description

`output = H5S.get_simple_extent_ndims(space_id)` returns the dimensionality (also called the rank) of a data space.

## **H5S.get\_simple\_extent\_npoints**

Number of elements in data space

### **Syntax**

```
output = H5S.get_simple_extent_npoints(space_id)
```

### **Description**

`output = H5S.get_simple_extent_npoints(space_id)` returns the number of elements in the data space specified by `space_id`.

# H5S.get\_simple\_extent\_type

Data space class

## Syntax

```
space_type = H5S.get_simple_extent_type(space_id)
```

## Description

`space_type = H5S.get_simple_extent_type(space_id)` returns the data space class of the data space specified by `space_id`.

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
space_id = H5D.get_space(dset_id);
space_type = H5S.get_simple_extent_type(space_id);
switch(space_type)
 case H5ML.get_constant_value('H5S_SCALAR')
 fprintf('scalar\n');
 case H5ML.get_constant_value('H5S_SIMPLE')
 fprintf('simple\n');
 case H5ML.get_constant_value('H5S_NULL')
 fprintf('none\n');
end
```

## See Also

[H5D.get\\_space](#) | [H5ML.get\\_constant\\_value](#) | [H5S.create](#)

## H5S.is\_simple

Determine if data space is simple

### Syntax

```
output = H5S.is_simple(space_id)
```

### Description

`output = H5S.is_simple(space_id)` returns a positive value if the data space specified by `space_id` is a simple data space, zero if it is not, and a negative value to indicate failure.

### Examples

Create a new data space and verify that it is simple.

```
dims = [100 200];
h5_dims = flip1r(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
val = H5S.is_simple(space_id);
```

Create a null data space and verify that it is not simple.

```
space_id = H5S.create('H5S_NULL');
val = H5S.is_simple(space_id);
```

### See Also

[H5S.create](#) | [H5S.create\\_simple](#)

# H5S.offset\_simple

Set offset of simple data space

## Syntax

```
H5S.offset_simple(space_id,offset)
```

## Description

`H5S.offset_simple(space_id,offset)` specifies the offset of the simple data space specified by `space_id`. This function allows the same shaped selection to be moved to different locations within a data space without requiring it to be redefined.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_start`, `h5_stride`, `h5_count` and `h5_block` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

## Examples

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([10 20]); block = fliplr([20 30]);
H5S.select_hyperslab(space_id, 'H5S_SELECT_SET', start,[],[],block);
offset = fliplr([3 5]);
H5S.offset_simple(space_id,offset)
[start,finish] = H5S.get_select_bounds(space_id);
start = fliplr(start);
finish = fliplr(finish);
```

## See Also

[H5S.get\\_select\\_bounds](#) | [H5S.select\\_hyperslab](#)

## H5S.select\_all

Select entire extent of data space

### Syntax

```
H5S.select_all(space_id)
```

### Description

H5S.select\_all(space\_id) selects the entire extent of the data space specified by space\_id.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
space_id = H5D.get_space(dset_id);
num_points1 = H5S.get_select_npoints(space_id);
H5S.select_none(space_id);
num_points2 = H5S.get_select_npoints(space_id);
H5S.select_all(space_id);
num_points3 = H5S.get_select_npoints(space_id);
```

# H5S.select\_elements

Specify coordinates to include in selection

## Syntax

```
H5S.select_elements(space_id,op,h5_coord)
```

## Description

`H5S.select_elements(space_id,op,h5_coord)` selects the array elements to be included in the selection for the data space specified by `space_id`. The `op` argument determines how the new selection is to be combined with the previously existing selection for the data space and can be specified by one of the following string values.

```
'H5S_SELECT_SET'
```

```
'H5S_SELECT_APPEND'
```

```
'H5S_SELECT_PREPEND'
```

`h5_coord` is a two-dimensional array of 0-based values specifying the coordinates of the elements being selected. If `m` is the rank of the data space and if `n` is the number of points, then `h5_coord` should be an `m`-by-`n` array.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_coord` parameter assumes coordinates have C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

## Examples

Select the corner points of a data space. In this case, `h5_coord` should have size 2x4.

```
dims = [100 200];
h5_dims = fliplr(dims);
```

```
space_id = H5S.create_simple(2,h5_dims,h5_dims);
coords = [0 0; 0 199; 99 0; 99 199];
h5_coords = fliplr(coords);
h5_coords = h5_coords';
H5S.select_elements(space_id, 'H5S_SELECT_SET',h5_coords);
```

## See Also

H5S.create\_simple | H5S.get\_select\_elem\_npoints |  
H5S.get\_select\_elem\_pointlist

# H5S.select\_hyperslab

Select hyperslab region

## Syntax

```
H5S.select_hyperslab(space_id,op,h5_start,h5_stride,h5_count,h5_block)
```

## Description

`H5S.select_hyperslab(space_id,op,h5_start,h5_stride,h5_count,h5_block)` selects a hyperslab region to add to the current selected region for the data space specified by `space_id`. The `op` argument determines how the new selection is to be combined with the previously existing selection for the data space. Possible values include: `H5S_SELECT_SET`, `H5S_SELECT_OR`, `H5S_SELECT_AND`, `H5S_SELECT_XOR`, `H5S_SELECT_NOTA`, or `H5S_SELECT_NOTB`.

The `h5_start` array determines the starting coordinates of the hyperslab to select. The `h5_count` array determines how many blocks to select from the data space, in each dimension. The `h5_stride` array specifies how many elements to move in each dimension. The `h5_block` array determines the size of the element block selected from the data space.

If `h5_stride` is specified as `[ ]`, then a contiguous hyperslab is selected, as if each value in `h5_stride` were set to 1. If `h5_count` is specified as `[ ]`, the number of blocks selected along each dimension defaults to 1. If `h5_block` is specified as `[ ]`, then the block size defaults to a single element in each dimension, as if each value in the block array were set to 1.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_start`, `h5_stride`, `h5_count` and `h5_block` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

## Examples

```
dims = [100 200];
```

```
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([10 20]); block = fliplr([20 30]);
H5S.select_hyperslab(space_id, 'H5S_SELECT_SET',start,[],[],block);
```

## See Also

H5S.create\_simple

## H5S.select\_none

Reset selection region to include no elements

### Syntax

```
H5S.select_none(space_id)
```

### Description

`H5S.select_none(space_id)` resets the selection region for the data space `space_id` to include no elements.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
space_id = H5D.get_space(dset_id);
num_points1 = H5S.get_select_npoints(space_id);
H5S.select_none(space_id);
num_points2 = H5S.get_select_npoints(space_id);
```

## H5S.select\_valid

Determine validity of selection

### Syntax

```
output = H5S.select_valid(space_id)
```

### Description

`output = H5S.select_valid(space_id)` returns a positive value if the selection of the data space `space_id` is within the extent of that data space, and zero if it is not. A negative value indicates failure.

### Examples

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([90 190]); count = [11 11];
H5S.select_hyperslab(space_id, 'H5S_SELECT_SET', start, [], count, []);
valid = H5S.select_valid(space_id);
```

### See Also

`H5S.create_simple` | `H5S.select_hyperslab`

## H5S.set\_extent\_none

Remove extent from data space

### Syntax

```
H5S.set_extent_none(space_id)
```

### Description

`H5S.set_extent_none(space_id)` removes the extent from a data space and sets the type to `H5S_NO_CLASS`.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer2D');
space_id = H5D.get_space(dset_id);
H5S.set_extent_none(space_id);
extent_type = H5S.get_simple_extent_type(space_id);
switch(extent_type)
 case H5ML.get_constant_value('H5S_SCALAR')
 fprintf('scalar\n');
 case H5ML.get_constant_value('H5S_SIMPLE')
 fprintf('simple\n');
 case H5ML.get_constant_value('H5S_NO_CLASS')
 fprintf('no class\n');
end
```

### See Also

`H5S.get_simple_extent_dims`

## H5S.set\_extent\_simple

Set size of data space

### Syntax

```
H5S.set_extent_simple(space_id,rank,h5_dims,h5_maxdims)
```

### Description

`H5S.set_extent_simple(space_id,rank,h5_dims,h5_maxdims)` sets the size of the data space identified by `space_id`. The `rank` argument is the number of dimensions used in the data space. `h5_dims` is an array specifying the size of each dimension of the dataset. `h5_maxdims` is an array specifying the upper limit on the size of each dimension.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_dims` and `h5_maxdims` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

### Examples

```
space_id = H5S.create('H5S_SIMPLE');
dims = [100 200];
h5_dims = fliplr(dims);
maxdims = [100 H5ML.get_constant_value('H5S_UNLIMITED')];
h5_maxdims = fliplr(maxdims);
H5S.set_extent_simple(space_id,2,h5_dims, h5_maxdims);
```

# H5T.close

Close data type

## Syntax

```
H5T.close(type_id)
```

## Description

H5T.close(type\_id) releases the data type specified by type\_id.

## See Also

H5A.get\_type | H5D.get\_type

## H5T.commit

Commit transient data type

### Syntax

```
H5T.commit(loc_id,name,type_id)
H5T.commit(loc_id,name,type_id,lcpl_id,tcpl_id,tapl_id)
```

### Description

`H5T.commit(loc_id,name,type_id)` commits a transient data type to a file, creating a new named data type. `loc_id` is a file or group identifier. `name` is the name of the data type and `type_id` is the data type id. This interface corresponds to the 1.6.x version of `H5Tcommit`.

`H5T.commit(loc_id,name,type_id,lcpl_id,tcpl_id,tapl_id)` commits a transient data type to a file, creating a new named data type. `loc_id` is a file or group identifier. `name` is the name of the data type and `type_id` is the data type id. `lcpl_id`, `tcpl_id`, and `tapl_id` are link creation, data type creation, and data type access property list identifiers. This interface corresponds to the 1.8.x version of `H5Tcommit`.

### Examples

Create a named variable-length data type.

```
plist_id = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5', 'H5F_ACC_TRUNC', plist_id, plist_id);
base_type_id = H5T.copy('H5T_NATIVE_DOUBLE');
vlen_type_id = H5T.vlen_create(base_type_id);
H5T.commit(fid, 'MyVlen', vlen_type_id);
H5T.close(vlen_type_id);
H5T.close(base_type_id);
H5F.close(fid);
```

### See Also

[H5T.close](#) | [H5T.committed](#)

# H5T.committed

Determine if data type is committed

## Syntax

```
output = H5T.committed(type_id)
```

## Description

`output = H5T.committed(type_id)` returns a positive value to indicate that the data type has been committed, and zero to indicate that it has not. A negative value indicates failure.

## Examples

```
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
is_committed = H5T.committed(type_id);
```

## See Also

H5T.commit

## H5T.copy

Copy data type

### Syntax

```
output_type_id = H5T.copy(type_id)
```

### Description

`output_type_id = H5T.copy(type_id)` copies the existing data type identifier, a dataset identifier specified by `type_id`, or a predefined data type such as `'H5T_NATIVE_DOUBLE'`. `output_type_id` is a data type identifier.

### Examples

```
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
type_size = H5T.get_size(type_id);
```

### See Also

`H5T.get_size`

# H5T.create

Create new data type

## Syntax

```
output = H5T.create(class_id,size)
```

## Description

`output = H5T.create(class_id,size)` creates a new data type of the class specified by `class_id`, with the number of bytes specified by `size`. The `output` argument is a data type identifier.

## Examples

Create a signed 32-bit enumerated data type.

```
type_id = H5T.create('H5T_ENUM',4);
H5T.set_order(type_id,'H5T_ORDER_LE');
H5T.set_sign(type_id,'H5T_SGN_2');
H5T.enum_insert(type_id,'black',0);
H5T.enum_insert(type_id,'white',1);
```

## See Also

[H5T.set\\_order](#) | [H5T.set\\_sign](#)

## H5T.detect\_class

Determine if data type contains specific class

### Syntax

```
output = H5T.detect_class(type_id, class_id)
```

### Description

`output = H5T.detect_class(type_id, class_id)` returns a positive value if the data type specified in `type_id` contains any data types of the data type class specified in `class_id`, or zero to indicate that it does not. A negative value indicates failure.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/v1en');
type_id = H5D.get_type(dset_id);
has_double = H5T.detect_class(type_id, 'H5T_FLOAT');
```

### See Also

H5D.get\_type

# H5T.equal

Determine equality of data types

## Syntax

```
output = H5T.equal(type1_id,type2_id)
```

## Description

`output = H5T.equal(type1_id,type2_id)` returns a positive number if the data type identifiers refer to the same data type, and zero to indicate that they do not. A negative value indicates failure. Either of the input values could be a string corresponding to an HDF5 data type.

## Examples

Determine if the data type of a dataset is a 32-bit little endian integer.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer2D');
dtype_id = H5D.get_type(dset_id);
if H5T.equal(dtype_id, 'H5T_STD_I32LE')
 fprintf('32-bit little endian integer\n');
end
```

## See Also

H5D.get\_type

## H5T.get\_class

Data type class identifier

### Syntax

```
class_id = H5T.get_class(type_id)
```

### Description

`class_id = H5T.get_class(type_id)` returns the data type class identifier of the data type specified by `type_id`.

Valid class identifiers include:

```
H5T_INTEGER
H5T_FLOAT
H5T_STRING
H5T_BITFIELD
H5T_OPAQUE
H5T_COMPOUND
H5T_ENUM
H5T_VLEN
H5T_ARRAY
```

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/enum');
type_id = H5D.get_type(dset_id);
class_id = H5T.get_class(type_id);
switch(class_id)
 case H5ML.get_constant_value('H5T_INTEGER')
```

```
 fprintf('Integer\n');
 case H5ML.get_constant_value('H5T_FLOAT')
 fprintf('Floating point\n');
 case H5ML.get_constant_value('H5T_STRING')
 fprintf('String\n');
 case H5ML.get_constant_value('H5T_BITFIELD')
 fprintf('Bitfield\n');
 case H5ML.get_constant_value('H5T_OPAQUE')
 fprintf('Opaque\n');
 case H5ML.get_constant_value('H5T_COMPOUND')
 fprintf('Compound\n');
 case H5ML.get_constant_value('H5T_ENUM')
 fprintf('Enumerated\n');
 case H5ML.get_constant_value('H5T_VLEN')
 fprintf('Variable length\n');
 case H5ML.get_constant_value('H5T_ARRAY')
 fprintf('Array\n');
end
```

## See Also

H5ML.get\_constant\_value

## H5T.get\_create\_plist

Copy of data type creation property list

### Syntax

```
plist_id = H5T.get_create_plist(datatype_id)
```

### Description

`plist_id = H5T.get_create_plist(datatype_id)` returns a property list identifier for the data type creation property list associated with the data type specified by `datatype_id`.

### See Also

`H5D.get_create_plist` | `H5F.get_create_plist`

## H5T.get\_native\_type

Native data type of dataset data type

### Syntax

```
output = H5T.get_native_type(type_id,direction)
```

### Description

`output = H5T.get_native_type(type_id,direction)` returns the equivalent native data type for the dataset data type specified in `type_id`. The `direction` argument indicates the order in which the library searches for a native data type match and must be either `'H5T_DIR_ASCEND'` or `'H5T_DIR_DESCEND'`.

## H5T.get\_size

Size of data type in bytes

### Syntax

```
type_size = H5T.get_size(type_id)
```

### Description

`type_size = H5T.get_size(type_id)` returns the size of a data type in bytes.  
`type_id` is a data type identifier.

### Examples

Determine the size of the data type for a specific dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/bitfield2D');
type_id = H5D.get_type(dset_id);
type_size = H5T.get_size(type_id);
```

### See Also

[H5D.get\\_type](#) | [H5T.set\\_size](#)

# H5T.get\_super

Base data type

## Syntax

```
super_type_id = H5T.get_super(type_id)
```

## Description

`super_type_id = H5T.get_super(type_id)` returns the base data type from which the data type type specified by `type_id` is derived.

## Examples

Retrieve the base data type for an enumerated dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/enum');
dtype_id = H5D.get_type(dset_id);
super_type_id = H5T.get_super(dtype_id);
```

## **H5T.lock**

Lock data type

### **Syntax**

```
H5T.lock(type_id)
```

### **Description**

`H5T.lock(type_id)` locks the data type specified by `type_id`, making it read-only and non-destructible.

# H5T.open

Open named data type

## Syntax

```
type_id = H5T.open(loc_id,name)
```

## Description

`type_id = H5T.open(loc_id,name)` opens a named data type at the location specified by `loc_id` and returns an identifier for the data type. `loc_id` is either a file or group identifier.

This function corresponds to the `H5Topen1` function in the HDF5 library C API.

## See Also

## H5T.array\_create

Create array data type object

### Syntax

```
array_type_id = H5T.array_create(base_id,h5_dims)
array_type_id = H5T.array_create(base_id,rank,h5_dims,perms)
```

### Description

`array_type_id = H5T.array_create(base_id,h5_dims)` creates a new array data type object. This interface corresponds to the 1.8 library version of `H5Tarray_create`.

`array_type_id = H5T.array_create(base_id,rank,h5_dims,perms)` creates a new array data type object. This interface corresponds to the 1.6 library version of `H5Tarray_create`. The `perms` parameter is not used at this time and can be omitted.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_dims` parameter assumes C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

### Examples

Create a 100-by-200 double precision array data type.

```
base_type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 200];
h5_dims = flip1r(dims);
array_type = H5T.array_create(base_type_id,h5_dims);
```

### See Also

[H5T.get\\_array\\_dims](#) | [H5T.get\\_array\\_ndims](#)

# H5T.get\_array\_dims

Array dimension extents

## Syntax

```
dimsizes = H5T.get_array_dims(type_id)
[ndims,dimsizes,perm] = H5T.get_array_dims(type_id)
```

## Description

`dimsizes = H5T.get_array_dims(type_id)` returns the sizes of the dimensions and the dimension permutations of the specified array data type object. This interface corresponds to the 1.8 version of `H5Tget_array_dims`.

`[ndims,dimsizes,perm] = H5T.get_array_dims(type_id)` corresponds to the 1.6 version of the interface. It is strongly deprecated.

---

**Note:** The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

---

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/array2D');
type_id = H5D.get_type(dset_id);
h5_dims = H5T.get_array_dims(type_id);
dims = fliplr(h5_dims);
```

## See Also

`H5T.array_create` | `H5T.get_array_ndims`

## H5T.get\_array\_ndims

Rank of array data type

### Syntax

```
output = H5T.get_array_ndims(type_id)
```

### Description

`output = H5T.get_array_ndims(type_id)` returns the rank, the number of dimensions, of an array data type object.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/array2D');
type_id = H5D.get_type(dset_id);
ndims = H5T.get_array_ndims(type_id);
```

### See Also

`H5T.get_array_dims`

# H5T.get\_cset

Character set of string data type

## Syntax

```
cset = H5T.get_cset(type_id)
```

## Description

`cset = H5T.get_cset(type_id)` returns the character set type of the data type specified by `type_id`.

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/string');
type_id = H5D.get_type(dset_id);
cset = H5T.get_cset(type_id);
switch(cset)
 case H5ML.get_constant_value('H5T_CSET_ASCII')
 fprintf('ASCII\n');
 case H5ML.get_constant_value('H5T_CSET_UTF8')
 fprintf('UTF-8\n');
end
```

## See Also

H5T.set\_cset

## H5T.get\_ebias

Exponent bias of floating-point type

### Syntax

```
output = H5T.get_ebias(type_id)
```

### Description

`output = H5T.get_ebias(type_id)` returns the exponent bias of a floating-point type. `type_id` is data type identifier.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/float');
type_id = H5D.get_type(dset_id);
ebias = H5T.get_ebias(type_id);
```

### See Also

`H5T.set_ebias`

# H5T.get\_fields

Floating-point data type bit field information

## Syntax

```
[spos, epos, esize, mpos, msize] = H5T.get_fields(type_id)
```

## Description

[spos, epos, esize, mpos, msize] = H5T.get\_fields(type\_id) returns information about the locations of the various bit fields of a floating point data type. `type_id` is a data type identifier. `spos` is the floating-point sign bit. `epos` is the exponent bit-position. `esize` is the size of the exponent in bits. `mpos` is the mantissa bit-position. `msize` is the size of the mantissa in bits.

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/float');
type_id = H5D.get_type(dset_id);
[spos, epos, esize, mpos, msize] = H5T.get_fields(type_id);
```

## H5T.get\_inpad

Internal padding type for floating-point data types

### Syntax

```
pad_type = H5T.get_inpad(type_id)
```

### Description

`pad_type = H5T.get_inpad(type_id)` returns the internal padding type for unused bits in floating-point data types. `type_id` is a data type identifier. `pad_type` can be `H5T_PAD_ZERO`, `H5T_PAD_ONE`, or `H5T_PAD_BACKGROUND`.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/float');
type_id = H5D.get_type(dset_id);
pad_type = H5T.get_inpad(type_id);
switch(pad_type)
 case H5ML.get_constant_value('H5T_PAD_ZERO')
 fprintf('pad zero\n');
 case H5ML.get_constant_value('H5T_PAD_ONE')
 fprintf('pad one\n');
 case H5ML.get_constant_value('H5T_PAD_BACKGROUND')
 fprintf('pad background\n');
end
```

### See Also

`H5T.set_inpad`

# H5T.get\_norm

Mantissa normalization type

## Syntax

