#### How to Rotate a Block

You can rotate a block 90 degrees by selecting one of these commands from the **Diagram** menu:

- **Rotate & Flip > Clockwise** (or **Ctrl+R**)
- **Rotate & Flip > Counterclockwise**

A rotation command effectively moves a block's ports from its sides to its top and bottom or from its top and bottom to its sides, depending on the initial orientation of the block. The final positions of the block ports depend on the block's *port rotation type*.

#### Port Rotation Type

After rotating a block clockwise, Simulink may, depending on the block, reposition the block's ports to maintain a left-to-right port numbering order for ports along the top and bottom of the block and a top-to-bottom port numbering order for ports along the

left and right sides of the block. A block whose ports are reordered after a clockwise rotation is said to have a *default port rotation* type. This policy helps to maintain the left-right and top-down block diagram orientation convention used in control system modeling applications. All nonmasked blocks and all masked blocks by default have the default rotation policy. The following figure shows the effect of using the **Rotate & Flip > Clockwise** command on a block with the default rotation policy.

A masked block can optionally specify that its ports not be reordered after a clockwise rotation (see “Port rotation”). Such a block is said to have a *physical port rotation* type. This policy facilitates layout of diagrams in mechanical and hydraulic systems modeling and other applications where diagrams do not have a preferred orientation. The following figure shows the effect of clockwise rotation on a block with a physical port rotation type

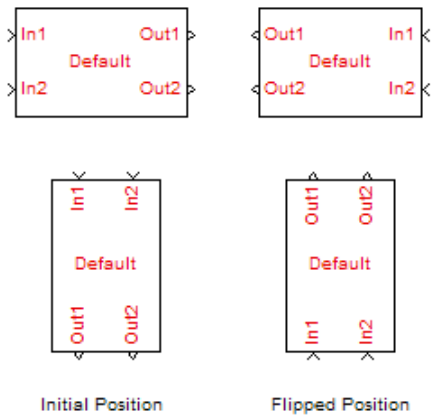

## How to Flip a Block

Simulink provides a set of commands that allow you to flip a block 180 degrees about its horizontal or vertical axis. The commands effectively move a block's input and output

ports to opposite sides of the block or reverse the ordering of the ports, depending on the block's port rotation type.

A block with the default rotation type has one flip command: **Diagram > Rotate & Flip > Flip Block (Ctrl+I)**. This command effectively moves the block's input and output ports to the side of the block opposite to the side on which they are initially located, i.e., from the left to the right side or from the top to the bottom side.

## Resize a Block

To change the size of a block, select it, then drag any of its selection handles. While you hold down the mouse button, a dotted rectangle shows the new block size. When you release the mouse button, the block is resized.

For example, the following figure below shows a Signal Generator block being resized. The lower-right handle was selected and dragged to the cursor position. When the mouse button is released, the block takes its new size.

---

**Tip** Use the model editor's resize blocks commands to make one block the same size as another (see “Align, Distribute, and Resize Groups of Blocks” on page 4-18).

---

## Displaying Parameters Beneath a Block

You can cause Simulink to display one or more of a block's parameters beneath the block. Specify the parameters to be displayed by using one of the following approaches:

- Enter an attributes format string in the **Attributes format string** field of the block's **Properties** dialog box (see “Set Block Properties” on page 31-4)
- Set the value of the block's `AttributesFormatString` property to the format string, using `set_param`

## Drop Shadows

By default, blocks appear with a drop shadow.

To increase the depth of a block drop shadow:

- 1 Select the block.
- 2 Select **Diagram > Format > Block Shadow**.

For example, in this model, the `Constant1` block has the **Block Shadow** option enabled, and the `Constant2` block uses the default drop shadow.

To remove the default drop shadows for all blocks, select **File > Simulink Preferences > Editor Defaults > Use classic diagram theme**.

## Manipulate Block Names

All block names in a model must be unique and must contain at least one character. By default, block names appear below blocks whose ports are on the sides, and to the left of blocks whose ports are on the top and bottom, as the following figure shows:

---

**Note** Simulink commands interprets a forward slash (/) as a block path delimiter. For example, the path `vdp/Mu` designates a block named `Mu` in the model named `vdp`. Therefore, avoid using forward slashes (/) in block names to avoid causing Simulink to interpret the names as paths.

---

### Change Block Names

You can edit a block name in one of these ways:

- To replace the block name, click the block name, select the entire name, and then enter the new name.
- To insert characters, click between two characters to position the insertion point, then insert text.
- To replace characters, drag the mouse to select a range of text to replace, then enter the new text.

To apply the block name edit, click the cursor anywhere else in the model, take any other action, or press **Esc**. If you try to change the name of a block to a name that already exists, Simulink displays an error message.

---

**Note** If you change the name of a library block, all links to that block become unresolved.

---

### Change Font of Block Name

To modify the font used in a block name by selecting the block, then choosing the **Font Style** menu item from the **Diagram > Format** menu.

- 1 Select the block name.
- 2 Select **Diagram > Format > Font Style**.

The Select Font dialog box opens.

- 3 Select a font and specify other font characteristics, such as the font size.

---

**Note:** Changing the block name font also changes the font of any text that appears inside the block.

---

This procedure also changes the font of any text that appears inside the block.

### **Change the Location of a Block Name**

To change the location of the name of a selected block, use one of these approaches:

- Drag the block name to the opposite side of the block.
- Choose **Diagram > Rotate & Flip > Flip Block Name**. This command changes the location of the block name to the opposite side of the block.

For more information about block orientation, see “How to Rotate a Block” on page 31-12.

### **Hide a Block Name**

By default the Simulink Editor displays the names of blocks (except for a few blocks, such as the Bus Creator block). To hide the name of a selected block, clear the **Diagram > Format > Show Block Name** menu option.

### **Specify Block Color**

See “Specify Block Diagram Colors” on page 4-4 for information on how to set the color of a block.

## Display Port Values for Debugging

### In this section...

“Display Port Values for Easy Debugging” on page 31-18

“Display Value for a Specific Port” on page 31-22

“Display Port Values for a Model” on page 31-25

“Port Value Display Limitations” on page 31-26

### Display Port Values for Easy Debugging

For many blocks whose signals carry data, Simulink can display signal values (block output) as port value labels (similar to tool tips) on the block diagram during and after a simulation. Port value labels display block output values when Simulink runs block output methods. This model shows a port value label for the port on the Fcn block, an output value of  $-3.03$ .

If the port value label appears empty, this means that no port value is currently available. For example, toggling a port value label on a continuous block when paused during simulation does not display any values in the label.

Port value labels are also empty when you have not yet simulated the model. This is because the block output methods do not run when the model does not simulate.

If you toggle or hover on a block that Simulink optimizes out of a simulation (such as a virtual subsystem block), while you simulate, the model displays the string `optimized`.

Displaying port value data tips can help during interactive debugging of a model. For example, the figure shows the output of a thermal model for a house.

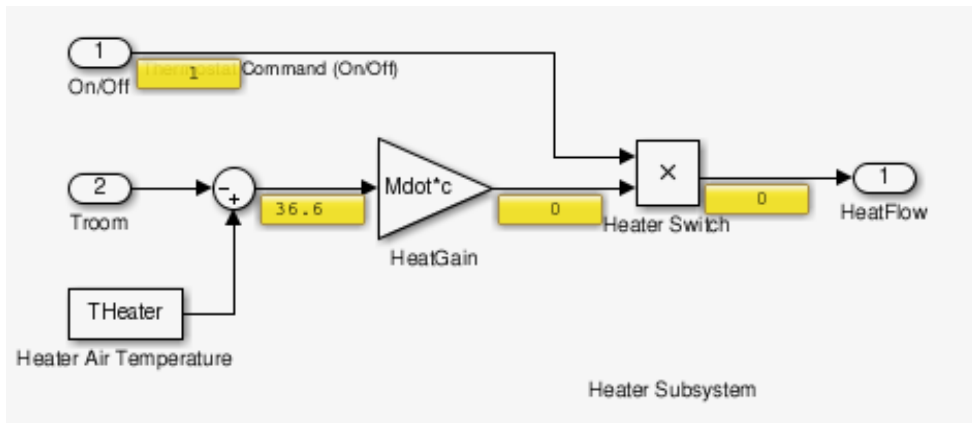

These results suggest a problem with the model because:

- The heating cost is 0 at all temperatures.
- The temperature inside the house matches ambient temperature almost exactly.

In such cases, debugging the blocks in the model interactively can help isolate the error. Port value labels provide information at the output of every block in the model. So in this example, if you step forward using Simulation Stepper, you can see that the output of the Heater subsystem is 0 at every time step.

To learn more, you can enable port value labels for blocks inside the Heater subsystem. Using Simulation Stepper, if you step forward again to display the values, you can see that there is an issue with the HeatGain block. The output is constant at 0.

This technique helps you isolate the issue.

To simplify debugging, you can turn on and off port value labels during simulation. Besides providing useful information for debugging, port value displays can help you monitor a signal value during simulation. However, these labels are not saved with a model.

For non-numeric data display, Simulink uses these strings:

| Message           | Explanation   |
|-------------------|---|
| action            | The signal executes action subsystems.  |
| fcn-call          | The signal is a function-call signal, e.g., Function Call Generator output.                     |
| ground            | The signal is coming from a Ground block.   |
| not a data signal | The signal does not contain valid data, e.g., the signal is from a block that is commented out. |

In some cases:

- The port value display may not be able to acquire the value signal or
- The signal's value cannot be easily displayed

In such cases, Simulink uses these strings:

| Message              | Explanation  |
|----------------------|--|
| ...                  | The signal dimension exceeds the maximum number of elements Simulink can display. For more information, see "Display Port Values for a Model" on page 31-25. |
| (no message)         | The simulation data available is insufficient. Step forward or press play to obtain more data.   |
| click to add signals | You have enabled a port value label on a bus. However, you have not selected a signal to display. Click the label to select bus signals.                     |
| inaccessible         | Simulink cannot obtain the port value. For an example, see "Signal Storage Reuse" on page 31-26.   |
| [m*n]                | This is a nonvector signal. Simulink cannot display the actual values of the matrix. It displays the matrix dimension instead.                               |

| Message     | Explanation   |
|-------------|---|
| no data yet | This message appears when: <ul style="list-style-type: none"><li>• The simulation data is not available. Start the simulation to see values.</li><li>• If the model contains subsystems (e.g enabled subsystem) and model references and they are not executed during a simulation.</li></ul> |
| not used    | Simulink cannot obtain the signal value due to optimization.  |
| removed     | Simulink cannot obtain the signal value due to block reduction.   |
| optimized   | Simulink cannot obtain the signal value due to optimization.  |
| unavailable | The simulation data available is insufficient. For example, see “Simulation Stepper” on page 31-27.   |

---

**Note:** You can force a value label to display the signal value by designating the signal as a test point. Use the **Properties** dialog box to do this.

---

## Display Value for a Specific Port

To display the value of a specific port or port values for a block, follow one of these steps:

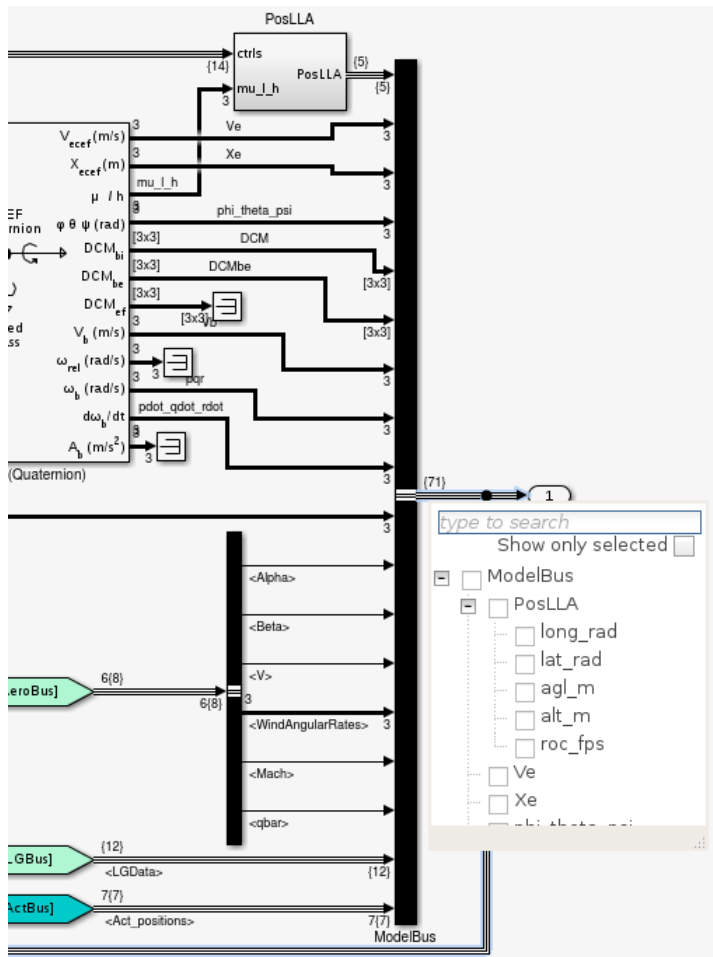

- Right click on the signal and select **Show Value Label of Selected Port**.
- In Simulink Editor, select the signal and click on **Display > Data Display in Simulation > Show Value Label of Selected Port**.

---

**Note:** To remove all data tips, select **Display > Data Display in Simulation > Remove All Value Labels**.

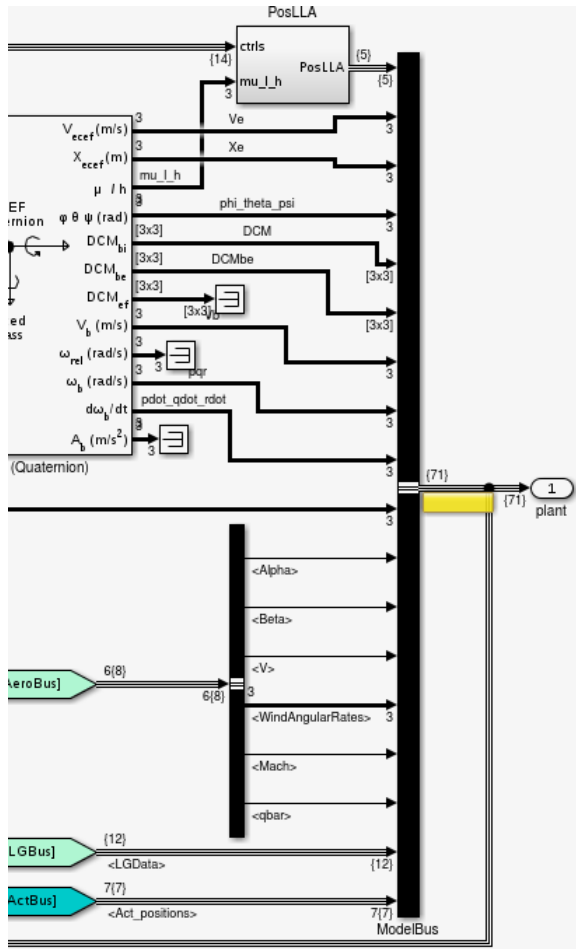

---

For bus signals, the **Show Value Label of Selected Port** option opens a dialog box where you can select from all signals in the bus. For example, in this model, you can see the dialog box for all signals that are contained in ModelBus.

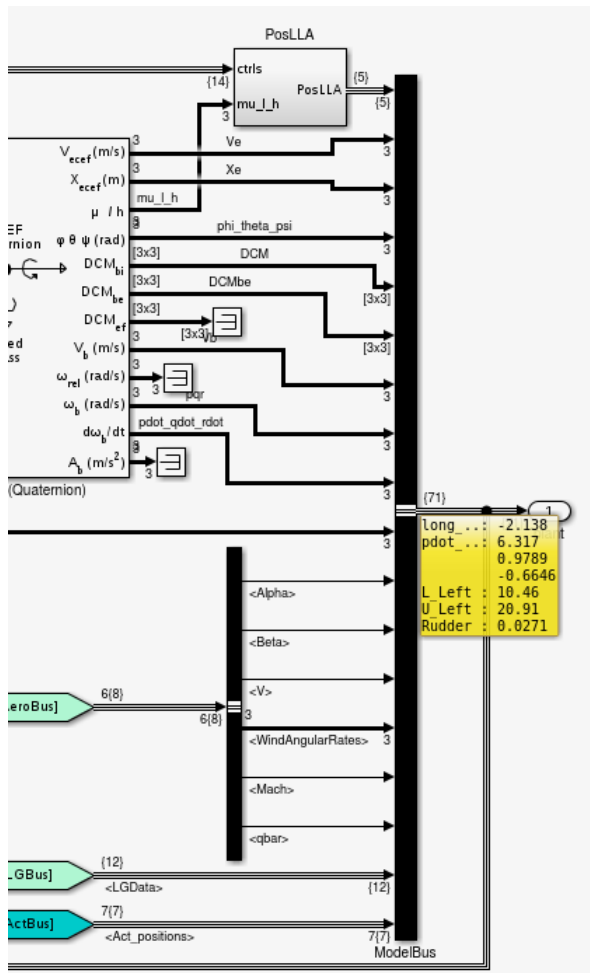

You can search for a signal by name or filter through the hierarchy. Select a parent signal to include all of the signals it contains. You can also filter the display to view only those signals you have selected.

Click anywhere outside the dialog box to close it. The port value label appears. The label is empty; it displays values when you simulate the model.

When you simulate the model, the port value label displays the names and values of the signals you chose. To change the signals to display, click on the port value label to reopen the dialog.

## Display Port Values for a Model

Specify port value display formatting and the frequency of updates. The Value Label Display Options dialog box controls these settings on the entire model.

- 1 In the model whose port values you want to display, select **Display > Data Display in Simulation > Options**.
- 2

- 3 In the Value Label Display Options dialog box, specify your preferences for:
- The display options, including font size, the refresh frequency, and the number of elements displayed for vector signals with signal widths greater than 1
  - The display mode
  - Floating-point or fixed-point format

## Port Value Display Limitations

### Performance

Enabling the hovering option for a model or setting at least one block to **Toggle Value Labels When Clicked** slows down simulation.

### Accelerated Modes

Port values work in Normal and Accelerator modes only. They do not work in Rapid Accelerator and External modes. The table shows how accelerator modes affect the display of port values.

| Accelerated Mode  | Port Values   |
|-------------------|---|
| Accelerator       | <ul style="list-style-type: none"> <li>• Signals not optimized in Accelerator mode display port values as in Normal mode. Signals optimized in Accelerator mode display port values as <b>optimized</b>. For more information, see “Display Port Values for Easy Debugging” on page 31-18.</li> <li>• Model reference blocks simulated in Accelerator mode do not get their port value displays updated.</li> </ul> |
| Rapid Accelerator | Incompatible. The limitation exists whether the model or its parent specifies accelerated simulation. For more information, see “Rapid Simulations”.  |

### Signal Storage Reuse

If the output port buffer of a block is shared with another block through the optimization of signal storage reuse, the port value displays as **inaccessible**. You can disable signal storage reuse using the **Configuration Parameters > Optimization > Signals and Parameters > Signal storage reuse** check box. However, disabling signal storage reuse increases the memory used during simulation.

## Signal Data Types

- Simulink displays the port value for ports connected to most kinds of signals, including signals with built-in data types (such as `double`, `int32`, or `Boolean`), `DYNAMICALLY_TYPED`, and several other data types.
- Simulink shows the floating format for only noncomplex signal value displays.
- Simulink displays the port value of fixed point data types based on the converted double value.
- Simulink does not display data for signals with some composite data types, such as bus signals.

## Subsystems

- You cannot display port values for subsystems contained in a variant subsystem when there are no signal lines connecting to them. In such cases, during simulation, Simulink automatically determines block connectivity based on the active variant. However, you can display port values within the subsystems contained in the variant subsystem. You can also display values on signal lines outside of the variant subsystem.
- When you disable a conditionally executed subsystem, the port value display for a signal that goes into an Outport block displays the value of the Outport block, depending on the **Output when disabled** setting.
- Simulink does not display data for the ports of an enabled subsystem that is not enabled.

## Simulation Stepper

If you do not enable port value display when stepping forward, the display will not be available when stepping back. When stepping back, if the port value is unavailable, the unavailable label is displayed.

## Refine Factor

Port value displays do not honor refine factor values (**Configuration Parameters > Data Import/Export > Refine factor**) because Simulink updates port value displays only during major time steps.

## Signal Specification Block and Inport Block

When you display port values on Signal Specification and Inport blocks in a subsystem, the value that is driving the blocks displays instead of the block values.

**Command-Line Simulations**

For efficiency, Simulink does not support port value displays during a command-line simulation using the `sim` command.

**Merge Block**

Simulink does not display the output value of a merge block. To see this value, refer to the source block.

**Command Line Interface**

You cannot specify port value displays through the command line interface.

**Non-Simulink signals**

You cannot place port values on non-Simulink signals, such as Simscape or SimEvents signals. This limitation applies to conditional breakpoints as well.

## Control and Display the Sorted Order

### In this section...

- “What Is Sorted Order?” on page 31-29
- “Display the Sorted Order” on page 31-29
- “Sorted Order Notation” on page 31-30
- “How Simulink Determines the Sorted Order” on page 31-40
- “Assign Block Priorities” on page 31-43
- “Rules for Block Priorities” on page 31-44
- “Block Priority Violations” on page 31-47

### What Is Sorted Order?

During the updating phase of simulation, Simulink determines the order in which to invoke the block methods during simulation. This block invocation ordering is the *sorted order*.

You cannot set this order, but you can assign priorities to nonvirtual blocks to indicate to Simulink their execution order relative to other blocks. Simulink tries to honor block priority settings, unless there is a conflict with data dependencies. To confirm the results of priorities that you have set, or to debug your model, display and review the sorted order of your nonvirtual blocks and subsystems.

---

**Note:** For more information about block methods and execution, see:

- “Block Methods” on page 3-15
  - “Conditional Execution Behavior” on page 9-52
- 

### Display the Sorted Order

To display the sorted order of the vdp model:

- 1 Open the van der Pol equation model:  
vdp
- 2 In the model window, select **Display > Blocks > Sorted Execution Order**.

Simulink displays a notation in the top-right corner of each nonvirtual block and each nonvirtual subsystem. These numbers indicate the order in which the blocks execute. The first block to execute has a sorted order of 0.

For example, in the van der Pol equation model, the Integrator block with the sorted order 0:0 executes first. The Out1 block, with the sorted order 0:1, executes second. Similarly, the remaining blocks execute in numeric order from 0:2 to 0:8.

You can save the sorted order setting with your model. To display the sorted order when you reopen the model, select **Simulation > Update diagram**.

## Sorted Order Notation

The sorted order notation varies depending on the type of block. The following table summarizes the different formats of sorted order notation. Each format is described in detail in the sections that follows the table.

| Block Type                        | Sorted Order Notation | Description  |
|-----------------------------------|-----------------------|--|
| “Nonvirtual Blocks” on page 31-33 | $s:b$                 | <ul style="list-style-type: none"> <li><math>s</math> is the system index of the model or subsystem the block resides in. For root-level models, <math>s</math> is always 0.</li> <li><math>b</math> specifies the block position within the sorted order for the designated execution context.</li> </ul> |

| Block Type  | Sorted Order Notation  | Description   |
|---|--|---|
| “Nonvirtual Subsystems” on page 31-34 (not including function-call and action subsystems) | $s:b$  | <ul style="list-style-type: none"> <li><math>s</math> is the system index of the model or subsystem.</li> <li><math>b</math> specifies the block position within the sorted order for the designated execution context.</li> </ul>  |
| “Virtual Blocks and Subsystems” on page 31-36   | Not applicable   | Virtual blocks do not execute.  |
| Action Subsystems   | $s:b'$   | <ul style="list-style-type: none"> <li><math>s</math> is the system index of the model or subsystem the block resides in. For root-level models, <math>s</math> is always 0.</li> <li><math>b'</math> is the block index of the action block (but not of the action subsystem).</li> </ul>                    |
| “Function-Call Subsystems” on page 31-37 and Function-Call models                         | One non-grounded initiator:<br>$s:b^i$   | <ul style="list-style-type: none"> <li><math>s</math> is the system index of the model or subsystem the block resides in. For root-level models, <math>s</math> is always 0.</li> <li><math>b^i</math> is the block index of the root initiator in the subsystem’s hierarchy.</li> </ul>                      |
|   | Two or more initiators:<br><ul style="list-style-type: none"> <li><math>s:b^{i1}, s:b^{i2}, \dots, s:b^{in}</math> where <math>n</math> is the number of non-grounded initiators.</li> </ul> | <ul style="list-style-type: none"> <li><math>s</math> is the system index of the model or subsystem the block resides in. For root-level models, <math>s</math> is always 0.</li> <li><math>b^{in}</math> is the block index of the <math>n</math>-th root initiator in the subsystem’s hierarchy.</li> </ul> |
|   | Initiators are either Ground blocks or are unconnected:<br><ul style="list-style-type: none"> <li><math>s:G</math></li> </ul>  | <ul style="list-style-type: none"> <li><math>s</math> is the system index of the model or subsystem the block resides in. For root-level models, <math>s</math> is always 0.</li> <li><math>G</math> indicates that all function-call initiators are grounded.</li> </ul>                                     |

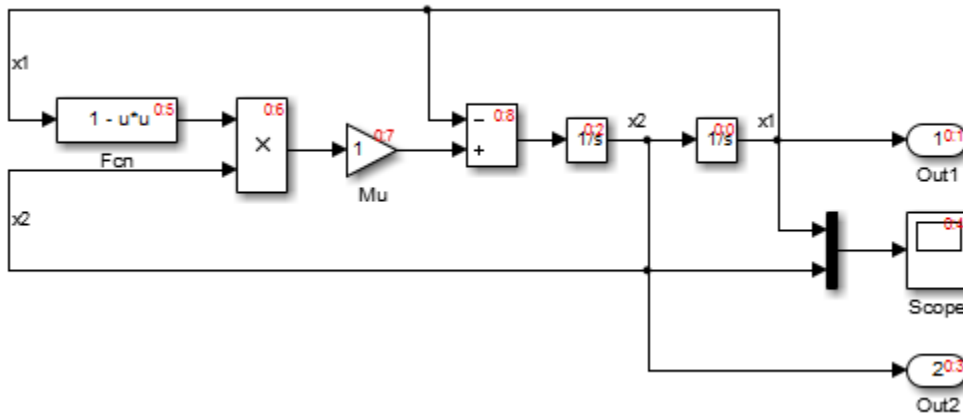

| Block Type   | Sorted Order Notation  | Description  |
|--|--|--|
| “Branched Function-Call Signals” on page 31-39           | $s : b^i [B_k]$  | <ul style="list-style-type: none"> <li>• <math>s</math> is the system index of the model or subsystem the block resides in. For root-level models, <math>s</math> is always 0.</li> <li>• <math>b^i</math> is the block index of the root initiator in the subsystem’s hierarchy.</li> <li>• <math>B_k</math> indicates that it is a branched function-call subsystem with branch index <math>k</math>.</li> </ul> |
| Function-Call Feedback Latch Blocks                      | $s : b^i [B_m]$  | <ul style="list-style-type: none"> <li>• <math>s</math> is the system index of the model or subsystem the block resides in. For root-level models, <math>s</math> is always 0.</li> <li>• <math>b^i</math> is the block index of the root initiator in the subsystem’s hierarchy.</li> <li>• <math>B_m</math> indicates that it is a branched subsystem with branch index <math>m</math>.</li> </ul>               |
| Blocks in a model with asynchronous function-call inputs | Function-call root-level Inport and Outport blocks: $F_i$  | <ul style="list-style-type: none"> <li>• <math>F</math> indicates that it is executed in a function-call context.</li> <li>• <math>i</math> is the function-call index.</li> </ul>   |
|  | Root-level data Inport blocks:<br>If they drive a function-call subsystem, it is the function-call index of the subsystem.<br><br>If they are part of the model that is not driven by asynchronous function-call inputs, then no function-call index is displayed. |  |
|  | Root-level function-call blocks: $F_i$<br>Root-level branched function-call blocks: $F_i [B_k]$  | <ul style="list-style-type: none"> <li>• <math>F</math> indicates that it is executed in a function-call context.</li> <li>• <math>i</math> is the function-call index.</li> </ul>   |

| Block Type  | Sorted Order Notation  | Description  |
|---|--|--|
| Blocks inside Export Function Models (See “Execution Order for Function-Call Root-level Inport Blocks” on page 9-8) | Function-call root-level Inport and Outport blocks: $F_i$  | <ul style="list-style-type: none"> <li>• <math>F</math> indicates that it is a function-call block.</li> <li>• <math>i</math> is the execution order for the function-call root-level Inport or Outport block in normal simulation mode.</li> </ul>  |
|   | Root-level function-call subsystems: $F_i$<br>Root-level branched function-call subsystems: $F_i[B_k]$                 | <ul style="list-style-type: none"> <li>• <math>F</math> indicates that it is a function-call block.</li> <li>• <math>i</math> is the execution order for the function-call root-level Inport block in normal simulation mode.</li> <li>• <math>B_k</math> indicates a branched function-call subsystem with index <math>k</math>.</li> </ul> |
|   | Merge and Data Store Memory blocks: $F_i, F_j, \dots$  | <ul style="list-style-type: none"> <li>• <math>F</math> indicates that it is a function-call block.</li> <li>• <math>i</math> is the block execution index.</li> </ul>   |
|   | Root-level data Inport and Outport blocks: Same execution order as the function-call subsystems they are connected to. |  |
| “Bus-Capable Blocks” on page 31-40  | $S : B$  | <ul style="list-style-type: none"> <li>• <math>S</math> is the system index of the model or subsystem the block resides in. For root-level models, <math>S</math> is always 0.</li> <li>• <math>B</math> indicates a bus-capable block.</li> </ul>   |

- “Nonvirtual Blocks” on page 31-33
- “Nonvirtual Subsystems” on page 31-34
- “Virtual Blocks and Subsystems” on page 31-36
- “Function-Call Subsystems” on page 31-37
- “Branched Function-Call Signals” on page 31-39
- “Bus-Capable Blocks” on page 31-40

### Nonvirtual Blocks

In the van der Pol equation model, all the nonvirtual blocks in the model have a sorted order. The system index for the top-level model is 0, and the block execution order ranges from 0 to 8.

### Nonvirtual Subsystems

The following model contains an atomic, nonvirtual subsystem named Discrete Cruise Controller.

When you enable the sorted order display for the root-level system, Simulink displays the sorted order of the blocks.

The Scope block in this model has the lowest sorted order, but its input depends on the output of the Car Dynamics subsystem. The Car Dynamics subsystem is virtual, so it does not have a sorted order and does not execute as an atomic unit. However, the blocks within the subsystem execute at the root level, so the Integrator block in the Car Dynamics subsystem executes first. The Integrator block sends its output to the Scope block in the root-level model, which executes second.

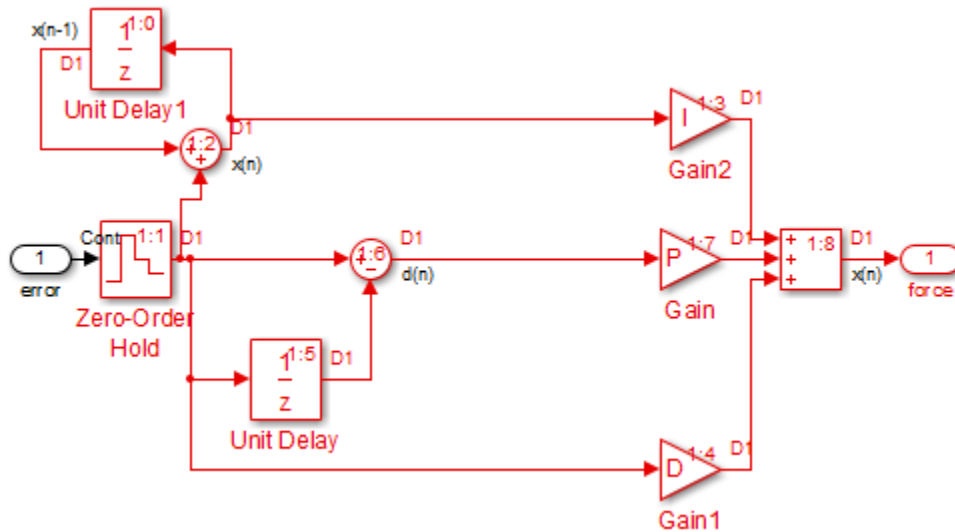

The Discrete Cruise Controller subsystem has a sorted order of **0:5**:

- **0** indicates that this atomic subsystem is part of the root level of the hierarchal system comprised of the primary system and the two subsystems.
- **5** indicates that the atomic subsystem is the sixth block that Simulink executes relative to the blocks within the root level.

The sorted order of each block inside the Discrete Cruise Controller subsystem has the form **1:b**, where:

- **1** is the system index for that subsystem.
- **b** is the block position in the execution order. In the Discrete Cruise Controller subsystem, the sorted order ranges from **0** to **8**.

### Virtual Blocks and Subsystems

Virtual blocks, such as the Mux block, exist only graphically and do not execute. Consequently, they are not part of the sorted order and do not display any sorted order notation.

Virtual subsystems do not execute as a unit, and like a virtual block, are not part of the sorted order. The blocks inside the virtual subsystem are part of the root-level system sorted order, and therefore share the system index.

In the model in “Nonvirtual Subsystems” on page 31-34, the virtual subsystem Car Dynamics does not have a sorted order. However, the blocks inside the subsystem have a sorted order in the execution context of the root-level model. The blocks have the same system index as the root-level model. The Integrator block inside the Car Dynamics subsystem has a sorted order of 0:0, indicating that the Integrator block is the first block executed in the context of the top-level model.

## Function-Call Subsystems

### Single Initiator

A function-call subsystem (or model) executes when the initiator invokes the function-call subsystem (or model) and, therefore, does not have a sorted order independent of its initiator. Specifically, for a subsystem that connects to one initiator, Simulink uses the notation  $s : b^i$ , where  $s$  is the index of the system that contains the initiator and  $b^i$  is the block index of the root initiator in the subsystems hierarchy.

For example, the sorted order for the subsystems  $f$  and  $g$  is  $0 : 0$ , since the sorted order of their root initiator,  $Chart$ , is  $0 : 0$ .

### Multiple Initiators

For a function-call subsystem that connects to more than one initiator, the sorted order notation is  $s:b^{i1}, s:b^{i2}, \dots, s:b^{in}$  where  $n$  is the number of non-grounded initiators,  $s$  is the system index of the model or subsystem the block resides in, and  $b^{in}$  is the block index of the  $n$ -th root initiator in the subsystem's hierarchy.

For example, open the `s1_subsys_fcncall16` model. The `f` subsystem has three initiators from the same level in the subsystem's hierarchy. Two are from the Stateflow chart, `Chart1`, and one from the Stateflow chart, `Chart`.

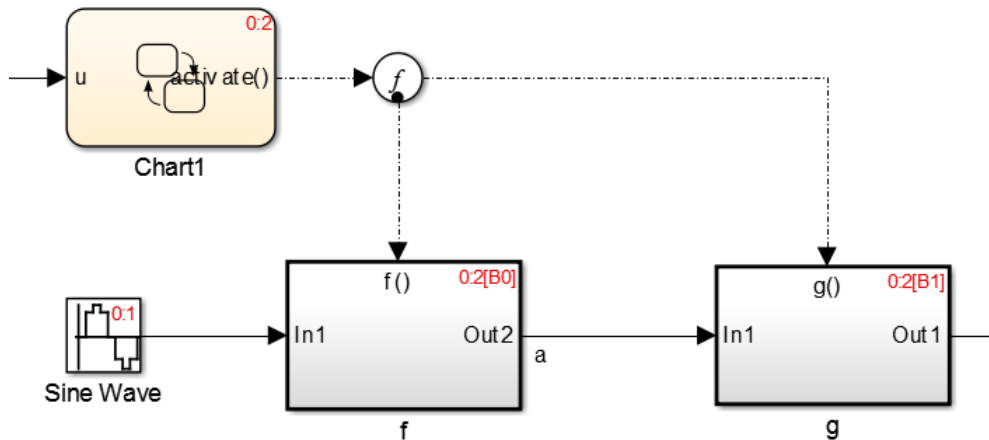

Because `Chart1` has a sorted order `0:2` and `Chart` has a sorted order of `0:4`, the function-call subsystem `f` has a sorted order notation of `0:2,0:4`.

### Branched Function-Call Signals

When a function-call signal is branched using a Function-Call Split block, Simulink displays the order in which subsystems (or models) that connect to the branches execute when the initiator invokes the function call. Simulink uses the notation  $s:b^i[B_k]$  to indicate this order.  $s$  is the system index of the model or subsystem the block resides in,  $b^i$  is the block index of the root initiator in the subsystem's hierarchy, and  $B_k$  indicates that it is a branched function-call subsystem with branch index  $k$ .

For example, open the `s1_subsys_fcncall111` model and display the sorted order. The sorted order indicates that the subsystem `f (B0)` executes before the subsystem `g (B1)`.

### Bus-Capable Blocks

A bus-capable block does not execute as a unit and therefore does not have a unique sorted order. Such a block displays its sorted order as  $s : B$  where  $B$  stands for bus.

For example, open the `sldemo_bus_arrays` model and display the sorted order. Open the For Each Subsystem to see that the sorted order for the Bus Assignment block appears as  $1 : B$ .

For more information, see “Bus-Capable Blocks” on page 61-21.

## How Simulink Determines the Sorted Order

### Direct-Feedthrough Ports Impact on Sorted Order

To ensure that the sorted order reflects data dependencies among blocks, Simulink categorizes block input ports according to the dependency of the block outputs on the

block input ports. An input port whose current value determines the current value of one of the block outputs is a *direct-feedthrough* port. Examples of blocks that have direct-feedthrough ports include:

- Gain
- Product
- Sum

Examples of blocks that have non-direct-feedthrough inputs:

- Integrator — Output is a function of its state.
- Constant — Does not have an input.
- Memory — Output depends on its input from the previous time step.

### Rules for Sorting Blocks

To sort blocks, Simulink uses the following rules:

- If a block drives the direct-feedthrough port of another block, the block must appear in the sorted order ahead of the block that it drives.

This rule ensures that the direct-feedthrough inputs to blocks are valid when Simulink invokes block methods that require current inputs.

- Blocks that do not have direct-feedthrough inputs can appear anywhere in the sorted order as long as they precede any direct-feedthrough blocks that they drive.

Placing all blocks that do not have direct-feedthrough ports at the beginning of the sorted order satisfies this rule. This arrangement allows Simulink to ignore these blocks during the sorting process.

Applying these rules results in the sorted order. Blocks without direct-feedthrough ports appear at the beginning of the list in no particular order. These blocks are followed by blocks with direct-feedthrough ports arranged such that they can supply valid inputs to the blocks which they drive.

The following model, from “Nonvirtual Subsystems” on page 31-34, illustrates this result. The following blocks do not have direct-feedthrough and therefore appear at the beginning of the sorted order of the root-level system:

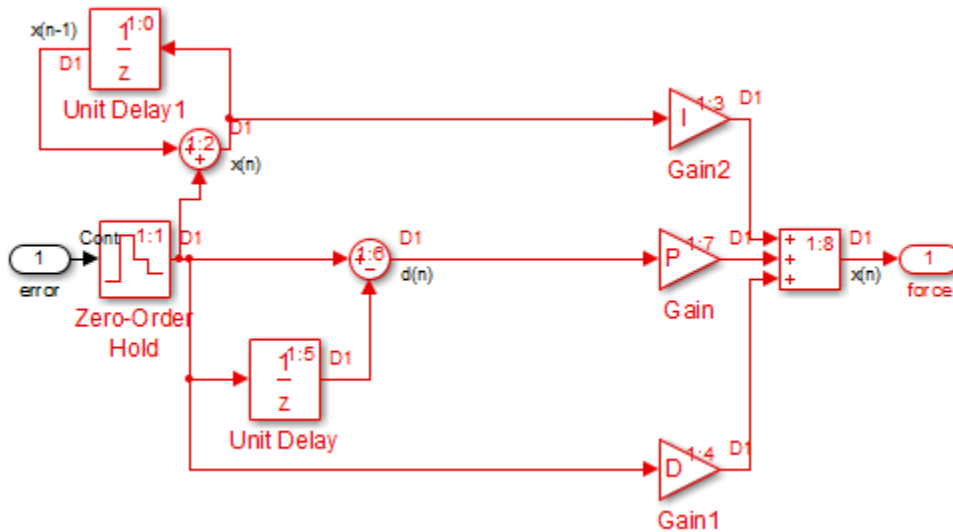

- Integrator block in the Car Dynamics virtual subsystem

- Speed block in the root-level model

Inside the Discrete Cruise Controller subsystem, all the Gain blocks, which have direct-feedthrough ports, run before the Sum block that they drive.

## Assign Block Priorities

You can assign a priority to a nonvirtual block or to an entire subsystem. Higher priority blocks appear before lower priority blocks in the sorted order. The lower the number, the higher the priority.

- “Assigning Block Priorities Programmatically” on page 31-43
- “Assigning Block Priorities Interactively” on page 31-43

### Assigning Block Priorities Programmatically

To set priorities programmatically, use the command:

```
set_param(b, 'Priority', 'n')
where
```

- `b` is the block path.
- `n` is any valid integer. (Negative integers and 0 are valid priority values.)

### Assigning Block Priorities Interactively

To set the priority of a block or subsystem interactively:

- 1 Right-click the block and select **Properties**.
- 2 On the **General** tab, in the **Priority** field, enter the priority.

## Rules for Block Priorities

Simulink honors the block priorities that you specify unless they violate data dependencies. (“Block Priority Violations” on page 31-47 describes situations that cause block property violations.)

In assessing priority assignments, Simulink attempts to create a sorted order such that the priorities for the individual blocks within the root-level system or within a nonvirtual subsystem are honored relative to one another.

Three rules pertain to priorities:

- “Priorities Are Relative” on page 31-44
- “Priorities Are Hierarchical” on page 31-45
- “Lack of Priority May Not Result in Low Priority” on page 31-46

### Priorities Are Relative

Priorities are relative; the priority of a block is relative to the priority of the blocks within the same system or subsystem.

For example, suppose you set the following priorities in the Discrete Cruise Controller subsystem in the model in “Nonvirtual Subsystems” on page 31-34.

| Block | Priority |
|-------|----------|
| Gain  | 3        |
| Gain1 | 2        |
| Gain2 | 1        |

After updating the diagram, the sorted order for the Gain blocks is as follows.

The sorted order values of the Gain, Gain1, and Gain2 blocks reflect the respective priorities assigned: Gain2 has highest priority and executes before Gain1 and Gain; Gain1 has second priority and executes after Gain2; and Gain executes after Gain1. Simulink takes into account the assigned priorities relative to the other blocks in that subsystem.

The Gain blocks are not the first, second, and third blocks to execute. Nor do they have consecutive sorted orders. The sorted order values do not necessarily correspond to the priority values. Simulink arranges the blocks so that their priorities are honored relative to each other.

### Priorities Are Hierarchical

In the Car Dynamics virtual subsystem, suppose you set the priorities of the Gain blocks as follows.

| Block | Priority |
|-------|----------|
| Gain  | 2        |
| Gain1 | 1        |

After updating the diagram, the sorted order for the Gain blocks is as illustrated. With these priorities, Gain1 always executes before Gain.

You can set a priority of 1 to one block in each of the two subsystems because of the hierarchical nature of the subsystems within a model. Simulink never compares the priorities of the blocks in one subsystem to the priorities of blocks in any other subsystem.

For example, consider this model again.

The blocks within the Car Dynamics virtual subsystem are part of the root-level system hierarchy and are part of the root-level sorted order. The Discrete Cruise Controller subsystem has an independent sorted order with the blocks arranged consecutively from 1:0 to 1:7.

### Lack of Priority May Not Result in Low Priority

A lack of priority does not necessarily result in a low priority (higher sorting order) for a given block. Blocks that do not have direct-feedthrough ports execute before blocks that have direct-feedthrough ports, regardless of their priority.

If a model has two atomic subsystems, A and B, you can assign priorities of 1 and 2 respectively to A and B. This priority causes all the blocks in A to execute before any of the blocks in B. The blocks within an atomic subsystem execute as a single unit, so the subsystem has its own system index and its own sorted order.

## Block Priority Violations

Simulink software honors the block priorities that you specify unless they violate data dependencies. If Simulink is unable to honor a block priority, it displays a **Block Priority Violation** diagnostic message.

As an example:

- 1 Open the `sldemo_bounce` model.

Notice that the output of the Memory block provides the input to the Coefficient of Restitution Gain block.

- 2 Set the priority of the Coefficient of Restitution block to 1, and set the priority of the Memory block to 2.

Setting these priorities specifies that the Coefficient of Restitution block execute before the Memory block. However, the Coefficient of Restitution block depends on the output of the Memory block, so the priorities you just set violate the data dependencies.

- 3 In the model window, enable sorted order by selecting **Format > Block displays > Sorted Order**.
- 4 Select **Simulation > Update Diagram**.

The block priority violation warning appears in the **Diagnostic Viewer**. To open the **Diagnostic Viewer** window, click **View > Diagnostic Viewer**. The warning includes the priority for the respective blocks:

```
Warning: Unable to honor user-specified priorities.  
'sldemo_bounce/Memory' (pri=[2]) has to execute  
before 'sldemo_bounce/Coefficient of Restitution'  
(pri=[1]) to satisfy data dependencies
```

- 5 Remove the priorities from the Coefficient of Restitution and Memory blocks and update the diagram again to see the correct sorted order.

## Access Block Data During Simulation

### In this section...

“About Block Run-Time Objects” on page 31-48

“Access a Run-Time Object” on page 31-48

“Listen for Method Execution Events” on page 31-49

“Synchronizing Run-Time Objects and Simulink Execution” on page 31-50

### About Block Run-Time Objects

Simulink provides an application programming interface, called the block run-time interface, that enables programmatic access to block data, such as block inputs and outputs, parameters, states, and work vectors, while a simulation is running. You can use this interface to access block run-time data from the MATLAB command line, the Simulink Debugger, and from Level-2 MATLAB S-functions (see “Write Level-2 MATLAB S-Functions” in the online Simulink documentation).

---

**Note** You can use this interface even when the model is paused or is running or paused in the debugger.

---

The block run-time interface consists of a set of Simulink data object classes (see “Data Objects” on page 55-38) whose instances provide data about the blocks in a running model. In particular, the interface associates an instance of `Simulink.RunTimeBlock`, called the block's run-time object, with each nonvirtual block in the running model. A run-time object's methods and properties provide access to run-time data about the block's I/O ports, parameters, sample times, and states.

### Access a Run-Time Object

Every nonvirtual block in a running model has a `RuntimeObject` parameter whose value, while the simulation is running, is a handle for the blocks' run-time object. This allows you to use `get_param` to obtain a block's run-time object. For example, the following statement

```
rto = get_param(gcb, 'RuntimeObject');
```

returns the run-time object of the currently selected block. Run-time object data is read-only. You cannot use run-time objects to change a block's parameters, input, output, and state data.

---

**Note** Virtual blocks (see “Nonvirtual and Virtual Blocks” on page 31-2) do not have run-time objects. Blocks eliminated during model compilation as an optimization also do not have run-time objects (see “Block reduction”). A run-time object exists only while the model containing the block is running or paused. If the model is stopped, `get_param` returns an empty handle. When you stop a model, all existing handles for run-time objects become empty.

---

## Listen for Method Execution Events

One application for the block run-time API is to collect diagnostic data at key points during simulation, such as the value of block states before or after blocks compute their outputs or derivatives. The block run-time API provides an event-listener mechanism that facilitates such applications. For more information, see the documentation for the `add_exec_event_listener` command. For an example of using method execution events, enter

```
sldemo_msfcn_lms
```

at the MATLAB command line. This Simulink model contains the S-function `adapt_lms.m`, which performs a system identification to determine the coefficients of an FIR filter. The S-function's `PostPropagationSetup` method initializes the block run-time object's `DWork` vector such that the second vector stores the filter coefficients calculated at each time step.

In the Simulink model, double-clicking on the annotation below the S-function block executes its `OpenFcn`. This function first opens a figure for plotting the FIR filter coefficients. It then executes the function `add_adapt_coef_plot.m` to add a `PostOutputs` method execution event to the S-function's block run-time object using the following lines of code.

```
% Add a callback for PostOutputs event
blk = 'sldemo_msfcn_lms/LMS Adaptive';

h    = add_exec_event_listener(blk, ...
    'PostOutputs', @plot_adapt_coefs);
```

The function `plot_adapt_coefs.m` is registered as an event listener that is executed after every call to the S-function's `Outputs` method. The function accesses the block run-time object's `DWork` vector and plots the filter coefficients calculated in the `Outputs` method. The calling syntax used in `plot_adapt_coefs.m` follows the standard needed for any listener. The first input argument is the S-function's block run-time object, and the second argument is a structure of event data, as shown below.

```
function plot_adapt_coefs(block, ei) %#ok<INUSD>
%
% Callback function for plotting the current adaptive filtering
% coefficients.

stemPlot = get_param(block.BlockHandle, 'UserData');

est = block.Dwork(2).Data;
set(stemPlot(2), 'YData', est);
drawnow('expose');
```

## Synchronizing Run-Time Objects and Simulink Execution

You can use run-time objects to obtain the value of a block output and display in the MATLAB Command Window by entering the following commands.

```
rto = get_param(gcf, 'RuntimeObject')
rto.OutputPort(1).Data
```

However, the displayed data may not be the true block output if the run-time object is not synchronized with the Simulink execution. Simulink only ensures the run-time object and Simulink execution are synchronized when the run-time object is used either within a Level-2 MATLAB S-function or in an event listener callback. When called from the MATLAB Command Window, the run-time object can return incorrect output data if other blocks in the model are allowed to share memory.

To ensure the `Data` field contains the correct block output, open the Configuration Parameters dialog box, and then clear the **Signal storage reuse** check box on the **Optimization > Signals and Parameters** pane (see “Signal storage reuse”).

## Configure a Block for Code Generation

Use the **State Attributes** pane of a Block Parameters dialog box to specify Simulink Coder code generation options for blocks with discrete states. See “Discrete Block State Naming in Generated Code” in the Simulink Coder documentation.

# Working with Block Parameters

---

- “Specify Block Parameter Values” on page 32-2
- “Block Parameter Data Types” on page 32-6
- “Calibrate Block Behavior Between Simulation Runs” on page 32-9
- “Manage Variables from Block Parameter” on page 32-11
- “Check Parameter Values” on page 32-14
- “Tunable Block Parameters” on page 32-18
- “Organize Related Parameters in Structures and Arrays of Structures” on page 32-20

## Specify Block Parameter Values

Many block parameters, including mathematical parameters, accept MATLAB expression strings as values. When Simulink compiles a model, for example, at the start of a simulation or when you update the model, Simulink sets the compiled values of the parameters to the result of evaluating the expressions.

### Access Block Parameters

- Use the `set_param` command. For a list of parameters for each block, see “Block-Specific Parameters”.
- In the Simulink Editor, select **View > Model Explorer**.

The Model Explorer allows you to quickly find one or more blocks and set their properties, thus facilitating global changes to a model, for example, changing the gain of all of a model’s Gain blocks. See “Model Explorer Overview” on page 11-2.

- Open the block parameter dialog box:
  - Select the block and choose **Block Parameters** from the **Diagram** menu or from the block’s context (right-click) menu.
  - Double-click the block.

---

**Note** Some blocks, such as Scope blocks, do not have a Block Parameters dialog box.

Double-clicking a block or using the Block Properties dialog box **Open Block** link to open the Block Parameters dialog box works for all blocks that have parameter dialog boxes, except for **Subsystem** and **Model** blocks. Use the Simulink Editor **Diagram** menu or the block context menu to open the Block Parameters dialog box for Subsystem and Model blocks.

---

### Specify Parameter Values

| Parameter Value Type | Examples                 | Usage Scenario  |
|----------------------|--------------------------|---|
| Literal value        | 2.3, $\sin(2*\pi)$ , 1/3 | <ul style="list-style-type: none"> <li>• The parameter value is unlikely to change or be reused.</li> </ul> |

| Parameter Value Type      | Examples   | Usage Scenario   |
|---------------------------|--|--|
|                           |  | <ul style="list-style-type: none"> <li>You want to rapidly prototype your model to understand block behavior.</li> </ul>   |
| Variable                  | At the command prompt:<br><code>myParam = 5;</code><br><br>In the block parameter:<br><code>myParam</code>               | <ul style="list-style-type: none"> <li>The parameter value is used in multiple places in the model.</li> <li>Change the parameter value without changing the model.</li> </ul> |
| Expression with variables | <code>myParam * myOtherparam + 3</code>  | Define the parameter value as a relationship between multiple variables or other block parameters.   |
| MATLAB structures         | <code>myParam.a.SpeedVect</code>   | Organize related numerical parameters that can be identified using structure fields.   |
| Data objects              | At the command prompt:<br><code>myParam = Simulink.Paramet</code><br><br>In the block parameter:<br><code>myParam</code> | Define more attributes for the parameter value, such as minimum, maximum, and dimensionality.  |

### Use Workspace Variables in Parameter Expressions

Block parameter expressions can include variables defined in the model's mask and model workspaces and in the MATLAB workspace. Using a workspace variable facilitates updating a model that sets multiple block parameters to the same value, i.e., it allows you to update multiple parameters by setting the value of a single workspace variable. For more information, see “Symbol Resolution” on page 4-95 and “Numeric Values with Symbols” on page 4-96.

Using a workspace variable also allows you to change the value of a parameter during simulation without having to open a block's parameter dialog box. For more information, see “Tunable Block Parameters” on page 32-18.

---

**Note:** If you have a Simulink Coder license, and you plan to generate code from a model, you can use workspace variables to specify the name, data type, scope, volatility, tunability, and other attributes of variables used to represent the parameter in the generated code. For more information, see “Parameter Storage in the Generated Code” in the Simulink Coder documentation.

---

### Resolve Variable References in Block Parameter Expressions

When evaluating a block parameter expression that contains a variable, Simulink by default searches the workspace hierarchy. If the variable is not defined in any workspace, Simulink halts compilation of the model and displays an error message. See “Symbol Resolution” on page 4-95 and “Numeric Values with Symbols” on page 4-96 for more information.

### Use Parameter Objects to Specify Parameter Values

You can use `Simulink.Parameter` objects in parameter expressions to specify parameter values. For example, `K` and `2*K` are both valid parameter expressions where `K` is a workspace variable that references a `Simulink.Parameter` object. In both cases, Simulink uses the parameter object’s `Value` property as the value of `K`.

You cannot use arrays of `Simulink.Parameter` objects as block parameters.

See “Symbol Resolution” on page 4-95 and “Numeric Values with Symbols” on page 4-96 for more information.

---

**Note:** Do not use expressions of the form `p.Value` where `p` is a parameter object in block parameter expressions. Such expressions cause evaluation errors when Simulink compiles the model.

---

### Convert Numeric Variable into Simulink.Parameter Object

You can convert a numeric variable into a `Simulink.Parameter` object as follows.

```
/* Define numeric variable in base workspace
myVar = 5;
/* Create data object and assign variable value
myObject = Simulink.Parameter(myVar);
```

## Block Parameter Data Types

When Simulink compiles a model, each of the model's blocks determines a data type for storing its parameter values that are specified using MATLAB expressions.

Most blocks use internal rules to determine the data type assigned to a specific parameter. Exceptions include the `Gain` block, whose parameter dialog box allows you to specify the data type assigned to the compiled value of its `Gain` parameter. You can configure your model to check whether the data type assigned to a parameter can accommodate the parameter value specified by the model (see “Data Validity Diagnostics Overview”).

### How Simulink Determines Parameter Data Type

| Parameter Specification              | Example                                    | Effective Parameter Data Type   |
|--------------------------------------|--|---|
| Numeric value                        | <code>15.3</code>                          | The block determines the parameter data type.   |
| Nontunable expression                | <code>1:K</code>                           | The block determines the parameter data type.   |
| Variable with double-precision value | <code>K = 5</code>                         | The block determines the parameter data type.   |
| Variable with explicit data type     | <code>K = int8(5)</code>                   | <p>The parameter uses the specified data type.</p> <p>However, the block can require a different data type, for example, if you specify a type in a <code>Gain</code> block dialog box. The block casts the parameter to the required type.</p> <p>In the generated code, the parameter uses the specified data type if the parameter is tunable.</p> |
| Parameter object                     | <code>K = Simulink.Parameter(10.23)</code> | The parameter object first casts the specified value, <code>10.23</code> , to the specified type, <code>single</code> .   |

| Parameter Specification | Example                            | Effective Parameter Data Type  |
|-------------------------|------------------------------------|--|
|                         | <code>K.DataType = 'single'</code> | Then, if the block requires a different data type, it casts the result to the required type. |

If you specify a block parameter using a mathematical expression, the block determines the final parameter data type using a combination of MATLAB and Simulink data typing rules.

For example, suppose that you define two parameter objects `int8Param` and `doubleParam`, and use the objects to specify the **Constant value** parameter in a Constant block.

```
int8Param = Simulink.Parameter(3);
int8Param.DataType = 'int8';

doubleParam = Simulink.Parameter(9.36);
doubleParam.DataType = 'double';
```

The Constant block determines the data type of the **Constant value** parameter using these steps:

- 1 Each parameter object casts the specified numeric value to the specified data type.

| Parameter object         | Data type           | Numeric value | Result                    |
|--------------------------|---------------------|---------------|---------------------------|
| <code>int8Param</code>   | <code>int8</code>   | 3             | <code>int8(3)</code>      |
| <code>doubleParam</code> | <code>double</code> | 9.36          | <code>double(9.36)</code> |

- 2 The block evaluates the specified expression, `int8Param * doubleParam`, using MATLAB rules.

An expression that involves a `double` data type and a different type returns a result of the different type. Therefore, the result of the expression `int8(3) * double(9.36)` is `int8(28)`.

## Display Parameter Data Type

You can use `get_param` to find the system and block parameter values for your model. See “Model Parameters” and “Common Block Properties” for arguments `get_param` accepts.

The model’s signal attributes and parameter expressions must be evaluated before some parameters are properly reported. This evaluation occurs during the simulation compilation phase. Alternatively, you can compile your model without first running it, and then obtain parameter information. For instance, to access the port width, data types, and dimensions of the blocks in your model, enter the following at the command prompt:

```
modelName([],[],[],'compile')
q=get_param(gcf,'PortHandles');
get_param(q.Inport,'CompiledPortDataType')
get_param(q.Inport,'CompiledPortWidth')
get_param(q.Inport,'CompiledPortDimensions')
modelName([],[],[],'term')
```

## Calibrate Block Behavior Between Simulation Runs

This example shows how to progressively iterate on the definitions of block parameters.

### Prototype Blocks Using Literal Values

Rapidly prototype your model by using literal mathematical values to tweak block behavior.

- 1 Open the `fuelsys` model.
- 2 Navigate to the **Fuel Calculation** submodel.
- 3 Open the block parameter dialog for the **F/A Rich** block by double-clicking it.
- 4 Change the **Constant value** parameter to  $1 / (17.5 * 0.8)$ .
- 5 Similarly, change the **Constant value** parameter of the **F/A Norm** block to  $1 / 17.5$ .
- 6 Simulate the model and observe the scopes for the change in output.

### Replace Literal Values with Numeric Variables

Having tweaked block behavior using literal values, replace these values with numeric variables.

- 1 Replace the **Constant value** parameter of the **F/A Rich** block,  $1 / (17.5 * 0.8)$ , with  $1 / (\text{mixture} * \text{coeff})$ .
- 2 Similarly, replace the **Constant value** parameter of the **F/A Norm** block with  $1 / \text{mixture}$ .
- 3 At the MATLAB prompt, define the variables `mixture` and `coeff` in the base workspace.

```
mixture = 17.5;
coeff = 0.8;
```
- 4 Simulate the model and observe that the scope output remains unchanged.

### Develop Variable Expressions for Reuse

Group numeric variables into reusable expressions that you can reuse in other models.

- 1 Replace the **Constant value** parameter of the **F/A Rich** block with `richRatio`.
- 2 Similarly, replace the **Constant value** parameter of the **F/A Norm** block with `withnormalRatio`.

- 3 At the MATLAB prompt, define the variables `mixture` and `coeff` and the expressions `richRatio` and `normalRatio` in the base workspace.

```
mixture = 17.5;  
coeff = 0.8;  
  
richRatio = 1/(mixture*coeff);  
normalRatio = 1/mixture;
```

- 4 Simulate the model and observe that the scope output remains unchanged.

### **Related Examples**

- “Specify Block Parameter Values” on page 32-2

### **More About**

- “Tunable Block Parameters” on page 32-18

## Manage Variables from Block Parameter

### In this section...

- “Rename Variable” on page 32-11
- “Edit Variable Value or Property” on page 32-12
- “Navigate to Mask Parameter” on page 32-12
- “Create Variable” on page 32-12

### Rename Variable

This example shows how to rename a variable by navigating to Model Explorer from a parameter in a block dialog box.

- 1 Open the model f14. The model loads data to the MATLAB base workspace.
- 2 Open the block dialog box for the Gain block that uses variable Mw.
- 3 Right-click the expression Mw in the **Gain** box and select **Explore Variable**.

Model Explorer opens with Mw as the selected variable in the base workspace.

- 4 In Model Explorer, right-click the variable Mw and select **Rename All**.
- 5 In the **Select a system** dialog box, click the name of the model f14 to select it as the context for renaming the variable Mw.
- 6 Clear the **Search in referenced models** check box, since f14 does not reference any models, and click **OK**.

With **Search in referenced models** selected, you can rename the target variable everywhere it is used in a model reference hierarchy. However, renaming the target variable in an entire hierarchy can take more time.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

- 7 Click **OK** in response to the message to update the model diagram.

Since you just opened the model, you must update the model diagram at least once before renaming a variable. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram

update, though you typically use that option when you make changes to the model while performing multiple variable renaming operations.

- 8 In the **Rename All** dialog box, type the new name for the variable in the **New name** box and click **OK**.
- 9 In the block dialog, click **OK** to accept the change to the block parameter.

## Edit Variable Value or Property

This example shows how to edit a variable from a parameter in a block dialog box. You can use this procedure to edit a variable made from a built-in or custom data type or from a class such as `Simulink.Parameter`.

- 1 Open the model `f14`. The model loads data to the MATLAB base workspace.
- 2 Open the block dialog box for the Gain block that uses the variable `MW`.
- 3 Right-click the expression `MW` in the **Gain** box and select **Open Variable**.
- 4 In the **Data properties** dialog box, type a new value for the variable in the **Value** box and click **OK**.

## Navigate to Mask Parameter

This example shows how to navigate to a mask parameter from a parameter in a block dialog box. When you explore a model that contains multiple masked subsystems and masked blocks, you can find the mask that defines a particular parameter.

- 1 Open the model `masking_example`.
- 2 Open the block dialog box for the Gain block that uses the mask parameter `m`.
- 3 Right-click the expression `m` in the **Gain** box and select **Open Variable**.

The mask dialog box that contains the mask parameter `m` appears.

## Create Variable

This example shows how to create a variable from a parameter in a block dialog box.

- 1 Open the model `sldemo_fuelsys`.
- 2 Open the block dialog box for the Constant block that has value `300`.
- 3 In the **Constant value** box, replace the expression `300` with `myVar`.

- 4 Right-click the expression `myVar` and select **Create Variable**.
- 5 In the **Create New Data** dialog box, type `300` in the **Value** box and click **Create**.

In the **Create New Data** dialog box you can choose the workspace to define the new variable. If a model is linked to a data dictionary, you can choose to create a variable in the dictionary.

- 6 In the **Data properties** dialog box, click **OK**.

## Check Parameter Values

### In this section...

“About Value Checking” on page 32-14

“Blocks That Perform Parameter Range Checking” on page 32-14

“Specify Ranges for Parameters” on page 32-15

“Perform Parameter Range Checking” on page 32-15

### About Value Checking

Many blocks perform range checking of their mathematical parameters. Generally, blocks that allow you to enter minimum and maximum values check to ensure that the values of applicable parameters lie within the specified range.

### Blocks That Perform Parameter Range Checking

The following blocks perform range checking for their parameters:

| Block                           | Parameters Checked                |
|---------------------------------|-----------------------------------|
| Constant                        | Constant value                    |
| Data Store Memory               | Initial value                     |
| Gain                            | Gain                              |
| Interpolation Using Prelookup   | Table data                        |
| 1-D Lookup Table                | Table data                        |
| 2-D Lookup Table                | Table data                        |
| n-D Lookup Table                | Table data                        |
| Relay                           | Output when on<br>Output when off |
| Repeating Sequence Interpolated | Vector of output values           |
| Repeating Sequence Stair        | Vector of output values           |
| Saturation                      | Upper limit                       |

| Block | Parameters Checked |
|-------|--------------------|
|       | Lower limit        |

## Specify Ranges for Parameters

In general, use the **Output minimum** and **Output maximum** parameters that appear on a block parameter dialog box to specify a range of valid values for the block parameters. The following exceptions apply:

- For the Gain block, use the **Parameter minimum** and **Parameter maximum** fields to specify a range for the **Gain** parameter.
- For the Data Store Memory block, use the **Minimum** and **Maximum** fields to specify a range for the **Initial value** parameter.

When specifying minimum and maximum values that constitute a range, enter only expressions that evaluate to a finite, scalar, real number with `double` data type. The default values for the minimum and maximum are [ ] (unspecified). The scalar values that you specify are subject to expansion, for example, when the block parameters that Simulink checks are nonscalar (see “Scalar Expansion of Inputs and Parameters” on page 60-34).

---

**Note:** You cannot specify the minimum or maximum value as NaN, `inf`, or `-inf`.

---

## Specifying Ranges for Complex Numbers

When you specify a minimum or maximum value for a parameter that is a complex number, the specified minimum and maximum apply separately to the real part and to the imaginary part of the complex number. If the value of either part of the number is less than the minimum, or greater than the maximum, the complex number is outside the specified range. No range checking occurs against any combination of the real and imaginary parts, such as  $(\text{sqrt}(a^2+b^2))$

## Perform Parameter Range Checking

You can initiate parameter range checking in the following ways:

- When you click the **OK** or **Apply** button on a block parameter dialog box, the block performs range checking for its parameters. However, the block checks only the

parameters that it can readily evaluate. For example, the block does not check parameters that use an undefined workspace variable.

- In the Simulink Editor, when you start a simulation or select **Simulation > Update Diagram**, Simulink performs parameter range checking for all blocks in that model.

Simulink performs parameter range checking by comparing the values of applicable block parameters with both the specified range (see “Specify Ranges for Parameters” on page 32-15) and the block data type. That is, Simulink performs the following check:

$$\text{DataTypeMin} \leq \text{MinValue} \leq \text{VALUE} \leq \text{MaxValue} \leq \text{DataTypeMax}$$

where

- **DataTypeMin** is the minimum value representable by the block data type.
- **MinValue** is the minimum value the block should output, specified by, e.g., **Output minimum**.
- **VALUE** is the numeric value of a block parameter.
- **MaxValue** is the maximum value the block should output, specified by, e.g., **Output maximum**.
- **DataTypeMax** is the maximum value representable by the block data type.

When Simulink detects a parameter value that violates the check, it displays an error message. For example, consider a model that contains a Constant block whose

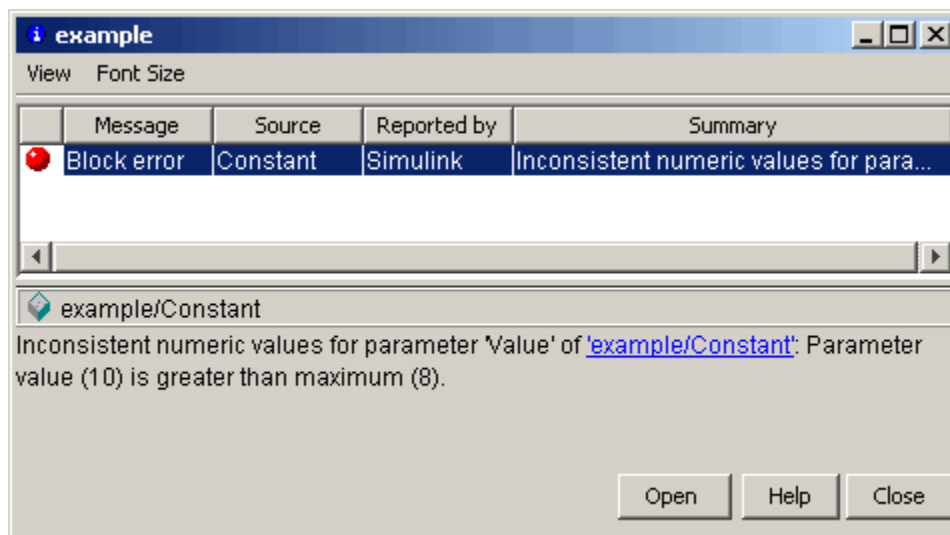

- **Constant value** parameter specifies the variable `const`, which you have yet to define in a workspace.
- **Output minimum** and **Output maximum** parameters are set to 2 and 8, respectively.
- **Output data type** parameter is set to `uint8`.

In this situation, Simulink does not perform parameter range checking when you click the **OK** button on the Constant block dialog box because the variable `const` is undefined. But suppose you define its value by entering

```
const = 10
```

at the MATLAB prompt, and then you update the diagram (see “Update Diagram and Run Simulation” on page 1-50). Simulink displays the following error message:

## Tunable Block Parameters

### In this section...

“Tune a Block Parameter” on page 32-18

“Specify Ranges for Tunable Parameters” on page 32-18

“Block Parameter Tunability During Rapid Accelerator Simulations” on page 32-19

“Tunable Parameters in Generated Code” on page 32-19

Simulink lets you change the values of many block parameters during simulation. Such parameters are called *tunable parameters*. In general, only parameters that represent mathematical variables, such as the **Gain** parameter of the **Gain** block, are tunable. Parameters that specify the appearance or structure of a block, e.g., the number of inputs of a **Sum** block, or when it is evaluated, e.g., a block’s sample time or priority, are not tunable.

You can determine whether a particular block parameter is tunable by examining its edit control in the block’s dialog box or Model Explorer during simulation. If the control is disabled, the parameter is nontunable.

### Tune a Block Parameter

You can use a block dialog box or Model Explorer to modify the tunable parameters of any block. To use the block parameter dialog box:

- 1 Open the block parameter dialog box.
- 2 Change the parameter value displayed in the dialog box.
- 3 Click **OK** or **Apply**.

You can also tune a parameter at the MATLAB command line, using either the `set_param` command or by assigning a new value to the MATLAB workspace variable that specifies the parameter’s value. You must update the model’s block diagram for the change to take effect (see “Update Diagram and Run Simulation” on page 1-50).

### Specify Ranges for Tunable Parameters

It is a best practice to specify the minimum and maximum values that you expect to use while tuning a parameter.

To specify value ranges for block parameters, see “Specify Ranges for Parameters” on page 32-15.

## Block Parameter Tunability During Rapid Accelerator Simulations

If a block parameter value references workspace variables, you cannot change the block parameter value during rapid accelerator simulation. Instead, you can tune the values of the referenced variables.

Alternatively, use parameter sets to tune runtime parameters in between rapid accelerator simulations. For more information, see “Tuning Runtime Parameters” on page 30-9.

## Tunable Parameters in Generated Code

Parameters that are tunable during simulation can appear as nontunable inlined parameters in the generated code. To control parameter tunability in the generated code, you can adjust the code generation settings for a model and for individual MATLAB variables. For more information, see “Tunable Parameter Storage” in the Simulink Coder documentation.

### About Structure Parameters

Separately defining all base workspace variables used in block parameter expressions can clutter the base workspace and result in very long lists of arguments to subsystems and referenced models. The technique provides no way to conveniently group related base workspace variables, or to configure generated code to reflect the variables' relationships.

To minimize the disadvantages of separately defining workspace variables used by block parameters, you can group numeric variables by specifying their names and values as the fields of a MATLAB structure in the base workspace. A MATLAB structure that Simulink uses in block parameter expressions is called a *structure parameter*. You can use structure parameters to:

- Simplify and modularize the base workspace by using multiple structures to group related variables and to prevent name conflicts
- Dereference the structure in block parameter expressions to provide values from structure fields rather than separate variables
- Pass all the fields in a structure to a subsystem or referenced model with a single argument.
- Improve generated code to use structures rather than multiple separate variables

To organize parameter structures that have similar characteristics, you can create a single parameter whose value is an array of structures. To use the parameter in a block dialog box, you specify an expression that references a field of one of the structures in the array.

You can also partition the parameter in a For Each subsystem. This technique helps you to organize workspace variables when a model executes an algorithm repeatedly, for example, by using identical subsystems. For an example, see “Repeat an Algorithm Using a For Each Subsystem” on page 61-98.

For information about creating and using MATLAB structures, see Structures in the MATLAB documentation. You can use all the techniques described there to manipulate structure parameters. This section assumes that you know those techniques, and provides only information that is specific to Simulink.

For information on structure parameters in the context of generated code for a model, see “Structure Parameters and Generated Code”. For an example of how to convert a model that uses unstructured workspace variables to a model that uses structure parameters, see `sldemo_applyVarStruct`.

## Define Structure Parameters

Defining a structure parameter is syntactically the same as defining any MATLAB structure, as described in Structures. Every field in a MATLAB structure that functions as a structure parameter must have a numeric data type, even if Simulink never uses the field. Different fields can have different numeric types.

In structure parameters, numeric types include enumerated types, by virtue of their underlying integers. The value of a structure parameter field, can be a real or complex scalar, vector, or multidimensional array. However, a structure that contains any multidimensional array cannot be tuned.

To create an array of structures, you can use the same syntax that you use to create arrays of numeric values. For example, you can define an array of structures `arrayStruct` by concatenating two similar structures.

```
arrayStruct = [struct('gain',1.5,'offset',30),...  
              struct('gain',2.1,'offset',40)]
```

You can also create `arrayStruct` by assigning values to the structure fields in the array.

```
arrayStruct(1).gain = 1.5;  
arrayStruct(1).offset = 30;  
  
arrayStruct(2).gain = 2.1;  
arrayStruct(2).offset = 40;
```

MATLAB structures, including those used as structure parameters, can have substructures to any depth. Structures and substructures at any level behave identically, so the following instructions refer only to structures unless substructures are specifically the point.

## Referencing Structure Parameters

You can use MATLAB syntax, as described in Structures, to dereference a structure parameter field anywhere in a block parameter expression that a MATLAB variable can appear. You cannot specify a structure name in a mathematical block parameter expression, because that would pass a structure rather than a number. For example, suppose you have defined the following parameter structure:

```
A          /* Root structure
|__x       /* Numeric field
|__y       /* Numeric field
|__z       /* Substructure
|   |__m   /* Numeric field
|   |__n   /* Numeric field
|   |__k   /* Numeric field
```

Given this structure, you can specify an individual field, such as `A.x`, in a block parameter expression, thereby passing only `x` to the block. The effect is exactly the same as if `x` were a separate base workspace variable whose value was the same as the value of `A.x`. Similarly, you could reference `A.z.m`, `A.z.n`, etc. The next figure shows an example that uses a Gain block:

The Gain block's **Gain** parameter is the value of `A.x + A.z.k`, a numeric expression. You could not reference `A` or `A.z` to provide a **Gain** parameter value, because neither resolves to a numeric value.

To specify a block parameter by using a field of an array of structures, use a single expression that selects a structure in the array and references a field of that structure. For example, suppose that you define an array of structures `arrayStruct`:

```
arrayStruct = [struct('gain',1.5,'offset',30),...
  struct('gain',2.1,'offset',40)]
```

To reference the field `offset` of the second structure in the array, use the expression `arrayStruct(2).offset`. The expression returns the value of the field, 40.

## Structure Parameter Arguments

You can use a parameter structure field as a masked subsystem or model reference argument by referencing the field, as described in the previous section, in Subsystem block mask, or Model block. For example, suppose you have defined the parameter structure used in the previous example:

```
A          /* Root structure
|__x       /* Numeric field
|__y       /* Numeric field
|__z       /* Substructure
|  |__ m   /* Numeric field
|  |__ n   /* Numeric field
|  |__ k   /* Numeric field
```

You could then:

- 1 Use a whole structure parameter as a masked subsystem argument or a referenced model argument by referencing the structure's name.
- 2 Dereference the structure as needed in the subsystem mask code, the subsystem itself, or the referenced model.

For example, you could pass `A`, providing access to everything in the root structure, or `A.z`, providing access only to that substructure. The dereferencing syntax for arguments is the same as in any other context, as described in Structures.

When you pass a structure parameter to a referenced model, the structure definitions must be identical in the parent model and the referenced model, including any unused fields. See “Systems and Subsystems” on page 3-10, “Block Masks”, and “Model Arguments” on page 8-60 more information about passing and using arguments.

## Parameter Structure Limitations

All of the structures in an array of structures must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics throughout the array:

- Field name
- Numeric data type, such as `single` or `int32`
- Complexity
- Dimensions

For example, suppose that you define an array of two structures.

```
paramStructArray = ...  
[struct('sensor1',int16(7),'sensor2',single(9.23)) ...  
 struct('sensor1',int32(9),'sensor2',single(11.71))];
```

You cannot use any of the fields of `paramStructArray` in a block parameter because the field `sensor1` uses a different data type in each structure.

## Generate Code with Structure Parameters

## About Lookup Table Blocks

A *lookup table* block uses an array of data to map input values to output values, approximating a mathematical function. Given input values, Simulink performs a “lookup” operation to retrieve the corresponding output values from the table. If the lookup table does not define the input values, the block estimates the output values based on nearby table values.

The following example illustrates a one-dimensional lookup table that approximates the function  $y = x^3$ . The lookup table defines its output ( $y$ ) data discretely over the input ( $x$ ) range  $[-3, 3]$ . The following table and graph illustrate the input/output relationship:

|   |     |    |    |   |   |   |    |
|---|-----|----|----|---|---|---|----|
| x | -3  | -2 | -1 | 0 | 1 | 2 | 3  |
| y | -27 | -8 | -1 | 0 | 1 | 8 | 27 |

An input of -2 enables the table to look up and retrieve the corresponding output value (-8). Likewise, the lookup table outputs 27 in response to an input of 3.

When the lookup table block encounters an input that does not match any of the table's  $x$  values, it can interpolate or extrapolate the answer. For instance, the lookup table does not define an input value of -1.5; however, the block can linearly interpolate the nearest data points (-2, -8) and (-1, -1) to estimate and return a value of -4.5.

Similarly, although the lookup table does not include data for  $x$  values beyond the range of  $[-3, 3]$ , the block can extrapolate values using a pair of data points at either end

of the table. Given an input value of 4, the lookup table block linearly extrapolates the nearest data points (2, 8) and (3, 27) to estimate an output value of 46.

Since table lookups and simple estimations can be faster than mathematical function evaluations, using lookup table blocks might result in speed gains when simulating a model. Consider using lookup tables in lieu of mathematical function evaluations when:

- An analytical expression is expensive to compute.
- No analytical expression exists, but the relationship has been determined empirically.

Simulink provides a broad assortment of lookup table blocks, each geared for a particular type of application. The sections that follow outline the different offerings, suggest how to choose the lookup table best suited to your application, and explain how to interact with the various lookup table blocks.

## Anatomy of a Lookup Table

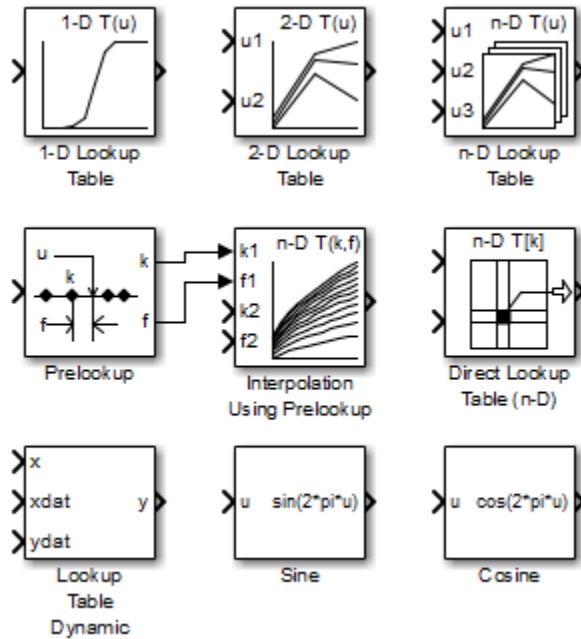

The following figure illustrates the anatomy of a two-dimensional lookup table. Vectors or *breakpoint data sets* and an array, referred to as *table data*, constitute the lookup table.

Each breakpoint data set is an index of input values for a particular dimension of the lookup table. The array of table data serves as a sampled representation of a function evaluated at the breakpoint values. Lookup table blocks use breakpoint data sets to relate a table's input values to the output values that it returns.

## Lookup Tables Block Library

Several lookup table blocks appear in the Lookup Tables block library.

The following table summarizes the purpose of each block in the library.

| Block Name                    | Description  |
|-------------------------------|--|
| 1-D Lookup Table              | Approximate a one-dimensional function.  |
| 2-D Lookup Table              | Approximate a two-dimensional function.  |
| n-D Lookup Table              | Approximate an N-dimensional function.   |
| Prelookup                     | Compute index and fraction for Interpolation Using Prelookup block.                                |
| Interpolation Using Prelookup | Use precalculated index and fraction values to accelerate approximation of N-dimensional function. |
| Direct Lookup Table (n-D)     | Index into an N-dimensional table to retrieve the corresponding outputs.                           |

| <b>Block Name</b>    | <b>Description</b>  |
|----------------------|---|
| Lookup Table Dynamic | Approximate a one-dimensional function using a dynamically specified table. |
| Sine                 | Use a fixed-point lookup table to approximate the sine wave function.       |
| Cosine               | Use a fixed-point lookup table to approximate the cosine wave function.     |

## Guidelines for Choosing a Lookup Table

### In this section...

“Data Set Dimensionality” on page 33-7

“Data Set Numeric and Data Types” on page 33-7

“Data Accuracy and Smoothness” on page 33-7

“Dynamics of Table Inputs” on page 33-8

“Efficiency of Performance” on page 33-8

“Summary of Lookup Table Block Features” on page 33-9

### Data Set Dimensionality

In some cases, the dimensions of your data set dictate which of the lookup table blocks is right for your application. If you are approximating a one-dimensional function, consider using either the 1-D Lookup Table or Lookup Table Dynamic block. If you are approximating a two-dimensional function, consider the 2-D Lookup Table block. Blocks such as the n-D Lookup Table and Direct Lookup Table (n-D) allow you to approximate a function of  $N$  variables.

### Data Set Numeric and Data Types

The numeric and data types of your data set influence the decision of which lookup table block is most appropriate. Although all lookup table blocks support real numbers, the Direct Lookup Table (n-D), 1-D Lookup Table, 2-D Lookup Table, and n-D Lookup Table blocks also support complex table data. All lookup table blocks support integer and fixed-point data in addition to double and single data types.

---

**Note:** For the Direct Lookup Table (n-D) block, fixed-point types are supported for the table data, output port, and optional table input port.

---

### Data Accuracy and Smoothness

The desired accuracy and smoothness of the data returned by a lookup table determine which of the blocks you should use. Most blocks provide options to perform interpolation

and extrapolation, improving the accuracy of values that fall between or outside of the table data, respectively. For instance, the Lookup Table Dynamic block performs linear interpolation and extrapolation, while the n-D Lookup Table block performs either linear or cubic spline interpolation and extrapolation. In contrast, the Direct Lookup Table (n-D) block performs table lookups without any interpolation or extrapolation. You can achieve a mix of interpolation and extrapolation methods by using the Prelookup block with the Interpolation Using Prelookup block.

## **Dynamics of Table Inputs**

The dynamics of the lookup table inputs impact which of the lookup table blocks is ideal for your application. The blocks use a variety of index search methods to relate the lookup table inputs to the table's breakpoint data sets. Most of the lookup table blocks offer a binary search algorithm, which performs well if the inputs change significantly from one time step to the next. The 1-D Lookup Table, 2-D Lookup Table, n-D Lookup Table, and Prelookup blocks offer a linear search algorithm. Using this algorithm with the option that resumes searching from the previous result performs well if the inputs change slowly. Some lookup table blocks also provide a search algorithm that works best for breakpoint data sets composed of evenly spaced breakpoints. You can achieve a mix of index search methods by using the Prelookup block with the Interpolation Using Prelookup block.

## **Efficiency of Performance**

When the efficiency with which lookup tables operate is important, consider using the Prelookup block with the Interpolation Using Prelookup block. These blocks separate the table lookup process into two components — an index search that relates inputs to the table data, followed by an interpolation and extrapolation stage that computes outputs. These blocks enable you to perform a single index search and then reuse the results to look up data in multiple tables. Also, the Interpolation Using Prelookup block can perform sub-table selection, where the block interpolates a portion of the table data instead of the entire table. For example, if your 3-D table data constitutes a stack of 2-D tables to be interpolated, you can specify a selection port input to select one or more of the 2-D tables from the stack for interpolation. A full 3-D interpolation has 7 sub-interpolations but a 2-D interpolation requires only 3 sub-interpolations. As a result, significant speed improvements are possible when some dimensions of a table are used for data stacking and not intended for interpolation. These features make table lookup operations more efficient, reducing computational effort and simulation time.

## Summary of Lookup Table Block Features

Use the following table to identify features that correspond to particular lookup table blocks, then select the block that best meets your requirements.

| Feature                                | 1-D Lookup Table | 2-D Lookup Table | Lookup Table Dynamic | n-D Lookup Table | Direct Lookup Table (n-D) | Prelookup | Interp. Using Prelookup |
|--|------------------|------------------|----------------------|------------------|---------------------------|-----------|-------------------------|
| <b>Interpolation Methods</b>           |                  |                  |                      |                  |                           |           |                         |
| Flat                                   | •                | •                | •                    | •                | •                         | •         | •                       |
| Linear                                 | •                | •                | •                    | •                |                           | •         | •                       |
| Cubic spline                           | •                | •                |                      | •                |                           |           |                         |
| <b>Extrapolation Methods</b>           |                  |                  |                      |                  |                           |           |                         |
| Clip                                   | •                | •                | •                    | •                | •                         | •         | •                       |

## Enter Breakpoints and Table Data

### In this section...

“Entering Data in a Block Parameter Dialog Box” on page 33-11

“Entering Data in the Lookup Table Editor” on page 33-11

“Entering Data Using Inports of the Lookup Table Dynamic Block” on page 33-13

### Entering Data in a Block Parameter Dialog Box

This example shows how to populate a 1-D **Lookup Table** block using the parameter dialog box. The lookup table in this example approximates the function  $y = x^3$  over the range  $[-3, 3]$ .

- 1 Copy a 1-D **Lookup Table** block from the **Lookup Tables** block library to a Simulink model.
- 2 In the 1-D **Lookup Table** block dialog box, enter the table dimensions and table data in the specified fields of the dialog box:
  - Set **Number of table dimensions** to 1.
  - Set **Table data** to  $[-27 \ -8 \ -1 \ 0 \ 1 \ 8 \ 27]$ .
- 3 Enter the breakpoint data set using either of two methods:
  - To specify evenly spaced data points, set **Breakpoint specification** to **Even spacing**. Set **First point** to  $-3$  and **Spacing** to 1. The block calculates the number of evenly spaced breakpoints based on the table data.
  - To specify breakpoint data explicitly, set **Breakpoint specification** to **Explicit values** and set **Breakpoints 1** to  $[-3:3]$ .

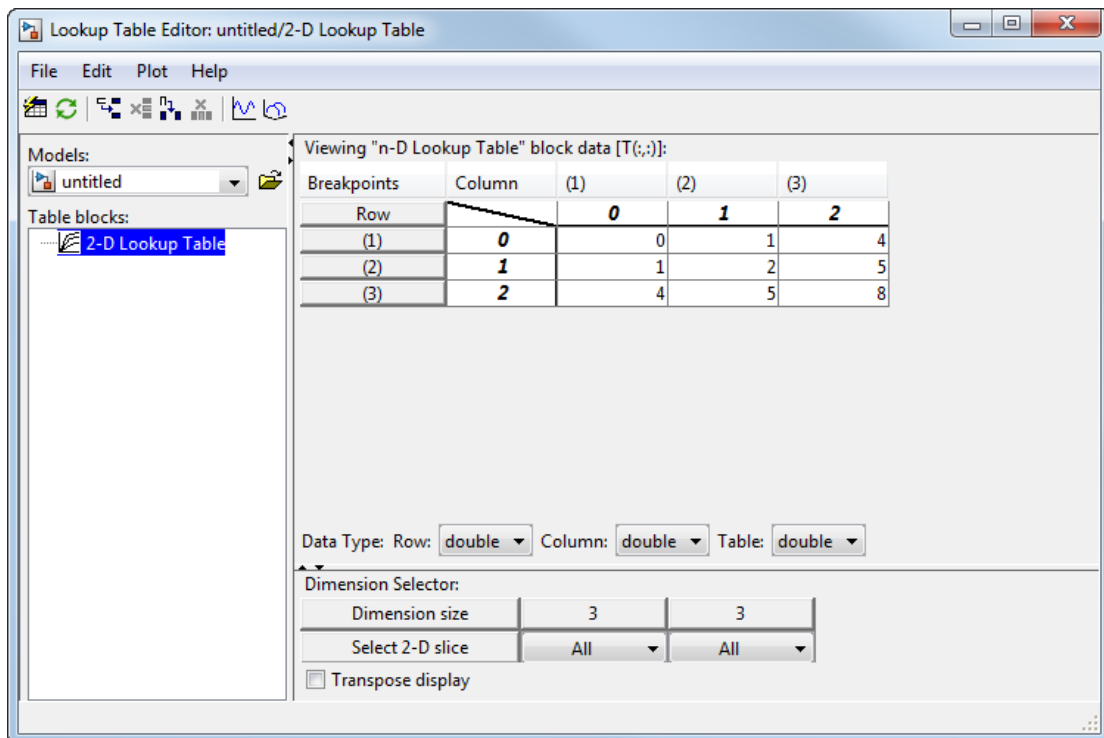

### Entering Data in the Lookup Table Editor

Use the following procedure to populate a 2-D **Lookup Table** block using the **Lookup Table Editor**. In this example, the lookup table approximates the function  $z = x^2 + y^2$  over the input ranges  $x = [0, 2]$  and  $y = [0, 2]$ .

- 1 Copy a 2-D **Lookup Table** block from the **Lookup Tables** block library to a Simulink model.

- 2 Open the Lookup Table Editor by selecting **Lookup Table Editor** from the Simulink **Edit** menu or by clicking **Edit table and breakpoints** on the dialog box of the 2-D Lookup Table block.
- 3 Under **Viewing "n-D Lookup Table" block data**, enter the breakpoint data sets and table data in the appropriate cells. To change data, click a cell, enter the new value, and press **Enter**.
  - In the cells associated with the **Row Breakpoints**, enter each of the values [0 1 2].
  - In the cells associated with the **Column Breakpoints**, enter each of the values [0 1 2].
  - In the table data cells, enter the values in the array [0 1 4; 1 2 5; 4 5 8].

The Lookup Table Editor looks like this:

- 4 In the Lookup Table Editor, select **File > Update Block Data** to update the data in the 2-D Lookup Table block.
- 5 Close the Lookup Table Editor.

## Entering Data Using Inports of the Lookup Table Dynamic Block

Use the following procedure to populate a **Lookup Table Dynamic** block using that block's inports. In this example, the lookup table approximates the function  $y = 3x^2$  over the range  $[0, 10]$ .

- 1 Copy a **Lookup Table Dynamic** block from the **Lookup Tables** block library to a Simulink model.
- 2 Copy the blocks needed to implement the equation  $y = 3x^2$  to the Simulink model:
  - One **Constant** block to define the input range, from the **Sources** library
  - One **Math Function** block to square the input range, from the **Math Operations** library
  - One **Gain** block to multiply the signal by 3, also from the **Math Operations** library
- 3 Assign the following parameter values to the **Constant**, **Math Function**, and **Gain** blocks using their dialog boxes:

| Block         | Parameter             | Value  |
|---------------|-----------------------|--------|
| Constant      | <b>Constant value</b> | 0:10   |
| Math Function | <b>Function</b>       | square |
| Gain          | <b>Gain</b>           | 3      |

- 4 Input the breakpoint data set to the **Lookup Table Dynamic** block by connecting the output of the **Constant** block to the inport of the **Lookup Table Dynamic** block labeled **xdat**. This signal is the input breakpoint data set for  $x$ .
- 5 Input the table data to the **Lookup Table Dynamic** block by branching the output signal from the **Constant** block and connecting it to the **Math Function** block. Then connect the **Math Function** block to the **Gain** block. Finally, connect the **Gain** block to the inport of the **Lookup Table Dynamic** block labeled **ydat**. This signal is the table data for  $y$ .

## Characteristics of Lookup Table Data

### Sizes of Breakpoint Data Sets and Table Data

The following constraints apply to the sizes of breakpoint data sets and table data associated with lookup table blocks:

- The memory limitations of your system constrain the overall size of a lookup table.
- Lookup tables must use consistent dimensions so that the overall size of the table data reflects the size of each breakpoint data set.

To illustrate the second constraint, consider the following vectors of input and output values that create the relationship in the plot.

Vector of input values: [-3 -2 -1 0 1 2 3]

Vector of output values: [-3 -1 0 -1 0 1 3]

In this example, the input and output data are the same size (1-by-7), making the data consistently dimensioned for a 1-D lookup table.

The following input and output values define the 2-D lookup table that is graphically shown.

Row index input values: [1 2 3]  
 Column index input values: [1 2 3 4]  
 Table data: [11 12 13 14; 21 22 23 24; 31 32 33 34]

|   | 1  | 2  | 3  | 4  |
|---|----|----|----|----|
| 1 | 11 | 12 | 13 | 14 |
| 2 | 21 | 22 | 23 | 24 |
| 3 | 31 | 32 | 33 | 34 |

In this example, the sizes of the vectors representing the row and column indices are 1-by-3 and 1-by-4, respectively. Consequently, the output table must be of size 3-by-4 for consistent dimensions.

## Monotonicity of Breakpoint Data Sets

The first stage of a table lookup operation involves relating inputs to the breakpoint data sets. The search algorithm requires that input breakpoint sets be *monotonically increasing*, that is, each successive element is equal to or greater than its preceding element. For example, the vector

$A = [0 \ 0.5 \ 1 \ 1.9 \ 2 \ 2 \ 2 \ 2.1 \ 3]$

repeats the value 2 while all other elements are increasingly larger than their predecessors; hence,  $A$  is monotonically increasing.

For lookup tables with data types other than `double` or `single`, the search algorithm requires an additional constraint due to quantization effects. In such cases, the input breakpoint data sets must be *strictly monotonically increasing*, that is, each successive element must be greater than its preceding element. Consider the vector

$B = [0 \ 0.5 \ 1 \ 1.9 \ 2 \ 2.1 \ 2.17 \ 3]$

in which each successive element is greater than its preceding element, making  $B$  strictly monotonically increasing.

---

**Note:** Although a breakpoint data set is strictly monotonic in `double` format, it might not be so after conversion to a fixed-point data type.

---

## Representation of Discontinuities in Lookup Tables

You can represent discontinuities in lookup tables that have monotonically increasing breakpoint data sets. To create a discontinuity, repeat an input value in the breakpoint data set with different output values in the table data. For example, these vectors of input ( $x$ ) and output ( $y$ ) values associated with a 1-D lookup table create the step transitions depicted in the plot that follows.

Vector of input values: [-2 -1 -1 0 0 1 1 2]  
 Vector of output values: [-1 -1 -2 -2 2 2 1 1]

This example has discontinuities at  $x = -1$ ,  $0$ , and  $+1$ .

When there are two output values for a given input value, the block chooses the output according to these rules:

- If the input signal is less than zero, the block returns the output value associated with the last occurrence of the input value in the breakpoint data set. In this example, if the input is  $-1$ ,  $y$  is  $-2$ , marked with a solid circle.
- If the input signal is greater than zero, the block returns the output value associated with the first occurrence of the input value in the breakpoint data set. In this example, if the input is  $1$ ,  $y$  is  $2$ , marked with a solid circle.
- If the input signal is zero and there are two output values specified at the origin, the block returns the average of those output values. In this example, if the input is  $0$ ,  $y$  is  $0$ , the average of the two output values  $-2$  and  $2$  specified at  $x = 0$ .

When there are three points specified at the origin, the block generates the output associated with the middle point. The following example demonstrates this special rule.

Vector of input values: [-2 -1 -1 0 0 0 1 1 2]  
 Vector of output values: [-1 -1 -2 -2 1 2 2 1 1]

In this example, three points define the discontinuity at the origin. When the input is 0,  $y$  is 1, the value of the middle point.

You can apply this same method to create discontinuities in breakpoint data sets associated with multidimensional lookup tables.

### Formulation of Evenly Spaced Breakpoints

You can represent evenly spaced breakpoints in a data set by using one of these methods.

| Formulation  | Example              | When to Use This Formulation  |
|--|----------------------|---|
| [first_value:spacing:last_value]                             | [10:10:200]          | The lookup table does <i>not</i> use <b>double</b> or <b>single</b> . |
| first_value + spacing * [0:(last_value-first_value)/spacing] | 1 + (0.02 * [0:450]) | The lookup table uses <b>double</b> or <b>single</b> .                |

Because floating-point data types cannot precisely represent some numbers, the second formulation works better for **double** and **single**. For example, use  $1 + (0.02 *$

[0:450]) instead of [1:0.02:10]. For a list of lookup table blocks that support evenly spaced breakpoints, see “Summary of Lookup Table Block Features” on page 33-9.

Among other advantages, evenly spaced breakpoints can make the generated code division-free and reduce memory usage. For more information, see:

- `fixpt_evenspace_cleanup` in the Simulink documentation
- “Effects of Spacing on Speed, Error, and Memory Usage” in the Fixed-Point Designer documentation
- “Identify questionable fixed-point operations” in the Simulink Coder documentation

---

**Tip** Do not use the MATLAB `linspace` function to define evenly spaced breakpoints. Simulink uses a tighter tolerance to check whether a breakpoint set has even spacing. If you use `linspace` to define breakpoints for your lookup table, Simulink considers the breakpoints to be unevenly spaced.

---

## Methods for Estimating Missing Points

### In this section...

“About Estimating Missing Points” on page 33-20

“Interpolation Methods” on page 33-20

“Extrapolation Methods” on page 33-21

“Rounding Methods” on page 33-22

“Example Output for Lookup Methods” on page 33-23

### About Estimating Missing Points

The second stage of a table lookup operation involves generating outputs that correspond to the supplied inputs. If the inputs match the values of indices specified in breakpoint data sets, the block outputs the corresponding values. However, if the inputs fail to match index values in the breakpoint data sets, Simulink estimates the output. In the block parameter dialog box, you can specify how to compute the output in this situation. The available lookup methods are described in the following sections.

### Interpolation Methods

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. Most lookup table blocks have the following interpolation methods available:

- **Flat** — Disables interpolation and uses the rounding operation titled **Use Input Below**. For more information, see “Rounding Methods” on page 33-22.
- **Nearest** — Disables interpolation and returns the table value corresponding to the breakpoint closest to the input. If the input is equidistant from two adjacent breakpoints, the breakpoint with the higher index is chosen.
- **Linear** — Fits a line between the adjacent breakpoints, and returns the point on that line corresponding to the input.
- **Cubic spline** — Fits a cubic spline to the adjacent breakpoints, and returns the point on that spline corresponding to the input.

---

**Note:** The Lookup Table Dynamic block does not let you select an interpolation method. The **Interpolation-Extrapolation** option in the **Lookup Method** field of the block parameter dialog box performs linear interpolation.

---

Each interpolation method includes a trade-off between computation time and the smoothness of the result. Although rounding is quickest, it is the least smooth. Linear interpolation is slower than rounding but generates smoother results, except at breakpoints where the slope changes. Cubic spline interpolation is the slowest method but produces the smoothest results.

## Extrapolation Methods

When an input falls outside the range of a breakpoint data set, the block extrapolates the output value from a pair of values at the end of the breakpoint data set. Most lookup table blocks have the following extrapolation methods available:

- **Clip** — Disables extrapolation and returns the table data corresponding to the end of the breakpoint data set range. This does not provide protection against out-of-range values.
- **Linear** — If the interpolation method is **Linear**, this extrapolation method fits a line between the first or last pair of breakpoints, depending on whether the input is less than the first or greater than the last breakpoint. If the interpolation method is **Cubic spline**, this extrapolation method fits a linear surface using the slope of the interpolant at the first or last break point, depending on whether the input is less than the first or greater than the last breakpoint. The extrapolation method returns the point on the generated linear surface corresponding to the input.
- **Cubic spline** — Fits a cubic spline to the first or last pair of breakpoints, depending if the input is less than the first or greater than the last breakpoint, respectively. This method returns the point on that spline corresponding to the input.

---

**Note:** The Lookup Table Dynamic block does not let you select an extrapolation method. The **Interpolation-Extrapolation** option in the **Lookup Method** field of the block parameter dialog box performs linear extrapolation.

---

In addition to these methods, some lookup table blocks, such as the n-D Lookup Table block, allow you to select an action to perform when encountering situations that require extrapolation. For instance, you can specify that Simulink generate either a warning or

an error when the lookup table inputs are outside the ranges of the breakpoint data sets. To specify such an action, select it from the **Diagnostic for out-of-range input** list on the block parameter dialog box.

## Rounding Methods

If an input falls between breakpoint values or outside the range of a breakpoint data set and you do not specify interpolation or extrapolation, the block rounds the value to an adjacent breakpoint and returns the corresponding output value. For example, the Lookup Table Dynamic block lets you select one of the following rounding methods:

- **Use Input Nearest** — Returns the output value corresponding to the nearest input value.
- **Use Input Below** — Returns the output value corresponding to the breakpoint value that is immediately less than the input value. If no breakpoint value exists below the input value, it returns the breakpoint value nearest the input value.
- **Use Input Above** — Returns the output value corresponding to the breakpoint value that is immediately greater than the input value. If no breakpoint value exists above the input value, it returns the breakpoint value nearest the input value.

## Example Output for Lookup Methods

In the following model, the Lookup Table Dynamic block accepts a vector of breakpoint data given by  $[-5:5]$  and a vector of table data given by  $\sinh([-5:5])$ .

The Lookup Table Dynamic block outputs the following values when using the specified lookup methods and inputs.

| Lookup Method                | Input | Output | Comment                                      |
|------------------------------|-------|--------|--|
| Interpolation-Extrapolation  | 1.4   | 2.156  | N/A  |
|                              | 5.2   | 83.59  | N/A  |
| Interpolation-Use End Values | 1.4   | 2.156  | N/A  |
|                              | 5.2   | 74.2   | The block uses the value for $\sinh(5.0)$ .  |
| Use Input Above              | 1.4   | 3.627  | The block uses the value for $\sinh(2.0)$ .  |
|                              | 5.2   | 74.2   | The block uses the value for $\sinh(5.0)$ .  |
| Use Input Below              | 1.4   | 1.175  | The block uses the value for $\sinh(1.0)$ .  |
|                              | -5.2  | -74.2  | The block uses the value for $\sinh(-5.0)$ . |
| Use Input Nearest            | 1.4   | 1.175  | The block uses the value for $\sinh(1.0)$ .  |

| “Edit N-Dimensional Lookup Tables” on page 33-24 |
| “Edit Custom Lookup Table Blocks” on page 33-26  |

You can edit a lookup table using:

- Lookup Table block dialog box
- Lookup Table Editor

To edit the lookup table in a block:

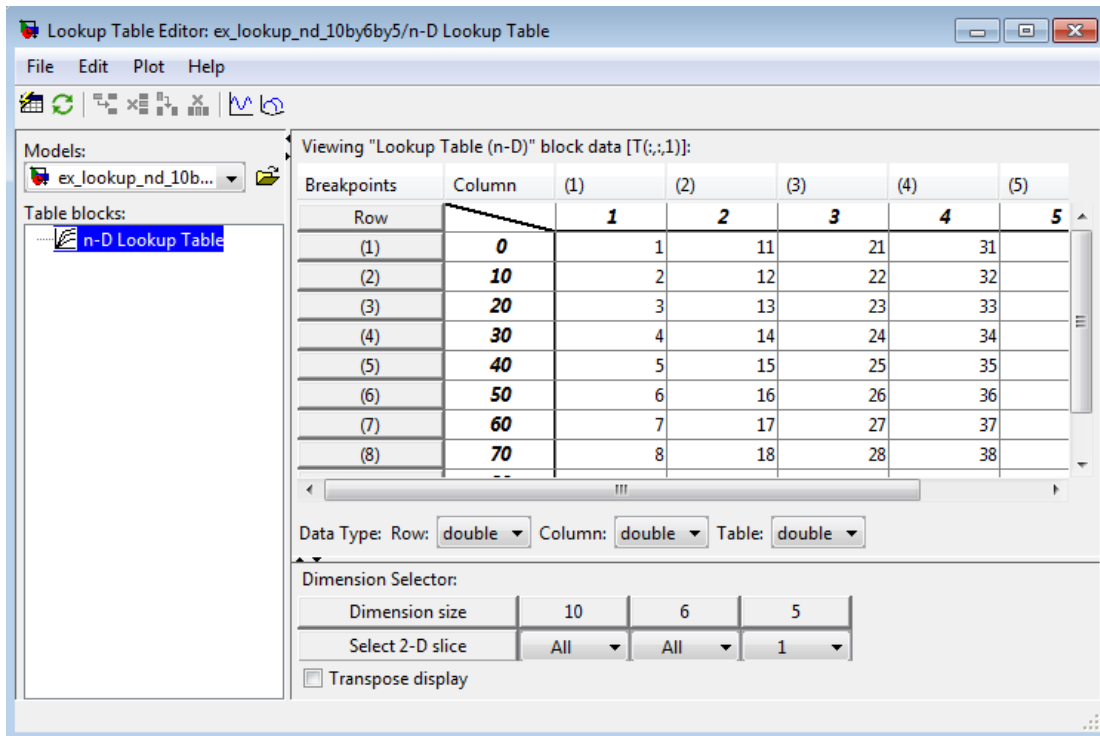

- 1** Open the subsystem that contains the lookup table block.
- 2** Open the lookup table block’s dialog box.
- 3** In the Table and Breakpoints tab, edit the **Table data** and relevant **Breakpoints** parameters as needed.

With the Lookup Table Editor, you can skip these steps and edit the desired lookup table without navigating to the block that uses it. However, you cannot use the Lookup Table Editor to change the dimensions of a lookup table. You must use the block parameter dialog box for this purpose.

### Edit N-Dimensional Lookup Tables

If the lookup table of the block currently selected in the Lookup Table Editor tree view has more than two dimensions, the table view displays a two-dimensional slice of the lookup table.

The **Dimension Selector** specifies which slice currently appears and lets you select another slice. The selector consists of a 2-by-N array of controls, where N is the number of dimensions in the lookup table. Each column corresponds to a dimension of the lookup table. The first column corresponds to the first dimension of the table, the second column to the second dimension of the table, and so on. The **Dimension size** row of the selector array displays the size of each dimension. The **Select 2-D slice** row specifies which dimensions of the table correspond to the row and column axes of the slice and the indices that select the slice from the remaining dimensions.

To select another slice of the table, specify the row and column axes of the slice in the first two columns of the **Select 2-D slice** row. Then select the indices of the slice from the pop-up index lists in the remaining columns.

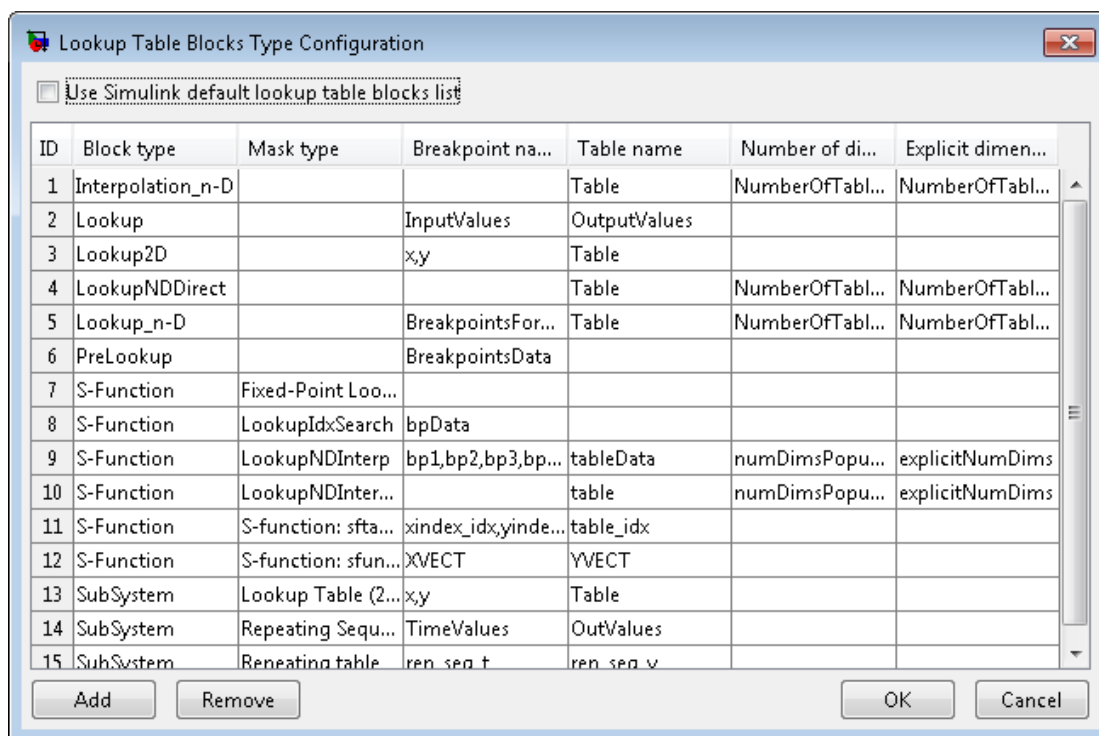

For example, the following selector displays slice  $(:,:,1)$  of a 3-D lookup table, as shown under Dimension Selector in the Lookup Table Editor.

To transpose the table display, select the **Transpose display** check box.

## Edit Custom Lookup Table Blocks

You can use the Lookup Table Editor to edit custom lookup table blocks that you have created. To do this, you must first configure the Lookup Table Editor to recognize the custom lookup table blocks in your model.

- 1 Select **File > Configure**. The Lookup Table Blocks Type Configuration dialog box appears.

The dialog box displays a table of the lookup table block types that the Lookup Table Editor currently recognizes. This table includes the standard blocks. Each row of the table displays key attributes of a lookup table block type.

- 2 Click **Add** on the dialog box. A new row appears at the bottom of the block type table.
- 3 Enter information for the custom block in the new row under these headings.

| Field Name           | Description  |
|----------------------|--|
| Block type           | Block type of the custom block. The block type is the value of the block's <b>BlockType</b> parameter. |
| Mask type            | Mask type of the custom block. The mask type is the value of the block's <b>MaskType</b> parameter.    |
| Breakpoint name      | Names of the block parameters that store the breakpoints.  |
| Table name           | Name of the block parameter that stores the table data.  |
| Number of dimensions | Leave empty.   |
| Explicit dimensions  | Leave empty.   |

**4** Click **OK**.

To remove a custom lookup table block type from the list that the Lookup Table Editor recognizes, select the custom entry in the table of the Lookup Table Blocks Type Configuration dialog box and click **Remove**. To remove all custom lookup table block types, select the **Use Simulink default lookup table blocks list** check box at the top of the dialog box.

## Import Lookup Table Data from MATLAB

### In this section...

“Import Standard Format Lookup Table Data” on page 33-28

“Propagate Standard Format Lookup Table Data” on page 33-29

“Import Nonstandard Format Lookup Table Data” on page 33-30

“Propagate Nonstandard Format Lookup Table Data” on page 33-31

You can import table and breakpoint data from variables in the MATLAB workspace by referencing them in the **Table and Breakpoints** tab of the dialog box. The following examples show how to import and export standard format and non-standard format data from the MATLAB workspace.

### Import Standard Format Lookup Table Data

Suppose you specify a 3-D lookup table in your n-D Lookup Table block.

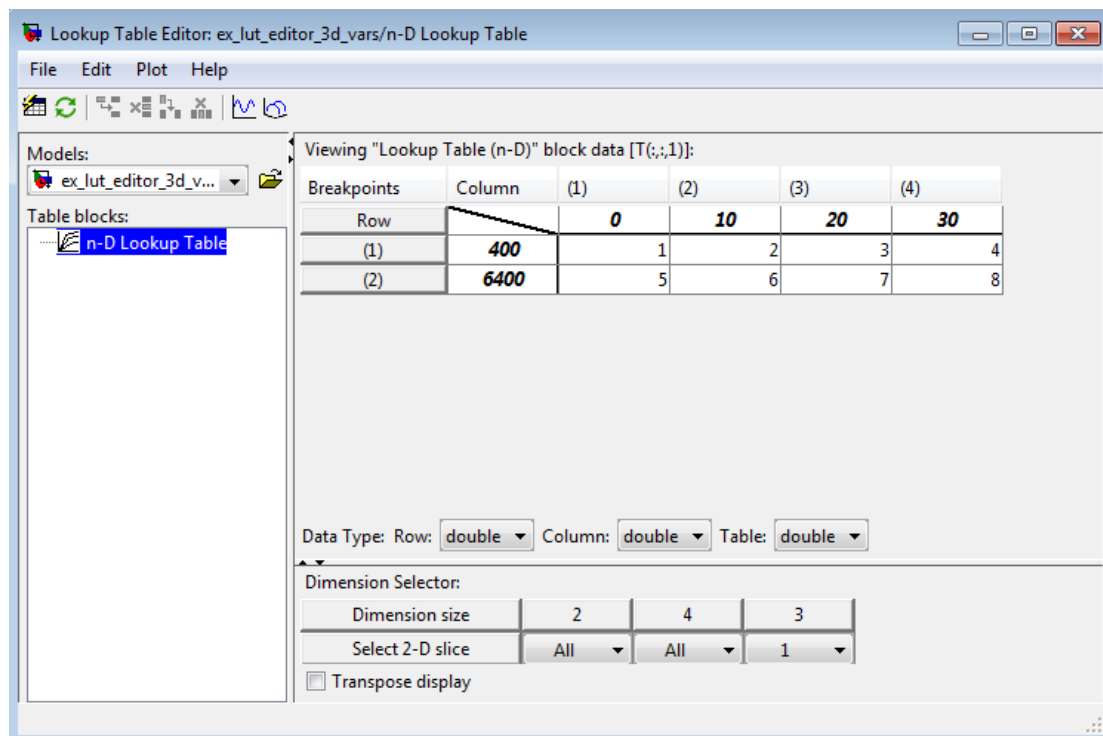

Create workspace variables to use as breakpoint and table data for the lookup table.

```
table3d_map = zeros(2,4,3);
table3d_map(:,:,1) = [ 1 2 3 4; 5 6 7 8];
table3d_map(:,:,2) = [ 11 12 13 14; 15 16 17 18];
table3d_map(:,:,3) = [ 111 112 113 114; 115 116 117 118];
bp3d_z = [ 0 10 20];
bp3d_x = [ 0 10 20 30];
bp3d_y = [ 400 6400];
```

Open the n-D Lookup Table block dialog box, and enter the following parameters in the Table and Breakpoints tab:

- Table data: table3d\_map
- Breakpoints 1: bp3d\_y
- Breakpoints 2: bp3d\_x
- Breakpoints 3: bp3d\_z

Click **Edit table and breakpoints** to open the Lookup Table Editor and show the data from the workspace variables.

## Propagate Standard Format Lookup Table Data

When you make changes to your lookup table data, consider propagating the changes back to the MATLAB workspace variables the data was imported from using **File > Update Block Data**.

Suppose you make a change to the lookup table variables imported from the MATLAB workspace variables in "Import Standard Format Lookup Table Data" on page 33-28. For example, change the value of the data in (1,1,1) from 1 to 33. To propagate this change back to `table3d_map` in the workspace, select **File > Update Block Data**. Click **Yes** to confirm that you want to overwrite `table3d_map`.

## Import Nonstandard Format Lookup Table Data

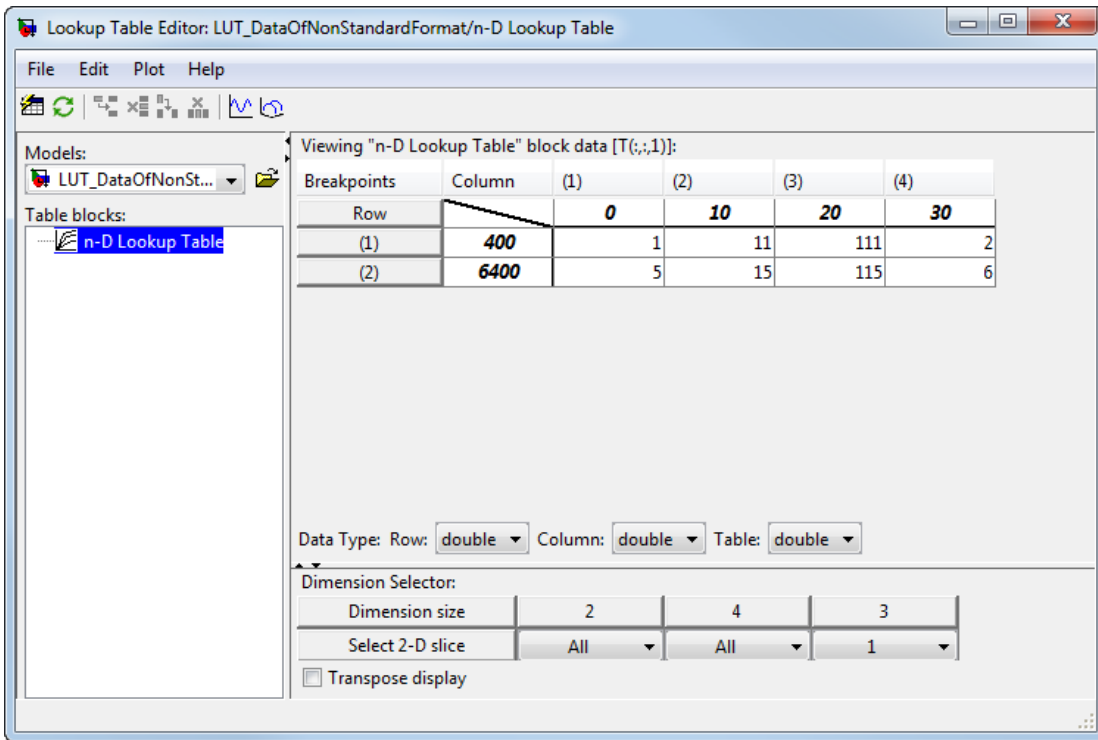

Suppose you specify a 3-D lookup table in your n-D Lookup Table block. Create workspace variables to use as breakpoint and table data for the lookup table. The variable for table data, `table3d_map_custom`, is a two-dimensional matrix.

```
table3d_map_custom = zeros(6,4);
table3d_map_custom = [ 1 2 3 4; 5 6 7 8;
11 12 13 14; 15 16 17 18;
111 112 113 114; 115 116 117 118];
bp3d_z =[ 0 10 20];
bp3d_x =[ 0 10 20 30];
bp3d_y =[ 400 6400];
```

Open the n-D Lookup Table block dialog box, and enter the following parameters in the Table and Breakpoints tab. Transform `table3d_map_custom` into a three-dimensional matrix for the table data input using the `reshape` command below.

- Table data: `reshape(table3d_map_custom,[2,4,3])`
- Breakpoints 1: `bp3d_y`
- Breakpoints 2: `bp3d_x`
- Breakpoints 3: `bp3d_z`

Click **Edit table and breakpoints** to open the Lookup Table Editor and show the data from the workspace variables.

Change 1 to 33 in the Lookup Table Editor. The Lookup Table Editor records your changes by maintaining a copy of the table. To restore the variable values from the MATLAB workspace, select **File > Reload Block Data**. To update the MATLAB workspace variables with the edited data, select **File > Update Block Data** in the Lookup Table Editor. You cannot propagate the change to `table3d_map_custom`, the workspace variable that contains the nonstandard table data for the n-D Lookup Table block. To propagate the change, you must register a customization function that resides on the MATLAB search path. For details, see “Propagate Nonstandard Format Lookup Table Data” on page 33-31.

## Propagate Nonstandard Format Lookup Table Data

This example shows how to propagate changes from the Lookup Table Editor to workspace variables of nonstandard format. Suppose your Simulink model from “Import Nonstandard Format Lookup Table Data” on page 33-30 has a three-dimensional lookup table that gets its table data from the two-dimensional workspace variable

`table3d_map_custom`. Update the lookup table in the Lookup Table Editor and propagate these changes back to `table3d_map_custom` using a customization function.

- 1 Create a file named `s1_customization.m` with these contents.

```
function s1_customization(cm)
cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle{end+1} = ...
@myGetTableConvertInfoFcn;
end
```

In this function:

- The argument `cm` is the handle to a customization manager object.
- The handle `@myGetTableConvertInfoFcn` is added to the list of function handles in the cell array for `cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle`. You can use any alphanumeric name for the function whose handle you add to the cell array.

- 2 In the same file, define the `myGetTableConvertInfoFcn` function.

```
function blkInfo = myGetTableConvertInfoFcn(blk, tableStr)
    blkInfo.allowTableConvertLocal = true;
    blkInfo.tableWorkSpaceVarName = 'table3d_map_custom';
    blkInfo.tableConvertFcnHandle = @myConvertTableFcn;
end
```

The `myGetTableConvertInfoFcn` function returns the `blkInfo` object containing three fields.

- `allowTableConvertLocal` — Allows table data conversion for a block.
- `tableWorkSpaceVarName` — Specifies the name of the workspace variable that has a nonstandard table format.
- `tableConvertFcnHandle` — Specifies the handle for the conversion function.

When `allowTableConvertLocal` is set to `true`, the table data for that block is converted to the nonstandard format of the workspace variable whose name matches `tableWorkSpaceVarName`. The conversion function corresponds to the handle that `tableConvertFcnHandle` specifies. You can use any alphanumeric name for the conversion function.

- 3 In the same file, define the `myConvertTableFcn` function. This function converts a three-dimensional lookup table of size *Rows* \* *Columns* \* *Height* to a two-dimensional variable of size *(Rows\*Height) \* Columns*.

```
% Converts 3-dimensional lookup table from Simulink format to
% nonstandard format used in workspace variable
function cMap = myConvertTableFcn(data)
```

```
% Determine the row and column number of the 3D table data
mapDim = size(data);
numCol = mapDim(2);
numRow = mapDim(1)*mapDim(3);
cMap = zeros(numRow, numCol);
% Transform data back to a 2-dimensional matrix
cMap = reshape(data,[numRow,numCol]);
end
```

- 4 Put `sl_customization.m` on the MATLAB search path. You can have multiple files named `sl_customization.m` on the search path. For more details, see “Behavior with Multiple Customization Functions” on page 33-34.
- 5 Refresh Simulink customizations at the MATLAB command prompt.
 

```
sl_refresh_customizations
```
- 6 Open the Lookup Table Editor for your lookup table block and select **File > Update Block Data**. Click **Yes** to overwrite the workspace variable `table3d_map_custom`.
- 7 Check the value of `table3d_map_custom` in the base workspace.

```
table3d_map_custom =

    33     2     3     4
     5     6     7     8
    11    12    13    14
    15    16    17    18
   111   112   113   114
   115   116   117   118
```

The change in the Lookup Table Editor has propagated to the workspace variable.

---

**Note:** If you do not overwrite the workspace variable `table3d_map_custom`, you are prompted to replace it with numeric data. Click **Yes** to replace the expression in the **Table data** field with numeric data. Click **No** if you do not want your Lookup Table Editor changes for the table data to appear in the block dialog box.

---

### Behavior with Multiple Customization Functions

At the start of a MATLAB session, Simulink loads each `sl_customization.m` customization file on the path and executes the `sl_customization` function. Executing each function establishes the customizations for that session.

When you select **File > Update Block Data** in the Lookup Table Editor, the editor checks the list of function handles in the cell array for `cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle`. If the cell array contains one or more function handles, the `allowTableConvertLocal` property determines whether changes in the Lookup Table Editor can be propagated.

- If the value is set to `true`, then the table data is converted to the nonstandard format in the workspace variable.
- If the value is set to `false`, then table data is not converted to the nonstandard format in the workspace variable.
- If the value is set to `true` and another customization function specifies it to be `false`, the Lookup Table Editor reports an error.

## Import Lookup Table Data from Excel

This example shows how to use the MATLAB `xlsread` function in a Simulink model to import data into a lookup table.

- 1 Save the Excel file in a folder on the MATLAB path.
- 2 Open the model containing the lookup table block and select **File > Model Properties > Model Properties**.
- 3 In the Model Properties dialog box, in the **Callbacks** tab, click **PostLoadFcn** callback in the model callbacks list.
- 4 Enter the code to import the Excel Spreadsheet data in the text box. Use the MATLAB `xlsread` function, as shown in this example for a 2-D lookup table.

```
% Import the data from Excel for a lookup table
data = xlsread('MySpreadsheet','Sheet1');
% Row indices for lookup table
breakpoints1 = data(2:end,1)';
% Column indices for lookup table
breakpoints2 = data(1,2:end);
% Output values for lookup table
table_data = data(2:end,2:end);
```

- 5 Click **OK**.

After you save your changes, the next time you open the model, Simulink invokes the callback and imports the data.

## Create a Logarithm Lookup Table

Suppose you want to approximate the common logarithm (base 10) over the input range [1, 10] without performing an expensive computation. You can perform this approximation using a lookup table block as described in the following procedure.

- 1 Copy the following blocks to a Simulink model:
  - One **Constant** block to input the signal, from the Sources library
  - One **n-D Lookup Table** block to approximate the common logarithm, from the Lookup Tables library
  - One **Display** block to display the output, from the Sinks library
- 2 Assign the table data and breakpoint data set to the n-D Lookup Table block:
  - a In the **Number of table dimensions** field, enter 1.
  - b In the **Table data** field, enter  
[0 .301 .477 .602 .699 .778 .845 .903 .954 1].
  - c In the **Breakpoints 1** field, enter [1:10].
  - d Click **Apply**.

The dialog box looks something like this:

- 3 Double-click the Constant block to open the parameter dialog box, and change the **Constant value** parameter to 5. Click **OK** to apply the changes and close the dialog box.
- 4 Connect the blocks as follows.

- 5 Start simulation.

The following behavior applies to the n-D Lookup Table block.

| Value of the Constant Block                        | Action by the n-D Lookup Table Block   | Example of Block Behavior |              |
|--|--|---------------------------|--------------|
|  |  | Input Value               | Output Value |
| Equals a breakpoint                                | Returns the corresponding output value   | 5                         | 0.699        |
| Falls between breakpoints                          | Linearly interpolates the output value using neighboring breakpoints                               | 7.5                       | 0.874        |
| Falls outside the range of the breakpoint data set | Linearly extrapolates the output value from a pair of values at the end of the breakpoint data set | 10.5                      | 1.023        |

For the n-D Lookup Table block, the default settings for **Interpolation method** and **Extrapolation method** are both **Linear**.

## Prelookup and Interpolation Blocks

The following examples show the benefits of using Prelookup and Interpolation Using Prelookup blocks.

| Action   | Benefit   | Example   |
|--|---|---|
| Use an index search to relate inputs to table data, followed by an interpolation and extrapolation stage that computes outputs | Enables reuse of index search results to look up data in multiple tables, which reduces simulation time   | To open the model, type <code>sldemo_bpcheck</code> at the command prompt.              |
| Set breakpoint and table data types explicitly   | Lowers memory required to store: <ul style="list-style-type: none"> <li>• Breakpoint data that uses a smaller type than the input signal</li> <li>• Table data that uses a smaller type than the output signal</li> </ul> | To open the model, type <code>sldemo_interp_memory</code> at the command prompt.        |
|  | Provides easier sharing of: <ul style="list-style-type: none"> <li>• Breakpoint data among Prelookup blocks</li> <li>• Table data among Interpolation Using Prelookup blocks</li> </ul>                                   | To open the model, type <code>fxpdemo_lookup_shared_param</code> at the command prompt. |
|  | Enables reuse of utility functions in the generated code  | To open the model, type <code>fxpdemo_prelookup_utilfcn</code> at the command prompt.   |
| Set the data type for intermediate results explicitly  | Enables use of higher precision for internal computations than for table data or output data  | To open the model, type <code>fxpdemo_interp_precision</code> at the command prompt.    |

## Optimize Generated Code for Lookup Table Blocks

### In this section...

“Remove Code That Checks for Out-of-Range Inputs” on page 33-40

“Optimize Breakpoint Spacing in Lookup Tables” on page 33-42

### Remove Code That Checks for Out-of-Range Inputs

By default, generated code for the following lookup table blocks include conditional statements that check for out-of-range breakpoint or index inputs:

- 1-D Lookup Table
- 2-D Lookup Table
- n-D Lookup Table
- Prelookup
- Interpolation Using Prelookup

To generate code that is more efficient, you can remove the conditional statements that protect against out-of-range input values.

| Block                         | Check Box to Select   |
|-------------------------------|---|
| 1-D Lookup Table              | <b>Remove protection against out-of-range input in generated code</b> |
| 2-D Lookup Table              |   |
| n-D Lookup Table              |   |
| Prelookup                     |   |
| Interpolation Using Prelookup | <b>Remove protection against out-of-range index in generated code</b> |

Selecting the check box on the block dialog box improves code efficiency because there are fewer statements to execute. However, if you are generating code for safety-critical applications, you should not remove the range-checking code.

To verify the usage of the check box, run the following Model Advisor checks and perform the recommended actions.

| <b>Model Advisor Check</b>   | <b>When to Run the Check</b>     |
|--|----------------------------------|
| <b>By Product &gt; Embedded Coder &gt; Identify lookup table blocks that generate expensive out-of-range checking code</b>                             | For code efficiency              |
| <b>By Product &gt; Simulink Verification and Validation &gt; Modeling Standards &gt; DO-178C/DO-331 Checks &gt; Check usage of lookup table blocks</b> | For safety-critical applications |

For more information about the Model Advisor, see “Consulting the Model Advisor” on page 5-2 in the Simulink documentation.

## Optimize Breakpoint Spacing in Lookup Tables

When breakpoints in a lookup table are tunable, the spacing does not affect efficiency or memory usage of the generated code. When breakpoints are *not* tunable, the type of spacing can affect the following factors.

| Factor          | Even Power of 2 Spaced Data   | Evenly Spaced Data   | Unevenly Spaced Data  |
|-----------------|---|--|---|
| Execution speed | The execution speed is the fastest. The position search and interpolation are the same as for evenly-spaced data. However, to increase speed a bit more for fixed-point types, a bit shift replaces the position search, and a bit mask replaces the interpolation. | The execution speed is faster than that for unevenly-spaced data because the position search is faster and the interpolation uses a simple division.                     | The execution speed is the slowest of the different spacings because the position search is slower, and the interpolation requires more operations. |
| Error           | The error can be larger than that for unevenly-spaced data because approximating a function with nonuniform curvature requires more points to achieve the same accuracy.  | The error can be larger than that for unevenly-spaced data because approximating a function with nonuniform curvature requires more points to achieve the same accuracy. | The error can be smaller because approximating a function with nonuniform curvature requires fewer points to achieve the same accuracy.             |
| ROM usage       | Uses less command ROM, but more data ROM.   | Uses less command ROM, but more data ROM.  | Uses more command ROM, but less data ROM.   |
| RAM usage       | Not significant.  | Not significant.   | Not significant.  |

Follow these guidelines:

- For fixed-point data types, use breakpoints with even, power-of-2 spacing.
- For non-fixed-point data types, use breakpoints with even spacing.

To identify opportunities for improving code efficiency in lookup table blocks, run the following Model Advisor checks and perform the recommended actions:

- **By Product > Embedded Coder > Identify questionable fixed-point operations**
- **By Product > Embedded Coder > Identify blocks that generate expensive saturation and rounding code**

For more information about the Model Advisor, see “Consulting the Model Advisor” on page 5-2 in the Simulink documentation.

## Update Lookup Table Blocks to New Versions

### In this section...

“Comparison of Blocks with Current Versions” on page 33-44

“Compatibility of Models with Older Versions of Lookup Table Blocks” on page 33-45

“How to Update Your Model” on page 33-46

“What to Expect from the Model Advisor Check” on page 33-46

### Comparison of Blocks with Current Versions

In R2011a, the following lookup table blocks were replaced with newer versions in the Simulink library:

| Block              | Changes   | Enhancements   |
|--------------------|---|--|
| Lookup Table       | <ul style="list-style-type: none"> <li>Block renamed as 1-D Lookup Table</li> <li>Icon changed</li> </ul> | <ul style="list-style-type: none"> <li>Default integer rounding mode changed from Floor to Simplest</li> <li>Support for the following features: <ul style="list-style-type: none"> <li>Specification of parameter data types different from input or output signal types</li> <li>Reduced memory use and faster code execution for nontunable breakpoints with even spacing</li> <li>Cubic-spline interpolation and extrapolation</li> <li>Table data with complex values</li> <li>Fixed-point data types with word lengths up to 128 bits</li> <li>Specification of data types for fraction and intermediate results</li> <li>Specification of index search method</li> <li>Specification of diagnostic for out-of-range inputs</li> </ul> </li> </ul> |
| Lookup Table (2-D) | <ul style="list-style-type: none"> <li>Block renamed as 2-D Lookup Table</li> <li>Icon changed</li> </ul> | <ul style="list-style-type: none"> <li>Default integer rounding mode changed from Floor to Simplest</li> <li>Support for the following features:</li> </ul>  |

| Block              | Changes   | Enhancements  |
|--------------------|---|---|
|                    |   | <ul style="list-style-type: none"> <li>• Specification of parameter data types different from input or output signal types</li> <li>• Reduced memory use and faster code execution for nontunable breakpoints with even spacing</li> <li>• Cubic-spline interpolation and extrapolation</li> <li>• Table data with complex values</li> <li>• Fixed-point data types with word lengths up to 128 bits</li> <li>• Specification of data types for fraction and intermediate results</li> <li>• Specification of index search method</li> <li>• Specification of diagnostic for out-of-range inputs</li> <li>• Check box for <b>Require all inputs to have the same data type</b> now selected by default</li> </ul> |
| Lookup Table (n-D) | <ul style="list-style-type: none"> <li>• Block renamed as n-D Lookup Table</li> <li>• Icon changed</li> </ul> | <ul style="list-style-type: none"> <li>• Default integer rounding mode changed from Floor to Simplest</li> </ul>  |

## Compatibility of Models with Older Versions of Lookup Table Blocks

When you load existing models that contain the Lookup Table, Lookup Table (2-D), and Lookup Table (n-D) blocks, those versions of the blocks appear. The current versions of the lookup table blocks appear only when you drag the blocks from the Simulink Library Browser into new models.

If you use the `add_block` function to add the Lookup Table, Lookup Table (2-D), or Lookup Table (n-D) blocks to a model, those versions of the blocks appear. If you want to add the *current* versions of the blocks to your model, change the source block path for `add_block`:

| Block        | Old Block Path                      | New Block Path                          |
|--------------|-------------------------------------|---|
| Lookup Table | simulink/Lookup Tables/Lookup Table | simulink/Lookup Tables/1-D Lookup Table |

| Block              | Old Block Path                            | New Block Path                          |
|--------------------|---|---|
| Lookup Table (2-D) | simulink/Lookup Tables/Lookup Table (2-D) | simulink/Lookup Tables/2-D Lookup Table |
| Lookup Table (n-D) | simulink/Lookup Tables/Lookup Table (n-D) | simulink/Lookup Tables/n-D Lookup Table |

## How to Update Your Model

To update your model to use current versions of the lookup table blocks, follow these steps:

| Step | Action   | Reason  |
|------|--|---|
| 1    | Run the Upgrade Advisor.   | Identify blocks that do not have compatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks. |
| 2    | For each block that does not have compatible settings: <ul style="list-style-type: none"> <li>Decide how to address each warning.</li> <li>Adjust block parameters as needed.</li> </ul> | Modify each Lookup Table or Lookup Table (2-D) block to ensure compatibility with the current versions.     |
| 3    | Repeat steps 1 and 2 until you are satisfied with the results of the Upgrade Advisor check.  | Ensure that block replacement works for the entire model.   |

After block replacement, the block names that appear in the model remain the same. However, the block icons match the ones for the 1-D Lookup Table and 2-D Lookup Table blocks. For more information about the Upgrade Advisor, see “Model Upgrades”.

## What to Expect from the Model Advisor Check

The Model Advisor check groups all Lookup Table and Lookup Table (2-D) blocks into three categories:

- Blocks that have compatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks
- Blocks that have incompatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks

- Blocks that have repeated breakpoints

### Blocks with Compatible Settings

When a block has compatible parameter settings, automatic block replacement can occur without backward incompatibilities.

| Lookup Method in the Lookup Table or Lookup Table (2-D) Block | Parameter Settings After Automatic Block Replacement |                |
|---|--|----------------|
|   | Interpolation  | Extrapolation  |
| Interpolation-Extrapolation                                   | Linear   | Linear         |
| Interpolation-Use End Values                                  | Linear   | Clip           |
| Use Input Below   | Flat   | Not applicable |

Depending on breakpoint spacing, one of two index search methods can apply.

| Breakpoint Spacing in the Lookup Table or Lookup Table (2-D) Block | Index Search Method After Automatic Block Replacement                         |
|--|---|
| Not evenly spaced  | Binary search   |
| Evenly spaced and tunable  | A prompt appears, asking you to select Binary search or Evenly spaced points. |
| Evenly spaced and not tunable                                      |   |

### Blocks with Incompatible Settings

When a block has incompatible parameter settings, the Model Advisor shows a warning and a recommended action, if applicable.

- If you perform the recommended action, you can avoid incompatibility during block replacement.
- If you use automatic block replacement without performing the recommended action, you might see numerical differences in your results.

| Incompatibility Warning                                    | Recommended Action  | What Happens for Automatic Block Replacement                        |
|--|---|---|
| The <b>Lookup Method</b> is Use Input Nearest or Use Input | Change the lookup method to one of the following options: | The <b>Lookup Method</b> changes to Interpolation - Use End Values. |

| Incompatibility Warning  | Recommended Action   | What Happens for Automatic Block Replacement   |
|--|--|--|
| Above. The replacement block does not support these lookup methods.  | <ul style="list-style-type: none"> <li>• Interpolation - Extrapolation</li> <li>• Interpolation - Use End Values</li> <li>• Use Input Below</li> </ul> | <p>In the replacement block, this setting corresponds to:</p> <ul style="list-style-type: none"> <li>• <b>Interpolation</b> set to <b>Linear</b></li> <li>• <b>Extrapolation</b> set to <b>Clip</b></li> </ul> |
| The <b>Lookup Method</b> is <b>Interpolation - Extrapolation</b> , but the input and output are not the same floating-point type. The replacement block supports linear extrapolation only when all inputs and outputs are the same floating-point type. | Change the extrapolation method or the port data types of the block.   | You also see a message that explains possible numerical differences.   |
| The block uses small fixed-point word lengths, so that interpolation uses only one rounding operation. The replacement block uses two rounding operations for interpolation.   | None   | You see a message that explains possible numerical differences.  |

### Blocks with Repeated Breakpoints

When a block has repeated breakpoints, the Model Advisor recommends that you change the breakpoint data and rerun the check. You cannot perform automatic block replacement for blocks with repeated breakpoints.

## Lookup Table Glossary

The following table summarizes the terminology used to describe lookup tables in the Simulink user interface and documentation.

| Term                              | Meaning  |
|-----------------------------------|--|
| breakpoint                        | A single element of a breakpoint data set. A breakpoint represents a particular input value to which a corresponding output value in the table data is mapped.   |
| breakpoint data set               | A vector of input values that indexes a particular dimension of a lookup table. A lookup table uses breakpoint data sets to relate its input values to the output values that it returns.  |
| extrapolation                     | A process for estimating values that lie beyond the range of known data points.  |
| interpolation                     | A process for estimating values that lie between known data points.  |
| lookup table                      | An array of data that maps input values to output values, thereby approximating a mathematical function. Given a set of input values, a “lookup” operation retrieves the corresponding output values from the table. If the lookup table does not explicitly define the input values, Simulink can estimate an output value using interpolation, extrapolation, or rounding. |
| monotonically increasing          | The elements of a set are ordered such that each successive element is greater than or equal to its preceding element.   |
| rounding                          | A process for approximating a value by altering its digits according to a known rule.  |
| strictly monotonically increasing | The elements of a set are ordered such that each successive element is greater than its preceding element.   |

| <b>Term</b> | <b>Meaning</b>  |
|-------------|---|
| table data  | An array that serves as a sampled representation of a function evaluated at a lookup table's breakpoint values. A lookup table uses breakpoint data sets to index the table data, ultimately returning an output value. |

## Block Masks

|                                   |
|-----------------------------------|
| <b>In this section...</b>         |
| “What Are Masks?” on page 34-2    |
| “When to Use Masks?” on page 34-2 |

### What Are Masks?

Masks are custom interfaces you can apply to Simulink blocks. A mask hides the user interface of the block, and instead displays a custom dialog control for specific parameters of the masked block.

When you mask a block, you change only the interface to the block, not its underlying characteristics. Masking a non atomic subsystem does not make it act as an atomic subsystem, and masking a virtual block does not convert it to a nonvirtual block.

---

**Note:** You cannot save a mask separately from the block that it masks. Also you cannot create an isolated mask definition and apply it to more than one block.

---

The mask icon and mask dialog box are analogous to the block icon and block dialog box, respectively.

You can use the mask parameters to control the mask display and change underlying subsystem content dynamically (add or delete blocks and set the parameters of those blocks). However, you can change subsystem content dynamically only if the subsystem is part of a library.

### When to Use Masks?

Masks are useful for customizing block interfaces, encapsulating logic, and providing restricted access to data.

Masks are comparable to subsystems, in that they both simplify the graphical appearance of a model. However, subsystems do not offer an interface for users to interact with underlying block parameters.

Consider masking a Simulink block when you want to:

- display a meaningful dynamic icon that reflects values within a block
- define customized parameters whose names reflect the purpose of a block
- provide a dialog box that enables you to access only select parameters of the underlying blocks
- provide users customized description that is specific to the masked block

If you use a mask only to represent the contents of a subsystem, consider using content preview instead. For that usage, content preview has these advantages, compared to using a mask:

- Automatically update changes in the subsystem (for a masked block, you need to manually update the mask image that represents the content of the item).
- Eliminates the setup tasks for icons for masked blocks.

Masked blocks do not support content preview. For details, see “Preview Content of Hierarchical Items” on page 1-43.

---

**Tip** To view the masking examples, see Simulink Masking Examples. Notice that the examples of similar type are grouped together. In an example model,

- To view the mask definition, double-click the View Mask block.
  - To view the mask dialog box, double-click the block.
- 

## More About

- “How Mask Parameters Work” on page 34-4
- “Mask a Block” on page 34-11

## How Mask Parameters Work

A masked block is a custom interface to underlying blocks that are governed by block parameters. Mask parameters are the links to underlying block parameters.

Mask parameters are defined in the mask workspace, while block parameters are defined in the model or base workspace.

You can provide access to one or more underlying block parameters by defining the corresponding number of mask parameters. Mask parameters appear in the **Mask Parameters** dialog box as fields that can be edited. Simulink applies the value of a mask parameter to the value of the corresponding block parameter during simulation.

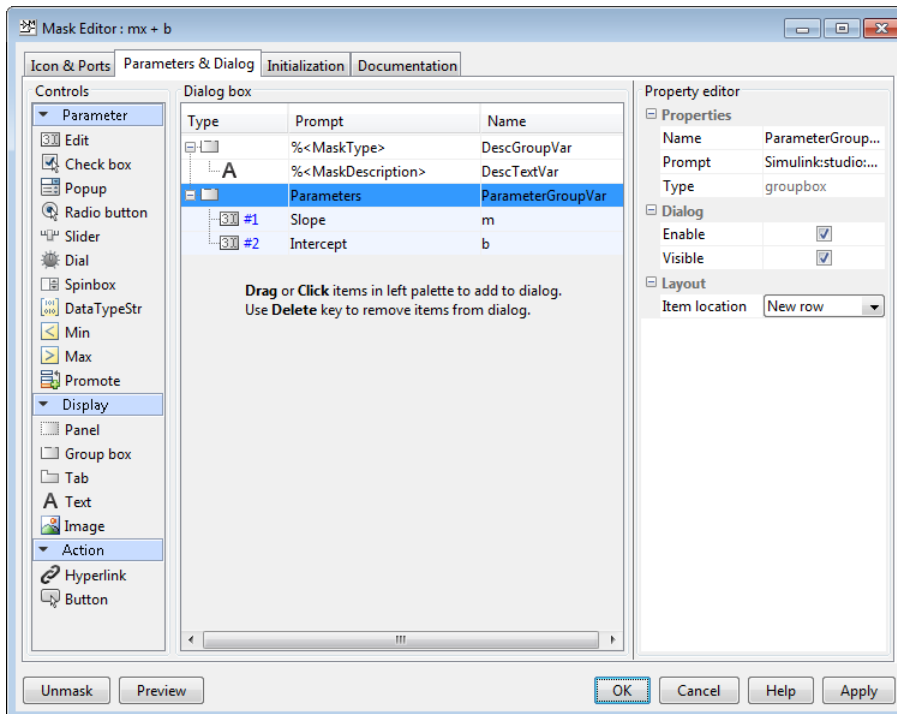

Consider the **Mask Parameters** dialog box of the model `masking_example`.

This dialog contains fields for mask parameters **Slope** and **Intercept**, both defined in the Mask Editor.

**Slope** corresponds to mask workspace variable  $m$ , and **Intercept**, to mask workspace variable  $b$ . Moreover, names  $m$  and  $b$  correspond to the **Gain** and **Constant value** parameters of the underlying blocks.

**Note:** The name of a mask parameter cannot match the name of any of the parameters of the underlying blocks. For example, if you are masking a Gain block, creating a mask parameter named **Gain** makes that mask parameter invalid.

In the mask dialog box, when you set **Slope** and **Intercept** to 5 and 2, respectively, Simulink assigns these values to  $m$  and  $b$ .

Before simulation begins, Simulink searches the workspace hierarchy, looking in the mask workspace first, for values to resolve the **Gain** parameter  $m$  and **Constant value** parameter  $b$ . Since variables  $m$  and  $b$  are defined in the mask workspace, Simulink applies their values to the block parameters.

To view related examples, see

- Set mask parameters
- Group parameters under tabs

- “Block Masks” on page 34-2
- “Mask a Block” on page 34-11

## Mask Code Execution

### In this section...

“Mask Code Placement” on page 34-7

“Drawing Command Execution” on page 34-7

“Initialization Command Execution” on page 34-8

“Callback Code Execution” on page 34-9

### Mask Code Placement

You can use MATLAB code to initialize a mask as well as to draw mask icons. Since the location of code affects model performance, place your code to reflect the functionality you need.

| Purpose                           | Placement in Mask Editor            | Programmatic Specification   |
|-----------------------------------|-------------------------------------|------------------------------|
| Initialize the mask               | <b>Initialization</b> pane          | MaskInitialization parameter |
| Draw mask icon                    | <b>Icon &amp; Ports</b> pane        | MaskDisplay parameter        |
| Callback code for mask parameters | <b>Parameters &amp; Dialog</b> pane | MaskCallbacks parameter      |

### Drawing Command Execution

Place MATLAB code for drawing mask icons in the **Icon Drawing Commands** section of the **Icon & Ports** pane. Simulink executes these commands sequentially to redraw the mask icon in the following cases:

- The drawing commands are dependent on mask parameters and the values of these mask parameters change.
- The block appearance is altered due to rotation or other changes.

---

**Note:** If you place MATLAB code for drawing mask icons in the **Initialization** pane, model performance is affected, because Simulink redraws the icon each time the masked block is evaluated in the model.

---

## Initialization Command Execution

When you open a model, Simulink locates visible masked blocks that reside at the top level of the model or in an open subsystem. Simulink only executes the initialization commands for these visible masked blocks if they meet either of the following conditions:

- The masked block has icon drawing commands.

---

**Note:** Simulink does not initialize masked blocks that do not have icon drawing commands, even if they have initialization commands.

---

- The masked subsystem belongs to a library and has the **Allow library block to modify its contents** parameter enabled.

Simulink initializes masked blocks that are not initially visible when you open the model that contains these blocks.

When you load a model into memory without displaying it graphically, no initialization commands initially run for any masked blocks. See “Load a Model” on page 1-10 and `load_system` for information about loading a model without displaying it.

Initialization commands for all masked blocks in a model that have drawing commands run when you:

- Update the diagram
- Start simulation
- Start code generation

Initialization commands for an individual masked block run when you:

- Change any of the parameters that define the mask, such as `MaskDisplay` and `MaskInitialization`, using the Mask Editor or `set_param`.
- Rotate or flip the masked block, if the icon depends on initialization commands.
- Cause the icon to be drawn or redrawn, and the icon drawing depends on initialization code.
- Change the value of a mask parameter by using the block dialog box or `set_param`.
- Copy the masked block within the same model or between different models.

## Callback Code Execution

Simulink executes the callback commands in the following cases:

- You open the mask dialog box. Callback commands execute sequentially, starting with the top mask dialog box.
- You modify a parameter value in the mask dialog box and then change the cursor's focus (that is, you press the **Tab** key or click into another field in the dialog box).

---

**Note:** When you modify the parameter value by using the `set_param` command, the callback commands do not execute.

---

- You modify the parameter value, either in the mask dialog box or using `set_param`, and then apply the change by clicking **Apply** or **OK**. Mask initialization commands execute after callback commands (See “Initialization Pane”).
- You hover over a masked block to see the data tip for the block, when the data tip contains parameter names and values. The callback executes again when the block data tip disappears.

---

**Note:** Callback commands do not execute if the mask dialog box is open when the block data tip appears.

---

- Update a diagram (for example, by pressing **Ctrl+D** or by selecting **Simulation > Update diagram** in the Simulink Editor).
- If you close a mask dialog box without saving the changes, the Callback command for parameters is sequentially executed.

To view related examples, see

- Sequence mask callbacks
- Unsafe mask callbacks
- Unsafe nested mask callbacks

## More About

- “Initialize Mask” on page 34-20

## Mask Terminology

Terminology Table

| Term                            | Description  |
|---------------------------------|--|
| <b>Mask icon</b>                | The masked block icon generated using drawing commands. This icon may be static or change dynamically with underlying block parameter values.                        |
| <b>Mask parameters</b>          | Parameters defined in the Mask Editor that link to underlying block parameters. Setting a mask parameter sets the corresponding block parameter.                     |
| <b>Mask initialization code</b> | MATLAB code that initializes a masked block or reflects current parameter values.  |
| <b>Mask callback code</b>       | MATLAB code that runs when the value of a mask parameter changes. Use callback code to modify a mask dialog box to reflect current parameter values.                 |
| <b>Mask documentation</b>       | Description and usage information for a masked block defined in the Mask Editor.   |
| <b>Mask dialog</b>              | A dialog box that contains fields for setting mask parameter values and provides mask description.   |
| <b>Mask workspace</b>           | Masks that define mask parameters or contain initialization code have a mask workspace. This workspace stores mask parameters and temporary values used by the mask. |

## Mask a Block

This example shows how to create a block mask and define its parameters.

### In this section...

“Create mask” on page 34-11

“Define mask parameters” on page 34-11

“Set mask parameter values” on page 34-12

### Create mask

- 1 Open the model `subsystem_example`. Alternately, execute the following command in MATLAB:

```
open_system([docroot ' /toolbox/simulink/ug/examples/masking...
/subsystem_example'])
```

This model contains a Subsystem block that models the equation for a line:  $y = mx + b$ .

- 2 Double-click the subsystem block to open it.

Notice that this subsystem contains the following blocks that are controlled by parameters.

- Gain block, named *Slope*
- Constant block, named *Intercept*

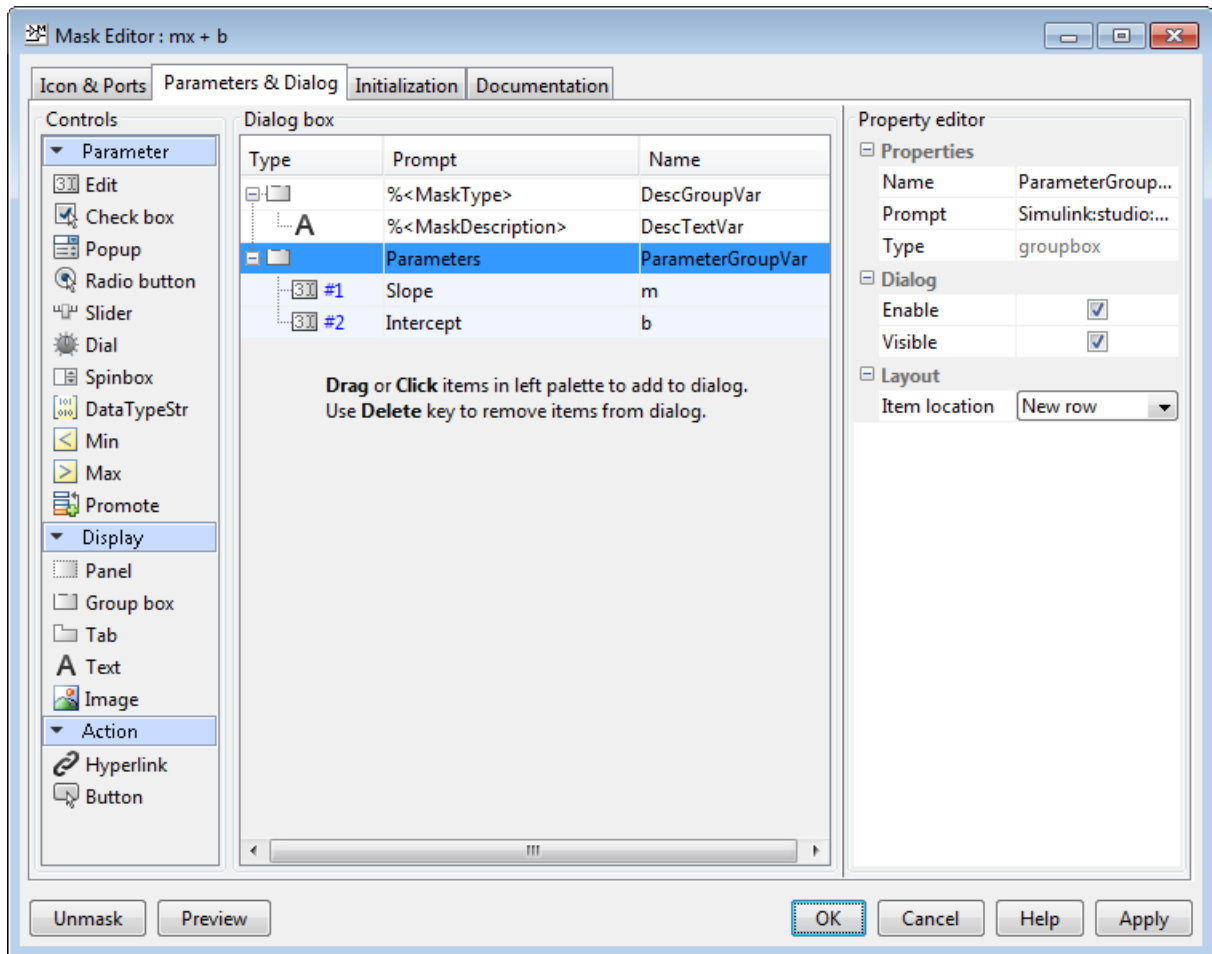

- 3 Return to the top-level model, right-click the subsystem block, and select **Mask > Create Mask**.

The Mask Editor opens.

### Define mask parameters

Define parameters to control the underlying blocks.

- 1 In the Mask Editor, click the **Parameters & Dialog** tab.
- 2 Click the **Edit** parameter icon and add two rows.
- 3 In the rows that appear, specify the parameters as follows.

- 4 Click **Apply**.

## Set mask parameter values

Provide values to the parameters.

- 1 Double-click the mask to view the mask dialog box.
- 2 Set **Slope** and **Intercept** as 5 and 2, respectively.

To control the underlying blocks, change these parameters.

- 3** Click **OK**.

## Draw Mask Icon

This example shows how to use drawing commands to create a mask icon. You can create icons that update when you change the mask parameters, thereby reflecting the purpose of the block.

| In this section...                  |
|-------------------------------------|
| “Draw static icon” on page 34-14    |
| “Draw dynamic icon” on page 34-16   |
| “Additional examples” on page 34-17 |

### Draw static icon

A static mask icon remains unchanged, independent of the value of the mask parameters.

- 1 Right-click the masked block that requires the icon and select **Mask > Edit Mask**.

The Mask Editor opens.

- 2 In the **Icons & Ports** tab, enter the following command in the **Icon Drawing commands** pane:

```
% Use specified image as mask icon
image('engine.jpg')
```

The image file must be on the MATLAB path. You can use images in `.svg` format as block mask image.

For more examples of drawing command syntax, explore the **Command** drop-down list in the **Examples of drawing commands** pane.

Images in formats: `.cur`, `.hdf4`, `.ico`, `.pcx`, `.ras`, `.xwd` cannot be used as block mask images. However, you can use images in these formats if you wrap the filename in the `imread()` function and use the RGB triplet. Using the `imread()` function is not efficient, however it is still supported for backward compatibility.

## Draw dynamic icon

A dynamic icon changes with the values of the mask parameters. Use it to represent the purpose of the masked block.

- 1 Right-click the masked block that requires the icon and select **Mask > Edit Mask**.

The Mask Editor opens.

- 2 In the **Icons & Ports** tab, enter the following command in the **Icon Drawing commands** pane:

```
pos = get_param(gcb, 'Position');
width = pos(3) - pos(1);
x = [0, width];
y = m*x + b;
plot(x,y)
```

- 3 Under **Options**, set **Icon Units** to **Pixels**.

The drop-down lists under **Options** allow you to specify icon frame visibility, icon transparency, drawing context, icon rotation, and port rotation.

- 4 Click **Apply**. If Simulink cannot evaluate all commands in the **Icon Drawing commands** pane to generate an icon, three question marks (? ? ?) appear on the mask. See model `masking_example` to view the icon generated.

## Additional examples

See model `slxMaskDisplayAndInitializationExample` for more examples of icon drawing commands. This model shows how to draw:

- a static mask
- a dynamic shape mask
- a dynamic text mask
- an image mask

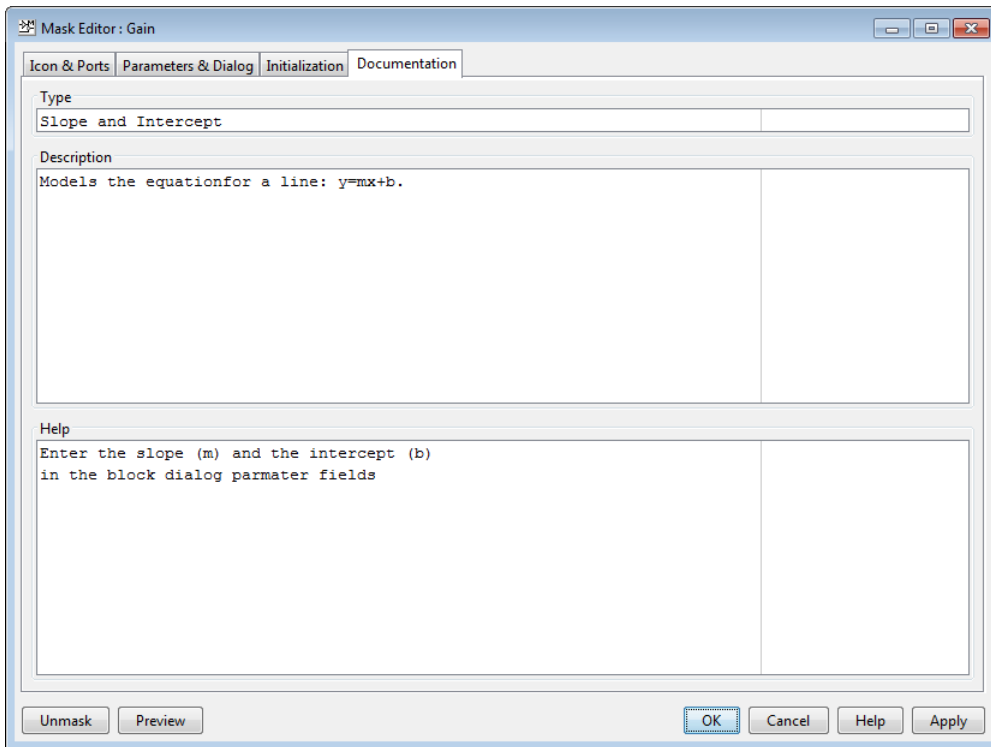

## Create Mask Documentation

This example shows how to create mask documentation for display in the mask dialog box.

- 1 Right-click the masked block to document and select **Mask > Edit Mask**.

The Mask Editor opens.

- 2 In the **Documentation** tab, type the following information:
  - **Type:** The name of the mask. This name appears at the top of the mask dialog box. New lines are not permitted.
  - **Description:** A summary of what the mask does. This description appears below the mask name, and it contains new lines as well as spaces.
  - **Help:** Additional mask information that appears when you click **Help** in the mask dialog box. You can use plain text, HTML and graphics, URLs, and `web` or `eval` commands.

## Initialize Mask

The initialization code is MATLAB code that you specify and that Simulink runs to initialize the masked subsystem at critical times, such as model loading and the start of a simulation run (see “Initialization Command Execution” on page 34-8). You can use the initialization code to set the initial values of the mask parameters.

The masked subsystem initialization code can refer only to variables in its local workspace.

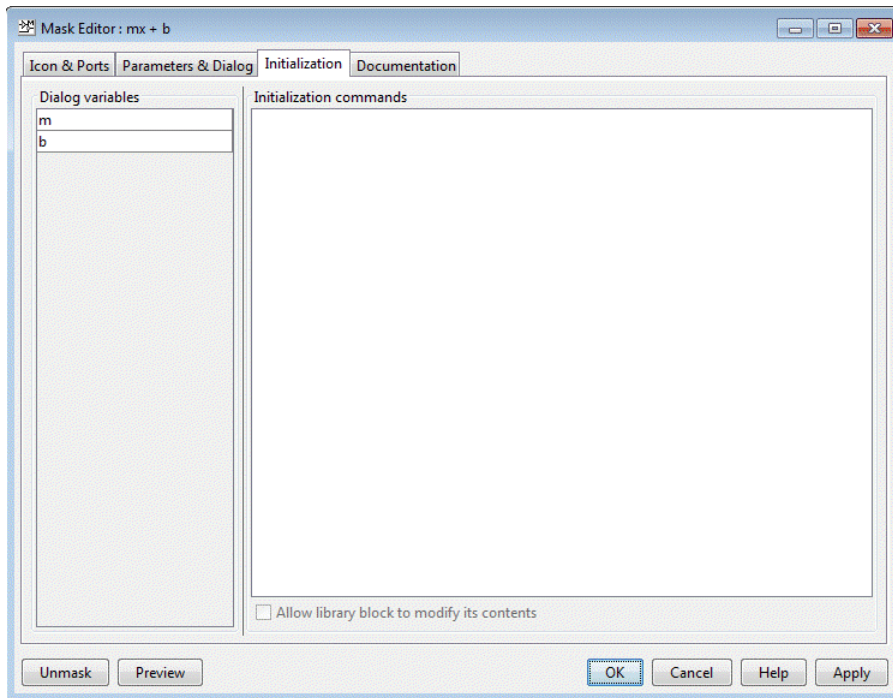

When you reference the block within, or copy the block into, a model, the mask dialog box displays the specified default values. You cannot use mask initialization code to change mask parameter default values in a library block or any other block.

### Mask Editor Initialization Pane

Use the Mask Editor **Initialization** pane to enter MATLAB commands that initialize a masked block. Reference information about the **Initialization** pane appears in “Initialization Pane”.

The **Initialization** pane has two sections:

- **Dialog variables** list
- **Initialization commands** edit area

## Dialog variables

The **Dialog variables** list displays the names of the variables associated with the mask parameters of the masked block (that is, the parameters defined in the **Parameters** pane).

You can copy the name of a parameter from this list and paste it into the adjacent **Initialization commands** field, using the Simulink keyboard copy and paste commands.

You can also use the list to change the names of mask parameter variables. To change a name, double-click the name in the list. An edit field containing the existing name appears. Edit the existing name and press **Enter** or click outside the edit field to confirm your changes.

## Initialization Commands

Enter the initialization commands in this field. You can enter any valid MATLAB expression, consisting of MATLAB functions and scripts, operators, and variables defined in the mask workspace. Initialization commands cannot access base workspace variables.

Terminate initialization commands with a semicolon to avoid echoing results to the MATLAB Command Window.

For information on debugging initialization commands, see “Initialization Command Limitations” on page 34-22 and “Debug Masks That Use MATLAB Code” on page 34-58.

To view related examples, see

- Define mask display and initialization
- Use handle graphics in masking

## Initialization Command Limitations

Mask initialization commands must observe the following rules:

- Do not use initialization code to create dynamic mask dialog boxes (that is, dialog boxes whose appearance or control settings change depending on changes made to other control settings). Instead, use the mask callbacks that are specifically for this purpose. For more information, see “Create Dynamic Mask Dialog Boxes” on page 34-48.
- Avoid using `set_param` commands on blocks residing in another masked subsystem that you are initializing. Trying to set parameters of blocks in lower-level masked subsystems can trigger unresolved symbol errors if lower-level masked subsystems reference symbols defined by higher-level masked subsystems. Suppose, for example, a masked subsystem A contains masked subsystem B, which contains Gain block C, whose Gain parameter references a variable defined by B. Suppose also that subsystem A has initialization code that contains the following command:

```
set_param([gcb '/B/C'], 'SampleTime', '-1');
```

Simulating or updating a model containing A causes an unresolved symbol error.

- You cannot use mask initialization code to create data objects. Data objects are objects of these classes:

- `Simulink.Parameter` and subclasses
- `Simulink.Signal` and subclasses

### **More About**

- “How Mask Parameters Work” on page 34-4
- “Mask Code Execution” on page 34-7

## Best Practices for Masking

These examples show best practices for masking Simulink blocks. There are also some examples that show practices to avoid.

| In this section...                       |
|--|
| “Use These Best Practices” on page 34-24 |
| “Avoid These Practices” on page 34-24    |

### Use These Best Practices

- Set mask parameters
- Group parameters under tabs
- Promote mask parameters
- Sequence mask callbacks
- Define mask display and initialization
- Create dynamic mask dialog boxes
- Use self-modifying library masks
- Use handle graphics in masking

### Avoid These Practices

- Unsafe mask callbacks
- Unsafe nested mask callbacks

## Considerations for Masking Model Blocks

### In this section...

“Referenced Model Name” on page 34-25

“Variable Workspace” on page 34-25

### Referenced Model Name

You can use a mask parameter to specify the name of a model referenced by

- a masked Model block, or
- a Model block in a masked subsystem

In these cases, the mask parameter receives the name of the reference model literally, without being evaluated, because Simulink updates model reference targets before mask parameters.

Use one of the following approaches to obtain the literal name of the referenced model:

- **Restricted model names:** In the **Parameters & Dialog** pane of the **Mask Editor**, select the parameter that stores the referenced model name. Set its **Type** to **popup** and clear the check box for **Evaluate**.

With this approach, users can only select a model name from a drop-down list in the mask dialog box. Further, since the **Evaluate** option is cleared, the name is provided literally and not numerically evaluated.

- **Unrestricted model names:** In the **Parameters & Dialog** pane of the **Mask Editor**, select the parameter that stores the referenced model name. Set its **Type** to **edit** and clear the check box for **Evaluate**.

With this approach, users can type the model name in the mask dialog box. However, since the **Evaluate** option is cleared, the name is provided literally and not numerically evaluated.

See “Parameters & Dialog Pane” for more information about **Pop-Up** and **Edit** controls.

### Variable Workspace

When you mask a model block that references another model, the referenced model cannot access the mask workspace of the model block.

Therefore, variables used by the referenced model must resolve either to workspaces defined by the referenced model or to the base workspace.

## Masks on Blocks in User Libraries

### In this section...

“About Masks and User-Defined Libraries” on page 34-27

“Masking a Block for Inclusion in a User Library” on page 34-27

“Masking a Block that Resides in a User Library” on page 34-27

“Masking a Block Copied from a User Library” on page 34-28

### About Masks and User-Defined Libraries

You can mask a block that is included in a user library or already resides in a user library, or you can mask an instance of a user library block that you have copied into a model. For example, a user library block might provide the capabilities that a model needs, but its native interface might be inappropriate or unhelpful in the context of the particular model. Masking the block could give it a more appropriate user interface.

### Masking a Block for Inclusion in a User Library

You can create a custom block by encapsulating a block diagram that defines the block's behavior in a masked subsystem and then placing the masked subsystem in a library. You can also apply a mask to any other type of block that supports masking, then include the block in a library.

Masking a block that is later included in a library requires no special provisions. Create the block and its mask as described in this section, and include the block in the library as described in “Create Block Libraries” on page 36-19.

### Masking a Block that Resides in a User Library

Creating or changing a library block mask immediately changes the block interface in all models that access the block using a library reference, but has no effect on instances of the block that already exist as separate copies.

To apply or change a library block mask, open the library that contains the block. Apply, change, or remove a mask as you could if the block did not reside in a library. In addition, you can specify non-default values for block mask parameters. When the block is referenced within or copied into a model, the specified default values appear on

the block's mask dialog box. By default, edit fields have a value of zero, check boxes are cleared, and drop-down lists select the first item in the list. To change the default for any field:

- 1 Fill in the desired default values or change check box or drop-down list settings
- 2 Click **Apply** or **OK** to save the changed values into the library block mask.

Be sure to save the library after changing the mask of any block that it contains. Additional information relating to masked library blocks appears in “Create Block Libraries” on page 36-19.

To view related example, see Use self-modifying library masks.

## **Masking a Block Copied from a User Library**

A block that was copied from a user library, as distinct from a block accessed by using a library reference, has no special status with respect to masking. You can add a mask to the copied block, or change or remove any mask that it already has.

### **More About**

- “Masking Linked Blocks” on page 34-59

## Parameter Promotion

**In this section...**

“Promote Underlying Parameters to Block Mask” on page 34-31

“Promote Underlying Parameters to Subsystem Mask” on page 34-32

“Best Practices” on page 34-34

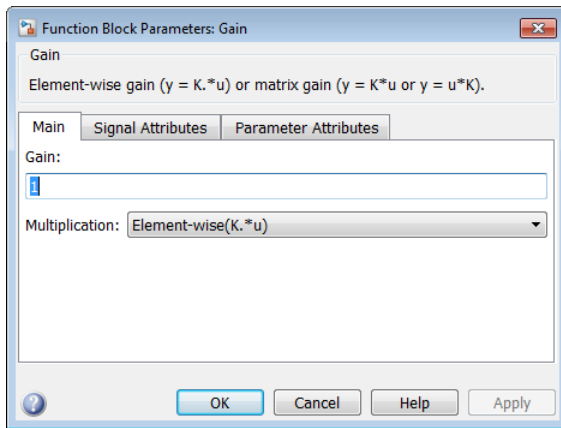

Blocks and subsystems can have multiple parameters associated with them. Block masks allow you to expose one or more of these parameters while hiding others from view. Promoting specific parameters to the mask block simplifies the interface and enables you to specify the parameters the user of the block can view and set.

**Promote** button on the Mask Editor enables you to promote any underlying parameter of a block either to a block mask or to a subsystem mask. The promoted block parameter gets associated with a parameter in the mask, allowing you to edit the parameter value from the mask dialog box.

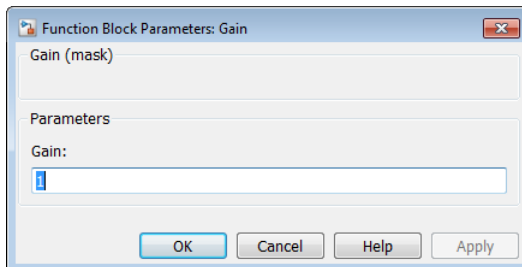

Promote parameters from the block dialog box to the mask:

- To customize the mask dialog box by moving the required parameters from the block dialog box to the mask dialog box.
- In the case of library blocks, you can reuse a block at different instances of a model. For each instance of the library block, you can create individual mask dialog box by promoting parameters for each.

Consider the block dialog box of the Gain block, which has parameters such as **Gain**, **Multiplication**.

To expose only the Gain parameter, mask the Gain block and promote the Gain parameter to the mask dialog box.

Similarly, you can mask a subsystem block and promote parameters to the mask. If the data type of subsystem parameters is the same, you can associate a single mask parameter with multiple promoted parameters. For example, you can promote multiple **Gain** parameters in a subsystem to a single dialog box on your mask.

If the parameter is of data type **popup** or **DataType** then the options must also be the same for the parameters to be promoted together. The **Evaluate** attribute for all the parameters to be promoted must be similar.

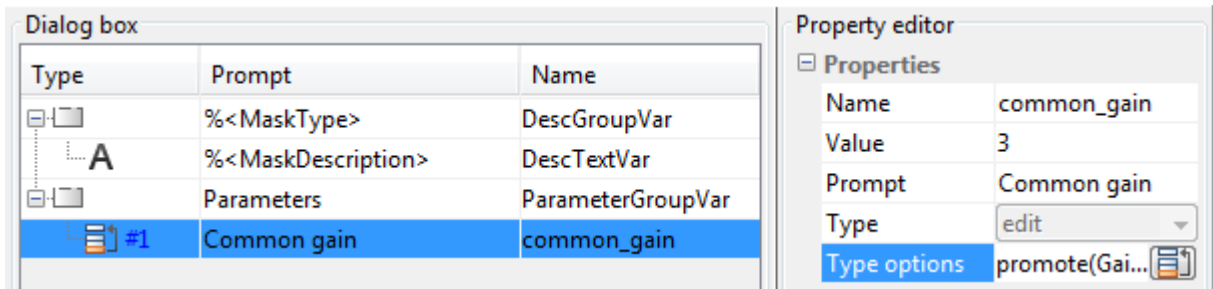

You can promote parameters on a linked block. However, you can edit the values only in the source block in the library.

To view related example, see Promote mask parameters.

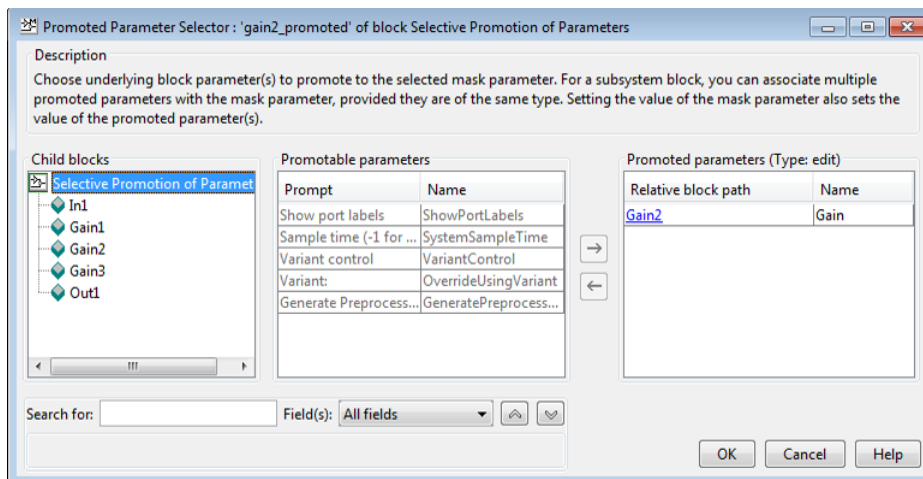

## Promote Underlying Parameters to Block Mask

- 1 Right-click the block whose parameter you want to promote and select **Mask > Create Mask**.
- 2 In the **Mask Editor** dialog box, click the **Parameters & Dialog** tab.
- 3 In the **Controls** pane, click **Promote**.
- 4 In the **Property editor** pane, next to **Type options**, click  .

Use the **Promoted Parameter Selector** dialog box to select the parameters that you want to promote.

- 5 To add a parameter to the **Promoted parameters** list, select a parameter from the **Promotable parameters** table and click the **Add to promoted parameter list** button .

To view the parameter properties such as **Type**, hover over the parameter name in the **Promotable parameter** pane.

---

**Tip**

- You can use the **Child blocks** list or the **Search** box to find underlying block parameters to promote.
- To prevent tuning of a property during simulation, you can disable the **Tunable** attribute while promoting a tunable parameter.

- 
- 6 Click **OK**.
  - 7 In the **Mask Editor** dialog box, edit the prompt names for the promoted parameters and click **OK**. You cannot edit the variable names.
  - 8 Click **OK**. Look at the block mask. Only the parameters you promoted are available to set.

---

**Note:**

- You can use **Promote all**  to promote all parameters. **Promote all** is available only for block masks and not for subsystem masks.
- To remove a promoted parameter, select the parameter and press **Delete** key.
- You cannot view or promote parameters of a masked or linked child block.

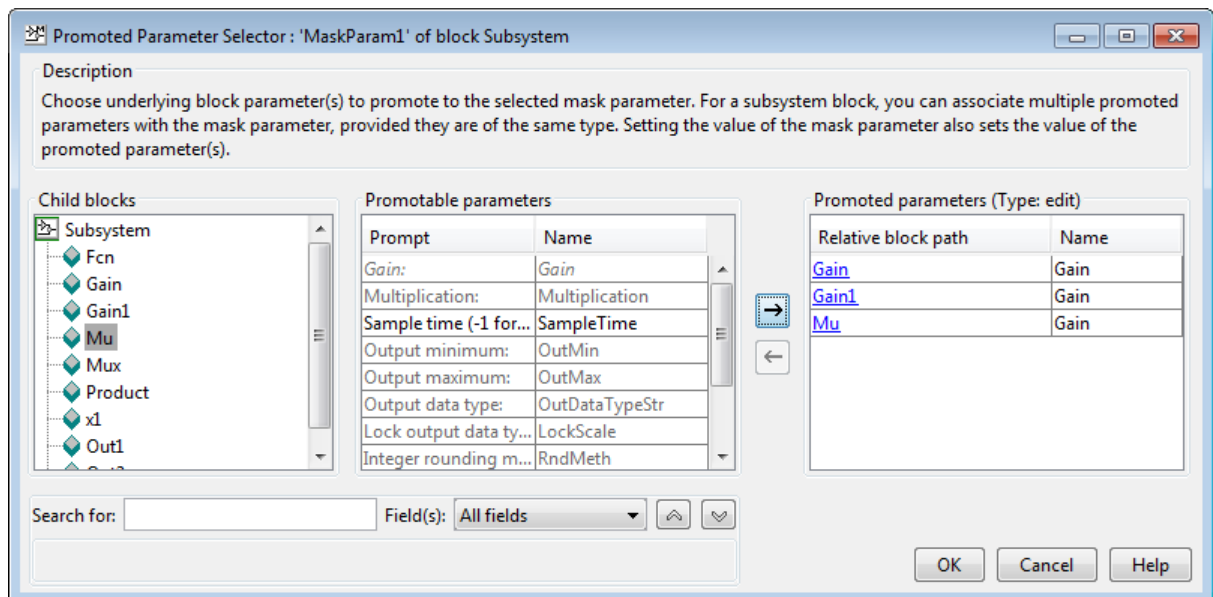

---

## Promote Underlying Parameters to Subsystem Mask

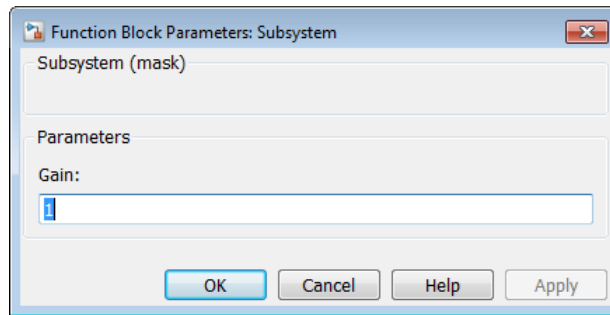

- 1 Right-click the subsystem and select **Mask > Create Mask**.
- 2 In the **Mask Editor** dialog box, click the **Parameters & Dialog** tab.
- 3 In the **Controls** pane, click **Promote**.

