# Simulink Design Optimization Product Description

#### Estimate and optimize Simulink model parameters

Simulink Design Optimization provides interactive tools, functions, and Simulink blocks for estimating and tuning Simulink model parameters using numerical optimization. An interactive tool lets you automatically estimate model parameters such as friction and aerodynamic coefficients from test data to increase model accuracy. You can preprocess test data, select model parameters to estimate, start an optimization, and validate estimation results.

You can also automatically tune design parameters in a Simulink model to meet objectives such as improved system performance and minimized energy consumption. Using design optimization techniques, you can meet both time- and frequency-domain constraints such as overshoot and phase margin. You can also jointly optimize physical plant parameters and algorithmic or controller gains to maximize overall system performance.

## **Key Features**

- · Model parameter estimation from test data
- Simultaneous optimization of time- and frequency-domain responses of Simulink models (with Simulink Control Design<sup>TM</sup>)
- Graphical specification of response requirements and visual monitoring of the optimization progress
- Optimization of parameters to meet requirements specified by Model Verification blocks
- · Custom constraints and cost functions for response optimization
- Scripting interface for programmatic specification of design optimization problems
- Robust design optimization, accounting for parameter variation or uncertainty

# Optimization Support for Simulink Models Using Third-Party Applications

You can use Simulink Design Optimization software to optimize Simulink models that invoke third-party simulation tools or contain legacy simulation code. To do so, use the S-function block in Simulink. When using the command-line functions, use MATLAB® MEX functions.

#### More About

"Introducing MEX Files"

# Ways to Speed Up Design Optimization Tasks

You can use the following ways to speed up parameter estimation, response optimization, and sensitivity analysis tasks:

#### In this section...

"Speed Up Using Parallel Computing" on page 1-4

"Speed Up Using Fast Restart Mode" on page 1-5

"Speed Up Using Accelerator Mode" on page 1-5

You can use a combination of these, but depending on the limitations associated with each, you may or may not see an increase in speed. For example, you can use parallel computing and fast restart together to speed up optimization. However, you do not see an increase in speed compared to using only parallel computing if the compilation phase of your model is short.

## **Speed Up Using Parallel Computing**

You can use Parallel Computing Toolbox<sup>™</sup> software to speed up parameter estimation, response optimization, and sensitivity analysis. When you use parallel computing, the software distributes the independent simulations on multiple MATLAB sessions. Thus, the simulations run in parallel, which reduces the optimization time.

Using parallel computing may reduce the optimization time in the following cases:

- The model contains many parameters to optimize, and you use the Gradient descent or Nonlinear least squares method.
- · The Pattern search method is selected as the optimization method.
- The model contains many uncertain parameters and uncertain parameter values.
- The model is complex and takes a long time to simulate.

You can use parallel computing in the Parameter Estimation and Response optimization tools or at the command line. For more information, see "How to Use Parallel Computing for Parameter Estimation", "How to Use Parallel Computing for Response Optimization", and "How to Use Parallel Computing for Sensitivity Analysis".

# **Speed Up Using Fast Restart Mode**

You can use the fast restart feature of Simulink to speed up design optimization of tunable parameters of a model.

Fast restart enables you to perform iterative simulations without compiling a model or terminating the simulation each time. Using fast restart, you compile a model only once. You can then tune parameters and simulate the model again without spending time on compiling. Fast restart associates multiple simulation phases with a single compile phase to make iterative simulations more efficient. You see a speedup of design optimization tasks using fast restart in models that have a long compilation phase. See "How Fast Restart Improves Iterative Simulations" in the Simulink documentation.

When you enable fast restart, you can only change tunable properties of the model during simulation. For more information about the limitations, see "Factors Affecting Fast Restart".

You can configure fast restart in the tool or at the command line. For more information see, "Use Fast Restart Mode During Parameter Estimation", "Use Fast Restart Mode During Response Optimization", or "Use Fast Restart Mode During Sensitivity Analysis".

# **Speed Up Using Accelerator Mode**

Simulink Design Optimization software supports Normal and Accelerator simulation modes. You can accelerate the design optimization computations by changing the simulation mode of your Simulink model to Accelerator. For information about these modes, see "How Acceleration Modes Work" in the Simulink documentation.

The default simulation mode is Normal. In this mode, Simulink uses interpreted code, rather than compiled C code during simulations.

In the Accelerator mode, Simulink Design Optimization software runs simulations during optimization with compiled C code. Using compiled C code speeds up the simulations and reduces the time to optimize the model response signals.

For information about the limitations, and how to use the Accelerator mode, see "How to Use Accelerator Mode During Simulations".

# **Required and Related Products**

Simulink Design Optimization software requires MATLAB, Simulink, and Optimization Toolbox  $^{\text{TM}}$  software.

The following table summarizes MathWorks® products that extend and complement the Simulink Design Optimization software. For current information about these and other MathWorks products, visit http://www.mathworks.com/products/.

Product	Description
Control System Toolbox	Enables you to design controllers for linear time-invariant (LTI) models using optimization methods.
Global Optimization Toolbox	Provides genetic algorithms, and direct search methods to estimate and optimize model parameters.
Neural Network Toolbox	Provides Simulink models of neural networks for optimization-based control design.
Parallel Computing Toolbox	Enables parallel computing on multicore processors and multiprocessor networks to speed up estimation and optimization.
Simulink Control Design	Lets you linearize Simulink models. Use Simulink Design Optimization software to design controllers for linearized models using optimization methods.
System Identification Toolbox	Lets you estimate linear and nonlinear models from measured data. Import the estimated model into Simulink software, and use Simulink Design Optimization software for optimization-based control design.

# **Parameter Estimation**

- "Supported Data" on page 2-2
- "Prepare Data for Parameter Estimation" on page 2-3
- "Estimate Parameters from Measured Data" on page 2-16

# Supported Data

From signal data, you can estimate model parameters and initial conditions of single or multiple input and output Simulink models.

Simulink Design Optimization software lets you estimate model parameters from the following types of data:

- *Time-domain* data Data with one or more input variables u(t) and one or more output variables y(t), sampled as a function of time. See "Import Data".
- Time-series data Data stored in time-series objects. See "Time-Series Data".

Simulink Design Optimization software estimates model parameters by comparing the measured signal data with simulation data generated from the Simulink model. Using optimization techniques, the software estimates the parameters and initial conditions of states to minimize a user-selected cost function. The cost function typically calculates a least-square error between the measured and simulated data. To learn more, see "Estimate Parameters from Measured Data" on page 2-16.

"Saving the Session" on page 2-14

#### **About This Tutorial**

- "Objectives" on page 2-3
- "About the Sample Data" on page 2-4  $\,$

#### **Objectives**

This tutorial explains how to import, analyze, and prepare measured input and output (I/O) data for estimating parameters of a Simulink model.

**Note:** Simulink Design Optimization software estimates parameters from real, timedomain data only.

Perform the following tasks using the Parameter Estimation tool:

- Import data from the MATLAB workspace.
- Analyze data quality using a time plot.
- · Select a subset of data for estimation.
- · Replace outliers.
- Filter high-frequency noise.

#### About the Sample Data

Load spe\_engine\_throttle1.mat, which contains I/O data measured from an engine throttle system. The MAT-file includes the following variables:

- input1 Input data samples
- position1 Output data samples
- time1 Time vector

**Note:** The number of input and output data samples must be equal to the length of the corresponding time vector.

The engine throttle system controls the flow of air and fuel mixture to the engine cylinders. The throttle body contains a butterfly valve which opens when a driver presses the accelerator pedal. Opening this valve increases the amount of fuel mixture entering the cylinders, which increases the engine speed. A DC motor controls the opening angle of the butterfly valve in the throttle system. The input to the throttle system is the motor current (in amperes), and the output is the angular position of the butterfly valve (in degrees).

spe\_engine\_throttle1 contains the Simulink model of the engine throttle system.

## **Start a Parameter Estimation Tool Session**

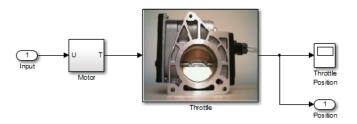

To perform parameter estimation, you must first start a Parameter Estimation tool session.

1 Open the engine throttle system model by typing the following at the MATLAB prompt:

```
spe_engine_throttle1
```

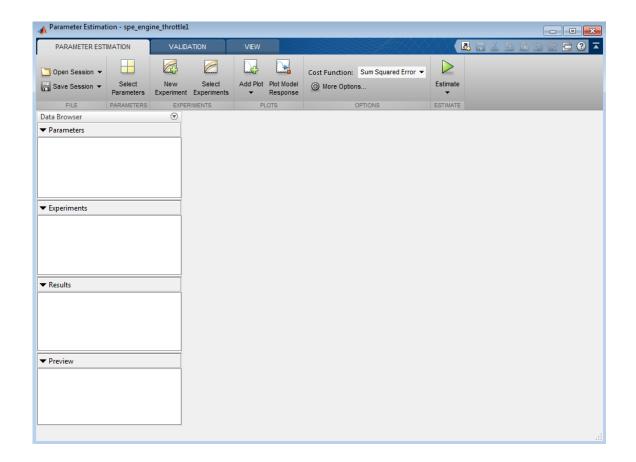

This command opens the Simulink model, and loads the data into the MATLAB workspace.

#### **Engine Throttle Model**

2 In the Simulink model window, select Analysis > Parameter Estimation.

This action opens a new session, **Parameter Estimation - spe\_engine\_throttle1**, in the Parameter Estimation tool.

**Note:** The Simulink model must remain open to perform parameter estimation tasks.

# **Create an Experiment for Parameter Estimation**

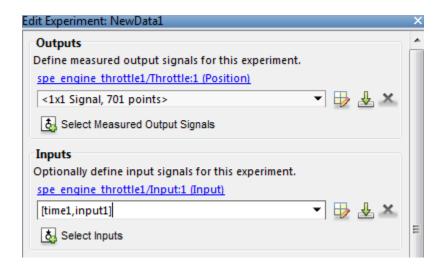

In the Parameter Estimation tool on the **Parameter Estimation** tab, click the **New Experiment** button. This will create an experiment with the name Exp in the **Experiments** list on the left pane. You can rename it by right-clicking and selecting **Rename** from the list. For example, call it NewData1.

### **Import Data**

This portion of the tutorial explains how to import measured I/O data into the experiment in the Parameter Estimation tool. Importing data assigns the data to the corresponding model input and output signals.

The model input and output signals are designated with the Inport Input and Outport Position blocks, respectively. To learn more about the blocks, see the Inport and Outport block reference pages in the Simulink documentation.

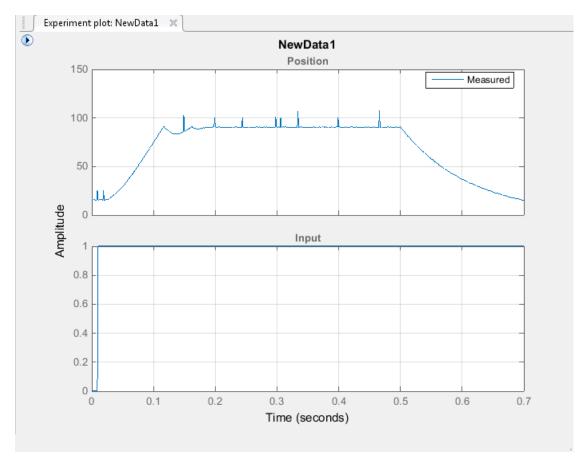

To import data into the experiment, right-click and select **Edit...** to launch the experiment editor. Import the output data by typing [time1,position1] in the dialog box in the **Outputs** panel. Import the input data by typing [time1,input1] in the dialog box in the **Inputs** panel.

## **Analyze Data**

This portion of the tutorial explains how to analyze the output data quality by viewing the data characteristics on a time plot. Based on the analysis, you can decide whether to preprocess the data before estimating parameters. For example, if the data contains noise, you might want to filter the noise from the system dynamics before estimating parameters.

The time plot shows the output data in response to a step input, as described in "About the Sample Data" on page 2-4. The plot shows a rapid decrease in the response after t=0.5 s because the system is shut down. To focus parameter estimation on the time period when the system is active, select the data samples between t=0 s and t=0.5 s, as in "Extract Data for Estimation" on page 2-9 .

The spikes in the data indicate *outliers*, defined as data values that deviate from the mean by more than three standard deviations. They might be caused by measurement errors or sensor problems. The response also contains noise. Before estimating model

parameters from this data, remove the outliers and filter the noise, as described in "Replacing Outliers" on page 2-10and "Filtering Data" on page 2-12.

You can also plot the experiment data by right-clicking the experiment, for example NewData1, and selecting **Plot measured experiment data** from the list.

#### **Extract Data for Estimation**

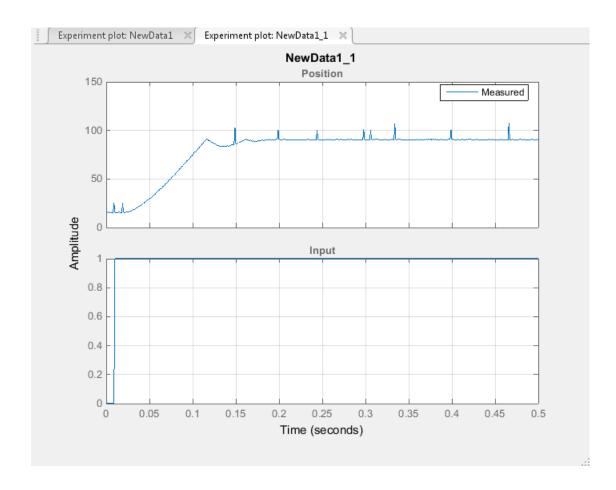

This portion of the tutorial explains how to select a subset of I/O data for estimation. As described in "Analyze Data" on page 2-7, the system is shut down at t = 0.5 s. To focus the estimation on the time period before t = 0.5 s, exclude the data samples beyond t = 0.5 s. This operation selects the data between t = 0 s and t = 0.5 s for estimation.

First, import the data into the experiment, as described in "Import Data" on page 2-7.

To select the portion of data between t = 0 s and t = 0.5 s:

- 1 Plot the measured data as described in "Analyze Data" on page 2-7, to have access to the **Experiment Plot** tab.
- 2 On the Experiment Plot tab, click Extract Data to launch the Extract Data tab.
- **3** Enter 0 in the **Start Time:** field and 0.5 in the **End Time:** field.
- 4 Click **Save As** to save data in a new experiment, for example, NewData1\_1.

The Parameter Estimation tool extracts the corresponding input data. To plot the new data, click on **Add Plot** on the **Parameter Estimation** tab. Select the experiment name, for example, NewData1\_1 in the **Experiment Plots** list to display the experiment plot of the data from t=0 s to t=0.5 s.

# **Replacing Outliers**

- "Why Replace Outliers" on page 2-10
- "How to Replace Outliers" on page 2-11

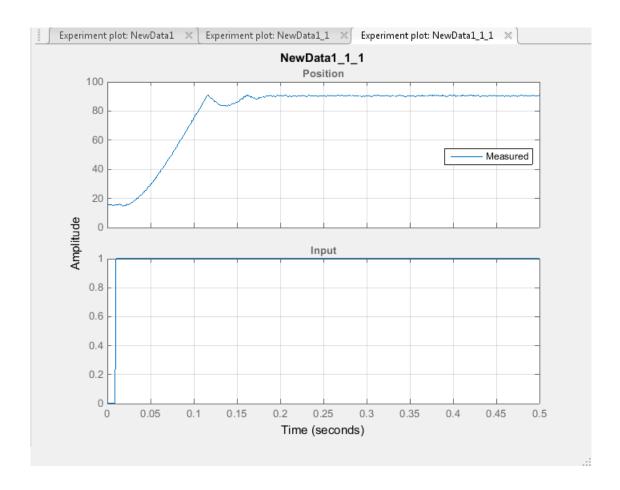

#### **Why Replace Outliers**

Outliers are data values that deviate from the mean by more than three standard deviations. When estimating parameters from data containing outliers, the results might not be accurate. Hence, you might choose to replace the outliers in the data before you estimate the parameters.

#### **How to Replace Outliers**

In the experiment plot of the data extracted as in "Extract Data for Estimation" on page 2-9, you can visually detect the data points that seem to be outliers. To replace these points:

- In the **Experiment Plot** tab, click **Replace data** to launch the **Replace data** tab. The experiment plot shows the preview data, which is in light brown. On the preview, select the data point that you want to replace.
- 2 On the **Replace Data** tab, click **Replace data** and select the constant value. For example, replace the output signal data that correspond to time points 0.00899 and 0.0189 with 15, that corresponds to the time point 0.149 with 86, and the rest of the outlier data points with 90.
- 3 Click the arrow in the **Apply** section and select **Save As: Create a new experiment from the modified data**. Parameter Estimation tool saves the modified data in the new experiment, for example, NewData1 1 1.
- 4 Click Add Plot on the Parameter Estimation tab and select the new experiment, for example, NewData1\_1\_1. This creates an experiment plot of the modified data. The spikes, that indicated outliers, no longer appear on the time plot.