```
norm_type = H5T.get_norm(type_id)
```

## Description

`norm_type = H5T.get_norm(type_id)` returns the mantissa normalization of a floating-point data type. `type_id` is a data type identifier. `norm_type` can be `H5T_NORM_IMPLIED`, `H5T_NORM_MSBSET`, or `H5T_NORM_NONE`.

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/float');
type_id = H5D.get_type(dset_id);
norm_type = H5T.get_norm(type_id);
switch(norm_type)
 case H5ML.get_constant_value('H5T_NORM_IMPLIED')
 fprintf('MSB of mantissa is not stored, always 1\n');
 case H5ML.get_constant_value('H5T_NORM_MSBSET')
 fprintf('MSB of mantissa is always 1\n');
 case H5ML.get_constant_value('H5T_NORM_NONE')
 fprintf('mantissa is not normalized\n');
end
```

## See Also

`H5T.set_norm`

## H5T.get\_offset

Bit offset of first significant bit

### Syntax

```
offset = H5T.get_offset(type_id)
```

### Description

`offset = H5T.get_offset(type_id)` returns the offset of the first significant bit. `type_id` is a data type identifier.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/float');
type_id = H5D.get_type(dset_id);
offset = H5T.get_offset(type_id);
```

### See Also

[H5T.set\\_offset](#)

# H5T.get\_order

Byte order of atomic data type

## Syntax

```
output = H5T.get_order(type_id)
```

## Description

`output = H5T.get_order(type_id)` returns the byte order of an atomic data type. `type_id` is a data type identifier. Possible return values are the constant values corresponding to the following strings:

```
'H5T_ORDER_LE'
'H5T_ORDER_BE'
'H5T_ORDER_VAX'
```

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g2/dset2.2');
type_id = H5D.get_type(dset_id);
switch(H5T.get_order(type_id))
 case H5ML.get_constant_value('H5T_ORDER_LE')
 fprintf('little endian\n');
 case H5ML.get_constant_value('H5T_ORDER_BE')
 fprintf('big endian\n');
 case H5ML.get_constant_value('H5T_ORDER_VAX')
 fprintf('vax\n');
end
```

## See Also

H5ML.get\_constant\_value | H5T.set\_order

## H5T.get\_pad

Padding type of least and most-significant bits

### Syntax

```
[lsb,msb] = H5T.get_pad(type_id)
```

### Description

[lsb,msb] = H5T.get\_pad(type\_id) returns the padding type of the least and most-significant bit padding. `type_id` is a data type identifier. `lsb` is the least-significant bit padding type. `msb` is the most-significant bit padding type. Values for `lsb` and `msb` can be `H5T_PAD_ZERO`, `H5T_PAD_ONE`, or `H5T_PAD_BACKGROUND`.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
type_id = H5D.get_type(dset_id);
[lsb,msb] = H5T.get_pad(type_id);
switch(lsb)
 case H5ML.get_constant_value('H5T_PAD_ZERO')
 fprintf('lsb pad type is zeros\n');
 case H5ML.get_constant_value('H5T_PAD_ONE');
 fprintf('lsb pad type is ones\n');
 case H5ML.get_constant_value('H5T_PAD_BACKGROUND')
 fprintf('lsb pad type is background\n');
end
switch(msb)
 case H5ML.get_constant_value('H5T_PAD_ZERO')
 fprintf('msb pad type is zeros\n');
 case H5ML.get_constant_value('H5T_PAD_ONE');
 fprintf('msb pad type is ones\n');
 case H5ML.get_constant_value('H5T_PAD_BACKGROUND')
 fprintf('msb pad type is background\n');
end
```

**See Also**

H5T.set\_pad

## H5T.get\_precision

Precision of atomic data type

### Syntax

```
output = H5T.get_precision(type_id)
```

### Description

`output = H5T.get_precision(type_id)` returns the precision of an atomic data type. `type_id` is a data type identifier.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
type_id = H5D.get_type(dset_id);
numbits = H5T.get_precision(type_id);
```

### See Also

[H5T.set\\_precision](#)

## H5T.get\_sign

Sign type for integer data type

### Syntax

```
sign_type = H5T.get_sign(type_id)
```

### Description

`sign_type = H5T.get_sign(type_id)` returns the sign type for an integer type. `type_id` is a data type identifier. Valid types are: `H5T_SGN_NONE` or `H5T_SGN_2`.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/integer');
type_id = H5D.get_type(dset_id);
sign_type = H5T.get_sign(type_id);
switch(sign_type)
 case H5ML.get_constant_value('H5T_SGN_NONE')
 fprintf('Unsigned integer type.\n');
 case H5ML.get_constant_value('H5T_SGN_2')
 fprintf('Signed integer type.\n');
end
```

### See Also

`H5T.set_sign`

## H5T.get\_strpad

Storage mechanism for string data type

### Syntax

```
output = H5T.get_strpad(type_id)
```

### Description

`output = H5T.get_strpad(type_id)` returns the storage mechanism (padding type) for a string data type. Possible values are:

|                  |                 |
|------------------|-----------------|
| H5T_STR_NULLPAD  | Pad with zeros  |
| H5T_STR_NULLTERM | Null-terminate  |
| H5T_STR_SPACEPAD | Pad with spaces |

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/string');
type_id = H5D.get_type(dset_id);
padding = H5T.get_strpad(type_id);
switch(padding)
 case H5ML.get_constant_value('H5T_STR_NULLTERM')
 fprintf('null-terminated\n');
 case H5ML.get_constant_value('H5T_STR_NULLPAD')
 fprintf('padded with zeros\n');
 case H5ML.get_constant_value('H5T_STR_SPACEPAD')
 fprintf('padded with spaces\n');
end
```

### See Also

H5T.set\_strpad

## H5T.set\_cset

Set character dataset for string data type

### Syntax

```
H5T.set_cset(type_id, cset)
```

### Description

`H5T.set_cset(type_id, cset)` sets the character encoding used to create strings. The only valid type is `H5T_CSET_ASCII`.

### Examples

```
type_id = H5T.copy('H5T_C_S1');
H5T.set_size(type_id,10);
encoding = H5ML.get_constant_value('H5T_CSET_ASCII');
H5T.set_cset(type_id,encoding);
```

### See Also

`H5T.get_cset`

## H5T.set\_ebias

Set exponent bias of floating-point data type

### Syntax

```
H5T.set_ebias(type_id,ebias)
```

### Description

`H5T.set_ebias(type_id,ebias)` sets the exponent bias of a floating-point type. `type_id` is a data type identifier. `ebias` is an exponent bias value.

### Examples

```
type_id = H5T.copy('H5T_NATIVE_FLOAT');
H5T.set_size(type_id,32);
H5T.set_ebias(type_id,99);
```

### See Also

`H5T.get_ebias`

## H5T.set\_fields

Set sizes and locations of floating-point bit fields

### Syntax

```
H5T.set_fields(type_id, spos, epos, esize, mpos, msize)
```

### Description

`H5T.set_fields(type_id, spos, epos, esize, mpos, msize)` sets the locations and sizes of the various floating-point bit fields. `spos` is the sign position. `epos` is the exponent in bits. `esize` is the size of exponent in bits. `mpos` is the mantissa bit position. `msize` is the size of the mantissa in bits.

### Examples

```
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
H5T.set_fields(type_id, 30, 24, 6, 0, 2);
```

### See Also

`H5T.get_fields`

## H5T.set\_inpad

Specify how unused internal bits are to be filled

### Syntax

```
H5T.set_inpad(type_id,pad)
```

### Description

`H5T.set_inpad(type_id,pad)` sets how unused internal bits of a floating point type are filled. `type_id` is the identifier of the data type. `inpad` specifies how to fill the bits: `H5T_PAD_ZERO`, `H5T_PAD_ONE`, or `H5T_PAD_BACKGROUND` (leave background alone).

### Examples

```
type_id = H5T.copy('H5T_NATIVE_FLOAT');
pad_type = H5ML.get_constant_value('H5T_PAD_ZERO');
H5T.set_inpad(type_id,pad_type);
```

### See Also

`H5T.get_inpad`

## H5T.set\_norm

Set mantissa normalization of floating-point data type

### Syntax

```
H5T.set_norm(type_id,norm)
```

### Description

`H5T.set_norm(type_id,norm)` sets the mantissa normalization of a floating-point data type. Valid normalization types are: `H5T_NORM_IMPLIED`, `H5T_NORM_MSBSET`, or `H5T_NORM_NONE`.

### Examples

```
type_id = H5T.copy('H5T_NATIVE_FLOAT');
norm_type = H5ML.get_constant_value('H5T_NORM_MSBSET');
H5T.set_norm(type_id,norm_type);
```

### See Also

`H5T.get_norm`

## H5T.set\_offset

Set bit offset of first significant bit

### Syntax

```
H5T.set_offset(type_id,offset)
```

### Description

`H5T.set_offset(type_id,offset)` sets the bit offset of the first significant bit. `type_id` is the identifier of the data type. `offset` specifies the number of bits of padding that appear.

### Examples

```
type_id = H5T.copy('H5T_NATIVE_INT');
H5T.set_offset(type_id,16);
```

### See Also

`H5T.get_offset`

# H5T.set\_order

Set byte ordering of atomic data type

## Syntax

```
H5T.set_order(type_id, type_order)
```

## Description

`H5T.set_order(type_id, type_order)` sets the byte ordering of an atomic data type. `type_order` can be one of the following values:

```
H5T_ORDER_LE
H5T_ORDER_BE
H5T_ORDER_VAX
```

## Examples

Create a big endian 32-bit integer type.

```
type_id = H5T.copy('H5T_NATIVE_INT');
order = H5ML.get_constant_value('H5T_ORDER_BE');
H5T.set_order(type_id, order);
```

## See Also

`H5ML.get_constant_value` | `H5T.get_order`

## H5T.set\_pad

Set padding type for least and most significant bits

### Syntax

```
H5T.set_pad(type_id,lsb,msb)
```

### Description

`H5T.set_pad(type_id,lsb,msb)` sets the padding type for the least and most-significant bits. `type_id` is the identifier of the data type. `lsb` specifies the padding type for least-significant bits; `msb` for most-significant bits. Valid padding types are `H5T_PAD_ZERO`, `H5T_PAD_ONE`, or `H5T_PAD_BACKGROUND` (leave background alone).

### Examples

```
type_id = H5T.copy('H5T_NATIVE_INT');
lsb = H5ML.get_constant_value('H5T_PAD_ONE');
msb = H5ML.get_constant_value('H5T_PAD_ZERO');
H5T.set_pad(type_id,lsb,msb);
```

### See Also

`H5T.get_pad`

## H5T.set\_precision

Set precision of atomic data type

### Syntax

```
H5T.set_precision(type_id,prec)
```

### Description

`H5T.set_precision(type_id,prec)` sets the precision of an atomic data type. `type_id` is a data type identifier. `prec` specifies the number of bits of precision for the data type.

## H5T.set\_sign

Set sign property for integer data type

### Syntax

```
H5T.set_sign(type_id,sign)
```

### Description

`H5T.set_sign(type_id,sign)` sets the sign property for an integer type. `type_id` is a data type identifier. `sign` specifies the sign type. Valid values are `H5T_SGN_NONE` or `H5T_SGN_2`.

### Examples

```
type_id = H5T.copy('H5T_NATIVE_LONG');
sgn = H5ML.get_constant_value('H5T_SGN_NONE');
H5T.set_sign(type_id,sgn);
```

### See Also

`H5T.get_sign`

## H5T.set\_size

Set size of data type in bytes

### Syntax

```
H5T.set_size(type_id,type_size)
```

### Description

`H5T.set_size(type_id,type_size)` sets the total size in bytes for the data type specified by `type_id`. The string `'H5T_VARIABLE'` can also be used if a variable length string is desired.

### Examples

Create a variable length string with null termination.

```
type_id = H5T.copy('H5T_C_S1');
H5T.set_size(type_id,'H5T_VARIABLE');
H5T.set_strpad(type_id,'H5T_STR_NULLTERM');
```

### See Also

`H5T.get_size`

## H5T.set\_strpad

Set storage mechanism for string data type

### Syntax

```
H5T.set_strpad(type_id,storage_type)
```

### Description

H5T.set\_strpad(type\_id,storage\_type) defines the storage mechanism for the string data type identified by type\_id. The storage type may be one of the following values.

|                    |                    |
|--------------------|--------------------|
| 'H5T_STR_NULLTERM' | Null terminated    |
| 'H5T_STR_NULLPAD'  | Padded with zeros  |
| 'H5T_STR_SPACEPAD' | Padded with spaces |

### Examples

Create a ten-character string data type with space padding.

```
type_id = H5T.copy('H5T_C_S1');
H5T.set_size(type_id,10);
H5T.set_strpad(type_id,'H5T_STR_SPACEPAD');
```

### See Also

H5T.get\_strpad

# H5T.get\_member\_class

Data type class for compound data type member

## Syntax

```
output = H5T.get_member_class(type_id, membno)
```

## Description

`output = H5T.get_member_class(type_id, membno)` returns the data type class of the compound data type member specified by `membno`. The `type_id` argument is the data type identifier of a compound object.

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/compound');
type_id = H5D.get_type(dset_id);
member_name = H5T.get_member_name(type_id, 0);
member_class = H5T.get_member_class(type_id, 0);
```

## See Also

`H5T.get_member_name`

## H5T.get\_member\_index

Index of compound or enumeration type member

### Syntax

```
idx = H5T.get_member_index(type_id,name)
```

### Description

`idx = H5T.get_member_index(type_id,name)` returns the index of a field of a compound data type or an element of an enumeration data type. `type_id` is a data type identifier and `name` is a text string that identifies the target field or element.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/compound');
type_id = H5D.get_type(dset_id);
idx = H5T.get_member_index(type_id,'b');
```

### See Also

`H5T.get_member_name`

# H5T.get\_member\_name

Name of compound or enumeration type member

## Syntax

```
name = H5T.get_member_name(type_id, membno)
```

## Description

`name = H5T.get_member_name(type_id, membno)` returns the name of a field of a compound data type or an element of an enumeration data type. `type_id` is a data type identifier. `membno` is a zero-based index of the field or element whose name is to be retrieved.

## Examples

Determine the name of the first field of a compound dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/compound');
dtype_id = H5D.get_type(dset_id);
member_name = H5T.get_member_name(dtype_id, 0);
```

## See Also

[H5T.get\\_member\\_index](#)

## H5T.get\_member\_offset

Offset of field of compound data type

### Syntax

```
output = H5T.get_member_offset(type_id, membno)
```

### Description

`output = H5T.get_member_offset(type_id, membno)` returns the byte offset of the field specified by `membno` in the compound data type specified by `type_id`. Note that zero (0) is a valid offset.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/compound');
type_id = H5D.get_type(dset_id);
idx = H5T.get_member_offset(type_id, 1);
```

### See Also

`H5T.get_member_name`

# H5T.get\_member\_type

Data type of specified member

## Syntax

```
type_id = H5T.get_member_type(type_id, membno)
```

## Description

`type_id = H5T.get_member_type(type_id, membno)` returns the data type of the member specified by `membno` in the data type specified by `type_id`.

## Examples

Get the size of the data type of the first member of a compound data type.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/compound');
compound_type_id = H5D.get_type(dset_id);
member_type_id = H5T.get_member_type(compound_type_id, 0);
type_size = H5T.get_size(member_type_id);
```

## See Also

[H5D.get\\_type](#)

## H5T.get\_nmembers

Number of elements in enumeration type

### Syntax

```
output = H5T.get_nmembers(type_id)
```

### Description

`output = H5T.get_nmembers(type_id)` retrieves the number of fields in a compound data type or the number of members of an enumeration data type. `type_id` is a data type identifier.

### Examples

Determine the number of fields in a compound dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/compound');
dtype_id = H5D.get_type(dset_id);
nmembers = H5T.get_nmembers(dtype_id);
```

## H5T.insert

Add member to compound data type

### Syntax

```
H5T.insert(type_id,name,offset,member_datatype)
```

### Description

`H5T.insert(type_id,name,offset,member_datatype)` adds another member to the compound data type specified by `type_id`. The `name` argument is a text string that specifies the name of the new member, which must be unique in the compound data type. `offset` specifies where you want to insert the new member and `member_datatype` specifies the data type identifier of the new member.

### Examples

```
type_id = H5T.create('H5T_COMPOUND',16);
H5T.insert(type_id,'first',0,'H5T_NATIVE_DOUBLE');
H5T.insert(type_id,'second',8,'H5T_NATIVE_INT');
H5T.insert(type_id,'third',12,'H5T_NATIVE_UINT');
```

### See Also

`H5T.create`

## H5T.pack

Recursively remove padding from compound data type

### Syntax

```
H5T.pack(type_id)
```

### Description

`H5T.pack(type_id)` recursively removes padding from within a compound data type to make it more efficient (space-wise) to store that data. `type_id` is a data type identifier.

## H5T.enum\_create

Create new enumeration data type

### Syntax

```
output = H5T.enum_create(parent_id)
```

### Description

`output = H5T.enum_create(parent_id)` creates a new enumeration data type based on the specified base data type, `parent_id`, which must be an integer type. `output` is a data type identifier for the new enumeration data type.

### Examples

```
parent_id = H5T.copy('H5T_NATIVE_UINT');
type_id = H5T.enum_create(parent_id);
H5T.enum_insert(type_id, 'red', 1);
H5T.enum_insert(type_id, 'green', 2);
H5T.enum_insert(type_id, 'blue', 3);
H5T.close(type_id);
H5T.close(parent_id);
```

### See Also

`H5T.enum_insert`

## H5T.enum\_insert

Insert enumeration data type member

### Syntax

```
H5T.enum_insert(type_id,name,value)
```

### Description

H5T.enum\_insert(type\_id,name,value) inserts a new enumeration data type member into the enumeration data type specified by type\_id. The name argument is a text string that specifies the name of the new member of the enumeration and value is the value of the member.

### Examples

```
parent_id = H5T.copy('H5T_NATIVE_UINT');
type_id = H5T.enum_create(parent_id);
H5T.enum_insert(type_id,'red',1);
H5T.enum_insert(type_id,'green',2);
H5T.enum_insert(type_id,'blue',3);
H5T.close(type_id);
H5T.close(parent_id);
```

### See Also

H5T.enum\_create

# H5T.enum\_nameof

Name of enumeration data type member

## Syntax

```
name = H5T.enum_nameof(type_id,value)
```

## Description

`name = H5T.enum_nameof(type_id,value)` returns the symbol name corresponding to a member of an enumeration data type. `type_id` specifies the enumeration data type. `value` identifies the member of the enumeration.

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/enum');
type_id = H5D.get_type(dset_id);
name0 = H5T.enum_nameof(type_id,int32(0));
name1 = H5T.enum_nameof(type_id,int32(1));
```

## See Also

H5T.enum\_valueof

## H5T.enum\_valueof

Value of enumeration data type member

### Syntax

```
value = H5T.enum_valueof(type_id,member_name)
```

### Description

`value = H5T.enum_valueof(type_id,member_name)` returns the value corresponding to a specified member of an enumeration data type. `type_id` specifies the enumeration data type and `member_name` specifies the member.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/enum');
type_id = H5D.get_type(dset_id);
num_members = H5T.get_nmembers(type_id);
for j = 1:num_members
 member_name{j} = H5T.get_member_name(type_id,j-1);
 member_value(j) = H5T.enum_valueof(type_id,member_name{j});
end
```

### See Also

`H5T.get_member_name` | `H5T.get_nmembers`

# H5T.get\_member\_value

Value of enumeration data type member

## Syntax

```
value = H5T.get_member_value(type_id, membno)
```

## Description

`value = H5T.get_member_value(type_id, membno)` returns the value of the enumeration data type member specified by `membno`. The `type_id` argument is the data type identifier for the enumeration data type.

## Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/enum');
type_id = H5D.get_type(dset_id);
num_members = H5T.get_nmembers(type_id);
for j = 1:num_members
 member_name{j} = H5T.get_member_name(type_id, j-1);
 member_value(j) = H5T.get_member_value(type_id, j-1);
end
```

## See Also

`H5T.get_member_name` | `H5T.get_nmembers`

## H5T.get\_tag

Tag associated with opaque data type

### Syntax

```
tag = H5T.get_tag(type_id)
```

### Description

`tag = H5T.get_tag(type_id)` returns the tag associated with the opaque data type specified by `type_id`.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/opaque');
dtype_id = H5D.get_type(dset_id);
tag = H5T.get_tag(dtype_id);
```

### See Also

H5T.set\_tag

## H5T.set\_tag

Tag opaque data type with description

### Syntax

```
H5T.set_tag(type_id,tag)
```

### Description

`H5T.set_tag(type_id,tag)` tags the opaque data type specified by `type_id`, with the descriptive ASCII string identifier, `tag`.

### Examples

Create an opaque data type with a length of 4 bytes and a particular tag.

```
type_id = H5T.create('H5T_OPAQUE',4);
H5T.set_tag(type_id,'Created by MATLAB.');
```

### See Also

[H5T.create](#) | [H5T.get\\_tag](#)

## H5T.is\_variable\_str

Determine if data type is variable-length string

### Syntax

```
output = H5T.is_variable_str(type_id)
```

### Description

`output = H5T.is_variable_str(type_id)` returns a positive value if the data type specified by `type_id` is a variable-length string and zero if it is not. A negative value indicates failure.

### Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid, '/g3/VLstring2D');
type_id = H5D.get_type(dset_id);
if H5T.is_variable_str(type_id) > 0
 fprintf('variable length string\n');
end
```

### See Also

[H5D.get\\_type](#) | [H5T.get\\_size](#) | [H5T.vlen\\_create](#)

## H5T.vlen\_create

Create new variable-length data type

### Syntax

```
vlen_type_id = H5T.vlen_create(base_id)
```

### Description

`vlen_type_id = H5T.vlen_create(base_id)` creates a new variable-length (VL) data type. `base_id` specifies the base type of the data type to create.

### Examples

Create a variable length data type for 64-bit floating-point numbers.

```
base_type_id = H5T.copy('H5T_NATIVE_DOUBLE');
vlen_type_id = H5T.vlen_create(base_type_id);
```

### See Also

`H5T.is_variable_str`

## H5Z.filter\_avail

Determine if filter is available

### Syntax

```
output = H5Z.filter_avail(filter_id)
```

### Description

`output = H5Z.filter_avail(filter_id)` determines whether the filter specified by the filter identifier is available to the application. `filter_id` can be specified by one of the following strings or its numeric equivalent.

```
'H5Z_FILTER_DEFLATE'
'H5Z_FILTER_SHUFFLE'
'H5Z_FILTER_FLETCHER32'
'H5Z_FILTER_SZIP'
'H5Z_FILTER_NBIT'
'H5Z_FILTER_SCALEOFFSET'
```

### Examples

Determine if the shuffle filter is available.

```
bool = H5Z.filter_avail('H5Z_FILTER_SHUFFLE');
```

### See Also

H5ML.get\_constant\_value

# H5Z.get\_filter\_info

Information about filter

## Syntax

```
filter_config_flags = H5Z.get_filter_info(filter)
```

## Description

`filter_config_flags = H5Z.get_filter_info(filter)` retrieves information about the filter specified by its identifier. At present, the information returned is the filter's configuration flags, indicating whether the filter is configured to decode data, to encode data, neither, or both. `filter_config_flags` should be used with the HDF5 constant values `H5Z_FILTER_CONFIG_ENCODE_ENABLED` and `H5Z_FILTER_CONFIG_DECODE_ENABLED` in a bitwise AND operation. If the resulting value is 0, then the encode or decode functionality is not available.

## Examples

Determine if encoding is enabled for the deflate filter.

```
flags = H5Z.get_filter_info('H5Z_FILTER_DEFLATE');
functionality = H5ML.get_constant_value('H5Z_FILTER_CONFIG_ENCODE_ENABLED');
enabled = bitand(flags,functionality) > 0;
```

## See Also

`bitand` | `H5ML.get_constant_value` | `H5Z.filter_avail`

# hadamard

Hadamard matrix

## Syntax

`H = hadamard(n)`

## Description

`H = hadamard(n)` returns the Hadamard matrix of order `n`.

## Definitions

Hadamard matrices are matrices of 1's and -1's whose columns are orthogonal,

$$H' * H = n * I$$

where `[n n]=size(H)` and `I = eye(n,n)` .,

They have applications in several different areas, including combinatorics, signal processing, and numerical analysis, [1], [2].

An `n`-by-`n` Hadamard matrix with `n > 2` exists only if `rem(n,4) = 0`. This function handles only the cases where `n`, `n/12`, or `n/20` is a power of 2.

## Examples

The command `hadamard(4)` produces the 4-by-4 matrix:

```
1 1 1 1
1 -1 1 -1
1 1 -1 -1
1 -1 -1 1
```

## handle class

Abstract class for deriving handle classes

### Description

`classdef MyHandleClass < handle` makes *MyHandleClass* a subclass of the `handle` class.

The `handle` class is the superclass for all classes that follow handle semantics. A *handle* is a reference to an object. If you copy an object's handle variable, MATLAB copies only the handle. Both the original and copy refer to the same object. For example, if a function modifies a handle object passed as an input argument, the modification affects the original input object.

In contrast, nonhandle objects (that is, value objects) are not references. Functions must return modified value objects to change the object outside of the function's workspace.

See “Object Modification” for information on passing objects to functions.

If you want to create a class that defines events, you must derive that class from the `handle` class.

The `handle` class is an abstract class, so you cannot create an instance of this class directly. You use the `handle` class to derive other classes, which can be concrete classes whose instances are handle objects. See “Handle Classes” for information on using handle classes.

### Methods

|                          |                                          |
|--------------------------|------------------------------------------|
| <code>addlistener</code> | Create event listener                    |
| <code>delete</code>      | Delete handle object                     |
| <code>findobj</code>     | Find handle objects                      |
| <code>findprop</code>    | Find <code>meta.property</code> object   |
| <code>isvalid</code>     | Determine valid handles                  |
| <code>notify</code>      | Notify listeners that event is occurring |

relationaloperators

Determine equality or sort handle objects

## Events

ObjectBeingDestroyed

Triggered when the handle object is about to be destroyed, but before calling the delete method. Listener callbacks execute before MATLAB destroys the handle object.

## Destroying Handle Objects

MATLAB destroys handle objects when there are no references to the object. You can explicitly remove a handle object by calling its delete method. The `handle` class enables you to control what happens when handle objects are destroyed, either implicitly when no references exist or explicitly when you delete the object.

### Define delete Method in Subclass

Subclasses of `handle` can define their own `delete` method. MATLAB calls this method when deleting an object of the subclass, enabling your subclass to perform any specific actions necessary before deleting an object.

For more information, see “Handle Class Destructor”.

### Create Listener for ObjectBeingDestroyed Event

Any code can respond to the pending deletion of a handle object by defining a listener for that object’s `ObjectBeingDestroyed` event. MATLAB triggers this event before calling the object’s `delete` method.

For more information on using events and listeners, see “Events and Listeners — Syntax and Techniques”.

## Attributes

Abstract

true

|                  |      |
|------------------|------|
| ConstructOnLoad  | true |
| HandleCompatible | true |

To learn about attributes of classes, see [Class Attributes](#) in the MATLAB Object-Oriented Programming documentation.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Examples

### Derive Class from handle

Derive MyClass from handle:

```
classdef MyClass < handle
 properties
 Prop1
 end
 methods
 function obj = MyClass(arg)
 obj.Prop1 = arg;
 end
 end
end
```

- [“Using Handles”](#)

# addlistener

**Class:** handle

Create event listener

## Syntax

```
lh = addlistener(Hsource,EventName,callback)
```

```
lh = addlistener(Hsource,property,EventName,callback)
```

## Description

`lh = addlistener(Hsource,EventName,callback)` creates a listener for the specified event when triggered on the source object.

If `Hsource` is not scalar, the listener responds to the named event on any object in the `Hsource` array.

`lh = addlistener(Hsource,property,EventName,callback)` creates a listener for one of the predefined property events. There are four predefined property events:

| Event Name | Event Occurs                                                                                |
|------------|---------------------------------------------------------------------------------------------|
| PreSet     | Immediately before the property value is set, before calling its set access method          |
| PostSet    | Immediately after the property value is set                                                 |
| PreGet     | Immediately before a property value query is serviced, before calling its get access method |
| PostGet    | Immediately after returning the property value to the query                                 |

## Tips

- To remove a listener, delete the listener object returned by `addlistener`. For example,

`delete(lh)`

calls the handle class `delete` method to delete the object from the workspace and remove the listener.

- Redefining or clearing the variable containing the handle of the listener (for example, `lh`) does not delete the listener. The event object (**Hsource**) still has a reference to the `event.listener` object. `addlistener` ties the listener's lifecycle to the object that is the source of the event.
- To define a listener that is not tied to the event object, use the `event.listener` constructor directly to create the listener.

## Input Arguments

### **Hsource** — Event source

handle array

Event source is the object that is source of the event, or an array of source objects, specified as a handle array.

### **EventName** — Name of event

character array

Name of event that is triggered on the source objects, specified as a case-sensitive, quoted string. For property events, the event name is one of the four predefined property events.

### **property** — Name of property

string

Name of the property whose property event triggers your listener, specified as one of these values:

- A scalar `meta.property` object
- An array or a cell array of `meta.property` objects
- A string or a cell array of strings, where each string is the name of a property defined for the objects in **Hsource**

You can listen to property events on dynamic properties only If **Hsource** is scalar. If **Hsource** is non-scalar, then the properties must belong to the class of **Hsource** and can not include dynamic properties (which are not part of the class definition).

The class defining the source property must set the `GetObservable` and `SetObservable` property attributes to enable you to listen to the property events.

**callback** — Listener callback

function handle

Listener callback specified as a function handle

Data Types: `function_handle`

## Output Arguments

**lh** — listener

`event.listener` or `event.proplistener`

Listener object created by `addlistener`, specified as the handle to an `event.listener` or an `event.proplistener` object.

## Attributes

Access public

To learn about attributes of methods, see [Method Attributes in the MATLAB Object-Oriented Programming documentation](#).

## Alternatives

When you need the lifecycle of the listener object to be independent of the source object lifecycle, use the `event.listener` or `event.proplistener` to create listeners.

---

# delete

**Class:** handle

Delete handle object

## Syntax

```
delete(h)
```

## Description

`delete(h)` deletes a handle object, but does not clear the handle variable from the workspace. The handle variable is not valid once the handle object has been deleted.

Subclasses of `handle` can implement a method named `delete` to perform cleanup tasks just before MATLAB destroys an object of the class. MATLAB calls the `delete` method of any `handle` object when the object is destroyed when the subclass `delete` method meets certain criteria.

For information on implementing a class destructor for a subclass of `handle`, see “Handle Class Destructor”.

## Input Arguments

**h** — Objects to destroy

handle array

Objects to destroy, specified as a handle array.

## Attributes

Access

`public`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

## **See Also**

isvalid

## **More About**

- “Handle Class Destructor”

# findobj

**Class:** handle

Find handle objects

## Syntax

```
Hmatch = findobj(H)
Hmatch = findobj(H,property,value,...,property,value)
Hmatch = findobj(H,'-not',property,value)
Hmatch = findobj(H,'-regexp',property,value)
Hmatch = findobj(H,property,value,'-logicaloperator',property,value)
Hmatch = findobj(H,'-function',fh)
Hmatch = findobj(H,'-function',property,fh)
Hmatch = findobj(H,'-property',property)
Hmatch = findobj(H,'-method',methodname)
Hmatch = findobj(H,'-event',eventname)
Hmatch = findobj(H,'-depth',d,___)
Hmatch = findobj(H,'flat',___)
```

## Description

`Hmatch = findobj(H)` returns the objects listed in `H` and all of their descendants.

`Hmatch = findobj(H,property,value,...,property,value)` finds handle objects that have the specified property set to the specified value.

`Hmatch = findobj(H,'-not',property,value)` inverts the expression in the following property value pair. That is, find objects whose specified property is not equal to `value`.

`Hmatch = findobj(H,'-regexp',property,value)` treats the content of the `value` argument as regular expressions.

`Hmatch = findobj(H,property,value,'-logicaloperator',property,value)` applies the logical operator to the name/value pairs. Supported logical operators include:

- `'-or'` (default if you do not specify an operator)
- `'-and'`
- `'-xor'`

`Hmatch = findobj(H, '-function', fh)` calls the function handle `fh` on the objects in `H` and returns the objects for which the function returns `true`.

`Hmatch = findobj(H, '-function', property, fh)` calls the function handle `fh` on the specified property's value for the objects in `H` and returns the objects for which the function returns `true`. The function must return a scalar logical value.

`Hmatch = findobj(H, '-property', property)` finds all object in `H` having the named property.

`Hmatch = findobj(H, '-method', methodname)` finds objects that have the specified method name.

`Hmatch = findobj(H, '-event', eventname)` finds objects that have the specified event name.

`Hmatch = findobj(H, '-depth', d, ___)` specifies how many levels in the instance hierarchies under the objects in `H` to search.

`Hmatch = findobj(H, 'flat', ___)` searches only the level of the objects in array `H`.

## Tips

- `findobj` has access only to public properties
- If there are no matches, `findobj` returns an empty array of the same class as the input array `H`.
- Logical operator precedence follows MATLAB precedence rules. For more information, see “Operator Precedence”.
- Control precedence by grouping within cell arrays

## Input Arguments

**H** — Objects to search from  
handle array

Objects to search from, specified as an array of object handles. Unless the you specify the '-depth' or 'flat' options, `findobj` searches the objects in the input array `H` and child objects in the instance hierarchy.

**property — Property name**

string

Property name, specified as a case-sensitive, quoted string.

**value — Property value**

any value

Property value, specified as a value or MATLAB expression.

**methodname — Method name**

string

Method name, specified as a case-sensitive quoted string.

**eventname — Event name**

string

Event name, specified as a case-sensitive quoted string.

**d — Depth of search**

integer  $\geq 0$

Depth of search, specified as an integer indicating the number of levels below any given object in the input array `H`.

- `d = n` — Search `n` levels of the hierarchy below each object in `H`
- `d = 0` — Search only the same level as the objects in `H`.
- `d = inf` — Search all levels below objects in `H`. This is the default.

**fh — Function handle**

function handle

Function handle, specifying the function that is evaluated for each object in the input array `H`. This function must return a scalar, logical value indicating whether there is a match (`true`) or not (`false`).

## Output Arguments

### **Hmatch** — Objects found by search

handle array

Objects found by search, returned as a handle array.

## Attributes

Access public

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

## Examples

### Object with Specific Property Value

Find the object with a specific property value. Given the handle class, `BasicHandle`:

```
classdef BasicHandle < handle
 properties
 Prop1
 end
 methods
 function obj = BasicHandle(val)
 if nargin > 0
 obj.Prop1 = val;
 end
 end
 end
end
```

Create an array of `BasicHandle` objects:

```
h(1) = BasicHandle(7);
h(2) = BasicHandle(11);
h(3) = BasicHandle(27);
```

Find the handle of the object whose `Prop1` property has a value of 7:

```
h7 = findobj(h, 'Prop1',7);
h7.Prop1
```

```
ans =
```

```
7
```

## Object with Specific Property Name

Find the object with a specific dynamic property. Given the `button` class:

```
classdef button < dynamicprops
 properties
 UiHandle
 end
 methods
 function obj = button(pos)
 if nargin > 0
 if length(pos) == 4
 obj.UiHandle = uicontrol('Position',pos,...
 'Style','pushbutton');
 else
 error('Improper position')
 end
 end
 end
 end
end
```

Create an array of button objects, only one element of which defines a dynamic property. Use `findobj` to get the handle of the object with the dynamic property named `ButtonCoord`:

```
b(1) = button([20 40 80 20]);
b(1).addprop('ButtonCoord');
b(1).ButtonCoord = [2,3];
b(2) = button([120 40 80 20]);
b(3) = button([220 40 80 20]);

h = findobj(b, '-property', 'ButtonCoord');
h.ButtonCoord
```

```
ans =
```

2 3

**See Also**

handle.findprop

# findprop

**Class:** handle

Find `meta.property` object

## Syntax

```
mp = findprop(h,property)
```

## Description

`mp = findprop(h,property)` returns the `meta.property` object associated with the named property of the object `h`. `property` can be a property defined by the class of `h` or a dynamic property defined only for the object `h`.

## Input Arguments

**h — handle object**

handle

Handle object, specified as a scalar handle.

**property — Name of property**

string

Name of property, specified as a case-sensitive, quoted string.

## Output Arguments

**mp — meta.property object**

`meta.property`

`meta.property` object that is associated with the named property. If `findprop` does not find the property on the object `h`, `findprop` returns a 0-by-1 empty `meta.property` object.

## Attributes

Access public

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

## Examples

### View Property Attribute Settings

Use `findprop` to view property attribute settings:

```
mp = findprop(containers.Map, 'Count')
```

```
mp =
```

```
property with properties:
```

```
 Name: 'Count'
 Description: 'Number of pairs in the collection'
DetailedDescription: ''
 GetAccess: 'public'
 SetAccess: 'private'
 Dependent: 1
 Constant: 0
 Abstract: 0
 Transient: 1
 Hidden: 0
GetObservable: 0
SetObservable: 0
 AbortSet: 0
 GetMethod: []
 SetMethod: []
 HasDefault: 0
 DefiningClass: [1x1 meta.class]
```

## isvalid

**Class:** handle

Determine valid handles

## Syntax

`B = isvalid(H)`

## Description

`B = isvalid(H)` returns a logical array in which each element is `true` if the corresponding element in `H` is a valid handle. A handle variable becomes invalid if the object has been deleted.

You cannot override the `isvalid` method in `handle` subclasses.

## Input Arguments

**H — Input array**

handle array

Input array, specified as an array of object handles.

## Output Arguments

**B — Result of validity test**

logical

Result of validity test, returned as a logical array the same size as `H` in which each element is `true` if the corresponding element in `H` is a valid handle.

## Attributes

Access

public

Sealed true

To learn about attributes of methods, see [Method Attributes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

### Test for Valid Handles

This example tests a handle array for valid members:

```
H = plot(rand(5));
delete(H(3:4))
B = invalid(H)
```

B =

```
1
1
0
0
1
```

## notify

**Class:** handle

Notify listeners that event is occurring

## Syntax

```
notify(H,EventName)
notify(H,EventName,data)
```

## Description

`notify(H,EventName)` notifies listeners that the named event is taking place on the handle objects in H.

`notify(H,EventName,data)` includes user-defined event data.

## Input Arguments

### **H — Event source**

handle array

Event source, specified as a handle array. All of the objects in H must define the named event.

### **EventName — Name of event**

string

Name of event, specified as a case-sensitive, quoted string that is defined by the class of H.

### **data — User-defined event data**

subclass of `event.EventData`

User-defined event data, specified as an object that is a subclass of the `event.EventData` class. For information on defining event data, see “Define Event-Specific Data”.

---

**Note:** Listener callbacks should not reuse the same event data object in subsequent calls to `notify`. Always create a new event data object to pass to `notify`.

---

## Attributes

Access public

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

## relationaloperators

**Class:** handle

Determine equality or sort handle objects

### Syntax

```
tf = eq(H1,H2)
tf = ne(H1,H2)
tf = lt(H1,H2)
tf = le(H1,H2)
tf = gt(H1,H2)
tf = ge(H1,H2)
```

### Description

tf = eq(H1,H2) Equal. (H1 == H2)

tf = ne(H1,H2) Not equal. (H1 ~= H2)

tf = lt(H1,H2) Less than. (H1 < H2)

tf = le(H1,H2) Less than or equal. (H1 <= H2)

tf = gt(H1,H2) Greater than. (H1 > H2)

tf = ge(H1,H2) Greater than or equal. (H1 >= H2)

For each pair of input arrays (H1 and H2), the operation returns a logical array of the same size. Each element in the returned array is an element-wise equality or comparison test result. These methods perform scalar expansion in the same way as the MATLAB built-in relational operators. See `relationaloperators` for more information.

The following guidelines apply to handle comparison:

- Copies of a handle variable always compare as equal.
- The repeated comparison of any two handles always yields the same result in the same MATLAB session.

- Different handles are always not equal.
- The order of handle values is purely arbitrary and has no connection to the state of the handle objects being compared.
- If the input arrays belong to different classes (including the case where one input array belongs to a non-handle class such as `double`) then the comparison is always false.
- If you make a comparison between a handle object and an object of a dominant class, the method of the dominant class is invoked. You should generally test only like objects because a dominant class might not define one of these methods.
- An error occurs if the input arrays are not the same size and neither is scalar.

Use `isequal` when you want to determine if different handle objects have the same data in all object properties.

## Input Arguments

### H1 — Left argument to operator

handle array

Left argument to operator, specified as a handle array.

### H2 — Right argument to operator

handle array

Right argument to operator, specified as a handle array.

## Output Arguments

### tf — Result of comparison

logical array

Result of comparison, returned as a logical array of the same size as the input arrays, where each element is an element-wise equality or comparison test result

- 1 — relationship is true
- 0 — relationship is not true

## **Attributes**

Access `public`

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

### **See Also**

`isequal`

# hankel

Hankel matrix

## Syntax

```
H = hankel(c)
H = hankel(c,r)
```

## Description

`H = hankel(c)` returns the square Hankel matrix whose first column is `c` and whose elements are zero below the first anti-diagonal.

`H = hankel(c,r)` returns a Hankel matrix whose first column is `c` and whose last row is `r`. If the last element of `c` differs from the first element of `r`, the last element of `c` prevails.

## Definitions

A Hankel matrix is a matrix that is symmetric and constant across the anti-diagonals, and has elements  $h(i,j) = p(i+j-1)$ , where vector `p = [c r(2:end)]` completely determines the Hankel matrix.

## Examples

A Hankel matrix with anti-diagonal disagreement is

```
c = 1:3; r = 7:10;
h = hankel(c,r)
h =
 1 2 3 8
 2 3 8 9
 3 8 9 10
```

`p = [1 2 3 8 9 10]`

**Introduced before R2006a**

# hasnext

Determine if ValueIterator has one or more values available

## Syntax

```
tf = hasnext(ValueIter)
```

## Description

`tf = hasnext(ValueIter)` returns logical 1 (true) if ValueIter has one or more values available; otherwise, it returns logical 0 (false).

## Examples

### Get Values from ValueIterator in Reduce Function

Use the `hasnext` and `getNext` functions in a `while` loop within the reduce function to iteratively get values from the ValueIterator object. For example,

```
function MeanDistReduceFun(sumLenKey, sumLenIter, outKVStore)
 sumLen = [0 0];
 while hasnext(sumLenIter)
 sumLen = sumLen + getNext(sumLenIter);
 end
 add(outKVStore, 'Mean', sumLen(1)/sumLen(2));
end
```

Always call `hasnext` before `getNext` to confirm availability of a value. `mapreduce` returns an error if you call `getNext` with no remaining values in the ValueIterator object.

## Input Arguments

**ValueIter** — Intermediate value iterator

ValueIterator object

Intermediate value iterator, specified as a `ValueIterator` object. The `mapreduce` function automatically creates this object during execution. The second input to the `reduce` function specifies the variable name for the `ValueIterator` object, which is the variable name to use with the `hasnext` and `getnext` functions.

For more information, see [Using ValueIterator Objects](#).

## More About

- [Using ValueIterator Objects](#)
- [“Build Effective Algorithms with MapReduce”](#)

**Introduced in R2014b**

# hdf5info

Information about HDF5 file

---

**Note:** `hdf5info` will be removed in a future version. Use `h5info` instead.

---

## Syntax

```
fileinfo = hdf5info(filename)
fileinfo = hdf5info(...,'ReadAttributes',BOOL)
[...] = hdf5info(..., 'V71Dimensions', BOOL)
```

## Description

`fileinfo = hdf5info(filename)` returns a structure `fileinfo` whose fields contain information about the contents of the HDF5 file `filename`. `filename` is a string that specifies the name of the HDF5 file.

`fileinfo = hdf5info(...,'ReadAttributes',BOOL)` specifies whether `hdf5info` returns the values of the attributes or just information describing the attributes. By default, `hdf5info` reads in attribute values (`BOOL = true`).

`[...] = hdf5info(..., 'V71Dimensions', BOOL)` specifies whether to report the dimensions of data sets and attributes as they were returned in previous versions of `hdf5info` (MATLAB 7.1 [R14SP3] and earlier). If `BOOL` is true, `hdf5info` swaps the first two dimensions of the data set. This behavior was intended to account for the difference in how HDF5 and MATLAB express array dimensions. HDF5 describes data set dimensions in row-major order; MATLAB stores data in column-major order. However, swapping these dimensions may not correctly reflect the intent of the data in the file and may invalidate metadata. When `BOOL` is false (the default), `hdf5info` returns data dimensions that correctly reflect the data ordering as it is written in the file—each dimension in the output variable matches the same dimension in the file.

---

**Note** If you use the `'V71Dimensions'` parameter and intend on passing the `fileinfo` structure returned to the `hdf5read` function, you should also specify the

'V71Dimensions' parameters with `hdf5read`. If you do not, `hdf5read` uses the new behavior when reading the data set and certain metadata returned by `hdf5info` does not match the actual data returned by `hdf5read`.

---

## Examples

```
fileinfo = hdf5info('example.h5');
```

To get more information about the contents of the HDF5 file, look at the `GroupHierarchy` field in the `fileinfo` structure returned by `hdf5info`.