- 4 In the **Property editor** pane, next to **Type options**, click .
- 5 In the **Promoted Parameter Selector** dialog box, select the parameters that you want to promote.
- 6 To add a parameter to the **Promoted parameters** list, select a parameter from the **Promotable parameters** table and click the **Add to promoted parameter list** button .

You can add parameters of the same data type, from different child blocks, to the **Promoted parameters** list. For example, the Gain parameter from different child block can be added to the **Promoted parameters** list to promote to the single Gain parameter on the mask.

- 7 Click **OK**.
- 8 In the **Mask Editor** dialog box, edit the prompt names for the promoted parameters and click **OK**. You cannot edit the variable names.
- 9 Click **OK**. Look at the block mask. Only the parameters you promoted are available to set.

## Best Practices

- Once you have promoted a parameter, set the value only in the mask. Do not look under the mask and set the value in the underlying the block dialog box or from the command line.
- Promote a parameter only once. You cannot promote a parameter from one mask to another.
- Do not edit the **Evaluate** attribute of the promoted parameter. This property is inherited from the block parameter.
- If you are promoting a nontunable parameter, do not edit the **Tunable** attribute.
- If you are promoting parameter to a block mask, do not promote multiple parameters to a single mask parameter.
- Parameters of a masked or linked child block cannot be viewed or promoted.
- Callbacks associated with a block parameter are promoted to the block mask and not to the subsystem mask. You can also specify user-defined callbacks. Your callbacks execute after the dynamic dialog callback executes.

## See Also

“How Mask Parameters Work” on page 34-4 | “Block Masks” on page 34-2

## Operate on Existing Masks

### In this section...

- “Change a Block Mask” on page 34-35
- “View Mask Parameters” on page 34-35
- “Look Under Block Mask” on page 34-35
- “Remove and Cache Mask” on page 34-36
- “Restore Cached Mask” on page 34-37
- “Permanently Delete Mask” on page 34-37

### Change a Block Mask

You can change an existing mask by reopening the Mask Editor and using the same techniques that you used to create the mask:

- 1 Select the masked block.
- 2 Select **Mask > Edit Mask**.

The Mask Editor reopens, showing the existing mask definition. Change the mask as needed. After you change a mask, be sure to save the model before closing it, or the changes will be lost.

### View Mask Parameters

To display a mask dialog box, double-click the block. Alternatively, right-click the block and select **Mask > Mask Parameters**.

To display the block dialog box that double-clicking would display if no mask existed, right-click the masked block and select **Block Parameters (BlockType)**.

### Look Under Block Mask

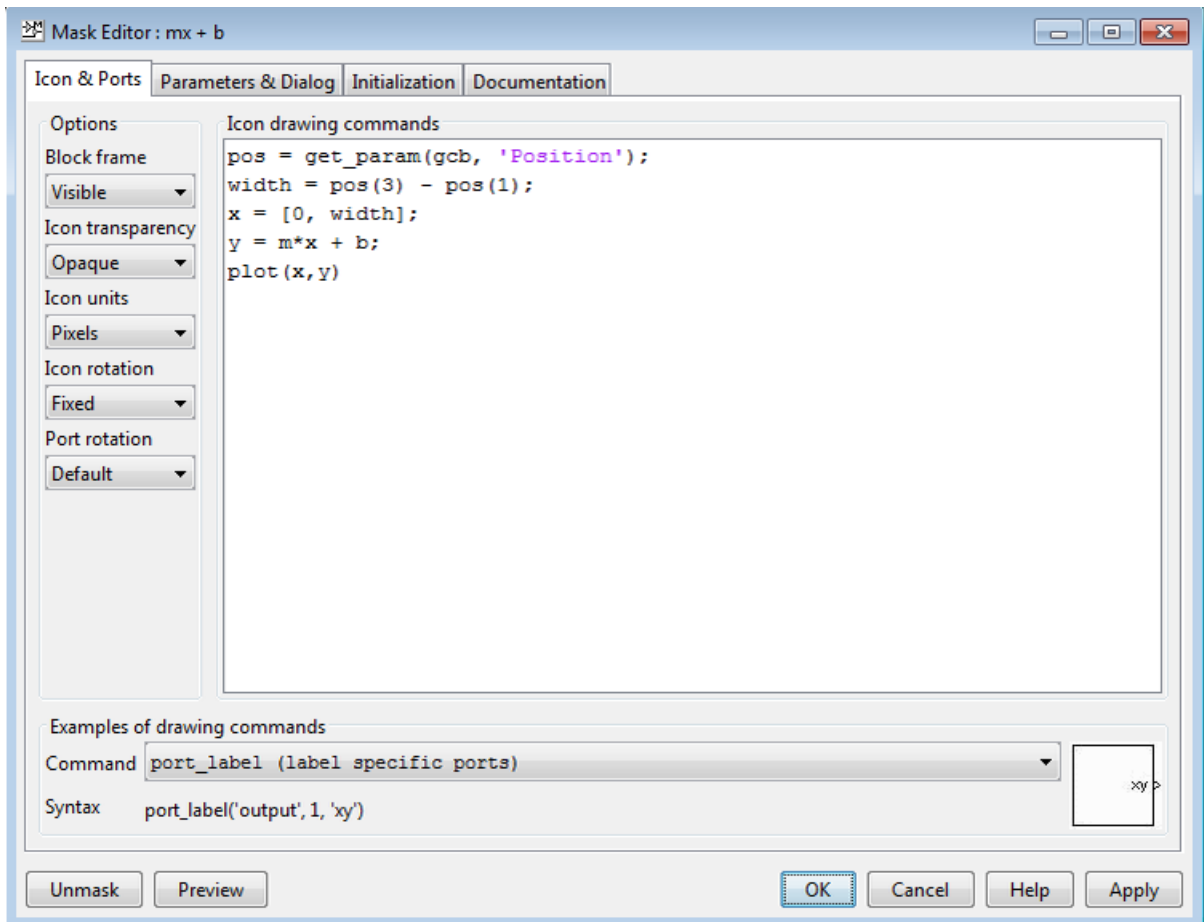

To see the block diagram under a masked Subsystem block, built-in block, or the model referenced by a masked model block, right-click the block and select **Mask > Look Under Mask**.

## Remove and Cache Mask

To remove a mask from a block and cache it for possible restoration later:

- 1 Right-click the block.
- 2 Select **Mask > Edit Mask**.

The Mask Editor opens and displays the existing mask, for example:

- 3 Click **Unmask** in the lower left corner of the Mask Editor.

The Mask Editor removes the mask from the block, saves the mask in a cache for possible restoration, then closes. The editor caches masks separately for each block, so removing a mask from one block has no effect on a mask cached for any other block. Closing the Mask Editor has no effect on cached masks.

When you have removed and cached a mask, you can later restore it, as described in “Restore Cached Mask” on page 34-37, or delete it, as described in “Permanently Delete Mask” on page 34-37. The removed cached mask has no further effect unless you restore it.

## Restore Cached Mask

As long as a model remains open, you can restore a mask that you removed as described in “Remove and Cache Mask” on page 34-36.

- 1 Right-click the block.
- 2 Select **Mask > Create Mask**.

The Mask Editor reopens, showing the cached masked definition.

- 3 Modify the definition if needed, using the techniques in “Mask a Block” on page 34-11
- 4 Click **Apply** or **OK** to restore the mask, including any changes that you made.

If you made any changes, be sure to save the model before closing it, or the changes will be lost.

## Permanently Delete Mask

To delete a mask permanently, first remove it as described in “Remove and Cache Mask” on page 34-36, then save and close the model. You do not need to close the model immediately after removing a mask that you intend to delete. The removed mask remains in the cache and has no further effect unless you restore it.

## Calculate Values Used Under the Mask

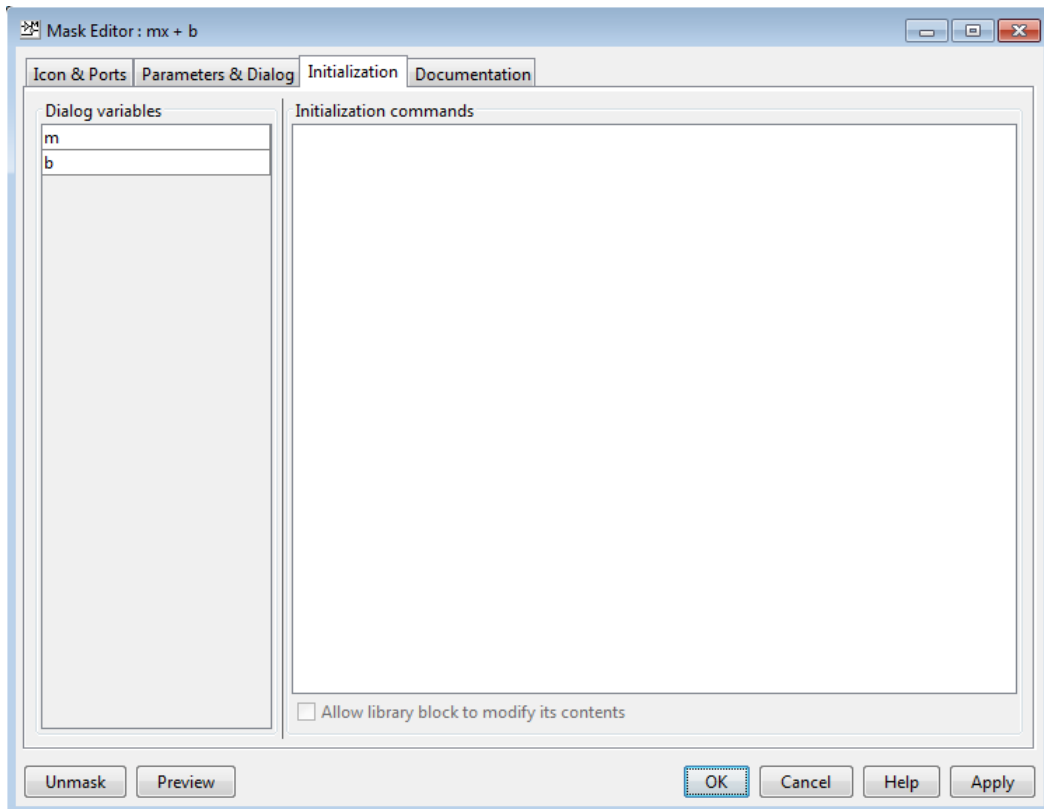

The `masking_example` assigns the values input using the mask dialog box directly to block parameters underneath the mask, as described in “How Mask Parameters Work” on page 34-4. The assignment occurs because the block parameter and the mask parameter have the same name, so the search that always occurs when a block parameter needs a value finds the mask parameter value automatically, as described in “Symbol Resolution” on page 4-95.

You can use the Mask Editor to insert any desired calculation between a value in the mask dialog box and an underlying block parameter

See the “Initialization Pane” reference for reference information about all **Initialization** pane capabilities. This section shows you how to use it for calculating block parameter values.

To calculate a value for a block parameter, first break the link between the mask and block parameters by giving them different names. To facilitate such changes, the Dialog variables subpane lists all mask parameters. The **Initialization** pane looks like this:

You cannot use mask initialization code to change mask parameter default values in a library block or any other block.

You can use the initialization code for a masked block to link mask parameters indirectly to block parameters. In this approach, the initialization code creates variables in the mask workspace whose values are functions of the mask parameters and that appear in expressions that set the values of parameters of blocks concealed by the mask.

If you need both the string entered and the evaluated value, clear the **Evaluate** option. To get the value of a base workspace variable entered as the literal value of the mask parameter, use the MATLAB `evalin` command in the mask initialization code. For example, suppose the user enters the string 'gain' as the literal value of the mask parameter `k` where `gain` is the name of a base workspace variable. To obtain the value of

the base workspace variable, use the following command in the initialization code for the mask:

```
value = evalin('base', k)
```

These values are stored in variables in the *mask workspace*. A masked block can access variables in its mask workspace. A workspace is associated with each masked subsystem that you create. The current values of the subsystem's parameters are stored in the workspace as well as any variables created by the block's initialization code and parameter callbacks.

To use a masked subsystem in a referenced model that uses model arguments, do not create in the mask workspace a variable that derives its value from a mask parameter. Instead, use blocks under the masked subsystem to perform the calculations for the mask workspace variable.

## **More About**

- “How Mask Parameters Work” on page 34-4

# Control Masks Programmatically

## In this section...

“Use `Simulink.Mask` and `Simulink.MaskParameter`” on page 34-41

“Use `get_param` and `set_param`” on page 34-42

“Programmatically Create Mask Parameters and Dialogs” on page 34-43

Simulink defines a set of parameters that help in setting and editing masks. To set and edit mask from the MATLAB command line, you can use instances of the `Simulink.Mask` and `Simulink.MaskParameter` classes. You can also use the `get_param` and `set_param` functions to set and edit masks. However, since these functions use de-limiters that do not support Unicode (Non English) characters you must use instances of the `Simulink.Mask` and `Simulink.MaskParameter` classes to control masks.

## Use `Simulink.Mask` and `Simulink.MaskParameter`

Use instances of `Simulink.Mask` and `Simulink.MaskParameter` classes to perform the following mask operations:

- Create, copy, and delete masks
- Create, edit, and delete mask parameters
- Determine the block that owns the mask
- Get workspace variables defined for a mask

**1** In this example the `Simulink.Mask.create` method is used to create a block mask:

```
maskObj = Simulink.Mask.create(gcb);
```

```
maskObj =
  Simulink.Mask handle
  Package: Simulink
  Properties:
      Type: ''
      Description: ''
      Help: ''
      Initialization: ''
      SelfModifiable: 'off'
```

```
        Display: ''
        IconFrame: 'on'
        IconOpaque: 'on'
RunInitForIconRedraw: 'off'
        IconRotate: 'none'
        PortRotate: 'default'
        IconUnits: 'autoscale'
        Parameters: []
Methods, Events, Superclasses
```

- 2 In this example the mask object is assigned to variable `maskObj` using the `Simulink.Mask.get` method:

```
maskObj = Simulink.Mask.get(gcb)

maskObj =
  Simulink.Mask handle
  Package: Simulink
  Properties:
      Type: ''
      Description: ''
      Help: ''
      Initialization: ''
      SelfModifiable: 'off'
      Display: ''
      IconFrame: 'on'
      IconOpaque: 'on'
RunInitForIconRedraw: 'off'
      IconRotate: 'none'
      PortRotate: 'default'
      IconUnits: 'autoscale'
      Parameters: [1x1 Simulink.MaskParameter]
  Methods, Events, Superclasses
```

For examples of other mask operations, like creating and editing mask parameters and copying and deleting masks see `Simulink.Mask` and `Simulink.MaskParameter` .

## Use `get_param` and `set_param`

The `set_param` and `get_param` functions have parameters for setting and controlling the mask. You can use these functions to set the mask of any block in the model or library based on a value passed from the MATLAB command line:

```
set_param(gcb, 'MaskStyleString', 'edit,edit', ..
```

```

'MaskVariables', 'maskparameter1=@1;maskparameter2=&2;',...
'MaskPromptString', 'Mask Parameter 1:|Mask Parameter 2:',...
'MaskValues', {'1', '2'});

get_param(gcb, 'MaskStyleString');

set_param(gcb, 'MaskStyles', {'edit', 'edit'}, 'MaskVariables',...
'maskparameter1=@1;maskparameter2=&2;', 'MaskPrompts',...
{'Mask Parameter 1:', 'Mask Parameter 2:'},...
'MaskValueString', '1|2');

get_param(gcb, 'MaskStyles');

```

where

- | separates individual string values for the mask parameters
- @ indicates that the parameter field is evaluated
- & indicates that the parameter field is not evaluated but assigned as a string

---

**Note:** When you use `get_param` to get the Value of a mask parameter, Simulink returns the value that was last applied using the mask dialog. Values that you have entered into the mask dialog but not applied will not be reflected when you use the `get_param` command.

---

See Mask Parameters for detailed information on the mask parameters.

## Programmatically Create Mask Parameters and Dialogs

This example shows how to create this simple mask dialog, add controls to the dialog, and change the properties of the controls.

- 1 Create the mask for a block you selected in the model.

```
maskobj = Simulink.Mask.create(gcb);
```

- 2 Create parameters for the mask. You can change the location of these parameters on the dialog in a subsequent step.

```
maskobj.AddParameter('Type','checkbox','Prompt','Option 1',...  
'Name','option1');  
maskobj.AddParameter('Type','checkbox','Prompt','Option 2',...  
'Name','option2');
```

These commands create a mask dialog with the default layout. Simulink adds the two parameters to the Parameters group, which is internally named as ParameterGroupVar by default.

You can verify the group name programmatically.

```
dlg = maskobj.getDialogControls();
dlg(2)

ans =
  Group with properties:
    Name: 'ParameterGroupVar'
    Prompt: 'Simulink:studio:ToolBarParametersMenu'
    Row: 'new'
    Enabled: 'on'
    Visible: 'on'
    DialogControls: [1x1 Simulink.dialog.parameter.CheckBox]
```

- 3 To customize the dialog and to use tabs instead of the default group, remove the Parameters group box.

```
maskobj.removeDialogControl('ParameterGroupVar');
```

Simulink preserves the child dialog controls, the two check boxes in this example, even when you delete the `ParametersGroupVar` group surrounding them. This is because these controls are parameters, which cannot be deleted using the dialog control methods.

You can delete parameters using methods such as `Simulink.Mask.removeAllParameters`, which belongs to the `Simulink.Mask` class.

- 4 In order to create tabs, first create a tab container and get its handle.

```
tabgroup = maskobj.addDialogControl('tabcontainer', 'tabgroup');
```

- 5 Create tabs within this tab container.

```
tab1 = tabgroup.addDialogControl('tab', 'tab1');
tab1.Prompt = 'First';
tab2 = tabgroup.addDialogControl('tab', 'tab2');
tab2.Prompt = 'Second';
tab3 = tabgroup.addDialogControl('tab', 'tab3');
tab3.Prompt = 'Third (invisible)';
```

Make the third tab invisible.

```
tab3.Visible = 'off'
```

```
tab3 =
```

```
Tab with properties:
```

```
    Name: 'tab3'
```

```
        Prompt: 'Third (invisible)'  
        Enabled: 'on'  
        Visible: 'on'  
    DialogControls: []
```

- 6 Move the mask parameters you created previously to the first tab.

```
opt1 = maskobj.getDialogControl('option1');  
opt2 = maskobj.getDialogControl('option2');  
  
opt1.moveTo(tab1);  
opt2.moveTo(tab1);
```

For more information on dialog controls and their properties, type `help Simulink.dialog.Control` at the MATLAB command line.

## More About

- “How Mask Parameters Work” on page 34-4

## Create Dynamic Mask Dialog Boxes

### In this section...

“About Dynamic Masked Dialog Boxes” on page 34-48

“Show parameter” on page 34-49

“Enable parameter” on page 34-49

“Create Dynamic Mask Dialog Box” on page 34-49

“Setting Nested Masked Block Parameters” on page 34-50

### About Dynamic Masked Dialog Boxes

You can create dialogs for masked blocks whose appearance changes in response to user input. Features of masked dialog boxes that can change in this way include

- Visibility of parameter controls

Changing a parameter can cause the control for another parameter to appear or disappear. The dialog expands or shrinks when a control appears or disappears, respectively.

- Enabled state of parameter controls

Changing a parameter can cause the control for another parameter to be enabled or disabled for input. A disabled control is grayed to indicate visually that it is disabled.

- Parameter values

Changing a mask dialog box parameter can cause related mask dialog box parameters to be set to appropriate values.

Creating a dynamic masked dialog box entails using the Mask Editor in combination with the `set_param` command. Specifically, you use the Mask Editor to define parameters of the dialog box, both static and dynamic. For each dynamic parameter, you enter a callback function that defines how the dialog box responds to changes to that parameter (see “Callback Code Execution” on page 34-9). The callback function can in turn use the `set_param` command to set mask parameters that affect the appearance and settings of other controls on the dialog box (see “Create Dynamic Mask Dialog Box” on page 34-49). Finally, you save the model or library containing the masked subsystem to complete the creation of the dynamic masked dialog box.

To view related example, see [Create dynamic mask dialog boxes](#).

## Show parameter

The selected parameter appears on the mask dialog box only if this option is checked (the default).

## Enable parameter

Clearing this option grays the prompt of the selected parameter and disables the edit control of the prompt.

## Create Dynamic Mask Dialog Box

This example shows how to create a mask dialog blocks whose appearance changes in response to your input.

You can set two parameters using this mask dialog box. The first parameter is a popup menu through which you select one of three gain values: **2**, **5**, or **User-defined**. Depending on the value that you select in this popup menu, an edit field for specifying the gain appears or disappears.

- 1 Mask a subsystem by right-clicking the block and selecting **Mask > Create Mask**.
- 2 Select the **Parameters & Dialog** pane on the Mask Editor.
- 3 Drag and drop a **Popup** parameter and select it in the Dialog box pane.
  - In the **Prompt** field, enter **Gain**.
  - In the **Name** field, enter **gainpopup**.
  - In the Property editor pane, clear **Evaluate** so that Simulink uses the literal values you specify for the popup.
  - In the **Type options** field, click the edit button to enter the following three values in the Popup Options dialog box:
 

```
2
5
User-defined
```
- 4 Enter the following code in the **Dialog callback** field:
 

```
% Get the mask parameter values. This is a cell
```

```
% array of strings.
maskStr = get_param(gcb, 'gainpopup');

% The pop-up menu is the first mask parameter.
% Check the value selected in the pop-up
if strcmp(maskStr(1), 'U'),

    % Set the visibility of both parameters on when
    % User-defined is selected in the pop-up.

    set_param(gcb, 'MaskVisibilities', {'on'; 'on'}),

else

    % Turn off the visibility of the Value field
    % when User-defined is not selected.

    set_param(gcb, 'MaskVisibilities', {'on'; 'off'}),

    % Set the string in the Values field equal to the
    % string selected in the Gain pop-up menu.

    %maskStr{2}=maskStr{1};
    set_param(gcb, 'editvalue', maskStr);
end
```

- 5 Drag and drop an **Edit** parameter and select it in the Dialog box pane.
  - In the **Prompt** field, enter **Value**.
  - In the **Name** field, enter **editvalue**.
  - In the Property editor pane, clear **Visible** so that Simulink turns off the visibility of this property by default.
- 6 Click **Apply**.
- 7 Double-click the masked subsystem to open the mask dialog box.

If you select 2 or 5 as the **Gain**, Simulink hides the **Value**. If you select **User-defined** as the **Gain** the **Value** is visible.

## Setting Nested Masked Block Parameters

Avoid using `set_param` commands to set parameters of blocks residing in masked subsystems that reside in the masked subsystem being initialized. Trying to set

parameters of blocks in lower-level masked subsystems can trigger unresolved symbol errors if lower-level masked subsystems reference symbols defined by higher-level masked subsystems. Suppose, for example, a masked subsystem A contains masked subsystem B, which contains Gain block C, whose Gain parameter references a variable defined by B. Suppose also that subsystem A's initialization code contains the command

```
set_param([gcb '/B/C'], 'SampleTime', '-1');
```

Simulating or updating a model containing A causes an unresolved symbol error.

### **More About**

- “Create Dynamic Masked Subsystems” on page 34-52

## Create Dynamic Masked Subsystems

### In this section...

“Allow library block to modify its contents” on page 34-52

“Create Self-Modifying Masks for Library Blocks” on page 34-52

“Evaluate Blocks Under Self-Modifying Mask” on page 34-56

### Allow library block to modify its contents

This check box is enabled only if the masked subsystem resides in a library. Checking this option allows the block initialization code to modify the contents of the masked subsystem (that is, it lets the code add or delete blocks and set the parameters of those blocks). Otherwise, an error is generated when a masked library block tries to modify its contents in any way. To set this option at the MATLAB prompt, select the self-modifying block and enter the following command.

```
set_param(gcf, 'MaskSelfModifiable', 'on');
```

Then save the block.

### Create Self-Modifying Masks for Library Blocks

You can create masked library blocks that can modify their structural contents. These self-modifying masks allow you to:

- Modify the contents of a masked subsystem based on parameters in the mask dialog box or when the subsystem is initially dragged from the library into a new model.
- Vary the number of ports on a multiport S-Function block that resides in a library.

#### Creating Self-Modifying Masks Using the Mask Editor

To create a self-modifying mask using the Mask Editor:

- 1 Unlock the library (see “Modify and Lock Libraries” on page 36-20).
- 2 Right-click the block in the library.
- 3 Select **Mask > Edit Mask**. The Mask Editor opens.

- 4 In the Mask Editor **Initialization** pane, select the **Allow library block to modify its contents** option.
- 5 Enter the code that modifies the masked subsystem in the mask **Initialization** pane.

Do not enter code that structurally modifies the masked subsystem in a dialog parameter callback (see “Mask Code Placement” on page 34-7). Doing so triggers an error when a user edits the parameter.

- 6 Click **Apply** to apply the change or **OK** to apply the change and close the Mask Editor.
- 7 Lock the library.

### Creating Self-Modifying Masks from the Command Line

To create a self-modifying mask from the command line:

- 1 Unlock the library using the following command:

```
set_param(gcs, 'Lock', 'off')
```

- 2 Specify that the block is self-modifying by using the following command:

```
set_param(block_name, 'MaskSelfModifiable', 'on')
```

where `block_name` is the full path to the block in the library.

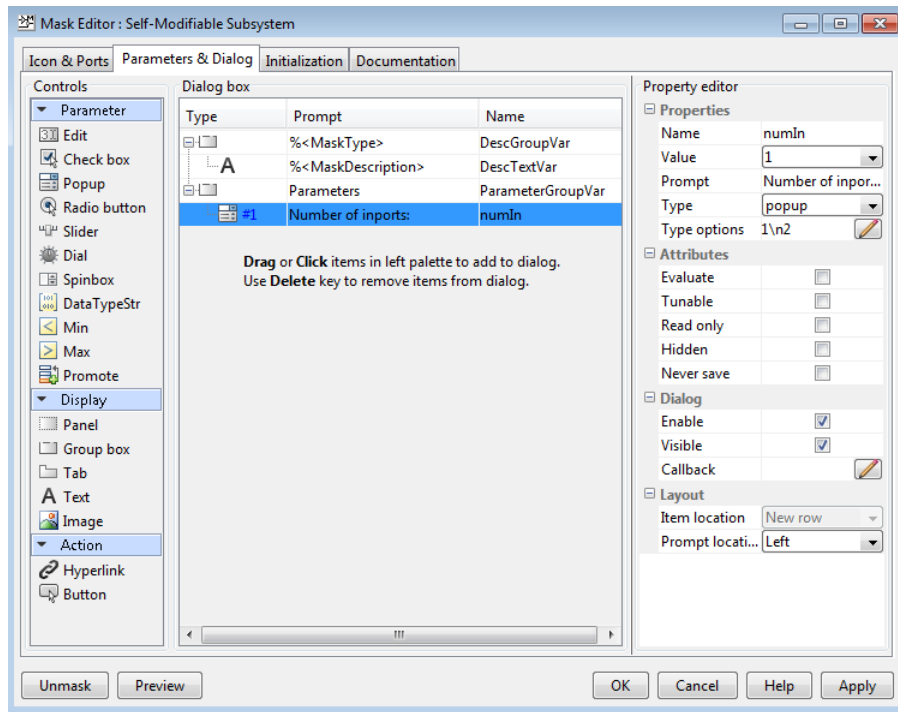

### Self-Modifying Mask Example

The library `selfModifying_example` contains a masked subsystem that modifies its number of input ports based on a selection made in the subsystem mask dialog box.

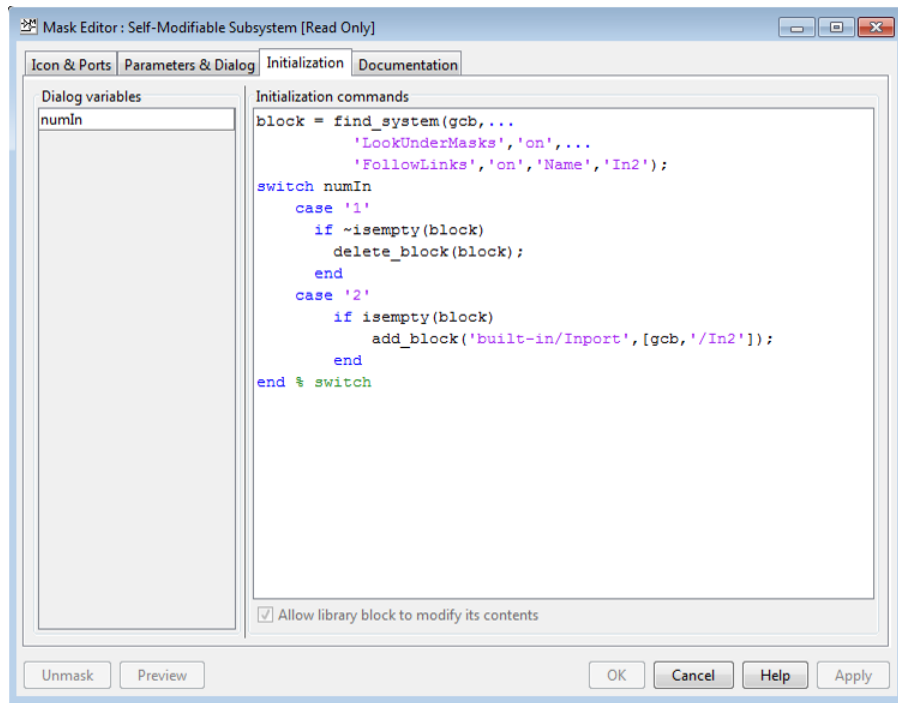

Right-click the subsystem then select **Mask > Edit Mask**. The Mask Editor opens. The Mask Editor **Parameters & Dialog** pane defines a parameter **numIn** that stores the value for the **Number of inports** option. This mask dialog box callback adds or removes Input ports inside the masked subsystem based on the selection made in the **Number of inports** list.

To allow the dialog box callback to function properly, the **Allow library block to modify its contents** option on the Mask Editor **Initialization** pane is selected. If this option were not selected, copies of the library block could not modify their structural contents and changing the selection in the **Number of inports** list would produce an error.

## Evaluate Blocks Under Self-Modifying Mask

This example shows how to force Simulink to evaluate blocks inside self-modifying masks.

Simulink evaluates elements of models containing masks in the following order:

- 1 Mask dialog box
- 2 Mask initialization code
- 3 Blocks or masked subsystems under the mask

Consider the following case:

A block named `myBlock` inside subsystem `mySubsys` masked by a self-modifying mask depends on mask parameter `myParam` to update itself.

`myParam` is exposed to the user through the **Mask Parameters** dialog box. `mySubsys` is updated through MATLAB code written in the **Mask Initialization** pane.

In this model, the sequence of updates is as follows:

- 1 You modify `myParam` through the mask dialog box.
- 2 The mask initialization code receives this change and modifies `mySubsys` under the mask.
- 3 `myBlock`, which lies under `mySubsys`, modifies itself based on the change to `myParam`.

In this sequence, Simulink does not evaluate `myBlock`, which lies under `mySubsys`, when the mask initialization code executes. Instead, Simulink only evaluates and updates the masked subsystem `mySubsys`. Meanwhile, `myBlock` remains unmodified.

You can force Simulink to evaluate such blocks earlier by using the `Simulink.Block.eval` method in the initialization code of the masked subsystem.

```
Simulink.Block.eval('mySubsys/myBlock');
```

## Debug Masks That Use MATLAB Code

|   |
|---|
| <b>In this section...</b>                                 |
| “Code Written in Mask Editor” on page 34-58               |
| “Code Written Using MATLAB Editor/Debugger” on page 34-58 |

### Code Written in Mask Editor

Debug initialization commands and parameter callbacks entered directly into the Mask Editor in one of the following ways:

- Remove the terminating semicolon from a command to echo its results to the MATLAB Command Window.
- Place a `keyboard` command in the code to stop execution and give control to the keyboard.

### Code Written Using MATLAB Editor/Debugger

---

**Note:** You cannot debug icon drawing commands using the MATLAB Editor/Debugger. Use the syntax examples provided in the Mask Editor **Icons & Ports** pane to help solve errors in the icon drawing commands.

---

Debug initialization commands and parameter callbacks written in files using the MATLAB Editor/Debugger in the same way that you would with any other MATLAB program file.

When debugging initialization commands, you can view the contents of the mask workspace. However, when debugging parameter callbacks, you can only access the base workspace of the block. If you need the value of a mask parameter, use `get_param`.

## Masking Linked Blocks

**In this section...**

“Guidelines for Mask Parameters” on page 34-60

“Mask Behavior for Masked, Linked Blocks” on page 34-61

Simulink libraries can contain blocks that have masks. An example of this type of block is the Ramp block. These blocks become library links when copied to a model or another library. You can add a new mask on this linked block. If this linked block is in a library and copied again, you can add another mask to this new linked block thus creating a stack of masks. Masking linked blocks allows you to add a custom interface to the link blocks similar to other Simulink blocks.

The block mask that is present as part of the library is the base mask. A derived mask is the one created on top of the base mask.

For example, in the figure, Library A contains Block A, which has a Mask A. Block A is copied to Library B, and Mask B is added to it. When Block A is copied to Library B, a library link from Library B to Library A is created.

Block B is then copied to a model, and Mask C is added to it. This creates a library link from Library B to Block C. Block C now has Mask A, Mask B, and Mask C. Mask C is the derived mask and Mask B is the base mask.

Note that for Block C:

- Mask parameter names are unique in the stack.
- You can set mask parameters for Mask B and Mask C.
- Mask B and Mask C inherit `MaskType` and `MaskSelfModifiable` parameters from Mask A.
- Mask initialization code for Mask C executes first, followed by Mask B and Mask A.
- Variables are resolved starting from the mask immediately above the current mask in the stack. If the current mask is the top mask, it follows the regular variable resolution rules.

## Guidelines for Mask Parameters

- You cannot use same names for the mask parameters. The exception is the `Promote` type mask parameter, for which the name is inherited and is the same as that of the parameter promoted to it.
- You cannot set mask parameters for masks below the base mask. Mask parameters for masks below the base mask are inherited from the library.

## Mask Behavior for Masked, Linked Blocks

The following are some of the behaviors that are important to understand about masked, linked blocks.

- The `MaskType` and the `MaskSelfModifiable` parameters are inherited from the base mask.
- Mask display code for the derived mask executes first, followed by the display code for the masks below it until we come across a mask whose `MaskIconFrame` parameter is set to `opaque`.
- Mask initialization code for the derived mask executes first, followed by the initialization code for the masks below it.
- Variables are resolved starting from the mask immediately above the current mask in the stack. If the current mask is the top mask, the regular variable resolution rules apply.
- When you save a Simulink model or library containing a block with multiple masks, using **File > Export Model to > Previous Version**, the `Sourceblock` parameter is modified to point to the library block having the bottom most mask.
- The following occurs when you disable, break, or reestablish links to libraries:
  - If you disable the link to the library block, the entire mask hierarchy is saved to the model file so that the block can act as a standalone block.
  - If you break the link to the library block, the block becomes a standalone block.
  - If you reestablish the link after disabling by doing a restore, all changes to the mask are discarded. If you mask subsystems, you must reestablish the link after disabling by doing a push. When you do a push, subsystem changes are pushed to the library block and top mask changes are pushed to the immediate library.

## More About

- “Masking Linked Blocks” on page 34-59

## Mask a Linked Block

### In this section...

“Create a Custom Library With Mask on Link Block” on page 34-62

“Add a Mask to the Masked, Link Block” on page 34-62

“View Masks Below the Top Mask” on page 34-63

This example shows the steps for creating masks on linked blocks. To view the example model, click Mask Linked Blocks.

### Create a Custom Library With Mask on Link Block

- 1 From the **Simulink Library Browser**, select **File > New > Library** .
- 2 Drag the Ramp block to the Library editor window.
- 3 Right-click the Ramp block and select **Mask > Create Mask**.

The Mask Editor opens.

- 4 In the **Icons & Ports** tab, enter the following command in the **Icon drawing commands** pane:

```
plot ([0:10],[0,1:10])
```

- 5 Click the  **Promote underlying block parameter(s) to this mask parameter** button.

Add **Slope** and **Initial Output** to the promoted parameters list, and click **OK**.

Add a custom parameter **Company Notes**.

- 6 Rename the block to **Derived Ramp Block**.

### Add a Mask to the Masked, Link Block

- 1 From the Simulink Library Browser, select **File > New > Model**.
- 2 Drag the Derived Ramp Block to the Model.

The Derived Ramp Block in the model has multiple masks on it. You can set parameters of the derived mask.

## View Masks Below the Top Mask

- Right click the Derived Ramp Block in the model and select **Mask > View Base Mask**. This opens the **Mask Editor** displaying the base mask definition.

- “Masking Linked Blocks” on page 34-59

# Creating Custom Blocks

---

- “When to Create Custom Blocks” on page 35-2
- “Types of Custom Blocks” on page 35-3
- “Comparison of Custom Block Functionality” on page 35-7
- “Expanding Custom Block Functionality” on page 35-18
- “Create a Custom Block” on page 35-19
- “Custom Block Examples” on page 35-42

## When to Create Custom Blocks

Custom blocks expand the modeling functionality provided with the Simulink product. Use a custom block to:

- Model behaviors that are not provided with a Simulink built-in solution.
- Build more advanced models.
- Encapsulate model components into a library block that you can copy into multiple models.
- Provide custom graphical user interfaces or analysis routines.

## Types of Custom Blocks

### In this section...

“MATLAB Function Blocks” on page 35-3

“MATLAB System Blocks” on page 35-3

“Subsystem Blocks” on page 35-4

“S-Function Blocks” on page 35-4

### MATLAB Function Blocks

A MATLAB Function block allows you to use the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing MATLAB function that models the custom functionality.
- You find it easier to model custom functionality using a MATLAB function than using a Simulink block diagram.
- The custom functionality does not include continuous or discrete dynamic states.

You can create a custom block from a MATLAB function using one of the following types of MATLAB function blocks.

- The `Fcn` block allows you to use a MATLAB expression to define a single-input, single-output (SISO) block.
- The `Interpreted MATLAB Function` block allows you to use a MATLAB function to define a SISO block.
- The `MATLAB Function` block allows you to define a custom block with multiple inputs and outputs that you can deploy to an embedded processor.

Each of these blocks has advantages in particular modeling applications. For example, you can generate code from models containing MATLAB Function blocks, whereas you cannot generate code for models containing an `Fcn` block.

### MATLAB System Blocks

A MATLAB System block allows you to use System objects written with the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing System object™ that models the custom functionality.
- You find it easier to model custom functionality using the MATLAB language than using a Simulink block diagram.
- The custom functionality includes discrete dynamic states.

## Subsystem Blocks

Subsystem blocks allow you to build a Simulink diagram to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have an existing Simulink diagram that models custom functionality.
- You find it easier to model custom functionality using a graphical representation rather than using handwritten code.
- The custom functionality is a function of continuous or discrete system states.
- You can model the custom functionality using existing Simulink blocks.

Once you have a Simulink subsystem that models the required behavior, you can convert it into a custom block by:

- 1 Masking the block to hide the block contents and provide a custom block dialog box.
- 2 Placing the block in a library to prohibit modifications and allow for easily updating copies of the block.

For more information, see “Libraries” and “Block Masks”.

## S-Function Blocks

S-function blocks allow you to write MATLAB, C, or C++ code to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have existing MATLAB, C, or C++ code that models custom functionality.
- You use continuous or discrete dynamic states or other system behaviors that require access to the S-function API.
- You cannot model the custom functionality using existing Simulink blocks.

You can create a custom block from an S-function using one of the following types of S-function blocks.

- The **Level-2 MATLAB S-Function** block allows you to write your S-function using the MATLAB language. (See “Write Level-2 MATLAB S-Functions”). You can debug a MATLAB S-function during a simulation using the MATLAB debugger.
- The **S-Function** block allows you to write your S-function in C or C++, or to incorporate existing code into your model using a C MEX wrapper. (See “C/C++ S-Functions”).)
- The **S-Function Builder** block assists you in creating a C MEX S-function or a wrapper function to incorporate legacy C or C++ code. (See “C/C++ S-Functions”).)
- The **Legacy Code Tool** transforms existing C or C++ functions into C MEX S-functions. (See “Integrate C Functions Using Legacy Code Tool”).)

The S-function target in the Simulink Coder product automatically generates a C MEX S-function from a graphical subsystem. If you want to build your custom block in a Simulink subsystem, but implement the final version of the block in an S-function, you can use the S-function target to convert the subsystem to an S-function. See “Generated S-Function Block” in the Simulink Coder User's Guide for details and limitations on using the S-function target.

### **Comparing MATLAB S-Functions to MATLAB Functions for Code Generation**

MATLAB S-functions and MATLAB functions for code generation have some fundamental differences.

- The Simulink Coder product can generate code for both MATLAB S-functions and MATLAB functions for code generation. However, MATLAB S-functions require a Target Language Compiler (TLC) file for code generation. MATLAB functions for code generation do not require a TLC-file.
- MATLAB S-functions can use any MATLAB function whereas MATLAB functions for code generation are a subset of the MATLAB language. For a list of supported functions for code generation, see “Functions and Objects Supported for C and C++ Code Generation — Alphabetical List” on page 42-2.
- MATLAB S-functions can model discrete and continuous state dynamics whereas MATLAB functions for code generation cannot model state dynamics.

### **Using S-Function Blocks to Incorporate Legacy Code**

Each S-function block allows you to incorporate legacy code into your model, as follows.

- A MATLAB S-function accesses legacy code through its TLC-file. Therefore, the legacy code is available only in the generated code, not during simulation.

- A C MEX S-function directly calls legacy C or C++ code.
- The S-Function Builder generates a wrapper function that calls the legacy C or C++ code.
- The Legacy Code Tool generates a C MEX S-function to call the legacy C or C++ code, which is optimized for embedded systems. See “Integrate C Functions Using Legacy Code Tool” for more information.

See “Integration Options” in the Simulink Coder User's Guide for more information.

See “S-Functions Incorporate Legacy C Code” in the Simulink Developing S-Functions for an example.

## Comparison of Custom Block Functionality

### In this section...

“Custom Block Considerations” on page 35-7

“Modeling Requirements” on page 35-11

“Speed and Code Generation Requirements” on page 35-14

### Custom Block Considerations

When creating a custom block, consider the following.

- Does the custom block need multiple input and output ports?
- Does the block model continuous or discrete state behavior?
- Do the block inputs and outputs have various data attributes, such as data types or complexity?
- How important is the effect of the custom block on the speed of updating the Simulink diagram or simulating the Simulink model?
- Do you need to generate code for a model containing the custom block?

The following two tables provide an overview of how each custom block type addresses the previous questions. More detailed information for each consideration follows these two tables.

### Modeling Requirements

| Custom Block Type | Supports Multiple Inputs and Outputs                   | Models State Dynamics | Supports Various Data Attributes  |
|-------------------|--|-----------------------|---|
| Subsystem         | Yes, including bus signals.                            | Yes.                  | Yes, including all data types, numeric types, and dimensions supported by the Simulink software. Also supports frame-based signals. |
| Fcn               | No. Must have a single vector input and scalar output. | No.                   | Supports only real scalar signals with a data type of double or single.   |

| Custom Block Type           | Supports Multiple Inputs and Outputs   | Models State Dynamics                                   | Supports Various Data Attributes  |
|-----------------------------|--|---|---|
| Interpreted MATLAB Function | No. Must have a single vector input and output.                                      | No.   | Supports only n-D, real, or complex signals with a data type of double.   |
| MATLAB Function             | Yes, including bus signals.  | No.   | Yes, including all data types, numeric types, and dimensions supported by the Simulink software. Also supports frame-based signals.                               |
| MATLAB System               | Yes, excluding bus signals.  | Yes.  | Yes, including all data types (except buses and enumerated), numeric types, and dimensions supported by the Simulink software. Also supports frame-based signals. |
| Level-2 MATLAB S-function   | Yes.   | Yes, including limited access to other S-function APIs. | Yes, including all data types, numeric types, and dimensions supported by the Simulink software. Also supports frame-based signals.                               |
| C MEX S-function            | Yes, including bus signals if using the Legacy Code Tool to generate the S-function. | Yes, including full access to all S-function APIs.      | Yes, including all data types, numeric types, and dimensions supported by the Simulink software. Also supports frame-based signals.                               |

### Speed and Code Generation Requirements

| Custom Block Type | Speed of Updating the Diagram  | Simulation Overhead   | Code Generation Support |
|-------------------|--|---|-------------------------|
| Subsystem         | Proportional to the complexity of the subsystem. For library blocks, can be slower the first time the library is loaded. | Proportional to the complexity of the subsystem. Library blocks introduce no additional overhead. | Natively supported.     |

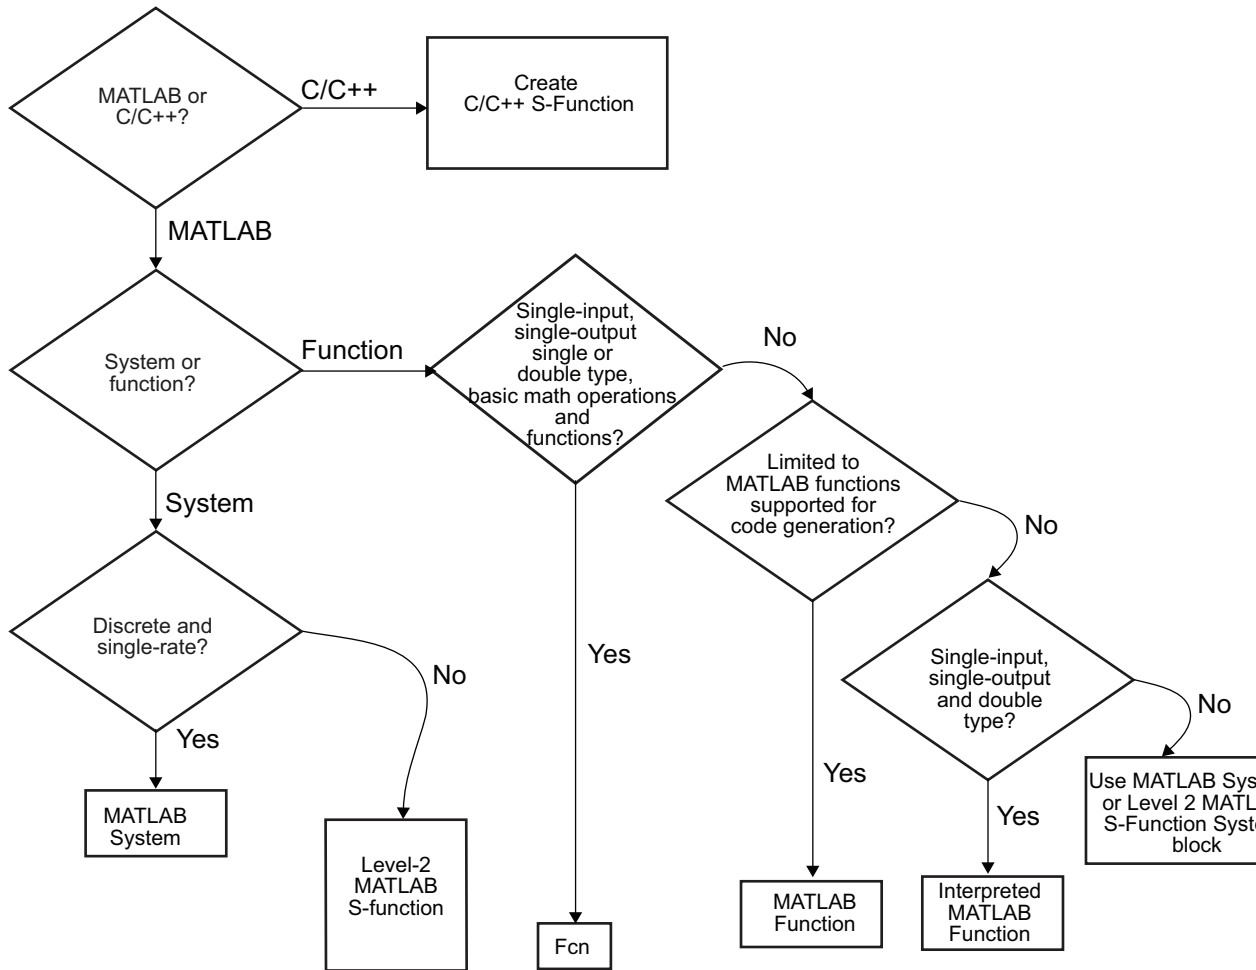

| Custom Block Type           | Speed of Updating the Diagram   | Simulation Overhead   | Code Generation Support   |
|-----------------------------|---|---|---|
| Fcn                         | Very fast.  | Minimal, but these blocks also provide limited functionality.   | Natively supported.   |
| Interpreted MATLAB Function | Fast.   | High and incurred when calling out to the MATLAB execution engine. Avoid these calls if simulation speed is a concern.  | Not supported.  |
| MATLAB Function             | Can be slower if code must be generated to update the diagram.                        | Minimal if the MATLAB execution engine is not called. Simulation speed is equivalent to C MEX S-functions when the MATLAB execution engine is not called.   | Natively supported, with exceptions. See “Code Generation” on page 35-17 for more information.  |
| MATLAB System               | Faster than MATLAB Function because code is not generated to update the diagram.      | In interpreted execution mode, the simulation has the overhead of calling the MATLAB execution engine. In code generation mode, the first simulation incurs code generation overhead. However, in subsequent runs, the block simulation speed is equivalent to C MEX S-functions. | Natively supported, with exceptions.  |
| Level-2 MATLAB S-function   | Can be slower if the S-function overrides methods executed when updating the diagram. | Higher than for Interpreted MATLAB Function blocks because the MATLAB execution engine is called for every S-function method used.  | MATLAB S-functions initialized as a <code>SimViewingDevice</code> do not generate code. Otherwise, MATLAB S-functions require a TLC-file for code generation. |

| Custom Block Type | Speed of Updating the Diagram   | Simulation Overhead  | Code Generation Support   |
|-------------------|---|--|---------------------------|
|                   |   | Very flexible, but very costly.  |                           |
| C MEX S-function  | Can be slower if the S-function overrides methods executed when updating the diagram. | Minimal, but proportional to the complexity of the algorithm and the efficiency of the code. | Might require a TLC-file. |

### Block Type Flowchart

The diagram shows how to decide which block to use. One deciding factor is whether you need the block for a function or a system. In this context:

- A function defines the relationship between a set of inputs and outputs.
- A system defines the relationship between a set of inputs and outputs. It can also define a set of states, parameters, and System object processing methods for initialization, output, update, termination, and so forth.

## Modeling Requirements

### Multiple Input and Output Ports

The following types of custom blocks support multiple input and output ports.

| Custom Block Type                | Multiple Input and Output Port Support   |
|----------------------------------|--|
| Subsystem                        | Supports multiple input and output ports, including bus signals. In addition, you can modify the number of input and output ports based on user-defined parameters. See “Self-Modifying Linked Subsystems” on page 36-6 for more information.  |
| Fcn, Interpreted MATLAB Function | Supports only a single input and a single output port. Use a Mux block to combine the inputs and a Demux block to separate the outputs if you pass multiple signals into or out of these blocks.   |
| MATLAB Function                  | Supports multiple input and output ports, including bus signals. See “How Structure Inputs and Outputs Interface with Bus Signals” on page 37-74 for more information.   |
| MATLAB System                    | Supports multiple input and output ports, excluding bus signals. See “Define System Objects” for more information.   |
| S-function (MATLAB or C MEX)     | Supports multiple input and output ports. In addition, you can modify the number of input and output ports based on user-defined parameters. S-functions generated using the Legacy Code Tool also accept Simulink bus signals. See “Integrate C Functions Using Legacy Code Tool” for more information. |

### State Behavior and the S-Function API

Simulink blocks communicate with the Simulink engine through the S-function API, a set of methods that fully specifies the behavior of blocks. Each custom block type accesses a different set of the S-function APIs, as follows.

| Custom Block Type                                 | S-Function API Support   |
|---|--|
| Subsystem   | Communicates directly with the engine. You can model state behaviors using appropriate blocks from the Continuous and Discrete Simulink block libraries.   |
| Fcn, Interpreted MATLAB Function, MATLAB Function | All create a <code>mdlOutputs</code> method to calculate the value of the outputs given the value of the inputs. You cannot access any other S-function API methods using one of these blocks and, therefore, cannot model state behavior. |
| MATLAB System                                     | Uses System object methods for S-function APIs: <code>mdlOutputs</code> ( <code>stepImpl</code> , <code>outputImpl</code> ), <code>mdlUpdate</code> ( <code>updateImpl</code> ),   |

| Custom Block Type | S-Function API Support  |
|-------------------|---|
|                   | mdlInitializeConditions (resetImpl), mdlStart (setupImpl), mdlTerminate (releaseImpl).  |
| MATLAB S-function | Accesses a larger subset of the S-function APIs, including methods you can use to model continuous and discrete states. For a list of supported methods, see “Level-2 MATLAB S-Function Callback Methods” in “Writing S-Functions”. |
| C MEX S-function  | Accesses the complete set of S-function APIs.   |

### Data Attribute Support

All custom block types support real scalar inputs and outputs with a data type of double.

| Custom Block Type            | Data Attribute Support   |
|------------------------------|--|
| Subsystem                    | Supports any data type supported by the Simulink software, including fixed-point types. Also supports complex, 2-D, n-D, and frame-based signals.                            |
| Fcn                          | Supports only double or single data types. In addition, the input and output cannot be complex and the output must be a scalar signal. Does not support frame-based signals. |
| Interpreted MATLAB Function  | Supports 2-D, n-D, and complex signals, but the signal must have a data type of double. Does not support frame-based signals.  |
| MATLAB Function              | Supports any data type supported by the Simulink software, including fixed-point types. Also supports complex, 2-D, n-D, and frame-based signals.                            |
| MATLAB System                | Supports any data type supported by the Simulink software, including fixed-point types. Also supports complex, 2-D, n-D, and frame-based signals.                            |
| S-function (MATLAB or C MEX) | Supports any data type supported by the Simulink software, including fixed-point types. Also supports complex, 2-D, n-D, and frame-based signals.                            |

## Speed and Code Generation Requirements

### Updating the Simulink Diagram

The Simulink software updates the diagram before every simulation and whenever requested by the user. Every block introduces some overhead into the “update diagram” process.

| Custom Block Type                | Speed of Updating the Diagram   |
|----------------------------------|---|
| Subsystem                        | The speed is proportional to the complexity of the algorithm implemented in the subsystem. If the subsystem is contained in a library, some cost is incurred when the Simulink software loads any unloaded libraries the first time the diagram is updated or readied for simulation. If all referenced library blocks remain unchanged, the Simulink software does not subsequently reload the library and compiling the model becomes faster than if the model did not use libraries.   |
| Fcn, Interpreted MATLAB Function | Does not incur greater update cost than other Simulink blocks.  |
| MATLAB Function                  | Performs simulation through code generation, so these blocks can take a significant amount of time when first updated. However, because code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed.  |
| MATLAB System                    | Faster than MATLAB Function because code is not generated to update the diagram. However, because code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed.  |
| S-function (MATLAB or C MEX)     | Incurs greater costs than other Simulink blocks only if it overrides methods executed when updating the diagram. If these methods become complex, they can contribute significantly to the time it takes to update the diagram. For a list of methods executed when updating the diagram, see the process view in “Simulink Engine Interaction with C S-Functions”. When updating the diagram, the Simulink software invokes all relevant methods in the model initialization phase up to, but not including, <code>mdlStart</code> . |

## Simulation Overhead

For most applications, any of the custom block types provide acceptable simulation performance. Use the Simulink profiler to obtain an indication of the actual performance. See “How Profiler Captures Performance Data” on page 27-5 for more information.

You can break simulation performance into two categories. The interface cost is the time it takes to move data from the Simulink engine into the block. The algorithm cost is the time it takes to perform the algorithm that the block implements.

| Custom Block Type           | Simulation Overhead  |
|-----------------------------|--|
| Subsystem                   | If included in a library, introduces no interface or algorithm costs beyond what would normally be incurred if the block existed as a regular subsystem in the model.  |
| Fcn                         | Has the least simulation overhead. The block is tightly integrated with the Simulink engine and implements a rudimentary expression language that is efficiently interpreted.  |
| Interpreted MATLAB Function | Has a higher interface cost than most blocks and the same algorithm cost as a MATLAB function.<br>When block data (such as inputs and outputs) is accessed or returned from an Interpreted MATLAB Function block, the Simulink engine packages this data into MATLAB arrays. This packaging takes additional time and causes a temporary increase in memory during communication. If you pass large amounts of data across this interface, such as, frames or arrays, this overhead can be substantial. Once the data has been converted, the MATLAB execution engine executes the algorithm. As a result, the algorithm cost is the same as for MATLAB function. Efficient code can be competitive with C code if MATLAB is able to optimize it, or if the code uses the highly optimized MATLAB library functions. |
| MATLAB Function             | Performs simulation through code generation and so incurs the same interface cost as standard blocks.<br>The algorithm cost of this block is harder to analyze because of the block's implementation. On average, a function for this block and a MATLAB function run at about the same speed. To reduce the algorithm cost, you can disable debugging for all the MATLAB Function blocks.<br>If the MATLAB Function block uses simulation-only capabilities to call out to the MATLAB execution engine, it incurs all the costs   |

| Custom Block Type | Simulation Overhead   |
|-------------------|---|
|                   | that a MATLAB S-function or Interpreted MATLAB Function block incur. Calling out to the MATLAB execution engine from a MATLAB Function block produces a warning to prevent you from doing so unintentionally.   |
| MATLAB System     | <p>Performs simulation through one of the following:</p> <ul style="list-style-type: none"> <li>• Interpreted execution, the model simulates the block using the MATLAB execution engine.</li> <li>• Code generation, the model simulates the block using generated code.</li> </ul> <p>For more information, see the MATLAB Function entry in this table.</p>  |
| MATLAB S-function | Incurs the same algorithm costs as the Interpreted MATLAB Function block, but with a slightly higher interface cost. Because MATLAB S-functions can handle multiple inputs and outputs, the packaging is more complicated than for the Interpreted MATLAB Function block. In addition, the Simulink engine calls the MATLAB execution engine for each block method you implement whereas for the Interpreted MATLAB Function block, it calls the MATLAB execution engine only for the <code>mdlOutputs</code> method. |
| C MEX S-function  | Simulates via the compiled code and so incurs the same interface cost as standard blocks. The algorithm cost depends on the complexity of the S-function.   |

## Code Generation

Not all custom block types support code generation with Simulink Coder.

| Custom Block Type           | Code Generation Support  |
|-----------------------------|--|
| Subsystem                   | Supports code generation.  |
| Fcn                         | Supports code generation.  |
| Interpreted MATLAB Function | Does not support code generation.  |
| MATLAB Function             | Supports code generation. However, if your MATLAB Function block calls out to the MATLAB execution engine, it will build with the Simulink Coder product only if the calls to the MATLAB execution engine do not affect the block outputs. Under this condition, the Simulink Coder product omits these calls from the generated C code. This feature allows you to leave visualization code in place, even when generating embedded code.               |
| MATLAB System               | Supports code generation. However, if your MATLAB System block calls out to the MATLAB execution engine, it will build with the Simulink Coder product only if the calls to the MATLAB execution engine do not affect the block outputs. Under this condition, the Simulink Coder product omits these calls from the generated C code. This feature allows you to leave visualization code in place, even when generating embedded code.                 |
| MATLAB S-function           | Generates code only if you implement the algorithm using a Target Language Compiler (TLC) function. In accelerated and external mode simulations, you can choose to execute the S-function in interpretive mode by calling back to the MATLAB execution engine without implementing the algorithm in TLC. If the MATLAB S-function is a <code>SimViewingDevice</code> , the Simulink Coder product automatically omits the block during code generation. |
| C MEX S-function            | Supports code generation. For noninlined S-functions, the Simulink Coder product uses the C MEX function during code generation. However, you must write a TLC-file for the S-function if you need to either inline the S-function or create a wrapper for hand-written code. See “S-Functions and Code Generation” in the Simulink Coder User's Guide for more information.   |

## Expanding Custom Block Functionality

You can expand the functionality of any custom block using callbacks and Handle Graphics.

Block callbacks perform user-defined actions at specific points in the simulation. For example, the callback can load data into the MATLAB workspace before the simulation or generate a graph of simulation data at the end of the simulation. You can assign block callbacks to any of the custom block types. For a list of available callbacks and more information on how to use them, see “Create Block Callbacks” on page 4-75.

GUIDE, the MATLAB graphical user interface development environment, provides tools for easily creating custom user interfaces. See “GUI Building” for more information on using GUIDE.

## Create a Custom Block

### In this section...

“How to Design a Custom Block” on page 35-19

“Defining Custom Block Behavior” on page 35-21

“Deciding on a Custom Block Type” on page 35-22

“Placing Custom Blocks in a Library” on page 35-26

“Adding a User Interface to a Custom Block” on page 35-29

“Adding Block Functionality Using Block Callbacks” on page 35-37

### How to Design a Custom Block

In general, use the following process to design a custom block:

- 1 “Defining Custom Block Behavior” on page 35-21
- 2 “Deciding on a Custom Block Type” on page 35-22
- 3 “Placing Custom Blocks in a Library” on page 35-26
- 4 “Adding a User Interface to a Custom Block” on page 35-29

Suppose you want to create a customized saturation block that limits the upper and lower bounds of a signal based on either a block parameter or the value of an input signal. In a second version of the block, you want the option to plot the saturation limits after the simulation is finished. The following tutorial steps you through designing these blocks. The library `customsat_lib` contains the two versions of the customized saturation block.

The example model `sldemo_customsat` uses the basic version of the block.

## Defining Custom Block Behavior

Begin by defining the features and limitations of your custom block. In this example, the block supports the following features:

- Turning on and off the upper or lower saturation limit.
- Setting the upper and/or lower limits via a block parameters.

- Setting the upper and/or lower limits using an input signal.

It also has the following restrictions:

- The input signal under saturation must be a scalar.
- The input signal and saturation limits must all have a data type of double.
- Code generation is not required.

## Deciding on a Custom Block Type

Based on the custom block features, the implementation needs to support the following:

- Multiple input ports
- A relatively simple algorithm
- No continuous or discrete system states

Therefore, this tutorial implements the custom block using a Level-2 MATLAB S-function. MATLAB S-functions support multiple inputs and, because the algorithm is simple, do not have significant overhead when updating the diagram or simulating the model. See “Comparison of Custom Block Functionality” on page 35-7 for a description of the different functionality provided by MATLAB S-functions as compared to other types of custom blocks.

### Parameterizing the MATLAB S-Function

Begin by defining the S-function parameters. This example requires four parameters:

- The first parameter indicates how the upper saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The second parameter is the value of the upper saturation limit. This value is used only if the upper saturation limit is set via a block parameter. In the event this parameter is used, you should be able to change the parameter value during the simulation, i.e., the parameter is tunable.
- The third parameter indicates how the lower saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The fourth parameter is the value of the lower saturation limit. This value is used only if the lower saturation limit is set via a block parameter. As with the upper saturation limit, this parameter is tunable when in use.

The first and third S-function parameters represent modes that must be translated into values the S-function can recognize. Therefore, define the following values for the upper and lower saturation limit modes:

- 1 indicates that the saturation limit is off.
- 2 indicates that the saturation limit is set via a block parameter.
- 3 indicates that the saturation limit is set via an input signal.

### Writing the MATLAB S-Function

After you define the S-function parameters and functionality, write the S-function. The template `msfuntmpl.m` provides a starting point for writing a Level-2 MATLAB S-function. You can find a completed version of the custom saturation block in the file `custom_sat.m`. Save this file to your working folder before continuing with this tutorial.

This S-function modifies the S-function template as follows:

- The `setup` function initializes the number of input ports based on the values entered for the upper and lower saturation limit modes. If the limits are set via input signals, the method adds input ports to the block. The `setup` method then indicates there are four S-function parameters and sets the parameter tunability. Finally, the method registers the S-function methods used during simulation.

```
function setup(block)

% The Simulink engine passes an instance of the Simulink.MSFcnRunTimeBlock
% class to the setup method in the input argument "block". This is known as
% the S-function block's run-time object.

% Register original number of input ports based on the S-function
% parameter values

try % Wrap in a try/catch, in case no S-function parameters are entered
    lowMode    = block.DialogPrm(1).Data;
    upMode     = block.DialogPrm(3).Data;
    numInPorts = 1 + isequal(lowMode,3) + isequal(upMode,3);
catch
    numInPorts=1;
end % try/catch
block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInpPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
block.InputPort(1).DatatypeID = 0; % double
```

```

block.InputPort(1).Complexity = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID = 0; % double
block.OutputPort(1).Complexity = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
%    set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
%    set via an input signal
block.NumDialogPrms = 4;
block.DialogPrmsTunable = {'Nontunable','Tunable','Nontunable', ...
    'Tunable'};

% Register continuous sample times [0 offset]
block.SampleTimes = [0 0];

%% -----
%% Options
%% -----
% Specify if Accelerator should use TLC or call back into

    lowPortNum = 3; % Move lower boundary down one port number
else
    upVal = inf;
end

% Check lower saturation limit
if isequal(lowMode,2), % Set via a block parameter
    lowVal = block.RuntimePrm(1).Data;
elseif isequal(lowMode,3), % Set via an input port
    lowVal = block.InputPort(lowPortNum).Data;
else
    lowVal = -inf;
end

% Assign new value to signal
if sigVal > upVal,
    sigVal = upVal;
elseif sigVal < lowVal,
    sigVal=lowVal;
end

block.OutputPort(1).Data = sigVal;

%end Outputs function
```

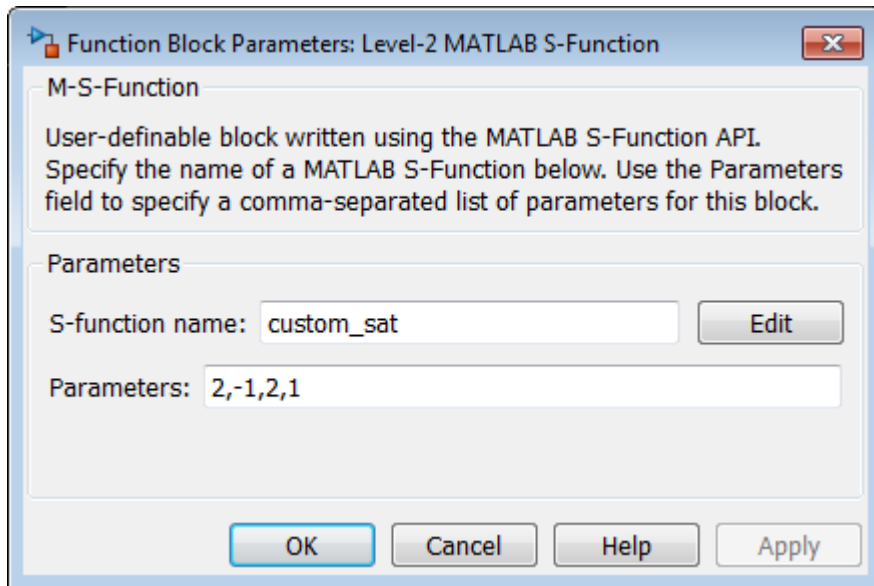

## Placing Custom Blocks in a Library

Libraries allow you to share your custom blocks with other users, easily update the functionality of copies of the custom block, and collect blocks for a particular project into a single location. This example places the custom saturation block into a library.

- 1 In the Simulink Library Browser, select **File > New > Library**.
- 2 From the User-Defined Functions library, drag a Level-2 MATLAB S-Function block into your new library.

- 3 Save your library with the filename `saturation_lib`.
- 4 Double-click the block to open its Function Block Parameters dialog box.
- 5 In the **S-function name** field, enter the name of the S-function. For example, enter `custom_sat`. In the **Parameters** field enter `2, -1, 2, 1`.

- 6 Click **OK**.

You have created a custom saturation block that you can share with other users.

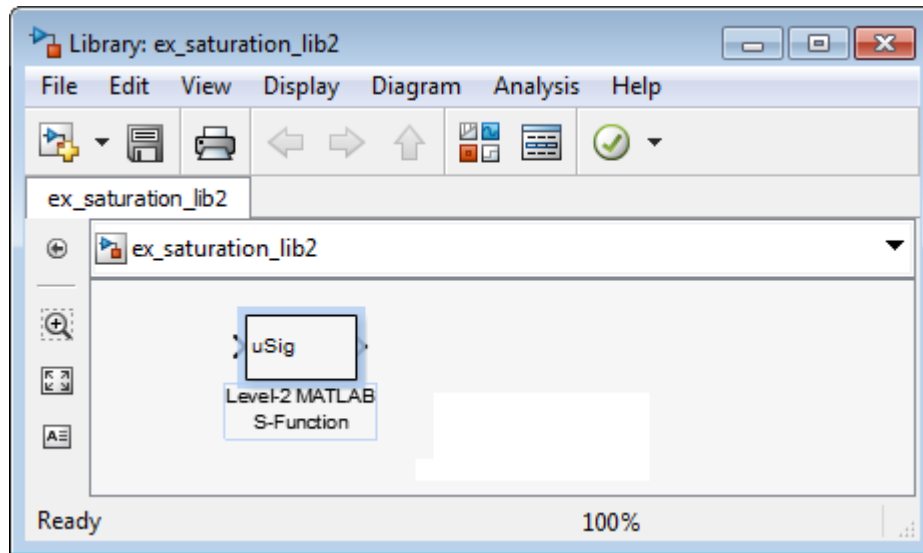

You can make the block easier to use by adding a customized user interface.

## Adding a User Interface to a Custom Block

You can create a block dialog box for a custom block using the masking features of Simulink. Masking the block also allows you to add port labels to indicate which ports corresponds to the input signal and the saturation limits.

- 1 Open the library `saturation_lib` that contains the custom block you created,
- 2 Right-click the Level-2 MATLAB S-Function block and select **Mask > Create Mask**.
- 3 On the **Icon & Ports** pane in the **Icons drawing commands** box, enter `port_label('input', 1, 'uSig')`, and then click **Apply**.

This command labels the default port as the input signal under saturation.

- 4 In the **Parameters & Dialog** pane, add four parameters corresponding to the four S-Function parameters. For each new parameter, drag a popup or edit control to the **Dialog box** section, as shown in the table. Drag each parameter into the Parameters group.

| Type  | Prompt         | Name   | Evaluate | Tunable | Popup options  | Callback                                  |
|-------|----------------|--------|----------|---------|--|---|
| popup | Upper boundary | upMode | ✓        |         | No limit<br><br>Enter limit as parameter<br><br>Limit using input signal | customsat_callback('upperbound_callback') |
| edit  | Upper limit:   | upVal  | ✓        | ✓       | N/A  | customsat_callback('upperparam_callback') |

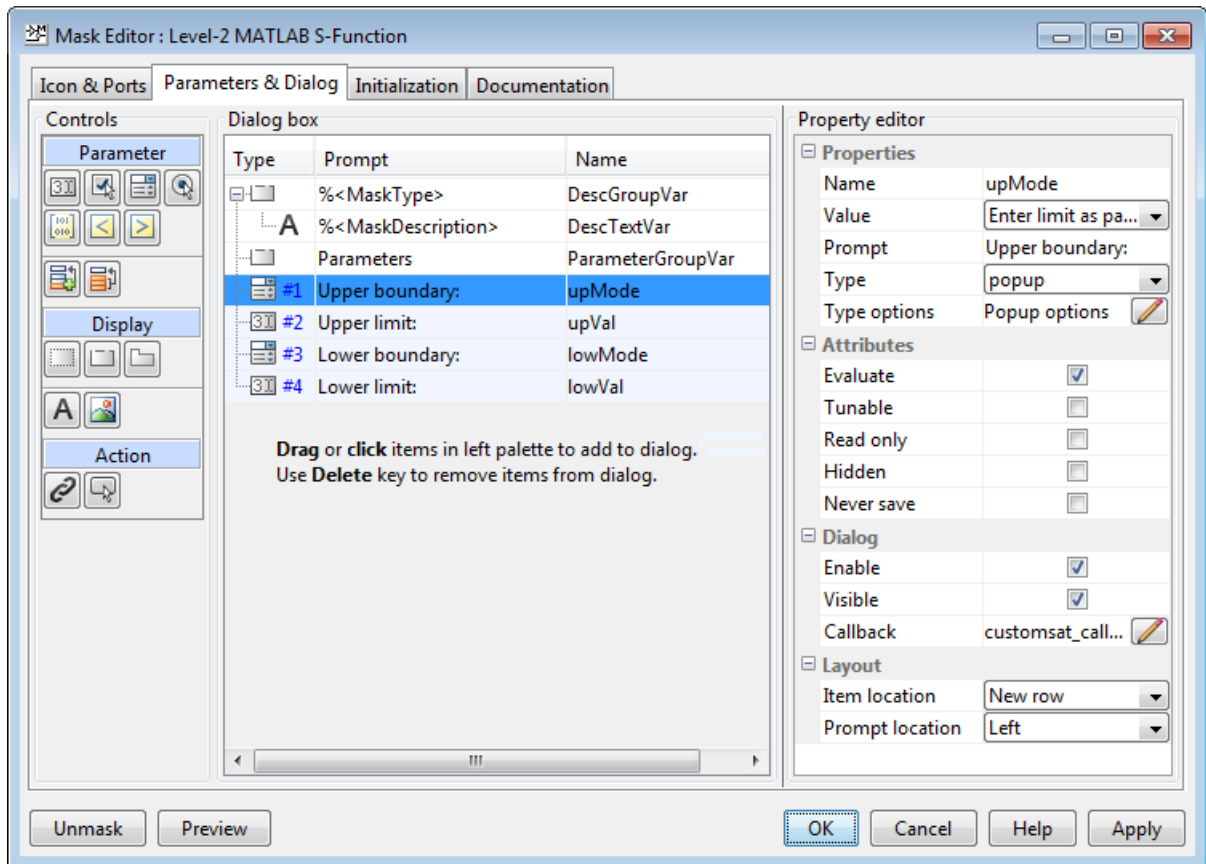

| Type  | Prompt         | Name    | Evaluate | Tunable | Popup options | Callback                                  |
|-------|----------------|---------|----------|---------|---------------|---|
| popup | Lower boundary | lowMode | ✓        |         | No limit      | customsat_callback('lowerbound_callback') |

| Type | Prompt       | Name   | Evaluate | Tunable | Popup options            | Callback                                  |
|------|--------------|--------|----------|---------|--------------------------|---|
|      |              |        |          |         | Enter limit as parameter |   |
|      |              |        |          |         | Limit using input signal |   |
| edit | Lower limit: | lowVal | ✓        | ✓       | N/A                      | customsat_callback('lowerparam_callback') |

The MATLAB S-Function script `custom_sat_final.m` contains the mask parameter callbacks. Save `custom_sat_final.m` to your working folder to define the callbacks in this example. This MATLAB script has two input arguments. The first input argument is a string indicating which mask parameter invoked the callback. The second input argument is the handle to the associated Level-2 MATLAB S-Function block.

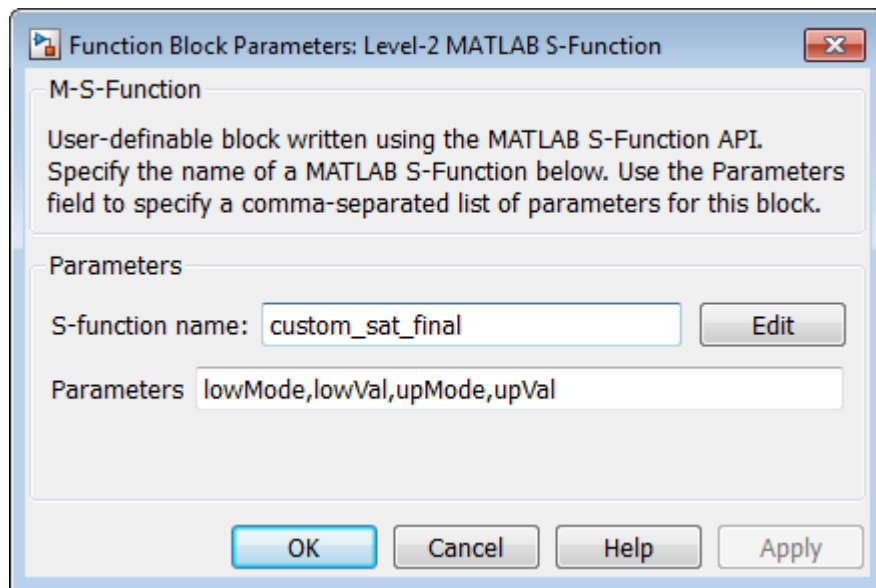

The figure shows the completed **Parameters & Dialog** pane in the Mask Editor.

- 5 In the **Initialization** pane, select the **Allow library block to modify its contents** check box. This setting allows the S-function to change the number of ports on the block.
- 6 In the **Documentation** pane:
  - In the **Mask type** field, enter  
Customized Saturation
  - In the **Mask description** field, enter  
Limit the input signal to an upper and lower saturation value set either through a block parameter or input signal.

- 7 Click **OK**.
- 8 To map the S-function parameters to the mask parameters, right-click the Level-2 MATLAB S-Function block and select **Mask > Look Under Mask**.
- 9 Change the **S-function name** field to `custom_sat_final` and the **Parameters** field to `lowMode,lowVal,upMode,upVal`.

The figure shows the Function Block Parameters dialog box after the changes.

- 10 Click **OK**. Save and close the library to exit the edit mode.
- 11 Reopen the library and double-click the customized saturation block to open the masked parameter dialog box.

To create a more complicated user interface, place a Handle Graphics user interface on top of the masked block. The block `OpenFcn` invokes the Handle Graphics user interface, which uses calls to `set_param` to modify the S-function block parameters based on settings in the user interface.

### Writing the Mask Callback

The function `customsat_callback.m` contains the mask callback code for the custom saturation block mask parameter dialog box. This function invokes local functions corresponding to each mask parameter through a call to `feval`.

The following local function controls the visibility of the upper saturation limit's field based on the selection for the upper saturation limit's mode. The callback begins by obtaining values for all mask parameters using a call to `get_param` with the property name `MaskValues`. If the callback needed the value of only one mask parameter, it could call `get_param` with the specific mask parameter name, for example, `get_param(block, 'upMode')`. Because this example needs two of the mask parameter values, it uses the `MaskValues` property to reduce the calls to `get_param`.

The callback then obtains the visibilities of the mask parameters using a call to `get_param` with the property name `MaskVisibilities`. This call returns a cell array of strings indicating the visibility of each mask parameter. The callback alters the values for the mask visibilities based on the selection for the upper saturation limit's mode and then updates the port label string.

The callback finally uses the `set_param` command to update the block's `MaskDisplay` property to label the block's input ports.

```
function customsat_callback(action,block)
% CUSTOMSAT_CALLBACK contains callbacks for custom saturation block

% Copyright 2003-2007 The MathWorks, Inc.

%% Use function handle to call appropriate callback
feval(action,block)

%% Upper bound callback
function upperbound_callback(block)

vals = get_param(block,'MaskValues');
vis = get_param(block,'MaskVisibilities');
portStr = {'port_label(''input'',1,'uSig')'};
switch vals{1}
    case 'No limit'
        set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
    case 'Enter limit as parameter'
        set_param(block,'MaskVisibilities',[vis(1);{'on'};vis(3:4)]);
    case 'Limit using input signal'
        set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
        portStr = [portStr;{'port_label(''input'',2,'up')'}];
end
if strcmp(vals{3},'Limit using input signal'),
    portStr = [portStr;{'port_label(''input'',',num2str(length(portStr)+1), ...
        ', 'low')'}]];
end
set_param(block,'MaskDisplay',char(portStr));
```

The final call to `set_param` invokes the `setup` function in the MATLAB S-function `custom_sat.m`. Therefore, the `setup` function can be modified to set the number of input ports based on the mask parameter values instead of on the S-function parameter values. This change to the `setup` function keeps the number of ports on the Level-2 MATLAB S-Function block consistent with the values shown in the mask parameter dialog box.

The modified MATLAB S-function `custom_sat_final.m` contains the following new `setup` function. If you are stepping through this tutorial, open the file and save it to your working folder.

```
%% Function: setup =====
```

```

function setup(block)

% Register original number of ports based on settings in Mask Dialog
ud = getPortVisibility(block);
numInPorts = 1 + isequal(ud(1),3) + isequal(ud(2),3);

block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInpPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
block.InputPort(1).DatatypeID = 0; % double
block.InputPort(1).Complexity = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID = 0; % double
block.OutputPort(1).Complexity = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
%    set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
%    set via an input signal
block.NumDialogPrms = 4;
block.DialogPrmsTunable = {'Nontunable', 'Tunable', 'Nontunable', 'Tunable'};

% Register continuous sample times [0 offset]
block.SampleTimes = [0 0];

%% -----
%% Options
%% -----
% Specify if Accelerator should use TLC or call back into
% MATLAB script
block.SetAccelRunOnTLC(false);

%% -----
%% Register methods called during update diagram/compilation
%% -----

block.RegBlockMethod('CheckParameters', @CheckPrms);
block.RegBlockMethod('ProcessParameters', @ProcessPrms);
block.RegBlockMethod('PostPropagationSetup', @DoPostPropSetup);
block.RegBlockMethod('Outputs', @Outputs);
block.RegBlockMethod('Terminate', @Terminate);
%endfunction

```

The `getPortVisibility` local function in `custom_sat_final.m` uses the saturation limit modes to construct a flag that is passed back to the `setup` function. The `setup` function uses this flag to determine the necessary number of input ports.

```
%% Function: Get Port Visibilities =====
function ud = getPortVisibility(block)

ud = [0 0];

vals = get_param(block.BlockHandle, 'MaskValues');
switch vals{1}
    case 'No limit'
        ud(2) = 1;
    case 'Enter limit as parameter'
        ud(2) = 2;
    case 'Limit using input signal'
        ud(2) = 3;
end

switch vals{3}
    case 'No limit'
        ud(1) = 1;
    case 'Enter limit as parameter'
        ud(1) = 2;
    case 'Limit using input signal'
        ud(1) = 3;
end
```

## Adding Block Functionality Using Block Callbacks

The User-Defined Saturation with Plotting block in `customsat_lib` uses block callbacks to add functionality to the original custom saturation block. This block provides an option to plot the saturation limits when the simulation ends. The following steps show how to modify the original custom saturation block to create this new block.

- 1 Add a check box to the mask parameter dialog box to toggle the plotting option on and off.
  - a Right-click the Level-2 MATLAB S-Function block in `saturation_lib` and select **Mask+Create Mask**.
  - b On the Mask Editor **Parameters** pane, add a fifth mask parameter with the following properties.

| Prompt                 | Name    | Type     | Tunable | Type options | Callback                           |
|------------------------|---------|----------|---------|--------------|------------------------------------|
| Plot saturation limits | plotche | checkbox | No      | NA           | customsat_callback('plotsaturation |

- c Click **OK**.

- 2 Write a callback for the new check box. The callback initializes a structure to store the saturation limit values during simulation in the Level-2 MATLAB S-Function block `UserData`. The MATLAB script `customsat_plotcallback.m` contains this new callback, as well as modified versions of the previous callbacks to handle the new mask parameter. If you are following through this example, open `customsat_plotcallback.m` and copy its local functions over the previous local functions in `customsat_callback.m`.

```

%% Plotting checkbox callback
function plotsaturation(block)

% Reinitialize the block's userdata
vals = get_param(block, 'MaskValues');
ud = struct('time', [], 'upBound', [], 'upVal', [], 'lowBound', [], 'lowVal', []);

if strcmp(vals{1}, 'No limit'),
    ud.upBound = 'off';
else
    ud.upBound = 'on';
end

if strcmp(vals{3}, 'No limit'),
    ud.lowBound = 'off';
else
    ud.lowBound = 'on';
end

set_param(gcb, 'UserData', ud);

```

- 3** Update the MATLAB S-function `Outputs` method to store the saturation limits, if applicable, as done in the new MATLAB S-function `custom_sat_plot.m`. If you are following through this example, copy the `Outputs` method in `custom_sat_plot.m` over the original `Outputs` method in `custom_sat_final.m`

```

%% Function: Outputs =====
function Outputs(block)

lowMode    = block.DialogPrm(1).Data;
upMode     = block.DialogPrm(3).Data;
sigVal     = block.InputPort(1).Data;
vals = get_param(block.BlockHandle, 'MaskValues');
plotFlag = vals{5};
lowPortNum = 2;

% Check upper saturation limit
if isequal(upMode, 2)
    upVal = block.RuntimePrm(2).Data;
elseif isequal(upMode, 3)
    upVal = block.InputPort(2).Data;
    lowPortNum = 3; % Move lower boundary down one port number
else
    upVal = inf;
end

% Check lower saturation limit
if isequal(lowMode, 2),
    lowVal = block.RuntimePrm(1).Data;
elseif isequal(lowMode, 3)
    lowVal = block.InputPort(lowPortNum).Data;
else
    lowVal = -inf;
end

```

```

% Use userdata to store limits, if plotFlag is on
if strcmp(plotFlag,'on');
    ud = get_param(block.BlockHandle,'UserData');
    ud.lowVal = [ud.lowVal;lowVal];
    ud.upVal = [ud.upVal;upVal];
    ud.time = [ud.time;block.CurrentTime];
    set_param(block.BlockHandle,'UserData',ud)
end

% Assign new value to signal
if sigVal > upVal,
    sigVal = upVal;
elseif sigVal < lowVal,
    sigVal=lowVal;
end

block.OutputPort(1).Data = sigVal;

%endfunction

```

- 4** Write the function `plotsat.m` to plot the saturation limits. This function takes the handle to the Level-2 MATLAB S-Function block and uses this handle to retrieve the block's `UserData`. If you are following through this tutorial, save `plotsat.m` to your working folder.

```

function plotSat(block)

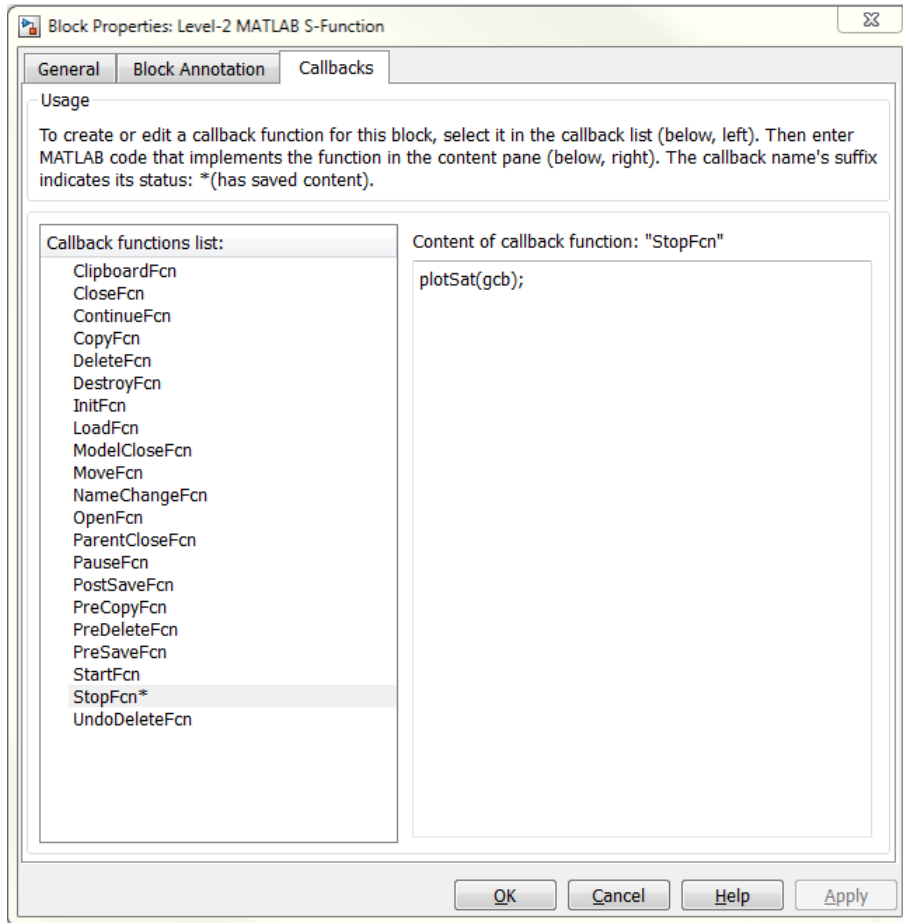

% PLOTSAT contains the plotting routine for custom_sat_plot
% This routine is called by the S-function block's StopFcn.

ud = get_param(block,'UserData');
fig=[];
if ~isempty(ud.time)
    if strcmp(ud.upBound,'on')
        fig = figure;
        plot(ud.time,ud.upVal,'r');
        hold on
    end
    if strcmp(ud.lowBound,'on')
        if isempty(fig),
            fig = figure;
        end
        plot(ud.time,ud.lowVal,'b');
    end
    if ~isempty(fig)
        title('Upper bound in red. Lower bound in blue.')
    end

% Reinitialize userdata
ud.upVal=[];
ud.lowVal=[];
ud.time = [];
set_param(block,'UserData',ud);
end

```

- 5 Right-click the Level-2 MATLAB S-Function block and select **Properties**. The Block Properties dialog box opens. On the **Callbacks** pane, modify the **StopFcn** to call the plotting callback as shown in the following figure, then click **OK**.

## Custom Block Examples

### Creating Custom Blocks from Masked Library Blocks

The Additional Math and Discrete Simulink library is a group of custom blocks created by extending the functionality of built-in Simulink blocks. The Additional Discrete library contains a number of masked blocks that extend the functionality of the standard Unit Delay block. See “Libraries” for more general information on Simulink libraries.

### Creating Custom Blocks from MATLAB Functions

The Simulink product provides a number of examples that show how to incorporate MATLAB functions into a custom block.

- The Single Hydraulic Cylinder Simulation, `sldemo_hydcyl`, uses a Fcn block to model the control valve flow. In addition, the Control Valve Flow block is a library link to one of a number of custom blocks in the library `hydlib`.
- The Radar Tracking Model, `sldemo_radar`, uses an Interpreted MATLAB Function block to model an extended Kalman filter. The MATLAB function `aero_extkalman.m` implements the Kalman filter found inside the Radar Kalman Filter subsystem. In this example, the MATLAB function requires three inputs, which are bundled together using a Mux block in the Simulink model.
- The Spiral Galaxy Formation example, `sldemo_eml_galaxy`, uses several MATLAB Function blocks to construct two galaxies and calculate the effects of gravity as these two galaxies nearly collide. The example also uses MATLAB Function blocks to plot the simulation results using a subset of MATLAB functions not supported for code generation. However, because these MATLAB Function blocks have no outputs, the Simulink Coder product optimizes them away during code generation.

## Creating Custom Blocks from System Objects

The Simulink product provides a number of examples that show how to incorporate System objects into a custom block. Access the MATLAB source code for each System object by clicking the **Source code** link from the block dialog box. For more information on using MATLAB System blocks and System objects, see “System Object Integration”).

- System Identification for an FIR System Using MATLAB System Blocks, `slexSysIdentMATLABSystemExample`, uses the MATLAB System block to implement Simulink blocks using a System object. It highlights two MATLAB System blocks.
- MATLAB System Block with Variable-Size Input and Output Signals, `slexVarSizeMATLABSystemExample`, uses the MATLAB System block to implement Simulink blocks with variable-size input and output signals. Due to the use of variable-size signals, the example uses System object propagation methods.
- Illustration of Law of Large Numbers Using MATLAB System Blocks, `slexLawOfLargeNumbersExample`, uses MATLAB System blocks to illustrate the law of large numbers. Due to the use of MATLAB functions not supported for code generation, the example uses System object propagation methods and interpreted execution.

## Creating Custom Blocks from S-Functions

The Simulink model `sfundemos` contains various examples of MATLAB and C MEX S-functions. For more information on writing MATLAB S-functions, see “Write Level-2 MATLAB S-Functions”. For more information on writing C MEX S-functions, see “C/C++ S-Functions”. For a list of available S-function examples, see “S-Function Examples” in Writing S-Functions.

# Working with Block Libraries

---

- “About Block Libraries and Linked Blocks” on page 36-2
- “Create and Work with Linked Blocks” on page 36-4
- “Work with Library Links” on page 36-8
- “Create Block Libraries” on page 36-19
- “Add Libraries to the Library Browser” on page 36-30

## About Block Libraries and Linked Blocks

### Block Libraries

A *block library* is a collection of blocks that you can use to create instances of blocks in a Simulink model.

---

**Note:** Simulink comes with some built-in block libraries in addition to the default Simulink library. These libraries support simulating models that contain these blocks. However, you cannot generate code or modify these blocks without the relevant product licences. You cannot change a built-in block library in any way.

---

### Benefits of Block Libraries

Block libraries are a useful componentization technique for:

- Providing frequently used, and seldom changed, modeling utilities
- Reusing components repeatedly in a model or in multiple models

For additional information about how libraries compare to other Simulink componentization techniques, see “Componentization Guidelines” on page 14-28.

### Library Browser

Simulink provides a Library Browser that you can use to display block libraries, search for blocks by name, and copy library blocks into models. All installed libraries appear in the Library Browser when you open it. See “Model Editing Environment” on page 1-35.

### Linked Blocks

When you copy a block from a library into a model, Simulink creates a *linked block* in the model, and connects it to the library block using a *library link*. The library block is the *prototype block*, and the linked block in the model is an *instance* of the library block. The linked block appearance and behavior are the same as the library block. For most purposes, you can ignore the underlying link and just think of a linked block as a clone of the library block.

Copying a block from a library to another library or model does not always create a linked block. Library blocks that support linking include subsystems, masked blocks, and charts. However, the block author can choose not to make the copy a linked block by modifying the `CopyFcn`, as done by the Simulink Subsystem block.

## Create and Work with Linked Blocks

### In this section...

“About Linked Blocks” on page 36-4

“Create a Linked Block” on page 36-4

“Update a Linked Block” on page 36-5

“Modify Linked Blocks” on page 36-6

“Find a Linked Block's Prototype” on page 36-7

“Find Linked Blocks in a Model” on page 36-7

### About Linked Blocks

A *linked block* is an instance of a library block and contains a link to that library block that serves as the block type's prototype. The link consists of the path of the library block that serves as the instance's prototype. The link allows the linked block to update whenever the corresponding prototype in the library changes (“Update a Linked Block” on page 36-5). This ensures that your model always uses the latest version of the block.

---

**Note:** The tooltip for a linked block shows the name of the library block it references.

---

You can change the values of a linked block's parameters (including in an existing mask). You cannot add a new mask for linked blocks or edit the mask setup, that is, add or remove mask parameters or change mask behavior.

Also, you cannot set callback parameters for a linked block. If the linked block's prototype is a subsystem, you can make nonstructural changes to the contents of the linked subsystem (see “Modify Linked Blocks” on page 36-6).

### Create a Linked Block

To create a linked block in a model or another library:

- 1 Open your model.

- 2 Open the Simulink Library Browser or another library.
- 3 Use the Library Browser to find the library block that serves as a prototype of the block you want to create.

---

**Note:** If you add a description to the library block through the Block Properties dialog box, Simulink does not propagate that description to the linked block. If you want to create a description that propagates, mask the library block and add the description in the **Documentation** pane of the mask.

---

- 4 Drag the library block from the Blocks pane and drop it into your model.

## Update a Linked Block

Simulink updates out-of-date linked blocks in a model or library when you:

- Load the model or library.
- Run the simulation.
- Use the `find_system` command.
- Query the `LinkStatus` parameter of a block, using the `get_param` command (see “Check and Set Link Status Programmatically” on page 36-15).

---

**Note** Querying the `StaticLinkStatus` parameter of a block does not update any out-of-date linked blocks.

---

- Save changes to a library block, then Simulink automatically refreshes all links to the block in open Model Editor windows.

When you edit a library block (in the Model Editor or at the command line), then Simulink indicates stale links which are open in the Model Editor by displaying the linked blocks grayed out. Simulink refreshes any stale links to edited blocks when you activate the Model Editor window, even if you have not saved the library yet.

To manually refresh links:

- Select **Simulation > Update Diagram** (or press **Ctrl+D**).
- Select **Diagram > Refresh Blocks** (or press **Ctrl+K**) to refresh links.
- Select **Go To Library Link**.

## Modify Linked Blocks

You cannot make structural changes to linked blocks, such as adding or deleting lines or blocks to the block diagram of a masked subsystem. If you want to make such changes, you must disable the linked block's link to its library prototype (see “Disable Links to Library Blocks” on page 36-11 ).

### Parameterized Links

If you change parameter values inside a linked block, you create a *parameterized link*. You can change the values of any masked subsystem linked block parameter that does not alter the block's structure, e.g., by adding or deleting lines, blocks, or ports. An example of a nonstructural change is a change to the value of a mathematical block parameter, such as the Gain parameter of the Gain block. A linked subsystem block whose parameter values of inner blocks differ from their corresponding library blocks is called a *parameterized link*. Changing the top-level mask values does not create a parameterized link.

When saving a model containing a parameterized link, Simulink saves the changes to the local copy of the subsystem together with the path to the library copy in the model's file. When you reopen the system, Simulink copies the library block into the loaded model and applies the saved changes.

---

**Tip** To determine whether a linked block's parameter values differ from those of its library prototype, open the linked block's block diagram in an editor window. The linked block's library link indicator (if displayed) changes to a red arrow and the title bar of the editor window displaying the subsystem displays “Parameterized Link” if the linked block's parameter values differ from the library block's parameter values.

---

See “Display Library Links” on page 36-8.

### Self-Modifying Linked Subsystems

Simulink allows linked subsystems to change their own structural contents without disabling the link. This allows you to create masked subsystems that modify their structural contents based on mask parameter dialog box values.

## Find a Linked Block's Prototype

To find the source library and the prototype of a linked block, right-click the linked block and select **Library Link > Go To Library Link**.

Alternatively, select the linked block and select **Diagram > Library Link > Go To Library Link**.

If the library is open, Simulink selects and highlights the library block and makes the source library the active window. If the library is not open, Simulink first opens it and then selects the library block.

## Find Linked Blocks in a Model

Use the `libinfo` command to get information about the linked blocks in the model and which library blocks they link to. The `ReferenceBlock` property gives the path of the library block to which a block links.

## Work with Library Links

### In this section...

- “Display Library Links” on page 36-8
- “Lock Links to Blocks in a Library” on page 36-9
- “Disable Links to Library Blocks” on page 36-11
- “Restore Disabled or Parameterized Links” on page 36-12
- “Check and Set Link Status Programmatically” on page 36-15
- “Break a Link to a Library Block” on page 36-17
- “Fix Unresolved Library Links” on page 36-18

### Display Library Links

A model can have a block linked to a library block, or it can have a local instance of a block that is not linked. To enable the display of library links:

- 1 In the Model Editor window, select **Display > Library Links** and from the submenu, select one of these options:
  - a **None** — displays no links
  - b **Disabled** — displays only disabled links (the default for new models)
  - c **User Defined** — displays only links to user libraries
  - d **All** — displays all links
- 2 Observe the library link indicators.

The library link indicator is a badge in the bottom left corner of each block. You can right-click the link badge to access link menu options.

The color and icon of the link badge indicates the status of the link. If you open a linked block, the Model Editor displays the same link badge at bottom left. You can right-click the link badge in the corner of the canvas to access link options such as **Go To Library Block**.

| Link Badge  | Status                                   |
|---|--|
| Black links<br>                      | Active link                              |
| Grey separated links<br>             | Inactive link                            |
| Black links with a red star icon<br> | Active and modified (parameterized link) |
| White links, black background<br>   | Locked link                              |

**Note:** If you have a variant subsystem block inside a link block, modifying the parameters on the variant subsystem creates a link data on the topmost link block. If the link badge is visible, presence of link data is indicated by a red star on the link badge.

## Lock Links to Blocks in a Library

You can lock links to a library. Lockable library links enable control of end user editing, to prevent unintentional disabling of these links. This ensures robust usage of mature stable libraries.

To lock links to a library, either:

- In your library window, select **Diagram > Lock Links To Library**.

- At the command line, use the `LockLinksToLibrary` property:

```
set_param('MyModelName', 'LockLinksToLibrary', 'on')
```

where `MyModelName` is the library file.

When you copy a block to a model from a library with locked links:

- The link is locked.
- You cannot disable locked links from the Model Editor.

If you select **Diagram** or right-click the linked block, you see the **Library Link** menu has changed to **Locked Library Link**, and the only enabled option is now **Go To Library Block**.

- If you display library links, the locked link icon has a black background.

- If you open a locked link, the window title is **Locked Link: *blockname***. The bottom left corner shows a lock icon and a link badge.

- You cannot edit locked link contents. If you try to make a structural change to a locked link (such as editing the diagram), you see a message stating that you cannot modify the link because it is either locked or inside another locked link.

- The mask and block parameter dialogs are disabled for blocks inside locked links. For a resolved linked block with a mask, its parameter dialog is always disabled.
- You cannot parameterize locked links in the Model Editor.
- You can disable locked links only from the command line as follows:

```
set_param(gcb, 'LinkStatus', 'inactive')
```

To unlock links to a library:

- In your library window, select **Diagram > Unlock Links To Library**
- At the command line:

```
set_param('MyModelName', 'LockLinksToLibrary', 'off')
```

The status of a link (locked or not) is determined by the library state when you copy the block. If you copy a block from a library with locked links, the link is locked. If you later unlock the library links, any existing linked blocks do not change to unlocked links until you refresh links.

If you use sublibraries as an organizational tool, when you lock links to a library, you might want also to lock links to any sublibraries.

## Disable Links to Library Blocks

To make a structural change to a linked block, you need to disable the link between the block and the library block that serves as its prototype.

You cannot disable *locked* links from the Model Editor. See “Lock Links to Blocks in a Library” on page 36-9.

---

**Note** When you use the Model Editor to make a structural change (such as editing the diagram) to a block with an active library link, Simulink offers to disable the library link for you (unless the link is locked). If you accept, Simulink disables the link and allows you to make changes to the subsystem block.

Do not use `set_param` to make a structural change to an active link; the result of this type of change is undefined.

---

To disable a link:

- 1 In the Model Editor window, right-click a linked block and select **Library Link > Disable Link**.
- 2 Alternatively, select a linked block and select the menu item **Diagram > Library Link > Disable Link**.

The library link is disabled and the library link indicator changes to gray. When a library block is disabled and it is within another library block (a child of a parent library block), the model also disables the parent block containing the child block.

To disable a link from the command-line, set the `LinkStatus` property to `inactive` as follows:

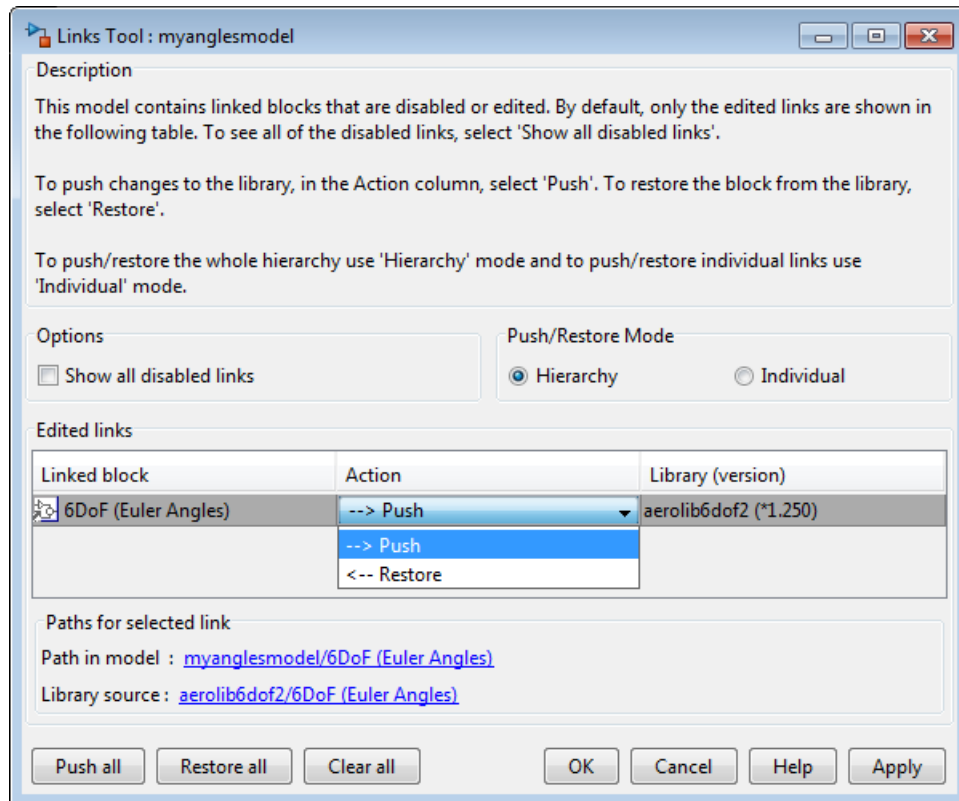

```
set_param(gcb, 'LinkStatus', 'inactive')
```

## Restore Disabled or Parameterized Links

After you make changes to a disabled linked block, you may want to restore its link to the library block and resolve any differences between the two blocks. The Links Tool helps you with this task.

- 1 In the Model Editor window, select a linked block with a disabled library link.
- 2 From the **Diagram** menu (or right-click context menu), select **Library Link > Resolve Link**.

The Links Tool window opens.

The **Edited links** table has the following columns:

- **Linked block** — List of linked blocks. The list of links includes library links with structural changes (disabled links), parameterized library links (edited links), and library links that were actively chosen to be resolved.
  - **Action** — Select an action to perform on the linked block or library.
  - **Library** — List of library names and version numbers.
- 3** Select the check box **Show all disabled links** if you want to view disabled links as well as parameterized links.
  - 4** Under **Push/Restore Mode**, choose a mode of action:
    - If you want to act on individual links, select **Individual**.

- If you want to act on the whole link hierarchy, leave the default setting on **Hierarchy**. See “Pushing or Restoring Link Hierarchies” on page 36-15.

5 From the **Linked block** list, select a block name.

The Links Tool updates the **Paths for selected link** panel with links to the linked block in the model and in the library.

6 From the **Action** list, select **Push** or **Restore** for the currently selected block.

| Action Choice      | Links Tool Action   |
|--------------------|---|
| Push               | The Links Tool looks for all changes in the link hierarchy and pushes all links with changes to their libraries. <b>Push</b> replaces the version of the block in the library with the version in the model.                              |
| Restore            | The Links Tool looks for all disabled or edited links in the link hierarchy and restores them all with their corresponding library blocks. <b>Restore</b> replaces the version of the block in the model with the version in the library. |
| Push Individual    | In <b>Individual</b> mode, the disabled or edited block is pushed to the library, preserving the changes inside it without acting on the hierarchy. All other links are unaffected.   |
| Restore Individual | In <b>Individual</b> mode, the disabled or edited block is restored from the library, and all other links are unaffected.   |

To select the same action for all linked blocks, click **Push all**, **Restore all**, or **Clear all**.

7 When you click **OK** or **Apply**, the Links Tool performs the push or restore actions you selected in the edited links table.

After resolving a link, the versions in the library and the linked block now match.

---

**Note:** Changes you push to the library are not saved until you actively save the library.

---

If a linked block name has a cautionary icon  before it, the model has other instances of this block linked from the same library block, and they have different changes. Choose

one of the instances to push changes to the library block and restore links to the other blocks, or choose to restore all of them with the library version.

### Pushing or Restoring Link Hierarchies

---

**Caution** Be cautious using Push or Restore in hierarchy mode if you have a large hierarchy of edited and disabled links. Ensure that you want to push or restore the whole hierarchy of links.

---

Pushing a hierarchy of disabled links affects the disabled links inside and outside in the hierarchy for a given link. If you push changes from a disabled link in the middle of a hierarchy, the inside links are pushed and the outside links are restored if without changes. This operation does not affect outside (parent) links with changes unless you also explicitly selected them for push. The Links Tool starts from the lowest links (the deepest inside) and then moves upward in the hierarchy.

Some simple examples:

- 1 Link A contains link B and both have changes.
  - Push A. The Links Tool pushes both A and B.
  - Push B. The Links Tool pushes B and not A.
- 2 Link A contains link B. A has no changes, and B has changes.
  - Push B. The Links Tool pushes B and restores A. When parent links are unmodified, they are restored.

If you have a hierarchy of parameterized links, the Links Tool can manipulate only the top level.

### Check and Set Link Status Programmatically

All blocks have a `LinkStatus` parameter and a `StaticLinkStatus` parameter that indicate whether the block is a linked block.

Use `get_param(gcb, 'StaticLinkStatus')` to query the link status without updating out-of-date linked blocks.

Use `get_param` and `set_param` to query and set the `LinkStatus`, which can have the following values.

| Get LinkStatus Value | Description   |
|----------------------|---|
| none                 | Block is not a linked block.  |
| resolved             | Resolved link.  |
| unresolved           | Unresolved link.  |
| implicit             | Block resides in library block and is itself not a link to a library block. For example, suppose that A is a link to a subsystem in a library that contains a Gain block. Further, suppose that you open A and select the Gain block. Then, <code>get_param(gcb, 'LinkStatus')</code> returns <code>implicit</code> . |
| inactive             | Disabled link.  |

| Set LinkStatus Value | Description  |
|----------------------|--|
| none                 | Breaks link. Use <code>none</code> to break a link, e.g., <code>set_param(gcb, 'LinkStatus', 'none')</code>  |
| inactive             | Disables link. Use <code>inactive</code> to disable a link, e.g., <code>set_param(gcb, 'LinkStatus', 'inactive')</code>  |
| restore              | Restores an inactive or disabled link to a library block and discards any changes made to the local copy of the library block. For example, <code>set_param(gcb, 'LinkStatus', 'restore')</code> replaces the selected block with a link to a library block of the same type, discarding any changes in the local copy of the library block.<br><br>This is equivalent to <b>Restore Individual</b> in the Links Tool. |
| propagate            | Pushes any changes made to the disabled link to the library block and re-establishes its link.<br><br>This is equivalent to <b>Push Individual</b> in the Links Tool.  |
| restoreHierarchy     | Restores all disabled links in the hierarchy with their corresponding library blocks. This is equivalent to <b>Restore in hierarchy mode</b> in the Links Tool.  |
| propagateHierarchy   | Pushes all links with changes in the hierarchy to their libraries. This is equivalent to <b>Push in hierarchy mode</b> in the Links Tool. See “Restore Disabled or Parameterized Links” on page 36-12.   |

---

**Note** Using `get_param` to query a block's `LinkStatus` also resolves any out-of-date block links. Use `get_param` to update library links in a model programmatically. Querying the `StaticLinkStatus` property does not resolve any out-of-date links. Query the `StaticLinkStatus` property when the call to `get_param` is in the callback of a child block querying the link status of its parent.

---

If you call `get_param` on a block inside a library link, Simulink resolves the link if necessary. This operation may involve loading part of the library and executing callbacks.

## Break a Link to a Library Block

You can break the link between a linked block and its library block to cause the linked block to become a simple copy of the library block, unlinked to the library block. Changes to the library block no longer affect the block. Breaking links to library blocks may enable you to transport a masked subsystem model as a standalone model, without the libraries (see “Block Masks”).

To break the link between a linked block and its library block, you can use any of the following actions.

- Disable the link, then right-click the block and choose **Library Link > Break Link** .
- At the command line, change the value of the `LinkStatus` parameter to 'none' using this command:

```
set_param(gcb, 'LinkStatus', 'none')
```

- Right-click and drag to copy a block, and you see an offer to break links, unless the parent library has `LockLinksToLibrary` set to `on`. If your copied block will be a locked link, then you do not see the option to break links.

To copy and break links to multiple blocks simultaneously, select multiple blocks and then drag. Any locked links are ignored and not broken.

- When saving the model, you can break links by supplying arguments to the `save_system` command. See `save_system`.

---

**Note** Breaking library links in a model does not guarantee that you can run the model standalone, especially if the model includes blocks from third-party libraries or optional Simulink blocksets. It is possible that a library block invokes functions supplied with

the library and hence can run only if the library is installed on the system running the model. Further, breaking a link can cause a model to fail when you install a new version of the library on a system.

---

For example, suppose a block invokes a function that is supplied with the library. Now suppose that a new version of the library eliminates the function. Running a model with an unlinked copy of the block results in invocation of a now nonexistent function, causing the simulation to fail. To avoid such problems, you should generally avoid breaking links to libraries.

## Fix Unresolved Library Links

If Simulink is unable to find either the library block or the source library on your MATLAB path when it attempts to update the linked block, the link becomes unresolved. Simulink changes the appearance of these blocks.

If you double-click the unresolved block, the parameter dialog box displays an error similar to the following:

```
Failed to find 'source-block-name'  
in library 'source-library-name'  
referenced by  
"linked-block-path".
```

To fix an unresolved link, you must do one of the following:

- Delete the unresolved block and copy the library block back into your model.
- Add the folder that contains the required library to the MATLAB path and select either **Simulation > Update Diagram** or **Diagram > Refresh Blocks**.
- Double-click the unresolved block to open its dialog box (see the **Unresolved Link** block reference page). On the dialog box that appears, correct the path name in the **Source block** field and click **OK**.

# Create Block Libraries

## In this section...

“Create a Library” on page 36-19

“Create a Sublibrary” on page 36-19

“Modify and Lock Libraries” on page 36-20

“Make Backward-Compatible Changes to Libraries” on page 36-21

## Create a Library

You can create your own block library and, optionally, add it to the Simulink Library Browser. The file types you can save the model as are also model file types. However, you cannot simulate in a library, and a library becomes locked (i.e., you cannot make changes to it without unlocking) each time you close it.

1

In the Library Browser, click the New Model button arrow  and select **New Library**. Simulink creates an empty library.

- 2 Drag blocks from models or other libraries into the new library. Make the changes you want to the blocks, such as changing block parameters, adding masks, or adding blocks to subsystems.
- 3 Save the library.

When you create an instance of a library block in a model, you can create a library link on the instance only if the block in the library had a mask. See “Linked Blocks” on page 36-2 for more information.

Once you have created a library, consider adding it to the Library Browser. See “Add Libraries to the Library Browser” on page 36-30 for more information.

## Create a Sublibrary

If your library contains many blocks, consider grouping the blocks into a hierarchy of sublibraries. Creating a sublibrary entails inserting a reference in the Simulink model file of one library to the model file of another library. The referenced file is called a

*sublibrary* of the parent (i.e., referencing) library. The sublibrary is said to be included by reference in the parent library.

To include a library in another library as a sublibrary:

- 1 Open the parent library.
- 2 Add a **Subsystem** block to the parent library.
- 3 Delete the subsystem's default input and output ports.
- 4 Create a mask for the subsystem that displays text or an image that conveys the sublibrary's purpose.
- 5 Set the subsystem's `OpenFcn` parameter to the name of the sublibrary's model file.
- 6 Save the parent library.

## Modify and Lock Libraries

When you open a library, it is automatically locked and you cannot modify its contents. To unlock the library, select **Diagram > Unlock Library**.

When you close the library window, Simulink locks the library.

Locking a library prevents a user from inadvertently modifying a library, for example, by moving a block in the library or adding or deleting a block from the library. If you attempt to modify a locked library, Simulink displays a dialog box that allows you to unlock the library and make the change.

To unlock a block library from the MATLAB command line, use the following command:

```
set_param('library_name', 'Lock', 'off');
```

You must then relock the library from the MATLAB command line to prevent further changes. Use the following command to relock a block library:

```
set_param('library_name', 'Lock', 'on');
```

If you want to control end user editing of linked blocks and prevent unintentional disabling of links, you can lock links to a library. See “Lock Links to Blocks in a Library” on page 36-9.

When you save a library, Simulink checks file permissions and offers to try to make the library writable if necessary.

## Make Backward-Compatible Changes to Libraries

Simulink provides the following features to facilitate making changes to library blocks without invalidating models that use the library blocks.

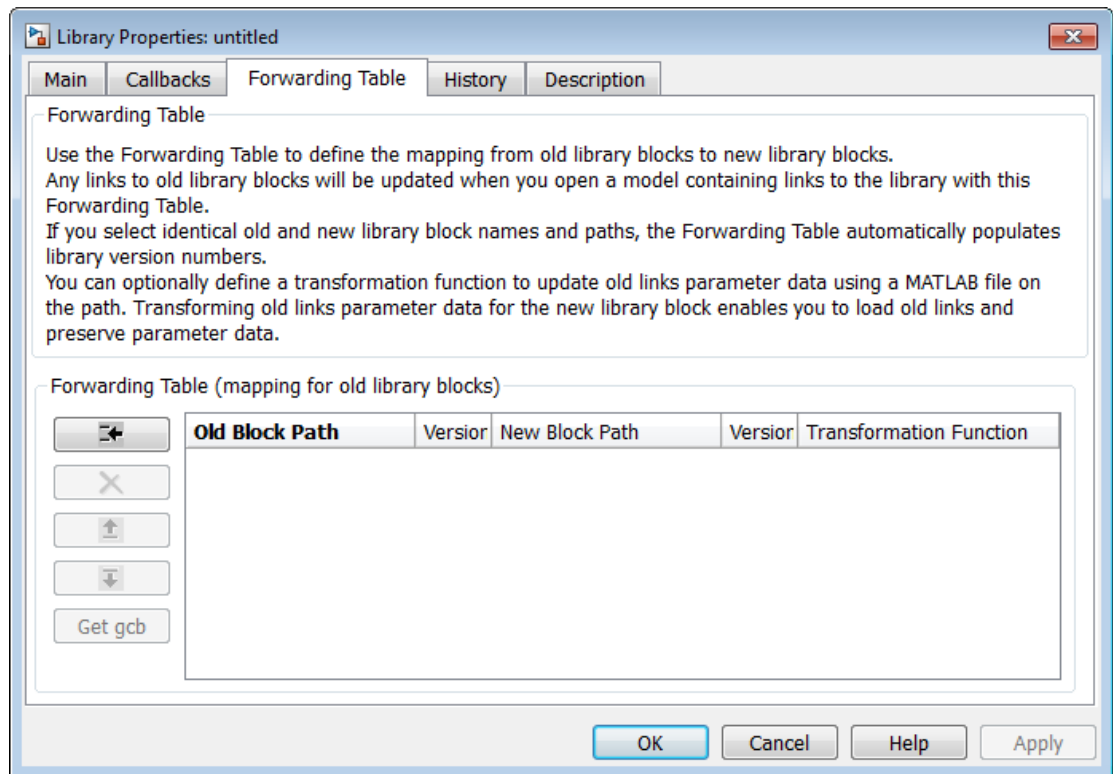

### Forwarding Tables

You can create forwarding tables for libraries to specify how to update links in models to reflect changes in the parameters. Use the Forwarding Table to map old library blocks to new library blocks. For example, if you rename or move a block in a library, you can use a forwarding table to enable Simulink to update models that link to the block.

After you specify the forwarding table entry in a library, any links to old library blocks will be updated when you load a model containing links to old blocks. Library authors can use the forwarding tables to automatically transform old links into updated links without any loss of functionality and data. Use the forwarding table to solve compatibility issues with models containing old links that cannot load in the current version of Simulink. Library authors do not need to run the Upgrade Advisor to upgrade old links, and can reduce maintenance of legacy blocks.

To set up a forwarding table for a library,

- 1 Select **Diagram > Unlock Library**.
- 2 Select **File > Library Properties > Library Properties**. The Library Properties dialog box opens.
- 3 Select the Forwarding Table tab.

- 4 Define the mapping from old library blocks to new library blocks.
  - a Click the Add New Entry button. A new row appears in the table.
  - b Enter values in **Old Block Path** and **New Block Path** columns.

Click **GCB** to get the path of the currently selected block.

If you select identical old and new library block names and paths, the Forwarding Table automatically populates library version numbers in the **Version** columns. The initial value of the `LibraryVersion` property is the `ModelVersion` of the library at the time the link was created. The value updates with increments in the model version of the library.

- c (Optional ) You can define a transformation function to update old link parameter data using a MATLAB file on the path. Specify the function in the

**Transformation Function** column. Transforming old link parameter data for the new library block enables you to load old links and preserve parameter data.

If you do not want to specify a transformation function, do not edit the field. When you save the library, the column will display **No Transformation**.

- 5 Click **OK** to apply changes and close the dialog box.

After specifying the forwarding table mapping, when you open a model containing links to the library, links to old library blocks will be updated.

To view an example of a forwarding table:

- 1 Enter

```
open_system('simulink')
```

- 2 Select **File > Library Properties > Library Properties**
- 3 Click the Forwarding Table tab.
- 4 View how the forwarding table specifies the mapping of old blocks to new blocks. You cannot make changes because the library is locked. Do not edit the forwarding table for your Simulink library.

Forwarding Table (mapping for old library blocks)

|  | Old Block Path   | Versio | New Block Path                              | Versio | Transformation Funct |
|--|--|--------|---|--------|----------------------|
|  | simulink/Discrete/Weight Moving Average                    | n/a    | simulink_need_slupdate/Moving Average       | n/a    | No Transformation    |
|  | simulink/Lookup Tables/Interpolation (n-D) using PreLookup | n/a    | simulink_need_slupdate/using PreLookup      | n/a    | No Transformation    |
|  | simulink/Lookup Tables/PreLookup Index Search              | n/a    | simulink_need_slupdate/Index Search         | n/a    | No Transformation    |
|  | simulink/Linear/Dot Prod                                   | n/a    | simulink/Math Operations/Dot Product        | n/a    | No Transformation    |
|  | simulink/Nonlinear/Look-Table (2-D)                        | n/a    | simulink_need_slupdate/ Table (2-D)         | n/a    | No Transformation    |
|  | simulink/Nonlinear/Alget                                   | n/a    | simulink/Math Operations/Algebraic Co       | n/a    | No Transformation    |
|  | simulink/Linear/Slider Gain                                | n/a    | simulink/Math Operations/Slider Gain        | n/a    | No Transformation    |
|  | simulink/Nonlinear/Coulc Viscous Friction                  | n/a    | simulink/Discontinuities/c Viscous Friction | n/a    | No Transformation    |
|  | simulink/Nonlinear/Manu                                    | n/a    | simulink/Signal Routing/Manual Switch       | n/a    | No Transformation    |
|  | simulink/Connections/Mc                                    | n/a    | simulink/Model-Wide Utilities/Model Info    | n/a    | No Transformation    |
|  | simulink/Linear/Matrix                                     | n/a    | simulink3/Math/Matrix                       | n/a    | No Transformation    |

5 Click **OK** to close the dialog

The following example shows a forwarding table that defines:

- A block with the same name moving to a different library (Constant A)
- A block changing name in the same library (Block X to Block Y)
- A block changing name, moving library, and applying a transformation function (Gain A to Gain B)
- A block with three version updates (Block A) using a transformation function. When you select identical old and new library block names and paths, the Forwarding Table automatically populates version numbers in the **Version** columns. If this is the first entry with identical names, version starts at 0, and the new version number is set to the `ModelVersion` of the library. For subsequent entries, the first version

is set to the previous entry's new version, and the new version is set to the current `ModelVersion` of the library.

Forwarding Table (mapping for old library blocks)

|   | Old Block Path  | Versio | New Block Path  | Versio | Transformation Function |
|---|-----------------|--------|-----------------|--------|-------------------------|
|  | LibA/Constant A | n/a    | LibB/Constant A | n/a    | No Transformation       |
|  | LibA/Block X    | n/a    | LibA/Block Y    | n/a    | No Transformation       |
|  | LibA/Gain A     | n/a    | LibB/Gain B     | n/a    | TransformationFcn1      |
|  | LibA/Block A    | 0.000  | LibA/Block A    | 0.900  | TransformationFcn2      |
|  | LibA/Block A    | 0.900  | LibA/Block A    | 1.100  | TransformationFcn2      |
| Get Gcb   | LibA/Block A    | 1.100  | LibA/Block A    | 1.150  | TransformationFcn2      |

At the command line you can create a simple forwarding table specifying the old locations and new locations of blocks that have moved within the library or to another library. You associate a forwarding table with a library by setting its `ForwardingTable` parameter to a cell array of two-element cell arrays, each of which specifies the old and new path of a block that has moved. For example, the following command creates a forwarding table and assigns it to a library named `Lib1`.

```
set_param('Lib1', 'ForwardingTable', {{'Lib1/A', 'Lib2/A'}
{'Lib1/B', 'Lib1/C'}});
```

The forwarding table specifies that block A has moved from `Lib1` to `Lib2`, and that block B is now named C. Suppose that you open a model that contains links to `Lib1/A` and `Lib1/B`. Simulink updates the link to `Lib1/A` to refer to `Lib2/A` and the link to `Lib1/B` to refer to `Lib1/C`. The changes become permanent when you subsequently save the model.

### Writing Transformation Functions

You can use transformation functions to add or remove parameters and define parameter values. Transforming old link parameter data for the new library block enables you to load old links and preserve parameter data that differs from library values. Define your transformation function using a MATLAB file on the path, then specify the function in the Forwarding Table **Transformation Function** column.

The transformation function in your MATLAB file must be like the following:

```
function outData = TransformationFcn(inData)
where inData is a structure with fields ForwardingTableEntry and InstanceData,
and ForwardingTableEntry is a structure.
```

This general transformation function can have many local functions defined in it. The function calls the appropriate local functions based on old block names and versions. Use this to combine many local functions into a single transformation function, to avoid having many transformation functions on the MATLAB path.

`InstanceData` and `NewInstanceData` are structures with fields `Name` and `Value`. Instance data means the names and values of parameters that are different from the library values.

`outData` is a structure with fields `NewInstanceData` and `NewBlockPath`.

The following example code shows how to define a transformation function that adds a parameter with value `uint8` to update a Compare To Constant block:

```
function [outData] = TransformationCompConstBlk(inData)
% Example transformation Function for old 'Compare To Const' block.
%
% If instanceData of old 'Compare To Const' block does not have
% the 'OutDataTypeStr' parameter,
% add the parameter with value 'uint8'.
%%

outData.NewBlockPath = '';
outData.NewInstanceData = [];

instanceData = inData.InstanceData;
% Get the field type 'Name' from instanceData
[ParameterNames{1:length(instanceData)}] = instanceData.Name;

if (~ismember('OutDataTypeStr',ParameterNames))
    % OutDataTypeStr parameter is not present in old link. Add it and set value uint8
    instanceData(end+1).Name = 'OutDataTypeStr';
    instanceData(end).Value = 'uint8';
end

outData.NewInstanceData = instanceData;
```

### Creating Aliases for Mask Parameters

Simulink lets you create aliases, i.e., alternate names, for a mask's parameters. A model can then refer to the mask parameter by either its name or its alias. This allows you to change the name of a mask parameter in a library block without having to recreate links to the block in existing models (see “Using Mask Parameter Aliases to Create Backward-Compatible Parameter Name Changes” on page 36-27).

To create aliases for a masked block's mask parameters, use the `set_param` command to set the block's `MaskVarAliases` parameter to a cell array that specifies the names of the aliases in the same order as the mask names appear in the block's `MaskVariables` parameter.

### Using Mask Parameter Aliases to Create Backward-Compatible Parameter Name Changes

The following example illustrates the use of mask parameter aliases to create backward-compatible parameter name changes.

- 1 Create a new library. **File > New > Library**
- 2 Open the model `masking_example` described in “How Mask Parameters Work” on page 34-4. Drag the masked block named `m $\times$ +b` into your new library and rename it to `Line`.
- 3 Right-click the block and select **Properties**. In the Block Properties dialog, select the **Block Annotation** tab. In the **Enter text and tokens for annotation** box, enter

```
m = %<m>
b = %<b>
```

The block displays the value of its `m` and `b` parameters,

- 4 Right-click the block, and select **Mask > Mask Parameters**. In the Block Parameter dialog, enter `0.5` for the **Slope** and `0` for the **Intercept**.
- 5 Save the new library with the filename `mylibrary`.
- 6 Create a new Simulink model. **File > New > Model**.
- 7 From the `mylibrary` window, drag an instance of the `Line` block to your new model. Rename the instance `LineA`.
- 8 Right-click the block and select **Mask > Mask Parameters**. In the Block Parameters dialog, change the value **Slope** to `-0.5` and change the value **Intercept** to `30`. Select **Display > Library Links > User Defined**.
- 9 Add a Scope and Clock block to your model and connect them to your block. Save the new model with the filename `mymodel`.
- 10 From the **Simulation** menu, select **Model Configuration Parameters**. From the **Type** list, select `Fixed-step`. From the **Solver** list, select `discrete (no continuous states)`. In the **Fixed-step size** box, enter `0.1`. Simulate model.

Note that the model simulates without error.

- 11 Save and close `mymodel`.
- 12 Open `mylibrary`.
- 13 Edit mask. Right-click block, select **Edit mask**. In the Mask Editor dialog,

- Select the **Parameters** tab. In the **Dialog parameters** section and **Variable** column, change the variable `m` to `slope` and `b` to `intercept`.
  - Select the **Icon & Ports** tab. In the **Icon Drawing** comments box, change the variable `m` to `slope` and `b` to `intercept`.
- 14** Right-click the **Line** block, select **Properties**. In the **Block Properties** dialog, .
- Select the **Block Annotation** tab . In the **Enter text and tokens of annotation** box, rename the `m` parameter to `slope` and the `b` parameter to `intercept`.
- 15** Click **OK** and save `mylibrary`.
- 16** Reopen `mymodel`.

Note that `LineA` icon has reverted to the appearance of its library master (i.e., `mylib/Line`) and that its annotation displays question marks for the values of `m` and `b`. These changes reflect the parameter name changes in the library block. In particular, Simulink cannot find any parameters named `m` and `b` in the library block and hence does not know what to do with the instance values for those parameters. As a result, `LineA` reverts to the default values for the `slope` and `intercept` parameters, thereby inadvertently changing the behavior of the model. The following steps show how to use parameter aliases to avoid this inadvertent change of behavior.

- 17** Close `mymodel`.
- 18** In the **Library: mylibrary** window, select the `Line` block.
- 19** Execute the following command at the MATLAB command line.

```
set_param(gcf, 'MaskVarAliases', {'m', 'b'})
```

This specifies that `m` and `b` are aliases for the `Line` block `slope` and `intercept` parameters.

- 20** Reopen `mymodel`.

Note that `LineA` appearance, not the annotation, now reflects the value of the `slope` parameter under its original name, i.e., `m`. This is because when Simulink opened the model, it found that `m` is an alias for `slope` and assigned the value of `m` stored in the model file to the `LineA slope` parameter.

- 21** Change `LineA` block annotation property to reflect `LineA` parameter name changes, replace

```
m = %<m>  
b = %<b>
```

with

```
m = %<slope>  
b = %<intercept>
```

LineA now appears with  $m = -0.5$  and  $b = 30$ .

Note that LineA annotation shows that, thanks to parameter aliasing, Simulink has correctly applied the parameter values stored for LineA in the `mymodels` file to the block renamed parameters.

## Add Libraries to the Library Browser

This example shows how to create a block library and add it to the Simulink Library Browser.

- 1 In the Simulink Editor, select **File > New > Library**.
- 2 Drag blocks from models or other libraries into the new library. You can modify the blocks in the library by changing block parameters, adding masks, or grouping blocks in subsystems.
- 3 Save the library in a folder that is on the MATLAB path. To add a folder to the MATLAB path, right-click the folder in MATLAB, and select **Add to Path > Selected Folders and Subfolders**.
- 4 Open the library and unlock it by selecting **Diagram > Unlock Library**.
- 5 At the MATLAB command prompt, enable the model property `EnableLBRepository` so that Simulink can add the library to the Library Browser.

```
set_param(gcs, 'EnableLBRepository', 'on');
```

- 6 In MATLAB, open the folder containing the library. Right-click and select **New File > Script**.
- 7 Save the file as `slblocks.m`.
- 8 Open `slblocks.m`, and add this function into it.

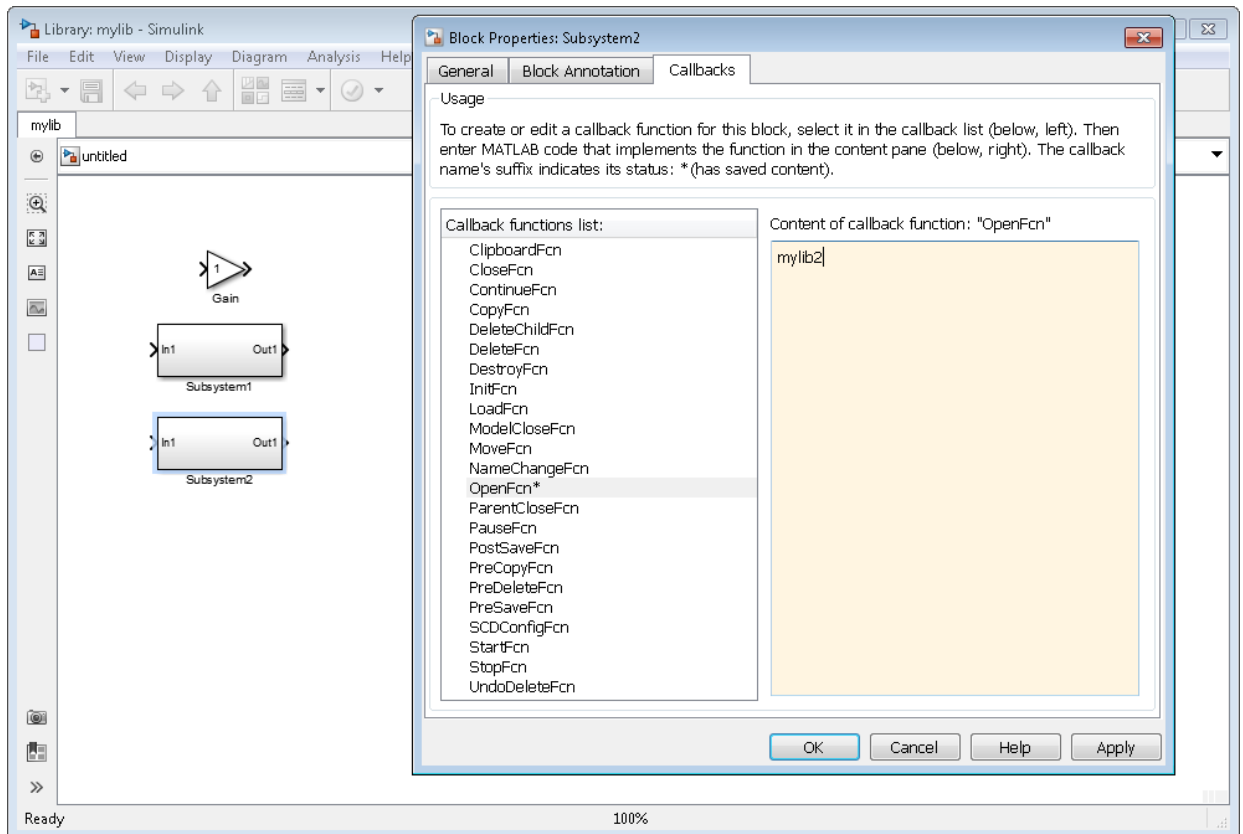

```
function blkStruct = slblocks
% This function specifies that the library should appear
% in the Library Browser
% and be cached in the browser repository

Browser.Library = 'mylib';
% 'mylib' is the name of the library

Browser.Name = 'My Library';
% 'My Library' is the library name that appears in the Library Browser

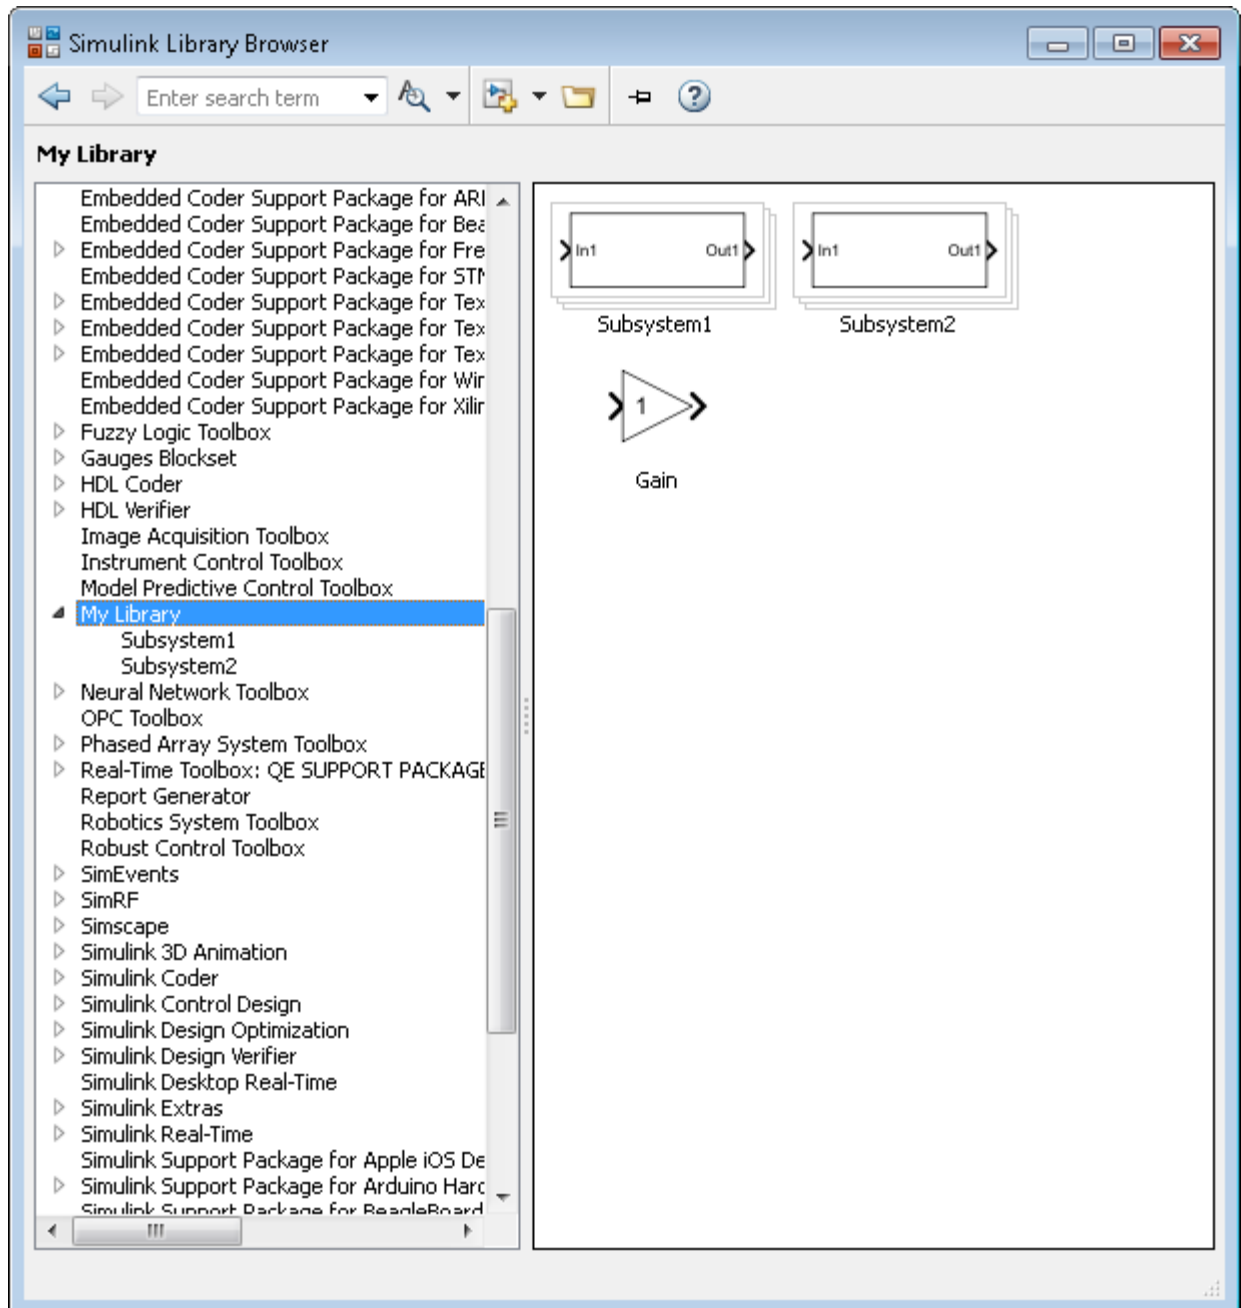

blkStruct.Browser = Browser;
```

The figure shows the example library `mylib.slx`, which contains a Gain block, the Subsystem1 block, which uses default properties, and the Subsystem2 block. The `OpenFcn` property of the Subsystem2 block points to the library `mylib2`.

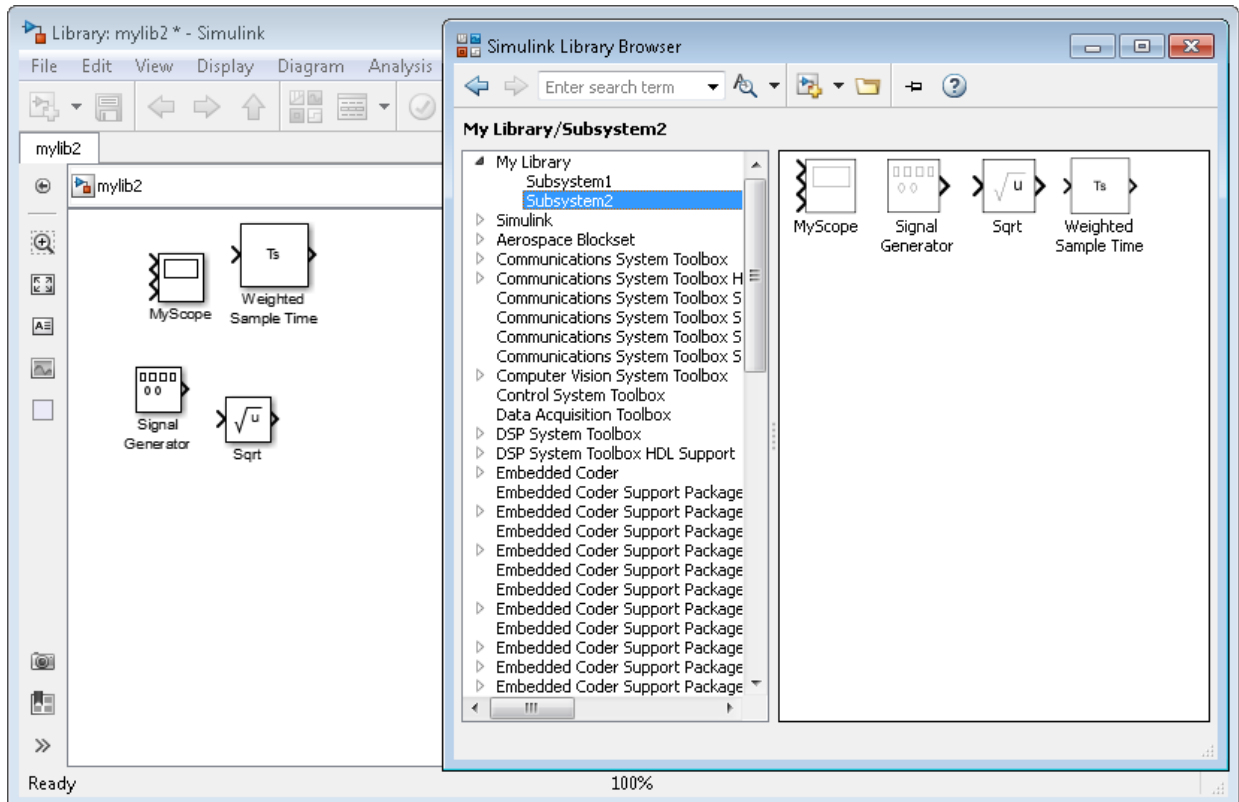

- 9 Save the file `s1blocks.m`. Open the Library Browser and refresh to view the new library. To refresh, right-click in the library list and select **Refresh Library Browser**.

The figure shows the example library `mylib` with the library browser name My Library.

Because of the callback you created, clicking Subsystem2 shows the contents of the mylib2 library in the right pane.

You can specify the location of your library relative to the other libraries by adding your own `sl_customization.m` file to the MATLAB path and setting the sort priority of your library. For example, to see your library at the top of the list, you can set the sort priority to `-2`. By default, the sort priority of the Simulink library is `-1`. All the other libraries have a sort priority of `0`.

This example shows sample content of the customization file that moves the new library to the top of the list of libraries.

```
function sl_customization(cm)
% Change the order of libraries in the Simulink Library Browser.
```

```
cm.LibraryBrowserCustomizer.applyOrder({'My Library',-2});  
end
```

For more information about registering user interface customizations, see “Registering Customizations” on page 63-25.

## Integrate MATLAB Algorithm in Model

Here is an example of a Simulink model that contains a MATLAB Function block:

The MATLAB Function block contains the following algorithm:

```
function [mean,stdev] = stats(vals)
% #codegen

% calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals,len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
plot(vals, '-+');

function mean = avg(array,size)
mean = sum(array)/size;
```

You will build this model in “Create Model That Uses MATLAB Function Block” on page 37-9.

### Defining Local Variables for Code Generation

If you intend to generate code from the MATLAB algorithm in a MATLAB Function block, you must explicitly assign the class, size, and complexity of local variables before using them in operations or returning them as outputs (see “Data Definition for Code Generation” on page 45-2. In the example function `stats`, the local variable `len` is defined before being used to calculate mean and standard deviation:

```
len = length(vals);
```

Generally, once you assign properties to a variable, you cannot redefine its class, size, or complexity elsewhere in the function body, but there are exceptions (see “Reassignment of Variable Properties” on page 44-9).

## What Is a MATLAB Function Block?

The MATLAB Function block allows you to add MATLAB functions to Simulink models for deployment to desktop and embedded processors. This capability is useful for coding algorithms that are better stated in the textual language of MATLAB than in the graphical language of Simulink. From the MATLAB Function block, you can generate readable, efficient, and compact C/C++ code for deployment to desktop and embedded applications.

### Calling Functions in MATLAB Function Blocks

MATLAB Function blocks can call any of the following types of functions:

- **Local functions**

Local functions are defined in the body of the MATLAB Function block. In the preceding example, `avg` is a local function. See “Call Local Functions” on page 53-9.

- **MATLAB toolbox functions that support code generation**

From MATLAB Function blocks, you can call toolbox functions that support code generation. When you build your model with Simulink Coder, these functions generate C code that is optimized to meet the memory and performance requirements of desktop and embedded environments. In the preceding example, `length`, `sqrt`, and `sum` are examples of toolbox functions that support code generation. See “Call Supported Toolbox Functions” on page 53-10. For a complete list of supported functions, see “Functions and Objects Supported for C and C++ Code Generation — Alphabetical List” on page 42-2.

- **MATLAB functions that do not support code generation**

From MATLAB Function blocks, you can also call *extrinsic* functions. These are functions on the MATLAB path that the compiler dispatches to MATLAB software for execution because the target language does not support them. These functions do not generate code; they execute only in the MATLAB workspace during simulation of the model. The Simulink Coder software attempts to compile all MATLAB functions unless you explicitly declare them to be extrinsic by using `coder.extrinsic`. See “Declaring MATLAB Functions as Extrinsic Functions” on page 53-12.

The code generation software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. For MEX code generation, it automatically calls out

to MATLAB for these functions. For standalone code generation, it does not generate code for these visualization functions. This capability removes the requirement to declare these functions extrinsic using the `coder.extrinsic` function.

See “Resolution of Function Calls for Code Generation” on page 53-2.

- **Functions from Simulink Function blocks and Stateflow blocks**

From MATLAB Function blocks, you can also call functions defined in a Simulink Function block. You can call Stateflow functions with **Export Chart Level Functions (Make Global)** and **Allow exported functions to be called by Simulink** checked in the chart Properties dialog box.

## Why Use MATLAB Function Blocks?

MATLAB Function blocks provide the following capabilities:

- **Allow you to build MATLAB functions into embeddable applications** — MATLAB Function blocks support a subset of MATLAB toolbox functions that generate efficient C/C++ code. For information see “Functions and Objects Supported for C and C++ Code Generation — Alphabetical List” on page 42-2.. With this support, you can use Simulink Coder to generate embeddable C code from MATLAB Function blocks that implement a variety of sophisticated mathematical applications. In this way, you can build executables that harness MATLAB functionality, but run outside the MATLAB environment.
- **Inherit properties from Simulink input and output signals** — By default, both the size and type of input and output signals to a MATLAB Function block are inherited from Simulink signals. You can also choose to specify the size and type of inputs and outputs explicitly in the Ports and Data Manager (see “Ports and Data Manager” on page 37-33) or in the Model Explorer (see “Model Explorer Overview” on page 11-2).

## Use Nondirect Feedthrough in a MATLAB Function Block

By default, MATLAB Function blocks have direct feedthrough enabled. To disable, in the Ports and Data Manager, clear the **Allow direct feedthrough** check box. Nondirect feedthrough enables semantics to ensure that outputs rely only on current state.

To use nondirect feedthrough, do not program outputs to rely on inputs or updated persistent variables. For example, do not use the following code in a nondirect feedthrough block:

```
counter = counter + 1; % update state
output = counter;     % compute output based on updated state
```

Instead, use code such as:

```
output = counter;     % compute output based on current state
counter = counter + 1; % update state
```

Also, nondirect feedthrough semantics require function inlining. Do not disable inlining.

Using nondirect feedthrough enables you to use MATLAB Function blocks in a feedback loop and prevent algebraic loops.

## Create Model That Uses MATLAB Function Block

### In this section...

“Adding a MATLAB Function Block to a Model” on page 37-9

“Programming the MATLAB Function Block” on page 37-10

“Building the Function and Checking for Errors” on page 37-11

“Defining Inputs and Outputs” on page 37-13

### Adding a MATLAB Function Block to a Model

- 1 Create a new Simulink model and add a MATLAB Function block to the model from the User-Defined Functions library:

- 2 Add the following Source and Sink blocks to the model:
  - From the Sources library, add a Constant block to the left of the MATLAB Function block and set its value to the vector  $[2 \ 3 \ 4 \ 5]$ .
  - From the Sinks library, add two Display blocks to the right of the MATLAB Function block.

- 3 In the Simulink Editor, select **File > Save As** and save the model as `call_stats_block1`.

## Programming the MATLAB Function Block

The following exercise demonstrates programming the block to calculate the mean and standard deviation for a vector of values:

- 1 Open the `call_stats_block1` model that you saved at the end of “Adding a MATLAB Function Block to a Model” on page 37-9. Double-click the MATLAB Function block `fcn` to open it for editing.

A default function signature appears, along with the `%#codegen` directive. In the MATLAB Function block, the `%#codegen` directive is included to emphasize that the block’s MATLAB algorithm is always intended for code generation. The `%#codegen` directive, or the absence of it, does not change the error checking behavior in the context of the MATLAB Function block. For more information see “Compilation Directive `%#codegen`” on page 53-8.

- 2 Edit the function header line:

```
function [mean,stdev] = stats(vals)
%#codegen
```

The function `stats` calculates a statistical mean and standard deviation for the values in the vector `vals`. The function header declares `vals` as an argument to the `stats` function, with `mean` and `stdev` as return values.

- 3 Save the model as `call_stats_block2`.
- 4 Complete the connections to the MATLAB Function block as shown.

- 5 In the MATLAB Function Block Editor, enter a line space after the function header and add the following code:

```
% calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals,len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
plot(vals,'-+');

function mean = avg(array,size)
mean = sum(array)/size;
```

### More about length

The function `length` is an example of a toolbox function that supports code generation. When you simulate this model, C code is generated for this function in the simulation application.

### More about len

The class, size, and complexity of local variable `len` matches the output of the toolbox function `length`, which returns a real scalar of type `double`.

By default, implicitly declared local variables like `len` are temporary. They come into existence only when the function is called and cease to exist when the function is exited. To make implicitly declared variables persist between function calls, see “Define and Initialize Persistent Variables” on page 44-10.

### More about plot

The function `plot` is not supported for code generation. The code generation software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. For MEX code generation, it automatically calls out to MATLAB for these functions. For standalone code generation, it does not generate code for these visualization functions.

- 6 Save the model as `call_stats_block2`.

## Building the Function and Checking for Errors

After programming a MATLAB Function block in a Simulink model, you can build the function and test for errors. This section describes the steps:

- 1 Set up your compiler.
- 2 Build the function.
- 3 Locate and fix errors.

### Setting Up Your Compiler

Building your MATLAB Function block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-supported compilers installed on your system, you can change the default using the `mex -setup` command. See “Change Default Compiler”.

### Supported Compilers for Simulation Builds

To view a list of compilers for building models containing MATLAB Function blocks for simulation:

- 1 Navigate to the Supported and Compatible Compilers Web page.
- 2 Select your platform.
- 3 In the table for Simulink and related products, find the compilers checked in the column titled Simulink for MATLAB Function blocks.

### Supported Compilers for Code Generation

To generate code for models that contain MATLAB Function blocks, you can use any of the C compilers supported by Simulink software for code generation with Simulink Coder. For a list of these compilers:

- 1 Navigate to the Supported and Compatible Compilers Web page.
- 2 Select your platform.
- 3 In the table for Simulink and related products, find the compilers checked in the column titled Simulink Coder.

### How to Generate Code for the MATLAB Function Block

- 1 Open the `call_stats_block2` model that you saved at the end of “Programming the MATLAB Function Block” on page 37-10.
- 2 Double-click its MATLAB Function block `stats` to open it for editing.
- 3 In the MATLAB Function Block Editor, select **Build Model** > **Build** to compile and build the example model.

If no errors occur, the **Simulation Diagnostics** window displays a message indicating success. Otherwise, this window helps you locate errors, as described in “How to Locate and Fix Errors” on page 37-13.

### How to Locate and Fix Errors

If errors occur during the build process, the **Simulation Diagnostics** window lists the errors with links to the offending code.

The following exercise shows how to locate and fix an error in a MATLAB Function block.

- 1 In the `stats` function, change the local function `avg` to a fictitious local function `aug` and then compile again to see the following messages in window:

The **Simulation Diagnostics** window displays each detected error with a red button.

- 2 Click the first error line to display its diagnostic message in the bottom error window.

The message also links to a report about compile-time type information for variables and expressions in your MATLAB functions. This information helps you diagnose error messages and understand type propagation rules. For more information about the report, see “MATLAB Function Reports” on page 37-46.

- 3 In the diagnostic message for the selected error, click the blue link after the function name to display the offending code.

The offending line appears highlighted in the MATLAB Function Block Editor:

- 4 Correct the error by changing `aug` back to `avg` and recompile.

### Defining Inputs and Outputs

In the `stats` function header for the MATLAB Function block you defined in “Programming the MATLAB Function Block” on page 37-10, the function argument `vals` is an input, and `mean` and `stdev` are outputs. By default, function inputs and outputs inherit their data type and size from the signals attached to their ports. In this topic, you examine input and output data for the MATLAB Function block to verify that it inherits the correct type and size.

- 1 Open the `call_stats_block2` model that you saved at the end of “Programming the MATLAB Function Block” on page 37-10. Double-click the MATLAB Function block `stats` to open it for editing.
- 2 In the MATLAB Function Block Editor, select **Edit Data**.

The Ports and Data Manager opens to help you define arguments for MATLAB Function blocks.

The left pane displays the argument `vals` and the return values `mean` and `stdev` that you have already created for the MATLAB Function block. Notice that `vals` is assigned a **Scope** of **Input**, which is short for **Input from Simulink**. `mean` and `stdev` are assigned the **Scope** of **Output**, which is short for **Output to Simulink**.

- 3 In the left pane of the Ports and Data Manager, click anywhere in the row for `vals` to highlight it.

The right pane displays the **Data** properties dialog box for `vals`. By default, the class, size, and complexity of input and output arguments are inherited from the signals attached to each input or output port. Inheritance is specified by setting **Size** to `-1`, **Complexity** to **Inherited**, and **Type** to **Inherit: Same as Simulink**.

The actual inherited values for size and type are set during compilation of the model, and are reported in the **Compiled Type** and **Compiled Size** columns of the left pane.

You can specify the type of an input or output argument by selecting a type in the **Type** field of the **Data** properties dialog box, for example, `double`. You can also specify the size of an input or output argument by entering an expression in the **Size** field. For example, you can enter `[2 3]` in the **Size** field to specify `vals` as a 2-by-3 matrix. See “Type Function Arguments” on page 37-59 and “Size Function Arguments” on page 37-66 for more information on the expressions that you can enter for type and size.

---

**Note:** The default first index for any arrays that you add to a MATLAB Function block function is 1, just as it would be in MATLAB.

---

For more information, see “Ports and Data Manager” on page 37-33.

## Code Generation Readiness Tool

**In this section...**

“Information That the Code Generation Readiness Tool Provides” on page 37-15

“Summary Tab” on page 37-16

“Code Structure Tab” on page 37-17

“See Also” on page 37-20

### Information That the Code Generation Readiness Tool Provides

The code generation readiness tool screens MATLAB code for features and functions that code generation does not support. The tool provides a report that lists the source files that contain unsupported features and functions. The report also indicates the amount of work required to make the MATLAB code suitable for code generation. It is possible that the tool does not detect all code generation issues. Under certain circumstances, it is possible that the tool can report false errors. Therefore, before you generate C code, verify that your code is suitable for code generation by generating a MEX function.

## Summary Tab

The **Summary** tab provides a **Code Generation Readiness Score**, which ranges from 1 to 5. A score of 1 indicates that the tool detects issues that require extensive changes to the MATLAB code to make it suitable for code generation. A score of 5 indicates that the tool does not detect code generation issues; the code is ready to use with minimal or no changes.

On this tab, the tool also displays information about:

- MATLAB syntax issues. These issues are reported in the MATLAB editor. To learn more about the issues and how to fix them, use the Code Analyzer.
- Unsupported MATLAB function calls.
- Unsupported MATLAB language features, such as anonymous function handles and nested functions.
- Unsupported data types.

## Code Structure Tab

If the code that you are checking calls other MATLAB functions, or you are checking multiple entry-point functions, the tool displays the **Code Structure Tab**.

This tab displays information about the relative size of each file and how suitable each file is for code generation.

### **Code Distribution**

The **Code Distribution** pane displays a pie chart that shows the relative sizes of the files and how suitable each file is for code generation. During the planning phase of a project, you can use this information for estimation and scheduling. If the report indicates that multiple files are not suitable for code generation, consider fixing files that require minor changes before addressing files with significant issues.

### **Call Tree**

The **Call Tree** pane displays information about the nesting of function calls. For each called function, the report provides a **Code Generation Readiness** score, which ranges from 1 to 5. A score of 1 indicates that the tool detects issues that require extensive changes to the MATLAB code to make it suitable for code generation. A score of 5 indicates that the tool does not detect code generation issues. The code is ready to use with minimal or no changes. The report also lists the number of lines of code in each file.

### **Show MATLAB Functions**

If you select **Show MATLAB Functions**, the report also lists the MATLAB functions that your function calls. For each of these MATLAB functions, if code generation supports the function, the report sets **Code Generation Readiness** to **Yes**.

## **See Also**

- “Check Code Using the Code Generation Readiness Tool” on page 37-21

# Check Code Using the Code Generation Readiness Tool

## In this section...

“Run Code Generation Readiness Tool at the Command Line” on page 37-21

“Run the Code Generation Readiness Tool From the Current Folder Browser” on page 37-21

## Run Code Generation Readiness Tool at the Command Line

- 1 Navigate to the folder that contains the file that you want to check for code generation readiness.
- 2 At the MATLAB command prompt, enter:

```
coder.screener('filename')
```

The **Code Generation Readiness** tool opens for the file named `filename`, provides a code generation readiness score, and lists issues that must be fixed prior to code generation.

## Run the Code Generation Readiness Tool From the Current Folder Browser

- 1 In the current folder browser, right-click the file that you want to check for code generation readiness.
- 2 From the context menu, select **Check Code Generation Readiness**.

The **Code Generation Readiness** tool opens for the selected file and provides a code generation readiness score and lists issues that must be fixed prior to code generation.

## Debugging a MATLAB Function Block

| In this section...  |
|---|
| “Debugging the Function in Simulation” on page 37-22          |
| “Watching Function Variables During Simulation” on page 37-25 |
| “Checking for Data Range Violations” on page 37-27            |
| “Debugging Tools” on page 37-28                               |

### Debugging the Function in Simulation

In “Create Model That Uses MATLAB Function Block” on page 37-9, you created an example model with a MATLAB Function block that calculates the mean and standard deviation for a set of input values. The software enables debugging for a MATLAB Function when you set a breakpoint.

To debug the MATLAB Function in this model:

- 1 Open the `call_stats_block2` model and double-click the MATLAB Function block `stats` to open the editor.
- 2 In the MATLAB Function Block Editor, click the dash (-) in the left margin of the line:

```
len = length(vals);
```

A red dot appears in the line margin, indicating the breakpoint.

```

1  function [mean, stdev] = stats(vals)
2  %#codegen
3
4  % Calculates a statistical mean and a standard deviation
5  % for the values in vals
6
7  - coder.extrinsic('plot');
8
9  ● len = length(vals);
10 - mean = avg(vals,len);
11 - stdev = sqrt(sum(((vals-avg(vals,len)).^2)/len);
12 - plot(vals,'-+');
13
14  function mean = avg(array,size)
15 - mean = sum(array)/size;

```

- 3 Simulate the model.

Simulation pauses when execution reaches the breakpoint. This is indicated by a green arrow in the margin.

```

1  function [mean, stdev] = stats(vals)
2  %#codegen
3
4  % Calculates a statistical mean and a standard deviation
5  % for the values in vals
6
7  - coder.extrinsic('plot');
8
9  ● → len = length(vals);
10 - mean = avg(vals,len);
11 - stdev = sqrt(sum(((vals-avg(vals,len)).^2)/len);
12 - plot(vals,'-+');
13
14  function mean = avg(array,size)
15 - mean = sum(array)/size;

```

- 4 In the toolbar, click **Step** to advance execution.

The execution arrow advances to the next line of `stats`, which calls the local function `avg`.

- 5 In the toolbar, click **Step In**.

Execution advances to enter the local function `avg`. Once you are in a local function, you can use the **Step** or **Step In** commands to advance execution. If the local function calls another local function, use **Step In** to enter it. If you want to execute the remaining lines of the local function, use **Step Out**.

- 6** Click **Step** to execute the only line in the local function `avg`. When the local function `avg` finishes executing, a green arrow, pointing down, appears under the last line of the function.
- 7** Click **Step** to return to the function `stats`.

Execution advances to the line after the call to the local function `avg`.

- 8** Click **Step** twice to calculate the `stdev` and to execute the `plot` function.

The `plot` function executes in MATLAB:

In the MATLAB Function Block Editor, a green arrow points down under the last line of code, indicating the completion of the function `stats`.

- 9 Click **Continue** to continue execution of the model.

The computed values of `mean` and `stdev` appear in the Display blocks.

- 10 In the MATLAB Function Block Editor, click **Quit Debugging** to stop simulation.

## Watching Function Variables During Simulation

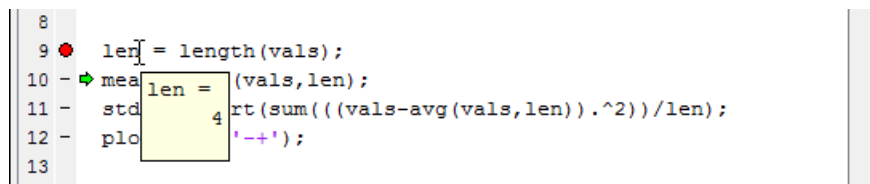

While you simulate a MATLAB Function block, you can use several tools to keep track of variable values in the function.

## Watching with the Interactive Display

To display the value of a variable in the function of a MATLAB Function block during simulation:

- 1 In the MATLAB Function Block Editor, place the mouse cursor over the variable text and observe the pop-up display.

For example, to watch the variable `len` during simulation, place the mouse cursor over the text `len` in the code. The value of `len` appears adjacent to the cursor, as shown:

The screenshot shows a MATLAB Function Block Editor window with a code editor on the left and a vertical toolbar on the right. The code editor contains the following lines:

```

8
9 len = length(vals);
10 mea (vals, len);
11 std rt(sum((vals-avg(vals, len)).^2)/len);
12 plo '-+');
13

```

A mouse cursor is positioned over the variable `len` in line 9. A yellow pop-up display box appears over the cursor, showing the value `len = 4`.

## Watching with the Command Line Debugger

You can report the values for a function variable with the Command Line Debugger utility in the MATLAB window during simulation. When you reach a breakpoint, the Command Line Debugger prompt, `debug>>`, appears. At this prompt, you can see the value of a variable defined for the MATLAB Function block by entering its name:

```
debug>> stdev
```

```
1.1180
```

```
debug>>
```

The Command Line Debugger also provides the following commands during simulation:

| Command                      | Description  |
|------------------------------|--|
| <code>ctrl-c</code>          | Quit debugging and terminate simulation.   |
| <code>dbcont</code>          | Continue execution to next breakpoint.   |
| <code>dbquit</code>          | Quit debugging and terminate simulation.   |
| <code>dbstep [in out]</code> | Advance to next program step after a breakpoint is encountered. Step over or step into/out of a MATLAB local function. |
| <code>help</code>            | Display help for command line debugging.   |

| Command                        | Description  |
|--------------------------------|--|
| <code>print &lt;var&gt;</code> | Display the value of the variable <code>var</code> in the current scope. If <code>var</code> is a vector or matrix, you can also index into <code>var</code> . For example, <code>var(1,2)</code> .  |
| <code>save</code>              | Saves all variables in the current scope to the specified file. Follows the syntax of the MATLAB <code>save</code> command. To retrieve variables to the MATLAB base workspace, use <code>load</code> command after simulation has been ended. |
| <code>&lt;var&gt;</code>       | Equivalent to " <code>print &lt;var&gt;</code> " if variable is in the current scope.  |
| <code>who</code>               | Display the variables in the current scope.  |
| <code>whos</code>              | Display the size and class (type) of all variables in the current scope.   |

You can issue any other MATLAB command at the `debug>>` prompt, but the results are executed in the workspace of the MATLAB Function block. To issue a command in the MATLAB base workspace at the `debug>>` prompt, use the `evalin` command with the first argument `'base'` followed by the second argument command string, for example, `evalin('base','whos')`. To return to the MATLAB base workspace, use the `dbquit` command.

### Watching with MATLAB

You can display the execution result of a MATLAB Function block line by omitting the terminating semicolon. If you do, execution results for the line are echoed to the MATLAB window during simulation.

### Display Size Limits

The MATLAB Function Block Editor does not display the contents of matrices that have more than two dimensions or more than 200 elements. For matrices that exceed these limits, the MATLAB Function Block Editor displays the shape and base type only.

## Checking for Data Range Violations

MATLAB Function blocks check inputs and outputs for data range violations when the input or output values enter or leave the blocks. To enable data range violation checking, set **Simulation range checking** in the **Diagnostics: Data Validity** pane of the Configuration Parameters dialog box to **error**.

### Specifying a Range

To specify a range for input and output data, follow these steps:

- 1 In the Ports and Data Manager, select the input or output of interest.

The data properties dialog box opens.

- 2 In the data properties dialog box, select the General tab and enter a limit range, as described in “Setting General Properties” on page 37-39.

## Debugging Tools

Use the following tools during a MATLAB Function block debugging session:

| Tool Button  | Description   | Shortcut Key        |
|--|---|---------------------|
| <br><b>Build</b>          | <p>Access this tool from the <b>Editor</b> tab by selecting <b>Build Model &gt; Build</b>.</p> <p>Check for errors and build a simulation application (if no errors are found) for the model containing this MATLAB Function block.</p>   | <b>Ctrl+B</b>       |
| <br><b>Update Diagram</b> | <p>Access this tool from the <b>Editor</b> tab by selecting <b>Build Model &gt; Update Diagram</b>.</p> <p>Check for errors based on the latest changes you make to the MATLAB Function block.</p>  | <b>Ctrl+D</b>       |
| <br><b>Update Ports</b> | <p>Access this tool from the <b>Editor</b> tab by selecting <b>Build Model &gt; Update Ports</b>.</p> <p>Updates the ports of the MATLAB Function block with the latest changes made to the function argument and return values without closing the MATLAB Function Block Editor.</p> | <b>Ctrl+Shift+A</b> |
| <br><b>Run Model</b>    | <p>Start simulation of the model containing the MATLAB Function block. If execution is paused at a breakpoint, continues debugging.</p>   | <b>F5</b>           |
| <br><b>Stop Model</b>   | <p>Stop simulation of the model containing the MATLAB Function block. Alternatively, from the <b>Editor</b> tab, select <b>Quit Debugging</b> if execution is paused at a breakpoint.</p>   | <b>Shift+F5</b>     |

| Tool Button  | Description  | Shortcut Key     |
|--|--|------------------|
| <br><b>Set/Clear</b>  | <p>Access this tool by selecting <b>Breakpoints &gt; Set/Clear</b>.</p> <p>Set a new breakpoint or clear an existing breakpoint for the selected line of code in the MATLAB Function block. The presence of the text cursor or highlighted text selects the line. A breakpoint indicator  appears in the on the selected line.</p> <p>Alternatively, click the hyphen character (-) next to the line number. A breakpoint indicator appears in place of the hyphen. Click the breakpoint indicator to clear the breakpoint.</p> | <b>F12</b>       |
| <br><b>Clear All</b>  | <p>Access this tool by selecting <b>Breakpoints &gt; Clear All</b>.</p> <p>Clear all existing breakpoints in the MATLAB Function block code.</p>   | <b>None</b>      |
| <br><b>Step</b>       | <p>Step through the execution of the next line of code in the MATLAB Function block. This tool steps past function calls and does not enter called functions for line-by-line execution. You can use this tool only after execution has stopped at a breakpoint.</p>   | <b>F10</b>       |
| <br><b>Step In</b>  | <p>Step through the execution of the next line of code in the MATLAB Function block. If the line calls a local function, step into the first line of the local function. You can use this tool only after execution has stopped at a breakpoint.</p>   | <b>F11</b>       |
| <br><b>Step Out</b> | <p>Step out of line-by-line execution of the current function or local function. If in a local function, the debugger continues to the line following the call to this local function. You can use this tool only after execution has stopped at a breakpoint.</p>   | <b>Shift+F11</b> |

| <b>Tool Button</b>   | <b>Description</b>  | <b>Shortcut Key</b> |
|--|---|---------------------|
| <br><b>Continue</b>       | Continue debugging after a pause, such as stopping at a breakpoint. You can use this tool only after execution has stopped at a breakpoint. | <b>F5</b>           |
| <br><b>Quit Debugging</b> | Exit debug mode. You can use this tool only after execution has stopped at a breakpoint.  | <b>Shift+F5</b>     |

## MATLAB Function Block Editor

### In this section...

“Customizing the MATLAB Function Block Editor” on page 37-31

“MATLAB Function Block Editor Tools” on page 37-31

“Editing and Debugging MATLAB Function Block Code” on page 37-32

“Ports and Data Manager” on page 37-33

### Customizing the MATLAB Function Block Editor

Use the toolbar icons to customize the appearance of the MATLAB Function Block Editor in the same manner as the MATLAB editor. See “Basic Settings”.

### MATLAB Function Block Editor Tools

Use the following tools to work with the MATLAB Function block:

| Tool Button   | Description  |
|---|--|
| <br><b>Edit Data</b>          | Opens the Ports and Data Manager dialog to add or modify arguments for the current MATLAB Function block (see “Ports and Data Manager” on page 37-33). |
| <br><b>View Report</b>       | Opens the MATLAB Function report for the MATLAB Function block. For more information, see “MATLAB Function Reports” on page 37-46.                     |
| <br><b>Simulation Target</b> | Opens the <b>Simulation Target</b> pane in the <b>Configuration Parameters</b> dialog to include custom code.  |
| <br><b>Go To Diagram</b>     | Displays the MATLAB function in its native diagram without closing the editor.   |

See “Defining Inputs and Outputs” on page 37-13 for an example of defining an input argument for a MATLAB Function block.

## Editing and Debugging MATLAB Function Block Code

### Manual Indenting

To indent a block of code manually:

- 1 Highlight the text that you would like to indent.
- 2 Select one of the Indent tools on the Editor tab:

| Tool  | Description                                |
|---|--|
|  | Applies smart indenting to selected text.  |
|  | Move selected text right one indent level. |
|  | Move selected text left one indent level.  |

### Opening a Selection

You can open a local function, function, file, or variable from within a file in the MATLAB Function Block Editor.

To open a selection:

- 1 Position the cursor in the name of the item you would like to open.
- 2 Right-click and select **Open <selection>** from the context menu.

The Editor chooses the appropriate tool to open the selection. For more information, refer to “Manage Files and Folders”.

---

**Note:** If you open a MATLAB Function block input or output parameter, the Ports and Data Manager opens with the selected parameter highlighted. You can use the Ports and Data Manager to modify parameter attributes. For more information, refer to “Ports and Data Manager” on page 37-33.

---

### Evaluating a Selection

You can use the **Evaluate a Selection** menu option to report the value for a MATLAB function variable or equation in the MATLAB window during simulation.

To evaluate a selection:

- 1 Highlight the variable or equation that you would like to evaluate.
- 2 Hold the mouse over the highlighted text and then right-click and select **Evaluate Selection** from the context menu. (Alternatively, select **Evaluate Selection** from the **Text** menu).

When you reach a breakpoint, the MATLAB command Window displays the value of the variable or equation at the Command Line Debugger prompt.

```
debug>> stdev
```

```
1.1180
```

```
debug>>
```

---

**Note:** You cannot evaluate a selection while MATLAB is busy, for example, running a MATLAB file.

---

### Setting Data Scope

To set the data scope of a MATLAB Function block input parameter:

- 1 Highlight the input parameter that you would like to modify.
- 2 Hold the mouse over the highlighted text and then right-click and select **Data Scope for <selection>** from the context menu.
- 3 Select:
  - **Input** if your input data is provided by the Simulink model via an input port to the MATLAB Function block.
  - **Parameter** if your input is a variable of the same name in the MATLAB or model workspace or in the workspace of a masked subsystem containing this block.

For more information, refer to “Setting General Properties” on page 37-39.

### Ports and Data Manager

The Ports and Data Manager provides a convenient method for defining objects and modifying their properties in a MATLAB Function block that is open and has focus.

The Ports and Data Manager provides the same data definition capabilities for individual MATLAB Function blocks as the Model Explorer provides across the model hierarchy (see “Model Explorer Overview” on page 11-2).

### Ports and Data Manager Dialog Box

The Ports and Data Manager dialog box allows you to add and define data arguments, input triggers, and function call outputs for MATLAB Function blocks. Using this dialog, you can also modify properties for the MATLAB Function block and the objects it contains.

The dialog box consists of two panes:

- The **Contents** (left) pane lists the objects that have been defined for the MATLAB Function block.
- The **Dialog** (right) pane displays fields for modifying the properties of the selected object.

Properties vary according to the scope and type of the object. Therefore, the Ports and Data Manager properties dialogs are dynamic, displaying only the property fields that are relevant for the object you add or modify.

When you first open the dialog box, it displays the properties of the MATLAB Function block.

### Opening the Ports and Data Manager

To open the Ports and Data Manager from the MATLAB Function Block Editor, select **Edit Data** on the Editor tab. The Ports and Data Manager appears for the MATLAB Function block that is open and has focus.

### Ports and Data Manager Tools

The following tools are specific to the Ports and Data Manager:

| Tool Button  | Description   |
|--|---|
| <br><b>Go to Block Editor</b> | Displays the MATLAB function in the MATLAB Function Block Editor. |

| Tool Button   | Description   |
|---|---|
| <br><b>Show Block Dialog</b> | Displays the default MATLAB function properties (see “MATLAB Function Block Properties” on page 37-35). Use this button to return to the settings used by the block after viewing data associated with the block arguments. |

## MATLAB Function Block Properties

This section describes each property of a MATLAB Function block.

### Name

Name of the MATLAB Function block, following the same naming conventions as for Simulink blocks (see “Manipulate Block Names” on page 31-15).

### Update method

Method for activating the MATLAB Function block. You can choose from the following update methods:

| Update Method       | Description   |
|---------------------|---|
| Inherited (default) | Input from the Simulink model activates the MATLAB Function block. If you define an input trigger, the MATLAB Function block executes in response to a Simulink signal or function-call event on the trigger port. If you do not define an input trigger, the MATLAB Function block implicitly inherits triggers from the model. These implicit events are the sample times (discrete or continuous) of the signals that provide inputs to the chart.<br>If you define data inputs, the MATLAB Function block samples at the rate of the fastest data input. If you do not define data inputs, the MATLAB Function block samples as defined by its parent subsystem's execution behavior. |
| Discrete            | The MATLAB Function block is sampled at the rate you specify as the block's <b>Sample Time</b> property. An implicit event is generated at regular time intervals corresponding to the specified rate. The sample time is in the same units as the Simulink simulation time. Note that other blocks in the model can have different sample times.   |
| Continuous          | The Simulink software wakes up (samples) the MATLAB Function block at each step in the simulation, as well as at intermediate time points   |

| Update Method | Description  |
|---------------|--|
|               | that can be requested by the solver. This method is consistent with the continuous method. |

### Saturate on integer overflow

Option that determines how the MATLAB Function block handles overflow conditions during integer operations:

| Setting           | Action When Overflow Occurs   |
|-------------------|---|
| Enabled (default) | Saturates an integer by setting it to the maximum positive or negative value allowed by the word size. Matches MATLAB behavior.       |
| Disabled          | In simulation mode, generates a run-time error. For Simulink Coder code generation, the behavior depends on your C language compiler. |

---

**Note:** The **Saturate on integer overflow** option is relevant only for integer arithmetic. It has no effect on fixed-point or double-precision arithmetic.

---

When you enable **Saturate on integer overflow**, MATLAB adds additional checks during simulation to detect integer overflow or underflow. Therefore, it is more efficient to disable this option if you are sure that integer overflow and underflow will not occur in your MATLAB Function block code.

Note that the code generated by Simulink Coder does *not* check for integer overflow or underflow and, therefore, may produce unpredictable results when **Saturate on integer overflow** is disabled. In this situation, it is recommended that you simulate first to test for overflow and underflow before generating code.

### Lock Editor

Option for locking the MATLAB Function Block Editor. When enabled, this option prevents users from making changes to the MATLAB Function block.

### Treat these inherited Simulink signal types as fi objects

Setting that determines whether to treat inherited fixed-point and integer signals as Fixed-Point Designer `fi` objects (“Ways to Construct `fi` Objects”).

- When you select **Fixed-point**, the MATLAB Function block treats all fixed-point inputs as Fixed-Point Designer `fi` objects.
- When you select **Fixed-point & Integer**, the MATLAB Function block treats all fixed-point and integer inputs as Fixed-Point Designer `fi` objects.

### **MATLAB Function block `fimath`**

Setting that defines `fimath` properties for the MATLAB Function block. The block associates the `fimath` properties you specify with the following objects:

- All fixed-point and integer input signals to the MATLAB Function block that you choose to treat as `fi` objects.
- All `fi` and `fimath` objects constructed in the MATLAB Function block.