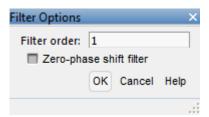

# **Filtering Data**

This portion of the tutorial explains how to filter the noise and remove any periodic trends from the output data. First remove the outliers from the output data, as described in "Replacing Outliers" on page 2-10.

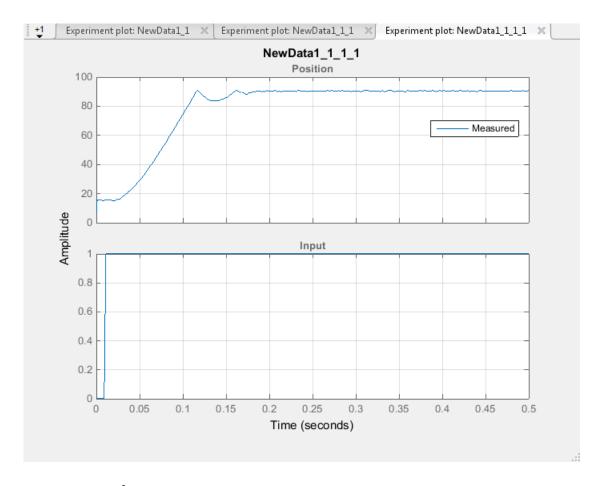

Click the experiment plot for the new experiment, for example, NewData1\_1\_1. On the Experiment Plot tab, click Low-Pass Filter.

1 On the Low-Pass Filter tab select Filter all signals.

- 2 Enter 0.4 in the Normalized cutoff frequency field.
- 3 Click Options. Enter 1 in the Filter order field and click OK.

- 4 Click the arrow in the **Apply** section and select **Save As: Create a new experiment from the modified data**. Parameter Estimation tool saves the modified data in the new experiment, for example, NewData1 1 1 1.
- 5 Click Add Plot on the Parameter Estimation tab and select the new experiment, NewData1\_1\_1\_1. This creates an experiment plot of the modified data. The noise is filtered and the output data appears smooth.

# Saving the Session

After you prepare the data, delete the data in the older experiments, for example, New Data1, New Data1\_1, New Data1\_1\_1. You can rename the last experiment, for example, NewData1\_1\_1\_1 as NewData1, and save the session.

To delete the experiments, right-click the experiment name in the **Experiments** pane, and select **Delete** from the list.

To save the session, click **Save Session** on the **Parameter Estimation** tab to select where to save the session. Specify a name for the session, for example,

spe\_engine\_throttle1\_sdosession.mat in the File name or Session field, and then click Save or OK. This saves your parameter estimation session as a MAT-file.

To learn how to estimate parameters from this data, see "Estimate Parameters from Measured Data" on page 2-16.

# **Estimate Parameters from Measured Data**

#### In this section...

"About This Tutorial" on page 2-16

"Estimate Model Parameters Using Default Estimation Settings" on page 2-19

"Improve Estimation Results Using Parameter Bounds" on page 2-29

"Validate Estimated Model Parameters" on page 2-32

#### **About This Tutorial**

- · "Objectives" on page 2-16
- "About the Model" on page 2-16

#### **Objectives**

This tutorial shows how to estimate parameters of a single-input single-output (SISO) Simulink model from measured input and output (I/O) data.

**Note:** Simulink Design Optimization software estimates parameters from real, timedomain data only.

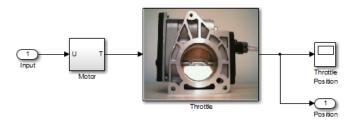

You can perform the following tasks using the Parameter Estimation tool:

- Load a saved session containing data
- Estimate model parameters using default settings
- · Validate the model, and refine the estimation results

#### About the Model

This tutorial uses the spe\_engine\_throttle1 Simulink model, which represents an engine throttle system.

#### **Engine Throttle Model**

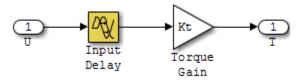

The throttle system controls the flow of air and fuel mixture to the engine cylinders. The throttle body contains a butterfly valve that opens when a driver presses the accelerator pedal. Opening this valve increases the amount of fuel mixture entering the cylinders, which increases the engine speed. A DC motor controls the opening angle of the butterfly valve in the throttle system. The models for these components are described in "Motor Subsystem" on page 2-17 and "Throttle Subsystem" on page 2-18.

The input to the throttle system is the motor current (in amperes), and the output is the angular position of the butterfly valve (in degrees).

#### **Motor Subsystem**

The Motor subsystem contains the DC motor model. To open the model, double-click the corresponding block.

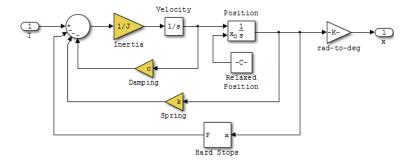

Components of the Motor subsystem	Description
Variables	U is the input current to the motor.
	T is the torque applied by the motor.
Parameters	K <sub>t</sub> is the torque gain of the motor, represented by
	Kt in the model.

Components of the Motor subsystem	Description
	$t_d$ is the input time delay of the motor, represented by input_delay in the model.
Equation	The torque applied by the motor is described in the following equation: $T(t)=K_tU(t-t_d)$ where $t$ is time.
Input	U
Output	T

#### **Throttle Subsystem**

The Throttle subsystem contains the butterfly valve model. To open the model, right-click the corresponding block, and select Mask > Look Under Mask.

The Hard Stops block models the valve angular position limit of 15° to 90°.

The following table describes the variables, parameters, states, differential equations, inputs, and outputs of the  $\cdot$ 

Components of the Throttle subsystem	Description
Variables	T is the torque applied by the DC motor.
	$\theta$ is the angular position of the valve, represented by <b>X</b> in the model.

Components of the Throttle subsystem	Description
	$T_{hardstop}$ is the torque applied by the hard stop.
Parameters	J is the valve inertia.
	c is the valve viscous friction.
	k is the valve spring constant.
States	$\theta$ is the angular position.
	$\dot{\theta}$ is the angular velocity.
Equations	The mathematical system for the butterfly valve is described in the following equation:
	$J\ddot{\theta} + c\dot{\theta} + k\theta = T + T_{hardstop}$
	where $15^{\circ} \le \theta \le 90^{\circ}$ , with initial conditions
	$\theta_0 = 15^{\circ}$ , and $\dot{\theta}_0 = 0$ .
	The torque applied by the Hard Stops block is described in the following equation:
	$T_{hardstop} = egin{cases} 0, & 15^{\circ} \leq \theta \leq 90^{\circ} \ K(90^{\circ} - \theta), \theta > 90^{\circ} \ K(15^{\circ} - \theta), \theta < 15^{\circ} \end{cases}$
	$\left[K(15^{\circ}- heta),  heta < 15^{\circ} ight]$
	where K is the gain of the Hard Stops block.
Input	T
Output	$\theta$

# **Estimate Model Parameters Using Default Estimation Settings**

- "Overview of the Estimation Process" on page 2-20
- "Specify Estimation Data and Parameters" on page 2-21

#### **Overview of the Estimation Process**

Simulink Design Optimization software uses optimization techniques to estimate model parameters. In each optimization iteration, it simulates the model with the current parameter values. It computes and minimizes the error between the simulated and measured output. The estimation is complete when the optimization method finds a local minimum.

To start the estimation process, first open the engine throttle system Simulink model by typing the following at the MATLAB prompt:

spe engine throttle1

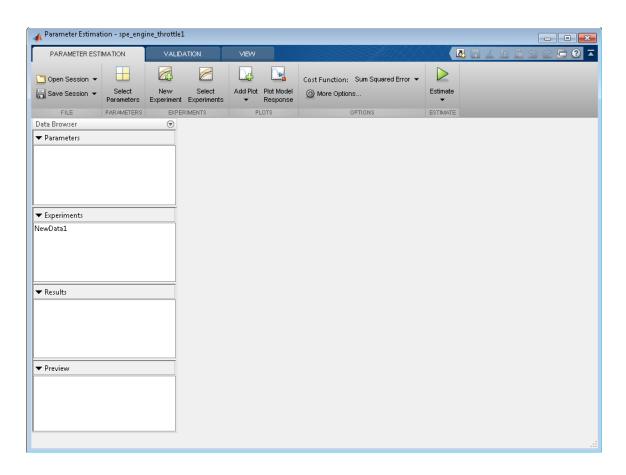

In the Simulink Editor, select Analysis > Parameter Estimation.

This action opens a new session with the name **Parameter Estimation** - **spe\_engine\_throttle1** in the Parameter Estimation tool.

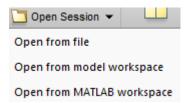

**Note:** The Simulink model must remain open to perform parameter estimation tasks.

### **Specify Estimation Data and Parameters**

1 Load or import the estimation data.

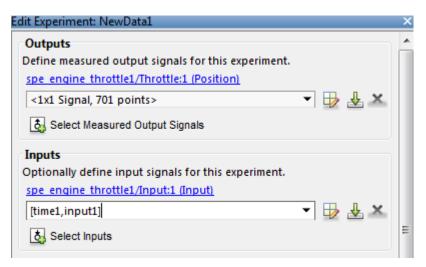

**a** If you prepared data and saved your session as described in "Prepare Data for Parameter Estimation" on page 2-3, load the preconfigured session. On the **Parameter Estimation** tab, click the **Open Session** drop down list.

Select the correct option to browse to the location of your saved session, for example, Open from file. Then select the MAT-file.

b If you do not have a previously saved session, create a new experiment. on the **Parameter Estimation** tab, click **New Experiment**. In the **Experiments** list on the left pane. You can rename it by right-clicking and selecting **Rename** from the list. For example, call it NewData1.

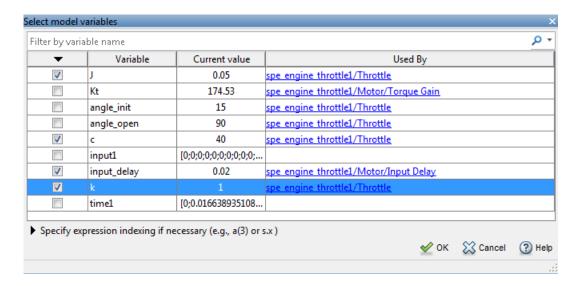

To import data into the experiment, right-click and select **Edit...** to launch the experiment editor. Import the output data by typing in the dialog box in the **Outputs** panel, for example [time1,position1]. Import the input data by typing in the dialog box in the **Inputs** panel, for example [time1,input1].

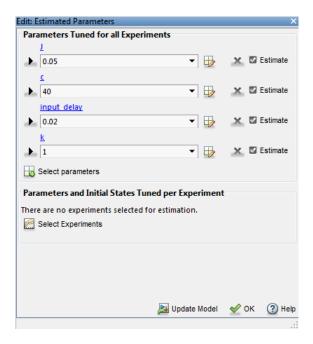

2 Specify parameters for estimation. On the Parameter Estimation tab, click the Select Parameters button to open the Edit: Estimated Parameters dialog box. In the Parameters Tuned for all Experiments panel, click the Select parameters button to launch the Select Model Variables dialog box.

Select the parameters J, c, input\_delay, and k, and click OK.

**Note:** In your application, if the model parameters you want to estimate are not listed in the Select Model Variables dialog box, first specify these parameters as variables. See, "Add Model Parameters as Variables for Estimation".

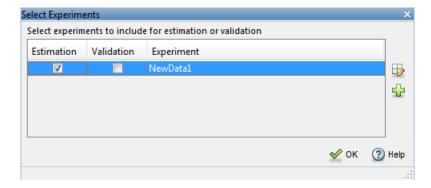

The Edit:Estimated Parameters window now looks as follows.

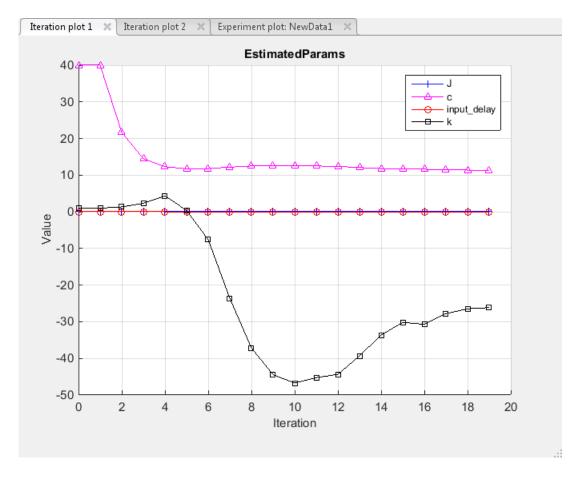

The tool selects the parameters you add for estimation by default. When estimating a large number of parameters, you can first select a subset of parameters to estimate.

3 Specify an experiment for estimation. On the **Parameter Estimation** tab, click **Select Experiments**, and select the box under the **Estimation** column. Click **OK**.

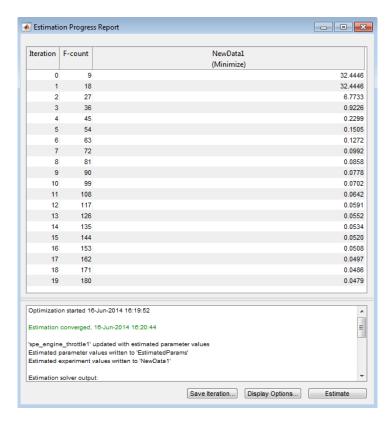

- 4 To add progress plots, click **Add Plot** on the **Parameter Estimation** tab. Here you can choose the **Parameter Trajectory** and **Estimation Cost** iteration plots. You can also choose an experiment plot of measured and simulated data for NewData1.
- 5 Estimate the parameters using the default settings. On the **Parameter Estimation** tab, click **Estimate** to open the **Parameter Trajectory** plot and **Estimation Progress Report** window and estimate the parameters. The **Parameter Trajectory** plot shows the change in the parameter values at each iteration.

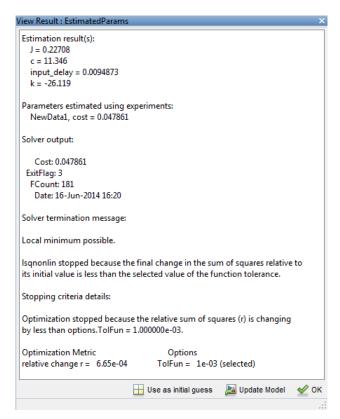

The **Estimation Progress Report** shows the iteration number, number of times the objective function is evaluated, and the value of the cost function at the end of

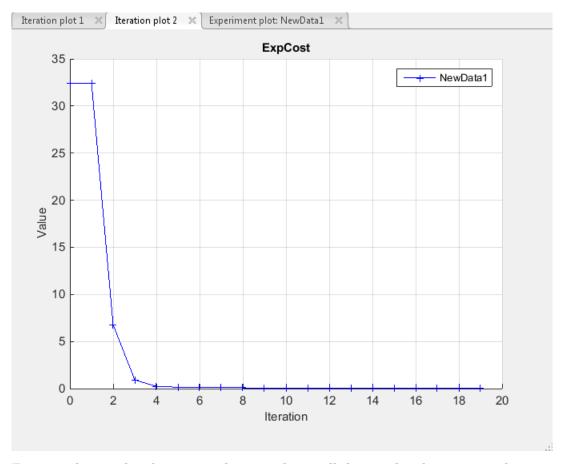

each iteration. After the estimation converges, the **Estimation Progress Report** looks like this figure.

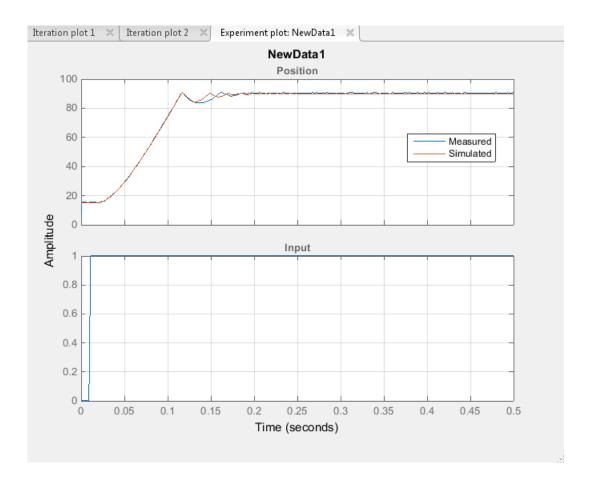

The estimated parameters are saved in the Parameter Estimation tool, in the **Results** section of the **Data Browser** pane, as **EstimatedParams**. Right-click **EstimatedParams**, and select **Open...** to view the results.

Examine the estimated cost function graph. Cost function is the error between the simulated and measured output. During estimation, the default optimization method Nonlinear least squares, lsqnonlin, minimizes the cost function by changing the parameter values. The following figure displays the change in the expected cost during iterations.