```
toplevel = fileinfo.GroupHierarchy
```

```
toplevel =
```

```
 Filename: [1x64 char]
 Name: '/'
 Groups: [1x2 struct]
 Datasets: []
 Datatypes: []
 Links: []
 Attributes: [1x2 struct]
```

To probe further into the file hierarchy, keep examining the `Groups` field.

## See also

`hdf5read`, `hdf5write`

# hdf5read

Read HDF5 file

---

**Note:** `hdf5read` will be removed in a future version. Use `h5read` instead.

---

## Syntax

```
data = hdf5read(filename,datasetname)
attr = hdf5read(filename,attributename)
[data, attr] = hdf5read(...,'ReadAttributes',BOOL)
data = hdf5read(hinfo)
[...] = hdf5read(..., 'V71Dimensions', BOOL)
```

## Description

`data = hdf5read(filename,datasetname)` reads all the data in the data set `datasetname` that is stored in the HDF5 file `filename` and returns it in the variable `data`. To determine the names of data sets in an HDF5 file, use the `hdf5info` function.

The return value, `data`, is a multidimensional array. `hdf5read` maps HDF5 data types to native MATLAB data types, whenever possible. If it cannot represent the data using MATLAB data types, `hdf5read` uses one of the HDF5 data type objects. For example, if an HDF5 file contains a data set made up of an enumerated data type, `hdf5read` uses the `hdf5.h5enum` object to represent the data in the MATLAB workspace. The `hdf5.h5enum` object has data members that store the enumerations (names), their corresponding values, and the enumerated data.

---

**Note:** `hdf5read` performs best when reading numeric datasets. If you need to read string, compound, or variable length datasets, MathWorks strongly recommends that you use the low-level HDF5 interface function, `H5D.read`. To read a subset of a dataset, you must use the low-level interface.

---

`attr = hdf5read(filename,attributename)` reads all the metadata in the attribute `attributename`, stored in the HDF5 file `filename`, and returns it in the variable `attr`. To determine the names of attributes in an HDF5 file, use the `hdf5info` function.

`[data, attr] = hdf5read(..., 'ReadAttributes', BOOL)` reads all the data, as well as all of the associated attribute information contained within that data set. By default, `BOOL` is false.

`data = hdf5read(hinfo)` reads all of the data in the data set specified in the structure `hinfo` and returns it in the variable `data`. The `hinfo` structure is extracted from the output returned by `hdf5info`, which specifies an HDF5 file and a specific data set.

`[...] = hdf5read(..., 'V71Dimensions', BOOL)` specifies whether to change the majority of data sets read from the file. If `BOOL` is true, `hdf5read` permutes the first two dimensions of the data set, as it did in previous releases (MATLAB 7.1 [R14SP3] and earlier). This behavior was intended to account for the difference in how HDF5 and MATLAB express array dimensions. HDF5 describes data set dimensions in row-major order; MATLAB stores data in column-major order. However, permuting these dimensions may not correctly reflect the intent of the data and may invalidate metadata. When `BOOL` is false (the default), the data dimensions correctly reflect the data ordering as it is written in the file — each dimension in the output variable matches the same dimension in the file.

## Examples

Use `hdf5info` to get information about an HDF5 file and then use `hdf5read` to read a data set, using the information structure (`hinfo`) returned by `hdf5info` to specify the data set.

```
hinfo = hdf5info('example.h5');
dset = hdf5read(hinfo.GroupHierarchy.Groups(2).Datasets(1));
```

## See Also

`hdf5info` | `hdf5write`

**Introduced before R2006a**

# hdf5write

Write data to file in HDF5 format

---

**Note:** hdf5write will be removed in a future version. Use h5write instead.

---

## Syntax

```
hdf5write(filename,location,dataset)
hdf5write(filename,details,dataset)
hdf5write(filename,details,attribute)
hdf5write(filename, details1, dataset1, details2, dataset2,...)
hdf5write(filename,...,'WriteMode',mode,...)
hdf5write(..., 'V71Dimensions', BOOL)
```

## Description

`hdf5write(filename,location,dataset)` writes the data `dataset` to the HDF5 file, `filename`. If `filename` does not exist, `hdf5write` creates it. If `filename` exists, `hdf5write` overwrites the existing file, by default, but you can also append data to an existing file using an optional syntax.

`location` defines where to write the data set in the file. HDF5 files are organized in a hierarchical structure similar to a UNIX directory structure. `location` is a string that resembles a UNIX path.

`hdf5write` maps the data in `dataset` to HDF5 data types according to rules outlined below.

`hdf5write(filename,details,dataset)` writes `dataset` to `filename` using the values in the `details` structure. For a data set, the `details` structure can contain the following fields.

| Field Name | Description                          | Data Type       |
|------------|--------------------------------------|-----------------|
| Location   | Location of the data set in the file | Character array |

| Field Name | Description                    | Data Type       |
|------------|--------------------------------|-----------------|
| Name       | Name to attach to the data set | Character array |

`hdf5write(filename,details,attribute)` writes the metadata `attribute` to `filename` using the values in the `details` structure. For an attribute, the `details` structure can contain following fields.

| Field Name | Description                                                                                       | Data Type       |
|------------|---------------------------------------------------------------------------------------------------|-----------------|
| AttachedTo | Location of the object this attribute modifies                                                    | Structure array |
| AttachType | Identifies what kind of object this attribute modifies; possible values are 'group' and 'dataset' | Character array |
| Name       | Name to attach to the data set                                                                    | Character array |

`hdf5write(filename, details1, dataset1, details2, dataset2,...)` writes multiple data sets and associated attributes to `filename` in one operation. Each data set and attribute must have an associated `details` structure.

`hdf5write(filename,...,'WriteMode',mode,...)` specifies whether `hdf5write` overwrites the existing file (the default) or appends data sets and attributes to the file. Possible values for `mode` are 'overwrite' and 'append'.

`hdf5write(...,'V71Dimensions', BOOL)` specifies whether to change the majority of data sets written to the file. If `BOOL` is true, `hdf5write` permutes the first two dimensions of the data set, as it did in previous releases (MATLAB 7.1 [R14SP3] and earlier). This behavior was intended to account for the difference in how HDF5 and MATLAB express array dimensions. HDF5 describes data set dimensions in row-major order; MATLAB stores data in column-major order. However, permuting these dimensions may not correctly reflect the intent of the data and may invalidate metadata. When `BOOL` is false (the default), the data written to the file correctly reflects the data ordering of the data sets — each dimension in the file's data sets matches the same dimension in the corresponding MATLAB variable.

## Data Type Mappings

The following table lists how `hdf5write` maps the data type from the workspace into an HDF5 file. If the data in the workspace that is being written to the file is a MATLAB

data type, `hdf5write` uses the following rules when translating MATLAB data into HDF5 data objects.

| <b>MATLAB Data Type</b>    | <b>HDF5 Data Set or Attribute</b>                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Numeric                    | Corresponding HDF5 native data type. For example, if the workspace data type is <code>uint8</code> , the <code>hdf5write</code> function writes the data to the file as 8-bit integers. The size of the HDF5 dataspace is the same size as the MATLAB array.                                                                                                                                                                                 |
| String                     | Single, null-terminated string                                                                                                                                                                                                                                                                                                                                                                                                               |
| Cell array of strings      | Multiple, null-terminated strings, each the same length. Length is determined by the length of the longest string in the cell array. The size of the HDF5 dataspace is the same size as the cell array.                                                                                                                                                                                                                                      |
| Cell array of numeric data | Numeric array, the same dimensions as the cell array. The elements of the array must all have the same size and type. The data type is determined by the first element in the cell array.                                                                                                                                                                                                                                                    |
| Structure array            | HDF5 compound type. Individual fields in the structure employ the same data translation rules for individual data types. For example, a cell array of strings becomes a multiple, null-terminated strings.                                                                                                                                                                                                                                   |
| HDF5 objects               | If the data being written to the file is composed of HDF5 objects, <code>hdf5write</code> uses the same data type when writing to the file. For all HDF5 objects, except <code>HDF5.h5enum</code> objects, the dataspace has the same dimensions as the array of HDF5 objects passed to the function. For <code>HDF5.h5enum</code> objects, the size and dimensions of the data set in the HDF5 file is the same as the object's Data field. |

## Examples

Write a 5-by-5 data set of `uint8` values to the root group.

```
hdf5write('myfile.h5', '/dataset1', uint8(magic(5)))
```

Write a 2-by-2 string data set in a subgroup.

```
dataset = {'north', 'south'; 'east', 'west'};
hdf5write('myfile2.h5', '/group1/dataset1.1', dataset);
```

Write a data set and attribute to an existing group.

```
dset = single(rand(10,10));
dset_details.Location = '/group1/dataset1.2';
dset_details.Name = 'Random';

attr = 'Some random data';
attr_details.Name = 'Description';
attr_details.AttachedTo = '/group1/dataset1.2/Random';
attr_details.AttachType = 'dataset';

hdf5write('myfile2.h5', dset_details, dset, ...
 attr_details, attr, 'WriteMode', 'append');
```

Write a data set using objects.

```
dset = hdf5.h5array(magic(5));
hdf5write('myfile3.h5', '/g1/objects', dset);
```

# hdfan

Gateway to HDF multifile annotation (AN) interface

## Syntax

```
[out1,...,outN] = hdfan(funcstr,input1,...,inputN)
```

## Description

`hdfan` is the MATLAB gateway to the HDF multifile annotation (AN) interface.

`[out1,...,outN] = hdfan(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the AN function in the HDF library specified by `funcstr`.

There is a one-to-one correspondence between AN functions in the HDF library and valid values for `funcstr`. For example, `hdfan('endaccess',annot_id)` corresponds to the C library call `ANendaccess(annot_id)`.

## Access Functions

Access functions initialize the interface and provide and terminate access to annotations.

| Value of <code>funcstr</code> | Function Syntax                                                         | Description                                                                                                                                                |
|-------------------------------|-------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'start'                       | <code>AN_id =<br/>hdfan('start',file_id)</code>                         | Initializes the multifile annotation interface.                                                                                                            |
| 'select'                      | <code>annot_id =<br/>hdfan('select',AN_id,<br/>index,annot_type)</code> | Selects and returns the identifier for the annotation identified by the given index value and annotation type.                                             |
| 'end'                         | <code>status =<br/>hdfan('end',AN_id)</code>                            | Terminates access to the multifile annotation interface.                                                                                                   |
| 'create'                      | <code>annot_id =<br/>hdfan('create',AN_id,tag,r</code>                  | Creates a data annotation for the object identified by the specified tag and reference number. <code>annot_type</code> can be 'data_label' or 'data_desc'. |

| Value of funcstr | Function Syntax                            | Description                                                                                         |
|------------------|--------------------------------------------|-----------------------------------------------------------------------------------------------------|
| 'createf'        | annot_id =<br>hdfan('createf', AN_id, anno | Creates a file label or file description annotation. annot_type can be 'file_label' or 'file_desc'. |
| 'endaccess'      | status =<br>hdfan('endaccess', annot_id    | Terminates access to an annotation.                                                                 |

## Read/Write Functions

Read/write functions read and write file or object annotations.

| Value of funcstr | Function Syntax                                          | Description                                                                                                                 |
|------------------|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| 'writeann'       | status =<br>hdfan('writeann', annot_id,                  | Writes the annotation corresponding to the given annotation identifier.                                                     |
| 'readann'        | [annot_string, status] =<br>hdfan('readann', annot_id)   | Reads the annotation corresponding to the given annotation identifier;                                                      |
|                  | [annot_string, status] =<br>hdfan('readann', annot_id, m | Reads the annotation corresponding to the given annotation identifier. annot_string will not be longer than max_str_length. |

## General Inquiry Functions

General inquiry functions return information about the annotations in a file.

| Value of funcstr | Function Syntax                                      | Description                                                                                   |
|------------------|------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| 'numann'         | num_annot =<br>hdfan('numann', AN_id, annot          | Gets number of annotations of specified type corresponding to given tag/ref pair.             |
| 'annlist'        | [ann_list, status] =<br>hdfan('annlist', AN_id, anno | Gets the list of annotations of given type in the file corresponding to a given tag/ref pair. |

| Value of funcstr | Function Syntax                                       | Description                                                                                                                   |
|------------------|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| 'annlen'         | length =<br>hdfan('annlen',annot_id)                  | Gets the length of annotation corresponding to the given annotation identifier.                                               |
| 'fileinfo'       | [nfl,nfd,ndl,ndd,status] =<br>hdfan('fileinfo',AN_id) | Gets number of file label, file description, data label, and data description annotations in the file corresponding to AN_id. |
| 'get_tagref'     | [tag,ref,status] =<br>hdfan('get_tagref',AN_id,i)     | Gets the tag/ref pair for the specified annotation type and index.                                                            |
| 'id2tagref'      | [tag,ref,status] =<br>hdfan('id2tagref',annot_id)     | Gets the tag/ref pair corresponding to the specified annotation identifier.                                                   |
| 'tagref2id'      | annot_id =<br>hdfan('tagref2id',AN_id,ta)             | Gets the annotation identifier corresponding to the specified tag/ref pair.                                                   |
| 'atype2tag'      | tag =<br>hdfan('atype2tag',annot_ty)                  | Gets the tag corresponding to the specified annotation type.                                                                  |
| 'tag2atype'      | annot_type =<br>hdfan('tag2atype',tag)                | Gets the annotation type corresponding to the specified tag.                                                                  |

## Input/Output Arguments

A status or identifier output of -1 indicates that the operation failed.

In general, the input argument `annot_type` can be one of these strings:

- 'file\_label'
- 'file\_desc'
- 'data\_label'
- 'data\_desc'

`AN_id` refers to the multifile annotation interface identifier.

`annot_id` refers to an individual annotation identifier.

You must terminate access to all opened identifiers using either `hdfan('end',AN_id)` or `hdfan('endaccess',annot_id)`. Otherwise, the HDF library might not properly write all data to the file.

# hdfdf24

Gateway to HDF 24-bit raster image (DF24) interface

## Syntax

```
[out1,...,outN] = hdfdf24(funcstr,input1,...,inputN)
```

## Description

hdfdf24 is the MATLAB gateway to the HDF 24-bit raster image interface.

[out1,...,outN] = hdfdf24(funcstr,input1,...,inputN) returns one or more outputs corresponding to the DF24 function in the HDF library specified by funcstr.

There is a one-to-one correspondence between DF24 functions in the HDF library and valid values for funcstr. For example, hdfdf24('lastref') corresponds to the C library call DF24lastref().

## Write Functions

Write functions create raster image sets and store them in new files or append them to existing files.

| Value of funcstr | Function Syntax                                  | Description                                                                                                                         |
|------------------|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| 'addimage'       | status =<br>hdfdf24('addimage',filename)         | Appends a 24-bit raster image to a file.                                                                                            |
| 'putimage'       | status =<br>hdfdf24('putimage',filename)         | Writes a 24-bit raster image to file by overwriting all existing data.                                                              |
| 'setcompress'    | status =<br>hdfdf24('setcompress',compress_type) | Sets the compress method for the next raster image written to the file. compress_type can be 'none', 'rle', 'jpeg', or 'imcomp'. If |

| Value of funcstr | Function Syntax                             | Description                                                                                                                                                                                                    |
|------------------|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  |                                             | compress_type is 'jpeg', then two additional parameters must be specified: quality (a scalar between 0 and 100) and force_baseline (either 0 or 1). Other compression types do not have additional parameters. |
| 'setdims'        | status =<br>hdfdf24('setdims',width,height) | Sets the dimensions for the next raster image written to the file.                                                                                                                                             |
| 'setil'          | status =<br>hdfdf24('setil',interlace)      | Sets the interlace format of the next raster image written to the file. interlace can be 'pixel', 'line', or 'component'.                                                                                      |
| 'lastref'        | ref = hdfdf24('lastref')                    | Reports the last reference number assigned to a 24-bit raster image.                                                                                                                                           |

## Read Functions

Read functions determine the dimensions and interlace format of an image set, read the actual image data, and provide sequential or random read access to any raster image set.

| Value of funcstr | Function Syntax                                                  | Description                                                                                                            |
|------------------|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| 'getdims'        | [width,height,interlace,status] =<br>hdfdf24('getdims',filename) | Retrieves the dimensions before reading the next raster image. interlace can be 'pixel', 'line', or 'component'.       |
| 'getimage'       | [RGB,status] =<br>hdfdf24('getimage',filename)                   | Reads the next 24-bit raster image.                                                                                    |
| 'reqil'          | status =<br>hdfdf24('reqil',interlace)                           | Specifies the interlace format before reading the next raster image. interlace can be 'pixel', 'line', or 'component'. |

| Value of funcstr | Function Syntax                              | Description                                                 |
|------------------|----------------------------------------------|-------------------------------------------------------------|
| 'readref'        | status =<br>hdfdf24('readref', filename)     | Reads 24-bit raster image with the specified raster number. |

| 'nimages'        | num_images =<br>hdfdf24('nimages', filename) | Reports the number of 24-bit raster images in a file.       |

## Input/Output Arguments

A `status` or identifier output of -1 indicates that the operation failed.

HDF uses C-style ordering of elements, in which elements along the last dimension vary fastest. MATLAB uses FORTRAN-style ordering, in which elements along the first dimension vary fastest. `hdfdf24` does not automatically convert from C-style ordering to MATLAB style ordering, which means that MATLAB image arrays need to be permuted when using `hdfdf24` to read or write from HDF files. The exact permutation depends on the interlace format specified by, for example, `hdfdf24('setil', ...)`. The following calls to `permute` converts HDF arrays to MATLAB arrays, according to the specified interlace format.