You can select one of the following options for the **MATLAB Function block `fimath`**.

| <b>Setting</b>        | <b>Description</b>  |
|-----------------------|---|
| <b>Same as MATLAB</b> | When you select this option, the block uses the same <code>fimath</code> properties as the current default <code>fimath</code> . The edit box appears dimmed and displays the current global <code>fimath</code> in read-only form.   |
| <b>Specify other</b>  | When you select this option, you can specify your own <code>fimath</code> object in the edit box. You can do so in one of two ways: <ul style="list-style-type: none"> <li>• Constructing the <code>fimath</code> object inside the edit box.</li> <li>• Constructing the <code>fimath</code> object in the MATLAB or model workspace and then entering its variable name in the edit box. If you use this option and plan to share your model with others, make sure you define the variable in the model workspace. See “Sharing Models with Fixed-Point MATLAB Function Blocks”.</li> </ul> <p>For more information on <code>fimath</code> objects, see “<code>fimath</code> Object Construction”.</p> |

### **Description**

Description of the MATLAB Function block.

**Document link**

Link to documentation for the MATLAB Function block. To document a MATLAB Function block, set the **Document link** property to a Web URL address or MATLAB expression that displays documentation in a suitable format (for example, an HTML file or text in the MATLAB Command Window). The MATLAB Function block evaluates the expression when you click the blue **Document link** text.

**Adding Data to a MATLAB Function Block**

You can define data arguments for MATLAB Function blocks using the following methods:

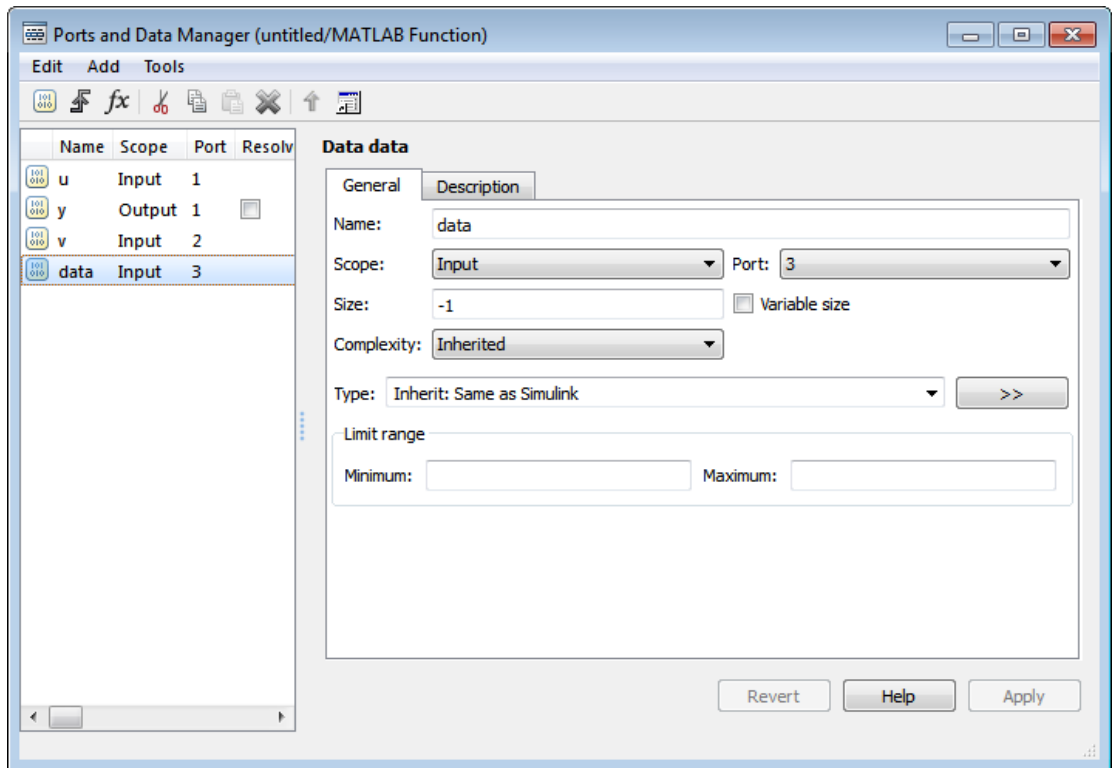

| Method   | For Defining   | Reference  |
|--|--|--|
| Define data directly in the MATLAB Function block code | Input and output data  | See “Defining Inputs and Outputs” on page 37-13.                 |
| Use the Ports and Data Manager                         | Input, output, and parameter data in the MATLAB Function block that is open and has focus        | See “Defining Data in the Ports and Data Manager” on page 37-38. |
| Use the Model Explorer                                 | Input, output, and parameter data in MATLAB Function blocks at all levels of the model hierarchy | See “Model Explorer Overview” on page 11-2                       |

**Defining Data in the Ports and Data Manager**

To add a data argument and modify its properties, follow these steps:

- 1 In the Ports and Data Manager, select **Add > Data**

The Ports and Data Manager adds a default definition of the data to the MATLAB Function block.

- 2 Modify data properties.
- 3 Return to the MATLAB Function block properties at any time by selecting **Tools > Block Dialog**.

### Setting General Properties

You can set the following properties in the General tab:

| Property     | Description   |
|--------------|---|
| <b>Name</b>  | Name of the data argument, following the same naming conventions used in MATLAB.  |
| <b>Scope</b> | Where data resides in memory, relative to its parent. Scope determines the range of functionality of the data argument. You can set scope to one of the following values: |

| Property   | Description   |
|--|---|
|  | <ul style="list-style-type: none"> <li>• <b>Parameter</b>— Specifies that the source for this data is a variable of the same name in the MATLAB or model workspace or in the workspace of a masked subsystem containing this block. If a variable of the same name exists in more than one of the workspaces visible to the block, the variable closest to the block in the workspace hierarchy is used (see “Model Workspaces” on page 4-84).</li> <li>• <b>Input</b>— Data provided by the model via an input port to the MATLAB Function block.</li> <li>• <b>Output</b>— Data provided by the MATLAB Function block via an output port to the model.</li> <li>• <b>Data Store Memory</b>— Data provided by a Data Store Memory block in the model.</li> </ul> <p>For more information, see “Defining Inputs and Outputs” on page 37-13 and “Add Parameter Arguments” on page 37-68.</p> |
| <b>Port</b>  | Index of the port associated with the data argument. This property applies only to input and output data.   |
| <b>Tunable</b>                                     | Indicates whether the parameter used as the source of this data item is tunable (see “Tunable Parameters” on page 3-8). This property applies only to parameter data. Clear this option if the parameter must be a constant expression, such as for MATLAB toolbox functions supported for code generation (see “Functions and Objects Supported for C and C++ Code Generation — Alphabetical List” on page 42-2).  |
| <b>Data must resolve to Simulink signal object</b> | Specifies that the data argument must resolve to a Simulink signal object. This property applies only to output data. See “Symbol Resolution” on page 4-95 for more information.  |
| <b>Size</b>  | Size of the data argument. Size can be a scalar value or a MATLAB vector of values. Size defaults to -1, which means that it is inherited, as described in “Inheriting Argument Sizes from Simulink” on page 37-66. This property does not apply to Data Store Memory data. For more details, see “Size Function Arguments” on page 37-66.  |
| <b>Variable Size</b>                               | Indicates whether the size of this data item is variable. This property does not apply to Data Store Memory data.   |

| Property           | Description  |
|--------------------|--|
| <b>Complexity</b>  | <p>Indicates real or complex data arguments. You can set complexity to one of the following values:</p> <ul style="list-style-type: none"> <li>• <b>Off</b>— Data argument is a real number</li> <li>• <b>On</b>— Data argument is a complex number</li> <li>• <b>Inherited</b>— Data argument inherits complexity based on its scope. Input and output data inherit complexity from the Simulink signals connected to them; parameter data inherits complexity from the parameter to which it is bound.</li> </ul>  |
| <b>Type</b>        | <p>Type of data object. You can specify the data type by:</p> <ul style="list-style-type: none"> <li>• Selecting a built-in type from the <b>Type</b> drop down list.</li> <li>• Entering an expression in the <b>Type</b> field that evaluates to a data type (see “About Data Types in Simulink” on page 55-2).</li> <li>• Using the Data Type Assistant to specify a data <b>Mode</b>, then specifying the data type based on that mode.</li> </ul> <hr/> <p><b>Note:</b> To display the Data Type Assistant, click the Show data type assistant button:</p> <div data-bbox="428 1008 583 1060" style="text-align: center;">  </div> <hr/> <p>For more information, see “Specifying Argument Types” on page 37-59.</p> |
| <b>Limit range</b> | <p>Specify the range of acceptable values for input or output data. The MATLAB Function block uses this range to validate the input or output as it enters or leaves the block. You can enter an expression or parameter that evaluates to a numeric scalar value.</p> <ul style="list-style-type: none"> <li>• <b>Minimum</b> — The smallest value allowed for the data item during simulation. The default value is <code>-inf</code>.</li> <li>• <b>Maximum</b> — The largest value allowed for the data item during simulation. The default value is <code>inf</code>.</li> </ul>  |

### Setting Description Properties

You can set the following properties on the Description tab:

| Property                                  | Description   |
|---|---|
| <b>Save final value to base workspace</b> | The MATLAB Function block assigns the value of the data argument to a variable of the same name in the MATLAB base workspace at the end of simulation.  |
| <b>Description</b>                        | Description of the data argument.   |
| <b>Document link</b>                      | Link to documentation for the data argument. You can enter a Web URL address or a MATLAB command that displays documentation in a suitable format, such as an HTML file or text in the MATLAB Command Window. When you click the blue text, <b>Document link</b> , displayed at the bottom of the <b>Data</b> properties dialog, the MATLAB Function block evaluates the link and displays the documentation. |

### Adding Input Triggers to a MATLAB Function Block

An input trigger is an event on the input port that causes the MATLAB Function block to execute. See “Create a Triggered Subsystem” on page 9-38.

You can define the following types of triggers in MATLAB Function blocks:

- Rising
- Falling
- Either (rising or falling)
- Function call

For a description of each trigger type, see “Setting Input Trigger Properties” on page 37-43.

Use the Ports and Data Manager to add input triggers to a MATLAB Function block that is open and has focus. To add an input trigger and modify its properties, follow these steps:

- 1 In the Ports and Data Manager, select **Add > Input Trigger**.

The Ports and Data Manager adds a default definition of the new input trigger to the MATLAB Function block and displays the Trigger properties dialog.

- 2 Modify trigger properties.

- 3** Return to the MATLAB Function block properties at any time by selecting **Tools > Block Dialog**.

### The Trigger Properties Dialog

The Trigger properties dialog in the Ports and Data Manager allows you to set and modify the properties of input triggers in MATLAB Function blocks.

To open the Trigger properties dialog, select an input trigger in the Contents pane.

### Setting Input Trigger Properties

You can set the following properties in the Trigger properties dialog:

| Property             | Description   |
|----------------------|---|
| <b>Name</b>          | Name of the input trigger, following the same naming conventions used in MATLAB.  |
| <b>Port</b>          | Index of the port associated with the input trigger. The default value is 1.  |
| <b>Trigger</b>       | Type of event that triggers execution of the MATLAB Function block. You can select one of the following types of triggers: <ul style="list-style-type: none"> <li>• <b>Rising</b> (default) — Triggers execution of the MATLAB Function block when the control signal rises from a negative or zero value to a positive value (or zero if the initial value is negative).</li> <li>• <b>Falling</b>— Triggers execution of the MATLAB Function block when the control signal falls from a positive or zero value to a negative value (or zero if the initial value is positive).</li> <li>• <b>Either</b>— Triggers execution of the MATLAB Function block when the control signal is either rising or falling.</li> <li>• <b>Function call</b>— Triggers execution of the MATLAB Function block from a block that outputs function-call events, or from an S-function</li> </ul> |
| <b>Description</b>   | Description of the input trigger.   |
| <b>Document link</b> | Link to documentation for the input trigger. You can enter a Web URL address or a MATLAB command that displays documentation in a suitable format, such as an HTML file or text in the MATLAB Command Window. When you click the blue text that reads <b>Document link</b> displayed at the bottom of the <b>Trigger</b> properties   |

| Property | Description  |
|----------|--|
|          | dialog, the MATLAB Function block evaluates the link and displays the documentation. |

### Adding Function Call Outputs to a MATLAB Function Block

A function call output is an event on the output port of a MATLAB Function block that causes a Function-Call Subsystem block in the Simulink model to execute. Another block can invoke a function-call subsystem directly during a simulation. See “Create a Function-Call Subsystem” on page 9-50.

Use the Ports and Data Manager to add and modify function call outputs to a MATLAB Function block that is open and has focus. To add a function call output and modify its properties, follow these steps:

- 1 In the Ports and Data Manager, select **Add > Function Call Output**.

The Ports and Data Manager adds a default definition of the new function call output to the MATLAB Function block and displays the Function Call properties dialog.

- 2 Modify function call output properties.
- 3 Return to the MATLAB Function block properties at any time by selecting **Tools > Block Dialog**.

### Considerations when Supplying Output to the Function-Call Subsystem

If a MATLAB Function block triggers a function-call subsystem, and supplies an output signal to the same function-call subsystem, the signal to the function-call subsystem can effectively be delayed by one time step compared to the function call. At the moment of the function call, the function-call subsystem sees the previous MATLAB Function block output value even if the output data has been updated within the block MATLAB code.

### The Function Call Properties Dialog

The Function Call properties dialog in the Ports and Data Manager allows you to edit the properties of function call outputs in MATLAB Function blocks.

To open the Function Call properties dialog, select a function call output in the Contents pane.

### Setting Function Call Output Properties

You can set the following properties in the Function Call properties dialog:

| <b>Property</b>      | <b>Description</b>   |
|----------------------|--|
| <b>Name</b>          | Name of the function call output, following the same naming conventions used in MATLAB.  |
| <b>Port</b>          | Index of the port associated with the function call output. Function call output ports are numbered sequentially after input and output ports.   |
| <b>Description</b>   | Description of the function call output.   |
| <b>Document link</b> | Link to documentation for the function call output. You can enter a Web URL address or a MATLAB command that displays documentation in a suitable format, such as an HTML file or text in the MATLAB Command Window. When you click <b>Document link</b> displayed at the bottom of the <b>Function Call</b> properties dialog, the MATLAB Function block evaluates the link and displays the documentation. |

“Keyboard Shortcuts for the MATLAB Function Report” on page 37-56

“Report Limitations” on page 37-57

### About MATLAB Function Reports

When you build a Simulink model that contains MATLAB Function blocks, Simulink generates a report in HTML format for each MATLAB Function block in your model. You can use the report to debug your MATLAB functions and verify that they are suitable for code generation. The report provides links to your MATLAB functions and compile-time type information for the variables and expressions in these functions. If your model fails to build, this information simplifies finding sources of error messages and aids understanding of type propagation rules.

---

**Note:** If you have a Stateflow license, there is one report for each Stateflow chart, regardless of the number of MATLAB functions it contains.

---

---

**Note:** If you have identical MATLAB Function blocks in your model, for example, one in a library and one in the model, a single report is generated for the identical blocks.

---

### Opening MATLAB Function Reports

Use one of the following methods:

- In the MATLAB Function Block Editor, select **View Report**.
- In the **Simulation Diagnostics** window, select the **report** link if compilation errors occur.

## Description of MATLAB Function Reports

When you build the MATLAB function, the code generation software generates an HTML report. The report provides the following information, as applicable:

- MATLAB code information, including a list of all functions and their compilation status
- Call stack information, providing information on the nesting of function calls
- Summary of compilation results, including type of target and number of warnings or errors
- List of all error and warning messages
- List of all variables in your MATLAB function

## Viewing Your MATLAB Function Code

To view your MATLAB function code, click the **MATLAB code** tab. The report displays the MATLAB code for the function highlighted in the list on this tab.

The **MATLAB code** tab provides:

- A list of the MATLAB functions that have been compiled. The report displays icons next to each function name to indicate whether compilation was successful:
  -  Errors in function.
  -  Warnings in function.
  -  Successful compilation, no errors or warnings.
- A filter control that you can use to sort your functions by:
  - Size
  - Complexity
  - Class

### Viewing Local Functions

The report annotates the local function with the name of the parent function in the list of functions on the **MATLAB code** tab.

For example, if the MATLAB function `fcn1` contains the local function `subfcn` and `fcn2` contains the local function `subfcn2`, the report displays:

```
fcn1 > subfcn1  
fcn2 > subfcn2
```

### Viewing Specializations

If your MATLAB function calls the same function with different types of inputs, the report numbers each of these **specializations** in the list of functions on the **MATLAB code** tab.

For example, if the function `fcn` calls the function `subfcn` with different types of inputs:

```
function y = fcn(u) %#codegen  
% Specializations  
y = y + subfcn(single(u));  
y = y + subfcn(double(u));  
The report numbers the specializations in the list of functions.
```

```
fcn > subfcn > 1  
fcn > subfcn > 2
```

### Viewing Call Stack Information

The report provides call stack information:

- On the **Call stack** tab.
- In the list of **Callers**.

If a function is called from more than one function, this list provides details of each call site. Otherwise, the list is disabled.

#### Viewing Call Stack Information on the Call Stack Tab

To view call stack information, click the **Call stack** tab. The call stack lists the functions in the order that the top-level function calls them. It also lists the local functions that each function calls.

### Viewing Function Call Sites in the Callers List

If a function is called from more than one function, this list provides details of each call site. To navigate between call sites, select a call site from the **Callers** list. If the function is not called more than once, this list is disabled.

### Viewing the Compilation Summary Information

To view a summary of the compilation results, including type of target and number of errors or warnings, click the **Summary** tab.

### Viewing Error and Warning Messages

The report provides information about errors and warnings. If errors occur during simulation of a Simulink model, simulation stops. If warnings occur, but no errors, simulation of the model continues.

The report provides information about warnings and errors by listing all errors and warnings in chronological order in the **All Messages** tab.

### Viewing Errors and Warnings in the All Messages Tab

If errors or warnings occurred during compilation, click the **All Messages** tab to view a complete list of these messages. The report lists the messages in the order that the compiler detects them. It is best practice to address the first message in the list, because often subsequent errors and warnings are related to the first message.

To locate the offending line of code for an error or warning in the list, click the message in the list. The report highlights errors in the list and MATLAB code in red and warnings in orange. Click the blue line number next to the offending line of code in the MATLAB code pane to go to the error in the source file.

---

**Note:** You can fix errors only in the source file.

---

Function: stats      Callers: Select a function call site: 

```

1 function [mean, stdev] = stats(vals)
2 %#codegen
3
4 % Calculates a statistical mean and a standard deviation
5 % for the values in vals
6
7 coder.extrinsic('plot');
8
9 len = length(vals);
10 mean = avg(vals, len);
11 stdev = sqrt(sum(((vals-avg(vals, len)).^2)/len);
12 plot(vals, '-+');
13

```

| Summary |   | All Messages (2) | Variables |                                       |
|---------|---|------------------|-----------|---------------------------------------|
| Order   | Type  | Function         | Line      | Description                           |
| 1       |  | stats            | 10        | Undefined function or variable 'avg'. |
| 2       |  | stats            | 11        | Undefined function or variable 'avg'. |

### Viewing Error and Warning Information in Your MATLAB Code

If errors or warnings occurred during compilation, the report underlines them in your MATLAB code. The report underlines errors in red and warnings in orange. To learn more about a particular error or warning, place your pointer over the underlined text.

### Viewing Variables in Your MATLAB Code

The report provides compile-time type information for the variables and expressions in your MATLAB code, including name, type, size, complexity, and class. It also provides type information for fixed-point data types, including word length and fraction length. You can use this type information to find the sources of error messages and to understand type propagation rules.

You can view information about the variables in your MATLAB code:

- On the **Variables** tab, view the list.

- In your MATLAB code, place your cursor over the variable name.

In the MATLAB code, an orange variable name indicates a compile-time constant argument to a specialized function. The information for a constant argument includes the value. This information helps you to see when code generation created function specializations for different constant argument values.

### Viewing Variables in the Variables Tab

To view a list of the variables in your MATLAB function, click the **Variables** tab. The report displays a complete list of variables in the order that they appear in the function that you selected on the **MATLAB code** tab. Clicking a variable in the list highlights instances of that variable, and scrolls the MATLAB code pane so that you can view the first instance.

As applicable, the report provides the following information about each variable:

- Order
- Name
- Type
- Size
- Complexity
- Class
- DataTypeMode (DT mode) — for fixed-point data types only. For more information, see “Data Type and Scaling Properties”.
- Signed — sign information for built-in data types, signedness information for fixed-point data types.
- Word length (WL) — for fixed-point data types only.
- Fraction length (FL) — for fixed-point data types only.

---

**Note:** For more information on viewing fixed-point data types, see “Use Fixed-Point Code Generation Reports”.

---

The report displays only a column if at least one variable in the code has information in that column. For example, if the code does not contain fixed-point data types, the report does not display the DT mode, WL or FL columns.

### Sorting Variables in the Variables Tab

By default, the report lists the variables in the order that they appear in the selected function.

You can sort the variables by clicking the column headings on the **Variables** tab. To sort the variables by multiple columns, hold down the **Shift** key when clicking the column headings.

To restore the list to the original order, click the **Order** column heading.

### Viewing Structures on the Variables Tab

You can expand structures listed on the **Variables** tab to display the field properties.

| Summary | All Messages (0) | Variables |       |         |        |  |
|---------|------------------|-----------|-------|---------|--------|--|
| Order   | Variable         | Type      | Size  | Complex | Class  |  |
| ☐ 1     | s                | Output    | 1 x 1 | -       | struct |  |
| 1.1     | <i>s.a</i>       | Field     | 1 x 1 | No      | double |  |
| 1.2     | <i>s.b</i>       | Field     | 1 x 1 | No      | double |  |
| 2       | a                | Input     | 1 x 1 | No      | double |  |
| 3       | b                | Input     | 1 x 1 | No      | double |  |

If you sort the variables by type, size, complexity, or class, a structure and its fields might not appear sequentially in the list. To restore the list to the original order, click the **Order** column heading.

### Viewing Information About Variable-Size Arrays in the Variables Tab

For variable-size arrays, the **Size** field includes information on the computed maximum size of the array. The size of each array dimension that varies is prefixed with a colon **:**.

In the following report, variable *A* is variable-size. Its maximum computed size is 1×100.

| Summary |          | All Messages (0) | Variables |         |        |  |
|---------|----------|------------------|-----------|---------|--------|--|
| Order   | Variable | Type             | Size      | Complex | Class  |  |
| 1       | B        | Output           | 1 x :100  | No      | double |  |
| 2       | A        | Input            | 1 x :100  | No      | double |  |
| 3       | tol      | Input            | 1 x 1     | No      | double |  |
| 4       | k        | Local            | 1 x 1     | No      | double |  |
| 5       | i        | Local            | 1 x 1     | No      | double |  |

If the code generation software cannot compute the maximum size of a variable-size array, the report displays the size as `?:`.

| Summary |   | All Messages (1)  | Variables |   |  |
|---------|---|-------------------|-----------|---|--|
| Order   | Type  | Function          | Line      | Description   |  |
| 1       |  | emldemo_uniquetol | 10        | Computed maximum size is not bounded.<br>Static memory allocation requires all sizes to be bounded.<br>The computed size is [1 x :?].<br>This error may be reported due to a limitation of the underlying analysis. |  |

If you declare a variable-size array, and then subsequently fix the dimensions of this array in the code, the report appends `*` to the size of the variable. In the generated C code, this variable appears as a variable-size array, but the size of its dimensions do not change during execution.

| Summary |          | All Messages (0) | Variables | Target Build Log |        |  |
|---------|----------|------------------|-----------|------------------|--------|--|
| Order   | Variable | Type             | Size      | Complex          | Class  |  |
| 1       | y        | Output           | 1 x 10 *  | No               | double |  |

For more information on how to use the size information for variable-size arrays, see “Variable-Size Data Definition for Code Generation”.

### Viewing Renamed Variables in the Variables Tab

If your MATLAB function reuses a variable with a different size, type, or complexity, the code generation software attempts to create separate, uniquely named variables in the generated code. For more information, see “Reuse the Same Variable with Different

Properties”. The report numbers the renamed variables in the list on the **Variables** tab. When you place your cursor over a renamed variable, the report highlights only the instances of this variable that share the same data type, size, and complexity.

For example, suppose your code uses the variable `t` in a for-loop to hold a scalar double, and reuses it outside the for-loop to hold a 5x5 matrix. The report displays two variables, `t>1` and `t>2`, in the list on the **Variables** tab.

```

6  if all(all(u))
7      % First time t is used to hold a scalar double value
8      t = mean(mean(u)) / numel(u);
9      u = u - t;
10 end

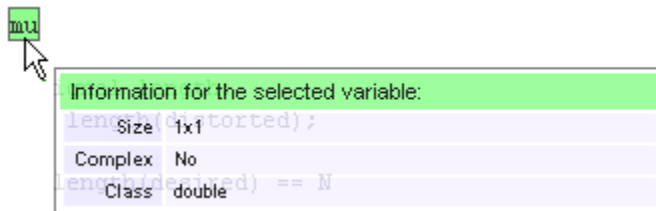

```

| Summary | All Messages (0) | Variables |       |         |        |
|---------|------------------|-----------|-------|---------|--------|
| Order   | Variable         | Type      | Size  | Complex | Class  |
| 1       | u                | Input     | 5 x 5 | No      | double |
| 2       | t > 1            | Local     | 5 x 5 | No      | double |
| 3       | t > 2            | Local     | 1 x 1 | No      | double |

### Viewing Information About Variables and Expressions in Your MATLAB Function Code

To view information about a particular variable or expression in your MATLAB function code, on the MATLAB code pane, place your cursor over the variable name or expression. The report highlights variables and expressions in different colors:

**Green, when the variable has data type information at this location in the code**

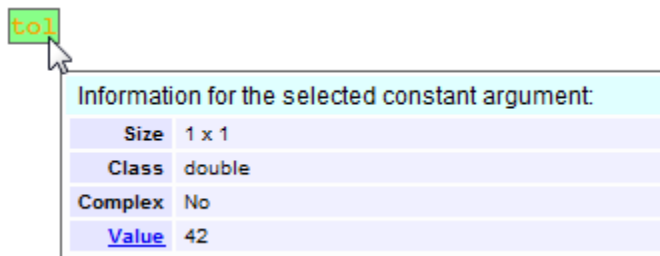

For variable-size arrays, the **Size** field includes information on the computed maximum size of the array. The size of each array dimension that varies is prefixed with a colon `:`. Here the array `A` is variable-size with a maximum computed size of `1 x 100`.

**Green with orange text, when a constant argument has data type and value information**

When the variable is a compile-time constant argument to a specialized function:

- The variable name is orange.
- The information for the variable includes the value.

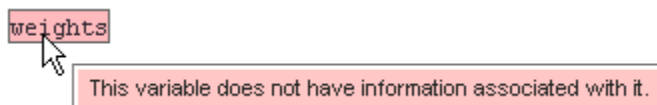

If you export the value as a variable to the base workspace, you can use the Workspace browser to view detailed information about the variable.

To export the value to the base workspace:

- 1 Click the **Value** link.
- 2 In the Export Constant Value dialog box, specify the **Variable name**.
- 3 Click **OK**.

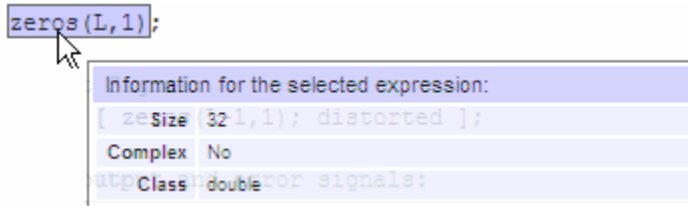

The variable and its value appear in the Workspace browser.

**Pink, when the variable has no data type information**

### Purple, information about expressions

You can also view information about expressions in your MATLAB code. On the MATLAB code pane, place your cursor over an expression. The report highlights expressions in purple and provides more detailed information.

### Red, when there is error information for an expression

If the code generation software cannot compute the maximum size of a variable-size array, the report underlines the variable name and provides error information.

## Keyboard Shortcuts for the MATLAB Function Report

You can use the following keyboard shortcuts to navigate between the different panes in the MATLAB Function report. Once you have selected a pane, use the Tab key to advance through data in that pane.

| To select:       | Use:   |
|------------------|--------|
| MATLAB Code Tab  | Ctrl+m |
| Call Stack Tab   | Ctrl+k |
| MATLAB Code Pane | Ctrl+w |
| Summary Tab      | Ctrl+s |

| To select:       | Use:   |
|------------------|--------|
| All Messages Tab | Ctrl+a |
| Variables Tab    | Ctrl+v |

## Report Limitations

The report displays information about the variables and expressions in your MATLAB code with the following limitations:

### varargin and varargout

The report does not support `varargin` and `varargout` arrays.

### Loop Unrolling

The report does not display full information for unrolled loops. It displays data types of one arbitrary iteration.

### Dead Code

The report does not display information about dead code.

### Structures

The report does not provide complete information about structures.

- The report does not provide information about all structure fields in the `struct()` constructor.
- If a structure has a nonscalar field, and an expression accesses an element of this field, the report does not provide information for the field.

### Column Headings on the Variables Tab

If you scroll through the list of variables, the report does not display the column headings on the **Variables** tab.

### Multiline Matrices

On the **MATLAB code** pane, the report does not support selection of multiline matrices. It supports only selection of individual lines at a time. For example, if you place your cursor over the following matrix, you cannot select the entire matrix.

```
out1 = [1 2 3;  
        4 5 6];
```

The report does support selection of single line matrices.

```
out1 = [1 2 3; 4 5 6];
```

# Type Function Arguments

## In this section...

“About Function Arguments” on page 37-59

“Specifying Argument Types” on page 37-59

“Inheriting Argument Data Types” on page 37-61

“Built-In Data Types for Arguments” on page 37-62

“Specifying Argument Types with Expressions” on page 37-62

“Specifying Fixed-Point Designer Data Properties” on page 37-63

## About Function Arguments

You create function arguments for a MATLAB Function block by entering them in its function header in the MATLAB Function Block Editor. When you define arguments, the Simulink software creates corresponding ports on the MATLAB Function block that you can attach to signals. You can select a *data type mode* for each argument that you define for a MATLAB Function block. Each data type mode presents its own set of options for selecting a *data type*.

By default, the data type mode for MATLAB Function block function arguments is **Inherited**. This means that the function argument inherits its data type from the incoming or outgoing signal. To override the default type, you first choose a data type mode and then select a data type based on the mode.

## Specifying Argument Types

To specify the type of a MATLAB Function block function argument:

- 1 From the MATLAB Function Block Editor, select **Edit Data** to open the Ports and Data Manager.
- 2 In the left pane, select the argument of interest.
- 3 In the **Data** properties dialog box (right pane), click the Show data type assistant button  to display the Data Type Assistant. Then, choose an option from the **Mode** drop-down menu.

The **Data** properties dialog box changes dynamically to display additional fields for specifying the data type associated with the mode.

- 4 Based on the mode you select, specify a desired data type:

| Mode              | What to Specify  |
|-------------------|--|
| Inherit (default) | <p>You cannot specify a value. The data type is inherited from previously-defined data, based on the scope you selected for the MATLAB Function block function argument:</p> <ul style="list-style-type: none"> <li>• If scope is <b>Input</b>, data type is inherited from the input signal on the designated port.</li> <li>• If scope is <b>Output</b>, data type is inherited from the output signal on the designated port.</li> <li>• If scope is <b>Parameter</b>, data type is inherited from the associated parameter, which can be defined in the Simulink masked subsystem or the MATLAB workspace.</li> </ul> <p>See “Inheriting Argument Data Types” on page 37-61.</p> |
| Built in          | <p>Select from the drop-down list of supported data types, as described in “Built-In Data Types for Arguments” on page 37-62.</p>  |
| Fixed point       | <p>Specify the fixed-point data properties as described in “Specifying Fixed-Point Designer Data Properties” on page 37-63.</p>  |
| Expression        | <p>Enter an expression that evaluates to a data type, as described in “Specifying Argument Types with Expressions” on page 37-62.</p>  |
| Bus Object        | <p>In the <b>Bus object</b> field, enter the name of a <code>Simulink.Bus</code> object to define the properties of a MATLAB structure. You must define the bus object in the base workspace. See “How Structure Inputs and Outputs Interface with Bus Signals” on page 37-74.</p> <hr/> <p><b>Note:</b> You can click the <b>Edit</b> button to create or modify <code>Simulink.Bus</code> objects using the Simulink Bus Editor (see “Attach Bus Signals to MATLAB Function Blocks” on page 37-72).</p>  |
| Enumerated        | <p>In the Enumerated field, enter the name of a <code>Simulink.IntEnumType</code> object that you define in the base workspace. See “Enumerated Types Supported in</p>   |

| Mode | What to Specify   |
|------|---|
|      | MATLAB Function Blocks” on page 37-97 and “Define Enumerated Data Types for MATLAB Function Blocks” on page 37-100. |

## Inheriting Argument Data Types

MATLAB Function block function arguments can inherit their data types, including fixed point types, from the signals to which they are connected. , and set data type mode using one of these methods:

- 1 Select the argument of interest in the Ports and Data Manager
- 2 In the **Data** properties dialog, select **Inherit: Same as Simulink** from the **Type** drop-down menu.

See “Built-In Data Types for Arguments” on page 37-62 for a list of supported data types.

---

**Note** An argument can also inherit its complexity (whether its value is a real or complex number) from the signal that is connected to it. To inherit complexity, set the **Complexity** field on the **Data** properties dialog to **Inherited**.

---

After you build the model, the **Compiled Type** column of the Ports and Data Manager gives the actual type inherited from Simulink in the compiled simulation application.

The inherited type of output data is inferred from diagram actions that store values in the specified output. In the preceding example, the variables `mean` and `stdev` are computed from operations with double operands, which yield results of type `double`. If the expected type matches the inferred type, inheritance is successful. In all other cases, a mismatch occurs during build time.

---

**Note** Library MATLAB Function blocks can have inherited data types, sizes, and complexities like ordinary MATLAB Function blocks. However, all instances of the library block in a given model must have inputs with the same properties.

---

## Built-In Data Types for Arguments

When you select **Built-in** for **Data type mode**, the **Data** properties dialog displays a **Data type** field that provides a drop-down list of supported data types. You can also choose a data type from the **Data Type** column in the Ports and Data Manager. The supported data types are:

| Data Type | Description                            |
|-----------|--|
| double    | 64-bit double-precision floating point |
| single    | 32-bit single-precision floating point |
| int32     | 32-bit signed integer                  |
| int16     | 16-bit signed integer                  |
| int8      | 8-bit signed integer                   |
| uint32    | 32-bit unsigned integer                |
| uint16    | 16-bit unsigned integer                |
| uint8     | 8-bit unsigned integer                 |
| boolean   | Boolean (1 = true; 0 = false)          |

## Specifying Argument Types with Expressions

You can specify the types of MATLAB Function block function arguments as expressions in the Ports and Data Manager.

- 1 Select `<data type expression>` from the **Type** drop-down menu of the Data properties dialog.
- 2 In the **Type** field, replace “`<data type expression>`” with an expression that evaluates to a data type. The following expressions are allowed:
  - Alias type from the MATLAB workspace, as described in “Creating a Data Type Alias”.
  - `fixdt` function to create a `Simulink.NumericType` object describing a fixed-point or floating-point data type
  - `type` operator, to base the type on previously defined data

## Specifying Fixed-Point Designer Data Properties

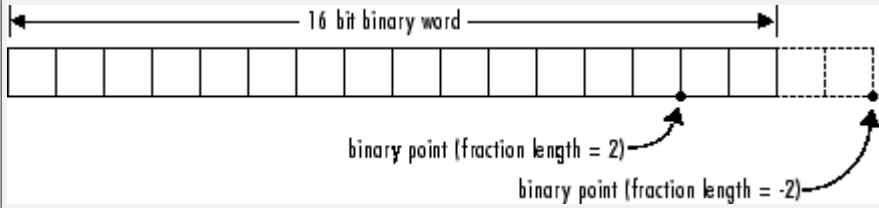

MATLAB Function blocks can represent signals and parameter values as fixed-point numbers. To simulate models that use fixed-point data in MATLAB Function blocks, you must install the Fixed-Point Designer product on your system.

You can set the following fixed-point properties:

**Signedness.** Select whether you want the fixed-point data to be **Signed** or **Unsigned**. Signed data can represent positive and negative quantities. Unsigned data represents positive values only. The default is **Signed**.

**Word length.** Specify the size (in bits) of the word that will hold the quantized integer. Large word sizes represent large quantities with greater precision than small word sizes. Word length can be any integer between 0 and 128 bits. The default is 16.

**Scaling.** Specify the method for scaling your fixed point data to avoid overflow conditions and minimize quantization errors. You can select the following scaling modes:

| Scaling Mode              | Description   |
|---------------------------|---|
| Binary point<br>(default) | <p>If you select this mode, the Data Type Assistant displays the <b>Fraction Length</b> field, specifying the binary point location.</p> <p>Binary points can be positive or negative integers. A positive integer moves the binary point left of the rightmost bit by that amount. For example, an entry of 2 sets the binary point in front of the second bit from the right. A negative integer moves the binary point further right of the rightmost bit by that amount, as in this example:</p>  <p>The diagram shows a 16-bit binary word represented as a horizontal row of 16 boxes. Above the boxes, a double-headed arrow spans the entire width and is labeled "16 bit binary word". Below the boxes, two arrows point to specific positions. The first arrow points to the second box from the right and is labeled "binary point (fraction length = 2)". The second arrow points to the right of the 16th box and is labeled "binary point (fraction length = -2)".</p> <p>The default is 0.</p> |
| Slope and bias            | If you select this mode, the Data Type Assistant displays fields for entering the <b>Slope</b> and <b>Bias</b> .  |

| Scaling Mode | Description   |
|--------------|---|
|              | <ul style="list-style-type: none"> <li>• Slope can be any <i>positive</i> real number. The default is 1.0.</li> <li>• Bias can be any real number. The default value is 0.0.</li> </ul> <p>You can enter slope and bias as expressions that contain parameters defined in the MATLAB workspace.</p> |

---

**Note:** You should use binary-point scaling whenever possible to simplify the implementation of fixed-point data in generated code. Operations with fixed-point data using binary-point scaling are performed with simple bit shifts and eliminate the expensive code implementations required for separate slope and bias values.

---

**Data type override.** Specify whether the data type override setting is **Inherit** (default) or **Off**.

**Calculate Best-Precision Scaling.** The Simulink software can automatically calculate “best-precision” values for both **Binary point** and **Slope and bias** scaling, based on the Limit range properties you specify.

To automatically calculate best precision scaling values:

- 1 Specify **Minimum**, **Maximum**, or both Limit range properties.
- 2 Click **Calculate Best-Precision Scaling**.

The Simulink software calculates the scaling values, then displays them in either the **Fraction Length**, or **Slope** and **Bias** fields.

---

**Note:** The Limit range properties do not apply to **Constant** or **Parameter** scopes. Therefore, Simulink cannot calculate best-precision scaling for these scopes.

---

**Fixed-point Details.** You can view the following Fixed-point details:

| Fixed-point Detail    | Description   |
|-----------------------|---|
| Representable maximum | The maximum number that can be represented by the chosen data type, sign, word length and fraction length (or data type, sign, slope and bias). |

| Fixed-point Detail    | Description   |
|-----------------------|---|
| Maximum               | The maximum value specified.  |
| Minimum               | The minimum value specified.  |
| Representable minimum | The minimum number that can be represented by the chosen data type, sign, word length and fraction length (or data type, sign, slope and bias). |
| Precision             | The precision for the given word length and fraction length (or slope and bias).  |

### Using Data Type Override with the MATLAB Function Block

If you set the Data Type Override mode to **Double** or **Single** in Simulink, the MATLAB Function block sets the type of all inherited input signals and parameters to `fi_double` or `fi_single` objects respectively (see “MATLAB Function Block with Data Type Override” for more information). You must check the data types of your inherited input signals and parameters and use the Ports and Data Manager (see “Ports and Data Manager” on page 37-33) to set explicit types for any inputs that should not be fixed-point. Some operations, such as `sin`, are not applicable to fixed-point objects.

---

**Note:** If you do not set the correct input types explicitly, you may encounter compilation problems after setting Data Type Override.

---

### How Do I Set Data Type Override?

To set Data Type Override, follow these steps:

- 1 From the Simulink **Analysis** menu, select **Fixed-Point Tool**.
- 2 Set the value of the **Data type override** parameter to **Double** or **Single**.

## Size Function Arguments

### In this section...

“Specifying Argument Size” on page 37-66

“Inheriting Argument Sizes from Simulink” on page 37-66

“Specifying Argument Sizes with Expressions” on page 37-67

### Specifying Argument Size

To examine or specify the size of an argument, follow these steps:

- 1 From the MATLAB Function Block Editor, select **Edit Data**.
- 2 Enter the size of the argument in the **Size** field of the Data properties dialog, located in the **General** pane.

---

**Note:** The default value is -1, indicating that size is inherited, as described in “Inheriting Argument Sizes from Simulink” on page 37-66.

---

### Inheriting Argument Sizes from Simulink

Size defaults to -1, which means that the data argument inherits its size from Simulink based on its scope:

| For Scope | Inherits Size  |
|-----------|--|
| Input     | From the Simulink input signal connected to the argument.  |
| Output    | From the Simulink output signal connected to the argument.   |
| Parameter | From the Simulink or MATLAB parameter to which it is bound. See “Add Parameter Arguments” on page 37-68. |

After you compile the model, the **Compiled Size** column in the **Contents** pane displays the actual size used in the compiled simulation application.

The size of an output argument is the size of the value that is assigned to it. If the expected size in the Simulink model does not match, a mismatch error occurs during compilation of the model.

---

**Note:** No arguments with inherited sizes are allowed for MATLAB Function blocks in a library.

---

## Specifying Argument Sizes with Expressions

The size of a data argument can be a scalar value or a MATLAB vector of values.

To specify size as a scalar, set the **Size** field to 1 or leave it blank. To specify **Size** as a vector, enter an array of up to two dimensions in [row column] format where

- Number of dimensions equals the length of the vector.
- Size of each dimension corresponds to the value of each element of the vector.

For example, a value of [2 4] defines a 2-by-4 matrix. To define a row vector of size 5, set the **Size** field to [1 5]. To define a column vector of size 6, set the **Size** field to [6 1] or just 6. You can enter a MATLAB expression for each [row column] element in the **Size** field. Each expression can use one or more of the following elements:

- Numeric constants
- Arithmetic operators, restricted to +, -, \*, and /
- Parameters
- Calls to the MATLAB functions `min`, `max`, and `size`

The following examples are valid expressions for **Size**:

```
k+1
size(x)
min(size(y),k)
```

In these examples, `k`, `x`, and `y` are variables of scope **Parameter**.

Once you build the model, the **Compiled Size** column displays the actual size used in the compiled simulation application.

## Add Parameter Arguments

Parameter arguments for MATLAB Function blocks do not take their values from signals in the Simulink model. Instead, Simulink searches up the workspace hierarchy. Simulink first looks in a masked workspace if the MATLAB Function block or a parent subsystem is masked. If the value is not found, it next looks in the model workspace and then the MATLAB base workspace.

You can provide a custom interface for parameters by masking the MATLAB Function block. Creating a mask for a block allows you to define the access for each parameter. See “How Mask Parameters Work” on page 34-4 for more information.

- 1 In the MATLAB Function Block Editor, add an argument to the function header of the MATLAB Function block. The name of the argument must match the name of the masked parameter or MATLAB variable that you want to pass to the MATLAB Function block.

The new argument appears as an input port on the MATLAB Function block in the model.

- 2 In the MATLAB Function Block Editor, click **Edit Data**.
- 3 Select the new argument.
- 4 Set **Scope** to **Parameter** and click **Apply**.

The input port for the parameter argument no longer appears in the MATLAB Function block.

---

**Note:** Parameter arguments appear as arguments in the function header of the MATLAB Function block to maintain MATLAB consistency. As a result, you can test functions in a MATLAB Function block by copying and pasting them to MATLAB.

---

For information on declaring parameters for masked blocks, see “How Mask Parameters Work” on page 34-4.

## Resolve Signal Objects for Output Data

### In this section...

“Implicit Signal Resolution” on page 37-69

“Eliminating Warnings for Implicit Signal Resolution in the Model” on page 37-69

“Disabling Implicit Signal Resolution for a MATLAB Function Block” on page 37-69

“Forcing Explicit Signal Resolution for an Output Data Signal” on page 37-70

### Implicit Signal Resolution

MATLAB Function blocks participate in signal resolution with Simulink signal objects. By default, output data from MATLAB Function blocks become associated with Simulink signal objects of the same name during a process called *implicit signal resolution*, as described in Simulink.Signal.

By default, implicit signal resolution generates a warning when you update the chart in the Simulink model. The following sections show you how to manage implicit signal resolution at various levels of the model hierarchy. See “Symbol Resolution” on page 4-95 and “Explicit and Implicit Symbol Resolution” on page 4-98 for more information.

### Eliminating Warnings for Implicit Signal Resolution in the Model

To enable implicit signal resolution for all signals in a model, but eliminate the attendant warnings, follow these steps:

- 1 In the Simulink Editor, select **Simulation > Model Configuration Parameters**.

The Configuration Parameters dialog appears.

- 2 In the left pane of the Configuration Parameters dialog, under Diagnostics, select **Data Validity**.

Data Validity configuration parameters appear in the right pane.

- 3 In the Signal resolution field, select **Explicit and implicit**.

### Disabling Implicit Signal Resolution for a MATLAB Function Block

To disable implicit signal resolution for a MATLAB Function block in your model, follow these steps:

- 1 Right-click the MATLAB Function block and select **Block Parameters (Subsystem)** in the context menu.

The Block Parameters dialog opens.

- 2 In the Permit hierarchical resolution field, select **ExplicitOnly** or **None**, and click **OK**.

## **Forcing Explicit Signal Resolution for an Output Data Signal**

To force signal resolution for an output signal in a MATLAB Function block, follow these steps:

- 1 In the Simulink model, right-click the signal line connected to the output that you want to resolve and select **Properties** from the context menu.
- 2 In the Signal Properties dialog, enter a name for the signal that corresponds to the signal object.
- 3 Select the **Signal name must resolve to Simulink signal object** check box and click **OK**.

## Types of Structures in MATLAB Function Blocks

In MATLAB Function blocks, you can define structure data as inputs or outputs that interact with bus signals. MATLAB Function blocks also support arrays of buses (for more information, see “Combine Buses into an Array of Buses” on page 61-82). You can also define structures inside MATLAB functions that are not part of MATLAB Function blocks (see “Structure Definition for Code Generation” on page 47-2).

The following table summarizes how to create different types of structures in MATLAB Function blocks:

| Scope      | How to Create   | Details   |
|------------|---|---|
| Input      | Create structure data with scope of Input.                | You can create structure data as inputs or outputs in the top-level MATLAB function for interfacing to other environments. See “Create Structures in MATLAB Function Blocks” on page 37-77. |
| Output     | Create structure data with scope of Output.               |   |
| Local      | Create a local variable implicitly in a MATLAB function.  | See “Define Scalar Structures for Code Generation” on page 47-4.  |
| Persistent | Declare a variable to be persistent in a MATLAB function. | See “Make Structures Persistent” on page 47-8.  |
| Parameter  | Create structure data with scope of Parameter.            | See “Define and Use Structure Parameters” on page 37-84.  |

Structures in MATLAB Function blocks can contain fields of any type and size, including muxed signals, buses, and arrays of structures.

## Attach Bus Signals to MATLAB Function Blocks

For an example of how to use structures in a MATLAB Function block, open the model `emldemo_bus_struct`.

In this model, a MATLAB Function block receives a bus signal using the structure `inbus` at input port 1 and outputs two bus signals from the structures `outbus` at output port 1 and `outbus1` at output port 2. The input signal comes from the Bus Creator block `MainBusCreator`, which bundles signals `ele1`, `ele2`, and `ele3`. The signal `ele3` is the output of another Bus Creator block `SubBusCreator`, which bundles the signals `a1` and `a2`. The structure `outbus` connects to a Bus Selector block `BusSelector1`; the structure `outbus1` connects to another Bus Selector block `BusSelector3`.

To explore the MATLAB function `fcn`, double-click the MATLAB Function block. Notice that the code implicitly defines a local structure variable `mystruct` using the `struct` function, and uses this local structure variable to initialize the value of the first output `outbus`. It initializes the second output `outbus1` to the value of field `ele3` of structure `inbus`.

### Structure Definitions in Example

Here are the definitions of the structures in the MATLAB Function block in the example, as they appear in the Ports and Data Manager:

|   | Name                 | Scope  | Port | Resolve Signal           | Data Type                 | Size |
|---|----------------------|--------|------|--------------------------|---------------------------|------|
|  | <code>inbus</code>   | Input  | 1    |                          | Inherit: Same as Simulink | -1   |
|  | <code>outbus</code>  | Output | 1    | <input type="checkbox"/> | Bus: MainBus              | 1    |
|  | <code>outbus1</code> | Output | 2    | <input type="checkbox"/> | Bus: SubBus               | 1    |

### Bus Objects Define Structure Inputs and Outputs

Each structure input and output must be defined by a `Simulink.Bus` object in the base workspace (see “Create Structures in MATLAB Function Blocks” on page 37-77). This means that the structure shares the same properties as the bus object, including number, name, type, and sequence of fields. In this example, the following bus objects define the structure inputs and outputs:

The screenshot shows the MATLAB workspace with a tree view on the left and a properties table on the right. The tree view shows a hierarchy: Base Workspace > MainBus > ele1, ele2, ele3(SubBus) > SubBus > a1, a2. The properties table lists the following:

| Name         | Data Type | Complexity | Dimensions | Dimensionality |
|--------------|-----------|------------|------------|----------------|
| ele1         | double    | real       | 1          | Fixed          |
| ele2         | single    | real       | 1          | Fixed          |
| ele3(SubBus) | SubBus    | real       | 1          | Fixed          |

The `Simulink.Bus` object `MainBus` defines structure input `inbus` and structure output `outbus`. The `Simulink.Bus` object `SubBus` defines structure output `outbus1`. Based on these definitions, `inbus` and `outbus` have the same properties as `MainBus` and, therefore, reference their fields by the same names as the fields in `MainBus`, using dot notation (see “Index Substructures and Fields” on page 37-76). Similarly, `outbus1` references its fields by the same names as the fields in `SubBus`. Here are the field references for each structure in this example:

| Structure            | First Field              | Second Field             | Third Field              |
|----------------------|--------------------------|--------------------------|--------------------------|
| <code>inbus</code>   | <code>inbus.ele1</code>  | <code>inbus.ele2</code>  | <code>inbus.ele3</code>  |
| <code>outbus</code>  | <code>outbus.ele1</code> | <code>outbus.ele2</code> | <code>outbus.ele3</code> |
| <code>outbus1</code> | <code>outbus1.a1</code>  | <code>outbus1.a2</code>  | —                        |

To learn how to define structures in MATLAB Function blocks, see “Create Structures in MATLAB Function Blocks” on page 37-77.

## How Structure Inputs and Outputs Interface with Bus Signals

Buses in a Simulink model appear inside the MATLAB Function block as structures; structure outputs from the MATLAB Function block appear as buses in Simulink models. When you create structure inputs, the MATLAB Function block determines the type, size, and complexity of the structure from the input signal. When you create structure outputs, you must define their type, size, and complexity in the MATLAB function.

You connect structure inputs and outputs from MATLAB Function blocks to any bus signal, including:

- Blocks that output bus signals — such as Bus Creator blocks
- Blocks that accept bus signals as input — such as Bus Selector and Gain blocks
- S-Function blocks
- Other MATLAB Function blocks

You can use global bus type data in Data Store Memory blocks with MATLAB Function blocks. For more information on using buses and Data Store Memory, see “Data Stores with Buses and Arrays of Buses” on page 58-8.

### Working with Virtual and Nonvirtual Buses

MATLAB Function blocks supports nonvirtual buses only (see “Virtual and Nonvirtual Buses” on page 61-11). When models that contain MATLAB Function block inputs and outputs are built, hidden converter blocks are used to convert bus signals for code generation from MATLAB, as follows:

- Converts incoming virtual bus signals to nonvirtual buses for inputs to structures in MATLAB Function blocks
- Converts outgoing nonvirtual bus signals from MATLAB Function blocks to virtual bus signals

## Rules for Defining Structures in MATLAB Function Blocks

Follow these rules when defining structures in MATLAB Function blocks:

- For each structure input or output in a MATLAB Function block, you must define a `Simulink.Bus` object in the base workspace to specify its type. For more information, see `Simulink.Bus`.
- MATLAB Function blocks support nonvirtual buses only (see “Working with Virtual and Nonvirtual Buses” on page 37-74).

## Index Substructures and Fields

As in MATLAB, you index substructures and fields structures in MATLAB Function blocks by using dot notation. However, for code generation from MATLAB, you must reference field values individually (see “Structure Definition for Code Generation” on page 47-2).

For example, in the `emldemo_bus_struct` model described in “Attach Bus Signals to MATLAB Function Blocks” on page 37-72, the MATLAB function uses dot notation to index fields and substructures:

```
function [outbus, outbus1] = fcn(inbus)
%#codegen
substruct.a1 = inbus.ele3.a1;
substruct.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5,'ele2',single(100),
                 'ele3',substruct);

outbus = mystruct;
outbus.ele3.a2 = 2*(substruct.a2);

outbus1 = inbus.ele3;
```

The following table shows how the code generation software resolves symbols in dot notation for indexing elements of the structures in this example:

| Dot Notation                    | Symbol Resolution   |
|---------------------------------|---|
| <code>substruct.a1</code>       | Field <code>a1</code> of local structure <code>substruct</code>   |
| <code>inbus.ele3.a1</code>      | Value of field <code>a1</code> of field <code>ele3</code> , a substructure of structure <code>inputinbus</code>                     |
| <code>inbus.ele3.a2(1,1)</code> | Value in row 1, column 1 of field <code>a2</code> of field <code>ele3</code> , a substructure of structure <code>input inbus</code> |

## Create Structures in MATLAB Function Blocks

Here is the workflow for creating a structure in a MATLAB Function block:

- 1 Decide on the type (or scope) of the structure (see “Types of Structures in MATLAB Function Blocks” on page 37-71).
- 2 Based on the scope, follow these guidelines for creating the structure:

| For Structure Scope: | Follow These Steps:   |
|----------------------|---|
| Input                | <p><b>a</b> Create a <code>Simulink.Bus</code> object in the base workspace to define the structure input.</p> <p><b>b</b> Add data to the MATLAB Function block, as described in “Adding Data to a MATLAB Function Block” on page 37-38. The data should have the following properties</p> <ul style="list-style-type: none"> <li>• <b>Scope</b> = Input</li> <li>• <b>Type</b> = Bus: &lt;object name&gt;</li> </ul> <p>For &lt;object name&gt;, enter the name of the <code>Simulink.Bus</code> object that defines the structure input</p> <p>See “Rules for Defining Structures in MATLAB Function Blocks” on page 37-75.</p>  |
| Output               | <p><b>a</b> Create a <code>Simulink.Bus</code> object in the base workspace to define the structure output.</p> <p><b>b</b> Add data to the MATLAB Function block with the following properties:</p> <ul style="list-style-type: none"> <li>• <b>Scope</b> = Output</li> <li>• <b>Type</b> = Bus: &lt;object name&gt;</li> </ul> <p>For &lt;object name&gt;, enter the name of the <code>Simulink.Bus</code> object that defines the structure output</p> <p><b>c</b> Define and initialize the output structure implicitly as a variable in the MATLAB function, as described in “Structure Definition for Code Generation” on page 47-2.</p> <p><b>d</b> Make sure the number, type, and size of fields in the output structure variable definition match the properties of the <code>Simulink.Bus</code> object.</p> |

| <b>For Structure Scope:</b> | <b>Follow These Steps:</b>   |
|-----------------------------|--|
| Local                       | Define the structure implicitly as a local variable in the MATLAB function, as described in “Structure Definition for Code Generation” on page 47-2. By default, local variables in MATLAB Function blocks are temporary.  |
| Persistent                  | Define the structure implicitly as a persistent variable in the MATLAB function, as described in “Make Structures Persistent” on page 47-8.  |
| Parameter                   | <p><b>a</b> Create a structure variable in the base workspace.</p> <p><b>b</b> Add data to the MATLAB Function block with the following properties:</p> <ul style="list-style-type: none"> <li>• <b>Name</b> = same name as the structure variable you created in step 1.</li> <li>• <b>Scope</b> = Parameter</li> </ul> <p>See “Define and Use Structure Parameters” on page 37-84.</p> |

## Assign Values to Structures and Fields

You can assign values to any structure, substructure, or field in a MATLAB Function block. Here are the guidelines:

| Operation  | Conditions  |
|--|---|
| Assign one structure to another structure                                      | You must define each structure with the same number, type, and size of fields, either as <code>Simulink.Bus</code> objects in the base workspace or locally as implicit structure declarations (see “Create Structures in MATLAB Function Blocks” on page 37-77). |
| Assign one structure to a substructure of a different structure and vice versa | You must define the structure with the same number, type, and size of fields as the substructure, either as <code>Simulink.Bus</code> objects in the base workspace or locally as implicit structure declarations.  |
| Assign an element of one structure to an element of another structure          | The elements must have the same type and size.  |

For example, the following table presents valid and invalid structure assignments based on the specifications for the model described in “Attach Bus Signals to MATLAB Function Blocks” on page 37-72:

| Assignment                         | Valid or Invalid? | Rationale   |
|------------------------------------|-------------------|---|
| <code>outbus = mystruct;</code>    | Valid             | Both <code>outbus</code> and <code>mystruct</code> have the same number, type, and size of fields. The structure <code>outbus</code> is defined by the <code>Simulink.Bus</code> object <code>MainBus</code> and <code>mystruct</code> is defined locally to match the field properties of <code>MainBus</code> . |
| <code>outbus = inbus;</code>       | Valid             | Both <code>outbus</code> and <code>inbus</code> are defined by the same <code>Simulink.Bus</code> object, <code>MainBus</code> .  |
| <code>outbus1 = inbus.ele3;</code> | Valid             | Both <code>outbus1</code> and <code>inbus.ele3</code> have the same type and size because each is defined by the <code>Simulink.Bus</code> object <code>SubBus</code> .   |

| <b>Assignment</b> | <b>Valid or Invalid?</b> | <b>Rationale</b>   |
|-------------------|--------------------------|--|
| outbus1 = inbus;  | Invalid                  | The structure <code>outbus1</code> is defined by a different Simulink.Bus object than the structure <code>inbus</code> . |

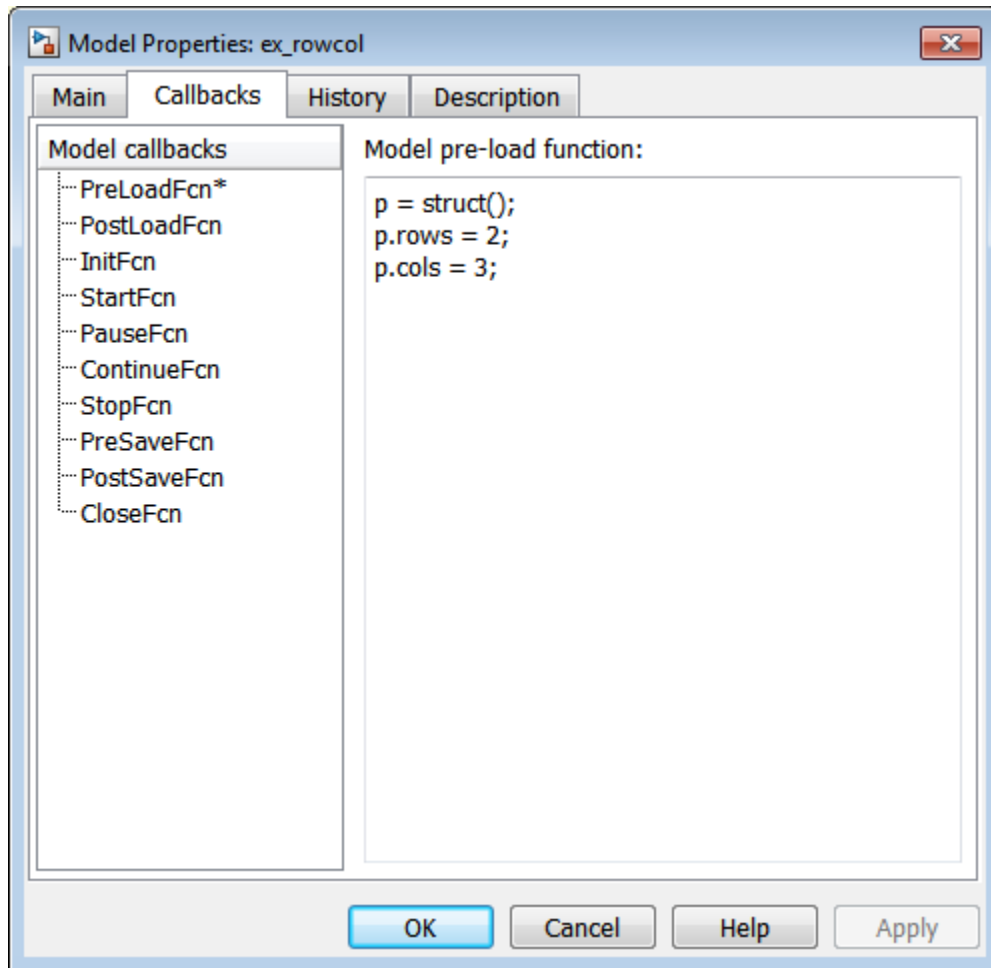

## Initialize a Matrix Using a Non-Tunable Structure Parameter

The following simple example uses a non-tunable structure parameter input to initialize a matrix output. The model looks like this:

This model defines a structure variable `p` in its pre-load callback function, as follows:

The structure `p` has two fields, `rows` and `cols`, which specify the dimensions of a matrix. The MATLAB Function block uses a constant input `u` to initialize the matrix output `y`. Here is the code:

```
function y = fcn(u, p)  
y = zeros(p.rows,p.cols) + u;
```

Running the model initializes each element of the 2-by-3 matrix `y` to 99, the value of `u`:

## Define and Use Structure Parameters

### In this section...

“Defining Structure Parameters” on page 37-84

“FIMATH Properties of Non-Tunable Structure Parameters” on page 37-84

### Defining Structure Parameters

To define structure parameters in MATLAB Function blocks, follow these steps:

- 1 Define and initialize a structure variable

A common method is to create a structure in the base workspace. For other methods, see “Organize Related Parameters in Structures and Arrays of Structures” on page 32-20.

- 2 In the Ports and Data Manager, add data in the MATLAB Function block with the following properties:

| Property | What to Specify  |
|----------|--|
| Name     | Enter same name as the structure variable you defined in the base workspace  |
| Scope    | Select <b>Parameter</b>  |
| Tunable  | Leave checked if you want to change (tune) the value of the parameter during simulation; otherwise, clear to make the parameter non-tunable and preserve the initial value during simulation |
| Type     | Select <b>Inherit: Same as Simulink</b>  |

- 3 Click **Apply**.

### FIMATH Properties of Non-Tunable Structure Parameters

FIMATH properties for non-tunable structure parameters containing fixed-point values are based on the initial values of the structure. They do *not* come from the FIMATH properties specified for fixed-point input signals to the parent MATLAB Function block. (These FIMATH properties appear in the properties dialog box for MATLAB Function blocks.)

## Limitations of Structures and Buses in MATLAB Function Blocks

- Structures in MATLAB Function blocks support a subset of the operations available for MATLAB structures (see “Structures”).
- You cannot use variable-size data with arrays of buses (see “Array of Buses Limitations” on page 61-84).

## What Is Variable-Size Data?

Variable-size data is data whose size may change at run time. By contrast, fixed-size data is data whose size is known and locked at compile time, and therefore cannot change at run time.

## How MATLAB Function Blocks Implement Variable-Size Data

You can define variable-size arrays and matrices as inputs, outputs, and local data in MATLAB Function blocks. However, the block must be able to determine the upper bounds of variable-size data at compile time.

For more information about using variable-size data in Simulink, see “Variable-Size Signal Basics” on page 62-2.

## Enable Support for Variable-Size Data

Support for variable-size data is enabled by default for MATLAB Function blocks. To modify this property for individual blocks:

- 1** In the MATLAB Function Block Editor, select **Edit Data**.
- 2** Select or clear the check box **Support variable-size arrays**.

## Declare Variable-Size Inputs and Outputs

- 1 In the MATLAB Function Block Editor, select **Edit Data**.
- 2 Select **Add > Data**
- 3 Select the **Variable size** check box.
- 4 Set **Scope** as either Input or Output.
- 5 Enter size:

| For:   | What to Specify   |
|--------|---|
| Input  | Enter -1 to inherit size from Simulink or specify the explicit size and upper bound.<br><br>For example, enter [2 4] to specify a 2-D matrix where the upper bounds are 2 for the first dimension and 4 for the second. |
| Output | Specify the explicit size and upper bound.  |

## Filter a Variable-Size Signal

### In this section...

“About the Example” on page 37-90  
 “Simulink Model” on page 37-90  
 “Source Signal” on page 37-91  
 “MATLAB Function Block: uniquify” on page 37-91  
 “MATLAB Function Block: avg” on page 37-93  
 “Variable-Size Results” on page 37-94

### About the Example

The following example appears throughout this section to illustrate how MATLAB Function blocks exchange variable-size data with other Simulink blocks. The model uses a variable-size vector to store the values of a white noise signal. The size of the vector may vary at run time as the signal values get pruned by functions that:

- Filter out signal values that are not unique within a specified tolerance of each other
- Average every two signal values and output only the resulting means

### Simulink Model

Open the example model by typing `emldemo_process_signal` at the MATLAB command prompt. The model contains the following blocks:

| Simulink Block                        | Description  |
|---------------------------------------|--|
| Band-Limited White Noise              | Generates a set of normally distributed random values as the source of the white noise signal. |
| MATLAB Function <code>uniquify</code> | Filters out signal values that are not unique to within a specified tolerance of each other.   |
| MATLAB Function <code>avg</code>      | Outputs the average of a specified number of unique signal values.                             |
| Unique values                         | Scope that displays the unique signal values output from the <code>uniquify</code> function.   |

| Simulink Block | Description  |
|----------------|--|
| Average values | Scope that displays the average signal values output from the <code>avg</code> function. |

## Source Signal

The band-limited white noise signal has these properties:

**Parameters**

Noise power:

Sample time:

Seed:

Interpret vector parameters as 1-D

The size of the noise power value defines the size of the matrix that holds the signal values — in this case, a 1-by-9 vector of double values.

## MATLAB Function Block: `uniquify`

This block filters out signal values that are not within a tolerance of 0.2 of each other. Here is the code:

```
function y = uniquify(u) %#codegen
y = emldemo_uniquetol(u,0.2);
```

The `uniquify` function calls an external MATLAB function `emldemo_uniquetol` to filter the signal values. `uniquify` passes the 1-by-9 vector of white noise signal values as the first argument and the tolerance value as the second argument. Here is the code for `emldemo_uniquetol`:

```
function B = emldemo_uniquetol(A,tol) %#codegen
```

```

A = sort(A);
coder.varsize('B',[1 100]);
B = A(1);
k = 1;
for i = 2:length(A)
    if abs(A(k) - A(i)) > tol
        B = [B A(i)];
        k = i;
    end
end
end

```

`emldemo_uniquetol` returns the filtered values of `A` in an output vector `B` so that  $\text{abs}(B(i) - B(j)) > \text{tol}$  for all `i` and `j`. Every time Simulink samples the Band-Limited White Noise block, it generates a different set of random values for `A`. As a result, `emldemo_uniquetol` may produce a different number of output signals in `B` each time it is called. To allow `B` to accommodate a variable number of elements, `emldemo_uniquetol` declares it as variable-size data with an explicit upper bound:

```
coder.varsize('B',[1 100]);
```

In this statement, `coder.varsize` declares `B` as a vector whose first dimension is fixed at 1 and whose second dimension can grow to a maximum size of 100. Accordingly, output `y` of the `uniquify` block must also be variable sized so it can pass the values returned from `emldemo_uniquetol` to the **Unique values** scope. Here are the properties of `y`:

**Data y**

General | Description

Name:

Scope:  Port:

Data must resolve to Simulink signal object

Size:   Variable size

Complexity:

Sampling mode:

Type:

For variable-size outputs, you must specify an explicit size and upper bound, shown here as [1 9].

## MATLAB Function Block: avg

This block averages signal values filtered by the `uniquify` block as follows:

| If number of signal values:       | The MATLAB Function block:   |
|-----------------------------------|--|
| > 1 and divisible by 2            | Averages every consecutive pair of values                                    |
| > 1 but <i>not</i> divisible by 2 | Drops the first (smallest) value and average the remaining consecutive pairs |
| = 1                               | Returns the value unchanged  |

The `avg` function outputs the results to the **Average values** scope. Here is the code:

```
function y = avg(u) %#codegen

if numel(u) == 1
    y = u;
else
    k = numel(u)/2;
    if k ~= floor(k)
        u = u(2:numel(u));
    end
    y = emldemo_navg(u,2);
end
```

Both input `u` and output `y` of `avg` are declared as variable-size vectors because the number of elements varies depending on how the `uniquify` function block filters the signal values. Input `u` inherits its size from the output of `uniquify`.

The screenshot shows the configuration window for a data block named 'u'. It has two tabs: 'General' and 'Description'. The 'General' tab is selected. The 'Name' field is 'u'. The 'Scope' is 'Input' and the 'Port' is '1'. The 'Size' is '-1' and the 'Variable size' checkbox is checked. The 'Complexity' is 'Inherited'. The 'Type' is 'Inherit: Same as Simulink'. There is a '>>' button at the bottom right.

The `avg` function calls an external MATLAB function `emldemo_navg` to calculate the average of every two consecutive signal values. Here is the code for `emldemo_navg`:

```
function B = emldemo_navg(A,n) %#codegen
assert(n>=1 && n<=numel(A));

B = zeros(1,numel(A)/n);
k = 1;
for i = 1 : numel(A)/n
    B(i) = mean(A(k + (0:n-1)));
    k = k + n;
end
```

## Variable-Size Results

Simulating the model produces the following results:

- The `uniquify` block outputs a variable number of signal values each time it executes:

- The avg block outputs a variable number of signal values each time it executes — approximately half the number of the unique values:

## Enumerated Types Supported in MATLAB Function Blocks

An enumerated type is a user-defined type whose values belong to a predefined set of enumerated values. Each enumerated value consists of a name and an underlying numeric value. For basic information about using enumerated data types in Simulink, see “Use Enumerated Data in Simulink Models” on page 56-7.

You can define an enumerated data type in an enumeration class definition file. For use in a MATLAB Function block, you must base the class on `Simulink.IntEnumType`, `int8`, `uint8`, `int16`, `uint16`, or `int32`. For example:

```
classdef PrimaryColors < Simulink.IntEnumType
    enumeration
        Red(1),
        Blue(2),
        Yellow(4)
    end
end
```

In this example, the statement `classdef PrimaryColors < Simulink.IntEnumType` means that the enumerated type `PrimaryColors` is based on the `Simulink.IntEnumType` class. `PrimaryColors` inherits the characteristics of the `Simulink.IntEnumType` class. It also defines its own unique characteristics. For example, `PrimaryColors` is restricted to three enumerated values.

| Enumerated Value | Enumerated Name | Underlying Numeric Value |
|------------------|-----------------|--------------------------|
| Red(1)           | Red             | 1                        |
| Blue(2)          | Blue            | 2                        |
| Yellow(4)        | Yellow          | 4                        |

If the enumerated type inherits from a base type supported for a MATLAB Function block, you can exchange enumerated data between MATLAB Function blocks and other Simulink blocks in a model.

You can also define an enumerated type by using the function `Simulink.defineIntEnumType`.

## Enumeration Class Base Types in MATLAB Function Block

For MATLAB Function blocks, you must base an enumerated type on the `Simulink.IntEnumType` class or one of the following built-in MATLAB integer data types:

- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`

You can use the base type to control the size of an enumerated type in generated C/C++ code. You can:

- Represent an enumerated type as a fixed-size integer that is portable to different targets.
- Reduce memory usage.
- Interface to legacy code.
- Match company standards.

The base type determines the representation of the enumerated type in generated C/C++ code.

## C Code Representation for `Simulink.IntEnumType` Base Type

If the base type is `Simulink.IntEnumType`, the code generation software generates a C enumeration type. Consider the following MATLAB enumerated type definition:

```
classdef LEDcolor < Simulink.IntEnumType
    enumeration
        GREEN(1),
        RED(2)
    end
end
```

This enumerated type definition results in the following C code:

```
typedef enum {
    GREEN = 1,
```

```
    RED  
} LEDcolor;
```

## C Code Representation for Built-In Integer Base Types

For built-in integer base types, the code generation software generates a `typedef` statement for the enumerated type and `#define` statements for the enumerated values. Consider the following MATLAB enumerated type definition:

```
classdef LEDcolor < int16  
    enumeration  
        GREEN(1),  
        RED(2)  
    end  
end
```

This enumerated type definition results in the following C code:

```
typedef int16_T LEDcolor;  
  
#define GREEN ((LEDcolor)1)  
#define RED ((LEDcolor)2)
```

## Define Enumerated Data Types for MATLAB Function Blocks

You can define enumerated data types for MATLAB Function blocks in two ways:

- Use the `Simulink.defineIntEnumType` function. See “Import Enumerations Defined Externally to MATLAB” on page 56-12.
- Define an enumerated type in a class definition file.

### Define Enumerated Type in Class Definition File

- 1 Create a class definition file.

In the Command Window, select **File > New > Class**.

- 2 Enter the class definition:

```
classdef EnumTypeName < BaseType
```

*EnumTypeName* is a case-sensitive string that must be unique among data type names and workspace variable names. *BaseType* must be `Simulink.IntEnumType`, `int8`, `uint8`, `int16`, `uint16`, or `int32`.

For example, the following code defines an enumerated type called `sysMode` that inherits from the built-in type `Simulink.IntEnumType`:

```
classdef sysMode < Simulink.IntEnumType
    ...
end
```

- 3 Define enumerated values in an enumeration section:

```
classdef EnumTypeName < BaseType
    enumeration
        EnumName(N)
        ...
    end
end
```

For example, the following code defines a set of two values for enumerated type `LEDcolor`:

```
classdef LEDcolor < Simulink.IntEnumType
    enumeration
```

```
        GREEN(1),  
        RED(2),  
    end  
end
```

- 4 Save the file on the MATLAB path.

The name of the file must match the name of the enumerated data type. The match is case sensitive.

For more information about the supported base types, see “Enumerated Types Supported in MATLAB Function Blocks” on page 37-97.

## Add Inputs, Outputs, and Parameters as Enumerated Data

You can add inputs, outputs, and parameters as enumerated data, according to these guidelines:

| For:       | Do This:   |
|------------|--|
| Inputs     | Inherit from the enumerated type of the connected Simulink signal or specify the enumerated type explicitly.   |
| Outputs    | Always specify the enumerated type explicitly.   |
| Parameters | For tunable parameters, specify the enumerated type explicitly.<br><br>For non-tunable parameters, derive properties from an enumerated parameter in a parent Simulink masked subsystem or enumerated variable defined in the MATLAB base workspace. |

To add enumerated data to a MATLAB Function block:

- 1 In the MATLAB Function Block Editor, select **Edit Data**.
- 2 In the Ports and Data Manager, select **Add > Data**.
- 3 In the **Name** field, enter a name for the enumerated data.

For parameters, the name must match the enumerated masked parameter or workspace variable name.

- 4 In the **Type** field, specify an enumerated type.

To specify an explicit enumerated type:

- a Select Enum:<class name> from the drop-down menu in the **Type** field.
- b Replace <class name> with the name of an enumerated data type that you defined in a MATLAB file on the MATLAB path.

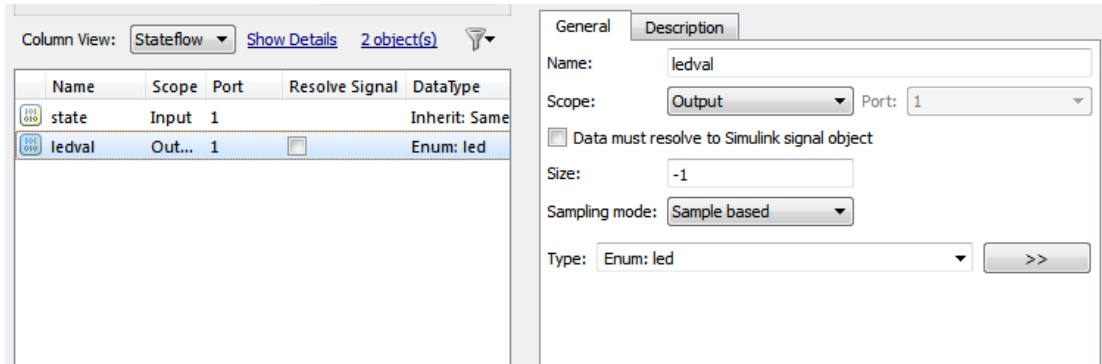

For example, you can enter Enum:led in the **Type** field (see “Define Enumerated Data Types for MATLAB Function Blocks” on page 37-100).

---

**Note:** The **Complexity** field disappears when you select Enum:<class name> because enumerated data types do not support complex values.

---

For example, the following output `ledval` has an explicit enumerated type, `led`:

To inherit the enumerated type from a connected Simulink signal (for inputs only):

- a Select `Inherit:Same` as Simulink from the drop-down menu in the **Type** field.

For example, the following input `state` inherits its enumerated type `switchmode` from a Simulink signal:

| Name   | Scope  | Port | Resolve Signal           | DataType                  | Compiled Type |
|--------|--------|------|--------------------------|---------------------------|---------------|
| ledval | Output | 1    | <input type="checkbox"/> | Enum: led                 | led           |
| state  | Input  | 1    |                          | Inherit: Same as Simulink | switchmode    |

- 5 Click **Apply**.

## Use Enumerated Data in MATLAB Function Blocks

The basic workflow for using enumerated data in MATLAB Function blocks:

| Step | Action  | How?  |
|------|---|---|
| 1    | Define an enumerated data type that inherits from <code>Simulink.IntEnumType</code> , <code>int8</code> , <code>uint8</code> , <code>int16</code> , <code>uint16</code> , or <code>int32</code> . | See “Define Enumerated Data Types for MATLAB Function Blocks” on page 37-100. |
| 1    | Add the enumerated data to your MATLAB Function block.  | See “Add Inputs, Outputs, and Parameters as Enumerated Data” on page 37-102.  |
| 1    | Instantiate the enumerated type in your MATLAB Function block.  | See “Instantiate Enumerated Data in MATLAB Function Blocks” on page 37-105.   |
| 1    | Simulate and/or generate code.  | See “Use Enumerated Data in Generated Code”.                                  |

## Instantiate Enumerated Data in MATLAB Function Blocks

To instantiate an enumerated type in a MATLAB Function block, use dot notation to specify *ClassName.EnumName*. For example, the following MATLAB function `checkState` instantiates the enumerated types `switchmode` and `led` from “Control an LED Display” on page 37-106. The dot notation appears highlighted in the code.

```
function led = checkState(state)
%#codegen

if state == switchmode.ON
    led = led.GREEN;
else
    led = led.RED;
end
```

## Control an LED Display

### In this section...

“About the Example” on page 37-106  
 “Class Definition: switchmode” on page 37-106  
 “Class Definition: led” on page 37-106  
 “Simulink Model” on page 37-107  
 “MATLAB Function Block: checkState” on page 37-108  
 “How the Model Displays Enumerated Data” on page 37-109

### About the Example

The following example illustrates how MATLAB Function blocks exchange enumerated data with other Simulink blocks. This simple model uses enumerated data to represent the modes of a device that controls the colors of an LED display. The MATLAB Function block receives an enumerated data input representing the mode and, in turn, outputs enumerated data representing the color to be displayed by the LED.

This example uses two enumerated types: `switchmode` to represent the set of allowable modes and `led` to represent the set of allowable colors. Both type definitions inherit from the built-in type `Simulink.IntEnumType` and must reside on the MATLAB path.

### Class Definition: switchmode

Here is the class definition of the `switchmode` enumerated data type:

```
classdef switchmode < Simulink.IntEnumType
    enumeration
        OFF(0)
        ON(1)
    end
end
```

This definition must reside on the MATLAB path in a MATLAB file with the same name as the class, `switchmode.m`.

### Class Definition: led

Here is the class definition of the `led` enumerated data type:

```

classdef led < Simulink.IntEnumType
    enumeration
        GREEN(1),
        RED(8)
    end
end

```

This definition must reside on the MATLAB path in a file called `led.m`. The set of allowable values do not need to be consecutive integers.

## Simulink Model

Open the example model by typing `emldemo_led_switch` at the MATLAB command prompt. The model contains the following blocks:

| Simulink Block  | Description   |
|---|---|
| Step  | Provides source of the on/off signal. Outputs an initial value of 0 (off) and at 10 seconds steps up to a value of 1 (on).  |
| Data Type Conversion from double to int32                     | Converts the Step signal of type double to type int32.  |
| Data Type Conversion from int32 to enumerated type switchmode | <p>Converts the value of type int32 to the enumerated type switchmode.</p> <p>In the Data Type Conversion block, you specify the enumerated data type using the prefix <b>Enum:</b> followed by the type name. You cannot set a minimum or maximum value for a signal of an enumerated type; leave these fields at the default value <code>[]</code>. For this example, the Data Type Conversion block parameters have these settings:</p> <ul style="list-style-type: none"> <li>• Output minimum: <code>[]</code></li> <li>• Output maximum: <code>[]</code></li> <li>• Output data type: <code>Enum:switchmode</code></li> </ul> <p>For more information about specifying enumerated types in Simulink models,</p> |

| Simulink Block             | Description  |
|----------------------------|--|
|                            | see “Define Enumerated Data Types for MATLAB Function Blocks” on page 37-100.  |
| MATLAB Function checkState | Evaluates enumerated data input <code>state</code> to determine the color to output as enumerated data <code>ledval</code> . See “MATLAB Function Block: checkState” on page 37-108. |
| Display                    | Displays the enumerated value of output <code>led</code> .   |

## MATLAB Function Block: checkState

The function `checkState` in the MATLAB Function block uses enumerated data to activate an LED display, based on the state of a device. It lights a green LED display to indicate the ON state and lights a red LED display to indicate the OFF state.

```
function ledval = checkState(state)
%#codegen

if state == switchmode.ON
    ledval = led.GREEN;
else
    ledval = led.RED;
end
```

The input `state` inherits its enumerated type `switchmode` from the Simulink step signal; the enumerated type of output `ledval` is explicitly declared as `Enum:led`:

| Name   | Scope  | Port | Resolve Signal           | DataType                  | Compiled Type |
|--------|--------|------|--------------------------|---------------------------|---------------|
| ledval | Output | 1    | <input type="checkbox"/> | Enum: led                 | led           |
| state  | Input  | 1    |                          | Inherit: Same as Simulink | switchmode    |

Explicit enumerated type declarations must include the prefix `Enum:`. For more information, see “Define Enumerated Data Types for MATLAB Function Blocks” on page 37-100.

## How the Model Displays Enumerated Data

Wherever possible, Simulink displays the name of an enumerated value, not its underlying integer. For instance, Display blocks display the name of enumerated values. In this example, when the model simulates for less than 10 seconds, the step signal is 0, resulting in a red LED display to signify the off state.

Similarly, if the model simulates for 10 seconds or more, the step signal is 1, resulting in a green LED display to signify the on state.

Simulink scope blocks work differently. For more information, see “Enumerations and Scopes” on page 56-5.

## Operations on Enumerated Data

Simulink software prevents enumerated values from being used as numeric values in mathematical computation (see “Operations on Enumerated Data” on page 37-110).

The code generation software supports the following enumerated data operations:

- Assignment (=)
- Relational operations (==, ~=, <, >, <=, >=, )
- Cast
- Indexing

For more information, see “Enumerated Data”.

## Enumerated Data in MATLAB Function Blocks

### In this section...

“When to Use Enumerated Data” on page 37-111

“Limitations of Enumerated Types” on page 37-111

### When to Use Enumerated Data

You can use enumerated types to represent program states and to control program logic, especially when you need to restrict data to a predetermined set of values and refer to these values by name. Even though you can sometimes achieve these goals by using integers or strings, enumerated types offer the following advantages:

- Provide more readable code than integers
- Allow more robust error checking than integers or strings

For example, if you mistype the name of an element in the enumerated type, the code generation software alerts you that the element does not belong to the set of allowable values.

- Produce more efficient code than strings

For example, comparisons of enumerated values execute faster than comparisons of strings.

### Limitations of Enumerated Types

Enumerated types in MATLAB Function blocks are subject to the limitations imposed by the code generation software. See “Enumerated Data Definition for Code Generation” on page 49-2.

## Share Data Globally

### In this section...

“When Do You Need to Use Global Data?” on page 37-112

“Using Global Data with the MATLAB Function Block” on page 37-112

“Choosing How to Store Global Data” on page 37-113

“How to Use Data Store Memory Blocks” on page 37-114

“How to Use Simulink.Signal Objects” on page 37-116

“Using Data Store Diagnostics to Detect Memory Access Issues” on page 37-118

“Limitations of Using Shared Data in MATLAB Function Blocks” on page 37-118

### When Do You Need to Use Global Data?

You might need to use global data with a MATLAB Function block if:

- You have multiple MATLAB functions that use global variables and you want to call these functions from MATLAB Function blocks.
- You have an existing model that uses a large amount of global data and you are adding a MATLAB Function block to this model, and you want to avoid cluttering your model with additional inputs and outputs.
- You want to scope the visibility of data to parts of the model.

### Using Global Data with the MATLAB Function Block

In Simulink, you store global data using data store memory. You implement data store memory using either **Data Store Memory** blocks or **Simulink.Signal** objects. How you store global data depends on the number and scope of your global variables. For more information, see “Local and Global Data Stores” on page 58-2 and “Choosing How to Store Global Data” on page 37-113.

#### How MATLAB Globals Relate to Data Store Memory

In MATLAB functions in Simulink, global declarations are not mapped to the MATLAB global workspace. Instead, you register global data with the MATLAB Function block to map the data to data store memory. This difference allows global data in MATLAB functions to inter-operate with the Simulink solver and to provide diagnostics if they are misused.

A global variable resolves hierarchically to the closest data store memory with the same name in the model. The same global variable occurring in two different MATLAB Function blocks might resolve to different data store memory depending on the hierarchy of your model. You can use this ability to scope the visibility of data to a subsystem.

### How to Use Globals with the MATLAB Function Block

To use global data in your MATLAB Function block, or in any code that this block calls, you must:

- 1 Declare a global variable in your MATLAB Function block, or in any code that is called by the MATLAB Function block.
- 2 Register a Data Store Memory block or `Simulink.Signal` object that has the same name as the global variable with the MATLAB Function block.

For more information, see “How to Use Data Store Memory Blocks” on page 37-114 and “How to Use Simulink.Signal Objects” on page 37-116.

### Choosing How to Store Global Data

The following table summarizes whether to use Data Store Memory blocks or `Simulink.Signal` objects.

| If you want to:   | Use:   | For more information:                                |
|---|--|--|
| Use a small number of global variables in a single model that does not use model reference. | Data Store Memory blocks.<br><br><b>Note:</b> Using Data Store Memory blocks scopes the data to the model.   | “How to Use Data Store Memory Blocks” on page 37-114 |
| Use a large number of global variables in a single model that does not use model reference. | <code>Simulink.Signal</code> objects defined in the model workspace.<br><code>Simulink.Signal</code> objects offer these advantages: <ul style="list-style-type: none"> <li>• You do not have to add numerous Data Store Memory blocks to your model.</li> </ul> | “How to Use Simulink.Signal Objects” on page 37-116  |

| If you want to:   | Use:  | For more information:                               |
|---|---|---|
|   | <ul style="list-style-type: none"> <li>You can load the <code>Simulink.Signal</code> objects in from a MAT-file.</li> </ul>   |   |
| Share data between multiple models (including referenced models). | <p><code>Simulink.Signal</code> objects defined in the base workspace</p> <hr/> <p><b>Note:</b> If you use Data Store Memory blocks as well as <code>Simulink.Signal</code>, note that using Data Store Memory blocks scopes the data to the model.</p> | “How to Use Simulink.Signal Objects” on page 37-116 |

## How to Use Data Store Memory Blocks

- 1 Add a MATLAB Function block to your model.
- 2 Double-click the MATLAB Function block to open its editor.
- 3 Declare a global variable in the MATLAB Function block code, or in any MATLAB file that the MATLAB Function block code calls. For example:

```
global A;
```

- 4 Add a Data Store Memory block to your model and set the following:
  - a Set the **Data store name** to match the name of the global variable in your MATLAB Function block code.
  - b Set **Data type** to an explicit data type.
 

The data type cannot be `auto`.
  - c Set the **Signal type**.
  - d Specify an **Initial value**.

The initial value of the Data Store Memory block cannot be unspecified.

- 5 Register the variable to the MATLAB Function block.

- a In the Ports and Data Manager, add data with the same name as the global variable.
- b Set the **Scope** of the data to **Data Store Memory**.

For more information on using the Ports and Data Manager, see “Ports and Data Manager” on page 37-33.

### Example: Using Data Store Memory with the MATLAB Function Block

This simple model demonstrates how a MATLAB Function block uses the global data stored in Data Store Memory block A.

- 1 Open the `dsm_demo` model. At the MATLAB command line, enter:
 

```
run(docpath(fullfile(docroot, 'toolbox', 'simulink', 'examples', 'dsm_demo.mdl')))
```
- 2 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.

The MATLAB Function block modifies the value of global data A each time it executes.

```
function y = fcn
%#codegen
global A;
A = A+1;
y = A;
```

- 3 In the MATLAB Function Block Editor, select **Edit Data**.
- 4 In the Ports and Data Manager, select the data A in the left pane.

The Ports and Data Manager displays the data attributes in the right pane. Note that A has a scope of **Data Store Memory**.

- 5 In the model, double-click the Data Store Memory block A.

The Block Parameters dialog box opens. Note that **A** has an initial value of 25.

- 6 Simulate the model.

The MATLAB Function block reads the initial value of global data stored in **A** and updates the value of **A** each time it executes.

## How to Use Simulink.Signal Objects

- 1 Create a `Simulink.Signal` object in the model workspace.

---

**Tip** Create a `Simulink.Signal` object in the base workspace to use the global data with multiple models.

---

- a In the Model Explorer, navigate to ***model\_name*** > **Model Workspace** in the **Model Hierarchy** pane.

- b Select **Add > Simulink Signal**.

- c Ensure that these settings apply to the `Simulink.Signal` object:

- i Set **Data type** to an explicit data type.

The data type cannot be `auto`.

- ii Set **Dimensions** to be fully specified.

The signal dimensions cannot be `-1` or `inherited`.

- iii Set the **Complexity**.

- iv Specify an **Initial value**.

The initial value of the signal cannot be unspecified.

- 2 Register the `Simulink.Signal` object to the MATLAB Function block.

- a In the Ports and Data Manager, add data with the same name as the `Simulink.Signal` object you created in the model (or base) workspace.

- b Set the **Scope** of the data to `Data Store Memory`.

- 3 Declare a global variable with the same name in the code for your MATLAB Function block.

```
global Sig;
```

For more information on using the Ports and Data Manager, see “Ports and Data Manager” on page 37-33.

### Example: Using a Simulink.Signal Object with a MATLAB Function Block

- 1 Open the `simulink_signal_local` model. At the MATLAB command line, enter:

```
addpath(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
simulink_signal_local
```

- 2 Double-click the MATLAB Function block to open its editor.

The MATLAB Function block modifies the value of global data `A` each time it executes.

```
function y = fcn
%#codegen
global A;
A = A+1;
y = A;
```

- 3 From the MATLAB Function Block Editor menu, select **Edit Data**.
- 4 In the Ports and Data Manager, select the data `A` in the left pane.

The Ports and Data Manager displays the data attributes in the right pane. Note that `A` has a scope of **Data Store Memory**.

- 5 From the model menu, select **View > Model Explorer**.
- 6 In the left pane of the Model Explorer, select the model workspace for the `simulink_signal_local` model.

The **Contents** pane displays the data in the model workspace.

- 7 Click the `Simulink.Signal` object `A`.

The right pane displays attributes for A, including.

| Attribute     | Value  |
|---------------|--------|
| Data type     | double |
| Complexity    | real   |
| Dimensions    | 1      |
| Initial value | 5      |

- 8 Simulate the model.

The MATLAB Function block reads the initial value of global data stored in A and updates the value of A each time it executes.

## Using Data Store Diagnostics to Detect Memory Access Issues

You can configure your model to provide run-time and compile-time diagnostics for avoiding problems with data stores. Diagnostics are available in the Configuration Parameters dialog box and the parameters dialog box for the Data Store Memory block. These diagnostics are available for Data Store Memory blocks only, not for Simulink.Signal objects. For more information on using data store diagnostics, see “Data Store Diagnostics” on page 58-43.

---

**Note:** If you pass data store memory arrays to functions, optimizations such as  $A = \text{foo}(A)$  might result in the code generation software marking the entire contents of the array as read or written even though only some elements were accessed.

---

## Limitations of Using Shared Data in MATLAB Function Blocks

There is no Data Store Memory support for:

- MATLAB structures
- Variable-sized data

## Create Custom Block Libraries

### In this section...

“When to Use MATLAB Function Block Libraries” on page 37-119

“How to Create Custom MATLAB Function Block Libraries” on page 37-119

“Code Reuse with Library Blocks” on page 37-132

“Debugging MATLAB Function Library Blocks” on page 37-137

“Properties You Can Specialize Across Instances of Library Blocks” on page 37-137

### When to Use MATLAB Function Block Libraries

In Simulink, you can create your own block libraries as a way to reuse the functionality of blocks or subsystems in one or more models. If you want to reuse a set of MATLAB algorithms in Simulink models, you can encapsulate your MATLAB code in a MATLAB Function block library.

As with other Simulink block libraries, you can specialize each instance of MATLAB Function library blocks in your model to use different data types, sample times, and other properties. Library instances that inherit the same properties can reuse generated code (see “Code Reuse with Library Blocks” on page 37-132).

For more information about Simulink block libraries, see “About Block Libraries and Linked Blocks” on page 36-2.

### How to Create Custom MATLAB Function Block Libraries

Here is a basic workflow for creating custom block libraries with MATLAB Function blocks. To work through these steps with an example, see “Example: Creating a Custom Signal Processing Filter Block Library” on page 37-120.

- 1 Add polymorphic MATLAB code to MATLAB Function blocks in a Simulink model.

Polymorphic code is code that can process data with different properties, such as type, size, and complexity.

- 2 Configure the blocks to inherit the properties you want to specialize.

For a list of properties you can specialize, see “Properties You Can Specialize Across Instances of Library Blocks” on page 37-137.

- 3 Optionally, customize your library code using masking.
- 4 Add instances of MATLAB Function library blocks to a Simulink model.

---

**Note:** If your MATLAB Function block library is masked, you cannot modify contents of the block with mask initialization code. The **Allow library block to modify its contents** option in the Mask dialog box is not support for MATLAB Function block libraries.

---

## Example: Creating a Custom Signal Processing Filter Block Library

- “What You Will Learn” on page 37-120
- “About the Filter Algorithms” on page 37-120
- “Step 1: Add the Filter Algorithms to MATLAB Function Library Blocks” on page 37-121
- “Step 2: Configure Blocks to Inherit Properties You Want to Specialize” on page 37-122
- “Step 3: Customize Your Library Using Masking” on page 37-123
- “Step 4: Add Instances of MATLAB Library Blocks to a Simulink Model” on page 37-127

### What You Will Learn

This simple example takes you through the workflow described in “How to Create Custom MATLAB Function Block Libraries” on page 37-119 to show you how to:

- Create a library of signal processing filter algorithms using MATLAB Function blocks
- Customize one of the library blocks using mask parameters
- Convert one of the filter algorithms to source-protected P-code that you can call from a MATLAB Function library block

### About the Filter Algorithms

The MATLAB filter algorithms are:

**my\_fft**

Performs a discrete Fourier transform on an input signal. The input can be a vector, matrix, or multidimensional array whose length is a power of 2.

**my\_conv**

Convolves two input vector signals. Outputs a subsection of the convolution with a size specified by a mask parameter, **Shape**.

**my\_sobel**

Convolves a 2D input matrix with a Sobel edge detection filter.

**Step 1: Add the Filter Algorithms to MATLAB Function Library Blocks**

- 1 In Simulink, create a library model by selecting **File > New > Library**
- 2 Drag three MATLAB Function blocks into the model from the User-Defined Functions section of the Simulink Library Browser and name them:
  - my\_fft\_filter
  - my\_conv\_filter
  - my\_sobel\_filter
- 3 Save the library model as my\_filter\_lib.
- 4 Open the MATLAB Function block named my\_fft\_filter, replace the template code with the following code, and save the block:

```
function y = my_fft(x)
```

```
y = fft(x);
```

- 5 Replace the template code in my\_conv\_filter block with the following code and save the block:

```
function c = my_conv(a, b)
```

```
c = conv(a, b);
```

- 6 Replace the template code in my\_sobel\_filter block with the following code and save the block:

```
function y = my_sobel(u)
```

```
%% "my_sobel_filter" is a MATLAB function
%% on the MATLAB path.
y = my_sobel_filter(u);
```

The `my_sobel` function acts as a wrapper that calls a MATLAB function, `my_sobel_filter`, on the code generation path. `my_sobel_filter` implements the algorithm that convolves a 2D input matrix with a Sobel edge detection filter. By calling the function rather than inlining the code directly in the MATLAB Function block, you can reuse the algorithm both as MATLAB code and in a Simulink model. You will create `my_sobel_filter` next.

- 7 In the same folder where you created `my_filter_lib`, create a new MATLAB function `my_sobel_filter` with the following code:

```
function y = my_sobel_filter(u)

% Sobel edge detection filter
h = [1  2  1;...
     0  0  0;...
    -1 -2 -1];

y = abs(conv2(u, h));
```

Save the file as `my_sobel_filter.m`.

### Step 2: Configure Blocks to Inherit Properties You Want to Specialize

In this example, the data in the signal processing filter algorithms must inherit size, type, and complexity from the Simulink model. By default, data in MATLAB Function blocks inherit these properties. To explicitly configure data to inherit properties:

- 1 Open a MATLAB Function block and select **Edit Data**.
- 2 In the left pane of the Ports and Data Manager, select the data of interest.
- 3 In the right pane, configure the data to inherit properties from Simulink:

| To Inherit | What to Specify  |
|------------|--|
| Size       | Enter -1 in Size field                                     |
| Complexity | Select <b>Inherited</b> from the Complexity menu           |
| Type       | Select <b>Inherit: Same as Simulink</b> from the Type menu |

For example, if you open the MATLAB Function block `my_fft_filter` and look at the properties of input `x` in the Ports and Data Manager, you see that `size`, `type`, and `complexity` are inherited by default.

---

**Note:** If your design has specific requirements or constraints, you can enter values for any of these properties, rather than inherit them from Simulink. For example, if your algorithm is not supposed to work with complex inputs, set **Complexity** to **Off**.

---

- “Ports and Data Manager” on page 37-33
- “Inheriting Argument Data Types” on page 37-61

### Step 3: Customize Your Library Using Masking

In this exercise you will modify the convolution filter `my_conv` to use a custom parameter `shape` that specifies what subsection of the convolution to output. To customize this algorithm for your library, place the `my_conv_filter` block under a masked subsystem and define `shape` as a mask parameter.

1 Convert the block to a masked subsystem:

- a Right-click the `my_conv_filter` block and select **Subsystem & Model Reference > Create Subsystem from Selection**.

The `my_conv_filter` block changes to a subsystem block.

- b Change the name of the subsystem to `my_conv_filter`.
- c Right-click the `my_conv_filter` subsystem and select **Mask > Create Mask** from the context menu.

The Mask Editor appears with the **Icon & Ports** tab open.

- d Enter in the **Icon drawing commands** text box:

```
disp('my_conv');  
port_label('output', 1, 'c');  
port_label('input', 1, 'a');  
port_label('input', 2, 'b');
```

- e Select the **Parameters & Dialog** tab.

- f** Highlight the **Parameters** line item in the Dialog box pane.
- g** Add a popup-type parameter by clicking **Popup** under the **Parameter** list in the **Controls** pane.

A new parameter will appear in the Dialog box pane.

- h** In the **Property editor** pane, set the **Properties**:

| Property            | Value  |
|---------------------|--|
| <b>Name</b>         | shape  |
| <b>Value</b>        | full   |
| <b>Prompt</b>       | shape  |
| <b>Type</b>         | popup  |
| <b>Type options</b> | Open the Type Options Editor and enter:<br><br>full<br>same<br>valid |

- i** Set the **Attributes**, **Dialog**, and **Layout** properties in the **Property editor** pane:

| Attributes, Dialog, and Layout Items | Value   |
|--------------------------------------|---|
| <b>Attributes</b>                    | <ul style="list-style-type: none"> <li>• Evaluate: Checked</li> <li>• Tunable: Cleared</li> <li>• Read only: Cleared</li> <li>• Hidden: Cleared</li> <li>• Never save: Cleared</li> </ul> |
| <b>Dialog</b>                        | <ul style="list-style-type: none"> <li>• Enable: Checked</li> <li>• Visible: Checked</li> <li>• Callback: no entry</li> </ul>   |
| <b>Layout</b>                        | <ul style="list-style-type: none"> <li>• Item location: Grayed out</li> <li>• Prompt location: Left</li> </ul>  |

- i** Click **OK**.

Your subsystem should now look like this:

- 2 Set subsystem properties for code reuse:
  - a Right-click the `my_conv_filter` subsystem and select **Block Parameters (Subsystem)** from the context menu.
  - b In the subsystem parameters dialog box, select the **Treat as atomic unit** check box.

The dialog box expands to display new fields.

- c To generate a reusable function, select the Code Generation tab and in the **Function packaging** field, select **Reusable function** from the drop-down menu.

---

**Note:** This is an optional step, required for this example. If you leave the default setting of **Auto**, the code generation software uses an internal rule to determine whether to inline the function or not.

---

- d Click **OK**.
- 3 Define the `shape` parameter in the MATLAB Function `my_conv`:
  - a Right-click the `my_conv_filter` subsystem and select **Mask > Look Under Mask** from the context menu.

The block diagram under the masked subsystem opens, containing the `my_conv_filter` block:

- b Change the names of the port blocks to match the data names as follows:

| Change: | To: |
|---------|-----|
| In1     | a   |
| In2     | b   |
| Out1    | c   |

- c Double-click the my\_conv\_filter block to open the MATLAB Function Block Editor.
- d In the MATLAB Function Block Editor, select **Edit Data**.
- e In the Ports and Data Manager, select **Add > Data**.

A new data element appears selected, along with its properties dialog.

- f Enter the following properties:

| Property | What To Specify           |
|----------|---------------------------|
| Name     | Enter <b>shape</b> .      |
| Scope    | Select <b>Parameter</b> . |
| Tunable  | Clear the box.            |

- g Leave **Size**, **Complexity**, and **Type** as inherited (the defaults), as described in “Step 2: Configure Blocks to Inherit Properties You Want to Specialize” on page 37-122.
  - h Click **Apply**, close the Ports and Data Manager, and return to the MATLAB Function Block Editor.
- 4 Use the **shape** parameter to determine the size of the convolution to output:

- a** In the MATLAB Function Block Editor, modify the `my_conv` function to call `conv` with the right shape:

```
function c = my_conv(a, b, shape)
if shape == 1
    c = conv(a, b, 'full');
elseif shape == 2
    c = conv(a, b, 'same');
else
    c = conv(a, b, 'valid');
end
```

- b** Save your changes and close the MATLAB Function Block Editor.

#### See Also

- “Block Masks”

### Step 4: Add Instances of MATLAB Library Blocks to a Simulink Model

In this exercise, you will add specialized instances of the `my_conv_filter` library block to a simple test model.

- 1 Open a new Simulink model.

For purposes of this exercise, set the following configuration parameters for simulation:

| Pane               | Section        | What to Specify  |
|--------------------|----------------|--|
| Solver             | Solver options | <ul style="list-style-type: none"> <li>• Select <b>Fixed-Step</b> for <b>Type</b></li> <li>• Select <b>discrete (no continuous states)</b> for <b>Solver</b></li> <li>• Enter <b>1</b> for <b>Fixed-step size</b></li> </ul> |
| Data Import/Export | Save options   | Structure for <b>Format</b>  |

- 2 Drag two instances of the `my_conv_filter` block from the `my_filter_lib` library into the model.

- 3 Add Constant, Outport, and Display blocks. Your model should look something like this:

Both library instances share the same size, type, and complexity for inputs **a** and **b** respectively.

- 4 Double-click each library instance.

The **shape** parameter defaults to **full** for both instances.

- 5 Simulate the model.

Each library instance outputs the same result, the full 2D convolution:

- 6 Specialize the second instance, `my_conv_filter1` by setting the value of its `shape` parameter to **same**.
- 7 Now simulate the model again.

This time, the outputs have different sizes: `my_conv_filter3` outputs the full 2D convolution, while `my_conv_filter1` displays the central part of the convolution as a 1-by-2 vector, the same size as `a`:

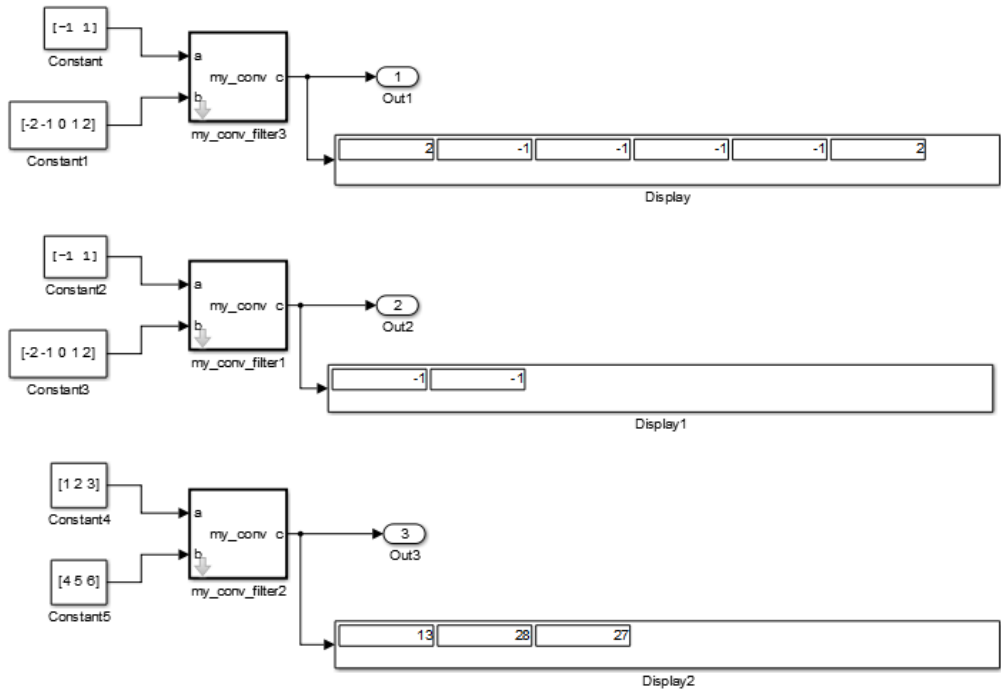

- 8 Now, add a third instance by copying my\_conv\_filter1. Specialize the new instance, my\_conv\_filter2, so that it does not inherit the same size inputs as the first two instances:

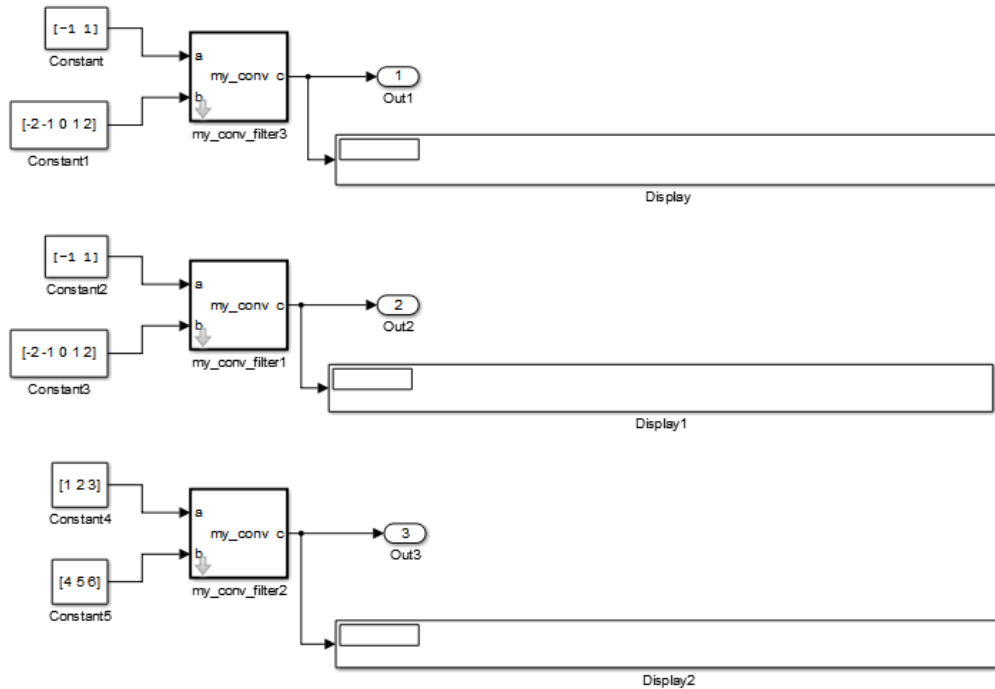

9 Simulate the model again.

This time, `my_conv_filter1` and `my_conv_filter2` each display the central part of the convolution, but the output sizes are different because each matches a different sized input `a`.

## Code Reuse with Library Blocks

When instances of MATLAB Function library blocks inherit the same properties, they can reuse generated code, as illustrated by an example based on “Step 4: Add Instances of MATLAB Library Blocks to a Simulink Model” on page 37-127:

In this model, the library instances `my_conv_filter` and `my_conv_filter1` inherit the same size, type, and complexity for each respective input. For each instance, input `a` is a 1-by-2 vector and input `b` is a 1-by-5 vector. By comparison, the inputs of `my_conv_filter2` inherit different respective sizes; both are 1-by-3 vectors.

In addition, each library instance has a mask parameter called `shape` that determines what subsection of the convolution to output. Assume that the value of `shape` is the same for each instance.

To generate code for this example, follow these steps:

- 1 Enable code reuse for the library block:
  - a In the library, right-click the MATLAB Function block `my_conv_filter` and select **Block Parameters (Subsystem)** from the context menu.
  - b In the Function Block Parameters dialog box, set these parameters:

- Select the **Treat as atomic unit** check box.
  - In the **Function packaging** field, select **Reusable** function from the drop-down menu.
- 2 Configure the model for code generation.

For purposes of this exercise, set the following configuration parameters:

| Pane                               | Section                 | What to Specify  |
|------------------------------------|-------------------------|--|
| <b>Code Generation</b>             | <b>Target selection</b> | Enter <b>ert.tlc</b> for System target file            |
| <b>Code Generation &gt; Report</b> |                         | Select <b>Create code generation report</b> check box. |

- 3 Build the model.

If you build this model, the generated C code reuses logic for the `my_conv_filter` and `my_conv_filter1` library instances because they inherit the same input properties:

```

/*
 * Output and update for atomic system:
 *   '<Root>/my_conv_filter'
 *   '<Root>/my_conv_filter1'
 */
void sp_algorithm_tes_my_conv_filter(const real32_T rtu_a[2], const real32_T
rtu_b[5], rtB_my_conv_filter_sp_algorithm *localB)
{
    int32_T jA;
    int32_T jA_0;
    real32_T s;
    int32_T jC;

    /* MATLAB Function Block: '<S1>/my_conv_filter' */
    /* MATLAB Function 'my_conv_filter/my_conv_filter': '<S4>:1' */
    /* '<S4>:1:4' */
    for (jC = 0; jC < 6; jC++) {
        if (5 < jC + 2) {
            jA = jC - 4;
        } else {
            jA = 0;
        }
    }
}

```

```
    }  
  
    if (2 < jC + 1) {  
        jA_0 = 2;  
    } else {  
        jA_0 = jC + 1;  
    }  
  
    s = 0.0F;  
    while (jA + 1 <= jA_0) {  
        s += rtu_b[jC - jA] * rtu_a[jA];  
        jA++;  
    }  
  
    localB->c[jC] = s;  
}  
  
/* end of MATLAB Function Block: '<S1>/my_conv_filter' */  
}
```

However, a separate function is generated for my\_conv\_filter2:

```
/* Output and update for atomic system: '<Root>/my_conv_filter2' */
void sp_algorithm_te_my_conv_filter2(const real_T rtu_a[3], const real_T rtu_b[3],
    rtB_my_conv_filter_sp_algorit_h *localB)
{
    int32_T jA;
    int32_T jA_0;
    real_T s;
    int32_T jC;

    /* MATLAB Function Block: '<S3>/my_conv_filter' */
    /* MATLAB Function 'my_conv_filter/my_conv_filter': '<S6>:1' */
    /* '<S6>:1:4' */
    for (jC = 0; jC < 5; jC++) {
        if (3 < jC + 2) {
            jA = jC - 2;
        } else {
            jA = 0;
        }

        if (3 < jC + 1) {
            jA_0 = 3;
        } else {
            jA_0 = jC + 1;
        }

        s = 0.0;
        while (jA + 1 <= jA_0) {
            s += rtu_b[jC - jA] * rtu_a[jA];
            jA++;
        }

        localB->c[jC] = s;
    }

    /* end of MATLAB Function Block: '<S3>/my_conv_filter' */
}
```

---

**Note:** Generating C code for this model requires a Simulink Coder or Embedded Coder license.

---

## Debugging MATLAB Function Library Blocks

You debug MATLAB Function library blocks the same way you debug any MATLAB Function block. However, when you add a breakpoint in a library block, the breakpoint is shared by all instances. As you continue execution, the debugger stops at the breakpoint in each instance.

For more information, see “Debugging a MATLAB Function Block” on page 37-22

## Properties You Can Specialize Across Instances of Library Blocks

You can specialize instances of MATLAB Function library blocks by allowing them to inherit any of the following properties from Simulink:

| Property                                     | Inherits by Default? | How to Specify Inheritance  |
|--|----------------------|---|
| Type   | Yes                  | Set data type property to <b>Inherit: Same as Simulink</b> .  |
| Size   | Yes                  | Set data size property to <b>-1</b> .   |
| Complexity                                   | Yes                  | Set data complexity property to <b>Inherited</b> .  |
| Limit range                                  | No                   | Specify minimum and maximum values as Simulink parameters.<br>For example, if minimum value = <code>aParam</code> and maximum value = <code>aParam + 3</code> , different instances of a MATLAB Function library block can resolve to different <code>aParam</code> parameters defined in their parent mask subsystems. |
| Sampling mode (input)                        | Yes                  | MATLAB Function block input ports always inherit sampling mode  |
| Data type override mode for fixed-point data | Yes                  | Set data type override property to <b>Inherit</b> .   |
| Sample time (block)                          | Yes                  | Set block sample time property to <b>-1</b> .   |

## Use Traceability in MATLAB Function Blocks

| In this section...   |
|--|
| “Extent of Traceability in MATLAB Function Blocks” on page 37-138        |
| “Traceability Requirements” on page 37-138                               |
| “Basic Workflow for Using Traceability” on page 37-138                   |
| “Tutorial: Using Traceability in a MATLAB Function Block” on page 37-139 |

### Extent of Traceability in MATLAB Function Blocks

Like other Simulink blocks, MATLAB Function blocks support bidirectional traceability, but extend navigation to lines of source code. That is, you can navigate between a line of generated code and its corresponding line of source code. In other Simulink blocks, you can navigate between a line of generated code and its corresponding object.

In addition, you can select to include the source code as comments in the generated code. When you select this option, the MATLAB source code appears immediately after the associated traceability tag. For more information, see “Include MATLAB Code as Comments in Generated Code” on page 37-142.

For information about how traceability works in Simulink blocks, see “What Is Code Tracing?”.

### Traceability Requirements

To enable traceability comments in your code, you must have a license for Embedded Coder software. These comments appear only in code that you generate for an Embedded Real-Time (ERT) target.

---

**Note:** Traceability is not supported for MATLAB files that you call from a MATLAB Function block.

---

### Basic Workflow for Using Traceability

The workflow for using traceability is described in “Trace Model Objects to Generated Code”. Here are the basic steps:

- 1 Open the MATLAB Function block in your Simulink model.
- 2 Define your system target file to be an Embedded Real-Time (ERT) target.
  - a In the model, select **Simulation > Model Configuration Parameters**.
  - b In the **Code Generation** pane, enter `ert.tlc` for the system target file.
- 3 Enable traceability options.
  - a In the **Code Generation > Report** pane, select **Create code generation report**.  
 This action automatically selects the **Open report automatically** and **Code-to-model** options.
  - b Select **Model-to-code**.  
 This action automatically selects all options in the **Traceability Report Contents** section.
- 4 Generate the source code and header files for your model.
- 5 Trace a line of code:

| To Trace:                                     | Do This:  |
|---|---|
| Line of source code to line of generated code | Right-click in a line in your source code and select <b>Code Generation &gt; Navigate to Code</b> from the context menu |
| Line of generated code to line of source code | Click a hyperlink in the traceability comment in your generated code  |

To learn how to complete each step in this workflow, see “Tutorial: Using Traceability in a MATLAB Function Block” on page 37-139

## Tutorial: Using Traceability in a MATLAB Function Block

This example shows how to trace between source code and generated code in a MATLAB Function block in the `eml_fire` model. Follow these steps:

- 1 Type `eml_fire` at the MATLAB prompt.
- 2 In the Simulink model window, double-click the `flame` block to open the MATLAB Function Block Editor.

- 3 In the Simulink model window, select **Simulation > Model Configuration Parameters**.
- 4 In the **Code Generation** pane, go to the **Target selection** section and enter `ert.tlc` for the system target file. Then click **Apply**.

---

**Note:** Traceability comments appear hyperlinked in generated code only for embedded real-time (`ert`) targets.

---

- 5 In the **Code Generation > Report** pane, select the **Create code generation report** option.

This action automatically selects the **Open report automatically** and **Code-to-model** options.

- 6 Select the **Model-to-code** option in the **Navigation** section. Then click **Apply**.

This action automatically selects all options in the **Traceability Report Contents** section.

---

**Note:** For large models that contain over 1000 blocks, disable the **Model-to-code** option to speed up code generation.

---

- 7 Go to the **Code Generation > Interface** pane. In the **Software environment** section, select the **continuous time** option. Then click **Apply**.

---

**Note:** Because this example model contains a block with a continuous sample time, you must perform this step before generating code.

---

- 8 In the **Code Generation** pane, click **Build** in the lower right corner.

This action generates source code and header files for the `eml_fire` model that contains the `flame` block. After the code generation process is complete, the code generation report appears automatically.

- 9 Click the `eml_fire.c` hyperlink in the report.
- 10 Scroll down through the code to see the traceability comments, which appear as links inside `/*...*/` brackets, as in this example.

```
for (b_x = 0; b_x < 256; b_x++) {
    /* '<S2>:1:19' */
    /* '<S2>:1:21' */
```

```
yb = loopVar_i + 2;  
  
/* '<S2>:1:22' */  
xb = b_x - 1;
```

---

**Note:** The line numbers shown above may differ from the numbers that appear in your code generation report.

---

- 11** Click the [<S2>:1:19](#) hyperlink in this traceability comment:

```
/* '<S2>:1:19' */
```

Line 19 of the function appears highlighted in the MATLAB Function Block Editor.

- 12** You can also trace a line in a MATLAB function to a line of generated code. For example, right-click in line 21 of your function and select **Code Generation > Navigate to Code** from the context menu.

The code location for line 21 appears highlighted in `eml_fire.c`.

## Include MATLAB Code as Comments in Generated Code

If you have a Simulink Coder license, you can include MATLAB source code as comments in the code generated for a MATLAB Function block. Including this information in the generated code enables you to:

- Correlate the generated code with your source code.
- Understand how the generated code implements your algorithm.
- Evaluate the quality of the generated code.

When you select this option, the generated code includes:

- The source code as a comment immediately after the traceability tag. When you enable traceability and generate code for ERT targets (requires an Embedded Coder license), the traceability tags are hyperlinks to the source code. For more information on traceability for the MATLAB Function block, see “Use Traceability in MATLAB Function Blocks” on page 37-138.

For examples and information on the location of the comments in the generated code, see “Location of Comments in Generated Code” on page 37-143.

- The function help text in the function body in the generated code. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it.

---

**Note:** With an Embedded Coder license, you can also include the function help text in the function banner of the generated code. For more information, see “Including MATLAB Function Help Text in the Function Banner” on page 37-145.

---

## How to Include MATLAB Code as Comments in the Generated Code

To include MATLAB source code as comments in the code generated for a MATLAB Function block:

- 1 In the model, select **Simulation > Model Configuration Parameters**.
- 2 In the **Code Generation > Comments** pane, select **MATLAB source code as comments** and click **Apply**.

## Location of Comments in Generated Code

The automatically generated comments containing the source code appear after the traceability tag in the generated code as follows.

### Straight-Line Source Code

The comment containing the source code precedes the generated code that implements the source code statement. This comment appears after any comments that you add that precede the generated code. The comments are separated from the generated code because the statements are assigned to function outputs.

#### MATLAB Code

```
function [x y] = straightline(r,theta)
%#codegen
% Convert polar to Cartesian
x = r * cos(theta);
y = r * sin(theta);
```

#### Commented C Code

```
/* MATLAB Function 'straightline': '<S1>:1' */
/* Convert polar to Cartesian */
/* '<S1>:1:4' x = r * cos(theta); */
/* '<S1>:1:5' y = r * sin(theta); */
straightline0_Y.x = straightline0_U.r * cos(straightline0_U.theta);

/* Output: '<Root>/y' incorporates:
 * Inport: '<Root>/r'
 * Inport: '<Root>/theta'
 * MATLAB Function Block: '<Root>/straightline'
 */
straightline0_Y.y = straightline0_U.r * sin(straightline0_U.theta);
```

### If Statements

The comment for the `if` statement immediately precedes the code that implements the statement. This comment appears after any comments that you add that precede the generated code. The comments for the `elseif` and `else` clauses appear immediately after the code that implements the clause, and before the code generated for statements in the clause.

#### MATLAB Code

```
function y = ifstmt(u,v)
```

```

%#codegen
if u > v
    y = v + 10;
elseif u == v
    y = u * 2;
else
    y = v - 10;
end

```

### Commented C Code

```

/* MATLAB Function 'MLFcn': '<S1>:1' */
/* '<S1>:1:3' if u > v */
if (MLFcn_U.u > MLFcn_U.v) {
    /* Output: '<Root>/y' */
    /* '<S1>:1:4' y = v + 10; */
    MLFcn_Y.y = MLFcn_U.v + 10.0;
} else if (MLFcn_U.u == MLFcn_U.v) {
    /* Output: '<Root>/y' */
    /* '<S1>:1:5' elseif u == v */
    /* '<S1>:1:6' y = u * 2; */
    MLFcn_Y.y = MLFcn_U.u * 2.0;
} else {
    /* Output: '<Root>/y' */
    /* '<S1>:1:7' else */
    /* '<S1>:1:8' y = v - 10; */
    MLFcn_Y.y = MLFcn_U.v - 10.0;
}

```

### For Statements

The comment for the `for` statement header immediately precedes the generated code that implements the header. This comment appears after any comments that you add that precede the generated code.

### MATLAB Code

```

function y = forstmt(u)
%#codegen
y = 0;
for i=1:u
    y = y + 1;
end

```

### Commented C Code

```

/* MATLAB Function 'MLFcn': '<S1>:1' */
/* '<S1>:1:3' y = 0; */

```

```
rtb_y = 0.0;

/* '<S1>:1:5' for i=1:u */
for (i = 1.0; i <= MLFcn_U.u; i++) {
    /* '<S1>:1:6' y = y + 1; */
    rtb_y++;
}
```

## While Statements

The comment for the `while` statement header immediately precedes the generated code that implements the statement header. This comment appears after any comments that you add that precede the generated code.

## Switch Statements

The comment for the `switch` statement header immediately precedes the generated code that implements the statement header. This comment appears after any comments that you add that precede the generated code. The comments for the `case` and `otherwise` clauses appear immediately after the generated code that implements the clause, and before the code generated for statements in the clause.

## Including MATLAB Function Help Text in the Function Banner

You can include the function help text in the function banner of the code generated for a MATLAB Function block. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it.

- 1 In the model, select **Simulation > Model Configuration Parameters**.
- 2 In the **Code Generation > Comments** pane, select **MATLAB function help text** and click **Apply**.

---

**Note:** If the function is inlined, the function help text is also inlined. Therefore, the help text for inlined functions appears in the function body in the generated code even when this option is selected.

---

## Limitations of MATLAB Source Code as Comments

The MATLAB Function block has the following limitations for including MATLAB source code as comments.

- You cannot include MATLAB source code as comments for:
  - MathWorks toolbox functions
  - P-code
  - Simulation targets
  - Stateflow Truth Table blocks
- The appearance or location of comments can vary depending on the following conditions:
  - Comments might still appear in the generated code even if the implementation code is eliminated, for example, due to constant folding.
  - Comments might be eliminated from the generated code if a complete function or code block is eliminated.
  - For certain optimizations, the comments might be separated from the generated code.
  - The generated code always includes legally required comments from the MATLAB source code, even if you do not choose to include source code comments in the generated code.

# Integrate C Code Using the MATLAB Function Block

## In this section...

“Call C Code from a Simulink model” on page 37-147

“Control Imported Bus and Enumeration Type Definitions” on page 37-149

## Call C Code from a Simulink model

You can call external C code from a Simulink model using a MATLAB Function block and the `coder.ceval` command. Follow these high-level steps:

- 1 Start with existing C code consisting of the source (.c) and header (.h) files.
- 2 In the MATLAB Function block, enter the MATLAB code that calls the C code. Use the command `coder.ceval`.
- 3 Specify the C source and header files for simulation in the **Simulation Target > Custom Code** pane of the Configuration Parameters dialog box.

Include the header file using double quotations, such as `#include "program.h"`.

- 4 If you need to access C source and header files outside your working folder, list the path in the **Simulation Target > Custom Code** pane of the Configuration Parameters dialog box, in the **Include Directories** text box.
- 5 Test your Simulink model and ensure it functions correctly.
- 6 To use the same source and header files for code generation, click **Use the same custom code settings as Simulation Target** in the **Code Generation > Custom Code** pane.

You can also specify different source and header files.

If you have a Simulink Coder license, you can generate code for targets using this method. For more information see `coder.ceval`.

## Call the doubleIt Program Using a MATLAB Function Block

This example shows how to call the simple C program `doubleIt` from a MATLAB Function block.

- 1 Create the source file `doubleIt.c` in your current working folder.

```

/* doubleIt, a simple program that returns double the input */
#include "doubleIt.h"

double doubleIt(double u)
{
    return(u*2.0);
}

```

- 2 Create the header file `doubleIt.h` in your current working folder.

```
double doubleIt(double u);
```

- 3 Create a new Simulink model.
- 4 Add a MATLAB Function block to the model and double-click the block to open the editor.
- 5 Enter code that calls the `doubleIt` program:

```

function y = callingDoubleIt(u)
%#codegen

y = 0.0;
y = coder.ceval('doubleIt',u);

```

- 6 Connect a Constant block having a value of 3.5 to the input port of the MATLAB Function block.
- 7 Connect a Display block to the output port.

- 8 In the Configuration Parameters dialog box, open the **Simulation Target > Custom Code** pane.
- 9 In the **Include custom C code in generated** section, select **Header file** from the list, and enter `#include "doubleIt.h"` in the **Header file** text box.
- 10 In the **Include list of additional** section, select **Source files** from the list, enter `doubleIt.c` in the **Source files** text box, and click **OK**.

## 11 Simulate the model.

The value 7 appears in the Display block.

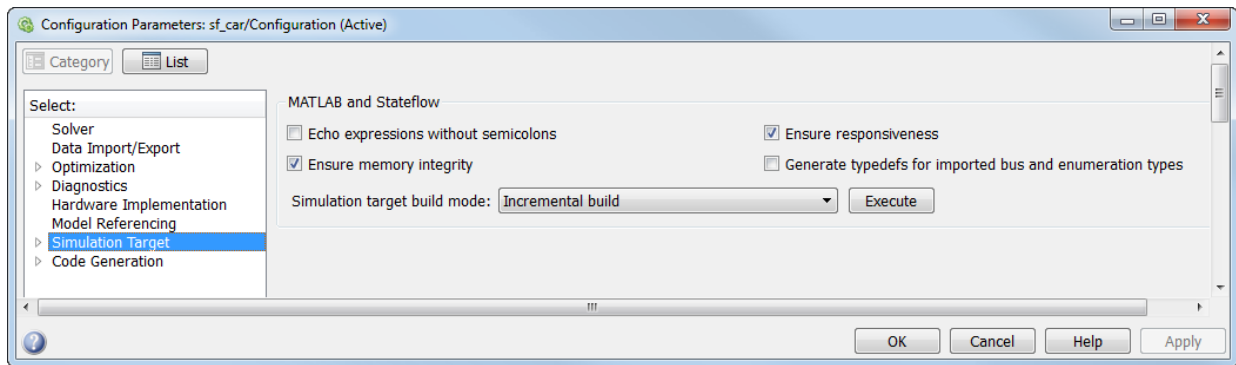

## Control Imported Bus and Enumeration Type Definitions

This procedure applies to simulation only.

Simulink generates code for MATLAB Function blocks and Stateflow to simulate the model. When you call external C code using MATLAB Function blocks or Stateflow,

you can control the type definitions for imported buses and enumerations in model simulation.

Simulink can generate type definitions, or you can supply a header file containing the type definitions. You control this behavior using the **Generate typedefs for imported bus and enumeration types** check box in the **Simulation Target** pane of the Configuration Parameters dialog box.

To include a custom header file defining the enumeration and bus types:

- 1 Clear the **Generate typedefs for imported bus and enumeration types** check box.
- 2 List the header file in the **Simulation Target > Custom Code** pane, in the **Header file** text box.

To configure Simulink to automatically generate type definitions:

- 1 Select the **Generate typedefs for imported bus and enumeration types** check box.
- 2 Do not list a header file that corresponds to the buses or enumerations.

For more information see “Simulation Target Pane: General”.

## Enhance Code Readability for MATLAB Function Blocks

### In this section...

“Requirements for Using Readability Optimizations” on page 37-151

“Converting If-Elseif-Else Code to Switch-Case Statements” on page 37-151

“Example of Converting Code for If-Elseif-Else Decision Logic to Switch-Case Statements” on page 37-153

### Requirements for Using Readability Optimizations

To use readability optimizations in your code, you must have an Embedded Coder license. These optimizations appear only in code that you generate for an embedded real-time (ert) target.

---

**Note:** These optimizations do not apply to MATLAB files that you call from the MATLAB Function block.

---

For more information, see “Code Generation Targets” and “Control Code Style” in the Embedded Coder documentation.

### Converting If-Elseif-Else Code to Switch-Case Statements

When you generate code for embedded real-time targets, you can choose to convert `if-elseif-else` decision logic to `switch-case` statements. This conversion can enhance readability of the code.

For example, when a MATLAB Function block contains a long list of conditions, the `switch-case` structure:

- Reduces the use of parentheses and braces
- Minimizes repetition in the generated code

#### How to Convert If-Elseif-Else Code to Switch-Case Statements

The following procedure describes how to convert generated code for the MATLAB Function block from `if-elseif-else` to `switch-case` statements.

| Step | Task   | Reference  |
|------|--|--|
| 1    | Verify that your block follows the rules for conversion. | “Verifying the Contents of the Block” on page 37-155 |
| 2    | Enable the conversion.                                   | “Enabling the Conversion” on page 37-156             |
| 3    | Generate code for your model.                            | “Generating Code for Your Model” on page 37-157      |

### Rules for Conversion

For the conversion to occur, the following rules must hold. LHS and RHS refer to the left-hand side and right-hand side of a condition, respectively.

| Construct             | Rules to Follow   |
|-----------------------|---|
| MATLAB Function block | <p>Must have two or more <i>unique</i> conditions, in addition to a default.</p> <p>For more information, see “How the Conversion Handles Duplicate Conditions” on page 37-153.</p> |
| Each condition        | Must test equality only.  |
|                       | Must use the same variable or expression for the LHS.   |
|                       | <b>Note:</b> You can reverse the LHS and RHS.   |
| Each LHS              | Must be a single variable or expression, not a compound statement.  |
|                       | Cannot be a constant.   |
|                       | Must have an integer or enumerated data type.   |
|                       | Cannot have any side effects on simulation.   |
|                       | For example, the LHS can read from but not write to global variables.   |
| Each RHS              | Must be a constant.   |
|                       | Must have an integer or enumerated data type.   |

## How the Conversion Handles Duplicate Conditions

If a MATLAB Function block has duplicate conditions, the conversion preserves only the first condition. The generated code discards all other instances of duplicate conditions.

After removal of duplicates, two or more unique conditions must exist. Otherwise, no conversion occurs and the generated code contains all instances of duplicate conditions.

The following examples show how the conversion handles duplicate conditions.

| Example of Generated Code   | Code After Conversion  |
|---|--|
| <pre>if (x == 1) {     block1 } else if (x == 2) {     block2 } else if (x == 1) { // duplicate     block3 } else if (x == 3) {     block4 } else if (x == 1) { // duplicate     block5 } else {     block6 }</pre> | <pre>switch (x) {     case 1:         block1; break;     case 2:         block2; break;     case 3:         block4; break;     default:         block6; break; }</pre> |
| <pre>if (x == 1) {     block1 } else if (x == 1) { // duplicate     block2 } else {     block3 }</pre>  | <p>No change, because only one unique condition exists</p>   |

## Example of Converting Code for If-Elseif-Else Decision Logic to Switch-Case Statements

Suppose that you have the following model with a MATLAB Function block. Assume that the output data type is `double` and the input data type is `Controller`, an enumerated type that you define. (For more information, see “Define Enumerated Data Types for MATLAB Function Blocks” on page 37-100.)

The block contains the following code:

```
function system = fcn(type)
%#codegen

if (type == Controller.P)
    system = 0;
elseif (type == Controller.I)
    system = 1;
elseif (type == Controller.PD)
    system = 2;
elseif (type == Controller.PI)
    system = 3;
elseif (type == Controller.PID)
    system = 4;
else
    system = 10;
end
```

The enumerated type definition in `Controller.m` is:

```
classdef Controller < Simulink.IntEnumType
    enumeration
        P(0)
        I(1)
        PD(2)
        PI(3)
        PID(4)
        UNKNOWN(10)
    end
end
```

If you generate code for an embedded real-time target using default settings, you see something like this:

```
if (if_to_switch_em1_blocks_U.In1 == P) {
```

```

/* '<S1>:1:4' */
/* '<S1>:1:5' */
if_to_switch_eml_blocks_Y.Out1 = 0.0;
} else if (if_to_switch_eml_blocks_U.In1 == I) {
/* '<S1>:1:6' */
/* '<S1>:1:7' */
if_to_switch_eml_blocks_Y.Out1 = 1.0;
} else if (if_to_switch_eml_blocks_U.In1 == PD) {
/* '<S1>:1:8' */
/* '<S1>:1:9' */
if_to_switch_eml_blocks_Y.Out1 = 2.0;
} else if (if_to_switch_eml_blocks_U.In1 == PI) {
/* '<S1>:1:10' */
/* '<S1>:1:11' */
if_to_switch_eml_blocks_Y.Out1 = 3.0;
} else if (if_to_switch_eml_blocks_U.In1 == PID) {
/* '<S1>:1:12' */
/* '<S1>:1:13' */
if_to_switch_eml_blocks_Y.Out1 = 4.0;
} else {
/* '<S1>:1:15' */
if_to_switch_eml_blocks_Y.Out1 = 10.0;
}

```

The LHS variable `if_to_switch_eml_blocks_U.In1` appears multiple times in the generated code.

---

**Note:** By default, variables that appear in the block do not retain their names in the generated code. Modified identifiers guarantee that no naming conflicts occur.

---

Traceability comments appear between each set of `/*` and `*/` markers. To learn more about traceability, see “Use Traceability in MATLAB Function Blocks” on page 37-138.

### Verifying the Contents of the Block

Check that the block follows all the rules in “Rules for Conversion” on page 37-152.

| Construct             | How the Construct Follows the Rules  |
|-----------------------|--|
| MATLAB Function block | Five unique conditions exist, in addition to the default: <ul style="list-style-type: none"> <li>(type == Controller.P)</li> </ul> |

| Construct      | How the Construct Follows the Rules  |
|----------------|--|
|                | <ul style="list-style-type: none"> <li>• (type == Controller.I)</li> <li>• (type == Controller.PD)</li> <li>• (type == Controller.PI)</li> <li>• (type == Controller.PID)</li> </ul>   |
| Each condition | Each condition: <ul style="list-style-type: none"> <li>• Tests equality</li> <li>• Uses the same input for the LHS</li> </ul>  |
| Each LHS       | Each LHS: <ul style="list-style-type: none"> <li>• Contains a single variable</li> <li>• Is the input to the block and therefore not a constant</li> <li>• Is of enumerated type <code>Controller</code>, which you define in <code>Controller.m</code> on the MATLAB path</li> <li>• Has no side effects on simulation</li> </ul> |
| Each RHS       | Each RHS: <ul style="list-style-type: none"> <li>• Is an enumerated value and therefore a constant</li> <li>• Is of enumerated type <code>Controller</code></li> </ul>   |

### Enabling the Conversion

- 1 Open the Configuration Parameters dialog box.
- 2 In the **Code Generation** pane, select `ert.tlc` for the **System target file**.

This step specifies an embedded real-time target for your model.

- 3 In the **Code Generation > Code Style** pane, select the **Convert if-elseif-else patterns to switch-case statements** check box.

---

**Tip** This conversion works on a per-model basis. If you select this check box, the conversion applies to:

- All MATLAB Function blocks in a model
- MATLAB functions in all Stateflow charts of that model

- Flow charts in all Stateflow charts of that model

For more information, see “Enhance Readability of Code for Flow Charts” in the Embedded Coder documentation.

---

## Generating Code for Your Model

In the **Code Generation** pane of the Configuration Parameters dialog box, click **Build** in the lower right corner.

The code for the MATLAB Function block uses `switch-case` statements instead of `if-elseif-else` code:

```
switch (if_to_switch_eml_blocks_U.In1) {
    case P:
        /* '<S1>:1:4' */
        /* '<S1>:1:5' */
        if_to_switch_eml_blocks_Y.Out1 = 0.0;
        break;

    case I:
        /* '<S1>:1:6' */
        /* '<S1>:1:7' */
        if_to_switch_eml_blocks_Y.Out1 = 1.0;
        break;

    case PD:
        /* '<S1>:1:8' */
        /* '<S1>:1:9' */
        if_to_switch_eml_blocks_Y.Out1 = 2.0;
        break;

    case PI:
        /* '<S1>:1:10' */
        /* '<S1>:1:11' */
        if_to_switch_eml_blocks_Y.Out1 = 3.0;
        break;

    case PID:
        /* '<S1>:1:12' */
        /* '<S1>:1:13' */
        if_to_switch_eml_blocks_Y.Out1 = 4.0;
        break;
```

```
default:
  /* '<S1>:1:15' */
  if_to_switch_eml_blocks_Y.Out1 = 10.0;
  break;
}
```

The **switch-case** statements provide the following benefits to enhance readability:

- The code reduces the use of parentheses and braces.
- The LHS variable `if_to_switch_eml_blocks_U.In1` appears only once, minimizing repetition in the code.

# Control Run-Time Checks

**In this section...**

“Types of Run-Time Checks” on page 37-159

“When to Disable Run-Time Checks” on page 37-159

“How to Disable Run-Time Checks” on page 37-160

## Types of Run-Time Checks

In simulation, the code generated for your MATLAB Function block includes the following run-time checks:

- Memory integrity checks

These checks detect violations of memory integrity in code generated for MATLAB Function blocks and stop execution with a diagnostic message.

---

**Caution** For safety, these checks are enabled by default. Without memory integrity checks, violations result in unpredictable behavior.

---

- Responsiveness checks in code generated for MATLAB Function blocks

These checks enable periodic checks for Ctrl+C breaks in the generated code. Enabling responsiveness checks also enables graphics refreshing.

---

**Caution** For safety, these checks are enabled by default. Without these checks, the only way to end a long-running execution might be to terminate MATLAB.

---

## When to Disable Run-Time Checks

Generally, generating code with run-time checks enabled results in more lines of generated code and slower simulation than generating code with the checks disabled. Disabling run-time checks usually results in streamlined generated code and faster simulation, with these caveats:

| Consider disabling:     | Only if:   |
|-------------------------|--|
| Memory integrity checks | You are sure that your code is safe and that all array bounds and dimension checking is unnecessary. |
| Responsiveness checks   | You are sure that you will not need to stop execution of your application using Ctrl+C.              |

## How to Disable Run-Time Checks

MATLAB Function blocks enable run-time checks by default, but you can disable them explicitly for all MATLAB Function blocks in your Simulink model. Follow these steps:

- 1 Open your MATLAB Function block.
- 2 In the MATLAB Function Block Editor, select **Simulation Target**.

The Configuration Parameters dialog box opens with **Simulation Target** selected.

- 3 Clear the **Ensure memory integrity** or **Ensure responsiveness** check boxes, as applicable, and click **Apply**.

# Track Object Using MATLAB Code

## In this section...

- “Tutorial Prerequisites” on page 37-161
- “Example: The Kalman Filter” on page 37-162
- “Files for the Tutorial” on page 37-165
- “Tutorial Steps” on page 37-166
- “Best Practices Used in This Tutorial” on page 37-184
- “Key Points to Remember” on page 37-185
- “Where to Learn More” on page 37-185

## Learning Objectives

In this tutorial, you will learn how to:

- Use the MATLAB Function block to add MATLAB functions to Simulink models for modeling, simulation, and deployment to embedded processors.

This capability is useful for coding algorithms that are better stated in the textual language of MATLAB than in the graphical language of Simulink.

- Use `coder.extrinsic` to call MATLAB code from a MATLAB Function block.

This capability allows you to do rapid prototyping. You can call existing MATLAB code from Simulink without having to make this code suitable for code generation.

- Check that existing MATLAB code is suitable for code generation before generating code.

You must prepare your code before generating code.

- Specify variable-size inputs when generating code.

## Tutorial Prerequisites

- “What You Need to Know” on page 37-162
- “Required Products” on page 37-162

## What You Need to Know

To complete this tutorial, you should have basic familiarity with MATLAB software. You should also understand how to create and simulate a basic Simulink model.

## Required Products

To complete this tutorial, you must install the following products:

- MATLAB
- MATLAB Coder
- Simulink
- Simulink Coder
- C compiler

For a list of supported compilers, see [http://www.mathworks.com/support/compilers/current\\_release/](http://www.mathworks.com/support/compilers/current_release/).

You must set up the C compiler before generating C code. See “Setting Up Your C Compiler” on page 37-167.

For instructions on installing MathWorks products, see the MATLAB installation documentation for your platform. If you have installed MATLAB and want to check which other MathWorks products are installed, enter `ver` in the MATLAB Command Window.

## Example: The Kalman Filter

- “Description” on page 37-162
- “Algorithm” on page 37-163
- “Filtering Process” on page 37-164
- “Reference” on page 37-165

## Description

This section describes the example used by the tutorial. You do not have to be familiar with the algorithm to complete the tutorial.

The example for this tutorial uses a Kalman filter to estimate the position of an object moving in a two-dimensional space from a series of noisy inputs based on past positions.

The position vector has two components,  $x$  and  $y$ , indicating its horizontal and vertical coordinates.

Kalman filters have a wide range of applications, including control, signal and image processing; radar and sonar; and financial modeling. They are recursive filters that estimate the state of a linear dynamic system from a series of incomplete or noisy measurements. The Kalman filter algorithm relies on the state-space representation of filters and uses a set of variables stored in the state vector to characterize completely the behavior of the system. It updates the state vector linearly and recursively using a state transition matrix and a process noise estimate.

### Algorithm

This section describes the algorithm of the Kalman filter and is implemented in the MATLAB version of the filter supplied with this tutorial.

The algorithm predicts the position of a moving object based on its past positions using a Kalman filter estimator. It estimates the present position by updating the Kalman state vector, which includes the position ( $x$  and  $y$ ), velocity ( $V_x$  and  $V_y$ ), and acceleration ( $A_x$  and  $A_y$ ) of the moving object. The Kalman state vector, `x_est`, is a persistent variable.

```
% Initial conditions
persistent x_est p_est
if isempty(x_est)
    x_est = zeros(6, 1);
    p_est = zeros(6, 6);
end
```

`x_est` is initialized to an empty 6x1 column vector and updated each time the filter is used.

The Kalman filter uses the laws of motion to estimate the new state:

$$X = X_0 + V_x \cdot dt$$

$$Y = Y_0 + V_y \cdot dt$$

$$V_x = V_{x_0} + A_x \cdot dt$$

$$V_y = V_{y_0} + A_y \cdot dt$$

These laws of motion are captured in the state transition matrix  $A$ , which is a matrix that contains the coefficient values of  $x$ ,  $y$ ,  $V_x$ ,  $V_y$ ,  $A_x$ , and  $A_y$ .

```

% Initialize state transition matrix
dt=1;
A=[ 1 0 dt 0 0 0;...
    0 1 0 dt 0 0;...
    0 0 1 0 dt 0;...
    0 0 0 1 0 dt;...
    0 0 0 0 1 0 ;...
    0 0 0 0 0 1 ];

```

### Filtering Process

The filtering process has two phases:

- Predicted state and covariance

The Kalman filter uses the previously estimated state,  $x_{est}$ , to predict the current state,  $x_{prd}$ . The predicted state and covariance are calculated in:

```

% Predicted state and covariance
x_prd = A * x_est;
p_prd = A * p_est * A' + Q;

```

- Estimation

The filter also uses the current measurement,  $z$ , and the predicted state,  $x_{prd}$ , to estimate a more accurate approximation of the current state. The estimated state and covariance are calculated in:

```

% Measurement matrix
H = [ 1 0 0 0 0 0; 0 1 0 0 0 0 ];
Q = eye(6);
R = 1000 * eye(2);

% Estimation
S = H * p_prd' * H' + R;
B = H * p_prd';
klm_gain = (S \ B)';

% Estimated state and covariance
x_est = x_prd + klm_gain * (z - H * x_prd);
p_est = p_prd - klm_gain * H * p_prd;

% Compute the estimated measurements
y = H * x_est;

```

## Files for the Tutorial

- “About the Tutorial Files” on page 37-165
- “Location of Files” on page 37-165
- “Names and Descriptions of Files” on page 37-165

### About the Tutorial Files

The tutorial uses the following files:

- Simulink model files for each step of the tutorial.
- Example MATLAB code files for each step of the tutorial.

Throughout this tutorial, you work with Simulink models that call MATLAB files containing a Kalman filter algorithm.

- A MAT-file that contains example input data.
- A MATLAB file for plotting.

### Location of Files

The tutorial files are available in the following folder: `docroot\toolbox\simulink\examples\kalman`. To run the tutorial, you must copy these files to a local folder. For instructions, see “Copying Files Locally” on page 37-167.

### Names and Descriptions of Files

| Type                        | Name        | Description   |
|-----------------------------|-------------|---|
| MATLAB<br>function<br>files | ex_kalman01 | Baseline MATLAB implementation of a scalar Kalman filter.       |
|                             | ex_kalman02 | Version of the original algorithm suitable for code generation. |

| Type                 | Name            | Description   |
|----------------------|-----------------|---|
|                      | ex_kalman03     | Version of Kalman filter suitable for code generation and for use with frame-based and packet-based inputs.       |
|                      | ex_kalman04     | Disabled inlining for code generation.  |
| Simulink model files | ex_kalman00     | Simulink model without a MATLAB Function block.   |
|                      | ex_kalman11     | Complete Simulink model with a MATLAB Function block for scalar Kalman filter.                                    |
|                      | ex_kalman22     | Simulink model with a MATLAB Function block for a Kalman filter that accepts fixed-size (frame-based) inputs.     |
|                      | ex_kalman33     | Simulink model with a MATLAB Function block for a Kalman filter that accepts variable-size (packet-based) inputs. |
|                      | ex_kalman44     | Simulink model to call <code>ex_kalman04.m</code> , which has inlining disabled.                                  |
| MATLAB data file     | position        | Contains the input data used by the algorithm.  |
| Plot files           | plot_trajectory | Plots the trajectory of the object and the Kalman filter estimated position.                                      |

## Tutorial Steps

- “Copying Files Locally” on page 37-167
- “Setting Up Your C Compiler” on page 37-167
- “About the ex\_kalman00 Model” on page 37-168
- “Adding a MATLAB Function Block to Your Model” on page 37-169
- “Checking the ex\_kalman11 Model” on page 37-171
- “Simulating the ex\_kalman11 Model” on page 37-172
- “Modifying the Filter to Accept a Fixed-Size Input” on page 37-174
- “Using the Filter to Accept a Variable-Size Input” on page 37-178
- “Debugging the MATLAB Function Block” on page 37-181

- “Generating C Code” on page 37-182

### Copying Files Locally

Copy the tutorial files to a local working folder:

- 1 Create a local *solutions* folder, for example, `c:\simulink\kalman\solutions`.
- 2 Change to the `docroot\toolbox\simulink\examples` folder. At the MATLAB command line, enter:

```
cd(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
```

- 3 Copy the contents of the `kalman` subfolder to your local *solutions* folder, specifying the full path name of the *solutions* folder:

```
copyfile('kalman', 'solutions')
```

For example:

```
copyfile('kalman', 'c:\simulink\kalman\solutions')
```

Your *solutions* folder now contains a complete set of solutions for the tutorial. If you do not want to perform the steps for each task in the tutorial, you can view the solutions to see how the code should look.

- 4 Create a local *work* folder, for example, `c:\simulink\kalman\work`.
- 5 Copy the following files from your *solutions* folder to your *work* folder.
  - `ex_kalman01`
  - `ex_kalman00`
  - `position`
  - `plot_trajectory`

Your *work* folder now contains all the files that you need to get started with the tutorial.

### Setting Up Your C Compiler

Building your MATLAB Function block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-supported compilers installed on your system, you can change the default using the `mex -setup` command. See “Change Default Compiler”.

### About the `ex_kalman00` Model

First, examine the `ex_kalman00` model supplied with the tutorial to understand the problem that you are trying to solve using the Kalman filter.

- 1 Open the `ex_kalman00` model in Simulink:
  - a Set your MATLAB current folder to the folder that contains your working files for this tutorial. At the MATLAB command line, enter:

```
cd work
where work is the full path name of the folder containing your files.
```

- b At the MATLAB command line, enter:

```
ex_kalman00
```

This model is an incomplete model to demonstrate how to integrate MATLAB code with Simulink. The complete model is `ex_kalman11`, which is also supplied with this tutorial.

### InitFcn Model Callback Function

The model uses this callback function to:

- Load position data from a MAT-file.
- Set up data used by the Index generator block, which provides the second input to the Selector block.

To view this callback:

- 1 Select **File > Model Properties > Model Properties**.
- 2 Select the **Callbacks** tab.
- 3 Select `InitFcn` in the **Model callbacks** pane.

The callback appears.

```
load position.mat;
[R,C]=size(position);
idx=(1:C)';
t=idx-1;
```

### Source Blocks

The model uses two Source blocks to provide position data and a scalar index to a Selector block.

### Selector Block

The model uses a Selector block that selects elements of its input signal and generates an output signal based on its index input and its **Index Option** settings. By changing the configuration of this block, you can generate different size signals.

To view the Selector block settings, double-click the Selector block to view the function block parameters.

In this model, the **Index Option** for the first port is **Select all** and for the second port is **Index vector (port)**. Because the input is a  $2 \times 310$  position matrix, and the index data increments from 1 to 310, the Selector block simply outputs one  $2 \times 1$  output at each sample time.

### MATLAB Function Block

The model uses a MATLAB Function block to plot the trajectory of the object and the Kalman filter estimated position. This function:

- First declares the `figure`, `hold`, and `plot_trajectory` functions as extrinsic because these MATLAB visualization functions are not supported for code generation. When you call an unsupported MATLAB function, you must declare it to be extrinsic so MATLAB can execute it, but does not try to generate code for it.
- Creates a figure window and holds it for the duration of the simulation. Otherwise a new figure window appears for each sample time.
- Calls the `plot_trajectory` function, which plots the trajectory of the object and the Kalman filter estimated position.

### Simulation Stop Time

The simulation stop time is 309, because the input to the filter is a vector containing 310 elements and Simulink uses zero-based indexing.

### Adding a MATLAB Function Block to Your Model

To modify the model and code yourself, work through the exercises in this section. Otherwise, open the supplied model `ex_kalman11` in your *solutions* subfolder to see the modified model.

For the purposes of this tutorial, you add the MATLAB Function block to the `ex_kalman00.mdl` model supplied with the tutorial. You would have to develop your own test bench starting with an empty Simulink model.

### Adding the MATLAB Function Block

To add a MATLAB Function block to the `ex_kalman00` model:

- 1** Open `ex_kalman00` in Simulink.  
`ex_kalman00`
- 2** Add a MATLAB Function block to the model:
  - a** At the MATLAB command line, type `simulink` to open the Simulink Library Browser.
  - b** From the list of Simulink libraries, select the `User-Defined Functions` library.
  - c** Click the MATLAB Function block and drag it into the `ex_kalman00` model. Place the block just above the red text annotation that reads `Place MATLAB Function Block here`.
  - d** Delete the red text annotations from the model.
  - e** Save the model in the current folder as `ex_kalman11`.

### Calling Your MATLAB Code from the MATLAB Function Block

To call your MATLAB code from the MATLAB Function block:

- 1** Double-click the MATLAB Function block to open the MATLAB Function Block Editor.
- 2** Delete the default code displayed in the editor.
- 3** Copy the following code to the MATLAB Function block.

```
function y = kalman(u)
%#codegen

y = ex_kalman01(u);
```

- 4** Save the model.

### Connecting the MATLAB Function Block Input and Output

- 1** Connect the MATLAB Function block input and output so that your model looks like this.

- 2 Save the model.

### Checking the `ex_kalman11` Model

To check the model:

- 1 In the Simulink model window, select **Simulation > Update Diagram**.

Simulink checks the model and generates a warning telling you to add the `%#codegen` compilation directive to the `ex_kalman01` file. Adding this directive indicates that the file is intended for code generation and turns on code generation error checking.

- 2 Open `ex_kalman01` file and add the `%#codegen` compilation directive after the function declaration.

```
function y = ex_kalman01(z) %#codegen
```

- 3 Modify the function name to `ex_kalman02` and save the file as `ex_kalman02.m`.

- 4 Modify the model to call `ex_kalman02` by updating the code in the MATLAB Function block.

```
function y = kalman(u)
%#codegen
```

```
y = ex_kalman02(u);
```

- 5 Save the model and update diagram again.

This time the model updates successfully.

You are now ready to simulate your model, as described in “Simulating the `ex_kalman11` Model” on page 37-172.

### **Simulating the ex\_kalman11 Model**

To simulate the model:

- 1** In the Simulink model window, select **Simulation > Run**.

As Simulink runs the model, it plots the trajectory of the object in blue and the Kalman filter estimated position in green. Initially, you see that it takes a short time for the estimated position to converge with the actual position of the object. Then three sudden shifts in position occur—each time the Kalman filter readjusts and tracks the object after a few iterations.

**2** The simulation stops.

You have proved that your MATLAB algorithm works in Simulink. You are now ready to modify the filter to accept a fixed-size input, as described in “Modifying the Filter to Accept a Fixed-Size Input” on page 37-174.

## Modifying the Filter to Accept a Fixed-Size Input

The filter you have worked on so far in this tutorial uses a simple batch process that accepts one input at a time, so you must call the function repeatedly for each input. In this part of the tutorial, you learn how to modify the algorithm to accept a fixed-sized input, which makes the algorithm suitable for frame-based processing. You then modify the model to provide the input as fixed-size frames of data and call the filter passing in the data one frame at a time.

### Modifying Your MATLAB Code

To modify the code yourself, work through the exercises in this section. Otherwise, open the supplied file `ex_kalman03.m` in your *solutions* subfolder to see the modified algorithm.

You can now modify the algorithm to process a vector containing more than one input. You need to find the length of the vector and call the filter code for each element in the vector in turn. You do this by calling the filter algorithm in a `for` loop.

- 1 Open `ex_kalman02.m` in the MATLAB Editor. At the MATLAB command line, enter:

```
edit ex_kalman02.m
```

- 2 Add a `for` loop around the filter code.

- a Before the comment:

```
% Predicted state and covariance  
insert:
```

```
for i=1:size(z,2)
```

- b After:

```
% Compute the estimated measurements  
y = H * x_est;  
insert:
```

```
end
```

- c Select the code between the `for` statement and the end statement, right-click to open the context menu and select **Smart Indent** to indent the code.

Your filter code should now look like this:

```

for i=1:size(z,2)
    % Predicted state and covariance
    x_prd = A * x_est;
    p_prd = A * p_est * A' + Q;

    % Estimation
    S = H * p_prd' * H' + R;
    B = H * p_prd';
    klm_gain = (S \ B)';

    % Estimated state and covariance
    x_est = x_prd + klm_gain * (z - H * x_prd);
    p_est = p_prd - klm_gain * H * p_prd;

    % Compute the estimated measurements
    y = H * x_est;
end

```

- 3** Modify the line that calculates the estimated state and covariance to use the  $i^{\text{th}}$  element of input  $z$ .

Change:

```

x_est = x_prd + klm_gain * (z - H * x_prd);
to:

```

```

x_est = x_prd + klm_gain * (z(1:2,i) - H * x_prd);

```

- 4** Modify the line that computes the estimated measurements to append the result to the  $i^{\text{th}}$  element of the output  $y$ .

Change:

```

y = H * x_est;
to:

```

```

y(:,i) = H * x_est;

```

The code analyzer message indicator in the top right turns orange to indicate that the code analyzer has detected warnings. The code analyzer underlines the offending code in orange and places a orange marker to the right.

- 5** Move your pointer over the orange marker to view the error information.

The code analyzer detects that `y` must be fully defined before sub-scripting it and that you cannot grow variables through indexing in generated code.

- 6 To address this warning, preallocate memory for the output `y`, which is the same size as the input `z`. Add this code before the `for` loop.

```
% Pre-allocate output signal:  
y=zeros(size(z));
```

The orange marker disappears and the code analyzer message indicator in the top right edge of the code turns green, which indicates that you have fixed all the errors and warnings detected by the code analyzer.

### Why Preallocate the Outputs?

You must preallocate outputs here because the code generation does not support increasing the size of an array over time. Repeatedly expanding the size of an array over time can adversely affect the performance of your program. See “Preallocating Memory”.

- 7 Change the function name to `ex_kalman03` and save the file as `ex_kalman03.m` in the current folder.

You are ready to begin the next task in the tutorial, “Modifying Your Model to Call the Updated Algorithm” on page 37-176.

### Modifying Your Model to Call the Updated Algorithm

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `ex_kalman22.mdl` in your *solutions* subfolder to see the modified model.

Next, update your model to provide the input as fixed-size frames of data and call `ex_kalman03` passing in the data one frame at a time.

- 1 Open `ex_kalman11` model in Simulink.

```
ex_kalman11
```

- 2 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.

- 3 Replace the code that calls `ex_kalman02` with a call to `ex_kalman03`.

```
function y = kalman(u)
```

```
##codegen
```

```
y = ex_kalman03(u);
```

4 Close the editor.

5 Modify the InitFcn callback:

a Select **File > Model Properties > Model Properties**.

The Model Properties dialog box opens.

b In this dialog box, select the **Callbacks** tab.

c Select InitFcn in the **Model callbacks** pane.

d Replace the existing callback with:

```
load position.mat;
[R,C]=size(position);
FRAME_SIZE=5;
idx=(1:FRAME_SIZE:C)';
LEN=length(idx);
t=(1:LEN)' - 1;
```

This callback sets the frame size to 5, and the index to increment by 5.

e Click **Apply** and close the Model Properties dialog box.

6 Update the Selector block to use the correct indices.

a Double-click the Selector block to view the function block parameters.

The Function Block Parameters dialog box opens.

b Set the second **Index Option** to **Starting index (port)**.

c Set the **Output Size** for the second input to `FRAME_SIZE`, click **Apply** and close the dialog box.

Now, the **Index Option** for the first port is **Select all** and for the second port is **Starting index (port)**. Because the index increments by 5 each sample time, and the output size is 5, the Selector block outputs a  $2 \times 5$  output at each sample time.

7 Change the model simulation stop time to 61. Now the frame size is 5, so the simulation completes in a fifth of the sample times.

a In the Simulink model window, select **Simulation > Model Configuration Parameters**.

- b** In the left pane of the Configuration Parameters dialog box, select **Solver**.
  - c** In the right pane, set **Stop time** to **61**.
  - d** Click **Apply** and close the dialog box.
- 8** Save the model as `ex_kalman22.mdl`.

### Testing Your Modified Algorithm

To simulate the model:

- 1** In the Simulink model window, select **Simulation > Run**.

As Simulink runs the model, it plots the trajectory of the object in blue and the Kalman filter estimated position in green as before when you used the batch filter.

- 2** The simulation stops.

You have proved that your algorithm accepts a fixed-size signal. You are now ready for the next task, “Using the Filter to Accept a Variable-Size Input” on page 37-178.

### Using the Filter to Accept a Variable-Size Input

In this part of the tutorial, you learn how to specify variable-size data in your Simulink model. Then you test your Kalman filter algorithm with variable-size inputs and see that the algorithm is suitable for processing packets of data of varying size. For more information on using variable-size data in Simulink, see “Variable-Size Signal Basics” on page 62-2.

### Updating the Model to Use Variable-Size Inputs

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `ex_kalman33.mdl` in your *solutions* subfolder to see the modified model.

- 1** Open `ex_kalman22.mdl` in Simulink.
- `ex_kalman22`
- 2** Modify the `InitFcn` callback:
- a** Select **File > Model Properties > Model Properties**.

The Model Properties dialog box opens.

- b** Select the **Callbacks** tab.
- c** Select **InitFcn** in the **Model callbacks** pane.
- d** Replace the existing callback with:

```
load position.mat;
idx=[ 1 1 ;2 3 ;4 6 ;7 10 ;11 15 ;16 30 ;
      31 70 ;71 100 ;101 200 ;201 250 ;251 310];
LEN=length(idx);
t=(0:1:LEN-1)';
```

This callback sets up indexing to generate eleven different size inputs. It specifies the start and end indices for each sample time. The first sample time uses only the first element, the second sample time uses the second and third elements, and so on. The largest sample, 101 to 200, contains 100 elements.

- e** Click **Apply** and close the **Model Properties** dialog box.
- 3** Update the Selector block to use the correct indices.
- a** Double-click the Selector block to view the function block parameters.  
The Function Block Parameters dialog box opens.
  - b** Set the second **Index Option** to **Starting and ending indices (port)**, then click **Apply** and close the dialog box.  
  
This setting means that the input to the index port specifies the start and end indices for the input at each sample time. Because the index input specifies different starting and ending indices at each sample time, the Selector block outputs a variable-size signal as the simulation progresses.
- 4** Use the Ports and Data Manager to set the MATLAB Function input **x** and output **y** as variable-size data.
- a** Double-click the MATLAB Function block to open the MATLAB Function Block Editor.
  - b** From the editor menu, select **Edit Data**.
  - c** In the Ports and Data Manager left pane, select the input **u**.  
  
The Ports and Data Manager displays information about **u** in the right pane.
  - d** On the **General** tab, select the **Variable size** check box and click **Apply**.
  - e** In the left pane, select the output **y**.
  - f** On the **General** tab:

- i Set the **Size** of  $y$  to  $[2\ 100]$  to specify a 2-D matrix where the upper bounds are 2 for the first dimension and 100 for the second, which is the maximum size input specified in the `InitFcn` callback.
      - ii Select the **Variable size** check box.
      - iii Click **Apply**.
    - g Close the Ports and Data Manager.
- 5 Now do the same for the other MATLAB Function block. Use the Ports and Data Manager to set the Visualizing block inputs  $y$  and  $z$  as variable-size data.
  - a Double-click the Visualizing block to open the MATLAB Function Block Editor.
  - b From the editor menu, select **Edit Data**.
  - c In the Ports and Data Manager left pane, select the input  $y$ .
  - d On the **General** tab, select the **Variable size** check box and click **Apply**.
  - e In the left pane, select the input  $z$ .
  - f On the **General** tab, select the **Variable size** check box and click **Apply**.
  - g Close the Ports and Data Manager.
- 6 Change the model simulation stop time to 10. This time, the filter processes one of the eleven different size inputs each sample time.
- 7 Save the model as `ex_kalman33.mdl`.

#### Testing Your Modified Model

To simulate the model:

- 1 In the Simulink model window, select **Simulation > Run**.

As Simulink runs the model, it plots the trajectory of the object in blue and the Kalman filter estimated position in green as before.

Note that the signal lines between the Selector block and the Tracking and Visualization blocks change to show that these signals are variable-size.

- 2 The simulation stops.

You have successfully created an algorithm that accepts variable-size inputs. Next, you learn how to debug your MATLAB Function block, as described in “Debugging the MATLAB Function Block” on page 37-181.

## Debugging the MATLAB Function Block

You can debug your MATLAB Function block just like you can debug a function in MATLAB.

- 1 Double-click the MATLAB Function block that calls the Kalman filter to open the MATLAB Function Block Editor.

- 2 In the editor, click the dash (-) character in the left margin of the line:

```
y = kalman03(u);
```

A small red ball appears in the margin of this line, indicating that you have set a breakpoint.

- 3 In the Simulink model window, select **Simulation > Run**.

The simulation pauses when execution reaches the breakpoint and a small green arrow appears in the left margin.

- 4 Place the pointer over the variable `u`.

The value of `u` appears adjacent to the pointer.

- 5 From the MATLAB Function Block Editor menu, select **Step In**.

The `kalman03.m` file opens in the editor and you can now step through this code using **Step**, **Step In**, and **Step Out**.

- 6 Select **Step Out**.

The `kalman03.m` file closes and the MATLAB Function block code reappears in the editor.

- 7 Place the pointer over the output variable `y`.

You can now see the value of `y`.

- 8 Click the red ball to remove the breakpoint.
- 9 From the MATLAB Function Block Editor menu, select **Quit Debugging**.
- 10 Close the editor.
- 11 Close the figure window.

Now you are ready for the next task, “Generating C Code” on page 37-182.

## Generating C Code

You have proved that your algorithm works in Simulink. Next you generate code for your model.

---

**Note:** Before generating code, you must check that your MATLAB code is suitable for code generation. If you call your MATLAB code as an extrinsic function, you must remove extrinsic calls before generating code.

---

- 1 Rename the MATLAB Function block to **Tracking**. To rename the block, double-click the annotation **MATLAB Function** below the MATLAB Function block and replace the text with **Tracking**.

When you generate code for the MATLAB Function block, Simulink Coder uses the name of the block in the generated code. It is good practice to use a meaningful name.

- 2 Before generating code, ensure that Simulink Coder creates a code generation report. This HTML report provides easy access to the list of generated files with a summary of the configuration settings used to generate the code.

- a In the Simulink model window, select **Simulation > Model Configuration Parameters**.

The Configuration Parameters dialog box opens.

- b In the left pane of the Configuration Parameters dialog box, select **Report** under **Code Generation**.

- c In the right pane, select **Create code generation report**.

The **Open report automatically** option is also selected.

- d Click **Apply** and close the Configuration Parameters dialog box.

- e Save your model.

- 3 To generate code for the Tracking block:

- a In your model, select the Tracking block.

- b In the Simulink model window, select **Code > C/C++ Code > Build Selected Subsystem**.

- 4 The Simulink software generates an error informing you that it cannot log variable-size signals as arrays. You need to change the format of data saved to the MATLAB workspace. To change this format:

- In the Simulink model window, select **Simulation > Model Configuration Parameters**.

The Configuration Parameters dialog box opens.

- In the left pane of the Configuration Parameters dialog box, select **Data Import/Export**.
- In the right pane, under **Save to workspace options**, set **Format** to **Structure with time**.

The logged data is now a structure that has two fields: a time field and a signals field, enabling Simulink to log variable-size signals.

- Click **Apply** and close the Configuration Parameters dialog box.
- Save your model.

- 5 Repeat step 3 to generate code for the Tracking block.

The Simulink Coder software generates C code for the block and launches the code generation report.

For more information on using the code generation report, see “Reports for Code Generation”.

- 6 In the left pane of the code generation report, click the **Tracking.c** link to view the generated C code. Note that in the code generated for the MATLAB Function block, **Tracking**, there is no code for the `ex_kalman03` function because inlining is enabled by default.
- 7 Modify your filter algorithm to disable inlining:

- a In `ex_kalman03.m`, after the function declaration, add:

```
coder.inline('never');
```

- b Change the function name to `ex_kalman04` and save the file as `ex_kalman04.m` in the current folder.

- c In your `ex_kalman33` model, double-click the Tracking block.

The MATLAB Function Block Editor opens.

- d Modify the call to the filter algorithm to call `ex_kalman04`.

```
function y = kalman(u)
    %#codegen
```

```
    y = ex_kalman04(u);
```

- e Save the model as `ex_kalman44.mdl`.

- 8 Generate code for the updated model.

- a Select the Tracking block.

- b In the model window, select **Code > C/C++Code > Build Selected Subsystem**.

The **Build code for Subsystem** dialog box appears.

- c Click the **Build** button.

The Simulink Coder software generates C code for the block and launches the code generation report.

- d In the left pane of the code generation report, click the `Tracking.c` link to view the generated C code.

This time the `ex_kalman04` function has code because you disabled inlining.

```
/* Forward declaration for local functions */
static void Tracking_ex_kalman04(const real_T z_data[620], const int32_T
    z_sizes[2], real_T y_data[620], int32_T y_sizes[2]);

/* Function for MATLAB Function Block: '<Root>/Tracking' */
static void Tracking_ex_kalman04(const real_T z_data[620], const int32_T    48
    z_sizes[2], real_T y_data[620], int32_T y_sizes[2])
```

## Best Practices Used in This Tutorial

### Best Practice — Saving Incremental Code Updates

Save your code before making modifications. This practice provides a fallback in case of error and a baseline for testing and validation. Use a consistent file naming convention. For example, add a two-digit suffix to the file name for each file in a sequence.

## Key Points to Remember

- Back up your MATLAB code before you modify it.
- Decide on a naming convention for your files and save interim versions frequently. For example, this tutorial uses a two-digit suffix to differentiate the various versions of the filter algorithm.
- For simulation purposes, before generating code, call your MATLAB code using `coder.extrinsic` to check that your algorithm is suitable for use in Simulink. This practice provides these benefits:
  - You do not have to make the MATLAB code suitable for code generation.
  - You can debug your MATLAB code in MATLAB while calling it from Simulink.
- Create a Simulink Coder code generation report. This HTML report provides easy access to the list of generated files with a summary of the configuration settings used to generate the code.

# Filter Audio Signal Using MATLAB Code

## In this section...

- “Learning Objectives” on page 37-187
- “Tutorial Prerequisites” on page 37-187
- “Example: The LMS Filter” on page 37-188
- “Files for the Tutorial” on page 37-191
- “Tutorial Steps” on page 37-192

## Learning Objectives

In this tutorial, you will learn how to:

- Use the MATLAB Function block to add MATLAB functions to Simulink models for modeling, simulation, and deployment to embedded processors.

This capability is useful for coding algorithms that are better stated in the textual language of MATLAB than in the graphical language of Simulink. For more information, see “What Is a MATLAB Function Block?” on page 37-5 and “Create Model That Uses MATLAB Function Block” on page 37-9.

- Use `coder.extrinsic` to call MATLAB code from a MATLAB Function block.

This capability allows you to call existing MATLAB code from Simulink without first having to make this code suitable for code generation, allowing for rapid prototyping.

- Check that existing MATLAB code is suitable for code generation.
- Convert a MATLAB algorithm from batch processing to streaming.
- Use persistent variables in code that is suitable for code generation.

You need to make the filter weights persistent so that the filter algorithm does not reset their values each time it runs.

## Tutorial Prerequisites

- “What You Need to Know” on page 37-188
- “Required Products” on page 37-188

## What You Need to Know

To work through this tutorial, you should have basic familiarity with MATLAB software. You should also understand how to create a basic Simulink model and how to simulate that model. For more information, see “Create a Simple Model”.

## Required Products

To complete this tutorial, you must install the following products:

- MATLAB
- MATLAB Coder
- Simulink
- Simulink Coder
- DSP System Toolbox

---

**Note:** If you do not have a DSP System Toolbox license, see “Track Object Using MATLAB Code” on page 37-161.

---

- C compiler

For a list of supported compilers, see [http://www.mathworks.com/support/compilers/current\\_release/](http://www.mathworks.com/support/compilers/current_release/).

For instructions on installing MathWorks products, refer to the installation documentation. If you have installed MATLAB and want to check which other MathWorks products are installed, enter `ver` in the MATLAB Command Window. For instructions on installing and setting up a C compiler, see “Setting Up the C or C++ Compiler”.

## Example: The LMS Filter

- “Description” on page 37-189
- “Algorithm” on page 37-189
- “Filtering Process” on page 37-190
- “Reference” on page 37-191

## Description

A least mean squares (LMS) filter is an adaptive filter that adjusts its transfer function according to an optimizing algorithm. You provide the filter with an example of the desired signal together with the input signal. The filter then calculates the filter weights, or coefficients, that produce the least mean squares of the error between the output signal and the desired signal.

This example uses an LMS filter to remove the noise in a music recording. There are two inputs. The first input is the distorted signal: the music recording plus the filtered noise. The second input is the desired signal: the unfiltered noise. The filter works to eliminate the difference between the output signal and the desired signal and outputs the difference, which, in this case, is the clean music recording. When you start the simulation, you hear both the noise and the music. Over time, the adaptive filter removes the noise so you hear only the music.

## Algorithm

This example uses the least mean squares (LMS) algorithm to remove noise from an input signal. The LMS algorithm computes the filtered output, filter error, and filter weights given the distorted and desired signals.

At the start of the tutorial, the LMS algorithm uses a batch process to filter the audio input. This algorithm is suitable for MATLAB, where you are likely to load in the entire signal and process it all at once. However, a batch process is not suitable for processing a signal in real time. As you work through the tutorial, you refine the design of the filter to convert the algorithm from batch-based to stream-based processing.

The baseline function signature for the algorithm is:

```
function [ signal_out, err, weights ] = ...
    lms_01(signal_in, desired)
```

The filtering is performed in the following loop:

```
for n = 1:SignalLength
    % Compute the output sample using convolution:
    signal_out(n,ch) = weights' * signal_in(n:n+FilterLength-1,ch);
    % Update the filter coefficients:
    err(n,ch) = desired(n,ch) - signal_out(n,ch) ;
    weights = weights + mu*err(n,ch)*signal_in(n:n+FilterLength-1,ch);
end
```

where `SignalLength` is the length of the input signal, `FilterLength` is the filter length, and `mu` is the adaptation step size.

### What Is the Adaptation Step Size?

LMS algorithms have a step size that determines the amount of correction to apply as the filter adapts from one iteration to the next. Choosing the appropriate step size requires experience in adaptive filter design. A step size that is too small increases the time for the filter to converge. Filter convergence is the process where the error signal (the difference between the output signal and the desired signal) approaches an equilibrium state over time. A step size that is too large might cause the adapting filter to overshoot the equilibrium and become unstable. Generally, smaller step sizes improve the stability of the filter at the expense of the time it takes to adapt.

### Filtering Process

The filtering process has three phases:

- Convolution

The convolution for the filter is performed in:

```
signal_out(n,ch) = weights' * signal_in(n:n+FilterLength-1,ch);
```

### What Is Convolution?

Convolution is the mathematical foundation of filtering. In signal processing, convolving two vectors or matrices is equivalent to filtering one of the inputs by the other. In this implementation of the LMS filter, the convolution operation is the vector dot product between the filter weights and a subset of the distorted input signal.

- Calculation of error

The error is the difference between the desired signal and the output signal:

```
err(n,ch) = desired(n,ch) - signal_out(n,ch);
```

- Adaptation

The new value of the filter weights is the old value of the filter weights plus a correction factor that is based on the error signal, the distorted signal, and the adaptation step size:

```
weights = weights + mu*err(n,ch)*signal_in(n:n+FilterLength-1,ch);
```

## Files for the Tutorial

- “About the Tutorial Files” on page 37-191
- “Location of Files” on page 37-191
- “Names and Descriptions of Files” on page 37-191

## About the Tutorial Files

The tutorial uses the following files:

- Simulink model files for each step of the tutorial.
- MATLAB code files for each step of the example.

Throughout this tutorial, you work with Simulink models that call MATLAB files that contain a simple least mean squares (LMS) filter algorithm.

## Location of Files

The tutorial files are available in the following folder: `docroot\toolbox\simulink\examples\lms`. To run the tutorial, you must copy these files to a local folder. For instructions, see “Copying Files Locally” on page 37-192.

## Names and Descriptions of Files

| Type         | Name   | Description   |
|--------------|--------|---|
| MATLAB files | lms_01 | Baseline MATLAB implementation of batch filter. Not suitable for code generation.         |
|              | lms_02 | Filter modified from batch to streaming.  |
|              | lms_03 | Frame-based streaming filter with Reset and Adapt controls.                               |
|              | lms_04 | Frame-based streaming filter with Reset and Adapt controls. Suitable for code generation. |
|              | lms_05 | Disabled inlining for code generation.  |

| Type                 | Name                 | Description  |
|----------------------|----------------------|--|
|                      | lms_06               | Demonstrates use of <code>coder.nullcopy</code> .                              |
| Simulink model files | acoustic_environment | Simulink model that provides an overview of the acoustic environment.          |
|                      | noise_cancel_00      | Simulink model without a MATLAB Function block.                                |
|                      | noise_cancel_01      | Complete <code>noise_cancel_00</code> model including a MATLAB Function block. |
|                      | noise_cancel_02      | Simulink model for use with <code>lms_02.m</code> .                            |
|                      | noise_cancel_03      | Simulink model for use with <code>lms_03.m</code> .                            |
|                      | noise_cancel_04      | Simulink model for use with <code>lms_04.m</code> .                            |
|                      | noise_cancel_05      | Simulink model for use with <code>lms_05.m</code> .                            |
|                      | noise_cancel_06      | Simulink model for use with <code>lms_06.m</code> .                            |
|                      | design_templates     | Simulink model containing Adapt and Reset controls.                            |

## Tutorial Steps

- “Copying Files Locally” on page 37-192
- “Setting Up Your C Compiler” on page 37-193
- “Running the `acoustic_environment` Model” on page 37-193
- “Adding a MATLAB Function Block to Your Model” on page 37-194
- “Calling Your MATLAB Code As an Extrinsic Function for Rapid Prototyping” on page 37-195
- “Simulating the `noise_cancel_01` Model” on page 37-198
- “Modifying the Filter to Use Streaming” on page 37-200
- “Adding Adapt and Reset Controls” on page 37-205
- “Generating Code” on page 37-209
- “Optimizing the LMS Filter Algorithm” on page 37-213

### Copying Files Locally

Copy the tutorial files to a local folder:

- 1 Create a local *solutions* folder, for example, `c:\test\lms\solutions`.
- 2 Change to the `docroot\toolbox\simulink\examples` folder. At the MATLAB command line, enter:

```
cd(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
```

- 3 Copy the contents of the `lms` subfolder to your *solutions* folder, specifying the full path name of the *solutions* folder:

```
copyfile('lms', 'solutions')
```

Your *solutions* folder now contains a complete set of solutions for the tutorial. If you do not want to perform the steps for each task, you can view the supplied solution to see how the code should look.