7 Examine the simulated response plot to see how well the simulated output matches the measured output. The experiment plot shows that the output simulated using the estimated parameters is close to the measured outputs.

## Improve Estimation Results Using Parameter Bounds

You can improve the accuracy of estimation by specifying bounds on parameter values. This technique restricts the region in which the optimization method searches for a local minima.

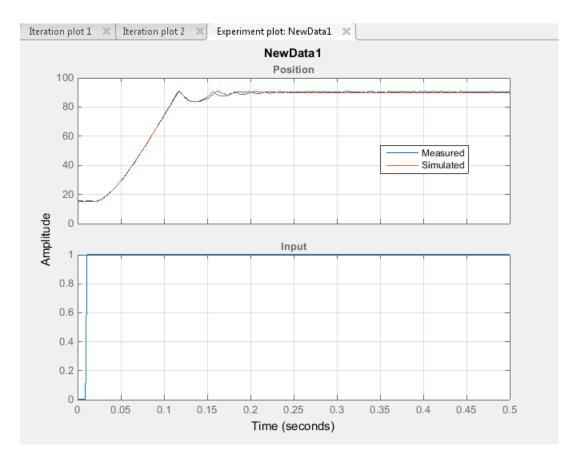

The engine throttle system has these characteristics:

- · All parameter values are positive.
- Maximum time delay of the system, represented by input\_delay, is 0.1 s.

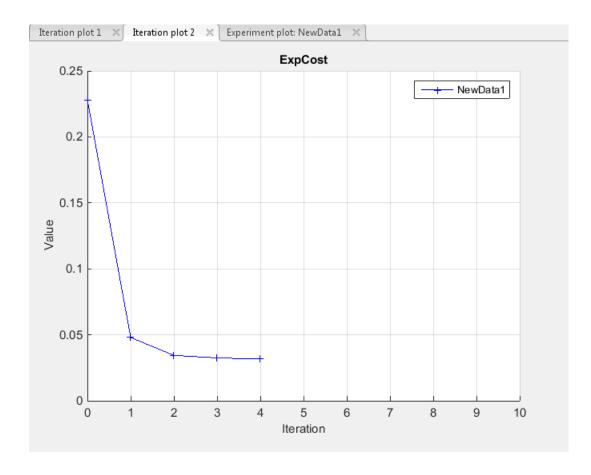

Therefore, specify 0 as the minimum value for all parameters, and 0.1 as the maximum value of input\_delay. In the Parameter Estimation tool, click the Select Parameters button to specify bounds on the parameter values. For each parameter, click the right arrow toggle to display the minimum, maximum, and scale fields. Specify the minimum value for each parameter by replacing -Inf with 0 in the Minimum field. Specify the maximum value for input\_delay by replacing +Inf with 0.1 in the corresponding Maximum field.

After estimating the parameters, analyze the results using the experiment plot and the plot for expected cost.

The data simulated using the estimated parameter values agree better with the measured data than when the parameter limits were not specified.

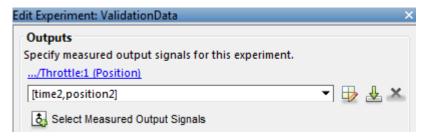

### **Validate Estimated Model Parameters**

After estimating model parameters, validate the model using another data set (validation data). A good match between the simulated response and the validation data indicates that you have not overfitted the model.

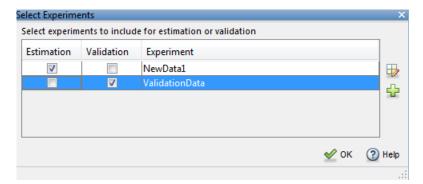

To validate the estimated parameters using a validation data set:

1 Create a new experiment to use for validation. Name it ValidationData. Import the validation I/O data, input2 and position2, and the time vector, time2 in the ValidationData experiment. To do this, in the Parameter Estimation tool, in the Experiments pane, right-click ValidationData and select Edit... to open the

experiment editor. Then, type [time2,position2] in the output dialog box and [time2,input2] in the input dialog box. For more information, see "Import Data".

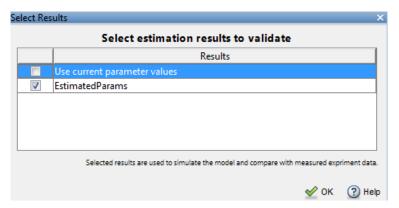

2 Select the experiment for validation. On the **Parameter Estimation** tab, click **Select Experiments**. By default, the **ValidationData** experiment is selected for estimation. Deselect the check box that corresponds to **ValidationData** for estimation and select the check box for validation.

3 Select results to use. On the Validation tab, click Select Results to Validate.

Deselect Use current parameter values and select EstimatedParams, and click OK.

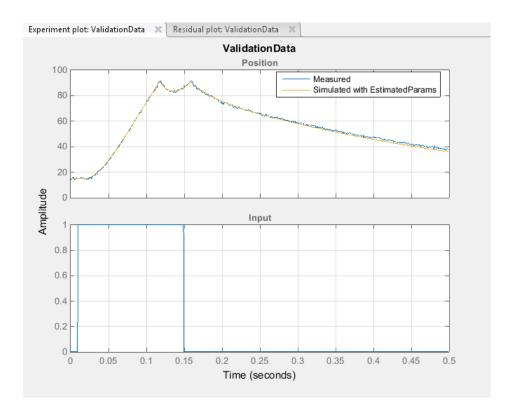

4 Select the plots for measured and simulated data, and residuals on the **Validation** tab. You can assess how much the data simulated using the estimated parameters agrees with the measured data using these plots.

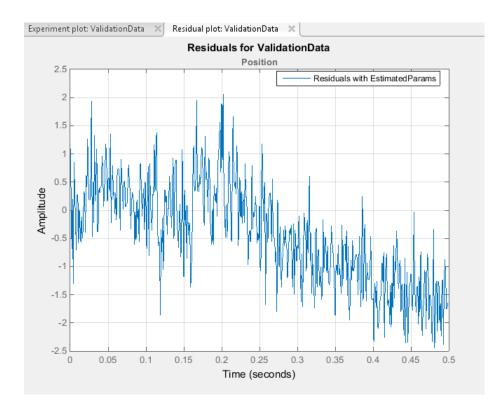

On the Validation tab, click Validate to start validation.

- **5** Examine the plots.
  - **a** Examine the experiment plot to see how well the simulated output matches the output data.

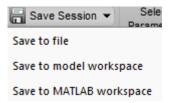

The simulated response as shown in light brown on the top experiment plot is overlaid on the measured out put data, and closely matches the measured validation data.

**b** Examine the residuals plot to compare the difference between the simulated response and measured data.

The difference between the simulated and measured data varies between 2 and -2.5. The residuals lie within 6% of the maximum output variation and do not display any systematic patterns. This indicates a good fit between the simulated output and measured data.

#### **6** Save the session. On the **Parameter Estimation** tab, click **Save Session**.

From the drop-down list select where to save the session. Specify the file name, and click  $\mathbf{Save}$  or  $\mathbf{OK}$  to save your parameter estimation session as a MAT-file.

- "Time-Domain Model Verification" on page 3-54

# **Supported Design Requirements**

You can optimize response of Simulink models to meet time- and frequency-domain design requirements.

Simulink Design Optimization software optimizes model response by formulating the requirements into a constrained optimization problem. It then solves the problem using optimization methods.

 For time-domain requirements, the software simulates the model during optimization, compares the current response with the requirement and uses gradient methods to modify design variables (model parameters) to meet the objectives.

You can specify time-domain requirements either in blocks from the **Signal Constraints** library or without adding blocks to the model. You can also include requirements specified in Check Static Range, Check Static Lower Bound and Check Static Upper Bound blocks from the Simulink **Model Verification** library.

• For frequency-domain requirements, the software linearizes the portion of the model between specified linearization inputs and outputs, compares the linear system with the requirement and uses gradient methods to modify the design variables to meet the objectives.

If you have Simulink Control Design software, you can optimize the model to meet frequency-domain requirements, such as Bode magnitude and gain and phase margin bounds. You can specify the frequency-domain requirements without adding blocks to the model or by using the "Model Verification" blocks of the Simulink Control Design software library.

# Design Optimization to Meet Step Response Requirements (GUI)

This example shows how to optimize controller parameters to meet step response design requirements using the Response Optimization tool. You specify the design requirements in a Check Step Response Characteristics block.

#### In this section...

"Model Structure" on page 3-4

"Design Requirements" on page 3-6

"Specify Step Response Requirements" on page 3-6

"Specify Design Variables" on page 3-9

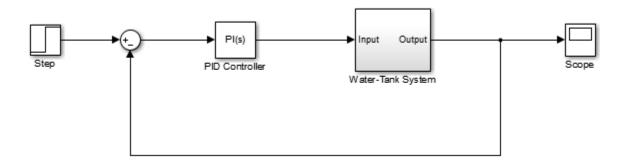

"Optimize Model Response" on page 3-12

"Save the Session" on page 3-15

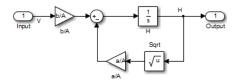

### **Model Structure**

The Simulink model watertank\_stepinput includes the nonlinear Water-Tank System plant and a PI controller in a single-loop feedback system.

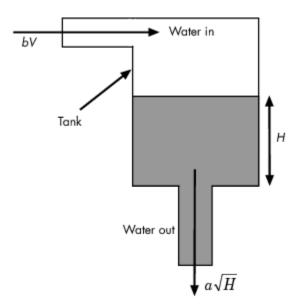

The Step block applies a step input. You can also use other types of input, such as a ramp, to optimize the response generated by such inputs.

This figure shows the Water-Tank System.

Water enters the tank at the top at a rate proportional to the valve opening. The valve opening is proportional to the voltage, V, applied to the pump. The water leaves through an opening in the tank base at a rate that is proportional to the square root of the water height, H. The presence of the square root in the water flow rate results in a nonlinear plant.

The following table describes the variables, parameters, differential equations, states, inputs, and outputs of the Water-Tank System.

Variables	H is the height of water in the tank.	
	Vol is the volume of water in the tank.	
	V is the voltage applied to the pump.	

Parameters	A is the cross-sectional area of the tank.
	b is a constant related to the flow rate into the tank.
	a is a constant related to the flow rate out of the tank.
Differential equation	$\frac{d}{dt}Vol = A\frac{dH}{dt} = bV - a\sqrt{H}$
States	H
Inputs	V
Outputs	H

### **Design Requirements**

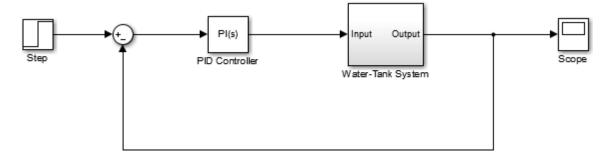

The height of water in the tank, H, must meet the following step response requirements:

- · Rise time less than 2.5 seconds
- · Settling time less than 20 seconds
- Overshoot less than 5%

# **Specify Step Response Requirements**

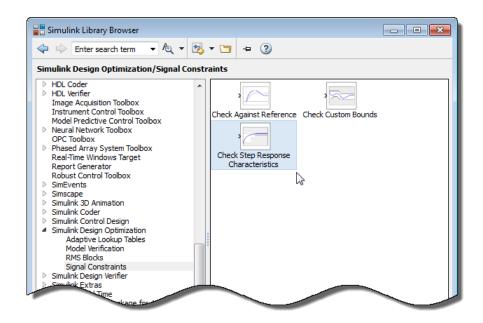

1 Open the Simulink model.

```
sys = 'watertank_stepinput';
open_system(sys);
```

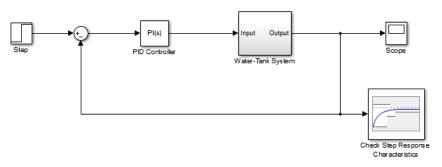

2 Add a Check Step Response Characteristics block to the model.

In the Simulink model window, select View > Library Browser. Expand the Simulink Design Optimization node and select Signal Constraints.

Drag and drop the Check Step Response Characteristics block into the model window and connect the block to the output. The block is connected to the signal for which you want to specify design requirements.

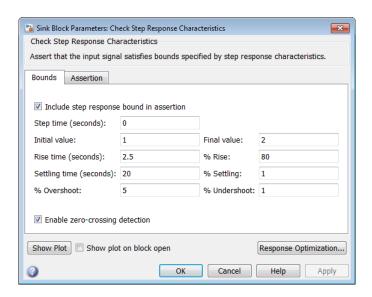

**3** Specify step response requirements.

Double-click the Check Step Response Characteristics block to open the Sink Block Parameters: Check Step Response Characteristics dialog box.

- In Rise time (seconds), enter 2.5.
- In Settling time (seconds), enter 20.
- In % Overshoot, enter 5.
- In **Initial value**, enter 1.
- In Final value, enter 2.

#### Click OK.

Instead of specifying time-domain requirements in the Check blocks, you can specify them in the Response Optimization tool without adding blocks. For an example that uses this approach, see "Design Optimization to Track Reference Signal (GUI)" on page 3-25.

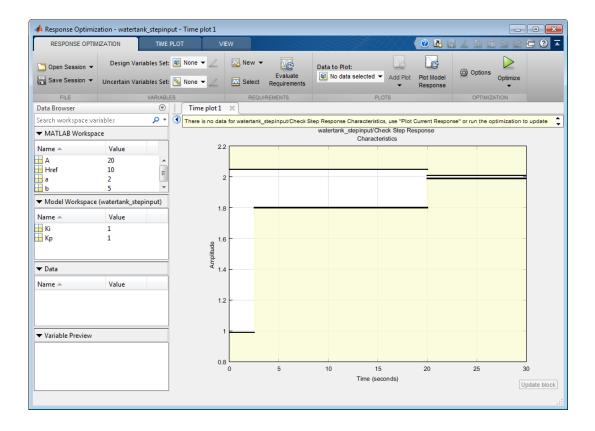

# **Specify Design Variables**

When you optimize the model response, the software modifies the design variable values to meet the design requirements. You specify which model parameters the software can modify.

1 Open a Response Optimization tool for the model.

In the Simulink model window, select **Analysis** > **Response Optimization**.

Alternatively, in the Sink Block Parameters dialog box, click **Response Optimization**.

The region bounded by black line segments in **Time plot 1** shows the step response requirements that you specified in the **Check Step Response Characteristics** block.

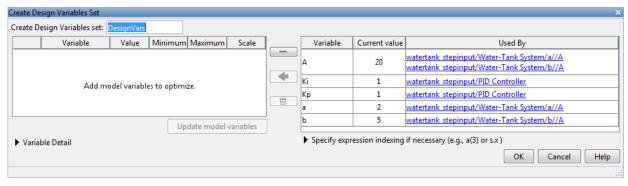

**2** Create a set of design variables.

In the **Design Variables Set** drop-down list, select **New**.

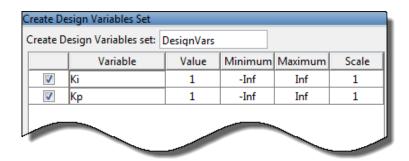

The Create Design Variables Set dialog box shows model parameters that you can use as design variables and indicates their locations within the model.

**Note:** In your application, if the model parameters you are interested in optimizing are not listed in the Create Design Variables Set dialog box, first specify these parameters as variables. See, "Add Model Parameters as Variables for Optimization".

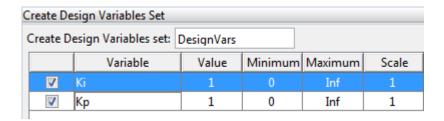

**3** Add parameters to the design variables set.

Select Ki and Kp, and click to add the selected parameters.

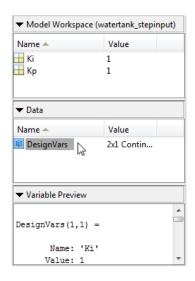

The design variables list displays the following variable settings:

- · Variable Variable name
- Value Current variable value
- Minimum and Maximum Variable bounds
- Scale Scaling factor for the variable
- Limit the design variables to positive values. To do so, enter 0 for the minimum value of each variable in the corresponding **Minimum** field and press **Enter** on your keyboard.

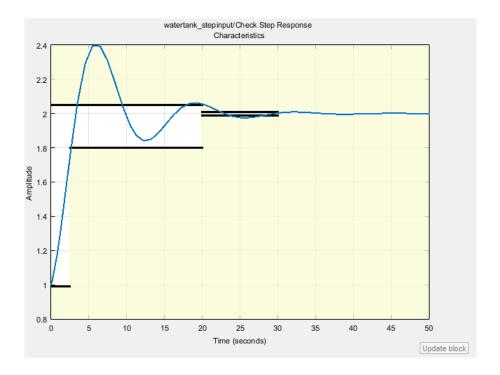

Click **OK**. A new design variable **DesignVars** is created and appears in the **Data** area of the Response Optimization tool. You can click the variable to view its contents in the **Variable Preview** area.