```

RGB = permute(RGB,[3 2 1]); 'pixel' interlace
RGB = permute(RGB,[3 1 2]); 'line' interlace
RGB = permute(RGB,[2 1 3]); 'component' interlace

```

## hdfdf8

Gateway to HDF 8-bit raster image (DFR8) interface

### Syntax

```
[out1,...,outN] = hdfdf8(funcstr,input1,...,inputN)
```

### Description

`hdfdf8` is the MATLAB gateway to the HDF 8-bit raster image (DFR8) interface.

`[out1,...,outN] = hdfdf8(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the DFR8 function in the HDF library specified by `funcstr`.

There is a one-to-one correspondence between DFR8 functions in the HDF library and valid values for `funcstr`. For example, `hdfdf8('setpalette',map)` corresponds to the C library call `DFR8setpalette(map)`.

### Write Functions

Write functions create raster image sets and store them in new files or append them to existing files.

| Value of <code>funcstr</code> | Function Syntax                                   | Description                                                                                                                            |
|-------------------------------|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| 'writeref'                    | <code>status = hdfdf8('writeref',filename)</code> | Stores the raster image using the specified reference number.                                                                          |
| 'setpalette'                  | <code>status = hdfdf8('setpalette',color)</code>  | Sets palette for multiple 8-bit raster images.                                                                                         |
| 'addimage'                    | <code>status = hdfdf8('addimage',filename)</code> | Appends an 8-bit raster image to a file. <code>compress</code> can be 'none', 'rle', 'jpeg', or 'imcomp'.                              |
| 'putimage'                    | <code>status = hdfdf8('putimage',filename)</code> | Writes an 8-bit raster image to an existing file or creates the file. <code>compress</code> can be 'none', 'rle', 'jpeg', or 'imcomp'. |

| Value of funcstr | Function Syntax                        | Description                                                                                                                                                                                                                                                                                           |
|------------------|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'setcompress'    | status =<br>hdfdf8('setcompress', comp | Sets the compression type. compress_type can be 'none', 'rle', 'jpeg', or 'imcomp'. If compress_type is 'jpeg', then two additional parameters must be passed in: quality (a scalar between 0 and 100) and force_baseline (either 0 or 1). Other compression types do not have additional parameters. |

## Read Functions

Read functions determine the dimension and palette assignment for an image set, read the actual image data, and provide sequential or random read access to any raster image set.

| Value of funcstr | Function Syntax                                              | Description                                                               |
|------------------|--------------------------------------------------------------|---------------------------------------------------------------------------|
| 'getdims'        | [width,height,hasmap,status] =<br>hdfdf8('getdims',filename) | Retrieves dimensions for an 8-bit raster image.                           |
| 'getimage'       | [X,map,status] =<br>hdfdf8('getimage',filename)              | Retrieves an 8-bit raster image and its palette.                          |
| 'readref'        | status =<br>hdfdf8('readref',filename)                       | Gets the next raster image with the specified reference number.           |
| 'restart'        | status =<br>hdfdf8('restart')                                | Ignores information about last file accessed and restarts from beginning. |
| 'nimages'        | num_images =<br>hdfdf8('nimages',filename)                   | Returns number of raster images in a file.                                |
| 'lastref'        | ref = hdfdf8('lastref')                                      | Returns reference number of last element accessed.                        |

## Input/Output Arguments

A status or identifier output of -1 indicates that the operation failed.

HDF uses C-style ordering of elements, in which elements along the last dimension vary fastest. MATLAB uses FORTRAN-style ordering, in which elements along the first dimension vary fastest. `hdfdf8` does not automatically convert from C-style ordering to MATLAB style ordering, which means that MATLAB image and colormap matrices must be transposed when using `hdfdf8` to read or write from HDF files.

Functions in `hdfdf8` that read and write palette information expect to use `uint8` data in the range [0,255], while MATLAB colormaps contain double-precision values in the range [0,1]. Therefore, HDF palettes must be converted to `double` and scaled to be used as MATLAB colormaps.

# hdfh

Gateway to HDF H interface

## Syntax

[out1,...,outN] = hdfh(funcstr,input1,...,inputN)

## Description

hdfh is the MATLAB gateway to the HDF H interface.

[out1,...,outN] = hdfh(funcstr,input1,...,inputN) returns one or more outputs corresponding to the H function in the HDF library specified by funcstr.

There is a one-to-one correspondence between H functions in the HDF library and valid values for funcstr. For example, hdfh('close',file\_id) corresponds to the C library call Hclose(file\_id).

## Functions

| Value of funcstr | Function Syntax                                               | Description                                                               |
|------------------|---------------------------------------------------------------|---------------------------------------------------------------------------|
| 'appendable'     | status =<br>hdfh('appendable',access_id)                      | Specifies that the element can be appended to.                            |
| 'close'          | status =<br>hdfh('close',file_id)                             | Closes the access path to the file.                                       |
| 'deldd'          | status =<br>hdfh('deldd',file_id,tag,ref)                     | Deletes a tag and reference number from the data descriptor list.         |
| 'dupdd'          | status =<br>hdfh('dupdd',file_id,tag,ref)                     |                                                                           |
| 'endaccess'      | status =<br>hdfh('endaccess',access_id)                       | Terminates access to a data object by disposing of the access identifier. |
| 'fidinquire'     | [filename,access_mode,attach,<br>= hdfh('fidinquire',file_id) | Returns information about specified file.                                 |

| Value of funcstr | Function Syntax                                                                            | Description                                                                                                                                      |
|------------------|--------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 'find'           | [tag,ref,offset,length,status] = hdfh('find',file_id,... search_tag,search_ref,search_dir) | Locates the next object to be searched for in an HDF file. search_type can be 'new' or 'continue'. The dir input can be 'forward' or 'backward'. |
| 'getelement'     | [data,status] = hdfh('getelement',file_id,tag,ref)                                         | Reads the data element for the specified tag and reference number.                                                                               |
| 'getfileversion' | [major,minor,release,info,status] = hdfh('getfileversion',file_id)                         | Returns version information for an HDF file.                                                                                                     |
| 'getlibversion'  | [major,minor,release,info,status] = hdfh('getlibversion')                                  | Returns version information for the current HDF library.                                                                                         |
| 'inquire'        | [file_id,tag,ref,length,offset,special,status] = hdfh('inquire',access_id)                 | Returns access information about a data element.                                                                                                 |
| 'ishdf'          | tf = hdfh('ishdf',filename)                                                                | Determines if a file is an HDF file.                                                                                                             |

| 'newref'         | ref = hdfh('newref',file_id)                                                               | Returns a reference number that can be used with any tag to product a unique tag/reference number pair.                                          |
| 'nextread'       | status = hdfh('nextread',access_id,tag,ref)                                                | Searches for the next data descriptor that matches the specified tag and reference number. origin can be 'start' or 'current'.                   |
| 'number'         | num = hdfh('number',file_id,tag)                                                           | Returns the number of instances of a tag in a file.                                                                                              |

| Value of funcstr | Function Syntax                                      | Description                                                                                         |
|------------------|------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| 'offset'         | offset =<br>hdfh('offset', file_id, tag, ref)        | Returns the offset of a data element in the file.                                                   |
| 'open'           | file_id =<br>hdfh('open', filename, access, r)       | Provides an access path to an HDF file by reading all the data descriptor blocks into memory.       |
| 'putelement'     | count =<br>hdfh('putelement', file_id, tag, X)       | Writes a data element or replaces an existing data element in an HDF file. X must be a uint8 array. |
| 'read'           | X =<br>hdfh('read', access_id, length)               | Reads the next segment in a data element.                                                           |
| 'seek'           | status =<br>hdfh('seek', access_id, offset, origin)  | Sets the access pointer to an offset within a data element. origin can be 'start' or 'current'.     |
| 'startread'      | access_id =<br>hdfh('startread', file_id, tag, ref)  |                                                                                                     |
| 'startwrite'     | access_id =<br>hdfh('startwrite', file_id, tag, ref) |                                                                                                     |
| 'sync'           | status =<br>hdfh('sync', file_id)                    |                                                                                                     |
| 'trunc'          | length =<br>hdfh('trunc', access_id, trunc)          | Truncates the specified data object to the given length.                                            |
| 'write'          | count =<br>hdfh('write', access_id, X)               | Writes the next data segment to a specified data element. X must be a uint8 array.                  |

## Output Arguments

A status or identifier output of -1 indicates that the operation failed.

## Limitations

- hdfh does not support these functions in the NCSA H interface:
  - Hcache
  - Hendbitaccess
  - Hexist
  - Hflushdd
  - Hgetbit
  - Hputbit
  - Hsetlength
  - Hshutdown
  - Htagnewref

## hdfhx

Gateway to HDF external data (HX) interface

### Syntax

```
[out1,...,outN] = hdfhx(funcstr,input1,...,inputN)
```

### Description

`hdfhx` is the MATLAB gateway to the HDF interface for manipulating linked and external data elements.

`[out1,...,outN] = hdfhx(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the HX function in the HDF library specified by `funcstr`.

There is a one-to-one correspondence between HX functions in the HDF library and valid values for `funcstr`. For example, `hdfhx('setdir',pathname);` corresponds to the C library call `HXsetdir(pathname)`.

### Functions

| Value of <code>funcstr</code> | Function Syntax                                    | Description                                                                                                                        |
|-------------------------------|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 'create'                      | <code>access_id = hdfhx('create',file_id,ta</code> | Creates a new external file special data element. (length)                                                                         |
| 'setcreatedir'                | <code>status = hdfhx('setcreatedir',path</code>    | Sets the directory location for writing external file.                                                                             |
| 'setdir'                      | <code>status = hdfhx('setdir',pathname);</code>    | Sets the directory for locating external files. <code>pathname</code> can contain multiple directories separated by vertical bars. |

### Input/Output Arguments

A `status` or identifier output of -1 indicates that the operation failed.

In cases where the HDF C library accepts NULL for certain inputs, an empty matrix ([ ] or ' ') can be used.

# hdfinfo

Information about HDF4 or HDF-EOS file

## Syntax

```
S = hdfinfo(filename)
S = hdfinfo(filename,mode)
```

## Description

`S = hdfinfo(filename)` returns a structure `S` whose fields contain information about the contents of an HDF4 or HDF-EOS file. `filename` is a string that specifies the name of the HDF4 file.

`S = hdfinfo(filename,mode)` reads the file as an HDF4 file, if `mode` is `'hdf'`, or as an HDF-EOS file, if `mode` is `'eos'`. If `mode` is `'eos'`, only HDF-EOS data objects are queried. To retrieve information on the entire contents of a file containing both HDF4 and HDF-EOS objects, `mode` must be `'hdf'`.

---

**Note** `hdfinfo` can be used on Version 4.x HDF files or Version 2.x HDF-EOS files. To get information about an HDF5 file, use `hdf5info`.

---

The set of fields in the returned structure `S` depends on the individual file. Fields that can be present in the `S` structure are shown in the following table.

| Mode | Field Name  | Description                        | Return Type     |
|------|-------------|------------------------------------|-----------------|
| HDF  | Attributes  | Attributes of the data set         | Structure array |
|      | Description | Annotation description             | Cell array      |
|      | Filename    | Name of the file                   | String          |
|      | Label       | Annotation label                   | Cell array      |
|      | Raster8     | Description of 8-bit raster images | Structure array |

| Mode | Field Name | Description                         | Return Type     |
|------|------------|-------------------------------------|-----------------|
|      | Raster24   | Description of 24-bit raster images | Structure array |
|      | SDS        | Description of scientific data sets | Structure array |
|      | Vdata      | Description of Vdata sets           | Structure array |
|      | Vgroup     | Description of Vgroups              | Structure array |
| EOS  | Filename   | Name of the file                    | String          |
|      | Grid       | Grid data                           | Structure array |
|      | Point      | Point data                          | Structure array |
|      | Swath      | Swath data                          | Structure array |

Those fields in the table above that contain structure arrays are further described in the tables shown below.

## Fields Common to Returned Structure Arrays

Structure arrays returned by `hdfinfo` contain some common fields. These are shown in the table below. Not all structure arrays will contain all of these fields.

| Field Name  | Description                                          | Data Type       |
|-------------|------------------------------------------------------|-----------------|
| Attributes  | Data set attributes. Contains fields Name and Value. | Structure array |
| Description | Annotation description                               | Cell array      |
| Filename    | Name of the file                                     | String          |
| Label       | Annotation label                                     | Cell array      |
| Name        | Name of the data set                                 | String          |
| Rank        | Number of dimensions of the data set                 | Double          |
| Ref         | Data set reference number                            | Double          |
| Type        | Type of HDF or HDF-EOS object                        | String          |

## Fields Specific to Certain Structures

Structure arrays returned by `hdfinfo` also contain fields that are unique to each structure. These are shown in the tables below.

### Fields of the Attribute Structure

| Field Name | Description                    | Data Type         |
|------------|--------------------------------|-------------------|
| Name       | Attribute name                 | String            |
| Value      | Attribute value or description | Numeric or string |

### Fields of the Raster8 and Raster24 Structures

| Field Name | Description                                                                                                     | Data Type |
|------------|-----------------------------------------------------------------------------------------------------------------|-----------|
| HasPalette | 1 ( <code>true</code> ) if the image has an associated palette, otherwise 0 ( <code>false</code> ) (8-bit only) | Logical   |
| Height     | Height of the image, in pixels                                                                                  | Number    |
| Interlace  | Interlace mode of the image (24-bit only)                                                                       | String    |
| Name       | Name of the image                                                                                               | String    |
| Width      | Width of the image, in pixels                                                                                   | Number    |

### Fields of the SDS Structure

| Field Name | Description                                                                                                                                                                                                                                                                    | Data Type       |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| DataType   | Data precision                                                                                                                                                                                                                                                                 | String          |
| Dims       | Dimensions of the data set. Contains fields <code>Name</code> , <code>DataType</code> , <code>Size</code> , <code>Scale</code> , and <code>Attributes</code> . <code>Scale</code> is an array of numbers to place along the dimension and demarcate intervals in the data set. | Structure array |
| Index      | Index of the SDS                                                                                                                                                                                                                                                               | Number          |

### Fields of the Vdata Structure

| Field Name     | Description                                                                                   | Data Type       |
|----------------|-----------------------------------------------------------------------------------------------|-----------------|
| DataAttributes | Attributes of the entire data set. Contains fields <code>Name</code> and <code>Value</code> . | Structure array |
| Class          | Class name of the data set                                                                    | String          |

| Field Name  | Description                                               | Data Type       |
|-------------|-----------------------------------------------------------|-----------------|
| Fields      | Fields of the Vdata. Contains fields Name and Attributes. | Structure array |
| NumRecords  | Number of data set records                                | Double          |
| IsAttribute | 1 (true) if Vdata is an attribute, otherwise 0 (false)    | Logical         |

### Fields of the Vgroup Structure

| Field Name | Description                             | Data Type       |
|------------|-----------------------------------------|-----------------|
| Class      | Class name of the data set              | String          |
| Raster8    | Description of the 8-bit raster image   | Structure array |
| Raster24   | Description of the 24-bit raster image  | Structure array |
| SDS        | Description of the Scientific Data sets | Structure array |
| Tag        | Tag of this Vgroup                      | Number          |
| Vdata      | Description of the Vdata sets           | Structure array |
| Vgroup     | Description of the Vgroups              | Structure array |

### Fields of the Grid Structure

| Field Name  | Description                                                                                                                           | Data Type       |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Columns     | Number of columns in the grid                                                                                                         | Number          |
| DataFields  | Description of the data fields in each Grid field of the grid. Contains fields Name, Rank, Dims, NumberType, FillValue, and TileDims. | Structure array |
| LowerRight  | Lower right corner location, in meters                                                                                                | Number          |
| Origin Code | Origin code for the grid                                                                                                              | Number          |
| PixRegCode  | Pixel registration code                                                                                                               | Number          |
| Projection  | Projection code, zone code, sphere code, and projection parameters of                                                                 | Structure       |

| Field Name | Description                                                              | Data Type |
|------------|--------------------------------------------------------------------------|-----------|
|            | the grid. Contains fields ProjCode, ZoneCode, SphereCode, and ProjParam. |           |
| Rows       | Number of rows in the grid                                               | Number    |
| UpperLeft  | Upper left corner location, in meters                                    | Number    |

### Fields of the Point Structure

| Field Name | Description                                                                                                | Data Type |
|------------|------------------------------------------------------------------------------------------------------------|-----------|
| Level      | Description of each level of the point. Contains fields Name, NumRecords, FieldNames, DataType, and Index. | Structure |

### Fields of the Swath Structure

| Field Name       | Description                                                                                     | Data Type       |
|------------------|-------------------------------------------------------------------------------------------------|-----------------|
| DataFields       | Data fields in the swath. Contains fields Name, Rank, Dims, NumberType, and FillValue.          | Structure array |
| GeolocationField | Geolocation fields in the swath. Contains fields Name, Rank, Dims, NumberType, and FillValue.   | Structure array |
| IdxMapInfo       | Relationship between indexed elements of the geolocation mapping. Contains fields Map and Size. | Structure       |
| MapInfo          | Relationship between data and geolocation fields. Contains fields Map, Offset, and Increment.   | Structure       |

## Examples

To retrieve information about the file `example.hdf`,

```
fileinfo = hdfinfo('example.hdf')
```

```
fileinfo =
 Filename: 'example.hdf'
 SDS: [1x1 struct]
 Vdata: [1x1 struct]
```

And to retrieve information from this about the scientific data set in `example.hdf`,

```
sds_info = fileinfo.SDS
```

```
sds_info =
 Filename: 'example.hdf'
 Type: 'Scientific Data Set'
 Name: 'Example SDS'
 Rank: 2
 DataType: 'int16'
 Attributes: []
 Dims: [2x1 struct]
 Label: {}
 Description: {}
 Index: 0
```

## See Also

`hdfread`

# hdfml

Utilities for working with MATLAB HDF gateway functions

## Syntax

```
hdfml('closeall')
hdfml('listinfo')
tag = hdfml('tagnum',tagname)
nbytes = hdfml('sizeof',data_type)
hdfml('defaultchartype',char_type)
```

## Description

`hdfml('closeall')` closes all open registered HDF file and data object identifiers.

`hdfml('listinfo')` prints information about all open registered HDF file and data object identifiers.

`tag = hdfml('tagnum',tagname)` returns the tag number corresponding to the tag name specified by `tagname`.

`nbytes = hdfml('sizeof',data_type)` returns size in bytes of specified data type.

`hdfml('defaultchartype',char_type)` defines the HDF data type for MATLAB strings. Valid values for `char_type` are `'char8'` or `'uchar8'`. The change persists until the MATLAB HDF gateway function is cleared from memory. MATLAB strings are mapped to `char8` by default.

The MATLAB HDF gateway functions maintain lists of certain HDF file and data object identifiers so that, for example, HDF objects and files can be properly closed when a user issues the command:

```
clear mex
```

These lists are updated whenever these identifiers are created or closed.

## hdfpt

Interface to HDF-EOS Point object

### Syntax

```
[out1,...,outN] = hdfpt(funcstr,input1,...,inputN)
```

### Description

`hdfpt` is the MATLAB gateway to the Point functions in the HDF-EOS C library, which is developed and maintained by EOSDIS (Earth Observing System Data and Information System). A Point data set comprises a series of data records taken at (possibly) irregular time intervals and at scattered geographic locations. Each data record consists of a set of one or more data values representing the state of a point in time and/or space.

`[out1,...,outN] = hdfpt(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the Point function in the HDF-EOS library specified by `funcstr`.

There is a one-to-one correspondence between PT functions in the HDF-EOS C library and valid values for `funcstr`. For example, `hdfpt('detach',point_id)` corresponds to the C library call `PTdetach(point_id)`.

### Programming Model

The programming model for accessing a point data set through `hdfpt` is as follows:

- 1 Open the file and initialize the PT interface by obtaining a file id from a file name.
- 2 Open or create a point data set by obtaining a point id from a point name.
- 3 Perform desired operations on the data set.
- 4 Close the point data set by disposing of the point id.
- 5 Terminate point access to the file by disposing of the file id.

To access a single point data set that already exists in an HDF-EOS file, use the following MATLAB commands:

```
fileid = hdfpt('open',filename,access);
pointid = hdfpt('attach',fileid,pointname);
```