- 4 Create a local *work* folder, for example, `c:\test\lms\work`.
- 5 Copy the following files from your *solutions* folder to your *work* folder.

- `lms_01`
- `lms_02`
- `noise_cancel_00`
- `acoustic_environment`
- `design_templates`

Your *work* folder now contains all the files that you need to get started.

You are now ready to set up your C compiler.

## Setting Up Your C Compiler

Building your MATLAB Function block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-supported compilers installed on your system, you can change the default using the `mex -setup` command. See “Change Default Compiler” and the list of .

## Running the `acoustic_environment` Model

Run the `acoustic_environment` model supplied with the tutorial to understand the problem that you are trying to solve using the LMS filter. This model adds band-limited white noise to an audio signal and outputs the resulting signal to a speaker.

To simulate the model:

- 1 Open the `acoustic_environment` model in Simulink:
  - a Set your MATLAB current folder to the folder that contains your working files for this tutorial. At the MATLAB command line, enter:

```
cd work
```

where *work* is the full path name of the folder containing your files. See “Find Files and Folders” for more information.
  - b At the MATLAB command line, enter:

```
acoustic_environment
```
- 2 Ensure that your speakers are on.
- 3 To simulate the model, from the Simulink model window, select **Simulation > Run**.

As Simulink runs the model, you hear the audio signal distorted by noise.
- 4 While the simulation is running, double-click the Manual Switch to select the audio source.

Now you hear the desired audio input without any noise.

The goal of this tutorial is to use a MATLAB LMS filter algorithm to remove the noise from the noisy audio signal. You do this by adding a MATLAB Function block to the model and calling the MATLAB code from this block. To learn how, see “Adding a MATLAB Function Block to Your Model” on page 37-194.

### **Adding a MATLAB Function Block to Your Model**

To modify the model and code yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_01` in your *solutions* subfolder to see the modified model.

For the purposes of this tutorial, you add the MATLAB Function block to the `noise_cancel_00` model supplied with the tutorial. In practice, you would have to develop your own test bench starting with an empty Simulink model.

To add a MATLAB Function block to the `noise_cancel_00` model:

- 1 Open `noise_cancel_00` in Simulink.

```
noise_cancel_00
```
- 2 Add a MATLAB Function block to the model:

- a At the MATLAB command line, type `simulink` to open the Simulink Library Browser.
- b From the list of Simulink libraries, select the `User-Defined Functions` library.
- c Click the MATLAB Function block and drag it into the `noise_cancel_00` model. Place the block just above the red text annotation `Place MATLAB Function Block here`.
- d Delete the red text annotations from the model.
- e Save the model in the current folder as `noise_cancel_01`.

### Calling Your MATLAB Code As an Extrinsic Function for Rapid Prototyping

In this part of the tutorial, you use the `coder.extrinsic` function to call your MATLAB code from the MATLAB Function block for rapid prototyping.

#### Why Call MATLAB Code As an Extrinsic Function?

Calling MATLAB code as an extrinsic function provides these benefits:

- For rapid prototyping, you do not have to make the MATLAB code suitable for code generation.
- Using `coder.extrinsic` enables you to debug your MATLAB code in MATLAB. You can add one or more breakpoints in the `lms_01.m` file, and then start the simulation in Simulink. When the MATLAB execution engine encounters a breakpoint, it temporarily halts execution so that you can inspect the MATLAB workspace and view the current values of all variables in memory. For more information about debugging MATLAB code, see “Debug a MATLAB Program”.

#### How to Call MATLAB Code As an Extrinsic Function

To call your MATLAB code from the MATLAB Function block:

- 1 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.
- 2 Delete the default code displayed in the MATLAB Function Block Editor.
- 3 Copy the following code to the MATLAB Function block.

```
function [ Signal_Out, Weights ] = LMS(Noise_In, Signal_In) %#codegen
    % Extrinsic:
```

```
    coder.extrinsic('lms_01');  
  
    % Compute LMS:  
    [ ~, Signal_Out, Weights ] = lms_01(Noise_In, Signal_In);  
end
```

### **Why Use the Tilde (~) Operator?**

Because the LMS function does not use the first output from `lms_01`, replace this output with the MATLAB `~` operator. MATLAB ignores inputs and outputs specified by `~`. This syntax helps avoid confusion in your program code and unnecessary clutter in your workspace, and allows you to reuse existing algorithms without modification.

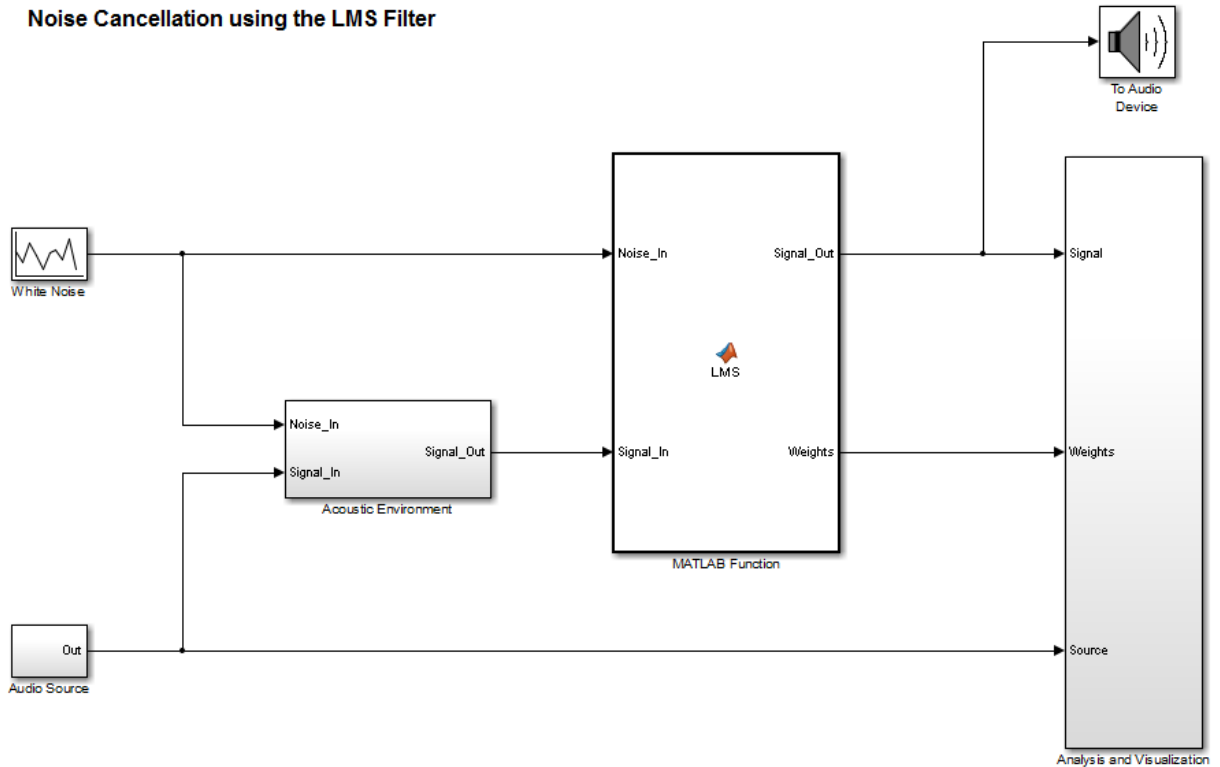

- 4** Save the model.

The `lms_01` function inputs `Noise_In` and `Signal_In` now appear as input ports to the block and the function outputs `Signal_Out` and `Weights` appear as output ports.

### **Connecting the MATLAB Function Block Inputs and Outputs**

- 1** Connect the MATLAB Function block inputs and outputs so that your model looks like this.

## Noise Cancellation using the LMS Filter

See “Block and Signal Line Shortcuts and Actions” on page 1-77 for more information.

- 2 In the MATLAB Function block code, preallocate the outputs by adding the following code after the extrinsic call:

```
% Outputs:
Signal_Out = zeros(size(Signal_In));
Weights = zeros(32,1);
```

The size of **Weights** is set to match the Numerator coefficients of the Digital Filter in the **Acoustic Environment** subsystem.

### Why Preallocate the Outputs?

For code generation, you must assign variables explicitly to have a specific class, size, and complexity before using them in operations or returning them as outputs in MATLAB functions. For more information, see “Differences in Behavior After Compiling MATLAB Code” on page 41-8.

- 3 Save the model.

You are now ready to check your model for errors.

### Simulating the `noise_cancel_01` Model

To simulate the model:

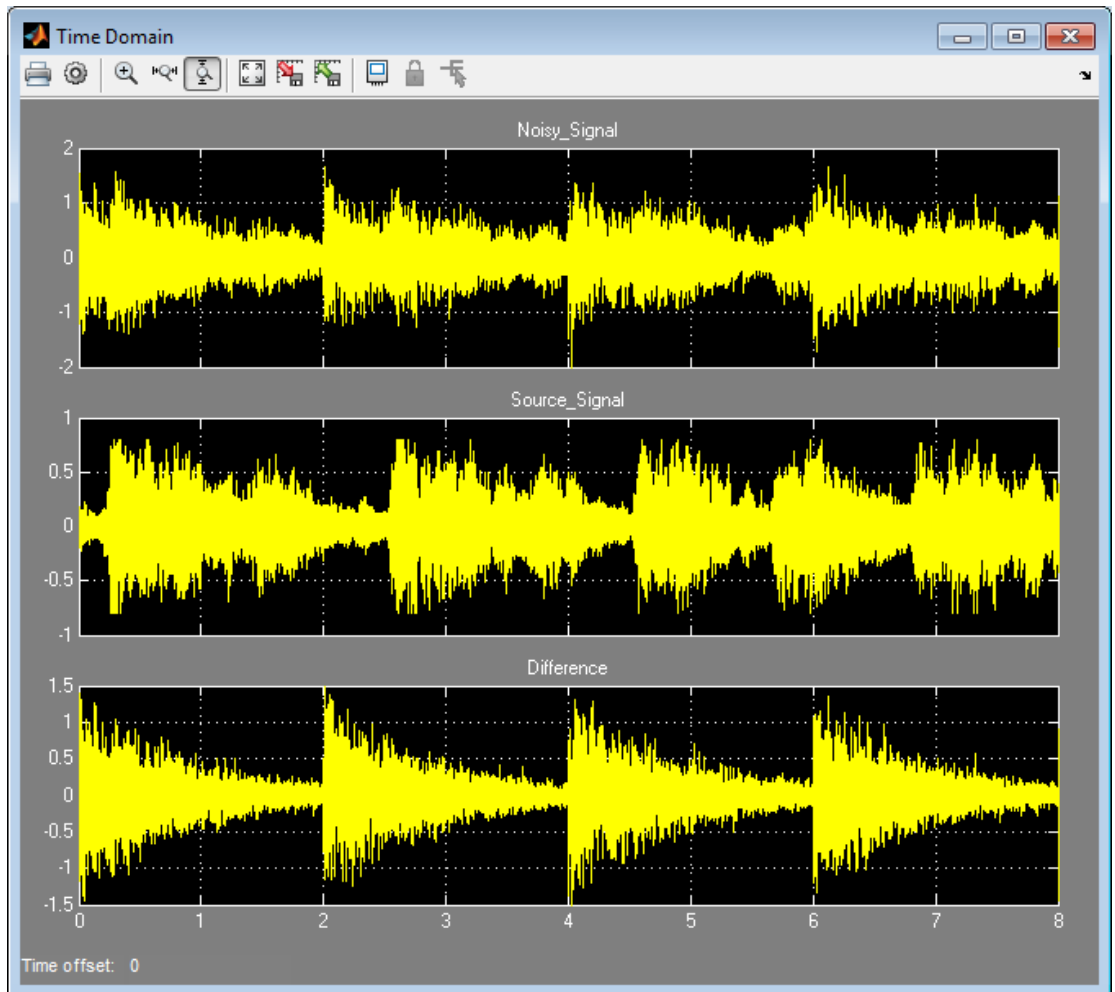

- 1 Ensure that you can see the **Time Domain** plots.

To view the plots, in the `noise_cancel_01` model, open the Analysis and Visualization block and then open the Time Domain block.

- 2 In the Simulink model window, select **Simulation > Run** .

As Simulink runs the model, you see and hear outputs. Initially, you hear the audio signal distorted by noise. Then the filter attenuates the noise gradually, until you hear only the music playing with very little noise remaining. After two seconds, you hear the distorted noisy signal again and the filter attenuates the noise again. This cycle repeats continuously.

MATLAB displays the following plot showing this cycle.

3 Stop the simulation.

### Why Does the Filter Reset Every 2 Seconds?

The filter resets every 2 seconds because the model uses 16384 samples per frame and a sampling rate of 8192, so the 16384 samples represent 2 seconds of audio.

To see the model configuration:

- 1 Double-click the White Noise subsystem and note that it uses a **Sample time** of  $1/F_s$  and **Samples per frame** of `FrameSize`. The music in the Audio Source subsystem also uses these values.
- 2 `FrameSize` is set in the model `InitFcn` callback. To view this callback:
  - a Right-click inside the model window and select **Model Properties** from the context menu.
  - b Select the **Callbacks** tab.
  - c Select `InitFcn` in the **Model callbacks** pane.

Note that `FrameSize = 16*1024`, which is 16384.

- 3 `Fs` is set in the model `PostLoadFcn` callback. To view this callback, select `PostLoadFcn` in the **Model callbacks** pane:

The following MATLAB commands set up `Fs`:

```
data = load('handel.mat');  
music = data.y;  
Fs = data.Fs;
```

### Modifying the Filter to Use Streaming

- “What Is Streaming?” on page 37-200
- “Why Use Streaming?” on page 37-200
- “Viewing the Modified MATLAB Code” on page 37-201
- “Summary of Changes to the Filter Algorithm” on page 37-201
- “Modifying Your Model to Call the Updated Algorithm” on page 37-202
- “Simulating the Streaming Algorithm” on page 37-203

### What Is Streaming?

A streaming filter is called repeatedly to process fixed-size chunks of input data, or *frames*, until it has processed the entire input signal. The frame size can be as small as a single sample, in which case the filter would be operating in a sample-based mode, or up to a few thousand samples, for frame-based processing.

### Why Use Streaming?

The design of the filter algorithm in `lms_01` has the following disadvantages:

- The algorithm does not use memory efficiently.

Preallocating a fixed amount of memory for each input signal for the lifetime of the program means more memory is allocated than is in use.

- You must know the size of the input signal at the time you call the function.

If the input signal is arriving in real time or as a stream of samples, you would have to wait to accumulate the entire signal before you could pass it, as a batch, to the filter.

- The signal size is limited to a maximum size.

In an embedded application, the filter is likely to be processing a continuous input stream. As a result, the input signal can be substantially longer than the maximum length that a filter working in batch mode could possibly handle. To make the filter work for any signal length, it must run in real time. One solution is to convert the filter from batch-based processing to stream-based processing.

### Viewing the Modified MATLAB Code

The conversion to streaming involves:

- Introducing a first-in, first-out (FIFO) queue

The FIFO queue acts as a temporary storage buffer, which holds a small number of samples from the input data stream. The number of samples held by the FIFO queue must be exactly the same as the number of samples in the filter's impulse response, so that the function can perform the convolution operation between the filter coefficients and the input signal.

- Making the FIFO queue and the filter weights persistent

The filter is called repeatedly until it has processed the entire input signal. Therefore, the FIFO queue and filter weights need to persist so that the adaptation process does not have to start over again after each subsequent call to the function.

Open the supplied file `lms_02.m` in your *work* subfolder to see the modified algorithm.

### Summary of Changes to the Filter Algorithm

Note the following important changes to the filter algorithm:

- The filter weights and the FIFO queue are declared as persistent:

```
persistent weights;  
persistent fifo;
```

- The FIFO queue is initialized:

```
fifo = zeros(FilterLength,ChannelCount);
```

- The FIFO queue is used in the filter update loop:

```
% For each channel:  
for ch = 1:ChannelCount  
  
    % For each sample time:  
    for n = 1:FrameSize  
  
        % Update the FIFO shift register:  
        fifo(1:FilterLength-1,ch) = fifo(2:FilterLength,ch);  
        fifo(FilterLength,ch) = signal_in(n,ch);  
  
        % Compute the output sample using convolution:  
        signal_out(n,ch) = weights' * fifo(:,ch);  
  
        % Update the filter coefficients:  
        err(n,ch) = desired(n,ch) - signal_out(n,ch) ;  
        weights = weights + mu*err(n,ch)*fifo(:,ch);  
  
    end  
end
```

- You cannot output a persistent variable. Therefore, a new variable, `weights_out`, is used to output the filter weights:

```
function [ signal_out, err, weights_out ] = ...  
    lms_02(distorted, desired)  
  
weights_out = weights;
```

### Modifying Your Model to Call the Updated Algorithm

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_02` in your *solutions* subfolder to see the modified model.

- 1 In the `noise_cancel_01` model, double-click the MATLAB Function block to open the MATLAB Function Block Editor.
- 2 Modify the MATLAB Function block code to call `lms_02`.
  - a Modify the extrinsic call.

```
% Extrinsic:
coder.extrinsic('lms_02');
```

- b** Modify the call to the filter algorithm.

```
% Compute LMS:
[ ~, Signal_Out, Weights ] = lms_02(Noise_In, Signal_In);
```

### Modified MATLAB Function Block Code

Your MATLAB Function block code should now look like this:

```
function [ Signal_Out, Weights ] = LMS(Noise_In, Signal_In)
% Extrinsic:
coder.extrinsic('lms_02');
% Outputs:
Signal_Out = zeros(size(Signal_In));
Weights = zeros(32,1);
% Compute LMS:
[ ~, Signal_Out, Weights ] = lms_02(Noise_In, Signal_In);
end
```

- 3** Change the frame size from 16384 to 64, which represents a more realistic value.
  - a** Right-click inside the model window and select **Model Properties** from the context menu.
  - b** Select the **Callbacks** tab.
  - c** In the **Model callbacks** list, select **InitFcn**.
  - d** Change the value of **FrameSize** to 64.
  - e** Click **Apply** and close the dialog box.
- 4** Save your model as `noise_cancel_02`.

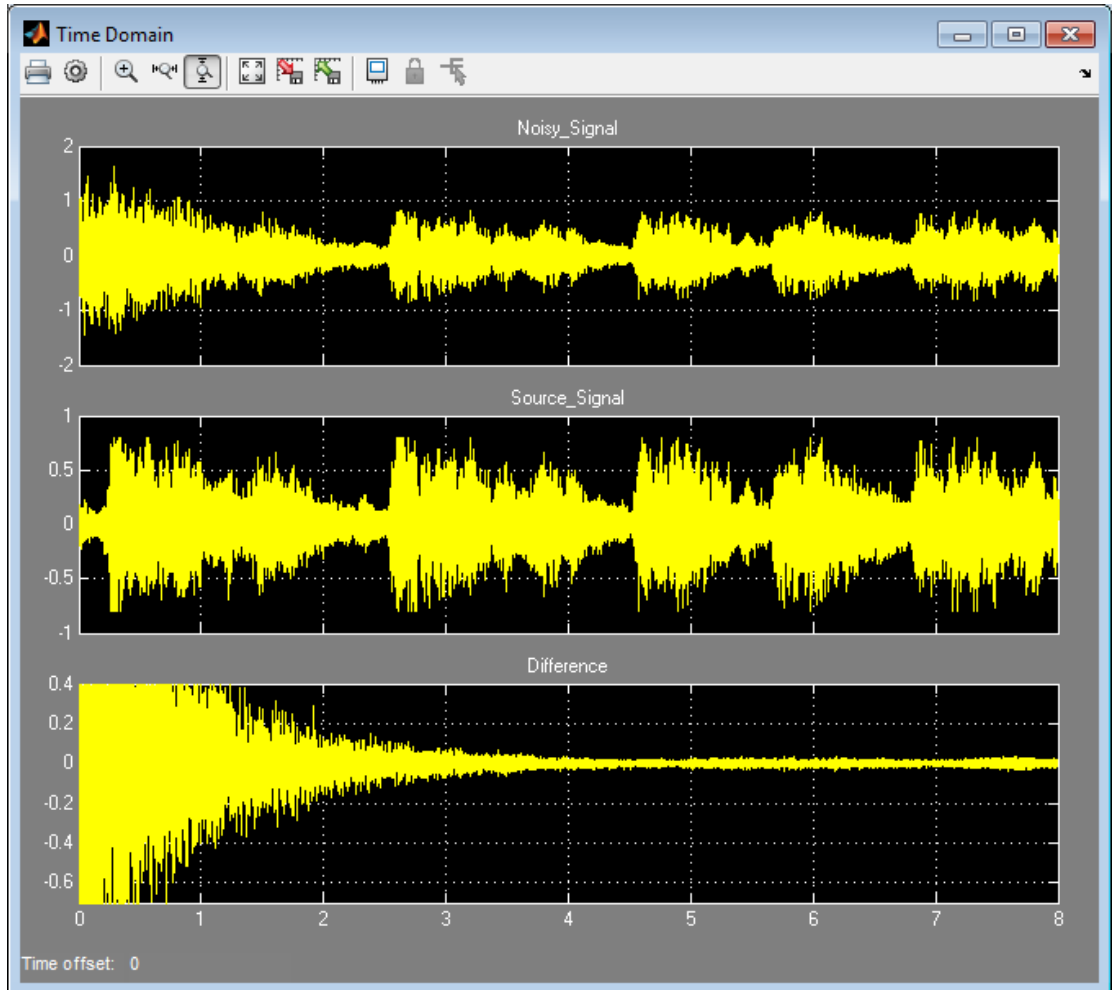

### Simulating the Streaming Algorithm

To simulate the model:

- 1** Ensure that you can see the **Time Domain** plots.
- 2** Start the simulation.

As Simulink runs the model, you see and hear outputs. Initially, you hear the audio signal distorted by noise. Then, during the first few seconds, the filter attenuates the noise gradually, until you hear only the music playing with very little noise

remaining. MATLAB displays the following plot showing filter convergence after only a few seconds.

### 3 Stop the simulation.

The filter algorithm is now suitable for Simulink. You are ready to elaborate your model to use **Adapt** and **Reset** controls.

## Adding Adapt and Reset Controls

- “Why Add Adapt and Reset Controls?” on page 37-205
- “Modifying Your MATLAB Code” on page 37-205
- “Modifying Your Model to Use Reset and Adapt Controls” on page 37-206
- “Simulating the Model with Adapt and Reset Controls” on page 37-208

## Why Add Adapt and Reset Controls?

In this part of the tutorial, you add Adapt and Reset controls to your filter. Using these controls, you can turn the filtering on and off. When **Adapt** is enabled, the filter continuously updates the filter weights. When **Adapt** is disabled, the filter weights remain at their current values. If **Reset** is set, the filter resets the filter weights.

## Modifying Your MATLAB Code

To modify the code yourself, work through the exercises in this section. Otherwise, open the supplied file `lms_03.m` in your *solutions* subfolder to see the modified algorithm.

To modify your filter code:

- 1 Open `lms_02.m`.
- 2 In the `Set up` section, replace
 

```
if ( isempty(weights) )
with
if ( reset || isempty(weights) )
```
- 3 In the filter loop, update the filter coefficients only if **Adapt** is ON.
 

```
if adapt
    weights = weights + mu*err(n,ch)*fifo(:,ch);
end
```
- 4 Change the function signature to use the **Adapt** and **Reset** inputs and change the function name to `lms_03`.
 

```
function [ signal_out, err, weights_out ] = ...
    lms_03(signal_in, desired, reset, adapt)
```
- 5 Save the file in the current folder as `lms_03.m`:

## Summary of Changes to the Filter Algorithm

Note the following important changes to the filter algorithm:

- The new input parameter `reset` is used to determine if it is necessary to reset the filter coefficients:

```
if ( reset || isempty(weights) )
    % Filter coefficients:
    weights = zeros(L,1);
    % FIFO Shift Register:
    fifo = zeros(L,1);
end
```

- The new parameter `adapt` is used to control whether the filter coefficients are updated or not.

```
if adapt
    weights = weights + mu*err(n)*fifo;
end
```

### Modifying Your Model to Use Reset and Adapt Controls

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_03` in your *solutions* subfolder to see the modified model.

- 1 Open the `noise_cancel_02` model.
- 2 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.
- 3 Modify the MATLAB Function block code:

- a Update the function declaration.

```
function [ Signal_Out, Weights ] = ...
    LMS(Adapt, Reset, Noise_In, Signal_In )
```

- b Update the extrinsic call.

```
coder.extrinsic('lms_03');
```

- c Update the call to the LMS algorithm.

```
% Compute LMS:
[ ~, Signal_Out, Weights ] = ...
    lms_03(Noise_In, Signal_In, Reset, Adapt);
```

- d Close the MATLAB Function Block Editor.

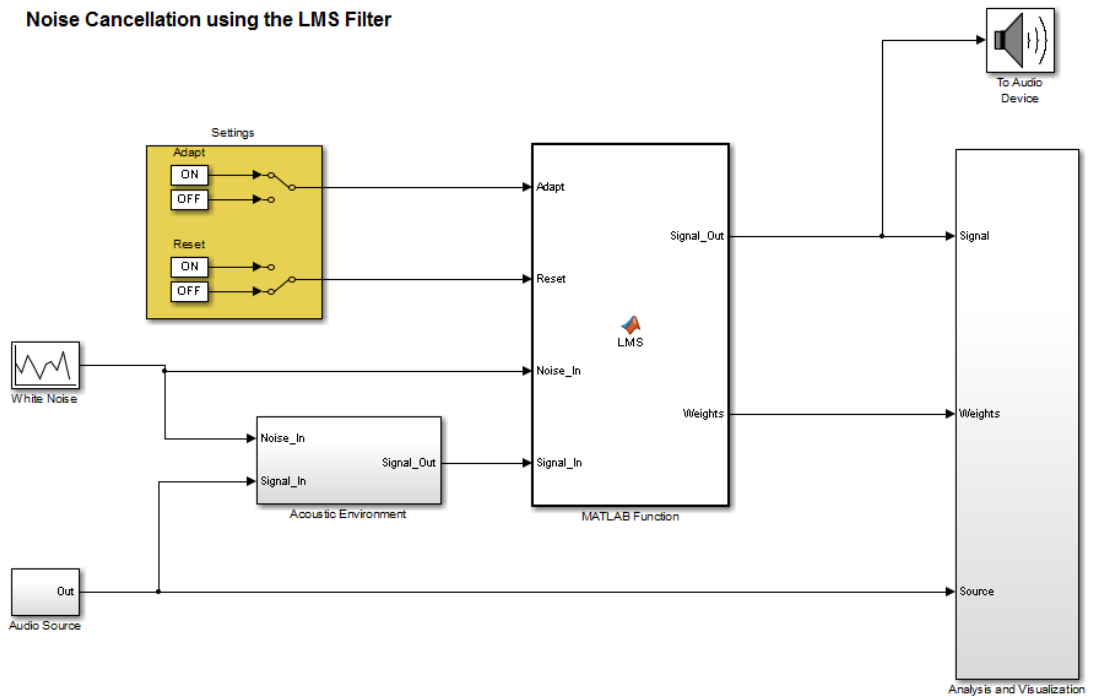

The `lms_03` function inputs `Reset` and `Adapt` now appear as input ports to the MATLAB Function block.

- 4 Open the `design_templates` model.

- 5 Copy the Settings block from this model to your `noise_cancel_02` model:
  - a From the `design_templates` model menu, select **Edit > Select All**.
  - b Select **Edit > Copy**.
  - c From the `noise_cancel_02` model menu, select **Edit > Paste**.
- 6 Connect the Adapt and Reset outputs of the Settings subsystem to the corresponding inputs on the MATLAB Function block. Your model should now appear as follows.

## Noise Cancellation using the LMS Filter

7 Save the model as `noise_cancel_03`.

### Simulating the Model with Adapt and Reset Controls

To simulate the model and see the effect of the Adapt and Reset controls:

- 1 In the `noise_cancel_03` model, view the Convergence scope:
  - a Double-click the Analysis and Visualization subsystem.
  - b Double-click the Convergence scope.
- 2 In the Simulink model window, select **Simulation > Run**.

Simulink runs the model as before. While the model is running, toggle the Adapt and Reset controls and view the Convergence scope to see their effect on the filter.

The filter converges when **Adapt** is **ON** and **Reset** is **OFF**, then resets when you toggle **Reset**. The results might look something like this:

- 3 Stop the simulation.

### Generating Code

You have proved that your algorithm works in Simulink. Next you generate code for your model. Before generating code, you must ensure that your MATLAB code is suitable for code generation. For code generation, you must remove the extrinsic call to your code.

#### Making Your Code Suitable for Code Generation

To modify the model and code yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_04` and file `lms_04.m` in your *solutions* subfolder to see the modifications.

- 1 Rename the MATLAB Function block to `LMS_Filter`. Select the annotation `MATLAB Function` below the MATLAB Function block and replace the text with `LMS_Filter`.

When you generate code for the MATLAB Function block, Simulink Coder uses the name of the block in the generated code. It is good practice to use a meaningful name.

- 2 In your `noise_cancel_03` model, double-click the MATLAB Function block.

The MATLAB Function Block Editor opens.

- 3 Delete the extrinsic declaration.

```
% Extrinsic:
coder.extrinsic('lms_03');
```

- 4 Delete the preallocation of outputs.

```
% Outputs:
Signal_Out = zeros(size(Signal_In));
Weights = zeros(32,1);
```

- 5 Modify the call to the filter algorithm.

```
% Compute LMS:
[ ~, Signal_Out, Weights ] = ...
    lms_04(Noise_In, Signal_In, Reset, Adapt);
```

- 6 Save the model as `noise_cancel_04`.

- 7 Open `lms_03.m`

- a Modify the function name to `lms_04`.
- b Turn on error checking specific to code generation by adding the `%codegen` compilation directive after the function declaration.

```
function [ signal_out, err, weights_out ] = ...
    lms_04(signal_in, desired, reset, adapt) %codegen
```

The code analyzer message indicator in the top right turns red to indicate that the code analyzer has detected code generation issues. The code analyzer underlines the offending code in red and places a red marker to the right of it.

- 8 Move your pointer over the first red marker to view the error information.

The code analyzer detects that code generation requires `signal_out` to be fully defined before subscripting it and does not support growth of variable size data through indexing.

- 9 Move your pointer over the second red marker and note that the code analyzer detects the same errors for `err`.
- 10 To address these errors, preallocate the outputs `signal_out` and `err`. Add this code after the filter setup.

```
% Output Arguments:

% Pre-allocate output and error signals:
signal_out = zeros(FrameSize,ChannelCount);
err = zeros(FrameSize,ChannelCount);
```

### Why Preallocate the Outputs?

You must preallocate outputs here because code generation does not support increasing the size of an array over time. Repeatedly expanding the size of an array over time can adversely affect the performance of your program. See “Preallocating Memory”.

The red error markers for the two lines of code disappear. The code analyzer message indicator in the top right edge of the code turns green, which indicates that you have fixed all the errors and warnings detected by the code analyzer.

- 11 Save the file as `lms_04.m`.

### Generating Code for `noise_cancel_04`

- 1 Before generating code, ensure that Simulink Coder creates a code generation report. This HTML report provides easy access to the list of generated files with a summary of the configuration settings used to generate the code.
  - a In the Simulink model window, select **Simulation > Model Configuration Parameters**.
  - b In the left pane of the Configuration Parameters dialog box, select **Code Generation > Report**.
  - c In the right pane, select **Create code generation report**.  
The **Launch report automatically** option is also selected.
  - d Click **Apply** and close the Configuration Parameters dialog box.
  - e Save your model.
- 2 To generate code for the LMS Filter subsystem:

- a In your model, select the LMS Filter subsystem.
- b From the Build Model tool menu, select **Build Selected Subsystem**.

The **Build code for subsystem** dialog box appears. Click the **Build** button.

The Simulink Coder software generates C code for the subsystem and launches the code generation report.

For more information on using the code generation report, see “Generate a Code Generation Report” in the Simulink Coder documentation.

- c In the left pane of the code generation report, click the `LMS_Filter.c` link to view the generated C code. Note that the `lms_04` function has no code because inlining is enabled by default.
- 3 Modify your filter algorithm to disable inlining:
- a In `lms_04.m`, after the function declaration, add:
 

```
coder.inline('never')
```
  - b Change the function name to `lms_05` and save the file as `lms_05.m` in the current folder.
  - c In your `noise_cancel_04` model, double-click the MATLAB Function block.
 

The MATLAB Function Block Editor opens.
  - d Modify the call to the filter algorithm to call `lms_05`.
 

```
% Compute LMS:
[ ~, Signal_Out, Weights ] = ...
    lms_05(Noise_In, Signal_In, Reset, Adapt);
```
  - e Save the model as `noise_cancel_05`.
- 4 Generate code for the updated model.
- a In the model, select the LMS Filter subsystem.

- b** From the Build Model tool menu, select **Build Selected Subsystem**.

The **Build code for subsystem** dialog box appears.

- c** Click the **Build** button.

The Simulink Coder software generates C code for the subsystem and launches the code generation report.

- d** In the left pane of the code generation report, click the `LMS_Filter.c` link to view the generated C code.

This time the `lms_05` function has code because you disabled inlining.

```
/* Forward declaration for local functions */
static void LMS_Filter_lms_05 ...
    (const real_T signal_in[64],const real_T ...
     desired[64], real_T reset, real_T adapt, ...
     real_T signal_out[64], ...
     real_T err[64], real_T weights_out[32]);

/* Function for MATLAB Function Block: 'root/LMS_Filter' */
static void LMS_Filter_lms_05 ...
    (const real_T signal_in[64], const real_T ...
     desired[64], real_T reset, real_T adapt, ...
     real_T signal_out[64], ...
     real_T err[64], real_T weights_out[32])
```

### Optimizing the LMS Filter Algorithm

This part of the tutorial demonstrates when and how to preallocate memory for a variable without incurring the overhead of initializing memory in the generated code.

In `lms_05.m`, the MATLAB code not only declares `signal_out` and `err` to be a `FrameSize`-by-`ChannelCount` vector of real doubles, but also initializes each element of `signal_out` and `err` to zero. These signals are initialized to zero in the generated C code.

| MATLAB Code  | Generated C Code   |
|--|--|
| <pre>% Pre-allocate output and error signals: signal_out = zeros(FrameSize,ChannelCount); err = zeros(FrameSize,ChannelCount);</pre> | <pre>/* Pre-allocate output and error signals: */ 79 for (i = 0; i &lt; 64; i++) { 80 signal_out[i] = 0.0;</pre> |

| MATLAB Code | Generated C Code         |
|-------------|--------------------------|
|             | 81 err[i] = 0.0;<br>82 } |

This forced initialization is unnecessary because both `signal_out` and `err` are explicitly initialized in the MATLAB code before they are read.

---

**Note:** You should not use `coder.nullcopy` when declaring the variables `weights` and `fifo` because these variables need to be initialized in the generated code. Neither variable is explicitly initialized in the MATLAB code before they are read.

---

Use `coder.nullcopy` in the declaration of `signal_out` and `err` to eliminate the unnecessary initialization of memory in the generated code:

- 1 In `lms_05.m`, preallocate `signal_out` and `err` using `coder.nullcopy`:

```
% Pre-allocate output and error signals:
signal_out = coder.nullcopy(zeros(FrameSize, ChannelCount));
err = coder.nullcopy(zeros(FrameSize, ChannelCount));
```

---

**Caution** After declaring a variable with `coder.nullcopy`, you must explicitly initialize the variable in your MATLAB code before reading it. Otherwise, you might get unpredictable results.

---

- 2 Change the function name to `lms_06` and save the file as `lms_06.m` in the current folder.
- 3 In your `noise_cancel_05` model, double-click the MATLAB Function block.

The MATLAB Function Block Editor opens.

- 4 Modify the call to the filter algorithm.

```
% Compute LMS:
[~, Signal_Out, Weights] = ...
    lms_06(Noise_In, Signal_In, Reset, Adapt);
```

- 5 Save the model as `noise_cancel_06`.

Generate code for the updated model.

- 1 Select the LMS Filter subsystem.

- 2 From the Build Model tool menu, select **Build Selected Subsystem**.

The **Build code for subsystem** dialog box appears. Click the **Build** button.

The Simulink Coder software generates C code for the subsystem and launches the code generation report.

- 3 In the left pane of the code generation report, click the `LMS_Filter.c` link to view the generated C code.

In the generated C code, this time there is no initialization to zero of `signal_out` and `err`.

## Encapsulating the Interface to External Code

Use the `coder.ExternalDependency` class to encapsulate the interface between external code and MATLAB code intended for code generation. With the encapsulation, you can separate the details of the interface from your MATLAB code. The methods of `coder.ExternalDependency`:

- specify the location of external files
- update build information
- define the programming interface for external functions

In your MATLAB code, you can call the external code without providing build information.

The workflow is:

- 1 Write a class definition file for a class that derives from `coder.ExternalDependency`.
- 2 Store the class definition file in a folder on the MATLAB path.
- 3 In your MATLAB code, use a method of the class to call an external function.
- 4 Generate code from your MATLAB code.

### See Also

`coder.ExternalDependency`

### Related Examples

- “Encapsulate Interface to an External C Library” on page 37-217

### More About

- “Best Practices for Using `coder.ExternalDependency`” on page 37-220

## Encapsulate Interface to an External C Library

This example shows how to encapsulate the interface to an external C dynamic linked library using `coder.ExternalDependency`.

Write a function `adder` that returns the sum of its inputs.

```
function c = adder(a,b)
    %#codegen
    c = a + b;
end
```

Generate a library that contains `adder`.

```
codegen('adder', '-args', {-2,5}, '-config:dll', '-report');
```

Write the class definition file `AdderAPI.m` to encapsulate the library interface.

```
%=====
% This class abstracts the API to an external Adder library.
% It implements static methods for updating the build information
% at compile time and build time.
%=====

classdef AdderAPI < coder.ExternalDependency
    %#codegen

    methods (Static)

        function bName = getDescriptiveName(~)
            bName = 'AdderAPI';
        end

        function tf = isSupportedContext(ctx)
            if ctx.isMatlabHostTarget()
                tf = true;
            else
                error('adder library not available for this target');
            end
        end

        function updateBuildInfo(buildInfo, ctx)
            [~, linkLibExt, execLibExt, ~] = ctx.getStdLibInfo();

            % Header files
```

```
hdrFilePath = fullfile(pwd, 'codegen', 'dll', 'adder');
buildInfo.addIncludePaths(hdrFilePath);

% Link files
linkFiles = strcat('adder', linkLibExt);
linkPath = hdrFilePath;
linkPriority = '';
linkPrecompiled = true;
linkLinkOnly = true;
group = '';
buildInfo.addLinkObjects(linkFiles, linkPath, ...
    linkPriority, linkPrecompiled, linkLinkOnly, group);

% Non-build files
nbFiles = 'adder';
nbFiles = strcat(nbFiles, execLibExt);
buildInfo.addNonBuildFiles(nbFiles, '', '');
end

%API for library function 'adder'
function c = adder(a, b)
    if coder.target('MATLAB')
        % running in MATLAB, use built-in addition
        c = a + b;
    else
        % running in generated code, call library function
        coder.cinclude('adder.h');

        % Because MATLAB Coder generated adder, use the
        % housekeeping functions before and after calling
        % adder with coder.ceval.
        % Call initialize function before calling adder for the
        % first time.

        coder.ceval('adder_initialize');
        c = 0;
        c = coder.ceval('adder', a, b);

        % Call the terminate function after
        % calling adder for the last time.

        coder.ceval('adder_terminate');
    end
end
```

```
        end
    end
end
```

Write a function `adder_main` that calls the external library function `adder`.

```
function y = adder_main(x1, x2)
%#codegen
    y = AdderAPI.adder(x1, x2);
end
```

Generate a MEX function for `adder_main`. The MEX Function exercises the `coder.ExternalDependency` methods.

```
codegen('adder_main', '-args', {7,9}, '-report')
```

Copy the library to the current folder using the file extension for your platform.

For Windows, use:

```
copyfile(fullfile(pwd, 'codegen', 'dll', 'adder', 'adder.dll'));
```

For Linux, use:

```
copyfile(fullfile(pwd, 'codegen', 'dll', 'adder', 'adder.so'));
```

Run the MEX function and verify the result.

```
adder_main_mex(2,3)
```

## See Also

`coder.BuildConfig` | `coder.ExternalDependency` | `error`

## More About

- “Encapsulating the Interface to External Code” on page 37-216

## Best Practices for Using `coder.ExternalDependency`

### In this section...

“Terminate Code Generation for Unsupported External Dependency” on page 37-220

“Parameterize Methods for MATLAB and Generated Code” on page 37-220

“Parameterize `updateBuildInfo` for Multiple Platforms” on page 37-221

### Terminate Code Generation for Unsupported External Dependency

The `isSupportedContext` method returns true if the external code interface is supported in the build context. If the external code interface is not supported, do not return false. Instead, use `error` to terminate code generation with an error message. For example:

```
function tf = isSupportedContext(ctx)
    if ctx.isMatlabHostTarget()
        tf = true;
    else
        error('MyLibrary is not available for this target');
    end
end
```

### Parameterize Methods for MATLAB and Generated Code

Parameterize methods that call external functions so that the methods run in MATLAB. For example:

```
...
if coder.target('MATLAB')
    % running in MATLAB, use built-in addition
    c = a + b;
else
    % running in generated code, call library function
    coder.ceval('adder_initialize');
end
...
```

## Parameterize `updateBuildInfo` for Multiple Platforms

Parameterize the `updateBuildInfo` method to support multiple platforms. For example, use `coder.BuildConfig.getStdLibInfo` to get the platform-specific library file extensions.

```
...
    [~, linkLibExt, execLibExt, ~] = ctx.getStdLibInfo()
% Link files
linkFiles = strcat('adder', linkLibExt);
buildInfo.addLinkObjects(linkFiles, linkPath, linkPriority, ...
    linkPrecompiled, linkLinkOnly, group);
...
```

## Update Build Information from MATLAB code

You can choose to control aspects of the build process that occur after code generation but before compilation. For example, you can specify compiler or linker options.

To customize the build from your MATLAB code:

- 1 In your MATLAB code, call `coder.updateBuildInfo` to update the build information object. You specify a build information object method and the input arguments for the method.
- 2 Generate code from your MATLAB code.

## What Are System Objects?

A System object is a specialized kind of MATLAB object. System Toolboxes include System objects and most System Toolboxes also have MATLAB functions and Simulink blocks. System objects are designed specifically for implementing and simulating dynamic systems with inputs that change over time. Many signal processing, communications, and controls systems are dynamic. In a dynamic system, the values of the output signals depend on both the instantaneous values of the input signals and on the past behavior of the system. System objects use internal states to store that past behavior, which is used in the next computational step. As a result, System objects are optimized for iterative computations that process large streams of data, such as video and audio processing systems.

For example, you could use System objects in a system that reads data from a file, filters that data and then writes the filtered output to another file. Typically, a specified amount of data is passed to the filter in each loop iteration. The file reader object uses a state to keep track of where in the file to begin the next data read. Likewise, the file writer object keeps tracks of where it last wrote data to the output file so that data is not overwritten. The filter object maintains its own internal states to assure that the filtering is performed correctly. This diagram represents a single loop of the system.

Many System objects support:

- Fixed-point arithmetic (requires a Fixed-Point Designer license)
- C code generation (requires a MATLAB Coder or Simulink Coder license)
- HDL code generation (requires an HDL Coder license)
- Executable files or shared libraries generation (requires a MATLAB Compiler™ license)

---

**Note:** Check your product documentation to confirm fixed-point, code generation, and MATLAB Compiler support for the specific System objects you want to use.

---

In addition to the System objects provided with System Toolboxes, you can also create your own System objects. See “Define System Objects”.

## System Design and Simulation in Simulink

You can use System objects in your model to simulate in Simulink.

- 1** Create a System object to be used in your model. See “Define New Kinds of System Objects for Use in Simulink” on page 38-17 for information.
- 2** Test your new System object in MATLAB. See “Test New System Objects in MATLAB” on page 38-22
- 3** Add the System object to your model using the **MATLAB System** block. See “Add System Objects to Your Simulink Model” on page 38-23 for information.
- 4** Add other Simulink blocks as needed and connect the blocks to construct your system.
- 5** Run the system

## System Objects in MATLAB Code Generation

### In this section...

“System Objects in Generated Code” on page 38-5

“System Objects in codegen” on page 38-9

“System Objects in the MATLAB Function Block” on page 38-10

“System Objects in the MATLAB System Block” on page 38-10

“System Objects and MATLAB Compiler Software” on page 38-10

### System Objects in Generated Code

You can generate C/C++ code in MATLAB from your system that contains System objects by using the MATLAB Coder product. Using this product, you can generate efficient and compact code for deployment in desktop and embedded systems and accelerate fixed-point algorithms. You do not need the MATLAB Coder product to generate code in Simulink.

#### System Objects Code with Persistent Objects for Code Generation

This example shows how to use System objects to make MATLAB code suitable for code generation. The example highlights key factors to consider, such as passing property values and using extrinsic functions. It also shows that by using persistent objects, the object states are maintained between calls.

```
function w = lmssystem(x, d)
% LMSSYSTEMIDENTIFICATION System identification using
% LMS adaptive filter
% #codegen

% Declare System objects as persistent
persistent hlms;

% Initialize persistent System objects only once.
% Do this with 'if isempty(persistent variable).'
```

% This condition will be false after the first time.

```
if isempty(hlms)
    % Create LMS adaptive filter used for system
    % identification. Pass property value arguments
```

```
        % as constructor arguments. Property values must
        % be constants during compile time.

        hlms = dsp.LMSFilter(11,'StepSize',0.01);
    end

    [~,~,w] = step(hlms,x,d);    % Filter weights
end
```

This example shows how to compile the `lmssystem` function and produce a MEX file with the same name in the current directory.

```
% LMSSYSTEMIDENTIFICATION System identification using
% LMS adaptive filter

coefs = fir1(10,.25);
hfilt = dsp.FIRFilter('Numerator', coefs);

x = randn(1000,1);    % Input signal
hSrc = dsp.SignalSource(x,100);    % Use x as input-signal with
    % 100 samples per frame

% Generate code for lmssystem
codegen lmssystem -args {ones(100,1),ones(100,1)}

while ~isDone(hSrc)
    in = step(hSrc);
    d = step(hfilt,in) + 0.01*randn(100,1);    % Desired signal
    w = lmssystem_mex(in,d);    % Call generated mex file
    stem([coefs.',w]);
end
```

For another detailed code generation example, see “Generate Code for MATLAB Handle Classes and System Objects” in the MATLAB Coder product documentation.

### Usage Rules and Limitations for System Objects for Generating Code

The following usage rules and limitations apply to using System objects in code generated from MATLAB.

#### Object Construction and Initialization

- If objects are stored in persistent variables, initialize System objects once by embedding the object handles in an `if` statement with a call to `isempty( )`.

- Set arguments to System object constructors as compile-time constants.
- You cannot initialize System objects properties with other MATLAB class objects as default values in code generation. You must initialize these properties in the constructor.

### Inputs and Outputs

- System objects accept a maximum of 32 inputs. A maximum of 8 dimensions per input is supported.
- The data type of the inputs should not change.
- If you want the size of inputs to change, verify that variable-size is enabled. Code generation support for variable-size data also requires that the `Enable variable sizing` option is enabled, which is the default in MATLAB.

---

**Note:** Variable-size properties in MATLAB Function block in Simulink are not supported. System objects predefined in the software do not support variable-size if their data exceeds the `DynamicMemoryAllocationThreshold` value.

---

- Do not set System objects to become outputs from the MATLAB Function block.
- Do not use the Save and Restore Simulation State as `SimState` option for any System object in a MATLAB Function block.
- Do not pass a System object as an example input argument to a function being compiled with `codegen`.
- Do not pass a System object to functions declared as extrinsic (functions called in interpreted mode) using the `coder.extrinsic` function. System objects returned from extrinsic functions and scope System objects that automatically become extrinsic can be used as inputs to another extrinsic function, but do not generate code.

### Tunable and Nontunable Properties

- The value assigned to a nontunable property must be a constant and there can be at most one assignment to that property (including the assignment in the constructor).
- For most System objects, the only time you can set their nontunable properties during code generation is when you construct the objects.
  - For System objects that are predefined in the software, you can set their tunable properties at construction time or using dot notation after the object is locked.
  - For System objects that you define, you can change their tunable properties at construction time or using dot notation during code generation. For

`getNumInputsImpl` and `getNumOutputsImpl` methods, if you set the return argument from an object property, that object property must have the `Nontunable` attribute.

- Objects cannot be used as default values for properties.
- In MATLAB simulations, default values are shared across all instances of an object. Two instances of a class can access the same default value if that property has not been overwritten by either instance.

#### Cell Arrays and Global Variables

- System objects can contain cell arrays, but cell arrays cannot contain System objects.
- Global variables are allowed in a System object, unless you will be using that System object in Simulink via the MATLAB System block. To avoid syncing global variables between a MEX file and the workspace, use a coder configuration object. For example:

```
f = coder.MEXConfig;  
f.GlobalSyncMethod = 'NoSync'
```

Then, include `'-config f'` in your `codegen` command.

#### Methods

- Code generation support is available only for these System object methods:
  - `get`
  - `getNumInputs`
  - `getNumOutputs`
  - `isDone` (for sources only)
  - `isLocked`
  - `release`
  - `reset`
  - `set` (for tunable properties)
  - `step`
- For System objects that you define,

Code generation support is available only for these methods:

- `getDiscreteStateImpl`
- `getNumInputsImpl`

- `getNumOutputsImpl`
  - `infoImpl`
  - `isDoneImpl`
  - `isInputDirectFeedThroughImpl`
  - `outputImpl`
  - `processTunedPropertiesImpl`
  - `releaseImpl` — Code is not generated automatically for the this method. To release an object, you must explicitly call the `release` method in your code.
  - `resetImpl`
  - `setupImpl`
  - `stepImpl`
  - `updateImpl`
  - `validateInputsImpl`
  - `validatePropertiesImpl`
- Code generation support for using dot notation depends on whether the System object is predefined in the software or is one that you defined.
    - For System objects that are predefined in the software, you cannot use dot notation to call methods.
    - For System objects that you define, you can use dot notation or function call notation, with the System object as first argument, to call methods.

## System Objects in codegen

You can include System objects in MATLAB code in the same way you include any other elements. You can then compile a MEX file from your MATLAB code by using the `codegen` command, which is available if you have a MATLAB Coder license. This compilation process, which involves a number of optimizations, is useful for accelerating simulations. See “Getting Started with MATLAB Coder” and “MATLAB Classes” for more information.

---

**Note:** Most, but not all, System objects support code generation. Refer to the particular object’s reference page for information.

---

## **System Objects in the MATLAB Function Block**

Using the MATLAB Function block, you can include any System object and any MATLAB language function in a Simulink model. This model can then generate embeddable code. System objects provide higher-level algorithms for code generation than do most associated blocks. For more information, see “What Is a MATLAB Function Block?” on page 37-5 in the Simulink documentation.

## **System Objects in the MATLAB System Block**

Using the MATLAB System block, you can include in a Simulink model individual System objects that you create with a class definition file . The model can then generate embeddable code. For more information, see “What Is the MATLAB System Block?” on page 40-2 in the Simulink documentation.

## **System Objects and MATLAB Compiler Software**

MATLAB Compiler software supports System objects for use inside MATLAB functions. The compiler product does not support System objects for use in MATLAB scripts.

## System Objects Methods That Support Code Generation

### In this section...

“Code Generation Supported System Objects Methods” on page 38-11

“Simulation-Only System Objects Methods” on page 38-11

### Code Generation Supported System Objects Methods

Only the following methods are supported in code generation.

- `getDiscreteStateImpl`
- `getNumInputsImpl`
- `getNumOutputsImpl`
- `isDoneImpl`
- `infoImpl`
- `isInputDirectFeedthroughImpl`
- `outputImpl`
- `processTunedPropertiesImpl`
- `releaseImpl` — Code is not generated automatically for the this method. To release an object, you must explicitly call the `release` method in your code.
- `resetImpl`
- `setupImpl`
- `stepImpl`
- `updateImpl`
- `validateInputsImpl`
- `validatePropertiesImpl`

### Simulation-Only System Objects Methods

The following methods are for simulation only and do not support code generation.

- `getDiscreteStateSpecificationImpl`
- `getHeaderImpl`

- `getInputNamesImpl`
- `getIconImpl`
- `getOutputDataTypeImpl`
- `getOutputNamesImpl`
- `getOutputSizeImpl`
- `getPropertyGroupsImpl`
- `isInactivePropertyImpl`
- `isOutputComplexImpl`
- `loadObjectImpl`
- `propagatedInputComplexity`
- `propagatedInputDataType`
- `propagatedInputFixedSize`
- `propagatedInputSize`
- `saveObjectImpl`
- `supportsMultipleInstanceImpl`

## System Objects in Simulink

| In this section...  |
|---|
| “System Objects in the MATLAB Function Block” on page 38-13 |
| “System Objects in the MATLAB System Block” on page 38-13   |

### System Objects in the MATLAB Function Block

You can include System object code in Simulink models using the `MATLAB Function` block. Your function can include one or more System objects. Portions of your system may be easier to implement in the MATLAB environment than directly in Simulink. Many System objects have Simulink block counterparts with equivalent functionality. Before writing MATLAB code to include in a Simulink model, check for existing blocks that perform the desired operation.

### System Objects in the MATLAB System Block

You can include individual System objects that you create with a class definition file into Simulink using the `MATLAB System` block. This provides one way to add your own algorithm blocks into your Simulink models. For information, see “System Object Integration” in the Simulink documentation.

## System Object Methods

### In this section...

“What Are System Object Methods?” on page 38-14

“The Step Method” on page 38-14

“Common Methods” on page 38-15

### What Are System Object Methods?

After you create a System object, you use various object methods to process data or obtain information from or about the object. All methods that are applicable to an object are described in the reference pages for that object. System object method names begin with a lowercase letter and class and property names begin with an uppercase letter. The syntax for using methods is `<method>(<handle>)`, such as `step(H)`, plus possible extra input arguments.

System objects use a minimum of two commands to process data—a constructor to create the object and the step method to run data through the object. This separation of declaration from execution lets you create multiple, persistent, reusable objects, each with different settings. Using this approach avoids repeated input validation and verification, allows for easy use within a programming loop, and improves overall performance. In contrast, MATLAB functions must validate parameters every time you call the function.

These advantages make System objects particularly well suited for processing streaming data, where segments of a continuous data stream are processed iteratively. This ability to process streaming data provides the advantage of not having to hold large amounts of data in memory. Use of streaming data also allows you to use simplified programs that use loops efficiently.

### The Step Method

The `step` method is the key System object method. You use `step` to process data using the algorithm defined by that object. The `step` method performs other important tasks related to data processing, such as initialization and handling object states. Every System object has its own customized `step` method, which is described in detail on the `step` reference page for that object. For more information about the step method and other available methods, see the descriptions in “Common Methods” on page 38-15.

## Common Methods

All System objects support the following methods, each of which is described in a method reference page associated with the particular object. In cases where a method is not applicable to a particular object, calling that method has no effect on the object.

| Method                        | Description   |
|-------------------------------|---|
| <code>step</code>             | Processes data using the algorithm defined by the object. As part of this processing, it initializes needed resources, returns outputs, and updates the object states. After you call the <code>step</code> method, you cannot change any input specifications (i.e., dimensions, data type, complexity). During execution, you can change only tunable properties. The <code>step</code> method returns regular MATLAB variables.<br><br>Example: <code>Y = step(H,X)</code> |
| <code>release</code>          | Releases any special resources allocated by the object, such as file handles and device drivers, and unlocks the object. For System objects, use the <code>release</code> method instead of a destructor.   |
| <code>reset</code>            | Resets the internal states of a locked object to the initial values for that object and leaves the object locked  |
| <code>getNumInputs</code>     | Returns the number of inputs (excluding the object itself) expected by the <code>step</code> method. This number varies for an object depending on whether any properties enable additional inputs.   |
| <code>getNumOutputs</code>    | Returns the number of outputs expected from the <code>step</code> method. This number varies for an object depending on whether any properties enable additional outputs.   |
| <code>getDiscreteState</code> | Returns the discrete states of the object in a structure. If the object is unlocked (when the object is first created and before you have run the <code>step</code> method on it or after you have released the object), the states are empty. If the object has no discrete states, <code>getDiscreteState</code> returns an empty structure.  |
| <code>clone</code>            | Creates another object of the same type with the same property values   |
| <code>isLocked</code>         | Returns a logical value indicating whether the object is locked.  |

| <b>Method</b>       | <b>Description</b>   |
|---------------------|--|
| <code>isDone</code> | Applies to source objects only. Returns a logical value indicating whether the step method has reached the end of the data file. If a particular object does not have end-of-data capability, this method value returns <b>false</b> . |
| <code>info</code>   | Returns a structure containing characteristic information about the object. The fields of this structure vary depending on the object. If a particular object does not have characteristic information, the structure is empty.        |

For a complete list of methods for writing new System objects, see “System Objects Methods for Defining New Objects” on page 39-3.

# System Design in Simulink Using System Objects

## In this section...

“Define New Kinds of System Objects for Use in Simulink” on page 38-17

“Test New System Objects in MATLAB” on page 38-22

“Add System Objects to Your Simulink Model” on page 38-23

## Define New Kinds of System Objects for Use in Simulink

- “Define System Object with Block Customizations” on page 38-17
- “Define System Object with Nondirect Feedthrough” on page 38-20

A System object is a component you can use to create your system in MATLAB. You can write the code in MATLAB and use that code to create a block in Simulink. To define your own System object, you write a class definition file, which is a text-based MATLAB file that contains the code defining your object. See “System Object Integration” in the Simulink documentation.

### Define System Object with Block Customizations

This example shows how to create a System object for use in Simulink. The example performs system identification using a least mean squares (LMS) adaptive filter and is similar to the System Identification Using MATLAB System Blocks Simulink example.

This example shows how to create a class definition text file to define your System object. The code in this example creates a least mean squares (LMS) filter and includes customizations to the block icon and dialog appearance.

---

**Note:** Instead of manually creating your class definition file, you can use the **New > System Object > Simulink Extension** menu option to open a template. This template includes customizations of the System object for use in the Simulink MATLAB System block. You edit the template file, using it as guideline, to create your own System object.

---

On the first line of the class definition file, specify the name of your System object and subclass from both `matlab.System` and `matlab.system.mixin.CustomIcon`. The `matlab.System` base class enables you to use all the basic System object methods and specify the block input and output names, title, and property groups. The `CustomIcon` mixin class enables the method that lets you specify the block icon.

Add the appropriate basic System object methods to set up, reset, set the number of inputs and outputs, and run your algorithm. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `setupImpl` method to perform one-time calculations and initialize variables.
- Use the `stepImpl` method to implement the block's algorithm.
- Use the `resetImpl` method to reset the state properties or `DiscreteState` properties.
- Use the `getNumInputsImpl` and `getNumOutputsImpl` methods to specify the number of inputs and outputs, respectively.

Add the appropriate `CustomIcon` methods to define the appearance of the MATLAB System block in Simulink. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `getHeaderImpl` method to specify the title and description to display on the block dialog.
- Use the `getPropertyGroupsImpl` method to specify groups of properties to display on the block dialog.
- Use the `getIconImpl` method to specify the text to display on the block icon.
- Use the `getInputNamesImpl` and `getOutputNamesImpl` methods to specify the labels to display for the block input and output ports.

The full class definition file for the least mean squares filter is:

```
classdef lmsSysObj < matlab.System &...
    matlab.system.mixin.CustomIcon
    % lmsSysObj Least mean squares (LMS) adaptive filtering.
    % #codegen

    properties
        % Mu Step size
        Mu = 0.005;
    end

    properties (Nontunable)
        % Weights Filter weights
        Weights = 0;
        % N Number of filter weights
        N = 32;
    end
end
```

```
properties (DiscreteState)
    X;
    H;
end

methods (Access = protected)
    function setupImpl(obj)
        obj.X = zeros(obj.N,1);
        obj.H = zeros(obj.N,1);
    end

    function [y, e_norm] = stepImpl(obj,d,u)
        tmp = obj.X(1:obj.N-1);
        obj.X(2:obj.N,1) = tmp;
        obj.X(1,1) = u;
        y = obj.X'*obj.H;
        e = d-y;
        obj.H = obj.H + obj.Mu*e*obj.X;
        e_norm = norm(obj.Weights'-obj.H);
    end

    function resetImpl(obj)
        obj.X = zeros(obj.N,1);
        obj.H = zeros(obj.N,1);
    end

end

% Block icon and dialog customizations
methods (Static, Access = protected)
    function header = getHeaderImpl
        header = matlab.system.display.Header(...
            'lmsSysObj', ...
            'Title', 'LMS Adaptive Filter');
    end

    function groups = getPropertyGroupsImpl
        upperGroup = matlab.system.display.SectionGroup(...
            'Title','General',...
            'PropertyList',{'Mu'});

        lowerGroup = matlab.system.display.SectionGroup(...
            'Title','Coefficients', ...
            'PropertyList',{'Weights','N'});
    end
end
```

```
        groups = [upperGroup,lowerGroup];
    end
end

methods (Access = protected)
    function icon = getIconImpl(~)
        icon = sprintf('LMS Adaptive\nFilter');
    end
    function [in1name, in2name] = getInputNamesImpl(~)
        in1name = 'Desired';
        in2name = 'Actual';
    end
    function [out1name, out2name] = getOutputNamesImpl(~)
        out1name = 'Output';
        out2name = 'EstError';
    end
end
end
```

### Define System Object with Nondirect Feedthrough

This example shows how to create a System object for use in Simulink. The example performs system identification using a least mean squares (LMS) adaptive filter and uses feedback loops. It is similar to the System Identification Using MATLAB System Blocks Simulink example. For information on feedback loops, see “Use System Objects in Feedback Loops” on page 40-14.

This example shows how to create a class definition text file to define your System object. The code in this example creates an integer delay and includes customizations to the block icon. It implements a System object that you can use for nondirect feedthrough.

On the first line of the class definition file, subclass from `matlab.System` and `matlab.system.mixin.CustomIcon`. The `matlab.System` base class enables you to use all the basic System object methods and specify the block input and output names, title, and property groups. The `CustomIcon` mixin class enables the method that lets you specify the block icon. The `Nondirect` mixin enables the methods that let you specify how the block is updated and what it outputs.

Add the appropriate basic System object methods to set up and reset the object and set and validate the properties. Since this object supports nondirect feedthrough, you do not implement the `stepImpl` method. You implement the `updateImpl` and `outputImpl`

methods instead. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `setupImpl` method to initialize some of the object's properties.
- Use the `resetImpl` method to reset the property states.
- Use the `validatePropertiesImpl` method to check that the property values are valid.

Add the following `Nondirect` mixin class methods instead of the `stepImpl` method to specify how the block updates its state and its output. See the reference pages and the full class definition file below for the implementation of each of these methods.

- Use the `outputImpl` method to implement code to calculate the block output.
- Use the `updateImpl` method to implement code to update the block's internal states.
- Use the `isInputDirectFeedthroughImpl` method to specify that the block is not direct feedthrough. Its inputs do not directly affect its outputs.

Add the `setIconImpl` method to define the block icon when it is used in Simulink via the MATLAB System block. See the reference page and the full class definition file below for the implementation of this method.

The full class definition file for the delay is:

```
classdef intDelaySysObj < matlab.System &...
    matlab.system.mixin.Nondirect &...
    matlab.system.mixin.CustomIcon
    % intDelaySysObj Delay input by specified number of samples.
    % #codegen

    properties
        % InitialOutput Initial output
        InitialOutput = 0;
    end

    properties (Nontunable)
        % NumDelays Number of delays
        NumDelays = 1;
    end

    properties (DiscreteState)
        PreviousInput;
    end
end
```

```
methods (Access = protected)
function setupImpl(obj, ~)
    obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
end

function [y] = outputImpl(obj, ~)
    % Output does not directly depend on input
    y = obj.PreviousInput(end);
end

function updateImpl(obj, u)
    obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
end

function flag = isInputDirectFeedthroughImpl(~,~)
    flag = false;
end

function validatePropertiesImpl(obj)
    if ((numel(obj.NumDelays)>1) || (obj.NumDelays <= 0))
        error('Number of delays must be positive non-zero scalar value.');
```

```
    end
    if (numel(obj.InitialOutput)>1)
        error('Initial output must be scalar value.');
```

```
    end
end

function resetImpl(obj)
    obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
end

function icon = getIconImpl(~)
    icon = sprintf('Integer\nDelay');
```

```
end
end
end
```

## Test New System Objects in MATLAB

- 1 Create an instance of your new System object. For example, create an instance of the `lmsSysObj`.

```
s = lmsSysObj;
```

- 2 Run the step method on the object multiple times with different inputs. This tests for syntax errors and other possible issues before you add it to Simulink. For example,

```
desired = 0;  
actual = 0.2;  
step(s,desired,actual);
```

## Add System Objects to Your Simulink Model

- 1 Add your System objects to your Simulink model by using the MATLAB System block as described in “Mapping System Objects to Block Dialog Box” on page 40-18.
- 2 Add other Simulink blocks, connect them, and configure any needed parameters to complete your model as described in the Simulink documentation. See the System Identification for an FIR System Using MATLAB System Blocks Simulink example.
- 3 Run your model in the same way you run any Simulink model.

## System Objects Methods for Defining New Objects

The following Impl methods comprise the System objects API for defining new System objects. For more information see “Define System Objects” “Define System Objects”.

- getDiscreteStateImpl
- getDiscreteStateSpecificationImpl
- getHeaderImpl
- getIconImpl
- getInputNamesImpl
- getNumInputsImpl
- getNumOutputsImpl
- getOutputDataTypeImpl
- getOutputNamesImpl
- getOutputSizeImpl
- isInputSizeLockedImpl
- getPropertyGroupsImpl
- getSimulateUsingImpl
- isDoneImpl
- infoImpl
- isInactivePropertyImpl
- isInputDirectFeedthroughImpl
- isOutputComplexImpl
- isOutputFixedSizeImpl
- loadObjectImpl
- outputImpl
- processTunedPropertiesImpl
- propagatedInputComplexity
- propagatedInputDataType
- propagatedInputFixedSize
- propagatedInputSize
- releaseImpl

- `resetImpl`
- `setProperties`
- `setupImpl`
- `showSimulateUsingImpl`
- `stepImpl`
- `supportsMultipleInstanceImpl`
- `updateImpl`
- `validateInputsImpl`
- `validatePropertiesImpl`

## Define Basic System Objects

This example shows how to create a basic System object that increments a number by one.

The class definition file contains the minimum elements required to define a System object.

### Create the Class Definition File

- 1 Create a MATLAB file named `AddOne.m` to contain the definition of your System object.

```
edit AddOne.m
```

- 2 Subclass your object from `matlab.System`. Insert this line as the first line of your file.

```
classdef AddOne < matlab.System
```

- 3 Add the `stepImpl` method, which contains the algorithm that runs when users call the `step` method on your object. You always set the `stepImpl` method access to `protected` because it is an internal method that users do not directly call or run.

All methods, except static methods, expect the System object handle as the first input argument. You can use any name for your System object handle.

In this example, instead of passing in the object handle, `~` is used to indicate that the object handle is not used in the function. Using `~` instead of an object handle prevents warnings about unused variables from occurring.

By default, the number of inputs and outputs are both one. To change the number of inputs or outputs, use the `getNumInputsImpl` or `getNumOutputsImpl` method, respectively.

```
methods (Access = protected)
    function y = stepImpl(~,x)
        y = x + 1;
    end
end
```

---

**Note:** Instead of manually creating your class definition file, you can use an option on the **New > System Object** menu to open a template. The **Basic** template opens a simple

System object template. The **Advanced** template includes more advanced features of System objects, such as backup and restore. The **Simulink Extension** template includes additional customizations of the System object for use in the Simulink MATLAB System block. You then can edit the template file, using it as guideline, to create your own System object.

---

### Complete Class Definition File for Basic System Object

```
classdef AddOne < matlab.System
% ADDONE Compute an output value one greater than the input value

% All methods occur inside a methods declaration.
% The stepImpl method has protected access
methods (Access = protected)

    function y = stepImpl(~,x)
        y = x + 1;
    end
end
end
```

matlab.System | getNumInputsImpl | getNumOutputsImpl | stepImpl

### Related Examples

- “Change Number of Step Inputs or Outputs” on page 39-7

## Change Number of Step Inputs or Outputs

This example shows how to specify two inputs and two outputs for the `step` method.

If you specify the inputs and outputs to the `stepImpl` method, you do not need to specify the `getNumInputsImpl` and `getNumOutputsImpl` methods. If you have a variable number of inputs or outputs (using `varargin` or `varargout`), include the `getNumInputsImpl` or `getNumOutputsImpl` method, respectively, in your class definition file.

---

**Note:** You should only use `getNumInputsImpl` or `getNumOutputsImpl` methods to change the number of System object inputs or outputs. Do not use any other handle objects within a System object to change the number of inputs or outputs.

---

You always set the `getNumInputsImpl` and `getNumOutputsImpl` methods access to `protected` because they are internal methods that users do not directly call or run.

### Update the Algorithm for Multiple Inputs and Outputs

Update the `stepImpl` method to specify two inputs and two outputs. You do not need to implement associated `getNumInputsImpl` or `getNumOutputsImpl` methods.

```
methods (Access = protected)
    function [y1,y2] = stepImpl(~,x1,x2)
        y1 = x1 + 1;
        y2 = x2 + 1;
    end
end
```

### Update the Algorithm and Associated Methods

Update the `stepImpl` method to use `varargin` and `varargout`. In this case, you must implement the associated `getNumInputsImpl` and `getNumOutputsImpl` methods to specify two or three inputs and outputs.

```
methods (Access = protected)
    function varargout = stepImpl(obj,varargin)
        varargout{1} = varargin{1}+1;
        varargout{2} = varargin{2}+1;
        if (obj.numInputsOutputs == 3)
            varargout{3} = varargin{3}+1;
        end
    end
end
```

```
        end
    end

    function validatePropertiesImpl(obj)
        if ~(obj.numInputsOutputs == 2) || ...
            (obj.numInputsOutputs == 3)
            error('Only 2 or 3 input and outputs allowed.');
```

```
        end
```

```
    end
```

```
    function numIn = getNumInputsImpl(obj)
```

```
        numIn = 3;
```

```
        if (obj.numInputsOutputs == 2)
```

```
            numIn = 2;
```

```
        end
```

```
    end
```

```
    function numOut = getNumOutputsImpl(obj)
```

```
        numOut = 3;
```

```
        if (obj.numInputsOutputs == 2)
```

```
            numOut = 2;
```

```
        end
```

```
    end
```

```
end
```

Use this syntax to run the algorithm with two inputs and two outputs.

```
x1 = 3;
x2 = 7;
[y1,y2] = step(AddOne,x1,x2);
```

To change the number of inputs or outputs, you must release the object before rerunning it.

```
release(AddOne)
x1 = 3;
x2 = 7;
x3 = 10
[y1,y2,y3] = step(AddOne,x1,x2,x3);
```

### Complete Class Definition File with Multiple Inputs and Outputs

```
classdef AddOne < matlab.System
    % ADDONE Compute output values one greater than the input values
```

```
% This property is nontunable and cannot be changed
% after the setup or step method has been called.
properties (Nontunable)
    numInputsOutputs = 3;    % Default value
end

% All methods occur inside a methods declaration.
% The stepImpl method has protected access
methods (Access = protected)
    function varargout = stepImpl(obj,varargin)
        if (obj.numInputsOutputs == 2)
            varargout{1} = varargin{1}+1;
            varargout{2} = varargin{2}+1;
        else
            varargout{1} = varargin{1}+1;
            varargout{2} = varargin{2}+1;
            varargout{3} = varargin{3}+1;
        end
    end
end

function validatePropertiesImpl(obj)
    if ~((obj.numInputsOutputs == 2) || ...
        (obj.numInputsOutputs == 3))
        error('Only 2 or 3 input and outputs allowed.');
```

end

## Specify System Block Input and Output Names

This example shows how to specify the names of the input and output ports of a System object–based block implemented using a MATLAB System block.

### Define Input and Output Names

This example shows how to use `getInputNamesImpl` and `getOutputNamesImpl` to specify the names of the input port as “source data” and the output port as “count.”

If you do not specify the `getInputNamesImpl` and `getOutputNamesImpl` methods, the object uses the `stepImpl` method input and output variable names for the input and output port names, respectively. If the `stepImpl` method uses *varargin* and *varargout* instead of variable names, the port names default to empty strings.

```
methods (Access = protected)
    function inputName = getInputNamesImpl(~)
        inputName = 'source data';
    end

    function outputName = getOutputNamesImpl(~)
        outputName = 'count';
    end
end
```

### Complete Class Definition File with Named Inputs and Outputs

```
classdef MyCounter < matlab.System

    % MyCounter Count values above a threshold

    properties
        Threshold = 1
    end
    properties (DiscreteState)
        Count
    end

    methods
        function obj = MyCounter(varargin)
            setProperties (obj,nargin,varargin{:});
        end
    end
end
```

```
methods (Access = protected)
  function setupImpl(obj)
    obj.Count = 0;
  end
  function resetImpl(obj)
    obj.Count = 0;
  end
  function y = stepImpl(obj,u)
    if (u > obj.Threshold)
      obj.Count = obj.Count + 1;
    end
    y = obj.Count;
  end
  function inputName = getInputNamesImpl(~)
    inputName = 'source data';
  end
  function outputName = getOutputNamesImpl(~)
    outputName = 'count';
  end
end
end
```

## Validate Property and Input Values

This example shows how to verify that the user's inputs and property values are valid.

### Validate Properties

This example shows how to validate the value of a single property using `set.PropertyName` syntax. In this case, the *PropertyName* is `Increment`.

```
methods
    % Validate the properties of the object
    function set.Increment(obj, val)
        if val >= 10
            error('The increment value must be less than 10');
        end
        obj.Increment = val;
    end
end
```

This example shows how to validate the value of two interdependent properties using the `validatePropertiesImpl` method. In this case, the `UseIncrement` property value must be `true` and the `WrapValue` property value must be less than the `Increment` property value.

```
methods (Access = protected)
    function validatePropertiesImpl(obj)
        if obj.UseIncrement && obj.WrapValue > obj.Increment
            error('Wrap value must be less than increment value');
        end
    end
end
```

### Validate Inputs

This example shows how to validate that the first input is a numeric value.

```
methods (Access = protected)
    function validateInputsImpl(~, x)
        if ~isnumeric(x)
            error('Input must be numeric');
        end
    end
end
```

```
end
```

### Complete Class Definition File with Property and Input Validation

```
classdef AddOne < matlab.System
% ADDONE Compute an output value by incrementing the input value

% All properties occur inside a properties declaration.
% These properties have public access (the default)
properties (Logical)
    UseIncrement = true
end

properties (PositiveInteger)
    Increment = 1
    WrapValue = 10
end

methods
% Validate the properties of the object
function set.Increment(obj,val)
    if val >= 10
        error('The increment value must be less than 10');
    end
    obj.Increment = val;
end
end

methods (Access = protected)
function validatePropertiesImpl(obj)
    if obj.UseIncrement && obj.WrapValue > obj.Increment
        error('Wrap value must be less than increment value');
    end
end

% Validate the inputs to the object
function validateInputsImpl(~,x)
    if ~isnumeric(x)
        error('Input must be numeric');
    end
end

function out = stepImpl(obj,in)
    if obj.UseIncrement
        out = in + obj.Increment;
    end
end
end
```

```
    else
      out = in + 1;
    end
  end
end
end
```

---

- “System Object Input Arguments and ~ in Code Examples” on page 39-92

## Initialize Properties and Setup One-Time Calculations

This example shows how to write code to initialize and set up a System object.

In this example, you allocate file resources by opening the file so the System object can write to that file. You do these initialization tasks one time during setup, rather than every time you call the step method.

### Define Public Properties to Initialize

In this example, you define the public `Filename` property and specify the value of that property as the nontunable string, `default.bin`. Users cannot change *nontunable* properties after the `setup` method has been called. Refer to the Methods Timing section for more information.

```
properties (Nontunable)
    Filename = 'default.bin'
end
```

### Define Private Properties to Initialize

Users cannot access *private* properties directly, but only through methods of the System object. In this example, you define the `pFileID` property as a private property. You also define this property as *hidden* to indicate it is an internal property that never displays to the user.

```
properties (Hidden,Access = private)
    pFileID;
end
```

### Define Setup

You use the `setupImpl` method to perform setup and initialization tasks. You should include code in the `setupImpl` method that you want to execute one time only. The `setupImpl` method is called once during the first call to the `step` method. In this example, you allocate file resources by opening the file for writing binary data.

```
methods
function setupImpl(obj)
    obj.pFileID = fopen(obj.Filename,'wb');
    if obj.pFileID < 0
        error('Opening the file failed');
```

```

    end
  end
end

```

Although not part of setup, you should close files when your code is done using them. You use the `releaseImpl` method to release resources.

### Complete Class Definition File with Initialization and Setup

```

classdef MyFile < matlab.System
% MyFile write numbers to a file

    % These properties are nontunable. They cannot be changed
    % after the setup or step method has been called.
    properties (Nontunable)
        Filename = 'default.bin' % the name of the file to create
    end

    % These properties are private. Customers can only access
    % these properties through methods on this object
    properties (Hidden,Access = private)
        pFileID; % The identifier of the file to open
    end

    methods (Access = protected)
        % In setup allocate any resources, which in this case
        % means opening the file.
        function setupImpl(obj)
            obj.pFileID = fopen(obj.Filename,'wb');
            if obj.pFileID < 0
                error('Opening the file failed');
            end
        end

        % This System object™ writes the input to the file.
        function stepImpl(obj,data)
            fwrite(obj.pFileID,data);
        end

        % Use release to close the file to prevent the
        % file handle from being left open.
        function releaseImpl(obj)
            fclose(obj.pFileID);
        end
    end
end

```

end

## Set Property Values at Construction Time

This example shows how to define a System object constructor and allow it to accept name-value property pairs as input.

### Set Properties to Use Name-Value Pair Input

Define the System object constructor, which is a method that has the same name as the class (MyFile in this example). Within that method, you use the `setProperties` method to make all public properties available for input when the user constructs the object. `nargin` is a MATLAB function that determines the number of input arguments. `varargin` indicates all of the object's public properties.

```
methods
    function obj = MyFile(varargin)
        setProperties(obj,nargin,varargin{:});
    end
end
```

### Complete Class Definition File with Constructor Setup

```
classdef MyFile < matlab.System
% MyFile write numbers to a file

    % These properties are nontunable. They cannot be changed
    % after the setup or step method has been called.
    properties (Nontunable)
        Filename = 'default.bin' % the name of the file to create
        Access = 'wb' % The file access string (write, binary)
    end

    % These properties are private. Customers can only access
    % these properties through methods on this object
    properties (Hidden,Access = private)
        pFileID; % The identifier of the file to open
    end

    methods
        % You call setProperties in the constructor to let
        % a user specify public properties of object as
        % name-value pairs.
        function obj = MyFile(varargin)
            setProperties(obj,nargin,varargin{:});
        end
    end
end
```

```
end

methods (Access = protected)
    % In setup allocate any resources, which in this case is
    % opening the file.
    function setupImpl(obj)
        obj.pFileID = fopen(obj.Filename,obj.Access);
        if obj.pFileID < 0
            error('Opening the file failed');
        end
    end
end

% This System object™ writes the input to the file.
function stepImpl(obj,data)
    fwrite(obj.pFileID,data);
end

% Use release to close the file to prevent the
% file handle from being left open.
function releaseImpl(obj)
    fclose(obj.pFileID);
end
end
end
```

## Reset Algorithm State

This example shows how to reset an object state.

### Reset Counter to Zero

pCount is an internal counter property of the System object obj. The user calls the reset method on the locked object, which calls the resetImpl method. In this example, pCount resets to 0.

---

**Note:** When resetting an object's state, make sure you reset the size, complexity, and data type correctly.

---

```
methods (Access = protected)
    function resetImpl(obj)
        obj.pCount = 0;
    end
end
```

### Complete Class Definition File with State Reset

```
classdef Counter < matlab.System
% Counter System object™ that increments a counter

    properties (Access = private)
        pCount
    end

    methods (Access = protected)
        % In step, increment the counter and return
        % its value as an output
        function c = stepImpl(obj)
            obj.pCount = obj.pCount + 1;
            c = obj.pCount;
        end

        % Reset the counter to zero.
        function resetImpl(obj)
            obj.pCount = 0;
        end
    end
end
```

end

See “Methods Timing” on page 39-89 for more information.

resetImpl

### **More About**

- “Methods Timing” on page 39-89

## Define Property Attributes

This example shows how to specify property attributes.

*Property attributes*, which add details to a property, provide a layer of control to your properties. In addition to the MATLAB property attributes, System objects can use these three additional attributes—`nontunable`, `logical`, and `positiveInteger`. To specify multiple attributes, separate them with commas.

### Specify Property as Nontunable

Use the *nontunable* attribute for a property when the algorithm depends on the value being constant once data processing starts. Defining a property as nontunable may improve the efficiency of your algorithm by removing the need to check for or react to values that change. For code generation, defining a property as nontunable allows the memory associated with that property to be optimized. You should define all properties that affect the number of input or output ports as nontunable.

System object users cannot change nontunable properties after the `setup` or `step` method has been called. In this example, you define the `InitialValue` property, and set its value to 0.

```
properties (Nontunable)
    InitialValue = 0;
end
```

### Specify Property as Logical

Logical properties have the value, `true` or `false`. System object users can enter 1 or 0 or any value that can be converted to a logical. The value, however, displays as `true` or `false`. You can use sparse logical values, but they must be scalar values. In this example, the `Increment` property indicates whether to increase the counter. By default, `Increment` is tunable property. The following restrictions apply to a property with the `Logical` attribute,

- Cannot also be `Dependent` or `PositiveInteger`
- Default value must be `true` or `false`. You cannot use 1 or 0 as a default value.

```
properties (Logical)
    Increment = true
end
```

### Specify Property as Positive Integer

In this example, the private property `MaxValue` is constrained to accept only real, positive integers. You cannot use sparse values. The following restriction applies to a property with the `PositiveInteger` attribute,

- Cannot also be `Dependent` or `Logical`

```
properties (PositiveInteger)
    MaxValue
end
```

### Specify Property as DiscreteState

If your algorithm uses properties that hold state, you can assign those properties the `DiscreteState` attribute. Properties with this attribute display their state values when users call `getDiscreteStateImpl` via the `getDiscreteState` method. The following restrictions apply to a property with the `DiscreteState` attribute,

- Numeric, logical, or `fi` value, but not a scaled double `fi` value
- Does not have any of these attributes: `Nontunable`, `Dependent`, `Abstract`, `Constant`, or `Transient`.
- No default value
- Not publicly settable
- `GetAccess` = `Public` by default
- Value set only using the `setupImpl` method or when the `System` object is locked during `resetImpl` or `stepImpl`

In this example, you define the `Count` property.

```
properties (DiscreteState)
    Count;
end
```

### Complete Class Definition File with Property Attributes

```
classdef Counter < matlab.System
% Counter Increment a counter to a maximum value

    % These properties are nontunable. They cannot be changed
    % after the setup or step method has been called.
    properties (Nontunable)
```

```
% The initial value of the counter
InitialValue = 0
end
properties (Nontunable, PositiveInteger)
% The maximum value of the counter
MaxValue = 3
end

properties (Logical)
% Whether to increment the counter
Increment = true
end

properties (DiscreteState)
% Count state variable
Count
end

methods (Access = protected)
% In step, increment the counter and return its value
% as an output

function c = stepImpl(obj)
    if obj.Increment && (obj.Count < obj.MaxValue)
        obj.Count = obj.Count + 1;
    else
        disp(['Max count, ' num2str(obj.MaxValue) ',reached'])
    end
    c = obj.Count;
end

% Setup the Count state variable
function setupImpl(obj)
    obj.Count = 0;
end

% Reset the counter to one.
function resetImpl(obj)
    obj.Count = obj.InitialValue;
end
end
```

end

## Hide Inactive Properties

This example shows how to hide the display of a property that is not active for a particular object configuration.

### Hide an inactive property

You use the `isInactivePropertyImpl` method to hide a property from displaying. If the `isInactiveProperty` method returns `true` to the property you pass in, then that property does not display.

```
methods (Access = protected)
    function flag = isInactivePropertyImpl(obj,propertyName)
        if strcmp(propertyName,'InitialValue')
            flag = obj.UseRandomInitialValue;
        else
            flag = false;
        end
    end
end
```

### Complete Class Definition File with Hidden Inactive Property

```
classdef Counter < matlab.System
    % Counter Increment a counter

    % These properties are nontunable. They cannot be changed
    % after the setup or step method has been called.
    properties (Nontunable)
        % Allow the user to set the initial value
        UseRandomInitialValue = true
        InitialValue = 0
    end

    % The private count variable, which is tunable by default
    properties (Access = private)
        pCount
    end

    methods (Access = protected)
        % In step, increment the counter and return its value
        % as an output
        function c = stepImpl(obj)
            obj.pCount = obj.pCount + 1;
        end
    end
end
```

```
    c = obj.pCount;
end

% Reset the counter to either a random value or the initial
% value.
function resetImpl(obj)
    if obj.UseRandomInitialValue
        obj.pCount = rand();
    else
        obj.pCount = obj.InitialValue;
    end
end

% This method controls visibility of the object's properties
function flag = isInactivePropertyImpl(obj,propertyName)
    if strcmp(propertyName,'InitialValue')
        flag = obj.UseRandomInitialValue;
    else
        flag = false;
    end
end
end
end
```

## Limit Property Values to Finite String Set

This example shows how to limit a property to accept only a finite set of string values.

### Specify a Set of Valid String Values

String sets use two related properties. You first specify the user-visible property name and default string value. Then, you specify the associated hidden property by appending “Set” to the property name. You must use a capital “S” in “Set.”

In the “Set” property, you specify the valid string values as a cell array of the `matlab.system.Stringset` class. This example uses `Color` and `ColorSet` as the associated properties.

```
properties
    Color = 'blue'
end

properties (Hidden,Transient)
    ColorSet = matlab.system.StringSet({'red','blue','green'});
end
```

### Complete Class Definition File with String Set

```
classdef Whiteboard < matlab.System
% Whiteboard Draw lines on a figure window
%
% This System object™ illustrates the use of StringSets

    properties
        Color = 'blue'
    end

    properties (Hidden,Transient)
        % Let them choose a color
        ColorSet = matlab.system.StringSet({'red','blue','green'});
    end

    methods (Access = protected)
        function stepImpl(obj)
            h = Whiteboard.getWhiteboard();
            plot(h, ...
                randn([2,1]),randn([2,1]), ...
                'Color',obj.Color(1));
        end
    end
end
```

```
end
function releaseImpl(obj)
    cla(Whiteboard.getWhiteboard());
    hold on
end
end

methods (Static)
function a = getWhiteboard()
    h = findobj('tag','whiteboard');
    if isempty(h)
        h = figure('tag','whiteboard');
        hold on
    end
    a = gca;
end
end
end
```

### String Set System Object Example

```
%%
% Each call to step draws lines on a whiteboard

%% Construct the System object
hGreenInk = Whiteboard;
hBlueInk = Whiteboard;

% Change the color
% Note: Press tab after typing the first single quote to
% display all enumerated values.
hGreenInk.Color = 'green';
hBlueInk.Color = 'blue';

% Take a few steps
for i=1:3
    hGreenInk.step();
    hBlueInk.step();
end

%% Clear the whiteboard
hBlueInk.release();

%% Display System object used in this example
```

```
type('Whiteboard.m');
```

## Process Tuned Properties

This example shows how to specify the action to take when a tunable property value changes during simulation.

The `processTunedPropertiesImpl` method is useful for managing actions to prevent duplication. In many cases, changing one of multiple interdependent properties causes an action. With the `processTunedPropertiesImpl` method, you can control when that action is taken so it is not repeated unnecessarily.

### Control When a Lookup Table Is Generated

This example of `processTunedPropertiesImpl` causes the `pLookupTable` to be regenerated when either the `NumNotes` or `MiddleC` property changes.

```
methods (Access = protected)
    function processTunedPropertiesImpl(obj)
        propChange = isChangedProperty(obj,obj.NumNotes)||...
                    isChangedProperty(obj,obj.MiddleC)
        if propChange
            obj.pLookupTable = obj.MiddleC *...
                (1+log(1:obj.NumNotes)/log(12));
        end
    endend
```

### Complete Class Definition File with Tuned Property Processing

```
classdef TuningFork < matlab.System
    % TuningFork Illustrate the processing of tuned parameters
    %

    properties
        MiddleC = 440
        NumNotes = 12
    end

    properties (Access = private)
        pLookupTable
    end

    methods (Access = protected)
        function resetImpl(obj)
            obj.MiddleC = 440;
            obj.pLookupTable = obj.MiddleC * ...

```

```
        (1+log(1:obj.NumNotes)/log(12));
end

function hz = stepImpl(obj,noteShift)
    % A noteShift value of 1 corresponds to obj.MiddleC
    hz = obj.pLookupTable(noteShift);
end

function processTunedPropertiesImpl(obj)
    propChange = isChangedProperty(obj,obj.NumNotes)||...
        isChangedProperty(obj,obj.MiddleC)
    if propChange
        obj.pLookupTable = obj.MiddleC *...
            (1+log(1:obj.NumNotes)/log(12));
    end
end
end
```

## Release System Object Resources

This example shows how to release resources allocated and used by the System object. These resources include allocated memory, files used for reading or writing, etc.

### Release Memory by Clearing the Object

This method allows you to clear the axes on the Whiteboard figure window while keeping the figure open.

```
methods
    function releaseImpl(obj)
        cla(Whiteboard.getWhiteboard());
        hold on
    end
end
```

### Complete Class Definition File with Released Resources

```
classdef Whiteboard < matlab.System
% Whiteboard Draw lines on a figure window
%
% This System object™ shows the use of StringSets
%
    properties
        Color = 'blue'
    end

    properties (Hidden)
        % Let user choose a color
        ColorSet = matlab.system.StringSet({'red','blue','green'});
    end

    methods (Access = protected)
        function stepImpl(obj)
            h = Whiteboard.getWhiteboard();
            plot(h, ...
                randn([2,1]), randn([2,1]), ...
                'Color',obj.Color(1));
        end

        function releaseImpl(obj)
            cla(Whiteboard.getWhiteboard());
            hold on
        end
    end
end
```

```
        end
    end

    methods (Static)
        function a = getWhiteboard()
            h = findobj('tag','whiteboard');
            if isempty(h)
                h = figure('tag','whiteboard');
                hold on
            end
            a = gca;
        end
    end
end
```

## Define Composite System Objects

This example shows how to define System objects that include other System objects.

This example defines a bandpass filter System object from separate highpass and lowpass filter System objects.

### Store System Objects in Properties

To define a System object from other System objects, store those other objects in your class definition file as properties. In this example, the highpass and lowpass filters are the separate System objects defined in their own class-definition files.

```
properties (Access = private)
    % Properties that hold filter System objects
    pLowpass
    pHighpass
end
```

### Complete Class Definition File of Bandpass Filter Composite System Object

```
classdef BandpassFIRFilter < matlab.System
    % Implements a bandpass filter using a cascade of eighth-order lowpass
    % and eighth-order highpass FIR filters.

    properties (Access = private)
        % Properties that hold filter System objects
        pLowpass
        pHighpass
    end

    methods (Access = protected)
        function setupImpl(obj)
            % Setup composite object from constituent objects
            obj.pLowpass = LowpassFIRFilter;
            obj.pHighpass = HighpassFIRFilter;
        end

        function y = stepImpl(obj,u)
            yLow = step(obj.pLowpass,u);
            yHigh = step(obj.pHighpass,yLow);
        end

        function resetImpl(obj)
```

```

        reset(obj.pLowpass);
        reset(obj.pHighpass);
    end
end
end

```

### Class Definition File for Lowpass FIR Component of Bandpass Filter

```

classdef LowpassFIRFilter < matlab.System
% Implements eighth-order lowpass FIR filter with 0.6pi cutoff

    properties (Nontunable)
        % Filter coefficients
        Numerator = [0.006, -0.0133, -0.05, 0.26, 0.6, 0.26, -0.05, -0.0133, 0.006];
    end

    properties (DiscreteState)
        State
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.State = zeros(length(obj.Numerator)-1,1);
        end
        function y = stepImpl(obj,u)
            [y,obj.State] = filter(obj.Numerator,1,u,obj.State);
        end
        function resetImpl(obj)
            obj.State = zeros(length(obj.Numerator)-1,1);
        end
    end
end
end

```

### Class Definition File for Highpass FIR Component of Bandpass Filter

```

classdef HighpassFIRFilter < matlab.System
% Implements eighth-order highpass FIR filter with 0.4pi cutoff

    properties (Nontunable)
        % Filter coefficients
        Numerator = [0.006, 0.0133, -0.05, -0.26, 0.6, -0.26, -0.05, 0.0133, 0.006];
    end

    properties (DiscreteState)
        State
    end
end

```

```
end

methods (Access = protected)
function setupImpl(obj)
    obj.State = zeros(length(obj.Numerator)-1,1);
end

function y = stepImpl(obj,u)
    [y,obj.State] = filter(obj.Numerator,1,u,obj.State);
end

function resetImpl(obj)
    obj.State = zeros(length(obj.Numerator)-1,1);
end
end
end
```

## Define Finite Source Objects

This example shows how to define a System object that performs a specific number of steps or specific number of reads from a file.

### Use the FiniteSource Class and Specify End of the Source

- 1 Subclass from finite source class.

```
classdef RunTwice < matlab.System & ...
    matlab.system.mixin.FiniteSource
```

- 2 Specify the end of the source with the `isDoneImpl` method. In this example, the source has two iterations.

```
methods (Access = protected)
    function bDone = isDoneImpl(obj)
        bDone = obj.NumSteps==2
    end
```

### Complete Class Definition File with Finite Source

```
classdef RunTwice < matlab.System & ...
    matlab.system.mixin.FiniteSource
    % RunTwice System object that runs exactly two times
    %
    properties (Access = private)
        NumSteps
    end

    methods (Access = protected)
        function resetImpl(obj)
            obj.NumSteps = 0;
        end

        function y = stepImpl(obj)
            if ~obj.isDone()
                obj.NumSteps = obj.NumSteps + 1;
                y = obj.NumSteps;
            else
                y = 0;
            end
        end

        function bDone = isDoneImpl(obj)
```

```
        bDone = obj.NumSteps==2;
    end
end
end
```

## Save System Object

This example shows how to save a System object.

### Save System Object and Child Object

Define a `saveObjectImpl` method to specify that more than just public properties should be saved when the user saves a System object. Within this method, use the default `saveObjectImpl@matlab.System` to save public properties to the struct, `s`. Use the `saveObject` method to save child objects. Save protected and dependent properties, and finally, if the object is locked, save the object's state.

```
methods (Access = protected)
    function s = saveObjectImpl(obj)
        s = saveObjectImpl@matlab.System(obj);
        s.child = matlab.System.saveObject(obj.child);
        s.protectedprop = obj.protectedprop;
        s.pdependentprop = obj.pdependentprop;
        if isLocked(obj)
            s.state = obj.state;
        end
    end
end
```

### Complete Class Definition Files with Save and Load

The `Counter` class definition file sets up an object with a count property. This counter is used in the `MySaveLoader` class definition file to count the number of child objects.

```
classdef Counter < matlab.System
    properties(DiscreteState)
        Count
    end
    methods (Access=protected)
        function setupImpl(obj, ~)
            obj.Count = 0;
        end
        function y = stepImpl(obj, u)
            if u > 0
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end
    end
end
```

```
    end
end

classdef MySaveLoader < matlab.System

    properties (Access = private)
        child
        pdependentprop = 1
    end

    properties (Access = protected)
        protectedprop = rand;
    end

    properties (DiscreteState = true)
        state
    end

    properties (Dependent)
        dependentprop
    end

    methods
        function obj = MySaveLoader(varargin)
            obj@matlab.System();
            setProperties(obj,nargin,varargin{:});
        end

        function set.dependentprop(obj, value)
            obj.pdependentprop = min(value, 5);
        end

        function value = get.dependentprop(obj)
            value = obj.pdependentprop;
        end
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.state = 42;
            obj.child = Counter;
        end
        function out = stepImpl(obj,in)
            obj.state = in + obj.state + obj.protectedprop + obj.pdependentprop;
            out = step(obj.child, obj.state);
        end
    end
end
```

```
    end
end

% Serialization
methods (Access = protected)
function s = saveObjectImpl(obj)
    % Call the base class method
    s = saveObjectImpl@matlab.System(obj);

    % Save the child System objects
    s.child = matlab.System.saveObject(obj.child);

    % Save the protected & private properties
    s.protectedprop = obj.protectedprop;
    s.pdependentprop = obj.pdependentprop;

    % Save the state only if object locked
    if isLocked(obj)
        s.state = obj.state;
    end
end

function loadObjectImpl(obj,s,wasLocked)
    % Load child System objects
    obj.child = matlab.System.loadObject(s.child);

    % Load protected and private properties
    obj.protectedprop = s.protectedprop;
    obj.pdependentprop = s.pdependentprop;

    % Load the state only if object locked
    if wasLocked
        obj.state = s.state;
    end

    % Call base class method to load public properties
    loadObjectImpl@matlab.System(obj,s,wasLocked);
end
end
end
```

## Load System Object

This example shows how to load and save a System object.

### Load System Object and Child Object

Define a `loadObjectImpl` method to load a previously saved System object. Within this method, use the `matlab.System.loadObject` to load the child System object, load protected and private properties, load the state if the object is locked, and use `loadObjectImpl` from the base class to load public properties.

```
methods (Access = protected)
    function loadObjectImpl(obj,s,wasLocked)
        obj.child = matlab.System.loadObject(s.child);

        obj.protectedprop = s.protectedprop;
        obj.pdependentprop = s.pdependentprop;

        if wasLocked
            obj.state = s.state;
        end

        loadObjectImpl@matlab.System(obj,s,wasLocked);
    end
end
```

### Complete Class Definition Files with Save and Load

The Counter class definition file sets up an object with a count property. This counter is used in the MySaveLoader class definition file to count the number of child objects.

```
classdef Counter < matlab.System
    properties (DiscreteState)
        Count
    end
    methods (Access=protected)
        function setupImpl(obj, ~)
            obj.Count = 0;
        end
        function y = stepImpl(obj, u)
            if u > 0
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end
    end
end
```

```
        end
    end
end

classdef MySaveLoader < matlab.System

    properties (Access = private)
        child
        pdependentprop = 1
    end

    properties (Access = protected)
        protectedprop = rand;
    end

    properties (DiscreteState = true)
        state
    end

    properties (Dependent)
        dependentprop
    end

    methods
        function obj = MySaveLoader(varargin)
            obj@matlab.System();
            setProperties(obj,nargin,varargin{:});
        end

        function set.dependentprop(obj, value)
            obj.pdependentprop = min(value, 5);
        end

        function value = get.dependentprop(obj)
            value = obj.pdependentprop;
        end
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.state = 42;
            obj.child = Counter;
        end
        function out = stepImpl(obj,in)
            obj.state = in + obj.state + obj.protectedprop + obj.pdependentprop;
        end
    end
end
```

```
        out = step(obj.child, obj.state);
    end
end

% Serialization
methods (Access = protected)
function s = saveObjectImpl(obj)
    % Call the base class method
    s = saveObjectImpl@matlab.System(obj);

    % Save the child System objects
    s.child = matlab.System.saveObject(obj.child);

    % Save the protected & private properties

## Define System Object Information

This example shows how to define information to display for a System object.

### Define System Object Info

You can define your own `info` method to display specific information for your System object. The default `infoImpl` method returns an empty struct. This `infoImpl` method returns detailed information when the `info` method is called using `info(x, 'details')` or only count information if it is called using `info(x)`.

```
methods (Access = protected)
    function s = infoImpl(obj,varargin)
        if nargin>1 && strcmp('details',varargin(1))
            s = struct('Name','Counter',...
                'Properties', struct('CurrentCount', ...
                    obj.pCount,'Threshold',obj.Threshold));
        else
            s = struct('Count',obj.pCount);
        end
    end
end
```

### Complete Class Definition File with InfoImpl

```
classdef Counter < matlab.System
    % Counter Count values above a threshold

    properties
        Threshold = 1
    end

    properties (DiscreteState)
        Count
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end

        function resetImpl(obj)
            obj.Count = 0;
        end
    end
end
```

```
function y = stepImpl(obj,u)
    if (u > obj.Threshold)
        obj.Count = obj.Count + 1;
    end
    y = obj.Count;
end

function s = infoImpl(obj,varargin)
    if nargin>1 && strcmp('details',varargin(1))
        s = struct('Name','Counter',...
            'Properties', struct('CurrentCount', ...
                obj.pCount, 'Threshold',obj.Threshold));
    else
        s = struct('Count',obj.pCount);
    end
end
end
end
```

## Define System Block Icon

This example shows how to define the block icon of a System object–based block implemented using a MATLAB System block.

### Use the CustomIcon Class and Define the Icon

- 1 Subclass from custom icon class.

```
classdef MyCounter < matlab.System & ...
    matlab.system.mixin.CustomIcon
```

- 2 Use `getIconImpl` to specify the block icon as `New Counter` with a line break (`\n`) between the two words.

```
methods (Access = protected)
    function icon = getIconImpl(~)
        icon = sprintf('New\nCounter');
    end
end
```

### Complete Class Definition File with Defined Icon

```
classdef MyCounter < matlab.System & ...
    matlab.system.mixin.CustomIcon

    % MyCounter Count values above a threshold

    properties
        Threshold = 1
    end
    properties (DiscreteState)
        Count
    end

    methods
        function obj = MyCounter(varargin)
            setProperties(obj,nargin,varargin{:});
        end
    end

    methods (Access = protected)
        function setupImpl(obj)
            obj.Count = 0;
        end
    end
```

```
function resetImpl(obj)
    obj.Count = 0;
end
function y = stepImpl(obj,u)
    if (u > obj.Threshold)
        obj.Count = obj.Count + 1;
    end
    y = obj.Count;
end
function icon = getIconImpl(~)
    icon = sprintf('New\nCounter');
end
end
end
```

## Add Header to System Block Dialog

This example shows how to add a header panel to a System object–based block implemented using a MATLAB System block.

### Define Header Title and Text

This example shows how to use `getHeaderImpl` to specify a panel title and text for the `MyCounter` System object.

If you do not specify the `getHeaderImpl`, the block does not display any title or text for the panel.

You always set the `getHeaderImpl` method access to `protected` because it is an internal method that end users do not directly call or run.

```
methods (Static, Access = protected)
    function header = getHeaderImpl
        header = matlab.system.display.Header('MyCounter',...
            'Title', 'My Enhanced Counter');
    end
end
```

### Complete Class Definition File with Defined Header

```
classdef MyCounter < matlab.System

    % MyCounter Count values

    properties
        Threshold = 1
    end
    properties (DiscreteState)
        Count
    end

    methods (Static, Access = protected)
        function header = getHeaderImpl
            header = matlab.system.display.Header('MyCounter',...
                'Title', 'My Enhanced Counter',...
                'Text', 'This counter is an enhanced version.');
```

```
methods (Access = protected)
    function setupImpl(obj,u)
        obj.Count = 0;
    end
    function y = stepImpl(obj,u)
        if (u > obj.Threshold)
            obj.Count = obj.Count + 1;
        end
        y = obj.Count;
    end
    function resetImpl(obj)
        obj.Count = 0;
    end
end
end
```

## Add Property Groups to System Object and Block Dialog

This example shows how to define property sections and section groups for System object display. The sections and section groups display as panels and tabs, respectively, in the MATLAB System block dialog.

### Define Section of Properties

This example shows how to use `matlab.system.display.Section` and `getPropertyGroupsImpl` to define two property group sections by specifying their titles and property lists.

If you do not specify a property in `getPropertyGroupsImpl`, the block does not display that property.

```
methods (Static, Access = protected)
    function groups = getPropertyGroupsImpl
        valueGroup = matlab.system.display.Section(...
            'Title', 'Value parameters', ...
            'PropertyList', {'StartValue', 'EndValue'});

        thresholdGroup = matlab.system.display.Section(...
            'Title', 'Threshold parameters', ...
            'PropertyList', {'Threshold', 'UseThreshold'});
        groups = [valueGroup, thresholdGroup];
    end
end
```

### Define Group of Sections

This example shows how to use `matlab.system.display.SectionGroup`, `matlab.system.display.Section`, and `getPropertyGroupsImpl` to define two tabs, each containing specific properties.

```
methods (Static, Access = protected)
    function groups = getPropertyGroupsImpl
        upperGroup = matlab.system.display.Section(...
            'Title', 'Upper threshold', ...
            'PropertyList', {'UpperThreshold'});
        lowerGroup = matlab.system.display.Section(...
            'Title', 'Lower threshold', ...
            'PropertyList', {'UseLowerThreshold', 'LowerThreshold'});

        thresholdGroup = matlab.system.display.SectionGroup(...
```

```
        'Title', 'Parameters', ...
        'Sections', [upperGroup,lowerGroup]);

    valuesGroup = matlab.system.display.SectionGroup(...
        'Title', 'Initial conditions', ...
        'PropertyList', {'StartValue'});

    groups = [thresholdGroup, valuesGroup];
end
end
```

### Complete Class Definition File with Property Group and Separate Tab

```
classdef EnhancedCounter < matlab.System
    % EnhancedCounter Count values considering thresholds

    properties
        UpperThreshold = 1;
        LowerThreshold = 0;
    end

    properties (Nontunable)
        StartValue = 0;
    end

    properties(Logical,Nontunable)
        % Count values less than lower threshold
        UseLowerThreshold = true;
    end

    properties (DiscreteState)
        Count;
    end

    methods (Static, Access = protected)
        function groups = getPropertyGroupsImpl
            upperGroup = matlab.system.display.Section(...
                'Title', 'Upper threshold', ...
                'PropertyList', {'UpperThreshold'});
            lowerGroup = matlab.system.display.Section(...
                'Title', 'Lower threshold', ...
                'PropertyList', {'UseLowerThreshold', 'LowerThreshold'});

            thresholdGroup = matlab.system.display.SectionGroup(...
                'Title', 'Parameters', ...
```

```
        'Sections', [upperGroup,lowerGroup]);

    valuesGroup = matlab.system.display.SectionGroup(...
        'Title', 'Initial conditions', ...
        'PropertyList', {'StartValue'});

    groups = [thresholdGroup, valuesGroup];
end
end

methods (Access = protected)
function setupImpl(obj)
    obj.Count = obj.StartValue;
end

function y = stepImpl(obj,u)
    if obj.UseLowerThreshold
        if (u > obj.UpperThreshold) || ...
            (u < obj.LowerThreshold)
            obj.Count = obj.Count + 1;
        end
    else
        if (u > obj.UpperThreshold)
            obj.Count = obj.Count + 1;
        end
    end
    y = obj.Count;
end
function resetImpl(obj)
    obj.Count = obj.StartValue;
end

function flag = isInactivePropertyImpl(obj, prop)
    flag = false;
    switch prop
        case 'LowerThreshold'
            flag = ~obj.UseLowerThreshold;
    end
end
end
```

end

## Control Simulation Type in System Block Dialog

This example shows how to specify a simulation type and whether the **Simulate using** parameter appears on the Simulink MATLAB System block dialog box. The simulation options are 'Code generation' and 'Interpreted mode'.

If you do not include the `getSimulateUsingImpl` method in your class definition file, the System object allows both simulation modes and defaults to 'Code generation'. If you do not include the `showSimulateUsingImpl` method, the **Simulate using** parameter appears on the block dialog box.

You must set the `getSimulateUsingImpl` and `showSimulateUsingImpl` methods to **static** and the access for these methods to **protected**.

Use `getSimulateUsingImpl` to specify that only interpreted execution is allowed for the System object.

```
methods(Static,Access = protected)
    function simMode = getSimulateUsingImpl
        simMode = 'Interpreted execution';
    end
end
```

View the method in the complete class definition file.

```
classdef PlotRamp < matlab.System
    % Display a button to launch a plot figure.

    properties (Nontunable)
        RampLimit = 10;
    end

    methods(Static, Access=protected)
        function group = getPropertyGroupsImpl
            group = matlab.system.display.Section(mfilename('class'));
            group.Actions = matlab.system.display.Action(@(~,obj)...
                visualize(obj),'Label','Visualize');
        end

        function simMode = getSimulateUsingImpl
            simMode = 'Interpreted execution';
        end
    end
end
```

```
methods
function obj = ActionDemo(varargin)
    setProperties(obj,nargin,varargin{:});
end

function visualize(obj)
    figure;
    d = 1:obj.RampLimit;
    plot(d);
end
methods(Static,Access = protected)
end
end
end
```

## Add Button to System Block Dialog Box

This example shows how to add a button to the MATLAB System block dialog box. This button launches a figure that plots a ramp function.

### Define Action for Dialog Button

This example shows how to use `matlab.system.display.Action` to define the MATLAB function or code associated with a button in the MATLAB System block dialog. The example also shows how to set button options.

```
methods(Static,Access = protected)
    function group = getPropertyGroupsImpl
        group = matlab.system.display.Section(mfilename('class'));
        group.Actions = matlab.system.display.Action(@(-,obj)...
            visualize(obj),'Label','Visualize');
    end
end

methods
    function obj = ActionDemo(varargin)
        setProperties(obj,nargin,varargin{:});
    end

    function visualize(obj)
        figure;
        d = 1:obj.RampLimit;
        plot(d);
    end
end
```

### Complete Class Definition File for Dialog Button

Define a property group and a second tab in the class definition file.

```
classdef PlotRamp < matlab.System
    % Display a button to launch a plot figure.

    properties (Nontunable)
        RampLimit = 10;
    end

    methods(Static, Access=protected)
```

```
function group = getPropertyGroupsImpl
group = matlab.system.display.Section(mfilename('class'));
group.Actions = matlab.system.display.Action(@(-,obj)...
    visualize(obj),'Label','Visualize');
end
end

methods
function obj = ActionDemo(varargin)
    setProperties(obj,nargin,varargin{:});
end

function visualize(obj)
    figure;
    d = 1:obj.RampLimit;
    plot(d);
end
end
end
```

## Specify Locked Input Size

This example shows how to specify whether the size of a System object input is locked. The size of a locked input cannot change until the System object is unlocked. Use the `step` method and run the object to lock it. Use `release` to unlock the object.

Use the `isInputSizeLockedImpl` method to specify that the input size is locked.

```
methods (Access = protected)
    function flag = isInputSizeLockedImpl(~,~)
        flag = true;
    end
end
```

View the method in the complete class definition file.

```
classdef Counter < matlab.System
    %Counter Count values above a threshold

    properties
        Threshold = 1
    end

    properties (DiscreteState)
        Count
    end

    methods
        function obj = Counter(varargin)
            setProperties(obj,nargin,varargin{:});
        end
    end

    methods (Access=protected)
        function resetImpl(obj)
            obj.Count = 0;
        end

        function y = stepImpl(obj, u1)
            if (any(u1 >= obj.Threshold))
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end
    end
end
```

```
function flag = isInputSizeLockedImpl(~,~)
    flag = true;
end
end
end
```

isInputSizeLockedImpl

## Set Output Size

This example shows how to specify the size of a System object output using the `getOutputSizeImpl` method. Use this method when Simulink cannot infer the output size from the inputs during model compilation.

---

**Note:** For variable-size inputs, the propagated input size from `propagatedInputSizeImpl` differs depending on the environment.

- MATLAB — When you first run step on an object, it uses the actual sizes of the inputs.
  - Simulink — The maximum of all the input sizes is set before the model runs and does not change during the run.
- 

Subclass from both the `matlab.System` base class and the `Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...
    matlab.system.mixin.Propagates
```

Use the `getOutputSizeImpl` method to specify the output size.

```
methods (Access = protected)
    function sizeout = getOutputSizeImpl(~)
        sizeout = [1 1];
    end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
    % CounterReset Count values above a threshold

    properties
        Threshold = 1
    end

    properties (DiscreteState)
        Count
    end

    methods (Access = protected)
```

```
function setupImpl(obj)
    obj.Count = 0;
end

function y = stepImpl(obj,u1,u2)
    % Add to count if u1 is above threshold
    % Reset if u2 is true
    if (u2)
        obj.Count = 0;
    elseif (any(u1 > obj.Threshold))
        obj.Count = obj.Count + 1;
    end
    y = obj.Count;
end

function resetImpl(obj)
    obj.Count = 0;
end

function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
    if strcmp(name,'Count')
        sz = [1 1];
        dt = 'double';
        cp = false;
    else
        error(['Error: Incorrect State Name: ' name '.']);
    end
end

function dataout = getOutputDataTypeImpl(~)
    dataout = 'double';
end

function sizeout = getOutputSizeImpl(~)
    sizeout = [1 1];
end

function cplxout = isOutputComplexImpl(~)
    cplxout = false;
end

function fixedout = isOutputFixedSizeImpl(~)
    fixedout = true;
end

function inLocked = isInputSizeLockedImpl(~,idx)
    if idx == 1
        inLocked = false;
    else
end
```

```
        inLocked = true;
    end
end
end
end
```

## Set Output Data Type

This example shows how to specify the data type of a System object output using the `getOutputDataTypeImpl` method. A second example shows how to specify a gain object with bus output. Use this method when Simulink cannot infer the data type from the inputs during model compilation or when you want bus output. To use bus output, you must include a property to define the bus name and you must include the `getOutputDataTypeImpl` method in your class definition file.

For both examples, subclass from both the `matlab.System` base class and the `matlab.system.mixin.Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...  
    matlab.system.mixin.Propagates
```

Use the `getOutputDataTypeImpl` method to specify the output data type as a double.

```
methods (Access = protected)  
    function dataout = getOutputDataTypeImpl(~)  
        dataout = 'double';  
    end  
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates  
    % CounterReset Count values above a threshold  
  
    properties  
        Threshold = 1  
    end  
  
    properties (DiscreteState)  
        Count  
    end  
  
    methods (Access = protected)  
        function setupImpl(obj)  
            obj.Count = 0;  
        end  
  
        function resetImpl(obj)  
            obj.Count = 0;  
        end  
    end
```

```

function y = stepImpl(obj,u1,u2)
    % Add to count if u1 is above threshold
    % Reset if u2 is true
    if (u2)
        obj.Count = 0;
    elseif (u1 > obj.Threshold)
        obj.Count = obj.Count + 1;
    end
    y = obj.Count;
end

function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
    if strcmp(name,'Count')
        sz = [1 1];
        dt = 'double';
        cp = false;
    else
        error(['Error: Incorrect State Name: 'name'.']);
    end
end

function dataout = getOutputDataTypeImpl(~)
    dataout = 'double';
end

function sizeout = getOutputSizeImpl(~)
    sizeout = [1 1];
end

function cplxout = isOutputComplexImpl(~)
    cplxout = false;
end

function fixedout = isOutputFixedSizeImpl(~)
    fixedout = true;
end
end
end

```

Use the `getOutputDataTypeImpl` method to specify the output data type as a bus. Specify the bus name in a property.

```

properties(Nontunable)
    OutputBusName = 'bus_name';
end

methods (Access = protected)
    function out = getOutputDataTypeImpl(obj)

```

```
        out = obj.OutputBusName;
    end
end
```

View the method in the complete class definition file. This class definition file also includes code to implement a custom icon for this object in the MATLAB System block

```
classdef busGain < matlab.System & matlab.system.mixin.Propagates
% busGain Apply a gain of two to bus input.
```

```
    properties
        GainK = 2;
    end

    properties(Nontunable)
        OutputBusName = 'bus_name';
    end

    methods (Access=protected)
        function out = stepImpl(obj,in)
            out.a = obj.GainK * in.a;
            out.b = obj.GainK * in.b;
        end

        function out = getOutputSizeImpl(obj)
            out = propagatedInputSize(obj, 1);
        end

        function out = isOutputComplexImpl(obj)
            out = propagatedInputComplexity(obj, 1);
        end

        function out = getOutputDataTypeImpl(obj)
            out = obj.OutputBusName;
        end

        function out = isOutputFixedSizeImpl(obj)
            out = propagatedInputFixedSize(obj,1);
        end
    end
end
```

## Set Output Complexity

This example shows how to specify whether a System object output is complex or real using the `isOutputComplexImpl` method. Use this method when Simulink cannot infer the output complexity from the inputs during model compilation.

Subclass from both the `matlab.System` base class and the `Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...  
    matlab.system.mixin.Propagates
```

Use the `isOutputComplexImpl` method to specify that the output is real.

```
methods (Access = protected)  
    function cplxout = isOutputComplexImpl(~)  
        cplxout = false;  
    end  
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates  
    % CounterReset Count values above a threshold  
  
    properties  
        Threshold = 1  
    end  
  
    properties (DiscreteState)  
        Count  
    end  
  
    methods (Access = protected)  
        function setupImpl(obj)  
            obj.Count = 0;  
        end  
  
        function resetImpl(obj)  
            obj.Count = 0;  
        end  
  
        function y = stepImpl(obj,u1,u2)  
            % Add to count if u1 is above threshold  
            % Reset if u2 is true
```

```

    if (u2)
        obj.Count = 0;
    elseif (u1 > obj.Threshold)
        obj.Count = obj.Count + 1;
    end
    y = obj.Count;
end

function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
    if strcmp(name,'Count')
        sz = [1 1];
        dt = 'double';
        cp = false;
    else
        error(['Error: Incorrect State Name: 'name'.']);
    end
end
function dataout = getOutputDataTypeImpl(~)
    dataout = 'double';
end
function sizeout = getOutputSizeImpl(~)
    sizeout = [1 1];
end
function cplxout = isOutputComplexImpl(~)
    cplxout = false;
end
function fixedout = isOutputFixedSizeImpl(~)
    fixedout = true;
end
end
end

```

## Specify Whether Output Is Fixed- or Variable-Size

This example shows how to specify that System object output is fixed- or variable-size.

This example shows how to specify that a System object output is fixed-size. Use the `isOutputFixedSizeImpl` method when Simulink cannot infer the output type from the inputs during model compilation.

Subclass from both the `matlab.System` base class and the `matlab.system.mixin.Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...  
    matlab.system.mixin.Propagates
```

Use the `isOutputFixedSizeImpl` method to specify that the output is fixed size.

```
methods (Access = protected)  
    function fixedout = isOutputFixedSizeImpl(~)  
        fixedout = true;  
    end  
end

## Specify Discrete State Output Specification

This example shows how to specify the size, data type, and complexity of a discrete state property using the `getDiscreteStateSpecificationImpl` method. Use this method when your System object has a property with the `DiscreteState` attribute and Simulink cannot infer the output specifications during model compilation.

Subclass from both the `matlab.System` base class and from the `Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...  
    matlab.system.mixin.Propagates
```

Use the `getDiscreteStateSpecificationImpl` method to specify the size and data type. Also specify the complexity of a discrete state property, which is used in the counter reset example.

```
methods (Access = protected)  
    function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)  
        sz = [1 1];  
        dt = 'double';  
        cp = false;  
    end  
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates  
    % CounterReset Count values above a threshold  
  
    properties  
        Threshold = 1  
    end  
  
    properties (DiscreteState)  
        Count  
    end  
  
    methods (Access = protected)  
        function setupImpl(obj)  
            obj.Count = 0;  
        end  
  
        function resetImpl(obj)
```

```

        obj.Count = 0;
    end

    function y = stepImpl(obj,u1,u2)
        % Add to count if u1 is above threshold
        % Reset if u2 is true
        if (u2)
            obj.Count = 0;
        elseif (u1 > obj.Threshold)
            obj.Count = obj.Count + 1;
        end
        y = obj.Count;
    end

    function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
        sz = [1 1];
        dt = 'double';
        cp = false;
    end
    function dataout = getOutputDataTypeImpl(~)
        dataout = 'double';
    end
    function sizeout = getOutputSizeImpl(~)
        sizeout = [1 1];
    end
    function cplxout = isOutputComplexImpl(~)
        cplxout = false;
    end
    function fixedout = isOutputFixedSizeImpl(~)
        fixedout = true;
    end
end
end
end

```

## Use Update and Output for Nondirect Feedthrough

This example shows how to implement nondirect feedthrough for a System object using the `updateImpl`, `outputImpl` and `isInputDirectFeedthroughImpl` methods. In nondirect feedthrough, the object's outputs depend only on the internal states and properties of the object, rather than the input at that instant in time. You use these methods to separate the output calculation from the state updates of a System object. This enables you to use that object in a feedback loop and prevent algebraic loops.

### Subclass from the Nondirect Mixin Class

To use the `updateImpl`, `outputImpl`, and `isInputDirectFeedthroughImpl` methods, you must subclass from both the `matlab.System` base class and the `Nondirect` mixin class.

```
classdef IntegerDelaySysObj < matlab.System & ...  
    matlab.system.mixin.Nondirect
```

### Implement Updates to the Object

Implement an `updateImpl` method to update the object with previous inputs.

```
methods (Access = protected)  
    function updateImpl(obj,u)  
        obj.PreviousInput = [u obj.PreviousInput(1:end-1)];  
    end  
end
```

### Implement Outputs from Object

Implement an `outputImpl` method to output the previous, not the current input.

```
methods (Access = protected)  
    function [y] = outputImpl(obj,~)  
        y = obj.PreviousInput(end);  
    end  
end
```

### Implement Whether Input Is Direct Feedthrough

Implement an `isInputDirectFeedthroughImpl` method to indicate that the input is nondirect feedthrough.

```
methods (Access = protected)
```

```

function flag = isInputDirectFeedthroughImpl(~,~)
    flag = false;
end
end

```

### Complete Class Definition File with Update and Output

```

classdef intDelaySysObj < matlab.System &...
    matlab.system.mixin.Nondirect &...
    matlab.system.mixin.CustomIcon
    % intDelaySysObj Delay input by specified number of samples.

    properties
        InitialOutput = 0;
    end
    properties (Nontunable)
        NumDelays = 1;
    end
    properties (DiscreteState)
        PreviousInput;
    end

    methods (Access = protected)
        function validatePropertiesImpl(obj)
            if ((numel(obj.NumDelays)>1) || (obj.NumDelays <= 0))
                error('Number of delays must be positive non-zero scalar value.');
            end
            if (numel(obj.InitialOutput)>1)
                error('Initial Output must be scalar value.');
            end
        end

        function setupImpl(obj)
            obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
        end

        function resetImpl(obj)
            obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
        end

        function [y] = outputImpl(obj,~)
            y = obj.PreviousInput(end);
        end
        function updateImpl(obj, u)
            obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
        end
    end
end

```

```
    end
    function flag = isInputDirectFeedthroughImpl(~,~)
        flag = false;
    end
end
end
```

## Enable For Each Subsystem Support

This example shows how to enable using a System object in a Simulink For Each subsystem. Include the `supportsMultipleInstanceImpl` method in your class definition file. This method applies only when the System object is used in Simulink via the MATLAB System block.

Use the `supportsMultipleInstanceImpl` method and have it return `true` to indicate that the System object supports multiple calls in a Simulink For Each subsystem.

```
methods (Access = protected)
    function flag = supportsMultipleInstanceImpl(obj)
        flag = true;
    end
end
```

View the method in the complete class definition file.

```
classdef RandSeed < matlab.System
% RANDSEED Random noise with seed for use in For Each subsystem

    properties (DiscreteState)
        count;
    end

    properties (Nontunable)
        seed = 20;
    end

    properties (Nontunable,Logical)
        useSeed = false;
    end

    methods (Access = protected)
        function y = stepImpl(obj,u1)
            % Initial use after reset/setup
            % and use the seed
            if (obj.useSeed && ~obj.count)
                rng(obj.seed);
            end
            obj.count = obj.count + 1;
            [m,n] = size(u1);
            % Uses default rng seed
            y = rand(m,n) + u1;
        end
    end
end
```

```
    end

    function setupImpl(obj)
        obj.count = 0;
    end
    function resetImpl(obj)
        obj.count = 0;
    end

    function flag = supportsMultipleInstanceImpl(obj)
        flag = obj.useSeed;
    end
end
end
```

## System Object Input Arguments and ~ in Code Examples

All methods, except static methods, expect the System object handle as the first input argument. You can use any name for your System object handle. In many examples, instead of passing in the object handle, ~ is used to indicate that the object handle is not used in the function. Using ~ instead of an object handle prevents warnings about unused variables.

## What Are Mixin Classes?

Mixin classes are partial classes that you can combine in various combinations to form desired behaviors using multiple inheritance. System objects are composed of a base class, `matlab.System` and may include one or more mixin classes. You specify the base class and mixin classes on the first line of your class definition file.

The following mixin classes are available for use with System objects.

- `matlab.system.mixin.CustomIcon` — Defines a block icon for System objects in the MATLAB System block
- `matlab.system.mixin.FiniteSource` — Adds the `isDone` method to System objects that are sources
- `matlab.system.mixin.Nondirect` — Allows the System object, when used in the MATLAB System block, to support nondirect feedthrough by making the runtime callback functions, `output` and `update` available
- `matlab.system.mixin.Propagates` — Enables System objects to operate in the MATLAB System block using the interpreted execution

## Best Practices for Defining System Objects

A System object is a specialized kind of MATLAB object that is optimized for iterative processing. Use System objects when you need to call the `step` method multiple times or process data in a loop. When defining your own System object, use the following suggestions to help your code run efficiently.

- Define all one-time calculations in the `setupImpl` method and cache the results in a private property. Use the `stepImpl` method for repeated calculations.
- If properties are accessed more than once in the `stepImpl` method, cache those properties as local variables inside the method. A typical example of multiple property access is a loop. Iterative calculations using cached local variables run faster than calculations that must access the properties of an object. When the calculations for the method complete, you can save the local cached results back to the properties of that System object. Copy frequently used tunable properties into private properties. This best practice also applies to the `updateImpl` and `outputImpl` methods.

In this example, `k` is accessed multiple times in each loop iteration, but is saved to the object property only once.

```
function y = stepImpl(obj,x)
    k = obj.MyProp;
    for p=1:100
        y = k * x;
        k = k + 0.1;
    end
    obj.MyProp = k;
end
```

- Do not use string comparisons or string-based switch statements in the `stepImpl` method. Instead, create a method handle in `setupImpl`. This handle points to a method in the same class definition file. Use that handle in a loop in `stepImpl`.

This example shows how to use method handles and cached local variables in a loop to implement an efficient object. In `setupImpl`, choose `myMethod1` or `myMethod2` based on a string comparison and assign the method handle to the `pMethodHandle` property. Because there is a loop in `stepImpl`, assign the `pMethodHandle` property to a local method handle, `myFun`, and then use `myFun` inside the loop.

```
classdef MyClass < matlab.System
    function setupImpl(obj)
        if strcmp(obj.Method, 'Method1')
```

```

        obj.pMethodHandle = @myMethod1;
    else
        obj.pMethodHandle = @myMethod2;
    end
end
function y = stepImpl(obj,x)
    myFun = obj.pMethodHandle;
    for p=1:1000
        y = myFun(obj,x)
    end
end
end
function y = myMethod1(x)
    y = x+1;
end
function y = myMethod2(x)
    y = x-1;
end
end
end

```

- If the number of System object inputs does not change, do not implement the `getNumInputsImpl` method. Also do not implement the `getNumInputsImpl` method when you explicitly list the inputs in the `stepImpl` method instead of using `varargin`. The same caveats apply to the `getNumOutputsImpl` and `varargout` outputs.
- For the `getNumInputsImpl` and `getNumOutputsImpl` methods, if you set the return argument from an object property, that object property must have the `Nontunable` attribute.
- If the variables in a method do not need to retain their values between calls use local scope for those variables in that method.
- For properties that do not change, define them in as `Nontunable` properties. `Tunable` properties have slower access times than `Nontunable` properties
- Use the `protected` or `private` attribute instead of the `public` attribute for a property, whenever possible. Some `public` properties have slower access times than `protected` and `private` properties.
- Avoid using customized `step`, `get`, or `set` methods, whenever possible.
- Avoid using string comparisons within customized `step`, `get`, or `set` methods, whenever possible. Use `setupImpl` for string comparisons instead.
- Specify Boolean values using `true` or `false` instead of 1 or 0, respectively.

## What Is the MATLAB System Block?

### In this section...

“Why Use the MATLAB System Block?” on page 40-2

“Choosing the Right Block Type” on page 40-2

“System Objects” on page 40-3

“Interpreted Execution or Code Generation” on page 40-3

“MATLAB System Block Limitations” on page 40-4

“MATLAB System and System Objects Examples” on page 40-5

## Why Use the MATLAB System Block?

System objects let you implement algorithms using the MATLAB language. The MATLAB System block enables you to use System objects in Simulink.

The MATLAB System block lets you:

- Share the same System object in MATLAB and Simulink
- Dedicate integration of System objects with Simulink
- Unit test your algorithm in MATLAB before using it in Simulink
- Customize dialog box customization
- Simulate efficiently with better initialization
- Handle states
- Customize block icons with port labels
- Access two simulation modes

## Choosing the Right Block Type

There are several mechanisms for including MATLAB algorithms in Simulink, such as:

- MATLAB System block
- MATLAB Function block

- Interpreted MATLAB Function block
- Level-2 MATLAB S-Function block
- Fcn block

For more information, see “Types of Custom Blocks” on page 35-3 and “Comparison of Custom Block Functionality” on page 35-7.

## System Objects

Before you use a MATLAB System block, you must have a System object to associate with the block. A System object is a specialized kind of MATLAB class. System objects are designed specifically for implementing and simulating dynamic systems with inputs that change over time.

For more information on creating System objects, see “Define System Objects”.

---

**Note:** To use your System object in the Simulink environment, it must have a constructor that you can call with no arguments. By default, the System object constructor has this capability and you do not need to define your own constructor. However, if you create your own System object constructor, you must be able to call it with no arguments.

---

System objects exist in other MATLAB products. MATLAB System block supports only the System objects written in the MATLAB language. In addition, if a System object has a corresponding Simulink block, you cannot implement a MATLAB System block for it.

## Interpreted Execution or Code Generation

You can use MATLAB System blocks in Simulink models for simulation via interpreted execution or code generation.

- With interpreted execution, the model simulates the block using the MATLAB execution engine.
- With code generation, the model simulates the block using code generation (requires the use of the subset of MATLAB code supported for code generation). For a list of supported functions, see “Functions and Objects Supported for C and C++ Code Generation — Alphabetical List” on page 42-2.

## MATLAB System Block Limitations

These capabilities are currently not supported.

| Category         | Limitation Description   | Workaround   |
|------------------|--|--|
| System Objects   | Tunable logical and string properties of the System object are nontunable parameters in the MATLAB System block.   | —  |
| Data Types       | <ul style="list-style-type: none"> <li>• The MATLAB System block does not support virtual buses as input or output.</li> <li>• The MATLAB System block does not support nonvirtual buses that contain variable-size signals.</li> <li>• System objects cannot use the enumerated data type.</li> <li>• System objects cannot use fixed-point signals with nonbinary point scaling or nonzero bias.</li> <li>• System objects cannot use user-defined opaque data types.</li> </ul> | —  |
| Sample Time      | Cannot use MATLAB System blocks to model continuous time or multirate systems.   | —  |
| Linearizations   | Cannot use Jacobian based linearization.   | —  |

## MATLAB System and System Objects Examples

For examples of MATLAB System and System objects, see:

| Example  | Description   |
|--|---|
| System Identification for an FIR System Using MATLAB System Blocks | This example shows how to use the MATLAB System block to implement Simulink blocks using a System object. It highlights two MATLAB System blocks. Access the MATLAB source code for each System object by clicking the <b>Source code</b> link from the block dialog box. |
| Variable-Size Input and Output Signals Using MATLAB System Blocks  | This example shows how to use the MATLAB System block to implement Simulink blocks with variable-size input and output signals. Due to the use of variable-size signals, the example uses propagation methods.  |
| Illustration of Law of Large Numbers Using MATLAB System Blocks    | This example shows how to use MATLAB System blocks to illustrate the law of large   |

| <b>Example</b>                        | <b>Description</b>  |
|---------------------------------------|---|
|                                       | numbers. Due to the use of MATLAB functions not supported for code generation, the example uses propagation methods and interpreted execution.  |
| Using Buses with MATLAB System Blocks | This example shows how to use MATLAB System blocks with nonvirtual buses at input or output. Due to the use Simulink buses, the example uses propagation methods. The example defines the bus types in the MATLAB base workspace using model callbacks. |

## Implement a MATLAB System Block

Implement a block and assign a System object to it. You can then explore the block to see the effect.

- 1 Create a new model and add the MATLAB System block from the User-Defined Functions library.

- 2 In the block dialog box, from the **New** list, select **Basic**, **Advanced**, or **Simulink Extension** if you want to create a new System object from a template. Modify the template according to your needs and save the System object.
- 3 Enter the full path name for the System object in the **System object name**. Click the list arrow. If valid System objects exist in the current folder, the names appear in the list.

The MATLAB System block icon and port labels update to those of the corresponding System object. For example, suppose you selected a System object named `lmsSysObj` in your current folder. The block updates as shown in the figure:

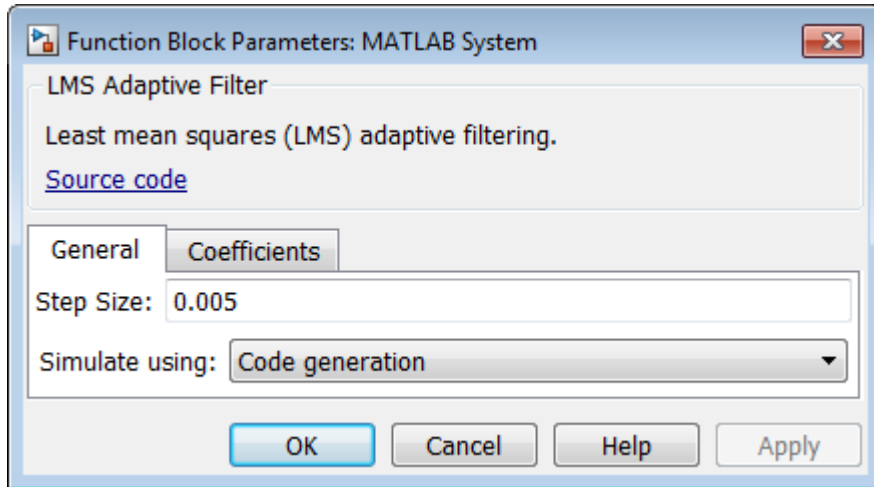

---

**Note:** After you associate the block with a System object class name, you cannot assign a new System object using the same MATLAB System block dialog box. Instead, right-click the MATLAB System block, select **Block Parameters (MATLABSystem)** and enter a new class name in **System object name**.

---

## Understanding the MATLAB System Block

- 1 Double-click the block. The MATLAB System dialog box reflects the System object parameters. The dialog box usually includes a **Source code** link that leads to the System object class file. For example:

The **Source code** link appears if the System object uses MATLAB language. It does not appear if you have:

- Converted the System object to P-code
  - Overridden the default behavior using the `getHeaderImpl` method
- 2 Click **Source code** and observe that the public and active properties in the System object appear in the MATLAB System block dialog box as block parameters.
  - 3 Select how you want the model to simulate the block using the **Simulate using** parameter. (This parameter appears at the bottom of each MATLAB System block if there is only one tab, or the bottom of the first of multiple tabs.)

You might want to add that note about not being able to get to the MATLAB System block dialog box the same way after you've associated the block with a System object. Look under mask is one way you can get to it.

## **More About**

- “Mapping System Objects to Block Dialog Box” on page 40-18
- “Simulation Modes” on page 40-16

## Change Blocks Implemented with System Objects

To implement a block with another System object, right-click the MATLAB System block and select Block Parameters (MATLABSystem). Then, use the block dialog box to identify a new class name in **System object name**. For more information, see “Implement a MATLAB System Block” on page 40-7.

## Change Block Icon and Port Labels

To change the icon appearance of your block, you must use the `matlab.system.mixin.CustomIcon` class. You can define port labels using `System` object methods.

- 1 Add the `matlab.system.mixin.CustomIcon` class name to the `System` object, after the `matlab.System` class. For example:

```
classdef lmsSysObj < matlab.System & matlab.system.mixin.CustomIcon
```

This code subclasses from the `matlab.system.mixin.CustomIcon` class in addition to the `matlab.System` base class.

- 2 To define the icon, implement the `getIconImpl` method.
- 3 To define the port labels, implement the following optional methods to change the input and output port labels. You do not need the `matlab.system.mixin.CustomIcon` class to use these methods.

```
getInputNamesImpl  
getOutputNamesImpl
```

If you do not implement these methods, the `System` object uses the input and output port names from the `stepImpl` method. If you are using the `matlab.system.mixin.Nondirect` class and do not implement these methods, the `System` object uses the input names from `updateImpl` and the output port names from `OutputImpl`.

## Modify MATLAB System Block Dialog

To change the MATLAB System block dialog, implement the methods for the following classes:

| Description                            | <code>matlab.system.display</code> Methods      |
|--|---|
| Define header text for property group. | <code>matlab.system.display.Header</code>       |
| Group properties together.             | <code>matlab.system.display.Section</code>      |
| Group properties into a separate tab.  | <code>matlab.system.display.SectionGroup</code> |

### **Related Examples**

## Nonvirtual buses and MATLAB System Block

The MATLAB System block supports nonvirtual buses as input and output signals. The corresponding System object input or output must be a MATLAB structure whose fields match those defined by the nonvirtual bus. If the System object output is a MATLAB structure, it must define propagator methods. In addition, the `getOutputDataTypeImpl` method must return the name of the corresponding bus object. This bus object must exist in the base workspace or a data dictionary linked to the model.

---

**Note:** If the output is the same bus type as the input, do not use the `propagatedInputDataType` method to obtain the name of the bus object. Instead, you must return the name of the bus object directly.

---

## Use System Objects in Feedback Loops

If your algorithm needs to process nondirect feedthrough data through the System object, use the `matlab.system.mixin.Nondirect` class. This class uses the `output` and `update` methods to process nondirect feedthrough data through a System object.

Most System objects use direct feedthrough, where the object's input is needed to generate the output. For these direct feedthrough objects, the `step` method calculates the output and updates the state values. For nondirect feedthrough, however, the object's output depends on internal states and not directly on the inputs. The inputs, or a subset of the inputs, are used to update the object states. For these objects, calculating the output is separated from updating the state values. This enables you to use an object as a feedback element in a feedback loop.

A delay object is an example of a nondirect feedthrough object.

- 1 Add the `matlab.system.mixin.Nondirect` class to the top of the parent class file for the System object, after the `matlab.System` class. For example:

```
IntegerDelaySysObj < matlab.System & matlab.system.mixin.Nondirect
```

This step subclasses from the `matlab.system.mixin.Nondirect` class in addition to the `matlab.System` base class.

- 2 Implement the following methods:

```
outputImpl  
updateImpl
```

When implementing the `outputImpl` method, do not access the System object inputs for which the direct feedthrough flag is false.

- 3 If the System object supports code generation and does not inherit from `matlab.system.mixin.Propagates`, Simulink can automatically infer the direct feedthrough settings from the System object MATLAB code. However, if the System object does not support code generation, the default `isInputDirectFeedthroughImpl` method returns false (no direct feedthrough). In this case, override this method if you want nondefault behavior.

The processing of the nondirect feedthrough changes the way that the software calls the System object methods within the context of the Simulink engine.

## Simulation Modes

### Interpreted Execution vs. Code Generation

You can use MATLAB System block in Simulink models for simulation via interpreted execution or code generation. Implementing a MATLAB System block with a valid System object class name enables the **Simulate using** parameter. This parameter appears at the bottom of each MATLAB System block if there is only one tab, or the bottom of the first of multiple tabs. Use the **Simulate using** parameter to control how the block simulates. The table describes how to choose the right value for your purpose.

- With interpreted execution, the model simulates the block using the MATLAB execution engine.

---

**Note:** With interpreted execution, if you set the **Optimization > Use division for fixed-point net slope computation** parameter to 'On' or 'Use division for reciprocals of integers only' in the Configuration Parameters dialog box, you might get unoptimized numeric results. This is because MATLAB code does not support this parameter.

---

- With code generation, the model simulates the block using code generation, using the subset of MATLAB code supported for code generation.

| Action  | Select                    | Pros                                    | Cons  |
|---|---------------------------|---|---|
| Upon first model run, simulate and generate code for MATLAB System using only the subset of MATLAB functions supported for code generation. Choosing this option causes the simulation to run the generated code. | Code generation (default) | Potentially better performance.         | System object is limited to the subset of MATLAB functions supported for code generation. Simulation may start more slowly. |
| Simulate model using all supported MATLAB functions.  | Interpreted execution     | System object can contain any supported | Potentially slower performance. If the MATLAB functions in the System object do not   |

| Action  | Select | Pros                                     | Cons   |
|---|--------|--|--|
| Choosing this option can slow simulation performance. |        | MATLAB function.<br>Faster startup time. | support code generation, the System object must contain propagation methods. |

To take advantage of faster performance, consider using propagation methods in your System object. For more information, see “Add and Implement Propagation Methods” on page 40-28.

## Simulation Using Code Generation

While simulating and generating code for one or more simulation targets (in this case, System object blocks), the model displays status messages in the bottom left of the Simulink Editor window. A model can have multiple copies of the same block, where blocks are considered the same if they

- Use the same System object.
- Have inputs and tunable parameters that have identical signals, data types, and complexities.
- Have nontunable parameters that have the same value.

When the model has multiple copies of the same block, the software does not regenerate the code for each block. It reuses the code from the first time that code was generated for one of these blocks. The status messages reflect this and do not show status messages for each of these blocks.

When the code generation process is complete, Simulink creates a MEX-file for the generated code.

## Mapping System Objects to Block Dialog Box

The System object source code controls the appearance of the block dialog box. This section describes System object to block dialog box mapping using the System Identification for an FIR System Using MATLAB System Blocks example. This example uses two System objects, one that uses default System object to block dialog box mapping, and one that uses a custom mapping.

| In this section...  |
|---|
| “System Object to Block Dialog Box Default Mapping” on page 40-18 |
| “System Object to Block Dialog Box Custom Mapping” on page 40-20  |

### System Object to Block Dialog Box Default Mapping

The following figure shows how the source code corresponds to the dialog box elements if you do not customize the dialog using the `getHeaderImpl` or `getPropertyGroupsImpl` methods. (The link to open the source code and the **Simulate using** parameter appear on all MATLAB System block dialog boxes.)

```

classdef WidgetTypes < matlab.System
%WidgetTypes Show available dialog widget types
% This class contains properties to illustrate how System block dialog
% widgets are rendered for different System object property types.

properties(Nontunable, Logical)
%LogicalProperty A logical property
% This property has the logical attribute.
LogicalProperty = true;
end

The Delay block from the System Identification for an FIR System Using MATLAB System Blocks is an example of a block that uses a System object that draws the dialog box using the default mapping. This block has one input and one output.

This block uses a System object that has direct feedthrough set to false (nondirect feedthrough). This setting means that the System object does not directly use the input to compute the output, enabling the model to use this block safely in a feedback system without introducing an algebraic loop. For more information on nondirect feedthrough, see “Use System Objects in Feedback Loops” on page 40-14.

For an example of a custom block dialog box, see “System Object to Block Dialog Box Custom Mapping” on page 40-20.

## System Object to Block Dialog Box Custom Mapping

The LMS Adaptive block is an example of a block with a custom header and property groups. The System object code uses the `getHeaderImpl` method from `matlab.system.display.Header` and `getPropertyGroupsImpl` method from `matlab.system.display.SectionGroup` to customize these block dialog elements.

The LMS Adaptive Filter block estimates the coefficients of an unknown system (formed by the Unknown System and Delay blocks). Its inputs are the desired signal and the actual signal. Its outputs are the estimated signal and the vector norm of the error in the estimated coefficients. It uses the `lmsSysObj` System object.

```

classdef lmsSysObj < matlab.System & matlab.system.mixin.CustomIcon
%lmsSysObj Least mean squares (LMS) adaptive filtering.

methods(Static, Access=protected)

function header = getHeaderImpl
header = matlab.system.display.Header(...
'Title', 'LMS Adaptive Filter');
end

function groups = getPropertyGroupsImpl
firstGroup = matlab.system.display.SectionGroup(...
'Title', 'General', ...
'PropertyList', {'Mu'});

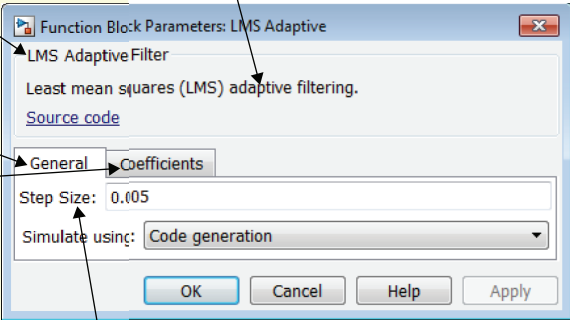

secondGroup = matlab.system.display.SectionGroup(...
'Title', 'Coefficients', ...
'PropertyList', {'TrueCoefficients', 'NumCoeff'});

groups = [firstGroup, secondGroup];
end
end
    
```

Header description from class help summary

Specified header title overrides class name

Tabs from SectionGroups

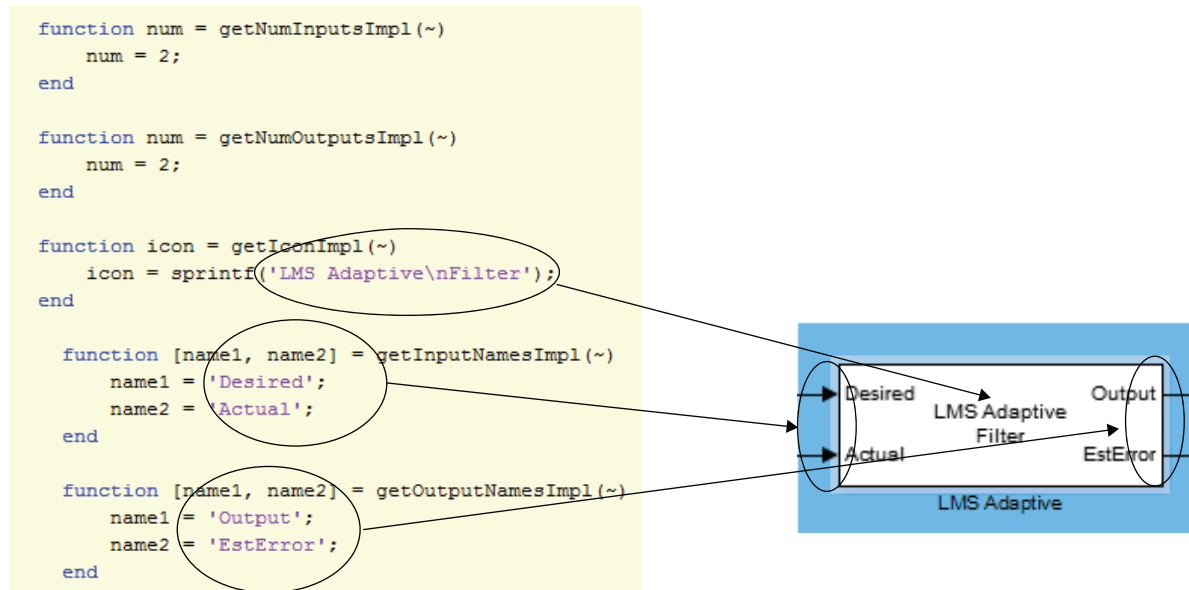

```

properties
% Mu Step Size
Mu = 0.005;
end
    
```

Label from product help summary

The source code for this System object also defines two input and output ports for the block.

# Considerations for Using System Objects in Simulink

## In this section...

“System Objects in Simulink” on page 40-23

“System Objects in For Each Subsystems” on page 40-24

## System Objects in Simulink

There are differences in how you can use System objects in a MATLAB System block in Simulink versus using the same object in MATLAB. You see these differences when working with variable-size signals and tunable parameters and when using System objects as properties.

### Variable-Size Signals

To use variable-size signals in a System object, you must implement `matlab.system.mixin.Propagates` methods. In particular, use the `isOutputFixedSizeImpl` method to specify if an output is variable-size or fixed-size. This is true for interpreted execution and code generation simulation methods.

### Tunable Parameters

Simulink registers public tunable properties of a System object as tunable parameters of the corresponding MATLAB System block. If a System object property is tunable, it is also tunable in the MATLAB System block. At runtime, you can change the parameter using one of the following approaches. The change applies at the top of the simulation loop.

- At the MATLAB command line, use the `set_param` to change the parameter value.
- In the Simulink editor, edit the MATLAB System block dialog box to change the parameter value, and then update the block diagram.

You cannot change public tunable properties from System object internal methods such as `stepImpl`.

During simulation, setting an invalid value on a tunable parameter causes an error message and stops simulation.

### **System Objects as Properties**

The MATLAB System block allows a System object to have other System objects as public or private properties. However:

- System objects and other MATLAB objects stored as public properties are read only. As a result, you cannot set the value of the parameter, you can only get the value of a parameter.
- System objects stored as property values appear dimmed in the MATLAB System block dialog box.

### **Default Property Values**

MATLAB does not require that objects assign default values to properties. However, in Simulink, if your System object has properties with no assigned default values, the associated dialog box parameter requires that the value data type be a built-in Simulink data type.

### **System Objects in For Each Subsystems**

To use the MATLAB System block within a For Each Subsystem block, implement the `matlab.system.supportsMultipleInstanceImpl` method. This method should return `true`. The MATLAB System block clones the System object for each For Each Subsystem iteration.

# Simulink Engine Interaction with System Object Methods

## Simulink Engine Phases Mapped to System Object Methods

This diagram shows a process view of the order in which the MATLAB System block invokes System object methods within the context of the Simulink engine.

Note the following:

- Simulink calls the `stepImpl`, `outputImpl`, and `updateImpl` methods multiple times during simulation at each time step. Simulink typically calls other methods once per simulation.

- The Simulink engine calls the `isOutputFixedSizeImpl`, `getDiscreteStateSpecificationImpl`, `isOutputComplexImpl`, `getOutputDataTypeImpl`, `getOutputSizeImpl` when using `matlab.system.mixin.Propagates`.
- Simulink calls `saveObjectImpl` and `loadObjectImpl` for saving and restoring `SimState`, the Simulation Stepper, and Fast Restart.
- Default implementations save and restore all properties with public access, including `DiscreteState`.

## Add and Implement Propagation Methods

| In this section...  |
|---|
| “When to Use Propagation Methods” on page 40-28           |
| “Add Propagation Methods to System Objects” on page 40-28 |
| “Implement Propagation Methods” on page 40-29             |

### When to Use Propagation Methods

Propagation methods define output specifications. Use them when the output specifications cannot be inferred directly from the inputs during Simulink model compilation.

Consider using propagation methods in your System object when:

- The System object requires access to all MATLAB functions that do not support code generation, which means that you cannot generate code for simulation. You must use propagation methods in this case. Use these methods to specify information for the outputs.
- You want to use variable-size signals.
- You do not care whether code is generated, but you want to improve startup performance. Use propagation methods to specify information for the inputs and outputs, enabling quicker startup time.

At startup, the Simulink software tries to evaluate the input and output ports of the model blocks for signal attribute propagation. In the case of MATLAB System blocks, if the software cannot perform this evaluation, it displays a message prompting you to add propagation methods to the System object.

### Add Propagation Methods to System Objects

Propagation methods are in the class `matlab.system.mixin.Propagates`. To add these methods to the System object, add the `matlab.system.mixin.Propagates` class to the top of the parent class file for the System object, after the `matlab.System` class. For example:

```
classdef Counter < matlab.System & matlab.system.mixin.Propagates
```

## Implement Propagation Methods

Simulink evaluates the uses of the propagation methods to evaluate the input and output ports of the MATLAB System block for startup.

Each method has a default implementation, listed in the **Default Implementation Should Suffice if** column. If your System object does not use the default implementation, you must implement a version of the propagation method for your System object.

| Description  | Propagation Method                 | Default Implementation Should Suffice if   | Example   |
|--|------------------------------------|--|---|
| Gets dimensions of output ports. The associated method is <code>getOutputSize</code> .                     | <code>getOutputSizeImpl</code>     | <ul style="list-style-type: none"> <li>• Only one input</li> <li>• Only one output</li> <li>• An input size that is the same as the output size</li> </ul>         | <ul style="list-style-type: none"> <li>• <code>FindIfFixedInput</code> or <code>FindIfVarSizeInput</code> block in MATLAB System Block with Variable-Size Input and Output Signals</li> <li>• Analysis block in Illustration of Law of Large Numbers</li> </ul> |
| Gets data types of output ports. The associated method is <code>getOutputDataType</code> .                 | <code>getOutputDataTypeImpl</code> | <ul style="list-style-type: none"> <li>• Only one input</li> <li>• Only one output</li> <li>• Output data type always the same as the input data type</li> </ul>   | <ul style="list-style-type: none"> <li>• <code>FindIfFixedInput</code> or <code>FindIfVarSizeInput</code> block in MATLAB System Block with Variable-Size Input and Output Signals</li> <li>• Analysis block in Illustration of Law of Large Numbers</li> </ul> |
| Indicates whether output ports are complex or not. The associated method is <code>isOutputComplex</code> . | <code>isOutputComplexImpl</code>   | <ul style="list-style-type: none"> <li>• Only one input</li> <li>• Only one output</li> <li>• Output complexity always the same as the input complexity</li> </ul> | <ul style="list-style-type: none"> <li>• <code>FindIfFixedInput</code> or <code>FindIfVarSizeInput</code> block in MATLAB System Block with Variable-Size Input and Output Signals</li> </ul>   |

| Description  | Propagation Method                             | Default Implementation Should Suffice if   | Example   |
|--|--|--|---|
|  |  |  | <ul style="list-style-type: none"> <li>Analysis block in Illustration of Law of Large Numbers</li> </ul>  |
| <p>Whether output ports are fixed size. The associated method is <code>isOutputFixedSize</code>.</p>   | <code>isOutputFixedSizeImpl</code>             | <ul style="list-style-type: none"> <li>Only one input</li> <li>Only one output</li> <li>Output and input are fixed-size</li> </ul> | <ul style="list-style-type: none"> <li><code>FindIfFixedSizeInput</code> or <code>FindIfVarSizeInput</code> block in MATLAB System Block with Variable-Size Input and Output Signals</li> <li>Analysis block in Illustration of Law of Large Numbers</li> </ul> |
| <p>Gets the size, data type, and complexity of a discrete state property. The associated method is <code>getDiscreteStateSpecification</code>.</p> | <code>getDiscreteStateSpecificationImpl</code> | <p>No <code>DiscreteState</code> properties</p>  | <p>N/A</p>  |

## Troubleshoot System Objects in Simulink

### In this section...

“Class Not Found” on page 40-31

“Error Invoking Object Method” on page 40-31

“Performance” on page 40-32

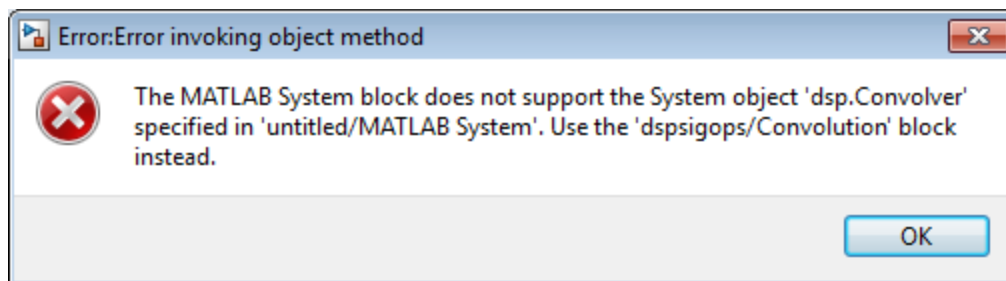

### Class Not Found

The MATLAB System block **System object name** parameter requires that you enter the full path to the System object class. In addition:

- Check that the System object class is on your MATLAB path.
- Check capitalization to make sure it matches.
- Check that the class name is a supported System object.
- Do not include the file extension.

### Error Invoking Object Method

The MATLAB System block supports only System objects written in the MATLAB language. If the software can identify an alternative block, it suggests that block in the error message, for example:

This message indicates that there is an existing dedicated and optimized block that you should use.

## Performance

For fastest performance, set the block **Simulate using** parameter to **Code generation**. This setting allows the MATLAB System block to run as fast as it can. The parameter is set to this value by default.

This setting causes a slower startup time, as the software generates C code and creates a MEX-file from it. However, after code generation, later simulations have better performance. When the block uses generated code to simulate, performance is typically better than simulation without generated code.

In some cases, the implementation of your System object does not allow you to generate code, which requires you to set **Simulate using** to **Interpreted execution**. For example, your System object can require MATLAB functions beyond the subset supported for code generation. In this case, use propagation methods to specify the block input and output port information. The MATLAB System block then propagates this signal attribution information.

## When to Generate Code from MATLAB Algorithms

Generating code from MATLAB algorithms for desktop and embedded systems allows you to perform your software design, implementation, and testing completely within the MATLAB workspace. You can:

- Verify that your algorithms are suitable for code generation
- Generate efficient, readable, and compact C/C++ code automatically, which eliminates the need to manually translate your MATLAB algorithms and minimizes the risk of introducing errors in the code.
- Modify your design in MATLAB code to take into account the specific requirements of desktop and embedded applications, such as data type management, memory use, and speed.
- Test the generated code and easily verify that your modified algorithms are functionally equivalent to your original MATLAB algorithms.
- Generate MEX functions to:
  - Accelerate MATLAB algorithms in certain applications.
  - Speed up fixed-point MATLAB code.
- Generate hardware description language (HDL) from MATLAB code.

## When Not to Generate Code from MATLAB Algorithms

Do not generate code from MATLAB algorithms for the following applications. Use the recommended MathWorks product instead.

| To:   | Use:   |
|---|--|
| Deploy an application that uses handle graphics                 | MATLAB Compiler  |
| Use Java  | MATLAB Compiler SDK™   |
| Use toolbox functions that do not support code generation       | Toolbox functions that you rewrite for desktop and embedded applications |
| Deploy MATLAB based GUI applications on a supported MATLAB host | MATLAB Compiler  |
| Deploy web-based or Windows applications                        | MATLAB Compiler SDK  |

| <b>To:</b>                   | <b>Use:</b>                      |

## Prerequisites for C/C++ Code Generation from MATLAB

To generate C/C++ or MEX code from MATLAB algorithms, you must install the following software:

- MATLAB Coder product
- C/C++ compiler

## MATLAB Code Design Considerations for Code Generation

When writing MATLAB code that you want to convert into efficient, standalone C/C++ code, you must consider the following:

- Data types

C and C++ use static typing. To determine the types of your variables before use, MATLAB Coder requires a complete assignment to each variable.

- Array sizing

Variable-size arrays and matrices are supported for code generation. You can define inputs, outputs, and local variables in MATLAB functions to represent data that varies in size at run time.

- Memory

You can choose whether the generated code uses static or dynamic memory allocation.

With dynamic memory allocation, you potentially use less memory at the expense of time to manage the memory. With static memory, you get better speed, but with higher memory usage. Most MATLAB code takes advantage of the dynamic sizing features in MATLAB, therefore dynamic memory allocation typically enables you to generate code from existing MATLAB code without modifying it much. Dynamic memory allocation also allows some programs to compile even when upper bounds cannot be found.

Static allocation reduces the memory footprint of the generated code, and therefore is suitable for applications where there is a limited amount of available memory, such as embedded applications.

- Speed

Because embedded applications must run in real time, the code must be fast enough to meet the required clock rate.

To improve the speed of the generated code:

- Choose a suitable C/C++ compiler. Do not use the default compiler that MathWorks supplies with MATLAB for Windows 32-bit platforms.
- Consider disabling run-time checks.

By default, for safety, the code generated for your MATLAB code contains memory integrity checks and responsiveness checks. Generally, these checks result in more generated code and slower simulation. Disabling run-time checks usually results in streamlined generated code and faster simulation. Disable these checks only if you have verified that array bounds and dimension checking is unnecessary.

### Why Are There Differences?

To convert MATLAB code to C/C++ code that works efficiently, the code generation process introduces optimizations that intentionally cause the generated code to behave differently — and sometimes produce different results — from the original source code. This section describes these differences.

### Character Size

MATLAB supports 16-bit characters, but the generated code represents characters in 8 bits, the standard size for most embedded languages like C. See “Code Generation for Characters and Strings” on page 45-8.

### Order of Evaluation in Expressions

Generated code does not enforce order of evaluation in expressions. For most expressions, order of evaluation is not significant. However, for expressions with side effects, the

generated code may produce the side effects in different order from the original MATLAB code. Expressions that produce side effects include those that:

- Modify persistent or global variables
- Display data to the screen
- Write data to files
- Modify the properties of handle class objects

In addition, the generated code does not enforce order of evaluation of logical operators that do not short circuit.

For more predictable results, it is good coding practice to split expressions that depend on the order of evaluation into multiple statements.

- Rewrite

```
A = f1() + f2();
```

as

```
A = f1();  
A = A + f2();
```

so that the generated code calls `f1` before `f2`.

- Assign the outputs of a multi-output function call to variables that do not depend on one another. For example, rewrite

```
[y, y.f, y.g] = foo;
```

as

```
[y, a, b] = foo;  
y.f = a;  
y.g = b;
```

- When you access the contents of multiple cells of a cell array, assign the results to variables that do not depend on one another. For example, rewrite

```
[y, y.f, y.g] = z{:};
```

as

```
[y, a, b] = z{:};
```

```
y.f = a;  
y.g = b;
```

## Termination Behavior

Generated code does not match the termination behavior of MATLAB source code. For example, optimizations remove infinite loops from generated code if they do not have side effects. As a result, the generated code may terminate even though the corresponding MATLAB code does not.

## Size of Variable-Size N-D Arrays

For variable-size N-D arrays, the `size` function might return a different result in generated code than in MATLAB source code. The `size` function sometimes returns trailing ones (singleton dimensions) in generated code, but always drops trailing ones in MATLAB. For example, for an N-D array `X` with dimensions `[4 2 1 1]`, `size(X)` might return `[4 2 1 1]` in generated code, but always returns `[4 2]` in MATLAB. See “Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays” on page 46-23.

## Size of Empty Arrays

The size of an empty array in generated code might be different from its size in MATLAB source code. See “Incompatibility with MATLAB in Determining Size of Empty Arrays” on page 46-24.

## Shape of Array When Index and Assigned Value Are Empty

When `X` is an empty matrix, generated code does not match MATLAB for the following MATLAB code:

```
A(X) = [];
```

In MATLAB, when `X` is not empty, `A` becomes a row vector. When `X` is empty, `A` does not change. In the generated code, `A` always becomes a row vector, even when `X` is empty.

For example, consider the following function:

```
function A = myfunction()
```

```
A = magic(4);
coder.varsize('A',[20 20],[1 1]);
A([]) = [];
```

In MATLAB, the answer is:

```
16     2     3    13
 5    11    10     8
 9     7     6    12
 4    14    15     1
```

In the generated code, the answer is:

```
16  5  9  4  2  11  7  14  3  10  6  15  13  8  12  1
```

## Floating-Point Numerical Results

The generated code might not produce the same floating-point numerical results as MATLAB in the following situations:

### When computer hardware uses extended precision registers

Results vary depending on how the C/C++ compiler allocates extended precision floating-point registers. Computation results might not match MATLAB calculations because of different compiler optimization settings or different code surrounding the floating-point calculations.

### For certain advanced library functions

The generated code might use different algorithms to implement certain advanced library functions, such as `fft`, `svd`, `eig`, `mldivide`, and `mrdivide`.

For example, the generated code uses a simpler algorithm to implement `svd` to accommodate a smaller footprint. Results might also vary according to matrix properties. For example, MATLAB might detect symmetric or Hermitian matrices at run time and switch to specialized algorithms that perform computations faster than implementations in the generated code.

### For implementation of BLAS library functions

For implementations of BLAS library functions, generated C/C++ code uses reference implementations of BLAS functions. These reference implementations can produce different results from platform-specific BLAS implementations in MATLAB.

## NaN and Infinity Patterns

The generated code might not produce exactly the same pattern of NaN and inf values as MATLAB code when these values are mathematically meaningless. For example, if MATLAB output contains a NaN, output from the generated code should also contain a NaN, but not necessarily in the same place.

## Code Generation Target

The `coder.target` function returns different values in MATLAB than in the generated code. The intent is to help you determine whether your function is executing in MATLAB or has been compiled for a simulation or code generation target. See `coder.target`.

## MATLAB Class Initial Values

Before code generation, at class loading time, MATLAB computes class initial values. The code generation software uses the value that MATLAB computes. It does not recompute the initial value. If the initialization uses a function call to compute the initial value, the code generation software does not execute this function. If the function modifies a global state, for example, a persistent variable, code generation software might provide a different initial value than MATLAB. For more information, see “Defining Class Properties for Code Generation” on page 50-4.

## Variable-Size Support for Code Generation

For incompatibilities with MATLAB in variable-size support for code generation, see:

- “Incompatibility with MATLAB for Scalar Expansion”
- “Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays”
- “Incompatibility with MATLAB in Determining Size of Empty Arrays”
- “Incompatibility with MATLAB in Vector-Vector Indexing”
- “Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation”

## Complex Numbers

See “Code Generation for Complex Data” on page 45-4.

# MATLAB Language Features Supported for C/C++ Code Generation

## MATLAB Features That Code Generation Supports

Code generation from MATLAB supports the following language features:

- N-dimensional arrays (see “Array Size Restrictions for Code Generation” on page 45-9)
- Matrix operations, including deletion of rows and columns
- Variable-sized data (see “Variable-Size Data Definition for Code Generation” on page 46-3)
- Subscripting (see “Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation” on page 46-26)
- Complex numbers (see “Code Generation for Complex Data” on page 45-4)
- Numeric classes (see “Supported Variable Types” on page 44-17)
- Double-precision, single-precision, and integer math
- Fixed-point arithmetic
- Program control statements `if`, `switch`, `for`, `while`, and `break`
- Arithmetic, relational, and logical operators
- Local functions
- Persistent variables (see “Define and Initialize Persistent Variables” on page 44-10)
- Global variables.
- Structures (see “Structure Definition for Code Generation” on page 47-2)
- Cell Arrays (see “Cell Arrays”)

Characters (see “Code Generation for Characters and Strings” on page 45-8)

- Function handles (see “Function Handle Definition for Code Generation” on page 51-2)
- Frames
- Variable length input and output argument lists
- Subset of MATLAB toolbox functions (see “Functions and Objects Supported for C and C++ Code Generation — Alphabetical List” on page 42-2)

- Subset of functions and System objects in Aerospace Toolbox, Communications System Toolbox, Computer Vision System Toolbox, DSP System Toolbox, Fixed-Point Designer, Image Processing Toolbox™, Signal Processing Toolbox™, Phased Array System Toolbox™, Statistics and Machine Learning Toolbox™ (see “Functions and Objects Supported for C and C++ Code Generation — Category List” on page 42-147)
- MATLAB classes (see “MATLAB Classes Definition for Code Generation” on page 50-2)
- Function calls (see “Resolution of Function Calls for Code Generation” on page 53-2)

## **MATLAB Language Features That Code Generation Does Not Support**

Code generation from MATLAB does not support the following frequently used MATLAB constructs:

- Anonymous functions
- Categorical Arrays
- Date and Time Arrays
- Java
- Map Containers
- Nested functions
- Recursion
- Sparse matrices
- Tables
- Time Series objects
- try/catch statements

This list is not exhaustive. To see if a construct is supported for code generation, see “MATLAB Features That Code Generation Supports” on page 41-13.

# Functions, Classes, and System Objects Supported for Code Generation

---

- “Functions and Objects Supported for C and C++ Code Generation — Alphabetical List” on page 42-2
- “Functions and Objects Supported for C and C++ Code Generation — Category List” on page 42-147

## Functions and Objects Supported for C and C++ Code Generation — Alphabetical List

You can generate efficient C and C++ code for a subset of MATLAB built-in functions and toolbox functions, classes, and System objects that you call from MATLAB code. These function, classes, and System objects appear in alphabetical order in the following table.

To find supported functions, classes, and System objects by MATLAB category or toolbox, see “Functions and Objects Supported for C and C++ Code Generation — Category List” on page 42-147.

---

**Note:** For more information on code generation for fixed-point algorithms, refer to “Code Acceleration and Code Generation from MATLAB”.

| BRISKPoints    | Computer Vision System Toolbox | Compile-time constant inputs: No restriction<br>Supports MATLAB Function block: No<br>To index locations with this object, use the syntax: <code>points.Location(idx, :)</code> , for <code>points</code> object. See <code>visionRecovertfomCodeGeneration_kernel.m</code> , which is used in the “Introduction to Code Generation with Feature Matching and Registration” example. |

| Name         | Product                     | Remarks and Limitations   |
|--------------|-----------------------------|---|
| broadside2az | Phased Array System Toolbox | Does not support variable-size inputs.  |
| bsxfun       | MATLAB                      | “Variable-Sizing Restrictions for Code Generation of Toolbox Functions” on page 46-30   |
| buttap       | Signal Processing Toolbox   | Filter order must be a constant. Expressions or variables are allowed if their values do not change.  |
| butter       | Signal Processing Toolbox   | Filter coefficients must be constants. Expressions or variables are allowed if their values do not change.  |
| buttord      | Signal Processing Toolbox   | All inputs must be constants. Expressions or variables are allowed if their values do not change.   |
| bwareaopen   | Image Processing Toolbox    | BW must be a 2-D binary image. N-D arrays are not supported. conn can only be one of the two-dimensional connectivities (4 or 8) or a 3-by-3 matrix. The 3-D connectivities (6, 18, and 26) are not supported. Matrices of size 3-by-3-by-...-by-3 are not supported. conn must be a compile-time constant. |
| bwdist       | Image Processing Toolbox    | The method argument must be a compile-time constant. Input images must have fewer than $2^{32}$ pixels.<br><br>Generated code for this function uses a precompiled, platform-specific shared library.   |
| bweuler      | Image Processing Toolbox    | If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library   |
| bwlabel      | Image Processing Toolbox    | When generating code, the parameter n must be a compile-time constant.  |

| Name            | Product                  | Remarks and Limitations  |
|-----------------|--------------------------|--|
| bwlookup        | Image Processing Toolbox | <p>For best results, specify an input image of class <code>logical</code>.</p> <p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p>   |
| bwmorph         | Image Processing Toolbox | <p>The text string specifying the operation must be a constant and, for best results, specify an input image of class <code>logical</code>.</p> <p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p>  |
| bwpack          | Image Processing Toolbox | <p>Generated code for this function uses a precompiled platform-specific shared library.</p>   |
| bwperim         | Image Processing Toolbox | <p>Supports only 2-D images. Does not support any no-output-argument syntaxes. The connectivity matrix input argument, <code>conn</code>, must be a compile-time constant.</p> <p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p>   |
| bwselect        | Image Processing Toolbox | <p>Supports only the 3 and 4 input argument syntaxes: <code>BW2 = bwselect(BW,c,r)</code> and <code>BW2 = bwselect(BW,c,r,n)</code>. The optional fourth input argument, <code>n</code>, must be a compile-time constant. In addition, with code generation, <code>bwselect</code> only supports only the 1 and 2 output argument syntaxes: <code>BW2 = bwselect(___)</code> or <code>[BW2, idx] = bwselect(___)</code>.</p> <p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p> |
| bwtraceboundary | Image Processing Toolbox | <p>The <code>dir</code>, <code>fstep</code>, and <code>conn</code> arguments must be compile-time constants.</p>   |

## Functions and Objects Supported for C and C++ Code Generation — Category List

You can generate efficient C and C++ code for a subset of MATLAB built-in functions and toolbox functions, classes, and System objects that you call from MATLAB code. These functions, classes, and System objects are listed by MATLAB category or toolbox category in the following tables.

For an alphabetical list of supported functions, classes, and System objects, see “Functions and Objects Supported for C and C++ Code Generation — Alphabetical List” on page 42-2.

---

**Note:** For more information on code generation for fixed-point algorithms, refer to “Code Acceleration and Code Generation from MATLAB”.