1

# **Optimize Model Response**

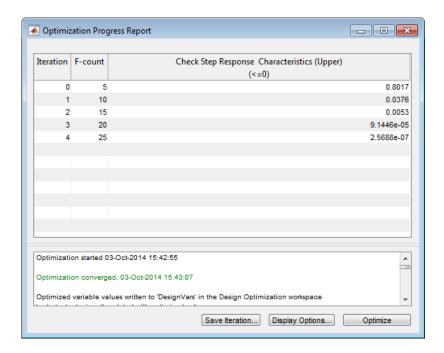

To view the current response of the model, click Plot Model Response.

The plot shows the model output, depicted by the blue line, lies outside the region of the specified step response.

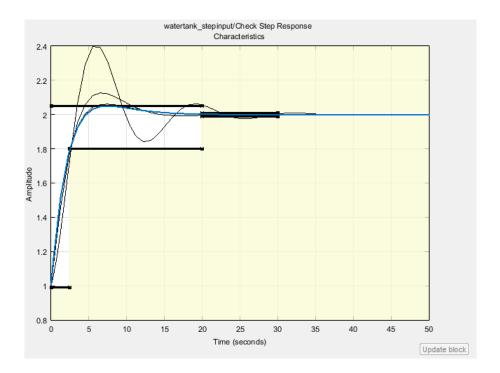

# 2 Click Optimize.

The default optimization solver **Gradient descent** (fmincon) modifies the design variables at each iteration so that the simulated response lies within the design requirement line segments. For more information, see "Selecting Optimization Methods" and "How the Optimization Algorithm Formulates Minimization Problems".

The message Optimization converged in the Optimization Progress Report indicates that the optimization solver found a solution that meets the design requirements within the tolerances and parameter bounds. For more information about the outputs displayed in the optimization, see "Iterative Display" in the Optimization Toolbox documentation.

 ${\bf 3} \quad \text{Verify that the model output meets the step response requirements}.$ 

The plot displays the last five iterations. The final response using the optimized variable parameter appears as the thick blue line. The optimized response lies in the white region bounded by the design requirement line segments and thus meets the requirements.

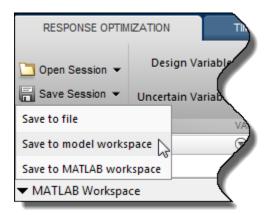

4 View the optimized parameter values. Click DesignVars in Model Workspace and view the updated values in the Variable Preview area.

The optimized values of the design variables are automatically updated in the Simulink model.

### Save the Session

After you optimize the model response to meet design requirements, you can save the Response Optimization tool session which includes the optimized parameter values.

In the Response Optimization tool, in the **Response Optimization** tab, in the **Save Session** drop-down list, select **Save to model workspace**.

In the Save Session window, specify the session name in the **Session** field.

**Tip** To open the saved session, in the Response Optimization tool for the model, in the **Open Session** drop-down list, click the **Open from model workspace** option.

# Design Optimization to Meet Step Response Requirements (Code)

#### In this section...

"Model Structure" on page 3-17

"Design Requirements" on page 3-19

"Specify Step Response Requirements" on page 3-19

"Specify Design Variables" on page 3-20

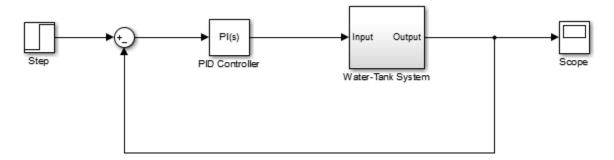

"Optimize Model Response" on page 3-21

This example shows how to programmatically optimize controller parameters to meet step response requirements using the sdo.optimize function.

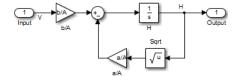

#### **Model Structure**

The Simulink model watertank\_stepinput includes the nonlinear Water-Tank System plant and a PI controller in a single-loop feedback system.

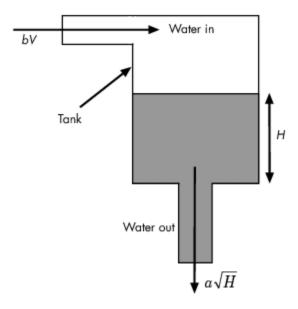

The Step block applies a step input. You can also use other types of input, such as a ramp, to optimize the response generated by such inputs.

This figure shows the Water-Tank System.

Water enters the tank at the top at a rate proportional to the valve opening. The valve opening is proportional to the voltage, V, applied to the pump. The water leaves through an opening in the tank base at a rate that is proportional to the square root of the water height, H. The presence of the square root in the water flow rate results in a nonlinear plant.

The following table describes the variables, parameters, differential equations, states, inputs, and outputs of the Water-Tank System.

Variables	H is the height of water in the tank.
	Vol is the volume of water in the tank.
	V is the voltage applied to the pump.
Parameters	A is the cross-sectional area of the tank.
	b is a constant related to the flow rate into the tank.
	a is a constant related to the flow rate out of the tank.

Differential equation	$\frac{d}{dt}Vol = A\frac{dH}{dt} = bV - a\sqrt{H}$
States	H
Inputs	V
Outputs	H

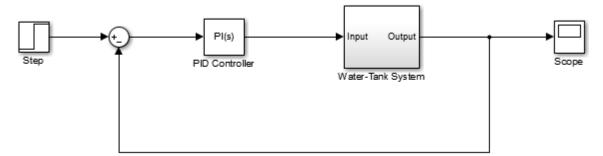

### **Design Requirements**

The height of water in the tank, H, must meet the following step response requirements:

- Rise time less than 2.5 seconds
- Settling time less than 20 seconds
- · Overshoot less than 5%

## **Specify Step Response Requirements**

1 Open the Simulink model.

2 Log the water level, H.

During optimization, the model is simulated using the current value of the model parameters and the logged signal is used to evaluate the design requirements.

PlantOutput = Simulink.SimulationData.SignalLoggingInfo;

```
PlantOutput.BlockPath = [sys '/Water-Tank System'];
PlantOutput.OutputPortIndex = 1;
PlantOutput.LoggingInfo.NameMode = 1;
PlantOutput.LoggingInfo.LoggingName = 'PlantOutput';
```

**3** Store the logging information.

```
simulator = sdo.SimulationTest(sys);
simulator.LoggingInfo.Signals = PlantOutput;
```

simulator is a sdo. Simulation Test object that you also use later to simulate the model.

**4** Specify step response requirements.

```
StepResp = sdo.requirements.StepResponseEnvelope;
StepResp.RiseTime = 2.5;
StepResp.SettlingTime = 20;
StepResp.PercentOvershoot = 5;
StepResp.FinalValue = 2;
StepResp.InitialValue = 1;
```

StepResp is a sdo.requirements.StepResponseEnvelope object. The values assigned to StepResp.FinalValue and StepResp.InitialValue correspond to a step change in the water tank height from 1 to 2.

### **Specify Design Variables**

When you optimize the model response, the software modifies parameter (design variable) values to meet the design requirements.

 Select model parameters to optimize. Here, optimize the parameters of the PID controller.

```
p = sdo.getParameterFromModel(sys,{'Kp','Ki'});
```

p is an array of 2 param. Continuous objects.

2 To limit the parameters to positive values, set the minimum value of each parameter to 0.

```
p(1).Minimum = 0;
p(2).Minimum = 0;
```

### **Optimize Model Response**

1 Create a design function to evaluate the system performance for a set of parameter values.

```
evalDesign = @(p) sldo_model1_design(p,simulator,StepResp);
```

evalDesign is an anonymous function that calls the cost function sldo\_model1\_design. The cost function simulates the model and evaluates the design requirements.

#### Tip Type edit sldo\_model1\_design to view this function.

- **2** Evaluate the current response. (Optional)
  - a Compute the model response using the current values of the design variables.

```
initDesign = evalDesign(p);
```

During simulation, the Step Response block throws assertion warnings at the MATLAB prompt, which indicate that the requirements specified in the block are not satisfied.

**b** Examine the nonlinear inequality constraints.

#### initDesign.Cleq

```
ans =

0.1739
0.0169
-0.0002
-0.0101
-0.0229
0.0073
-0.0031
0.0423
```

Some Cleq values are positive, beyond the specified tolerance, which indicates the response using the current parameter values violates the design requirements.

**3** Specify optimization options.

```
opt = sdo.OptimizeOptions;
opt.MethodOptions.Algorithm = 'sqp';
```

The software configures opt to use the default optimization method, fmincon, and the sequential quadratic programming algorithm for fmincon.

**4** Optimize the response.

```
[pOpt,optInfo] = sdo.optimize(evalDesign,p,opt);
```

At each optimization iteration, the software simulates the model and the default optimization solver fmincon modifies the design variables to meet the design requirements. For more information, see "Selecting Optimization Methods" and "How the Optimization Algorithm Formulates Minimization Problems".

After the optimization completes, the command window displays the following results:

			max		Step-size	First-order
Iter	F-count	f(x	) constr	aint		optimality
0	5	(	0 0.	1739		
1	10		0.0	3411	1	0.81
2	15		0	0	0.235	0.0429
3	15		0	0	2.26e-18	0
Local	minimum	found that	satisfies	the	constraints.	

Optimization completed because the objective function is non-decreasing in feasible directions, to within the selected value of the function tolerance, and constraints are satisfied to within the selected value of the constraint tolerance.

The message Local minimum found that satisfies the constraints indicates that the optimization solver found a solution that meets the design requirements within specified tolerances. For more information about the outputs displayed during the optimization, see "Iterative Display" in the Optimization Toolbox documentation.

5 Examine the optimization termination information contained in the optinfo output argument. This information helps you verify that the response meets the step response requirements.

For example, check the following fields:

• Cleq, which shows the optimized nonlinear inequality constraints.

```
optInfo.Cleq
ans =
```

```
-0.0001
-0.0028
-0.0050
-0.0101
-0.0135
-0.0050
-0.0050
```

All values satisfy  $Cleq \le 0$  within the optimization tolerances, which indicates that the step response requirements are satisfied.

exitflag, which identifies why the optimization terminated.

The value is 1, which indicates that the solver found a solution that was less than the specified tolerances on the function value and constraint violations.

**6** View the optimized parameter values.

#### p0pt

```
p0pt(1,1) =
       Name: 'Kp'
      Value: 2.0545
    Minimum: 0
    Maximum: Inf
       Free: 1
      Scale: 1
       Info: [1x1 struct]
p0pt(2,1) =
       Name: 'Ki'
      Value: 0.3801
    Minimum: 0
    Maximum: Inf
       Free: 1
      Scale: 1
       Info: [1x1 struct]
```

- **7** Simulate the model with the optimized values.
  - a Update optimized parameter values in the model.

```
sdo.setValueInModel(sys,pOpt);
b Simulate the model.
sim(sys);
```

- "Design Optimization to Track Reference Signal (GUI)" on page 3-25

# **Design Optimization to Track Reference Signal (GUI)**

This example shows how to optimize controller parameters to track a reference signal using the Response Optimization tool. You specify the reference signal without adding any Check blocks to the model.

#### In this section...

"Model Structure" on page 3-25

"Design Requirements" on page 3-26

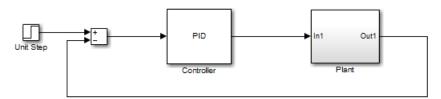

"Specify Reference Signal" on page 3-26

"Specify Design Variables" on page 3-35

"Optimize Model Response" on page 3-38

#### **Model Structure**

The model sldo model1 includes these blocks:

- Controller block, a PID controller, controls the output of the Plant subsystem.
- Unit Step block applies a step input.

You can also use other types of inputs, such as ramp, to optimize the response generated by such inputs.

• Plant subsystem is a second-order system with delay. It contains Transfer Function and Transport Delay blocks.

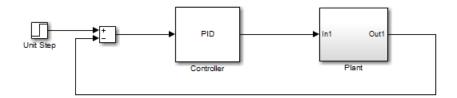

### **Design Requirements**

The model output must track a reference signal  $y = 1 - \exp(-0.1 \times t)$ , where t is time.

# **Specify Reference Signal**

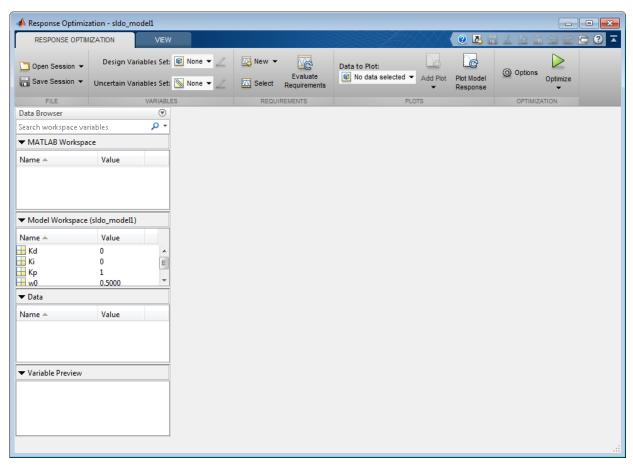

1 Open the Simulink model.

```
sys = 'sldo_model1';
open_system(sys);
```

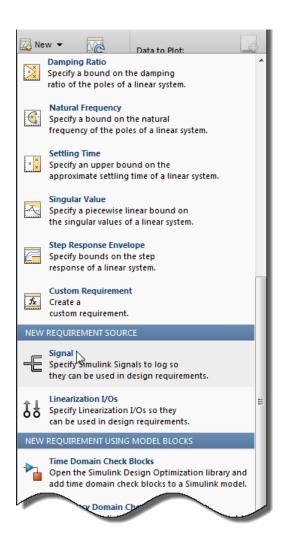

To learn more about the model, see "Model Structure" on page 3-25.

2 To open the Response Optimization tool, select Analysis > Response Optimization.

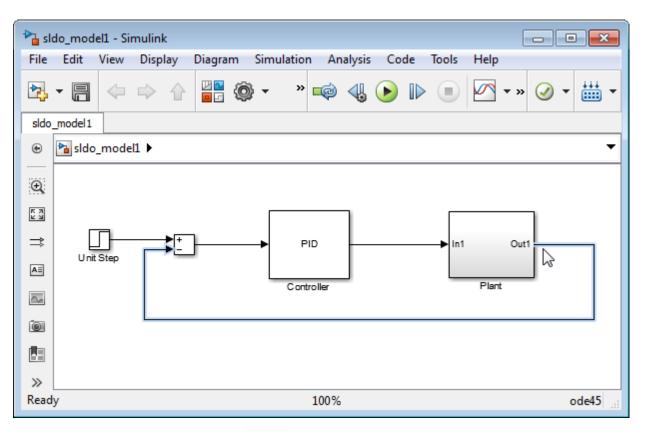

- **3** Select the model signal to track the reference signal.
  - a In the New drop-down list, select Signal to open the Create Signal Set window.

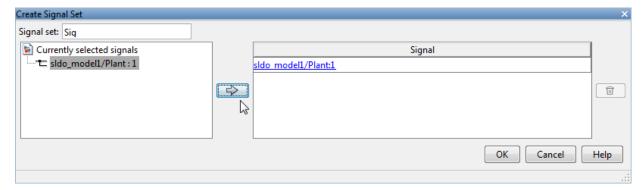

**b** To display the signal in the window, click the output of the Plant block in the Simulink model window.

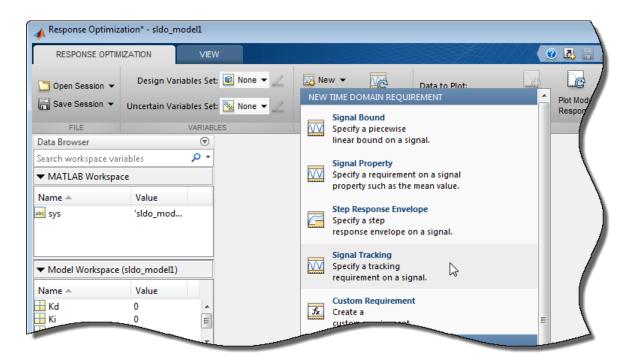

Select the signal, and click to add it to the signal set.

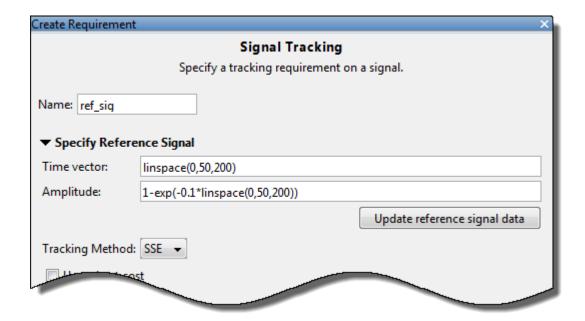

**d** In **Signal set**, enter **PlantOutput** as the selected signal name.

Click  $\mathbf{OK}$  to create the variable PlantOutput. It appears in the  $\mathbf{Data}$  area of the Response Optimization tool.