```
% Optional operations on the data set...
```

```
status = hdfpt('detach',pointid);
status = hdfpt('close',fileid);
```

To access several files at the same time, obtain a separate file identifier for each file to be opened. To access more than one point data set, obtain a separate point id for each data set.

It is important to properly dispose of point id's and file id's so that buffered operations are written completely to disk. If you quit MATLAB or clear all MEX-files with PT identifiers still open, MATLAB issues a warning and automatically disposes of them.

Note that file identifiers returned by `hdfpt` are not interchangeable with file identifiers returned by any other HDF-EOS or HDF function.

## Access Routines

Access routines initialize and terminate access to the PT interface and point data sets (including opening and closing files).

| Value of funcstr | Function Syntax                                           | Description                                                                                                                                                                                                                          |
|------------------|-----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'open'           | <code>file_id = hdfpt('open',filename,access)</code>      | Given the filename and desired access mode, opens or creates an HDF file in order to create, read, or write a point. <code>access</code> can be 'read', 'readwrite', or 'create'. <code>file_id</code> is -1 if the operation fails. |
| 'create'         | <code>point_id = hdfpt('create',file_id,pointname)</code> | Creates a point data set with the specified name. <code>pointname</code> is a string contain the name of the point data set. <code>point_id</code> is -1 if the operation fails.                                                     |
| 'attach'         | <code>point_id = hdfpt('attach',file_id,pointname)</code> | Attaches to an existing point data set within the file.                                                                                                                                                                              |

| Value of funcstr | Function Syntax                      | Description                            |
|------------------|--------------------------------------|----------------------------------------|
|                  |                                      | point_id is -1 if the operation fails. |
| 'detach'         | status =<br>hdfpt('detach',point_id) | Detaches from point data set.          |
| 'close'          | status =<br>hdfpt('close',file_id)   | Closes file.                           |

## Definition Routines

Definition routines allow the user to set key features of a point data set.

| Value of funcstr | Function Syntax                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'deflevel'       | status =<br>hdfpt('deflevel',point_id,<br>fieldList,fieldTypes,fieldOrders) | Defines a new level within a point data set. levelname is the name of the level to be defined. fieldList is a string containing a comma-separated list of field names in the new level. fieldTypes is a cell array containing the number type string for each field. Valid number type strings include 'uchar8', 'uchar', 'char8', 'char', 'double', 'uint8', 'uint16', 'uint32', 'float', 'int8', 'int16', and 'int32'. fieldOrders is a vector containing the order for each field. |
| 'deflinkage'     | status =<br>hdfpt('deflinkage',point_id,levelname,childname,linkfield)      | Defines a linkfield between two adjacent levels. parent is the name of the parent level. child is the name of the child level. linkfield is the name of a field that is defined at both levels.                                                                                                                                                                                                                                                                                       |

## Basic I/O Routines

Basic I/O routines read and write data and metadata to a point data set.

| Value of funcstr | Function Syntax                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'writelevel'     | status =<br>hdfpt('writelevel',point_id)                                   | Appends new records to the specified level in a point data set. <b>level</b> is the desired level index (zero-based). <b>data</b> must be a P-by-1 cell array where P is the number of fields defined for the specified level. Each cell of <b>data</b> must contain an M(k)-by-N matrix of data, where M(k) is the order of the k-th field (the number of scalar values in the field) and N is the number of records. The MATLAB class of the cells must match the HDF data type defined for the corresponding fields. A MATLAB string is automatically converted to match any of the HDF char types. Other data types must match exactly. |
| 'readlevel'      | [data,status] =<br>hdfpt('readlevel',point_id,<br>level,fieldList,records) | Reads data from a given level in a point data set. <b>level</b> is the index (zero-based) of the desired level. <b>fieldList</b> is a string containing a comma-separated list of the fields to read. <b>records</b> is a vector containing the indices (zero-based) of the records to read. <b>data</b> is a P-by-1 cell array where P is the number of requested fields. Each cell of <b>data</b> contains an M(k)-by-N matrix of data where M(k) is the order of the k-                                                                                                                                                                  |

| Value of funcstr | Function Syntax                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|-------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  |                                                                               | th field and N is the number of records, or <code>length(records)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 'updatelevel'    | <code>status = hdfpt('updatelevel',point_level,fieldList,records,data)</code> | Updates (corrects) data in a particular level of a point data set. <code>level</code> is the index (zero-based) of the desired level. <code>fieldList</code> is a string containing a comma-separated list of field names to update. <code>records</code> is a vector containing the indices (zero-based) of the records to update. <code>data</code> is a P-by-1 cell array where P is the number of specified fields. Each cell of <code>data</code> must contain an M(k)-by-N matrix of data, where M(k) is the order of the k-th field (the number of scalar values in the field) and N is the number of records, or <code>length(records)</code> . The MATLAB class of the cells must match the HDF data type defined for the corresponding fields. A MATLAB string is automatically converted to match any of the HDF char types. Other data types must match exactly. |
| 'writeattr'      | <code>status = hdfpt('writeattr',point_id,attribute,value)</code>             | Writes or updates the point data set attribute with the specified name. If the attribute does not already exist, it is created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 'readattr'       | <code>[data,status] = hdfpt('readattr',point_id,attribute)</code>             | Reads the attribute data from the specified attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Inquiry Routines

Inquiry routines return information about data contained in a point data set.

| Value of funcstr | Function Syntax                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                             |
|------------------|------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'nlevels'        | nlevels =<br>hdfpt('nlevels',point_id)                                             | Returns the number of levels in a point data set. nlevels is -1 if the operation fails.                                                                                                                                                                                                                                                                                                 |

## Input/Output Arguments

Most routines return the flag, **status**, which is 0 when the routine succeeds and -1 when the routine fails. Routines with syntaxes which do not contain **status** return failure information in one of its outputs as notated in the function syntaxes.

levelName is a string.

Some of the C library functions accept input values that are defined in terms of C macros. For example, the C POpen() function requires an access mode input that can be DFACC\_READ, DFACC\_RDWR, or DFACC\_CREATE, where these symbols are defined in the appropriate C header file. Where macro definitions are used in the C library, the equivalent MATLAB syntaxes use strings derived from the macro names. You can either use a string containing the entire macro name, or you can omit the common prefix. You can use either upper or lower case. For example, this C function call:

```
status = POpen("PointFile.hdf",DFACC_CREATE)
is equivalent to these MATLAB function calls:
```

```
status = hdfpt('open','PointFile.hdf','DFACC_CREATE')
status = hdfpt('open','PointFile.hdf','dfacc_create')
status = hdfpt('open','PointFile.hdf','CREATE')
status = hdfpt('open','PointFile.hdf','create')
```

In cases where a C function returns a value with a macro definition, the equivalent MATLAB function returns the value as a string containing the lowercase short form of the macro.

HDF number types are specified by strings, including 'uchar8', 'uchar', 'char8', 'char', 'double', 'uint8', 'uint16', 'uint32', 'float', 'int8', 'int16', and 'int32'.

In cases where the HDF-EOS library accepts NULL, use an empty matrix ([ ]).

## hdfread

Read data from HDF4 or HDF-EOS file

### Syntax

```
data = hdfread(filename, datasetname)
data = hdfread(hinfo)
data = hdfread(...,param,value,...)
data = hdfread(filename,EOSname,param,value,...)
[data,map] = hdfread(...)
```

### Description

`data = hdfread(filename, datasetname)` returns all the data in the data set specified by `datasetname` from the HDF4 or HDF-EOS file specified by `filename`. To determine the name of a data set in an HDF4 file, use the `hdfinfo` function.

---

**Note** `hdfread` can be used on Version 4.x HDF files or Version 2.x HDF-EOS files. To read data from an HDF5 file, use `h5read`.

---

`data = hdfread(hinfo)` returns all the data in the data set specified by the `structurehinfo`, returned by the `hdfinfo` function. Specify the field in the `hinfo` structure that relates to a particular type of data set, and use indexing to specify which data set, when there are more than one. See “Specify data set to read” on page 1-3945 for more information.

`data = hdfread(...,param,value,...)` returns subsets of the data according to the specified parameter and value pairs. See the tables below to find the valid parameters and values for different types of data sets.

`data = hdfread(filename,EOSname,param,value,...)` subsets the data field from the HDF-EOS point, grid, or swath specified by `EOSname`.

`[data,map] = hdfread(...)` returns the image `data` and the colormap `map` for an 8-bit raster image.

## Subsetting Parameters

The following tables show the subsetting parameters that can be used with the `hdfread` function for certain types of HDF4 data. These data types are

- HDF Scientific Data (SD)
- HDF Vdata (V)
- HDF-EOS Grid Data
- HDF-EOS Point Data
- HDF-EOS Swath Data

Note the following:

- If a parameter requires multiple values, use a cell array to store the values. For example, the 'Index' parameter requires three values: `start`, `stride`, and `edge`. Enclose these values in curly braces as a cell array.

```
hdfread(..., 'Index', {start, stride, edge})
```

- All values that are indices are 1-based.

### Subsetting Parameters for HDF Scientific Data (SD) Data Sets

When you are working with HDF SD files, `hdfread` supports the parameters listed in this table.

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'Index'   | <p>Three-element cell array, <code>{start, stride, edge}</code>, specifying the location, range, and values to be read from the data set</p> <ul style="list-style-type: none"> <li>• <b>start</b> — A 1-based array specifying the position in the file to begin reading</li> </ul> <p>Default: 1, start at the first element of each dimension. The values specified must not exceed the size of any dimension of the data set.</p> <ul style="list-style-type: none"> <li>• <b>stride</b> — A 1-based array specifying the interval between the values to read</li> </ul> <p>Default: 1, read every element of the data set.</p> |

| Parameter | Description                                                                                                                                                                                              |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <ul style="list-style-type: none"> <li>edge — A 1-based array specifying the length of each dimension to read</li> </ul> <p>Default: An array containing the lengths of the corresponding dimensions</p> |

For example, this code reads the data set `Example SDS` from the HDF file `example.hdf`. The `'Index'` parameter specifies that `hdfread` start reading data at the beginning of each dimension, read until the end of each dimension, but only read every other data value in the first dimension.

```
data = hdfread('example.hdf','Example SDS','Index',{[],[2 1],[1]})
```

## Subsetting Parameters for HDF Vdata Sets

When you are working with HDF Vdata files, `hdfread` supports these parameters.

| Parameter                  | Description                                                                                                      |
|----------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>'Fields'</code>      | Text string specifying the name of the field to be read. When specifying multiple field names, use a cell array. |
| <code>'FirstRecord'</code> | 1-based number specifying the record from which to begin reading                                                 |
| <code>'NumRecords'</code>  | Number specifying the total number of records to read                                                            |

For example, this code reads the Vdata set `Example Vdata` from the HDF file `example.hdf`.

```
data = hdfread('example.hdf','Example Vdata','FirstRecord', 2,'NumRecords', 5)
```

## Subsetting Parameters for HDF-EOS Grid Data

When you are working with HDF-EOS grid data, `hdfread` supports three types of parameters:

- Required parameters
- Optional parameters
- Mutually exclusive parameters — You can only specify one of these parameters in a call to `hdfread`, and you cannot use these parameters in combination with any optional parameter.

| Parameter                 | Description |
|---------------------------|-------------|
| <b>Required Parameter</b> |             |

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'Fields'                                      | String specifying the field to be read. You can specify only one field name for a Grid data set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Mutually Exclusive Optional Parameters</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 'Index'                                       | <p>Three-element cell array, {<b>start</b>, <b>stride</b>, <b>edge</b>}, specifying the location, range, and values to be read from the data set</p> <p><b>start</b> — An array specifying the position in the file to begin reading</p> <p>Default: 1, start at the first element of each dimension. The values must not exceed the size of any dimension of the data set.</p> <p><b>stride</b> — An array specifying the interval between the values to read</p> <p>Default: 1, read every element of the data set.</p> <p><b>edge</b> — An array specifying the length of each dimension to read</p> <p>Default: An array containing the lengths of the corresponding dimensions</p> |
| 'Interpolate'                                 | Two-element cell array, { <b>longitude</b> , <b>latitude</b> }, specifying the longitude and latitude points that define a region for bilinear interpolation. Each element is an N-length vector specifying longitude and latitude coordinates.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 'Pixels'                                      | <p>Two-element cell array, {<b>longitude</b>, <b>latitude</b>}, specifying the longitude and latitude coordinates that define a region. Each element is an N-length vector specifying longitude and latitude coordinates. This region is converted into pixel rows and columns with the origin in the upper left corner of the grid.</p> <p>Note: This is the pixel equivalent of reading a 'Box' region.</p>                                                                                                                                                                                                                                                                           |
| 'Tile'                                        | Vector specifying the coordinates of the tile to read, for HDF-EOS Grid files that support tiles                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Optional Parameters</b>                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 'Box'                                         | Two-element cell array, { <b>longitude</b> , <b>latitude</b> }, specifying the longitude and latitude coordinates that define a region. <b>longitude</b> and <b>latitude</b> are each two-element vectors specifying longitude and latitude coordinates.                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'Time'     | Two-element cell array, [ <code>start stop</code> ], where <code>start</code> and <code>stop</code> are numbers that specify the start and end-point for a period of time                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 'Vertical' | <p>Two-element cell array, {<code>dimension, range</code>}</p> <p><code>dimension</code> — String specifying the name of the data set field to be read from. You can specify only one field name for a Grid data set.</p> <p><code>range</code> — Two-element array specifying the minimum and maximum range for the subset. If <code>dimension</code> is a dimension name, then <code>range</code> specifies the range of elements to extract. If <code>dimension</code> is a field name, then <code>range</code> specifies the range of values to extract.</p> <p>'Vertical' subsetting can be used alone or in conjunction with 'Box' or 'Time'. To subset a region along multiple dimensions, vertical subsetting can be used up to eight times in one call to <code>hdfread</code>.</p> |

For example,

```
data = hdfread('grid.hdf','PolarGrid','Fields','ice_temp','Index', {[5 10],[],[15 20]})
```

## Subsetting Parameters for HDF-EOS Point Data

When you are working with HDF-EOS Point data, `hdfread` has two required parameters and three optional parameters.

| Parameter                                     | Description                                                                                                                                                                                                                                                        |
|-----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Required Parameters</b>                    |                                                                                                                                                                                                                                                                    |
| 'Fields'                                      | String naming the data set field to be read. For multiple field names, use a comma-separated list.                                                                                                                                                                 |
| 'Level'                                       | 1-based number specifying which level to read from in an HDF-EOS Point data set                                                                                                                                                                                    |
| <b>Mutually Exclusive Optional Parameters</b> |                                                                                                                                                                                                                                                                    |
| 'Box'                                         | Two-element cell array, { <code>longitude, latitude</code> }, specifying the longitude and latitude coordinates that define a region. <code>longitude</code> and <code>latitude</code> are each two-element vectors specifying longitude and latitude coordinates. |

| Parameter       | Description                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'RecordNumbers' | Vector specifying the record numbers to read                                                                                                           |
| 'Time'          | Two-element cell array, [ <b>start stop</b> ], where <b>start</b> and <b>stop</b> are numbers that specify the start and endpoint for a period of time |

For example,

```
hdfread(...,'Fields',{field1, field2},...
 'Level',level,'RecordNumbers',[1:50, 200:250])
```

## Subsetting Parameters for HDF-EOS Swath Data

When you are working with HDF-EOS Swath data, `hdfread` supports three types of parameters:

- Required parameters
- Optional parameters
- Mutually exclusive

You can only use one of the mutually exclusive parameters in a call to `hdfread`, and you cannot use these parameters in combination with any optional parameter.

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Required Parameter</b>                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 'Fields'                                      | String naming the data set field to be read. You can specify only one field name for a Swath data set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Mutually Exclusive Optional Parameters</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 'Index'                                       | <p>Three-element cell array, {<b>start, stride, edge</b>}, specifying the location, range, and values to be read from the data set</p> <ul style="list-style-type: none"> <li>• <b>start</b> — An array specifying the position in the file to begin reading<br/>Default: 1, start at the first element of each dimension. The values must not exceed the size of any dimension of the data set.</li> <li>• <b>stride</b> — An array specifying the interval between the values to read<br/>Default: 1, read every element of the data set.</li> <li>• <b>edge</b> — An array specifying the length of each dimension to read</li> </ul> |

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                            | Default: An array containing the lengths of the corresponding dimensions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 'Time'                     | <p>Three-element cell array, {start, stop, mode}, where <b>start</b> and <b>stop</b> specify the beginning and the endpoint for a period of time, and <b>mode</b> is a string defining the criterion for the inclusion of a cross track in a region. The cross track is within a region if any of these conditions is met:</p> <ul style="list-style-type: none"> <li>• Its midpoint is within the box (mode= 'midpoint').</li> <li>• Either endpoint is within the box (mode= 'endpoint').</li> </ul>                                                                                                                                                                                                                                                  |
| <b>Optional Parameters</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 'Box'                      | <p>Three-element cell array, {longitude, latitude, mode} specifying the longitude and latitude coordinates that define a region. <b>longitude</b> and <b>latitude</b> are two-element vectors that specify longitude and latitude coordinates. <b>mode</b> is a string defining the criterion for the inclusion of a cross track in a region. The cross track is within a region if any of these conditions is met:</p> <ul style="list-style-type: none"> <li>• Its midpoint is within the box (mode= 'midpoint').</li> <li>• Either endpoint is within the box (mode= 'endpoint').</li> <li>• Any point is within the box (mode= 'anypoint').</li> </ul>                                                                                              |
| 'Vertical'                 | <p>Two-element cell array, {dimension, range}</p> <ul style="list-style-type: none"> <li>• <b>dimension</b> is a string specifying either a dimension name or field name to subset the data by.</li> <li>• <b>range</b> is a two-element vector specifying the minimum and maximum range for the subset. If <b>dimension</b> is a dimension name, then <b>range</b> specifies the range of elements to extract. If <b>dimension</b> is a field name, then <b>range</b> specifies the range of values to extract.</li> </ul> <p>'Vertical' subsetting can be used alone or in conjunction with 'Box' or 'Time'. To subset a region along multiple dimensions, vertical subsetting can be used up to eight times in one call to <code>hdfread</code>.</p> |

For example,

```
hdfread('swath.hdf', 'Example Swath', 'Fields', 'Temperature', ...
 'Time', {5000, 6000, 'midpoint'})
```

## Examples

### Read Data Set in HDF File

Specify the name of the HDF file and the name of the data set. This example reads a data set named `temperature` from a sample HDF file.

```
data = hdfread('sd.hdf', 'temperature');
```

### Specify data set to read

Call `hdfinfo` to retrieve information about the contents of the HDF file.

```
fileinfo = hdfinfo('sd.hdf')
```

```
fileinfo =
```

```
 Filename: 'B:\matlab\toolbox\matlab\imagesci\sd.hdf'
 Attributes: [1x1 struct]
 SDS: [1x2 struct]
 Vdata: [1x1 struct]
```

Extract the structure containing information about the particular data set you want to import from the data returned by `hdfinfo`. This example uses the structure in the `SDS` field to retrieve a scientific data set.

```
sds_info = fileinfo.SDS(2)
```

```
sds_info =
```

```
 Filename: 'B:\matlab\toolbox\matlab\imagesci\sd.hdf'
 Type: 'Scientific Data Set'
 Name: 'temperature'
 Rank: 2
 DataType: 'double'
 Attributes: [1x11 struct]
 Dims: [2x1 struct]
 Label: {}
```

```
Description: {}
Index: 1
```

Pass this structure to `hdfread` to import the data in the data set.

```
data = hdfread(sds_info);
```

## Read Data from HDF-EOS Grid Field

Read data from the HDF-EOS global grid field, `TbOceanRain`, in the example file, `example.hdf`.

```
data1 = hdfread('example.hdf', 'MonthlyRain', 'Fields', 'TbOceanRain');
```

Read data for the northern hemisphere for the same field. Use the `Box` parameter to specify the longitude and latitude coordinates for that region.

```
data2 = hdfread('example.hdf', 'MonthlyRain', ...
 'Fields', 'TbOceanRain', ...
 'Box', {[0 360],[0 90]});
```

## Read Subset of Data in Data Set

Retrieve info about the example file, `example.hdf`.

```
fileinfo = hdfinfo('example.hdf');
```

Retrieve information about Scientific Data Set in `example.hdf`.

```
data_set_info = fileinfo.SDS;
```

Check the size of the data set.

```
data_set_info.Dims.Size
```

```
ans =
```

```
16
```

```
ans =
```

```
5
```

Read a subset of the data in the data set using the 'index' parameter with `hdfread`. This example specifies a starting index of [3 3], an interval of 1 between values ([ ] meaning the default value of 1), and a length of 10 rows and 2 columns.

```
data = hdfread(data_set_info,'Index',{[3 3],[1],[10 2]});
data(:,1)
```

```
ans =
```

```
7
8
9
10
11
12
13
14
15
16
```

```
data(:,2)
```

```
ans =
```

```
8
9
10
11
12
13
14
15
16
17
```

### Access Data in Fields of Vdata

Use the `Vdata` field from the information returned by `hdfinfo` to read three fields of the data, `Idx`, `Temp`, and `Dewpt`.