## Aerospace Toolbox

C and C++ code generation for the following Aerospace Toolbox quaternion functions requires the Aerospace Blockset software.

| Function      | Remarks and Limitations |
|---------------|-------------------------|
| quatconj      | —                       |
| quatdivide    | —                       |
| quatinv       | —                       |
| quatmod       | —                       |
| quatmultiply  | —                       |
| quatnorm      | —                       |
| quatnormalize | —                       |

## Arithmetic Operations in MATLAB

See “Array vs. Matrix Operations” for detailed descriptions of the following operator equivalent functions.

| Function   | Remarks and Limitations  |
|------------|--|
| ctranspose | —  |
| idivide    | <ul style="list-style-type: none"> <li>For efficient generated code, MATLAB rules for divide by zero are supported only for the 'round' option.</li> </ul> |
| isa        | —  |
| ldivide    | —  |
| minus      | —  |
| mldivide   | —  |

| Function               | Remarks and Limitations   |
|------------------------|---|
| <code>mpower</code>    | If A is a 2-by-2 or larger matrix and B is Inf or -Inf, <code>mpower(A,B)</code> returns a matrix of NaNs.  |
| <code>mrdivide</code>  | —   |
| <code>mtimes</code>    | <ul style="list-style-type: none"> <li>Multiplication of pure imaginary numbers by non-finite numbers might not match MATLAB. The code generation software does not specialize multiplication by pure imaginary numbers—it does not eliminate calculations with the zero real part. For example, <math>(\text{Inf} + 1i) * 1i = (\text{Inf} * 0 - 1 * 1) + (\text{Inf} * 1 + 1 * 0)i = \text{NaN} + \text{Infi}</math>.</li> <li>“Variable-Sizing Restrictions for Code Generation of Toolbox Functions” on page 46-30</li> </ul>   |
| <code>plus</code>      | —   |
| <code>power</code>     | <ul style="list-style-type: none"> <li>Generates an error during simulation. When both X and Y are real, but <code>power(X,Y)</code> is complex, returns NaN in the generated code. To get the complex result, make the input value X complex by passing in <code>complex(X)</code>. For example, <code>power(complex(X),Y)</code>.</li> <li>Generates an error during simulation. When both X and Y are real, but <code>X.^Y</code> is complex, returns NaN in generated code. To get the complex result, make the input value X complex by using <code>complex(X)</code>. For example, <code>complex(X).^Y</code>.</li> </ul> |
| <code>rdivide</code>   | —   |
| <code>times</code>     | Multiplication of pure imaginary numbers by non-finite numbers might not match MATLAB. The code generation software does not specialize multiplication by pure imaginary numbers—it does not eliminate calculations with the zero real part. For example, $(\text{Inf} + 1i) * 1i = (\text{Inf} * 0 - 1 * 1) + (\text{Inf} * 1 + 1 * 0)i = \text{NaN} + \text{Infi}$ .  |
| <code>transpose</code> | —   |
| <code>uminus</code>    | —   |
| <code>uplus</code>     | —   |

## Bit-Wise Operations MATLAB

| Function              | Remarks and Limitations |
|-----------------------|-------------------------|
| <code>flintmax</code> | —                       |

| Function  | Remarks and Limitations  |
|-----------|--|
| swapbytes | Inheritance of the class of the input to <code>swapbytes</code> in a MATLAB Function block is supported only when the class of the input is <code>double</code> . For non-double inputs, the input port data types must be specified, not inherited. |

## Casting in MATLAB

| Function                      | Remarks and Limitations  |
|-------------------------------|--|
| cast                          | —  |
| char                          | Does not support cell arrays.  |
| class                         | —  |
| double                        | —  |
| int8, int16, int32, int64     | No integer overflow detection for <code>int64</code> in MEX or MATLAB Function block simulation on Windows 32-bit platforms.   |
| logical                       | —  |
| single                        | —  |
| typecast                      | <ul style="list-style-type: none"> <li>Value of string input argument <code>type</code> must be lowercase.</li> <li>When you use <code>typecast</code> with inheritance of input port data types in MATLAB Function blocks, you can receive a size error. To avoid this error, specify the block input port data types explicitly.</li> <li>Integer input or result classes must map directly to a C type on the target hardware.</li> <li>The input must be a variable-length vector or a fixed-size vector. See “Variable-Sizing Restrictions for Code Generation of Toolbox Functions” on page 46-30</li> <li>The output vector always has the same orientation as the input vector.</li> </ul> |
| uint8, uint16, uint32, uint64 | No integer overflow detection for <code>int64</code> in MEX or MATLAB Function block simulation on Windows 32-bit platforms.   |

## Communications System Toolbox

C and C++ code generation for the following functions and System objects requires the Communications System Toolbox software.

| Name                                  | Remarks and Limitations                    |

## Complex Numbers in MATLAB

| Function  | Remarks and Limitations  |
|-----------|--|
| complex   | —  |
| conj      | —  |
| imag      | —  |
| isnumeric | —  |
| isreal    | —  |
| isscalar  | —  |
| real      | —  |
| unwrap    | <ul style="list-style-type: none"> <li>Row vector input is only supported when the first two inputs are vectors and nonscalar</li> </ul> |

| Function | Remarks and Limitations   |
|----------|---|
|          | <ul style="list-style-type: none"> <li>Performs arithmetic in the output class. Hence, results might not match MATLAB due to different rounding errors</li> </ul> |

## Computer Vision System Toolbox

C and C++ code generation for the following functions and System objects requires the Computer Vision System Toolbox software.

| Name   | Remarks and Limitations   |
|--|---|
| <b>Feature Detection, Extraction, and Matching</b> |   |
| BRISKPoints  | Supports MATLAB Function block: No To index locations with this object, use the syntax: <code>points.Location(idx, :)</code> , for <code>points</code> object. See <code>visionRecoverfromCodeGeneration_kernel.m</code> , which is used in the “Introduction to Code Generation with Feature Matching and Registration” example. |
| cornerPoints                                       | Supports MATLAB Function block: No To index locations with this object, use the syntax: <code>points.Location(idx, :)</code> , for <code>points</code> object. See <code>visionRecoverfromCodeGeneration_kernel.m</code> , which is used in the “Introduction to Code Generation with Feature Matching and Registration” example. |
| detectBRISKFeatures                                | Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.  |
| detectFASTFeatures                                 | Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.  |
| detectHarrisFeatures                               | Compile-time constant input: 'FilterSize'<br>Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.   |

| Name                   | Remarks and Limitations   |
|------------------------|---|
| detectMinEigenFeatures | Compile-time constant input: 'FilterSize'<br>Supports MATLAB Function block: No<br>Generated code for this function uses a precompiled platform-specific shared library.  |
| detectMSERFeatures     | Supports MATLAB Function block: No<br>Generated code for this function uses a precompiled platform-specific shared library.<br>For code generation, the function outputs <code>regions.PixelList</code> as an array. The region sizes are defined in <code>regions.Lengths</code> .             |
| detectSURFFeatures     | Supports MATLAB Function block: No<br>Generated code for this function uses a precompiled platform-specific shared library.   |
| extractFeatures        | Generates platform-dependent library: Yes for BRISK, FREAK, and SURF methods only.<br>Compile-time constant input restrictions: 'Method'<br>Supports MATLAB Function block: Yes for Block method only.<br>Generated code for this function uses a precompiled platform-specific shared library. |
| extractHOGFeatures     | Supports MATLAB Function block: No  |
| extractLBPFeatures     | Generates platform-dependent library: No<br>Supports MATLAB Function block: Yes   |
| matchFeatures          | Generates platform-dependent library: Yes for MATLAB host.<br>Generates portable C code for non-host target.<br>Compile-time constant input: 'Method' and 'Metric'.<br>Supports MATLAB Function block: Yes  |

| <b>Name</b>   | <b>Remarks and Limitations</b>  |
|---|---|
| MSERRegions   | Supports MATLAB Function block: Yes<br>For code generation, you must specify both the <code>pixellist</code> cell array and the <code>length</code> of each array, as the second input. The object outputs, <code>regions.Pixellist</code> as an array. The region sizes are defined in <code>regions.Lengths</code> .<br>Generated code for this function uses a precompiled platform-specific shared library. |
| SURFPoints  | Supports MATLAB Function block: No<br>To index locations with this object, use the syntax: <code>points.Location(idx, :)</code> , for <code>points</code> object. See <code>visionRecovertransformCodeGeneration_kernel.m</code> , which is used in the “Introduction to Code Generation with Feature Matching and Registration” example.   |
| vision.BoundaryTracer                                   | Supports MATLAB Function block: Yes<br>“System Objects in MATLAB Code Generation”   |
| vision.EdgeDetector                                     | Supports MATLAB Function block: Yes<br>“System Objects in MATLAB Code Generation”   |
| <b>Image Registration and Geometric Transformations</b> |   |
| estimateGeometricTransform                              | Supports MATLAB Function block: No  |
| vision.GeometricRotator                                 | Supports MATLAB Function block: Yes<br>“System Objects in MATLAB Code Generation”   |
| vision.GeometricScaler                                  | Supports MATLAB Function block: Yes<br>“System Objects in MATLAB Code Generation”   |
| vision.GeometricShearer                                 | Supports MATLAB Function block: Yes<br>“System Objects in MATLAB Code Generation”   |
| vision.GeometricTransformer                             | Supports MATLAB Function block: Yes<br>“System Objects in MATLAB Code Generation”   |
| vision.GeometricTranslator                              | Supports MATLAB Function block: Yes<br>“System Objects in MATLAB Code Generation”   |
| <b>Object Detection and Recognition</b>                 |   |

| Name                                  | Remarks and Limitations   |
|---------------------------------------|---|
| ocr                                   | Compile-time constant input: 'TextLayout', 'Language', and 'CharacterSet'. Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library. |
| ocrText                               | Supports MATLAB Function block: No  |
| vision.PeopleDetector                 | Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library. “System Objects in MATLAB Code Generation”                                 |
| vision.CascadeObjectDetector          | Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library. “System Objects in MATLAB Code Generation”                                 |
| <b>Tracking and Motion Estimation</b> |   |
| assignDetectionsToTracks              | Supports MATLAB Function block: Yes   |
| opticalFlowFarneback                  | Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.  |
| opticalFlowHS                         | Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.  |
| opticalFlowLKDoG                      | Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.  |
| opticalFlowLK                         | Supports MATLAB Function block: No Generated code for this function uses a precompiled platform-specific shared library.  |
| opticalFlow                           | Supports MATLAB Function block: Yes   |

| Name  | Remarks and Limitations   |
|---|---|
| vision.ForegroundDetector                   | Supports MATLAB Function block: No<br>Generates platform-dependent library: Yes for MATLAB host.<br>Generates portable C code for non-host target.<br>Generated code for this function uses a precompiled platform-specific shared library.<br>“System Objects in MATLAB Code Generation” |
| vision.HistogramBasedTracker                | Supports MATLAB Function block: Yes<br>“System Objects in MATLAB Code Generation”   |
| vision.KalmanFilter                         | Supports MATLAB Function block: Yes<br>“System Objects in MATLAB Code Generation”   |
| vision.PointTracker                         | Supports MATLAB Function block: No<br>“System Objects in MATLAB Code Generation”  |
| vision.TemplateMatcher                      | Supports MATLAB Function block: Yes<br>“System Objects in MATLAB Code Generation”   |
| <b>Camera Calibration and Stereo Vision</b> |   |
| bboxOverlapRatio                            | Supports MATLAB Function block: No  |
| bbox2points                                 | Supports MATLAB® Function block: Yes  |
| disparity                                   | Compile-time constant input restriction: 'Method'.<br>Supports MATLAB Function block: No<br>Generated code for this function uses a precompiled platform-specific shared library.   |
| cameraMatrix                                | Supports MATLAB Function block: No  |
| cameraPose                                  | Supports MATLAB Function block: No  |
| cameraParameters                            | Supports MATLAB Function block: No<br>Use the toStruct method to pass a cameraParameters object into generated code.<br>See the “Code Generation for Depth Estimation From Stereo Video” example.   |

| Name                              | Remarks and Limitations  |
|-----------------------------------|--|
| detectCheckerboardPoints          | Supports MATLAB Function block: No<br>Code generation will not support specifying images as file names or cell arrays of file names. It supports only checkerboard detection in a single image or stereo pair of images. For example, these syntaxes are supported: <ul style="list-style-type: none"> <li>• detectCheckerboardPoints(I1)</li> <li>• detectCheckerbarPoints(I1, I2)</li> </ul> I1 and I2 are single grayscale or RGB images. |
| generateCheckerboardPoints        | Supports MATLAB Function block: No   |
| epipolarline                      | Supports MATLAB Function block: Yes  |
| estimateFundamentalMatrix         | Compile-time constant input restriction: 'Method', 'OutputClass', 'DistanceType', and 'ReportRuntimeError'.<br>Supports MATLAB Function block: Yes   |
| estimateUncalibratedRectification | Supports MATLAB Function block: Yes  |
| extrinsics                        | Supports MATLAB Function block: No   |
| isEpipoleInImage                  | Supports MATLAB Function block: Yes  |
| lineToBorderPoints                | Supports MATLAB Function block: Yes  |
| reconstructScene                  | Supports MATLAB Function block: No   |
| rectifyStereoImages               | Compile-time constant input restriction: 'interp' and 'OutputView'<br>Supports MATLAB Function block: No   |
| selectStrongestBbox               | Supports MATLAB Function block: No   |
| stereoParameters                  | Supports MATLAB Function block: No<br>Use the toStruct method to pass a stereoParameters object into generated code. See the “Code Generation for Depth Estimation From Stereo Video” example.   |
| triangulate                       | Supports MATLAB Function block: No   |

| Name   | Remarks and Limitations  |
|--|--|
| undistortImage                               | Compile-time constant input restriction: 'interp' and 'OutputView'<br>Supports MATLAB Function block: No |

## Control Flow in MATLAB

| Function                | Remarks and Limitations  |
|-------------------------|--|
| break                   | —  |
| continue                | —  |
| end                     | —  |
| for                     | —  |
| if, elseif, else        | —  |
| parfor                  | Treated as a for-loop in a MATLAB Function block.  |
| return                  | —  |
| switch, case, otherwise | <ul style="list-style-type: none"> <li>• If all case expressions are scalar integer values, generates a C switch statement. At run time, if the switch value is not an integer, generates an error.</li> <li>• When the case expressions contain noninteger or nonscalar values, the code generation software generates C if statements in place of a C switch statement.</li> </ul> |
| while                   | —  |

## Data and File Management in MATLAB

| Function | Remarks and Limitations  |
|----------|--|
| computer | <ul style="list-style-type: none"> <li>Information about the computer on which the code generation software is running.</li> <li>Use only when the code generation target is S-function (Simulation) or MEX-function.</li> </ul>   |
| fclose   | —  |
| feof     | —  |
| fopen    | <ul style="list-style-type: none"> <li>Does not support:             <ul style="list-style-type: none"> <li>machineformat, encoding, or fileID inputs</li> <li>message output</li> <li>fopen('all')</li> </ul> </li> <li>If you disable extrinsic calls, you cannot return fileIDs created with fopen to MATLAB or extrinsic functions. You can use such fileIDs only internally.</li> <li>When generating C/C++ executables, static libraries, or dynamic libraries, you can open up to 20 files.</li> <li>The generated code does not report errors from invalid file identifiers. Write your own file open error handling in your MATLAB code. Test whether fopen returns -1, which indicates that the file open failed. For example:             <pre> ... fid = fopen(filename, 'r'); if fid == -1     % fopen failed  else     % fopen successful, okay to call fread     A = fread(fid); ... </pre> </li> <li>The behavior of the generated code for fread is compiler-dependent if you:             <ol style="list-style-type: none"> <li>Open a file using fopen with a permission of a+.</li> </ol> </li> </ul> |

| Function                    | Remarks and Limitations   |
|-----------------------------|---|
|                             | <p><b>2</b> Read the file using <code>fread</code> before calling an I/O function, such as <code>fseek</code> or <code>frewind</code>, that sets the file position indicator.</p>   |
| <p><code>fprintf</code></p> | <ul style="list-style-type: none"> <li>• Does not support:                             <ul style="list-style-type: none"> <li>• <code>b</code> and <code>t</code> subtypes on <code>%u</code>, <code>%o</code> <code>%x</code>, and <code>%X</code> formats.</li> <li>• <code>\$</code> flag for reusing input arguments.</li> <li>• printing arrays.</li> </ul> </li> <li>• There is no automatic casting. Input arguments must match their format types for predictable results.</li> <li>• Escaped characters are limited to the decimal range of 0–127.</li> <li>• A call to <code>fprintf</code> with <code>fileID</code> equal to 1 or 2 becomes <code>printf</code> in the generated C/C++ code in the following cases:                             <ul style="list-style-type: none"> <li>• The <code>fprintf</code> call is inside a <code>parfor</code> loop.</li> <li>• Extrinsic calls are disabled.</li> </ul> </li> <li>• When the MATLAB behavior differs from the C compiler behavior, <code>fprintf</code> matches the C compiler behavior in the following cases:                             <ul style="list-style-type: none"> <li>• The format specifier has a corresponding C format specifier, for example, <code>%e</code> or <code>%E</code>.</li> <li>• The <code>fprintf</code> call is inside a <code>parfor</code> loop.</li> <li>• Extrinsic calls are disabled.</li> </ul> </li> <li>• When you call <code>fprintf</code> with the format specifier <code>%s</code>, do not put a null character in the middle of the input string. Use <code>fprintf(fid, '%c', char(0))</code> to write a null character.</li> <li>• When you call <code>fprintf</code> with an integer format specifier, the type of the integer argument must be a type that the target hardware can represent as a native C type. For example, if you call <code>fprintf('%d', int64(n))</code>, the target hardware must have a native C type that supports a 64-bit integer.</li> </ul> |

| Function | Remarks and Limitations   |
|----------|---|
| fread    | <ul style="list-style-type: none"> <li>• precision must be a constant.</li> <li>• The source and output that precision specifies cannot have values long, ulong, unsigned long, bitN, or ubitN.</li> <li>• You cannot use the machineformat input.</li> <li>• If the source or output that precision specifies is a C type, for example, int, the target and production sizes for that type must:               <ul style="list-style-type: none"> <li>• Match.</li> <li>• Map directly to a MATLAB type.</li> </ul> </li> <li>• The source type that precision specifies must map directly to a C type on the target hardware.</li> <li>• If the fread call reads the entire file, all of the data must fit in the largest array available for code generation.</li> <li>• If sizeA is not constant or contains a nonfinite element, then dynamic memory allocation is required.</li> <li>• Treats a char value for source or output as a signed 8-bit integer. Use values between 0 and 127 only.</li> <li>• The generated code does not report file read errors. Write your own file read error handling in your MATLAB code. Test that the number of bytes read matches the number of bytes that you requested. For example:               <pre style="margin-left: 20px;"> ... N = 100; [vals, numRead] = fread(fid, N, '*double'); if numRead ~= N     % fewer elements read than expected end ... </pre> </li> </ul> |
| frewind  | —   |

| Function | Remarks and Limitations  |
|----------|--|
| load     | <ul style="list-style-type: none"> <li>• Use only when generating MEX or code for Simulink simulation. To load compile-time constants, use <code>coder.load</code>.</li> <li>• Does not support use of the function without assignment to a structure or array. For example, use <code>S = load(filename)</code>, not <code>load(filename)</code>.</li> <li>• The output <code>S</code> must be the name of a structure or array without any subscripting. For example, <code>S(i) = load('myFile.mat')</code> is not allowed.</li> <li>• Arguments to <code>load</code> must be compile-time constant strings.</li> <li>• Does not support loading objects.</li> <li>• If the MAT-file contains unsupported constructs, use <code>load(filename, variables)</code> to load only the supported constructs.</li> <li>• You cannot use <code>save</code> in a function intended for code generation. The code generation software does not support the <code>save</code> function. Furthermore, you cannot use <code>coder.extrinsic</code> with <code>save</code>. Prior to generating code, you can use <code>save</code> to save the workspace data to a MAT-file.</li> </ul> <p>You must use <code>coder.varsizes</code> to explicitly declare variable-size data loaded using the <code>load</code> function.</p> |

## Data Types in MATLAB

| Function   | Remarks and Limitations  |
|------------|--|
| cell       | “Cell Array Requirements and Limitations for Code Generation” on page 48-5 |
| deal       | —  |
| fieldnames | Does not support objects. The input must be a structure.                   |
| iscell     | —  |
| isfield    | Does not support cell arrays for the second argument.                      |
| isobject   | —  |
| isstruct   | —  |
| nargchk    | • Output structure does not include stack information.                     |

## Fixed-Point Designer

In addition to function-specific limitations listed in the table, the following general limitations apply to the use of Fixed-Point Designer functions in generated code, with `fiaccl`:

- `fipref` and `quantizer` objects are not supported.
- Word lengths greater than 128 bits are not supported.
- You cannot change the `fimath` or `numericType` of a given `fi` variable after that variable has been created.
- The `boolean` value of the `DataTypeMode` and `DataType` properties are not supported.
- For all `SumMode` property settings other than `FullPrecision`, the `CastBeforeSum` property must be set to `true`.
- You can use parallel for (`parfor`) loops in code compiled with `fiaccl`, but those loops are treated like regular `for` loops.
- When you compile code containing `fi` objects with nontrivial slope and bias scaling, you may see different results in generated code than you achieve by running the same code in MATLAB.
- The general limitations of C/C++ code generated from MATLAB apply. For more information, see “MATLAB Language Features Supported for C/C++ Code Generation”.

| Function              | Remarks/Limitations |
|-----------------------|---------------------|
| <code>abs</code>      | N/A                 |
| <code>accumneg</code> | N/A                 |

## Image Processing Toolbox

The following table lists the Image Processing Toolbox functions that have been enabled for code generation. You must have the MATLAB Coder software installed to generate C code from MATLAB for these functions.

Image Processing Toolbox provides three types of code generation support:

- Functions that generate C code.
- Functions that generate C code that depends on a platform-specific shared library (`.dll`, `.so`, or `.dylib`). Use of a shared library preserves performance optimizations in these functions, but this limits the target platforms for which you can generate code. For more information, see “Code Generation for Image Processing”.
- Functions that generate C code or C code that depends on a shared library, depending on which target platform you specify in MATLAB Coder. If you specify the generic MATLAB Host Computer target platform, these functions generate C code that

depends on a shared library. If you specify any other target platform, these functions generate C code.

In generated code, each supported toolbox function has the same name, arguments, and functionality as its Image Processing Toolbox counterpart. However, some functions have limitations. The following table includes information about code generation limitations that might exist for each function. In the following table, all the functions generate C code. The table identifies those functions that generate C code that depends on a shared library, and those functions that can do both, depending on which target platform you choose.

| Function                | Remarks/Limitations   |
|-------------------------|---|
| <code>affine2d</code>   | When generating code, you can only specify single objects—arrays of objects are not supported.  |
| <code>bwareaopen</code> | BW must be a 2-D binary image. N-D arrays are not supported. <code>conn</code> can only be one of the two-dimensional connectivities (4 or 8) or a 3-by-3 matrix. The 3-D connectivities (6, 18, and 26) are not supported. Matrices of size 3-by-3-by-...-by-3 are not supported. <code>conn</code> must be a compile-time constant. |
| <code>bwdist</code>     | The <code>method</code> argument must be a compile-time constant. Input images must have fewer than $2^{32}$ pixels.<br><br>Generated code for this function uses a precompiled, platform-specific shared library.  |
| <code>bweuler</code>    | If you choose the generic <b>MATLAB Host Computer</b> target platform, generated code uses a precompiled, platform-specific shared library.   |
| <code>bwlabel</code>    | When generating code, the parameter <code>n</code> must be a compile-time constant.   |
| <code>bwlookup</code>   | For best results, specify an input image of class <code>logical</code> .<br><br>If you choose the generic <b>MATLAB Host Computer</b> target platform, generated code uses a precompiled, platform-specific shared library.   |
| <code>bwmorph</code>    | The text string specifying the operation must be a constant and, for best results, specify an input image of class <code>logical</code> .<br><br>If you choose the generic <b>MATLAB Host Computer</b> target platform, generated code uses a precompiled, platform-specific shared library.  |

| Function                       | Remarks/Limitations  |
|--------------------------------|--|
| <code>bwpack</code>            | Generated code for this function uses a precompiled platform-specific shared library.  |
| <code>bwperim</code>           | <p>Supports only 2-D images. Does not support any no-output-argument syntaxes. The connectivity matrix input argument, <code>conn</code>, must be a compile-time constant.</p> <p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p>   |
| <code>bwselect</code>          | <p>Supports only the 3 and 4 input argument syntaxes: <code>BW2 = bwselect(BW,c,r)</code> and <code>BW2 = bwselect(BW,c,r,n)</code>. The optional fourth input argument, <code>n</code>, must be a compile-time constant. In addition, with code generation, <code>bwselect</code> only supports only the 1 and 2 output argument syntaxes: <code>BW2 = bwselect(___)</code> or <code>[BW2, idx] = bwselect(___)</code>.</p> <p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p> |
| <code>bwtraceboundary</code>   | The <code>dir</code> , <code>fstep</code> , and <code>conn</code> arguments must be compile-time constants.  |
| <code>bwunpack</code>          | Generated code for this function uses a precompiled platform-specific shared library.  |
| <code>conndef</code>           | Input arguments must be compile-time constants.  |
| <code>edge</code>              | <p>The <code>method</code>, <code>direction</code>, and <code>sigma</code> arguments must be a compile-time constants. In addition, nonprogrammatic syntaxes are not supported. For example, the syntax <code>edge(im)</code>, where <code>edge</code> does not return a value but displays an image instead, is not supported.</p> <p>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.</p>  |
| <code>fitgeotrans</code>       | <p>The <code>transformtype</code> argument must be a compile-time constant. The function supports the following transformation types: 'nonreflectivesimilarity', 'similarity', 'affine', or 'projective'.</p>  |
| <code>fspecial</code>          | Inputs must be compile-time constants. Expressions or variables are allowed if their values do not change.   |
| <code>getrangefromclass</code> | —  |

| Function      | Remarks/Limitations   |
|---------------|---|
| grayconnected | If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.  |
| histeq        | All the syntaxes that include indexed images are not supported. This includes all syntaxes that accept <code>map</code> as input and return <code>newmap</code> .<br><br>If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library. |
| hough         | The optional parameter names 'Theta' and 'RhoResolution' must be compile-time string constants. The optional Theta vector must have a bounded size.   |
| houghlines    | The optional parameter names 'FillGap' and 'MinLength' must be compile-time string constants. Their associated values need not be compile-time constants.   |
| houghpeaks    | The optional parameter names 'Threshold' and 'NHoodSize' must be compile-time string constants. Their associated values need not be compile-time constants.   |
| im2int16      | If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.  |
| im2uint8      | If you choose the generic MATLAB Host Computer target platform, generated code uses a precompiled, platform-specific shared library.  |

## Neural Network Toolbox

You can use `genFunction` in the Neural Network Toolbox™ to generate a standalone MATLAB function for a trained neural network. You can generate C/C++ code from this standalone MATLAB function. To generate Simulink blocks, use the `genSim` function. See “Deploy Neural Network Functions”.

## Numerical Integration and Differentiation in MATLAB

| Function              | Remarks and Limitations   |
|-----------------------|---|
| <code>cumtrapz</code> | —   |
| <code>de12</code>     | —   |
| <code>diff</code>     | <ul style="list-style-type: none"> <li>If supplied, the arguments representing the number of times to apply <code>diff</code> and the dimension along which to calculate the difference must be constants.</li> </ul>   |
| <code>gradient</code> | —   |
| <code>ode23</code>    | <ul style="list-style-type: none"> <li>All <code>odeset</code> option arguments must be constant.</li> <li>Does not support a constant mass matrix in the options structure. Provide a mass matrix as a function .</li> <li>You must provide at least the two output arguments <code>T</code> and <code>Y</code>.</li> <li>Input types must be homogeneous—all double or all single.</li> <li>Variable-sizing support must be enabled. Requires dynamic memory allocation when <code>tspan</code> has two elements or you use event functions.</li> </ul> |

| Function | Remarks and Limitations   |
|----------|---|
| ode45    | <ul style="list-style-type: none"> <li>• All <code>odeset</code> option arguments must be constant.</li> <li>• Does not support a constant mass matrix in the options structure. Provide a mass matrix as a function .</li> <li>• You must provide at least the two output arguments <code>T</code> and <code>Y</code>.</li> <li>• Input types must be homogeneous—all double or all single.</li> <li>• Variable-sizing support must be enabled. Requires dynamic memory allocation when <code>tspan</code> has two elements or you use event functions.</li> </ul> |
| odeget   | The <code>name</code> argument must be constant.  |
| odeset   | All inputs must be constant.  |
| quad2d   | <ul style="list-style-type: none"> <li>• Generates a warning if the size of the internal storage arrays is not large enough. If a warning occurs, a possible workaround is to divide the region of integration into pieces and sum the integrals over each piece.</li> </ul>  |
| quadgk   | —   |
| trapz    | <ul style="list-style-type: none"> <li>• If supplied, <code>dim</code> must be a constant.</li> <li>• “Variable-Sizing Restrictions for Code Generation of Toolbox Functions” on page 46-30</li> </ul>  |

## Optimization Functions in MATLAB

| Function   | Remarks and Limitations   |
|------------|---|
| fminsearch | <ul style="list-style-type: none"> <li>• Ignores the <code>Display</code> option. Does not print status information during execution. Test the <code>exitflag</code> output for the exit condition.</li> <li>• The output structure does not include the <code>algorithm</code> or <code>message</code> fields.</li> <li>• Ignores the <code>OutputFcn</code> and <code>PlotFcns</code> options.</li> </ul> |
| fzero      | <ul style="list-style-type: none"> <li>• The first argument must be a function handle. Does not support structure, inline function, or string inputs for the first argument.</li> <li>• Supports up to three output arguments. Does not support the fourth output argument (the <code>output</code> structure).</li> </ul>  |
| optimget   | Input parameter names must be constant.   |
| optimset   | <ul style="list-style-type: none"> <li>• Does not support the syntax that has no input or output arguments:</li> </ul>  |

| Function | Remarks and Limitations   |
|----------|---|
|          | optimset <ul style="list-style-type: none"> <li>• Functions specified in the options must be supported for code generation.</li> <li>• The fields of the options structure <code>oldopts</code> must be fixed-size fields.</li> <li>• For code generation, optimization functions ignore the <code>Display</code> option.</li> <li>• Does not support the additional options in an options structure created by the Optimization Toolbox <code>optimset</code> function. If an input options structure includes the additional Optimization Toolbox options, the output structure does not include them.</li> </ul> |

## Phased Array System Toolbox

C and C++ code generation for the following functions and System objects requires the Phased Array System Toolbox software.

| Name  | Remarks and Limitations   |
|---|---|
| <b>Antenna and Microphone Elements</b>          |   |
| <code>aperture2gain</code>                      | Does not support variable-size inputs.  |
| <code>azel2phithetapat</code>                   | Does not support variable-size inputs.  |
| <code>azel2uvpat</code>                         | Does not support variable-size inputs.  |
| <code>circpol2pol</code>                        | Does not support variable-size inputs.  |
| <code>gain2aperture</code>                      | Does not support variable-size inputs.  |
| <code>phased.CosineAntennaElement</code>        | <ul style="list-style-type: none"> <li>• <code>pattern</code>, <code>patternAzimuth</code>, <code>patternElevation</code>, and <code>plotResponse</code> methods are not supported.</li> <li>• See “System Objects in MATLAB Code Generation”.</li> </ul> |
| <code>phased.CrossedDipoleAntennaElement</code> | <ul style="list-style-type: none"> <li>• <code>pattern</code>, <code>patternAzimuth</code>, <code>patternElevation</code>, and <code>plotResponse</code> methods are not supported.</li> <li>• See “System Objects in MATLAB Code Generation”.</li> </ul> |

| Name                                    | Remarks and Limitations   |
|---|---|
| phased.CustomAntennaElement             | <ul style="list-style-type: none"> <li>• <code>pattern</code>, <code>patternAzimuth</code>, <code>patternElevation</code>, and <code>plotResponse</code> methods are not supported.</li> <li>• See “System Objects in MATLAB Code Generation”.</li> </ul> |
| phased.CustomMicrophoneElement          | <ul style="list-style-type: none"> <li>• <code>pattern</code>, <code>patternAzimuth</code>, <code>patternElevation</code>, and <code>plotResponse</code> methods are not supported.</li> <li>• See “System Objects in MATLAB Code Generation”.</li> </ul> |
| phased.IsotropicAntennaElement          | <ul style="list-style-type: none"> <li>• <code>pattern</code>, <code>patternAzimuth</code>, <code>patternElevation</code>, and <code>plotResponse</code> methods are not supported.</li> <li>• See “System Objects in MATLAB Code Generation”.</li> </ul> |
| phased.OmnidirectionalMicrophoneElement | <ul style="list-style-type: none"> <li>• <code>pattern</code>, <code>patternAzimuth</code>, <code>patternElevation</code>, and <code>plotResponse</code> methods are not supported.</li> <li>• See “System Objects in MATLAB Code Generation”.</li> </ul> |
| phased.ShortDipoleAntennaElement        | <ul style="list-style-type: none"> <li>• <code>pattern</code>, <code>patternAzimuth</code>, <code>patternElevation</code>, and <code>plotResponse</code> methods are not supported.</li> <li>• See “System Objects in MATLAB Code Generation”.</li> </ul> |
| phitheta2azelpat                        | Does not support variable-size inputs.  |
| phitheta2uvpat                          | Does not support variable-size inputs.  |
| pol2circpol                             | Does not support variable-size inputs.  |
| polellip                                | Does not support variable-size inputs.  |
| polloss                                 | Does not support variable-size inputs.  |
| polratio                                | Does not support variable-size inputs.  |

| Name                                 | Remarks and Limitations   |
|--------------------------------------|---|
| polsignature                         | <ul style="list-style-type: none"> <li>Does not support variable-size inputs.</li> <li>Supported only when output arguments are specified.</li> </ul>   |

| ifftshift | —  |
| svd       | Uses a different SVD implementation than MATLAB. Because the singular value decomposition is not unique, left and right singular vectors might differ from those computed by MATLAB.   |
| zp2tf     | —  |

## Signal Processing Toolbox

C and C++ code generation for the following functions requires the Signal Processing Toolbox software. These functions do not support variable-size inputs, you must define the size and type of the function inputs. For more information, see “Specifying Inputs in Code Generation from MATLAB”.

---

**Note:** Many Signal Processing Toolbox functions require constant inputs in generated code. To specify a constant input for `codegen`, use `coder.Constant`.

---

| Function       | Remarks/Limitations  |
|----------------|--|
| barthannwin    | Window length must be a constant. Expressions or variables are allowed if their values do not change.      |

# System Objects Supported for Code Generation

---

## Code Generation for System Objects

You can generate C and C++ code for a subset of System objects provided by the following toolboxes.

| Toolbox Name                   | See  |
|--------------------------------|--|
| Communications System Toolbox  | “System Objects in MATLAB Code Generation” in the DSP System Toolbox documentation.  |
| Computer Vision System Toolbox | “System Objects in MATLAB Code Generation” in the Computer Vision System Toolbox documentation.  |
| DSP System Toolbox             | “System Objects in MATLAB Code Generation” in the DSP System Toolbox documentation.  |
| Image Acquisition Toolbox      | <ul style="list-style-type: none"> <li>• <code>imaq.VideoDevice</code>.</li> <li>• “Code Generation with VideoDevice System Object” in the Image Acquisition Toolbox documentation.</li> </ul> |
| Phased Array System Toolbox    | “Code Generation” in the Phased Array System Toolbox documentation.  |
| System Identification Toolbox  | “Generate Code for Online Parameter Estimation in MATLAB” in the System Identification Toolbox documentation.  |

To use these System objects, you need to install the requisite toolbox. For a list of System objects supported for C and C++ code generation, see “Functions and Objects Supported for C and C++ Code Generation — Alphabetical List” on page 42-2 and “Functions and Objects Supported for C and C++ Code Generation — Category List” on page 42-147.

System objects are MATLAB object-oriented implementations of algorithms. They extend MATLAB by enabling you to model dynamic systems represented by time-varying algorithms. System objects are well integrated into the MATLAB language, regardless of whether you are writing simple functions, working interactively in the command window, or creating large applications.

In contrast to MATLAB functions, System objects automatically manage state information, data indexing, and buffering, which is particularly useful for iterative

computations or stream data processing. This enables efficient processing of long data sets. For general information about MATLAB objects, see “Object-Oriented Programming”.

# Defining MATLAB Variables for C/C++ Code Generation

---

- “Avoid Overflows in for-Loops” on page 44-15
- “Supported Variable Types” on page 44-17

## Variables Definition for Code Generation

In the MATLAB language, variables can change their properties dynamically at run time so you can use the same variable to hold a value of any class, size, or complexity. For example, the following code works in MATLAB:

```
function x = foo(c) %#codegen
if(c>0)
    x = 0;
else
    x = [1 2 3];
end
disp(x);
end
```

However, statically-typed languages like C must be able to determine variable properties at compile time. Therefore, for C/C++ code generation, you must explicitly define the class, size, and complexity of variables in MATLAB source code before using them. For example, rewrite the above source code with a definition for *x*:

```
function x = foo(c) %#codegen
x = zeros(1,3);
if(c>0)
    x = 0;
else
    x = [1 2 3];
end
disp(x);
end
```

For more information, see “Best Practices for Defining Variables for C/C++ Code Generation” on page 44-3.

## Best Practices for Defining Variables for C/C++ Code Generation

### In this section...

“Define Variables By Assignment Before Using Them” on page 44-3

“Use Caution When Reassigning Variables” on page 44-5

“Use Type Cast Operators in Variable Definitions” on page 44-5

“Define Matrices Before Assigning Indexed Variables” on page 44-6

### Define Variables By Assignment Before Using Them

For C/C++ code generation, you should explicitly and unambiguously define the class, size, and complexity of variables before using them in operations or returning them as outputs. Define variables by assignment, but note that the assignment copies not only the value, but also the size, class, and complexity represented by that value to the new variable. For example:

| Assignment:                              | Defines:                                     |
|--|--|
| <code>a = 14.7;</code>                   | a as a real double scalar.                   |
| <code>b = a;</code>                      | b with properties of a (real double scalar). |
| <code>c = zeros(5,2);</code>             | c as a real 5-by-2 array of doubles.         |
| <code>d = [1 2 3 4 5; 6 7 8 9 0];</code> | d as a real 5-by-2 array of doubles.         |
| <code>y = int16(3);</code>               | y as a real 16-bit integer scalar.           |

Define properties this way so that the variable is defined on the required execution paths during C/C++ code generation (see Defining a Variable for Multiple Execution Paths).

The data that you assign to a variable can be a scalar, matrix, or structure. If your variable is a structure, define the properties of each field explicitly (see Defining Fields in a Structure).

Initializing the new variable to the value of the assigned data sometimes results in redundant copies in the generated code. To avoid redundant copies, you can define variables without initializing their values by using the `coder.nullcopy` construct as described in “Eliminate Redundant Copies of Variables in Generated Code” on page 44-7.

When you define variables, they are local by default; they do not persist between function calls. To make variables persistent, see “Define and Initialize Persistent Variables” on page 44-10.

### Defining a Variable for Multiple Execution Paths

Consider the following MATLAB code:

```
...
if c > 0
    x = 11;
end
% Later in your code ...
if c > 0
    use(x);
end
...
```

Here,  $x$  is assigned only if  $c > 0$  and used only when  $c > 0$ . This code works in MATLAB, but generates a compilation error during code generation because it detects that  $x$  is undefined on some execution paths (when  $c \leq 0$ ),

To make this code suitable for code generation, define  $x$  before using it:

```
x = 0;
...
if c > 0
    x = 11;
end
% Later in your code ...
if c > 0
    use(x);
end
...
```

### Defining Fields in a Structure

Consider the following MATLAB code:

```
...
if c > 0
    s.a = 11;
    disp(s);
else
    s.a = 12;
end
```

```

    s.b = 12;
end
% Try to use s
use(s);
...

```

Here, the first part of the `if` statement uses only the field `a`, and the `else` clause uses fields `a` and `b`. This code works in MATLAB, but generates a compilation error during C/C++ code generation because it detects a structure type mismatch. To prevent this error, do not add fields to a structure after you perform certain operations on the structure. For more information, see “Structure Definition for Code Generation” on page 47-2.

To make this code suitable for C/C++ code generation, define all fields of `s` before using it.

```

...
% Define all fields in structure s
s = struct('a',0, 'b', 0);
if c > 0
    s.a = 11;
    disp(s);
else
    s.a = 12;
    s.b = 12;
end
% Use s
use(s);
...

```

## Use Caution When Reassigning Variables

In general, you should adhere to the "one variable/one type" rule for C/C++ code generation; that is, each variable must have a specific class, size and complexity. Generally, if you reassign variable properties after the initial assignment, you get a compilation error during code generation, but there are exceptions, as described in “Reassignment of Variable Properties” on page 44-9.

## Use Type Cast Operators in Variable Definitions

By default, constants are of type `double`. To define variables of other types, you can use type cast operators in variable definitions. For example, the following code defines variable `y` as an integer:

```

...

```

```
x = 15; % x is of type double by default.  
y = uint8(x); % y has the value of x, but cast to uint8.  
...
```

## Define Matrices Before Assigning Indexed Variables

When generating C/C++ code from MATLAB, you cannot grow a variable by writing into an element beyond its current size. Such indexing operations produce run-time errors. You must define the matrix first before assigning values to its elements.

For example, the following initial assignment is not allowed for code generation:

```
g(3,2) = 14.6; % Not allowed for creating g  
           % OK for assigning value once created
```

For more information about indexing matrices, see “Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation” on page 46-26.

# Eliminate Redundant Copies of Variables in Generated Code

## In this section...

“When Redundant Copies Occur” on page 44-7

“How to Eliminate Redundant Copies by Defining Uninitialized Variables” on page 44-7

“Defining Uninitialized Variables” on page 44-8

## When Redundant Copies Occur

During C/C++ code generation, MATLAB checks for statements that attempt to access uninitialized memory. If it detects execution paths where a variable is used but is potentially not defined, it generates a compile-time error. To prevent these errors, define variables by assignment before using them in operations or returning them as function outputs.

Note, however, that variable assignments not only copy the properties of the assigned data to the new variable, but also initialize the new variable to the assigned value. This forced initialization sometimes results in redundant copies in C/C++ code. To eliminate redundant copies, define uninitialized variables by using the `coder.nullcopy` function, as described in “How to Eliminate Redundant Copies by Defining Uninitialized Variables” on page 44-7.

## How to Eliminate Redundant Copies by Defining Uninitialized Variables

- 1 Define the variable with `coder.nullcopy`.
- 2 Initialize the variable before reading it.

When the uninitialized variable is an array, you must initialize all of its elements before passing the array as an input to a function or operator — even if the function or operator does not read from the uninitialized portion of the array.

### What happens if you access uninitialized data?

Uninitialized memory contains arbitrary values. Therefore, accessing uninitialized data may lead to segmentation violations or nondeterministic program behavior (different runs of the same program may yield inconsistent results).

## Defining Uninitialized Variables

In the following code, the assignment statement `X = zeros(1,N)` not only defines `X` to be a 1-by-5 vector of real doubles, but also initializes each element of `X` to zero.

```
function X = fcn %#codegen

N = 5;
X = zeros(1,N);
for i = 1:N
    if mod(i,2) == 0
        X(i) = i;
    else
        X(i) = 0;
    end
end
```

This forced initialization creates an extra copy in the generated code. To eliminate this overhead, use `coder.nullcopy` in the definition of `X`:

```
function X = fcn2 %#codegen

N = 5;
X = coder.nullcopy(zeros(1,N));
for i = 1:N
    if mod(i,2) == 0
        X(i) = i;
    else
        X(i) = 0;
    end
end
```

## Reassignment of Variable Properties

For C/C++ code generation, there are certain variables that you can reassign after the initial assignment with a value of different class, size, or complexity:

### **Dynamically sized variables**

A variable can hold values that have the same class and complexity but different sizes. If the size of the initial assignment is not constant, the variable is dynamically sized in generated code. For more information, see “Variable-Size Data”.

### **Variables reused in the code for different purposes**

You can reassign the type (class, size, and complexity) of a variable after the initial assignment if each occurrence of the variable can have only one type. In this case, the variable is renamed in the generated code to create multiple independent variables. For more information, see “Reuse the Same Variable with Different Properties” on page 44-11.

## Define and Initialize Persistent Variables

Persistent variables are local to the function in which they are defined, but they retain their values in memory between calls to the function. To define persistent variables for C/C++ code generation, use the `persistent` statement, as in this example:

```
persistent PROD_X;
```

The definition should appear at the top of the function body, after the header and comments, but before the first use of the variable. During code generation, the value of the persistent variable is initialized to an empty matrix by default. You can assign your own value after the definition by using the `isempty` statement, as in this example:

```
function findProduct(inputvalue) %#codegen
persistent PROD_X

if isempty(PROD_X)
    PROD_X = 1;
end
PROD_X = PROD_X * inputvalue;
end
```

## Reuse the Same Variable with Different Properties

### In this section...

“When You Can Reuse the Same Variable with Different Properties” on page 44-11

“When You Cannot Reuse Variables” on page 44-11

“Limitations of Variable Reuse” on page 44-14

### When You Can Reuse the Same Variable with Different Properties

You can reuse (reassign) an input, output, or local variable with different class, size, or complexity if MATLAB can unambiguously determine the properties of each occurrence of this variable during C/C++ code generation. If so, MATLAB creates separate uniquely named local variables in the generated code. You can view these renamed variables in the code generation report (see “Viewing Variables in Your MATLAB Code” on page 37-50).

A common example of variable reuse is in `if-elseif-else` or `switch-case` statements. For example, the following function `example1` first uses the variable `t` in an `if` statement, where it holds a scalar double, then reuses `t` outside the `if` statement to hold a vector of doubles.

```
function y = example1(u) %#codegen
if all(all(u>0))
    % First, t is used to hold a scalar double value
    t = mean(mean(u)) / numel(u);
    u = u - t;
end
% t is reused to hold a vector of doubles
t = find(u > 0);
y = sum(u(t(2:end-1)));
```

To compile this example and see how MATLAB renames the reused variable `t`, see Variable Reuse in an `if` Statement.

### When You Cannot Reuse Variables

You cannot reuse (reassign) variables if it is not possible to determine the class, size, and complexity of an occurrence of a variable unambiguously during code generation. In this case, variables cannot be renamed and a compilation error occurs.

For example, the following `example2` function assigns a fixed-point value to `x` in the `if` statement and reuses `x` to store a matrix of doubles in the `else` clause. It then uses `x` after the `if-else` statement. This function generates a compilation error because after the `if-else` statement, variable `x` can have different properties depending on which `if-else` clause executes.

```
function y = example2(use_fixpoint, data) %#codegen
    if use_fixpoint
        % x is fixed-point
        x = fi(data, 1, 12, 3);
    else
        % x is a matrix of doubles
        x = data;
    end
    % When x is reused here, it is not possible to determine its
    % class, size, and complexity
    t = sum(sum(x));
    y = t > 0;
end
```

### Variable Reuse in an if Statement

To see how MATLAB renames a reused variable `t`:

- 1 Create a MATLAB file `example1.m` containing the following code.

```
function y = example1(u) %#codegen
if all(all(u>0))
    % First, t is used to hold a scalar double value
    t = mean(mean(u)) / numel(u);
    u = u - t;
end
% t is reused to hold a vector of doubles
t = find(u > 0);
y = sum(u(t(2:end-1)));
end
```

- 2 Compile `example1`.

For example, to generate a MEX function, enter:

```
codegen -o example1x -report example1.m -args {ones(5,5)}
```

---

**Note:** `codegen` requires a MATLAB Coder license.

---

When the compilation is complete, `codegen` generates a MEX function, `example1x` in the current folder, and provides a link to the code generation report.

- 3 Open the code generation report.
- 4 In the MATLAB code pane of the code generation report, place your pointer over the variable `t` inside the `if` statement.

The code generation report highlights both instances of `t` in the `if` statement because they share the same class, size, and complexity. It displays the data type information for `t` at this point in the code. Here, `t` is a scalar double.

```
% First time t is used to hold a scalar double value.
t = mean(mean(u)) / numel(u);
u = u - t;
```

| Information for the selected variable: |        |
|--|--------|
| Size                                   | 1 x 1  |
| Complex                                | No     |
| Class                                  | double |

- 5 In the MATLAB code pane of the report, place your pointer over the variable `t` outside the for-loop.

This time, the report highlights both instances of `t` outside the `if` statement. The report indicates that `t` might hold up to 25 doubles. The size of `t` is `:25`, that is, a column vector containing a maximum of 25 doubles.

```
t = find(u);
y = sum(u(t(2:end-1)));
```

| Information for the selected variable: |        |
|--|--------|
| Size                                   | :25    |
| Complex                                | No     |
| Class                                  | double |

- 6 Click the **Variables** tab to view the list of variables used in `example1`.

The report displays a list of the variables in `example1`. There are two uniquely named local variables `t>1` and `t>2`.

- 7** In the list of variables, place your pointer over `t>1`.

The code generation report highlights both instances of `t` in the `if` statement.

- 8** In the list of variables, place your pointer over `t>2`

The code generation report highlights both instances of `t` outside the `if` statement.

## Limitations of Variable Reuse

The following variables cannot be renamed in generated code:

- Persistent variables.
- Global variables.
- Variables passed to C code using `coder.ref`, `coder.rref`, `coder.wref`.
- Variables whose size is set using `coder.ysize`.
- Variables whose names are controlled using `coder.cstructname`.
- The index variable of a `for`-loop when it is used inside the loop body.
- The block outputs of a MATLAB Function block in a Simulink model.
- Chart-owned variables of a MATLAB function in a Stateflow chart.

## Avoid Overflows in for-Loops

When memory integrity checks are enabled, if the code generation software detects that a loop variable might overflow on the last iteration of the `for`-loop, it reports an error.

To avoid this error, use the workarounds provided in the following table.

| Loop conditions causing the error   | Workaround  |
|---|---|
| <ul style="list-style-type: none"> <li>The loop counter increments by 1</li> <li>The end value equals the maximum value of the integer type</li> <li>The loop is not covering the full range of the integer type</li> </ul>   | <p>Rewrite the loop so that the end value is not equal to the maximum value of the integer type. For example, replace:</p> <pre>N=intmax('int16') for k=N-10:N</pre> <p>with:</p> <pre>for k=1:10</pre>   |
| <ul style="list-style-type: none"> <li>The loop counter decrements by 1</li> <li>The end value equals the minimum value of the integer type</li> <li>The loop is not covering the full range of the integer type</li> </ul>   | <p>Rewrite the loop so that the end value is not equal to the minimum value of the integer type. For example, replace:</p> <pre>N=intmin('int32') for k=N+10:-1:N</pre> <p>with:</p> <pre>for k=10:-1:1</pre>   |
| <ul style="list-style-type: none"> <li>The loop counter increments or decrements by 1</li> <li>The start value equals the minimum or maximum value of the integer type</li> <li>The end value equals the maximum or minimum value of the integer type</li> </ul> <p>The loop covers the full range of the integer type.</p> | <p>Rewrite the loop casting the type of the loop counter start, step, and end values to a bigger integer or to double. For example, rewrite:</p> <pre>M= intmin('int16'); N= intmax('int16'); for k=M:N % Loop body end to  M= intmin('int16'); N= intmax('int16'); for k=int32(M):int32(N) % Loop body</pre> |

| Loop conditions causing the error   | Workaround  |
|---|---|
| <ul style="list-style-type: none"><li>• The loop counter increments or decrements by a value not equal to 1</li><li>• On last loop iteration, the loop variable value is not equal to the end value</li></ul> | end<br><br>Rewrite the loop so that the loop variable on the last loop iteration is equal to the end value. |
| <b>Note:</b> The software error checking is conservative. It may incorrectly report a loop as being potentially infinite.   |   |

## Supported Variable Types

You can use the following data types for C/C++ code generation from MATLAB:

| Type                          | Description   |
|-------------------------------|---|
| char                          | Character array (string)  |
| complex                       | Complex data. Cast function takes real and imaginary components |
| double                        | Double-precision floating point                                 |
| int8, int16, int32, int64     | Signed integer  |
| logical                       | Boolean true or false   |
| single                        | Single-precision floating point                                 |
| struct                        | Structure   |
| uint8, uint16, uint32, uint64 | Unsigned integer  |
| Fixed-point                   | See “Fixed-Point Data Types”.                                   |

# Defining Data for Code Generation

## Data Definition for Code Generation

To generate efficient standalone code, you must define the following types and classes of data differently than you normally would when running your code in the MATLAB environment:

| Data             | What's Different  | More Information   |
|------------------|---|--|
| Arrays           | Maximum number of elements is restricted  | “Array Size Restrictions for Code Generation” on page 45-9 |
| Complex numbers  | <ul style="list-style-type: none"> <li>Complexity of variables must be set at time of assignment and before first use</li> <li>Expressions containing a complex number or variable evaluate to a complex result, even if the result is zero</li> </ul> <p><b>Note:</b> Because MATLAB does not support complex integer arithmetic, you cannot generate code for functions that use complex integer arithmetic</p> | “Code Generation for Complex Data” on page 45-4            |
| Characters       | Restricted to 8 bits of precision   | “Code Generation for Characters and Strings” on page 45-8  |
| Enumerated data  | <ul style="list-style-type: none"> <li>Supports integer-based enumerated types only</li> <li>Restricted use in <code>switch</code> statements and <code>for</code>-loops</li> </ul>   | “Enumerated Data”  |
| Function handles | <ul style="list-style-type: none"> <li>Same bound variable cannot reference</li> </ul>  | “Function Handles”   |

| Data | What's Different  | More Information |
|------|---|------------------|
|      | <p data-bbox="647 300 862 357">different function handles</p> <ul data-bbox="609 374 911 604" style="list-style-type: none"><li data-bbox="609 374 911 496">• Cannot pass function handles to or from primary or extrinsic functions</li><li data-bbox="609 513 911 604">• Cannot view function handles from the debugger</li></ul> |                  |

## Code Generation for Complex Data

### In this section...

“Restrictions When Defining Complex Variables” on page 45-4

“Code Generation for Complex Data with Zero-Valued Imaginary Parts” on page 45-4

“Results of Expressions That Have Complex Operands” on page 45-7

### Restrictions When Defining Complex Variables

For code generation, you must set the complexity of variables at the time of assignment. Assign a complex constant to the variable or use the `complex` function. For example:

```
x = 5 + 6i; % x is a complex number by assignment.
y = complex(5,6); % y is the complex number 5 + 6i.
```

After assignment, you cannot change the complexity of a variable. Code generation for the following function fails because  $x(k) = 3 + 4i$  changes the complexity of  $x$ .

```
function x = test1( )
x = zeros(3,3); % x is real
for k = 1:numel(x)
    x(k) = 3 + 4i;
end
end
```

To resolve this issue, assign a complex constant to  $x$ .

```
function x = test1( )
x = zeros(3,3)+ 0i; %x is complex
for k = 1:numel(x)
    x(k) = 3 + 4i;
end
end
```

### Code Generation for Complex Data with Zero-Valued Imaginary Parts

For code generation, complex data that has all zero-valued imaginary parts remains complex. This data does not become real. This behavior has the following implications:

- In some cases, results from functions that sort complex data by absolute value can differ from the MATLAB results. See “Functions That Sort Complex Values by Absolute Value” on page 45-5.
- For functions that require that complex inputs are sorted by absolute value, complex inputs with zero-valued imaginary parts must be sorted by absolute value. These functions include `ismember`, `union`, `intersect`, `setdiff`, and `setxor`.

### Functions That Sort Complex Values by Absolute Value

Functions that sort complex values by absolute value include `sort`, `issorted`, `sortrows`, `median`, `min`, and `max`. These functions sort complex numbers by absolute value even when the imaginary parts are zero. In general, sorting the absolute values produces a different result than sorting the real parts. Therefore, when inputs to these functions are complex with zero-valued imaginary parts in generated code, but real in MATLAB, the generated code can produce different results than MATLAB. In the following examples, the input to `sort` is real in MATLAB, but complex with zero-valued imaginary parts in the generated code:

- **You Pass Real Inputs to a Function Generated for Complex Inputs**

- 1 Write this function:

```
function myout = mysort(A)
myout = sort(A);
end
```

- 2 Call `mysort` in MATLAB.

```
A = -2:2;
mysort(A)

ans =

    -2    -1     0     1     2
```

- 3 Generate a MEX function for complex inputs.

```
A = -2:2;
codegen mysort -args {complex(A)} -report
```

- 4 Call the MEX Function with real inputs.

```
mysort_mex(A)

ans =
```

```
0    1    -1    2    -2
```

You generated the MEX function for complex inputs, therefore, it treats the real inputs as complex numbers with zero-valued imaginary parts. It sorts the numbers by the absolute values of the complex numbers. Because the imaginary parts are zero, the MEX function returns the results to the MATLAB workspace as real numbers.

- **Input to `sort` Is Output from a Function That Returns Complex in Generated Code**

- 1 Write this function:

```
function y = myfun(A)
x = eig(A);
y = sort(x, 'descend');
```

The output from `eig` is the input to `sort`. In generated code, `eig` returns a complex result. Therefore, in the generated code, `x` is complex.

- 2 Call `myfun` in MATLAB.

```
A = [2 3 5;0 5 5;6 7 4];
myfun(A)
```

```
ans =
```

```
12.5777
 2.0000
-3.5777
```

The result of `eig` is real. Therefore, the inputs to `sort` are real.

- 3 Generate a MEX function for complex inputs.

```
codegen myfun -args {complex(A)}
```

- 4 Call the MEX function.

```
myfun_mex(A)
```

```
ans =
```

```
12.5777
-3.5777
 2.0000
```

In the MEX function, `eig` returns a complex result. Therefore, the inputs to `sort` are complex. The MEX function sorts the inputs in descending order of the absolute values.

## Results of Expressions That Have Complex Operands

In general, expressions that contain one or more complex operands produce a complex result in generated code, even if the value of the result is zero. Consider the following line of code:

```
z = x + y;
```

Suppose that at run time, `x` has the value  $2 + 3i$  and `y` has the value  $2 - 3i$ . In MATLAB, this code produces the real result  $z = 4$ . During code generation, the types for `x` and `y` are known, but their values are not known. Because either or both operands in this expression are complex, `z` is defined as a complex variable requiring storage for a real and an imaginary part. `z` equals the complex result  $4 + 0i$  in generated code, not  $4$ , as in MATLAB code.

Exceptions to this behavior are:

- Functions that take complex arguments but produce real results return real values.

```
y = real(x); % y is the real part of the complex number x.  
y = imag(x); % y is the real-valued imaginary part of x.  
y = isreal(x); % y is false (0) for a complex number x.
```

- Functions that take real arguments but produce complex results return complex values.

```
z = complex(x,y); % z is a complex number for a real x and y.
```

## Code Generation for Characters and Strings

The code generation software translates the 16-bit Unicode encoding of a character in MATLAB to an 8-bit encoding that the locale setting determines. The code generation software does not support characters that require more than 1 byte in MATLAB. This restriction applies to constant strings and strings that are passed between MATLAB and the code generation software. For example, the restriction applies to entry-point function inputs and to outputs from extrinsic calls. For code generation, some MATLAB functions accept only 7-bit ASCII strings. See “Functions and Objects Supported for C and C++ Code Generation — Alphabetical List” on page 42-2.

If a character is not in the 7-bit ASCII codeset, casting the character to a numeric type, such as double, produces a different result in the generated code than in MATLAB. A best practice for code generation is to avoid performing arithmetic with characters.

### More About

- “Locale Settings for MATLAB Process”

## Array Size Restrictions for Code Generation

For code generation, the maximum number of elements of an array is constrained by the code generation software and the target hardware. The maximum number of elements is the smaller of:

- `intmax('int32')`.
- The largest integer that fits in the C `int` data type on the target hardware.

These restrictions apply even on a 64-bit platform.

For a fixed-size array, if the number of elements exceeds the maximum, the code generation software reports an error at compile time. For a variable-size array, if the number of elements exceeds the maximum during simulation, the software reports an error. Generated standalone code cannot report array size violations.

### See Also

- “Variable-Size Data”

## Code Generation for Constants in Structures and Arrays

The code generation software does not recognize constant structure fields or array elements in the following cases:

### Fields or elements are assigned inside control constructs

In the following code, the code generation software recognizes that the structure fields `s.a` and `s.b` are constants.

```
function y = mystruct()  
s.a = 3;  
s.b = 5;  
y = zeros(s.a,s.b);
```

If any structure field is assigned inside a control construct, the code generation software does not recognize the constant fields. This limitation also applies to arrays with constant elements. Consider the following code:

```
function y = mystruct(x)  
s.a = 3;  
if x > 1  
    s.b = 4;  
else  
    s.b = 5;  
end  
y = zeros(s.a,s.b);
```

The code generation software does not recognize that `s.a` and `s.b` are constant. If variable-sizing is enabled, `y` is treated as a variable-size array. If variable-sizing is disabled, the code generation software reports an error.

### Constants are assigned to array elements using non-scalar indexing

In the following code, the code generation software recognizes that `a(1)` is constant.

```
function y = myarray()  
a = zeros(1,3);  
a(1) = 20;  
y = coder.const(a(1));
```

In the following code, because `a(1)` is assigned using non-scalar indexing, the code generation software does not recognize that `a(1)` is constant.

```
function y = myarray()  
a = zeros(1,3);  
a(1:2) = 20;  
y = coder.const(a(1));
```

### **A function returns a structure or array that has constant and nonconstant elements**

For an output structure that has both constant and nonconstant fields, the code generation software does not recognize the constant fields. This limitation also applies to arrays that have constant and nonconstant elements. Consider the following code:

```
function y = mystruct_out(x)  
s = create_structure(x);  
y = coder.const(s.a);  
  
function s = create_structure(x)  
s.a = 10;  
s.b = x;
```

Because `create_structure` returns a structure `s` that has one constant field and one nonconstant field, the code generation software does not recognize that `s.a` is constant. The `coder.const` call fails because `s.a` is not constant.

## What Is Variable-Size Data?

Variable-size data is data whose size can change at run time. By contrast, fixed-size data is data whose size is known and locked at compile time and, therefore, cannot change at run time.

For example, in the following MATLAB function `nway`, `B` is a variable-size array; its length is not known at compile time.

```
function B = nway(A,n)
% Compute average of every N elements of A and put them in B.
if ((mod(numel(A),n) == 0) && (n >= 1 && n <= numel(A)))
    B = ones(1,numel(A)/n);
    k = 1;
    for i = 1 : numel(A)/n
        B(i) = mean(A(k + (0:n-1)));
        k = k + n;
    end
else
    error('n <= 0 or does not divide number of elements evenly');
end
```

## Variable-Size Data Definition for Code Generation

In the MATLAB language, data can vary in size. By contrast, the semantics of generated code constrains the class, complexity, and shape of every expression, variable, and structure field. Therefore, for code generation, you must use each variable consistently. Each variable must:

- Be either complex or real (determined at first assignment)
- Have a consistent shape

For fixed-size data, the shape is the same as the size returned in MATLAB. For example, if `size(A) == [4 5]`, the shape of variable `A` is 4 x 5. For variable-size data, the shape can be abstract. That is, one or more dimensions can be unknown (such as `4x?` or `?x?`).

By default, the compiler detects code logic that attempts to change these fixed attributes after initial assignments, and flags these occurrences as errors during code generation. However, you can override this behavior by defining variables or structure fields as variable-size data.

For more information, see “Bounded Versus Unbounded Variable-Size Data” on page 46-4

## Bounded Versus Unbounded Variable-Size Data

*Bounded variable-size data* has fixed upper bounds. *Unbounded variable-size data* does not have fixed upper bounds; this data *must* be allocated on the heap and requires dynamic memory allocation. You cannot use dynamic memory allocation for variable-size data in MATLAB Function blocks. Use bounded instead of unbounded variable-size data.

# Specify Variable-Size Data Without Dynamic Memory Allocation

## In this section...

“Fixing Upper Bounds Errors” on page 46-5

“Specifying Upper Bounds for Variable-Size Data” on page 46-5

## Fixing Upper Bounds Errors

If MATLAB cannot determine or compute the upper bound, you must specify an upper bound. See “Specifying Upper Bounds for Variable-Size Data” on page 46-5 and “Diagnosing and Fixing Errors in Detecting Upper Bounds” on page 46-19

## Specifying Upper Bounds for Variable-Size Data

- “When to Specify Upper Bounds for Variable-Size Data” on page 46-5
- “Specifying Upper Bounds for Local Variable-Size Data” on page 46-5
- “Using a Matrix Constructor with Nonconstant Dimensions” on page 46-6

## When to Specify Upper Bounds for Variable-Size Data

When using static allocation on the stack during code generation, MATLAB must be able to determine upper bounds for variable-size data. Specify the upper bounds explicitly for variable-size data from external sources, such as inputs and outputs.

## Specifying Upper Bounds for Local Variable-Size Data

When using static allocation, MATLAB uses a sophisticated analysis to calculate the upper bounds of local data at compile time. However, when the analysis fails to detect an upper bound or calculates an upper bound that is not precise enough for your application, you need to specify upper bounds explicitly for local variables.

## Constraining the Value of a Variable That Specifies Dimensions of Variable-Size Data

Use the `assert` function with relational operators to constrain the value of variables that specify the dimensions of variable-size data. For example:

```
function y = dim_need_bound(n) %#codegen
assert (n <= 5);
L = ones(n,n);
```

```
M = zeros(n,n);  
M = [L; M];  
y = M;
```

This `assert` statement constrains input `n` to a maximum size of 5, defining `L` and `M` as variable-sized matrices with upper bounds of 5 for each dimension.

### Specifying the Upper Bounds for All Instances of a Local Variable

Use the `coder.versize` function to specify the upper bounds for all instances of a local variable in a function. For example:

```
function Y = example_bounds1(u) %#codegen  
Y = [1 2 3 4 5];  
coder.versize('Y',[1 10]);  
if (u > 0)  
    Y = [Y Y+u];  
else  
    Y = [Y Y*u];  
end
```

The second argument of `coder.versize` specifies the upper bound for each instance of the variable specified in the first argument. In this example, the argument `[1 10]` indicates that for every instance of `Y`:

- First dimension is fixed at size 1
- Second dimension can grow to an upper bound of 10

By default, `coder.versize` assumes dimensions of 1 are fixed size. For more information, see the `coder.versize` reference page.

### Using a Matrix Constructor with Nonconstant Dimensions

You can define a variable-size matrix by using a constructor with nonconstant dimensions. For code in a MATLAB Function block, you must also add an `assert` statement to provide upper bounds for the dimensions. For example:

```
function y = var_by_assign(u) %#codegen  
assert (u < 20);  
if (u > 0)  
    y = ones(3,u);  
else  
    y = zeros(3,1);  
end
```

## Variable-Size Data in Code Generation Reports

| In this section...   |
|--|
| “What Reports Tell You About Size” on page 46-7            |
| “How Size Appears in Code Generation Reports” on page 46-8 |
| “How to Generate a Code Generation Report” on page 46-8    |

### What Reports Tell You About Size

Code generation reports:

- Differentiate fixed-size from variable-size data
- Identify variable-size data with unknown upper bounds
- Identify variable-size data with fixed dimensions

If you define a variable-size array and then subsequently fix the dimensions of this array in the code, the report appends \* to the size of the variable. In the generated C code, this variable appears as a variable-size array, but the size of its dimensions does not change during execution.

- Provide guidance on how to fix size mismatch and upper bounds errors.

## How Size Appears in Code Generation Reports

| Variable | Type   | Size     |
|----------|--------|----------|
| B        | Output | 1 x :?   |
| A        | Input  | 1 x :100 |
| n        | Input  | 1 x 1    |

:? means variable size, unknown upper bound  
 No colon prefix (:) means fixed size  
 :100 means variable size, upper bound = 100

| Variable | Type   | Size    |
|----------|--------|---------|
| y        | Output | 1 x 10* |

\* means that you declared y as variable size, but subsequently fixed its dimensions

## How to Generate a Code Generation Report

When you build a Simulink model that contains MATLAB Function blocks, Simulink automatically generates a report in HTML format for each MATLAB Function block in your model. See “MATLAB Function Reports” on page 37-46

## Define Variable-Size Data for Code Generation

### In this section...

“When to Define Variable-Size Data Explicitly” on page 46-9

“Using a Matrix Constructor with Nonconstant Dimensions” on page 46-9

“Inferring Variable Size from Multiple Assignments” on page 46-10

“Defining Variable-Size Data Explicitly Using `coder.varsizes`” on page 46-11

### When to Define Variable-Size Data Explicitly

For code generation, you must assign variables to have a specific class, size, and complexity before using them in operations or returning them as outputs. Generally, you cannot reassign variable properties after the initial assignment. Therefore, attempts to grow a variable or structure field after assigning it a fixed size might cause a compilation error. In these cases, you must explicitly define the data as variable sized using one of these methods:

| Method   | See   |
|--|---|
| Assign the data from a variable-size matrix constructor such as <ul style="list-style-type: none"> <li>• <code>ones</code></li> <li>• <code>zeros</code></li> <li>• <code>repmat</code></li> </ul> | “Using a Matrix Constructor with Nonconstant Dimensions” on page 46-9                     |
| Assign multiple, constant sizes to the same variable before using (reading) the variable.  | “Inferring Variable Size from Multiple Assignments” on page 46-10                         |
| Define all instances of a variable to be variable sized  | “Defining Variable-Size Data Explicitly Using <code>coder.varsizes</code> ” on page 46-11 |

### Using a Matrix Constructor with Nonconstant Dimensions

You can define a variable-size matrix by using a constructor with nonconstant dimensions. For code in a MATLAB Function block, you must also add an `assert` statement to provide upper bounds for the dimensions. For example:

```
function y = var_by_assign(u) %#codegen
assert (u < 20);
if (u > 0)
    y = ones(3,u);
else
    y = zeros(3,1);
end
```

## Inferring Variable Size from Multiple Assignments

You can define variable-size data by assigning multiple, constant sizes to the same variable before you use (read) the variable in your code. When MATLAB uses static allocation on the stack for code generation, it infers the upper bounds from the largest size specified for each dimension. When you assign the same size to a given dimension across all assignments, MATLAB assumes that the dimension is fixed at that size. The assignments can specify different shapes as well as sizes.

### Inferring Upper Bounds from Multiple Definitions with Different Shapes

```
function y = var_by_multiassign(u) %#codegen
if (u > 0)
    y = ones(3,4,5);
else
    y = zeros(3,1);
end
```

When static allocation is used, this function infers that `y` is a matrix with three dimensions, where:

- First dimension is fixed at size 3
- Second dimension is variable with an upper bound of 4
- Third dimension is variable with an upper bound of 5

The code generation report represents the size of matrix `y` like this:

| Variable | Type   | Size        |
|----------|--------|-------------|
| y        | Output | 3 x :4 x :5 |

## Defining Variable-Size Data Explicitly Using `coder.varsizes`

Use the function `coder.varsizes` to define one or more variables or structure fields as variable-size data. Optionally, you can also specify which dimensions vary along with their upper bounds (see “Specifying Which Dimensions Vary” on page 46-11). For example:

- Define **B** as a variable-size 2-by-2 matrix, where each dimension has an upper bound of 64:

```
coder.varsizes('B', [64 64]);
```

- Define **B** as a variable-size matrix:

```
coder.varsizes('B');
```

When you supply only the first argument, `coder.varsizes` assumes all dimensions of **B** can vary and that the upper bound is `size(B)`.

For more information, see the `coder.varsizes` reference page.

### Specifying Which Dimensions Vary

You can use the function `coder.varsizes` to specify which dimensions vary. For example, the following statement defines **B** as a row vector whose first dimension is fixed at 2, but whose second dimension can grow to an upper bound of 16:

```
coder.varsizes('B',[2, 16],[0 1])
```

The third argument specifies which dimensions vary. This argument must be a logical vector or a double vector containing only zeros and ones. Dimensions that correspond to zeros or `false` have fixed size; dimensions that correspond to ones or `true` vary in size. `coder.varsizes` usually treats dimensions of size 1 as fixed (see “Defining Variable-Size Matrices with Singleton Dimensions” on page 46-12).

For more information about the syntax, see the `coder.varsizes` reference page.

### Allowing a Variable to Grow After Defining Fixed Dimensions

Function `var_by_if` defines matrix **Y** with fixed 2-by-2 dimensions before first use (where the statement `Y = Y + u` reads from **Y**). However, `coder.varsizes` defines **Y** as a variable-size matrix, allowing it to change size based on decision logic in the `else` clause:

```
function Y = var_by_if(u) %#codegen
```

```
if (u > 0)
    Y = zeros(2,2);
    coder.varsize('Y');
    if (u < 10)
        Y = Y + u;
    end
else
    Y = zeros(5,5);
end
```

Without `coder.varsize`, MATLAB infers `Y` to be a fixed-size, 2-by-2 matrix and generates a size mismatch error during code generation.

### Defining Variable-Size Matrices with Singleton Dimensions

A singleton dimension is a dimension for which `size(A,dim) = 1`. Singleton dimensions are fixed in size when:

- You specify a dimension with an upper bound of 1 in `coder.varsize` expressions.

For example, in this function, `Y` behaves like a vector with one variable-size dimension:

```
function Y = dim_singleton(u) %#codegen
Y = [1 2];
coder.varsize('Y', [1 10]);
if (u > 0)
    Y = [Y 3];
else
    Y = [Y u];
end
```

- You initialize variable-size data with singleton dimensions using matrix constructor expressions or matrix functions.

For example, in this function, both `X` and `Y` behave like vectors where only their second dimensions are variable sized:

```
function [X,Y] = dim_singleton_vects(u) %#codegen
Y = ones(1,3);
X = [1 4];
coder.varsize('Y','X');
if (u > 0)
    Y = [Y u];
else
```

```

        X = [X u];
    end

```

You can override this behavior by using `coder.versize` to specify explicitly that singleton dimensions vary. For example:

```

function Y = dim_singleton_vary(u) %#codegen
Y = [1 2];
coder.versize('Y', [1 10], [1 1]);
if (u > 0)
    Y = [Y Y+u];
else
    Y = [Y Y*u];
end

```

In this example, the third argument of `coder.versize` is a vector of ones, indicating that each dimension of `Y` varies in size. For more information, see the `coder.versize` reference page.

### Defining Variable-Size Structure Fields

To define structure fields as variable-size arrays, use colon (`:`) as the index expression. The colon (`:`) indicates that all elements of the array are variable sized. For example:

```

function y=struct_example() %#codegen

d = struct('values', zeros(1,0), 'color', 0);
data = repmat(d, [3 3]);
coder.versize('data(:).values');

for i = 1:numel(data)
    data(i).color = rand-0.5;
    data(i).values = 1:i;
end

y = 0;
for i = 1:numel(data)
    if data(i).color > 0
        y = y + sum(data(i).values);
    end;
end

```

The expression `coder.versize('data(:).values')` defines the field `values` inside each element of matrix `data` to be variable sized.

Here are other examples:

- `coder.varsize('data.A(:).B')`

In this example, `data` is a scalar variable that contains matrix `A`. Each element of matrix `A` contains a variable-size field `B`.

- `coder.varsize('data(:).A(:).B')`

This expression defines field `B` inside each element of matrix `A` inside each element of matrix `data` to be variable sized.

## C Code Interface for Arrays

### C Code Interface for Statically Allocated Arrays

For statically allocated arrays, the generated code contains the definition of the array and the size of the array.

For example, consider the MATLAB function `myunique_tol`.

```
function B = myunique_tol(A, tol) %#codegen
A = sort(A);
coder.varsize('B', [1 100], [0 1]);
B = A(1);
k = 1;
for i = 2:length(A)
    if abs(A(k) - A(i)) > tol
        B = [B A(i)];
        k = i;
    end
end
```

The statement `coder.varsize('B', [1 100], [0 1])` specifies that `B` is a variable-size array whose first dimension is fixed at 1 and second dimension can vary up to 100 elements. Without this statement, `B` is a dynamically allocated array.

Generate code for `myunique_tol` specifying that input `A` is a variable-size real double vector whose first dimension is fixed at 1 and second dimension can vary up to 100 elements.

```
codegen -config:lib -report myunique_tol -args {coder.typeof(0,[1 100],1),coder.typeof(0)}
```

In the generated code, the function declaration is:

```
extern void myunique_tol(const double A_data[], const int A_size[2], double tol,
    double B_data[], int B_size[2])
```

The function signature declares the input argument `A` and the output argument `B`. `A_size` contains the size of `A`. `B_size` contains the size of `B` after the call to `myunique_tol`. Use `B_size` to determine the number of elements of `B` that you can access after the call to `myunique_tol`. `B_size[0]` contains the size of the first dimension. `B_size[1]` contains the size of the second dimension. Therefore, the number of elements

of B is `B_size[0]*B_Size[1]`. Even though B has 100 elements in the C code, only `B_size[0]*B_Size[1]` elements contain valid data.

The following C main function shows how to call `myuniquetol`.

```
void main()
{
    double A[100], B[100];
    int A_size[2] = { 1, 100 };
    int B_size[2];
    int i;
    for (i = 0; i < 100; i++) {
        A[i] = (double)1/i;
    }
    myuniquetol(A, A_size, 0.1, B, B_size);
}
```

## Diagnose and Fix Variable-Size Data Errors

### In this section...

“Diagnosing and Fixing Size Mismatch Errors” on page 46-17

“Diagnosing and Fixing Errors in Detecting Upper Bounds” on page 46-19

### Diagnosing and Fixing Size Mismatch Errors

Check your code for these issues:

#### Assigning Variable-Size Matrices to Fixed-Size Matrices

You cannot assign variable-size matrices to fixed-size matrices in generated code. Consider this example:

```
function Y = example_mismatch1(n) %#codegen
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B;
end
Y = A;
```

Compiling this function produces this error:

```
??? Dimension 1 is fixed on the left-hand side
but varies on the right ...
```

There are several ways to fix this error:

- Allow matrix A to grow by adding the `coder.varsize` construct:

```
function Y = example_mismatch1_fix1(n) %#codegen
coder.varsize('A');
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B;
end
Y = A;
```

```
Y = A;
```

- Explicitly restrict the size of matrix B to 3-by-3 by modifying the `assert` statement:

```
function Y = example_mismatch1_fix2(n) %#codegen
coder.varsize('A');
assert(n == 3)
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B;
end
Y = A;
```

- Use explicit indexing to make B the same size as A:

```
function Y = example_mismatch1_fix3(n) %#codegen
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
    A = B(1:3, 1:3);
end
Y = A;
```

### Empty Matrix Reshaped to Match Variable-Size Specification

If you assign an empty matrix `[]` to variable-size data, MATLAB might silently reshape the data in generated code to match a `coder.varsize` specification. For example:

```
function Y = test(u) %#codegen
Y = [];
coder.varsize('Y', [1 10]);
if u < 0
    Y = [Y u];
end
```

In this example, `coder.varsize` defines Y as a column vector of up to 10 elements, so its first dimension is fixed at size 1. The statement `Y = []` designates the first dimension of Y as 0, creating a mismatch. The right hand side of the assignment is an empty matrix and the left hand side is a variable-size vector. In this case, MATLAB reshapes the empty matrix `Y = []` in generated code to `Y = zeros(1,0)` so it matches the `coder.varsize` specification.

## Performing Binary Operations on Fixed and Variable-Size Operands

You cannot perform binary operations on operands of different sizes. Operands have different sizes if one has fixed dimensions and the other has variable dimensions. For example:

```
function z = mismatch_operands(n) %#codegen
assert(n >= 3 && n < 10);
x = ones(n,n);
y = magic(3);
z = x + y;
```

When you compile this function, you get an error because `y` has fixed dimensions (3 x 3), but `x` has variable dimensions. Fix this problem by using explicit indexing to make `x` the same size as `y`:

```
function z = mismatch_operands_fix(n) %#codegen
assert(n >= 3 && n < 10);
x = ones(n,n);
y = magic(3);
z = x(1:3,1:3) + y;
```

## Diagnosing and Fixing Errors in Detecting Upper Bounds

Check your code for these issues:

### Using Nonconstant Dimensions in a Matrix Constructor

You can define variable-size data by assigning a variable to a matrix with nonconstant dimensions. For example:

```
function y = dims_vary(u) %#codegen
if (u > 0)
    y = ones(3,u);
else
    y = zeros(3,1);
end
```

However, compiling this function generates an error because you did not specify an upper bound for `u`.

To fix the problem, add an `assert` statement before the first use of `u`:

```
function y = dims_vary_fix(u) %#codegen
```

```
assert (u < 20);  
if (u > 0)  
    y = ones(3,u);  
else  
    y = zeros(3,1);  
end
```

## Incompatibilities with MATLAB in Variable-Size Support for Code Generation

### Incompatibility with MATLAB for Scalar Expansion

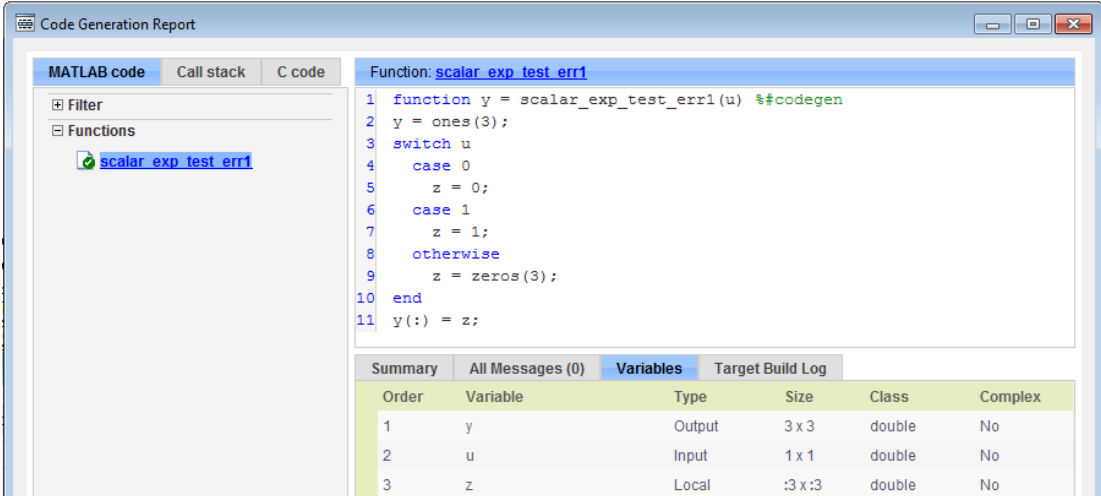

Scalar expansion is a method of converting scalar data to match the dimensions of vector or matrix data. Except for some matrix operators, MATLAB arithmetic operators work on corresponding elements of arrays with equal dimensions. For vectors and rectangular arrays, both operands must be the same size unless one is a scalar. If one operand is a scalar and the other is not, MATLAB applies the scalar to every element of the other operand—this property is known as *scalar expansion*.

During code generation, the standard MATLAB scalar expansion rules apply except when operating on two variable-size expressions. In this case, both operands must be the same size. The generated code does not perform scalar expansion even if one of the variable-size expressions turns out to be scalar at run time. Instead, it generates a size mismatch error at run time for MEX functions. Run-time error checking does not occur for non-MEX builds; the generated code will have unspecified behavior.

For example, in the following function, `z` is scalar for the `switch` statement `case 0` and `case 1`. MATLAB applies scalar expansion when evaluating `y(:) = z`; for these two cases.

```
function y = scalar_exp_test_err1(u) %#codegen
y = ones(3);
switch u
    case 0
        z = 0;
    case 1
        z = 1;
    otherwise
        z = zeros(3);
end
y(:) = z;
```

When you generate code for this function, the code generation software determines that `z` is variable size with an upper bound of 3.

The screenshot shows the 'Code Generation Report' window. The 'MATLAB code' tab is selected, displaying the following code for the function `scalar_exp_test_err1`:

```
1 function y = scalar_exp_test_err1(u) %#codegen
2 y = ones(3);
3 switch u
4     case 0
5         z = 0;
6     case 1
7         z = 1;
8     otherwise
9         z = zeros(3);
10 end
11 y(:) = z;
```

Below the code, the 'Variables' tab is selected, showing a summary table:

| Order | Variable | Type   | Size   | Class  | Complex |
|-------|----------|--------|--------|--------|---------|
| 1     | y        | Output | 3 x 3  | double | No      |
| 2     | u        | Input  | 1 x 1  | double | No      |
| 3     | z        | Local  | :3 x:3 | double | No      |

If you run the MEX function with `u` equal to zero or one, even though `z` is scalar at run time, the generated code does not perform scalar expansion and a run-time error occurs.

```
scalar_exp_test_err1_mex(0)
Sizes mismatch: 9 ~= 1.
```

```
Error in scalar_exp_test_err1 (line 11)
```

```
y(:) = z;
```

### Workaround

Use indexing to force `z` to be a scalar value:

```
function y = scalar_exp_test_err1(u) %#codegen
y = ones(3);
switch u
    case 0
        z = 0;
    case 1
        z = 1;
    otherwise
        z = zeros(3);
end
y(:) = z(1);
```

## Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays

For variable-size N-D arrays, the `size` function can return a different result in generated code than in MATLAB. In generated code, `size(A)` returns a fixed-length output because it does not drop trailing singleton dimensions of variable-size N-D arrays. By contrast, `size(A)` in MATLAB returns a variable-length output because it drops trailing singleton dimensions.

For example, if the shape of array `A` is `?x:?x:?` and `size(A,3)==1`, `size(A)` returns:

- Three-element vector in generated code
- Two-element vector in MATLAB code

### Workarounds

If your application requires generated code to return the same size of variable-size N-D arrays as MATLAB code, consider one of these workarounds:

- Use the two-argument form of `size`.

For example, `size(A,n)` returns the same answer in generated code and MATLAB code.

- Rewrite `size(A)`:

```
B = size(A);  
X = B(1:ndims(A));
```

This version returns X with a variable-length output. However, you cannot pass a variable-size X to matrix constructors such as `zeros` that require a fixed-size argument.

## Incompatibility with MATLAB in Determining Size of Empty Arrays

The size of an empty array in generated code might be different from its size in MATLAB source code. The size might be `1x0` or `0x1` in generated code, but `0x0` in MATLAB. Therefore, you should not write code that relies on the specific size of empty matrices.

For example, consider the following code:

```
function y = foo(n) %#codegen  
x = [];  
i = 0;  
while (i < 10)  
    x = [5 x];  
    i = i + 1;  
end  
if n > 0  
    x = [];  
end  
y = size(x);  
end
```

Concatenation requires its operands to match on the size of the dimension that is not being concatenated. In the preceding concatenation the scalar value has size `1x1` and `x` has size `0x0`. To support this use case, the code generation software determines the size for `x` as `[1 x :?]`. Because there is another assignment `x = []` after the concatenation, the size of `x` in the generated code is `1x0` instead of `0x0`.

### Workaround

If your application checks whether a matrix is empty, use one of these workarounds:

- Rewrite your code to use the `isempty` function instead of the `size` function.
- Instead of using `x=[]` to create empty arrays, create empty arrays of a specific size using `zeros`. For example:

```
function y = test_empty(n) %#codegen
```

```

x = zeros(1,0);
i=0;
while (i < 10)
    x = [5 x];
    i = i + 1;
end
if n > 0
    x = zeros(1,0);
end
y=size(x);
end

```

## Incompatibility with MATLAB in Determining Class of Empty Arrays

The class of an empty array in generated code can be different from its class in MATLAB source code. Therefore, do not write code that relies on the class of empty matrices.

For example, consider the following code:

```

function y = fun(n)
x = [];
if n > 1
    x = ['a' x];
end
y=class(x);
end

```

`fun(0)` returns `double` in MATLAB, but `char` in the generated code. When the statement `n > 1` is false, MATLAB does not execute `x = ['a' x]`. The class of `x` is `double`, the class of the empty array. However, the code generation software considers all execution paths. It determines that based on the statement `x = ['a' x]`, the class of `x` is `char`.

### Workaround

Instead of using `x=[]` to create an empty array, create an empty array of a specific class. For example, use `blanks(0)` to create an empty array of characters.

```

function y = fun(n)
x = blanks(0);
if n > 1
    x = ['a' x];
end
y=class(x);
end

```

## Incompatibility with MATLAB in Vector-Vector Indexing

In vector-vector indexing, you use one vector as an index into another vector. When either vector is variable sized, you might get a run-time error during code generation. Consider the index expression `A(B)`. The general rule for indexing is that `size(A(B)) == size(B)`. However, when both `A` and `B` are vectors, MATLAB applies a special rule: use the orientation of `A` as the orientation of the output. For example, if `size(A) == [1 5]` and `size(B) == [3 1]`, then `size(A(B)) == [1 3]`.

In this situation, if the code generation software detects that both `A` and `B` are vectors at compile time, it applies the special rule and gives the same result as MATLAB. However, if either `A` or `B` is a variable-size matrix (has shape `?x?`) at compile time, the code generation software applies only the general indexing rule. Then, if both `A` and `B` become vectors at run time, the code generation software reports a run-time error when you run the MEX function. Run-time error checking does not occur for non-MEX builds; the generated code will have unspecified behavior. It is best practice to generate and test a MEX function before generating C code.

### Workaround

Force your data to be a vector by using the colon operator for indexing: `A(B(:))`. For example, suppose your code intentionally toggles between vectors and regular matrices at run time. You can do an explicit check for vector-vector indexing:

```
...
if isvector(A) && isvector(B)
    C = A(:);
    D = C(B(:));
else
    D = A(B);
end
...
```

The indexing in the first branch specifies that `C` and `B(:)` are compile-time vectors. As a result, the code generation software applies the standard vector-vector indexing rule.

## Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation

The following limitations apply to matrix indexing operations for code generation:

- Initialization of the following style:

```
for i = 1:10
    M(i) = 5;
end
```

In this case, the size of `M` changes as the loop is executed. Code generation does not support increasing the size of an array over time.

For code generation, preallocate `M` as highlighted in the following code.

```
M = zeros(1,10);
for i = 1:10
    M(i) = 5;
end
```

- `M(i:j)` where `i` and `j` change in a loop

During code generation, memory is not dynamically allocated for the size of the expressions that change as the program executes. To implement this behavior, use `for`-loops as shown in the following example:

```
...
M = ones(10,10);
for i = 1:10
    for j = i:10
        M(i,j) = 2*M(i,j);
    end
end
...
```

---

**Note:** The matrix `M` must be defined before entering the loop, as shown in the highlighted code.

---

## Incompatibility with MATLAB in Concatenating Variable-Size Matrices

For code generation, when you concatenate variable-size arrays, the dimensions that are not being concatenated must match exactly.

## Differences When Curly-Brace Indexing of Variable-Size Cell Array Inside Concatenation Returns No Elements

Suppose that:

- `c` is a variable-size cell array.
- You access the contents of `c` by using curly braces. For example, `c{2:4}`.
- You include the results in concatenation. For example, `[a c{2:4} b]`.
- `c{I}` returns no elements. Either `c` is empty or the indexing inside the curly braces produces an empty result.

For these conditions, MATLAB omits `c{I}` from the concatenation. For example, `[a c{I} b]` becomes `[a b]`. The code generation software treats `c{I}` as the empty array `[c{I}]`. The concatenation becomes `[... [c{i}] ...]`. This concatenation then omits the array `[c{I}]`. So that the properties of `[c{I}]` are compatible with the concatenation `[... [c{i}] ...]`, the code generation software assigns the class, size, and complexity of `[c{I}]` according to these rules:

- The class and complexity are the same as the base type of the cell array.
- The size of the second dimension is always 0.
- For the rest of the dimensions, the size of `Ni` depends on whether the corresponding dimension in the base type is fixed or variable size.
  - If the corresponding dimension in the base type is variable size, the dimension has size 0 in the result.
  - If the corresponding dimension in the base type is fixed size, the dimension has that size in the result.

Suppose that `c` has a base type with class `int8` and size `10x7x8x?:`. In the generated code, the class of `[c{I}]` is `int8`. The size of `[c{I}]` is `0x0x8x0`. The second dimension is 0. The first and last dimensions are 0 because those dimensions are variable size in the base type. The third dimension is 8 because the size of the third dimension of the base type is a fixed size 8.

Inside concatenation, if curly-brace indexing of a variable-size cell array returns no elements, the generated code can have the following differences from MATLAB:

- The class of `[...c{i}...]` in the generated code can differ from the class in MATLAB.

When `c{I}` returns no elements, MATLAB removes `c{I}` from the concatenation. Therefore, `c{I}` does not affect the class of the result. MATLAB determines the class of the result based on the classes of the remaining arrays, according to a precedence of classes. See “Valid Combinations of Unlike Classes”. In the generated code, the

class of  $[c\{I}]$  affects the class of the result of the overall concatenation  $[ \dots [c\{I}] \dots ]$  because the code generation software treats  $c\{I}$  as  $[c\{I}]$ . The previously described rules determine the class of  $[c\{I}]$ .

- In the generated code, the size of  $[c\{I}]$  can differ from the size in MATLAB.

In MATLAB, the concatenation  $[c\{I}]$  is a 0x0 double. In the generated code, the previously described rules determine the size of  $[c\{I}]$ .

## **Dynamic Memory Allocation Not Supported for MATLAB Function Blocks**

You cannot use dynamic memory allocation for variable-size data in MATLAB Function blocks. Use bounded instead of unbounded variable-size data.

## Variable-Sizing Restrictions for Code Generation of Toolbox Functions

### In this section...

“Common Restrictions” on page 46-30

“Toolbox Functions with Variable Sizing Restrictions” on page 46-31

### Common Restrictions

The following common restrictions apply to multiple toolbox functions, but only for code generation. To determine which of these restrictions apply to specific library functions, see the table in “Toolbox Functions with Variable Sizing Restrictions” on page 46-31.

#### Variable-length vector restriction

Inputs to the library function must be variable-length vectors or fixed-size vectors. A variable-length vector is a variable-size array that has the shape  $1 \times n$  or  $n \times 1$  (one dimension is variable sized and the other is fixed at size 1). Other shapes are not permitted, even if they are vectors at run time.

#### Automatic dimension restriction

When the function selects the working dimension automatically, it bases the selection on the upper bounds for the dimension sizes. In the case of the `sum` function, `sum(X)` selects its working dimension automatically, while `sum(X, dim)` uses `dim` as the explicit working dimension.

For example, if `X` is a variable-size matrix with dimensions  $1 \times 3 \times 5$ , `sum(x)` behaves like `sum(X,2)` in generated code. In MATLAB, it behaves like `sum(X,2)` provided `size(X,2)` is not 1. In MATLAB, when `size(X,2)` is 1, `sum(X)` behaves like `sum(X,3)`. Consequently, you get a run-time error if an automatically selected working dimension assumes a length of 1 at run time.

To avoid the issue, specify the intended working dimension explicitly as a constant value.

#### Array-to-vector restriction

The function issues an error when a variable-size array that is not a variable-length vector assumes the shape of a vector at run time. To avoid the issue, specify the input explicitly as a variable-length vector instead of a variable-size array.

**Array-to-scalar restriction**

The function issues an error if a variable-size array assumes a scalar value at run time. To avoid this issue, specify scalars as fixed size.

**Toolbox Functions with Variable Sizing Restrictions**

The following restrictions apply to specific toolbox functions, but only for code generation.

| Function | Restrictions with Variable-Size Data  |
|----------|---|
| all      | <ul style="list-style-type: none"> <li>• See “Automatic dimension restriction” on page 46-30.</li> <li>• An error occurs if you pass the first argument a variable-size matrix that is 0-by-0 at run time.</li> </ul> |

- “Assign Values to Structures and Fields” on page 47-11
- “Pass Large Structures as Input Parameters” on page 47-13

## Structure Definition for Code Generation

To generate efficient standalone code for structures, you must define and use structures differently than you normally would when running your code in the MATLAB environment:

| What's Different  | More Information  |
|---|---|
| Use a restricted set of operations.                                 | “Structure Operations Allowed for Code Generation” on page 47-3 |
| Observe restrictions on properties and values of scalar structures. | “Define Scalar Structures for Code Generation” on page 47-4     |
| Make structures uniform in arrays.                                  | “Define Arrays of Structures for Code Generation” on page 47-6  |
| Reference structure fields individually during indexing.            | “Index Substructures and Fields” on page 37-76                  |
| Avoid type mismatch when assigning values to structures and fields. | “Assign Values to Structures and Fields” on page 37-79          |

## Structure Operations Allowed for Code Generation

To generate efficient standalone code for MATLAB structures, you are restricted to the following operations:

- Define structures as local and persistent variables by assignment and using the `struct` function
- Index structure fields using dot notation
- Define primary function inputs as structures
- Pass structures to local functions

## Define Scalar Structures for Code Generation

### In this section...

“Restrictions When Defining Scalar Structures by Assignment” on page 47-4  
 “Adding Fields in Consistent Order on Each Control Flow Path” on page 47-4  
 “Restriction on Adding New Fields After First Use” on page 47-5

### Restrictions When Defining Scalar Structures by Assignment

When you define a scalar structure by assigning a variable to a preexisting structure, you do not need to define the variable before the assignment. However, if you already defined that variable, it must have the same class, size, and complexity as the structure you assign to it. In the following example, `p` is defined as a structure that has the same properties as the predefined structure `S`:

```
...
S = struct('a', 0, 'b', 1, 'c', 2);
p = S;
...
```

### Adding Fields in Consistent Order on Each Control Flow Path

When you create a structure, you must add fields in the same order on each control flow path. For example, the following code generates a compiler error because it adds the fields of structure `x` in a different order in each `if` statement clause:

```
function y = fcn(u) %#codegen
if u > 0
    x.a = 10;
    x.b = 20;
else
    x.b = 30; % Generates an error (on variable x)
    x.a = 40;
end
y = x.a + x.b;
```

In this example, the assignment to `x.a` comes before `x.b` in the first `if` statement clause, but the assignments appear in reverse order in the `else` clause. Here is the corrected code:

```
function y = fcn(u) %#codegen
if u > 0
    x.a = 10;
    x.b = 20;
else
    x.a = 40;
    x.b = 30;
end
y = x.a + x.b;
```

## Restriction on Adding New Fields After First Use

You cannot add fields to a structure after you perform the following operations on the structure:

- Reading from the structure
- Indexing into the structure array
- Passing the structure to a function

For example, consider this code:

```
...
x.c = 10; % Defines structure and creates field c
y = x; % Reads from structure
x.d = 20; % Generates an error
...
```

In this example, the attempt to add a new field `d` after reading from structure `x` generates an error.

This restriction extends across the structure hierarchy. For example, you cannot add a field to a structure after operating on one of its fields or nested structures, as in this example:

```
function y = fcn(u) %#codegen

x.c = 10;
y = x.c;
x.d = 20; % Generates an error
```

In this example, the attempt to add a new field `d` to structure `x` after reading from the structure's field `c` generates an error.

## Define Arrays of Structures for Code Generation

### In this section...

“Ensuring Consistency of Fields” on page 47-6

“Using repmat to Define an Array of Structures with Consistent Field Properties” on page 47-6

“Defining an Array of Structures by Using struct” on page 47-7

“Defining an Array of Structures Using Concatenation” on page 47-7

### Ensuring Consistency of Fields

For code generation, when you create an array of MATLAB structures, corresponding fields in the array elements must have the same size, type, and complexity.

Once you have created the array of structures, you can make the structure fields variable-size using `coder. varsizes`. For more information, see “Declare a Variable-Size Structure Field.”.

### Using repmat to Define an Array of Structures with Consistent Field Properties

You can create an array of structures from a scalar structure by using the MATLAB `repmat` function, which replicates and tiles an existing scalar structure:

- 1 Create a scalar structure, as described in “Define Scalar Structures for Code Generation” on page 47-4.
- 2 Call `repmat`, passing the scalar structure and the dimensions of the array.
- 3 Assign values to each structure using standard array indexing and structure dot notation.

For example, the following code creates `X`, a 1-by-3 array of scalar structures. Each element of the array is defined by the structure `s`, which has two fields, `a` and `b`:

```
...  
s.a = 0;  
s.b = 0;  
X = repmat(s,1,3);
```

```

X(1).a = 1;
X(2).a = 2;
X(3).a = 3;
X(1).b = 4;
X(2).b = 5;
X(3).b = 6;
...

```

## Defining an Array of Structures by Using `struct`

To create an array of structures using the `struct` function, specify the field value arguments as cell arrays. Each cell array element is the value of the field in the corresponding structure array element. For code generation, corresponding fields in the structures must have the same type. Therefore, the elements in a cell array of field values must have the same type.

For example, the following code creates a 1-by-3 structure array. For each structure in the array of structures, `a` has type `double` and `b` has type `char`.

```
s = struct('a', {1 2 3}, 'b', {'a' 'b' 'c'});
```

## Defining an Array of Structures Using Concatenation

To create a small array of structures, you can use the concatenation operator, square brackets ( `[ ]` ), to join one or more structures into an array (see “Concatenating Matrices”). For code generation, the structures that you concatenate must have the same size, class, and complexity.

For example, the following code uses concatenation and a local function to create the elements of a 1-by-3 structure array:

```

...
W = [ sab(1,2) sab(2,3) sab(4,5) ];

function s = sab(a,b)
    s.a = a;
    s.b = b;
...

```

## Make Structures Persistent

To make structures persist, you define them to be persistent variables and initialize them with the `isempty` statement, as described in “Define and Initialize Persistent Variables” on page 44-10.

For example, the following function defines structure `X` to be persistent and initializes its fields `a` and `b`:

```
function f(u) %#codegen
persistent X

if isempty(X)
    X.a = 1;
    X.b = 2;
end
```

## Index Substructures and Fields

Use these guidelines when indexing substructures and fields for code generation:

### Reference substructure field values individually using dot notation

For example, the following MATLAB code uses dot notation to index fields and substructures:

```
...
substruct1.a1 = 15.2;
substruct1.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5,'ele2',single(100),
                 'ele3',substruct1);

substruct2 = mystruct;
substruct2.ele3.a2 = 2*(substruct1.a2);
...
```

The generated code indexes elements of the structures in this example by resolving symbols as follows:

| Dot Notation            | Symbol Resolution  |
|-------------------------|--|
| substruct1.a1           | Field a1 of local structure substruct1   |
| substruct2.ele3.a1      | Value of field a1 of field ele3, a substructure of local structure substruct2                    |
| substruct2.ele3.a2(1,1) | Value in row 1, column 1 of field a2 of field ele3, a substructure of local structure substruct2 |

### Reference field values individually in structure arrays

To reference the value of a field in a structure array, you must index into the array to the structure of interest and then reference that structure's field individually using dot notation, as in this example:

```
...
y = X(1).a % Extracts the value of field a
           % of the first structure in array X
...
```

To reference all the values of a particular field for each structure in an array, use this notation in a `for` loop, as in this example:

```
...
s.a = 0;
s.b = 0;
X = repmat(s,1,5);
for i = 1:5
    X(i).a = i;
    X(i).b = i+1;
end
```

This example uses the `repmat` function to define an array of structures, each with two fields `a` and `b` as defined by `s`. See “Define Arrays of Structures for Code Generation” on page 47-6 for more information.

### **Do not reference fields dynamically**

You cannot reference fields in a structure by using dynamic names, which express the field as a variable expression that MATLAB evaluates at run time (see “Generate Field Names from Variables”).

## Assign Values to Structures and Fields

When assigning values to a structure, substructure, or field for code generation, use these guidelines:

### Field properties must be consistent across structure-to-structure assignments

| If:  | Then:  |
|--|--|
| Assigning one structure to another structure.                                      | Define each structure with the same number, type, and size of fields.                    |
| Assigning one structure to a substructure of a different structure and vice versa. | Define the structure with the same number, type, and size of fields as the substructure. |
| Assigning an element of one structure to an element of another structure.          | The elements must have the same type and size.   |

### For structures with constant fields, do not assign field values inside control flow constructs

In the following code, the code generation software recognizes that the structure fields `s.a` and `s.b` are constants.

```
function y = mystruct()
s.a = 3;
s.b = 5;
y = zeros(s.a,s.b);
```

If a field of a structure is assigned inside a control flow construct, the code generation software does not recognize that `s.a` and `s.b` are constant. Consider the following code:

```
function y = mystruct(x)
s.a = 3;
if x > 1
    s.b = 4;
else
    s.b = 5;
end
y = zeros(s.a,s.b);
```

If variable-sizing is enabled, `y` is treated as a variable-size array. If variable-sizing is disabled, `y`, the code generation software reports an error.

**Do not assign mxArray to structures**

You cannot assign `mxArrays` to structure elements; convert `mxArrays` to known types before code generation (see “Working with `mxArrays`” on page 53-17).

**Do not assign classes to structure fields**

You cannot assign classes to structure fields.

**Do not assign cell arrays to structure fields**

You cannot assign cell arrays to structure fields.

## Pass Large Structures as Input Parameters

If you generate a MEX function for a MATLAB function that takes a large structure as an input parameter, for example, a structure containing fields that are matrices, the MEX function might fail to load. This load failure occurs because, when you generate a MEX function from a MATLAB function that has input parameters, the code generation software allocates memory for these input parameters on the stack. To avoid this issue, pass the structure by reference to the MATLAB function. For example, if the original function signature is:

```
y = foo(a, S)
```

where **S** is the structure input, rewrite the function to:

```
[y, S] = foo(a, S)
```

# Code Generation for Cell Arrays

---

- “Homogeneous vs. Heterogeneous Cell Arrays” on page 48-2
- “Control Whether a Cell Array is Homogeneous or Heterogeneous” on page 48-4
- “Cell Array Requirements and Limitations for Code Generation” on page 48-5
- “Cell Arrays in Code Generation Reports” on page 48-8

## Homogeneous vs. Heterogeneous Cell Arrays

The code generation software classifies a cell array as *homogeneous* or *heterogeneous*. This classification determines how a cell array is represented in the generated C/C++ code. It also determines how you can use the cell array in MATLAB code from which you generate C/C++ code.

A homogeneous cell array has the following characteristics:

- The cell array is represented as a C array in the generated code.
- All elements have the same properties. The type associated with the cell array specifies the properties of all elements rather than the properties of individual elements.
- The cell array can be variable size.
- You can index into the cell array using an index whose value is determined at run time.

A heterogeneous cell array has the following characteristics:

- The cell array is represented as a C structure in the generated code. Each element is represented as a field of the structure.
- The elements can have different properties. The type associated with the cell array specifies the properties of each element individually.
- The cell array cannot be variable size.
- You must index into the cell array using a constant index or using `for`-loops with constant bounds.

The code generation software uses heuristics to determine the classification of a cell array as homogeneous or heterogeneous. It considers the properties (class, size, complexity) of the elements and other factors such as how you use the cell array in your program. A particular cell array can be homogeneous in one case and heterogeneous in another case. For example, consider the cell array `{1 [2 3]}`. This cell array can be a heterogeneous 1x2 cell array whose first element is double scalar and whose second element is a 1x2 array of doubles. However, if you index into this cell array with an index whose value is determined at run time, the cell array is a homogeneous cell array. The elements are variable-size arrays of doubles with an upper bound of 2.

To see whether a cell array is homogeneous or heterogeneous, view the variable in the code generation report. See “Cell Arrays in Code Generation Reports” on page 48-8.

For more information, see “Control Whether a Cell Array is Homogeneous or Heterogeneous” on page 48-4.

### **More About**

- “Cell Array Requirements and Limitations for Code Generation” on page 48-5

## Control Whether a Cell Array is Homogeneous or Heterogeneous

As long as you do not specify conflicting requirements, you can control whether a cell array is homogeneous or heterogeneous.

- If you use `coder. varsize` with the cell array, the cell array is homogeneous.
- If you index the cell array with an index whose value is determined at run time, the cell array is homogeneous.
- If you use `coder. cstructname` with the cell array, the cell array is heterogeneous.
- If the elements have different classes, the cell array is heterogeneous.

If the code generation software detects conflicting requirements for a cell array, the code generation fails. For example, you cannot use `coder. varsize` with a cell array whose elements have different classes.

### See Also

`coder. cstructname` | `coder. varsize`

### More About

- “Homogeneous vs. Heterogeneous Cell Arrays” on page 48-2

# Cell Array Requirements and Limitations for Code Generation

## Cell Array Definition

- You must completely assign cell arrays at compile time. You must assign each cell array element on all execution paths.

If you use `cell` to create a cell array, you must assign values to all elements of the cell array. The following code is not allowed because `y{2}` is not assigned.

```
function y = foo()
y = cell(1,3);
y{1} = 1;
y{3} = 3;
end
```

Even if the element is not used, you must assign a value so that the code generation software can determine whether the cell array is homogeneous or heterogeneous. Assign a value that is consistent with how you plan to use the cell array. See “Homogeneous vs. Heterogeneous Cell Arrays” on page 48-2.

In the preceding example, if `y{2}` is double, `y` is homogeneous. If `y{2}` is empty, its size is `0x0` not `1x1` like the other elements. In this case, `y` is heterogeneous.

- The assignment must be consistent on all execution paths. The following code is not allowed because `y{2}` is double on one execution path and char on the other execution path.

```
function y = foo(n)
y = cell(1,3)
if n > 1;
    y{1} = 1
    y{2} = 2;
    y{3} = 3;
else
    y{1} = 10;
    y{2} = 'a';
    y{3} = 30;
end
```

## Cell Array Indexing

- You cannot index cell arrays by using smooth parentheses ( ). Instead, consider indexing cell arrays by using curly braces { } to access the contents of the cell.
- You must index into heterogeneous cell arrays by using constant indexes or by using for-loops with constant bounds.

For example, the following code is not allowed:

```
x = {1, 'mystring'};  
disp(x{randi});
```

If the index A and B are constant, the following code is allowed:

```
x = {1, 'mystring'};  
for i = A:B  
    disp(x{i});
```

When the for-loop has constant bounds, it is unrolled. For large cell arrays, the unrolling can increase compile time and generate inefficient code.

## Variable-Size Cell Arrays

- Heterogeneous cell arrays cannot be variable size.
- You cannot use the cell function to create a variable-size cell array. For example, the following code is not allowed:

```
function y = foo(n)  
y = cell(1,n);
```

Instead, use repmat. For example:

```
function y = foo(n)  
y = repmat({1}, [1 n]);
```

- If you use the cell function to create a cell array, you cannot use coder.varsize with that cell array.

## Cell Array Contents

- Cell arrays cannot contain mxArray's. In a cell array, you cannot store a value that an extrinsic function returns.

- Cell arrays cannot contain classes or System objects.
- Cell arrays cannot contain function handles.

## Cell Arrays in Structures

Structures cannot contain cell arrays.

## Passing to External C/C++ Functions

You cannot pass a cell array to `coder.ceval`. If a variable is an input argument to `coder.ceval`, define the variable as an array or structure instead of as a cell array.

## Use in MATLAB Function Block

You can use cells arrays inside a MATLAB Function block. You cannot use cell arrays for Simulink signals, parameters, or data store memory.

## More About

- “Differences in Behavior After Compiling MATLAB Code” on page 41-8

## Cell Arrays in Code Generation Reports

### Cell Array Variable in the MATLAB Code Pane

When you place your cursor over a cell array variable in the **MATLAB code** pane, the report shows that the variable has class `cell`.

If the cell array has all constant elements, or some constant and some nonconstant elements, the variable name is orange. When you place your cursor over the variable, the report shows the values of the elements. The report displays a nonconstant element as an empty array. If you export the cell array variable to the base workspace, a nonconstant element is an empty array in the base workspace. See “Viewing Variables in Your MATLAB Code” on page 37-50.

### Cell Array Variable on the Variables Tab

On the **Variables** tab, for a cell array, the report shows class `cell`. By default, the report collapses the list of cell array elements. To see the properties of the elements, expand the list.

For a homogeneous cell array, the report has one entry that specifies the properties of all elements. The notation `{:}` indicates that all elements of the cell array have the same properties.

| Summary | All Messages (0) | Variables | Target Build Log |        |         |
|---------|------------------|-----------|------------------|--------|---------|
| Order   | Variable         | Type      | Size             | Class  | Complex |
| 1       | z                | Output    | 1 x 1            | double | No      |
| 2       | c                | Input     | 1 x 3            | cell   | -       |
| 2.1     | c{:}             | Element   | 1 x 1            | double | No      |

For a heterogeneous cell array, the report has an entry for each element. For example, for a heterogeneous cell array `c` with two elements, the entry for `c{1}` shows the properties for the first element. The entry for `c{2}` shows the properties for the second element.

| Summary | All Messages (0)  | Variables | Target Build Log |        |         |  |
|---------|-------------------|-----------|------------------|--------|---------|--|
| Order   | Variable          | Type      | Size             | Class  | Complex |  |
| 1       | <code>z</code>    | Output    | 1 x 1            | char   | -       |  |
| 2       | <code>c</code>    | Input     | 1 x 2            | cell   | -       |  |
| 2.1     | <code>c{1}</code> | Element   | 1 x 1            | char   | -       |  |
| 2.2     | <code>c{2}</code> | Element   | 1 x 1            | double | No      |  |

## Enumerated Data Definition for Code Generation

To generate efficient standalone code for enumerated data, you must define and use enumerated types differently than you do in the MATLAB environment:

| Difference  | More Information   |
|---|--|
| Supports integer-based enumerated types only                                    | “Enumerated Types Supported in MATLAB Function Blocks” on page 37-97             |
| Each enumerated data type must be defined in a separate file on the MATLAB path | “Define Enumerated Data Types for MATLAB Function Blocks” on page 37-100         |
| Restricted set of operations  | “Operations on Enumerated Data” on page 37-110                                   |
| Restricted use in <code>for</code> -loops                                       | “Restrictions on Use of Enumerated Data in <code>for</code> -Loops” on page 49-4 |

## Customize Enumerated Types for MATLAB Function Blocks

To customize an enumerated type that you use in a MATLAB Function block, use the same techniques that work with MATLAB classes, as described in [Modifying Superclass Methods and Properties](#). For more information, see “[Customize Simulink Enumeration](#)” on page 56-9.

## Restrictions on Use of Enumerated Data in for-Loops

### Do not use enumerated data as the loop counter variable in for - loops

To iterate over a range of enumerated data with consecutive values, in the loop counter, cast the enumerated data to a built-in integer type. The size of the built-in integer type must be big enough to contain the enumerated value.

For example, suppose you define an enumerated type `ColorCodes` as follows:

```
classdef ColorCodes < int32
    enumeration
        Red(1),
        Blue(2),
        Green(3),
        Yellow(4),
        Purple(5)
    end
end
```

Because the enumerated values are consecutive, you can use `ColorCodes` data in a for-loop like this:

```
...
for i = int32(ColorCodes.Red):int32(ColorCodes.Purple)
    c = ColorCodes(i);
    ...
end
```

## Toolbox Functions That Support Enumerated Types for Code Generation

The following MATLAB toolbox functions support enumerated types for code generation:

- `cast`
- `cat`
- `circshift`
- `fliplr`
- `flipud`
- `histc`
- `intersect`
- `ipermute`
- `isequal`
- `isequaln`
- `isfinite`
- `isinf`
- `ismember`
- `isnan`
- `issorted`
- `length`
- `permute`
- `repmat`
- `reshape`
- `rot90`
- `setdiff`
- `setxor`
- `shiftdim`
- `sort`
- `sortrows`
- `squeeze`

- union
- unique

## MATLAB Classes Definition for Code Generation

To generate efficient standalone code for MATLAB classes, you must use classes differently than when running your code in the MATLAB environment.

| What's Different   | More Information  |
|--|---|
| Class must be in a single file. Because of this limitation, code generation is not supported for a class definition that uses an @-folder. | "Create a Single, Self-Contained Class Definition File"   |
| Restricted set of language features.   | "Language Limitations" on page 50-2   |
| Restricted set of code generation features.  | "Code Generation Features Not Compatible with Classes" on page 50-3   |
| Definition of class properties.  | "Defining Class Properties for Code Generation" on page 50-4  |
| Use of handle classes.   | "Generate Code for MATLAB Handle Classes and System Objects" on page 50-14<br><br>"Handle Object Limitations for Code Generation" on page 50-21 |
| Calls to base class constructor.   | "Calls to Base Class Constructor" on page 50-5  |
| Global variables containing MATLAB objects are not supported for code generation.  | N/A   |
| Inheritance from built-in MATLAB classes is not supported.   | "Inheritance from Built-In MATLAB Classes Not Supported" on page 50-6   |

### Language Limitations

Although code generation support is provided for common features of classes such as properties and methods, there are a number of advanced features which are not supported, such as:

- Events

- Listeners
- Arrays of objects
- Recursive data structures
  - Linked lists
  - Trees
  - Graphs
- Overloadable operators `subsref`, `subsassign`, and `subsindex`

In MATLAB, classes can define their own versions of the `subsref`, `subsassign`, and `subsindex` methods. Code generation does not support classes that have their own definitions of these methods.

- The empty method

In MATLAB, classes have a built-in static method, `empty`, which creates an empty array of the class. Code generation does not support this method.

- The following MATLAB handle class methods:
  - `addlistener`
  - `delete`
  - `eq`
  - `findobj`
  - `findpro`
- The `AbortSet` property attribute

## Code Generation Features Not Compatible with Classes

- You can generate code for entry-point MATLAB functions that use classes, but you cannot generate code directly for a MATLAB class.

For example, if `ClassNameA` is a class definition, you cannot generate code by executing:

```
codegen ClassNameA
```

- If an entry-point MATLAB function has an input or output that is a MATLAB class, you cannot generate code for this function.

For example, if function `foo` takes one input, `a`, that is a MATLAB object, you cannot generate code for `foo` by executing:

```
codegen foo -args {a}
```

- Code generation does not support classes in matrices or structures.
- Code generation does not support assigning an object of a value class into a nontunable property. For example, `obj.prop=v;` is invalid when `prop` is a nontunable property and `v` is an object based on a value class.
- You cannot use `coder.extrinsic` to declare a class or method as extrinsic.
- You cannot pass a MATLAB class to the `coder.ceval` function.
- If you use classes in code in the MATLAB Function block, you cannot use the debugger to view class information.
- The `coder.nullcopy` function does not support MATLAB classes as inputs.

## Defining Class Properties for Code Generation

For code generation, you must define class properties differently than you normally would when running your code in the MATLAB environment:

- After defining a property, do not assign it an incompatible type. Do not use a property before attempting to grow it.

When you define class properties for code generation, consider the same factors that you take into account when defining variables. In the MATLAB language, variables can change their class, size, or complexity dynamically at run time so you can use the same variable to hold a value of varying class, size, or complexity. C and C++ use static typing. Before using variables, to determine their type, the code generation software requires a complete assignment to each variable. Similarly, before using properties, you must explicitly define their class, size, and complexity.

- Initial values:
  - If the property does not have an explicit initial value, the code generation software assumes that it is undefined at the beginning of the constructor. The code generation software does not assign an empty matrix as the default.
  - If the property does not have an initial value and the code generation software cannot determine that the property is assigned prior to first use, the software generates a compilation error.

- For System objects, if a nontunable property is a structure, you must completely assign the structure. You cannot do partial assignment using subscripting.

For example, for a nontunable property, you can use the following assignment:

```
mySystemObject.nonTunableProperty=struct('fieldA','a','fieldB','b');
```

You cannot use the following partial assignments:

```
mySystemObject.nonTunableProperty.fieldA = a;
mySystemObject.nonTunableProperty.fieldB = b;
```

- If dynamic memory allocation is enabled, code generation supports variable-size properties for handle classes. Without dynamic memory allocation, you cannot generate code for handle classes that have variable-size properties.
- `coder. varsize` is not supported for class properties.
- MATLAB computes class initial values at class loading time before code generation. If you use persistent variables in MATLAB class property initialization, the value of the persistent variable computed when the class loads belongs to MATLAB; it is not the value used at code generation time. If you use `coder.target` in MATLAB class property initialization, `coder.target('MATLAB')` returns `true (1)`.

## Calls to Base Class Constructor

If a class constructor contains a call to the constructor of the base class, the call to the base class constructor must come before `for`, `if`, `return`, `switch` or `while` statements.

For example, if you define a class `B` based on class `A`:

```
classdef B < A
    methods
        function obj = B(varargin)
            if nargin == 0
                a = 1;
                b = 2;
            elseif nargin == 1
                a = varargin{1};
                b = 1;
            elseif nargin == 2
                a = varargin{1};
                b = varargin{2};
            end
        end
    end
end
```

```
        obj = obj@A(a,b);
    end

end

end
```

Because the class definition for **B** uses an **if** statement before calling the base class constructor for **A**, you cannot generate code for function **callB**:

```
function [y1,y2] = callB
x = B;
y1 = x.p1;
y2 = x.p2;
end
```

However, you can generate code for **callB** if you define class **B** as:

```
classdef B < A
    methods
        function obj = NewB(varargin)
            [a,b] = getaandb(varargin{:});
            obj = obj@A(a,b);
        end

    end

end

function [a,b] = getaandb(varargin)
if nargin == 0
    a = 1;
    b = 2;
elseif nargin == 1
    a = varargin{1};
    b = 1;
elseif nargin == 2
    a = varargin{1};
    b = varargin{2};
end
end
```

## Inheritance from Built-In MATLAB Classes Not Supported

You cannot generate code for classes that inherit from built-in MATLAB classes. For example, you cannot generate code for the following class:

```
classdef myclass < double
```

## Classes That Support Code Generation

You can generate code for MATLAB value and handle classes and user-defined System objects. Your class can have multiple methods and properties and can inherit from multiple classes.

| To generate code for:                                | Example:   |
|--|--|
| Value classes  | “Generate Code for MATLAB Value Classes” on page 50-9                      |
| Handle classes including user-defined System objects | “Generate Code for MATLAB Handle Classes and System Objects” on page 50-14 |

For more information, see:

- “Role of Classes in MATLAB”
- “MATLAB Classes Definition for Code Generation” on page 50-2

## Generate Code for MATLAB Value Classes

This example shows how to generate code for a MATLAB value class and then view the generated code in the code generation report.

- 1 In a writable folder, create a MATLAB value class, `Shape`. Save the code as `Shape.m`.

```
classdef Shape
% SHAPE Create a shape at coordinates
% centerX and centerY
    properties
        centerX;
        centerY;
    end
    properties (Dependent = true)
        area;
    end
    methods
        function out = get.area(obj)
            out = obj.getarea();
        end
        function obj = Shape(centerX,centerY)
            obj.centerX = centerX;
            obj.centerY = centerY;
        end
    end
end
methods(Abstract = true)
    getarea(obj);
end
methods(Static)
    function d = distanceBetweenShapes(shape1,shape2)
        xDist = abs(shape1.centerX - shape2.centerX);
        yDist = abs(shape1.centerY - shape2.centerY);
        d = sqrt(xDist^2 + yDist^2);
    end
end
end
```

- 2 In the same folder, create a class, `Square`, that is a subclass of `Shape`. Save the code as `Square.m`.

```
classdef Square < Shape
% Create a Square at coordinates center X and center Y
```

```

% with sides of length of side
properties
    side;
end
methods
    function obj = Square(side,centerX,centerY)
        obj@Shape(centerX,centerY);
        obj.side = side;
    end
    function Area = getarea(obj)
        Area = obj.side^2;
    end
end
end

```

- 3 In the same folder, create a class, Rhombus, that is a subclass of Shape. Save the code as Rhombus.m.

```

classdef Rhombus < Shape
    properties
        diag1;
        diag2;
    end
    methods
        function obj = Rhombus(diag1,diag2,centerX,centerY)
            obj@Shape(centerX,centerY);
            obj.diag1 = diag1;
            obj.diag2 = diag2;
        end
        function Area = getarea(obj)
            Area = 0.5*obj.diag1*obj.diag2;
        end
    end
end
end

```

- 4 Write a function that uses this class.

```

function [TotalArea, Distance] = use_shape
    %#codegen
    s = Square(2,1,2);
    r = Rhombus(3,4,7,10);
    TotalArea = s.area + r.area;
    Distance = Shape.distanceBetweenShapes(s,r);

```

- 5 Generate a static library for use\_shape and generate a code generation report.

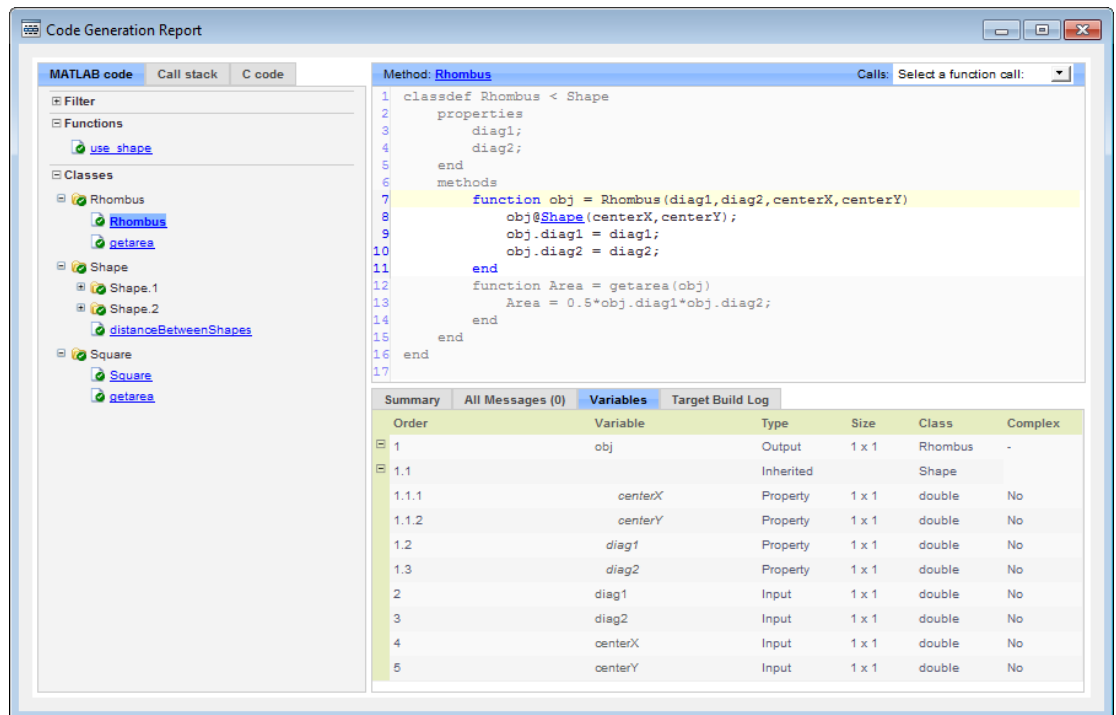

codegen -config:lib -report use\_shape

codegen generates a C static library with the default name, use\_shape, and supporting files in the default folder, codegen/lib/use\_shape.

- 6 Click the **View report** link.
- 7 In the report, on the **MATLAB code** tab, click the link to the Rhombus class.

The report displays the class definition of the Rhombus class and highlights the class constructor. On the **Variables** tab, it provides details of the variables used in the class. If a variable is a MATLAB object, by default, the report displays the object without displaying its properties. To view the list of properties, expand the list. Within the list of properties, the list of inherited properties is collapsed. In the following report, the lists of properties and inherited properties are expanded.

The screenshot shows the Code Generation Report window with the following content:

**MATLAB code** Call stack C code

  - Square
  - getarea

Method: Rhombus Calls: Select a function call:

```

1 classdef Rhombus < Shape
2     properties
3         diag1;
4         diag2;
5     end
6     methods
7         function obj = Rhombus(diag1,diag2,centerX,centerY)
8             obj@Shape(centerX,centerY);
9             obj.diag1 = diag1;
10            obj.diag2 = diag2;
11        end
12        function Area = getarea(obj)
13            Area = 0.5*obj.diag1*obj.diag2;
14        end
15    end
16 end
17

```

Summary All Messages (0) Variables Target Build Log

| Order | Variable | Type      | Size  | Class   | Complex |
|-------|----------|-----------|-------|---------|---------|
| 1     | obj      | Output    | 1 x 1 | Rhombus | -       |
| 1.1   |          | Inherited |       | Shape   |         |
| 1.1.1 | centerX  | Property  | 1 x 1 | double  | No      |
| 1.1.2 | centerY  | Property  | 1 x 1 | double  | No      |
| 1.2   | diag1    | Property  | 1 x 1 | double  | No      |
| 1.3   | diag2    | Property  | 1 x 1 | double  | No      |
| 2     | diag1    | Input     | 1 x 1 | double  | No      |
| 3     | diag2    | Input     | 1 x 1 | double  | No      |
| 4     | centerX  | Input     | 1 x 1 | double  | No      |
| 5     | centerY  | Input     | 1 x 1 | double  | No      |

- 8 At the top right side of the report, expand the **Calls** list.

The **Calls** list shows that there is a call to the Rhombus constructor from `use_shape` and that this constructor calls the Shape constructor.

The screenshot shows the 'Code Generation Report' window. On the left, a tree view shows the class hierarchy: `use_shape` (Function), `Rhombus` (Class), `Shape` (Class), `Shape.1` (Class), `Shape.2` (Class), and `Square` (Class). The `Rhombus` class is selected, and its `use_shape` function is highlighted. The main pane shows the MATLAB code for the `Rhombus` class, with the constructor function highlighted. A 'Calls' dropdown menu is open, showing the call stack: 'Select a function call:', 'Calls to this function', 'From use\_shape line 4', 'Calls from this function', and 'From line 8 to Shape'. Below the code, a table summarizes the variables used in the function.

| Order | Variable | Type      | Size  | Class   | Complex |
|-------|----------|-----------|-------|---------|---------|
| 1     | obj      | Output    | 1 x 1 | Rhombus | -       |
| 1.1   |          | Inherited |       | Shape   |         |
| 1.1.1 | centerX  | Property  | 1 x 1 | double  | No      |
| 1.1.2 | centerY  | Property  | 1 x 1 | double  | No      |
| 1.2   | diag1    | Property  | 1 x 1 | double  | No      |
| 1.3   | diag2    | Property  | 1 x 1 | double  | No      |
| 2     | diag1    | Input     | 1 x 1 | double  | No      |
| 3     | diag2    | Input     | 1 x 1 | double  | No      |
| 4     | centerX  | Input     | 1 x 1 | double  | No      |
| 5     | centerY  | Input     | 1 x 1 | double  | No      |

- 9 The constructor for the Rhombus class calls the Shape method of the base Shape class: `obj@Shape`. In the report, click the Shape link in this call.

The screenshot shows the 'Code Generation Report' window. On the left, a tree view shows the class hierarchy: Rhombus (with methods [Rhombus](#) and [getarea](#)), Shape (with methods [Shape.1](#), [Shape.2](#), and [distanceBetweenShapes](#)), and Square (with methods [Square](#) and [getarea](#)). A link [use\\_shape](#) is also visible under Functions.

The main pane displays the MATLAB code for the `Rhombus` class. The code is as follows:

```

1 classdef Rhombus < Shape
2     properties
3         diag1;
4         diag2;
5     end
6     methods
7         function obj = Rhombus(diag1,diag2,centerX,centerY)
8             obj@Shape(centerX,centerY);
9             obj.diag1 = diag1;
10            obj.diag2 = diag2;
11        end
12        function Area = getarea(obj)
13            Area = 0.5*obj.diag1*obj.diag2;
14        end
15    end
16 end
17

```

Below the code is a table with tabs for 'Summary', 'All Messages (0)', 'Variables', and 'Target Build Log'. The 'Variables' tab is active, showing the following data:

| Order | Variable | Type      | Size  | Class   | Complex |
|-------|----------|-----------|-------|---------|---------|
| 1     | obj      | Output    | 1 x 1 | Rhombus | -       |
| 1.1   |          | Inherited |       | Shape   |         |
| 1.1.1 | centerX  | Property  | 1 x 1 | double  | No      |
| 1.1.2 | centerY  | Property  | 1 x 1 | double  | No      |
| 1.2   | diag1    | Property  | 1 x 1 | double  | No      |
| 1.3   | diag2    | Property  | 1 x 1 | double  | No      |
| 2     | diag1    | Input     | 1 x 1 | double  | No      |
| 3     | diag2    | Input     | 1 x 1 | double  | No      |
| 4     | centerX  | Input     | 1 x 1 | double  | No      |
| 5     | centerY  | Input     | 1 x 1 | double  | No      |

The link takes you to the `Shape` method in the `Shape` class definition.

## Generate Code for MATLAB Handle Classes and System Objects

This example shows how to generate code for a user-defined System object and then view the generated code in the code generation report.

- 1 In a writable folder, create a System object, `AddOne`, which subclasses from `matlab.System`. Save the code as `AddOne.m`.

```
classdef AddOne < matlab.System
% ADDONE Compute an output value that increments the input by one

    methods (Access=protected)
        % stepImpl method is called by the step method
        function y = stepImpl(~,x)
            y = x+1;
        end
    end
end
```

- 2 Write a function that uses this System object.

```
function y = testAddOne(x)
%#codegen
    p = AddOne();
    y = p.step(x);
end
```

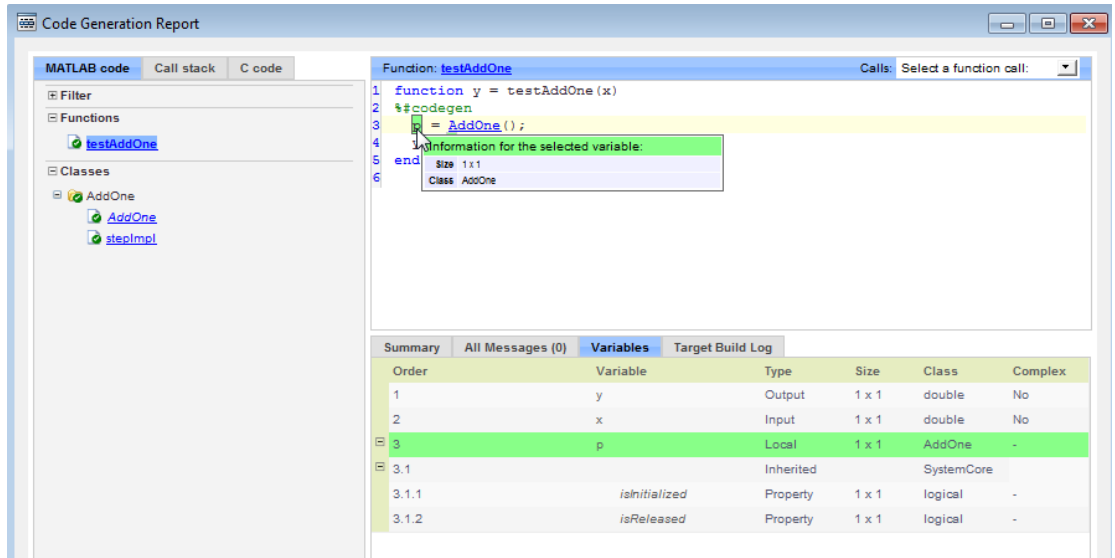

- 3 Generate a MEX function for this code.

```
codegen -report testAddOne -args {0}
```

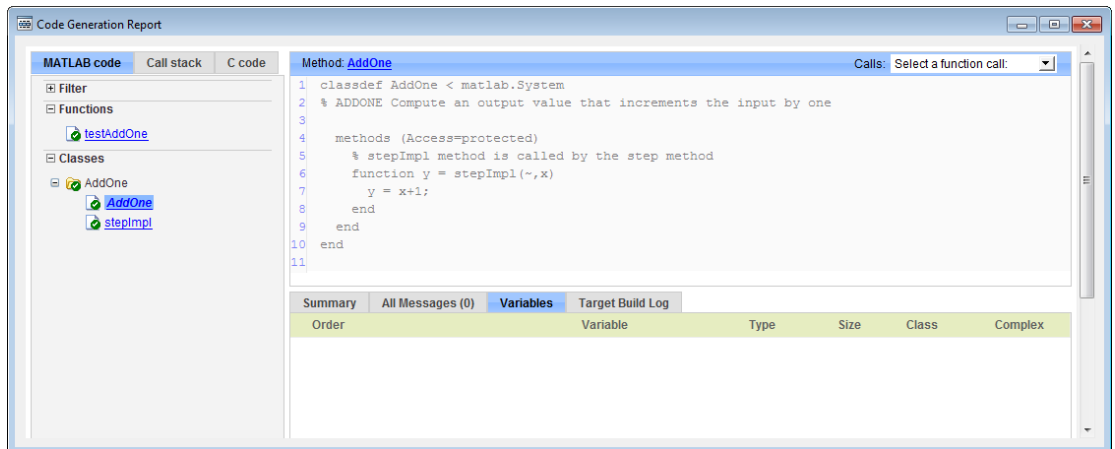

The `-report` option instructs `codegen` to generate a code generation report, even if no errors or warnings occur. The `-args` option specifies that the `testAddOne` function takes one scalar double input.

```
>> codegen -report testAddOne -args {0}
Code generation successful: View report
```

- 4 Click the **View report** link.
- 5 In the report, on the **MATLAB Code** tab **Functions** panel, click `testAddOne`, then click the **Variables** tab. You can view information about the variable `p` on this tab.

6 To view the class definition, on the **Classes** panel, click **AddOne**.

## MATLAB Classes in Code Generation Reports

### What Reports Tell You About Classes

Code generation reports:

- Provide a hierarchical tree of the classes used in your MATLAB code.
- Display a list of methods for each class in the MATLAB code tab.
- Display the objects used in your MATLAB code together with their properties on the **Variables** tab.
- Provide a filter so that you can sort methods by class, size, and complexity.
- List the set of calls from and to the selected method in the **Calls** list.

### How Classes Appear in Code Generation Reports

#### In the MATLAB Code Tab

The report displays an alphabetical hierarchical list of the classes used in the your MATLAB code. For each class, you can:

- Expand the class information to view the class methods.
- View a class method by clicking its name. The report displays the methods in the context of the full class definition.
- Filter the methods by size, complexity, and class by using the **Filter functions and methods** option.

#### Default Constructors

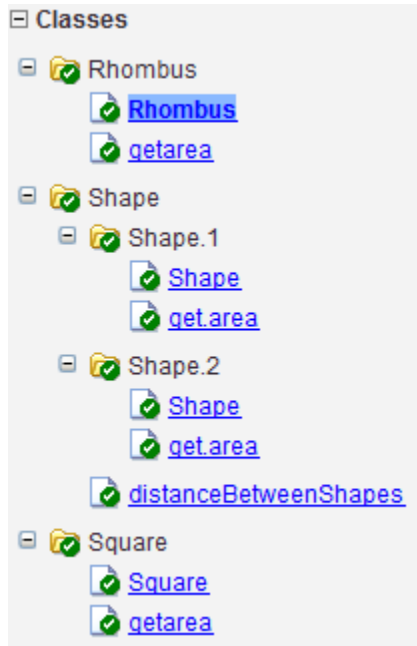

If a class has a default constructor, the report displays the constructor in italics.

#### Specializations

If the same class is specialized into multiple different classes, the report differentiates the specializations by grouping each one under a single node in the tree. The report associates the class definition functions and static methods with the primary node. It associates the instance-specific methods with the corresponding specialized node.

For example, consider a base class, **Shape** that has two specialized subclasses, **Rhombus** and **Square**. The **Shape** class has an abstract method, `getarea`, and a static method, `distanceBetweenShapes`. The code generation report, displays a

node for the specialized `Rhombus` and `Square` classes with their constructors and `getarea` method. It displays a node for the `Shape` class and its associated static method, `distanceBetweenShapes`, and two instances of the `Shape` class, `Shape1` and `Shape2`.

## Packages

If you define classes as part of a package, the report displays the package in the list of classes. You can expand the package to view the classes that it contains. For more information about packages, see “Packages Create Namespaces”.

## In the Variables Tab

The report displays the objects in the selected function or class. By default, for classes that have properties, the list of properties is collapsed. To expand the list, click the + symbol next to the object name. Within the list of properties, the list of inherited properties is collapsed. To expand the list of inherited properties, click the + symbol next to `Inherited`.

The report displays the properties using just the base property name, not the fully qualified name. For example, if your code uses variable `obj1` that is a MATLAB object

with property `prop1`, then the report displays the property as `prop1` not `obj1.prop1`. When you sort the **Variables** column, the sort order is based on the fully qualified property name.

### **In the Call Stack**

The call stack lists the functions and methods in the order that the top-level function calls them. It also lists the local functions that each function calls.

## **How to Generate a Code Generation Report**

Add the `-report` option to your `codegen` command (requires a MATLAB Coder license)

## Troubleshooting Issues with MATLAB Classes

### Class `cClass` does not have a property with name `name`

If a MATLAB class has a method, `mymethod`, that returns a handle class with a property, `myprop`, you cannot generate code for the following type of assignment:

```
obj.mymethod().myprop=...
```

For example, consider the following classes:

```
classdef MyClass < handle
    properties
        myprop
    end
    methods
        function this = MyClass
            this.myprop = MyClass2;
        end
        function y = mymethod(this)
            y = this.myprop;
        end
    end
end

classdef MyClass2 < handle
    properties
        aa
    end
end
```

You cannot generate code for function `foo`.

```
function foo
    h = MyClass;
```

```
    h.mymethod().aa = 12;
```

In this function, `h.mymethod()` returns a handle object of type `MyClass2`. In MATLAB, the assignment `h.mymethod().aa = 12;` changes the property of that object. Code generation does not support this assignment.

**Workaround**

Rewrite the code to return the object and then assign a value to a property of the object.

```
function foo  
  
h = MyClass;  
  
b=h.mymethod();  
b.aa=12;
```

## Handle Object Limitations for Code Generation

The code generation software statically determines the lifetimes of handle objects. It can reuse memory rather than rely on a dynamic memory management scheme such as reference counting or garbage collection. It generates code that does not use dynamic memory allocation or incur the overhead of run-time automatic memory management. These characteristics of the generated code are important for some safety-critical and real-time applications.

When you use handle objects, the static analysis that the code generation software uses requires that you adhere to the following restrictions:

- “A Variable Outside a Loop Cannot Refer to a Handle Object Created Inside a Loop” on page 50-21
- “A Handle Object That a Persistent Variable Refers To Must Be a Singleton Object” on page 50-21

### A Variable Outside a Loop Cannot Refer to a Handle Object Created Inside a Loop

Consider the handle class `mycls` and the function `usehandle1`. The code generation software reports an error because `p`, which is outside the loop, has a property that refers to a `mycls` object created inside the loop.

```
classdef mycls < handle
    properties
        prop
    end
end

function usehandle1
    p = mycls;
    for i = 1:10
        p.prop = mycls;
    end
end
```

### A Handle Object That a Persistent Variable Refers To Must Be a Singleton Object

If a persistent variable refers to a handle object, the code generation software allows only one instance of the object during the program’s lifetime. The object must be a *singleton*

object. To create a singleton handle object, enclose statements that create the object in the `if isempty()` guard for the persistent variable.

For example, consider the class `mycls` and the function `usehandle2`. The code generation software reports an error for `usehandle2` because `p.prop` refers to the `mycls` object that the statement `inner = mycls` creates. This statement creates a `mycls` object for each invocation of `usehandle2`.

```
classdef mycls < handle
    properties
        prop
    end
end

function usehandle2(x)
    assert(isa(x, 'double'));
    persistent p;
    inner = mycls;
    inner.prop = x;
    if isempty(p)
        p = mycls;
        p.prop = inner;
    end
end
```

If you move the statements `inner = mycls` and `inner.prop = x` inside the `if isempty()` guard, code generation succeeds. The statement `inner = mycls` executes only once during the program's lifetime.

```
function usehandle2(x)
    assert(isa(x, 'double'));
    persistent p;
    if isempty(p)
        inner = mycls;
        inner.prop = x;
        p = mycls;
        p.prop = inner;
    end
end
```

Consider the function `usehandle3`. The code generation software reports an error for `usehandle3` because the persistent variable `p` refers to the `mycls` object that the statement `myobj = mycls` creates. This statement creates a `mycls` object for each invocation of `usehandle3`.

```
function usehandle3(x)
```

```
assert(isa(x, 'double'));
myobj = mycls;
myobj.prop = x;
doinit(myobj);
disp(myobj.prop);
function doinit(obj)
persistent p;
if isempty(p)
    p = obj;
end
```

If you make `myobj` persistent and enclose the statement `myobj = mycls` inside an `if isempty()` guard, code generation succeeds. The statement `myobj = mycls` executes only once during the program's lifetime.

```
function usehandle3(x)
assert(isa(x, 'double'));
persistent myobj;
if isempty(myobj)
    myobj = mycls;
end

doinit(myobj);

function doinit(obj)
persistent p;
if isempty(p)
    p = obj;
end
```

## System Objects Requirements and Limitations for Code Generation

The following usage rules and limitations apply to using System objects in code generated from MATLAB.

### Object Construction and Initialization

- If objects are stored in persistent variables, initialize System objects once by embedding the object handles in an `if` statement with a call to `isempty( )`.
- Set arguments to System object constructors as compile-time constants.
- You cannot initialize System objects properties with other MATLAB class objects as default values in code generation. You must initialize these properties in the constructor.

### Inputs and Outputs

- System objects accept a maximum of 32 inputs. A maximum of 8 dimensions per input is supported.
- The data type of the inputs should not change.
- If you want the size of inputs to change, verify that variable-size is enabled. Code generation support for variable-size data also requires that the `Enable variable sizing` option is enabled, which is the default in MATLAB.

---

**Note:** Variable-size properties in MATLAB Function block in Simulink are not supported. System objects predefined in the software do not support variable-size if their data exceeds the `DynamicMemoryAllocationThreshold` value.

---

- Do not set System objects to become outputs from the MATLAB Function block.
- Do not use the Save and Restore Simulation State as `SimState` option for any System object in a MATLAB Function block.
- Do not pass a System object as an example input argument to a function being compiled with `codegen`.
- Do not pass a System object to functions declared as extrinsic (functions called in interpreted mode) using the `coder.extrinsic` function. System objects returned from extrinsic functions and scope System objects that automatically become extrinsic can be used as inputs to another extrinsic function, but do not generate code.

### Tunable and Nontunable Properties

- The value assigned to a nontunable property must be a constant and there can be at most one assignment to that property (including the assignment in the constructor).
- For most System objects, the only time you can set their nontunable properties during code generation is when you construct the objects.
  - For System objects that are predefined in the software, you can set their tunable properties at construction time or using dot notation after the object is locked.
  - For System objects that you define, you can change their tunable properties at construction time or using dot notation during code generation. For `getNumInputsImpl` and `getNumOutputsImpl` methods, if you set the return argument from an object property, that object property must have the `Nontunable` attribute.
- Objects cannot be used as default values for properties.
- In MATLAB simulations, default values are shared across all instances of an object. Two instances of a class can access the same default value if that property has not been overwritten by either instance.

#### Cell Arrays and Global Variables

- System objects can contain cell arrays, but cell arrays cannot contain System objects.
- Global variables are allowed in a System object, unless you will be using that System object in Simulink via the MATLAB System block. To avoid syncing global variables between a MEX file and the workspace, use a coder configuration object. For example:

```
f = coder.MEXConfig;  
f.GlobalSyncMethod = 'NoSync'  
Then, include '-config f' in your codegen command.
```

#### Methods

- Code generation support is available only for these System object methods:
  - `get`
  - `getNumInputs`
  - `getNumOutputs`
  - `isDone` (for sources only)
  - `isLocked`
  - `release`

- `reset`
- `set` (for tunable properties)
- `step`
- For System objects that you define,

Code generation support is available only for these methods:

- `getDiscreteStateImpl`
- `getNumInputsImpl`
- `getNumOutputsImpl`
- `infoImpl`
- `isDoneImpl`
- `isInputDirectFeedThroughImpl`
- `outputImpl`
- `processTunedPropertiesImpl`
- `releaseImpl` — Code is not generated automatically for the this method. To release an object, you must explicitly call the `release` method in your code.
- `resetImpl`
- `setupImpl`
- `stepImpl`
- `updateImpl`
- `validateInputsImpl`
- `validatePropertiesImpl`
- Code generation support for using dot notation depends on whether the System object is predefined in the software or is one that you defined.
  - For System objects that are predefined in the software, you cannot use dot notation to call methods.
  - For System objects that you define, you can use dot notation or function call notation, with the System object as first argument, to call methods.

# Code Generation for Function Handles

---

- “Function Handle Definition for Code Generation” on page 51-2
- “Define and Pass Function Handles for Code Generation” on page 51-3
- “Function Handle Limitations for Code Generation” on page 51-5

## Function Handle Definition for Code Generation

You can use function handles to invoke functions indirectly and parameterize operations that you repeat frequently. You can perform the following operations with function handles:

- Define handles that reference user-defined functions and built-in functions supported for code generation (see “Functions and Objects Supported for C and C++ Code Generation — Alphabetical List” on page 42-2)

---

**Note:** You cannot define handles that reference extrinsic MATLAB functions.

---

- Define function handles as scalar values
- Define structures that contain function handles
- Pass function handles as arguments to other functions (excluding extrinsic functions)

To generate efficient standalone code for function handles, you are restricted to using a subset of the operations you can perform with function handles in MATLAB, as described in “Function Handle Limitations for Code Generation” on page 51-5

## Define and Pass Function Handles for Code Generation

The following code example shows how to define and call function handles for code generation. You can copy the example to a MATLAB Function block in Simulink or MATLAB function in Stateflow. To convert this function to a MEX function using `codegen`, uncomment the two calls to the `assert` function, highlighted below:

```
function addval(m)
%#codegen

% Define class and size of primary input m
% Uncomment next two lines to build MEX function with codegen
% assert(isa(m,'double'));
% assert(all (size(m) == [3 3]));

% Pass function handle to addone
% to add one to each element of m
m = map(@addone, m);
disp(m);

% Pass function handle to addtwo
% to add two to each element of m
m = map(@addtwo, m);
disp(m);

function y = map(f,m)
    y = m;
    for i = 1:numel(y)
        y(i) = f(y(i));
    end

function y = addone(u)
    y = u + 1;

function y = addtwo(u)
    y = u + 2;
```

This code passes function handles `@addone` and `@addtwo` to the function `map` which increments each element of the matrix `m` by the amount prescribed by the referenced function. Note that `map` stores the function handle in the input variable `f` and then uses `f` to invoke the function — in this case `addone` first and then `addtwo`.

If you have MATLAB Coder, you can use the function `codegen` to convert the function `addval` to a MEX executable that you can run in MATLAB. Follow these steps:

- 1 At the MATLAB command prompt, issue this command:

```
codegen addval
```

- 2 Define and initialize a 3-by-3 matrix by typing a command like this at the MATLAB prompt:

```
m = zeros(3)
```

- 3 Execute the function by typing this command:

```
addval(m)
```

You should see the following result:

```
0    0    0
0    0    0
0    0    0

1    1    1
1    1    1
1    1    1

3    3    3
3    3    3
3    3    3
```

For more information, see “MEX Function Generation at the Command Line”.

## Function Handle Limitations for Code Generation

### **You cannot use the same bound variable to reference different function handles.**

After you bind a variable to a specific function, you cannot use the same variable to reference two different function handles, as in this example:

```
%Incorrect code
...
x = @plus;
x = @minus;
...
```

This code produces a compilation error.

### **You cannot pass function handles to or from `coder.ceval`.**

You cannot pass function handles as inputs to or outputs from `coder.ceval`. For example, suppose that `f` and `str.f` are function handles:

```
f = @sin;
str.x = pi;
str.f = f;
```

The following statements result in compilation errors:

```
coder.ceval('foo', @sin);
coder.ceval('foo', f);
coder.ceval('foo', str);
```

### **You cannot pass function handles to or from extrinsic functions.**

You cannot pass function handles to or from `feval` and other extrinsic MATLAB functions. For more information, see “Declaring MATLAB Functions as Extrinsic Functions” on page 53-12.

### **You cannot pass function handles to or from primary functions.**

You cannot pass function handles as inputs to or outputs from primary functions. For example, consider this function:

```
function x = plotFcn(fhandle, data)

assert(isa(fhandle, 'function_handle') && isa(data, 'double'));
```

```
plot(data, fhandle(data));  
x = fhandle(data);
```

In this example, the function `plotFcn` receives a function handle and its data as primary inputs. `plotFcn` attempts to call the function referenced by the `fhandle` with the input `data` and plot the results. However, this code generates a compilation error. The error indicates that the function `isa` does not recognize `'function_handle'` as a class name when called inside a MATLAB function to specify properties of primary inputs.

### **You cannot view function handles from the debugger**

You cannot display or watch function handles from the debugger. The function handles appear as empty matrices.

# Defining Functions for Code Generation

---

- “Specify Variable Numbers of Arguments” on page 52-2
- “Supported Index Expressions” on page 52-3
- “Apply Operations to a Variable Number of Arguments” on page 52-4
- “Implement Wrapper Functions” on page 52-6
- “Pass Property/Value Pairs” on page 52-7
- “Variable Length Argument Lists for Code Generation” on page 52-9

## Specify Variable Numbers of Arguments

You can use `varargin` in a function definition to specify that the function accepts a variable number of input arguments for a given input argument. You can use `varargout` in a function definition to specify that the function returns a variable number of arguments for a given output argument.

When you use `varargin` and `varargout` for code generation, there are the following limitations:

- You cannot use `varargout` in the function definition for a top-level function.
- You cannot use `varargin` in the function definition for a top-level function in a MATLAB Function block in a Simulink model, or in a MATLAB function in a Stateflow diagram.
- If you use `varargin` to define an argument to a top-level function, the code generation software generates the function with a fixed number of arguments. This fixed number of arguments is based on the number of example arguments that you provide on the command line or in a MATLAB Coder project test file.

Common applications of `varargin` and `varargout` for code generation are to:

- “Apply Operations to a Variable Number of Arguments” on page 52-4
- “Implement Wrapper Functions” on page 52-6
- “Pass Property/Value Pairs” on page 52-7

Code generation relies on loop unrolling to produce simple and efficient code for `varargin` and `varargout`. This technique permits most common uses of `varargin` and `varargout`, but some uses are not allowed (see “Variable Length Argument Lists for Code Generation” on page 52-9).

For more information about using `varargin` and `varargout` in MATLAB functions, see [Passing Variable Numbers of Arguments](#).

## Supported Index Expressions

In MATLAB, `varargin` and `varargout` are cell arrays. Generated code does not support cell arrays, but does allow you to use the most common syntax — curly braces `{}` — for indexing into `varargin` and `varargout` arrays, as in this example:

```

%#codegen
function [x,y,z] = fcn(a,b,c)
[x,y,z] = subfcn(a,b,c);

function varargout = subfcn(varargin)
for i = 1:length(varargin)
    varargout{i} = varargin{i};
end

```

You can use the following index expressions. The *exp* arguments must be constant expressions or depend on a loop index variable.

| Expression                                 |                                  | Description   |
|--|----------------------------------|---|
| <code>varargin</code><br>(read only)       | <code>varargin{exp}</code>       | Read the value of element <i>exp</i>                        |
|  | <code>varargin{exp1:exp2}</code> | Read the values of elements <i>exp1</i> through <i>exp2</i> |
|  | <code>varargin{:}</code>         | Read the values of all elements                             |
| <code>varargout</code><br>(read and write) | <code>varargout{exp}</code>      | Read or write the value of element <i>exp</i>               |

**Note:** The use of `()` is not supported for indexing into `varargin` and `varargout` arrays.

## Apply Operations to a Variable Number of Arguments

You can use `varargin` and `varargout` in `for`-loops to apply operations to a variable number of arguments. To index into `varargin` and `varargout` arrays in generated code, the value of the loop index variable must be known at compile time. Therefore, during code generation, the compiler attempts to automatically unroll these `for`-loops. Unrolling eliminates the loop logic by creating a separate copy of the loop body in the generated code for each iteration. Within each iteration, the loop index variable becomes a constant. For example, the following function automatically unrolls its `for`-loop in the generated code:

```

%#codegen
function [cmLen,cmwth,cmhgt] = conv_2_metric(inlen,inwth,inhgt)

[cmLen,cmwth,cmhgt] = inch_2_cm(inlen,inwth,inhgt);

function varargout = inch_2_cm(varargin)
for i = 1:length(varargin)
    varargout{i} = varargin{i} * 2.54;
end

```

## When to Force Loop Unrolling

To automatically unroll `for`-loops containing `varargin` and `varargout` expressions, the relationship between the loop index expression and the index variable must be determined at compile time.

In the following example, the function `fcn` cannot detect a logical relationship between the index expression `j` and the index variable `i`:

```

%#codegen
function [x,y,z] = fcn(a,b,c)

[x,y,z] = subfcn(a,b,c);

function varargout = subfcn(varargin)
j = 0;
for i = 1:length(varargin)
    j = j+1;
    varargout{j} = varargin{j};
end

```

As a result, the function does not unroll the loop and generates a compilation error:

Nonconstant expression or empty matrix.  
This expression must be constant because  
its value determines the size or class of some expression.

To fix the problem, you can force loop unrolling by wrapping the loop header in the function `coder.unroll`, as follows:

```

%#codegen
function [x,y,z] = fcn(a,b,c)
    [x,y,z] = subfcn(a,b,c);

function varargout = subfcn(varargin)
    j = 0;
    for i = coder.unroll(1:length(varargin))
        j = j + 1;
        varargout{j} = varargin{j};
    end;

```

## Using Variable Numbers of Arguments in a for-Loop

The following example multiplies a variable number of input dimensions in inches by 2.54 to convert them to centimeters:

```

%#codegen
function [cmLen,cmwth,cmhgt] = conv_2_metric(inlen,inwth,inhgt)

[cmLen,cmwth,cmhgt] = inch_2_cm(inlen,inwth,inhgt);

function varargout = inch_2_cm(varargin)
for i = 1:length(varargin)
    varargout{i} = varargin{i} * 2.54;
end

```

### Key Points About the Example

- `varargin` and `varargout` appear in the local function `inch_2_cm`, not in the top-level function `conv_2_metric`.
- The index into `varargin` and `varargout` is a for-loop variable

For more information, see “Variable Length Argument Lists for Code Generation” on page 52-9.

## Implement Wrapper Functions

You can use `varargin` and `varargout` to write wrapper functions that accept up to 64 inputs and pass them directly to another function.

### Passing Variable Numbers of Arguments from One Function to Another

The following example passes a variable number of inputs to different optimization functions, based on a specified input method:

```
%#codegen
function answer = fcn(method,a,b,c)
answer = optimize(method,a,b,c);

function answer = optimize(method,varargin)
    if strcmp(method,'simple')
        answer = simple_optimization(varargin{:});
    else
        answer = complex_optimization(varargin{:});
    end
    ...
```

#### Key Points About the Example

- You can use `{:}` to read all elements of `varargin` and pass them to another function.
- You can mix variable and fixed numbers of arguments.

For more information, see “Variable Length Argument Lists for Code Generation” on page 52-9.

## Pass Property/Value Pairs

You can use `varargin` to pass property/value pairs in functions. However, for code generation, you must take precautions to avoid type mismatch errors when evaluating `varargin` array elements in a `for`-loop:

| If   | Do This:   |
|--|--|
| You assign <code>varargin</code> array elements to local variables in the <code>for</code> -loop | Verify that for all pairs, the size, type, and complexity are the same for each property and the same for each value               |
| Properties or values have different sizes, types, or complexity                                  | Do not assign <code>varargin</code> array elements to local variables in a <code>for</code> -loop; reference the elements directly |

For example, in the following function `test1`, the sizes of the property strings and numeric values are not the same in each pair:

```

%#codegen
function test1
    v = create_value('size', 18, 'rgb', [240 9 44]);
end

function v = create_value(varargin)
    v = new_value();
    for i = 1 : 2 : length(varargin)
        name = varargin{i};
        value = varargin{i+1};
        switch name
            case 'size'
                v = set_size(v, value);
            case 'rgb'
                v = set_color(v, value);
            otherwise
            end
        end
    end
end
...

```

Generated code determines the size, type, and complexity of a local variable based on its first assignment. In this example, the first assignments occur in the first iteration of the `for`-loop:

- Defines local variable `name` with size equal to 4
- Defines local variable `value` with a size of scalar

However, in the second iteration, the size of the property string changes to 3 and the size of the numeric value changes to a vector, resulting in a type mismatch error. To avoid such errors, reference `varargin` array values directly, not through local variables, as highlighted in this code:

```

%#codegen
function test1
    v = create_value('size', 18, 'rgb', [240 9 44]);
end

function v = create_value(varargin)
    v = new_value();
    for i = 1 : 2 : length(varargin)
        switch varargin{i}
            case 'size'
                v = set_size(v, varargin{i+1});
            case 'rgb'
                v = set_color(v, varargin{i+1});
            otherwise
                end
        end
    end
end
...
```

## Variable Length Argument Lists for Code Generation

### Use variable length argument lists in top-level functions according to guidelines

When you use `varargout` and `varargin` for code generation, there are the following limitations:

- You cannot use `varargout` in the function definition for a top-level function.
- You cannot use `varargin` in the function definition for a top-level function in a MATLAB Function block in a Simulink model, or in a MATLAB function in a Stateflow diagram.
- If you use `varargin` to define an argument to a top-level function, the code generation software generates the function with a fixed number of arguments. This fixed number of arguments is based on the number of example arguments that you provide on the command line or in a MATLAB Coder project test file.

A *top-level function* is:

- The function called by Simulink in a MATLAB Function block or by Stateflow in a MATLAB function.
- The function that you provide on the command line to `codegen` or `fiaccl`.

For example, the following code generates compilation errors:

```

%#codegen
function varargout = inch_2_cm(varargin)
for i = 1:length(varargin)
    varargout{i} = varargin{i} * 2.54;
end

```

To fix the problem, write a top-level function that specifies a fixed number of inputs and outputs. Then call `inch_2_cm` as an external function or local function, as in this example:

```

%#codegen
function [cmL, cmW, cmH] = conv_2_metric(inL, inW, inH)
[cmL, cmW, cmH] = inch_2_cm(inL, inW, inH);

function varargout = inch_2_cm(varargin)
for i = 1:length(varargin)
    varargout{i} = varargin{i} * 2.54;
end

```

**Use curly braces {} to index into the argument list**

For code generation, you can use curly braces {}, but not parentheses (), to index into `varargin` and `varargout` arrays. For more information, see “Supported Index Expressions” on page 52-3.

**Verify that indices can be computed at compile time**

If you use an expression to index into `varargin` or `varargout`, make sure that the value of the expression can be computed at compile time. For examples, see “Apply Operations to a Variable Number of Arguments” on page 52-4.

**Do not write to varargin**

Generated code treats `varargin` as a read-only variable. If you want to write to input arguments, copy the values into a local variable.

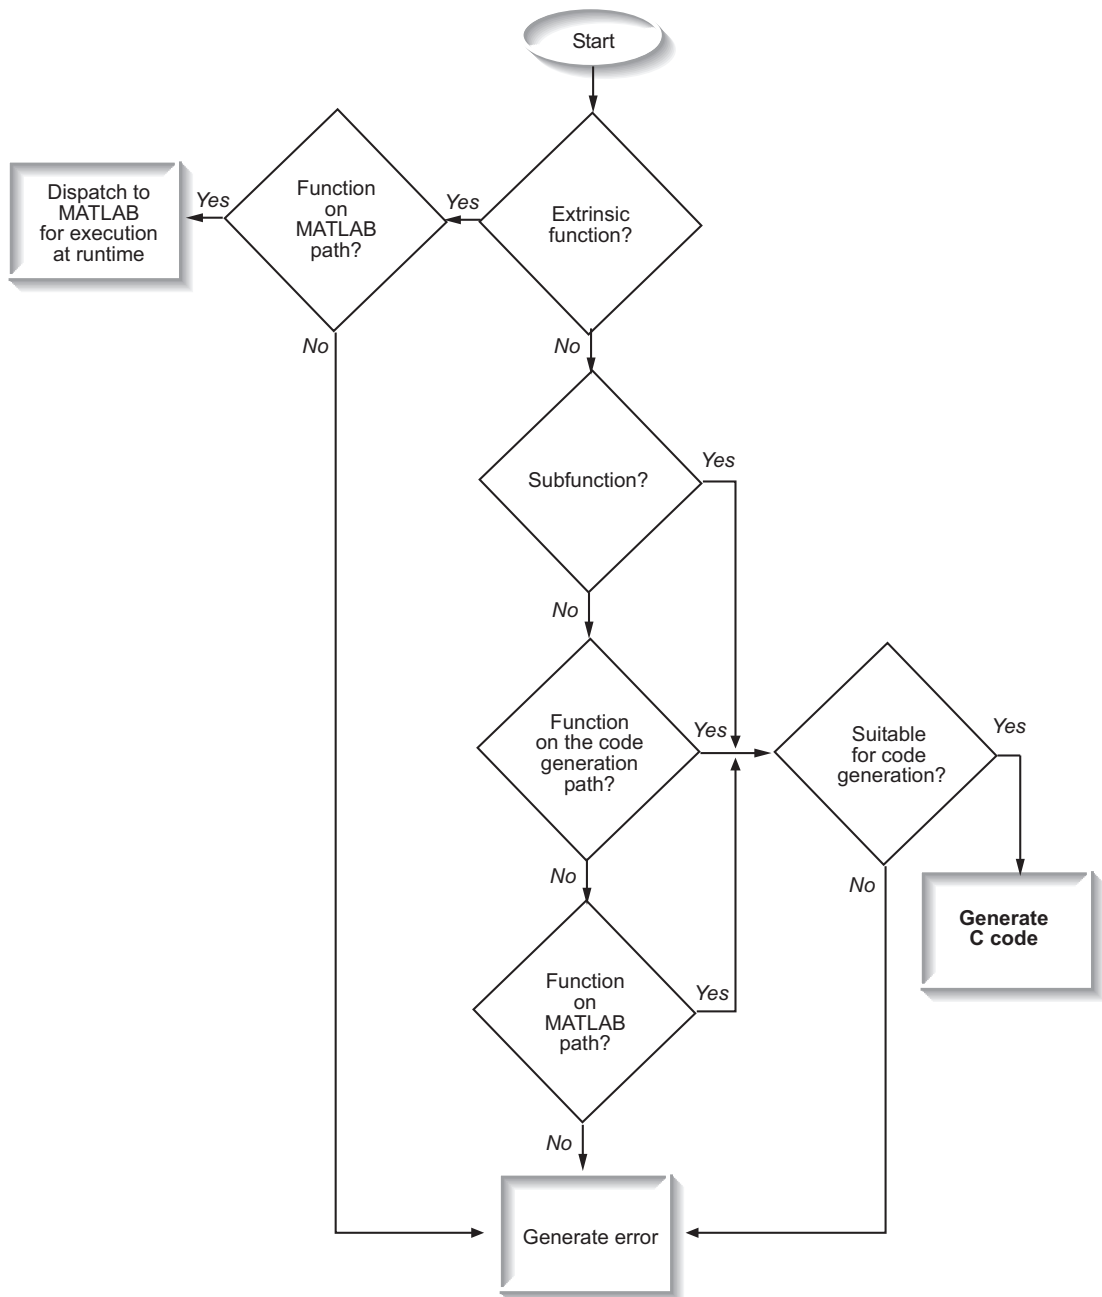

# Calling Functions for Code Generation

---

- “Resolution of Function Calls for Code Generation” on page 53-2
- “Resolution of File Types on Code Generation Path” on page 53-6
- “Compilation Directive %#codegen” on page 53-8
- “Call Local Functions” on page 53-9
- “Call Supported Toolbox Functions” on page 53-10
- “Call MATLAB Functions” on page 53-11

## Resolution of Function Calls for Code Generation

From a MATLAB function, you can call local functions, supported toolbox functions, and other MATLAB functions. MATLAB resolves function names for code generation as follows:

## Key Points About Resolving Function Calls

The diagram illustrates key points about how MATLAB resolves function calls for code generation:

- Searches two paths, the code generation path and the MATLAB path

See “Compile Path Search Order” on page 53-4.

- Attempts to compile functions unless the code generation software determines that it should not compile them or you explicitly declare them to be extrinsic.

If a MATLAB function is not supported for code generation, you can declare it to be extrinsic by using the construct `coder.extrinsic`, as described in “Declaring MATLAB Functions as Extrinsic Functions” on page 53-12. During simulation, the code generation software generates code for the call to an extrinsic function, but does not generate the function's internal code. Therefore, simulation can run only on platforms where MATLAB software is installed. During standalone code generation, MATLAB attempts to determine whether the extrinsic function affects the output of the function in which it is called — for example by returning `mxArrays` to an output variable. Provided that the output does not change, MATLAB proceeds with code generation, but excludes the extrinsic function from the generated code. Otherwise, compilation errors occur.

The code generation software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. The software treats these functions like extrinsic functions but you do not have to declare them extrinsic using the `coder.extrinsic` function.

- Resolves file type based on precedence rules described in “Resolution of File Types on Code Generation Path” on page 53-6

## Compile Path Search Order

During code generation, function calls are resolved on two paths:

- 1 Code generation path

MATLAB searches this path first during code generation. The code generation path contains the toolbox functions supported for code generation.

- 2 MATLAB path

If the function is not on the code generation path, MATLAB searches this path.

MATLAB applies the same dispatcher rules when searching each path (see “Function Precedence Order”).

## **When to Use the Code Generation Path**

Use the code generation path to override a MATLAB function with a customized version. A file on the code generation path shadows a file of the same name on the MATLAB path.

## **Resolution of File Types on Code Generation Path**

MATLAB uses the following precedence rules for code generation:

## Compilation Directive `%#codegen`

Add the `%#codegen` directive (or pragma) to your function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB code analyzer to help you diagnose and fix violations that would result in errors during code generation.

```
function y = my_fcn(x) %#codegen
```

```
.....
```

## Call Local Functions

Local functions are functions defined in the body of MATLAB function. They work the same way for code generation as they do when executing your algorithm in the MATLAB environment.

The following example illustrates how to define and call a local function `mean`:

```
function [mean, stdev] = stats(vals)
%#codegen

% Calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals, len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
plot(vals, '-+');

function mean = avg(array,size)
mean = sum(array)/size;
```

## Call Supported Toolbox Functions

You can call toolbox functions directly if they are supported for code generation. For a list of supported functions, see “Functions and Objects Supported for C and C++ Code Generation — Alphabetical List” on page 42-2.

## Call MATLAB Functions

The code generation software attempts to generate code for functions, even if they are not supported for C code generation. The software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. The software treats these functions like extrinsic functions but you do not have to declare them extrinsic using `coder.extrinsic`. During simulation, the code generation software generates code for these functions, but does not generate their internal code. During standalone code generation, MATLAB attempts to determine whether the visualization function affects the output of the function in which it is called. Provided that the output does not change, MATLAB proceeds with code generation, but excludes the visualization function from the generated code. Otherwise, compilation errors occur.

For example, you might want to call `plot` to visualize your results in the MATLAB environment. If you generate a MEX function from a function that calls `plot` and then run the generated MEX function, the code generation software dispatches calls to the `plot` function to MATLAB. If you generate a library or executable, the generated code does not contain calls to the `plot` function. The code generation report highlights calls from your MATLAB code to extrinsic functions so that it is easy to determine which functions are supported only in the MATLAB environment.

The screenshot shows the MATLAB IDE interface. On the left, the 'MATLAB code' tab is active, displaying a 'Call stack' and 'C code' view. The 'Call stack' shows a function named 'stats' with a sub-call to 'avg'. The main editor window shows the source code for the 'stats' function. The code is as follows:

```

1 function [mean, stdev] = stats(vals)
2 %#codegen
3
4 % Calculates a statistical mean and a standard
5 % deviation for the values in vals.
6
7 len = length(vals);
8 mean = avg(vals, len);
9 stdev = sqrt(sum((vals-avg(vals,len)).^2)/len);
10 plot(vals, '-+');
11

```

The `plot` function call on line 10 is highlighted in red, and a tooltip box points to it with the text: "Only supported within the MATLAB environment."

For unsupported functions other than common visualization functions, you must declare the functions (like `pause`) to be extrinsic (see “Resolution of Function Calls for Code Generation” on page 53-2). Extrinsic functions are not compiled, but instead executed in MATLAB during simulation (see “How MATLAB Resolves Extrinsic Functions During Simulation” on page 53-16).

There are two ways to declare a function to be extrinsic:

- Use the `coder.extrinsic` construct in main functions or local functions (see “Declaring MATLAB Functions as Extrinsic Functions” on page 53-12).
- Call the function indirectly using `feval` (see “Calling MATLAB Functions Using `feval`” on page 53-16).

## Declaring MATLAB Functions as Extrinsic Functions

To declare a MATLAB function to be extrinsic, add the `coder.extrinsic` construct at the top of the main function or a local function:

```
coder.extrinsic('function_name_1', ... , 'function_name_n');
```

### Declaring Extrinsic Functions

The following code declares the MATLAB `patch` function extrinsic in the local function `create_plot`:

```
function c = pythagoras(a,b,color) %#codegen
% Calculates the hypotenuse of a right triangle
% and displays the triangle.
```

```
c = sqrt(a^2 + b^2);
create_plot(a, b, color);
```

```
function create_plot(a, b, color)
%Declare patch and axis as extrinsic
```

```
coder.extrinsic('patch');
```

```
x = [0;a;a];
y = [0;0;b];
patch(x, y, color);
axis('equal');
```

The code generation software detects that `axis` is not supported for code generation and automatically treats it as an extrinsic function. The compiler does not generate code for `patch` and `axis`, but instead dispatches them to MATLAB for execution.

To test the function, follow these steps:

- 1 Convert `pythagoras` to a MEX function by executing this command at the MATLAB prompt:

```
codegen -report pythagoras -args {1, 1, [.3 .3 .3]}
```

- Click the link to the code generation report and then, in the report, view the MATLAB code for `create_plot`.

The report highlights the `patch` and `axis` functions to indicate that they are supported only within the MATLAB environment.

The screenshot shows the MATLAB code generation report for the `create_plot` function. The code is as follows:

```

7
8
9 function create_plot(a, b, color)
10 %Declare patch and axis as extrinsic
11
12 coder.extrinsic('patch'); % , 'axis');
13
14 x = [0;a;a];
15 y = [0;0;b];
16 patch(x, y, color);
17 axis('equal');

```

A tooltip points to the `axis('equal')` call, with the text: "Only supported within the MATLAB environment."

- Run the MEX function by executing this command:

```
pythagoras_mex(3, 4, [1.0 0.0 0.0]);
```

MATLAB displays a plot of the right triangle as a red patch object:

### When to Use the `coder.extrinsic` Construct

Use the `coder.extrinsic` construct to:

- Call MATLAB functions that do not produce output — such as `pause` — during simulation, without generating unnecessary code (see “How MATLAB Resolves Extrinsic Functions During Simulation” on page 53-16).
- Make your code self-documenting and easier to debug. You can scan the source code for `coder.extrinsic` statements to isolate calls to MATLAB functions, which can potentially create and propagate `mxArrays` (see “Working with `mxArrays`” on page 53-17).

- Save typing. With one `coder.extrinsic` statement, each subsequent function call is extrinsic, as long as the call and the statement are in the same scope (see “Scope of Extrinsic Function Declarations” on page 53-15).
- Declare the MATLAB function(s) extrinsic throughout the calling function scope (see “Scope of Extrinsic Function Declarations” on page 53-15). To narrow the scope, use `feval` (see “Calling MATLAB Functions Using `feval`” on page 53-16).

### Rules for Extrinsic Function Declarations

Observe the following rules when declaring functions extrinsic for code generation:

- Declare the function extrinsic before you call it.
- Do not use the extrinsic declaration in conditional statements.

### Scope of Extrinsic Function Declarations

The `coder.extrinsic` construct has function scope. For example, consider the following code:

```
function y = foo %#codegen
coder.extrinsic('rat','min');
[N D] = rat(pi);
y = 0;
y = min(N, D);
```

In this example, `rat` and `min` are treated as extrinsic every time they are called in the main function `foo`. There are two ways to narrow the scope of an extrinsic declaration inside the main function:

- Declare the MATLAB function extrinsic in a local function, as in this example:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0;
y = mymin(N, D);

function y = mymin(a,b)
coder.extrinsic('min');
y = min(a,b);
```

Here, the function `rat` is extrinsic every time it is called inside the main function `foo`, but the function `min` is extrinsic only when called inside the local function `mymin`.

- Call the MATLAB function using `feval`, as described in “Calling MATLAB Functions Using `feval`” on page 53-16.

## Calling MATLAB Functions Using `feval`

The function `feval` is automatically interpreted as an extrinsic function during code generation. Therefore, you can use `feval` to conveniently call functions that you want to execute in the MATLAB environment, rather than compiled to generated code.

Consider the following example:

```
function y = foo
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0;
y = feval('min', N, D);
```

Because `feval` is extrinsic, the statement `feval('min', N, D)` is evaluated by MATLAB — not compiled — which has the same result as declaring the function `min` extrinsic for just this one call. By contrast, the function `rat` is extrinsic throughout the function `foo`.

## How MATLAB Resolves Extrinsic Functions During Simulation

MATLAB resolves calls to extrinsic functions — functions that do not support code generation — as follows:

During simulation, MATLAB generates code for the call to an extrinsic function, but does not generate the function's internal code. Therefore, you can run the simulation only on platforms where you install MATLAB software.

During code generation, MATLAB attempts to determine whether the extrinsic function affects the output of the function in which it is called — for example by returning `mxArrays` to an output variable (see “Working with `mxArrays`” on page 53-17). Provided that the output does not change, MATLAB proceeds with code generation, but excludes the extrinsic function from the generated code. Otherwise, MATLAB issues a compiler error.

## Working with `mxArrays`

The output of an extrinsic function is an `mxArray` — also called a MATLAB array. The only valid operations for `mxArrays` are:

- Storing `mxArrays` in variables

- Passing `mxArrays` to functions and returning them from functions
- Converting `mxArrays` to known types at run time

To use `mxArrays` returned by extrinsic functions in other operations, you must first convert them to known types, as described in “Converting `mxArrays` to Known Types” on page 53-18.

### Converting `mxArrays` to Known Types

To convert an `mxArray` to a known type, assign the `mxArray` to a variable whose type is defined. At run time, the `mxArray` is converted to the type of the variable assigned to it. However, if the data in the `mxArray` is not consistent with the type of the variable, you get a run-time error.

For example, consider this code:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = min(N, D);
```

Here, the top-level function `foo` calls the extrinsic MATLAB function `rat`, which returns two `mxArrays` representing the numerator `N` and denominator `D` of the rational fraction approximation of `pi`. Although you can pass these `mxArrays` to another MATLAB function — in this case, `min` — you cannot assign the `mxArray` returned by `min` to the output `y`.

If you run this function `foo` in a MATLAB Function block in a Simulink model, the code generates the following error during simulation:

```
Function output 'y' cannot be of MATLAB type.
```

To fix this problem, define `y` to be the type and size of the value that you expect `min` to return — in this case, a scalar double — as follows:

```
function y = foo %#codegen
coder.extrinsic('rat');
[N D] = rat(pi);
y = 0; % Define y as a scalar of type double
y = min(N,D);
```

## Restrictions on Extrinsic Functions for Code Generation

The full MATLAB run-time environment is not supported during code generation. Therefore, the following restrictions apply when calling MATLAB functions extrinsically:

- MATLAB functions that inspect the caller, or read or write to the caller's workspace do not work during code generation. Such functions include:
  - `dbstack`
  - `evalin`
  - `assignin`
  - `save`
- The MATLAB debugger cannot inspect variables defined in extrinsic functions.
- Functions in generated code may produce unpredictable results if your extrinsic function performs the following actions at run time:
  - Change folders
  - Change the MATLAB path
  - Delete or add MATLAB files
  - Change warning states
  - Change MATLAB preferences
  - Change Simulink parameters

## Limit on Function Arguments

You can call functions with up to 64 inputs and 64 outputs.

## Optimization Strategies

MATLAB Coder introduces certain optimizations when generating C/C++ code or MEX functions from your MATLAB code. For more information, see “MATLAB Coder Optimizations in Generated Code”.

To optimize your generated code further, you can:

- Adapt your MATLAB code.
- Control code generation using the configuration object from the command-line or the project settings dialog box.

To optimize the execution speed of generated code, for these conditions, perform the following actions as necessary:

| Condition  | Action  |
|--|---|
| You have <code>for</code> -loops whose iterations are independent of each other.   | “Generate Code with Parallel for-Loops ( <code>parfor</code> )” |
| You have variable-size arrays in your MATLAB code.   | “Minimize Dynamic Memory Allocation”                            |
| You have multiple variable-size arrays in your MATLAB code. You want dynamic memory allocation for larger arrays and static allocation for smaller ones. | “Set Dynamic Memory Allocation Threshold”                       |
| You want your generated function to be called by reference.  | “Eliminate Redundant Copies of Function Inputs”                 |
| You are calling small functions in your MATLAB code.   | “Inline Code”   |
| You have limited target memory for your generated code. You want to inline small functions and generate separate code for larger ones.                   | “Control Inlining”  |
| You do not want to generate code for expressions that contain constants only.  | “Fold Function Calls into Constants”                            |
| You have loop operations in your MATLAB code that do not depend on the loop index.   | “Minimize Redundant Operations in Loops”                        |

| Condition  | Action                                   |
|--|--|
| You have integer operations in your MATLAB code. You know beforehand that integer overflow does not occur during execution of your generated code. | “Disable Support for Integer Overflow”   |
| You know beforehand that Infs and NaNs do not occur during execution of your generated code.   | “Disable Support for Non-Finite Numbers” |
| You have for-loops with few iterations.  | “Unroll for-Loops”                       |
| You already have legacy C/C++ code optimized for your target environment.  | “Integrate Custom Code”                  |

To optimize the memory usage of generated code, for these conditions, perform the following actions as necessary:

| Condition  | Action   |
|--|--|
| You have if/else/elseif statements or switch/case/otherwise statements in your MATLAB code. You do not require some branches of the statements in your generated code. | “Prevent Code Generation for Unused Execution Paths” |
| You want your generated function to be called by reference.  | “Eliminate Redundant Copies of Function Inputs”      |
| You have limited stack space for your generated code.  | “Control Stack Space Usage”                          |
| You are calling small functions in your MATLAB code.   | “Inline Code”  |
| You have limited target memory for your generated code. You want to inline small functions and generate separate code for larger ones.                                 | “Control Inlining”                                   |
| You do not want to generate code for expressions that contain constants only.  | “Fold Function Calls into Constants”                 |
| You have loop operations in your MATLAB code that do not depend on the loop index.   | “Minimize Redundant Operations in Loops”             |
| You have integer operations in your MATLAB code. You know beforehand that  | “Disable Support for Integer Overflow”               |

| Condition   | Action                                   |
|---|--|
| integer overflow does not occur during execution of your generated code.  |  |
| You know beforehand that Inf-s and NaN-s does not occur during execution of your generated code.  | “Disable Support for Non-Finite Numbers” |
| Your MATLAB code has variables that are large arrays or structures. The variable reuse optimization preserves your variable names. You want to see if the extra memory required to preserve the variable names of the large arrays or structures affects performance. | “Reuse Large Arrays and Structures”      |

## Modularize MATLAB Code

For large MATLAB code, streamline code generation by modularizing the code:

- 1 Break up your MATLAB code into smaller, self-contained sections.
- 2 Save each section in a MATLAB function.
- 3 Generate C/C++ code for each function.
- 4 Call the generated C/C++ functions in sequence from a wrapper MATLAB function using `coder.ceval`.
- 5 Generate C/C++ code for the wrapper function.

Besides streamlining code generation for the original MATLAB code, this approach also supplies you with C/C++ code for the individual sections. You can reuse the code for the individual sections later by integrating them with other generated C/C++ code using `coder.ceval`.

## Eliminate Redundant Copies of Function Inputs

You can reduce the number of copies in your generated code by writing functions that use the same variable as both an input and an output. For example:

```
function A = foo( A, B ) %#codegen
A = A * B;
end
```

This coding practice uses a reference parameter optimization. When a variable acts as both input and output, the generated code passes the variable by reference instead of redundantly copying the input to a temporary variable. In the preceding example, input `A` is passed by reference in the generated code because it also acts as an output for function `foo`:

```
...
/* Function Definitions */
void foo(double *A, double B)
{
    *A *= B;
}
...
```

The reference parameter optimization reduces memory usage and execution time, especially when the variable passed by reference is a large data structure. To achieve these benefits at the call site, call the function with the same variable as both input and output.

By contrast, suppose that you rewrite function `foo` without the optimization:

```
function y = foo2( A, B ) %#codegen
y = A * B;
end
```

The generated code passes the inputs by value and returns the value of the output:

```
...
/* Function Definitions */
double foo2(double A, double B)
{
    return A * B;
}
...
```

In some cases, the output of the function cannot be a modified version of its inputs. If you do not use the inputs later in the function, you can modify your code to operate on the inputs instead of on a copy of the inputs. One method is to create additional return values for the function. For example, consider the code:

```
function y1=foo(u1) %#codegen
    x1=u1+1;
    y1=bar(x1);
end

function y2=bar(u2)
    % Since foo does not use x1 later in the function,
    % it would be optimal to do this operation in place
    x2=u2.*2;
    % The change in dimensions in the following code
    % means that it cannot be done in place
    y2=[x2,x2];
end
```

You can modify this code to eliminate redundant copies.

```
function y1=foo(u1) %#codegen
    u1=u1+1;
    [y1, u1]=bar(u1);
end

function [y2, u2]=bar(u2)
    u2=u2.*2;
    % The change in dimensions in the following code
    % still means that it cannot be done in place
    y2=[u2,u2];
end
```

The reference parameter optimization does not apply to constant inputs. If the same variable is an input and an output, and the input is constant, the code generation software treats the output as a separate variable. For example, consider the function foo:

```
function A = foo( A, B ) %#codegen
A = A * B;
end
```

Generate code in which A has a constant value 2.

```
codegen -config:lib foo -args {coder.Constant(2) 3} -report
```

The generated code defines the constant A and returns the value of the output.

```
...  
#define A                               (2.0)  
...  
double foo(double B)  
{  
    return A * B;  
}  
...
```

## Inline Code

MATLAB uses internal heuristics to determine whether to inline functions in the generated code. You can use the `coder.inline` directive to fine-tune these heuristics for individual functions. For more information, see `coder.inline`.

### In this section...

“Prevent Function Inlining” on page 54-9

“Use Inlining in Control Flow Statements” on page 54-9

## Prevent Function Inlining

In this example, function `foo` is not inlined in the generated code:

```
function y = foo(x)
    coder.inline('never');
    y = x;
end
```

## Use Inlining in Control Flow Statements

You can use `coder.inline` in control flow code. If the software detects contradictory `coder.inline` directives, the generated code uses the default inlining heuristic and issues a warning.

Suppose you want to generate code for a division function that will be embedded in a system with limited memory. To optimize memory use in the generated code, the following function, `inline_division`, manually controls inlining based on whether it performs scalar division or vector division:

```
function y = inline_division(dividend, divisor)

% For scalar division, inlining produces smaller code
% than the function call itself.
if isscalar(dividend) && isscalar(divisor)
    coder.inline('always');
else
% Vector division produces a for-loop.
% Prohibit inlining to reduce code size.
    coder.inline('never');
```

```
end

if any(divisor == 0)
    error('Can not divide by 0');
end

y = dividend / divisor;
```

### **Related Examples**

- “Control Inlining”

# Control Inlining

Restrict inlining when:

- The size of generated code exceeds desired limits due to excessive inlining of functions. Suppose that you include the statement, `coder.inline('always')`, inside a certain function. You then call that function at many different sites in your code. The generated code can be large due to the function being inlined every time it is called.