- **4** Specify the reference signal for the model output to track.
  - **a** In the **New** drop-down list, select **Signal Tracking** to open a Create Requirement window.

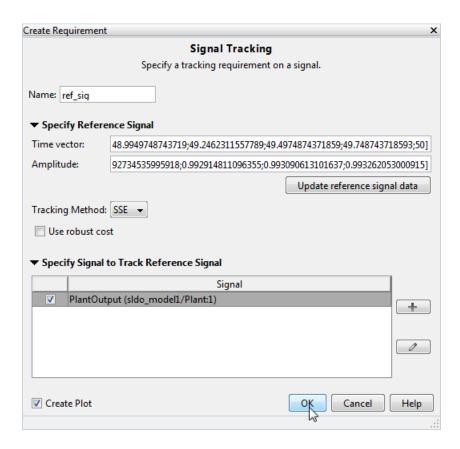

- **b** In the **Name** edit box, enter ref\_sig.
- c In the Time vector edit box, enter linspace (0,50,200)
- d In the Amplitude edit box, enter 1-exp(-0.1\*linspace(0,50,200)).

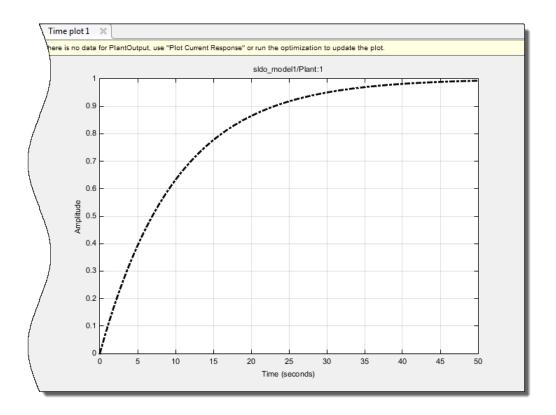

Leave the **Tracking Method** as **SSE** which means, at each optimization iteration, the solver attempts to reduce the sum of squared errors between the simulated output and reference signal.

- e Click Update reference signal data.
- f In the **Specify Signal to Track Reference Signal** area, select the check-box corresponding to the signal you selected in the previous step, and click **OK**.

A new reference signalref\_sig is created and appears in the **Data** area. The Response Optimization window updates to plot the reference signal.

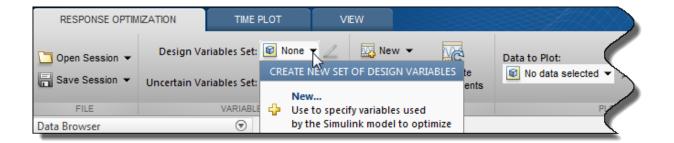

### **Specify Design Variables**

When you optimize the model response, the software modifies the design variable values to meet the design requirements.

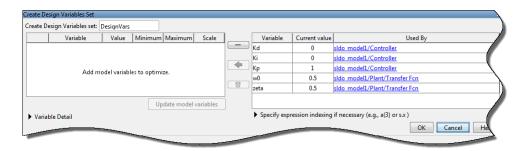

#### In the **Response Optimization** tab:

1 Create a new set of design variables.

In the  $\bf Design\ Variables\ Set\ drop\text{-}down\ list\ select\ New.$ 

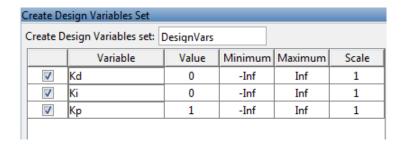

The Create Design Variables Set window shows model parameters that you can use as design variables and indicates their locations within the model subsystems.

2 Add parameters to the design variables set.

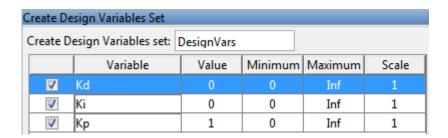

Select Kd, Ki, and Kp, and click to add the selected parameters.

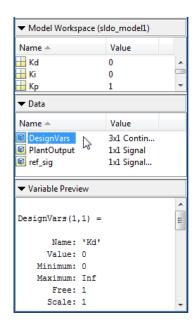

The design variables list displays the following parameter settings:

• Variable — Parameter name

- · Value Current parameter value
- Minimum and Maximum Parameter bounds
- Scale Scaling factor for the parameter
- 3 Limit the parameters to positive values. To do so, enter 0 for the minimum value of each parameter in the corresponding Minimum field, and press Enter on your keyboard.

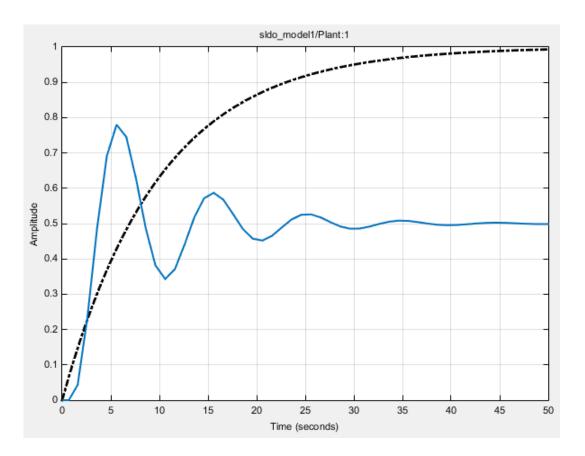

Click **OK**. A new design variable **DesignVars** is created and appears in the **Data** area of the Response Optimization tool.

### **Optimize Model Response**

To view the current model response, click Plot Model Response.

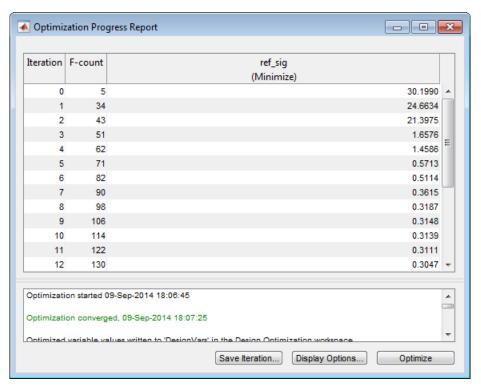

The plot shows that the model response does not track the reference signal.

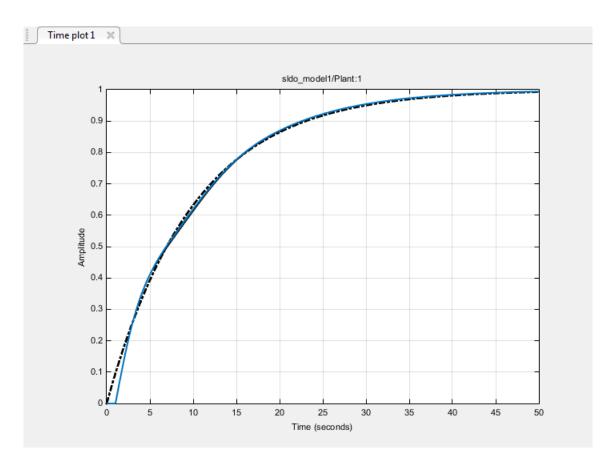

2 Click Optimize.

At each iteration, the optimization solver **Gradient descent** (fmincon) modifies the controller parameters to minimize the error between the simulated response and the reference signal. To learn more, see "How the Optimization Algorithm Formulates Minimization Problems".

The message Optimization converged in the Optimization Progress Report indicates that the optimization method found a solution that tracks the reference signal within the tolerances and parameter bounds. For more information about the outputs displayed in the Optimization Progress Report, see "Iterative Display" in the Optimization Toolbox documentation.

**3** Verify that the response tracks the reference signal by observing the amplitude versus time plot.

The optimized response closely tracks the reference signal.

**4** To view the optimized parameter values, click <code>DesignVars</code> in the <code>Data</code> area of the Response Optimization tool. View the updated values in the <code>Variable Preview</code> area.

The optimized values of the design variables are automatically updated in the Simulink model.

### **Related Examples**

• "Design Optimization to Meet Step Response Requirements (Code)" on page 3-17

# Design Optimization Using Frequency-Domain Check Blocks (GUI)

This example shows how to optimize a design to meet frequency-domain requirements using the Response Optimization tool. Simulink Control Design software must be installed to optimize a design to meet frequency-domain design requirements.

In this example, you specify the design requirements in a Check Bode Characteristics block. You optimize rectifier filter parameters to meet gain and bandwidth requirements by minimizing a custom objective.

#### In this section...

"Model Structure" on page 3-42

"Design Requirements" on page 3-43

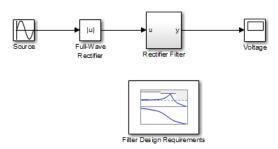

"Specify Design Requirements" on page 3-43

"Specify Design Variables" on page 3-46

"Optimize Design" on page 3-47

#### **Model Structure**

The model sdorectifier includes the following blocks:

- Full-Wave Rectifier block An Abs block
- Rectifier Filter subsystem RLC filter implemented using integrator and gain blocks
- Filter Design Requirements block Check Bode Characteristics block that specifies the gain and bandwidth design requirements

### **Design Requirements**

The design optimization problem has several objectives. The design must:

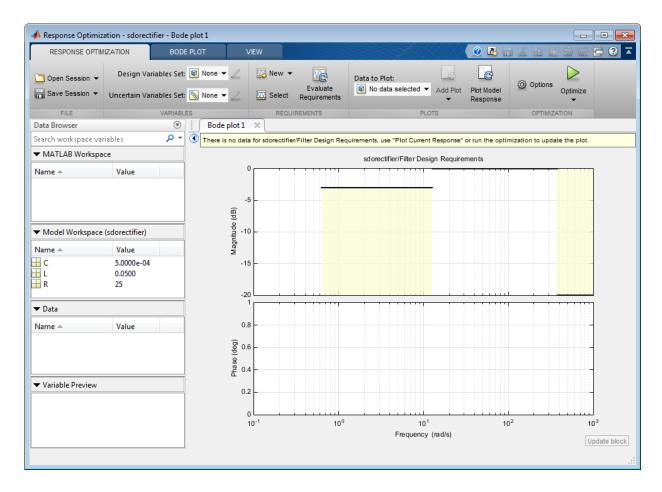

- Have a -3 dB bandwidth of at least 2 Hz
- Limit the gain across the frequency range 2 Hz 60 Hz to at most 0 dB
- Limit the gain above 60 Hz to at most -20 dB
- Maximize the filter resistance R
- Minimize the filter inductance L

The requirements ensure that the rectifier filter combination has minimal high frequency content, responds quickly to voltage changes, and limits filter currents.

### **Specify Design Requirements**

1 Open the Response Optimization tool for the model.

```
sdotool('sdorectifier')
```

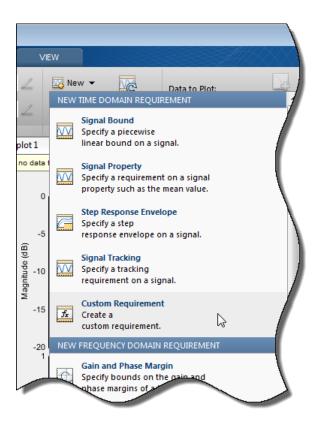

The **Bode plot 1** tab shows the gain and bandwidth requirements specified in the Filter Design Requirements block in the model. To see their values, double-click the block to open the Block Parameters dialog box, and select the **Bounds** tab.

**2** Specify a custom objective to minimize the filter inductance and maximize the resistance.

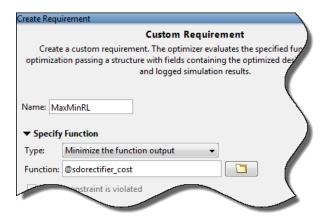

The custom objective is already defined in the  $sdorectifier\_cost$  function. The function accepts the design variables R and L and returns the objective to be minimized.

Tip Type edit sdorectifier\_cost in the command line to view this function.

a In the **New** drop-down list, select **Custom Requirement**.

- **b** Specify the following values in the Create Requirement window, and click **OK**:
  - In the Name edit box, enter MaxMinRL.
  - ullet In the  $\mathbf{Type}\ \mathrm{edit}\ \mathrm{box},\ \mathrm{select}\ \mathrm{Minimize}$  the function output
  - In the **Function** edit box, enter **@sdorectifier\_cost**. The optimization solver calls the specified function handle.

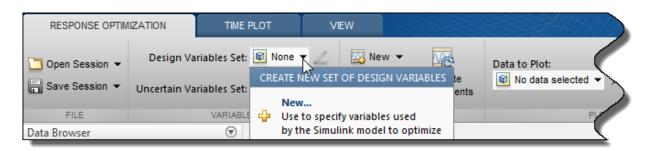

A new requirement variable MaxMinRL is created, and appears in the **Data** area in the Response Optimization tool. The **Iteration plot 1** tab shows the value of MaxMinRL at each iteration during the optimization.

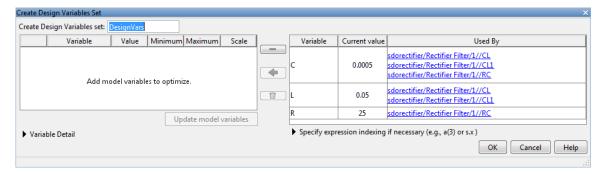

### **Specify Design Variables**

When you optimize the model response, the software modifies the design variable values to meet the design requirements.

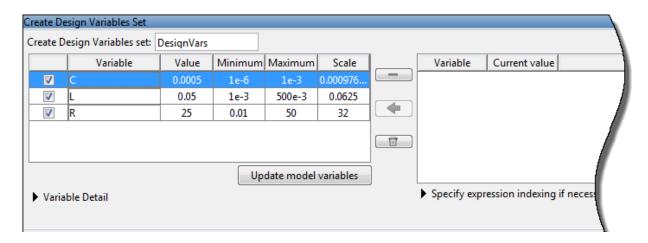

1 In the **Design Variables Set** drop-down list, select **New**.

Select C, L, and R in the Create Design Variable Set window. Click to add the selected parameters to a design variables set.

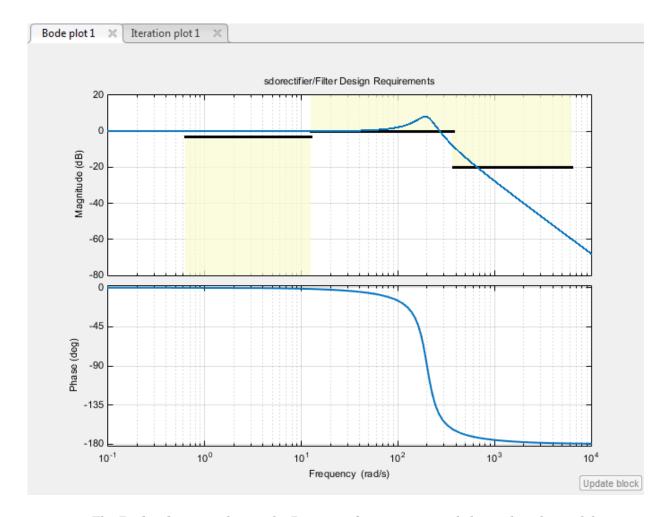

- **2** Specify the value range for each design variable, and click **OK**:
  - C in the range 1 µF-1 mF
  - L in the range 1–500 mH
  - R in the range 0.01–50 ohms

A new variable DesignVars is created, and appears in the **Data** area of the Response Optimization tool.

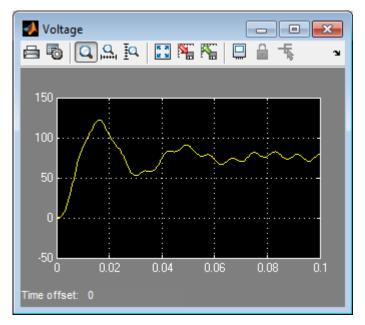

### **Optimize Design**

To view the current response of the model, click Plot Model Response.

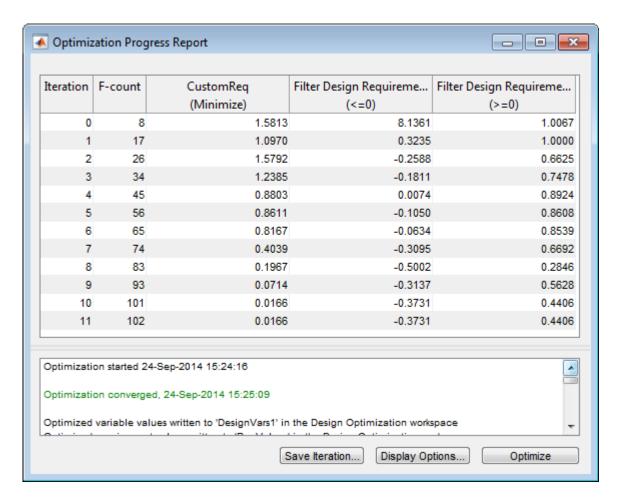

The **Bode plot 1** window in the Response Optimization tool shows that the model output goes out of the region bounded by the design requirement line segments.