```
s = hdfinfo('example.hdf');
data = hdfread(s.Vdata(1), 'Fields', {'Idx', 'Temp', 'Dewpt'})
```

```
data =
```

```
 [1x10 int16]
 [1x10 int16]
 [1x10 int16]
```

# hdf5tool

Browse and import data from HDF4 or HDF-EOS files

## Syntax

```
hdf5tool
hdf5tool(filename)
h = hdf5tool(___)
```

## Description

`hdf5tool` starts the HDF Import Tool, a graphical user interface used to browse the contents of HDF4 and HDF-EOS files and import data and subsets of data from these files. To open an HDF4 or HDF-EOS file, select **Open** from the **Home** tab. You can open multiple files in the HDF Import Tool by selecting **Open** from the **Home** tab.

`hdf5tool(filename)` opens the HDF4 or HDF-EOS file specified by `filename` in the HDF Import Tool.

`h = hdf5tool( ___ )` returns a handle `h` to the HDF Import Tool. To close the tool from the command line, use `close(h)`.

## Examples

```
hdf5tool('example.hdf');
```

## hdfv

Gateway to HDF Vgroup (V) interface

### Syntax

```
[out1,...,outN] = hdfv(funcstr,input1,...,inputN)
```

### Description

`hdfv` is the MATLAB gateway to the HDF Vgroup (V) interface.

`[out1,...,outN] = hdfv(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the V function in the HDF library specified by `funcstr`.

There is a one-to-one correspondence between V functions in the HDF library and valid values for `funcstr`. For example, `hdfv('nattrs',vgroup_id)` corresponds to the C library call `Vnattrs(vgroup_id)`.

### Access Functions

Access functions open files, initialize the Vgroup interface, and access individual groups. They also terminate access to vgroups and the Vgroup interface and close HDF files.

| Value of <code>funcstr</code> | Function Syntax                                        | Description                                               |
|-------------------------------|--------------------------------------------------------|-----------------------------------------------------------|
| 'start'                       | <code>status =<br/>hdfv('start',file_id)</code>        | Initializes the V interface.                              |
| 'attach'                      | <code>vgroup_id =<br/>hdfv('attach',file_id,vgr</code> | Establishes access to a vgroup. access can be 'r' or 'w'. |
| 'detach'                      | <code>status =<br/>hdfv('detach',vgroup_id)</code>     | Terminates access to a vgroup.                            |
| 'end'                         | <code>status =<br/>hdfv('end',file_id)</code>          | Terminates access to the V interface.                     |

## Create Functions

Create functions organize, label, and add data objects to vgroups.

| Value of funcstr | Function Syntax                          | Description                                                                       |
|------------------|------------------------------------------|-----------------------------------------------------------------------------------|
| 'setclass'       | status =<br>hdfv('setclass',vgroup_id    | Assigns a class to a vgroup.                                                      |
| 'setname'        | status =<br>hdfv('setname',vgroup_id,    | Assigns a name to a vgroup.                                                       |
| 'insert'         | ref =<br>hdfv('insert',vgroup_id,<br>id) | Adds a vgroup or vdata to an existing group. id can be a vdata id or a vgroup id. |
| 'addtagref'      | status =<br>hdfv('addtagref',vgroup_i    | Adds any HDF data object to an existing vgroup.                                   |
| 'setattr'        | status =<br>hdfv('setattr',vgroup_id,    | Sets the attribute of a vgroup.                                                   |

## File Inquiry Functions

File inquiry functions return information about how vgroups are stored in a file. They are useful for locating vgroups in a file.

| Value of funcstr | Function Syntax                             | Description                                                                                          |
|------------------|---------------------------------------------|------------------------------------------------------------------------------------------------------|
| 'lone'           | [refs,count] =<br>hdfv('lone',file_id,maxsi | Returns the reference numbers of vgroups not included in other vgroups.                              |
| 'getid'          | next_ref =<br>hdfv('getid',file_id,vgro     | Returns the reference number for the next vgroup in the HDF file.                                    |
| 'find'           | vgroup_ref =<br>hdfv('find',file_id,vgrou   | Returns the reference number of the vgroup with the specified name if successful and zero otherwise. |
| 'findclass'      | vgroup_ref =<br>hdfv('findclass',file_id,   | Returns the reference number of the vgroup with the specified class.                                 |

## Vgroup Inquiry Functions

Vgroup inquiry functions provide specific information about a specific vgroup. This information includes the class, name, member count, and additional member information.

| Value of funcstr | Function Syntax                                          | Description                                                                                               |
|------------------|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| 'getclass'       | [class_name,status] =<br>hdfv('getclass',vgroup_id)      | Returns the name of the class of the specified group.                                                     |
| 'getname'        | [vgroup_name,status] =<br>hdfv('getname',vgroup_id)      | Returns the name of the specified group.                                                                  |
| 'inquire'        | [num_entries,name,status] =<br>hdfv('inquire',vgroup_id) | Returns the number of entries and the name of a vgroup.                                                   |
| 'isvg'           | status =<br>hdfv('isvg',vgroup_id,ref)                   | Checks if the object specified by ref refers to a child vgroup of the vgroup specified by vgroup_id.      |
| 'isvs'           | status =<br>hdfv('isvs',vgroup_id,vdata_ref)             | Checks if the object specified by vdata_ref refers to a child vdata of the vgroup specified by vgroup_id. |
| 'gettagref'      | [tag,ref,status] =<br>hdfv('gettagref',vgroup_id)        | Retrieves a tag/reference number pair for a data object in the specified vgroup.                          |
| 'ntagrefs'       | count =<br>hdfv('ntagrefs',vgroup_id)                    | Returns the number of tag/reference number pairs contained in the specified vgroup.                       |
| 'gettagrefs'     | [tag,refs,count] =<br>hdfv('gettagrefs',vgroup_id)       | Retrieves the tag/reference pairs of all the data objects within a vgroup.                                |
| 'inqtagref'      | tf =<br>hdfv('inqtagref',vgroup_id)                      | Checks if an object belongs to a vgroup.                                                                  |
| 'getversion'     | version =<br>hdfv('getversion',vgroup_id)                | Queries the vgroup version of a given vgroup.                                                             |

| Value of funcstr | Function Syntax                                                         | Description                                                                                            |
|------------------|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| 'nattrs'         | count =<br>hdfv('nattrs',vgroup_id)                                     | Queries the total number of vgroup attributes.                                                         |
| 'attrinfo'       | [name,data_type,count,nby =<br>hdfv('attrinfo',vgroup_id<br>attr_index) | Queries information on a given vgroup attribute.                                                       |
| 'getattr'        | [values,status] =<br>hdfv('getattr',vgroup_id,                          | Queries the values of a given attribute.                                                               |
| 'Queryref'       | ref =<br>hdfv('Queryref',vgroup_id                                      | Returns the reference number of the specified vgroup.                                                  |
| 'Querytag'       | tag =<br>hdfv('Querytag',vgroup_id                                      | Returns the tag of the specified vgroup.                                                               |
| 'flocate'        | vdata_ref =<br>hdfv('flocate',vgroup_id,                                | Returns the reference number of the vdata containing the specified field name in the specified vgroup. |
| 'nrefs'          | count =<br>hdfv('nrefs',vgroup_id,ta                                    | Returns the number of data objects with the specified tag in the specified vgroup.                     |

## Output Arguments

A status or identifier output of -1 indicates that the operation failed.

# hdfvf

Gateway to VF functions in HDF Vdata interface

## Syntax

```
[out1,...,outN] = hdfvf(funcstr,input1,...,inputN)
```

## Description

hdfvf is the MATLAB gateway to the VF unctions in the HDF Vdata interface.

[out1,...,outN] = hdfvf(funcstr,input1,...,inputN) returns one or more outputs corresponding to the VF function in the HDF library specified by funcstr.

There is a one-to-one correspondence between VF functions in the HDF library and valid values for funcstr. For example, hdfvf('nfields',vdata\_id) corresponds to the C library call VFnfields(vdata\_id).

## Field Inquiry Functions

Field inquiry functions provide specific information about the fields in a given vdata, including the field's size, name, order, type, and number of fields in the vdata.

| Value of funcstr | Function Syntax                         | Description                                                          |
|------------------|-----------------------------------------|----------------------------------------------------------------------|
| 'fieldesize'     | fsize =<br>hdfvf('fieldesize',vdata_id) | Retrieves the field size (as stored in a file) of a specified field. |
| 'fieldisize'     | fsize =<br>hdfvf('fieldisize',vdata_id) | Retrieves the field size (as stored in memory) of a specified field. |
| 'fieldname'      | name =<br>hdfvf('fieldname',vdata_id,   | Retrieves the name of the specified field in the given vdata.        |
| 'fieldorder'     | order =<br>hdfvf('fieldorder',vdata_id) | Retrieves the order of the specified field in the given vdata.       |

| Value of funcstr | Function Syntax                            | Description                                                         |
|------------------|--------------------------------------------|---------------------------------------------------------------------|
| 'fieldtype'      | data_type =<br>hdfvf('fieldtype',vdata_id, | Retrieves the data type for the specified field in the given vdata. |
| 'nfields'        | count =<br>hdfvf('nfields',vdata_id)       | Retrieves the total number of fields in the specified vdata.        |

## Output Arguments

A status or identifier output of -1 indicates that the operation failed.

# hdfvh

Gateway to VH functions in HDF Vdata interface

## Syntax

```
[out1,...,outN] = hdfvh(funcstr,input1,...,inputN)
```

## Description

hdfvh is the MATLAB gateway to VH functions in the HDF Vdata interface.

[out1,...,outN] = hdfvh(funcstr,input1,...,inputN) returns one or more outputs corresponding to the VH function in the HDF library specified by **funcstr**.

There is a one-to-one correspondence between VH functions in the HDF library and valid values for **funcstr**.

## High-level Vdata Functions

High-level Vdata functions write data to single-field vdatas.

| Value of <b>funcstr</b> | Function Syntax                                                                        | Description                                                                          |
|-------------------------|----------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| 'makegroup'             | <code>vgroup_ref =<br/>hdfvh('makegroup',file_id,<br/>vgroup_name,vgroup_class)</code> | Groups a collection of data objects within a vgroup.                                 |
| 'storedata'             | <code>count =<br/>hdfvh('storedata',file_id,<br/>vdata_name,vdata_class)</code>        | Creates vdatas containing records limited to one field with one component per field. |
| 'storedatam'            | <code>count =<br/>hdfvh('storedatam',file_id,<br/>vdata_name,vdata_class)</code>       | Creates vdatas containing records with one field containing one or more components.  |

## Output Arguments

A **status** or identifier output of -1 indicates that the operation failed.

## hdfvs

Gateway to VS functions in HDF Vdata interface

### Syntax

```
[out1,...,outN] = hdfvs(funcstr,input1,...,inputN)
```

### Description

`hdfvs` is the MATLAB gateway to the VS functions in the HDF Vdata interface.

`[out1,...,outN] = hdfvs(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the VS function in the HDF library specified by `funcstr`.

There is a one-to-one correspondence between VS functions in the HDF library and valid values for `funcstr`. For example, `hdfvs('detach',vdata_id)` corresponds to the C library call `VSdetach(vdata_id)`.

### Access Functions

Access functions attach, or allow access, to vdatas. Data transfer can only occur after a vdata has been accessed. These routines also detach from, or properly terminate access to, vdatas when data transfer has been completed.

| Value of <code>funcstr</code> | Function Syntax                                       | Description                                                        |
|-------------------------------|-------------------------------------------------------|--------------------------------------------------------------------|
| 'attach'                      | <code>vdata_id =<br/>hdfvs('attach',file_id,vd</code> | Establishes access to a specified vdata. access can be 'r' or 'w'. |
| 'detach'                      | <code>status =<br/>hdfvs('detach',vdata_id)</code>    | Terminates access to a specified vdata.                            |

### Read and Write Functions

Read and write functions read and write the contents of a vdata.

| Value of funcstr | Function Syntax                           | Description                                                                                                                                                                                                                                                                                                                                          |
|------------------|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'fdefine'        | status =<br>hdfvs('fdefine',vdata_id,     | Defines a new vdata field. <b>data_type</b> is a string specifying the HDF number type. It can be any these strings: 'uchar8', 'uchar', 'char8', 'char', 'double', 'uint8', 'uint16', 'uint32', 'float', 'int8', 'int16', or 'int32'.                                                                                                                |
| 'setclass'       | status =<br>hdfvs('setclass',vdata_id     | Assigns a class to a vdata.                                                                                                                                                                                                                                                                                                                          |
| 'setfields'      | status =<br>hdfvs('setfields',vdata_i     | Specifies the vdata fields to be written.                                                                                                                                                                                                                                                                                                            |
| 'setinterlace'   | status =<br>hdfvs('setinterlace',vdat     | Sets the interlace mode for a vdata. <b>interlace</b> can be 'full' or 'no'.                                                                                                                                                                                                                                                                         |
| 'setname'        | status =<br>hdfvs('setname',vdata_id,     | Assigns a name to a vdata.                                                                                                                                                                                                                                                                                                                           |
| 'write'          | count = hdfvs('write',<br>vdata_id, data) | Writes to a vdata. <b>data</b> must be an <b>nfields</b> -by-1 cell array. Each cell must contain an <b>order(i)</b> -by- <b>n</b> vector of data where <b>order(i)</b> is the number of scalar values in each field. The types of the data must match the field types set via <b>hdfvs('setfields')</b> or the fields in an already existing vdata. |

| Value of funcstr  | Function Syntax                               | Description                                                                                                                                                                                                                                                      |
|-------------------|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 'read'            | [data,count] =<br>hdfvs('read',vdata_id,n)    | Reads from a vdata. Data is returned in a nfields-by-1 cell array. Each cell contains a order(i)-by-n vector of data where order is the number of scalar values in each field. The fields are returned in the same order as specified in hdfvs('setfields',...). |
| 'seek'            | pos =<br>hdfvs('seek',vdata_id,rec)           | Seeks to a specified record in a vdata.                                                                                                                                                                                                                          |
| 'setattr'         | status =<br>hdfvs('setattr',vdata_id,         | Sets the attribute of a vdata field or vdata.                                                                                                                                                                                                                    |
| 'setexternalfile' | status =<br>hdfvs('setexternalfile',v         | Stores vdata information in an external file.                                                                                                                                                                                                                    |
| 'getattr'         | [value,status] =<br>hdfvs('getattr',vdata_id, | Reads the value of an attribute attached to a vdata or a vdata field. Set field_index to 'vdata' to retrieve an attribute attached to the field itself. Set field_index to the numerical index of the field to retrieve an attribute attached to a vdata field.  |
| 'setattr'         | status =<br>hdfvs('setattr',vdata_id,         | Sets the attribute of a vdata field or vdata.field_index can be an index number or 'vdata'.                                                                                                                                                                      |

## File Inquiry Functions

File inquiry functions provide information about how vdatas are stored in a file. They are useful for locating vdatas in a file.

| Value of funcstr | Function Syntax                          | Description                                                |
|------------------|------------------------------------------|------------------------------------------------------------|
| 'find'           | vdata_ref =<br>hdfvs('find',file_id,vdat | Searches for a given vdata name in the specified HDF file. |

| Value of funcstr | Function Syntax                             | Description                                                                                 |
|------------------|---------------------------------------------|---------------------------------------------------------------------------------------------|
| 'findclass'      | vdata_ref =<br>hdfvs('findclass',file_id)   | Returns the reference number of the first vdata corresponding to the specified vdata class. |
| 'getid'          | next_ref =<br>hdfvs('getid',file_id,vda     | Returns the identifier of the next vdata in the file.                                       |
| 'lone'           | [refs,count] =<br>hdfvs('lone',file_id,maxs | Returns the reference numbers of the vdatas that are not linked into vgroups.               |

## Vdata Inquiry Functions

Vdata inquiry functions provide specific information about a given vdata, including the vdata's name, class, number of fields, number of records, tag and reference pairs, interlace mode, and size.

| Value of funcstr | Function Syntax                                                 | Description                                               |
|------------------|-----------------------------------------------------------------|-----------------------------------------------------------|
| 'fexist'         | status =<br>hdfvs('fexist',vdata_id,f                           | Tests for the existence of fields in the specified vdata. |
| 'inquire'        | [n,interlace,fields,nbyte<br>= ...<br>hdfvs('inquire',vdata_id) | Returns information about the specified vdata.            |
| 'elts'           | count =<br>hdfvs('elts',vdata_id)                               | Returns the number of records in the specified vdata.     |
| 'getclass'       | [class_name,status] =<br>hdfvs('getclass',vdata_id)             | Returns the HDF class of the specified vdata.             |
| 'getfields'      | [field_names,count] =<br>hdfvs('getfields',vdata_i              | Returns all field names within the specified vdata.       |
| 'getinterlace'   | [interlace,status] =<br>hdfvs('getinterlace',vdat               | Retrieves the interlace mode of the specified vdata.      |
| 'getname'        | [vdata_name,status] =<br>hdfvs('getname',vdata_id)              | Retrieves the name of the specified vdata.                |
| 'getversion'     | version =<br>hdfvs('getversion',vdata_                          | Returns the version number of a vdata.                    |

| Value of funcstr | Function Syntax                                     | Description                                                                                   |
|------------------|-----------------------------------------------------|-----------------------------------------------------------------------------------------------|
| 'sizeof'         | nbytes =<br>hdfvs('sizeof',vdata_id,f               | Returns the fields sizes of the specified vdata.                                              |
| 'Queryfields'    | [fields,status] =<br>hdfvs('Queryfields',vdata      | Returns the field names of the specified vdata.                                               |
| 'Queryname'      | [name,status] =<br>hdfvs('Queryname',vdata_i        | Returns the name of the specified vdata.                                                      |
| 'Queryref'       | ref =<br>hdfvs('Queryref',vdata_id                  | Retrieves the reference number of the specified vdata.                                        |
| 'Querytag'       | tag =<br>hdfvs('Querytag',vdata_id                  | Retrieves the tag of the specified vdata.                                                     |
| 'Querycount'     | [count,status] =<br>hdfvs('Querycount',vdata_       | Returns the number of records in the specified vdata.                                         |
| 'Queryinterlace' | [interlace,status] =<br>hdfvs('Queryinterlace',vd   | Returns the interlace mode of the specified vdata.                                            |
| 'Queryvsize'     | vsize =<br>hdfvs('Queryvsize',vdata_                | Retrieves the local size in bytes of the specified vdata record.                              |
| 'findex'         | [field_index,status] =<br>hdfvs('findex',vdata_id,f | Queries the index of a vdata field given the field name.                                      |
| 'nattrs'         | count =<br>hdfvs('nattrs',vdata_id)                 | Returns the number of attributes of the specified vdata and the vdata fields contained in it. |
| 'fnattrs'        | count =<br>hdfvs('fnattrs',vdata_id,                | Queries the total number of vdata attributes.                                                 |
| 'findattr'       | attr_index =<br>hdfvs('findattr',vdata_id           | Retrieves the index of an attribute given the attribute name.                                 |
| 'isattr'         | tf =<br>hdfvs('isattr',vdata_id)                    | Determines if the given vdata is an attribute.                                                |

| Value of funcstr | Function Syntax                                                                  | Description                                                                                                                                  |

# height

Number of table rows

## Syntax

H = height(T)

## Description

H = height(T) returns the number of rows in the table, T.

height(T) is equivalent to size(T,1).

## Examples

### Number of Table Rows

Create a table, T.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
T = table(Age,Height,Weight,BloodPressure, 'RowNames',LastName)
```

T =

|          | Age | Height | Weight | BloodPressure |    |
|----------|-----|--------|--------|---------------|----|
| Smith    | 38  | 71     | 176    | 124           | 93 |
| Johnson  | 43  | 69     | 163    | 109           | 77 |
| Williams | 38  | 64     | 131    | 125           | 83 |
| Jones    | 40  | 67     | 133    | 117           | 75 |
| Brown    | 49  | 64     | 119    | 122           | 80 |

Find the number of rows in table T.

```
H = height(T)
```

```
H =
```

```
5
```

T contains five rows; `height` does not count the variable names.

## Input Arguments

**T** — Input table

table

Input table, specified as a table.

## See Also

`numel` | `size` | `width`

**Introduced in R2013b**

# help

Help for functions in Command Window

## Syntax

```
help
help name
```

## Description

`help` lists all primary help topics in the Command Window. Each main help topic corresponds to a folder name on the MATLAB search path.

`help name` displays the help text for the functionality specified by `name`, such as a function, method, class, toolbox or variable.

## Input Arguments

### `name`

String that specifies an operator symbol (such as `+`) or the name of a function, class, method, package, toolbox folder, variable, or other functionality.

Some classes and other packaged items require that you specify the package name. Events, properties, and some methods require that you specify the class name. Separate the components of the name with periods, such as:

```
help className.name
help packageName.name
help packageName.className.name
```

If `name` is a variable, `help` displays the help text for the class of that variable.

```
help name
```

To get help for the methods of the `name` class, specify

```
help name.methodname
```

If `name` is overloaded, that is, appears in multiple folders on the search path, `help` displays the help text for the first instance of `name` found on the search path, and displays a hyperlinked list of the overloaded functions and their folders.

When `name` specifies the name or partial path of a toolbox folder:

- If the folder contains a nonempty `Contents.m` file, the `help` function displays the file. `Contents.m` contains a list of MATLAB program files in the folder and their descriptions. If `Contents.m` exists, but is empty, MATLAB responds with `No help found for name`.
- If the folder does not contain a `Contents.m` file, the `help` function lists the first line of help text for each program file in the folder.
- If `name` is the name of both a function and a toolbox, `help` displays the associated text for both the toolbox and the function.

## Examples

### Functions and Overloaded Methods

Display help for the MATLAB `close` function.

```
help close
```

Because `close` refers to the name of a function and to the name of several methods, the help text includes hyperlinks to the overloaded methods.

Request help for the Database Toolbox™ `close` method.

```
help database.close
```

### Package, Class, and Method Help

Display help for the `containers` package, `Map` class, and the `isKey` method.

```
help containers
help containers.Map
help containers.Map.isKey
```

Not all packages, classes, and associated methods or events require complete specification. For example, display the help for the `throwAsCaller` method of the `MException` class.

help `throwAsCaller`

## Variable Help

Display help for a variable `t = datetime`.

```
t = datetime
help t
```

Because `t` is of type `datetime`, the `help` function displays help text for the `datetime` class.

Request help for `Day`, a method of the `datetime` class.

```
help t.Day
```

## Functions in Folder

List all of the functions in the folder `matlabroot/toolbox/matlab/general` by specifying a partial path.

```
help general
```

## Alternatives

View more extensive help using the `doc` command or the Function Browser. To open the Function Browser, click its icon, .

## More About

### Tips

- Some help text displays the names of functions in uppercase characters to make them stand out from the rest of the text. When typing these function names, use lowercase. For function names that appear in mixed case (such as `javaObject`), type the names as shown.
- To prevent long descriptions from scrolling off the screen before you have time to read them, enter `more on`, and then enter the `help` statement.
- Some classes require that you specify the package name to display the help text. To identify the package name, create an instance of the class, and then call `class(obj)`.