The call sites must be different. For instance, inlining does not lead to large code if the function to be inlined is called several times inside a loop.

- You have limited RAM or stack space.

## In this section...

“Control Size of Functions Inlined” on page 54-11

“Control Size of Functions After Inlining” on page 54-12

“Control Stack Size Limit on Inlined Functions” on page 54-12

## Control Size of Functions Inlined

You can use the MATLAB Coder app or the command-line interface to control the maximum size of functions that can be inlined. The function size is measured in terms of an abstract number of instructions, not actual MATLAB instructions or instructions in the target processor. Experiment with this parameter to obtain the inlining behavior that you want.

- Using the app, in the project settings dialog box, on the **All Settings** tab, set the value of the field, **Inline threshold**, to the maximum size that you want.
- At the command line, create a `codegen` configuration object. Set the value of the property, `InlineThreshold`, to the maximum size that you want.

```
cfg = coder.config('lib');  
cfg.InlineThreshold = 100;
```

Generate code using this configuration object.

## Control Size of Functions After Inlining

You can use the MATLAB Coder app or the command-line interface to control the maximum size of functions after inlining. The function size is measured in terms of an abstract number of instructions, not actual MATLAB instructions or instructions in the target processor. Experiment with this parameter to obtain the inlining behavior that you want.

- Using the app, in the project settings dialog box, on the **All Settings** tab, set the value of the field, **Inline threshold max**, to the maximum size that you want.
- At the command line, create a `codegen` configuration object. Set the value of the property, `InlineThresholdMax`, to the maximum size that you want.

```
cfg = coder.config('lib');  
cfg.InlineThresholdMax = 100;
```

Generate code using this configuration object.

## Control Stack Size Limit on Inlined Functions

Specifying a limit on the stack space constrains the amount of inlining allowed. For out-of-line functions, stack space for variables local to the function is released when the function returns. However, for inlined functions, stack space remains occupied by the local variables even after the function is executed. The value of the property, `InlineStackLimit`, is measured in bytes. Based on information from the target hardware settings, the software estimates the number of stack variables that a certain value of `InlineStackLimit` can accommodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

You can use the MATLAB Coder app or the command-line interface to control the stack size limit on inlined functions.

- Using the app, in the project settings dialog box, on the **All Settings** tab, set the value of the field, **Inline stack limit**, to the maximum size that you want.
- At the command line, create a `codegen` configuration object. Set the value of the property, `InlineStackLimit`, to the maximum size that you want.

```
cfg = coder.config('lib');  
cfg.InlineStackLimit = 2000;
```

Generate code using this configuration object.

## **Related Examples**

## Fold Function Calls into Constants

This example shows how to specify constants in generated code using `coder.const`. The code generation software folds an expression or a function call in a `coder.const` statement into a constant in generated code. Because the generated code does not have to evaluate the expression or call the function every time, this optimization reduces the execution time of the generated code.

Write a function `AddShift` that takes an input `Shift` and adds it to the elements of a vector. The vector consists of the square of the first 10 natural numbers. `AddShift` generates this vector.

```
function y = AddShift(Shift) %#codegen
y = (1:10).^2+Shift;
```

Generate code for `AddShift` using the `codegen` command. Open the Code Generation Report.

```
codegen -config:lib -launchreport AddShift -args 0
```

The code generation software generates code for creating the vector. It adds `Shift` to each element of the vector during vector creation. The definition of `AddShift` in generated code looks as follows:

```
void AddShift(double Shift, double y[10])
{
    int k;
    for (k = 0; k < 10; k++) {
        y[k] = (double)((1 + k) * (1 + k)) + Shift;
    }
}
```

Replace the statement

```
y = (1:10).^2+Shift;
```

with

```
y = coder.const((1:10).^2)+Shift;
```

Generate code for `AddShift` using the `codegen` command. Open the Code Generation Report.

```
codegen -config:lib -launchreport AddShift -args 0
```

The code generation software creates the vector containing the squares of the first 10 natural numbers. In the generated code, it adds `Shift` to each element of this vector. The definition of `AddShift` in generated code looks as follows:

```
void AddShift(double Shift, double y[10])
{
    int i0;
    static const signed char iv0[10] = { 1, 4, 9, 16, 25, 36,
                                         49, 64, 81, 100 };

    for (i0 = 0; i0 < 10; i0++) {
        y[i0] = (double)iv0[i0] + Shift;
    }
}
```

`coder.const`

## Control Stack Space Usage

This example shows how to set the maximum stack space that the generated code uses. Set the maximum stack usage when:

- You have limited stack space, for instance, in embedded targets.
- Your C compiler reports a run-time stack overflow.

The value of the property, `StackUsageMax`, is measured in bytes. Based on information from the target hardware settings, the software estimates the number of stack variables that a certain value of `StackUsageMax` can accommodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

### Control Stack Space Usage Using the MATLAB Coder App

- 1 To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
- 2 Set **Build type** to `Source Code`, `Static Library`, `Dynamic Library`, or `Executable` (depending on your requirements).
- 3 Click **More Settings**.
- 4 On the **Memory** tab, set **Stack usage max** to the value that you want.

### Control Stack Space Usage at the Command Line

- 1 Create a configuration object for code generation.

Use `coder.config` with arguments `'lib'`, `'dll'`, or `'exe'` (depending on your requirements). For example:

```
cfg = coder.config('lib');
```

- 2 Set the property, `StackUsageMax`, to the value that you want.

```
cfg.StackUsageMax=400000;
```

### More About

- “Stack Allocation and Performance”

## Stack Allocation and Performance

By default, local variables are allocated on the stack. Large variables that do not fit on the stack are statically allocated in memory.

Stack allocation typically uses memory more efficiently than static allocation. However, stack space is sometimes limited, typically in embedded processors. MATLAB Coder allows you to manually set a limit on the stack space usage to make your generated code suitable for your target hardware. You can choose this limit based on the target hardware configurations. For more information, see “Control Stack Space Usage”.

## Dynamic Memory Allocation and Performance

To achieve faster execution of generated code, minimize dynamic (or run-time) memory allocation of arrays.

MATLAB Coder does not provide a size for unbounded arrays in generated code. Instead, such arrays are referenced indirectly through pointers. For such arrays, memory cannot be allocated during compilation of generated code. Based on storage requirements for the arrays, memory is allocated and freed at run time as required. This run-time allocation and freeing of memory leads to slower execution of the generated code. For more information on dynamic memory allocation, see “Bounded Versus Unbounded Variable-Size Data”.

### When Dynamic Memory Allocation Occurs

Dynamic memory allocation occurs when the code generation software cannot find upper bounds for variable-size arrays. The software cannot find upper bounds when you specify the size of an array using a variable that is not a compile-time constant. An example of such a variable is an input variable (or a variable computed from an input variable).

Instances in the MATLAB code that can lead to dynamic memory allocation are:

- Array initialization: You specify array size using a variable whose value is known only at run time.
- After initialization of an array:
  - You declare the array as variable-size using `coder.varsize` without explicit upper bounds. After this declaration, you expand the array by concatenation inside a loop. The number of loop runs is known only at run time.
  - You use a `reshape` function on the array. At least one of the size arguments to the `reshape` function is known only at run time.

If you know the maximum size of the array, you can avoid dynamic memory allocation. You can then provide an upper bound for the array and prevent dynamic memory allocation in generated code. For more information, see “Minimize Dynamic Memory Allocation” on page 54-19.

## Minimize Dynamic Memory Allocation

When possible, minimize dynamic memory allocation because it leads to slower execution of generated code. Dynamic memory allocation occurs when the code generation software cannot find upper bounds for variable-size arrays.

If you know the maximum size of a variable-size array, you can avoid dynamic memory allocation. Follow these steps:

- 1 “Provide Maximum Size for Variable-Size Arrays” on page 54-20.
- 2 Depending on your requirements, do one of the following:
  - “Disable Dynamic Memory Allocation During Code Generation” on page 54-26.
  - “Set Dynamic Memory Allocation Threshold”

---

**Caution** If a variable-size array in the MATLAB code does not have a maximum size, disabling dynamic memory allocation leads to a code generation error. Before disabling dynamic memory allocation, you must provide a maximum size for variable-size arrays in your MATLAB code.

---

### More About

- “Dynamic Memory Allocation and Performance”

## Provide Maximum Size for Variable-Size Arrays

To constrain array size for variable-size arrays, do one of the following:

- **Constrain Array Size Using `assert` Statements**

If the variable specifying array size is not a compile-time constant, use an `assert` statement with relational operators to constrain the variable. Doing so helps the code generation software to determine a maximum size for the array.

The following examples constrain array size using `assert` statements:

- **When Array Size Is Specified by Input Variables**

Define a function `array_init` which initializes an array `y` with input variable `N`:

```
function y = array_init (N)
    assert(N <= 25); % Generates exception if N > 25
    y = zeros(1,N);
```

The `assert` statement constrains input `N` to a maximum size of 25. In the absence of the `assert` statement, `y` is assigned a pointer to an array in the generated code, thus allowing dynamic memory allocation.

- **When Array Size Is Obtained from Computation Using Input Variables**

Define a function, `array_init_from_prod`, which takes two input variables, `M` and `N`, and uses their product to specify the maximum size of an array, `y`.

```
function y = array_init_from_prod (M,N)
    size=M*N;
    assert(size <= 25); % Generates exception if size > 25
    y=zeros(1,size);
```

The `assert` statement constrains the product of `M` and `N` to a maximum of 25.

Alternatively, if you restrict `M` and `N` individually, it leads to dynamic memory allocation:

```
function y = array_init_from_prod (M,N)
    assert(M <= 5);
    assert(N <= 5);
    size=M*N;
    y=zeros(1,size);
```

This code causes dynamic memory allocation because  $M$  and  $N$  can both have unbounded negative values. Therefore, their product can be unbounded and positive even though, individually, their positive values are bounded.

---

**Tip** Place the `assert` statement on a variable immediately before it is used to specify array size.

---

---

**Tip** You can use `assert` statements to restrict array sizes in most cases. When expanding an array inside a loop, this strategy does not work if the number of loop runs is known only at run time.

---

- **Restrict Concatenations in a Loop Using `coder.versize` with Upper Bounds**

You can expand arrays beyond their initial size by concatenation. When you concatenate additional elements inside a loop, there are two syntax rules for expanding arrays.

- 1 Array size during initialization is not a compile-time constant**

If the size of an array during initialization is not a compile-time constant, you can expand it by concatenating additional elements:

```
function out=ExpandArray(in) % Expand an array by five elements
    out = zeros(1,in);
    for i=1:5
        out = [out 0];
    end
```

- 2 Array size during initialization is a compile-time constant**

Before concatenating elements, you have to declare the array as variable-size using `coder.versize`:

```
function out=ExpandArray() % Expand an array by five elements
    out = zeros(1,5);
    coder.versize('out');
    for i=1:5
        out = [out 0];
    end
```

Either case leads to dynamic memory allocation. To prevent dynamic memory allocation in such cases, use `coder. varsize` with explicit upper bounds. This example shows how to use `coder. varsize` with explicit upper bounds:

### Restrict Concatenations Using `coder. varsize` with Upper Bounds

- 1 Define a function, `RunningAverage`, that calculates the running average of an `N`-element subset of an array:

```
function avg=RunningAverage(N)

% Array whose elements are to be averaged
NumArray=[1 6 8 2 5 3];

% Initialize average:
% These will also be the first two elements of the function output
avg=[0 0];

% Place a bound on the argument
coder. varsize('avg',[1 8]);

% Loop to calculate running average
for i=1:N
    s=0;
    s=s+sum(NumArray(1:i));
    avg=[avg s/i];
% Increase the size of avg as required by concatenation
end
```

The output, `avg`, is an array that you can expand as required to accommodate the running averages. As a new running average is calculated, it is added to the array `avg` through concatenation, thereby expanding the array.

Because the maximum number of running averages is equal to the number of elements in `NumArray`, you can supply an explicit upper bound for `avg` in the `coder. varsize` statement. In this example, the upper bound is 8 (the two initial elements plus the six elements of `NumArray`).

- 2 Generate code for `RunningAverage` with input argument of type `double`:

```
codegen -config:lib -report RunningAverage -args 2
```

In the generated code, `avg` is assigned an array of size 8 (static memory allocation). The function definition for `RunningAverage` appears as follows (using built-in C types):

```
void RunningAverage (double N, double avg_data[8], int avg_size[2])
```

- 3** By contrast, if you remove the explicit upper bound, the generated code dynamically allocates `avg`.

Replace the statement

```
coder.varsize('avg',[1 8]);
```

with:

```
coder.varsize('avg');
```

- 4** Generate code for `RunningAverage` with input argument of type `double`:

```
codegen -config:lib -report RunningAverage -args 2
```

In the generated code, `avg` is assigned a pointer to an array, thereby allowing dynamic memory allocation. The function definition for `RunningAverage` appears as follows (using built-in C types):

```
void Test(double N, mxArray_real_T *avg)
```

---

**Note:** Dynamic memory allocation also occurs if you precede `coder.varsize('avg')` with the following `assert` statement:

```
assert(N < 6);
```

The `assert` statement does not restrict the number of concatenations within the loop.

---

- **Constrain Array Size When Rearranging a Matrix**

The statement `out = reshape(in,m,n,...)` takes an array, `in`, as an argument and returns array, `out`, having the same elements as `in`, but reshaped as an `m`-by-`n`-by-`...` matrix. If one of the size variables `m`, `n`, `...` is not a compile-time constant, then dynamic memory allocation of `out` takes place.

To avoid dynamic memory allocation, use an `assert` statement before the `reshape` statement to restrict the size variables `m`, `n`, `...` to `numel(in)`. This example shows how to use an `assert` statement before a `reshape` statement:

### Rearrange a Matrix into Given Number of Rows

- 1 Define a function, `ReshapeMatrix`, which takes an input variable, `N`, and reshapes a matrix, `mat`, to have `N` rows:

```
function [out1,out2] = ReshapeMatrix(N)

    mat = [1 2 3 4 5; 4 5 6 7 8]
    % Since mat has 10 elements, N must be a factor of 10
    % to pass as argument to reshape

    out1 = reshape(mat,N,[]);
    % N is not restricted

    assert(N < numel(mat));
    % N is restricted to number of elements in mat
    out2 = reshape(mat,N,[]);
```

- 2 Generate code for `ReshapeArray` using the `codegen` command (the input argument does not have to be a factor of 10):

```
codegen -config:lib -report ReshapeArray -args 3
```

While `out1` is dynamically allocated, `out2` is assigned an array with size 100 (=10 X 10) in the generated code.

---

**Tip** If your system has limited memory, do not use the `assert` statement in this way. For an `n`-element matrix, the `assert` statement creates an `n`-by-`n` matrix, which might be large.

---

### Related Examples

- “Disable Dynamic Memory Allocation During Code Generation”
- “Set Dynamic Memory Allocation Threshold”

## **More About**

- “Dynamic Memory Allocation and Performance”

## Disable Dynamic Memory Allocation During Code Generation

To disable dynamic memory allocation using the MATLAB Coder app:

- 1 To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
- 2 Click **More Settings**.
- 3 On the **Memory** tab, under **Variable Sizing Support**, set **Dynamic memory allocation** to **Never**.

To disable dynamic memory allocation at the command line:

- 1 In the MATLAB workspace, define the configuration object:

```
cfg=coder.config('lib');
```
- 2 Set the `DynamicMemoryAllocation` property of the configuration object to `Off`:

```
cfg.DynamicMemoryAllocation = 'Off';
```

If a variable-size array in the MATLAB code does not have a maximum upper bound, disabling dynamic memory allocation leads to a code generation error. Therefore, you can identify variable-size arrays in your MATLAB code that do not have a maximum upper bound. These arrays are the arrays that are dynamically allocated in the generated code.

### Related Examples

### More About

- “Dynamic Memory Allocation and Performance”

## Set Dynamic Memory Allocation Threshold

This example shows how to specify a dynamic memory allocation threshold for variable-size arrays. Dynamic memory allocation optimizes storage requirements for variable-size arrays, but causes slower execution of generated code. Instead of disabling dynamic memory allocation for all variable-size arrays, you can disable dynamic memory allocation for arrays less than a certain size.

Specify this threshold when you want to:

- Disable dynamic memory allocation for smaller arrays. For smaller arrays, static memory allocation can speed up generated code. Static memory allocation can lead to unused storage space. However, you can decide that the unused storage space is not a significant consideration for smaller arrays.
- Enable dynamic memory allocation for larger arrays. For larger arrays, when you use dynamic memory allocation, you can significantly reduce storage requirements.

### Set Dynamic Memory Allocation Threshold Using the MATLAB Coder App

- 1 To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
- 2 Click **More Settings**.
- 3 On the **Memory** tab, select the **Enable variable-sizing** check box.
- 4 Set **Dynamic memory allocation** to **For arrays with max size at or above threshold**.
- 5 Set **Dynamic memory allocation threshold** to the value that you want.

The **Dynamic memory allocation threshold** value is measured in bytes. Based on information from the target hardware settings, the software estimates the size of the array that a certain value of `DynamicMemoryAllocationThreshold` can accommodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

## Set Dynamic Memory Allocation Threshold at the Command Line

- 1 Create a configuration object for code generation. Use `coder.config` with arguments `'lib'`, `'dll'`, or `'exe'` (depending on your requirements). For example:

```
cfg = coder.config('lib');
```

- 2 Set `DynamicMemoryAllocation` to `'Threshold'`.

```
cfg.DynamicMemoryAllocation='Threshold';
```

- 3 Set the property, `DynamicMemoryAllocationThreshold`, to the value that you want.

```
cfg.DynamicMemoryAllocationThreshold = 40000;
```

The value stored in `DynamicMemoryAllocationThreshold` is measured in bytes. Based on information from the target hardware settings, the software estimates the size of the array that a certain value of `DynamicMemoryAllocationThreshold` can accommodate. This estimate excludes possible C compiler optimizations such as putting variables in registers.

## Excluding Unused Paths from Generated Code

In certain situations, you do not need some branches of an: `if`, `elseif`, `else` statement, or a `switch`, `case`, `otherwise` statement in your generated code. For instance:

- You have a MATLAB function that performs multiple tasks determined by a control-flow variable. You might not need some of the tasks in the code generated from this function.
- You have an `if/elseif/if` statement in a MATLAB function performing different tasks based on the nature (type/value) of the input. In some cases, you know the nature of the input beforehand. If so, you do not need some branches of the `if` statement.

You can prevent code generation for the unused branches of an `if/elseif/else` statement or a `switch/case/otherwise` statement. Declare the control-flow variable as a constant. The code generation software generates code only for the branch that the control-flow variable chooses.

### Related Examples

- “Prevent Code Generation for Unused Execution Paths”

## Prevent Code Generation for Unused Execution Paths

### In this section...

“Prevent Code Generation When Local Variable Controls Flow” on page 54-30

“Prevent Code Generation When Input Variable Controls Flow” on page 54-31

If a variable controls the flow of an: `if`, `elseif`, `else` statement, or a `switch`, `case`, `otherwise` statement, declare it as constant so that code generation takes place for one branch of the statement only.

Depending on the nature of the control-flow variable, you can declare it as constant in two ways:

- If the variable is local to the MATLAB function, assign it to a constant value in the MATLAB code. For an example, see “Prevent Code Generation When Local Variable Controls Flow” on page 54-30.
- If the variable is an input to the MATLAB function, you can declare it as constant using `coder.Constant`. For an example, see “Prevent Code Generation When Input Variable Controls Flow” on page 54-31.

### Prevent Code Generation When Local Variable Controls Flow

- 1 Define a function `SquareOrCube` which takes an input variable, `in`, and squares or cubes its elements based on whether the choice variable, `ch`, is set to `s` or `c`:

```
function out = SquareOrCube(ch,in) %#codegen
    if ch=='s'
        out = in.^2;
    elseif ch=='c'
        out = in.^3;
    else
        out = 0;
    end
```

- 2 Generate code for `SquareOrCube` using the `codegen` command:

```
codegen -config:lib SquareOrCube -args {'s',zeros(2,2)}
```

The generated C code squares or cubes the elements of a 2-by-2 matrix based on the input for `ch`.

- 3 Add the following line to the definition of `SquareOrCube`:

```
ch = 's';
```

The generated C code squares the elements of a 2-by-2 matrix. The choice variable, `ch`, and the other branches of the `if/elseif/if` statement do not appear in the generated code.

## Prevent Code Generation When Input Variable Controls Flow

- 1 Define a function `MathFunc`, which performs different mathematical operations on an input, `in`, depending on the value of the input, `flag`:

```
function out = MathFunc(flag,in) %#codegen
    %# codegen
    switch flag
        case 1
            out=sin(in);
        case 2
            out=cos(in);
        otherwise
            out=sqrt(in);
    end
```

- 2 Generate code for `MathFunc` using the `codegen` command:

```
codegen -config:lib MathFunc -args {1,zeros(2,2)}
```

The generated C code performs different math operations on the elements of a 2-by-2 matrix based on the input for `flag`.

- 3 Generate code for `MathFunc`, declaring the argument, `flag`, as a constant using `coder.Constant`:

```
codegen -config:lib MathFunc -args {coder.Constant(1),zeros(2,2)}
```

The generated C code finds the sine of the elements of a 2-by-2 matrix. The variable, `flag`, and the `switch/case/otherwise` statement do not appear in the generated code.

## More About

- “Excluding Unused Paths from Generated Code”

## Generate Code with Parallel for-Loops (parfor)

This example shows how to generate C code for a MATLAB algorithm that contains a `parfor`-loop.

- 1 Write a MATLAB function that contains a `parfor`-loop. For example:

```
function a = test_parfor %#codegen
a=ones(10,256);
r=rand(10,256);
parfor i=1:10
    a(i,:)=real(fft(r(i,:)));
end
```

- 2 Generate C code for `test_parfor`. At the MATLAB command line, enter:

```
codegen -config:lib test_parfor
```

Because you did not specify the maximum number of threads to use, the generated C code executes the loop iterations in parallel on the available number of cores.

- 3 To specify a maximum number of threads, rewrite the function `test_parfor` as follows:

```
function a = test_parfor(u) %#codegen
a=ones(10,256);
r=rand(10,256);
parfor (i=1:10,u)
    a(i,:)=real(fft(r(i,:)));
end
```

- 4 Generate C code for `test_parfor`. Use `-args 0` to specify that the input, `u`, is a scalar double. At the MATLAB command line, enter:

```
codegen -config:lib test_parfor -args 0
```

In the generated code, the iterations of the `parfor`-loop run on at most the number of cores specified by the input, `u`. If less than `u` cores are available, the iterations run on the cores available at the time of the call.

### More About

- “Algorithm Acceleration Using Parallel for-Loops (`parfor`)”
- “Classification of Variables in `parfor`-Loops”

- “Reduction Assignments in parfor-Loops”

## Minimize Redundant Operations in Loops

This example shows how to minimize redundant operations in loops. When a loop operation does not depend on the loop index, performing it inside a loop is redundant. This redundancy often goes unnoticed when you are performing multiple operations in a single MATLAB statement inside a loop. For example, in the following code, the inverse of the matrix **B** is being calculated 100 times inside the loop although it does not depend on the loop index:

```
for i=1:100
    C=C + inv(B)*A^i*B;
end
```

Performing such redundant loop operations can lead to unnecessary processing. To avoid unnecessary processing, move operations outside loops as long as they do not depend on the loop index.

- 1 Define a function, `SeriesFunc(A,B,n)`, that calculates the sum of  $n$  terms in the following power series expansion:

$$C = 1 + B^{-1}AB + B^{-1}A^2B + \dots$$

```
function C=SeriesFunc(A,B,n)

% Initialize C with a matrix having same dimensions as A
C=zeros(size(A));

% Perform the series sum
for i=1:n
    C=C+inv(B)*A^i*B;
end
```

- 2 Generate code for `SeriesFunc` with 4-by-4 matrices passed as input arguments for **A** and **B**:

```
X = coder.typeof(zeros(4));
codegen -config:lib -launchreport SeriesFunc -args {X,X,10}
```

In the generated code, the inversion of **B** is performed  $n$  times inside the loop. It is more economical to perform the inversion operation once outside the loop because it does not depend on the loop index.

- 3 Modify `SeriesFunc` as follows:

```
function C=SeriesFunc(A,B,n)

% Initialize C with a matrix having same dimensions as A
C=zeros(size(A));

% Perform the inversion outside the loop
inv_B=inv(B);

% Perform the series sum
for i=1:n
    C=C+inv_B*A^i*B;
end
```

This procedure performs the inversion of **B** only once, leading to faster execution of the generated code.

## Unroll for-Loops

Unrolling `for`-loops eliminates the loop logic by creating a separate copy of the loop body in the generated code for each iteration. Within each iteration, the loop index variable becomes a constant.

You can also force loop unrolling for individual functions by wrapping the loop header in a `coder.unroll` function. For more information, see `coder.unroll`.

### Limit Copying the for-loop Body in Generated Code

To limit the number of times that you copy the body of a `for`-loop in generated code:

- 1 Write a MATLAB function `getrand(n)` that uses a `for`-loop to generate a vector of length `n` and assign random numbers to specific elements. Add a test function `test_unroll`. This function calls `getrand(n)` with `n` equal to values both less than and greater than the threshold for copying the `for`-loop in generated code.

```
function [y1, y2] = test_unroll() %#codegen
% The directive %#codegen indicates that the function
% is intended for code generation
% Calling getrand 8 times triggers unroll
y1 = getrand(8);
% Calling getrand 50 times does not trigger unroll
y2 = getrand(50);
```

```
function y = getrand(n)
% Turn off inlining to make
% generated code easier to read
coder.inline('never');

% Set flag variable downroll to repeat loop body
% only for fewer than 10 iterations
downroll = n < 10;
% Declare size, class, and complexity
% of variable y by assignment
y = zeros(n, 1);
% Loop body begins
for i = coder.unroll(1:2:n, downroll)
    if (i > 2) && (i < n-2)
        y(i) = rand();
    end;
```

```
end;
% Loop body ends
```

- 2 In the default output folder, `codegen/lib/test_unroll`, generate C static library code for `test_unroll`:

```
codegen -config:lib test_unroll
```

In `test_unroll.c`, the generated C code for `getrand(8)` repeats the body of the `for`-loop (unrolls the loop) because the number of iterations is less than 10:

```
static void getrand(double y[8])
{
    /* Turn off inlining to make */
    /* generated code easier to read */
    /* Set flag variable dounroll to repeat loop body */
    /* only for fewer than 10 iterations */
    /* Declare size, class, and complexity */
    /* of variable y by assignment */
    memset(&y[0], 0, sizeof(double) << 3);

    /* Loop body begins */
    y[2] = b_rand();
    y[4] = b_rand();

    /* Loop body ends */
}
```

The generated C code for `getrand(50)` does not unroll the `for`-loop because the number of iterations is greater than 10:

```
static void b_getrand(double y[50])
{
    int i;
    int b_i;

    /* Turn off inlining to make */
    /* generated code easier to read */
    /* Set flag variable dounroll to repeat loop body */
    /* only for fewer than 10 iterations */
    /* Declare size, class, and complexity */
    /* of variable y by assignment */
    memset(&y[0], 0, 50U * sizeof(double));

    /* Loop body begins */
```

```
for (i = 0; i < 25; i++) {  
    b_i = (i << 1) + 1;  
    if ((b_i > 2) && (b_i < 48)) {  
        y[b_i - 1] = b_rand();  
    }  
}
```

## Support for Integer Overflow and Non-Finites

The code generation software generates supporting code for the following situations:

- The result of an integer operation falls outside the range that a data type can represent. This situation is known as integer overflow.
- An operation generates non-finite values (`inf` and `NaN`). The supporting code is contained in the files `rt_nonfinite.c`, `rtGetInf.c`, and `rtGetNaN.c` (with corresponding header files).

If you know that these situations do not occur, you can suppress generation of the supporting code. You therefore reduce the size of the generated code and increase its speed. However, if one of these situations occurs, it is possible that the generated code will not match the behavior of the original MATLAB code.

### Disable Support for Integer Overflow

You can use the MATLAB Coder app or the command-line interface to disable support for integer overflow. When you disable this support, the overflow behavior of your generated code depends on your target C compiler. Most C compilers wrap on overflow.

- Using the app:
  - 1 To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
  - 2 Click **More Settings**.
  - 3 To disable support for integer overflow, on the **Speed** tab, clear **Saturate on integer overflow**.
- At the command line:
  - 1 Create a configuration object for code generation. Use `coder.config` with arguments `'lib'`, `'dll'`, or `'exe'` (depending on your requirements). For example:

```
cfg = coder.config('lib');
```
  - 2 To disable support for integer overflow, set the `SaturateOnIntegerOverflow` property to `false`.

```
cfg.SaturateOnIntegerOverflow = false;
```

## Disable Support for Non-Finite Numbers

You can use the MATLAB Coder app or the command-line interface to disable support for non-finite numbers(`inf` and `NaN`).

- Using the app:
  - 1 To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow .
  - 2 Set **Build type** to `Source Code`, `Static Library`, `Dynamic Library`, or `Executable` (depending on your requirements).
  - 3 Click **More Settings**.
  - 4 On the **Speed** tab, clear the **Support non-finite numbers** check box.
- At the command line:
  - 1 Create a configuration object for code generation. Use `coder.config` with arguments `'lib'`, `'dll'`, or `'exe'` (depending on your requirements). For example:

```
cfg = coder.config('lib');
```
  - 2 To disable support for integer overflow, set the `SupportNonFinite` property to `false`.

```
cfg.SupportNonFinite = false;
```

## Integrate Custom Code

This example shows how to integrate custom code to enhance performance of generated code. Although MATLAB Coder generates optimized code for most applications, you might have legacy code optimized for your specific requirements. For example:

- You have custom libraries optimized for your target environment.
- You have custom libraries for functions not supported by MATLAB Coder.
- You have custom libraries that meet standards set by your company.

In such cases, you can integrate your custom code with the code generated by MATLAB Coder.

This example illustrates how to integrate the function `cublasSgemm` from the NVIDIA® CUDA® Basic Linear Algebra Subroutines (CUBLAS) library in generated code. This function performs matrix multiplication on a Graphics Processing Unit (GPU).

- 1 Define a class `ExternalLib_API` that derives from the class `coder.ExternalDependency`. `ExternalLib_API` defines an interface to the CUBLAS library through the following methods:
  - `getDescriptiveName`: Returns a descriptive name for `ExternalLib_API` to be used for error messages.
  - `isSupportedContext`: Determines if the build context supports the CUBLAS library.
  - `updateBuildInfo`: Adds header file paths and link files to the build information.
  - `GPU_MatrixMultiply`: Defines the interface to the CUBLAS library function `cublasSgemm`.

### ExternalLib\_API.m

```
classdef ExternalLib_API < coder.ExternalDependency
    %#codegen

    methods (Static)

        function bName = getDescriptiveName(-)
            bName = 'ExternalLib_API';
        end
    end
end
```

```
function tf = isSupportedContext(ctx)
    if ctx.isMatlabHostTarget()
        tf = true;
    else
        error('CUBLAS library not available for this target');
    end
end

function updateBuildInfo(buildInfo, ctx)
    [~, linkLibExt, ~, ~] = ctx.getStdLibInfo();

    % Include header file path
    % Include header files later using coder.cinclude
    hdrFilePath = 'C:\My_Includes';
    buildInfo.addIncludePaths(hdrFilePath);

    % Include link files
    linkFiles = strcat('libcublas', linkLibExt);
    linkPath = 'C:\My_Libs';
    linkPriority = '';
    linkPrecompiled = true;
    linkLinkOnly = true;
    group = '';
    buildInfo.addLinkObjects(linkFiles, linkPath, ...
        linkPriority, linkPrecompiled, linkLinkOnly, group);

    linkFiles = strcat('libcudart', linkLibExt);
    buildInfo.addLinkObjects(linkFiles, linkPath, ...
        linkPriority, linkPrecompiled, linkLinkOnly, group);

end

%API for library function 'cuda_MatrixMultiply'
function C = GPU_MatrixMultiply(A, B)
    assert(isa(A,'single'), 'A must be single.');
```

```
    assert(isa(B,'single'), 'B must be single.');
```

```
    if(coder.target('MATLAB'))
        C=A*B;
    else

        % Include header files
        %     for external functions and typedefs
```

```
% Header path included earlier using updateBuildInfo
coder.cinclude('cuda_runtime.h');
coder.cinclude('cublas_v2.h');

% Compute dimensions of input matrices
m = int32(size(A, 1));
k = int32(size(A, 2));
n = int32(size(B, 2));

% Declare pointers to matrices on destination GPU
d_A = coder.opaque('float*');
d_B = coder.opaque('float*');
d_C = coder.opaque('float*');

% Compute memory to be allocated for matrices
% Single = 4 bytes
size_A = m*k*4;
size_B = k*n*4;
size_C = m*n*4;

% Define error variables
error = coder.opaque('cudaError_t');
cudaSuccessV = coder.opaque('cudaError_t', ...
    'cudaSuccess');

% Assign memory on destination GPU
error = coder.ceval('cudaMalloc', ...
    coder.wref(d_A), size_A);
assert(error == cudaSuccessV, ...
    'cudaMalloc(A) failed');
error = coder.ceval('cudaMalloc', ...
    coder.wref(d_B), size_B);
assert(error == cudaSuccessV, ...
    'cudaMalloc(B) failed');
error = coder.ceval('cudaMalloc', ...
    coder.wref(d_C), size_C);
assert(error == cudaSuccessV, ...
    'cudaMalloc(C) failed');

% Define direction of copying
hostToDevice = coder.opaque('cudaMemcpyKind', ...
    'cudaMemcpyHostToDevice');

% Copy matrices to destination GPU
```

```
error = coder.ceval('cudaMemcpy', ...
    d_A, coder.rref(A), size_A, hostToDevice);
assert(error == cudaSuccessV, 'cudaMemcpy(A) failed');

error = coder.ceval('cudaMemcpy', ...
    d_B, coder.rref(B), size_B, hostToDevice);
assert(error == cudaSuccessV, 'cudaMemcpy(B) failed');

% Define type and size for result
C = zeros(m, n, 'single');

error = coder.ceval('cudaMemcpy', ...
    d_C, coder.rref(C), size_C, hostToDevice);
assert(error == cudaSuccessV, 'cudaMemcpy(C) failed');

% Define handle variables for external library
handle = coder.opaque('cublasHandle_t');
blasSuccess = coder.opaque('cublasStatus_t', ...
    'CUBLAS_STATUS_SUCCESS');

% Initialize external library
ret = coder.opaque('cublasStatus_t');
ret = coder.ceval('cublasCreate', coder.wref(handle));
assert(ret == blasSuccess, 'cublasCreate failed');

TRANSA = coder.opaque('cublasOperation_t', ...
    'CUBLAS_OP_N');
alpha = single(1);
beta = single(0);

% Multiply matrices on GPU
ret = coder.ceval('cublasSgemm', handle, ...
    TRANSA, TRANSA, m, n, k, ...
    coder.rref(alpha), d_A, m, ...
    d_B, k, ...
    coder.rref(beta), d_C, k);

assert(ret == blasSuccess, 'cublasSgemm failed');

% Copy result back to local host
deviceToHost = coder.opaque('cudaMemcpyKind', ...
    'cudaMemcpyDeviceToHost');
error = coder.ceval('cudaMemcpy', coder.wref(C), ...
```

```

        d_C, size_C, deviceToHost);
    assert(error == cudaSuccessV, 'cudaMemcpy(C) failed');

    end
end
end
end
end

```

- 2 To perform the matrix multiplication using the interface defined in method `GPU_MatrixMultiply` and the build information in `ExternalLib_API`, include the following line in your MATLAB code:

```
C= ExternalLib_API.GPU_MatrixMultiply(A,B);
```

For instance, you can define a MATLAB function `Matrix_Multiply` that solely performs this matrix multiplication.

```
function C = Matrix_Multiply(A, B) %#codegen
    C= ExternalLib_API.GPU_MatrixMultiply(A,B);
```

- 3 Define a MEX configuration object using `coder.config`. For using the CUBLAS libraries, set the target language for code generation to C++.

```
cfg=coder.config('mex');
cfg.TargetLang='C++';
```

- 4 Generate code for `Matrix_Multiply` using `cfg` as the configuration object and two 2 X 2 matrices of type `single` as arguments. Since `cublasSgemm` supports matrix multiplication for data type `float`, the corresponding MATLAB matrices must have type `single`.

```
codegen -config cfg Matrix_Multiply ...
        -args {ones(2,'single'),ones(2,'single')}
```

- 5 Test the generated MEX function `Matrix_Multiply_mex` using two 2 X 2 identity matrices of type `single`.

```
Matrix_Multiply_mex(eye(2, 'single'),eye(2, 'single'))
```

The output is also a 2 X 2 identity matrix.

## MATLAB Coder Optimizations in Generated Code

### In this section...

“Constant Folding” on page 54-47

“Loop Fusion” on page 54-48

“Successive Matrix Operations Combined” on page 54-48

“Unreachable Code Elimination” on page 54-49

In order to improve the execution speed and memory usage of generated code, MATLAB Coder introduces the following optimizations:

### Constant Folding

When possible, the code generation software evaluates expressions in your MATLAB code that involve compile-time constants only. In the generated code, it replaces these expressions with the result of the evaluations. This behavior is known as constant folding. Because of constant folding, the generated code does not have to evaluate the constants during execution.

The following example shows MATLAB code that is constant-folded during code generation. The function `MultiplyConstant` multiplies every element in a matrix by a scalar constant. The function evaluates this constant using the product of three compile-time constants, `a`, `b`, and `c`.

```
function out=MultiplyConstant(in) %#codegen
    a=pi^4;
    b=1/factorial(4);
    c=exp(-1);
    out=in.*(a*b*c);
end
```

The code generation software evaluates the expressions involving compile-time constants, `a`, `b`, and `c`. It replaces these expressions with the result of the evaluation in generated code.

Constant folding can occur when the expressions involve scalars only. To explicitly enforce constant folding of expressions in other cases, use the `coder.const` function. For more information, see “Fold Function Calls into Constants”.

## Control Constant Folding

You can control the maximum number of instructions that can be constant-folded from the command line or the project settings dialog box.

- At the command line, create a configuration object for code generation. Set the property `ConstantFoldingTimeout` to the value that you want.

```
cfg=coder.config('lib');  
cfg.ConstantFoldingTimeout = 200;
```

- Using the app, in the project settings dialog box, on the **All Settings** tab, set the field **Constant folding timeout** to the value that you want.

## Loop Fusion

When possible, the code generation software fuses successive loops with the same number of runs into a single loop in the generated code. This optimization reduces loop overhead.

The following code contains successive loops, which are fused during code generation. The function `SumAndProduct` evaluates the sum and product of the elements in an array `Arr`. The function uses two separate loops to evaluate the sum `y_f_sum` and product `y_f_prod`.

```
function [y_f_sum,y_f_prod] = SumAndProduct(Arr) %#codegen  
    y_f_sum = 0;  
    y_f_prod = 1;  
    for i = 1:length(Arr)  
        y_f_sum = y_f_sum+Arr(i);  
    end  
    for i = 1:length(Arr)  
        y_f_prod = y_f_prod*Arr(i);  
    end
```

The code generated from this MATLAB code evaluates the sum and product in a single loop.

## Successive Matrix Operations Combined

When possible, the code generation software converts successive matrix operations in your MATLAB code into a single loop operation in generated code. This optimization

reduces excess loop overhead involved in performing the matrix operations in separate loops.

The following example contains code where successive matrix operations take place. The function `ManipulateMatrix` multiplies every element of a matrix `Mat` with a `factor`. To every element in the result, the function then adds a `shift`:

```
function Res=ManipulateMatrix(Mat, factor, shift)
    Res=Mat*factor;
    Res=Res+shift;
end
```

The generated code combines the multiplication and addition into a single loop operation.

## Unreachable Code Elimination

When possible, the code generation software suppresses code generation from unreachable procedures in your MATLAB code. For instance, if a branch of an `if`, `elseif`, `else` statement is unreachable, then code is not generated for that branch.

The following example contains unreachable code, which is eliminated during code generation. The function `SaturateValue` returns a value based on the range of its input `x`.

```
function y_b = SaturateValue(x) %#codegen
    if x>0
        y_b = x;
    elseif x>10 %This is redundant
        y_b = 10;
    else
        y_b = -x;
    end
```

The second branch of the `if`, `elseif`, `else` statement is unreachable. If the variable `x` is greater than 10, it is also greater than 0. Therefore, the first branch is executed in preference to the second branch.

MATLAB Coder does not generate code for the unreachable second branch.

## Generate Reusable Code

With MATLAB, you can generate reusable code in the following ways:

- Write reusable functions using standard MATLAB function file names which you can call from different locations, for example, in a Simulink model or MATLAB function library.
- Compile external functions on the MATLAB path and integrate them into generated C code for embedded targets.

See “Resolution of Function Calls for Code Generation”.

Common applications include:

- Overriding generated library function with a custom implementation.
- Implementing a reusable library on top of standard library functions that can be used with Simulink.
- Swapping between different implementations of the same function.

## About Data Types in Simulink

### In this section...

“About Data Types” on page 55-2

“Data Typing Guidelines” on page 55-3

“Data Type Propagation” on page 55-3

### About Data Types

The term *data type* refers to the way in which a computer represents numbers in memory. A data type determines the amount of storage allocated to a number, the method used to encode the number's value as a pattern of binary digits, and the operations available for manipulating the type. Most computers provide a choice of data types for representing numbers, each with specific advantages in the areas of precision, dynamic range, performance, and memory usage. To optimize performance, you can specify the data types of variables used in the MATLAB technical computing environment. The Simulink software builds on this capability by allowing you to specify the data types of Simulink signals and block parameters.

The ability to specify the data types of a model's signals and block parameters is particularly useful in real-time control applications. For example, it allows a Simulink model to specify the optimal data types to use to represent signals and block parameters in code generated from a model by automatic code-generation tools, such as the Simulink Coder product. By choosing the most appropriate data types for your model's signals and parameters, you can dramatically increase performance and decrease the size of the code generated from the model.

Simulink performs extensive checking before and during a simulation to ensure that your model is *typesafe*, that is, that code generated from the model will not overflow or underflow and thus produce incorrect results. Simulink models that use the default data type (**double**) are inherently typesafe. Thus, if you never plan to generate code from your model or use a nondefault data type in your models, you can skip the remainder of this section.

On the other hand, if you plan to generate code from your models and use nondefault data types, read the remainder of this section carefully, especially the section on data type rules (see “Data Typing Guidelines” on page 55-3). In that way, you can avoid introducing data type errors that prevent your model from running to completion or simulating at all.

## Data Typing Guidelines

Observing the following rules can help you to create models that are typesafe and, therefore, execute without error:

- Signal data types generally do not affect parameter data types, and vice versa.

A significant exception to this rule is the Constant block, whose output data type is determined by the data type of its parameter.

- If the output of a block is a function of an input and a parameter, and the input and parameter differ in type, the Simulink software converts the parameter to the input type before computing the output.
- In general, a block outputs the data type that appears at its inputs.

Significant exceptions include Constant blocks and Data Type Conversion blocks, whose output data types are determined by block parameters.

- Virtual blocks accept signals of any type on their inputs.

Examples of virtual blocks include Mux and Demux blocks and unconditionally executed subsystems.

- The elements of a signal array connected to a port of a nonvirtual block must be of the same data type.
- The signals connected to the input data ports of a nonvirtual block cannot differ in type.
- Control ports (for example, Enable and Trigger ports) accept any data type.
- Solver blocks accept only **double** signals.
- Connecting a non-**double** signal to a block disables zero-crossing detection for that block.

## Data Type Propagation

Whenever you start a simulation, enable display of port data types, or refresh the port data type display, the Simulink software performs a processing step called data type propagation. This step involves determining the types of signals whose type is not otherwise specified and checking the types of signals and input ports to ensure that they do not conflict. If type conflicts arise, an error dialog is displayed that specifies the signal and port whose data types conflict. The signal path that creates the type conflict is also highlighted.

---

**Note** You can insert typecasting (data type conversion) blocks in your model to resolve type conflicts. For more information, see [Data Type Conversion](#).

- “Specify Data Types Using Data Type Assistant” on page 55-24

## More About

- “Data Types Supported by Simulink” on page 55-5
- “Data Types for Bus Signals” on page 55-37

## Data Types Supported by Simulink

Simulink supports all built-in numeric MATLAB data types except `int64` and `uint64`. The term *built-in data type* refers to data types defined by MATLAB itself as opposed to data types defined by MATLAB users. Unless otherwise specified, the term data type in the Simulink documentation refers to built-in data types.

The following table lists the built-in MATLAB data types supported by Simulink.

| Name                | Description                     |
|---------------------|---------------------------------|
| <code>double</code> | Double-precision floating point |
| <code>single</code> | Single-precision floating point |
| <code>int8</code>   | Signed 8-bit integer            |
| <code>uint8</code>  | Unsigned 8-bit integer          |
| <code>int16</code>  | Signed 16-bit integer           |
| <code>uint16</code> | Unsigned 16-bit integer         |
| <code>int32</code>  | Signed 32-bit integer           |
| <code>uint32</code> | Unsigned 32-bit integer         |

Besides these built-in types, Simulink defines a `boolean` (`true` or `false`) type. The values `1` and `0` represent `true` and `false` respectively. For this data type, Simulink represents real, nonzero numeric values (including `Inf`) as `true` (`1`).

### Block Support for Data and Signal Types

All Simulink blocks accept signals of type `double` by default. Some blocks prefer `boolean` input and others support multiple data types on their inputs. For more information on the data types supported by a specific block for parameter and input and output values, in the Simulink documentation see the **Data Type Support** section of the reference page for that block. If the documentation for a block does not specify a data type, the block inputs or outputs only data of type `double`.

Several blocks support bus objects (`Simulink.Bus`) as data types. See “Data Types for Bus Signals” on page 55-37.

Many Simulink blocks also support fixed-point data types. For more information about fixed-point data, see “Specify Fixed-Point Data Types” on page 55-22. For more

information on the data types supported by a specific block for parameter and input and output values, in the Simulink documentation see the **Data Type Support** section of the reference page for that block. If the documentation for a block does not specify a data type, the block inputs or outputs only data of type **double**.

To view a table that summarizes the data types supported by the blocks in the Simulink block libraries, execute the following command at the MATLAB command line:

```
showblockdatatypetable
```

## More About

- “About Data Types in Simulink” on page 55-2
- “Data Types for Bus Signals” on page 55-37

## Control Signal Data Types

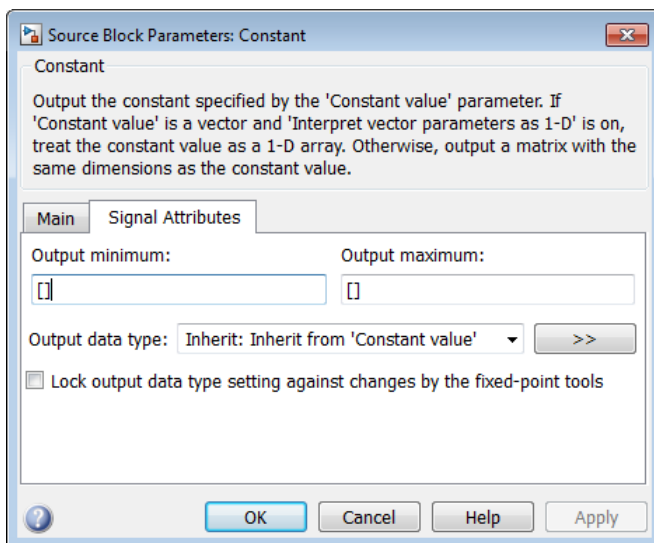

To view the signal data types in your model, in the Simulink Editor, select **Display > Signals & Ports > Port Data Types**. The port data type display is not automatically updated when you change the data type of a diagram element. To refresh the display, press **Ctrl+D**.

To control the data type of a signal in a Simulink model, you specify a data type for the corresponding block output.

You can also introduce a new signal of a specific data type into a model in any of the following ways:

- Load signal data of the desired type from the MATLAB workspace into your model via a root-level **Inport** block or a **From Workspace** block.
- Create a **Constant** block in your model and set its parameter to the desired type.
- Use a **Data Type Conversion** block to convert a signal to the desired data type.

Simulink blocks determine the data type of their outputs by default. Many blocks allow you to override the default type and explicitly specify an output data type, using a block parameter that is typically named **Output data type**. For example, the **Output data type** parameter appears on the **Signal Attributes** pane of the Constant block dialog box.

See the following topics for more information:

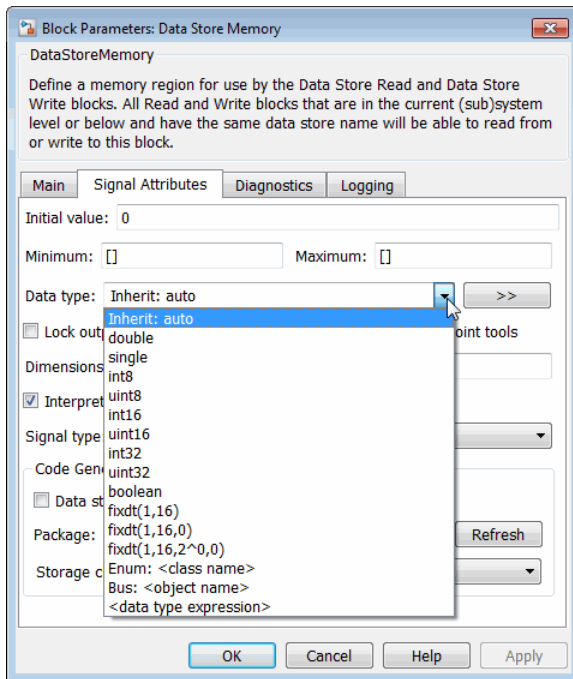

| For Information About...   | See...   |
|--|--|
| Valid data type values that you can specify                          | “Entering Valid Data Type Values” on page 55-9               |
| An assistant that helps you specify valid data type values           | “Specify Data Types Using Data Type Assistant” on page 55-24 |
| Specifying valid data type values for multiple blocks simultaneously | “Using the Model Explorer for Batch Editing” on page 55-12   |

## Entering Valid Data Type Values

In general, you can specify the output data type as any of the following:

- A rule that inherits a data type (see “Data Type Inheritance Rules” on page 55-10)
- The name of a built-in data type (see “Built-In Data Types” on page 55-11)
- An expression that evaluates to a data type (see “Data Type Expressions” on page 55-11)

Valid data type values vary among blocks. You can use the pull-down menu associated with a block data type parameter to view the data types that a particular block supports. For example, the **Data type** pull-down menu on the Data Store Memory block dialog box lists the data types that it supports, as shown here.

For more information about the data types that a specific block supports, see the documentation for the block in the Simulink documentation.

### Data Type Inheritance Rules

Blocks can inherit data types from a variety of sources, including signals to which they are connected and particular block parameters. You can specify the value of a data type parameter as a rule that determines how the output signal inherits its data type. To view the inheritance rules that a block supports, use the data type pull-down menu on the block dialog box. The following table lists typical rules that you can select.

| Inheritance Rule                      | Description   |
|---------------------------------------|---|
| Inherit: Inherit via back propagation | Simulink automatically determines the output data type of the block during data type propagation (see “Data Type Propagation” on page 55-3). In this case, the block uses the data type of a downstream block or signal object. |

| Inheritance Rule                   | Description  |
|------------------------------------|--|
| Inherit: Same as input             | The block uses the data type of its sole input signal for its output signal.   |
| Inherit: Same as first input       | The block uses the data type of its first input signal for its output signal.  |
| Inherit: Same as second input      | The block uses the data type of its second input signal for its output signal.   |
| Inherit: Inherit via internal rule | The block uses an internal rule to determine its output data type. The internal rule chooses a data type that optimizes numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. It is not always possible for the software to optimize efficiency and numerical accuracy at the same time. |

### Built-In Data Types

You can specify the value of a data type parameter as the name of a built-in data type, for example, `single` or `boolean`. To view the built-in data types that a block supports, use the data type pull-down menu on the block dialog box. See “Data Types Supported by Simulink” on page 55-5 for a list of all built-in data types that are supported.

### Data Type Expressions

You can specify the value of a data type parameter as an expression that evaluates to a numeric data type object. Simply enter the expression in the data type field on the block dialog box. In general, enter one of the following expressions:

- **fixdt Command**

Specify the value of a data type parameter as a command that invokes the `fixdt` function. This function allows you to create a `Simulink.NumericType` object that describes a fixed-point or floating-point data type. See the documentation for the `fixdt` function for more information.

- **Data Type Object Name**

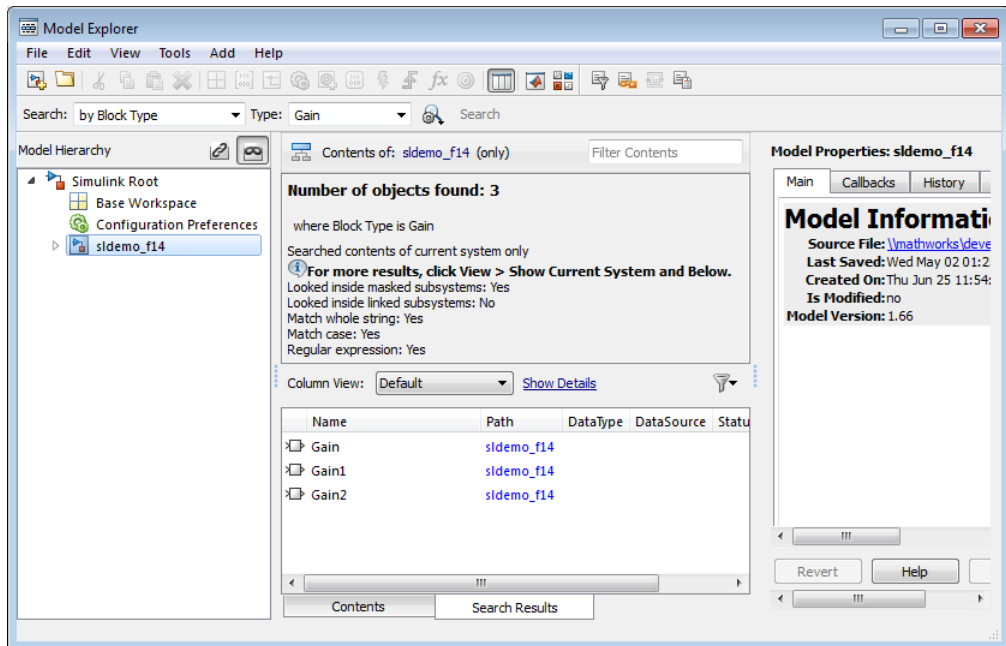

Specify the value of a data type parameter as the name of a data object that represents a data type. Simulink data objects that you instantiate from classes, such as `Simulink.NumericType` and `Simulink.AliasType`, simplify the task of making model-wide changes to output data types and allow you to use custom aliases for data types. See “Data Objects” on page 55-38 for more information about Simulink data objects.

## Using the Model Explorer for Batch Editing

Using the Model Explorer (see “Model Explorer Overview” on page 11-2), you can assign the same output data type to multiple blocks simultaneously. For example, the `slexAircraftExample` model that comes with the Simulink product contains numerous Gain blocks. Suppose you want to specify the **Output data type** parameter of all the Gain blocks in the model as `single`. You can achieve this task as follows:

- 1 Use the Model Explorer search bar (see “Search Using Model Explorer” on page 11-60) to identify all blocks in the `slexAircraftExample` model of type `Gain`.

The Model Explorer **Contents** pane lists all Gain blocks in the model.

- 2 In the Model Explorer **Contents** pane, select all the Gain blocks whose **Output data type** parameter you want to specify.

Model Explorer highlights the rows corresponding to your selections.

- 3 In the Model Explorer **Contents** pane, click the data type associated with one of the selected Gain blocks.

Model Explorer displays a pull-down menu with valid data type options.

- 4 In the pull-down menu, enter or select the desired data type, for example, `single`.

Model Explorer specifies the data type of all selected items as `single`.

- “Data Types for Bus Signals” on page 55-37

## Validate a Floating-Point Embedded Model

You can use data type override mode to switch the data types in your model. This capability allows you to maintain one model but simulate and generate code for multiple data types, and also validate the numerical behavior for each type. For example, if you implement an algorithm using double-precision data types and want to check whether the algorithm is also suitable for single-precision use, you can apply a data type override to floating-point data types to replace all doubles with singles without affecting any other data types in your model.

### Apply a Data Type Override to Floating-Point Data Types

To apply a data type override, you must specify the data type that you want to apply and the data type that you want to replace.

You can set a data type override using one of the following methods. In these examples, both methods change all floating-point data types to single.

#### From the Command Line

For example:

```
set_param(gcs, 'DataTypeOverride', 'Single');  
set_param(gcs, 'DataTypeOverrideAppliesTo', 'Floating-point');
```

#### Using the Fixed-Point Tool

For example:

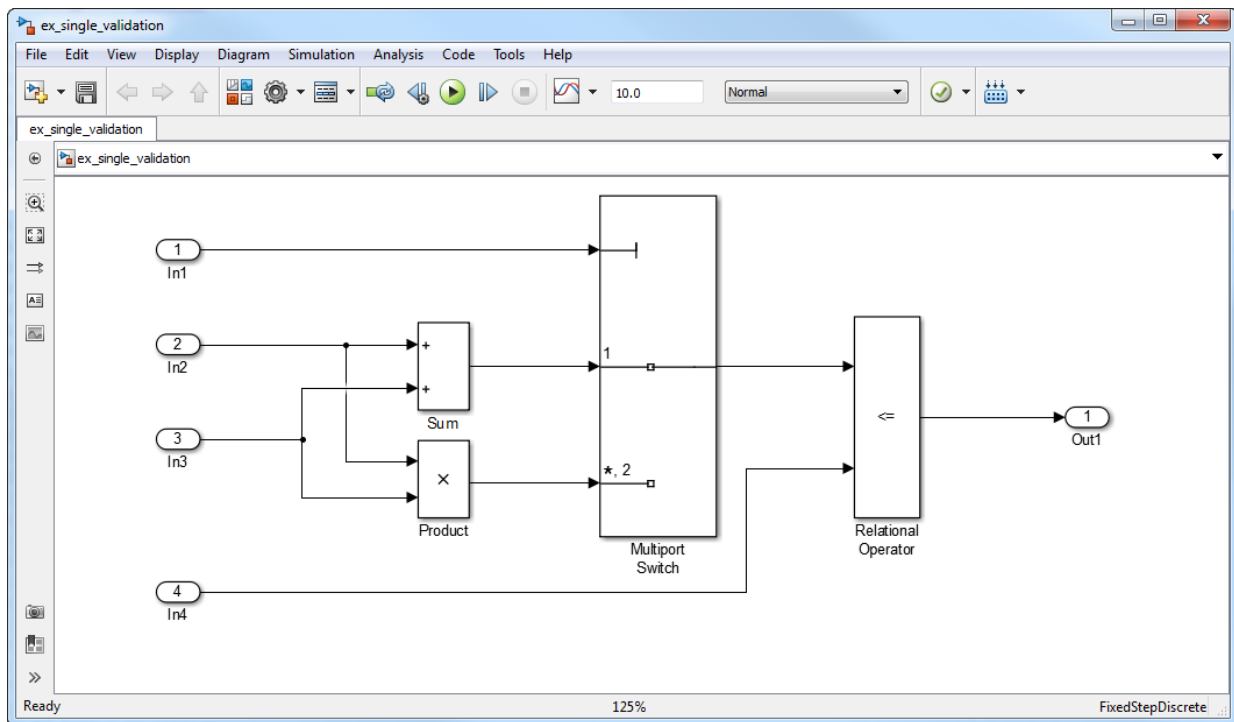

- 1** In the Simulink Editor, select **Analysis > Fixed-Point Tool**.  
  
The Fixed-Point Tool opens.
- 2** Select **View > Show Settings for Selected System**.
- 3** In the Fixed-Point Tool right pane, under **Settings for selected system**:
  - a** Set **Data type override** to **Single**.
  - b** Set **Data type override applies** to **Floating-point**.

For more information on data type override settings, see `fxptdlg`.

## Validate a Single-Precision Model

This example uses the `ex_single_validation` model to show how you can use data type overrides. It proves that an algorithm, which implements double-precision data types, is also suitable for single-precision embedded use.

### About the Model

- The inputs `In2` and `In3` are double-precision inputs to the `Sum` and `Product` blocks.
- The outputs of the `Sum` and `Product` blocks are data inputs to the `Multiport Switch` block.
- The input `In1` is the control input to the `Multiport Switch` block. The value of this control input determines which of its other inputs, the sum of `In2` and `In3` or the product of `In2` and `In3`, passes to the output port. Because `In1` is a control input, its data type is `int8`.

- The **Relational Operator** block compares the output of the **Multiport Switch** block to **In4**, and outputs a Boolean signal.

## Run the Example

### Open the Model

- 1 Open the `ex_single_validation` model. At the MATLAB command line, enter:

```
addpath(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
ex_single_validation
```

### Run Model Advisor Check

- 1 From the model menu, select **Analysis > Model Advisor > Model Advisor**.
- 2 In the System Selector dialog box, click **OK**.

The Model Advisor opens.

- 3 In the Model Advisor, expand the **By Task** node and, under **Modeling Single-Precision Systems**, select the **Identify questionable operations for strict single-precision design** check.
- 4 In the right pane, click **Run This Check**.

The check generates a warning that multiple blocks use double-precision floating-point operations.

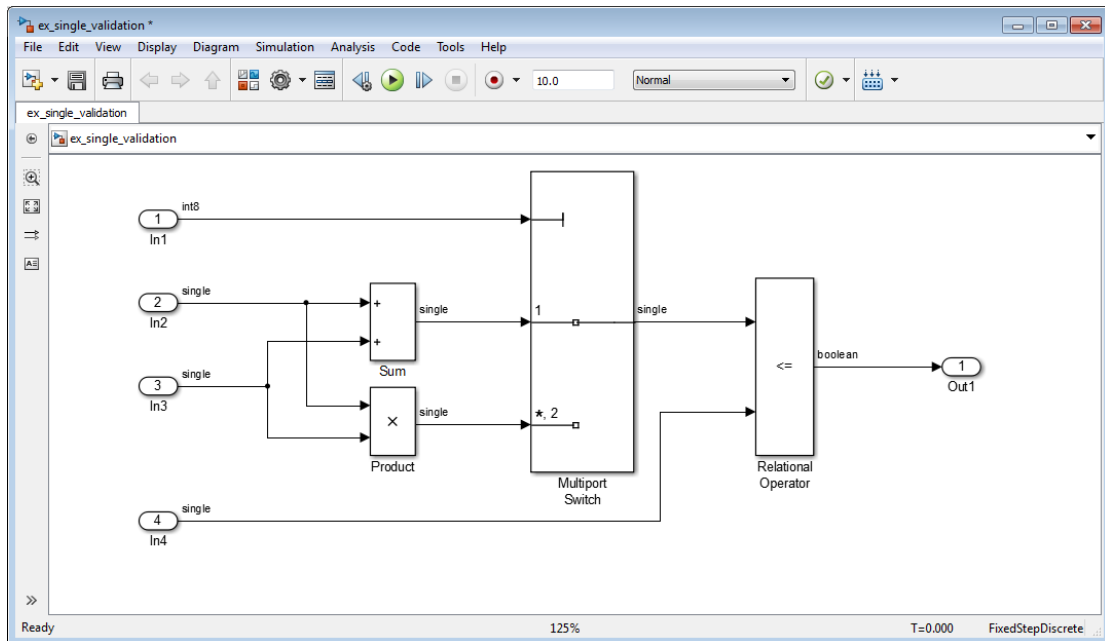

### Override Floating-Point Data Types With Singles

- 1 In the Simulink Editor, select **Analysis > Fixed-Point Tool**.

The Fixed-Point Tool opens.

- 2 In the Fixed-Point Tool right pane, under **Settings for selected system**:
  - a Set **Data type override** to **Single**.
  - b Set **Data type override applies to** **Floating-point**.
  - c Click **Apply**.
- 3 In the model menu, select **Simulation > Update Diagram**.

The data type override replaces all the floating-point (**double**) data types in the model with **single** data types, but does not affect the integer or Boolean data types.

### Re-run the Model Advisor Check

In the Model Advisor, run the **Identify questionable operations for strict single-precision design** check again.

The check passes indicating that this algorithm is suitable for single-precision embedded use.

### More About

- “About Data Types in Simulink” on page 55-2

- “Data Types Supported by Simulink” on page 55-5

## Specify Fixed-Point Data Types

The Simulink software allows you to create models that use fixed-point numbers to represent signals and parameter values. Use of fixed-point data can reduce the memory requirements and increase the speed of code generated from a model.

To execute a model that uses fixed-point numbers, you must have the Fixed-Point Designer product installed on your system. Specifically, you must have the product to:

- Update a Simulink diagram (**Ctrl+D**) containing fixed-point data types
- Run a model containing fixed-point data types
- Generate code from a model containing fixed-point data types
- Log the minimum and maximum values produced by a simulation
- Automatically scale the output of a model using the autoscaling tool

If the Fixed-Point Designer product is not installed on your system, you can execute a fixed-point model as a floating-point model by enabling automatic conversion of fixed-point data to floating-point data during simulation. See “Overriding Fixed-Point Specifications” on page 55-22 for details.

If you do not have the Fixed-Point Designer product installed and do not enable automatic conversion of fixed-point to floating-point data, an error occurs if you try to execute a fixed-point model.

---

**Note:** You do not need the Fixed-Point Designer product to edit a model containing fixed-point blocks, or to use the Data Type Assistant to specify fixed-point data types, as described in “Specifying a Fixed-Point Data Type” on page 55-27.

---

## Overriding Fixed-Point Specifications

Most of the functionality in the Fixed-Point Tool is for use with the Fixed-Point Designer software. However, even if you do not have Fixed-Point Designer software, you can configure data type override settings to simulate a model that specifies fixed-point data types. In this mode, the Simulink software temporarily overrides fixed-point data types with floating-point data types when simulating the model.

---

**Note:** If you use `fi` objects or embedded numeric data types in your model or workspace, you might introduce fixed-point data types into your model. You can set `fipref` to prevent the checkout of a Fixed-Point Designer license.

---

To simulate a model without using Fixed-Point Designer:

- 1 In the **Model Hierarchy** pane, select the root model.
- 2 In the Simulink Editor, select **Analysis > Fixed-Point Tool**.

The Fixed-Point Tool opens.

- 3 In the section **Settings for selected system**:
  - Set **Fixed-point instrumentation mode** to `Force off`.
  - Set **Data type override** to `Double` or `Single`.
  - Set **Data type override applies to All numeric types**.
- 4 If you use `fi` objects or embedded numeric data types in your model, set the `fipref` `DataTypeOverride` property to `TrueDoubles` or `TrueSingles` (to be consistent with the model-wide data type override setting) and the `DataTypeOverrideAppliesTo` property to `All numeric types`.

For example, at the MATLAB command line, enter:

```
p = fipref('DataTypeOverride', 'TrueDoubles', ...  
         'DataTypeOverrideAppliesTo', 'AllNumericTypes');
```

## Specify Data Types Using Data Type Assistant

The **Data Type Assistant** is an interactive graphical tool that simplifies the task of specifying data types for blocks and data objects. The assistant appears on block and object dialog boxes, adjacent to parameters that provide data type control, such as the **Output data type** parameter. For example, it appears on the **Signal Attributes** pane of the Constant block dialog box shown here.

You can selectively show or hide the **Data Type Assistant** by clicking the applicable button:

- Click the **Show data type assistant** button  to display the assistant.
- Click the **Hide data type assistant** button  to hide a visible assistant.

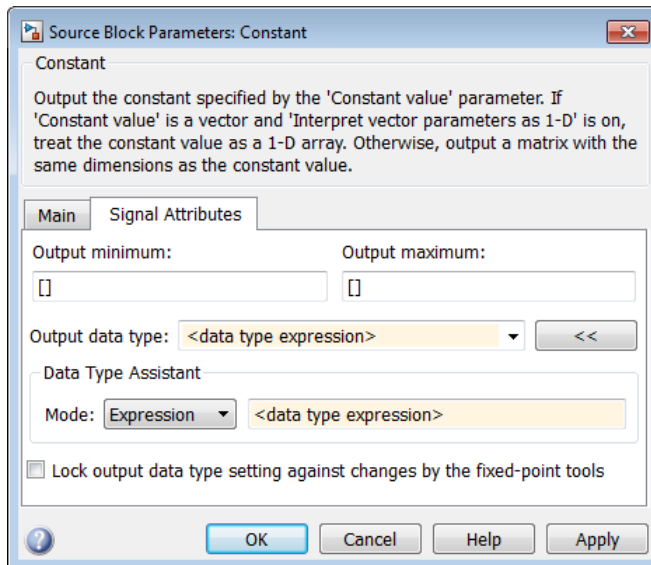

Use the **Data Type Assistant** to specify a data type as follows:

- 1 In the **Mode** field, select the category of data type that you want to specify. In general, the options include the following:

| Mode        | Description                             |
|-------------|---|
| Inherit     | Inheritance rules for data types        |
| Built in    | Built-in data types                     |
| Fixed point | Fixed-point data types                  |
| Enumerated  | Enumerated data types                   |
| Bus object  | Bus object data types                   |
| Expression  | Expressions that evaluate to data types |

The assistant changes dynamically to display different options that correspond to the selected mode. For example, setting **Mode** to **Expression** causes the Constant block dialog box to appear as follows.

- 2 In the field that is to the right of the **Mode** field, select or enter a data type.

For example, suppose that you designate the variable `myDataType` as an alias for a single data type. You create an instance of the `Simulink.AliasType` class and set its `BaseType` property by entering the following commands:

```
myDataType = Simulink.AliasType
```

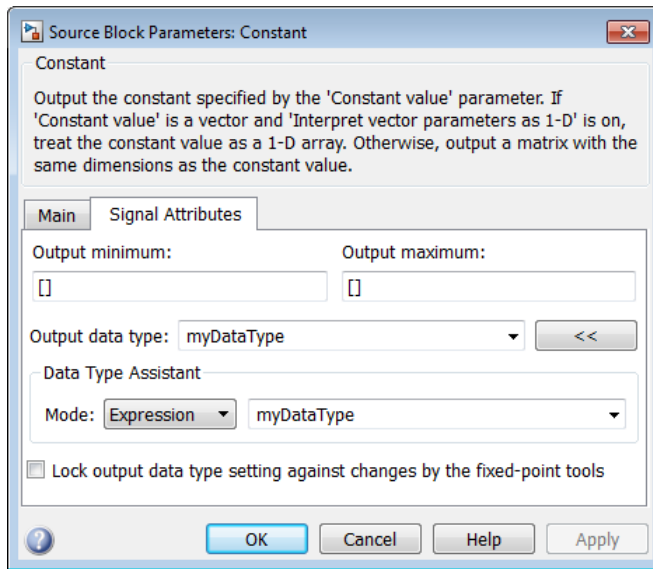

```
myDataType.BaseType = 'single'
```

You can use this data type object to specify the output data type of a Constant block. Enter the data type alias name, `myDataType`, as the value of the expression in the assistant.

- 3 Click the **OK** or **Apply** button to apply your changes.

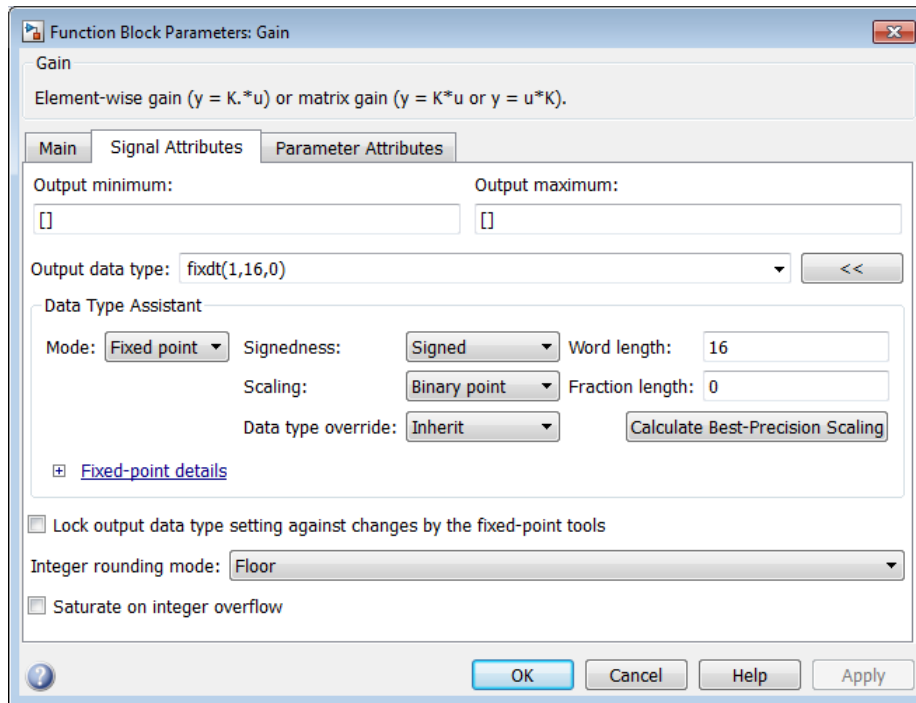

The assistant uses the data type that you specified to populate the associated data type parameter in the block or object dialog box. In the following example, the **Output data type** parameter of the Constant block specifies the same expression that you entered using the assistant.

For more information about the data types that you can specify using the **Data Type Assistant**, see “Entering Valid Data Type Values” on page 55-9. For details about specifying fixed-point data types, see “Specify Fixed-Point Data Types with the Data Type Assistant”.

## Specifying a Fixed-Point Data Type

When the Data Type Assistant **Mode** is **Fixed point**, the Data Type Assistant displays fields for specifying information about your fixed-point data type. For a detailed discussion about fixed-point data, see “Fixed-Point Basics”. For example, the next figure shows the Block Parameters dialog box for a Gain block, with the **Signal Attributes** tab selected and a fixed-point data type specified.

If the **Scaling** is **Slope** and **bias** rather than **Binary point**, the Data Type Assistant displays a **Slope** field and a **Bias** field rather than a **Fraction length** field:

You can use the Data Type Assistant to set these fixed-point properties:

## Signedness

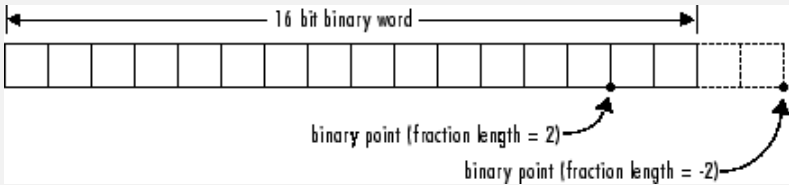

Specify whether you want the fixed-point data to be **Signed** or **Unsigned**. Signed data can represent positive and negative values, but unsigned data represents positive values only. The default setting is **Signed**.

## Word length

Specify the bit size of the word that will hold the quantized integer. Large word sizes represent large values with greater precision than small word sizes. Word length can be any integer between 0 and 32. The default bit size is 16.

## Scaling

Specify the method for scaling your fixed-point data to avoid overflow conditions and minimize quantization errors. The default method is **Binary point** scaling. You can select one of two scaling modes:

| Scaling Mode   | Description  |
|----------------|--|
| Binary point   | <p>If you select this mode, the Data Type Assistant displays the <b>Fraction Length</b> field, which specifies the binary point location.</p> <p>Binary points can be positive or negative integers. A positive integer moves the binary point left of the rightmost bit by that amount. For example, an entry of 2 sets the binary point in front of the second bit from the right. A negative integer moves the binary point further right of the rightmost bit by that amount, as in this example:</p>  <p>The default binary point is 0.</p> |
| Slope and bias | <p>If you select this mode, the Data Type Assistant displays fields for entering the <b>Slope</b> and <b>Bias</b>.</p> <p>Slope can be any positive real number, and the default slope is 1.0. Bias can be any real number, and the default bias is 0.0. You can enter</p>   |

| Scaling Mode | Description   |
|--------------|---|
|              | slope and bias as expressions that contain parameters you define in the MATLAB workspace. |

---

**Note** Use binary-point scaling whenever possible to simplify the implementation of fixed-point data in generated code. Operations with fixed-point data using binary-point scaling are performed with simple bit shifts and eliminate expensive code implementations, which are required for separate slope and bias values.

---

For more information about fixed-point scaling, see “Scaling”.

### Data type override

When the **Mode** is **Built in** or **Fixed point**, you can use the **Data type override** option to specify whether you want this data type to inherit or ignore the data type override setting specified for its context, that is, for the block, `Simulink.Signal` object or Stateflow chart in Simulink that is using the signal. The default behavior is **Inherit**.

| Data Type Override Mode | Description   |
|-------------------------|---|
| Inherit (default)       | Inherits the data type override setting from its context, that is, from the block, <code>Simulink.Signal</code> object or Stateflow chart in Simulink that is using the signal. |
| Off                     | Ignores the data type override setting of its context and uses the fixed-point data type specified for the signal.  |

The ability to turn off data type override for an individual data type provides greater control over the data types in your model when you apply data type override. For example, you can use this option to ensure that data types meet the requirements of downstream blocks regardless of the data type override setting.

### Calculate Best-Precision Scaling

Click this button to calculate best-precision values for both **Binary point** and **Slope and bias** scaling, based on the specified minimum and maximum values. The Simulink software displays the scaling values in the **Fraction Length** field or the **Slope** and **Bias** fields. For more information, see “Constant Scaling for Best Precision”.

## Showing Fixed-Point Details

When you specify a fixed-point data type, you can use the **Fixed-point details** subpane to see information about the fixed-point data type that is currently displayed in the Data Type Assistant. To see the subpane, click the expander next to **Fixed-point details** in the Data Type Assistant. The **Fixed-point details** subpane appears at the bottom of the Data Type Assistant:

Output minimum:  Output maximum:

Output data type:  <<

Data Type Assistant

Mode:  Signedness:  Word length:

Scaling:  Slope:

Bias:

Data type override:

[Fixed-point details](#)

|                        |                                 |
|------------------------|---------------------------------|
| Representable maximum: | 32767                           |
| Output maximum:        | <input type="text" value="[]"/> |
| Constant value:        | 90                              |
| Output minimum:        | <input type="text" value="[]"/> |
| Representable minimum: | -32768                          |

Precision:

The rows labeled **Output minimum** and **Output maximum** show the same values that appear in the corresponding **Output minimum** and **Output maximum** fields above the Data Type Assistant. The names of these fields may differ from those shown. For example, a fixed-point block parameter would show **Parameter minimum** and **Parameter maximum**, and the corresponding **Fixed-point details** rows would be labeled accordingly. See “Signal Ranges” on page 60-41 and “Check Parameter Values” on page 32-14 for more information.

The rows labeled **Representable minimum**, **Representable maximum**, and **Precision** always appear. These rows show the minimum value, maximum value, and precision that can be represented by the fixed-point data type currently displayed in the Data Type Assistant. For information about these three quantities, see “Fixed-Point Basics”.

The values displayed by the **Fixed-point details** subpane *do not* automatically update if you click **Calculate Best-Precision Scaling**, or change the range limits, the values that define the fixed-point data type, or anything elsewhere in the model. To update the values shown in the **Fixed-point details** subpane, click **Refresh Details**. The Data Type Assistant then updates or recalculates all values and displays the results.

Clicking **Refresh Details** does not change anything in the model, it only changes the display. Click **OK** or **Apply** to put the displayed values into effect. If the value of a field cannot be known without first compiling the model, the **Fixed-point details** subpane shows the value as **Unknown**.

If any errors occur when you click **Refresh Details**, the **Fixed-point details** subpane shows an error flag on the left of the applicable row, and a description of the error on the right. For example, the next figure shows two errors:

Output minimum:  Output maximum:

Output data type:  <<

Data Type Assistant

Mode:  Signedness:  Word length:

Scaling:  Fraction length:

Data type override:

[Fixed-point details](#)

|                        |          |  |
|------------------------|----------|--|
| Representable maximum: | 32767    |  |
| Output maximum:        | 50000    | Outside representable range by 17233 (17233 x precision) |
| Output minimum:        | MySymbol | Cannot evaluate  |
| Representable minimum: | -32768   |  |

Precision:

The row labeled **Output minimum** shows the error **Cannot evaluate** because evaluating the expression **MySymbol**, specified in the **Output minimum** field, did not return an appropriate numeric value. When an expression does not evaluate successfully, the **Fixed-point details** subpane displays the unevaluated expression (truncating to 10 characters if necessary to save space) in place of the unavailable value.

To correct the error in this case, you would need to define **MySymbol** in an accessible workspace to provide an appropriate numeric value. After you clicked **Refresh Details**,

the value of `MySymbol` would appear in place of its unevaluated text, and the error indicator and error description would disappear.

To correct the error shown for `Output maximum`, you would need to decrease **Output maximum**, increase **Word length**, or decrease **Fraction length** (or some combination of these changes) sufficiently to allow the fixed-point data type to represent the maximum value that it could have.

Other values relevant to a particular block can also appear in the **Fixed-point details** subpane. For example, on a Discrete-Time Integrator block's **Signal Attributes** tab, the subpane could look like this:

|                          |                                     |
|--------------------------|-------------------------------------|
| <input type="checkbox"/> | <a href="#">Fixed-point details</a> |
| Representable maximum:   | 32767                               |
| Output maximum:          | <input type="checkbox"/>            |
| Upper saturation limit:  | inf                                 |
| Initial condition:       | 1 .. 4                              |
| Lower saturation limit:  | -inf                                |
| Output minimum:          | <input type="checkbox"/>            |
| Representable minimum:   | -32768                              |
| Precision:               | 1                                   |

Note that the values displayed for `Upper saturation limit` and `Lower saturation limit` are greyed out. This appearance indicates that the corresponding parameters are not currently used by the block. The greyed-out values can be ignored.

Note also that `Initial condition` displays the value `1 .. 4`. The actual value is a vector or matrix whose smallest element is 1 and largest element is 4. To conserve space, the **Fixed-point details** subpane shows only the smallest and largest element of a vector or matrix. An ellipsis (`..`) replaces the omitted values. The underlying definition of the vector or matrix is unaffected.

### Lock output data type setting against changes by the fixed-point tools

Select this check box to prevent replacement of the current data type with a type that the Fixed-Point Tool or Fixed-Point Advisor chooses. For instructions on autoscaling fixed-point data, see “Scaling”.

## Specify an Enumerated Data Type

You can specify an enumerated data type by selecting the **Enum: <class name>** option and specify an enumerated object.

In the **Data Type Assistant**, you can use the **Mode** parameter to specify a bus as a data object for a block. Select the **Enumerated** option and specify an enumerated object.

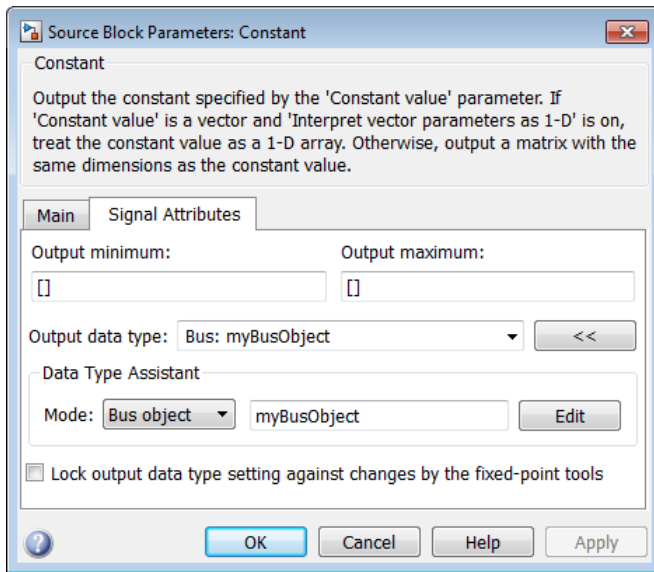

For details about enumerated data types, see “Data Types”.

## Specify a Bus Object Data Type

The blocks listed in the section called “Data Types for Bus Signals” on page 55-37 support your specifying a bus object as a data type. For those blocks, in the **Data type** parameter, select the **Bus: <object name>** option and specify a bus object. You cannot use the **Expression** option to specify a bus object as a data type for a block.

In the **Data Type Assistant**, you can use the **Mode** parameter to specify a bus as a data object for a block. Select the **Bus** option and specify a bus object.

You can specify a bus object as the data type for data objects such as `Simulink.Signal`, `Simulink.Parameter`, and `Simulink.BusElement`. In the Model Explorer, in Properties dialog box for a data object, in the **Data type** parameter, select the **Bus: <object name>** option and specify a bus object. You can also use the **Expression** option to specify a bus object.

For more information on specifying a bus object data type, see “Associating Bus Objects with Simulink Blocks” on page 61-24

- “Data Types for Bus Signals” on page 55-37

## Data Types for Bus Signals

A bus object (`Simulink.Bus`) specifies the architectural properties of a bus, as distinct from the values of the signals it contains. For example, a bus object can specify the number of elements in a bus, the order of those elements, whether and how elements are nested, and the data types of constituent signals; but not the signal values.

You can specify a bus object as a data type for the following blocks:

- Bus Creator
- Constant
- Data Store Memory
- Inport
- Outport
- Signal Specification

You can specify a bus object as a data type for the following classes:

- `Simulink.BusElement`
- `Simulink.Parameter`
- `Simulink.Signal`

See “Specify a Bus Object Data Type” on page 55-34 for information about how to specify a bus object as a data type for blocks and classes.

You can create *data objects* to specify values, value ranges, data types, tunability, and other characteristics of signals, states, and block parameters. You use the object names in Simulink dialog boxes to specify signal, state, and parameter characteristics. The objects exist in a workspace such as the base workspace, a model workspace, or a Simulink data dictionary. Data objects allow you to make model-wide changes to signal, state, and parameter characteristics by changing only the values of workspace objects.

You create data objects as instances of data classes. Memory structures called *data class packages* contain the data class definitions. The built-in package `Simulink` defines two data classes, `Simulink.Signal` and `Simulink.Parameter`, that you can use to create data objects.

You can customize data object properties and methods by defining subclasses of the built-in data classes. For more information about creating a data class package, see “Define Data Classes” on page 55-56.

## Data Class Naming Conventions

Simulink uses dot notation to name data classes:

*package.class*

- *package* is the name of the package that contains the class definition.
- *class* is the name of the class.

This notation allows you to create and reference identically named classes that belong to different packages. In this notation, the name of the package *qualifies* the name of the class.

Class and package names are case sensitive. For example, you cannot use `MYPACKAGE.MYCLASS` and `mypackage.myClass` interchangeably to refer to the same class.

## Use Data Objects in Simulink Models

To specify simulation and code generation options for signals, block parameters, and states by modifying variables in a workspace or data dictionary, use data objects. Associate the objects with signals, parameters, and states in a model diagram.

### Use Parameter Objects

You can use parameter objects, instead of numeric MATLAB variables, to specify values for block parameters. For example, to create and use a `Simulink.Parameter` object to specify the **Gain** parameter of a Gain block:

- 1 Create a parameter object. For example, create an object using the built-in package `Simulink`.

```
myParam = Simulink.Parameter;
```

- 2 Assign a numeric value to the `Value` property.

```
myParam.Value = 15.23;
```

- 3 Specify other characteristics for the block parameter by adjusting the object properties. For example, to specify the parameter data type as `single`, use the `DataType` object property.

```
myParam.DataType = 'single';
```

- 4 In a block dialog box, specify the value of a parameter as `myParam`. For example, in a Gain block dialog box, specify **Gain** as `myParam`.

During simulation, the **Gain** parameter uses the value `single(15.23)`.

### Use Signal Objects

To use a signal object to control the characteristics of a signal in a model, create the object in a workspace by using the same name as the signal.

- 1 Create a `Simulink.Signal` object. For example, create an object using the built-in package `Simulink`.

```
mySig = Simulink.Signal;
```

- 2 Specify the signal characteristics by adjusting the object properties. For example, to specify the signal data type as `boolean`, use the `DataType` object property.

```
mySig.DataType = 'boolean';
```

- 3 In the Signal Properties dialog box for the signal in the model, specify **Signal name** as `mySig`. Click **Apply**.

- 4 Select the check box next to **Signal name must resolve to Simulink signal object**.

This option forces the model signal to use the properties that the signal object `mySig` defines. To learn how to control the way that signal names resolve to signal objects, see “Symbol Resolution” on page 4-95.

You can use a signal object to control the characteristics of a block state, such as that of the Discrete-Time Integrator block.

- 1 Create a `Simulink.Signal` object. For example, create an object using the built-in package `Simulink`.

```
myState = Simulink.Signal;
```

- 2 Specify the state characteristics by adjusting the object properties. For example, to specify the state data type as `int16`, use the `DataType` object property.

```
myState.DataType = 'int16';
```

- 3 In a block dialog box, on the **State Attributes** tab, specify **State name** as `myState`. Click **Apply**.

- 4 Select the check box next to **State name must resolve to Simulink signal object**.

## Data Object Properties

To control parameter and signal characteristics using data objects, you specify values for the data object properties. For example, parameter and signal data objects have a **Data Type** property that determines the data type of the target block parameter or signal. Data class definitions determine the names, value types, default values, and valid value ranges of data object properties.

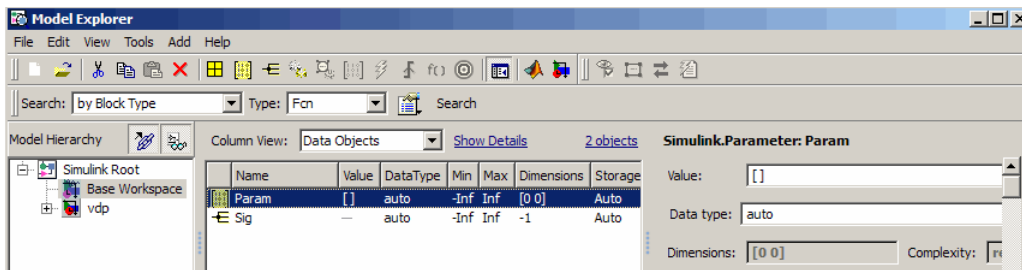

You can use either the Model Explorer or MATLAB commands to change a data object's properties.

For a list of signal object properties, see `Simulink.Signal`. For a list of parameter object properties, see `Simulink.Parameter`.

### Use the Model Explorer to Change an Object's Properties

To use the Model Explorer to change an object's properties, select the workspace that contains the object in the Model Explorer's **Model Hierarchy** pane. Then select the object in the Model Explorer's **Contents** pane.

The Model Explorer displays the object's property dialog box in its **Dialog** pane (if the pane is visible).

You can configure the Model Explorer to display some or all of the properties of an object in the **Contents** pane (see “Model Explorer: Contents Pane” on page 11-19). To edit a property, click its value in the **Contents** or **Dialog** pane. The value is replaced by a control that allows you to change the value.

### Use MATLAB Commands to Change an Object's Properties

You can also use MATLAB commands to get and set data object properties. Use the following dot notation in MATLAB commands and programs to get and set a data object's properties:

```
value = obj.property;  
obj.property = value;
```

where *obj* is a variable that references either the object if it is an instance of a value class or a handle to the object if the object is an instance of a handle class (see “Handle Versus Value Classes” on page 55-52), **PROPERTY** is the property's name, and **VALUE** is the property's value. For example, the following MATLAB code creates a data type alias object (i.e., an instance of `Simulink.AliasType`) and sets its base type to `uint8`:

```
gain = Simulink.AliasType;  
gain.BaseType = 'uint8';
```

You can use dot notation recursively to get and set the properties of objects that are values of other object's properties, e.g.,

```
gain.CoderInfo.StorageClass = 'ExportedGlobal';
```

## Create Parameter Object with Specific Numeric Data Type

To create a parameter object that uses a specific numeric data type, specify the **Value** property using a double number. Specify the **DataType** property using a string. Simulation and code generation cast that number in the **Value** property to the numeric data type that you specify in the **DataType** property.

For example, this code creates a parameter object `myParam` with numeric value `18.25` and numeric data type `single`.

```
myParam = Simulink.Parameter;  
myParam.Value = 18.25;  
myParam.DataType = 'single';
```

## Create Data Objects from Built-In Data Class Package Simulink

The built-in package `Simulink` defines two data object classes `Simulink.Parameter` and `Simulink.Signal`. You can create these data objects using the user interface or programmatically.

### Create Data Objects

- 1 In the Model Explorer **Model Hierarchy** pane, select a workspace to contain the data objects. For example, click **Base Workspace**.

- 2 On the toolbar, click the arrow next to Add Parameter  or Add Signal . From the drop-down list, select **Simulink Parameter** or **Simulink Signal**.

A parameter or signal object appears in the base workspace. The default name for new parameter objects is `Param`. The default name for new signal objects is `Sig`.

- 3 To create more objects, click Add Parameter or Add Signal.

### Programmatically Create Data Objects

```
% Create a Simulink.Parameter object named myParam whose value is 15.23.
myParam = Simulink.Parameter(15.23);
```

```
% Create a Simulink.Signal object named mySig.
mySig = Simulink.Signal;
```

## Create Data Objects from Another Data Class Package

You can create your own package to define custom data object classes that subclass `Simulink.Parameter` and `Simulink.Signal`. You can use this technique to add your own properties and methods to data objects. If you have an Embedded Coder license, you can define custom storage classes and memory sections in the package. For more information about creating a data class package, see “Define Data Classes” on page 55-56.

### Create Data Objects from Another Package

Suppose that you define a data class package called `myPackage`. Before you can create data objects from the package, you must include the package folder on your MATLAB path.

- 1 In the Model Explorer **Model Hierarchy** pane, select a workspace to contain the data objects. For example, click `Base Workspace`.
- 2 Click the arrow next to Add Parameter  or Add Signal  and select **Customize class lists**.
- 3 In the dialog box, select the check box next to the class that you want. For example, select the check boxes next to `myPackage.Parameter` and `myPackage.Signal`. Click **OK**.
- 4 Click the arrow next to Add Parameter or Add Signal. Select the class for the data object that you want to create. For example, select **myPackage Parameter** or **myPackage Signal**.

A parameter or signal object appears in the base workspace. The default name for new parameter objects is `Param`. The default name for new signal objects is `Sig`.

- 5 To create more data objects from the package `myPackage`, click **Add Parameter** or **Add Signal** again.

### Programmatically Create Data Objects from Another Package

Suppose that you define a data class package called `myPackage`. Before you can create data objects from the package, you must include the package folder on your MATLAB path.

```
% Create a myPackage.Parameter object named myParam whose value is 15.23.  
myParam = myPackage.Parameter(15.23);
```

```
% Create a myPackage.Signal object named mySig.  
mySig = myPackage.Signal;
```

### Create Data Objects Directly from Dialog Boxes

When you open a Signal Properties dialog box or a block dialog box, you can efficiently create a signal or parameter data object in a workspace or data dictionary.

#### Create Parameter Object from Block Dialog Box

- 1 In a numeric block parameter in the dialog box, specify the name that you want for the data object. For example, specify the name `myParam`.
- 2 Right-click the block parameter edit field. Select **Create Variable**.
- 3 In the **Create New Data** dialog box, specify **Value** as `Simulink.Parameter`.

Alternatively, you can specify the name of a data class that you created, such as `myPackage.Parameter`. You can also use the drop-down list to select from a list of available data object classes.

- 4 Specify **Location** as **Base Workspace** and click **Create**.

You can use the **Location** option to select a workspace to contain the new data object. If a model is linked to a data dictionary, you can choose to create a data object in the dictionary.

- 5 In the dialog box that opens, configure the data object properties. Specify a numeric value for the parameter in the **Value** box. Click **OK**.

The parameter object `myParam` appears in the base workspace.

- 6 In the block parameter dialog box, click **OK**.

### Create Signal Object from Signal Properties Dialog Box

- 1 In the **Signal name** box, specify a signal name such as `mySig`. Click **Apply**.
- 2 Right-click the **Signal name** edit field. Select **Create Variable**.
- 3 In the **Create New Data** dialog box, specify **Value** as `Simulink.Signal`.

Alternatively, you can specify the name of a data class that you created, such as `myPackage.Signal`. Also, from the drop-down list, you can select a data object class that exists on the MATLAB path.

- 4 Specify **Location** as **Base Workspace** and click **Create**.

You can use the **Location** option to select a workspace to contain the new data object. If a model is linked to a data dictionary, you can choose to create a data object in the dictionary.

- 5 In the dialog box that opens, configure the data object properties and click **OK**.

The signal object `mySig` appears in the base workspace.

- 6 In the Signal Properties dialog box, select the check box next to **Signal name must resolve to Simulink signal object** and click **OK**.

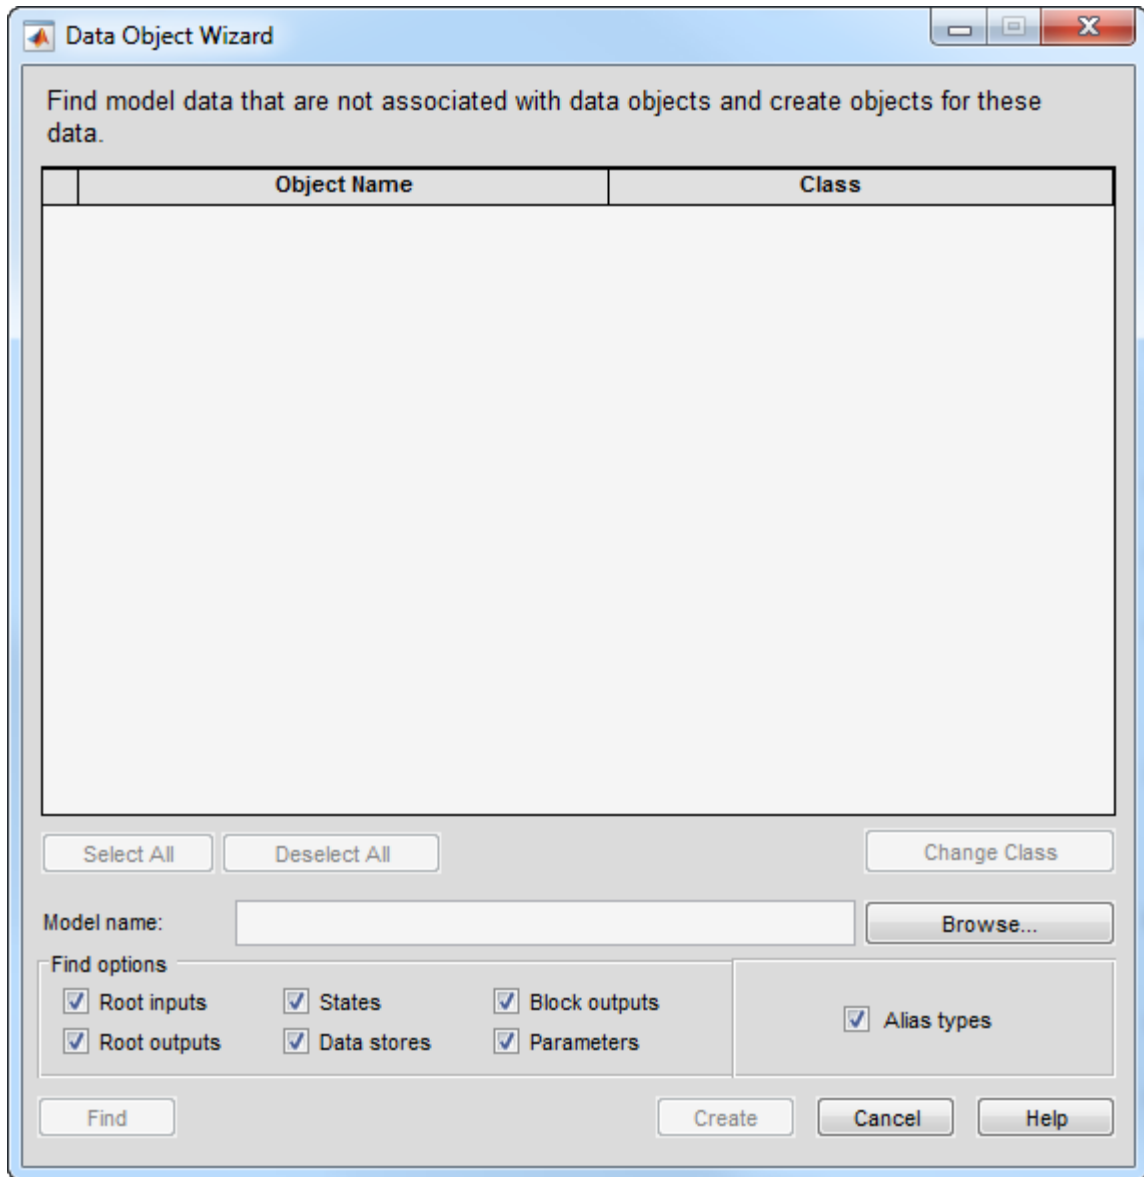

## Create Data Objects for a Model Using Data Object Wizard

To create data objects that represent signals, parameters, and states in a model, you can use the Data Object Wizard. The wizard finds data in the model that do not have corresponding data objects.

Based on specifications in the model, the wizard creates the objects and assigns these characteristics:

- Signal, parameter, or state name.
- Numeric value for parameter objects.
- Data type. For signal objects, includes alias types such as `SumLink.AliasType` and `Simulink.NumericType`.

- 1 In the Simulink Editor, select **Code > Data Objects > Data Object Wizard**.

- 2 In the **Model name** box, enter the name of the model that you want to search.

By default, the box contains the name of the model from which you opened the wizard.

- Under **Find options**, select the check boxes next to the data object types that you want to create. The table describes the options.

| Option               | Description   |
|----------------------|---|
| <b>Root inputs</b>   | Named signals from root-level Inport blocks.  |
| <b>Root outputs</b>  | Named signals from root-level Outport blocks.   |
| <b>States</b>        | States associated with these discrete blocks:<br>Discrete Filter<br>Discrete State-Space<br>Discrete-Time Integrator<br>Discrete Transfer Fcn<br>Discrete Zero-Pole<br>Memory<br>PID Controller<br>PID Controller (2DOF)<br>Unit Delay  |
| <b>Data stores</b>   | Data stores. For more information about data stores, see “Local and Global Data Stores” on page 58-2 .  |
| <b>Block outputs</b> | Named signals whose sources are non-root-level blocks.  |
| <b>Parameters</b>    | <ul style="list-style-type: none"> <li>Numeric parameters, for example the parameters in these blocks:<br/>Constant<br/>Gain<br/>Relay</li> <li>Stateflow data with <b>Scope</b> set to <b>Parameter</b>.</li> </ul> <p>For more information, see “Share Simulink Parameters with Charts” in the Stateflow documentation.</p> |
| <b>Alias types</b>   | Data type replacement names that you specify in <b>Configuration Parameters &gt; Code Generation &gt; Data Type Replacement</b> . If you have an Embedded Coder license, the Data Object Wizard creates <code>Simulink.AliasType</code> objects for these data type replacement names. For more information about data type   |

| Option | Description   |
|--------|---|
|        | replacement, see “Data Type Replacement” in the Embedded Coder documentation. |

- 4 Click **Find**.

The data object table displays the proposed objects.

- 5 (Optional) To create objects from a data class other than the default classes, select the check box next to the objects whose class you want to change. To select all of the objects, click **Select All**. Click **Change Class**. In the dialog box that opens, select classes by using the drop-down lists next to **Parameter** and **Signal**.

If the classes that you want do not appear in the drop-down list, select **Customize class lists**. In the dialog box that opens, select the check box next to the classes that you want, and click **OK**.

To change the default parameter and signal classes that the wizard uses to propose objects:

- On the Model Explorer **Model Hierarchy** pane, select a workspace. For example, select **Base Workspace**.
- On the toolbar, click the arrow next to Add Parameter  or Add Signal .
- From the drop-down list, select the class that you want the wizard to use. For example, select **myPackage Parameter** or **myPackage Signal**.

A parameter or signal object appears in the selected workspace. The default name for new parameter objects is `Param`. The default name for new signal objects is `Sig`.

The next time that you use the Data Object Wizard, the wizard proposes objects using the parameter or signal class that you selected in Model Explorer.

- 6 Select the check box next to the proposed objects that you want to create. To select all of the proposed objects, click **Select All**.
- 7 Click **Create**.

The data objects appear in the base workspace. If the target model is linked to a data dictionary, the objects appear in the dictionary.

The wizard changes settings in your model depending on the configuration parameter **Configuration Parameters > Diagnostics > Data Validity > Signal resolution**.

- If you set the parameter to `Explicit only`, the wizard forces the corresponding signals in your model to resolve to the new signal objects. The wizard selects the option **Signal name must resolve to Simulink signal object** in each Signal Properties dialog box.
- If you set the parameter to `Explicit and implicit` or `Explicit and warn implicit`, the wizard does not change the setting of **Signal name must resolve to Simulink signal object** for any signals.

Consider turning off implicit signal object resolution for your model by using the function `disableimplicitresolution`. For more information, see “Explicit and Implicit Symbol Resolution” on page 4-98.

## Data Object Wizard Troubleshooting

The Data Object Wizard does not suggest creation of data objects for these entities in a model:

- Multiple separate signals that have the same name
- Signal with the same name as a variable used in a block parameter
- Signal that lacks a single contiguous source block
- Signal whose source block is commented out or commented through

## Create Data Objects from External Data Source Programmatically

This example shows how to create data objects based on an external data source (such as a Microsoft Excel file) by using a script.

- 1 Create a new `.m` script file.
- 2 Place information in the file that describes the data in the external file that you want to convert to data objects. For example, the following information creates two Simulink data objects with the indicated properties. The first is for a parameter and the second is for a signal:

```
% Parameters
ParCon = Simulink.Parameter;
ParCon.StorageClass = 'Custom'
ParCon.CoderInfo.CustomStorageClass = 'Const';
ParCon.Value = 3;
% Signals
SigGlb = Simulink.Signal;
SigGlb.DataType = 'int8';
```

- 3 Run the `.m` file. The data objects appear in the MATLAB workspace.

If you want to import the target data from the external source, you can write MATLAB functions and scripts that read the information, convert the information to data objects, and load the objects into the base workspace.

You can use these functions to interact with files that are external to MATLAB:

- `xmlread`
- `xmlwrite`
- `xlsread`

- `xlswrite`
- `csvread`
- `csvwrite`
- `dlmread`
- `dlmwrite`

## Data Object Methods

Data classes define functions, called methods, for creating and manipulating the objects that they define. A class may define any of the following kinds of methods.

### Dynamic Methods

A dynamic method is a method whose identity depends on its name and the class of an object specified implicitly or explicitly as its first argument. You can use either function or dot notation to specify this object, which must be an instance of the class that defines the method or an instance of a subclass of the class that defines the method. For example, suppose class `A` defines a method called `setName` that assigns a name to an instance of `A`. Further, suppose the MATLAB workspace contains an instance of `A` assigned to the variable `obj`. Then, you can use either of the following statements to assign the name `'foo'` to `obj`:

```
obj.setName('foo');  
setName(obj, 'foo');
```

A class may define a set of methods having the same name as a method defined by one of its super classes. In this case, the method defined by the subclass overrides the behavior of the method defined by the parent class. The Simulink software determines which method to invoke at runtime from the class of the object that you specify as its first or implicit argument. Hence, the term dynamic method.

---

**Note:** Most Simulink data object methods are dynamic methods. Unless the documentation for a method specifies otherwise, you can assume that a method is a dynamic method.

---

### Static Methods

A static method is a method whose identity depends only on its name and hence cannot change at runtime. To invoke a static method, use its fully qualified name,

which includes the name of the class that defines it followed by the name of the method itself. For example, `Simulink.ModelAdvisor` class defines a static method named `getModelAdvisor`. The fully qualified name of this static method is `Simulink.ModelAdvisor.getModelAdvisor`. The following example illustrates invocation of a static method.

```
ma = Simulink.ModelAdvisor.getModelAdvisor('vdp');
```

### Constructors

Every data class defines a method for creating instances of that class. The name of the method is the same as the name of the class. For example, the name of the `Simulink.Parameter` class's constructor is `Simulink.Parameter`. The constructors defined by Simulink data classes take no arguments.

The value returned by a constructor depends on whether its class is a handle class or a value class. The constructor for a handle class returns a handle to the instance that it creates if the class of the instance is a handle class; otherwise, it returns the instance itself (see “Handle Versus Value Classes” on page 55-52).

## Handle Versus Value Classes

Simulink classes, including data object classes, fall into two categories: value classes and handle classes.

### About Value Classes

The constructor for a *value* class (see “Constructors” on page 55-52) returns an instance of the class and the instance is permanently associated with the MATLAB variable to which it is initially assigned. Reassigning or passing the variable to a function causes MATLAB to create and assign or pass a copy of the original object.

For example, `Simulink.NumericType` is a value class. Executing the following statements

```
>> x = Simulink.NumericType;  
>> y = x;
```

creates two instances of class `Simulink.NumericType` in the workspace, one assigned to the variable `x` and the other to `y`.

## About Handle Classes

The constructor for a *handle* class returns a handle object. The handle can be assigned to multiple variables or passed to functions without causing a copy of the original object to be created. For example, `Simulink.Parameter` class is a handle class. Executing

```
>> x = Simulink.Parameter;  
>> y = x;
```

creates only one instance of `Simulink.Parameter` class in the MATLAB workspace. Variables `x` and `y` both refer to the instance via its handle.

A program can modify an instance of a handle class by modifying any variable that references it, e.g., continuing the previous example,

```
>> x.Description = 'input gain';  
>> y.Description
```

```
ans =  
input gain
```

Most Simulink data object classes are value classes. Exceptions include `Simulink.Signal` and `Simulink.Parameter` class.

You can determine whether a variable is assigned to an instance of a class or to a handle to that class by displaying the variable at the MATLAB command line. MATLAB appends the text (*handle*) to the name of the object class in the value display, e.g.,

```
>> gain = Simulink.Parameter  
  
gain =  
  
Simulink.Parameter (handle)  
    Value: []  
    CoderInfo: [1x1 Simulink.CoderInfo]  
Description: ''  
    DataType: 'auto'  
        Min: []  
        Max: []  
    DocUnits: ''  
    Complexity: 'real'  
    Dimensions: [0 0]
```

## Copy Handle Classes

Use the `copy` method of a handle class to create copies of instances of that class. For example, `Simulink.ConfigSet` is a handle class that represents model configuration sets. The following code creates a copy of the current model's active configuration set and attaches it to the model as an alternate configuration geared to model development.

```
activeConfig = getActiveConfigSet(gcs);
develConfig = copy(activeConfig);
develConfig.Name = 'develConfig';
attachConfigSet(gcs, develConfig);
```

## Compare Data Objects

Simulink data objects provide a method, named `isequal`, that determines whether object property values are equal. This method compares the property values of one object with those belonging to another object and returns true (1) if all of the values are the same or false (0) otherwise. For example, the following code instantiates two signal objects (A and B) and specifies values for particular properties.

```
A = Simulink.Signal;
B = Simulink.Signal;
A.DataType = 'int8';
B.DataType = 'int8';
A.InitialValue = '1.5';
B.InitialValue = '1.5';
```

Afterward, use the `isequal` method to verify that the object properties of A and B are equal.

```
>> result = isequal(A,B)
```

```
result =
```

```
1
```

## Save and Load Data Objects

You can use the `save` command to save data objects in a MAT-file and the `load` command to restore them to the MATLAB workspace in the same or a later session. Definitions of the classes of saved objects must exist on the MATLAB path for them to be restored. If the class of a saved object acquires new properties after the object is saved,

Simulink adds the new properties to the restored version of the object. If the class loses properties after the object is saved, only the properties that remain are restored.

## Create Persistent Data Objects

To preserve data objects so that they persist when you close MATLAB, you can:

- Configure a model to load the objects from a MAT-file or script file when the model loads.
- Save the objects in a data dictionary. Data dictionaries offer more control over model data than the base workspace or a model workspace. For more information about data dictionaries, see “What Is a Data Dictionary?” on page 59-2.

To load data objects from a file when you load a model, write a script that creates the objects and configures their properties. Alternatively, save the objects in a MAT-file (see “Save and Load Data Objects” on page 55-54). Then use either the script or a load command as the `PreLoadFcn` callback routine for the model that uses the objects. Suppose that you save the data objects in a file named `data_objects.mat`, and the model to which they apply is open and active. At the command prompt, entering:

```
set_param(gcs, 'PreLoadFcn', 'load data_objects');
```

sets `load data_objects` as the model's preload function. Whenever you open the model, the data objects appear in the base workspace.

## Define Data Classes

This example shows how to subclass Simulink data classes.

Use MATLAB class syntax to create a data class in a package. Optionally, assign properties to the data class and define custom storage classes.

### Use an example to define data classes

- 1 View the `+SimulinkDemos` data class package in the folder `matlabroot/toolbox/simulink/simdemos/dataclasses` (open).

This package contains predefined data classes.

- 2 Copy the folder to the location where you want to define your data classes.
- 3 Rename the folder `+mypkg` and add its parent folder to the MATLAB path.
- 4 Modify the data class definitions.

### Manually define data class

- 1 Create a package folder `+mypkg` and add its parent folder to the MATLAB path.
- 2 Create class folders `@Parameter` and `@Signal` inside `+mypkg`.

---

**Note:** Simulink requires data classes to be defined inside `+Package/@Class` folders.

---

- 3 In the `@Parameter` folder, create a MATLAB file `Parameter.m` and open it for editing.
- 4 Define a data class that is a subclass of `Simulink.Parameter` using MATLAB class syntax.

```
classdef Parameter < Simulink.Parameter
end % classdef
```

To use a custom class name other than `Parameter` or `Signal`, name the class folders using the custom name. For example, to define a class `myParameter`:

- Define the data class as a subclass of `Simulink.Parameter` or `Simulink.Signal`.

```
classdef myParameter < Simulink.Parameter
end % classdef
```

- In the class definition, name the constructor method as `myParameter` or `mySignal`.
- Name the class folder, which contains the class definition, as `@myParameter` or `@mySignal`.

### Optional: Add properties to data class

The `properties` and `end` keywords enclose a property definition block.

```
classdef Parameter < Simulink.Parameter
    properties % Unconstrained property type
        Prop1 = [];
    end

    properties(PropertyType = 'logical scalar')
        Prop2 = false;
    end

    properties(PropertyType = 'char')
        Prop3 = '';
    end

    properties(PropertyType = 'char',...
        AllowedValues = {'red'; 'green'; 'blue'})
        Prop4 = 'red';
    end
end % classdef
```

---

**Note:** The MATLAB editor does not recognize the attributes `PropertyType` and `AllowedValues`, because they are only defined for Simulink data classes. You can suppress `mlint` warnings about these unrecognized attributes by right-clicking the attribute in the MATLAB editor and selecting **Suppress “Unknown attribute name ‘...’” > In This File**.

---

If you add properties to a subclass of `Simulink.Parameter`, `Simulink.Signal`, or `Simulink.CustomStorageClassAttributes`, you can specify the following property types.

| Property Type | Syntax  |
|---------------|---|
| Double number | <code>properties(PropertyType = 'double scalar')</code> |

| Property Type                             | Syntax   |
|---|--|
| int32 number                              | properties(PropertyType = 'int32 scalar')                          |
| Logical number                            | properties(PropertyType = 'logical scalar')                        |
| String (char)                             | properties(PropertyType = 'char')                                  |
| String with limited set of allowed values | properties(PropertyType = 'char', AllowedValues = {'a', 'b', 'c'}) |

### Optional: Add initialization code to data class

You can add a constructor within your data class to perform initialization activities when the class is instantiated.

In this example, the constructor initializes the value of object `obj` based on an optional input argument.

```
classdef Parameter < Simulink.Parameter
    methods
        function obj = Parameter(optionalValue)
            if (nargin == 1)
                obj.Value = optionalValue;
            end
        end
    end % methods
end % classdef
```

### Optional: Define custom storage classes

Use the `setupCoderInfo` method to configure the `CoderInfo` object of your class. Then, create a call to the `useLocalCustomStorageClasses` method and open the Custom Storage Class Designer.

- 1 In the constructor within your data class, call the `useLocalCustomStorageClasses` method.

```
classdef Parameter < Simulink.Parameter
    methods
        function setupCoderInfo(obj)
            useLocalCustomStorageClasses(obj, 'mypkg');

            obj.CoderInfo.StorageClass = 'Custom';
        end
    end
end
```

```

    end
end % methods
end % classdef

```

- 2 Open the Custom Storage Class Designer for your package.

```
cscdesigner('mypkg')
```

- 3 Define custom storage classes.

### Optional: Define custom attributes for custom storage classes

- 1 Create a MATLAB file `myCustomAttribs.m` and open it for editing. Save this file in the `+mypkg/@myCustomAttribs` folder, where `+mypkg` is the folder containing the `@Parameter` and `@Signal` folders.
- 2 Define a subclass of `Simulink.CustomStorageClassAttributes` using MATLAB class syntax. For example, consider a custom storage class that defines data using the original identifier but also provides an alternate name for the data in generated code.

```

classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
    properties(PropertyType = 'char')
        AlternateName = '';
    end
end % classdef

```

- 3 Override the default implementation of the `isAddressable` method to determine whether the custom storage class is writable.

```

classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
    properties(PropertyType = 'logical scalar')
        IsAlternateNameInstanceSpecific = true;
    end

    methods
        function retVal = isAddressable(hObj, hCSCDefn, hData)
            retVal = false;
        end
    end % methods
end % classdef

```

- 4 Override the default implementation of the `getInstanceSpecificProps` method.

For an example, see `CSCTypeAttributes_FlatStructure.m` in the folder `matlabroot\toolbox\simulink\simulink\dataclasses\+Simulink\@CSCTypeAttributes_FlatStructure` (open).

**Note:** This is an optional step. By default, all custom attributes are instance-specific and are modifiable for each data object. However, you can limit which properties are allowed to be instance-specific.

- 5 Override the default implementation of the `getIdentifiersForInstance` method to define identifiers for objects of the data class.

**Note:** In its default implementation, this method queries the name or identifier of the data object and uses that identifier in generated code. By overriding this method, you can control the identifier of your data objects in generated code.

```
classdef myCustomAttribs < Simulink.CustomStorageClassAttributes
    properties(PropertyType = 'char')
        GetFunction = '';
        SetFunction = '';
    end

    methods
        function retVal = getIdentifiersForInstance(hCSCAttrib, hCSCDefn, hData, identifier)
            retVal = struct('GetFunction', hData.CoderInfo.CustomAttributes.GetFunction, ...
                'SetFunction', hData.CoderInfo.CustomAttributes.SetFunction);
        end%
    end % methods
end % classdef
```

- 6 If you are using grouped custom storage classes, override the default implementation of the `getIdentifiersForGroup` method to specify the identifier for the group in generated code.

For an example, see `CSCTypeAttributes_FlatStructure.m` in the folder `matlabroot\toolbox\simulink\simulink\dataclasses\+Simulink\@CSCTypeAttributes_FlatStructure` (open).

## Determine Where to Store Data for Simulink Models

You can store, partition, and share model data in a location that is appropriate for your design. This data can include:

- Numeric values for block parameters, such as `Simulink.Parameter` objects and MATLAB variables
- Signals, such as `Simulink.Signal` objects
- Data types
- Model configuration sets
- Simulation input and output data

Choose the appropriate storage locations to more easily manage the data.

| In this section...                         |
|--|
| “Types of Data” on page 55-61              |
| “Store Data for Your Design” on page 55-62 |
| “Storage Locations” on page 55-64          |

### Types of Data

The storage location that you choose can depend on the nature of the data.

- *Simulation data* is the set of input data that you use to drive a simulation and the set of output data that a simulation generates. For example, you can use variables to store input data that a simulation imports through Inport and From Workspace blocks. A simulation can generate output data through Outport blocks, To Workspace blocks, and logged signals.

You can store simulation data for your current session in the base workspace. To permanently store the data, save it in a MAT-file or script file. For more information about loading, generating, and storing simulation data, see “Techniques for Importing Signal Data” on page 57-75 and “Export Simulation Data” on page 57-4.

- *Design data* is the set of variables that you use to specify block parameters and signal characteristics in a model. For example, design data includes numeric MATLAB variables, parameter and signal data objects, data type objects, and bus objects.

You can store design data in the base workspace, model workspaces, or the Design Data section of a data dictionary. To store local design data with a model, use model

workspaces. To share design data between models, use data dictionaries or the base workspace. Data dictionaries permanently store the data, and you can control the data scope to establish ownership, partition the data to ease readability and maintenance, and track changes. If you use the base workspace, to permanently store the data, you must save it in a MAT-file or script file.

- *Configuration sets* are sets of model configuration parameters. By default, configuration sets reside in the model file, so you do not need to store the sets separately from the model. However, you cannot share these sets with other models.

To share configuration sets between models, you must create `Simulink.ConfigSet` objects. Each object represents a standalone configuration set. You can store these objects in the base workspace or in the Configurations section of a data dictionary. If you use data dictionaries, you can define the scope of each configuration set, compare different configuration sets, and track changes. A data dictionary inherently partitions configuration sets from other kinds of data.

## Store Data for Your Design

The table shows the techniques you can use to store, partition, and manage data for your design.

| Design                                      | Description  | Data Storage Techniques   |
|---|--|---|
| Rapid prototyping and model experimentation | <p>You want to create temporary data, such as variables to specify numeric block parameters, while you learn to use Simulink.</p> <p>You want to experiment with modeling techniques. You do not need to permanently store the data that you create.</p> | Store data in the base workspace so you can quickly create and change the data. |

| Design                                    | Description  | Data Storage Techniques   |
|---|--|---|
| Standalone model                          | You have a single model that does not depend on other systems for data. The model stands alone because it is not a piece of a larger system.                       | <p>Store data in the model workspace. Use a data dictionary to store data that you cannot store in the model workspace.</p> <p>Alternatively, store all of the model data in a data dictionary. If you use a dictionary, you can partition the data by using referenced dictionaries.</p>   |
| Standalone hierarchy of referenced models | You have a hierarchy of referenced models that does not depend on other systems for data. The hierarchy stands alone because it is not a piece of a larger system. | <p>Store local model data in each model workspace.</p> <p>Store data that the models share, such as bus objects and configuration sets, in a data dictionary. ## Storage Locations

Choose any of these locations to store data:

- The MATLAB base workspace. Use the base workspace to store variables while you experiment with temporary models.
- A model workspace. Use a model workspace to permanently store data that is local to a model.
- A data dictionary. Use data dictionaries to permanently store global data, share data between models, and track changes made to data.

The chart shows the capabilities and advantages of each storage location.

| Capability                          | Base Workspace | Model Workspace | Data Dictionary |
|-------------------------------------|----------------|-----------------|-----------------|
| Data-model linkage                  | implicit       | implicit        | ✓               |
| Unified interface for defining data | ✓              | ✓               | ✓               |
| Model-data dependency               | ✓              | ✓               | ✓               |
| Data entry comparison               | ✓              | ✓               | ✓               |
| Data entry persistence              |                | ✓               | ✓               |

| Capability                                 | Base Workspace | Model Workspace | Data Dictionary |

### Temporary Data: Base Workspace

Use the base workspace to temporarily store data:

- While you learn to use Simulink
- When you need to quickly create variables while experimenting with modeling techniques
- When you do not need to store the data permanently

To create variables in the base workspace, you can use the MATLAB command prompt or the Model Explorer. All open models can use the data that you create in the base workspace.

If you use variables to specify numeric block parameters in the model, you can programmatically change the parameter values during simulation by using commands at the command prompt. To programmatically change the values of parameters that you store in the model workspace or data dictionaries, you must use the function interfaces for those storage locations.

To permanently store base workspace data before you end a MATLAB session, you can save the data in a MAT-file or a script file. During a later session, you can load the data from the file. However, if you make changes to the data in the base workspace, you must save the data to the file again. Consider instead using a model workspace or data dictionary to permanently store data.

### Local Data: Model Workspace

Use a model workspace to store data that you use only in the associated model. This data can include:

- Constant parameters, for example, numeric variables that you use to specify block parameter values.
- Data objects, such as `Simulink.Signal` and `Simulink.Parameter` objects, that you use to control signal and parameter characteristics. However, the objects can use only the `Auto` storage class.
- `Simulink.NumericType` objects that you use to specify data types. However, you cannot use the object as a data type alias. You must set the `ISAlias` property to `false`.
- Model arguments.

You can improve model portability and establish data ownership by storing the data in the model workspace. In this case, the model file permanently stores the data.

In a model reference hierarchy, each model workspace acts as a unique namespace. Therefore, you can use the same variable name in multiple model workspaces. You can then assign a unique variable value for each model.

You can use the Model Explorer to manipulate model workspace data. Alternatively, you can use the command prompt or scripts in conjunction with the model workspace programmatic interface.

For more information about using model workspaces to store local data, see “Model Workspaces” on page 4-84.

### **Global and Shared Data: Data Dictionary**

A data dictionary is a standalone file that permanently stores data. Use data dictionaries to partition data, track changes, control access, and share data.

As you can with model workspaces, you can use data dictionaries to directly associate data with a model. You can use this association to scope the data and to establish ownership.

When you use dictionaries, you can partition the data by storing it in additional referenced dictionaries. However, each entry in a dictionary must use a unique name. You must manage each dictionary as a separate file.

Use a data dictionary to store data that multiple models or system components share. This data can include:

- Numeric variables that multiple models use to specify block parameter values.

- `Simulink.AliasType` and `Simulink.NumericType` objects that you use to specify data types in multiple models at once.
- Data objects that use a storage class other than `Auto`. If you have a Simulink Coder license, these objects can represent signals and tunable parameters that appear as global variables in the generated code.
- `Simulink.Bus` objects that you use to define signal interfaces between referenced models.
- `Simulink.ConfigSet` objects that you use to maintain configuration parameter uniformity across multiple models.
- Enumerated type definitions, which you store using `Simulink.data.dictionary.EnumTypeDefinition` objects.

You can use the Model Explorer to manipulate dictionary data. Alternatively, you can use the command prompt or scripts in conjunction with the data dictionary programmatic interface.

For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 59-2.

## Upgrade Level-1 Data Classes

Simulink no longer supports level-1 data classes. You must upgrade data classes that you created using the level-1 data class infrastructure, which was removed in a previous release.

Run the following utility function while specifying the destination folder for the upgraded classes.

---

**Note:** Property types defined in level-1 data classes that are not subclasses of `Simulink.Parameter`, `Simulink.Signal`, or `Simulink.CustomStorageClassAttributes` are not preserved during an upgrade. Only subclasses of these three classes will preserve attributes `PropertyType` and `AllowedValues`.

---

- 1 This command upgrades all your level-1 data class packages. You cannot upgrade selected data packages.

```
Simulink.data.upgradeClasses('C:\MyDataClasses')
```

Here, `C:\MyDataClasses` is the destination folder for your level-2 data classes.

---

**Note:** Do not place your upgraded level-2 classes and their equivalent level-1 classes in the same folder.

---

`Simulink.data.upgradeClasses` uses the `packagedefn.mat` file in your level-1 class packages for the upgrade and creates level-2 classes in the specified destination folder. Then, `Simulink.data.upgradeClasses` adds the folder to top of the MATLAB path and saves the path.

---

**Note:** If `Simulink.data.upgradeClasses` cannot save the MATLAB path because of restricted access, a warning appears. In this case, manually add the folder to the top of the MATLAB path and save the path using `savepath`.

---

- 2 You can change the location of the level-2 package folders after they have been generated. However, you will need to update your MATLAB path so that MATLAB can find these package folders.

- 3** Resave MAT-files and models that contain level-1 data objects.
- 4** Retain your level-1 classes on the MATLAB path until you have resaved all of your models and MAT-files that contain level-1 data objects. Any models or MAT-files that contain level-1 data objects will continue to load successfully while your level-1 data classes are on the MATLAB path.

---

**Note:** You cannot use both level-1 and level-2 data classes at the same time. Level-2 classes need to be above the level-1 classes on the MATLAB path so that they are found by MATLAB.

---

## Associating User Data with Blocks

You can use the `set_param` command to associate your own data with a block. For example, the following command associates the value of the variable `mydata` with the currently selected block.

```
set_param(gcf, 'UserData', mydata)
```

The value of `mydata` can be any MATLAB data type, including arrays, structures, objects, and Simulink data objects.

Use `get_param` to retrieve the user data associated with a block.

```
get_param(gcf, 'UserData')
```

The following command saves the user data associated with a block in the model file of the model containing the block.

```
set_param(gcf, 'UserDataPersistent', 'on');
```

---

**Note** If persistent `UserData` for a block contains any Simulink data objects, the directories containing the definitions for the classes of those objects must be on the MATLAB path when you open the model containing the block.

---

## Design Minimum and Maximum

### In this section...

“Use of Design Minimum and Maximum” on page 55-71

“Valid Values for Design Minimum and Maximum” on page 55-71

### Use of Design Minimum and Maximum

You can specify the design minimum and maximum for model data such as blocks and data objects. Simulink uses the design minimum and maximum as follows.

- To define a valid range for Simulink parameters and signals and use it in range-checking
- To calculate best-precision scaling for fixed-point data types
- To calculate derived minimum and maximum for model data for which design minimum and maximum are not specified

### Valid Values for Design Minimum and Maximum

Simulink no longer allows you to specify the design minimum and maximum as  $-Inf / Inf$ . The default design minimum or maximum is  $[ ]$ .

Previously, you could specify the design minimum and maximum as  $-Inf / Inf$ . However, this specification is ambiguous.

It may imply that the design minimum and maximum are explicitly specified; in other words, it may imply that the parameter or signal can have any value. It may also imply that the design minimum and maximum are unspecified. While this ambiguity may not have a significant effect on range-checking, it could affect the calculation of derived minimum and maximum or the checking of data type validity.

---

**Note:** Simulink generates an error or warning when you specify the design minimum and maximum as  $-Inf / Inf$ .

---

### Avoiding Specifying Infinite Design Minimum or Maximum

There are three sources for the warning Simulink generates if the design minimum and/or maximum are set to  $-Inf / Inf$ . Each source requires a different solution.

**1** MATLAB code

- i** Use error handling tools such as `dbstop` and `lastwarn` to locate the MATLAB code that is setting the design minimum and maximum to `-Inf/Inf`.
- ii** Either remove these lines of code from the MATLAB file or replace instances of `-Inf` and `Inf` with `[]`.

**2** MAT-file: Resave the MAT-file**3** SLX file: Resave the SLX file**Related Examples**

## Support Limitations for Simulink Software Features

The software does not support the following Simulink software features. Avoid using these unsupported features.

| Not Supported                             | Description   |
|---|---|
| Variable-step solvers                     | <p>The software supports only fixed-step solvers.</p> <p>For more information, see “Choose a Fixed-Step Solver” on page 22-16 in the Simulink documentation.</p>  |
| Callback functions                        | <p>The software does not execute model callback functions during the analysis. The results that the analysis generates, such as the harness model, may behave inconsistently with the expected behavior.</p> <ul style="list-style-type: none"> <li>• If a model or any referenced model calls a callback function that changes any block parameters, model parameters, or workspace variables, the analysis does not reflect those changes.</li> <li>• Changing the storage class of base workspace variables on model callback functions or mask initializations is not supported.</li> <li>• Callback functions called prior to analysis, such as the <code>PreLoadFcn</code> or <code>PostLoadFcn</code> model callbacks, are fully supported.</li> </ul> |
| Model callback functions                  | <p>The software only supports model callback functions if the <code>InitFcn</code> callback of the model is empty.</p>  |
| Algebraic loops                           | <p>The software does not support models that contain algebraic loops.</p> <p>For more information, see “Algebraic Loops” on page 3-37 in the Simulink documentation.</p>  |
| Masked subsystem initialization functions | <p>The software does not support models whose masked subsystem initialization modifies any attribute of any workspace parameter.</p>  |
| Complex signals                           | <p>The software supports only real signals.</p>   |

| Not Supported                    | Description   |
|----------------------------------|---|
|                                  | For more information, see “Complex Signals” on page 60-15 in the Simulink documentation.  |
| Variable-size signals            | <p>The software does not support variable-size signals. A variable-size signal is a signal whose size (number of elements in a dimension), in addition to its values, can change during model execution.</p> <p>For more information, see “Variable-Size Signal Basics” on page 62-2 in the Simulink documentation.</p>   |
| Multiword fixed-point data types | The software does not support multiword fixed-point data types.   |
| Nonzero start times              | <p>Although Simulink allows you to specify a nonzero simulation start time, the analysis generates signal data that begins only at zero. If your model specifies a nonzero start time:</p> <ul style="list-style-type: none"> <li>• If you do not select the <b>Reference input model in generated harness</b> parameter (the default), the harness model is a subsystem. The analysis sets the start time of the harness model to 1 and continues the analysis.</li> <li>• If you select the <b>Reference input model in generated harness</b> parameter, a Model block references the harness model. The software cannot change the start time of the harness model, so the analysis stops and you see a recommendation to set the <b>Start time</b> parameter to 0.</li> </ul> |

| Not Supported   | Description  |
|---|--|
| Nonfinite data  | <p>The software does not support nonfinite data (for example, NaN and Inf) and related operations.</p> <p>In the Relational Operator block, the software assigns the output as follows:</p> <ul style="list-style-type: none"> <li>• If the <b>Relational operator</b> parameter is <code>isFinite</code>, the output is always 1.</li> <li>• If the <b>Relational operator</b> parameter is <code>isNan</code> or <code>isInf</code>, the output is always 0.</li> </ul> <p>In the MATLAB Function block, the software assigns the return value as follows:</p> <ul style="list-style-type: none"> <li>• For the <code>isFinite</code> function, the output is always 1.</li> <li>• For the <code>isNan</code> and <code>isInf</code> functions, the output is always 0.</li> </ul> |
| Concurrent execution  | The software does not support models that are configured for concurrent execution.   |
| Signals with nonzero sample time offset   | The software does not support models with signals that have nonzero sample time offsets.   |
| Models with no output ports   | The software only supports models that have one or more output ports.  |
| Large floating-point constants outside the range [ <code>-realmax/2</code> , <code>realmax/2</code> ] | The use of large floating-point constants can cause out of memory errors or substantial loss of precision. Avoid using such constants if possible.   |

## Supported and Unsupported Simulink Blocks

The software provides various levels of support for Simulink blocks:

- Fully supported
- Partially supported
- Not supported

If your model contains unsupported blocks, you can enable automatic stubbing. Automatic stubbing considers the interface of the unsupported blocks, but not their behavior. If any of the unsupported blocks affect the simulation outcome, however, the analysis may achieve only partial results. For details about automatic stubbing, see “Handle Incompatibilities with Automatic Stubbing”.

To achieve 100% coverage, avoid using unsupported blocks in models that you analyze. Similarly, for partially supported blocks, specify only the block parameters that the software recognizes.

The following tables summarize the analysis support for Simulink blocks. Each table lists the blocks in a Simulink library and describes support information for that particular block.

### Additional Math and Discrete Library

The software supports all blocks in the Additional Math and Discrete library.

### Commonly Used Blocks Library

The Commonly Used Blocks library includes blocks from other libraries. Those blocks are listed under their respective libraries.

### Continuous Library

| Block                  | Support Notes                   |
|------------------------|---------------------------------|
| Derivative             | Not supported                   |
| Integrator             | Not supported and not stubbable |
| Integrator Limited     | Not supported and not stubbable |
| PID Controller         | Not supported                   |
| PID Controller (2 DOF) | Not supported                   |

| <b>Block</b>                    | <b>Support Notes</b>            |
|---------------------------------|---------------------------------|
| Second Order Integrator         | Not supported and not stubbable |
| Second Order Integrator Limited | Not supported and not stubbable |
| State-Space                     | Not supported and not stubbable |
| Transfer Fcn                    | Not supported and not stubbable |
| Transport Delay                 | Not supported                   |
| Variable Time Delay             | Not supported                   |
| Variable Transport Delay        | Not supported                   |
| Zero-Pole                       | Not supported and not stubbable |

### **Discontinuities Library**

The software supports all blocks in the Discontinuities library.

### **Discrete Library**

| <b>Block</b>                    | <b>Support Notes</b> |
|---------------------------------|----------------------|
| Delay                           | Supported            |
| Difference                      | Supported            |
| Discrete Derivative             | Supported            |
| Discrete Filter                 | Supported            |
| Discrete FIR Filter             | Supported            |
| Discrete PID Controller         | Supported            |
| Discrete PID Controller (2 DOF) | Supported            |
| Discrete State-Space            | Not supported        |
| Discrete Transfer Fcn           | Supported            |
| Discrete Zero-Pole              | Not supported        |
| Discrete-Time Integrator        | Supported            |
| First-Order Hold                | Supported            |
| Memory                          | Supported            |
| Tapped Delay                    | Supported            |

| Block                    | Support Notes |
|--------------------------|---------------|
| Transfer Fcn First Order | Supported     |
| Transfer Fcn Lead or Lag | Supported     |
| Transfer Fcn Real Zero   | Supported     |
| Unit Delay               | Supported     |
| Zero-Order Hold          | Supported     |

### Logic and Bit Operations Library

The software supports all blocks in the Logic and Bit Operations library.

### Lookup Tables Library

| Block                         | Support Notes   |
|-------------------------------|---|
| Cosine                        | Supported   |
| Direct Lookup Table (n-D)     | Supported   |
| Interpolation Using Prelookup | Not supported when: <ul style="list-style-type: none"> <li>The <b>Interpolation method</b> parameter is <b>Linear</b> and the <b>Number of table dimensions</b> parameter is greater than 4.</li> </ul> or <ul style="list-style-type: none"> <li>The <b>Interpolation method</b> parameter is <b>Linear</b> and the <b>Number of sub-table selection dimensions</b> parameter is not 0.</li> </ul> |
| 1-D Lookup Table              | Not supported when the <b>Interpolation method</b> or the <b>Extrapolation method</b> parameter is <b>Cubic Spline</b> .  |
| 2-D Lookup Table              | Not supported when the <b>Interpolation method</b> or the <b>Extrapolation method</b> parameter is <b>Cubic Spline</b> .  |
| n-D Lookup Table              | Not supported when: <ul style="list-style-type: none"> <li>The <b>Interpolation method</b> or the <b>Extrapolation method</b> parameter is <b>Cubic Spline</b>.</li> </ul> or   |

| Block                | Support Notes   |
|----------------------|---|
|                      | <ul style="list-style-type: none"> <li>The <b>Interpolation method</b> parameter is <b>Linear</b> and the <b>Number of table dimensions</b> parameter is greater than 5.</li> </ul> |
| Lookup Table Dynamic | Supported   |
| Prelookup            | Supported   |
| Sine                 | Supported   |

### Math Operations Library

| Block                      | Support Notes  |             |           |             |     |     |            |        |           |      |     |       |
|----------------------------|--|-------------|-----------|-------------|-----|-----|------------|--------|-----------|------|-----|-------|
| Abs                        | Supported  |             |           |             |     |     |            |        |           |      |     |       |
| Add                        | Supported  |             |           |             |     |     |            |        |           |      |     |       |
| Algebraic Constraint       | Supported  |             |           |             |     |     |            |        |           |      |     |       |
| Assignment                 | Supported  |             |           |             |     |     |            |        |           |      |     |       |
| Bias                       | Supported  |             |           |             |     |     |            |        |           |      |     |       |
| Complex to Magnitude-Angle | Not supported  |             |           |             |     |     |            |        |           |      |     |       |
| Complex to Real-Imag       | Supported  |             |           |             |     |     |            |        |           |      |     |       |
| Divide                     | Supported  |             |           |             |     |     |            |        |           |      |     |       |

### Signal Attributes Library

The software supports all blocks in the Signal Attributes library.

### Signal Routing Library

| Block                  | Support Notes |
|------------------------|---------------|
| Bus Assignment         | Supported     |
| Bus Creator            | Supported     |
| Bus Selector           | Supported     |
| Data Store Memory      | Supported     |
| Data Store Read        | Supported     |
| Data Store Write       | Supported     |
| Demux                  | Supported     |
| Environment Controller | Supported     |

| Block               | Support Notes  |
|---------------------|--|
| From                | Supported  |
| Goto                | Supported  |
| Goto Tag Visibility | Supported  |
| Index Vector        | Supported  |
| Manual Switch       | The Manual Switch block is compatible with the software, but the analysis ignores this block in a model. The analysis does not flag the coverage objectives for this block as satisfiable or unsatisfiable.<br><br>Model coverage data is collected for the Manual Switch block. |
| Merge               | Supported  |
| Multiport Switch    | Supported  |
| Mux                 | Supported  |
| Selector            | Supported  |
| Switch              | Supported  |
| Vector Concatenate  | Supported  |

### Sinks Library

| Block           | Support Notes                   |
|-----------------|---------------------------------|
| Display         | Supported                       |
| Floating Scope  | Supported                       |
| Outport (Out1)  | Supported                       |
| Scope           | Supported                       |
| Stop Simulation | Not supported and not stubbable |
| Terminator      | Supported                       |
| To File         | Supported                       |
| To Workspace    | Supported                       |
| XY Graph        | Supported                       |

## Sources Library

| Block                           | Support Notes  |
|---------------------------------|--|
| Band-Limited White Noise        | Not supported  |
| Chirp Signal                    | Not supported  |
| Clock                           | Supported  |
| Constant                        | Supported unless <b>Constant value</b> is <code>inf</code> .   |
| Counter Free-Running            | Supported  |
| Counter Limited                 | Supported  |
| Digital Clock                   | Supported  |
| Enumerated Constant             | Supported  |
| From File                       | Not supported. When MAT-file data is stored in MATLAB <code>timeseries</code> format, not stubbable. |
| From Workspace                  | Not supported  |
| Ground                          | Supported  |
| Inport (In1)                    | Supported  |
| Pulse Generator                 | Supported  |
| Ramp                            | Supported  |
| Random Number                   | Not supported and not stubbable  |
| Repeating Sequence              | Not supported  |
| Repeating Sequence Interpolated | Not supported  |
| Repeating Sequence Stair        | Supported  |
| Signal Builder                  | Not supported  |
| Signal Generator                | Not supported  |
| Sine Wave                       | Not supported  |
| Step                            | Supported  |
| Uniform Random Number           | Not supported and not stubbable  |

**User-Defined Functions Library**

| <b>Block</b>                | <b>Support Notes</b>  |
|-----------------------------|---|
| Fcn                         | Supports all operators except ^, and supports only the mathematical functions <code>abs</code> , <code>ceil</code> , <code>fabs</code> , <code>floor</code> , <code>rem</code> , and <code>sgn</code> .<br><br>Parameter configurations are not supported. The analysis ignores parameter configurations that you specify for these blocks. |
| Interpreted MATLAB Function | Not supported   |
| Level-2 MATLAB S-Function   | For limitations, see “Support Limitations for S-Functions”.   |
| MATLAB Function             | For limitations, see “Support Limitations for MATLAB for Code Generation”.  |
| S-Function                  | For limitations, see “Support Limitations for S-Functions”.   |
| S-Function Builder          | For limitations, see “Support Limitations for S-Functions”.   |
| Simulink Function           | Not supported   |

## Support Limitations for Stateflow Software Features

The software does not support the following Stateflow software features. Avoid using these unsupported features in models that you analyze.

### In this section...

“ml Namespace Operator, ml Function, ml Expressions” on page 55-87

“C Math Functions” on page 55-87

“Atomic Subcharts That Call Exported Graphical Functions Outside a Subchart” on page 55-88

“Atomic Subchart Input and Output Mapping” on page 55-88

“Recursion and Cyclic Behavior” on page 55-88

“Custom C or C++ Code” on page 55-90

“Machine-Parented Data” on page 55-90

“Textual Functions with Literal String Arguments” on page 55-90

### ml Namespace Operator, ml Function, ml Expressions

The software does not support calls to MATLAB functions or access to MATLAB workspace variables, which the Stateflow software allows. (See “Access Built-In MATLAB Functions and Workspace Data” in the Stateflow documentation.)

### C Math Functions

The software supports calls to the following C math functions:

- abs
- ceil
- fabs
- floor
- fmod
- labs
- ldexp
- pow (only for integer exponents)

The software does not support calls to other C math functions, which the Stateflow software allows. If automatic stubbing is enabled, which it is by default, the software eliminates these unsupported functions during the analysis.

For information about C math functions in Stateflow, see “Call C Functions in C Charts” in the Stateflow documentation.

---

**Note:** For details about automatic stubbing, see “Handle Incompatibilities with Automatic Stubbing”.

---

## Atomic Subcharts That Call Exported Graphical Functions Outside a Subchart

The software does not support atomic subcharts that call exported graphical functions, which the Stateflow software allows.

---

**Note:** For information about exported functions, see “Export Stateflow Functions for Reuse” in the Stateflow documentation.

---

## Atomic Subchart Input and Output Mapping

If an input or output in an atomic subchart maps to chart-level data of a different scope, the software does not support the chart that contains that atomic subchart.

For an atomic subchart input, this incompatibility applies when the input maps to chart-level data of output, local, or parameter scope. For an atomic subchart output, this incompatibility applies when the output maps to chart-level data of local scope.

## Recursion and Cyclic Behavior

The software does not support recursive functions, which occur when a function calls itself directly or indirectly through another function call. Stateflow software allows you to implement recursion using graphical functions.

In addition, the software does not support recursion that the Stateflow software allows you to implement using a combination of event broadcasts and function calls.

---

**Note:** For information about avoiding recursion in Stateflow charts, see “Guidelines for Avoiding Unwanted Recursion in a Chart” in the Stateflow documentation.

---

Stateflow software also allows you to create *cyclic behavior*, where a sequence of steps is repeated indefinitely. If your model has a chart with cyclic behavior, the software cannot analyze it.

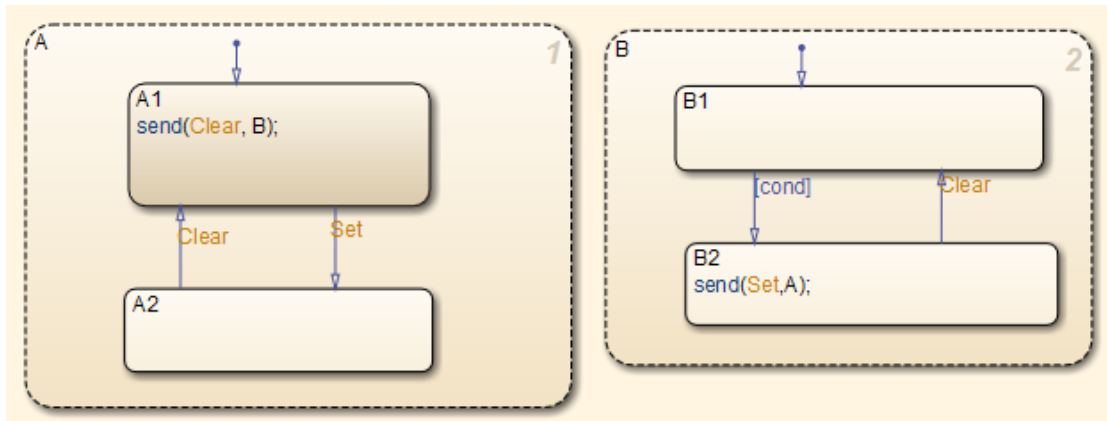

---

**Note:** For information about cyclic behavior in Stateflow charts, see “Cyclic Behavior in a Chart” in the Stateflow documentation.

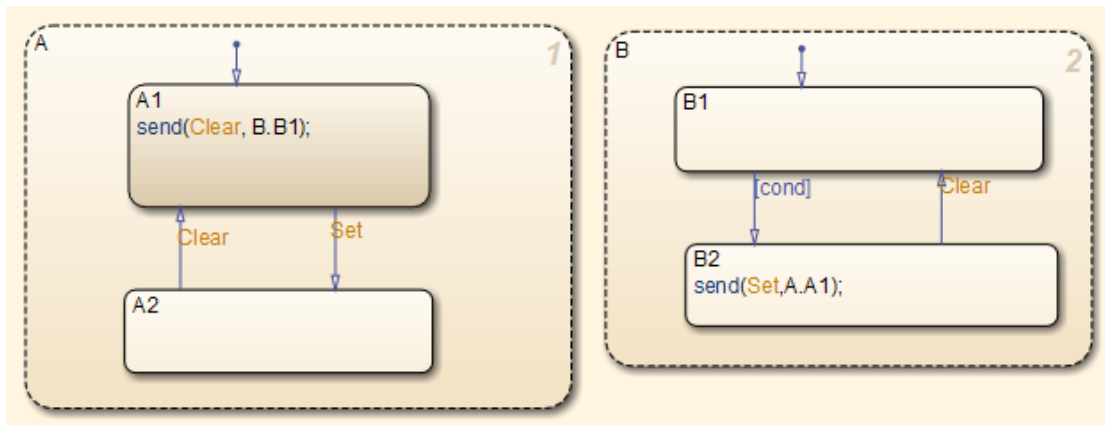

---

However, you can modify a chart with cyclic behavior so that it is compatible, as in the following example.

The following chart creates cyclic behavior. State A calls state A1, which broadcasts a **Clear** event to state B, which calls state B2, which broadcasts a **Set** event back to state A, causing the cyclic behavior.

If you change the `send` function calls to use directed event broadcasts so that the `Set` and `Clear` events are broadcast directly to the states B1 and A1, respectively, the cyclic behavior disappears and the software can analyze the model.

---

**Note:** For information about the benefits of directed event broadcasts, see “Broadcast Events to Synchronize States” in the Stateflow documentation.

---

## Custom C or C++ Code

The software does not support custom C or C++ code, which the Stateflow software allows.

## Machine-Parented Data

The software does not support machine-parented data (i.e., defined at the level of the Stateflow machine), which the Stateflow software allows.

For more information, see “Best Practices for Using Data in Charts” in the Stateflow documentation.

## Textual Functions with Literal String Arguments

The software does not support literal string arguments to textual functions in a Stateflow chart.

# Enumerations and Modeling

---

- “Simulink Enumerations” on page 56-2
- “Use Enumerated Data in Simulink Models” on page 56-7

## Simulink Enumerations

*Enumerated data* is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code.

Simulink enumerations are built on enumerations defined for the MATLAB language. They are subclasses of the abstract superclass `Simulink.IntEnumType`, and inherit from that superclass the capabilities necessary to be used in the Simulink environment.

Before you begin to use enumerations in a modeling context, you should understand information provided in “Enumerations”.

The following examples show how to use enumerations in Simulink and Stateflow.

| Example  | Shows How To Use...   |
|--|---|
| Data Typing in Simulink                                | Data types in Simulink, including enumerated data types                   |
| Modeling a CD Player/Radio Using Enumerated Data Types | Enumerated data types in a Simulink model that contains a Stateflow chart |

For information on using enumerations in Stateflow, see “Enumerated Data”.

### Simulink Constructs that Support Enumerations

- “Overview” on page 56-2
- “Block Support” on page 56-3
- “Class Support” on page 56-4
- “Logging Enumerated Data” on page 56-4
- “Importing Enumerated Data” on page 56-5

#### Overview

In general, all Simulink tools and constructs support enumerated types for which the support makes sense given the purpose of enumerated types: to represent program states and to control program logic. The Simulink Editor, Simulink Debugger, Port

Value Displays, referenced models, subsystems, masks, buses, data logging, and most other Simulink capabilities support enumerated types without imposing any special requirements.

Enumerated types are not intended for mathematical computation, so no block that computes a numeric output (as distinct from passing a numeric input through to the output) supports enumerated types. Thus an enumerated type is not considered to be a numeric type, even though an enumerated value has an underlying integer. See “Enumerated Values in Computation” on page 56-22 for more information.

Most capabilities that do not support enumerated types obviously could not support them. Therefore, the Simulink documentation usually mentions enumerated type nonsupport only where necessary to prevent a misconception or describe an exception. See “Simulink Enumeration Limitations” on page 56-5 for information about certain constructs that could support enumerated types but do not.

### **Block Support**

The following Simulink blocks support enumerated types:

- Constant (but Enumerated Constant is preferable)
- Data Type Conversion
- Data Type Conversion Inherited
- Data Type Duplicate
- Display
- MATLAB Function
- Enumerated Constant
- Floating Scope
- From File
- From Workspace
- Inport
- Interval Test
- Interval Test Dynamic
- Multipoint Switch
- Outport
- Probe (input only)

- Relational Operator
- Relay (output only)
- Repeating Sequence Stair
- Scope
- Signal Specification
- Switch
- Switch Case
- To File
- To Workspace

All members of the following categories of Simulink blocks support enumerated types:

- Bus-capable blocks (see “Bus-Capable Blocks” on page 61-21)
- Pass-through blocks:
  - With state, like the Data Store Memory and Unit Delay blocks.
  - Without state, like the Mux block.

Many Simulink blocks in addition to those named above support enumerated types, but they either belong to one of the categories listed above, or are rarely used with enumerated types. The Data Type Support section of each block reference page describes all data types that the block supports.

### **Class Support**

The following Simulink classes support enumerated types:

- Simulink.Signal
- Simulink.Parameter
- Simulink.AliasType
- Simulink.BusElement

### **Logging Enumerated Data**

Root-level outports, To Workspace blocks, and Scope blocks can all export enumerated values. Signal and State logging work with enumerated data in the same way as with any other data. All logging formats are supported. The From File block does not

support enumerated data. Use the `From Workspace` block instead, combined with some technique for transferring data between a file and a workspace. See “Save Runtime Data from Simulation” for more information.

### Importing Enumerated Data

Root-level inports and `From Workspace` blocks can output enumerated signals during simulation. Data must be provided in a `Structure`, `Structure with Time`, or `TimeSeries` object. No interpolation occurs for enumerated values between the specified simulation times. `From File` blocks produce only data of type `double`, so they do not support enumerated types. See “Load Signal Data for Simulation” for more information.

## Simulink Enumeration Limitations

- “Enumerations and Scopes” on page 56-5
- “Enumerated Types for Switch Blocks” on page 56-5
- “Nonsupport of Enumerations” on page 56-6

### Enumerations and Scopes

When a `Scope` block displays an enumerated signal, the vertical axis displays the names of the enumerated values only if the scope was open during simulation. If you open the `Scope` block for the first time before any simulation has occurred, or between simulations, the block displays only numeric values. When simulation begins, enumerated names replace the numeric values, and thereafter appear whenever the `Scope` block is opened.

When a `Floating Scope` block displays multiple signals, the names of enumerated values appear on the Y axis only if all signals are of the same enumerated type. If the `Floating Scope` block displays more than one type of enumerated signal, or any numeric signal, no names appear, and any enumerated values are represented by their underlying integers.

### Enumerated Types for Switch Blocks

The control input of a `Switch` block can be of any data type supported by Simulink software. However, the `u2 ~= 0` mode is not supported for enumerations. If the control input has an enumeration, choose one of the following methods to specify the criteria for passing the first input:

- Select `u2 >= Threshold` or `u2 > Threshold` and specify a threshold value of the same enumerated type as the control input.

- Use a **Relational Operator** block to do the comparison and then feed the Boolean result of this comparison into the control port of the **Switch** block.

### **Nonsupport of Enumerations**

The following limitations exist when using enumerated data types with Simulink:

- Packages cannot contain enumeration class definitions.
- The **If Action** block might support enumerations, but currently does not do so.
- Generated code does not support logging enumerated data.
- Custom Stateflow targets do not support enumerated types.
- HDL Coder does not support enumerations.

## Use Enumerated Data in Simulink Models

### In this section...

“Define Simulink Enumerations” on page 56-7

“Simulate with Enumerations” on page 56-14

“Specify Enumerations as Data Types” on page 56-16

“Get Information About Enumerated Data Types” on page 56-17

“Enumeration Value Display” on page 56-17

“Instantiate Enumerations” on page 56-19

“Enumerated Values in Computation” on page 56-22

*Enumerated data* is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code.

For basic conceptual information about enumerations in Simulink, see “Simulink Enumerations” on page 56-2.

For information about generating code with enumerations, see “Use Enumerated Data in Generated Code” in the Simulink Coder documentation.

## Define Simulink Enumerations

To define an enumerated data type that you can use in Simulink models, use one of these methods:

- Define an enumeration class using a `classdef` block in a MATLAB file.
- Use the function `Simulink.defineIntEnumType`. You do not need a script file to define the type. For more information, see the function reference page.

### Workflow to Define a Simulink Enumeration

- 1 Create a class definition.
- 2 Optionally, customize the enumeration.
- 3 Optionally, save the enumeration in a MATLAB file.

### Create Simulink Enumeration Class

To create a Simulink enumeration class, in the class definition:

- Define the class as a subclass of `Simulink.IntEnumType`. You can also base an enumerated type on one of these built-in integer data types: `int8`, `uint8`, `int16`, `uint16`, and `int32`.
- Add an `enumeration` block that specifies enumeration values with underlying integer values.

Consider the following example:

```
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
end
```

The first line defines an integer-based enumeration that is derived from built-in class `Simulink.IntEnumType`. The enumeration is integer-based because `IntEnumType` is derived from `int32`.

The `enumeration` section specifies three enumerated values.

| Enumerated Value | Enumerated Name | Underlying Integer |
|------------------|-----------------|--------------------|
| Red(0)           | Red             | 0                  |
| Yellow(1)        | Yellow          | 1                  |
| Blue(2)          | Blue            | 2                  |

When defining an enumeration class for use in the Simulink environment, consider the following:

- The name of the enumeration class must be unique among data type names and base workspace variable names, and is case-sensitive.
- Underlying integer values in the `enumeration` section need not be unique within the class and across types.
- Often, the underlying integers of a set of enumerated values are consecutive and monotonically increasing, but they need not be either consecutive or ordered.

- For simulation, an underlying integer can be any `int32` value. Use the MATLAB functions `intmin` and `intmax` to get the limits.
- For code generation, every underlying integer value must be representable as an integer on the target hardware, which may impose different limits. See “Target” and “Hardware Implementation Pane” for more information.

For more information on superclasses, see “Converting to Superclass Value”. For information on how enumeration classes are handled when there is more than one name for an underlying value, see “How to Alias Enumeration Names”.

## Customize Simulink Enumeration

### About Simulink Enumeration Customizations

You can customize a Simulink enumeration by implementing specific static methods in the class definition. If you define these methods using the appropriate syntax, you can change the behavior of the class during simulation and in generated code.

The table shows the methods you can implement to customize an enumeration.

| Static Method                | Purpose  | Default Value Without Implementing Method            | Custom Return Value   | Usage Context                  |
|------------------------------|--|--|---|--------------------------------|
| <code>getDefaultValue</code> | Specifies the default enumeration member for the class.  | First member specified in the enumeration definition | A string containing the name of an enumeration member in the class (see “Instantiate Enumerations” on page 56-19) | Simulation and code generation |
| <code>getDescription</code>  | Specifies a description of the enumeration class.  | ''   | A string containing the description of the type   | Code generation                |
| <code>getHeaderFile</code>   | Specifies the name of a header file. The method <code>getDataScope</code> determines the significance of the file. | ''   | A string containing the name of the header file that defines the enumerated type                                  | Code generation                |

| Static Method                   | Purpose   | Default Value Without Implementing Method | Custom Return Value                                     | Usage Context   |
|---------------------------------|---|---|---|-----------------|
| <code>getDataScope</code>       | Specifies whether generated code exports or imports the definition of the enumerated data type. Use the method <code>getHeaderFile</code> to specify the generated or included header file that defines the type. | 'Auto'                                    | One of these strings: 'Auto', 'Exported', or 'Imported' | Code generation |
| <code>addClassNameToEnum</code> | Specifies whether to prefix the class name in generated code.   | false                                     | true or false   | Code generation |

For more examples of these methods as they apply to code generation, see “Customize Enumerated Data Type” in the Simulink Coder documentation.

### Specify a Default Enumerated Value

Simulink software and related generated code use an enumeration's default value for ground-value initialization of enumerated data when you provide no other initial value. For example, an enumerated signal inside a conditionally executed subsystem that has not yet executed has the enumeration's default value. Generated code uses an enumeration's default value if a safe cast fails, as described in “Type Casting for Enumerations” in the Simulink Coder documentation.

Unless you specify otherwise, the default value for an enumeration is the first value in the enumeration class definition. To specify a different default value, add your own `getDefaultValue` method to the `methods` section. The following code shows a shell for the `getDefaultValue` method:

```
function retVal = getDefaultValue()
% GETDEFAULTVALUE Specifies the default enumeration member.
% Return a valid member of this enumeration class to specify the default.
% If you do not define this method, Simulink uses the first member.
retVal = ThisClass.EnumName;
end
```

To customize this method, provide a value for *ThisClass.EnumName* that specifies the desired default.

- *ThisClass* must be the name of the class within which the method exists.
- *EnumName* must be the name of an enumerated value defined in that class.

For example:

```
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
    methods (Static)
        function retVal = getDefaultValue()
            retVal = BasicColors.Blue;
        end
    end
end
```

This example defines the default as `BasicColors.Blue`. If this method does not appear, the default value would be `BasicColors.Red`, because that is the first value listed in the enumerated class definition.

The seemingly redundant specification of *ThisClass* inside the definition of that same class is necessary because `getDefaultValue` returns an instance of the default enumerated value, not just the name of the value. The method, therefore, needs a complete specification of what to instantiate. See “Instantiate Enumerations” on page 56-19 for more information.

### Save Enumeration in a MATLAB File

You can define an enumeration within a MATLAB file.

- The name of the definition file must match the name of the enumeration exactly, including case. For example, the definition of enumeration `BasicColors` must reside in a file named `BasicColors.m`. Otherwise, MATLAB will not find the definition.
- You must define each class definition in a separate file.
- Save each definition file on the MATLAB search path. MATLAB searches the path to find a definition when necessary.

To add a file or folder to the MATLAB search path, type `addpath pathname` at the MATLAB command prompt. For more information, see “What Is the MATLAB Search Path?”, `addpath`, and `savepath`.

- You do not need to execute an enumeration class definition to use the enumeration. The only requirement, as indicated in the preceding bullet, is that the definition file be on the MATLAB search path.

### Change and Reload Enumerations

You can change the definition of an enumeration by editing and saving the file that contains the definition. You do not need to inform MATLAB that a class definition has changed. MATLAB automatically reads the modified definition when you save the file. However, the class definition changes do not take full effect if any class instances (enumerated values) exist that reflect the previous class definition. Such instances might exist in the base workspace or might be cached.

The following table explains options for removing instances of an enumeration from the base workspace and cache.

| If In Base Workspace...  | If In Cache...  |
|--|---|
| Do one of the following: <ul style="list-style-type: none"> <li>• Locate and delete specific obsolete instances.</li> <li>• Delete everything from the workspace by using the <code>clear</code> command.</li> </ul> | <ul style="list-style-type: none"> <li>• Delete obsolete instances by closing all models that you updated or simulated while the previous class definition was in effect.</li> <li>• Clear functions and close models that are caching instances of the class.</li> </ul> |

For more information about applying enumeration changes, see “Automatic Updates for Modified Classes”.

### Import Enumerations Defined Externally to MATLAB

If you have enumerations defined externally to MATLAB— for example, in a data dictionary, that you want to import for use within the Simulink environment, you can do so programmatically with calls to the function `Simulink.defineIntEnumType`. This function defines an enumeration that you can use in MATLAB as if it is defined by a class definition file. In addition to specifying the enumeration class name and values, each function call can specify:

- String that describes the enumeration class.
- Which of the enumeration values is the default.

For code generation, you can specify:

- Header file in which the enumeration is defined for generated code.
- Whether the code generator applies the class name as a prefix to enumeration members — for example, `BasicColors_Red` or `Red`.

As an example, consider the following class definition:

```
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
    methods (Static = true)
        function retVal = getDescription()
            retVal = 'Basic colors...';
        end
        function retVal = getDefaultValue()
            retVal = BasicColors.Blue;
        end
        function retVal = getHeaderFile()
            retVal = 'mybasiccolors.h';
        end
        function retVal = addClassNameToEnumNames()
            retVal = true;
        end
    end
end
```

The following function call defines the same class for use in MATLAB:

```
Simulink.defineIntEnumType('BasicColors', ...
    {'Red', 'Yellow', 'Blue'}, [0;1;2],...
    'Description', 'Basic colors', ...
    'DefaultValue', 'Blue', ...
    'HeaderFile', 'mybasiccolors.h', ...
    'DataScope', 'Imported', ...
    'AddClassNameToEnumNames', true);
```

## Simulate with Enumerations

Consider the following enumeration class definition — `BasicColors` with enumerated values `Red`, `Yellow`, and `Blue`, with `Blue` as the default value:

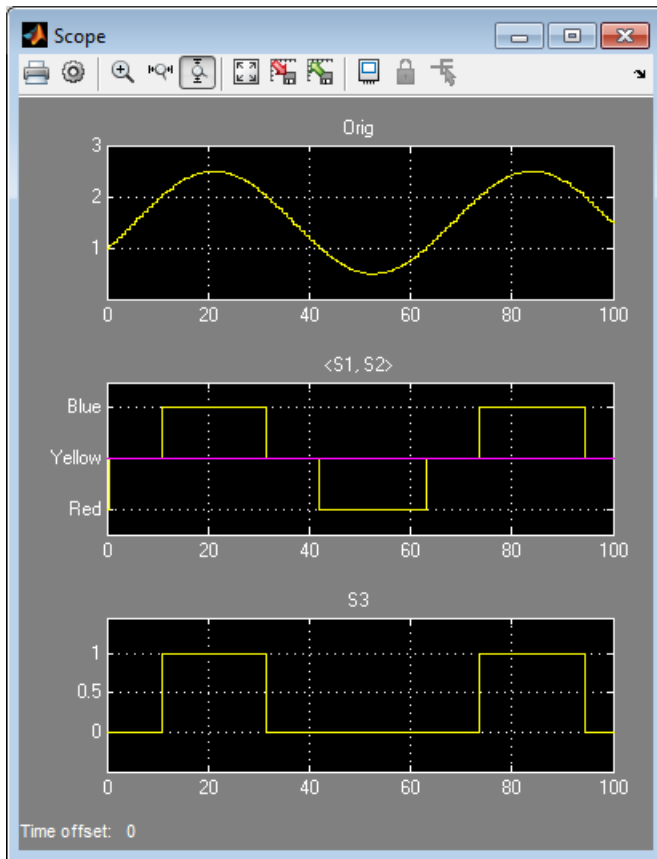

```
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
    methods (Static)
        function retVal = getDefaultValue()
            retVal = BasicColors.Blue;
        end
    end
end
```

Once this class definition is known to MATLAB, you can use the enumeration in Simulink and Stateflow models. Information specific to enumerations in Stateflow appears in “Enumerated Data”. The following Simulink model uses the enumeration defined above:

The output of the model looks like this:

The Data Type Conversion block **OrigToInt** specifies an **Output data type** of **int32** and **Integer rounding mode: Floor**, so the block converts the **Sine Wave** block output, which appears in the top graph of the Scope display, to a cycle of integers: 1, 2, 1, 0, 1, 2, 1. The Data Type Conversion block **IntToColor** uses these values to select colors from the enumerated type **BasicColors** by referencing their underlying integers.

The result is a cycle of colors: **Yellow, Blue, Yellow, Red, Yellow, Blue, Yellow**, as shown in the middle graph. The Enumerated Constant block **EnumConst** outputs **Yellow**, which appears in the second graph as a straight line. The Relational Operator block compares the constant **Yellow** to each value in the cycle of colors. It outputs 1 (**true**) when **Yellow** is less than the current color, and 0 (**false**) otherwise, as shown in the third graph.

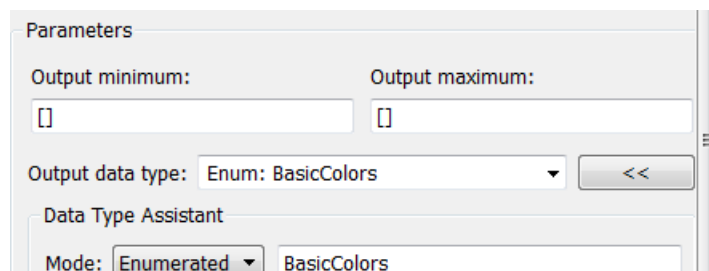

The sort order used by the comparison is the numeric order of the underlying integers of the compared values, *not* the lexical order in which the enumerated values appear in the enumerated class definition. In this example the two orders are the same, but they need not be. See “Specify Enumerations as Data Types” on page 56-16 and “Enumerated Values in Computation” on page 56-22 for more information.

## Specify Enumerations as Data Types

Once you define an enumeration, you can use it much like any other data type. Because an enumeration is a class rather than an instance, you must use the prefix `?` or `Enum:` when specifying the enumeration as a data type. You must use the prefix `?` in the MATLAB Command Window. However, you can use either prefix in a Simulink model. `Enum:` has the same effect as the `?` prefix, but `Enum:` is preferred because it is more self-explanatory in the context of a graphical user interface.

Depending on the context, type `Enum:` followed by the name of an enumeration, or select `Enum: <class name>` from a menu (for example, for the **Output data type** block parameter), and replace `<class name>`.

To use the Data Type Assistant, set the **Mode** to `Enumerated`, then enter the name of the enumeration. For example, in the previous model, the Data Type Conversion block **IntToColor**, which outputs a signal of type `BasicColors`, has the following output signal specification:

You cannot set a minimum or maximum value for a signal defined as an enumeration, because the concepts of minimum and maximum are not relevant to the purpose of enumerations. If you change the minimum or maximum for a signal of an enumeration from the default value of [ ], an error occurs when you update the model. See “Enumerated Values in Computation” on page 56-22 for more information.

## Get Information About Enumerated Data Types

The functions `enumeration` and `Simulink.data.getEnumTypeInfo` return information about enumerated data types.

### Get Information About Enumeration Members

Use the function `enumeration` to:

- Return an array that contains all enumeration values for an enumeration class in the MATLAB Command Window
- Get the enumeration values programmatically
- Provide the values to a Simulink block parameter that accepts an array or vector of enumerated values, such as the **Case conditions** parameter of the Switch Case block

### Get Information About Enumerated Class

Use the function `Simulink.data.getEnumTypeInfo` to return information about an enumeration class, such as:

- The default enumeration member
- The name of the header file that defines the type in generated code
- The data type used in generated code to store the integer values underlying the enumeration members

## Enumeration Value Display

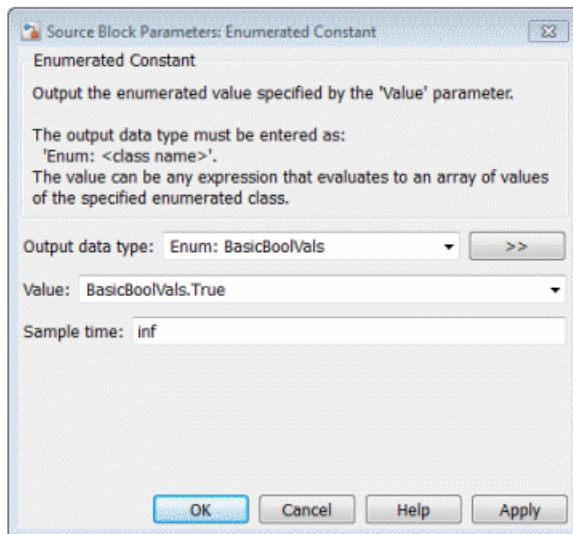

Wherever possible, Simulink software displays enumeration values by name, not by the underlying integer value. However, the underlying integers can affect value display in Scope and Floating Scope blocks.

| Block...       | Affect on Value Display...  |
|----------------|---|
| Scope          | When displaying an enumerated signal, the names of the enumerated values appear as labels on the Y axis. The names appear in the order given by their underlying integers, with the lowest value at the bottom. |
| Floating Scope | When displaying signals that are of the same enumeration, names appear on the Y axis as they would for a Scope block. If the Floating Scope block displays mixed data types, no names                           |

| Block... | Affect on Value Display...  |
|----------|---|
|          | appear, and any enumerated values are represented by their underlying integers. |

### Enumerated Values with Non-Unique Integers

More than one value in an enumeration can have the same underlying integer value, as described in “Specify Enumerations as Data Types” on page 56-16. When this occurs, the value on an axis of Scope block output or in Display block output always is the first value listed in the enumerated class definition that has the shared underlying integer. For example:

Although the Enumerated Constant block outputs True, both On and True have the same underlying integer, and On is defined first in the class definition enumeration

section. Therefore, the Display block shows **On**. Similarly, a **Scope** axis would show only **On**, never **True**, no matter which of the two values is input to the Scope block.

## Instantiate Enumerations

Before you can use an enumeration, you must instantiate it. You can instantiate an enumeration in MATLAB, in a Simulink model, or in a Stateflow chart. The syntax is the same in all contexts.

### Instantiating Enumerations in MATLAB

To instantiate an enumeration in MATLAB, enter *ClassName.EnumName* in the MATLAB Command Window. The instance is created in the base workspace. For example, if **BasicColors** is defined as in “Create Simulink Enumeration Class” on page 56-8, you can type:

```
bcy = BasicColors.Yellow
```

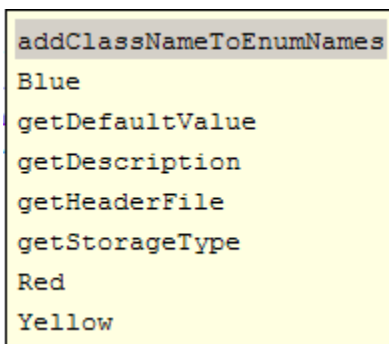

```
bcy =
```

```
Yellow
```

Tab completion works for enumerations. For example, if you enter:

```
bcy = BasicColors.<tab>
```

MATLAB displays the elements and methods of **BasicColors** in alphabetical order:

```
addClassNameToEnumNames
Blue
getDefaultvalue
getDescription
getHeaderFile
getStorageType
Red
Yellow
```

Double-click an element or method to insert it at the position where you pressed **<tab>**. See “Tab Completion” for more information.

### Casting Enumerations in MATLAB

In MATLAB, you can cast directly from an integer to an enumerated value:

```
bcb = BasicColors(2)
```

```
bcb =
```

```
Blue
```

You can also cast from an enumerated value to its underlying integer:

```
>> bci = int32(bcb)
```

```
bci =
```

```
2
```

In either case, MATLAB returns the result of the cast in a 1x1 array of the relevant data type.

Although casting is possible, use of enumeration values is not robust in cases where enumeration values and the integer equivalents defined for an enumeration class might change.

### Instantiating Enumerations in Simulink (or Stateflow)

To instantiate an enumeration in a Simulink model, you can enter *ClassName.EnumName* as a value in a dialog box. For example, consider the following model:

The Enumerated Constant block **EnumConst**, which outputs the enumerated value Yellow, defines that value as follows:

You can enter any valid MATLAB expression that evaluates to an enumerated value, including arrays and workspace variables. For example, you could enter `BasicColors(1)`, or if you had previously executed `bcy = BasicColors.Yellow` in the MATLAB Command Window, you could enter `bcy`. As another example, you could enter an array, such as `[BasicColors.Red, BasicColors.Yellow, BasicColors.Blue]`.

You can use a **Constant** block to output enumerated values. However, that block displays parameters that do not apply to enumerated types, such as **Output Minimum** and **Output Maximum**.

If you create a `Simulink.Parameter` object as an enumeration, you must specify the **Value** parameter as an enumeration member and the **Data type** with the `Enum:` or `?` prefix, as explained in “Specify Enumerations as Data Types” on page 56-16.

You *cannot* specify the integer value of an enumeration member for the **Value** parameter. See “Enumerated Values in Computation” on page 56-22 for more information. Thus, the following fails even though the integer value for `BasicColors.Yellow` is 1.

The same syntax and considerations apply in Stateflow. See “Enumerated Data” for more information.

## Enumerated Values in Computation

By design, Simulink prevents enumerated values from being used as numeric values in mathematical computation, even though an enumerated class is a subclass of the MATLAB `int32` class. Thus, an enumerated type does not function as a numeric type despite the existence of its underlying integers. For example, you cannot input an enumerated signal directly to a Gain block.

You can use a Data Type Conversion block to convert in either direction between an integer type and an enumerated type, or between two enumerated types. That is, you can use a Data Type Conversion block to convert an enumerated signal to an integer signal (consisting of the underlying integers of the enumerated signal values) and input the resulting integer signal to a Gain block. See “Casting Enumerated Signals” on page 56-22 for more information.

Enumerated types in Simulink are intended to represent program states and control program logic in blocks like the Relational Operator block and the Switch block. When a Simulink block compares enumerated values, the values compared must be of the same enumerated type. The block compares enumerated values based on their underlying integers, not their order in the enumerated class definition.

When a block like the Switch block or Multiport Switch block selects among multiple data signals, and any data signal is of an enumerated type, all the data signals must be of that same enumerated type. When a block inputs both control and data signals, as Switch and Multiport Switch do, the control signal type need not match the data signal type.

### Casting Enumerated Signals

You can use a Data Type Conversion block to cast an enumerated signal to a signal of any numeric type, provided that the underlying integers of all enumerated values input to the block are within the range of the numeric type. Otherwise, an error occurs during simulation.

Similarly, you can use a Data Type Conversion block to cast a signal of any integer type to an enumerated signal, provided that every value input to the Data Type Conversion block is the underlying integer of some value in the enumerated type. Otherwise, an error occurs during simulation.

You cannot use a Data Type Conversion block to cast a numeric signal of any non-integer data type to an enumerated type. For example, the model used in “Simulate with

Enumerations” on page 56-14 needed two Data Conversion blocks to convert a sine wave to enumerated values.

The first block casts `double` to `int32`, and the second block casts `int32` to `BasicColors`. You cannot cast a complex signal to an enumerated type regardless of the data types of its real and imaginary parts.

### Casting Enumerated Block Parameters

You cannot cast a block parameter of any numeric data type to an enumerated data type. For example, suppose that an Enumerated Constant block specifies a **Value** of 2 and an **Output data type** of Enum: `BasicColors`:

An error occurs because the specifications implicitly cast a `double` value to an enumerated type. The error occurs even though the numeric value corresponds arithmetically to one of the enumerated values in the enumerated type.

You cannot cast a block parameter of an enumeration to any other data type. For example, suppose that a Constant block specifies a **Constant value** of `BasicColors.Blue` and an **Output data type** of `int32`.

An error occurs because the specifications implicitly cast an enumerated value to a numeric type. The error occurs even though the enumerated value's underlying integer is a valid `int32`.

# Using Simulation Data

## Working with Simulation Data

During simulation, you can:

- Import input signal and initial state data from a workspace or file.
- Export output signal and state data to a workspace or file.

Exporting (logging) simulation data provides a baseline for analyzing and debugging a model. Use standard or custom MATLAB functions to generate simulated system input signals and to graph, analyze, or otherwise postprocess the system outputs.

Also, import data into a model for testing and analysis, as well as to continue a paused or stopped simulation.

## Export Simulation Data

### In this section...

“Simulation Data” on page 57-4

“Approaches for Exporting Signal Data” on page 57-4

“Enable Simulation Data Export” on page 57-7

“View Logged Simulation Data With the Simulation Data Inspector” on page 57-7

“Memory Performance” on page 57-7

### Simulation Data

Simulation data can include any combination of signal, time, output, state, and data store logging data.

Exporting simulation data involves saving signal values to the MATLAB workspace or to a MAT-file during simulation for later retrieval and postprocessing. Exporting data is also known as “data logging” or “saving simulation data.”

If you have data logged in different formats:

- Array
- Structure
- Structure with time
- MATLAB timeseries
- ModelDataLogs

Consider converting this data to the Dataset format. This can simplify the post-processing of data. For more information, see “Data Set Conversion for Logged Data” on page 57-15.

You can also import the exported data to use as input for simulating a model.