In the Voltage scope window, you see that the filter voltage signal overshoots its steady-state value and contains significant harmonic content.

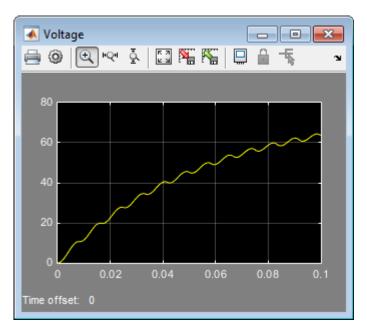

# 2 Click Optimize.

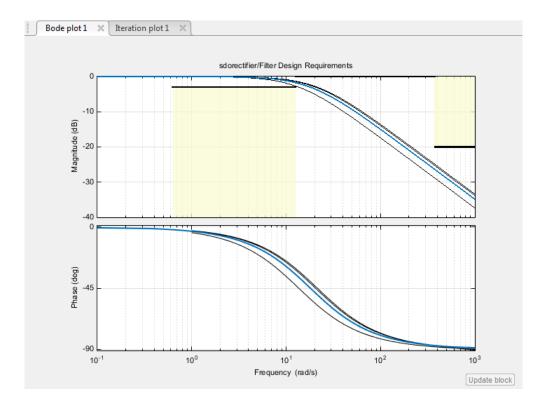

The Optimization converged message in the Optimization Progress Report indicates that the optimization method found a solution to satisfy the filter bandwidth requirements.

The harmonic content in the filter voltage signal is reduced from the initial design.

**3** Verify that the model meets the gain and bandwidth requirements.

The plot displays the output of the last five iterations. The final response using the optimized parameter values appears as the thick blue line.

The optimized response lies in the white region bounded by the design requirement line segments and thus meets the requirements.

4 Click DesignVars in the **Data** area and view the updated values in the **Variable Preview** area.

The optimized values of the design variables are automatically updated in the Simulink model.

### **See Also**

Check Bode Characteristics

# **Related Examples**

• "Design Optimization to Meet Frequency-Domain Requirements (GUI)"

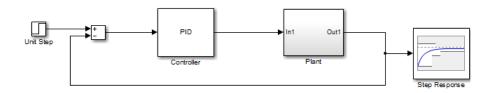

### **Time-Domain Model Verification**

This example shows how to perform time-domain model verification using Simulink Design Optimization **Model Verification** blocks. During time-domain verification, the software monitors a signal to check if it meets time-domain characteristics such as step response characteristics and upper and lower amplitudes, or tracks a reference signal.

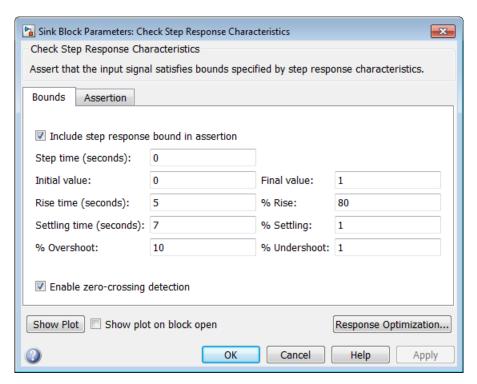

You can also use blocks from Simulink and Simulink Control Design **Model Verification** libraries to design complex assertion logic for time- and frequency-domain verification, and signal monitoring. If you have Simulink Verification and Validation software, you can construct simulation tests for your model using the Verification Manager tool in the Signal Builder.

1 Open Simulink model.

```
sys = 'sldo_model1_stepblk';
open system(sys);
```

The model includes a Step Response block which is a Check Step Response Characteristics block from the Simulink Design Optimization **Model Verification** library and has default step response bounds.

2 In the Simulink Editor, click Simulation > Run.

The block asserts multiple times during simulation because the signal to which the block is connected violates the specified bounds. Assertion warnings appear in the MATLAB command window.

You can optimize model parameters to satisfy the bounds and eliminate assertion warnings. See "Design Optimization to Meet Step Response Requirements (GUI)" on page 3-4.

# When to Use Optimization-Based Linear Control Design

When you have Control System Toolbox software installed, you can design and optimize control systems for LTI models by optimizing controller parameters in the SISO Design Tool. To use optimization methods for linear control design, also known as *optimization-based tuning*, you must already have an initial controller. You can then use optimization-based tuning to refine the controller design to meet additional design requirements. For more information on designing controllers, see the Control System Toolbox documentation.

**Note:** Optimization-based tuning only changes the value of the controller parameters and not the controller structure itself.

Optimization-based tuning provides flexibility in terms of specifying additional design requirements for the controller. When you have a large number of design requirements, you can first design an initial controller by selecting a subset of requirements and subsequently select additional requirements to refine the design.

Optimization-based tuning also provides flexibility in terms of selecting a subset of controller parameters to optimize, and specifying bounds on the controller parameters.

To design linear controllers for Simulink models using optimization-based tuning, you must first linearize the model using the Simulink Control Design software. For more information on linearizing Simulink models, see the Simulink Control Design documentation.

# Types of Time- and Frequency-Domain Design Requirements for Optimization-Based Control Design

When you design linear controllers for LTI or Simulink models using the Simulink Design Optimization software, you can specify both time- and frequency-domain requirements on the system response. You can specify design requirements on the following plots:

- Root Locus plot
- · Open-Loop and Prefilter Bode plots
- · Open-Loop Nichols plot
- Step/Impulse Response plots

For more information, see "Time- and Frequency-Domain Requirements in SISO Design Tool".

Simulink Design Optimization software uses the frequency-domain requirements to compute the frequency response of the system. It then uses optimization methods to reduce the distance between the current response and the requirements by modifying the controller parameters. The software does not change the controller structure when optimizing the controller parameters.

# Quick Start — Optimization-Based Linear Control Design

In this quick start, you get an overview of the typical tasks for optimization-based linear control design using the SISO Design Tool:

- 1 Open a SISO Design Tool session.
- **2** Configure a project for optimization-based control design.
- **3** Specify the controller parameters to design.
- **4** Specify the design requirements.
- **5** Design the controller.
- **6** Evaluate the controller design.

**Note:** The same workflow applies to optimization-based control design for LTI models created at the command line using Control System Toolbox software. To learn how to create LTI models, see "Linear (LTI) Models" in the Control System Toolbox documentation.

Prerequisites for optimization-based linear control design include:

• Simulink Compensator Design Task that contains a linearized version of the Simulink model and, optionally, any response plots you configure.

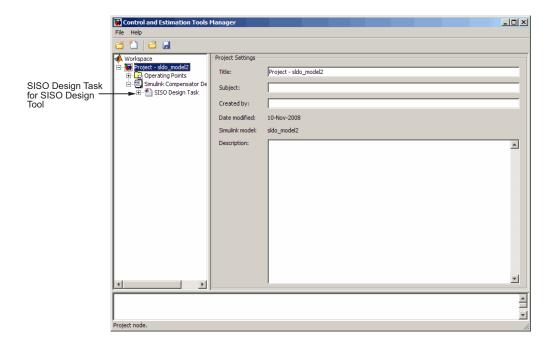

For more information on how to linearize a Simulink model for control design, see the Simulink Control Design documentation.

· Time- and frequency-domain design requirements

To design a controller using optimization methods:

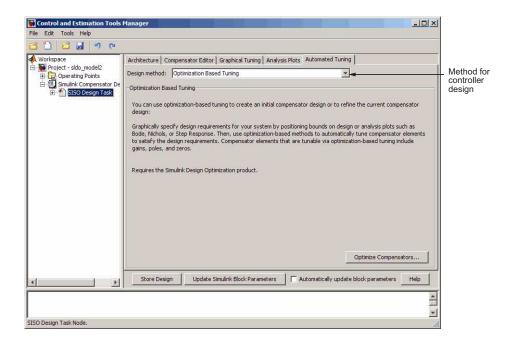

1 Open a SISO Design Tool session by typing the following command at the MATLAB prompt:

```
controlSystemDesigner('projectname.mat')
```

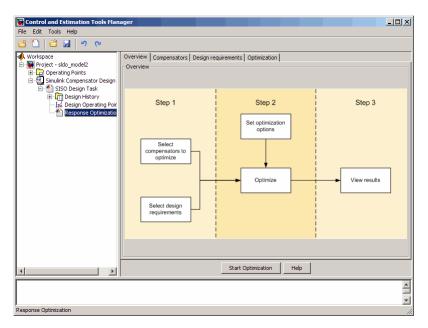

The command also opens a SISO Design for SISO Design Task window by default and any response plots you configured when you linearized the Simulink model using Simulink Control Design software.

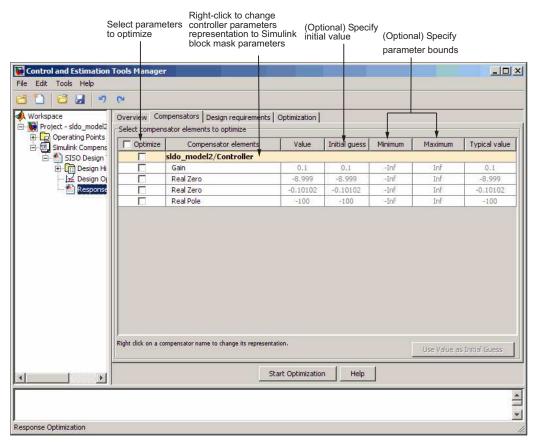

2 Configure a project for optimization-based control design by clicking **Optimize**Compensators in the Automated Tuning tab of the SISO **Design Task**.

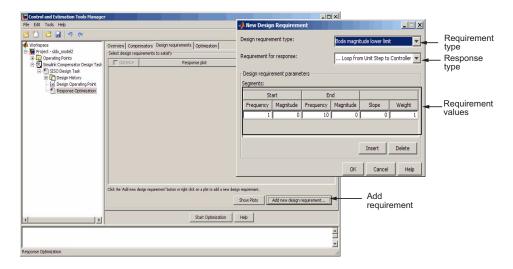

This action creates a new **Response Optimization** node in the Control and Estimation Tools Manager.

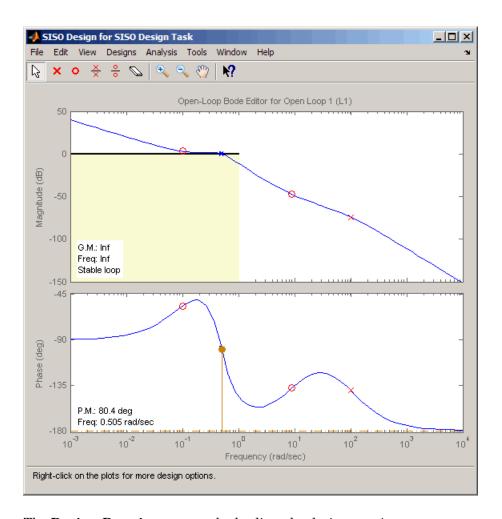

3 Specify the controller parameters to design in the Compensators tab.

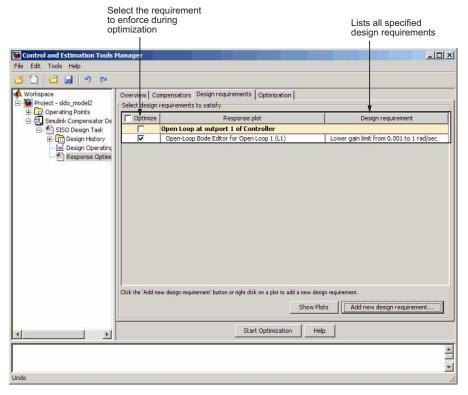

- 4 Specify the design requirements.
  - a In the **Design requirements** tab, click **Add new design requirement**. Specify the design requirements, for example Bode magnitude lower limit, in the New Design Requirement dialog box.

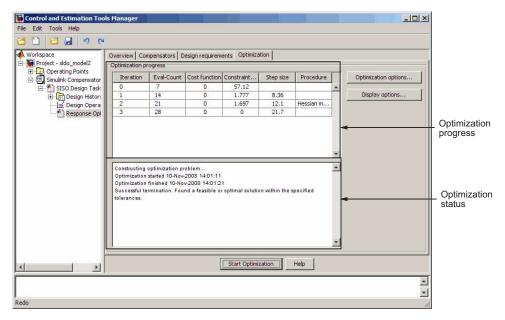

In the SISO Design window, the yellow region with the black line segment represents the design requirement on the response plot.

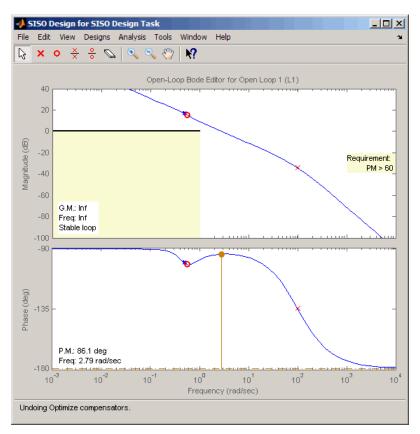

The **Design Requirements** tab also lists the design requirement.

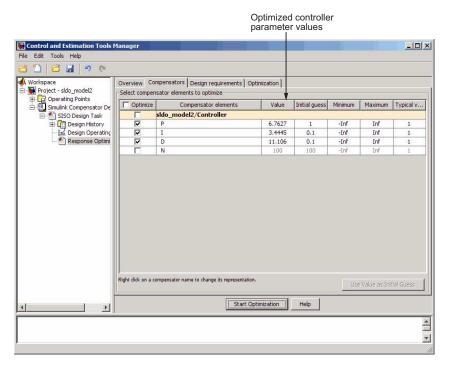

- **b** Repeat step a to specify additional time- and frequency-domain requirements.
- 5 Start the optimization to design the controller by clicking **Start Optimization** in the **Optimization** tab.

- **6** Evaluate the controller design.
  - Examine the system's response in the response plot, for example the Bode plot, to see if it meets the requirements. The system's response must lie in the white region in order to meet the design requirement.

**b** Examine the controller parameter values in the **Compensator** tab.

Write the controller parameter values into the Simulink model. To do so, click Update Simulink Block Parameters in the SISO Design Task node.

## **About This Tutorial**

- "Objectives" on page 4-15
- "About the Model" on page 4-15
- "Design Requirements" on page 4-16

### **Objectives**

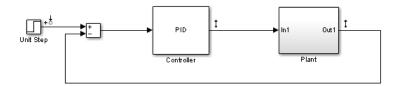

In this tutorial, you learn to use optimization methods to design a PID controller to meet frequency-domain design requirements on a system's response.

You accomplish the following tasks using the GUI:

- Specify frequency-domain Bode magnitude and phase margin requirements.
- Design an initial controller to meet the frequency-domain requirements.
- · Refine the initial controller design to limit the controller's output signal.

#### About the Model

In this tutorial, you use the Simulink model named sldo\_model2, as shown in the next figure.

The model contains a Controller block, which is a PID Controller. This block controls the output of the Plant subsystem.

Using the Simulink Control Design software has linearized the Simulink model at the operating point specified in the model. The sldo\_model2.mat file contains a preconfigured SISO Design Tool session saved after linearizing the model. To learn more about linearizing Simulink models for control design, see "Control Design".

Double-click the Plant subsystem to open it. The plant is modeled as a second-order system with delay. It contains Transfer Function and Transport Delay blocks, as shown in the next figure.

To learn more about the blocks, see Transfer Fcn and Transport Delay block reference pages.

### **Design Requirements**

The compensator you design in this tutorial must meet the following design requirements:

- Bode lower magnitude bound of 0 in the frequency range 1e-3 to 1 rad/sec
- · Phase margin greater than 60 degrees
- Controller output bounds in the range [-250 550]

# Configuring a Project for Optimization-Based Control Design

To design a linear controller for a Simulink model, you must first configure a Control and Estimation Tools Manager project.

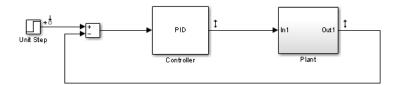

1 Open a SISO Design Tool session for the linearized Simulink model by typing the following command at the MATLAB prompt:

```
controlSystemDesigner('sldo_model2.mat')
```

**Note:** sldo\_model2.mat file contains a preconfigured SISO Design Tool session. This session was saved after Simulink Control Design software linearized the sldo model2 Simulink model.