## helpdlg

Create help dialog box

### Syntax

```
helpdlg
helpdlg('helpstring')
helpdlg('helpstring','dlgname')
h = helpdlg(...)
```

### Description

helpdlg creates a nonmodal help dialog box or brings the named help dialog box to the front.

---

**Note** A nonmodal dialog box enables the user to interact with other windows before responding. For more information, see [WindowStyle](#) in the [MATLAB Figure Properties](#).

---

helpdlg displays a dialog box named 'Help Dialog' containing the string 'This is the default help string.'

helpdlg('helpstring') displays a dialog box named 'Help Dialog' containing the string specified by 'helpstring'.

helpdlg('helpstring','dlgname') displays a dialog box named 'dlgname' containing the string 'helpstring'.

h = helpdlg(...) returns the handle of the dialog box.

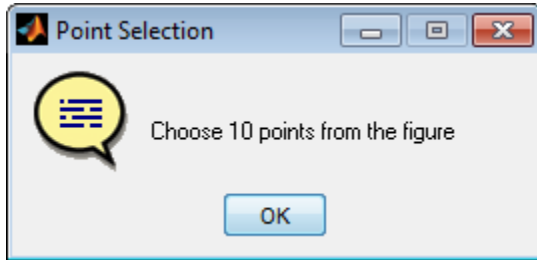

### Examples

The statement

```
helpdlg('Choose 10 points from the figure',...
```

```
'Point Selection');
```

displays this dialog box:

## More About

### Tips

MATLAB wraps the text in `'helpstring'` to fit the width of the dialog box. The dialog box remains on your screen until you press the **OK** button or the **Enter** key. After either of these actions, the help dialog box disappears.

# helpwin

Provide access to help comments for all functions

---

**Note:** helpwin will be removed in a future release. Use doc instead.

---

## Syntax

```
helpwin
helpwin topic
```

## Description

helpwin lists topics for groups of functions in the MATLAB Help browser. It shows brief descriptions of the topics and provides links to display help comments for the functions. You cannot follow links in the helpwin list of functions if the MATLAB software is busy (for example, running a program).

helpwin topic displays help information for the topic. If topic is a folder, it displays all functions in the folder. If topic is a function, helpwin displays help for that function. From the page, you can access a list of folders (**Default Topics** link) as well as the reference page help for the function (**Go to online doc** link). You cannot follow links in the helpwin list of functions if MATLAB is busy (for example, running a program).

## Examples

Typing

```
helpwin datafun
```

displays the functions in the datafun folder and a brief description of each.

Typing

helpwin fft

displays the help for the fft function.

## hess

Hessenberg form of matrix

### Syntax

```
H = hess(A)
[P,H] = hess(A)
[AA,BB,Q,Z] = hess(A,B)
```

### Description

`H = hess(A)` finds `H`, the Hessenberg form of matrix `A`.

`[P,H] = hess(A)` produces a Hessenberg matrix `H` and a unitary matrix `P` so that  $A = P*H*P'$  and  $P'*P = \text{eye}(\text{size}(A))$ .

`[AA,BB,Q,Z] = hess(A,B)` for square matrices `A` and `B`, produces an upper Hessenberg matrix `AA`, an upper triangular matrix `BB`, and unitary matrices `Q` and `Z` such that  $Q*A*Z = AA$  and  $Q*B*Z = BB$ .

### Definitions

A Hessenberg matrix is zero below the first subdiagonal. If the matrix is symmetric or Hermitian, the form is tridiagonal. This matrix has the same eigenvalues as the original, but less computation is needed to reveal them.

### Examples

`H` is a 3-by-3 eigenvalue test matrix:

```
H =
 -149 -50 -154
 537 180 546
 -27 -9 -25
```

Its Hessenberg form introduces a single zero in the (3,1) position:

```
hess(H) =
 -149.0000 42.2037 -156.3165
 -537.6783 152.5511 -554.9272
 0 0.0728 2.4489
```

# matlab.mixin.Heterogeneous class

**Package:** matlab.mixin

Superclass for heterogeneous array formation

## Description

`matlab.mixin.Heterogeneous` is an abstract class that provides support for the formation of heterogeneous arrays. A heterogeneous array is an array of objects that differ in their specific class, but are all derived from or are instances of a root class. The root class derives directly from `matlab.mixin.Heterogeneous`.

## Heterogeneous Hierarchy

Use `matlab.mixin.Heterogeneous` to define hierarchies of classes whose instances you can combine into heterogeneous arrays.

The following class definition enables the formation of heterogeneous arrays that combine instances of any classes derived from `HierarchyRoot`.

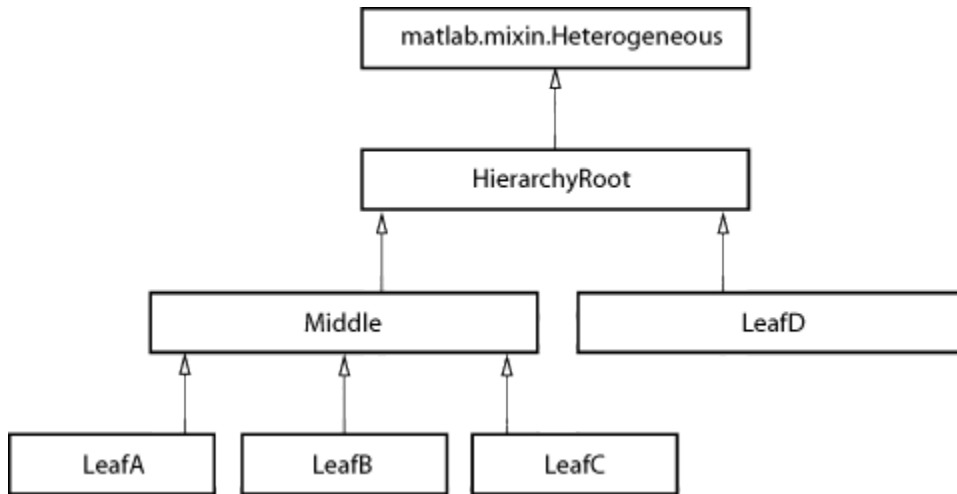

```
classdef HierarchyRoot < matlab.mixin.Heterogeneous
 % HierarchyRoot is a direct subclass of
 % matlab.mixin.Heterogeneous
 % HierarchyRoot is the root of this heterogeneous hierarchy
end
```

Deriving the `HierarchyRoot` class directly from `matlab.mixin.Heterogeneous` enables the `HierarchyRoot` class to become the root of a hierarchy of classes. You can combine instances of the members of this hierarchy into a heterogeneous array. Only instances of classes derived from the same root class can combine to form a valid heterogeneous array.

## Class of a Heterogeneous Array

The class of a heterogeneous array is always the class of the most specific superclass common to all objects in the array. For example, suppose you define the following class hierarchy:

Forming an array (harray) of an instance of LeafA with an instance of LeafB creates an array of class Middle:

```
harray = [LeafA,LeafB];
class(harray)
```

```
ans =
Middle
```

Forming an array (harray) of an instance of LeafC with an instance of LeafD creates an array of class HierarchyRoot:

```
harray = [LeafC,LeafD];
class(harray)
```

```
ans =
HierarchyRoot
```

Forming an array (harray) of an instance of LeafA with an other instance of LeafA creates a homogeneous array of class LeafA:

```
harray = [LeafA,LeafA];
class(harray)
```

```
ans =
LeafA
```

## Restrictions on Heterogeneous Array Formation

You can form heterogeneous arrays only with objects that are derived from the same hierarchy root (that is, the `HierarchyRoot` class in the hierarchy shown previously).

You can form heterogeneous arrays with objects that derive from multiple superclasses, but only one branch in the hierarchy can define a heterogeneous root.

## Forming a Heterogeneous Array

Heterogeneous arrays are the result of operations that produces arrays containing instances of two or more classes from the heterogeneous hierarchy. Usually, concatenation or indexed assignment form these arrays. For example, these statements form `harray` using indexed assignment:

```
harray(1) = LeafA;
harray(2) = LeafC;
class(harray)
```

```
ans =
Middle
```

## Growing the Array Can Change Its Class

Assigning new objects into an array containing objects derived from `matlab.mixin.Heterogeneous` can change the class of the array. For example, given a homogeneous array containing objects only of the `LeafA` class:

```
harray = [LeafA,LeafA,LeafA];
class(harray)
```

```
ans =
LeafA
```

Adding an object of another class derived from the same root to `harray` converts the array's class to the most specific superclass:

```
harray(4) = LeafB;
class(harray)
```

```
ans =
Middle
```

## Method Dispatching

When MATLAB invokes a method for which the dominant argument is a heterogeneous array, the method:

- Must be defined for the class of the heterogeneous array, either directly by the class of the array or inherited from a superclass.
- Must be `Sealed = true` (cannot be overridden by a subclass).

The class of the heterogeneous array determines which class method executes for any given method invocation, as is the case with a homogeneous array. MATLAB does not consider the class of individual elements in the array when dispatching to methods.

### Sealing Inherited Methods

The requirement that methods called on a heterogeneous array be `Sealed = true` ensures correct and predictable behavior with all array elements.

You must override methods that are inherited from outside the heterogeneous hierarchy if these methods are not `Sealed = true` and you want to call these methods on heterogeneous arrays.

For example, suppose you define a heterogeneous array by subclassing `matlab.mixin.SetGet`, in addition to `matlab.mixin.Heterogeneous`. Override the `set` method to call the `matlab.mixin.SetGet` superclass method as required by your class design:

```
methods(Sealed)
 function varargout = set(obj,varargin)
 if nargin == 0
 set@matlab.mixin.SetGet(obj, varargin{:});
 else
 varargout{:} = set@matlab.mixin.SetGet(obj,varargin{:});
 end
 end
end
```

Method implementations can take advantage of the fact that, given a heterogeneous array `harray`, and a scalar index `n`, the expression

```
harray(n)
```

is not a heterogeneous array. Therefore, when invoking a method on a single element of a heterogeneous array, special requirements for heterogeneous arrays do not apply.

## Defining the Default Object

When working with object arrays (both heterogeneous and homogeneous), MATLAB creates default objects to fill in missing array elements by calling the class constructor with no arguments. Filling in missing array elements becomes necessary in cases such as:

- Indexed assignment creates an array with gaps. For example, if `harray` is not previously defined:  

```
harray(5) = LeafA;
```
- Loading a heterogeneous array from a MAT-file when MATLAB cannot find the class definition of a specific object.

The `matlab.mixin.Heterogeneous` class provides a default implementation of a method called `getDefaultScalarElement`. This method returns an instance of the root class of the heterogeneous hierarchy, unless the root class is abstract.

If the root class is abstract or is not an appropriate default object for the classes in the heterogeneous hierarchy, you can override the `getDefaultScalarElement` method to return an instance of a class derived from the root class.

### Defining the `getDefaultScalarElement` Method

Specify the class of the default object by overriding the `matlab.mixin.Heterogeneous` method called `getDefaultScalarElement` in the root class of the heterogeneous hierarchy. You can override `getDefaultScalarElement` only in the root class (direct subclasses of `matlab.mixin.Heterogeneous`).

`getDefaultScalarElement` has the following signature:

```
methods (Static, Sealed, Access = protected)
 function default_object = getDefaultScalarElement
 ...
 end
end
```

The `getDefaultScalarElement` method must satisfy these criteria:

- Static — MATLAB calls this method without an object.
- Protected — MATLAB calls this method, object users do not.
- Sealed (not required) — Seal this method to ensure users of the heterogeneous hierarchy do not change the intended behavior of the class.
- It must return a scalar object
- It must pass the `isa` test for the root class, that is:

```
(isa(getDefaultScalarElement, 'HierarchyRoot'))
```

where *HierarchyRoot* is the name of the heterogeneous hierarchy root class. This means the default object can be an instance of any class derived from the root class.

## Cannot Redefine Indexing or Concatenation

The use of heterogeneous arrays requires consistent indexing and concatenation behaviors. Therefore, subclasses of `matlab.mixin.Heterogeneous` cannot change their default indexed reference, indexed assignment, or concatenation behavior.

You cannot override the following methods in your subclasses:

- `cat`
- `horzcat`
- `vertcat`
- `subref`
- `subsasign`

In cases involving multiple inheritance in which your subclass inherits from superclasses in addition to `matlab.mixin.Heterogeneous`, the superclasses cannot define any of these methods.

### Default Concatenation Behavior

Statements of the form:

```
a = [obj1,obj2,...];
```

create an array, `a`, containing the objects listed in brackets.

Concatenating `Heterogeneous` objects of the same specific class retains the class of the objects and does not form a heterogeneous array.

Concatenating **Heterogeneous** objects derived from the same root superclass, but that are of different specific classes, yields a heterogeneous array. MATLAB does not attempt to convert the class of any array members if all are part of the same root hierarchy.

## **Indexed Assignment Behavior**

Statements of the form:

```
a(m:n) = [objm, ... objn];
```

assign the right-hand side objects to the array elements (**m:n**), specified on the left side of the assignment.

Indexed assignment to a heterogeneous array can:

- Increase or decrease the size of the array
- Overwrite existing array elements
- Change property values of objects within the array
- Change the class of the array
- Change whether the array is heterogeneous

## **Indexed Reference Behavior**

Statements of the form:

```
a = harray(m:n);
```

assign the elements of `harray` referenced by indices **m:n**, to array **a**.

Indexed reference on a heterogeneous array returns a sub-range of the original array. Depending on the specific elements within that sub-range (**m:n**), the result might have a different class than the original array, and might not be heterogeneous.

## **Converting Nonmember Objects**

If you attempt to form a heterogeneous array with objects that are not derived from the same root class, MATLAB calls the `convertObject` method, if it exists, to convert objects to the dominant class. Implementing a `convertObject` method enables the formation of heterogeneous arrays containing objects that are not part of the heterogeneous hierarchy.

## When Is Conversion Necessary

Suppose there are two classes A and B, where B is not derived from `matlab.mixin.Heterogeneous`, or where A and B are derived from different root classes that are derived from `matlab.mixin.Heterogeneous`.

MATLAB attempts to call the `convertObject` method implemented by the root class of A in the following cases:

- The indexed assignment:

`A(k) = B`

- Horizontal and vertical concatenations:

`[A,B]` and `[A;B]`

Implement a `convertObject` method if you want to support conversion of objects whose class is not defined in your heterogeneous hierarchy. You do not need to implement this method if your class design does not require this conversion.

## Implementing `convertObject`

Only the root class of the heterogeneous hierarchy can implement a `convertObject` method.

The `convertObject` method must have the following signature:

```
Method (Static, Sealed, Access = protected)
 function cobj = convertObject('DomClass',objToConvert)
 ...
 end
end
```

For indexed assignment `A(k) = B` and concatenation `[A,B]`:

- *DomClass* — Name of the class of the array A
- `objToConvert` — Object to be converted, B in this case
- `cobj` — Legal member of the heterogeneous hierarchy to which A belongs

You must implement `convertObject` to return a valid object of class A or MATLAB issues an error.

## Handle Compatibility

The `matlab.mixin.Heterogeneous` class is handle compatible. It can be combined with either handle or value classes when defining a subclass using multiple superclasses. See “Support Both Handle and Value Subclasses” for information on handle compatibility.

The `matlab.mixin.Heterogeneous` class is a value class. To learn how value classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation.

## How To

- Class Attributes
- “Heterogeneous Arrays”
- “Create Subclasses — Syntax and Techniques”

## cat

**Class:** matlab.mixin.Heterogeneous

**Package:** matlab.mixin

Concatenation for heterogeneous arrays

## Syntax

```
C = cat(dim,A,B)
```

## Description

`C = cat(dim,A,B)` concatenates objects `A` and `B` along the dimension `dim`. The class of object arrays `A` and `B` must be derived from the same root class of a `matlab.mixin.Heterogeneous` hierarchy.

- If `A` and `B` are of the same class, the class of the resulting array is unchanged.
- If `A` and `B` are of different subclasses of a common superclass that is derived from `matlab.mixin.Heterogeneous`, then the result is a heterogeneous array and the array's class is that of the most specific superclass shared by `A` and `B`.

The `cat` method is sealed in the class `matlab.mixin.Heterogeneous` and, therefore, you cannot override it in subclasses.

## Input Arguments

**dim**

Scalar dimension along which to concatenate arrays

**Default:**

**A**

Object array derived from the same root subclass of `matlab.mixin.Heterogeneous` as `B`

## **B**

Object array derived from the same root subclass of `matlab.mixin.Heterogeneous` as `A`

## **Output Arguments**

### **c**

Array resulting from the specified concatenation. The class of this array is that of the most specific superclass shared by `A` and `B`.

## **Attributes**

`Sealed` `true`

# matlab.mixin.Heterogeneous.getDefaultScalarElement

**Class:** matlab.mixin.Heterogeneous

**Package:** matlab.mixin

Return default object for heterogeneous array operations

## Syntax

```
defaultObject = getDefaultScalarElement
```

## Description

`defaultObject = getDefaultScalarElement` returns the default object for a heterogeneous hierarchy. Override this method if the “Root Class” on page 1-3990 is abstract or is not an appropriate default object for the classes in the heterogeneous hierarchy. `getDefaultScalarElement` must return an instance of another member of the heterogeneous hierarchy.

The `matlab.mixin.Heterogeneous` class provided a default implementation of this method that returns an instance of the “Root Class” on page 1-3990.

MATLAB calls the `getDefaultScalarElement` method when requiring a default object. See `matlab.mixin.Heterogeneous` for more information on heterogeneous arrays and default objects.

## Tips

- Override `getDefaultScalarElement` only if the “Root Class” on page 1-3990 is not suitable as a default object.
- Override `getDefaultScalarElement` only in the “Root Class” on page 1-3990 of the heterogeneous hierarchy.
- `getDefaultScalarElement` must return a scalar object.
- `getDefaultScalarElement` must be a static method with protected access. While not required by MATLAB, you can seal this method to prevent overriding by other classes.

- MATLAB returns an error if the value returned by `getDefaultScalarElement` is not scalar or is not an instance of a class that is a valid member of the hierarchy.

## Output Arguments

### `defaultObject`

The default object for heterogeneous array operations.

## Definitions

### Root Class

Root class – The direct subclass of `matlab.mixin.Heterogeneous` that forms the root of a heterogeneous hierarchy. Classes of objects that you can combine into heterogeneous arrays must derive from this root class.

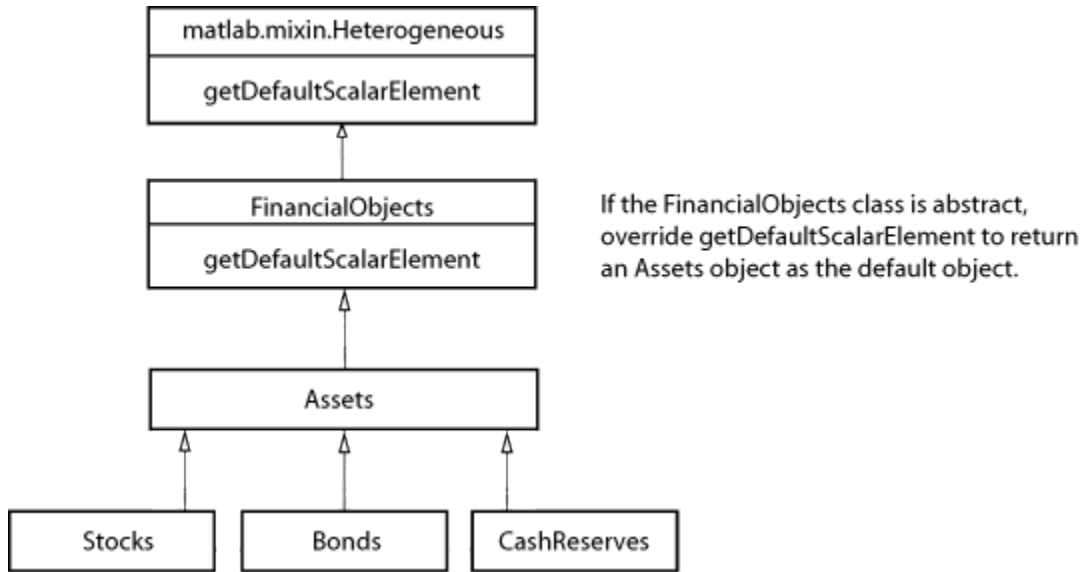

## Attributes

|        |                   |
|--------|-------------------|
| Static | true              |
| Access | Protected         |
| Sealed | true not required |

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

## Examples

This example describes a heterogeneous hierarchy with a root class (`FinancialObjects`) that is an abstract class and cannot, therefore, be used for the default object. The `FinancialObjects` class definition includes an override of the `getDefaultScalarElement` method which returns an instance of the `Assets` class as the default object.

The root class can override the `getDefaultScalarElement` method that is defined in `matlab.mixin.Heterogeneous` class and return an `Assets` object as the default object.

```

classdef FinancialObjects < matlab.mixin.Heterogeneous
 methods (Abstract)
 val = determineCurrentValue(obj)
 end
 methods (Static, Sealed, Access = protected)
 function default_object = getDefaultScalarElement
 default_object = Assets;
 end
 end
end
end
end

```