### Approaches for Exporting Signal Data

Exporting simulation data very often involves exporting signal data. You can use a variety of approaches for exporting signal data.

| Export Approach                                | Usage   | Documentation |
|--|---|---------------|
| Connect a Scope block or viewer to a signal.   | <p>If you use a Scope block for viewing results during simulation, consider also using the Scope block to export data.</p> <p>Save output at a sample rate other than the base sample rate.</p> <p>Scopes store data and can be memory intensive.</p> | Scope         |
| Connect a signal to a To File block.           | <p>Consider using a To File block for exporting large amounts of data.</p> <p>Save output at a sample rate other than the base sample rate.</p> <p>Use the MAT-file only after the simulation has completed.</p>                                      | To File       |
| Connect a signal to a To Workspace block.      | <p>Document in the diagram the workspace variables used to store signal data.</p> <p>Save output at a sample rate other than the base sample rate.</p>  | To Workspace  |
| Connect a signal to a root-level Output block. | <p>Consider using this approach for logging data in a top-level model, if the model already includes an Output block.</p>   | Output        |

| Export Approach   | Usage   | Documentation  |
|---|---|--|
| Set the signal logging properties for a signal.                           | <p>Use signal logging to avoid adding blocks.</p> <p>Log signals based on individual signal rates.</p> <p>Data is available only when simulation is paused or completed.</p> <p>Use signal logging to log array of buses signals.</p>   | “Export Signal Data Using Signal Logging” on page 57-36  |
| Configure Simulink to export time, state, and output data.                | <p>Consider exporting this data to capture complete information about the simulation as a whole.</p> <p>Outputs and states are logged at the base sample rate of the model.</p>   | <p>“Data Format for Exported Simulation Data” on page 57-9</p> <p>“Limit Amount of Exported Data” on page 57-31</p> <p>“Samples to Export for Variable-Step Solvers” on page 57-33</p> |
| Log a data store.   | Log a data store to share data throughout a model hierarchy, capturing the order of all data store writes.  | “Log Data Stores” on page 58-31  |
| Use the <code>sim</code> command to log simulation data programmatically. | <p>Use <code>sim</code> to export to one data object the time, states, and signal simulation data.</p> <p>Select the <b>Return as single object</b> parameter when simulating the model using the <code>sim</code> command inside a function or a <code>parfor</code> loop.</p> | <code>sim</code>   |

## Enable Simulation Data Export

To export the states and root-level outputs of a model to the MATLAB base workspace during simulation of the model, use one of these interfaces:

- **Configuration Parameters > Data Import/Export** pane (for details, see “Data Import/Export Pane”)
- `sim` command

In both approaches, specify:

- The kinds of simulation data that you want to export:
  - Signal logging
  - Time
  - Output
  - State or final state
  - Data store

Each kind of simulation data export has an associated default variable. You can specify your own variables for the exported data.

- The characteristics of the logged data, including:
  - “Data Format for Exported Simulation Data” on page 57-9
  - “Limit Amount of Exported Data” on page 57-31
  - “Samples to Export for Variable-Step Solvers” on page 57-33

## View Logged Simulation Data With the Simulation Data Inspector

To inspect exported simulation data interactively, consider using the “Customize the Simulation Data Inspector Interface” on page 25-42.

The Simulation Data Inspector has some limitations on the kinds of logged data that it displays. See “Limitations of the Simulation Data Inspector” on page 25-54.

## Memory Performance

When exporting simulation data in a simulation mode other than Rapid Accelerator, Simulink optimizes memory usage in the following situations.

- When time steps happen at regular intervals, Simulink uses compressed time representation. Simulink stores the value for the first time stamp, the length of the interval (time step), and the total number of time stamps.
- When multiple signals use identical sequences of time stamps, the signals share a single stored time stamp sequence. This may reduce memory use for logged data by as much as a factor of two. An example when this memory performance can be a critical performance factor is when logging bus signals that have thousands of bus elements.

## Data Format for Exported Simulation Data

### In this section...

“Data Format for Block-Based Exported Data” on page 57-9

“Data Format for Model-Based Exported Data” on page 57-9

“Signal Logging Format” on page 57-9

“Logged Data Store Format” on page 57-10

“Time, State, and Output Data Format” on page 57-10

### Data Format for Block-Based Exported Data

You can use the `Scope`, `To File`, or `To Workspace` blocks to export simulation data. Each of these blocks has a data format parameter.

### Data Format for Model-Based Exported Data

The data format for model-based exporting of simulation data specifies how Simulink stores the exported data.

Simulink uses different data formats, depending on the kind of data that you export. For details, see:

- “Signal Logging Format” on page 57-9
- “Logged Data Store Format” on page 57-10
- “Time, State, and Output Data Format” on page 57-10

### Signal Logging Format

Use the `Dataset` format for signal logging data in new models. Select the format using the **Configuration Parameters > Data Import/Export > Signal logging format** parameter.

For details, see “Specify the Signal Logging Data Format” on page 57-52.

For backwards compatibility, Simulink supports the `ModelDataLogs` format for signal logging. The `ModelDataLogs` format will be removed in a future release. For details, see “Migrate from ModelDataLogs to Dataset Format” on page 57-53.

For formats other than `Dataset`, you can convert to the `Dataset` format. For more information, see “Data Set Conversion for Logged Data” on page 57-15.

## Logged Data Store Format

When you log data store data, Simulink uses a `Simulink.SimulationData.Dataset` object.

For details, see “Accessing Data Store Logging Data” on page 58-33.

## Time, State, and Output Data Format

For exported time, states, and output data, use one of the following formats:

- “Dataset” on page 57-10 (default)
- “Array” on page 57-11
- “Structure with Time” on page 57-11
- “Structure” on page 57-14

If you select the **Configuration Parameters > Data Import/Export > Output** check box, Simulink logs fixed-point data as double. To log fixed-point data, consider using one of these approaches:

- Signal logging — For details, see “Export Signal Data Using Signal Logging” on page 57-36.
  - 1 In the Simulink Editor, select one or more signals.
  - 2 Click the **Simulation Data Inspector** button arrow  and click **Log Selected Signals to Workspace**.
- To File block
- To Workspace block — In the To Workspace block parameters dialog box, enable the **Log fixed-point data as a fi object** parameter.

For information about the format for logged final state data, see “State Information” on page 57-144.

### Dataset

Dataset format:

- Uses MATLAB timeseries objects to store logged data (rather than `Simulink.Timeseries` and `Simulink.TsArray` objects). MATLAB `timeseries` objects allow you to work with logged data in MATLAB without a Simulink license.
- Supports logging multiple data values for a given time step, which can be important for Iterator subsystem and Stateflow signal logging.
- Does not support logging nonvirtual bus data for code generation or Rapid Accelerator mode.

### Array

If you select this Array option, Simulink saves the states and outputs of a model in a state and output array, respectively.

The state matrix has the name specified in the **Save to workspace** area (for example, `xout`). Each row of the state matrix corresponds to a time sample of the states of a model. Each column corresponds to an element of a state. For example, suppose that your model has two continuous states, each of which is a two-element vector. Then the first two elements of each row of the state matrix contains a time sample of the first state vector. The last two elements of each row contain a time sample of the second state vector.

The model output matrix has the name specified in the **Save to workspace** area (for example, `yout`). Each column corresponds to a model output port, and each row to the outputs at a specific time.

---

**Note:** Use array format to save your model outputs and states only if the logged data is:

- Either all scalars or all vectors (or all matrices for states)
- Either all real or all complex
- All of the same data type

If your model outputs and states do not meet these conditions, use the **Structure** or **Structure with time** output formats (see “Structure with Time” on page 57-11).

---

### Structure with Time

If you select this format, Simulink saves the model states and outputs in structures that have their names specified in the **Save to workspace** area. By default, the structures are `xout` for states and `yout` for output.

The structure used to save outputs has two top-level fields:

- **time**

Contains a vector of the simulation times.

- **signals**

Contains an array of substructures, each of which corresponds to a model output port.

Each substructure has four fields:

- **values**

Contains the outputs for the corresponding output port.

- If the outputs are scalars or vectors, the **values** field is a matrix each of whose rows represents an output at the time specified by the corresponding element of the time vector.
- If the outputs are matrix (2-D) values, the **values** field is a 3-D array of dimensions **M-by-N-by-T** where **M-by-N** is the dimensions of the output signal and **T** is the number of output samples.
- If **T = 1**, MATLAB drops the last dimension. Therefore, the **values** field is an **M-by-N** matrix.

- **dimensions**

Specifies the dimensions of the output signal.

- **label**

Specifies the label of the signal connected to the output port, S-Function block, or the type of state (continuous or discrete). The label is **DSTATE** or **CSTATE**, except for S-Function block state labels. For S-Function block state labels for discrete states, the label is the name of the state (instead of **DSTATE**).

- **blockName**

Specifies the name of the corresponding output port or block with states.

- **inReferencedModel**

Contains a value of **1** if the **signals** field records the final state of a block that resides in the reference model. Otherwise, the value is false (**0**).

The following example shows the structure-with-time format for a nonreferenced model.

```
xout.signals(1)

ans =

    values: [296206x1 double]
  dimensions: 1
    label: 'CSTATE'
   blockName: 'vdp/x1'
inReferencedModel: 0
```

The structure used to save states has a similar organization. The states structure has two top-level fields:

- **time**

The **time** field contains a vector of the simulation times.

- **signals**

The field contains an array of substructures, each of which corresponds to one of the states of the model.

Each **signals** structure has four fields: **values**, **dimensions**, **label**, and **blockName**. The **values** field contains time samples of a state of the block specified by the **blockName** field. The **label** field for built-in blocks indicates the type of state: either **CSTATE** (continuous state) or **DSTATE** (discrete state). For S-Function blocks, the label contains whatever name is assigned to the state by the S-Function block.

The time samples of a state are stored in the **values** field as a matrix of values. Each row corresponds to a time sample. Each element of a row corresponds to an element of the state. If the state is a matrix, the matrix is stored in the **values** array in column-major order. For example, suppose that the model includes a 2-by-2 matrix state and that 51 samples of the state are logged during a simulation run.

The **values** field for this state would contain a 51-by-4 matrix. Each row corresponds to a time sample of the state, and the first two elements of each row correspond to the first column of the sample. The last two elements correspond to the second column of the sample.

---

**Note:** Simulink can read back simulation data saved to the MATLAB workspace in the `Structure with time` output format. See “Examples of Specifying Signal and Time Data” on page 57-142 for more information.

---

### **Structure**

This format is the same as for `Structure with time` output format, except that Simulink does not store simulation times in the `time` field of the saved structure.

## Data Set Conversion for Logged Data

### In this section...

“Why Convert to Dataset Format” on page 57-15

“Results of Conversion” on page 57-16

“Dataset Conversion Limitations” on page 57-18

### Why Convert to Dataset Format

You can use the `Simulink.SimulationData.Dataset` constructor to convert a MATLAB workspace variable that contains data that was logged in one of these formats to `Dataset` format:

- Array
- Structure
- Structure with time
- MATLAB times eries
- `ModelDataLogs`

Converting data from other Simulink logging formats to `Dataset` format simplifies writing scripts to post-process data logged. Some formats come from the logging techniques that Simulink supports. For example, for models with multiple To Workspace blocks using different data formats or for models that use To Workspace blocks and log signals using `ModelDataLogs` format.

Different simulation modes have different levels of support for data logging formats. Switching between Normal and Accelerator modes can require changes to the logging formats used.

The conversion to `Dataset` format also makes it easier to take advantage of features that require `Dataset` format. You can easily convert data logged in earlier releases that used a format other than `Dataset` to work well with `Dataset` data in a more recent release.

The `Dataset` format:

- Uses MATLAB timeseries objects to store logged data, which allows you to work with logging data in MATLAB without a Simulink license. For example, to manipulate the

logged data, you can use MATLAB time-series methods such as `filter`, `detrend`, and `resample`.

- Supports logging multiple data values for a given time step, which is important for Iterator subsystem and Stateflow signal logging.

By default, the resulting `Dataset` object uses the variable name as its name. You can use a Name-Value pair to specify a `Dataset` name.

You can use the `Simulink.SimulationData.DataSet.concat` method to combine `Dataset` objects into one concatenated `Dataset` object.

## Results of Conversion

`Dataset` objects hold data as elements. To display the elements of a `Dataset` variable, enter the variable name at the MATLAB command prompt. The elements of `Dataset` objects are different types, depending on the data they store. For example, signal logging stores data as `Simulink.SimulationData.Signal` elements and state logging in `Dataset` format stores data as `Simulink.SimulationData.State` elements. Each element holds data as a MATLAB time-series object. At conversion, the elements and time-series field populate as much as possible from the converted object.

| Format             | Conversion Result Notes  |
|--------------------|--|
| MATLAB time series | <p>If you log nonbus data, during conversion, the software first adds the data as a <code>Simulink.SimulationData.Signal</code> object. It then adds that object as an element of the newly created <code>Dataset</code>.</p> <p>If you log bus data in time-series format, one time series corresponds to each element of a bus. Converting arranges the logged data as a structure with time-series objects as leaf nodes. This structure hierarchy matches the bus hierarchy. Conversion of this type of structure of time-series objects adds the whole structure to a <code>Simulink.SimulationData.Signal</code> object. It then adds that object as an element of the data set.</p> |

| Format                            | Conversion Result Notes  |
|-----------------------------------|--|
|                                   | Time-series objects hold relevant information such as block path and time stamps. The conversion tries to preserve this information.   |
| Structure and structure with time | <p>Structure and structure with time formats do not always contain as much information as if you log in <b>Dataset</b> format. However, before converting structure and structure with time formats, the data structure must have <b>time</b> and <b>signals</b> fields.</p> <p>Conversion populates a <b>Simulink.SimulationData.Signal</b> object with the structure and adds it as an element of the data set. If other information is available, converting also adds it to the element or time-series values. For example, if the structure has a field called <b>blockName</b>, converting adds it to the block path. Otherwise, the block path is empty.</p> <p>When scope data is logged in structure format, the logged structure has a <b>PlotStyle</b> field. The software uses this field to set the interpolation in the <b>Dataset</b> object.</p> |
| Array                             | <p>Arrays contain little information. For example, there is no block path information.</p> <p>Conversion adds the array to a <b>Simulink.SimulationData.Signal</b> object and adds it as an element of the <b>Dataset</b> object. The conversion leaves unavailable information such as block path and time stamp fields as either empty or with default values.</p>   |
| ModelDataLogs                     | Converts data from <b>ModelDataLogs</b> format to <b>Dataset</b> format.   |

## Dataset Conversion Limitations

- Converting logged data to **Dataset** format results in a **Dataset** object that contains all of the information that the original logged data included. However, if there is no corresponding information for the other **Dataset** properties, the conversion uses default values for that information.
- To log variable-size signals, use the **To Workspace** block. If you convert data logged with **To Workspace** to be **Dataset** format, you lose the information about the variable-size signals.
- When you log a bus signal in array, structure, or structure with time formats, the logged data is organized with the first column containing the data for the first signal in the bus, the second column containing data for the second bus signal, and so on. When you convert that data to **Dataset**, the **Dataset** preserves that organization. But if you log the bus signal in **Dataset** format without conversion, the conversion captures the bus data as a structure of time-series objects.
- If the logged data does not include a time vector, when you convert that data to **Dataset**, the conversion inserts a time vector, with one time step for each data value. However, the simulation time steps and the **Dataset** timesteps can vary.
- **Dataset** format ignores the specification of frame signals. Conversion of structure or structure with time data to **Dataset** reshapes the data for logged frame signals.

## Convert Logged Data to Dataset Format

### In this section...

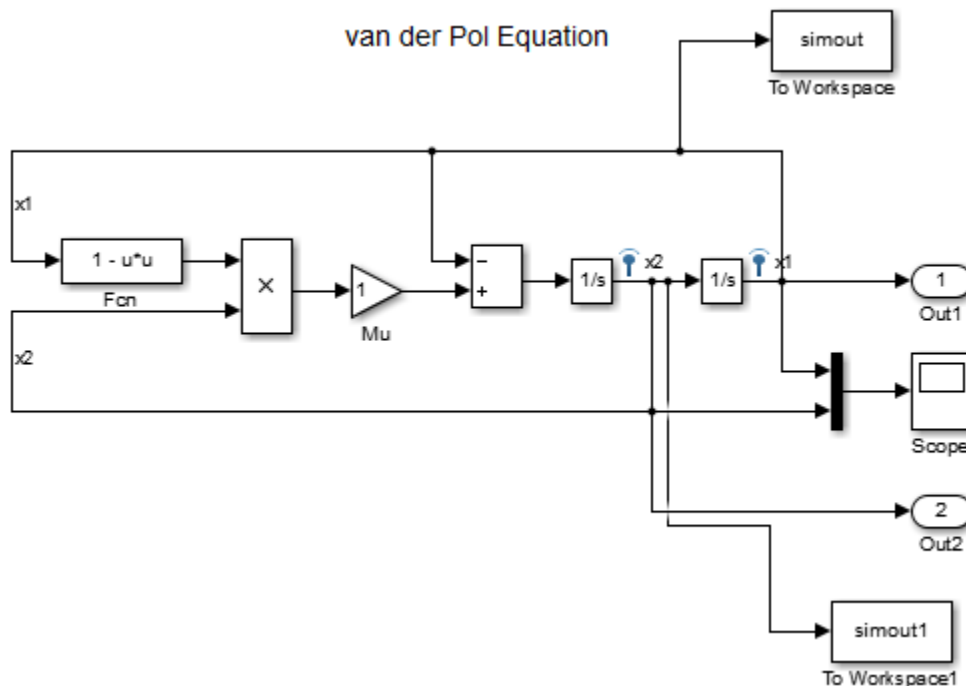

“Convert Workspace Data to Dataset” on page 57-19

“Convert Structure Without Time to Dataset” on page 57-21

“Programmatically Access Logged Signal Data Saved in Dataset Format” on page 57-25

### Convert Workspace Data to Dataset

This example shows how to convert MATLAB time-series data to Dataset format. `myvdp_timeseries` is the vdp model with two To Workspace blocks configured for `simout` and `simout1` logging data in MATLAB time-series format. Consider using a procedure like this one if you have models that use To Workspace blocks to log data to MATLAB time-series format.

Use the `Simulink.SimulationData.Dataset` constructor to convert the MATLAB time-series data to `Dataset` format and then concatenate the two data sets.

- 1 Starting with the `vdp` model, add two To Workspace blocks to the model as shown.
- 2 Set the **Save format** parameter of both blocks. Set `Timeseries`.
- 3 Save the model as `myvdp_timeseries`.
- 4 Simulate the model.

The simulation logs data using the To Workspace blocks.

- 5 Access the signal logging format, `logouts`.

```
logouts
```

```
logouts =
```

```
Simulink.SimulationData.Dataset  
Package: Simulink.SimulationData
```

```
Characteristics:  
    Name: 'logouts'  
  Total Elements: 2
```

```
Elements:  
  1: 'x1'  
  2: 'x2'
```

```
-Use get or getElement to access elements by index or name.  
-Use addElement or setElement to add or modify elements.
```

```
Methods, Superclasses
```

- 6 Convert the MATLAB time-series data from both To Workspace blocks to `Dataset`.

```
ds = Simulink.SimulationData.Dataset(simout);  
ds1 = Simulink.SimulationData.Dataset(simout1);
```

`ds` is the variable name of the first To Workspace block data. `ds1` is the variable name of the second To Workspace block data.

- 7 Concatenate both datasets into `dsfinal`. Observe that the format of `dsfinal` matches that of `logouts`.

```
dsfinal = ds.concat(ds1)
```

```
dsfinal =  
  
    Simulink.SimulationData.Dataset  
    Package: Simulink.SimulationData  
  
    Characteristics:  
        Name: 'simout'  
        Total Elements: 2  
  
    Elements:  
        1: 'x1'  
        2: 'x2'  
  
    -Use get or getElement to access elements by index or name.  
    -Use addElement or setElement to add or modify elements.  
  
    Methods, Superclasses
```

## Convert Structure Without Time to Dataset

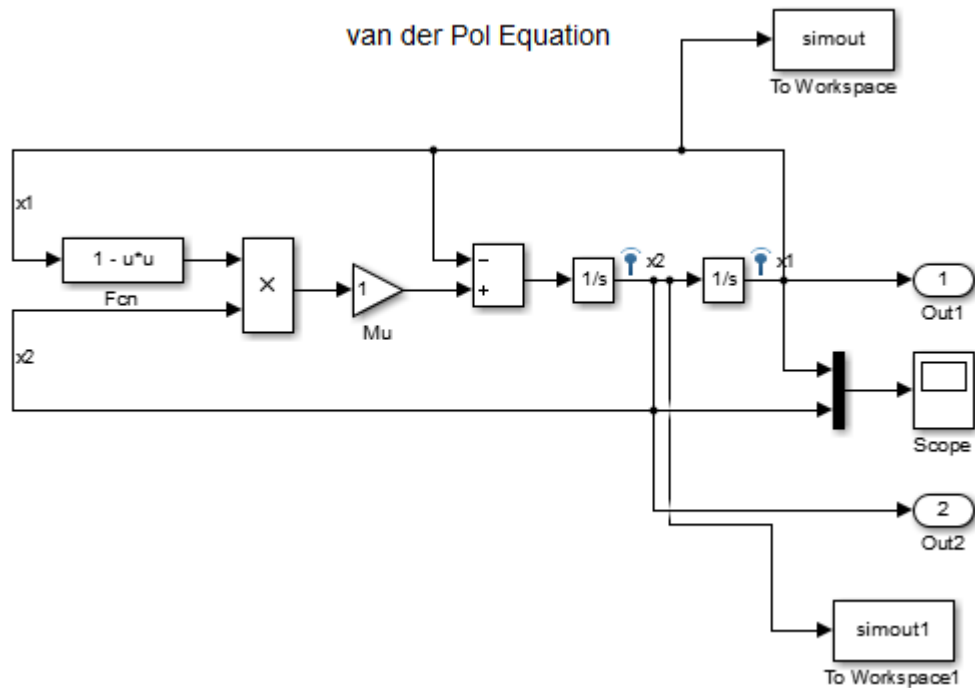

This example shows how to convert structure without time data to Dataset format. myvdp\_structure is the vdp model with two To Workspace blocks configured for simout and simout1 logging data in structure format, as shown.

If you have models that use To Workspace blocks to log data to structure format, consider using a procedure like this one to convert them to `Dataset` format.

- 1 Starting with the `vdp` model, add two To Workspace blocks to the model as shown.

- 2 In the **Save format** parameter of both blocks, select **Structure**.
- 3 Enable signal logging for the two signals going to the two **To Workspace** blocks to log in **DS** format.
- 4 Save the model as `myvdp_structure`.
- 5 Simulate the model.

The simulation logs data using the **To Workspace** blocks.

- 6 Convert the structure data from both **To Workspace** blocks to **Dataset**.

```
ds = Simulink.SimulationData.Dataset(simout);
ds1 = Simulink.SimulationData.Dataset(simout1);
```

*simout* is the variable name of the first **To Workspace** block data. *simout1* is the variable name of the second **To Workspace** block data.

With the conversion of structure without time or an array, time starts at  $t=0$  and increments by 1.

- 7 Get the values of the first element in *ds*.

```
ds.get(1).Values.Time
```

```
ans =
```

```
0
1
2
3
.
.
.
61
62
63
```

- 8 Get the time values of the first element from signal logging.

```
logcout.get(1).Values.Time
```

```
ans =
```

```
0
0.0001
0.0006
0.0031
.
.
.
19.2802
19.6802
20.0000
```

- 9 Observe the discrepancy in time stamps between
- Data logged in structure without time that you convert to **Dataset** format
  - Data logged in **Dataset** format

## Programmatically Access Logged Signal Data Saved in Dataset Format

When you use the default `Dataset` signal logging format, Simulink saves the logging data in a `Simulink.SimulationData.Dataset` object. For information about extracting signal data from that object, see the `Simulink.SimulationData.Dataset` reference page.

The `Simulink.SimulationData.Dataset` object contains a `Simulink.SimulationData.Signal` object for each logged signal.

For bus signals, the `Simulink.SimulationData.Signal` object contains a structure of MATLAB timeseries objects.

The `Simulink.SimulationData.Dataset` class provides two methods for accessing the signal logging data and its associated information.

| Name   | Description  |
|--|--|
| <code>Simulink.SimulationData.DataSet.get</code><br><br>You can also use the <code>getElement</code> method, which shares the same syntax and behavior as the <code>get</code> method. | Get element or collection of elements from the dataset, based on index, name, or block path. |
| <code>Simulink.SimulationData.DataSet.numElements</code>   | Get number of elements in the dataset.   |

For examples of accessing signal logging data that uses the `Dataset` format, see `Simulink.SimulationData.Dataset`.

### Access Array of Buses Signal Logging Data

Signal logging data for an array of buses uses `Dataset` signal logging format.

The general approach to access data for a specific signal in an array of buses is:

- 1 Use a `Simulink.SimulationData.Dataset.get` (or `getElement`) method to access a specific signal in the logged data (by default, the `logouts` variable).
- 2 To get the values, index within the array of buses.
- 3 Index again to get data for a specific bus.

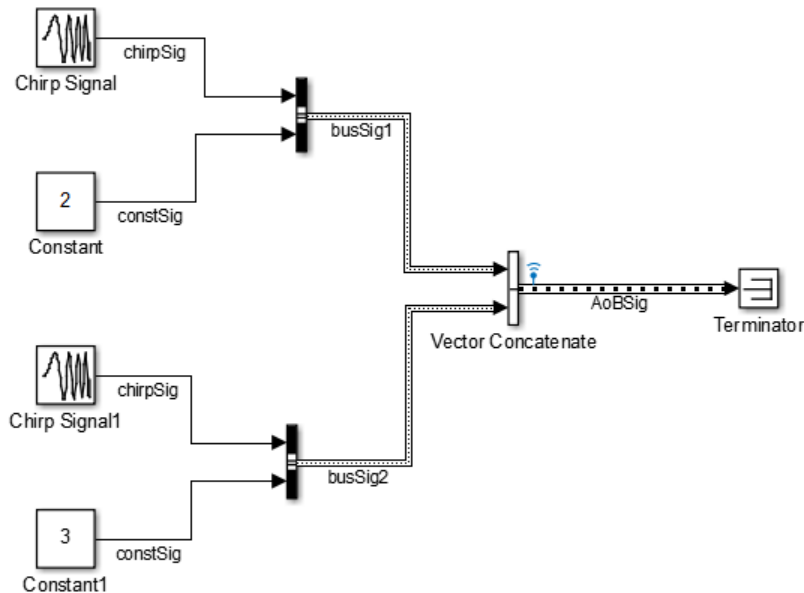

For example, to obtain the signal logging data for the `Constant6` block in the `ex_log_nested_aob` model, for the `topBus` signal that feeds the `Terminator` block:

```
logouts.getElement('topBus').Values.a(2,2).firstConst.data
```

Below are additional examples of accessing array of buses signal logging data. For another example that shows how to log array of buses data, see `sldemo_mdhref_bus`.

### Simple Array of Buses

The `ex_log_simple_aob` model includes an array of buses signal `AoBSig` that combines two bus signals (`busSig1` and `busSig2`).

To access the signal logging data for the array of buses signal, navigate through the structure hierarchy and use an index to access a specific node. This example shows navigation to the `chirpSig` signal value in `busSig2`.

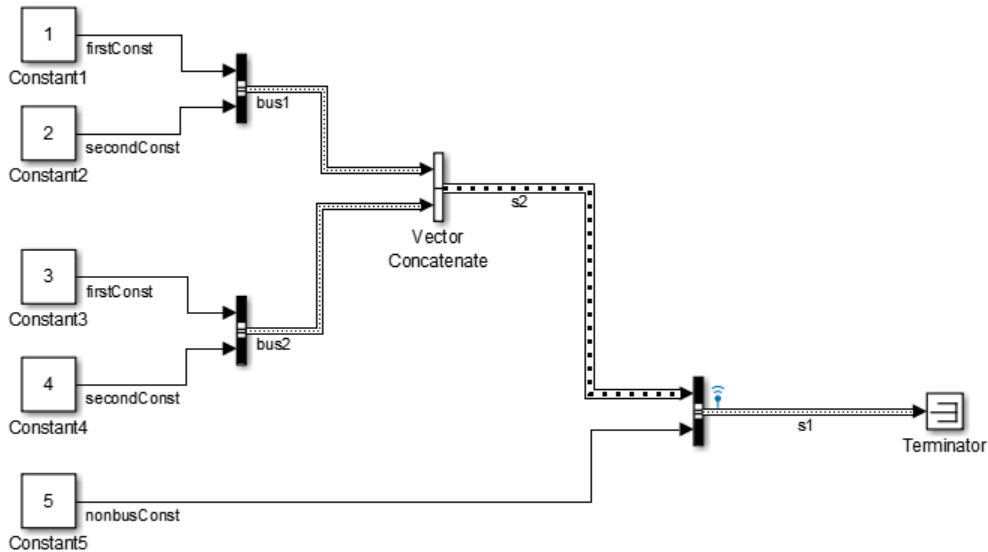

```
logout.getElement('AoBSig').Values(2).chirpSig.Data
```

```
ans=
```

```
0
0.9585
```

### Array of Buses in a Bus

The `ex_log_aob_in_bus` model has an array of buses (`s2`) that feeds into bus `s1`.

This example shows navigation to the Constant3 block, which is a signal in bus2.

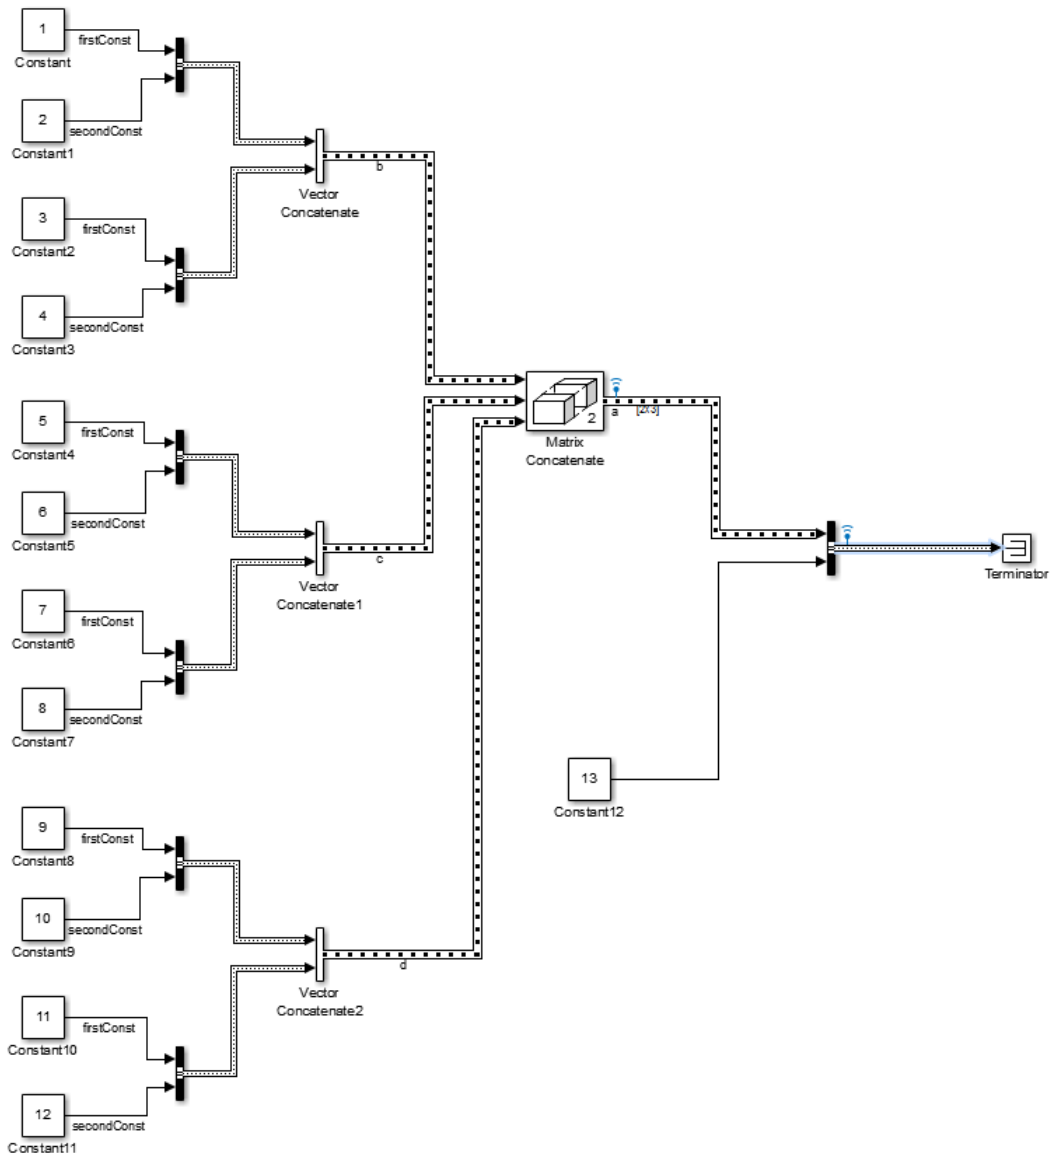

```
logout.getElement('s1').Values.s2(2).firstConst.Data
```

```
ans=
```

```
3
3
3
3
3
3
3
```

### Nested Arrays of Buses

The `ex_log_nested_aob` model has an array of buses (a) that is made up of three arrays of buses: b, c, and d. The Matrix Concatenate block combines the nested arrays of buses into array of buses a.

This example shows navigation to the Constant6 block.

```
logout.getElement('topBus').Values.a(2,2).firstConst.Data
```

```
ans=
```

```
7  
7  
7  
7  
7  
7  
7  
7  
7  
7  
7  
7
```

### Accessing Data for Signals with a Duplicate Name

For a model with multiple signals that have the same signal name, the signal logging data includes a `Simulink.SimulationData.Signal` object for each signal that has a duplicate name.

To access a specific signal that has a duplicate name, use *one* of these approaches:

- Visually inspect the displayed output of `Simulink.SimulationData.Signal` objects to find the data for the specific signal.
- Use the `Simulink.SimulationData.Dataset.getElement` method, specifying the blockpath for the source block of the signal.
- Create a script to iterate through the signals with a duplicate signal name, using the `Simulink.SimulationData.Dataset.getElement` method with an index argument.
- Use the Signal Properties dialog box to specify a different name. Consider using this approach when the signals with a duplicate name do not appear in multiple instances of a referenced model in Normal mode.
  - 1 In the model, right-click the signal.
  - 2 In the context menu, select **Properties**.
  - 3 In the Signal Properties dialog box, set **Logging name** to **Custom** and specify a different name than the signal name.

- 4 Simulate the model and use the `Simulink.SimulationData.Dataset.getElement` method with a name argument.

---

**Tip** Alternatively, you can use the Signal Logging Selector to access a specific signal. For details, see “Override Signal Logging Settings with the Signal Logging Selector” on page 57-59.

---

### Handling Newline Characters in Signal Logging Data

To handle newline characters in logging names in signal logging data that uses `Dataset` format, use a `sprintf` command within a `getElement` call. For example:

```
topOut.getElement(sprintf('INCREMENT\nBUS'))
```

### See Also

`Simulink.SimulationData.Dataset`

### More About

- “Use the Dataset Format for Signal Logging in New Models” on page 57-53

## Limit Amount of Exported Data

### In this section...

“Decimation” on page 57-31

“Limit Data Points to Last” on page 57-31

“Logging Intervals” on page 57-32

### Decimation

To skip samples when exporting data, apply a decimation factor. For example, a decimation factor of 2 saves every other sample. By default, decimation is set to 1, which does not skip any samples.

The approach you use to specify a decimation factor depends on the kind of logging data.

| Kind of Data       | How to Specify   |
|--------------------|--|
| Signal logging     | Right-click the signal. In the Signal Properties dialog box, select the <b>Decimation</b> parameter.   |
| Data store logging | From the block parameters dialog box for that block, open the <b>Logging</b> tab. Apply a decimation factor using the <b>Decimation</b> parameter. |
| State and output   | Enter a value in the field to the right of the <b>Decimation</b> label.  |

### Limit Data Points to Last

To limit the number of samples saved to be only the most recent samples, set the **Limit Data Points to Last** parameter.

The approach you use depends on the kind of logging data.

| Kind of Data   | How to Specify  |
|----------------|---|
| Signal logging | Right-click the signal. In the Signal Properties dialog box, select the <b>Limit Data Points to Last</b> parameter. |

| Kind of Data       | How to Specify   |
|--------------------|--|
| Data store logging | From the block parameters dialog box for that block, open the <b>Logging</b> tab. Select the <b>Limit Data Points to Last</b> parameter. |
| State and output   | Enter a value in the field to the right of the <b>Limit Data Points to Last</b> label.   |

## Logging Intervals

To specify an interval for logging, use the **Configuration Parameters > Data Import/Export > Logging intervals** parameter. Limiting logging to a specified interval allows you to examine specific logged data without changing the model or adding complexity to a model.

The logging intervals apply to data logged for:

- Time
- States
- Output
- Signal logging
- The To Workspace block
- The To File block

The logging intervals do not apply to final state logged data, scopes, or streaming data to the Simulation Data Inspector.

The intervals specified with **Logging intervals** establish the set of times to which the **Decimation** and **Limit data points to last** parameters apply. For example, suppose you set the logging interval [2, 4; 7, 9] with a fixed-step solver with a fixed-step size of 1. The logged times are 2, 3, 4, 7, 8, and 9.

For details, see “Logging intervals”.

## Samples to Export for Variable-Step Solvers

### In this section...

“Output Options” on page 57-33

“Refine Output” on page 57-33

“Produce Additional Output” on page 57-34

“Produce Specified Output Only” on page 57-35

### Output Options

Use the **Output options** list on the **Data Import/Export** configuration pane to control how much output the simulation generates when your model uses a variable-step solver.

- Refine output (default)
- Produce additional output
- Produce specified output only

### Refine Output

The **Refine output** option provides additional output points when the simulation output does not include as many points as you would like. This parameter provides an integer number of output points between time steps. For example, a refine factor of 2 provides output midway between the time steps as well as at the steps. The default refine factor is 1.

Suppose that a sample simulation generates output at these times:

0, 2.5, 5, 8.5, 10

Choosing **Refine output** and specifying a refine factor of 2 generates output at these times:

0, 1.25, 2.5, 3.75, 5, 6.75, 8.5, 9.25, 10

To get smoother output more efficiently, change the refine factor instead of reducing the step size. When you change the refine factor, the solver generates additional points by evaluating a continuous extension formula at sample points. This option changes

the simulation step size so that time steps coincide with the times that you specify for additional output.

The refine factor applies to variable-step solvers and is most useful when you are using `ode45`. The `ode45` solver is capable of taking large steps. However, when you graph simulation output, the output from this solver sometimes is not sufficiently smooth. In such cases, run the simulation again with a larger refine factor. A value of such as 4 for `ode45` should provide much smoother results.

---

**Note** This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see “Zero-Crossing Detection” on page 3-23).

---

## Produce Additional Output

Use the `Produce additional output` option to specify directly those additional times at which the solver generates output. When you select this option, the **Data Import/Export** pane displays an **Output times** parameter. In this parameter, enter a MATLAB expression that evaluates to an additional time or a vector of additional times. The solver produces hit times at the output times that you specify, in addition to the times it needs to more accurately simulate the model.

Suppose that a sample simulation generates output at these times:

0, 2.5, 5, 8.5, 10

Choosing the `Produce additional output` option and specifying `[0:10]` generates output at these times:

0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10

and perhaps at additional times, depending on the step size chosen by the variable-step solver.

### Tips

- This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see “Zero-Crossing Detection” on page 3-23).
- Set the **Output times** parameter to a value other than the default empty matrix (`[]`).
- For triggered subsystems and function-call subsystems, the calling function must inherit the sampling rate.

## Produce Specified Output Only

Simulink generates output at the start and stop times, in addition to the times that you specify.

Suppose that a sample simulation generates output at these times:

0, 2.5, 5, 8.5, 10

Choosing the `Produce specified output only` option and specifying `[1:9]` generates output at these times:

0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10

This option changes the simulation step size so that time steps coincide with the times that you specify for producing output. The solver may hit other time steps to accurately simulate the model. However, the output does not include these points. This option is useful when you are comparing different simulations to check that the simulations produce output at the same times.

### Tips

- This option helps the solver locate zero crossings, although it does not ensure that Simulink detects all zero crossings (see “Zero-Crossing Detection” on page 3-23).
- Set the **Output times** parameter to a value other than the default empty matrix (`[]`).
- In Normal, Accelerator, and Rapid Accelerator modes, Simulink generates output at the start and stop times, as well as at the times that you specify.
- When you simulate a model in Normal mode, triggered subsystems and function-call subsystems use the times that you specify, all of the time steps in between the values that you specify, and the simulation start and stop times.
- For triggered subsystems and function-call subsystems, the calling function must inherit the sampling rate.

## Export Signal Data Using Signal Logging

### In this section...

- “Signal Logging” on page 57-36
- “Signal Logging Workflow” on page 57-36
- “Signal Logging in Rapid Accelerator Mode” on page 57-37
- “Signal Logging for Array of Buses Signals” on page 57-38
- “Signal Logging Limitations” on page 57-38

### Signal Logging

To capture signal data from a simulation, in most cases use signal logging. Mark the signals that you want to log and enable signal logging for the model. For details, see “Configure a Signal for Logging” on page 57-39 and “Enable Signal Logging for a Model” on page 57-52.

For a summary of other approaches to capture signal data, see “Export Simulation Data” on page 57-4.

### Signal Logging Workflow

To collect and use signal logging data, perform these tasks.

- 1 Mark individual signals for signal logging. See “Configure a Signal for Logging” on page 57-39.
- 2 Enable signal logging for a model. See “Enable Signal Logging for a Model” on page 57-52.
- 3 Simulate the model.
- 4 Access the signal logging data. See “Access Signal Logging Data” on page 57-71.

### Log Subsets of Signals

One approach for testing parts of a model as you develop it is to mark a superset of signals for logging, and select different subsets of signals to log by overriding signal logging settings. You can use the Signal Logging Selector or a programmatic interface. See “Override Signal Logging Settings” on page 57-58.

Use this approach to log signals in models that use model referencing. See “Models with Model Referencing: Overriding Signal Logging Settings” on page 57-62.

### Additional Signal Logging Options

In conjunction with the basic signal logging workflow, you can specify additional options related to the data that signal logging collects and to how that data is displayed. You can:

- Specify a name for the signal logging data for a signal. See “Specify Signal-Level Logging Name” on page 57-41.
- Control how much data the simulation generates for a signal. See “Limit the Data Logged for a Signal” on page 57-43.
- Review the signal logging configuration for a model. See “View the Signal Logging Configuration” on page 57-46.
- Specify the format for the signal logging data. Use the default format (**Dataset**) except for backwards compatibility with older models. See “Specify the Signal Logging Data Format” on page 57-52.
- Specify which samples to export for models with variable-step solvers. See “Samples to Export for Variable-Step Solvers” on page 57-33.
- Configure the model to display signal logging data in the Simulation Data Inspector. See “View Logged Signal Data with the Simulation Data Inspector” on page 57-72.

### Signal Logging in Rapid Accelerator Mode

Use the **Dataset** format for signal logging data in Rapid Accelerator mode. Select the format using the **Configuration Parameters > Data Import/Export > Signal logging format** parameter.

For details, see “Specify the Signal Logging Data Format” on page 57-52.

Signal logging in Rapid Accelerator mode does not log the following kinds of signals. When you update or simulate a model that contains these signals, Simulink displays a warning that those signals are not logged.

- Signals inside Stateflow charts
- Signals that use a custom data type

You cannot use signal logging in Rapid Accelerator mode if you set the **Configuration Parameters > Solver > Sample time constraint** parameter to **Ensure sample time independent**.

## Signal Logging for Array of Buses Signals

Use the **Dataset** format for logging array of buses signals. Select the format using the **Configuration Parameters > Data Import/Export > Signal logging format** parameter.

For details, see “Specify the Signal Logging Data Format” on page 57-52.

## Signal Logging Limitations

- Rapid Accelerator mode supports signal logging, with the requirements and limitations described in “Signal Logging in Rapid Accelerator Mode” on page 57-37.
- Top-model software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulation modes support signal logging. For a description of limitations of signal logging using SIL and PIL modes, see “Internal Signal Logging Support” in the Embedded Coder documentation.
- Array of buses signals support signal logging, with the requirements described in “Signal Logging for Array of Buses Signals” on page 57-38.
- You cannot log signals in For Each subsystems.
- You cannot log local data in Stateflow Truth Table blocks.

## Configure a Signal for Logging

### In this section...

- “Mark a Signal for Signal Logging” on page 57-39
- “Specify Signal-Level Logging Name” on page 57-41
- “Limit the Data Logged for a Signal” on page 57-43
- “Set Sample Time for a Logged Signal” on page 57-44

### Mark a Signal for Signal Logging

Enable logging by marking a signal, using one of the following techniques:

- “Enable Signal Logging Using Simulink Editor Menu Options” on page 57-39
- “Enable Signal Logging Using the Signal Properties Dialog Box” on page 57-40
- “Enable Signal Logging Using Model Explorer” on page 57-40
- “Programmatic Interface” on page 57-40

The Simulink Editor menu options generally are the simplest way to mark signals for signal logging

A signal for which you enable signal logging is a *logged signal*. By default, Simulink displays a logged signal indicator  for each logged signal.

#### Enable Signal Logging Using Simulink Editor Menu Options

- 1 In the Simulink Editor, select one or more signals.
- 2

Click the **Simulation Data Inspector** button arrow  and click **Log Selected Signals to Workspace**.

Alternatively, you can select one or more signals and check **Simulation > Output > Log Selected Signals to Workspace**.

If you select multiple signals, the signal logging configuration that Simulink sets depends on whether any of the selected signals are marked for signal logging.

| Signal Logging for Selected Signals  | Result of Enabling the Log/Unlog Selected Signals Option |
|--|--|
| At least one of the selected signals does not have signal logging enabled. | Enables signal logging for all of the selected signals   |
| All selected signals have signal logging enabled.                          | Disables signal logging for all of the selected signals  |

### Enable Signal Logging Using the Signal Properties Dialog Box

- 1 In the Simulink Editor, right-click the signal.
- 2 From the context menu, select **Signal Properties**.
- 3 In the Signal Properties dialog box, in the **Logging and accessibility** tab, select **Log signal data**.
- 4 Click **OK**.

### Enable Signal Logging Using Model Explorer

---

**Note:** The only signals that Model Explorer displays are named signals. See “Signal Names and Labels” on page 60-5.

---

- 1 In the Model Explorer **Model Hierarchy** pane, select the node that contains the signal for which you want to enable signal logging.
- 2 If the **Contents** pane does not display the **DataLogging** property, set the **Column view** to **Signals** or add the **DataLogging** property to the current view. For details about column views, see “Control Model Explorer Contents Using Views” on page 11-25.
- 3 Enable the **DataLogging** property for one or more signals.

However, the Model Explorer:

- Does not display unnamed signals
- Might need to be reconfigured to display the **DataLogging** property (which sets up logging for a signal)

### Programmatic Interface

To enable signal logging programmatically for selected blocks, use the output **DataLogging** property. Set this property using the `set_param` command. For example:

- 1 At the MATLAB Command Window, open a model. Type  
vdp
- 2 Get the port handles of the signal to log. For example, for the Mu block outputport signal.  

```
ph = get_param('vdp/Mu', 'PortHandles')
```
- 3 Enable signal logging for the desired outputport signal.  

```
set_param(ph.Outputport(1), 'DataLogging', 'on')
```

  
The logged signal indicator appears.

### Logging Referenced Model Signals

You can log any logged signal in a referenced model. Use the Signal Logging Selector to configure signal logging for a model reference hierarchy. For details, see “Models with Model Referencing: Overriding Signal Logging Settings” on page 57-62.

## Specify Signal-Level Logging Name

You can specify a signal-level logging name to the object that Simulink uses to store logging data for a signal. Specifying a signal-level logging name can be useful for signals that are unnamed or that share a duplicate name with another signal in the model hierarchy. Specifying signal-level logging names, rather than using the names that Simulink generates, can make the logged data easier to analyze.

To specify a signal-level logging name, use *one* of the following approaches:

- “Using the Simulink Editor to Specify a Signal-Level Logging Name” on page 57-42
- “Using the Model Explorer to Specify a Signal-Level Logging Name” on page 57-42
- “Programmatically Specifying a Signal-Specific Logging Name” on page 57-42

If you do not specify a custom signal-level logging name, Simulink uses the signal name. If the signal does not have a name, the action Simulink takes depends on the signal logging format:

- **Dataset** — Uses a blank name
- **ModelDataLogs** — Generates a default name that is composed of the block name and port number. For example, if the block name is **MyBlock** and the signal being logged is the first output of this block, Simulink generates the name **SL\_MyBlock1**.

---

**Note:** The signal-level logging name is distinct from the model-level signal logging name, which is the name for the object containing all the logged signal data for the whole model. The default model-level signal logging name is `logsout`. For details about the model-level signal logging name, see “Specify a Name for the Signal Logging Data for a Model” on page 57-57.

---

### Using the Simulink Editor to Specify a Signal-Level Logging Name

- 1 In the Simulink Editor, right-click the signal.
- 2 From the context menu, select **Signal Properties**.
- 3 Specify the logging name:
  - a In the Signal Properties dialog box, select the **Logging and accessibility** tab.
  - b From the **Logging name** list, select **Custom**.
  - c Enter the logging name in the adjacent text field.

### Using the Model Explorer to Specify a Signal-Level Logging Name

- 1 In the Model Explorer **Model Hierarchy** pane, select the node that contains the signal for which you want to specify a logging name.
- 2 If the **Contents** pane does not display the `LoggingName` property, add the `LoggingName` property to the current view. For details about column views, see “Control Model Explorer Contents Using Views” on page 11-25.
- 3 Enter a logging name for one or more signals using the `LoggingName` column.

### Programmatically Specifying a Signal-Specific Logging Name

Enable signal logging programmatically for selected blocks with the output `DataLogging` property. Set this property using the `set_param` command.

- 1 At the MATLAB Command Window, open a model. For example, type:

```
vdp
```
- 2 Get the port handles of the signal to log. For example, for the Mu block output signal:

```
ph = get_param('vdp/Mu', 'PortHandles');
```
- 3 Enable signal logging for the desired output signal:

```
set_param(ph.Output(1), 'DataLogging', 'on');
```

The logged signal indicator appears.

- 4 Issue commands that use the `DataLoggingNameMode` and `DataLoggingName` parameters. For example:

```
set_param(ph.Outputport(1), 'DataLoggingNameMode', 'Custom');  
set_param(ph.Outputport(1), 'DataLoggingName', 'x2_log');
```

## Limit the Data Logged for a Signal

You can limit the amount of data logged for a signal by:

- Specifying a decimation factor
- Limiting the number of samples saved to be only the most recent samples

You can limit data logged for a signal by using the Signal Properties dialog box, the Model Explorer, the Signal Logging Selector, or programmatically. The following sections describe the first two approaches.

### Using the Signal Properties Dialog Box to Limit the Amount of Data Logged

- 1 In the Simulink Editor, right-click the signal.
- 2 From the context menu, select **Signal Properties**.
- 3 In the Signal Properties dialog box, click the **Logging and accessibility** tab. Then select one or both of these options:
  - **Limit data points to last**
  - **Decimation**

### Using the Model Explorer to Limit Data Logged

- 1 In the Model Explorer **Model Hierarchy** pane, select the node that contains the signal for which you want to limit the amount of data logged.
- 2 If the **Contents** pane does not display the `DataLoggingDecimation` property or the `DataLoggingLimitDataPoints` property, add one or both of those properties to the current view. For details about column views, see “Control Model Explorer Contents Using Views” on page 11-25.
- 3 To specify a decimation factor, edit the `Decimation` and `DecimateData` properties. To limit the number of samples logged, edit the `LimitDataPoints` property.

## Set Sample Time for a Logged Signal

To set the sample time for a logged signal, in the Signal Properties dialog box, use the **Sample Time** option. This option:

- Separates design and testing, because you do not need to insert a Rate Transition block to have a consistent sample time for logged signals
- Reduces the amount of logged data for a continuous time signal, for which setting decimation is not relevant
- Eliminates the need to postprocess logged signal data for signals with different sample times

### Usage Notes

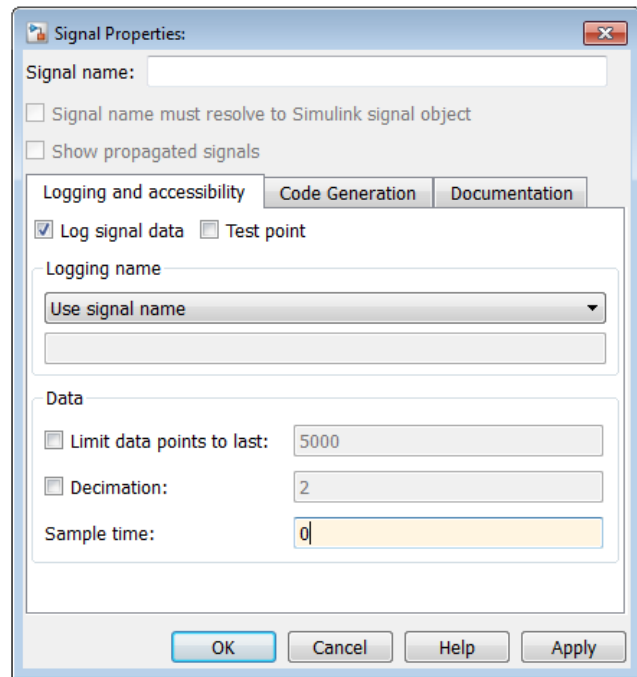

Do not specify a sample time for:

- Frame-based signals
- Conditional subsystems (for example, function-call or triggered subsystems) and conditional referenced models, which require an inherited sample time

If you simulate in SIL mode, signal logging ignores the sample times you specify for logged signals.

When you mark a signal for signal logging, Simulink inserts a hidden To Workspace block. When you specify a sample time for a logged signal, Simulink inserts a hidden Rate Transition block, as well as a hidden To Workspace block.

Specifying a sample time for signal logging does not affect the simulation result. However, it is possible that the signal logging output for a logged signal varies depending on whether you specify a sample rate. For example, the interpolation method can differ depending on whether you specify a sample time for signal logging. Suppose a model includes a continuous signal and the sample time is inherited (-1). The logged output for that signal shows the interpolation method is **linear**.

```
logout.get(1).Values.DataInfo
```

```
tsdata.datametadate
  Package: tsdata
```

```
Common Properties:
  Units: ''
  Interpolation: linear (tsdata.interpolation)
```

If you change the sample time to be continuous (0), the logged output for that signal shows the interpolation method is **zoh** (zero-order hold).

## View the Signal Logging Configuration

### In this section...

“Approaches for Viewing the Signal Logging Configuration” on page 57-46

“Use Simulink Editor to View Signal Logging Configuration” on page 57-47

“Use Signal Logging Selector to View Signal Logging Configuration” on page 57-49

“Use Model Explorer to View Signal Logging Configuration” on page 57-51

### Approaches for Viewing the Signal Logging Configuration

| Signal Logging Configuration Viewing Approach           | Usage  | Documentation  |
|---|--|--|
| In the Simulink Editor, view signal logging indicators. | <p>Consider using this approach for models that have few signals marked for signal logging and have a shallow model hierarchy.</p> <p>This approach avoids leaving the Simulink Editor.</p> <p>You need to open the Signal Properties dialog box for each signal.</p>            | “Use Simulink Editor to View Signal Logging Configuration” on page 57-47         |
| Use the Signal Logging Selector.                        | <p>Consider using this approach for models with deep hierarchies.</p> <p>View a model that has signal logging override settings for some signals.</p> <p>View the configuration as part of specifying a subset of signals to log from all signals marked for signal logging.</p> | “Use Signal Logging Selector to View Signal Logging Configuration” on page 57-49 |

| Signal Logging Configuration Viewing Approach | Usage   | Documentation   |
|---|---|---|
|   | <p>View signal logging configuration without displaying the signal logging indicators in the model.</p> <p>View signal logging configuration information such as decimation and output options in one window.</p> |   |
| Use the Model Explorer.                       | <p>View signal logging configuration in the context of other model component properties.</p> <p>You may need to adjust the column view to display signal logging properties.</p>                                  | “Use Model Explorer to View Signal Logging Configuration” on page 57-51 |

## Use Simulink Editor to View Signal Logging Configuration

By default, Simulink Editor displays an indicator on each signal that is marked for signal logging. To view the signal logging setting for a signal:

- 1 Right-click the signal. From the context menu, select **Signal Properties**.
- 2 Select the **Logging and accessibility** tab.

For example, in the following model the output of the Sine Wave block is logged:

If you use the command-line interface to override logging for a signal, the Simulink Editor continues to display the signal logging indicator for that signal. When you simulate the model, Simulink displays a red signal logging indicator for all signals marked to be logged, reflecting any overrides. For details about configuring a signal for logging, see “Configure a Signal for Logging” on page 57-39.

A logged signal can also be a test point. See “Test Points” on page 60-57 for information about test points.

To turn the display of logging indicators off, clear **Display > Signals & Ports > Testpoint & Logging Indicators**.

## Use Signal Logging Selector to View Signal Logging Configuration

- 1 Open the model for which you want to view the signal logging configuration.
- 2 Open the Signal Logging Selector, using one of the following approaches:
  - In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
 

If necessary, select **Signal logging** to enable the **Configure Signals to Log** button.
  - For a model that includes a Model block, you can also use the following approach:
    - a In the Simulink Editor, right-click a Model block.
    - b In the context-menu, select **Log Referenced Signals**.
- 3 In the **Model Hierarchy** pane, select the model node for which you want to view the signal logging configuration. For example:

To expand a node in the **Model Hierarchy** pane, right-click the arrow to the left of the node.

If no signals for a node are marked for signal logging, the **Contents** pane is empty.

If you open the Signal Logging Selector for a model that uses model referencing, then in the **Model Hierarchy** pane, the check box to the left of a model node indicates the override configuration of the node.

| Check Box   | Signal Logging Configuration   |
|---|--|
|  | For the top-level model node, logs all logged signals in the top model.<br><br>For a Model block node, logs all logged signals in the model reference hierarchy for that block.  |
|  | For the top-level model node, disables logging for all logged signals in the top model.<br><br>For a Model block node, disables logging for all signals in the model reference hierarchy for that block.   |
|  | For the top-level model node, logs all logged signals that have the DataLogging setting enabled.<br><br>For a Model block node, logs all logged signals in the model reference hierarchy for that block that have the DataLogging setting enabled. |

### Viewing the Signal Logging Configuration for Subsystems, Masked Subsystems, and Linked Libraries

The following table describes default **Model Hierarchy** pane display of subsystems, masked subsystems, and linked library nodes.

| Node             | Display Default                                     |
|------------------|---|
| Subsystem        | Displays subsystems all that include logged signals |
| Masked subsystem | Does not display masked subsystems                  |
| Linked library   | Displays all subsystems that include logged signals |

You can control how the **Model Hierarchy** pane displays subsystems, masked subsystems, and linked libraries. Use icons at the top of the **Model Hierarchy** pane or use the **View** menu, using the same approach as you use in the Model Explorer. For details, see “Displaying Linked Library Subsystems” on page 11-13 and “Displaying Masked Subsystems” on page 11-13.

- To display all subsystems, including subsystems that do not include signals marked for logging, select the  icon or **View > Show All Subsystems**. This

subsystem setting also applies to masked subsystems, if you specify to display masked subsystems.

- To display masked subsystems with logged signals, use the  icon or **View > Show Masked Subsystems**
- To display linked libraries, use the  icon or **View > Show Library Links**

### Filtering Signal Logging Selector Contents

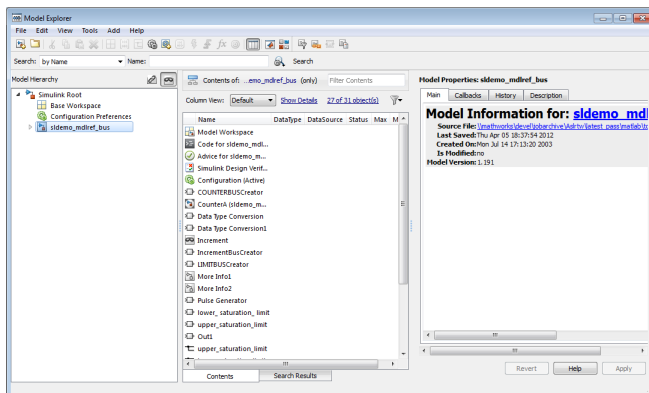

To find a specific signal or property value for a signal, use the **Filter Contents** edit box. Use the same approach as you use in the Model Explorer; for details, see “Filtering Contents” on page 11-44.

### Highlighting a Block in a Model

To use the Model Hierarchy pane to highlight a block in model, right-click the block or signal and select **Highlight block in model**.

## Use Model Explorer to View Signal Logging Configuration

- 1 Open the model for which you want to view the signal logging configuration. Select the top-level model in a model reference hierarchy to access the logging configuration information for referenced models.
- 2 In the **Contents** pane, set **Column View** to the Signals view.

For further information, see “Model Explorer: Model Hierarchy Pane” on page 11-9 and “Model Explorer: Contents Pane” on page 11-19.

## Enable Signal Logging for a Model

### In this section...

“Enable and Disable Logging at the Model Level” on page 57-52

“Specify the Signal Logging Data Format” on page 57-52

“Specify a Name for the Signal Logging Data for a Model” on page 57-57

### Enable and Disable Logging at the Model Level

To log a signal, you must mark it for signal logging. For details, see “Configure a Signal for Logging” on page 57-39.

Enable or disable logging globally for all signals that you mark for signal logging in a model. By default, signal logging is enabled. Simulink logs signals only if **Configuration Parameters > Data Import/Export > Signal logging** parameter is checked. If the option is not checked, Simulink ignores the signal logging settings for individual signals.

To disable signal logging, use *one* of these approaches.

- Clear the **Configuration Parameters > Data Import/Export > Signal logging** parameter.
- Use the `SignalLogging` parameter. For example:

```
set_param(bdroot, 'SignalLogging', 'off')
```

### Selecting a Subset of Signals to Log

You can select a subset of signals to log for a model that has:

- Signal logging enabled
- Logged signals

For details, see “Override Signal Logging Settings” on page 57-58.

### Specify the Signal Logging Data Format

The signal logging format determines how Simulink stores the logged signal data. You can store the data using either the `Dataset` or `ModelDataLogs` format.

## Set the Signal Logging Format

To set the signal logging format, use either of these approaches:

- Set the **Configuration Parameters > Data Import/Export > Signal logging format** parameter to either `Dataset` (default) or `ModelDataLogs`.
- Use the `SignalLoggingSaveFormat` parameter, with a value of `Dataset` or `ModelDataLogs`. For example:

```
set_param(bdroot, 'SignalLoggingSaveFormat', 'Dataset')
```

## Use the Dataset Format for Signal Logging in New Models

Use the `Dataset` format for signal logging for new models. The `ModelDataLogs` format is supported for backwards compatibility. The `ModelDataLogs` format will be removed in a future release.

The `Dataset` format:

- Provides an easy to analyze format for logged signal data for models with deep hierarchies, bus signals, and signals with duplicate or invalid names.
- Supports signal logging in Rapid Accelerator mode.
- Avoids the limitations of the `ModelDataLogs` format, which Bug Report 495436 describes.

When you specify the `Dataset` format, Simulink stores the data using a `Simulink.SimulationData.Dataset` object.

---

**Note:** Use the `Dataset` format to log arrays of buses.

---

## Migrate from ModelDataLogs to Dataset Format

The `ModelDataLogs` logging format is supported for backwards compatibility. The `ModelDataLogs` format will be removed in a future release. To enable existing models that use `ModelDataLogs` format to continue to work in future releases, migrate those models to use `Dataset` format.

Use the Upgrade Advisor to upgrade a model to use `Dataset` format, using *one* of these approaches:

- In the Simulink Editor, select **Analysis > Model Advisor > Upgrade Advisor**

- From the MATLAB command line, use the `upgradeadvisor` function.

If you have already logged signal data in the `ModelDataLogs` format, you can use the `Simulink.ModelDataLogs.convertToDataset` function to update the `ModelDataLogs` signal logging dataset to use `Dataset` format. For example, to update the `older_model_dataset` from `ModelDataLogs` format to `Dataset` format:

```
new_dataset = logouts.convertToDataset('older_model_dataset')
```

Depending upon your particular circumstances, converting a model from using `ModelDataLogs` format to using `Dataset` format may require that you make some modifications to your existing models and to code in callbacks, functions, scripts, or tests. The following table identifies possible issues that you may need to address after converting to `Dataset` format. The table provides solutions for each issue.

| Possible Issue After Conversion to Dataset Format   | Solution   |
|---|--|
| Code in existing callbacks, functions, scripts, or tests that used the <code>ModelDataLogs</code> programmatic interface to access data may result in an error. | <p>Check for code that uses <code>ModelDataLogs</code> format access methods. Update that code to use <code>Dataset</code> format access methods.</p> <p>For example, suppose existing code includes the following line:</p> <pre>logouts.('Subsystem Name').X.data</pre> <p>Replace that code with a <code>Dataset</code> access method:</p> <pre>logouts.getElement('x').Values.data</pre> |
| Logging bus signals requires a configuration parameter change.  | <p>Logging buses in <code>Dataset</code> format requires that <b>Configuration Parameters &gt; Diagnostics &gt; Connectivity &gt; Mux blocks used to create bus signals</b> be set to error.</p> <p>To configure a model for proper bus usage, run the Upgrade Advisor with the <b>Check bus usage</b> check.</p>  |
| Mux block signal names are lost.  | <p>The <code>Dataset</code> format treats Mux block signals as a vector.</p> <p>If you need to identify signals by signal names, replace Mux blocks with a Bus Creator blocks. Set</p>   |

| Possible Issue After Conversion to Dataset Format  | Solution   |
|--|--|
|  | <b>Configuration Parameters &gt; Diagnostics &gt; Connectivity &gt; Mux blocks used to create bus signals to error.</b>  |
| Signal Viewer cannot be used for signal logging.   | <p>If you use the <b>Dataset</b> format for signal logging, then Simulink does not log the signals to be logged in the Signal Viewer.</p> <p>Configure the signal for signal logging.</p>  |
| The <code>unpack</code> method generates an error. | <p>The <code>unpack</code> method, which is supported for <code>Simulink.ModelDataLogs</code> and <code>Simulink.SubsysDataLogs</code> objects, is <i>not</i> supported for <code>Simulink.SimulationData.Dataset</code> objects.</p> <p>For example, if the logged data has three fields: <code>x</code>, <code>y</code>, and <code>z</code>, then:</p> <ul style="list-style-type: none"> <li>• For <code>ModelDataLogs</code> format data, the <code>mlog.unpack</code> method creates three variables in the base workspace.</li> <li>• For <code>Dataset</code> format data, access methods by names. For example:</li> </ul> <pre>x = logcout.getElement('x').Values</pre> |

| Possible Issue After Conversion to Dataset Format   | Solution   |
|---|--|
| The <code>ModelDataLogs</code> and <code>Dataset</code> formats have different naming rules for unnamed signals.  | <p>If necessary, add signal names.</p> <ul style="list-style-type: none"> <li>In <code>ModelDataLogs</code> format, for an unnamed signal coming from a block, Simulink assigns a name in this form:<br/><br/><code>SL_BlockName+&lt;portIndex&gt;</code><br/><br/>For example, <code>SL_Gain1</code>.</li> <li>In <code>Dataset</code> format, elements do not need a name, so Simulink leaves the signal name empty.</li> <li>For both <code>ModelDataLogs</code> and <code>Dataset</code> formats, Simulink assigns the same name to unnamed signals that come from Bus Selector blocks.</li> </ul> |
| Test points in referenced models are not logged.  | Consider enabling signal logging for test points in a referenced model.  |
| Running or updating a model that uses model referencing might return a signal logging format inconsistency error. | Follow the approach described in “Model Reference Signal Logging Format Consistency” on page 57-56.  |

### Model Reference Signal Logging Format Consistency

If signal logging is enabled for a top model, then the signal logging format for the non-protected referenced models must be the same as the signal logging format for the top model.

Simulink performs signal logging format consistency checking during model update or when you run a simulation. Simulink does not report inconsistencies during code generation for model reference simulation target code.

If Simulink reports a signal logging format inconsistency, then use *one* of the following approaches:

- Use the Upgrade Advisor (with the `upgradeadvisor` function) to upgrade a model to use `Dataset` format.

- Use the `Simulink.SimulationData.updateDatasetFormatLogging` function to convert a model and its referenced models to use `Dataset` format for signal logging.
- Turn off signal logging for the model, including for all referenced models, by clearing the **Configuration Parameters > Data Import/Export > Signal logging** parameter check box.
- Disable logging for all signals in this top-level Model block.
  - 1 Select the **Configuration Parameters > Data Import/Export > Configure Signals to Log** button.
  - 2 In the Signal Logging Selector dialog box, in the **Model Hierarchy** pane, clear the check box for the top Model block in the model reference hierarchy.

## Specify a Name for the Signal Logging Data for a Model

You use the model-level signal logging name to access the signal logging data for a model. The default name for the signal logging data is `logouts`. Specifying a model-level signal logging name can make it easier to identify the source of the logged data. For example, you could specify the signal logging name `car_logouts` to identify the data as being the signal logging data for the `car` model.

To specify a different model-level signal logging name, use either of these approaches:

- In the edit box next to the **Configuration Parameters > Data Import/Export > Signal logging** parameter, enter the signal logging name.
- Use the `SignalLoggingName` parameter, specifying a signal logging name. For example:

```
set_param(bdroot, 'SignalLoggingName', 'heater_model_signals')
```

## Override Signal Logging Settings

### In this section...

“Benefits of Overriding Signal Logging Settings” on page 57-58

“Two Interfaces for Overriding Signal Logging Settings” on page 57-58

“Scope of Signal Logging Setting Overrides” on page 57-59

“Override Signal Logging Settings with the Signal Logging Selector” on page 57-59

“Override Signal Logging Settings from MATLAB” on page 57-65

### Benefits of Overriding Signal Logging Settings

As you develop a model, you may want to override the signal logging settings for a specific simulation run. You can override signal logging properties without changing the model in the Simulink Editor.

Override signal logging properties to reduce memory overhead and to facilitate the analysis of simulation logging results. By overriding signal logging settings, you can avoid recompiling a model.

Overriding signal logging properties is useful when you want to:

- Focus on only a few signals by disabling logging for most of the signals marked for logging. You can mark a superset of signals for logging, and then select different subsets of them for logging.
- Exclude a few signals from the signal logging output.
- Override specific signal logging properties, such as decimation, for a signal.
- Collect only what you need when running multiple test vectors.

### Two Interfaces for Overriding Signal Logging Settings

Use either of two interfaces to override signal logging settings:

- “Override Signal Logging Settings with the Signal Logging Selector” on page 57-59
- “Override Signal Logging Settings from MATLAB” on page 57-65

You can use a combination of the two interfaces. The Signal Logging Selector creates `Simulink.SimulationData.ModelLoggingInfo` objects when

saving the override settings. The command-line interface has properties whose names correspond to the Signal Logging Selector interface. For example, the `Simulink.SimulationData.ModelLoggingInfo` class has a `LoggingMode` property, which corresponds to the **Logging Mode** parameter in the Signal Logging Selector.

## Scope of Signal Logging Setting Overrides

When you override signal logging settings, Simulink uses those override settings when you simulate the model.

Simulink saves in the model the signal logging override configuration that you specify. However, Simulink does not change the signal logging settings in the Signal Properties dialog box for each signal in the model.

In the Signal Logging Selector, if you override some signal logging settings, and then set the **Logging Mode** to **Log all signals as specified in model**, the logging settings defined in the model appear in the Signal Logging Selector. The override settings are greyed out, indicating that you cannot override these settings. To reactivate the override settings, set **Logging Mode** to **Override signals**. Using the Signal Logging Selector to override logging for a specific signal does not affect the signal logging indicator for that signal.

If you close and then reopen the model, the logging setting overrides that you made are in effect, if logging mode is set to override signals for that model. When the model displays the signal logging indicators, it displays the indicators for all logged signals, including logged signals that you have overridden.

---

**Note:** Simulink rebuilds a model in the following situation:

- 1 The model contains one or more signals marked for signal logging.
  - 2 You simulate the model in Rapid Accelerator mode.
  - 3 You use the Signal Logging Selector or MATLAB command line to modify the signal logging configuration.
  - 4 You simulate the model in Rapid Accelerator mode again.
- 

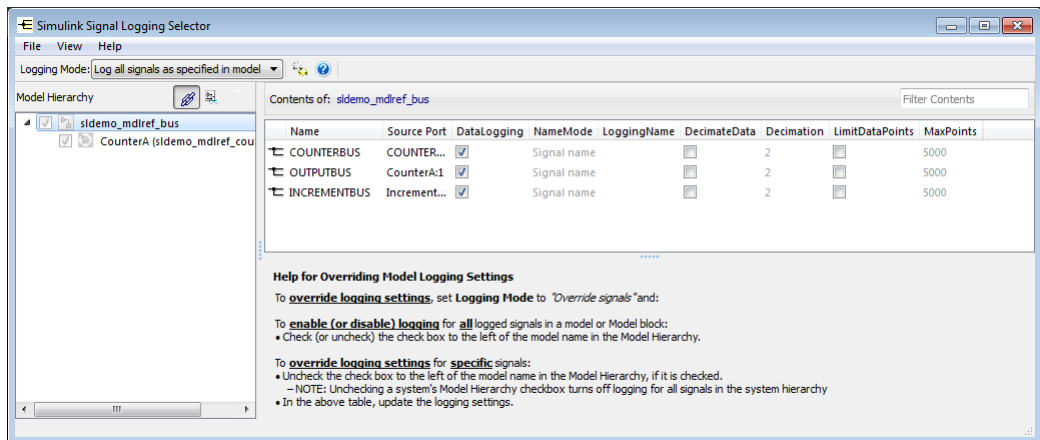

## Override Signal Logging Settings with the Signal Logging Selector

- 1 Open the Signal Logging Selector, using one of the following approaches:

- In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.

If necessary, select **Signal logging** to enable the **Configure Signals to Log** button.

- For a model that includes a Model block, you can also use the following approach:
  - a In the Simulink Editor, right-click a Model block.
  - b In the context-menu, select **Log Referenced Signals**.

## 2 Set **Logging Mode** to **Override signals**.

**Note:** The **Override signals** setting affects all levels of the model hierarchy. This setting can result in turning off logging for any signal throughout the hierarchy, based on existing settings. To review settings, select the appropriate node in the **Model Hierarchy** pane.

- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See "Use Signal Logging Selector to View Signal Logging Configuration" on page 57-49.
- 4 Override signal logging settings. Use one of the following approaches, depending on whether or not your model uses model referencing:

- “Models Without Model Referencing: Overriding Signal Logging Settings” on page 57-61
- “Models with Model Referencing: Overriding Signal Logging Settings” on page 57-62

---

**Tip** To open the **Configuration Parameters > Data Import/Export** pane from the Signal Logging Selector, use the  button.

---

### Models Without Model Referencing: Overriding Signal Logging Settings

If your model does not use model referencing (that is, the model does not include any Model blocks), override signal logging settings using the following procedure.

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
  - If necessary, select **Signal logging** to enable the **Configure Signals to Log** button.

- 2 Set **Logging Mode** to **Override signals**.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems.

See “Use Signal Logging Selector to View Signal Logging Configuration” on page 57-49.

- 4 In the **Contents** pane table, select the signal whose logging settings you want to override.
- 5 Override logging settings:
  - To disable logging for a signal, clear the **DataLogging** check box for that signal.
  - To override other signal logging settings (for example, decimation), ensure that the **DataLogging** check box is selected. Then, edit values in the appropriate columns.

### Models with Model Referencing: Overriding Signal Logging Settings

If your model uses model referencing (that is, the model includes at least one Model block), override signal logging settings using the one or more of the following procedures:

- “Enable Logging for All Logged Signals” on page 57-62
- “Disable Logging for All Logged Signals in a Model Node” on page 57-63
- “Override Signal Logging for a Subset of Signals” on page 57-63
- “Override Other Signal Logging Properties” on page 57-64

#### Enable Logging for All Logged Signals

By default, Simulink logs all the logged signals in a model, including the logged signals throughout model reference hierarchies.

If logging is disabled for any logged signals in the top-level model or in the top-level Model block in a model reference hierarchy, then in the **Model Hierarchy** pane, the check box to the left of that node is either solid () , if logging is disabled for some of signals, or empty () , if logging is disabled for all of the signals.

To enable logging of all logged signals for a node:

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
- 2 Set **Logging Mode** to **Override** signals.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems.

See “Use Signal Logging Selector to View Signal Logging Configuration” on page 57-49.

- 4 In the **Model Hierarchy** pane, select the check box to the left of the node, so that the check box has a check mark ().
  - For the top-level model, logging is enabled for all logged signals in the top-level model, but not for logged signals in model reference hierarchies.
  - For a Model block at the top of a model referencing hierarchy, logging is enabled for the whole model reference hierarchy for the selected referenced model.

#### Disable Logging for All Logged Signals in a Model Node

If signal logging is enabled for any signals in a model node, then in the **Model Hierarchy** pane, the check box to the left of the node is either solid () , if logging is enabled for some signals, or checked () , if logging is enabled for all signals.

To disable logging for all logged signals in a node of a model:

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
- 2 Set **Logging Mode** to **Override** signals.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “Use Signal Logging Selector to View Signal Logging Configuration” on page 57-49.
- 4 In the **Model Hierarchy** pane, clear the check box to the left of the node, so that the check box is empty ().
  - For the top-level model, logging is disabled for all logged signals in the top-level model, but not for logged signals in model reference hierarchies.
  - For a Model block at the top of a model referencing hierarchy, logging is disabled for the whole model reference hierarchy for the selected reference model.

#### Override Signal Logging for a Subset of Signals

To log some, but not all, logged signals in a model node:

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.
- 2 Set **Logging Mode** to **Override signals**.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “Use Signal Logging Selector to View Signal Logging Configuration” on page 57-49.
- 4 In the **Model Hierarchy** pane, ensure that the check box for the top-level model or Model block is either solid () , if logging is disabled for some of the signals, or empty () , if logging is disabled for all the signals. Click the check box to cycle through different states.
- 5 In the **Contents** pane table, for the signals that you want to log, select the check box in the **DataLogging** column.

To enable logging for multiple signals, hold the **Shift** or **Ctrl** key and select a range of signals or individual signals. Select the check box in the **DataLogging** column of one of the highlighted signals.

---

**Note:** You cannot use the Signal Logging Selector to override a subset of signals for model reference variant systems, including:

- Model reference variants
- Model blocks that contain a Subsystem Variant or model reference variant

You can override programmatically a subset of signals in those configurations. For details, see “Override Signal Logging Settings from MATLAB” on page 57-65.

---

### Override Other Signal Logging Properties

In addition to overriding the setting for the **DataLogging** property for a signal, you can override other signal logging properties, such as decimation.

- 1 Open the Signal Logging Selector. In the **Configuration Parameters > Data Import/Export** pane, in the **Signals** area, select the **Configure Signals to Log** button.

- 2 Set **Logging Mode** to **Override** signals.
- 3 View the node containing the logged signals that you want to override. If necessary, expand nodes or configure the Model Hierarchy pane to display masked subsystems. See “Use Signal Logging Selector to View Signal Logging Configuration” on page 57-49.
- 4 In the **Model Hierarchy** pane, ensure that the check box for the top-level model or Model block is solid () if logging is disabled for some signals, or empty () if logging is disabled for all signals. Click the check box to cycle through different states.
- 5 In the **Contents** pane table, for the signals for which you want to override logging properties, enable logging by selecting the check box in the **DataLogging** column.

To enable logging for multiple signals, hold the **Shift** or **Ctrl** key and select a range of signals or individual signals. Select the check box in the **DataLogging** column of one of the highlighted signals.

- 6 In the **Contents** pane table, modify the settings for properties, such as **DecimateData** and **Decimation**.

## Override Signal Logging Settings from MATLAB

The MATLAB command-line interface for overriding signal logging settings includes:

- The `DataLoggingOverride` model parameter — Use to view or set signal logging override values for a model
- The following classes:
  - `Simulink.SimulationData.ModelLoggingInfo` — Specify signal logging override settings for a model. This class corresponds to the overall Signal Logging Selector interface.
  - `Simulink.SimulationData.SignalLoggingInfo` — Override settings for a specific signal. This class corresponds to a row in the logging property table in the Signal Logging Selector:

| Source Port  | DataLogging                         | NameMode | LoggingName | DecimateData             | Decimation | LimitDataPoints          | MaxPoints |
|--------------|-------------------------------------|----------|-------------|--------------------------|------------|--------------------------|-----------|
| Bus Creat... | <input checked="" type="checkbox"/> | Custom   | inner_bus   | <input type="checkbox"/> | 2          | <input type="checkbox"/> | 5000      |

- `Simulink.SimulationData.LoggingInfo` — Overrides for signal logging settings such as decimation. This class corresponds to the editable columns in a row in the logging property table in the Signal Logging Selector.

To query a model for its signal logging override status, use the `DataLoggingOverride` parameter.

To configure signal logging from the command line, use methods and properties of the three classes listed above. To apply the configuration, use `set_param` with the `DataLoggingOverride` model parameter.

The following sections describe how to use the command-line interface to perform some common signal logging configuration tasks.

- “Create a Model Logging Information Object” on page 57-66
- “Specify Which Models to Log” on page 57-67
- “Log a Subset of Signals” on page 57-68
- “Override Other Signal Logging Properties” on page 57-70

### Create a Model Logging Information Object

To use the command-line interface for overriding signal logging settings, first create a `Simulink.SimulationData.ModelLoggingInfo` object. For example, use the following commands to create the model logging override object for the `ex_bus_logging` model and automatically add each logged signal in the model to that object:

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_mdhref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
'examples', 'ex_bus_logging')));
mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel(...
'ex_bus_logging')
```

```
mi =
```

```
ModelLoggingInfo with properties:
```

```
          Model: 'ex_bus_logging'
      LoggingMode: 'OverrideSignals'
LogAsSpecifiedByModels: {}
          Signals: [1x4 Simulink.SimulationData.SignalLoggingInfo]
```

The `LoggingMode` property is set to `OverrideSignals`, which configures the model logging override object to log only the signals specified in the `Signals` property.

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

You can control the kinds of systems from which to include logged signals. By default, the `Simulink.SimulationData.ModelLoggingInfo` object includes logged signals from:

- Libraries
- Masked subsystems
- Referenced models
- Active variants

As an alternative, you can use the `Simulink.SimulationData.ModelLoggingInfo` constructor and specify a `Simulink.SimulationData.SignalLoggingInfo` object for each signal. To ensure that you specified valid signal logging settings for a model, use the `verifySignalAndModelPaths` method with the `Simulink.SimulationData.ModelLoggingInfo` object for the model.

### Specify Which Models to Log

Use the `LoggingMode` property of a `Simulink.SimulationData.ModelLoggingInfo` object to specify whether to use the signal logging settings as specified in the model and all referenced models, or to override those settings.

You can control whether a top-level model and referenced models use override signal logging settings or use the signal logging settings specified by the model, as described in the `Simulink.SimulationData.ModelLoggingInfo` documentation.

The following example shows how to log all signals as specified in the top model and all referenced models. The signal logging output is stored in `topOut`.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_mdhref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_bus_logging')));
mi = Simulink.SimulationData.ModelLoggingInfo...
    ('ex_bus_logging');
mi.LoggingMode = 'LogAllAsSpecifiedInModel'

mi =
```

ModelLoggingInfo with properties:

```
        Model: 'ex_bus_logging'  
        LoggingMode: 'LogAllAsSpecifiedInModel'  
        LogAsSpecifiedByModels: {}  
        Signals: []
```

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

The following example shows how to log only signals in the top model:

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...  
'examples', 'ex_mdhref_counter_bus')));  
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...  
'examples', 'ex_bus_logging')));  
mi = Simulink.SimulationData.ModelLoggingInfo...  
    ('ex_bus_logging');  
mi.LoggingMode = 'OverrideSignals';  
mi = mi.setLogAsSpecifiedInModel('ex_bus_logging', true);
```

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

### Log a Subset of Signals

For a simple model with a limited number of logged signals, you could create an empty `Simulink.SimulationData.ModelDataLogInfo` object. Then create `Simulink.SimulationData.SignalLoggingInfo` objects for each of the signals that you want to log, and assign those objects to the model logging information object.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...  
'examples', 'ex_mdhref_counter_bus')));  
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...  
'examples', 'ex_bus_logging')));  
mdl = 'ex_bus_logging';  
blk = 'ex_bus_logging/IncrementBusCreator';  
blkPort = 1;  
  
load_system(mdl);
```

```

ov = Simulink.SimulationData.ModelLoggingInfo mdl;
so = Simulink.SimulationData.SignalLoggingInfo(blk,blkPort);
ov.Signals(1) = so;

% apply this object so the model
set_param mdl, 'DataLoggingOverride', ov;

% Simulate
sim mdl;

% observe that only the signal
topOut

```

To apply the model override object settings, use:

```
set_param mdl, 'DataLoggingOverride', ov;
```

Simulink saves the settings when you save the model.

For a model that uses model referencing, or that is complex, to specify a subset of logged signals to log, consider using the `findSignal` method with a `Simulink.SimulationData.ModelLoggingInfo` object. For example, to log only one signal from the referenced model instance referenced by :

```

open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_mdhref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_bus_logging')));

mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel(...
    'ex_bus_logging');
pos = mi.findSignal({'ex_bus_logging/CounterA' ...
    'ex_mdhref_counter_bus/Bus Creator'}, 1)

pos =

    4

for idx=1:length(mi.Signals)
    mi.Signals(idx).LoggingInfo.DataLogging = (idx == pos);

```

end

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

---

**Note:** You can override programmatically a subset of signals for model reference variant systems, including:

- Model reference variants
- Model blocks that contain a Subsystem Variant or model reference variant

To log a subset of signals for these model reference variant systems, set the `SignalLoggingSaveFormat` parameter to `Dataset`.

---

## Override Other Signal Logging Properties

In addition to overriding the setting for the `DataLogging` property for a signal, you can override other signal logging properties, such as decimation.

Use `Simulink.SimulationData.LoggingInfo` properties to override signal logging properties. The following example shows how to set the decimation override settings.

```
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_mdhref_counter_bus')));
open_system(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
    'examples', 'ex_bus_logging')));
mi = Simulink.SimulationData.ModelLoggingInfo.createFromModel...
    ('ex_bus_logging');
pos = mi.findSignal({'ex_bus_logging/CounterA' ...
    'ex_mdhref_counter_bus/Bus Creator'}, 1);
mi.Signals(pos).LoggingInfo.DecimateData = true;
mi.Signals(pos).LoggingInfo.Decimation = 2;
```

To apply the model override object settings, use:

```
set_param(ex_bus_logging, 'DataLoggingOverride', mi);
```

Simulink saves the settings when you save the model.

## Access Signal Logging Data

### In this section...

“View Signal Logging Data” on page 57-71

“Signal Logging Object” on page 57-71

“View Logged Signal Data with the Simulation Data Inspector” on page 57-72

“Handling Spaces and Newlines in Logged Names” on page 57-72

“Programmatically Access Logged Signal Data Saved in ModelDataLogs Format” on page 57-74

## View Signal Logging Data

You can view the signal logging data for a paused or completed simulation, using one of these interfaces:

- The Simulation Data Inspector
- Programmatically, using MATLAB commands

To access signal logging data programmatically, the approach you use depends on the signal logging data format (**Dataset** or **ModelDataLogs**). For details, see:

- “Programmatically Access Logged Signal Data Saved in Dataset Format” on page 57-25
- `Simulink.ModelDataLogs`

---

**Note:** If you do not see logging data for a signal that you marked in the model for signal logging, check the logging configuration using the Signal Logging Selector. Use the Signal Logging Selector to enable logging for a signal whose logging is overridden. For details, see “View the Signal Logging Configuration” on page 57-46 and “Override Signal Logging Settings” on page 57-58.

---

## Signal Logging Object

Simulink saves signal logging data in a signal logging object, which you access using a MATLAB workspace variable.

The type of the signal logging object depends on the signal logging format that you choose. For details, see “Specify the Signal Logging Data Format” on page 57-52.

- **Dataset** format — Uses a `Simulink.SimulationData.Dataset` object
- **ModelDataLogs** format — Uses a `Simulink.ModelDataLogs` object

The default name of the signal logging variable is `logout`. You can change the variable name. For details, see “Specify a Name for the Signal Logging Data for a Model” on page 57-57.

## View Logged Signal Data with the Simulation Data Inspector

You can use the Simulation Data Inspector to view logged signal data.

To view logged signal data with the Simulation Data Inspector, open the Simulink Editor and use one of the following approaches:

- To display logged signals when a simulation ends or when you pause a simulation, select **Simulation > Output > Send Logged Workspace Data to Data Inspector**.
- To launch the Simulation Data Inspector to display the logged data, select **Simulation > Output > Simulation Data Inspector**.

For additional information about using the Simulation Data Inspector, see “Inspect Signal Data with Simulation Data Inspector” on page 25-2.

## Handling Spaces and Newlines in Logged Names

Signal names in data logs can have spaces or newlines in their names when:

- The signal is named and the name includes a space or newline character.
- The signal is unnamed and originates in a block whose name includes a space or newline character.
- The signal exists in a subsystem or referenced model, and the name of the subsystem, Model block, or of any superior block, includes a space or newline character.

The following three examples show a signal whose name contains a space, a signal whose name contains a newline, and an unnamed signal that originates in a block whose name contains a newline:

The following example shows how to handle spaces or new lines in logged names, if a model uses:

- **Dataset** for the signal logging format
- The default of **logouts** for the signal logging data

logouts

logouts =

```
Simulink.SimulationData.Dataset
Package: Simulink.SimulationData
```

```
Characteristics:
    Name: 'logouts'
    Total Elements: 3
```

```
Elements:
    1: ''
    2: 'x y'
    3: 'a
b'
```

b'

To access a signal with a space or newline, use the index. For example, to access the `x y` signal:

```
>> logouts.getElement(2)
```

## **Programmatically Access Logged Signal Data Saved in ModelDataLogs Format**

---

**Note:** The ModelDataLogs signal logging format is supported for backward compatibility. For new models, use the Dataset format.

---

For information on extracting signal data from that object, see `Simulink.ModelDataLogs`.

## Techniques for Importing Signal Data

### In this section...

“Signal Data Import Techniques Summary” on page 57-75

“Comparison of Techniques” on page 57-76

“Time and Signal Values for Imported Data” on page 57-77

### Signal Data Import Techniques Summary

Simulink provides several techniques for importing signal data into a model.

| Signal Data Import Technique   | Description  |
|--|--|
| Root-level Inport, Trigger, Enable, or Function-Call Subsystem block | <p>Supplies external inputs from the MATLAB (base), model, or mask workspace. Specify the external inputs in the <b>Configuration Parameters &gt; Data Import/Export &gt; Input</b> parameter or as a <code>sim</code> command argument.</p> <p>To import and map signal and bus data to root-level inports at the same time, you can use the Inport Mapping tool. For details, see “Import and Map Root-Level Inport Data” on page 57-100. Use this method if you have many signals to import and map.</p> <p>For an example of a more manual way to import signal data and map it to root-level inport, see “Import Data to Root-Level Input Ports” on page 57-87. Consider this method if you have few signals to import and map.</p> |
| From File block  | <p>Reads data from a MAT-file and outputs the data as a signal.</p>  |
| From Workspace block   | <p>Reads data from the MATLAB (base), model, or mask workspace and outputs the data as a signal.</p> <p>For an example, see “Use From Workspace Block to Import an Input Test Case” on page 57-84.</p>   |
| Signal Builder block   | <p>Provides a graphical interface for creating and generating interchangeable groups of signals.</p>   |

Each of these techniques:

- Uses blocks to represent the signal data import sources visually
- Supports data interpolation and extrapolation, which support the use of incomplete sets of signal data
- Supports zero-crossing detection

## Comparison of Techniques

Each technique is well-suited to meet one or more of the following modeling considerations.

| Modeling Consideration  | Suggested Technique  |
|---|--|
| <b>Purpose of importing signal data</b>                                     |  |
| To perform local, temporary testing by importing a small set of signal data | <ul style="list-style-type: none"> <li>• From File block</li> <li>• From Workspace block</li> <li>• Signal Builder block</li> <li>• Root-level Inport, Trigger, Enable, or Function-Call Subsystem block</li> </ul>  |
| To test a model to be used as a referenced model                            | Root-level Inport, Trigger, Enable, or Function-Call Subsystem block   |
| To verify a model using multiple test cases                                 | Signal Builder block, using signal groups.<br><br>If the Simulink Verification and Validation software is installed, in signal groups you can use the Verification Manager to enable or disable individual Model Verification blocks. For details, see “Model Verification Blocks and the Verification Manager”. |
| To perform local, temporary testing by importing a small set of signal data | Depending on the modeling goal, as discussed in “Time and Signal Values for Imported Data” on page 57-77, choose from the following techniques: <ul style="list-style-type: none"> <li>• From File block</li> <li>• From Workspace block</li> <li>• Signal Builder block</li> </ul>                              |

| Modeling Consideration                     | Suggested Technique  |
|--|--|
|  | <ul style="list-style-type: none"> <li>• Root-level Inport, Trigger, Enable, or Function-Call Subsystem block</li> </ul>                                 |
| <b>Signal data</b>                         |  |
| Very large dataset                         | From File block, which incrementally loads the data  |
| Data exported using a To File block        | From File block  |
| Data exported using a To Workspace block   | From Workspace block   |
| Excel spreadsheet                          | Signal Builder block, which can import Excel spreadsheet data directly into Simulink   |
| Variable-size signals                      | From Workspace block   |
| Array of buses signals                     | root Inport block  |
| <b>Data storage</b>                        |  |
| In a block                                 | Signal Builder block   |
| In the base or model workspace             | <ul style="list-style-type: none"> <li>• From Workspace block</li> <li>• Root-level Inport, Trigger, Enable, or Function-Call Subsystem block</li> </ul> |
| In a MAT-file separate from the model file | From File block  |

## Time and Signal Values for Imported Data

Depending on your model development or testing goal, the approach for specifying time and signal values can vary. Each of these guidelines applies to one or more of the signal data import techniques (From File, From Workspace, Signal Builder, and root-level Inport or Trigger blocks).

| Modeling Goal                               | Time and Signal Values   | Additional Notes   |
|---|--|--|
| Import data representing a continuous plant | Specify a time vector and signal values extracted a continuous plant (for example, data that you acquire experimentally or from the results of a previous simulation). | <p>In the Inport block parameters dialog box, select <b>Interpolate data</b>.</p> <p>To ensure that the Simulink variable time solver executes at the times that you specify</p> |

| Modeling Goal                    | Time and Signal Values  | Additional Notes   |
|----------------------------------|---|--|
|                                  | <p>Use any of the data formats listed in “Input Data” on page 57-88. Here are recommended formats for the following imported data sources:</p> <ul style="list-style-type: none"> <li>• Another simulation — Dataset</li> <li>• An equation — MATLAB time expression</li> <li>• Experimental data — MATLAB <code>timeseries</code>, data array, or structure</li> </ul> <p>For details, see “Specify Time Data” on page 57-141. For an example of using a structure to specify the time and signal values, see “Import Data to Model a Continuous Plant” on page 57-80.</p> | <p>in the imported data, set the <b>Configuration Parameters &gt; Data Import/Export &gt; Output options</b> parameter to Produce additional output.</p> |
| <p>Test a discrete algorithm</p> | <p>Use a structure, with an empty time vector.</p> <p>Specify signal values, but no time vector. (One signal value is read at each time step, using the sample time of the source block.)</p> <p>For an example of using a structure to specify the signal values, see “Import Data to Test a Discrete Algorithm” on page 57-82.</p>  | <p>In the Inport block parameters dialog box, clear <b>Interpolate data</b>.</p>   |

| Modeling Goal  | Time and Signal Values  | Additional Notes  |
|--|---|---|
| <p>Create an input test case</p> <p>(An input test case is typically composed of steps and ramps, with discontinuities.)</p> | <p>Specify a time vector and signal values, but specify only the time steps at points where the shape of the output jumps.</p> <p>For details about specifying a time vector, see “Specify Time Data” on page 57-141.</p> <p>Use any of the input data formats described in “Input Data” on page 57-88, except for MATLAB time expressions.</p> | <p>Select the <b>Interpolate data</b> parameter.</p> <p>For the input, consider using a From Workspace, From File, or Signal Builder block, which trigger a zero-crossing at the discontinuities.</p> <p>For examples of using a From Workspace block and a Signal Builder block, see “Import Data for an Input Test Case” on page 57-83.</p> |

## Import Data to Model a Continuous Plant

### In this section...

“Share Simulation Data Across Models” on page 57-80

“Example of Importing Data to Model a Continuous Plant” on page 57-80

### Share Simulation Data Across Models

When reusing data from a variable step size simulation for simulation in another model, the second simulation must read the data at the same time steps as the first simulation.

The following example illustrates how to reuse signal logging data from the simulation of one model in the simulation of a second model. For more information, see “Import Signal Logging Data” on page 57-86.

### Example of Importing Data to Model a Continuous Plant

- 1 Open the `ex_data_import_continuous` model.

This model uses the `ode15s` solver and produces continuous signals.

- 2 To use the output of this model as input to the simulation of another model, log the signal that you want to reuse. In the Simulink Editor, select that signal, click the

**Simulation Data Inspector** button arrow  and click **Log Selected Signals to Workspace**.

---

**Note:** To enable signal logging, select the **Configuration Parameters > Data Import/Export > Signal logging** parameter. This model has **Signal logging** enabled, and has the **Signal logging format** parameter set to **Dataset**.

---

- 3 Simulate the model.

Simulating the model saves a variable-step signal to the workspace, using the `logsout` variable. The signal logging output is a `Simulink.SimulationData.Dataset` object.

Use the `Simulink.SimulationData.Dataset.getElement` method to access the logged data. The logged data for individual signals is stored in `Simulink.SimulationData.Signal` objects. For this model, there is one logged signal: `StepResponse`.

- 4 Open a second model, named `ex_data_import_continuous_second`.

You can configure this second model to simulate using the logged data from the first model. In this example, the second model uses a root-level Inport block to import the logged data. The Inport block has the **Interpolate data** option selected.

- 5 In the second model, select the **Configuration Parameters > Data Import/Export > Input** parameter.

Use the `Simulink.SimulationData.Signal.getElement` method to specify the `StepResponse` signal element, as shown below:

- 6 Specify that for the second model, the Simulink solver runs at the time steps specified in the saved data (`u`). In the Data Import/Export pane, set the **Output options** parameter to **Produce additional output** and the **Output times** parameter to:

```
logsout.getElement('StepResponse').Values.Time
```

- 7 Simulate the second model.

---

**Note:** Simulink does not feed minor time-step data through root input ports. For details about minor time steps, see “Minor Time Steps” on page 3-22.

---

## Import Data to Test a Discrete Algorithm

### In this section...

“Specify a Signal-Only Structure” on page 57-82

“Example of Importing Data to Test a Discrete Algorithm” on page 57-82

### Specify a Signal-Only Structure

To import data for a discrete signal, specify a signal-only structure as the input value. Do not specify a time vector.

### Example of Importing Data to Test a Discrete Algorithm

- 1 Set the sample time for the Inport, Trigger, or From Workspace block.
- 2 For the data that you want to import, specify a structure variable that does *not* include a time vector. For example, for the variable called `import_var`:

```
import_var.time = [];  
import_var.signals.values = [0; 1; 5; 8; 10];  
import_var.signals.dimension = 1;
```

The input for the first time step is read from the first element of an input port value array. The value for the second time step is read from the second element of the value array, and so on.

For details about how to specify the signal value and dimension data, see “Specify Signal Data” on page 57-140.

- 3 In the block parameters dialog box for the block that imports the data, clear the **Interpolate data** parameter.
- 4 If you are using a From Workspace block to import data, set the **Form output after final data value by** parameter to a value other than **Extrapolation**.

## Import Data for an Input Test Case

| In this section...  |
|---|
| “Guidelines for Importing a Test Case” on page 57-83                  |
| “Example of Test Case Data” on page 57-83                             |
| “Use From Workspace Block to Import an Input Test Case” on page 57-84 |
| “Use Signal Builder Block to Import an Input Test Case” on page 57-85 |

### Guidelines for Importing a Test Case

Typically when importing a test case in Simulink, you want to:

- Create a signal that has ramps and steps. In other words, the signal has one or more discontinuities.
- Create the signal using the fewest points possible.
- Have the Simulink solver execute at the specified discontinuities.

To import this signal in Simulink, use a From Workspace, From File, or Signal Builder block, all of which support zero-crossing detection.

### Example of Test Case Data

The following is an example of test case data:

The following two examples use this test case data.

## Use From Workspace Block to Import an Input Test Case

- 1 Open the model `ex_data_import_test_case_from_workspace`.

- 2 Enable zero-crossing detection. In the From Workspace block dialog, select **Enable zero-crossing detection**.
- 3 Create a signal structure for the test case. At each discontinuity, enter a duplicate entry in the time vector. As described in the From Workspace block documentation,

this generates a zero-crossing and forces the variable-step solver to take a time step at this exact time.

Define the `var` structure representing the test case:

```
var.time = [0 1 1 5 5 8 8 10];
var.signals.values = [0 0 2 2 2 3 3 3]';
var.signals.dimensions = 1;
```

- 4 To import the test case structure, in the From Workspace block dialog, in the **Data** parameter, specify `var`.
- 5 Simulate the model. The Scope block reflects the test case data.

## Use Signal Builder Block to Import an Input Test Case

As an alternative to using a From Workspace block, you can use a Signal Builder block to either create a signal interactively or to import a signal from a MAT-file.

- 1 Open the `ex_data_import_signal_builder` model.

- 2 Create a structure and save it in a MAT-file:

```
var.time = [0 1 1 5 5 8 8 10];
var.signals.values = [0 0 2 2 2 3 3 3]';
var.signals.dimensions = 1;
var.signals.label = 'var';
save var.mat var
```

- 3 Double-click the Signal Builder block to open its dialog box.
- 4 Select **File > Import From File** menu item, and select the `var.mat` file.
- 5 In the **Select** parameter, select **Replace existing dataset**. In the **Data to Import** section, select the **Select All** check box. Confirm the selection and click **OK**.

The Signal Builder block display reflects the test case data.

## Import Signal Logging Data

You can log signal data from a simulation, and then import that data into a model.

The imported signal logging data provides the input for simulating the model. You can use imported signal logging data to perform standalone simulation of a referenced model.

- 1 Set the **Configuration Parameters > Data Import/Export > Signal logging format** parameter to **Dataset**.
- 2 Use the default signal logging output variable, `logargout`, or specify a variable using the **Configuration Parameters > Data Import/Export > Signal logging** edit box.
- 3 Simulate the parent model.

The signal logging output is a `Simulink.SimulationData.Dataset` object.

- 4 Use the `Simulink.SimulationData.Dataset.getElement` method to access the logged data. The logging data for individual signals is stored in `Simulink.SimulationData.Signal` objects.
- 5 For the referenced model that you want to simulate standalone, use the `Simulink.SimulationData.Signal.getElement` method to specify signal elements for the **Configuration Parameters > Data Import/Export > Input** parameter.

For example:

- 6 Simulate the referenced model.

For an example of loading logged signal data into a model:

- 1 Open the `sldemo_md1ref_bus` model.
- 2 In the right corner of the model, double-click the blue block labeled **Interface Specification**.
- 3 See the “Logging Model Reference Signals” and “Loading Data” sections.

To import signal logging data for array of buses signals, see “Import Array of Buses Data” on page 57-94.

## Import Data to Root-Level Input Ports

### In this section...

“Root-Level Input Ports” on page 57-87

“Enable Data Import” on page 57-88

“Input Data” on page 57-88

“Import Bus Data” on page 57-90

### Root-Level Input Ports

You can import data from a workspace and apply it to a root-level:

- Enable block
- Inport block
- Trigger block that has an edge-based (rising, falling, or either) trigger type

These blocks import data from the workspace based on the value of the **Configuration Parameters > Data Import/Export > Input** parameter.

---

**Note:** You cannot use input ports to import buses in RSim or External modes. To import bus data in Rapid Accelerator mode, use **Dataset** format.

---

You can also import data from a workspace using a From Workspace block. For details, see the **From Workspace** documentation and “Import Data for an Input Test Case” on page 57-83.

If you want to import many signals to root-level input ports, see “Import and Map Root-Level Inport Data” on page 57-100.

If your target is an RSim target, you can import root-level inport data from workspace variables in a MAT-file using the following command:

```
!model -i ws_variables.mat
```

The software does not support this feature for other targets. For more information, see “Set Up Rapid Simulation Input Data” and “Run Rapid Simulations”.

## Enable Data Import

To enable data import:

- 1 Select the **Configuration Parameters > Data Import/Export > Input** parameter.
- 2 Enter an external input specification in the adjacent edit box and click **Apply**.

For details, see “Input Data” on page 57-88.

## Input Data

Use the **Configuration Parameters > Data Import/Export > Input** parameter to import data from a workspace and apply it to the root-level input ports of a model during a simulation run.

Simulink linearly interpolates or extrapolates input values as necessary if you select the **Interpolate data** option for the corresponding **Inport**, **Enable**, or **Trigger** block.

---

**Note:** The use of the **Input** box is independent of the setting of the **Format** list on the **Data Import/Export** pane.

---

Simulink resolves symbols used in the external input specification as described in “Symbol Resolution” on page 4-95. See the documentation of the `sim` command for some data import capabilities that are available only for programmatic simulation.

## Forms of Input Data

The input data can take any of the following forms:

- A `Simulink.SimulationData.Dataset` object — Collection of logged data in MATLAB timeseries format. For details, see “Import Dataset Data” on page 57-131.
- MATLAB timeseries — For details, see the following sections:
  - “Import MATLAB timeseries Data” on page 57-132
  - “Import Bus Data to Root-Level Input Ports” on page 57-91
- Array — See “Import Data Arrays” on page 57-135.

- `Simulink.SimulationData.Signal` — For details, see “Import Signal Logging Data” on page 57-86
- Structure — See “Import Data Structures” on page 57-139.
- A structure array containing data for all input ports.
- Empty matrix — Use an empty matrix for ports for which you want to use ground values, without having to create data values.
- Time expression — See “Import MATLAB Time Expression Data” on page 57-138.
- `Simulink.Timeseries` and `Simulink.TsArray` — See “Import Simulink.Timeseries and Simulink.TsArray Data” on page 57-134.

---

**Note:** The `Simulink.Timeseries` and `Simulink.TsArray` formats are supported for compatibility with earlier releases. In new models, use one of the other supported formats.

---

### Input Expressions

In the **Input** box, specify the signal input using either of these approaches:

- Create data at runtime for each simulation time step using the input  $u = UT(t)$  for either a MATLAB function (expressed as a string) or MATLAB expression.
- Specify the data directly, using either:
  - A `Simulink.SimulationData.Dataset` object. Specify only one `Dataset` object.
  - A 2D array of input values versus time for all input ports, in the form  $UT = [T, U1, \dots, Un]$ , where  $T = [t1, \dots, tm]'$
  - A comma-separated list of variables or MATLAB expressions. Do not include a `Dataset` object in a comma-separated list. For details, see “Comma-Separated Lists for the Input Parameter” on page 57-89.

### Comma-Separated Lists for the Input Parameter

Each variable or expression corresponds to a specific input port. Each variable or expression in the list should evaluate to the appropriate object that corresponds to one of the root-level input ports of the model, with the first item corresponding to the first root-level input port, the second to the second root-level input port, and so on.

If you specify `Dataset` data, specify only one `Dataset` object. Do not include it in a comma-separated list.

For an Enable or Trigger block, the signal driving the enable or trigger port must be the last item in the comma-separated list. If you have both an enable and a trigger port, then specify the enable port as the next-to-last item in the list, and the trigger port as the last item.

To simplify the specification of external data to input, you can load data for a subset of root-level Inport ports, without having to create data structures for the ports for which you want to use ground values. For information about ground values, see “Initialize Signals and Discrete States” on page 60-48.

Use an empty matrix to specify ground values for a port. For example, to load data for input ports `in1` and `in3`, and to use ground values for port `in2`, enter the following in the **Input** parameter:

```
in1, [], in3
```

## Import Bus Data

To import bus data to root input ports, use a structure of MATLAB `timeseries` objects or a `Dataset` object that includes a structure of `timeseries` objects. For details, see “Import Bus Data to Root-Level Input Ports” on page 57-91.

You can specify an empty matrix in a comma-separated list. The empty matrix uses the ground values for the bus signal.

For example, to load data for input ports `in1` and `in3`, and to use ground values for port `in2`, enter the following in the **Input** parameter:

```
in1, [], in3
```

You can initialize bus signals, including using partial specification of initialization data. For details, see “Specify Initial Conditions for Bus Signals” on page 61-65.

For details about importing array of bus data to a root Inport block, see “Import Array of Buses Data” on page 57-94.

## Import Bus Data to Root-Level Input Ports

### In this section...

“Imported Bus Data Requirements” on page 57-91

“Convert Simulink.TsArray Objects” on page 57-91

“Import Bus Data to a Root Inport” on page 57-92

“Import Array of Buses Data” on page 57-94

### Imported Bus Data Requirements

To import bus data to a root-level input port, use a structure of MATLAB `timeseries` objects. The `timeseries` objects represent the bus elements that you want to specify values for. Any bus elements for which you do not include a field in the structure use ground values. You can include a structure of `timeseries` objects as a `Dataset` object element.

In the root-level Inport block, set **Data type** to **Bus** and specify the name of a bus object.

A root-level input port defined by a bus object (see `Simulink.Bus`) can import data from a `Dataset` object or from that represent the bus elements for which you want to specify values. Any bus elements for which you do not include a field in the structure use ground values.

The structure of MATLAB `timeseries` objects must match the bus elements in terms of:

- Hierarchy
- Name of the structure field, which must match the bus element name. (The `name` property of the `timeseries` object does not need to match the bus element name.)
- Data type (for tunable parameters)
- Dimensions
- Complexity

The order of the structure fields does not have to match the order of the bus elements.

### Convert Simulink.TsArray Objects

If you use logged data from a model whose **Configuration Parameters > Data Import/Export > Signal logging format** parameter is set to `ModelDataLogs` format

instead of the default `Dataset` format, consider converting the data to a structure of MATLAB `timeseries` objects. The `ModelDataLogs` format is supported for backwards compatibility. The `ModelDataLogs` format will be removed in a future release.

### Convert to a Structure of Timeseries Objects

To create a structure of MATLAB `timeseries` objects from a `Simulink.TsArray` object, use `Simulink.SimulationData.createStructOfTimeseries`. For example, if `tsa` is a `Simulink.TsArray` object:

```
input = Simulink.SimulationData.createStructOfTimeseries(tsa);
```

---

**Note:** If you use a structure of MATLAB `timeseries` objects for a root Inport block in a model that has multiple root Inport blocks, all the root Inport blocks must use MATLAB `timeseries` objects. Convert any root Inport block data that uses `Simulink.TsArray` or `Simulink.Timeseries` objects to be MATLAB `timeseries` objects.

---

### Import Bus Data to a Root Inport

Assume that you have a model set up as follows:

- The `TopBusObject` bus object has two elements:
  - `c`
  - `s1`, which is a sub-bus that has two elements: `a` and `b`.

- The model has two root Inport blocks: `In1` and `In2`.
    - The `In1` Inport block imports non-bus data.
    - The `In2` Inport block imports bus data of type `TopBusObject`.
- 1 Create a MATLAB `timeseries` object for each root Inport or Trigger block for which you want to import non-bus data.

For example:

```
N = 10;
Ts = 1;
t1 = ((0:N)* Ts)';
d1 = sin(t1);
in1 = timeseries(d1,t1)
```

- 2 Create a structure of MATLAB `timeseries` objects, with one `timeseries` object for each leaf bus element for which you do not want to use ground values.

For example, to specify non-ground values for all the elements in the `s2` bus:

```
in2.c = timeseries(d1,t1);
in2.s1.a = timeseries(d2,t2);
in2.s1.b = timeseries(d3,t3);
```

The MATLAB `timeseries` objects that you create must match the corresponding bus elements, as described in “Imported Bus Data Requirements” on page 57-91.

To determine the number of MATLAB `timeseries` objects and data type, complexity, and dimensions needed for creating a structure of `timeseries` objects from a bus, you can use the `Simulink.Bus.getNumLeafBusElements` and `Simulink.Bus.getLeafBusElements` methods. For example, for the bus object `MyBus`:

```
num_el = MyBus.getNumLeafBusElements;
el_list = MyBus.getLeafBusElements;
```

To create a structure of MATLAB `timeseries` objects from a bus object and a cell array of `timeseries` or `Simulink.Timeseries` objects, use the `Simulink.SimulationData.createStructOfTimeseries` utility. For example:

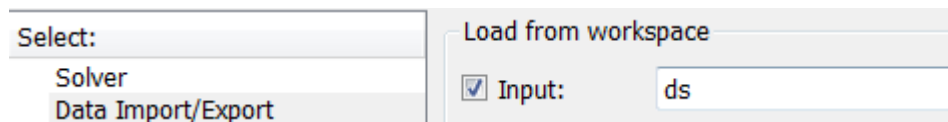

```
input = ...
Simulink.SimulationData.createStructOfTimeseries('MyBus',...
{ts1,ts2,ts3});
```

The number of `timeseries` objects in the cell array must match the number of leaf elements in the bus object (in this example, `num_el`). The data type, dimensions, and complexity of each `timeseries` object must match those attributes of the corresponding bus object leaf node (in this example, the attributes listed in `el_list`).

- 3 Create a `Dataset` object and add `in1` and `in2` to the data set.

```
ds = Simulink.SimulationData.Dataset;  
ds.addElement(in1);  
ds.addElement(in2);
```

- 4 In the **Configuration Parameters** > **Import/Export** > **Input** parameter edit box, enter the `Dataset` object `ds`.

The screenshot shows a configuration dialog for an Inport block. On the left, a 'Select:' dropdown menu is open, showing 'Solver' and 'Data Import/Export' as options. On the right, there is a 'Load from workspace' section with a checked checkbox and an 'Input:' text box containing the value 'ds'.

## Import Array of Buses Data

To import (load) array of buses data using a root Inport block, use an array of structures of MATLAB `timeseries` objects.

---

**Note:** You cannot use an Enable, Trigger, From Workspace, or From File block to import data for an array of buses.

---

### Full Specification of Data

You can use the logged data for an array of buses signal from a previous simulation as roundtrip input to a root-level Inport block in a subsequent simulation run. The logged data is a full specification of data for the Inport block.

If you construct an array of structures of MATLAB `timeseries` objects to fully specify the data to import:

- Specify the structure fields in the same order as the signals in the bus signals.
- Do not include more fields in the structure than there are signals in the bus.

For leaf fields, match exactly the data type, dimensions, and complexity of the corresponding signal in the bus.

### Partial Specification of Data

To specify partial data for array of buses, create a MATLAB array of structures with MATLAB `timeseries` objects at the leaf nodes.

The structure that you create to specify partial data must be consistent with these rules:

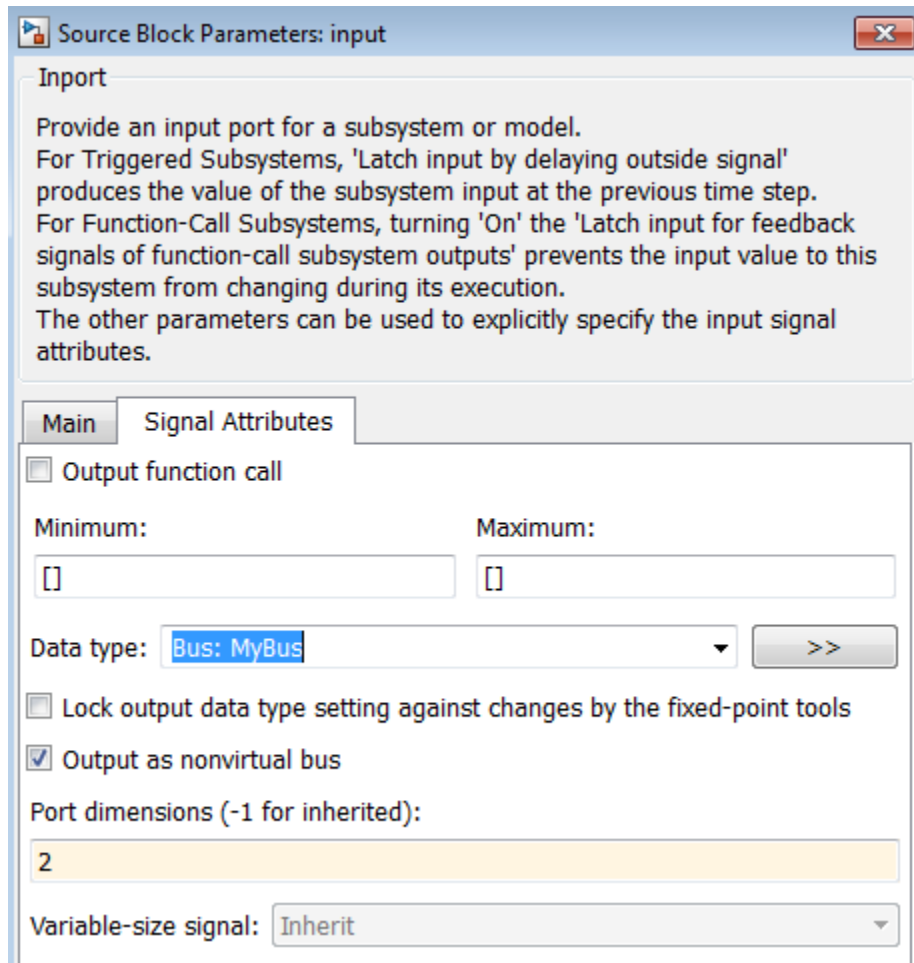

- You can omit fields, including leaf nodes and sub-branches. You can also omit dimensions. If you do not specify a field, Simulink uses the ground value for that field.
- For sub-bus nodes, make the dimension of each field equal to, or smaller than, the dimension for the corresponding node of the array of buses.

This example shows how you can specify partial data to be imported using a root Inport block whose data type is defined as bus object MyBus. You can open the model (`ex_partial_loading_aob_model`) and the MATLAB code that defines the data to import (`ex_partial_loading_aob_data.m`).

When you simulate `ex_partial_loading_aob_model`, it looks like this:

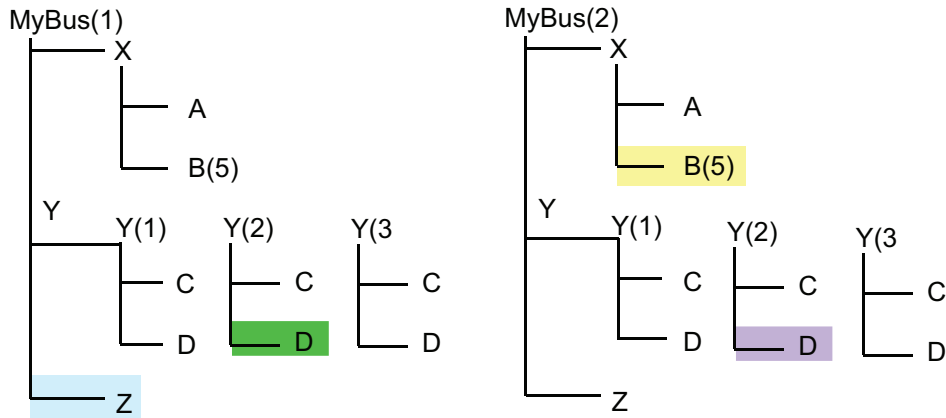

The input Inport block uses the MyBus bus object as its data type.

The MyBus array of buses includes MyBus (1) and MyBus (2). The port dimension is set to 2 to reflect the two buses in the array of buses, and **Output as nonvirtual bus** is enabled.

Here are the elements of the array of buses, which includes MyBus (1) and MyBus (2). The color highlighting shows the nodes of the array of buses for which data is being imported.

Here is MATLAB code that defines the data to import. The color that highlights the code matches the color of the corresponding node in the array of buses. To view the code used in this model, open the MATLAB code file `ex_partial_loading_aob_data.m`.

```
7 %% Create timeseries data for leaf signals
8 - N = 10; Ts = 1;
9 - Time = ((0:N)*Ts)';
10 - [m, n] = size(Time);
11
12 - ZData = repmat(ex_partial_loading_aob_basicColors.Blue,m,n);
13 - BData = repmat(ex_partial_loading_aob_basicColors.Yellow,m,5);
14 - D1Data = repmat(ex_partial_loading_aob_basicColors.Green,m,n);
15 - D2Data = repmat(ex_partial_loading_aob_basicColors.Purple,m,n);
16
17 %% Create individual timeseries objects to represent Z, B, D1 and D2
18 - ZT = timeseries(ZData, Time, 'Name', 'Z');
19 - BT = timeseries(BData, Time, 'Name', 'B');
20 - D1T = timeseries(D1Data, Time, 'Name', 'D1');
21 - D2T = timeseries(D2Data, Time, 'Name', 'D2');
22
23 %% Construct MyBusValue(1)
24
25 % Y(2).D
26 - Y(2) = struct('D',D1T);
27
28 % Set X.B to empty to allow the second element to support specification for
29 % this field
30 - X = struct('B',[]);
31
32 % MyBusValue(1)
33 - MyBusValue(1) = struct('Z',ZT,'Y',Y,'X',X);
34 - clear X Y;
35
36 %% Construct MyBusValue(2)
37
38 % Specify timeseries for MyBusValue(2).X.B
39 - MyBusValue(2).X.B = BT;
40
41 % Specify timeseries for MyBusValue(2).Y(2).D
42 - MyBusValue(2).Y(2).D = D2T;
43
```

In the code that defines the import data:

- The `timeseries` object `MyBusValue` specifies the data for the highlighted nodes.
- The `timeseries` object `BT` for `MyBus(2)`, because `BT` is a leaf node, it must match exactly the dimensions, data type, and complexity of the corresponding bus element.
- The structure specifies data for `Y(2)`. You can skip the first and last sub-buses of `Y` (that is, `Y(1)` and `Y(3)`).

This example specifies data for `Y(2)`; you can skip the first and last sub-buses of `Y` (that is, `Y(1)` and `Y(3)`).

After you define the `MyBusValue` variable for the import data, set the **Configuration Parameters** > **Data Import/Export** > **Input** parameter to `MyBusValue`.

## Import and Map Root-Level Inport Data

### Root Inport Mapping

To import, visualize, and map signal and bus data to root-level inports, use the Root Inport Mapping tool. For alternative ways to import data, see “Techniques for Importing Signal Data” on page 57-75.

To start Root Inport Mapping, in the Simulink Editor for your model, click the **Connect Input** button in **Simulation > Model Configuration Parameters > Data Import/Export**. The model name displays in the top left of the tool.

## Importing and Mapping Workflow

- 1 Identify the signals you want to import and map to the model root-level inports (see “Identify Signal Data to Import and Map” on page 57-101).
- 2 Import data (see “Import Signal and Bus Data” on page 57-105).
- 3 Visualize data (see “View and Inspect Signal Data” on page 57-107).
- 4 Determine how you want to map the data, for example, by block path or signal name, (see “Select Map Mode” on page 57-110).
- 5 Select options to map signals (see “Set Options for Mapping” on page 57-111).
- 6 Map the data (see “Map Data” on page 57-112).
- 7 Save data for future reference or for others to use (see “Export Data” on page 57-116).
- 8 Save the current Root Inport Mapping scenario for future reference or to share with others (see “Work with Scenarios” on page 57-117).

To create a custom mapping file function to map data to root-level inports, see “Create Custom Mapping File Function” on page 57-128.

## Identify Signal Data to Import and Map

You can import data from these sources.

| Data Source    | Description  |
|----------------|--|
| Base workspace | You can selectively import from the base workspace. If there are overlapping signal names, the most recently imported signal overwrites the signal already loaded in the Root Inport Mapping tool. For more information on supported data formats, see “Supported Base Workspace and MAT-File Formats” on page 57-102.   |
| Data files     | <p>You can selectively import signals contained in MAT-files and Microsoft Excel files. Each time you import the contents of one of these files, the contents overwrite all existing data already loaded in the Root Inport Mapping tool.</p> <ul style="list-style-type: none"> <li>• For more information on supported data formats in MAT-files, see “Supported Base Workspace and MAT-File Formats” on page 57-102.</li> </ul> |

| Data Source | Description   |
|-------------|---|
|             | <ul style="list-style-type: none"> <li>For more information on supported data formats in Excel files, see “Supported Excel File Formats” on page 57-104.</li> </ul> |

### Supported Base Workspace and MAT-File Formats

The Root Inport Mapping tool supports these MATLAB data types or formats.

| Data Formats                                   | Block Name | Block Path                       | Signal Name | Port Order | Custom |
|--|------------|----------------------------------|-------------|------------|--------|
| Simulink.SimulationData.Datas                  | ✓          | ✓                                | ✓           | ✓          | ✓      |
| Timeseries (MATLAB and Simulink)               | ✓          | ✓ (only for Simulink timeseries) | ✓           | ✓          | ✓      |
| Simulink.SimulationData.-Signal                | ✓          | ✓                                | ✓           | ✓          | ✓      |
| Stateflow.SimulationData.State                 | ✓          | ✓                                | ✓           | ✓          | ✓      |
| Structure with Time, Structure Without Time    |            |                                  |             | ✓          |        |
| Data Array                                     |            |                                  |             | ✓          |        |
| Array of Buses                                 | ✓          |                                  | ✓           | ✓          | ✓      |
| “Specifying Function-Call Inputs” on page 9-13 | ✓          |                                  | ✓           | ✓          | ✓      |

For example, a signal data MAT-file with three signals (*signal1*, *signal2*, and *signal3*) with block path specified might have workspace variables as shown in this code sample. This file has signals that have signal names, block names, block paths, and port order index values, which enables mapping the data using **Signal Name**, **Block Name**, **Block Path**, or **Port Order** mapping mode. If there are corresponding root-level inports with corresponding port order, signal names, or block paths, the tool maps the signal to those ports.

```
signal1 =
```

```
Simulink.SimulationData.Signal
Package: Simulink.SimulationData

Properties:
    Name: 'signalGain5'
    BlockPath: [1x1 Simulink.SimulationData.BlockPath]
    PortType: 'outport'
    PortIndex: 1
    Values: [1x1 timeseries]

Methods, Superclasses
>> signal2

signal2 =

Simulink.SimulationData.Signal
Package: Simulink.SimulationData

Properties:
    Name: 'signalGain10'
    BlockPath: [1x1 Simulink.SimulationData.BlockPath]
    PortType: 'outport'
    PortIndex: 1
    Values: [1x1 timeseries]

Methods, Superclasses
>> signal3

signal3 =

Simulink.SimulationData.Signal
Package: Simulink.SimulationData

Properties:
    Name: 'signalGain15'
    BlockPath: [1x1 Simulink.SimulationData.BlockPath]
    PortType: 'outport'
    PortIndex: 1
    Values: [1x1 timeseries]

Methods, Superclasses
```

Notes for MAT-files and base workspace:

- Only one `Simulink.SimulationData.Dataset` per base workspace or MAT-file can load. If there are multiple data sets of this type, the first data set listed alphabetically loads.
- The number of signals with the formats structures, with and without time, must be the same as the number of model inports, enable ports, and trigger ports.
- Data arrays are matrices. If you have a data array where the *number of columns*-1 is equal to the sum of the port widths of all root-level input port blocks in the model, the Root Inport Mapping tool tries to map this data for the entire model. In this case, you can choose only the **Port Order** mapping method. If the *number of columns*-1 does not equal the number of root-level inports (including trigger and enable ports), the Root Inport Mapping tool tries to map the data array to a single inport. In this case, you can choose any of the mapping methods.
- If your MAT-file or base workspace contains a format that Simulink does not support, the tool ignores it.

In the case of time expressions, Simulink supports this format, but the Root Inport Mapping tool does not.

- If you have time series data with enumeration, and the enumeration class is not on your MATLAB path, the tool ignores that time series data.
- If data sets have non-unique element names, you can only map using the **Port Order** mapping method.

### Supported Excel File Formats

The Root Inport Mapping tool supports Microsoft Excel spreadsheets only for Windows systems.

- The tool imports an Excel worksheet as a `Simulink.SimulationData.Dataset` object that contains time series elements.
- The tool exports a `Simulink.SimulationData.Dataset` object as one Excel worksheet that contains time series data having the same number of time elements.

For Microsoft Excel spreadsheets:

- The tool interprets each worksheet as a `Simulink.SimulationData.Dataset` data set.
- Each worksheet name must be a valid MATLAB variable name.
- The tool interprets the first row of a worksheet as signal names. If you do not specify a signal name, the tool assigns a default one using the format `Signal#`.

- If all columns do not have signal names, the tool assigns signal names using the format `Signal#`, where `#` increments with each additional signal.
- All signal-name columns must be filled in. If there are empty signals, the tool returns an error at import.
- The tool interprets the first column as time. In this column, the time values must increase.
- The tool interprets the remaining columns as signals.

## Import Signal and Bus Data

You can import signal and bus data. Before you can import bus data, you first need to set up bus data.

### Set Up Bus Data

You can import and map bus data as well as signal data. For more information on buses, see “Bus Objects” on page 61-23.

- 1 In the MATLAB workspace, create or load a “Bus Objects” on page 61-23 for the bus data you want to import and map.
- 2 If creating a bus object in the base workspace, save the bus object definition to a MAT-file, for example, `d_myBusObj.mat`.
- 3 Have a different MAT-file that contains the bus data you want to import for the bus object. This can be an existing MAT-file that already contains a MATLAB struct or `Simulink.TSArray`, or you can create the bus in the base workspace and save it to a MAT-file.
- 4 Set up the model to load the bus object.

Continue to “Import Data” on page 57-105.

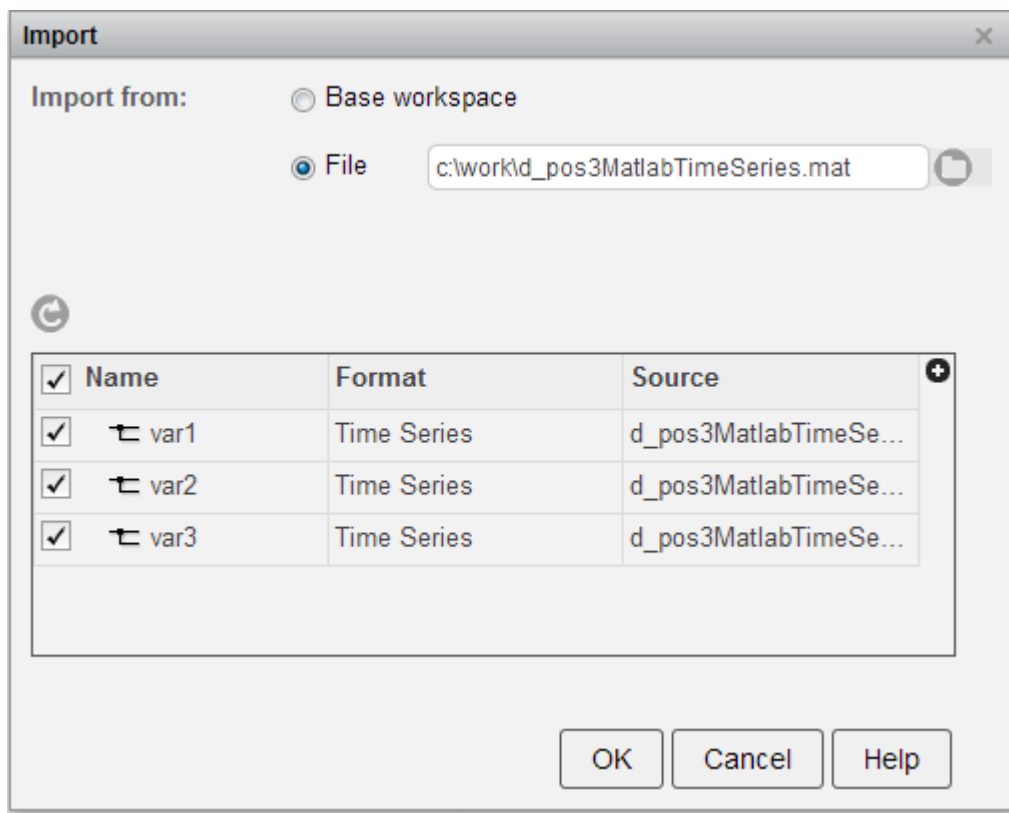

### Import Data

Before you can import data, you must set up the signals you want to import. See “Identify Signal Data to Import and Map” on page 57-101.

- 1 In the Simulink model you want to import the signal or bus data to, open the Configuration Parameters dialog box.
- 2 In the Data Import/Export pane, in the **Load from workspace** section, click **Connect Input**.

- 3 In the Import dialog box, select the data source, **Base workspace** or **File** (default).
  - Select **File** to browse to the MAT-file or Excel file that contains the signals you want to import, click **Open** to return to the Import dialog box, then click **OK**.
  - Select **Base workspace** to display a list of base workspace variables that you can import. Select the variables you want to import and click **OK**.

The Input dialog box displays the contents of the file or base workspace.

- 4 Select the data that you want to import, and then click **OK**.

The Root Import Mapping tool updates with the imported data.

Choose your next action:

- To visualize and inspect the signal properties of the imported data, see “View and Inspect Signal Data” on page 57-107.
- To select a mapping mode, see “Select Map Mode” on page 57-110.

### **Import from Other Sources**

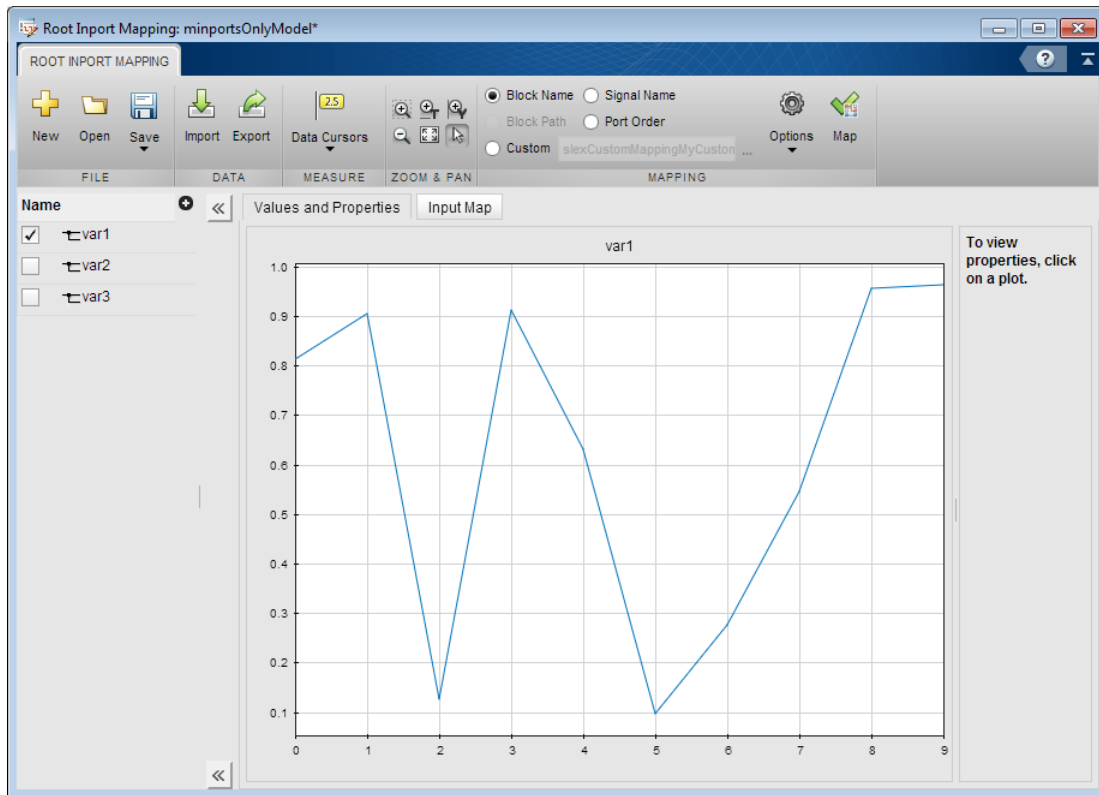

You can also use the Root Inport Mapping tool to import signals from other sources:

- To import signals from models that contain **Signal Builder** blocks, see “Convert Test Harness Model to Harness-Free Mode” on page 57-119.
- To convert and import test vectors from Simulink Design Verifier, see “Import Test Vectors from Simulink Design Verifier Environment” on page 57-126.

## **View and Inspect Signal Data**

After you have imported signal or bus data (see “Import Signal and Bus Data” on page 57-105), you can view and inspect signal data.

- 1 To plot the signal, click the check box next to the signal. If the format is a bus, click the expander (▶) to see and select the elements of the bus.

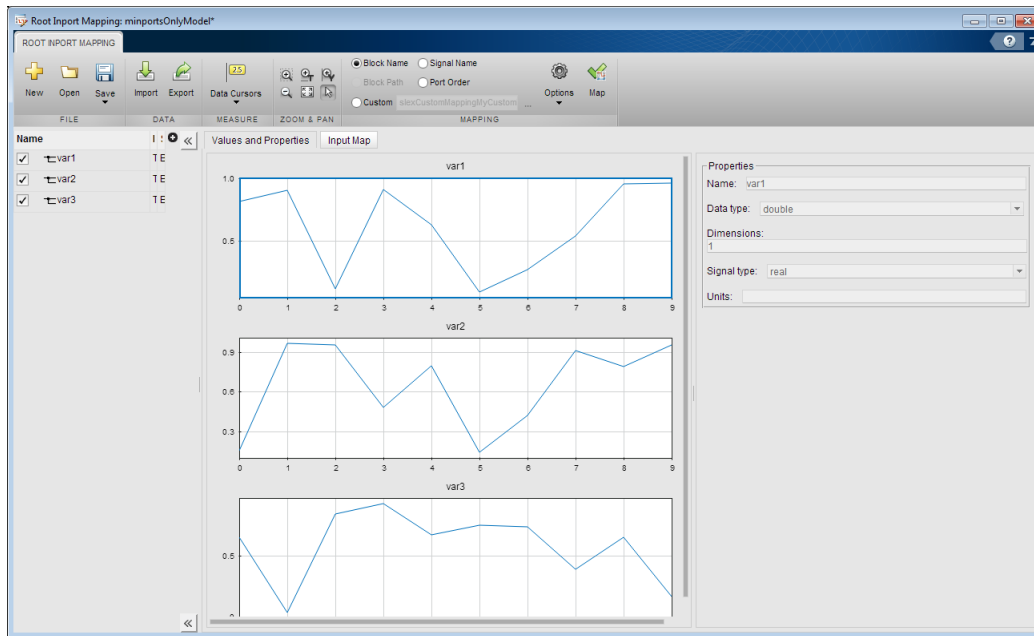

- 2 Explore the plots using the **Measure** and **Zoom & Pan** sections of the toolbar.
  - In the **Measure** section, use the **Data Cursors** button to display one or two cursors for the plot. These cursors display the T and Y values of a data point in the plot. Click a point on the line to view a data point.
  - In the **Zoom & Pan** section, select how you want to zoom and pan the signal plots. Zooming is only for the selected axis.

| To...  | Click... |
|--|----------|
| Zoom in along the T and Y axes.  |          |
| Zoom in along the time axis. After selecting the icon, on the graph, click |          |

| To...   | Click...  |
|---|---|
| and hold the left mouse button and drag the mouse to select an area to enlarge.   |   |
| Zoom in along the data value axis. After selecting the icon, on the graph, click and hold the left mouse button and drag the mouse to select an area to enlarge.                        |  |
| Zoom out from the graph.  |  |
| Fit the plot to the graph. After selecting the icon, click the graph to enlarge the plot to fill the graph.   |  |
| Pan the graph up, down, left, or right. After selecting the icon, on the graph, click and hold the left mouse button and move the mouse to the area of the graph that you want to view. |  |

- 3 To view the properties of a signal, click inside the plot area. The signal properties update:

To select a mapping mode, see “Select Map Mode” on page 57-110.

## Select Map Mode

Map data to root-level ports using one of these methods:

| Goal   | Map Mode          |
|--|-------------------|
| Assign signals to ports according to the name of the root-inport block. If the name of a signal or bus element matches the name of a root-inport block, the data is mapped to the corresponding port.    | <b>Block Name</b> |
| Assign signals to ports according to the block path of the root-inport block. If the block path of a signal matches the block path of a root-inport block, the data is mapped to the corresponding port. | <b>Block Path</b> |

| Goal   | Map Mode           |
|--|--------------------|
| Assign signals to ports according to the name of the signal on the port. If the signal name of a data element matches the name of a signal at a port, the signal is mapped to the corresponding port.  | <b>Signal Name</b> |
| Assign sequential port numbers to the imported data, starting at 1 and map this signal to the corresponding inport. <ul style="list-style-type: none"> <li>• If there is more data than inports, the remaining data are mapped first to enable and then trigger inports.</li> <li>• If the data is not in the form of a data set, the data is processed in the order in which it is passed or parsed from the data file, i.e., the order in which the data appears in the file.</li> </ul> | <b>Port Order</b>  |
| Assign signals to ports according to the definitions in a custom file.   | <b>Custom</b>      |

---

**Tip** When identifying signals to import, consider using a naming convention for signals and buses such that this grouping of data (signal group) is interchangeable. For example, you can have two MAT-files whose data has different values but the same variable names. This convention allows you to quickly switch the groups of input data into and out of a model.

---

Choose your next action:

- To select mapping options before mapping, see “Set Options for Mapping” on page 57-111.
- To map data right away, see “Map Data” on page 57-112.

## Set Options for Mapping

If you want to set up mapping options, in the Root Inport Mapping toolstrip, click **Options**. To map the signals, see “Map Data” on page 57-112.

| Goal  | Option  |
|---|---|
| Compile the model and check the data types of root-level inports and imported data. | <p><b>Compile.</b> See “Understand Mapping Results” on page 57-113. If the comparison data is inherited from the connected block, a warning appears.</p> <p>If you do not select this option, the tool maps the imported data to the root-level inport but does not compile the model. When you select this option, the tool compares the data and inport parameters to the root-level port and displays the results.</p> |
| Import bus data that is only partially defined.                                     | <b>Allow partial.</b> Select this option to make sure that any partially specified bus data you import maps properly to root-level inports.   |

## Map Data

After you have imported signals or buses (see “Import Signal and Bus Data” on page 57-105), you can map data.

- In the Root Import Mapping toolstrip, click **Map**.

The results of a signal mapping display on the Input Map tab.

- The Input Map tab lists the input data and the status of the mapping.

**Note:** To understand the mapping results, see “Understand Mapping Results” on page 57-113.

- The mapping definition for the input data is applied to the model.

After you save and close the model, the next time you load input data of the same signal group into the workspace, the model uses the mapping definition during simulation.

After you save the mapping definition for a model, you can automate data loading. For more information, see “Alternative Workflows to Load Data” on page 57-127.

## Understand Mapping Results

When you complete the import and map process, the Root Inport Mapping Input Map tool displays the results in the status area.

| Status  | Compile  | Continue Without Compile   |
|---|--|--|
|  | The properties of the mapped data and the inport are appropriate for simulation. | The data type, dimension, and signal type properties of the data and inport are compatible.  |
|  | N/A  | <p>Comparison of data and root-level port data type, dimension, and signal type properties cannot determine if there is a match. If you do not compile before mapping, the tool cannot evaluate whether all the data types match unless you explicitly specify the inport data types. Make sure these block parameters are set correctly:</p> <ul style="list-style-type: none"> <li>• Inport block parameter <b>Data type</b> is not set to <b>Inherit:auto</b>.</li> <li>• Inport block parameter <b>Dimension</b> is not set to <b>-1</b>.</li> <li>• Inport block parameter <b>Signal type</b> cannot be <b>auto</b>.</li> </ul> |

| Status  | Compile  | Continue Without Compile  |
|---|--|---|
|  | The properties of the mapped data and the inport are not appropriate for simulation. | One or more of the data type, dimensions, and signal type properties of the data and inport are not compatible. |

Root-level input ports that have not been mapped display as empty ([]).

This figure shows mapping successes and failures.

| Values and Properties |            | Input Map - Port Order |               |   |
|-----------------------|------------|------------------------|---------------|---|
| Port                  | Block Name | Source                 | Mapped Signal | Status  |
| 1                     | Counter    | dStreamBus.mat         | aBus          |  |
| 2                     | InputBus   |                        | []            |  |
| 3                     | In2        |                        | []            |  |
| 4                     | Tone       |                        | []            |  |
| 5                     | Speed      |                        | []            |  |

In the Root Inport Mapping tool, clicking **Map** selects the **Input** check box in the **Data Import/Export** pane of the model Configuration Parameters dialog box. Mapping also sets the value to the imported data variables. To apply the changes to the model configuration, in the **Data Import/Export** pane, click **OK** in the Configuration Parameters dialog box.

To inspect the imported data, you can:

- Connect the output to a scope, simulate the model, and observe the data.
- Log the signals, and use the Simulation Data Inspector tool to observe the data.

Select an item in the Input Map tab to highlight the associated Inport block. If there are warnings or failures, the **Inport** block associated with the data appears highlighted in the model.

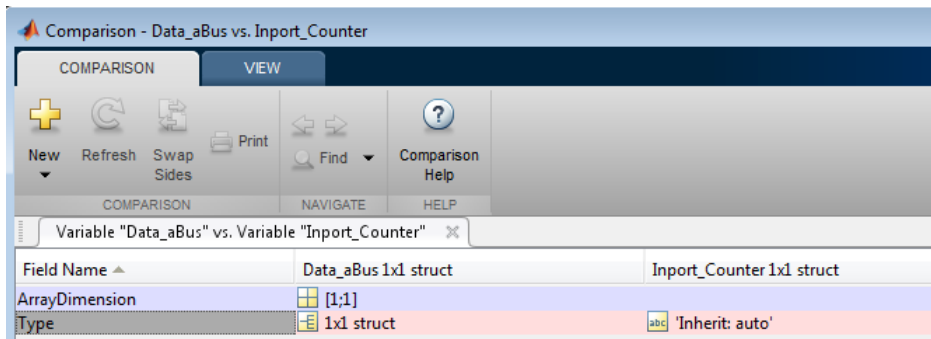

- Failures display as yellow Inport blocks outlined with bold red.
- Warnings display as yellow Inport blocks outlined in orange.
- Successes display as normal Inport blocks outlined with blue.

The figures shows that when you select the Counter block name in the Input Map tab, the Counter block in the model is highlighted. The highlighting indicates an error.

Use the Comparison Tool to evaluate your next action. The Comparison Tool shows the properties for the root-level inport and the signals you are trying to map to the inport. You can tell from this table if there is a mismatch that prevents the mapping. For example, if there is a mismatch, you can update the imported signals or edit the root-level inport. When you are done, reimport the data to map it.

To investigate warnings and failures, click the line item you want to inspect in the Input Map tab. The Comparison Tool lists the selected variable, including the field name, input data, and root-level inport.

**Note:** When the input is a bus, click the levels of the bus object to drill down to the individual elements in the bus.

In some cases, the Comparison Tool shows a warning or error, but your investigation of the elements indicates that there is no problem with mapping the data. In these cases, if you did not select the **Compile** check box in the **Options** menu, select it and click **Map** again.

**Tip** Each time you click a non-green status item, a new Comparison Tool instance appears. To dock all Comparison Tool instances in one window, click the Dock button .

For more information on the Comparison Tool, see “Comparing Files and Folders”.

## Export Data

To save the data you have been working on, export it to the base workspace or a data file.

- 1 In the Root Inport Mapping toolstrip, click **Export**.
- 2 In the **Export** dialog box, select:
  - **Base workspace** to export the data to the base workspace. If the base workspace contains signals with the same name, the tool overwrites those signals with the exported signal.

- **File** to browse to a writable folder in which to save the signals file. Enter a MAT-file or Microsoft Excel file name. If the file exists and contains signals with the same name, the tool overwrites those signals with the exported signal.

## Work with Scenarios

The Root Inport Mapping tool uses scenarios to save a snapshot of the current state of the imported and mapped signals in an MLDATX file. A scenario file contains information about:

- Location of signal files (MAT-file or Microsoft Excel files)
- Location of the model
- Mapping mode
- Mapping options
- Mapped state

When sharing scenario files, include the scenario file and signal files (MAT-file or Microsoft Excel). Place the signal files in the last known location or the MATLAB path.

Use the Root Inport Mapping tool to create new scenarios, save scenarios, and load previously saved scenarios.

- “Create New Scenarios” on page 57-119
- “Save Scenarios” on page 57-117
- “Open Existing Scenarios” on page 57-118

### Save Scenarios

You can save a scenario when the **Save** icon turns blue or when the model name in the title bar is has an asterisk (\*).

- 1 In the Root Inport Mapping toolbar, select **Save > Save As**.
- 2 In the **Save As** dialog box, browse to a writable folder, specify a scenario file name, and then click **Save**.
  - Click **Yes** to save the signals and the scenario file.

If you loaded signals from the base workspace and have not saved the signals from the scenario, the tool prompts you to save the signals to a MAT-file. If

a MAT-file is already associated with the scenario, the tool appends the base workspace variables to this file.

To save a scenario to an existing file (the file from which the scenario was last loaded):

- 1 In the Root Inport Mapping tool toolbar, click **Save**.
- 2 Browse to the MLDATX file in which to save the scenario, then click **Save**.

If you have not saved the signals from the scenario, the tool prompts you to save the signals to a MAT-file.

| To...   | Click...   |
|---|------------|
| Overwrite the existing MLDATX file.                   | <b>Yes</b> |
| Exit the dialog. The tool does not save the scenario. | <b>No</b>  |

### Open Existing Scenarios

You can open previously saved scenario files in one of the following ways:

- Double-click the previously saved scenario file (\*.mldatx). The Root Inport Mapping tool opens and loads the model. Alternatively, right-click the file and select **Open**.
- When loading the scenario file, the tool first looks for the associated model and MAT-file or Microsoft Excel file in the last known location, then on the MATLAB path. An error occurs if the tool cannot find the model or signal files in these two locations.
- If the previously saved scenario has mapped signals, then when you open the scenario, the tool applies the mapping and adds the signals to the base workspace so that you can simulate the model.
- Open the Root Inport Mapping tool for the model, click **Open**, and select the previously saved scenario file.

If the model is already open, the new scenario overwrites the existing scenario for the model. If there are unsaved changes in the open scenario, the tool prompts you:

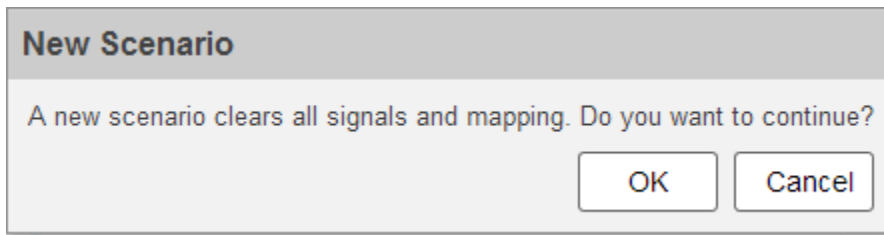

| To...   | Click...   |
|---|------------|
| Save the existing scenario and associated data before loading the new scenario. | <b>Yes</b> |

| To...   | Click... |
|---|----------|
| Open the new scenario without saving the existing scenario. This option also removes the data in the existing scenario. | No       |

### Create New Scenarios

To create a new scenario, click **New**. If you are working in another scenario, the Root Inport Mapping tool displays the message:

| To...  | Click... |
|--|----------|
| Open a new scenario. This action removes the existing scenario without saving it.  | OK       |
| Cancel. Then use the <b>Save</b> button to save the existing scenario first, and click the <b>New</b> button again to open a new scenario. | Cancel   |

### Convert Test Harness Model to Harness-Free Mode

If you have a model that uses the **Signal Builder** block and want to convert to using the Root Inport Mapping tool, export the signals from that block to the Root Inport Mapping tool. The workflow is:

- 1 In the model, export signals from the Signal Builder block to a variable in the base workspace.
- 2 Import the variables from the base workspace to the Root Inport Mapping tool.
- 3 Remove the Signal Builder block from the model.

- 4 Add Inport blocks to the model. The number of Inport blocks must equal the number of output lines from the Signal Builder block you removed.
- 5 Connect the Inport blocks to these lines.

The following example describes how to replace the Signal Builder block in the `sldemo_autotrans` model.

## Converting Harness-Driven Models to Use Harness-Free External Inputs

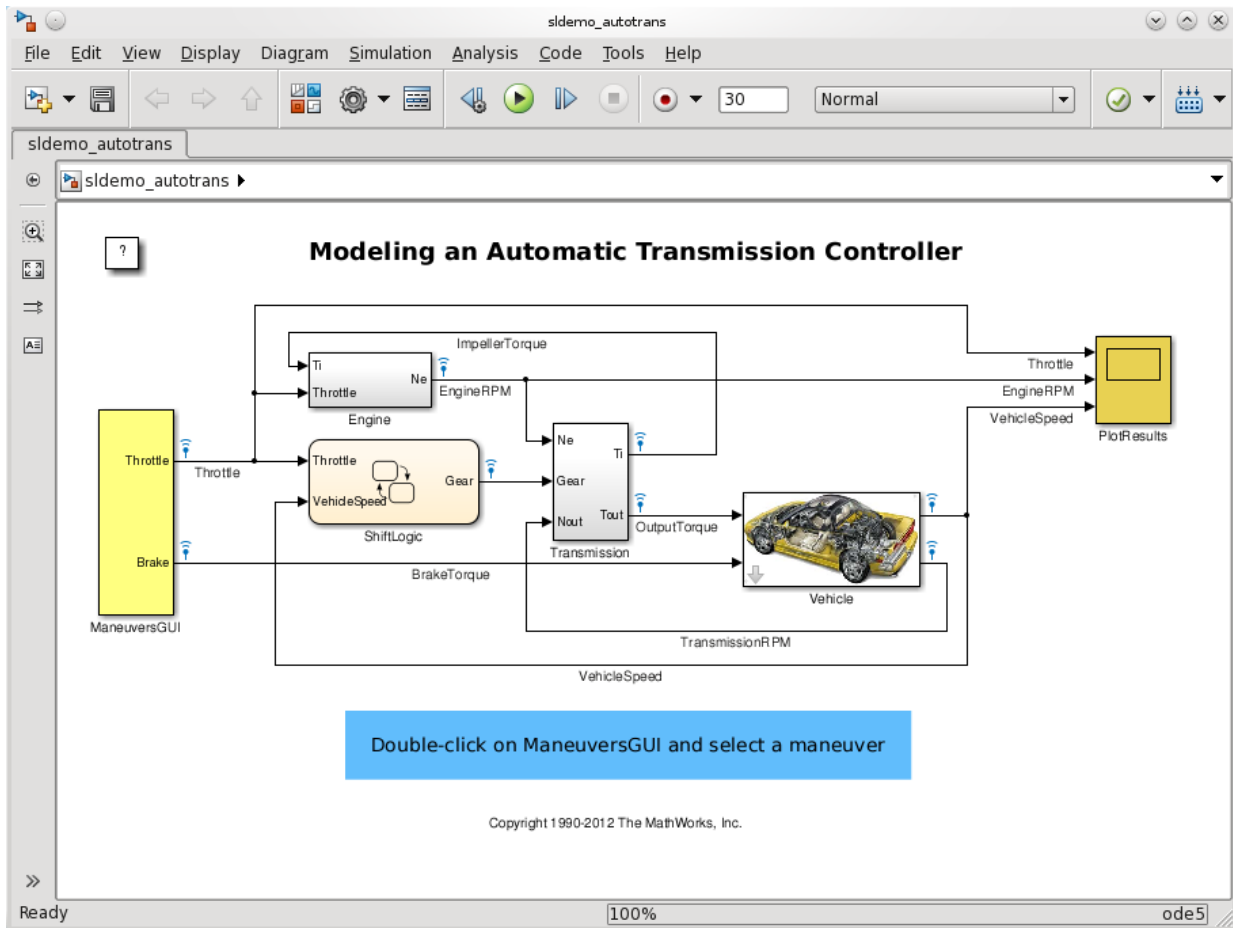

This example shows how to convert a harness model that uses a Signal Builder block as an input to a harness-free model with root inports. The example collects data from the harness model and stores it in MAT-files, for use by the harness-free model. After storing the data, the example removes the Signal Builder block from the harness model and adds root inports to create a harness-free model. Then, the data in the MAT-files is mapped to the root inports of the model.

### Save Harness Data to MAT-Files

Before converting the model to be harness-free, capture the test cases in the harness.

For this example, you will modify the model `sldemo_autotrans` from the **Modeling an Automatic Transmission Controller** example.

Open the example model. In the MATLAB Command Window type `sldemo_autotrans`.

Use MATLAB function `slexAutotransRootImportsSaveActiveGroup` to save the Signal Builder block data of the active group into a MAT-file. At the command line type `slexAutotransRootImportsSaveActiveGroup('slexAutotransRootImport','ManeuversGUI')`. This function creates a MAT-file in the current directory with the same name as the active group. The function `slexAutotransRootImportsSaveActiveGroup` has been provided with this example.

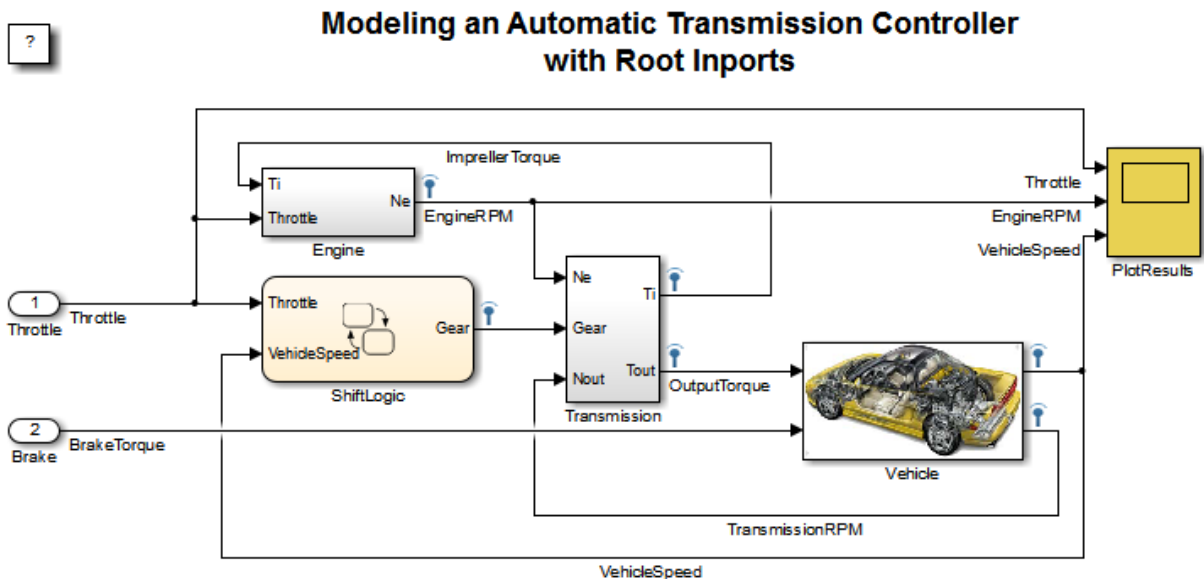

### Remove the Signal Builder Block

Remove the Signal Builder block named `ManeuversGUI` and replace it with two inports.

- 1 Delete the Signal Builder block named ManeuversGUI.
- 2 Open the **Simulink Library Browser** and select **Commonly Used Blocks**.
- 3 Drag and drop two **input ports** from the **Library Browser** to the model.
- 4 Connect the input ports to the lines previously connected to the Signal Builder block.
- 5 Rename the inport ports. Name the input port connected to the Throttle line **Throttle**. Name the input port connected to the BrakeTorque line **Brake**.

Save the model as `slexAutotransRootInportsExample1.slx` or use the example `slexAutotransRootInportsExample.slx`.

The remaining steps of this example use the model `slexAutotransRootInportsExample.slx`. If you saved the model with a different name use your model name in the steps going forward.

Copyright 2012 - 2014 The MathWorks, Inc.

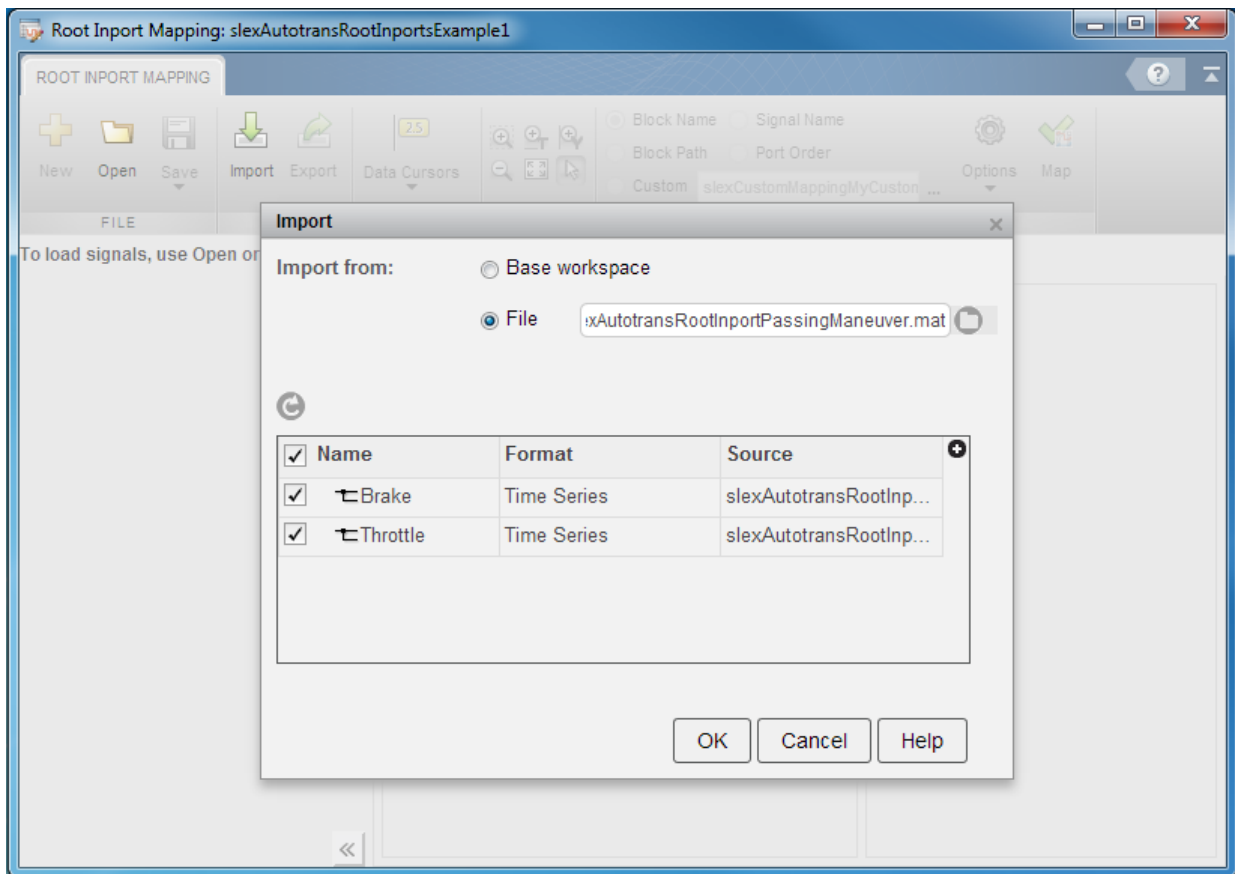

## Set Up Harness-Free Inputs

Now that the model is harness-free, set up the inputs that you already saved (See "Save Harness Data to MAT-Files").

From the **Simulation->Model Configuration Parameters->Data Import/Export** pane, click the **Connect Input** button.

## Map Signals to Root Input

The Root Input Mapping tool opens.

This example uses this tool to set up the model inputs from the MAT-file and map those inputs to an input port, based on a mapping algorithm. To select the MAT-file that contains the input data, click the **Import** button on the Root Inport Mapping toolbar. On the Import popup, select the **File** radio button and click the Open Folder button. In the browser, select the MAT-file that you saved earlier.

### Select a Mapping Mode

Once you select the MAT-file `slexAutotransRootInportPassingManeuver.mat` that contains the input data, determine the root input port to which to send input data. Simulink matches input data with input ports based on one of five criteria:

- **Port Order** - Maps in the order it appears in the file to the corresponding port number.
- **Block Name** - Maps by variable name to the corresponding root inport with the matching block name.
- **Signal Name** - Maps by variable name to the corresponding root inport with the matching signal name.
- **Block Path** - Maps by the BlockPath parameter to the corresponding root inport with the matching block path.
- **Custom** - Maps using a MATLAB function.

Earlier in this example, you used the `slexAutotransRootInportsSaveActiveGroup` to save input data to variables of the same name as the harness signals `Throttle` and `Brake`, and you added input ports with names matching the variables. Given the set of conditions for the input data and the model input ports, the best choice for a mapping criteria is **Block Name**. Using this criteria, Simulink tries to match input data variable names to the names of the input ports. To select this option:

- 1 Click the **Block Name** radio button.
- 2 Click the **Options** button and select `Compile` from the dropdown. This will provide some verification on the mapping.
- 3 Click the **Map** button.

When compiling the data, Simulink evaluates inports against the following criteria to determine whether or not there is a compatibility issue. The status of this compatibility is reflected by the table colors green, orange, or red. Clicking a cell in the table which has orange or red color will open the Comparison Tool for further inspection.

- **Data Type** - Double, single, enum, ....

- **Complexity** - Real or complex
- **Dimensions** - Signal dimensions vs port dimensions

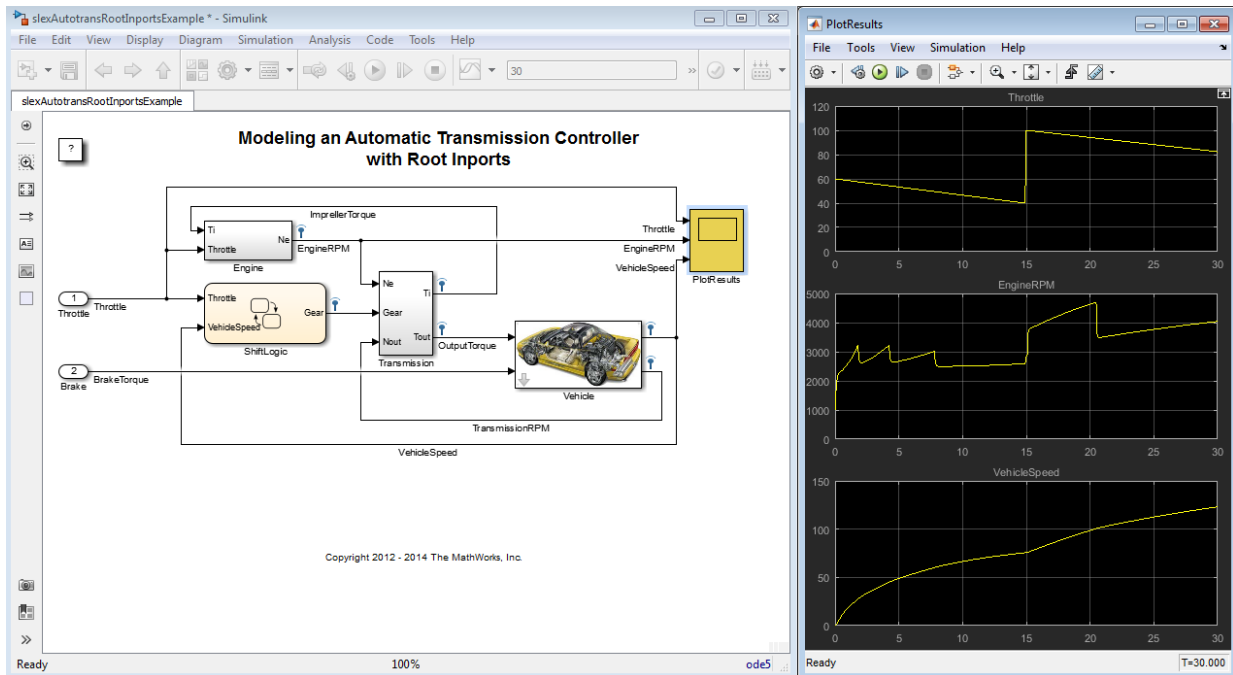

### Finalize the Inputs to the Model

Review the results of the mapping compatibility. The **Map** action has loaded the data that was mapped to the input ports from the MAT-file to the base workspace. Simulink sets the **Model Configuration Parameters->Data Import/Export->External Input** edit box with the proper comma separated list of inputs. To apply the changes to the model, in the Configuration Parameters dialog, click **Apply**.

## Simulating the Model

With the changes applied you can now simulate the model and view the results. Click the **Play** button on the model. To view the results of the simulation, double-click the Scope Block **PlotResults**.

## Import Test Vectors from Simulink Design Verifier Environment

You can import and map Simulink Design Verifier test vectors. The following workflow shows how you can use the Simulink Design Verifier `sldvsimdata` function to convert a Simulink Design Verifier test structure to a `Simulink.SimulationData.Dataset` object. This workflow requires a Simulink Design Verifier license.

- 1 Load a MAT-file that contains a Simulink Design Verifier test vector structure. `sldvData`. For example:

```
load sqrt_sldvdata.mat
```

- 2 Use the `sldvsimdata` function to convert a test vector structure to a `Simulink.SimulationData.Dataset` object that the Root Inport Mapping tool supports. This example converts the first test case in `sldvData`. For example:

```
sldvDataConverted = sldvsimdata(sldvData,1)
```

- 3 Save the `Simulink.SimulationData.Dataset` object aSLDs to a MAT-file. For example:

```
save sldvData.mat sldvDataConverted
```

You can now import `sldvData.mat` into the Root Inport Mapping tool as you do any support MAT-file. For more information on importing signals, see “Import Signal and Bus Data” on page 57-105.

## Alternative Workflows to Load Data

After saving the mapping definition to a model, you can automate data loading and/or simulation. Consider one of the following methods.

### Command Line or Script

To load data and simulate the model from the MATLAB command line, use commands like:

```
load('signaldata.mat');
simout = sim('model_name');
```

To automate testing and load different signal groups, consider using a script.

For example, the following example code creates timeseries data and simulates a model after loading each signal group. It:

- 1 Creates signal groups with variable names *In1*, *In2*, and *In3*, and saves these variables to MAT-files.
- 2 Simulates a model after loading each signal group.

---

**Note:** The variable names must match the import data variables in the **Data Import/Export > Input** parameter of the Configuration Parameters dialog box.

---

```
% Create signal groups
fileName = 'testCase';
```

```
for k =1 :3

    % Create the timeseries data
    var1 = timeseries(rand(10,1));
    var2 = timeseries(rand(10,1));
    var3 = timeseries(rand(10,1));

    % Save the data
    save([fileName '_' num2str(k) '.mat' ],'var1','var2','var3');
end
clear all

% After mapping and saving the model loop over signal groups and simulate
% Set the filename to append testcase # to
fileName = 'testCase';
% Loop backwards to preallocate
for k=3:-1:1
    % Load the MAT-file.
    load([fileName '_' num2str(k) '.mat' ]);

    % Simulate the model
    simOut{k} = sim('model_name');
end
```

### Use the PreLoadFcn Pane

If you are satisfied with the data and mapping, you can set up your model to automatically load a MAT-file of the same signal group by calling the `load` function in the model PreLoadFcn model property node.

- 1 After saving the MAT-file, in the Simulink editor, select **File > Model Properties > Model Properties**.
- 2 In the Model Properties window, select the PreLoadFcn node.
- 3 Enter a load function to load the signal data MAT-file. For example,  

```
load d_signal_data.mat;
```
- 4 Click **OK** and save the model.

### Create Custom Mapping File Function

Create a custom mapping file function if you do not want to use the mapping modes in the Root Inport Mapping tool to map your data to root-level input ports. For example, consider creating a custom mapping file function if:

- Your signal data contains a common prefix that is not in your model.
- You want to explicitly map a signal.

The custom mapping file function is also useful if you want to map by block name, but the data contains a signal whose name does not match one of the block names.

See these files in the folder *matlabroot/help/toolbox/simulink/examples* (open) for examples.

| File                            | Description  |
|---------------------------------|--|
| BlockNameIgnorePrefixMap.m      | Custom mapping file function that ignores the prefix of a signal name when importing |
| BlockNameIgnorePrefixData.mat   | MAT-file of signal data to be imported   |
| ex_BlockNameIgnorePrefixExample | Model file into which you can import and map data                                    |

In addition, see the example *Attaching Input Data to External Inputs via Custom Input Mappings*.

Follow these general steps to create a custom mapping file function:

- 1 Create a MATLAB function with the following input parameters:
  - Model name
  - Signal names specified as a cell array of strings
  - Signals specified as a cell array of signal data
- 2 In the function, call the `getRootInportMap` function to create a variable that contains the mapping object (for an example, see `BlockNameIgnorePrefixMap.m`).
- 3 Save and close the MATLAB function file.
- 4 Add the path for the new function to the MATLAB path.

To use the custom mapping file function:

- 1 Open the model you want to import data to (for example, `ex_BlockNameIgnorePrefixExample`).
- 2 Open the Configuration Parameters dialog box for the model and select the Data Import/Export pane.
- 3 In the **Load from workspace** section, click **Connect Input**.

- 4 Import your signal (for example, `BlockNameIgnorePrefixData.mat`).
- 5 In the **Mapping** section of the toolstrip, click **Custom**.
- 6 In the **Custom** text box, select the MATLAB function file (for example, `BlockNameIgnorePrefixMap.m`) using the browser.

By default, this text box contains `slexcustomMappingMyCustomMap`, which is the custom function for the Attaching Input Data to External Inputs via Custom Input Mappings example.

---

**Tip** The Root Inport Mapping tool parses your custom code. Parsing reorders output alphabetically and verifies that data types are consistent.

---

- 7 Click **Options** and select the **Compile** check box.
- 8 Click **Map**.

The model compiles and the Root Inport Mapping tool updates.

To understand the mapping results, see “Understand Mapping Results” on page 57-113.

- 9 Save and close the model.

The next time you load input data of the same signal group into the workspace, the model uses the mapping definition during simulation.

After you save the mapping definition for a model, you can automate data loading. For more information, see “Alternative Workflows to Load Data” on page 57-127.

### Custom Mapping Modes Similar to Simulink Modes

If you have a custom mapping mode that is similar to one of the Simulink mapping modes, you can use the `getSlRootInportMap` function in your custom mapping file function.

For an example of a custom mapping function that uses this function, see Using Mapping Modes with Custom-Mapped External Inputs.

### Command-Line Interface for Input Variables

Use the `getInputString` function to programmatically supply a set of input variables to the `sim` command or to a list of input variables that you can manually paste in the **Configuration Parameters > Data Import/Export > Input** parameter.

## Import Dataset Data

### In this section...

“Specify a Dataset Using the Input Parameter” on page 57-131

“Dataset Elements” on page 57-131

“Import Dataset Objects for Buses” on page 57-131

### Specify a Dataset Using the Input Parameter

You can use a Dataset object as a value for the **Configuration Parameters > Data Import/Export > Input** parameter. Specify only one Dataset object and do not include it in a comma-separated list.

### Dataset Elements

A Dataset object can include elements with different data types. The elements can be:

- A MATLAB timeseries object
- A structure, if each leaf node is either empty or a MATLAB timeseries object
- An array that meets one of these requirements:
  - An array with time in the first column and the remaining columns each corresponding to an input port. See “Import Data Arrays” on page 57-135.
  - An  $n \times 1$  array for a root inport that drives a function-call subsystem. See “Arrays for Input Ports Driving Function-Call Subsystems” on page 57-136.
- A Simulink.SimulationData.Signal object
- An empty matrix

The number of elements in the data set must match the number of root-level input ports.

### Import Dataset Objects for Buses

You can use a Dataset object to import bus data for a root-level input port. For details, see “Import Bus Data to Root-Level Input Ports” on page 57-91.

## Import MATLAB timeseries Data

### In this section...

“Specify Time Dimension” on page 57-132

“Models with Multiple Root Inport Blocks” on page 57-133

A root-level Inport, Enable, Trigger, and From Workspace block can import data specified by a MATLAB timeseries object residing in a workspace.

**Note:** This documentation about importing MATLAB timeseries data includes examples of root Inport blocks. Unless specifically noted otherwise, the examples are applicable to root-level Enable, Trigger, and From Workspace blocks.

### Specify Time Dimension

When you create a MATLAB timeseries object to import data to Simulink, the time dimension depends on the dimension and the type of signal data.

| Signal Data Dimension or Type                    | Time Dimension Alignment | Example of timeseries Constructor   |
|--|--------------------------|---|
| Scalar or a 1D vector                            | First                    | Constructor for a scalar signal. Time is aligned with the first dimension.<br><br><pre>t = (0:10)'; ts = timeseries(sin(t), t);</pre> |
| 2D (including row and column vectors) or greater | Last                     | Constructor for a matrix signal. Time is aligned with the last dimension.<br><br><pre>t = 0; ts = timeseries([1 2; 3 4], t);</pre>    |
| 2D row vector, and there is only one time step   | Last                     | 'InterpretSingleRowDataAs3D', true<br>For example:<br><br><pre>t = 0; ts = timeseries([1 2], t, 'Interpret</pre>                      |

## Models with Multiple Root Inport Blocks

To use a MATLAB `timeseries` object for a root Inport block in a model that has multiple root Inport blocks, convert all of the other root Inport block data that uses `Simulink.TsArray` or `Simulink.Timeseries` objects to MATLAB `timeseries` objects or to a structure of MATLAB `timeseries` objects.

You can use the `Simulink.Timeseries.convertToMATLABTimeseries` method to convert a `Simulink.Timeseries` object to a MATLAB `timeseries` object. For example, if `sim_ts` is a `Simulink.Timeseries` object, then the following line converts `sim_ts` to a MATLAB `timeseries` object:

```
ts = sim_ts.convertToMATLABTimeseries;
```

## Import Simulink.Timeseries and Simulink.TsArray Data

| In this section...                                    |
|---|
| “Use MATLAB Timeseries for New Models” on page 57-134 |
| “Simulink.TsArray Data” on page 57-134                |

### Use MATLAB Timeseries for New Models

For new models, have root-level `Inport` block or `Trigger` blocks import MATLAB `timeseries` data.

However, you can import existing `Simulink.Timeseries` object data. Importing `Simulink.Timeseries` objects allows you to import data logged by a previous simulation run that used the `ModelDataLogs` format for signal logging (see “Export Signal Data Using Signal Logging” on page 57-36).

### Simulink.TsArray Data

Objects of the `Simulink.TsArray` class have a variable number of properties. The first property, called `Name`, specifies the log name of the logged signal. The remaining properties reference logs for the elements of the logged signal: `Simulink.Timeseries` objects for elementary signals and `Simulink.TsArray` objects for mux or bus signals. The name of each property is the log name of the corresponding signal.

## Import Data Arrays

### In this section...

“Data Array Format” on page 57-135

“Specify the Input Expression” on page 57-135

“Arrays for Input Ports Driving Function-Call Subsystems” on page 57-136

### Data Array Format

This import format consists of a real (noncomplex) matrix of data type `double`. The first column of the matrix must be a vector of times in ascending order. The remaining columns specify input values. In particular, each column represents the input for a different Inport or Trigger block signal (in sequential order) and each row is the input value for the corresponding time point. For a Trigger block, the signal driving the trigger port must be the last data item.