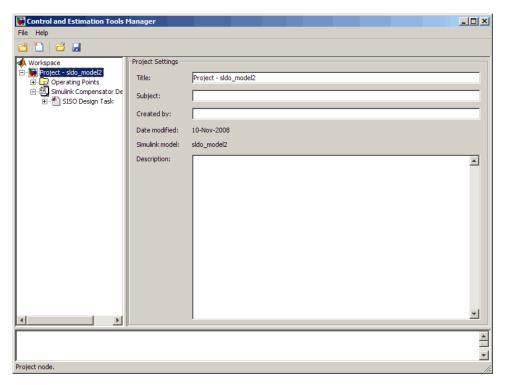

This command opens the following windows:

· Simulink model

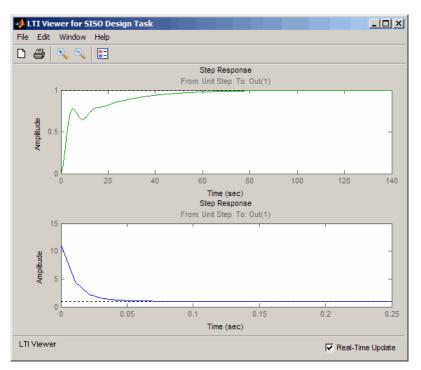

To learn more about the model, see "About the Model" on page 4-15.

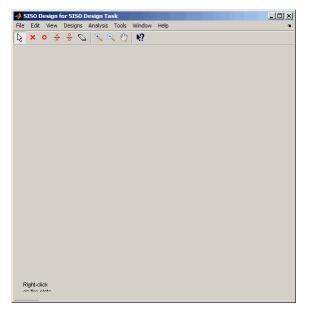

Control and Estimation Tools Manager GUI, which contains a **SISO Design Task** node under the **Simulink Compensator Design Task** node.

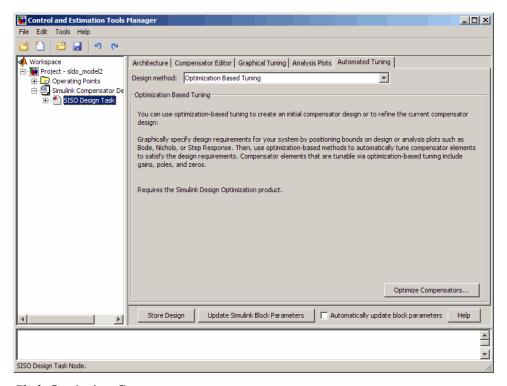

- Linear System Analyzer for SISO Design Task window, which contains the following plots:
  - · Closed-loop step response of the system in the top plot
  - Output of the Controller block in the bottom plot

· A blank SISO Design for SISO Design Task window

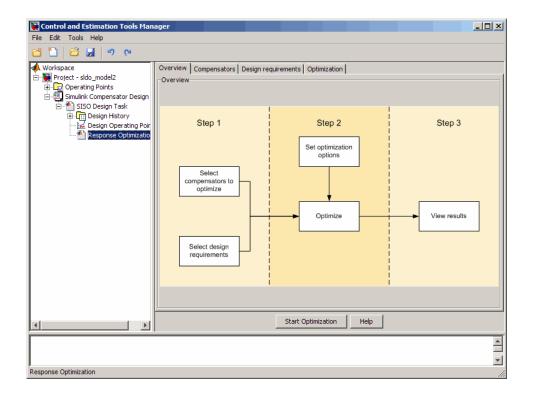

2 In the Control and Estimation Tools Manager GUI, select the **Automated Tuning** tab in the **SISO Design Task** node.

## 3 Click Optimize Compensators.

This action creates a new **Response Optimization** node.

# Designing an Initial PID Controller to Meet Bode Magnitude and Phase Margins Requirements

- "Specifying the Controller Parameters" on page 4-22
- "Specifying Bode Magnitude and Phase Margin Design Requirements" on page 4-26
- "Designing the Controller" on page 4-36

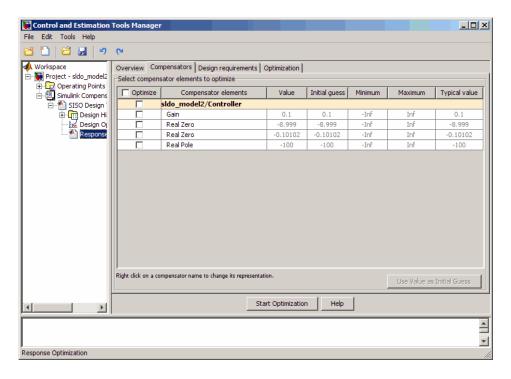

# **Specifying the Controller Parameters**

In this portion of the tutorial, you specify the controller parameters to design.

You must have already configured a project for control design, as described in "Configuring a Project for Optimization-Based Control Design" on page 4-16.

To specify the controller parameters to design:

1 In the Control and Estimation Tools Manager GUI, select the **Compensators** tab in the **Response Optimization** node.

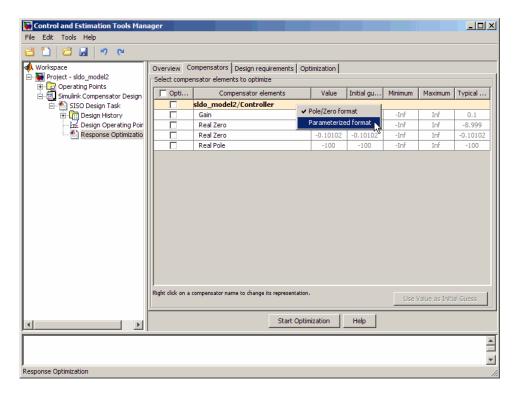

The controller parameters appear as poles and zeros in the **Compensator elements** column and represent the following:

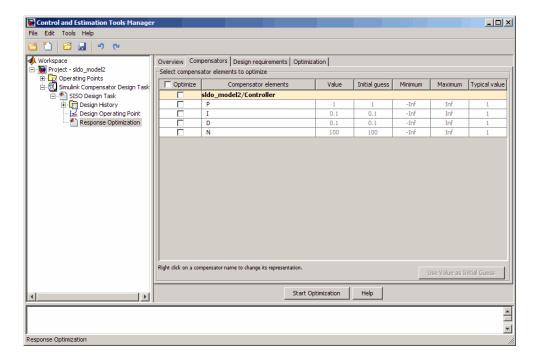

- Gain Overall gain of the controller
- · Real zeros Zeros resulting from the differentiator and integrator
- ullet Real pole Pole resulting from the low-pass filter of the differentiator

**Tip** To view the structure of the Controller block, right-click the block and select **Mask > Look Under Mask**.

**2** For convenience, change the PID controller parameters to Simulink block mask parameters format. To do so, right-click the **sldo\_model2/Controller** column, and select **Parameterized format**.

This action displays the controller parameters as Simulink block mask parameters P, I, and D, as shown in the next figure. To learn more about mask parameters, see "Mask Parameters" in the Simulink documentation.

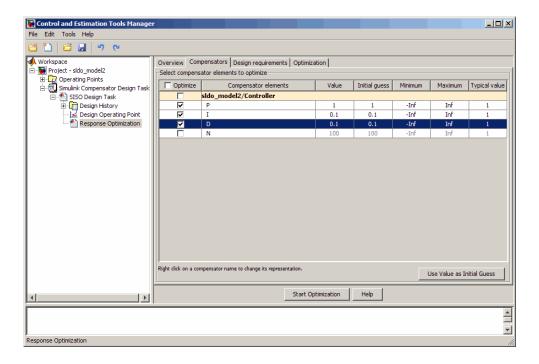

The **Compensators** tab displays the following parameter settings:

- · Value Current controller parameter value
- Initial Guess Initial controller parameter value
- ${\bf Minimum}$  and  ${\bf Maximum}$  Controller parameter bounds
- Typical Value Scaling factor for the controller parameter

**Note:** Compensator elements or parameters cannot have uncertainty when used with frequency-domain based response optimization.

 ${f 3}$  In the  ${f Optimize}$  column, select the check boxes for P, I, and D.

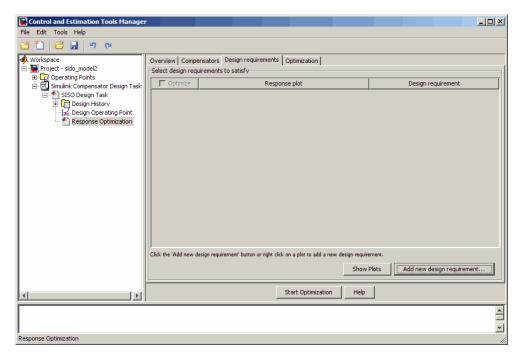

# Specifying Bode Magnitude and Phase Margin Design Requirements

In this portion of the tutorial, you specify the Bode magnitude and phase margin requirements that the controller must satisfy.

Before you specify the design requirements, you can specify the controller parameters to design, as described in "Specifying the Controller Parameters" on page 4-22.

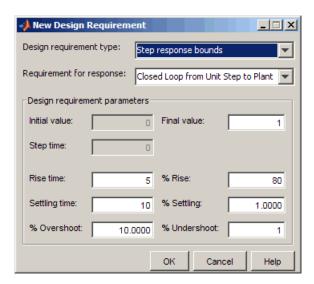

To specify the Bode design requirements:

In the **Response Optimization** node of the Control and Estimation Tools Manager GUI, select the **Design requirements** tab.

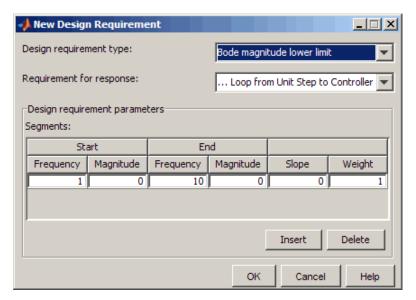

# 2 Click Add new design requirement.

This action opens the New Design Requirement dialog box.

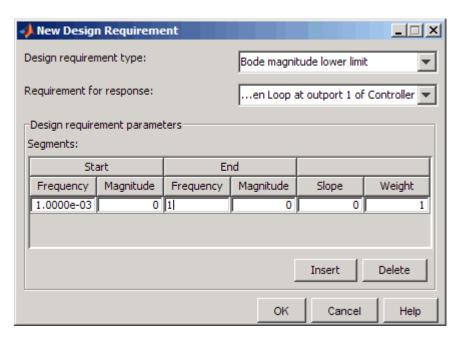

- **3** Specify the Bode magnitude lower limit requirement:
  - a In the New Design Requirement dialog box, select Bode magnitude lower limit from the **Design requirement type** drop-down list.

This action updates the New Design Requirement dialog box, as shown in the next figure.

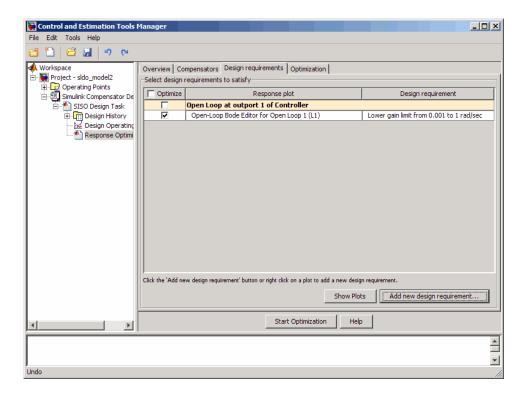

- **b** Select Open Loop at outport 1 of Controller from the **Requirement for response** drop-down list.
- c In the Frequency field of the Start column, enter 1e-3.
- **d** In the **Frequency** field of the **End** column, enter 1.

The New Design Requirement dialog box resembles the following figure.

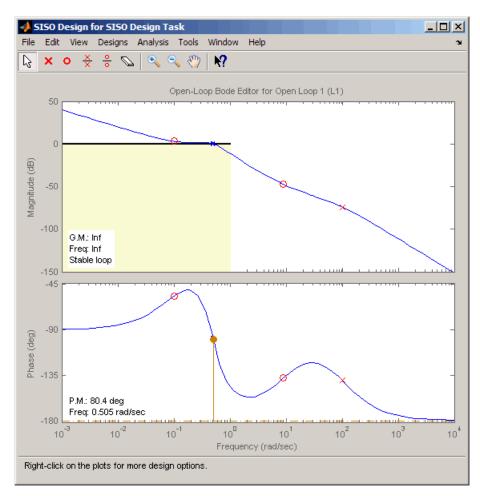

e Click OK to close the New Design Requirement dialog box.

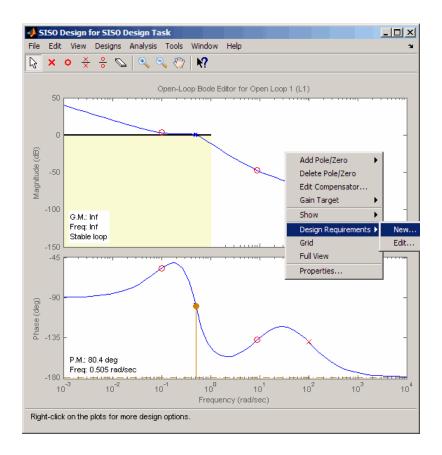

The Bode lower magnitude limit is added to the **Design requirements** tab, as shown in the next figure.

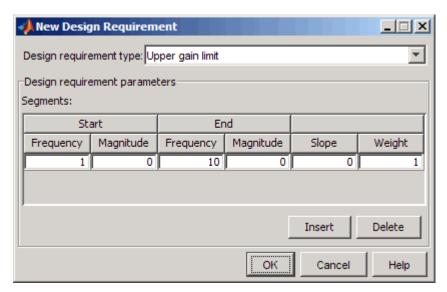

The SISO Design for SISO Design task window also updates to show the Bode plot with the design requirement displayed as the black line segment.

- 4 Add the phase margin requirement:
  - a In the SISO Design window, right-click the white area on the top plot, and select Design requirement > New.

This action opens the New Design Requirement dialog box, as shown in the next figure.

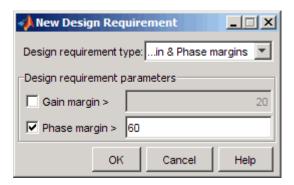

**b** In the New Design Requirement dialog box, select Gain & phase margins from the **Design requirement type** drop-down list.

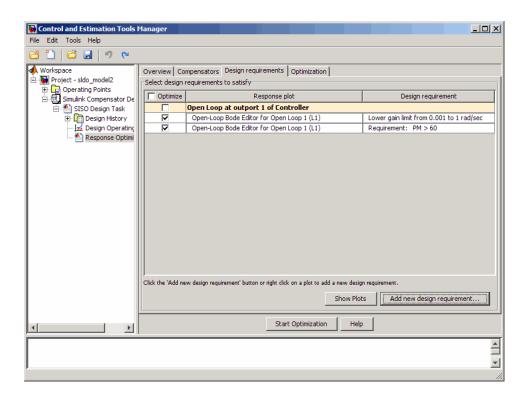

The New Design Requirement dialog box updates to display the **Gain Margin** > and **Phase Margin** > options, as shown in the next figure.

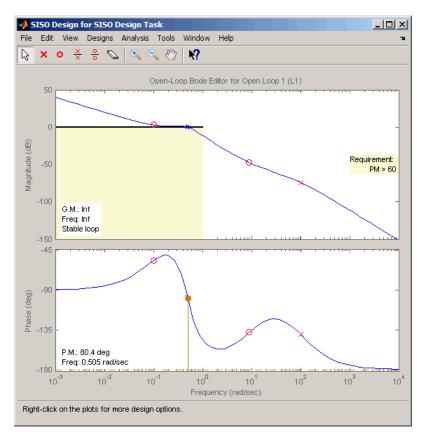

c Select the **Phase margin >** check box, and enter **60** in the adjacent field. Then, click **OK** to close the dialog box.

The **Design requirements** tab in the Control and Estimation Tools Manager GUI updates. It now displays the phase margin requirement, as shown in the next figure.

The SISO Design window also updates to display the phase margin requirement.

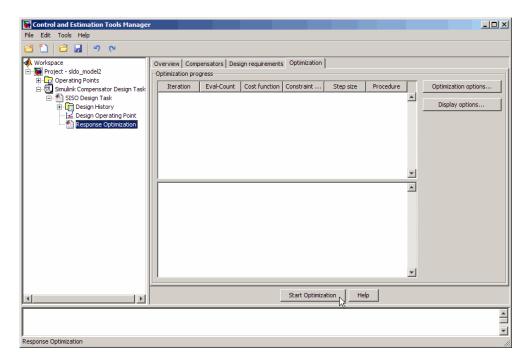

## **Designing the Controller**

In this portion of the tutorial, you design the controller to meet the Bode magnitude and phase requirements.

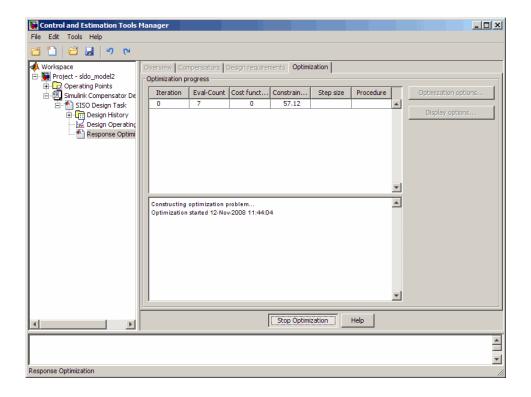

You must have already specified the controller parameters to design, as described in "Specifying the Controller Parameters" on page 4-22, and the design requirements, as described in "Specifying Bode Magnitude and Phase Margin Design Requirements" on page 4-26.

To design the controller:

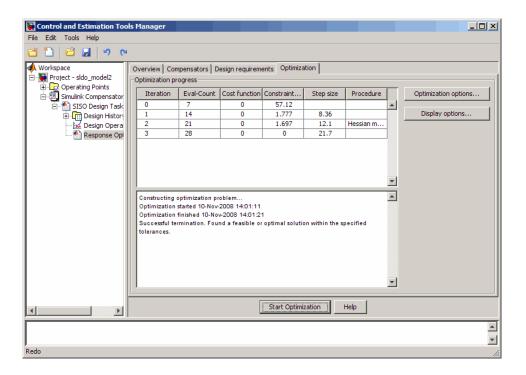

1 In the Optimization tab, click Start Optimization.

The **Optimization** tab updates as shown in the next figure.

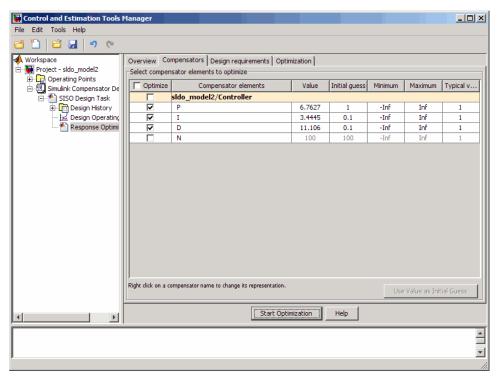

- At every optimization iteration, the default optimization method **Gradient descent** reduces the distance between the current response and the magnitude requirement line segment by modifying the controller parameters. Simultaneously, the software also computes the phase margin and reduces the distance between the current response and the phase margin. To learn more about the optimization method, see "Selecting Optimization Methods".
- After the optimization completes, the **Optimization** tab displays the
  optimization iterations and status, as shown in the next figure.

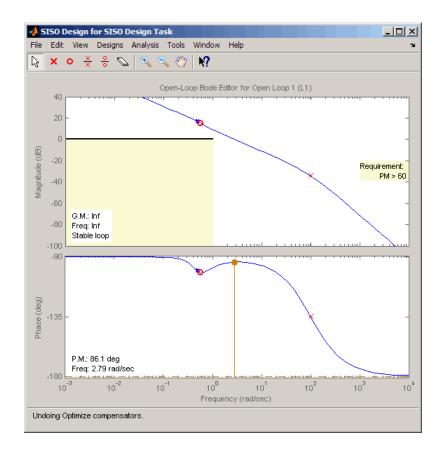

The message Successful termination indicates that the optimization method found a solution that meets the design requirements. For more information about the outputs displayed in the **Optimization progress** table, see "Iterative Display" in the Optimization Toolbox documentation.

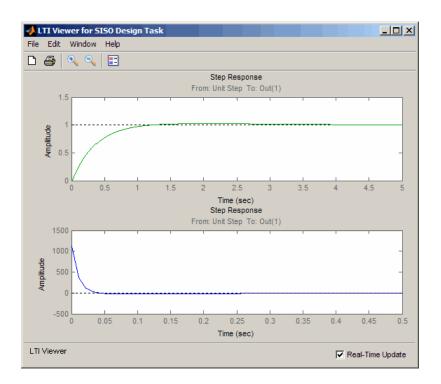

- **2** Examine the controller parameters and the system's response:
  - view the optimized parameter values in the Value field of the Compensator tab.

- **b** Examine the system's response on the following plots:
  - The SISO Design window

- The top plot shows that the magnitude of the system, displayed as the blue curve, lies outside the yellow region. This plot indicates that the system has met the Bode magnitude requirement.
- The bottom plot displays the phase margin (P.M.) value of 86.1 degrees. This indicates that the system has met the phase margin design requirement of >60 degrees.
- · The Linear System Analyzer

- The top plot shows that the closed-loop response of the system is stable. The system with the designed controller thus meets both the magnitude and phase margin requirements.
- The bottom plot in the Linear System Analyzer shows that the peak value of the controller's output is 1000, which is very large and can cause damage to the plant. To limit the controller output, you apply lower and upper bounds on the signal, as described in "Refining the Controller Design to Meet Controller Output Bounds" on page 4-42.

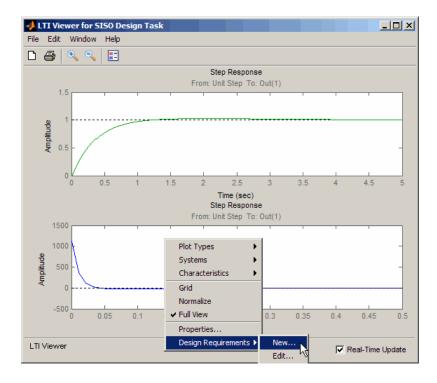

## Refining the Controller Design to Meet Controller Output Bounds

In this portion of the tutorial, you refine the controller to satisfy bounds on the controller's output.

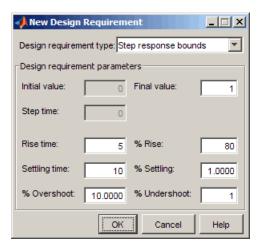

You must have already designed an initial controller, as described in "Designing an Initial PID Controller to Meet Bode Magnitude and Phase Margins Requirements" on page 4-22.

To tune the compensator parameters to meet the bounds on the controller's signal:

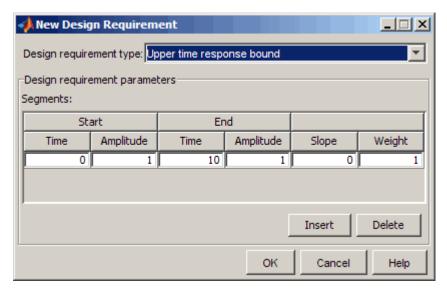

- 1 Add the upper-bound on the controller's output:
  - **a** In the Linear System Analyzer, right-click the white area on the bottom plot, and select **Design requirement > New**.

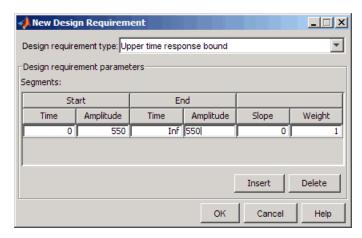

This action opens the New Design Requirement dialog box.

**b** In the New Design Requirement dialog box, select Upper time response bound from the **Design requirement type** drop-down list.

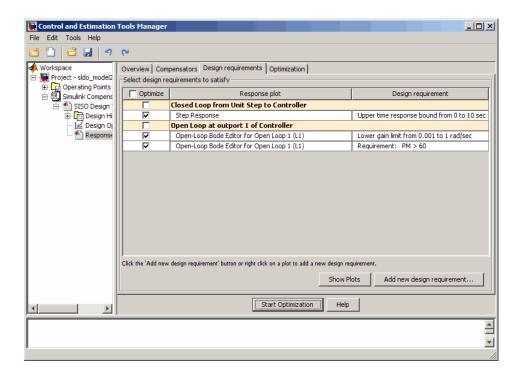

- c In the **Time** field of the **End** column, enter **Inf**.
- **d** In the **Amplitude** field of the **Start** column, enter 550.
- e In the Amplitude field of the End column, enter 550.

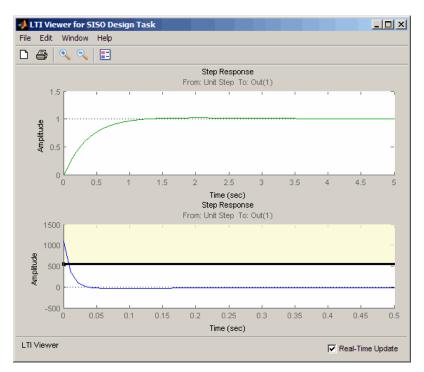

**f** Click **OK** to close the dialog box.

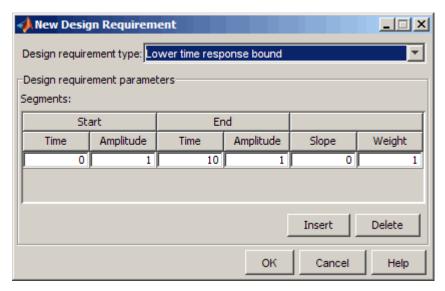

The **Design requirements** tab in the Control and Estimation Tools Manager GUI updates. It now displays the upper-bound requirement, as shown in the next figure.

The Linear System Analyzer also updates to show the design requirement, as shown in the next figure.

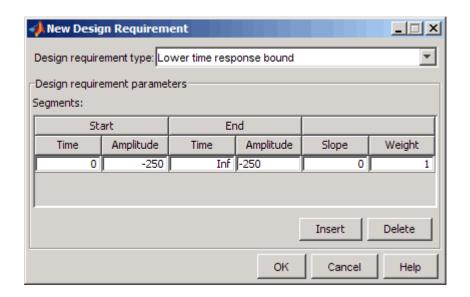

- **2** Add the lower-bound on the controller's output:
  - Right-click the white area in the bottom plot in the Linear System Analyzer, and select **Design requirement > New**.
    - This action opens the New Design Requirement dialog box.
  - **b** Select Lower time response bound from the **Design requirement type** drop-down list.
    - The New Design Requirement dialog box updates to show the lower bound, as shown in the next figure.

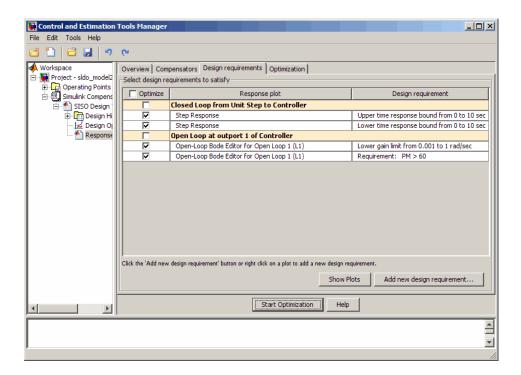

- c In the **Time** field of the **End** column, enter **Inf**.
- **d** In the **Amplitude** field of the **Start** column, enter -250.
- e In the Amplitude field of the End column, enter -250.

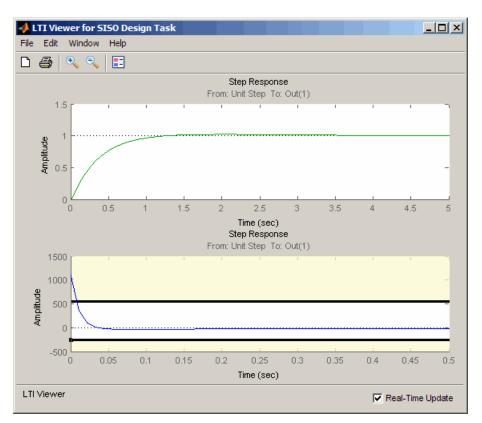

The New Design Requirement dialog box resembles the next figure. Click  $\mathbf{OK}$  to close the dialog box.

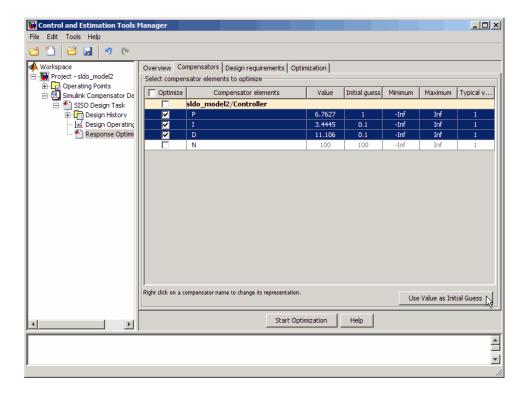

The **Design requirements** tab in the Control and Estimation Tools Manager GUI updates. It now displays the lower-limit requirement, as shown in the next figure.

The Linear System Analyzer also updates to show the lower-bound on the controller's output, as shown in the next figure.

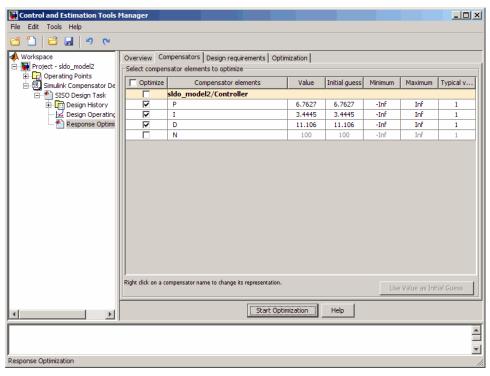

- **3** Optimize the parameters to meet the design requirements on the controller output:
  - a In the Compensators tab, select the rows containing P, I, and D, and click Use Value as Initial Guess.

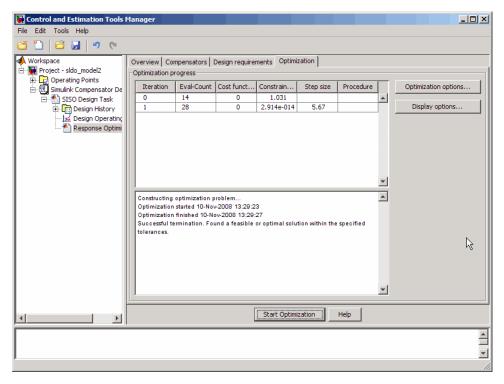

When you run the optimization again, the optimization method uses the updated parameter values as the starting point for refining the values.

Clicking **Use Value as Initial Guess** updates the values in the **Initial Guess** column, as shown in the next figure.

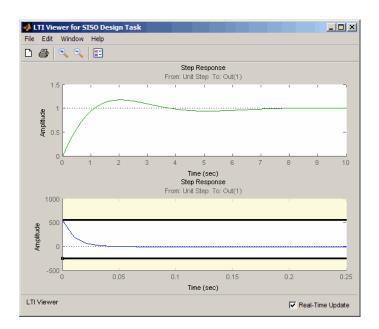

## **b** In the **Optimization** tab, click **Start Optimization**.

- At every optimization iteration, the optimization method reduces the distance between the current response and the upper and lower bounds on the signal.
- After the optimization completes, the **Optimization** tab resembles the next figure.

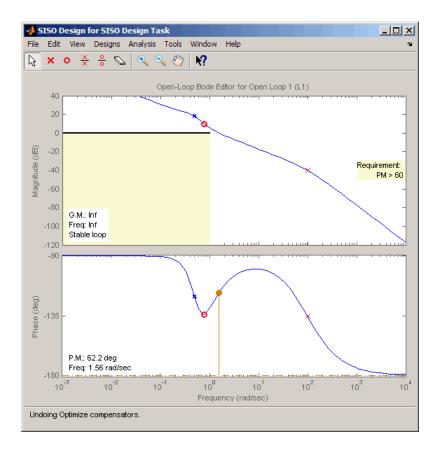

- **4** Examine the parameter values refined controller and the system's response:
  - **a** Examine the following response plots:
    - The Linear System Analyzer

The bottom plot shows that the controller output lies between 550 and -250, and thus meets the design requirement on the controller's output.

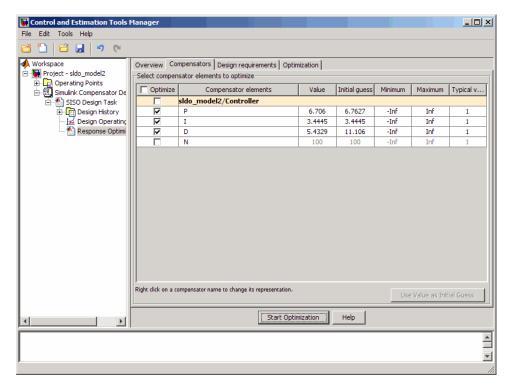

**Note:** You must also check that the closed-loop response, shown in the top plot, remains stable after refining the controller design.

The SISO Design window

The plots show that after refining the design, the system continues to meet the magnitude and phase margin requirements specified in "Design Requirements" on page 4-16.

**b** View the optimized controller parameter values in the **Value** field in the **Compensators** tab.

5 Select the SISO Design Task node, and click Update Simulink Block Parameters.

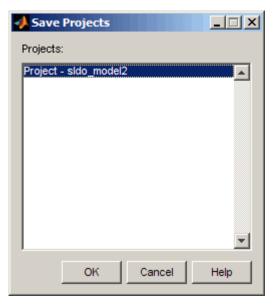

This action writes the optimized controller parameter values to the Controller block in the Simulink model.

## Saving the Project

To save a project with the optimized controller parameters:

1 In Control and Estimation Tools Manager GUI, select **File > Save**.

This action opens the Save Projects dialog box.

- 2 In the Save Projects dialog box, select **Project sldo\_model2**, and click **OK** to open the Save Projects window .
- 3 In the Save Projects window, enter sldo\_model2\_optimized.mat in the File name field, and click Save.

The action saves the project as a MAT-file.

**Tip** You can reload this project by typing controlSystemDesigner('sldo\_model2\_optimized') at the MATLAB prompt.