The total number of columns of the input matrix must equal  $n + 1$ , where  $n$  is the total number of signals entering the model's input ports.

### Specify the Input Expression

The default input expression for a model is `[t,u]` and the default input format is `Array`. So if you define `t` and `u` in the MATLAB workspace, you need only select the **Input** option to input data from the model workspace. For example, suppose that a model has two input ports, `In1` that accepts two signals, and `In2` that accepts one signal. Also, suppose that the MATLAB workspace defines `t` and `u` as follows:

```
N = 10;  
Ts = 0.1  
t = ((0:N)* Ts)';  
u = [sin(t), cos(t), 4*cos(t)];
```

When the simulation runs, the signals `sin(t)` and `cos(t)` will be assigned to `In1` and the signal `4*cos(t)` will be assigned to `In2`.

---

**Note** The array input format allows you to load only real (noncomplex) scalar or vector data of type `double`. Use the structure format to input complex data, matrix (2-D) data, and/or data types other than `double`.

---

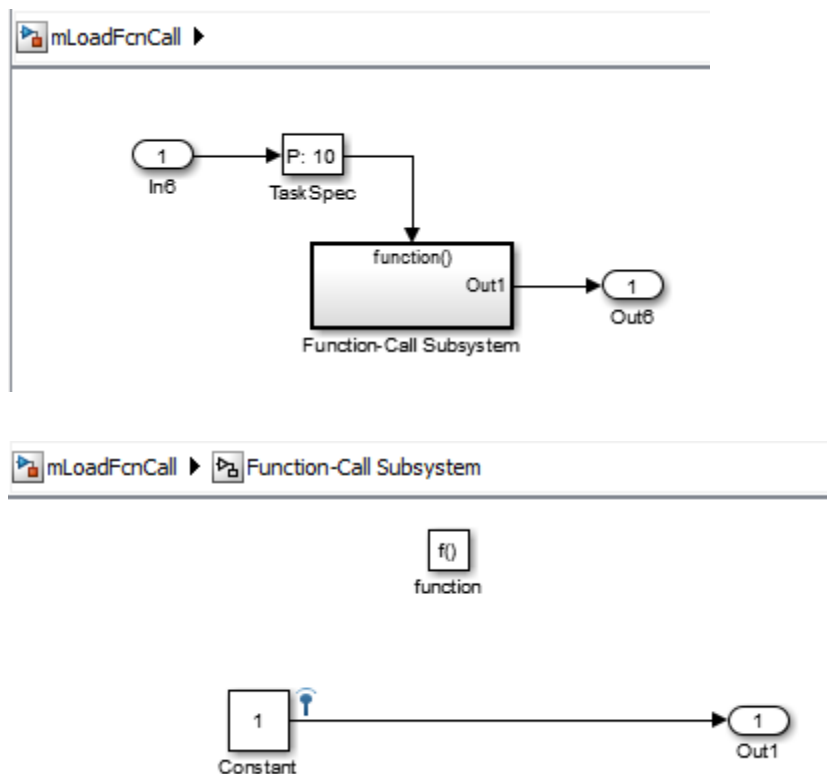

## Arrays for Input Ports Driving Function-Call Subsystems

You can use an array to drive a Function-Call Subsystem through a root-level input port. You can use an array or an array that is a **Dataset** element. The array must be an  $n \times 1$  array. For the root-level Inport block, you select **Output function call**.

For example, if you have a **Dataset** object with an array element:

```
ds = Simulink.SimulationData.Dataset;
x = [1 3 7 8]';
ds = ds.addElement(x, 'theElementName');
```

This model uses the **ds** data set in the **Configuration Parameters > Data Import/Export > Input** parameter.

When you simulate the model, you see that the Function-Call Subsystem was triggered only for the times specified in array stored in `ds`.

```
>> logout.get(1).Values.Time
```

```
ans =
```

```
1  
3  
7  
8
```

## Import MATLAB Time Expression Data

### Specify the Input Expression

You can use a MATLAB time expression to import data from a workspace. To use a time expression, enter the expression as a string (i.e., enclosed in single quotes) in the **Input** field of the **Data Import/Export** pane. The time expression can be any MATLAB expression that evaluates to a row vector equal in length to the number of signals entering the input ports of the model. For example, suppose that a model has one vector Inport that accepts two signals. Furthermore, suppose that `timefcn` is a user-defined function that returns a row vector two elements long. The following are valid input time expressions for such a model:

```
'[3*sin(t), cos(2*t)]'
```

```
'4*timefcn(w*t)+7'
```

The expression is evaluated at each step of the simulation, applying the resulting values to the model's input ports. Note that the Simulink software defines the variable `t` when it runs the simulation. Also, you can omit the time variable in expressions for functions of one variable. For example, the expression `sin` is interpreted as `sin(t)`.

## Import Data Structures

### In this section...

“Data Structures” on page 57-139

“One Structure for All Ports or a Structure for Each Port” on page 57-140

“Specify Signal Data” on page 57-140

“Specify Time Data” on page 57-141

“Examples of Specifying Signal and Time Data” on page 57-142

### Data Structures

The Simulink software can read data from the workspace in the form of a structure, whose name you specify in the **Configuration Parameters** > **Data Import/Export** > **Input** parameter.

For information about defining MATLAB structures, see “Create a Structure Array” in the MATLAB documentation.

The structure always includes a signals substructure, which contains a values field and a dimensions field. For details about the signal data, see “Specify Signal Data” on page 57-140. Depending on the modeling task that you want to perform, the structure can also include a time field.

You can specify structures for the model as a whole or on a per-port basis. For information about specifying per-port structures for the **Input** parameter, see “One Structure for All Ports or a Structure for Each Port” on page 57-140.

The form of a structure that you use depends on whether you are importing data for discrete signals (the signal is defined at evenly-spaced values of time) or continuous signals (the signal is defined for all values of time). For discrete signals, use a structure that has an empty time vector. For continuous signals, the approach that you use depends on whether the data represents a smooth curve or a curve that has discontinuities (jumps) over its range. For details, see:

- “Import Data to Test a Discrete Algorithm” on page 57-82
- “Import Data to Model a Continuous Plant” on page 57-80
- “Import Data for an Input Test Case” on page 57-83

For both discrete and continuous signals, specify a **signals** field, which contains an array of substructures, each of which corresponds to a model input port. For details, see “Specify Signal Data” on page 57-140.

For continuous signals, you may want to specify a **time** field, which contains a time vector. See “Time and Signal Values for Imported Data” on page 57-77.

## One Structure for All Ports or a Structure for Each Port

You can specify one structure to provide input to all root-level input ports in a model, or you can specify a separated structure for each port.

The per-port structure format consists of a separate structure-with-time or structure-without-time for each port. Each port's input data structure has only one **signals** field. To specify this option, enter the names of the structures in the **Input** text field as a comma-separated list, **in1, in2, ..., inN**, where **in1** is the data for your model's first port, **in2** for the second input port, and so on.

The rest of the section about importing structure data focuses on specifying one structure for all ports.

## Specify Signal Data

Each **signals** substructure must contain two fields: **values** and **dimensions**.

### The Values Field

The **values** field must contain an array of inputs for the corresponding input port. If you specify a time vector, each input must correspond to a time value specified in the **time** field.

If the inputs for a port are scalar or vector values, the **values** field must be an **M-by-N** array. If you specify a time vector, **M** must be the number of time points specified by the **time** field and **N** is the length of each vector value.

If the inputs for a port are matrices (2-D arrays), the **values** field must be an **M-by-N-by-T** array where **M** and **N** are the dimensions of each matrix input and **T** is the number of time points. For example, suppose that you want to input 51 time samples of a 4-by-5 matrix signal into one of your model's input ports. Then, the corresponding **dimensions** field of the workspace structure must equal **[4 5]** and the **values** array must have the dimensions **4-by-5-by-51**.

## The Dimensions Field

The `dimensions` field specifies the dimensions of the input. If each input is a scalar or vector (1-D array) value, the `dimensions` field must be a scalar value that specifies the length of the vector (1 for a scalar). If each input is a matrix (2-D array), the `dimensions` field must be a two-element vector whose first element specifies the number of rows in the matrix and whose second element specifies the number of columns.

---

**Note** You must set the **Port dimensions** parameter of the **Inport** or the **Trigger** block to be the same value as the `dimensions` field of the corresponding input structure. If the values differ, an error message is displayed when you try to simulate the model.

---

## Specify Time Data

You can specify a time vector as part of the data structure to import. The “Time and Signal Values for Imported Data” on page 57-77 section indicates when you may want to add a time vector.

The following table provides recommendations for how to specify time values, based on the kind of signal data you want to import.

| Signal Data   | Time Data Recommendation  |
|---|---|
| Inport or Trigger block with a discrete sample time | Do not specify a time vector. Simulink reads one signal value at each time step.  |
| Evenly-spaced discrete signals                      | Consider using an expression in the following form:<br><br><code>TimeVector = Ts * (0:N);</code><br><br>where <code>Ts</code> is the time step and <code>N</code> is the number of time steps.  |
| Unevenly-spaced values                              | Use any valid MATLAB array expression; for example, <code>[1:5 5:10]</code> or <code>(1 6 10 15)</code> .<br><br>If the root-level input port is from a From Workspace, From File, or Signal Builder block, which support zero-crossing |

| Signal Data | Time Data Recommendation   |
|-------------|--|
|             | detection, you can specify a zero-crossing time by using a duplicate time entry. |

## Examples of Specifying Signal and Time Data

In the first example, consider the following model that has a single input port:

- 1 Create an input structure for loading 11 time samples of a two-element signal vector of type `int8` into the model:

```
N = 10
Ts = 0.1
a.time = (0:N)*Ts';
c1 = int8([0:1:10]');
c2 = int8([0:10:100]');
a.signals(1).values = [c1 c2];
a.signals(1).dimensions = 2;
```

- 2 In the **Configuration Parameters** > **Data Import/Export** > **Input** parameter edit box, specify the variable `a`.
- 3 In the Inport block dialog box, in the **Signal Attributes** tab, set **Port dimensions** to 2 and **Data type** to `int8`.

As another example, consider a model that has two inputs:

Suppose that you want to input a sine wave into the first port and a cosine wave into the second port. To do this, define a structure, `a`, as follows, in the MATLAB workspace:

```
a.time = (0:0.1:1)';  
a.signals(1).values = sin(a.time);  
a.signals(1).dimensions = 1;  
a.signals(2).values = cos(a.time);  
a.signals(2).dimensions = 1;
```

Enter the structure name (`a`) in the **Configuration Parameters > Data Import/Export > Input** parameter edit box.

---

**Note:** Note that in this model you do not need to specify the dimension and data type, because the default values are `1` and `double`.

---

## State Information

### In this section...

“Simulation State Information” on page 57-144

“Types of State Information” on page 57-144

“Format for State Information Saved Without SimState” on page 57-147

“State Information for Referenced Models” on page 57-148

### Simulation State Information

Some blocks maintain state information that they use during simulation. For example, the state information for a Unit Delay block is the output signal value from the previous simulation step. The block uses the state information for calculating the output signal value for the current simulation step.

Some examples of uses of saved state information include:

- Stopping a simulation for a model and using the saved state information as input when you restart the simulation.
- Simulating one model and using the saved state information as input for the simulation of another model that builds on the results of the first model.
- Examining changes in state information throughout a simulation.

### Types of State Information

You can save these kinds of state information.

| Type of State Information       | Description   | Configuration Parameters in Data Import/Export Pane |
|---------------------------------|---|---|
| States for each simulation step | State information of blocks (referred to as partial state data) at each time step of a simulation | <b>States</b>                                       |
| Final state                     | State information of blocks at the end of the simulation  | <b>Final states</b>                                 |

| Type of State Information | Description   | Configuration Parameters in Data Import/Export Pane           |
|---------------------------|---|---|
| Final state with SimState | Final state with a SimState object that captures additional internal information that Simulink uses during simulation | <b>Final States and Save complete SimState in final state</b> |

SimState provides more complete final simulation state information than final states information by itself does. However, if the requirements and limitations of using SimState do not meet your modeling requirements, save final state information without SimState.

### Comparison of SimState and Final State Logging

| Characteristic     | Final State  | Final State with SimState   |
|--------------------|--|---|
| Simulation mode    | Supports all simulation modes  | Normal or Accelerator.  |
| Model reference    | “State Information for Referenced Models” on page 57-148   | See “Model Referencing” on page 22-42.  |
| Resumed simulation | Not supported  | Supported.  |
| Saved state data   | Only logged states — the continuous and discrete states of blocks — which are a subset of the complete simulation state of the model<br><br>User data, run-time parameters, or logs of the model not saved | Complete state information<br><br>Does not save user data, run-time parameters, or logs of the model.   |
| Block output       | User data, run-time parameters, or logs of the model not saved   | Simulink tries to save the output of a block as part of a SimState even if S-functions declare that no SimState states exist in the block. If the block output is of custom type, Simulink displays an error. |

| Characteristic            | Final State  | Final State with SimState  |
|---------------------------|--|--|
| Readability               | Use structure with time format for best readability  | To examine a simplified view of the data, consider using looking at the <code>loggedStates</code> property of the <code>Simulink.SimState.ModelSimState</code> class.  |
| Restoring state data      | Can save and restore in different simulation modes. If logged state information is not sufficient, you can obtain different results in the two simulation modes. | Cannot save in Normal mode and restore in Accelerator, or conversely save in Accelerator mode and restore in Normal mode.  |
| Restoring multiple states | You can initialize only one out of multiple logged states in the model.  | You restore all states in the model. You cannot load a subset of states.   |
| Structural changes        | You can make structural changes between simulation and restoring the simulation.   | You cannot make structural changes to the model between when you save the <code>SimState</code> and when you restore the simulation using the <code>SimState</code> . For example, you cannot add or remove a block after saving the <code>SimState</code> without repeating the simulation and saving the new <code>SimState</code> . |
| Input to model function   | To input to model function, use <code>Array</code> format with non-complex data of type <code>double</code> .  | You cannot input the <code>SimState</code> to model function.  |
| Code generation           | Supported  | Not supported  |

For both `SimState` and final state logging, Simulink saves state information at one of these points:

- At the final time step

- At the execution time at which the simulation paused or stopped

For additional information about `SimState`, see “Limitations of `SimState`” on page 22-41.

## Format for State Information Saved Without `SimState`

If you do not use the `SimState` for saving state information, then use **Configuration Parameters > Data Import/Export > Format** to specify the data format for the saved state information.

You can set **Format** to:

- Array (default)
- Structure
- Structure with time
- Dataset

The Array option for the **Configuration Parameters > Data Import/Export > Format** option supports compatibility with models developed in earlier releases, when Simulink supported only the array format for saving state information.

The array format reflects the order of signals. The order of saved state information can change between simulations when you change any of the following:

- The model (even without changing the signal)
- The simulation mode
- The code generation mode

The **Structure** and **Structure with time** formats are easier to read and consistent across simulations. Also, these two formats are useful when using state information to initialize a model for simulation, allowing you to:

- Associate initial state values directly with the full path name to the states. This association eliminates errors that can occur if Simulink reorders the states, but the order of the initial state array does not change correspondingly.
- Assign a different data type to the initial value of each state.
- Initialize only a subset of the states.

- **Dataset format:**
  - Uses MATLAB timeseries objects to store logged data (rather than `Simulink.Timeseries` and `Simulink.TsArray` objects). MATLAB `timeseries` objects allow you to work with logged data in MATLAB without a Simulink license.
  - Supports logging multiple data values for a given time step, which can be important for Iterator subsystem and Stateflow signal logging
  - Does not support logging nonvirtual bus data for code generation or Rapid Accelerator mode.

## State Information for Referenced Models

When Simulink saves states in the structure or structure-with-time format, it adds an `inReferencedModel` subfield to the `signals` field of the structure. The value of this additional subfield is true (1) if the `signals` field records the final state of a block that resides in the reference model. For example:

```
xout.signals(1)

ans =

        values: [101x1 double]
  dimensions: 1
         label: 'DSTATE'
    blockName: [1x66 char]
inReferencedModel: 1
```

If the `signals` field records a referenced model state, its `blockName` subfield contains a compound path of a top model path and a reference model path. The top model path is the path from the model root to the Model block that references the reference model. The reference model path is the path from the reference model root to the block whose state the `signals` field records. The compound path uses a `|` character to separate the top and reference model paths. For example:

```
>> xout.signals(1).blockName

ans =

sldemo_md1ref_basic/CounterA|sldemo_md1ref_counter/Previous Output
```

## Save State Information

### In this section...

“Save State Information for Each Simulation Step” on page 57-150

“Save Partial Final State Information” on page 57-150

“Examine State Information Saved Without the SimState” on page 57-151

“Save Final State Information with SimState” on page 57-152

### Save State Information for Each Simulation Step

You can save state information for logged states for each simulation step during a simulation. That level of state information can be helpful for debugging.

- 1 Select the **Configuration Parameters > Data Import/Export > States** check box.
- 2 In the **States** edit box, you can specify a different variable for the state information, if you do not want to use the default `xout` variable.
- 3 Also in the **Data Import/Export** pane, set the **Format** parameter to **Dataset**, **Structure**, or **Structure with time**, unless you use array format for compatibility with a legacy model. **Dataset** format does not support code generation or Rapid Accelerator simulation mode.
- 4 Click **Apply**.
- 5 Simulate the model.

### Save Partial Final State Information

To save just the logged states (the continuous and discrete states of blocks):

- 1 Select the **Configuration Parameters > Data Import/Export > Final states** check box.
- 2 In the **Final states** edit box, you can specify a different variable for the state information, if you do not want to use the default `xFinal` variable.
- 3 Clear the **Save complete SimState in final state** parameter.
- 4 Set the **Format** parameter to **Dataset**, **Structure** or **Structure with time**.
- 5 Click **Apply**.

6 Simulate the model.

## Examine State Information Saved Without the SimState

If you enable the **Configuration Parameters > Data Import/Export > Final states** or **States** parameters, Simulink saves the state information in the format that you specify with the **Format** parameter. The default variable for **Final state** information is `xFinal`, and the variable for state information for States information is `xout`.

If a model has no states saved, then `xFinal` and `xout` are empty variables. To determine whether a model has states saved, use the `isempty(xout)` command.

### Final State Information in Dataset Format

For example, suppose that you saved final state information in **Dataset** format, and use the default `xFinal` variable for the saved state information.

```
xFinal
```

```
xFinal =
```

```
Simulink.SimulationData.Dataset
Package: Simulink.SimulationData
```

```
Characteristics:
      Name: 'xFinal'
  Total Elements: 2
```

```
Elements:
  1: 'CSTATE'
  2: 'DSTATE'
```

Examine the first element of the state dataset.

```
xFinal.get(1)
```

```
ans =
```

```
Simulink.SimulationData.State
Package: Simulink.SimulationData
```

```
Properties:
      Name: 'CSTATE'
```

```
BlockPath: [1x1 Simulink.SimulationData.BlockPath]
Label: CSTATE
Values: [1x1 timeseries]
```

### Final State Information in Structure with Time Format

For example, suppose that you saved final state information in a structure with time format, and use the default `xFinal` variable for the saved state information.

To find the simulation time and number of states in the `vdp` model, enter the `xFinal` variable.

```
xFinal
xFinal =
    time: 20
  signals: [1x2 struct]
```

In this case, the simulation time is 20 and there are two states. To examine the first state, use this command.

```
xFinal.signals(1)
ans =
    values: 2.0108
  dimensions: 1
    label: 'CSTATE'
  blockName: 'vdp/x1'
    stateName: ''
  inReferencedModel: 0
```

The `values` and `blockName` fields of the first state structure show that the final value for the output signal of the `x1` block is 2.018.

---

**Note:** If you write a script to analyze state information, use a combination of `label` and `blockName` values to identify a specific state uniquely. Do not rely on the order of the states.

---

### Save Final State Information with SimState

To save complete state information, save the `SimState` for a simulation.

- 1** Select the **Configuration Parameters > Data Import/Export > Final states** check box.
- 2** Also in the Data Import/Export pane, select the **Save complete SimState in final state** parameter.
- 3** In the edit box next to the **Save complete SimState in final state** parameter, enter a variable name for the **SimState** and click **Apply**.
- 4** Simulate the model.

For more information about using the **SimState**, see “Save and Restore Simulation State as SimState” on page 22-36.

## Related Examples

## Load State Information

### In this section...

“Import Initial States” on page 57-154

“Initialize a State” on page 57-154

“Initialize States in Referenced Models” on page 57-155

### Import Initial States

To initialize a simulation, you can use:

- Final state information (with or without `SimState`) from a previous simulation
- State information that you create in MATLAB

Use **Configuration Parameters > Data Import/Export** parameters to import initial states.

- 1 Enable the **Initial state** parameter.
- 2 In the **Initial state** edit box, enter the name of the variable for the state information that you want to use for initialization.

The initial values that the variable specifies override the initial state values that the blocks in the model specify in initial condition parameters.

### Initialize a State

You can initialize a specific state. For example, the following commands create an initial state structure that initializes the `x2` state of the `vdp` model. The `x1` state is not initialized in the structure. Therefore, during simulation, Simulink uses the value in the Integrator block associated with the state.

- 1 Obtain an initial state structure.

```
open_system('vdp');
states = Simulink.BlockDiagram.getInitialState('vdp');
```
- 2 Set the initial value of the signals structure element associated with `x2` to 2.

```
states.signals(2).values = 2;
```

- 3 Remove the signals structure element associated with x1.

```
states.signals(1) = [];
```

- 4 Use the `states` variable for the vdp model. Enable the **Configuration Parameters > Data Import/Export > Initial state** option. Enter `states` in the edit field.

When you simulate the model, note that both states have the initial value of 2. The initial value of the x2 state is assigned in the `states` structure, while the initial value of the x1 state is assigned in its Integrator block.

## Initialize States in Referenced Models

To initialize the states of a top model and the models that it references, use the structure or structure with time format or use `SimState`.

To view `SimState` to initialize blocks that are inside a referenced model in Accelerator mode, set **Configuration Parameters > Data Import/Export > Signal logging format** to `Dataset`. You cannot use these logged states to initialize a model referenced in Accelerator mode.

- “Order Data Store Access” on page 58-36
- “Data Store Diagnostics” on page 58-43
- “Data Stores and Software Verification” on page 58-52

## Local and Global Data Stores

A *data store* is a repository to which you can write data, and from which you can read data, without having to connect an input or output signal directly to the data store. Data stores are accessible across model levels, so subsystems and referenced models can use data stores to share data without using I/O ports. You can define two types of data stores:

- A *local data store* is accessible from anywhere in the model hierarchy that is at or below the level at which you define the data store, except from referenced models. You can define a local data store graphically in a model or by creating a model workspace signal object (`Simulink.Signal`).
- A *global data store* is accessible from throughout the model hierarchy, including from referenced models. Define a global data store only in the MATLAB base workspace, using a signal object. The only type of data store that a referenced model can access is a global data store.

In general, locate a data store at the lowest level in the model that allows access to the data store by all the parts of the model that need that access. Some examples of local and global data stores appear in “Data Store Examples” on page 58-28.

For information about using referenced models, see “Model Reference”.

## Customized Data Store Access Functions in Generated Code

Embedded Coder provides a custom storage class that you can use to specify customized data store access functions in generated code. See “Control Data Representation by Applying Custom Storage Classes” and “Access Data Through Functions with Custom Storage Class GetSet”.

## Related Examples

- “Apply Data Stores” on page 58-6

- “Data Store Examples” on page 58-28

## More About

- “Access Data Through Functions with Custom Storage Class GetSet”
- “When to Use a Data Store” on page 58-3

## When to Use a Data Store

Data stores can be useful when multiple signals at different levels of a model need the same global values, and connecting all the signals explicitly would clutter the model unacceptably or take too long to be feasible. Data stores are analogous to global variables in programs, and have similar advantages and disadvantages, such as making verification more difficult. See “Data Stores and Software Verification” on page 58-52 for more information.

In some cases, you may be able to use a simpler technique, **Goto** blocks and **From** blocks, to obtain results similar to those provided by data stores. The principal disadvantage of data Goto/From links is that they generally are not accessible across nonvirtual subsystem boundaries, while an appropriately configured data store can be accessed anywhere. See the **Goto** and **From** block reference pages for more information about Goto/From links.

### More About

- “Data Stores and Software Verification” on page 58-52
- “Local and Global Data Stores” on page 58-2

## Create Data Stores

To create a data store, you create a **Data Store Memory** block or a **Simulink.Signal** object. The block or signal object represents the data store and specifies its properties. Every data store must have a unique name.

- A **Data Store Memory** block implements a local data store. See “Data Stores with Data Store Memory Blocks” on page 58-10.
- A **Simulink.Signal** object can act as a local or global data store. See “Data Stores with Signal Objects” on page 58-14.

Data stores implemented with Data Store Memory blocks:

- Support data store initialization
- Provide control of data store scope and options at specific levels in the model hierarchy
- Require a block to represent the data store
- Cannot be accessed within referenced models
- Cannot be in a subsystem that a For Each Subsystem block represents.

Data stores implemented with **Simulink.Signal** objects:

- Provide model-wide control of data store scope and options
- Do not require a block to represent the data store
- Can be accessed in referenced models, if the data store is global

Be careful not to equate local data stores with Data Store Memory blocks, and global data stores with **Simulink.Signal** objects. Either technique can define a local data store, and a signal object can define either a local or a global data store.

## Apply Data Stores

---

**Note:** To use buses and arrays of buses with data stores, perform *both* the following procedure and “Setting Up a Model to Use Data Stores with Buses and Arrays of Buses” on page 58-8.

---

The following is a general workflow for configuring data stores. You can perform the tasks in a different order, or separately from the rest, depending on how you use data stores.

- 1 Where applicable, plan your use of data stores to minimize their effect on software verification. For more information, see “Data Stores and Software Verification” on page 58-52.
- 2 Create data stores using the techniques described in “Data Stores with Data Store Memory Blocks” on page 58-10 or “Data Stores with Signal Objects” on page 58-14. For greater reliability, consider assigning rather than inheriting data store attributes, as described in “Specifying Data Store Memory Block Attributes” on page 58-10.
- 3 Add to the model Data Store Write and Data Store Read blocks to write to and read from the data stores, as described in “Access Data Stores with Simulink Blocks” on page 58-17.
- 4 Configure the model and the blocks that access each data store to avoid concurrency failures when reading and writing the data store, as described in “Order Data Store Access” on page 58-36.
- 5 Apply the techniques described in “Data Store Diagnostics” on page 58-43 as needed to prevent data store errors, or to diagnose them if they occur during simulation.
- 6 If you intend to generate code for your model, see “Data Stores in Generated Code” in the Simulink Coder documentation.

- “Data Stores and Software Verification” on page 58-52
- “Local and Global Data Stores” on page 58-2

## Data Stores with Buses and Arrays of Buses

Benefits of using data stores with buses and arrays of buses include:

- Simplifying the model layout by associating multiple signals with a single data store
- Producing generated code that represents the data in the store data as structures that reflect the bus hierarchy
- Writing to and reading from data stores without creating data copies, which results in more efficient data access

You cannot use a bus or array of buses that contains:

- Variable-dimension signals
- Frame-based signals

### Setting Up a Model to Use Data Stores with Buses and Arrays of Buses

This procedure applies to local and global data stores, and to data stores defined with a Data Store Memory block or a `Simulink.Signal` object. Before performing the procedure, you must understand how to use data stores in a model, as described in “Apply Data Stores” on page 58-6.

To use buses and arrays of buses with data stores:

- 1 Use the Bus Editor to define a bus object whose properties match the bus data that you want to write to and read from a data store. For details, see “Manage Bus Objects with the Bus Editor” on page 61-27.
- 2 Add a data store (using a Data Store Memory block or a `Simulink.Signal` object) for storing the bus data.
- 3 Specify the bus object as the data type of the data store. For details, see “Specify a Bus Object Data Type” on page 55-34.
- 4 In the **Model Configuration Parameters > Diagnostics > Connectivity** pane, set the **Mux blocks used to create bus** diagnostic to **error**. For details, see “Prevent Bus and Mux Mixtures” on page 61-113.
- 5 If you use a MATLAB structure for the initial value of the data store, then in the **Model Configuration Parameters > Diagnostics > Data Validity** pane, set the **Underspecified initialization detection** diagnostic to **Simplified**. For details, see “Specify Initial Conditions for Bus Signals” on page 61-65 and “Underspecified initialization detection”.

- 6 (Optional) Select individual bus elements to write to or read from a data store. For details, see “Accessing Specific Bus and Matrix Elements” on page 58-19.

## Data Stores with Data Store Memory Blocks

### In this section...

“Creating the Data Store” on page 58-10

“Specifying Data Store Memory Block Attributes” on page 58-10

### Creating the Data Store

To use a Data Store Memory block to define a data store, drag an instance of the block into the model at the topmost level from which you want the data store to be visible. The result is a local data store, which is not accessible within referenced models.

- To define a data store that is visible at every level within a given model, except within Model blocks, drag the Data Store Memory block into the root level of the model.
- To define a data store that is visible only within a particular subsystem and the subsystems that it contains, but not within Model blocks, drag the Data Store Memory block into the subsystem.

Once you have added the Data Store Memory block, use its parameters dialog box to define the data store's properties. The **Data store name** property specifies the name to of the data store that the Data Store Write and Data Store Read blocks access. See **Data Store Memory** documentation for details.

You can specify data store properties beyond those definable with Data Store Memory block parameters by selecting the **Data store name must resolve to Simulink signal object** option and using a signal object as the data store name. See “Specifying Attributes Using a Signal Object” on page 58-11 for details.

### Specifying Data Store Memory Block Attributes

A Data Store Memory block can inherit three data attributes from its corresponding Data Store Read and Data Store Write blocks. The inheritable attributes are:

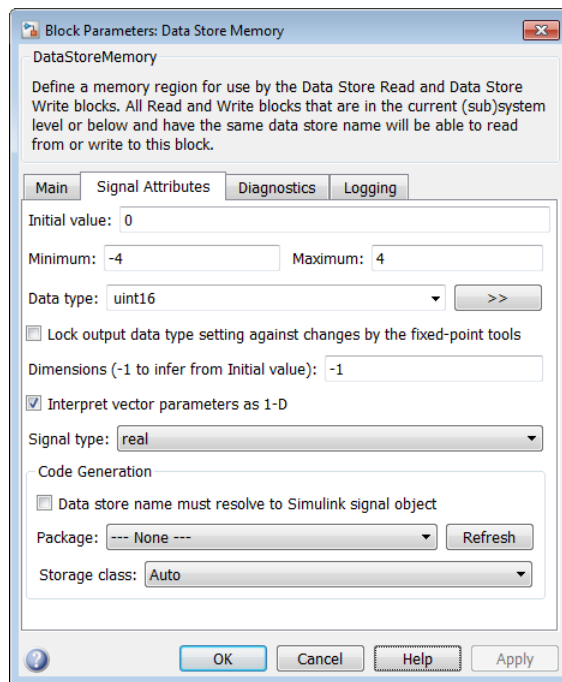

- Data type
- Complexity
- Sample time

However, allowing these attributes to be inherited can cause unexpected results that can be difficult to debug. To prevent such errors, use the Data Store Memory block dialog or a `Simulink.Signal` object to specify the attributes explicitly.

### Specifying Attributes Using Block Parameters

You can use the Data Store Memory block dialog box to specify the data type and complexity of a data store. In the next figure, the dialog box sets the **Data type** to `uint16` and the **Signal type** to `real`.

### Specifying Attributes Using a Signal Object

You can use a `Simulink.Signal` object to specify data store attributes for a Data Store Memory block.

---

**Tip** To establish an implicit data store, as described in “Data Stores with Signal Objects” on page 58-14, use the same general approach as when you explicitly associate a signal object with a Data Store Memory block.

---

The next figure shows a Data Store Memory block that specifies resolution to a `Simulink.Signal` object, named `A`. To use a signal object for the data store, set **Data store name** to the name of the signal object. For compile-time checking, open the **Signal Attributes** tab and select the **Data store name must resolve to Simulink signal object** parameter.

The signal object specifies values for all three data attributes that the data store would otherwise inherit. In this example, which defines a local data store, the `Simulink.Signal` object `A` has the following inherited properties: `DataType`, `Complexity`, and `SampleTime`.

`A =`

```
Simulink.Signal (handle)
  CoderInfo: [1x1 Simulink.CoderInfo]
  Description: ''
  DataType: 'auto'
  Min: []
  Max: []
```

```
DocUnits: ''  
Dimensions: 1  
DimensionsMode: 'auto'  
Complexity: 'auto'  
SampleTime: -1  
InitialValue: 0
```

For more information about specifying signal object attributes for local and global data stores, see “Signal Object Attributes for Data Stores” on page 58-14.

## Data Stores with Signal Objects

### In this section...

“Creating the Data Store” on page 58-14

“Local and Global Data Stores” on page 58-14

“Signal Object Attributes for Data Stores” on page 58-14

### Creating the Data Store

To use a `Simulink.Signal` object to define a data store without using a Data Store Memory block, create the signal object in a workspace that is visible to every component that needs to access the data store. The name of the associated data store is the name of the signal object. You can use this name in Data Store Read and Data Store Write blocks, just as if it were the **Data store name** of a Data Store Memory block. Simulink creates an associated data store when you use the signal object for data storage.

### Local and Global Data Stores

You can use a `Simulink.Signal` object to define either a local or a global data store.

- If you define the object in the MATLAB base workspace, the result is a global data store, which is accessible in every model within Simulink, including all referenced models.
- If you create the object in a model workspace, the result is a local data store, which is accessible at every level in a model except any referenced models.

### Signal Object Attributes for Data Stores

Those data store attributes that a signal object does not define have the same default values that they do in a Data Store Memory block. The parameter values of a signal object used as a data store have different requirements, depending on whether the data store is local or global.

Once you have created the object, set the properties of the signal object to the values that you want the corresponding data store properties to have. For example, the following commands define a data store named `ERROR` in the MATLAB base workspace:

```
Error = Simulink.Signal;
```

```
Error.Description = 'Use to signal that subsystem output is invalid';
Error.DataType = 'boolean';
Error.Complexity = 'real';
Error.Dimensions = 1;
Error.SampleTime = 0.1;
```

### Attributes for Local Data Stores

For a local data store, for each parameter listed below, you can either set the value explicitly or you can have the data store inherit the value from the Data Store Write and Data Store Read blocks.

- `DataType`
- `Complexity`
- `SampleTime`

To define a local data store using a Data Store Memory block, you can use a signal object for the **Data store name** parameter. For compile-time checking, in the **Signal Attributes** tab, select the **Data store must resolve to Simulink signal object** parameter. The **Data store must resolve to Simulink signal object** parameter causes Simulink to display an error and stop compilation if Simulink cannot find the signal object or if the signal object properties are inconsistent with the signal object properties.

### Attributes for Global Data Stores

The following table describes the parameter requirements for global data stores.

| Parameter               | Global Data Store Value |
|-------------------------|-------------------------|
| <code>DataType</code>   | Must be set explicitly  |
| <code>Complexity</code> | Must be set explicitly  |
| <code>Dimensions</code> | Can be set or inherited |
| <code>SampleTime</code> | Can be set or inherited |

## Access Data Stores with Simulink Blocks

### In this section...

- “Writing to a Data Store” on page 58-17
- “Reading from a Data Store” on page 58-17
- “Accessing a Global Data Store” on page 58-18
- “Accessing Specific Bus and Matrix Elements” on page 58-19

### Writing to a Data Store

To set the value of a data store at each time step:

- 1 Create an instance of a **Data Store Write** block at the level of your model that computes the value.
- 2 Set the Data Store Write block **Data store name** parameter to the name of the data store to which you want it to write data.
- 3 Connect the output of the block that computes the value to the input of the Data Store Write block.

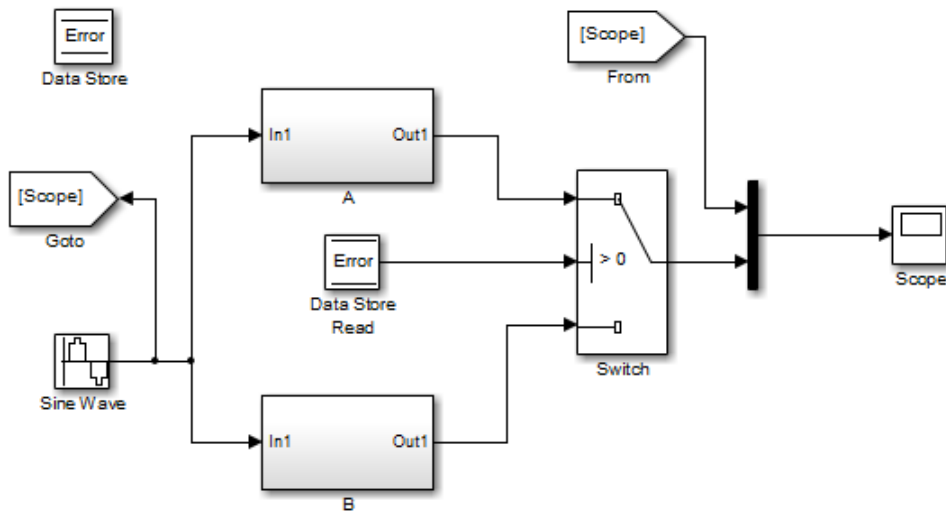

### Reading from a Data Store

To get the value of a data store at each time step:

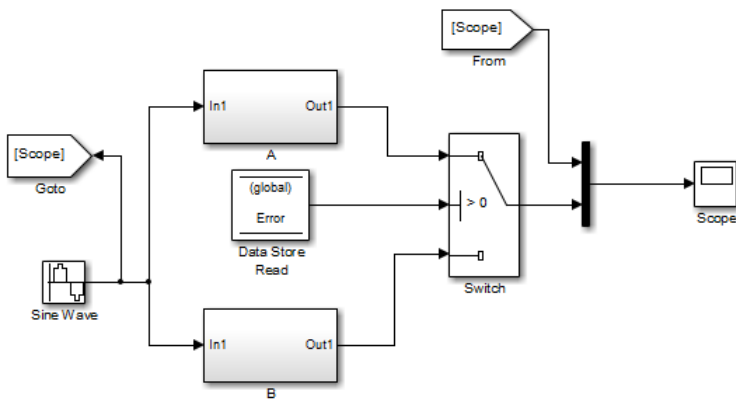

- 1 Create an instance of a **Data Store Read** block at the level of your model that needs the value.
- 2 Set the Data Store Read block **Data store name** parameter to the name of the data store from which you want it to read.

- 3 Connect the output of the Data Store Read block to the input of the block that needs the data store value.

## Accessing a Global Data Store

When connected to a global data store (one that is defined by a signal object in the MATLAB workspace), a Data Store Read or Data Store Write block displays the word `global` above the data store name.

## Accessing Specific Bus and Matrix Elements

### Configuring a Data Store for Composite Signals

You can store composite signals such as nonvirtual bus signals, arrays of buses, and vector signals in a data store. To configure a model and a data store for composite signals, see “Data Stores with Buses and Arrays of Buses” on page 58-8.

### Selecting Specific Bus or Matrix Elements

By default, a model writes and reads all bus and matrix elements to and from a data store.

To select specific bus or matrix elements to write to or read from a data store, use the **Element Assignment** pane of the **Data Store Write** block and the **Element Selection** pane of the **Data Store Read** block. Selecting specific bus or matrix elements offers the following benefits:

- Reducing the number of blocks in the model. For example, you can eliminate a Data Store Read and Bus Selector block pair or a Data Store Write and Bus Assignment block pair for each specific bus element that you want to access).
- Faster simulation of models with large buses and arrays of buses.

### Writing Specific Elements to a Data Store

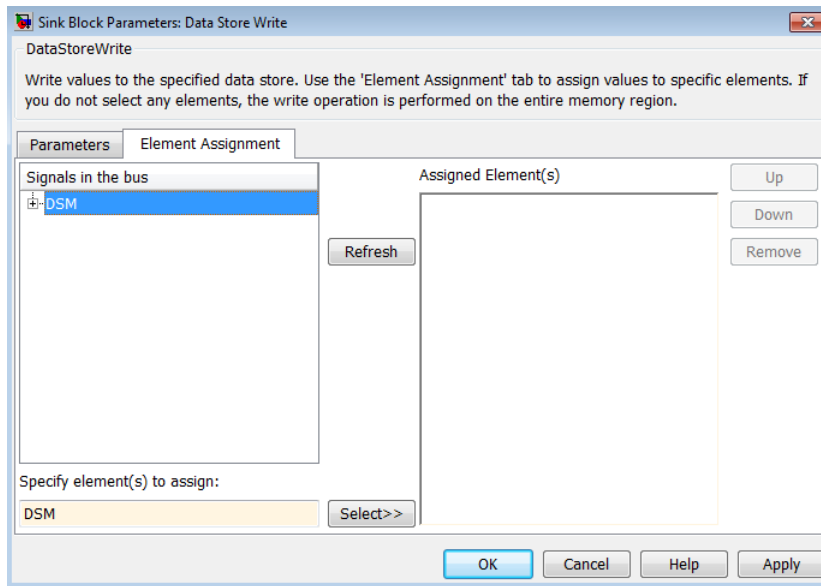

---

**Note:** The following procedure describes how to use the Data Store Write block interface to write specific elements to a data store. You can also perform this task at the command line, using the `DataStoreElements` parameter to specify elements. For details, see “Specification using the command line” on page 58-24.

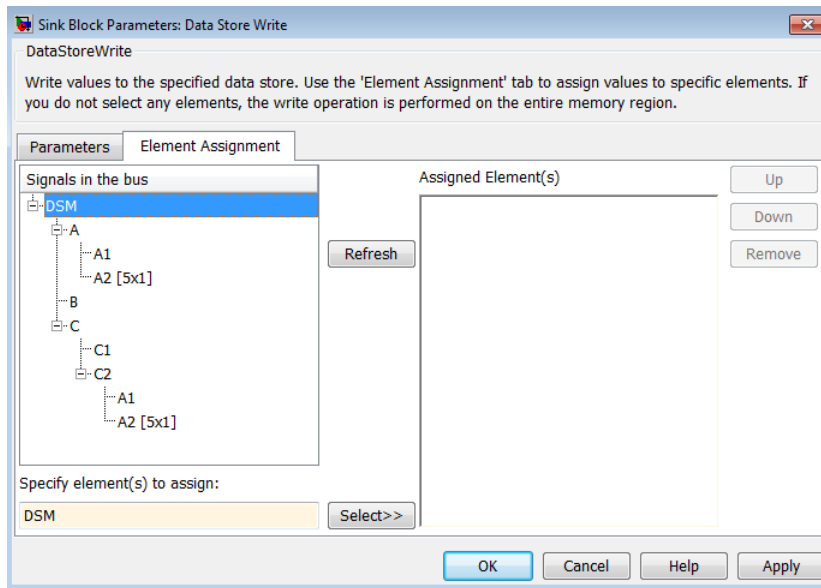

---

To assign specific bus or matrix elements to write to a data store:

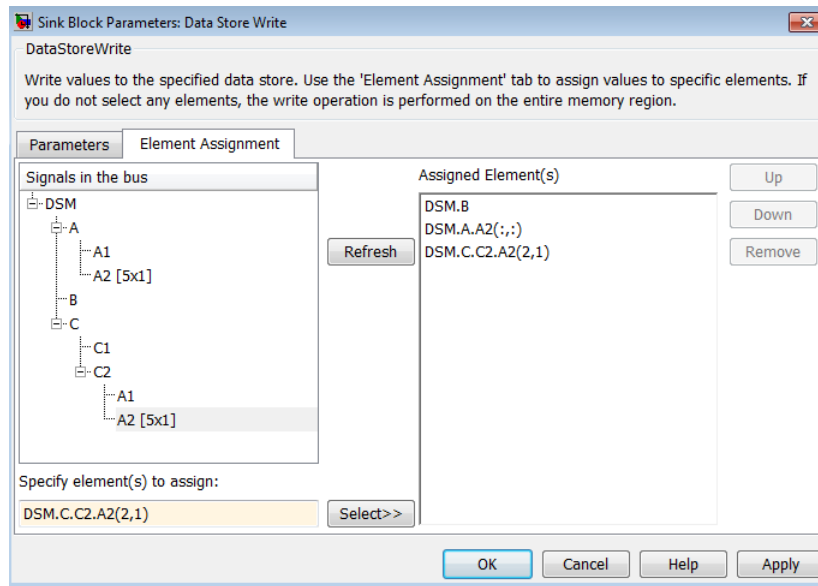

- 1 Select the Data Store Write block and in the parameters dialog box, select the **Element Assignment** pane. For example, suppose you are using a bus with a data store named DSM:

- 2 Expand all the elements in the **Signals in the bus** list.

- 3** Specify the elements that you want to write to the data store. For example:
- In the **Signals in the bus** list, click B. Then click **Select>>** to select the element B.
  - To write all the elements of A2 (in the A subbus), select A2 [5x1]. Then click **Select>>**.
  - To write the second element of A2 in the C2 subbus, select the A2 [5x1] element. In the **Specify element(s) to assign** text box, edit the text to say `DSM.C.C2.A2(2,1)`.

For more examples, see “Specifying Elements to Assign or Select” on page 58-23.

- 4 (Optional) Reorder the assigned elements, which changes the order of the ports of the Data Store Write block.
  - To reorder an assigned element, in the **Assigned element(s)** list, select the element that you want to move, and click **Up** or **Down**.
  - To remove an assigned element, click **Remove**.
- 5 To apply the assigned elements, click **OK**.

The Data Store Write block has a port for each assigned element. The names of the selected elements that correspond to each port appear in the block icon. If you assign several signals, these additions may diminish the readability of the model. To improve readability, you can expand the size of the block or create multiple Data Store Write blocks.

### Reading Specific Elements from a Data Store

Reading specific elements from a data store involves very similar steps as described in “Writing Specific Elements to a Data Store” on page 58-19. The Data Store Read block differs slightly from the Data Store Write block. A Data Store Read block has:

- An **Element Selection** pane instead of an **Element Assignment** pane
- A **Selected element(s)** list instead of an **Assigned element(s)** list

### Specifying Elements to Assign or Select

Use MATLAB matrix element syntax to specify specific elements. For details about specifying matrices in MATLAB, see “Creating and Concatenating Matrices”.

---

**Note:** To select matrix elements, you cannot use dynamic indexing with the **Element Assignment** and **Element Selection** panes of Data Store Read and Bus Assignment block pairs or Data Store Write and Bus Selector block pairs. You can, however, use a MATLAB `Function` block for dynamic indexing.

---

### Valid element specifications

The following table shows examples of valid syntax for specifying elements to assign or select. These examples use the A2 subbus of the A bus, as shown in the bus hierarchy used in “Writing Specific Elements to a Data Store” on page 58-19.

| Valid Syntax                       | Description                                  |
|------------------------------------|--|
| <code>DSM.A.A2 (:, :)</code>       | Selects all elements in every dimension      |
| <code>DSM.A.A2 ([1,3,5], 1)</code> | Selects the first, third, and fifth elements |
| <code>DSM.A.A2 (2:5, 1)</code>     | Selects the second through the fifth element |

### Invalid element specifications

The following table shows examples of invalid syntax for specifying elements to assign or select. These examples use the **A2** subbus of the **A** bus, as shown in the bus hierarchy used in “Writing Specific Elements to a Data Store” on page 58-19.

| Invalid Syntax                   | Reason the Syntax Is Invalid  |
|----------------------------------|---|
| <code>DSM.A.A2 (:)</code>        | You must specify a colon for each dimension. For the bus hierarchy used in these examples, you must use two colons. |
| <code>DSM.A.A2 (2:end, 1)</code> | You cannot use the <code>end</code> operator.   |
| <code>DSM.A.A2 (idx, 1)</code>   | You cannot use variables to specify indices. Consider using a <code>MATLAB Function</code> block.                   |
| <code>DSM.A.A2 (-1, 1)</code>    | The dimension <code>-1</code> is not within the valid dimension bounds.   |

### Specification using the command line

To set the elements to write to or read from, use the `DataStoreElements` parameter. Use a pound sign (`#`) to delimit multiple elements. For example, select the Data Store Write or Data Store Read block for which you want to specify elements and enter a command such as:

```
set_param(gcb, 'DataStoreElements', 'DSM.A#DSM.B#DSM.C(3,4)')
```

This specification results in the block now having three ports corresponding to the elements that you specified.

- “Apply Data Stores” on page 58-6
- “Create Data Stores” on page 58-4
- “Rename Data Stores” on page 58-26
- “Log Data Stores” on page 58-31

## **More About**

- “When to Use a Data Store” on page 58-3
- “Local and Global Data Stores” on page 58-2

## Rename Data Stores

|  |
|--|
| <b>In this section...</b>                                  |
| “Rename Data Store Defined by Block” on page 58-26         |
| “Rename Data Store Defined by Signal Object” on page 58-26 |

### Rename Data Store Defined by Block

Rename a data store everywhere it is used by Data Store Read and Data Store Write blocks in a model.

- 1 In a Data Store Memory block dialog box, type a new name in the **Data store name** box, and click **Rename All**.
- 2 In the **Rename All** dialog box, confirm the new data store name in the **New name** field, and click **OK**

---

**Note:** You cannot use **Rename All** to rename a data store if you create a `Simulink.Signal` object in a workspace to control the code generated for the data store. Instead, you must rename the corresponding `Simulink.Signal` object using Model Explorer. For an example, see “Rename Data Store Defined by Signal Object” on page 58-26.

---

### Rename Data Store Defined by Signal Object

This example shows how to rename a data store defined by a `Simulink.Signal` object. You can use Model Explorer to rename the object everywhere it is used by Data Store Read and Data Store Write blocks in a model or in a model reference hierarchy.

- 1 Open the model `sldemo_mdhref_dsm`. The model creates a `Simulink.Signal` object `ErrorCond` in the MATLAB base workspace and uses the object as a global data store in a model reference hierarchy.
- 2 Open Model Explorer.
- 3 In the **Model Hierarchy** pane, select the base workspace.
- 4 In the **Contents** pane, right-click the data store `ErrorCond` and select **Rename All**.

- 5 In the **Select a system** dialog box, click the name of the model `sldemo_md1ref_dsm` to select it as the context for renaming the data store `ErrorCond`.
- 6 Select **Search in referenced models** since `ErrorCond` is a global data store that is used in a referenced model. Click **OK**.

The **Update diagram to include recent changes** check box is cleared by default to save time by avoiding unnecessary model diagram updates. Select the check box to incorporate recent changes you made to the model by forcing a diagram update.

- 7 Click **OK** in response to the message to update the model diagram.

Since you just opened the model, you must update the model diagram at least once before renaming a variable such as `ErrorCond`. You could have selected **Update diagram to include recent changes** in the **Select a system** dialog box to force an initial diagram update, though you typically use that option when you make changes to the model while performing multiple variable renaming operations.

- 8 In the **Rename All** dialog box, type the new name for the data store in the **New name** box and click **OK**.

## Data Store Examples

| In this section...                        |
|---|
| “Overview” on page 58-28                  |
| “Local Data Store Example” on page 58-28  |
| “Global Data Store Example” on page 58-29 |

### Overview

The following examples illustrate techniques for defining and accessing data stores. See “Order Data Store Access” on page 58-36 for techniques that control data store access over time, such as ensuring that a given data store is always written before it is read. See “Data Store Diagnostics” on page 58-43 for techniques you can use to help detect and correct potential data store errors without needing to run any simulations.

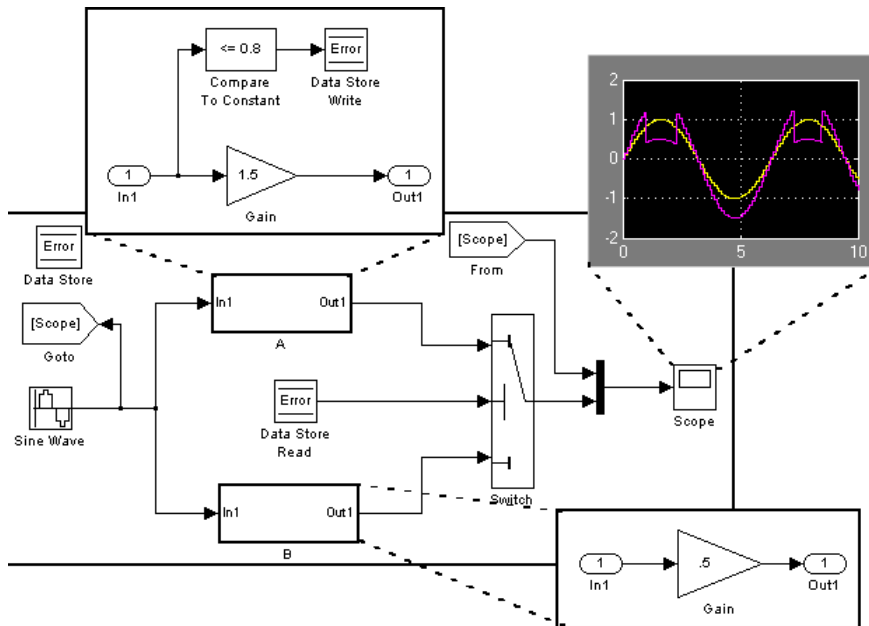

---

**Note:** In addition to the following examples, see the `sldemo_mdref_dsm` model, which shows how to use global data stores to share data among referenced models.

---

### Local Data Store Example

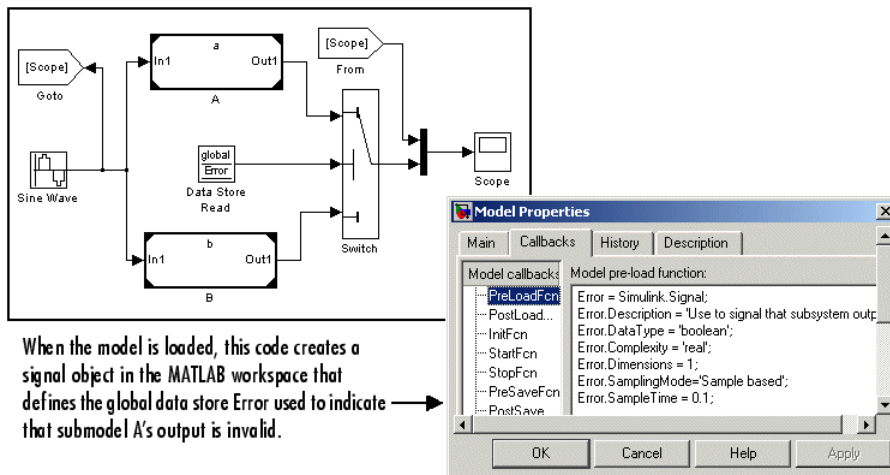

The following model illustrates creation and access of a local data store, which is visible only in a model or particular subsystem.

This model uses a data store to permit subsystem A to signal that its output is invalid. If subsystem A's output is invalid, the model uses the output of subsystem B.

## Global Data Store Example

The following model replaces the subsystems of the previous example with functionally identical referenced models to illustrate use of a global data store to share data in a model reference hierarchy.

In this example, the top model uses a signal object in the MATLAB workspace to define the error data store. This is necessary because data stores are visible across model boundaries only if they are defined by signal objects in the MATLAB workspace.

## Log Data Stores

### In this section...

“Logging Local and Global Data Store Values” on page 58-31

“Supported Data Types, Dimensions, and Complexity for Logging Data Stores” on page 58-31

“Data Store Logging Limitations” on page 58-31

“Logging Data Stores Created with a Data Store Memory Block” on page 58-32

“Logging Icon for the Data Store Memory Block” on page 58-32

“Logging Data Stores Created with a Simulink.Signal Object” on page 58-33

“Accessing Data Store Logging Data” on page 58-33

### Logging Local and Global Data Store Values

You can log the values of a local or global data store data variable for all the steps in a simulation. Two common uses of data store logging are for:

- Model debugging – view the order of all data store writes
- Confirming a model modification – use the logged data to establish a baseline for comparing results for identifying the impact of a model modification

To see an example of logging a global data store, see the `sldemo_mdref_dsm` model.

### Supported Data Types, Dimensions, and Complexity for Logging Data Stores

You can log data stores that use the following data types:

- All built-in data types
- Enumerated data types
- Fixed-point data types

You can log data stores that use any dimension level or complexity.

### Data Store Logging Limitations

Limitations for using data store logging in a model are:

- To log data for a data store memory:
  - Simulate the top-level model in Normal mode.
  - For local data stores, the model containing the Data Store Memory block must be in Model Reference Normal mode.
  - Any block in a referenced model that writes to the data store memory must be executed in model reference Normal mode.
- If you set the **Model Configuration Parameters > Solver > Tasking mode for periodic sample times** parameter to **MultiTasking**, then you cannot log Data Store Memory blocks that use asynchronous sample times or hybrid sample times (that is, sample times resulting from when different data sources for the data store have different sample times).

For details about viewing information about sample times, see “View Sample Time Information” on page 7-9.

- You cannot log data stores that use custom data types.

## Logging Data Stores Created with a Data Store Memory Block

To log a local data store that you create with a Data Store Memory block:

- 1 In the Block Parameters dialog box for the Data Store Memory block that you want to log, select the **Logging** pane.
- 2 Select the **Log signal data** check box.
- 3 Optionally, specify limits for the amount of data logged, using the **Minimum** and **Maximum** parameters.
- 4 Enable data store logging with the **Model Configuration Parameters > Data Import/Export > Data stores** parameter.
- 5 Simulate the model.

## Logging Icon for the Data Store Memory Block

When you enable logging for a model, and you configure a local data store for logging, the Data Store Memory block displays a blue icon. If you do not enable logging for the model, then the icon is gray.

## Logging Data Stores Created with a Simulink.Signal Object

You can create local and global data stores using a `Simulink.Signal` object. See “Data Stores with Signal Objects” on page 58-14 for details.

To log a data store that you create with a `Simulink.Signal` object:

- 1 Create a `Simulink.Signal` object in a workspace that is visible to every component that needs to access the data store, as described in “Data Stores with Signal Objects” on page 58-14.
- 2 Use the name of the `Simulink.Signal` object in the **Data store name** block parameters of the Data Store Read and Data Store Write blocks that you want to write to and read from the data store.
- 3 From the MATLAB command line, set `DataLogging` (which is a property of the `LoggingInfo` property of `Simulink.Signal`) to 1.

For example, if you use a `Simulink.Signal` object called `DataStoreSignalObject` to create a data store, use the following command:

```
DataStoreSignalObject.LoggingInfo.DataLogging = 1
```

- 4 Optionally, specify limits for the amount of data logged, using the following properties, which are properties of the `LoggingInfo` property of the `Simulink.Signal` object: `Decimation`, `LimitDataPoints`, and `MaxPoints`.
- 5 Enable data store logging with the **Model Configuration Parameters > Data Import/Export > Data stores** parameter.
- 6 Simulate the model.

## Accessing Data Store Logging Data

The following Simulink classes represent data from data store logging and provide methods for accessing that data:

| Class  | Description   |
|--|---|
| <code>Simulink.SimulationData.BlockPath</code>       | Represents a fully specified Simulink block path; use for capturing the full model reference hierarchy  |
| <code>Simulink.SimulationData.Dataset</code>         | Stores logged data elements and provides searching capabilities; use to group <code>Simulink.SimulationData.Element</code> objects in a single object |
| <code>Simulink.SimulationData.DataStoreMemory</code> | Stores logging information from a data store during simulation  |

You can also convert data logged in formats other than Dataset. For more information, see “Data Set Conversion for Logged Data” on page 57-15.

### Viewing Data Store Data

To view data store logging data from the command line, view the output data set in the base workspace. The default variable for the data store logging data set is `dsmout`.

The `sldemo_mdref_dsm` model illustrates approaches for viewing data store logging data.

### Accessing Elements in the Data Store Logging Data

To find an element in the data store logging data, based on the `Name` or `BlockType` property, use the `getElement` method of `Simulink.SimulationData.Dataset`. For example:

```
dsmout.getElement('RefSignalVal')

ans =
Simulink.SimulationData.DataStoreMemory
Package: Simulink.SimulationData

Properties:
    Name: 'RefSignalVal'
    Blockpath: [1x1 Simulink.SimulationData.BlockPath]
    Scope: 'local'
    DSMWriterBlockPaths: [1x2 Simulink1.SimulationData.BlockPath]
    DSMWriters: [101x1 uint32]
    Values: 101x1 timeseries]
```

To access an element by index, use the `Simulink.SimulationData.Dataset.getElement` method.

## Order Data Store Access

| In this section...   |
|--|
| “About Data Store Access Order” on page 58-36                  |
| “Ordering Access Using Function Call Subsystems” on page 58-36 |
| “Ordering Access Using Block Priorities” on page 58-40         |

### About Data Store Access Order

To obtain correct results from data stores, you must control the order of execution of the data store’s reads and writes. If a data store’s read occurs before its write, latency is introduced into the algorithm: the read obtains the value that was computed and stored in the previous time step, rather than the value computed and stored in the current time step.

Such latency may cause the system to behave other than as designed, and in some cases may destabilize the system. Even if these problems do not occur, an uncontrolled access order could change from one release of Simulink to the next.

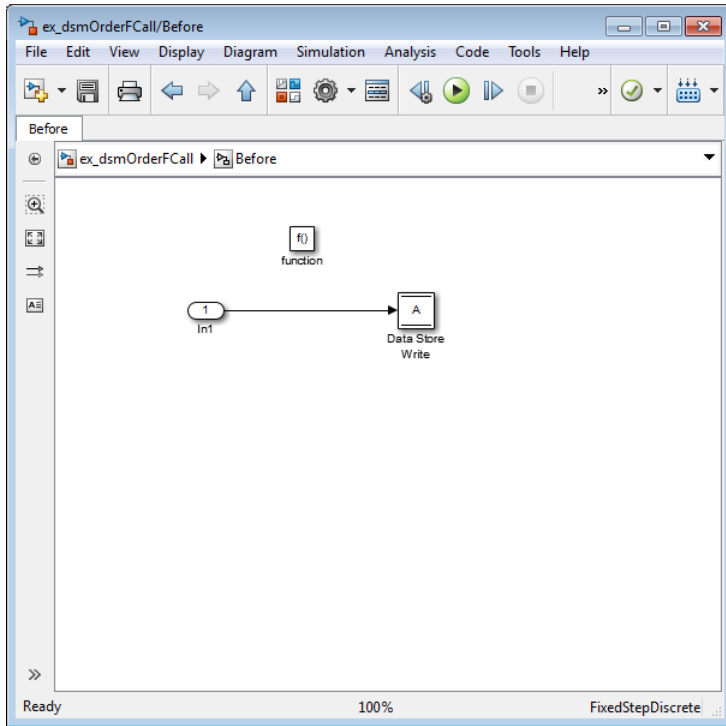

This section describes several strategies for explicitly controlling the order of execution of a data store’s reads and writes. See “Data Store Diagnostics” on page 58-43 for techniques you can use to detect and correct potential data store errors without running simulations.

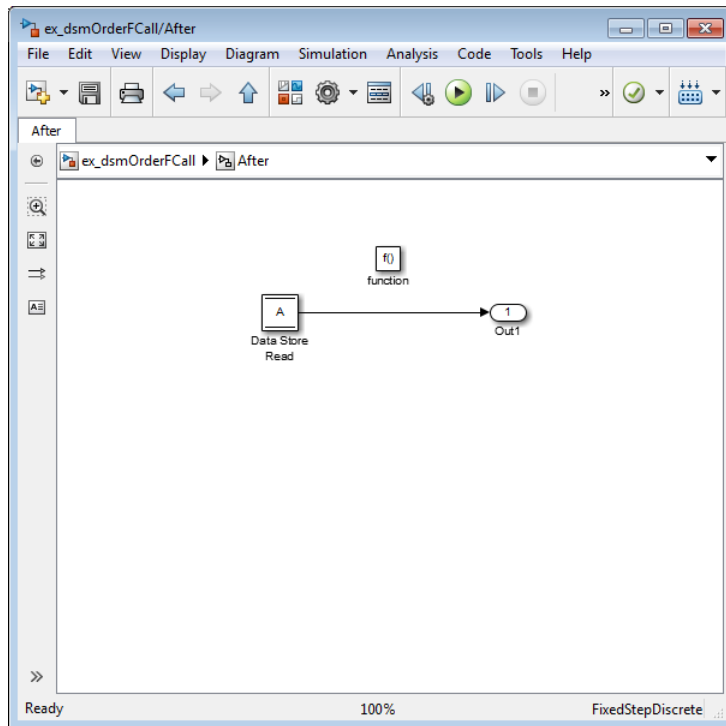

### Ordering Access Using Function Call Subsystems

You can use function call subsystems to control the execution order of model components that access data stores. The next figure shows this technique:

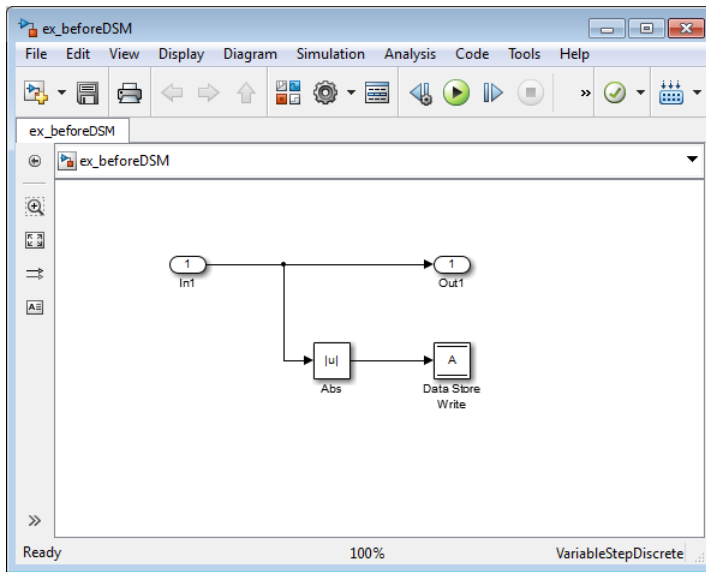

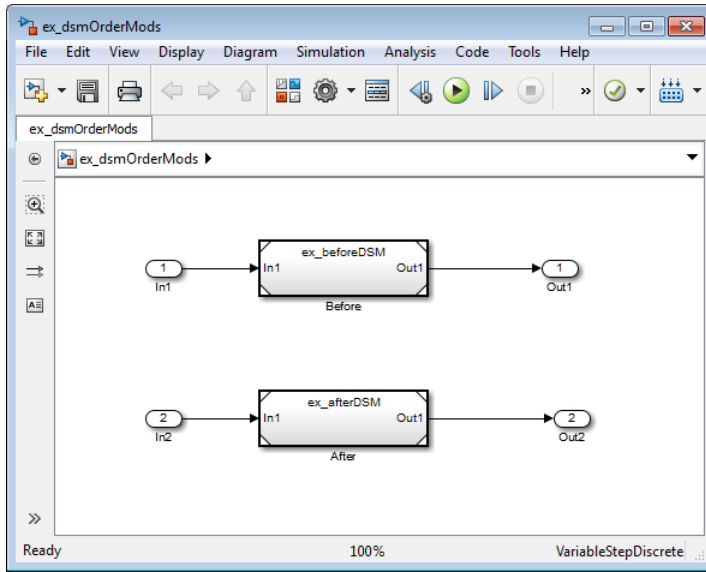

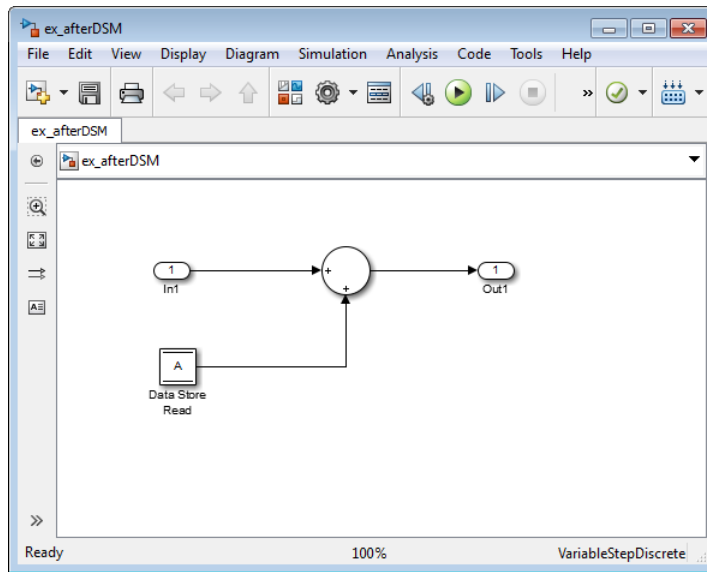

The subsystem **Before** contains the Data Store Write, and the Stateflow chart calls that subsystem before it calls the subsystem **After**, which contains the Data Store Read.

## Ordering Access Using Block Priorities

You can embed data store reads and writes inside atomic subsystems or Model blocks whose priorities specify their relative execution order.

The Model block `beforeDSM` has a lower priority than `afterDSM`, so it is guaranteed to execute first. Since `beforeDSM` is atomic, all of its operations, including the Data Store Write, will execute prior to `afterDSM` and all of its operations, including the Data Store Read.

- “Data Store Diagnostics in the Model Advisor” on page 58-50

### About Data Store Diagnostics

Simulink provides various run-time and compile-time diagnostics that you can use to help avoid problems with data stores. Diagnostics are available in the Model Configuration Parameters dialog box and the Data Store Memory block's parameters dialog box. The Simulink Model Advisor provides support by listing cases where data store errors are more likely because diagnostics are disabled.

### Detecting Access Order Errors

- “Data Store Diagnostics and Models Referenced in Accelerator Mode” on page 58-45
- “Data Store Diagnostics and the MATLAB Function Block” on page 58-46

You can use data store run-time diagnostics to detect unintended sequences of data store reads and writes that occur during simulation. You can apply these diagnostics to all data stores, or allow each Data Store Memory block to set its own value. The diagnostics are:

- Detect read before write:** Detect when a data store is read from before written.
- Detect write after read:** Detect when a data store is written.
- Detect write after write:** Detect when a data store is written.

These diagnostics appear in the **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory Block** pane, where each can have one of the following values:

- **Disable all** — Disables this diagnostic for all data stores accessed by the model.
- **Enable all as warnings** — Displays the diagnostic as a warning in the MATLAB Command Window.
- **Enable all as errors** — Halts the simulation and displays the diagnostic in an error dialog box.
- **Use local settings** — Allow each Data Store Memory block to set its own value for this diagnostic (default).

The same diagnostics also appear in each Data Store Memory block parameters dialog box **Diagnostics** tab. You can set each diagnostic to **none**, **warning**, or **error**. The value specified by an individual block takes effect only if the corresponding configuration parameter is **Use local settings**. See “Diagnostics Pane: Data Validity” and the **Data Store Memory** documentation for more information.

The most conservative technique is to set all data store diagnostics to **Enable all as errors** in **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory Block**. However, this setting is not best in all cases, because it can flag intended behavior as erroneous. For example, the next figure shows a model that uses block priorities to force the Data Store Read block to execute before the Data Store Write block:

An error occurred during simulation because the data store A is read from the Data Store Read block before the Data Store Write block updates the store. If the associated delay is intended, you can suppress the error by setting the global parameter **Detect read before write** to **Use local settings**, then setting that parameter to **none** in the **Diagnostics** pane of the Data Store Memory block dialog box. If you use this technique, set the parameter to **error** in all other Data Store Memory blocks aside from those that are to be intentionally excluded from the diagnostic.

### Data Store Diagnostics and Models Referenced in Accelerator Mode

For models referenced in Accelerator mode, Simulink ignores the following **Configuration Parameters > Diagnostics > Data Validity > Data Store Memory Block** parameters if you set them to a value other than **Disable** **all**.

- **Detect read before write** (ReadBeforeWriteMsg)
- **Detect write after read** (WriteAfterReadMsg)
- **Detect write after write** (WriteAfterWriteMsg)

You can use the Model Advisor to identify models referenced in Accelerator mode for which Simulink ignores the configuration parameters listed above.

- 1 In the Simulink Editor, select **Analysis > Model Advisor**.
- 2 Select **By Task**.
- 3 Run the **Check diagnostic settings ignored during accelerated model reference simulation** check.

## Data Store Diagnostics and the MATLAB Function Block

Diagnostics might be more conservative for data store memory used by MATLAB Function blocks. For example, if you pass arrays of data store memory to MATLAB functions, optimizations such as  $A=f_{OO}(A)$  might result in MATLAB marking the entire contents of the array as read or written, even though only some elements were accessed.

## Detecting Multitasking Access Errors

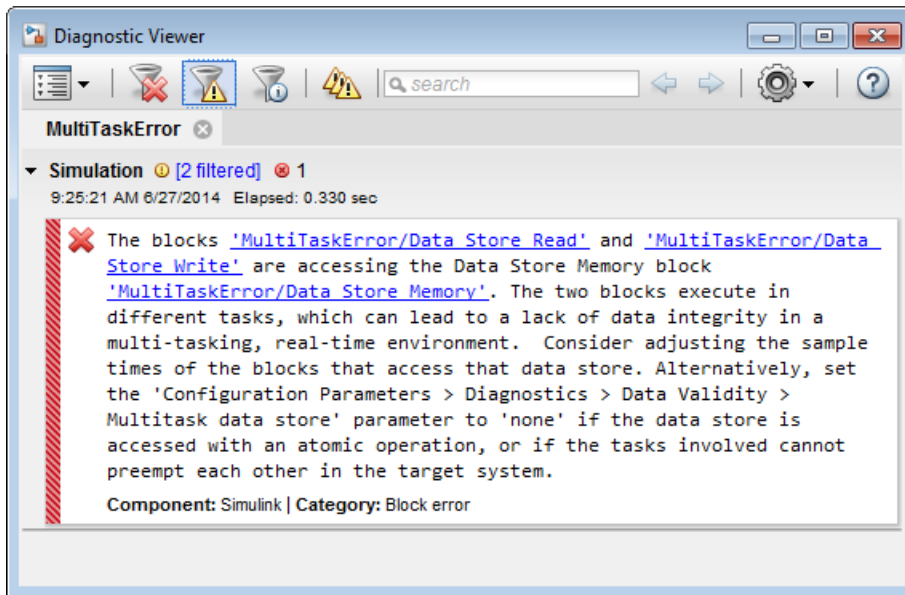

Data integrity may be compromised if a data store is read from in one task and written to in another task. For example, suppose that:

- 1 A task is writing to a data store.
- 2 A second task interrupts the first task.
- 3 The second task reads from that data store.

If the first task had only partly updated the data store when the second task interrupted, the resulting data in the data store is inconsistent. For example, if the value is a vector, some of its elements may have been written in the current time step, while the rest were written in the previous step. If the value is a multi-word, it may be left in an inconsistent state that is not even partly correct.

Unless you are certain that task preemption cannot cause data integrity problems, set the compile-time diagnostic **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory Block > Multitask Data Store** to warning (the default) or error. This diagnostic flags any case of a data store that is read from and written to in different tasks. The next figure illustrates a problem detected by setting **Multitask Data Store** to error:

Since the data store A is written to in the fast task and read from in the slow task, an error is reported, with suggested remedy. This diagnostic is applicable even in the case that a data store read or write is inside of a conditional subsystem. Simulink correctly identifies the task that the block is executing within, and uses that task for the purpose of evaluating the diagnostic.

The next figure shows one solution to the problem shown above: place a rate transition block after the data store read, which previously accessed the data store at the slower rate.

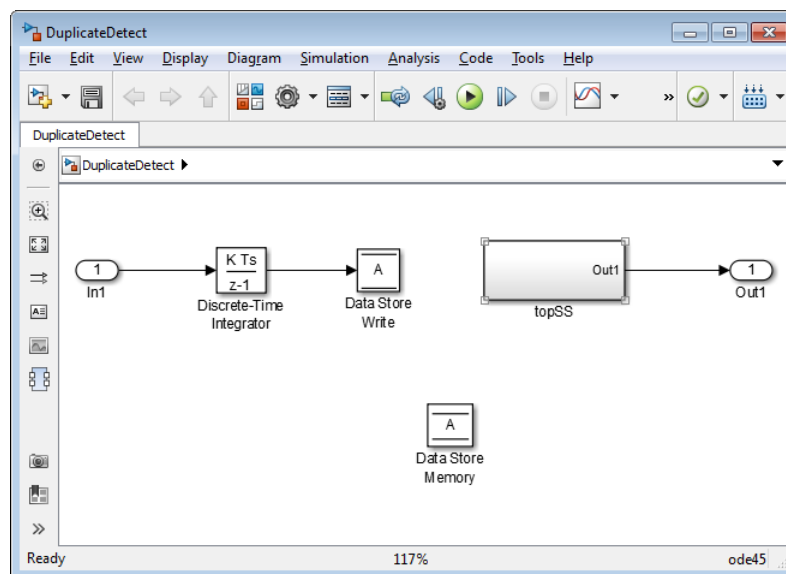

With this change, the data store write can continue to occur at the faster rate. This may be important if that data store must be read at that faster rate elsewhere in the model.

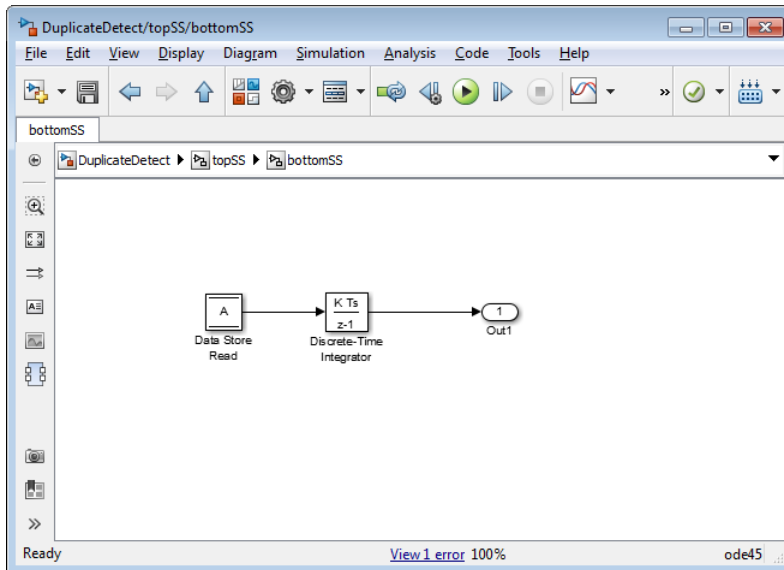

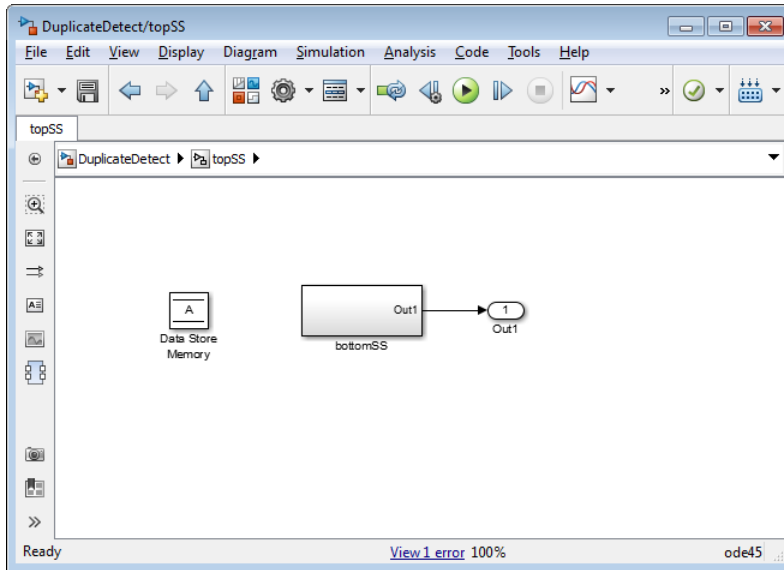

The **Multitask Data Store** diagnostic also applies to data store reads and writes in referenced models. If two different child models execute a data store's reads and writes in differing tasks, the error will be detected when Simulink compiles their common parent model.

## Detecting Duplicate Name Errors

Data store errors can occur due to duplicate uses of a data store name within a model. For instance, data store shadowing occurs when two or more data store memories in different nested scopes have the same data store name. In this situation, the data store memory referenced by a data store read or write block at a low level may not be the intended store.

To prevent errors caused by duplicate data store names, set the compile-time diagnostic **Model Configuration Parameters > Diagnostics > Data Validity > Data Store Memory Block > Duplicate Data Store Names** to warning or error. By default, the value of the diagnostic is **none**, suppressing duplicate name detection. The next figure shows a problem detected by setting **Duplicate Data Store Names** to error:

The data store read at the bottom level of a subsystem hierarchy refers to a data store named A, and two Data Store Memory blocks in the same model have that name, so an error is reported. This diagnostic guards against assuming that the data store read refers to the Data Store Memory block in the top level of the model. The read actually refers to the Data Store Memory block at the intermediate level, which is closer in scope to the Data Store Read block.

## Data Store Diagnostics in the Model Advisor

The Model Advisor provides several diagnostics that you can use with data stores. See these sections for information about Model Advisor diagnostics for data stores:

“Check Data Store Memory blocks for multitasking, strong typing, and shadowing issues”

“Check data store block sample times for modeling errors”

“Check if read/write diagnostics are enabled for data store blocks”

- “Local and Global Data Stores” on page 58-2
- “Data Stores and Software Verification” on page 58-52

## Data Stores and Software Verification

Data stores can have significant effects on software verification, especially in the area of data coupling and control. Models and subsystems that use only inports and outports to pass data result in clean, well-specified, and easily verifiable interfaces in the generated code.

Data stores, like any type of global data, make verification more difficult. If your development process includes software verification, consider planning for the effect of data stores early in the design process.

For more information, see RTCA DO-331, “Model-Based Development and Verification Supplement to DO-178C and DO-278A,” Section MB.6.3.3.b.

## What Is a Data Dictionary?

A data dictionary is a persistent repository of data that are relevant to your model. You can also use the base workspace to store design data that are used by your model during simulation. However, a data dictionary provides more capabilities.

The dictionary stores design data, which define parameters and signals, and include data that define the behavior of the model. The dictionary does not store simulation data, which are inputs or outputs of model simulation.

### In this section...

“Dictionary Capabilities” on page 59-2

“Sections of a Dictionary” on page 59-3

“Import and Export File Formats” on page 59-4

## Dictionary Capabilities

| Dictionary Capability                     | Benefit  |
|---|--|
| Dictionary as data source                 | All entries in a dictionary are persistent. You do not need to reload data during development.   |
| Explicit data-model linkage               | You can define a data dictionary as the data source for a model. During model simulation and code generation, the model retrieves design data from the data dictionary.                                      |
| Change tracking                           | When you modify an entry, its status is updated in the dictionary and stored as metadata that can be tracked. The dictionary also tracks who made the changes and when. You can also view or revert changes. |
| Entry comparison                          | Compare values of entries in two dictionaries.   |
| Data grouping into reference dictionaries | Partition and organize data items into reference dictionaries.   |
| Model-data dependency                     | Discover how entries are used in the model.  |
| Store and partition reference data        | Store and partition data that are relevant to a model, such as equipment specifications, but not used by the model during simulation.  |

| Dictionary Capability               | Benefit   |
|-------------------------------------|---|
| Unified interface for defining data | Use the Model Explorer to work with design data in a dictionary.                |
| Incremental update in memory        | Improved performance and scalability with minimal footprint on memory.          |
| Requirements traceability linking   | Navigate from a data dictionary entry to a location in a requirements document. |

## Sections of a Dictionary

A Simulink data dictionary is made up of three parts called sections.

- 1 **Design Data:** Contains the variables and data types that define parameters, signals, and design data that determine the behavior of the model. Design data created or imported in a dictionary are stored in this section.

This section can store only certain classes and data types. See “Valid Design Data Classes” on page 59-7 for more information.

- 2 **Configurations:** Contains configuration sets, which are objects of the `Simulink.ConfigSet` class, that determine how the model is configured during simulation. These objects control attributes such as sample time and simulation start time.

When you store configuration sets in a data dictionary, you use configuration references to access the configuration sets. Models that are linked to a dictionary resolve configuration references to configuration sets in the dictionary. For more information about configuration references, see “About Configuration References” on page 12-28.

This section can also store variant configuration objects, which belong to the `Simulink.VariantConfigurationData` class. These objects store information about variant configurations, active and default variant settings, and definitions of the control variable associated with each configuration.

- 3 **Other Data:** Contains information that is relevant to your model but not used by the model during simulation. Use this section to store reference information such as data that describe physical equipment and processes that are represented by your model.

This section can store almost any built-in or custom class or data type. See “Invalid Other Data Classes” on page 59-7 for more information.

## Import and Export File Formats

| File Format   | Import to Dictionary | Export from Dictionary |
|---------------|----------------------|------------------------|
| MAT-file      | ✓                    | ✓                      |
| MATLAB script | ✓                    | ✓                      |

## More About

- “Considerations before Migrating to Data Dictionary” on page 59-5

## Considerations before Migrating to Data Dictionary

### In this section...

“Check for Data-Loading Callbacks” on page 59-5

“Check Scripts” on page 59-5

“Check Tunable Parameters” on page 59-6

“Data Shared by Model References” on page 59-6

“Valid Design Data Classes” on page 59-7

“Invalid Other Data Classes” on page 59-7

“Data Dictionary Limitations” on page 59-8

### Check for Data-Loading Callbacks

You can use model callbacks such as the `PreLoadFcn` callback to load design data from a file into the base workspace when a model is loaded. For example, the following callback loads design data from the MAT file `myData.mat`.

```
load myData
```

After you migrate to a data dictionary, these callbacks will continue to load design data into the base workspace. Since the model then derives design data from the dictionary, manually remove or comment out these data-loading callbacks.

You can use the Simulink Manifest Tools to find data-loading callbacks. See “Analyze Model Dependencies” on page 17-19.

### Check Scripts

If you make explicit references to the base workspace by using the handle `base` in your scripts, consider changing these references. When you move any of your data to a data dictionary, the model no longer looks into the base workspace to find design data.

After you migrate design data to a data dictionary, explicit references to the base workspace cannot resolve and errors can occur.

Consider this example. Here, the script searches the base workspace for variable `sensor` and sets the parameter `enable` depending on the value of `sensor.noiseEnable`.

```
if evalin('base','sensor.noiseEnable')
```

```
    enable = 'Enabled';  
else  
    enable = 'Disabled';  
end
```

When you migrate to a data dictionary, replace these explicit references to `base` as follows:

```
if Simulink.data.evalinGlobal(myExampleModel,...  
'sensor.noiseEnable')  
    enable = 'Enabled';  
else  
    enable = 'Disabled';  
end
```

The `Simulink.data.evalinGlobal` function evaluates an expression in the global scope of the specified model. Here, the global scope can be in a data dictionary or the base workspace, if the model is not linked to a dictionary.

## Check Tunable Parameters

- If your model is linked to a data dictionary, Simulink ignores storage class information specified in the tunable parameters table of the model.
- If you use the Simulink interface to migrate a model to use a data dictionary, Simulink also migrates the storage class information of the model. If your model contains storage class information for variables in the base workspace, Simulink converts these variables into `Simulink.Parameter` objects during migration. Then, Simulink sets the storage class of these `Simulink.Parameter` objects using the storage class information from the model.
- If you migrate this model back to the base workspace, Simulink does not restore the storage class information in the model. To preserve the storage class for these variables, use the parameter objects from the data dictionary. You can also manually reset the storage class information in the model.
- If you set the `DataDictionary` property of a model from the command line, convert tunable variables to `Simulink.Parameter` objects using the `tunablevars2parameterobjects` function.

## Data Shared by Model References

When you use model referencing to break a large system of models into smaller components and subcomponents, you can create data dictionaries to segregate the *design*

*data*. Design data is the set of workspace variables that the models use to specify block parameters and signal characteristics.

The models in a model reference hierarchy typically share data. Data ownership, the number of shared variables, and the complexity of your sharing strategy can influence the way that you use dictionaries. For more information, see “Determine Where to Store Data for Simulink Models” on page 55-61.

## Valid Design Data Classes

You can import, store, or create design data objects of the following data classes in the **Design Data** section of a Simulink data dictionary.

- `Simulink.AliasType`
- `Simulink.Bus`
- `Simulink.NumericType`
- `Simulink.Parameter`
- `Simulink.Signal`
- `Simulink.Variant`
- `Simulink.data.dictionary.EnumTypeDefinition`
- `embedded.fi`
- `embedded.fimath`
- `numlti`

In addition, you can import, store, or create configuration objects of the following classes in the **Configurations** section of a Simulink data dictionary.

- `Simulink.ConfigSet`
- `Simulink.VariantConfigurationData`

## Invalid Other Data Classes

You can import, store, or create data objects of many built-in and custom classes or data types in the **Other Data** section of a Simulink data dictionary, except for the following:

- `timeseries`
- Function handles

- `embedded.numericType`
- Classes in the Simulink or MATLAB packages that the Design Data and Configurations sections do not accept
- Sparse matrices
- `Simulink.ConfigSetRef`
- Arrays of objects created from built-in or custom classes
- Custom classes that have a property with any of these names:
  - `LastModified`
  - `LastModifiedBy`
  - `DataSource`
  - `Status`
  - `Variant`

## Data Dictionary Limitations

- Simulink cannot automatically migrate variables used only by inactive variant models into a data dictionary.
- You cannot import certain kinds of design data such as `meta` class objects and `timeseries` objects into the Design Data section of a data dictionary.
- Simulink does not allow **Explicit and Implicit** signal resolution for a model linked to a data dictionary. The **Signal Resolution** parameter of the model is specified in **Model Configuration Parameters > Diagnostics > Data Validity**. To use a data dictionary, set **Signal Resolution** to **Explicit only**.
- The data dictionary does not support models that contain From Workspace blocks. Further, Simulink does not import simulation data such as `timeseries` objects into the Design Data section of a data dictionary. You can migrate such models in one of the following ways.
  - Before migration, replace From Workspace blocks in your model with other source blocks or a combination of source blocks.
  - Migrate the model without replacing From Workspace blocks. After migration, replace the From Workspace blocks.
- If a model reference hierarchy is already linked to a data dictionary, you can protect a referenced model that is part of the hierarchy. However, if you migrate a model reference hierarchy that includes a protected model, simulation will fail.

In other words, migrate a model to use a data dictionary before protecting it.

## Migrate Enumerated Types into Data Dictionary

This example shows how to migrate enumerated types that are used by a model into a data dictionary.

### Import Design Data

- 1 Open a model that uses enumerated types for design data or for blocks in the model.
- 2 In the Simulink Editor, click **File > Model Properties > Link to Data Dictionary**.
- 3 In the **Model Properties** dialog box, set **Defined in** to **Data Dictionary** and click **New** to create a data dictionary.

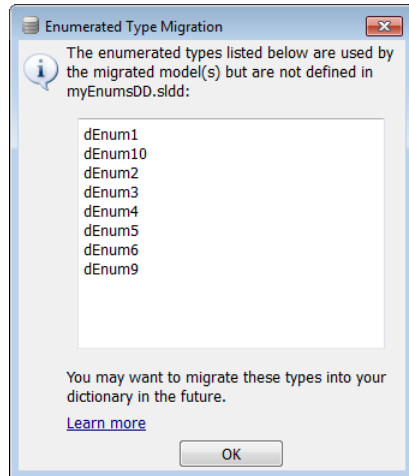

- 4 Name the data dictionary, save it, and click **Apply**.
- 5 Click **Add path**, if you see the message to add the dictionary location to the MATLAB path.
- 6 Click **Yes** in response to the message that explains how Simulink migrates design data stored in the base workspace.

A message appears, reporting the number of items imported from the base workspace to the data dictionary.

- 7 Simulink reports the enumerated types that were not imported into the data dictionary.

- 8 Click **OK**.

A notification appears in the Simulink Editor, reporting that your model is now linked to the data dictionary.

### Import Enumerated Types

Import the definitions of enumerated types only after you import all the design data that were creating using the types. When you import enumerated types to a data dictionary, Simulink disables MATLAB files or P-files that contain the type definitions, causing variables that remain in the MATLAB base workspace to lose their definitions.

- 1 At the MATLAB command prompt, get the names of enumerated types that are used in model blocks.

```
% Find all variables and enumerated types used in model blocks
usedTypesVars = Simulink.findVars('EnumsReporting', 'IncludeEnumTypes', true);
% Here, EnumsReporting is the name of the model and
% usedTypesVars is an array of Simulink.VariableUsage objects

% Find indices of enumerated types that are defined by MATLAB files or P-files
```

```

enumTypesFile = strcmp({usedTypesVars.SourceType}, 'MATLAB file');

% Find indices of enumerated types that are defined using the function
% Simulink.defineIntEnumType
enumTypesDynamic = strcmp({usedTypesVars.SourceType}, 'dynamic class');

% In one array, represent indices of both kinds of enumerated types
enumTypesIndex = enumTypesFile | enumTypesDynamic;

% Use logical indexing to return the names of used enumerated types
enumTypeNames = {usedTypesVars(enumTypesIndex).Name}

enumTypeNames =

    'dEnum1'
    'dEnum10'
    'dEnum2'
    'dEnum3'
    'dEnum4'
    'dEnum5'
    'dEnum6'
    'dEnum9'

```

- 2 Open the data dictionary, and represent it with a `Simulink.data.Dictionary` object.

```

ddConnection = Simulink.data.dictionary.open('myEnumsDD.sldd')

ddConnection =

    Dictionary with properties:

        DataSources: {0x1 cell}
        HasUnsavedChanges: 0
        NumberOfEntries: 3

```

- 3 Import the enumerated types that are used by blocks in the model.

```

[successfulMigrations, unsuccessfulMigrations] = ...
importEnumTypes(ddConnection, enumTypeNames)

successfulMigrations =

    1x6 struct array with fields:

        className
        renamedFiles

```

```
unsuccessfulMigrations =  
  
1x2 struct array with fields:  
  
    className  
    reasons
```

When enumerated types are imported, `importEnumTypes` renames the enumerated class definition file by appending `.save` to the file name. For example, if the original enumerated class definition is named `Enum1.m`, Simulink renamed the file as `Enum1.m.save`.

The structure `unsuccessfulMigrations` reports enumerated types that are not be migrated. In this example, two enumerated type instances are defined in the model workspace and can be imported after closing the model. Close the model to import these enumerated types.

- 4 Open the dictionary to view the migrated enumerated types.

## Related Examples

## More About

- “Simulink Enumerations” on page 56-2
- “Enumerations in Data Dictionary” on page 59-15

## Enumerations in Data Dictionary

These examples show how to operate on existing enumerations in a data dictionary.

| In this section...  |
|---|
| “Rename Enumerated Type Definition” on page 59-15             |
| “Rename Enumeration Members” on page 59-15                    |
| “Delete Enumeration Members” on page 59-15                    |
| “Change Underlying Value of Enumeration Member” on page 59-16 |

### Rename Enumerated Type Definition

- 1 In the data dictionary, create a copy of the enumerated type, and rename the copy instead.
- 2 Find enumeration objects used by your model that are derived from the type with the old name.
- 3 Replace these objects with those derived from the renamed type.
- 4 Delete the type with the old name.

### Rename Enumeration Members

Use one of the following approaches.

- Select the enumeration within the dictionary, and rename one or more enumeration members.
- If your model references enumeration members as strings, change these strings to match the renamed member.

### Delete Enumeration Members

- 1 Find references in your model to an enumeration member you want to delete.
- 2 Replace these references with an alternate member.
- 3 Delete the original member from the enumeration.

## Change Underlying Value of Enumeration Member

You can change the values of enumeration members when you represent these values as MATLAB variables or by using Value field of `Simulink.Parameter` objects.

- 1 Find references in your model to an enumeration member whose value you want to change.
- 2 Make a note of these references.
- 3 Change the value of the enumeration member.
- 4 Manually update references to the enumeration member in your model.

### More About

- “Simulink Enumerations” on page 56-2

## Migrate Single Model to Use Dictionary

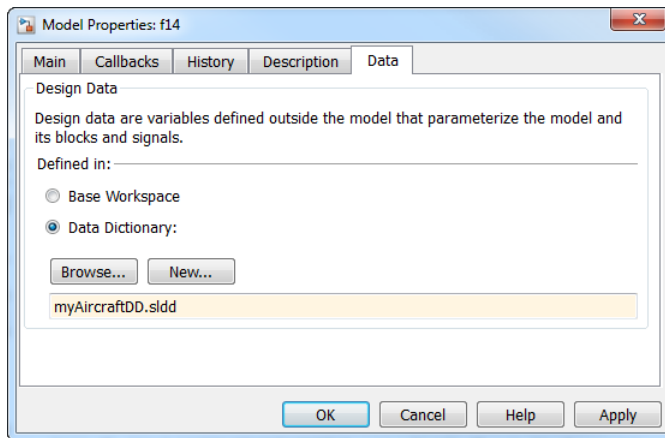

This example shows how to link a model to a data dictionary and import model design data from the base workspace into the data dictionary.

---

**Note:** Simulink does not import simulation data such as Timeseries objects into the data dictionary.

---

- 1 Open the f14 model, which loads design data into the base workspace.
- 2 In the Simulink Editor, click **File > Model Properties > Link to Data Dictionary**.
- 3 In the **Model Properties** dialog box, set **Defined in** to **Data Dictionary** and click **New** to create a data dictionary.

- 4 Name the data dictionary, save it, and click **Apply**.
- 5 Click **Add path**, if you see the message to add the dictionary location to the MATLAB path.
- 6 Click **Yes** in response to the message that explains how Simulink migrates design data stored in the base workspace.

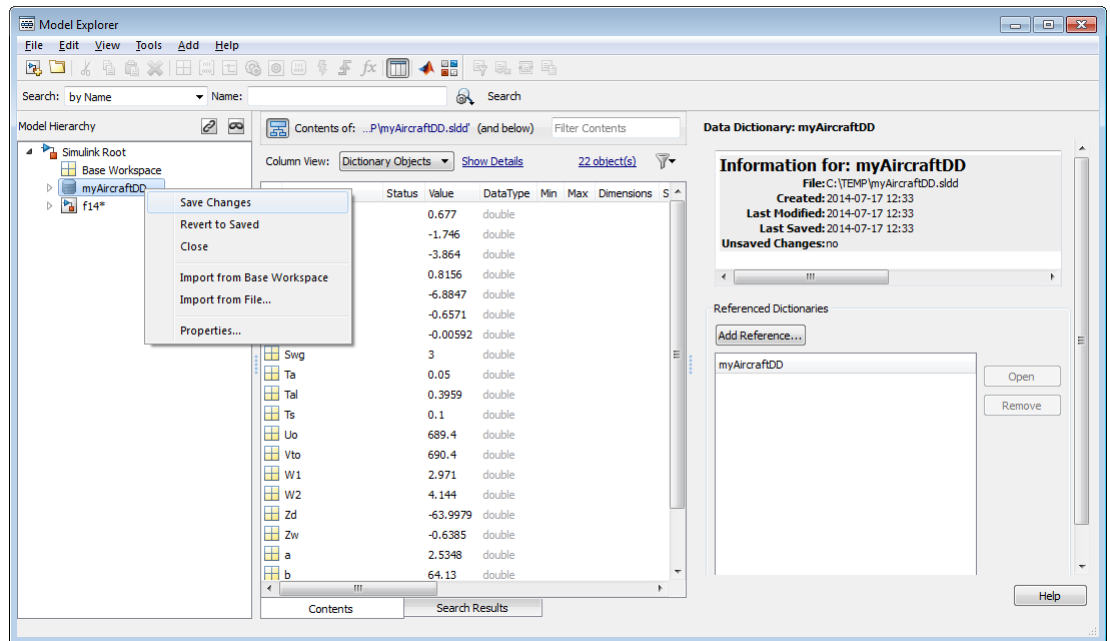

A message appears, reporting the number of items imported from the base workspace to the data dictionary.

- 7 Click **OK** in the **Model Properties** dialog box.

A notification appears in the Simulink Editor, reporting that your model is now linked to the data dictionary.

- 8 In the Simulink Editor, click the data dictionary badge  in the bottom left corner to open the dictionary.
- 9 Right-click the dictionary node and select **Save Changes**.

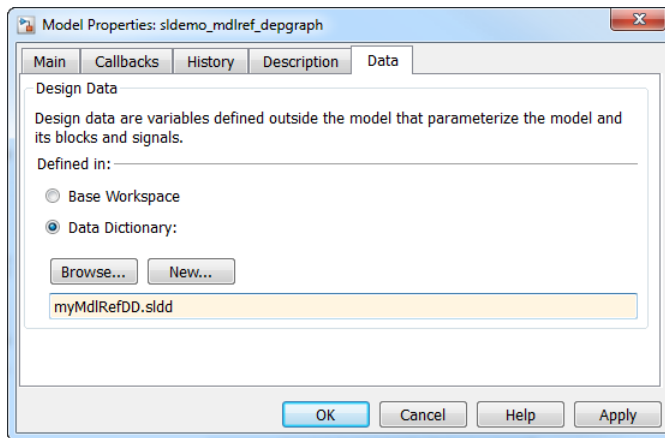

## Related Examples

- “Import Data to Dictionary from File” on page 59-22
- “View and Revert Changes to Dictionary Entries” on page 59-29
- “Migrate Model Reference Hierarchy to Use Dictionary” on page 59-20
- “Programmatically Migrate Single Model to Use Dictionary” on page 59-55

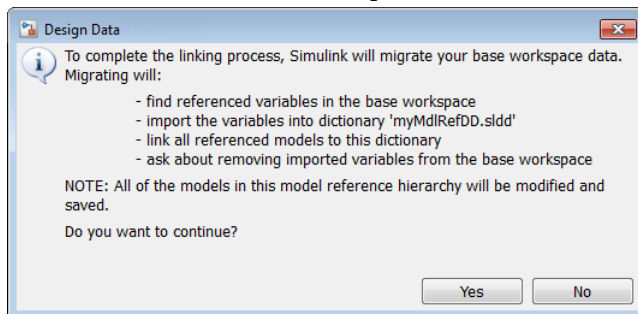

## Migrate Model Reference Hierarchy to Use Dictionary

This example shows how to link a parent model and all its referenced models to a single data dictionary.

- 1 Open the top model containing the model reference hierarchy.
- 2 In the Simulink Editor, click **File > Model Properties > Link to Data Dictionary**.
- 3 In the **Model Properties** dialog box, set **Defined in** to **Data Dictionary** and click **New** to create a data dictionary.

- 4 Name the data dictionary, save it, and click **Apply**.
- 5 Click **Yes** in response to the message that explains how Simulink migrates design data stored in the base workspace.

A message appears, reporting the number of items imported to the data dictionary.

## **Related Examples**

- “View and Revert Changes to Dictionary Entries” on page 59-29

## Import Data to Dictionary from File

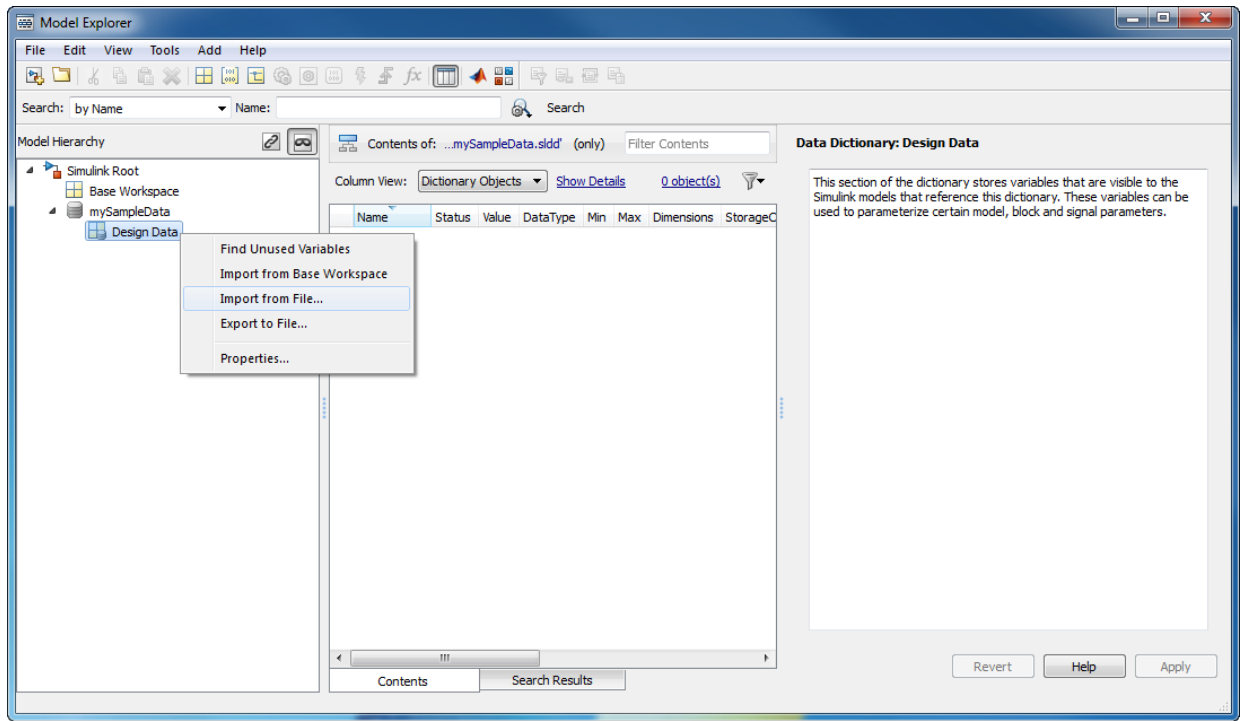

You can import data from a MATLAB file or MAT-file to a data dictionary using the Model Explorer window. Import variables and data objects that are used by a model during simulation to the Design Data section of a dictionary. Import variables and objects that you want to store with a model, but that are not used by the model during simulation, to the Other Data section of a dictionary.

### Import Design Data from File

This example shows how to import design data from a file into the Design Data section of a dictionary.

- 1 In the Simulink Editor, select **View > Model Explorer** to open the Model Explorer.
- 2 Click **File > Open**. Then browse to an existing dictionary.
- 3 In the **Model Hierarchy** pane, right-click the **Design Data** section of the dictionary and select **Import from File**. Then browse to and select the MAT-file or MATLAB file that contains the data to import.

Design data from the MAT-file populate the dictionary. Data appear with **DataSource** set to the name of the dictionary.

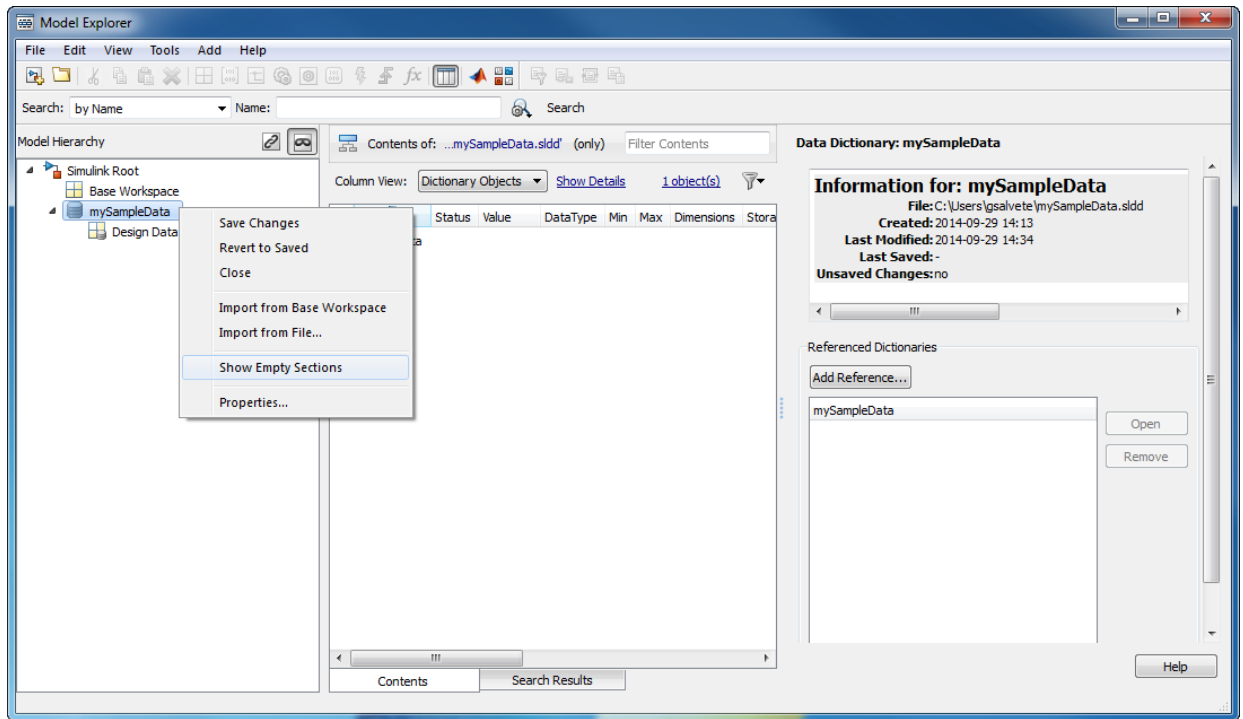

If you import from the same MAT-file again, Simulink only imports changed or new entries into the dictionary.

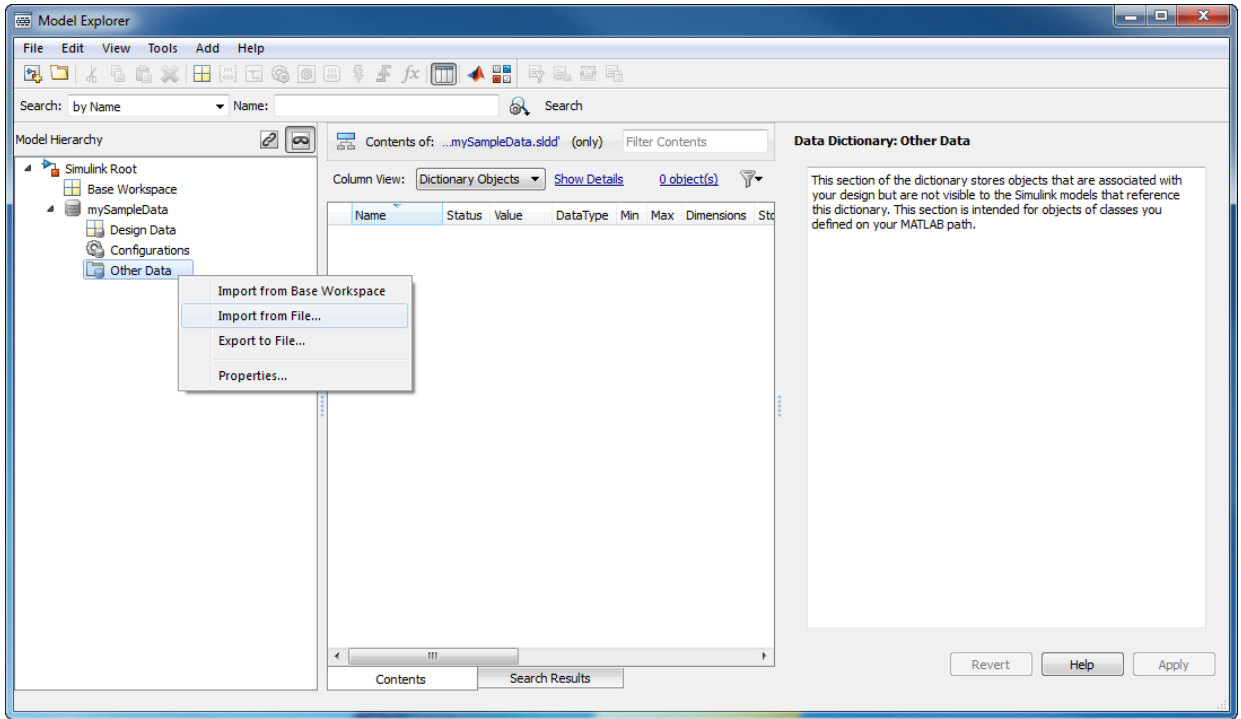

## Import Other Data from File

This example shows how to import data from a file into the Other Data section of a data dictionary. Use this section to store reference information that is not used by Simulink during simulation, such as data that describe physical equipment and processes that are represented by your model.

- 1 In the Simulink Editor, select **View > Model Explorer** to open the Model Explorer.
- 2 Click **File > Open**. Then browse to an existing dictionary.
- 3 In the **Model Hierarchy** pane, right-click the dictionary node and select **Show Empty Sections**. Model Explorer reveals the **Other Data** and **Configurations** sections of the dictionary, even if they are empty, in addition to the **Design Data** section.

- 4 In the **Model Hierarchy** pane, right-click the **Other Data** section of the dictionary and select **Import from File**. Then browse to and select the MAT-file or MATLAB file that contains the reference data to import.

Data from the MAT-file populate the Other Data section of the dictionary. Data appear with **DataSource** set to the name of the dictionary.

If you import from the same MAT-file again, Simulink only imports changed or new entries into the dictionary.

## Export Design Data from Dictionary

This example shows how to export model design data from a data dictionary into a MAT-file or MATLAB script.

- 1 In the Simulink Editor, select **View > Model Explorer** to open the Model Explorer.
- 2 Open a data dictionary using **File > Open Data Dictionary**.
- 3 In the **Model Hierarchy** pane, expand the dictionary node and select **Design Data > Export to File**. Then save the design data to a MAT-file or MATLAB script.

## View and Revert Changes to Dictionary Entries

This example shows how to view unsaved changes to dictionary entries, who made them, and when. You can view changes to entries in any section, including data stored in the Other Data section and configuration sets stored in the Configurations section.

- 1 Open the `sldemo_fuelsys_dd_controller` model.
- 2 Open the data dictionary linked to this model by clicking the data dictionary badge  in the bottom left corner of each model.
- 3 In the **Contents** pane, change `st_range` to `0.0002` and `zero_thresh` to `200`.

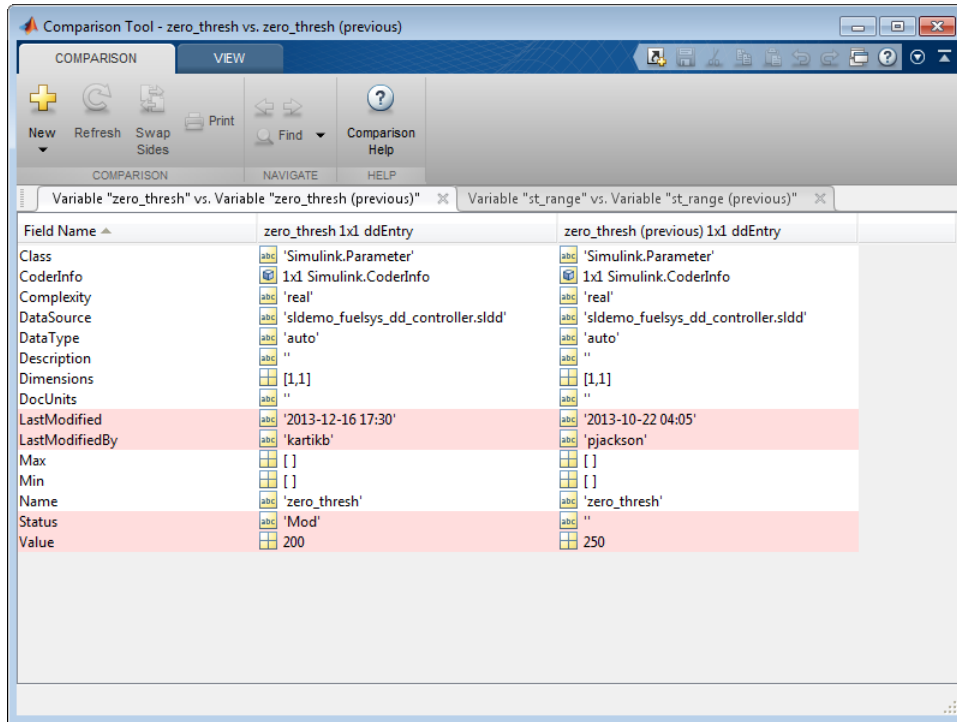

The **Status** column of these entries changes to **MOD**, indicating that they have been modified.

- 4 Click the heading of the **Status** column to sort the entries. Then, select the modified entries, which are indicated by the **MOD** status.

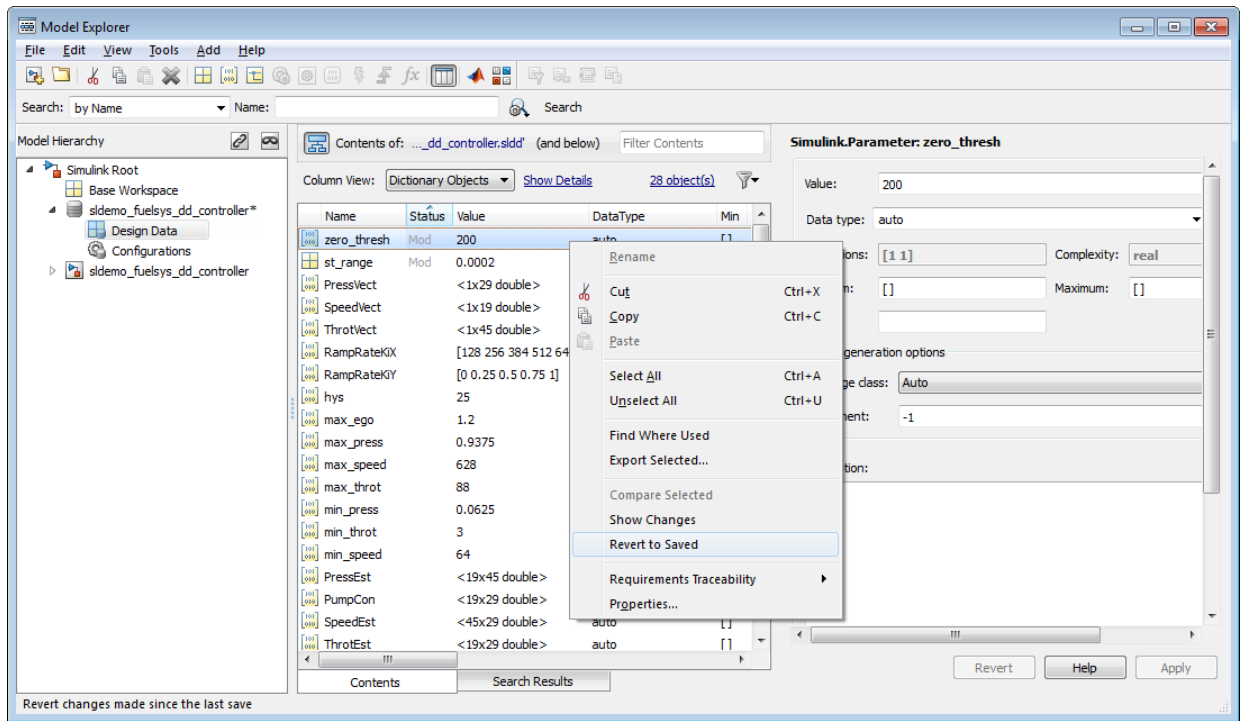

- 5 Right-click and select **Show Changes**.

The Comparison Tool appears, displaying changed entries in separate tabs. The tool highlights changed values.

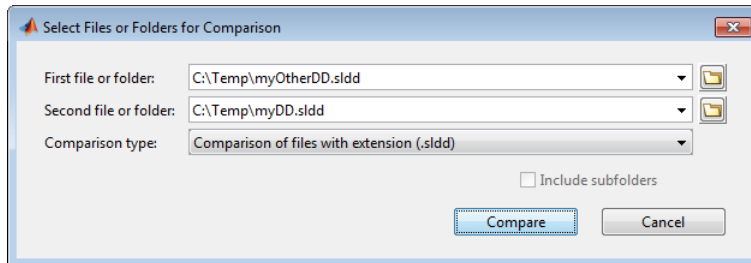

- 6 In the **Contents** pane of the Model Explorer, right-click `zero_thresh` and select **Revert to Saved**.

Simulink reverts `zero_thresh` to its value at the time of the last save action.

- 7 You can merge entries between dictionaries using the Comparison Tool. From the MATLAB desktop, on the **Home** tab, in the **File** section, click **Compare**.
- 8 Select the dictionaries to compare and merge.

- 9 In the comparison report, select the merge direction for each dictionary entry.

## View and Revert Changes to Entire Dictionary

If you store model variables in a data dictionary, you can view and manage the changes that you make while you work. You can use the Comparison Tool to see the changes made to a dictionary, which compares the modified dictionary with the most recent saved version.

When you view the changes to a dictionary, you can choose to discard changes to individual entries or dictionary references, which reverts to the last saved state. You can use this technique to recover entries that you delete in your modified version or dictionary references that you remove.

If you view changes to a dictionary that references other dictionaries, the Comparison Tool also reports changes made to the entries in the referenced dictionaries.

- 1 View the example data dictionary `sldemo_fuelsys_dd` in Model Explorer.

```
dictionary = Simulink.data.dictionary.open('sldemo_fuelsys_dd.sldd');
show(dictionary)
```

The dictionary contains entries that are defined in several referenced dictionaries, including `sldemo_fuelsys_dd_controller` and `sldemo_fuelsys_dd_plant`.

- 2 Run the script `ex_dictionary_changes`, which makes changes to `sldemo_fuelsys_dd`. Later, you can use the Comparison Tool to investigate the changes.
- 3 In the **Model Hierarchy** pane of Model Explorer, right-click the node `sldemo_fuelsys_dd` and select **Show Changes**.

The Comparison Tool displays the changes made to the dictionary.

sldemo\_fuelsys\_dd.sldd

### Show Changes in Dictionary - sldemo\_fuelsys\_dd.sldd

| <a href="#">min_throt</a> | Design Data | sldemo_fuelsys_dd_controller.sldd | Simulink Parameter | <a href="#">min_throt</a> | Design Data | sldemo_fuelsys_dd_controller.sldd | Simulink Parameter | modified ( <a href="#">compare</a> ) | 2015-03-11 09:05 | <a href="#">Revert to Saved</a>    |

| Dictionary references in sldemo_fuelsys_dd.sldd |      |                 |                                   |
|---|------|-----------------|-----------------------------------|
| Saved References                                |      | Unsaved Changes |                                   |
| Name  | Name | Change Summary  | Action (no undo)                  |
| sldemo_fuelsys_dd_plant.sldd                    |      | removed         | <a href="#">Recover Reference</a> |

- 4 In the table at the top of the report, click **compare** in the Change Summary column of the row that corresponds to the entry `min_throt`.

A new tab shows the changes made to `min_throt`. The script changed the parameter data type from `auto` to `int8` and the parameter value from 3 to 4.

- 5 Click the tab that shows the changes made to the dictionary. In the Action column of the row that corresponds to the entry `min_throt`, click **Revert to Saved**.

The entry reverts to the definition from the last saved version of the dictionary.

- 6 The remaining row in the report shows that the script deleted the entry `PressVect`, which was defined in the referenced dictionary `sldemo_fuelsys_dd_controller`. Click **Recover from Saved**, which recovers the entry in the referenced dictionary.
- 7 The table **Dictionary references in sldemo\_fuelsys\_dd.sldd** shows that the script removed the reference to the dictionary `sldemo_fuelsys_dd_plant`. In the Action column, click **Recover Reference**.

The report shows that there are no more unsaved changes to `sldemo_fuelsys_dd`.

## More About

- “What Is a Data Dictionary?” on page 59-2

## Partition Data Dictionary

This example shows how to partition a data dictionary into reference dictionaries that can be shared in a team.

### Open dictionary for partitioning

- 1 Open the Model Explorer. In the Simulink Editor, select **View > Model Explorer**.
- 2 Click **File > Open**.

Browse and locate your dictionary.

### Create reference dictionary

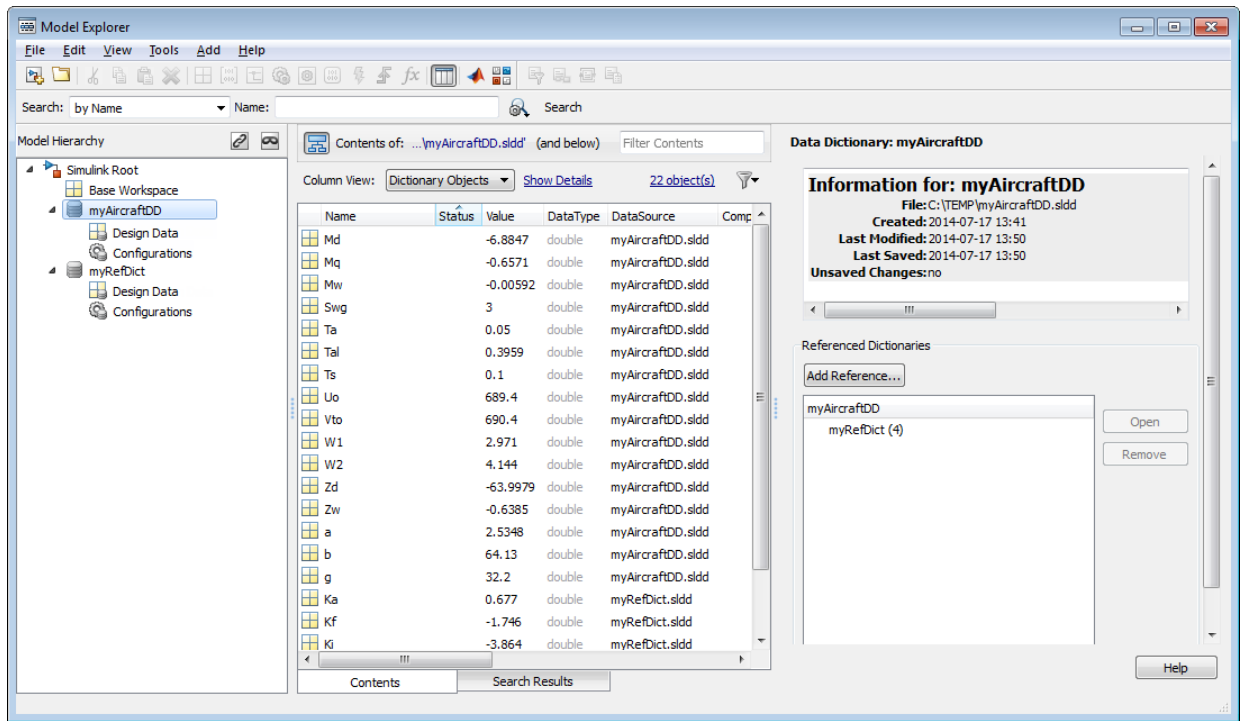

Use a reference dictionary to store a subset of entries from the main dictionary.

- 1 Click **File > New > Data Dictionary**.

Name the reference dictionary and save it.

Both dictionaries appear as nodes in the **Model Hierarchy** pane.

- 2 In the **Model Hierarchy** pane, select the dictionary that serves as the parent.
- 3 In the dialog box pane, click **Add Reference** in the **Referenced Dictionaries** section. Browse to the location of the reference dictionary and add it as a reference.

### Move entries into reference dictionary

- 1 In the **Model Hierarchy** pane, select **Design Data** node of the parent dictionary.
- 2 In the **Contents** pane, select the entries you want to move to the reference dictionary.
- 3 For one of the selected entries, set **DataSource** to the reference dictionary using the dropdown menu. You can also drag and drop entries between dictionaries.

## Partition Data for Model Reference Hierarchy Using Data Dictionaries

When you use model referencing to break a large system of models into smaller components and subcomponents, you can create data dictionaries to segregate the *design data*. Design data is the set of workspace variables that the models use to specify block parameters and signal characteristics. For basic information about data dictionaries, see “What Is a Data Dictionary?” on page 59-2.

You can migrate all of the models in a model reference hierarchy to use one or more data dictionaries using either of these techniques:

- Migrate all of the models in the hierarchy at once to use a single dictionary. Then, create separate referenced dictionaries to organize the design data.
- Incrementally migrate by beginning with the models at the bottom of the hierarchy. Use this technique if you cannot migrate all of the models at once.

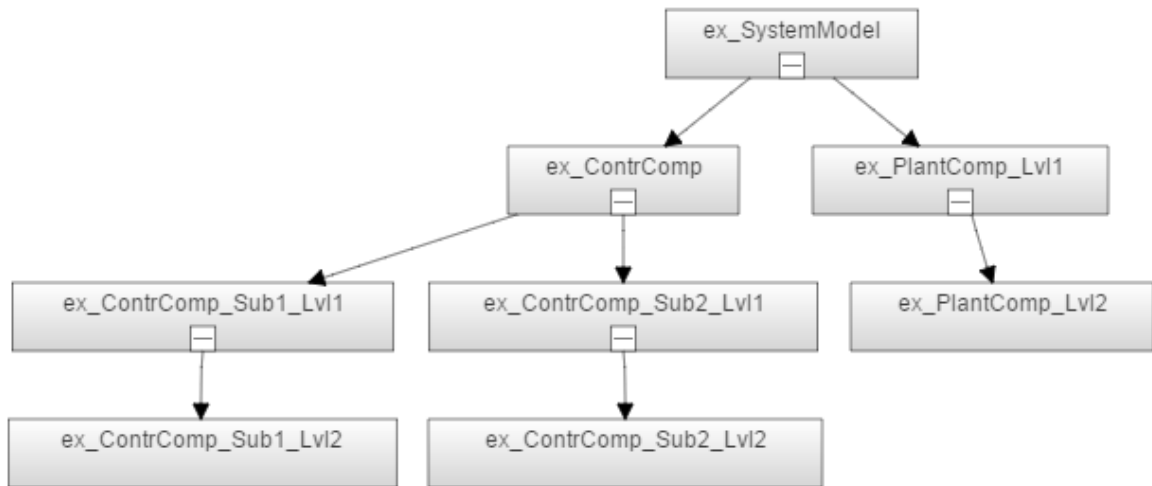

### Create a Dictionary for Each Component

This example shows how to partition design data into dictionaries. When you finish, each component and subcomponent in the system has a dictionary, and dictionary references allow the components and subcomponents to share data.

#### Explore Example Model Hierarchy

- 1 Navigate to the folder `matlabroot/help/toolbox/simulink/examples` (open).
- 2 Copy these files to a writable folder:
  - `ProjectData.mat`
  - `ex_SystemModel`
  - `ex_PlantComp_Lv11`
  - `ex_PlantComp_Lv12`
  - `ex_ContrComp`
  - `ex_ContrComp_Sub1_Lv11`
  - `ex_ContrComp_Sub1_Lv12`
  - `ex_ContrComp_Sub2_Lv11`

- `ex_ContrComp_Sub2_Lvl2`
- 3 Load the MAT-file `ProjectData.mat` to create design data in the base workspace.
  - 4 Open the example model `ex_SystemModel`. This model is at the top of a reference hierarchy that includes the other example models.
  - 5 Select **Analysis > Model Dependencies > Model Dependency Viewer > Models Only**. The model reference hierarchy contains a system model, a plant component with two models, and a controller component. The controller component contains two subcomponents, each of which consist of two models.

- 6 In the model, update the diagram. The signals in the model use the `Simulink.Bus` objects `SensorBus` and `CtrlBus` in the base workspace.

The referenced models `ex_PlantComp_Lvl1` and `ex_ContrComp` also use the bus objects. Therefore, the plant and controller components share the objects.

- 7 In the MATLAB base workspace, double-click the bus object `SensorBus` to view it in the Bus Editor. The data type of each signal element is set to `FloatType`, which is a `Simulink.NumericType` object in the base workspace.

All of the models in the hierarchy use `FloatType` to control the data types of signals and parameters.

- 8 In the Model Explorer **Model Hierarchy** pane, expand the node `ex_SystemModel`.

The node Reference to SimConfigSet appears. SimConfigSet is a Simulink.ConfigSet object in the base workspace. All of the models in the hierarchy use references to SimConfigSet to maintain configuration parameter uniformity for simulation.

- 9 Right-click the node Controller (ex\_ContrComp) and select **Open**. In the Model Explorer **Model Hierarchy** pane, expand the new node ex\_ContrComp.

The nodes Reference to SimConfigSet and Reference to CodeGenConfigSet appear. CodeGenConfigSet is a Simulink.ConfigSet object in the base workspace. All of the models in the controller component use references to CodeGenConfigSet to maintain configuration parameter uniformity for code generation. The models in the plant component do not use CodeGenConfigSet.

- 10 In the **Model Hierarchy** pane, select **Base Workspace**. In the **Contents** pane, right-click the variable diff and select **Find Where Used**. In the **Select a system** dialog box, select ex\_SystemModel and click **OK**. If you see a message about updating the diagram, click **OK**.

In the **Contents** pane, the variable diff is used by Constant blocks in the models ex\_ContrComp\_Sub1\_Lvl1 and ex\_ContrComp\_Sub1\_Lvl2, which make up the first controller subcomponent. Similarly, other models in the hierarchy share the base workspace variables coeff, init, and mu.

The table shows the models that share each variable in the base workspace.

| Variable Name    | Models Using the Variable              | Scope of Sharing                   |
|------------------|--|------------------------------------|
| SimConfigSet     | All models in the hierarchy            | Shared globally by entire system   |
| FloatType        | All models in the hierarchy            | Shared globally by entire system   |
| CtrlBus          | All models in the hierarchy            | Shared globally by entire system   |
| SensorBus        | All models in the hierarchy            | Shared globally by entire system   |
| CodeGenConfigSet | All models in the controller component | Shared by controller subcomponents |

| Variable Name | Models Using the Variable                               | Scope of Sharing                                       |
|---------------|---|--|
| init          | ex_ContrComp_Sub1_Lv11<br>and<br>ex_ContrComp_Sub2_Lv11 | Shared by controller subcomponents                     |
| diff          | ex_ContrComp_Sub1_Lv11<br>and<br>ex_ContrComp_Sub1_Lv12 | Shared by models in the first controller subcomponent  |
| coeff         | ex_ContrComp_Sub2_Lv11<br>and<br>ex_ContrComp_Sub2_Lv12 | Shared by models in the second controller subcomponent |
| mu            | ex_PlantComp_Lv11 and<br>ex_PlantComp_Lv12              | Shared by models in plant component                    |

Suppose that three teams of developers maintain the plant component and the two controller subcomponents. You can use data dictionaries to store and scope the shared design data.

### Create System Dictionary

- 1 In the model `ex_SystemModel`, select **File > Model Properties > Link to Data Dictionary**.
- 2 In the dialog box, under **Defined in**, select **Data Dictionary**. Click **New**.
- 3 Set the new dictionary name to **System** and click **Save**.
- 4 In the **Model Properties** dialog box, click **OK**.
- 5 Click **Yes** in response to the message about migrating workspace data.
- 6 Click **Yes** in response to the message about removing imported items from the base workspace.
- 7 Save the model.

You can simulate and generate code from the models in the hierarchy. All of the models in the hierarchy are linked to the dictionary. All of the variables in the base workspace now reside in the new dictionary `System.slidd`.

### Create Dictionary for Plant Component

- 1 Open the model `ex_PlantComp_Lv11`.
- 2 Select **File > Model Properties > Link to Data Dictionary**.

- 3 In the dialog box, under **Defined in**, click **New**.
- 4 Set the new dictionary name to **Plant** and click **Save**.
- 5 In the **Model Properties** dialog box, click **OK**.
- 6 In response to the message, click **Move Data**.
- 7 Click **Yes** in response to the message about migrating data.
- 8 Save the model.

The models in the plant component, `ex_PlantComp_Lv11` and `ex_PlantComp_Lv12`, are linked to the new dictionary `Plant.sldd`. The other models in the hierarchy remain linked to `System.sldd`. Because the model `ex_PlantComp_Lv11` uses globally shared variables such as `CtrlBus` and `FloatType`, the migration process moves the variables to `Plant.sldd`. However, `System.sldd` references `Plant.sldd`, so all of the models in the hierarchy can continue to use the globally shared variables.

The variable that the plant models share, `mu`, also resides in `Plant.sldd`. Other variables such as `init` and `diff` remain in `System.sldd`.

The plant component can stand alone from the rest of the system because all of its data is in `Plant.sldd`. However, the controller component depends on the shared data that is also defined in `Plant.sldd`.

### **Create Dictionary for Controller Component**

Open the model `ex_ContrComp`, which is the top model in the controller component. Link this model to a new dictionary named `Contr.sldd`. Then, save the model.

When you finish, the five models in the controller component are linked to `Contr.sldd`. Because the globally shared variables such as `CtrlBus` and `FloatType` still reside in the dictionary `Plant.sldd`, the dictionary `Contr.sldd` references `Plant.sldd`. Due to this reference, the models in the controller component can continue to use the globally shared variables.

The variables that the controller models share, such as `diff`, `init`, and `CodeGenConfigSet`, now reside in `Contr.sldd`.

### **Create Dictionary for First Controller Subcomponent**

Open the model `ex_ContrComp_Sub1_Lv11`. Link this model to a new dictionary named `ContrSub1.sldd`. Then, save the model.

When you finish, the models in the first controller subcomponent, `ex_ContrComp_Sub1_Lv11` and `ex_ContrComp_Sub1_Lv12`, are linked to `ContrSub1.sldd`. The models in the second subcomponent remain linked to the dictionary `Contr.sldd`.

### Create Dictionary for Second Controller Subcomponent

Open the model `ex_ContrComp_Sub2_Lv11`. Link this model to a new dictionary named `ContrSub2.sldd`. Then, save the model.

The controller dictionary `Contr.sldd` references the subcomponent dictionaries, `ContrSub1.sldd` and `ContrSub2.sldd`. Therefore, the controller dictionary can use all of the data defined in the subcomponent dictionaries.

The first subcomponent dictionary, `ContrSub1.sldd`, defines data that the subcomponents share, such as `CodeGenConfigSet`. The second subcomponent dictionary, `ContrSub2.sldd`, references `ContrSub1.sldd` so that the second subcomponent can use this shared data.

The subcomponent dictionaries `ContrSub1.sldd` and `ContrSub2.sldd` reference `Plant.sldd`. Therefore, all of the models in the hierarchy can continue to use globally shared variables such as `SensorBus` and `SimConfigSet`, which are defined in `Plant.sldd`.

### Inspect Data Storage

In the Model Explorer **Model Hierarchy** pane, select the dictionary node `System`. In the **Contents** pane, to view the contents of `System.sldd`, click the **Show Current System**

**and Below** button . The contents of the Design Data and Configurations sections appear.

Column View: Dictionary Objects [Show Details](#) 11 object(s)

| Name             | DataType  | Status | DataTypeMode | DataSource     | StorageClass   |
|------------------|-----------|--------|--------------|----------------|----------------|
| diff             | FloatType |        |              | ContrSub1.sldd | Auto           |
| init             | FloatType |        |              | ContrSub1.sldd | Auto           |
| CodeGenConfigSet |           |        |              | ContrSub1.sldd |                |
| coeff            | FloatType |        |              | ContrSub2.sldd | ExportedGlobal |
| CtrlBus          |           |        |              | Plant.sldd     |                |
| FloatType        |           |        | Single       | Plant.sldd     |                |
| SensorBus        |           |        |              | Plant.sldd     |                |
| mu               | FloatType |        |              | Plant.sldd     | Auto           |
| SimConfigSet     |           |        |              | Plant.sldd     |                |
| Design Data      |           |        |              |                |                |
| Configurations   |           |        |              |                |                |

The **DataSource** column shows the variables that each dictionary stores.

All of the globally shared variables, such as `FloatType` and `SimConfigSet`, reside in `Plant.sldd`. The variable `init`, which both of the controller subcomponents share, resides in `ContrSub1.sldd`. Due to dictionary references created by the migration process, the models can still share these variables.

If the development teams assigned to the controller subcomponents must make changes to the globally shared variables, they must access the plant dictionary file. Similarly, if the team assigned to the second controller subcomponent must make changes to the variable `init`, they must access the first subcomponent dictionary file.

### Optimize Data Sharing Using Reference Dictionaries

To share global variables such as `SimConfigSet`, `FloatType`, and `SensorBus` by clearly defining variable scope, you can create a reference dictionary. Add the new dictionary as a reference to all of the component and subcomponent dictionaries that require the shared data.

- 1 Close all of the models that you have open.

```
bdclose all
```

- 2 In Model Explorer, select **File > New > Data Dictionary**.
- 3 Set the new dictionary name to **GlobalShare** and click **Save**.
- 4 In the **Model Hierarchy** pane, select the node **ContrSub2**. In the Dialog pane, click **Add Reference**.
- 5 Double-click **GlobalShare.sldd**.
- 6 In the **Model Hierarchy** pane, right-click the node **ContrSub2** and select **Save Changes**.
- 7 Add **GlobalShare.sldd** as a reference to the dictionaries **ContrSub1.sldd** and **Plant.sldd**. Save each dictionary after you add the reference.
- 8 In the **Model Hierarchy** pane, select the node **System**.
- 9 In the **Contents** pane, select the globally shared variables:
  - **CtrlBus**
  - **SensorBus**
  - **SimConfigSet**
  - **FloatType**
- 10 In the **DataSource** column, select **GlobalShare.sldd** for any of the selected variables.

All of the variables move from **Plant.sldd** to **GlobalShare.sldd**.
- 11 Save changes to the dictionary **System.sldd**.

Now, if any of the three development teams need to make changes to the globally shared variables such as **SimConfigSet** and **CtrlBus**, they can access the dictionary **GlobalShare.sldd**. This dictionary contains only the variables that all of the models in the system share. Because the component and subcomponent dictionaries **Plant.sldd**, **ContrSub1.sldd**, and **ContrSub2.sldd** all reference the globally shared dictionary **GlobalShare.sldd**, all of the models in the hierarchy can use the data.

To further partition and scope the shared data, create another reference dictionary to contain the variables that the controller subcomponents share: **init** and **CodeGenConfigSet**.

- 1 In Model Explorer, select **File > New > Data Dictionary**.
- 2 Set the new dictionary name to **ContrShare** and click **Save**.
- 3 In the **Model Hierarchy** pane, select the dictionary node **ContrSub2**. In the Dialog pane, select **Add Reference**.

- 4 In the dialog box, double-click `ContrShare.sldd`.
- 5 In the **Model Hierarchy** pane, right-click the node `ContrSub2` and select **Save Changes**.
- 6 Add `ContrShare.sldd` as a reference to `ContrSub1.sldd` and save the dictionary `ContrSub1.sldd`.
- 7 Add `GlobalShare.sldd` as a reference to `ContrShare.sldd` and save the dictionary `ContrShare.sldd`.
- 8 In the **Model Hierarchy** pane, select the node `System`.
- 9 In the **Contents** pane, select these variables:
  - `CodeGenConfigSet`
  - `init`
- 10 In the **DataSource** column, select `ContrShare.sldd` for any of the selected variables.

All of the variables move from `ContrSub2.sldd` to `ContrShare.sldd`.
- 11 Save changes to the dictionary `System.sldd`.

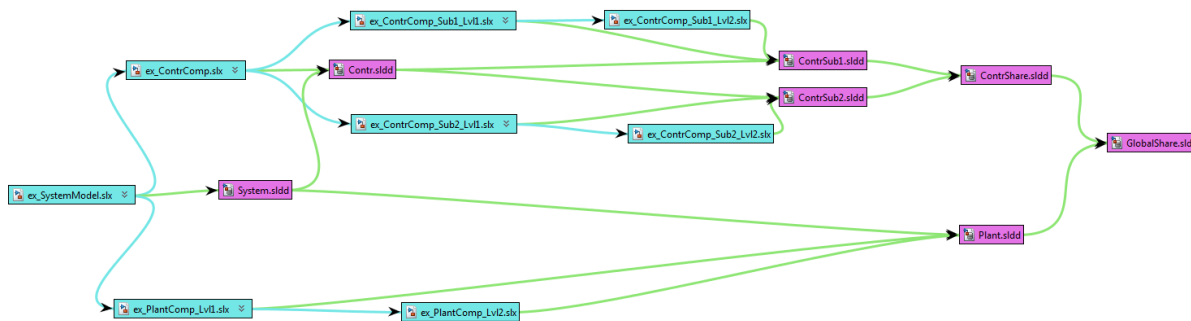

To further optimize the dictionary hierarchy, remove the unnecessary references that the migration process created. Also, remove the unnecessary references that you created from `ContrSub1.sldd` and `ContrSub2.sldd` to `GlobalShare.sldd`. Because `ContrShare.sldd` references `GlobalShare.sldd`, the controller subcomponent dictionaries can use the data in `GlobalShare.sldd` without referencing `GlobalShare.sldd`.

- 1 In the Model Explorer **Model Hierarchy** pane, select the dictionary node `ContrSub2`. In the Dialog pane, in the **Referenced Dictionaries** list, select `Plant` and click **Remove**. Remove the references to `GlobalShare.sldd` and `ContrSub1.sldd`. Save the changes to `ContrSub2.sldd`.
- 2 Remove the references to `GlobalShare.sldd` and `Plant.sldd` from `ContrSub1.sldd`. Save the changes to `ContrSub1.sldd`.
- 3 Remove the reference to `Plant.sldd` from `Contr.sldd`. Save the changes to `Contr.sldd`.

### Inspect Dictionary Hierarchy

To view the entire dictionary and model hierarchy, you can perform a dependency analysis in a Simulink project.

- 1 Open your saved model `ex_SystemModel`. Select **File > Simulink Project > Create Project from Model**.
- 2 Specify a name for the project in the **Project name** box. Click **Create**.
- 3 In the Simulink Project, click **Dependency Analysis**. Click **Analyze**.

The system model, `ex_SystemModel`, is linked to the dictionary `System.sldd`. The plant component, the controller component, and the controller subcomponents are each linked to a separate dictionary. These dictionaries form a reference hierarchy. To access the shared data, the component and subcomponent dictionaries reference the dictionaries `ContrShare.sldd` and `GlobalShare.sldd`.

To inspect the data in the dictionaries, use Model Explorer.

- 1 In your saved model `ex_SystemModel`, click the data dictionary badge .
- 2 In the Model Explorer **Contents** pane, click the column name **DataSource** to sort the design data. The dictionaries in the hierarchy partition the data based on the shared scope of each variable.
- 3 In the **Model Hierarchy** pane, under the node `System`, click the node `Configurations`. In the **Contents** pane, the `Simulink.ConfigSet` objects `CodeGenConfigSet` and `SimConfigSet` are stored in the shared dictionaries.

### Strategies to Discover Shared Data

To learn how the models in a model reference hierarchy share data, use these techniques:

- In an open model, select **Edit > Find Referenced Variables**. The Model Explorer displays the variables that the model uses, as well as the variables that referenced

models use. You can then right-click a variable and select **Find Where Used** to display all of the models that use the variable. For more information, see “Workspace Variables in Model Explorer” on page 11-47.

- At the command prompt, use the function `Simulink.findVars` to determine the variables a model uses. You can then use the function `intersect` to determine the variables two models, components, or subcomponents share.

## Migrate Model Hierarchy to Dictionaries Incrementally

If you cannot migrate all of the models in a model reference hierarchy to a single dictionary at once, you can migrate an individual model, component, or subcomponent in the hierarchy. Over time, you can migrate the entire hierarchy.

The component that you migrate cannot share any design data with other models in the hierarchy. In the example “Create a Dictionary for Each Component” on page 59-37, the components and subcomponents of a model reference hierarchy share data in the base workspace, such as `Simulink.Bus` and `Simulink.Parameter` objects. Due to these dependencies, you cannot independently migrate the components and subcomponents.

If you use configuration set references to maintain configuration parameter uniformity throughout the hierarchy, the component that you choose to migrate cannot share a configuration set with other models in the hierarchy. When you migrate the component, you must choose one of these options:

- Move the shared configuration set into the new dictionary. In this case, the other models in the hierarchy cannot use the configuration set.
- Copy the shared configuration set into the new dictionary. In this case, the models in the component no longer share the configuration set with the rest of the models in the hierarchy.

To migrate the component, you must first eliminate the dependency that the component has on the shared configuration set.

If you choose to migrate a model reference hierarchy incrementally by using this technique, you must begin with the models or components at the bottom of the hierarchy. In the example “Create a Dictionary for Each Component” on page 59-37, a controller model references two subcomponents, each of which contains two models. You cannot migrate the controller model before you migrate the models in the controller subcomponents.

### Explore Example Model Hierarchy

- 1 Navigate to the folder `matlabroot/help/toolbox/simulink/examples` (open).
- 2 Copy these files to a writable folder:
  - `ProjectData_ind.mat`
  - `ex_SystemModel_ind`
  - `ex_Plant_L1_ind`
  - `ex_Plant_L2_ind`
  - `ex_Contr_L1_ind`
  - `ex_Contr_L2_ind`
- 3 Load the MAT-file `ProjectData_ind.mat` to create design data in the base workspace.
- 4 Open the example model `ex_SystemModel_ind`. This model is at the top of a reference hierarchy that includes the other example models.
- 5 Select **Analysis > Model Dependencies > Model Dependency Viewer > Models Only**. The model reference hierarchy contains a system model, a plant component with two models, and a controller component with two models.

- 6 In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**. In the **Contents** pane, right-click the variable `diff` and select **Find Where Used**. In the

Select a **system** dialog box, select `ex_SystemModel_ind` and click **OK**. If you see a message about updating the diagram, click **OK**.

In the **Contents** pane, the variable `diff` is used by Constant blocks in the models `ex_Contr_L1_ind` and `ex_Contr_L2_ind`, which make up the controller component. Similarly, other models in the hierarchy share the base workspace variable `mu`.

The table shows the models that share each workspace variable.

| Variable Name     | Models Using the Variable   | Scope of Sharing                             |
|-------------------|---|--|
| <code>diff</code> | <code>ex_ContrComp_Lv11</code> and <code>ex_ContrComp_Lv12</code> | Shared by models in the controller component |
| <code>mu</code>   | <code>ex_PlantComp_Lv11</code> and <code>ex_PlantComp_Lv12</code> | Shared by models in plant component          |

Suppose that two teams of developers maintain the plant component and the controller component. You can use data dictionaries to store and scope the design data. The teams can incrementally migrate the components to use data dictionaries.

### Create Data Dictionary for Controller Component

Suppose that only the controller component team is ready to migrate their models to a data dictionary. You can independently migrate these two models.

- 1 Open the example model `ex_Contr_L1_ind`. This model is at the top of the controller component.
- 2 Select **File > Model Properties > Link to Data Dictionary**.
- 3 In the dialog box, under **Defined in**, select **Data Dictionary** and click **New**.
- 4 Set the new dictionary name to `Contr` and click **Save**.
- 5 In the **Model Properties** dialog box, click **OK**.
- 6 Click **Yes** in response to the message about migrating workspace data.
- 7 Click **Yes** in response to the message about removing imported items from the base workspace.
- 8 Save the model.

You can simulate and generate code from the model hierarchy. The models in the controller component use the data in the dictionary `Contr`, which contains the variable `diff`. The other models in the hierarchy continue to use the data in the base workspace.

### Create Data Dictionary for Plant Component

Open the example model `ex_Plant_L1_ind`. Link this model to a new data dictionary `Plant.sldd`. After you link the model to the new dictionary, save the model.

The migration process moves the variable `mu` into the new dictionary.

### Create Data Dictionary for System Model

Open the example model `ex_SystemModel_ind`. Link this model to a new data dictionary `System.sldd`. After you link the model to the new dictionary, save the model.

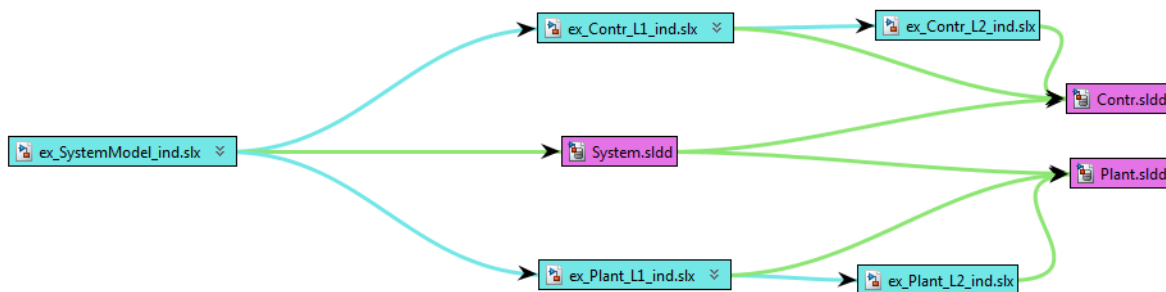

The migration process causes the new dictionary, `System.sldd`, to reference the other dictionaries that you created.

### Inspect Dictionary Hierarchy

Each of the components has a data dictionary. To view the entire dictionary and model hierarchy, you can perform a dependency analysis in a Simulink project.

- 1 In your saved model `ex_SystemModel_ind`, select **File > Simulink Project > Create Project from Model**.
- 2 Specify a name for the project in the **Project name** box. Click **Create**.
- 3 In the Simulink Project, click **Dependency Analysis**. Click **Analyze**.

Each team's models are linked to the appropriate dictionaries. The system dictionary references the component dictionaries.

To inspect the data in the dictionaries, use the Model Explorer.

- 1 In your saved model `ex_SystemModel_ind`, click the data dictionary badge .
- 2 In the Model Explorer **Contents** pane, the data source for each entry is the dictionary for the appropriate component.

### Data Dictionary Management

A data dictionary stores Simulink model data and offers more data management features than the MATLAB base workspace or the model workspace. Use `Simulink.data.Dictionary` objects to interact with entire data dictionaries.

| Goal   | Use  |
|--|--|
| Represent existing data dictionary with <code>Simulink.data.Dictionary</code> object   | <code>Simulink.data.dictionary.open</code>                           |
| Create and represent data dictionary with <code>Simulink.data.Dictionary</code> object | <code>Simulink.data.dictionary.create</code>                         |
| Interact with data dictionary  | <code>Simulink.data.Dictionary</code> class                          |
| Import variables to data dictionary from MATLAB base workspace                         | <code>Simulink.data.Dictionary.importFromBaseWorkspace</code> method |
| Add reference dictionary to a data dictionary  | <code>Simulink.data.Dictionary.addDataSource</code> method           |

| Goal  | Use   |
|---|---|
| Remove reference dictionary from a data dictionary  | <code>Simulink.data.Dictionary.removeDataSource</code> method |
| Save changes to data dictionary   | <code>Simulink.data.Dictionary.saveChanges</code> method      |
| Discard changes to data dictionary  | <code>Simulink.data.Dictionary.discardChanges</code> method   |
| View a list of entries stored in data dictionary  | <code>Simulink.data.Dictionary.listEntry</code> method        |
| Import enumerated type definitions to data dictionary                                     | <code>Simulink.data.Dictionary.importEnumTypes</code> method  |
| Return file name and path of data dictionary  | <code>Simulink.data.Dictionary.filepath</code> method         |
| Show data dictionary in Model Explorer window   | <code>Simulink.data.Dictionary.show</code> method             |
| Hide data dictionary from Model Explorer window   | <code>Simulink.data.Dictionary.hide</code> method             |
| Close connection between data dictionary and <code>Simulink.data.Dictionary</code> object | <code>Simulink.data.Dictionary.close</code> method            |

## Dictionary Section Management

Data dictionaries store data as entries contained in sections, and by default all dictionaries have at least three sections named Design Data, Other Data, and Configurations. Use `Simulink.data.dictionary.Section` objects to interact with data dictionary sections.

| Goal  | Use   |
|---|---|
| Represent data dictionary section with <code>Section</code> object. | <code>Simulink.data.Dictionary.getSection</code> method |
| Interact with data dictionary section                               | <code>Simulink.data.dictionary.Section</code> class     |

| Goal   | Use   |
|--|---|
| Import variables to data dictionary section from MAT-file or MATLAB file | <code>Simulink.data.dictionary.Section.importFromFile</code> method |
| Export entries in data dictionary section to MAT-file or MATLAB file     | <code>Simulink.data.dictionary.Section.exportToFile</code> method   |
| Delete entry from data dictionary section                                | <code>Simulink.data.dictionary.Section.deleteEntry</code> method    |
| Evaluate MATLAB expression in data dictionary section                    | <code>Simulink.data.dictionary.Section.evalin</code> method         |
| Search for entries in data dictionary section                            | <code>Simulink.data.dictionary.Section.find</code> method           |
| Determine whether entry exists in data dictionary section                | <code>Simulink.data.dictionary.Section.exist</code> method          |

## Dictionary Entry Manipulation

A variable that is stored in a data dictionary is called an entry of the dictionary. Entries have additional properties that store status information, such as the time and date the entry was last modified. Use `Simulink.data.dictionary.Entry` objects to manipulate data dictionary entries.

| Goal  | Use  |
|---|--|
| Represent data dictionary entry with <code>Entry</code> object                    | <code>Simulink.data.dictionary.Section.getEntry</code> method  |
| Add data dictionary entry to section and represent with <code>Entry</code> object | <code>Simulink.data.dictionary.Section.addEntry</code> method  |
| Manipulate data dictionary entry  | <code>Simulink.data.dictionary.Entry</code> class              |
| Assign new value to data dictionary entry   | <code>Simulink.data.dictionary.Entry.setValue</code> method    |
| Display changes made to data dictionary entry                                     | <code>Simulink.data.dictionary.Entry.showChanges</code> method |

| Goal   | Use   |
|--|---|
| Save changes made to data dictionary           | <code>Simulink.data.Dictionary.saveChanges</code> method          |
| Discard changes made to data dictionary entry  | <code>Simulink.data.dictionary.Entry.discardChanges</code> method |
| Search in an array of data dictionary entries  | <code>Simulink.data.dictionary.Entry.find</code> method           |
| Return value of data dictionary entry          | <code>Simulink.data.dictionary.Entry.getValue</code> method       |
| Delete data dictionary entry                   | <code>Simulink.data.dictionary.Entry.deleteEntry</code> method    |
| Store enumerated type definition in dictionary | <code>Simulink.data.dictionary.EnumTypeDefinition</code> class    |

## Transition to Using Data Dictionary

These functions help you transition to data dictionaries by operating on Simulink model data either in the base workspace or in a data dictionary, as appropriate for the model.

| Goal  | Use                                       |
|---|---|
| Change value of data dictionary entry or workspace variable in context of Simulink model        | <code>Simulink.data.assignInGlobal</code> |
| Evaluate MATLAB expression in context of Simulink model   | <code>Simulink.data.evalInGlobal</code>   |
| Determine existence of data dictionary entry or workspace variable in context of Simulink model | <code>Simulink.data.existsInGlobal</code> |

## Programmatically Migrate Single Model to Use Dictionary

To change the data source of a Simulink model from the MATLAB base workspace to a new data dictionary, use this example code as a template.

```
% Define the model name and the data dictionary name
```

```
modelName = 'f14';
dictionaryName = 'myNewDictionary.slidd';

% Load the target model
load_system(modelName);

% Identify all model variables that are defined in the base workspace
varsToImport = Simulink.findVars(modelName,'SourceType','base workspace');
varNames = {varsToImport.Name};

% Create the data dictionary
dictionaryObj = Simulink.data.dictionary.create(dictionaryName);

% Import to the dictionary the model variables defined in the base
% workspace, and clear the variables from the base workspace
[importSuccess,importFailure] = importFromBaseWorkspace(dictionaryObj,...
    'varList',varNames,'clearWorkspaceVars',true);

% Link the dictionary to the model
set_param(modelName,'DataDictionary',dictionaryName);
```

---

**Note:** This code does not migrate the definitions of enumerated data types that were used to define model variables. If you import model variables of enumerated data types to a data dictionary but do not migrate the enumerated type definitions, the dictionary is less portable and might not function properly if used by someone else. To migrate enumerated data type definitions to a data dictionary, see “Migrate Enumerated Types into Data Dictionary” on page 59-10.

---

## Import Directly From External File to Dictionary

This example shows how to use a custom MATLAB function to import data directly from an external file to a data dictionary without creating or altering variables in the base workspace.

- 1 Create a two-dimensional lookup table in one sheet of a Microsoft Excel workbook. Use the upper-left corner of the sheet to provide names for the two breakpoints and for the table. Use column B and row 2 to store the two breakpoints, and use the rest of the sheet to store the table. For example, your lookup table might look like this:

|   | A         | B         | C    | D   | E    | F   | G    | H |
|---|-----------|-----------|------|-----|------|-----|------|---|
| 1 |           | bkpt2Name |      |     |      |     |      |   |
| 2 | bkpt1Name | tableName | 0.1  | 0.2 | 0.3  | 0.4 | 0.5  |   |
| 3 |           | 0.25      | 0.35 | 0.6 | 0.85 | 1.1 | 1.35 |   |
| 4 |           | 0.5       | 0.45 | 0.7 | 0.95 | 1.2 | 1.45 |   |
| 5 |           | 0.75      | 0.55 | 0.8 | 1.05 | 1.3 | 1.55 |   |
| 6 |           | 1         | 0.65 | 0.9 | 1.15 | 1.4 | 1.65 |   |
| 7 |           | 1.25      | 0.75 | 1   | 1.25 | 1.5 | 1.75 |   |
| 8 |           |           |      |     |      |     |      |   |

Save the workbook in your current folder as `my2DLUT.xlsx`.

- Copy this custom function definition into a MATLAB file, and save the file in your current folder as `importLUTToDD.m`.

```
function importLUTToDD(workbookFile,dictionaryName)
    % IMPORTLUTTODD(workbookFile,dictionaryName) imports data for a
    % two-dimensional lookup table from a workbook directly into a data
    % dictionary. The two-dimensional lookup table in the workbook can be
    % any size but must follow a standard format.

    % Read in the entire first sheet of the workbook.
    [data,names,~] = xlsread(workbookFile,1,'');

    % Divide the raw imported data into the breakpoints, the table, and their
    % names.
    % Assume breakpoint 1 is in the first column and breakpoint 2 is in the
    % first row.
    % Assume cells A1, B1, and B2 define the breakpoint names and table name.
    bkpt1 = data(2:end,1);
    bkpt2 = data(1,2:end);
    table = data(2:end,2:end);
    bkpt1Name = names{2,1};
    bkpt2Name = names{1,2};
    tableName = names{2,2};

    % Prepare to import to the Design Data section of the target data
    % dictionary.
    myDictionaryObj = Simulink.data.dictionary.open(dictionaryName);
    dDataSectObj = getSection(myDictionaryObj,'Design Data');

    % Create entries in the dictionary to store the imported breakpoints and
    % table. Name the entries using the breakpoint and table names imported
    % from the workbook.
    addEntry(dDataSectObj,bkpt1Name,bkpt1);
```

```

addEntry(dDataSectObj,bkpt2Name,bkpt2);
addEntry(dDataSectObj,tableName,table);

% Save changes to the dictionary and close it.
saveChanges(myDictionaryObj)
close(myDictionaryObj)

```

- 3 At the MATLAB command prompt, create a data dictionary to store the lookup table data.

```
myDictionaryObj = Simulink.data.dictionary.create('myLUTDD.slidd');
```

- 4 Call the custom function to import your lookup table to the new data dictionary.

```
importLUTToDD('my2DLUT.xlsx','myLUTDD.slidd')
```

- 5 Open the data dictionary in Model Explorer.

```
show(myDictionaryObj)
```

Three new entries store the imported breakpoints and lookup table. These entries are ready to use in a 2-D Lookup Table block.

## Programmatically Partition Data Dictionary

To partition a data dictionary into reference dictionaries, use this example code as a template. You can use reference dictionaries to make large data dictionaries more manageable and to contain standardized data that is useful for multiple models.

```

% Define the names of a parent data dictionary and two
% reference data dictionaries
parentDDName = 'myParentDictionary.slidd';
typesDDName = 'myTypesDictionary.slidd';
paramsDDName = 'myParamsDictionary.slidd';

% Create the parent data dictionary and a
% Simulink.data.Dictionary object to represent it
parentDD = Simulink.data.dictionary.create(parentDDName);

% Create a Simulink.data.dictionary.Section object to represent
% the Design Data section of the parent dictionary
designData_parentDD = getSection(parentDD,'Design Data');

% Import some data to the parent dictionary from the file partDD_Data_ex_API.m
importFromFile(designData_parentDD,'partDD_Data_ex_API.m');

```

```

% Create two reference dictionaries
Simulink.data.dictionary.create(typesDDName);
Simulink.data.dictionary.create(paramsDDName);

% Create a reference dictionary hierarchy by adding reference dictionaries
% to the parent dictionary
addDataSource(parentDD,typesDDName);
addDataSource(parentDD,paramsDDName);

% Migrate all Simulink.Parameter objects from the parent data dictionary to
% a reference dictionary
paramEntries = find(designData_parentDD, '-value', '-class', 'Simulink.Parameter');
for i = 1:length(paramEntries)
    paramEntries(i).DataSource = 'myParamsDictionary.sldd';
end

% Migrate all Simulink.NumericType objects from the parent data dictionary
% to a reference dictionary
typeEntries = find(designData_parentDD, '-value', '-class', 'Simulink.NumericType');
for i = 1:length(typeEntries)
    typeEntries(i).DataSource = 'myTypesDictionary.sldd';
end

% Save all changes to the parent data dictionary
saveChanges(parentDD)

```

## Sweep Data Dictionary Parameter Using Parallel Simulation

To use parallel simulation to sweep a model parameter that is defined in a data dictionary, use this code as a template. Change the names and values of the model, data dictionary, and swept parameter to match your application.

You cannot use this code for parallel Rapid Accelerator Mode or Accelerator Mode simulation. For an example of parallel simulation using Rapid Accelerator Mode, see “Parallel Simulations Using Parfor: Parameter Sweep in Rapid Accelerator Mode”.

You must have a Parallel Computing Toolbox license to perform parallel simulation.

```

% For convenience, define names of model and data dictionary
model = 'myParamSweepMdl';
dd = 'myParamSweepDD.sldd';

% Define parameter sweeping values
ParamValues = [20 35 49 78 106 123 148 192 205 225];

```

```
% Grant each worker in the parallel pool an independent data dictionary
% so they can use the data without interference
spmd
    Simulink.data.dictionary.setupWorkerCache
end

% Determine the number of times to simulate
numberOfSims = length(ParamValues);

% Prepare a nondistributed array to contain simulation output
simOut = cell(1,numberOfSims);

parfor index = 1:numberOfSims
    % Create objects to interact with dictionary data
    % You must create these objects for every iteration of the parfor-loop
    dictObj = Simulink.data.dictionary.open(dd);
    sectObj = getSection(dictObj,'Design Data');
    entryObj = getEntry(sectObj,'SpeedVect');
    % Suppose SpeedVect is a Simulink.Parameter stored in the data dictionary

    % Modify the value of the Simulink.Parameter stored in the data dictionary
    temp = getValue(entryObj);
    temp.Value = ParamValues(index);
    setValue(entryObj,temp);

    % Simulate and store simulation output in the nondistributed array
    simOut{index} = sim(model);

    % Each worker must discard all changes to the data dictionary and
    % close the dictionary when finished with an iteration of the parfor-loop
    discardChanges(dictObj);
    close(dictObj);
end

% Restore default settings that were changed by the function
% Simulink.data.dictionary.setupWorkerCache
spmd
    Simulink.data.dictionary.cleanupWorkerCache
end
```

“Testing Signals” on page 60-6

### About Signals

A *signal* is a time-varying quantity that has values at all points in time. You can specify a wide range of signal attributes, including:

- Signal name
- Data type (for example, 8-bit, 16-bit, or 32-bit integer)
- Numeric type (real or complex)
- Dimensionality (one-dimensional, two-dimensional, or multidimensional array)

Many blocks can accept or output signals of any data or numeric type and dimensionality. Other blocks impose restrictions on the attributes of the signals that they can handle.

In Simulink, signals are the outputs of dynamic systems represented by blocks in a Simulink diagram and by the diagram itself. The lines in a block diagram represent mathematical relationships among the signals defined by the block diagram. For example, a line connecting the output of block A to the input of block B indicates that the signal output of B depends on the signal output of A.

Simulink block diagrams represent signals with lines that have an arrowhead. The source of the signal corresponds to the block that writes to the signal during evaluation of its block methods (equations). The destinations of the signal are blocks that read the signal during the evaluation of the block methods (equations).

---

**Note** Simulink signals are mathematical, not physical, entities. The lines in a block diagram represent mathematical, not physical, relationships among blocks. Simulink

signals do not travel along the lines that connect blocks in the same way that electrical signals travel along a wire. Block diagrams do not represent physical connections between blocks.

---

## Creating Signals

Create a signal by adding a source block to your model. For example, you can create a signal that varies sinusoidally with time by adding an instance of the Sine block from the Simulink Sources library into your model. For information about blocks that create signals in a model, see “Sources” .

You can use the Signal & Scope Manager to create signals in your model without using blocks. For more information, see “Signal and Scope Manager” on page 24-57 .

## Signal Line Styles

A Simulink model can include many different types of signals. For details, see “Signal Types” on page 60-8. Different line styles help you to differentiate the signal types.

As you construct a block diagram, all signal types appear as a thin, solid line. After you update the diagram or start simulation, the signals appear with the specified line styles. The only line style that you can customize is the nonscalar signal type. For information about this option, see “Wide Nonscalar Lines” on page 60-63.

| Signal Type   | Line Style  |
|---|---|
| Scalar and nonscalar  |  |
| Nonscalar (with the <b>Wide nonscalar lines</b> option enabled—see “Display Signal Attributes” on page 60-60) |  |
| Control signal  |  |
| Virtual bus   |  |
| Nonvirtual bus  |  |
| Array of buses  |  |

| Signal Type   | Line Style  |
|---------------|---|
| Variable-size |  |

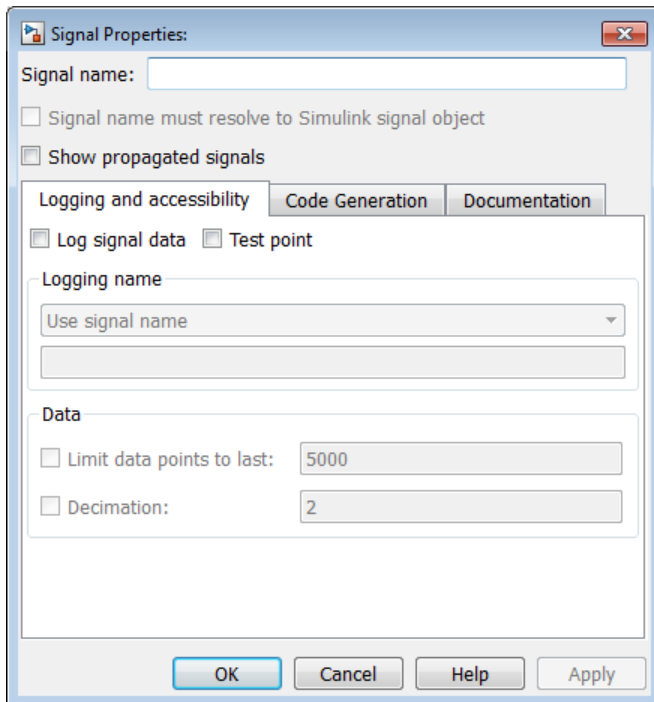

## Signal Properties

### Specifying Signal Properties

Use the Signal Properties dialog box to specify properties for:

- Signal names and labels
- Signal logging
- Simulink Coder to use to generate code
- Documentation of the signal

To open the Signal Properties dialog box, right-click a signal and choose **Properties**.

## Signal Names and Labels

You can name a signal. By default, the signal name appears below a signal, displayed as a *signal label*. You can name a signal interactively in the model or by using the Signal Properties dialog box. You can also name the signal at the command prompt (see “Name a Signal Programmatically” on page 1-12). For a summary of how to work with signal names and labels in the Simulink Editor, see “Signal Name and Label Actions” on page 1-78.

The syntactic requirements for a signal name depend on how you use the name. The most common cases are:

- The signal name can resolve to a `Simulink.Signal` object. (See `Simulink.Signal`.) The signal name must then be a legal MATLAB identifier. This identifier starts with an alphabetic character, followed by alphanumeric or underscore characters up to the length given by the function `namelengthmax`.
- The signal has a name so the signal can be identified and referenced by name in a data log. (See “Export Signal Data Using Signal Logging” on page 57-36.) Such a signal name can contain space and newline characters. These characters can improve readability but sometimes require special handling techniques, as described in “Handling Spaces and Newlines in Logged Names” on page 57-72
- The signal name exists only to clarify the diagram and has no computational significance. Such a signal name can contain anything and does not need special handling.
- The signal is an element of a bus object. Use a valid C language identifier for the signal name.
- Inputs to a Bus Creator block must have unique names. If there are duplicate names, the Bus Creator block appends (`signal#`) to all input signal names, where `#` is the input port index.

Making every signal name a legal MATLAB identifier handles a wide range of model configurations. Unexpected requirements can require changing signal names to follow a more restrictive syntax. You can use the function `isvarname` to determine whether a signal name is a legal MATLAB identifier.

## Signal Display Options

Displaying signal attributes in the model diagram can make the model easier to read. For example, in the Simulink Editor, use the **Display > Signals & Ports** menu to include in the model layout information about signal attributes, such as:

- Port data types
- Design ranges
- Signal dimensions
- Signal resolution

For details, see “Display Signal Attributes” on page 60-60.

You can also highlight a signal and its source or destination blocks. For details, see “Display Signal Sources and Destinations” on page 60-38.

## Testing Signals

You can perform the following kinds of tests on signals:

- “Minimum and Maximum Values” on page 60-6
- “Connection Validation” on page 60-6

### Minimum and Maximum Values

For many Simulink blocks, you can specify a range of valid values for the output signals. Simulink provides a diagnostic for detecting when blocks generate signals that exceed their specified ranges during simulation. For details, see “Signal Ranges” on page 60-41.

### Connection Validation

Many Simulink blocks have limitations on the types of signals that they accept. Before simulating a model, Simulink checks all blocks to ensure that the blocks can accommodate the types of signals output by the ports to which the blocks connect and reports errors about incompatibilities.

To detect signal compatibility errors before running a simulation, update the diagram.

### Signal Groups

The **Signal Builder** block displays interchangeable groups of signal sources. Use the Signal Builder to create or edit groups of signals and to switch the groups into and out of a model.

Signal groups can help with testing a model, especially when you use them with Simulink **Assertion** blocks and the Model Coverage Tool in the Simulink Verification and Validation product.

For details, see “Signal Groups” on page 60-65.

## Signal Types

### In this section...

“Summary of Signal Types” on page 60-8

“Control Signals” on page 60-8

“Composite (Bus) Signals” on page 60-9

### Summary of Signal Types

You can use many different kinds of signals in a model. The following table summarizes the signal types, and links to sections that describe each type in detail.

| Signal Type     | Description  |
|-----------------|--|
| Array of buses  | An array whose elements are buses. See “Combine Buses into an Array of Buses” on page 61-82.   |
| Bus (Composite) | A Simulink composite signal made up of other signals, optionally including other bus signals. See “Composite (Bus) Signals” on page 60-9.  |
| Control         | Signal used by one block to initiate execution of another block. For example, a signal that executes a function-call or action subsystem. For details, see “Control Signals” on page 60-8. |
| Nonvirtual      | Signal that occupies its own storage. A nonvirtual bus reads inputs and writes outputs by accessing copies of the component signals.   |
| Mux             | A virtual vector created with a Mux block. See “Mux Signals” on page 60-11.  |
| Variable-Size   | Signal whose size (the number of elements in a dimension), in addition to its values, can change during a model simulation.  |
| Virtual         | Signal that represents another signal or set of signals. A virtual signal is used for graphical purposes and has no functional effect. See “Virtual Signals” on page 60-11.                |

### Control Signals

A *control signal* is a signal used by one block to initiate execution of another block. For example, a signal that executes a function-call or action subsystem is a control signal.

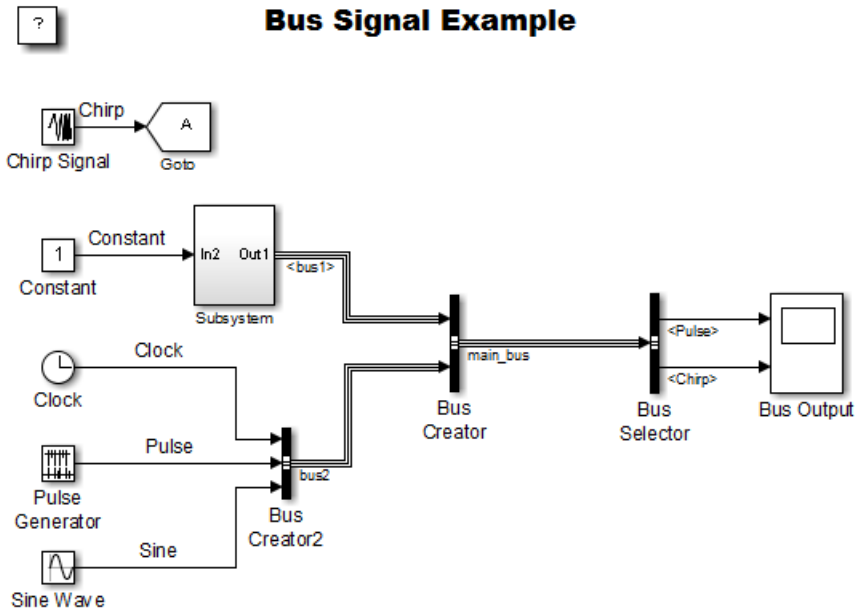

When you update or simulate a block diagram, Simulink uses a dash-dot pattern to redraw lines representing the control signals.

## Composite (Bus) Signals

You can group multiple signals into a hierarchical composite signal, called a *bus*, route the bus from block to block, and extract constituent signals from the bus where needed. When you have many parallel signals, buses can simplify the appearance of a model and help to clarify generated code. A bus can be either virtual or nonvirtual.

For example, if you open and simulate the `Bus Signal` example model, the `bus1`, `bus2`, and `main_bus` signals are bus signals. These virtual bus signals use the triple line style.

For details, see “Composite Signals” on page 61-3.

# Virtual Signals

**In this section...**

“About Virtual Signals” on page 60-11

“Mux Signals” on page 60-11

## About Virtual Signals

A *virtual signal* is a signal that graphically represents other signals or parts of other signals. Virtual signals are purely graphical entities; they have no mathematical or physical significance. Simulink ignores them when simulating a model, and they do not exist in generated code. Some blocks, such as the Mux block, always generate virtual signals. Others, such as Bus Creator, can generate either virtual or nonvirtual signals.

The nonvirtual components of a virtual signal are called *regions*. A virtual signal can contain the same region more than once. For example, if the same nonvirtual signal is connected to two input ports of a Mux block, the block outputs a virtual signal that has two regions. The regions behave as they would if they had originated in two different nonvirtual signals, even though the resulting behavior duplicates information.

Bus signals can also be virtual or nonvirtual. For details, see “Types of Simulink Buses” on page 61-6.

## Mux Signals

A Simulink *mux* is a virtual signal that graphically combines two or more scalar or vector signals into one signal line. A Simulink mux is not a hardware multiplexer, which combines multiple data streams into a single channel. A Simulink mux does not combine signals in any functional sense: it exists only virtually, and its only purpose is to simplify the visual appearance of a model. Using a mux has no effect on simulation or generated code.

You can use a mux anywhere that you could use an ordinary (contiguous) vector. For example, you can perform calculations on a mux. The computation affects each constituent value in the mux just as if the values existed in a contiguous vector, and the result is a contiguous vector, not a mux. Using a mux to perform computations on multiple vectors avoids the overhead of copying the separate values to contiguous storage.

The Simulink documentation refers, sometimes interchangeably, to “muxes”, “vectors”, and “wide signals”, and all three terms appear in Simulink GUI labels and API names. This terminology can be confusing, because most vector signals, which are also called wide signals, are nonvirtual and hence are not muxes. To avoid confusion, reserve the term “mux” to refer specifically to a virtual vector.

A mux is a *virtual* vector signal. The constituent signals of a mux retain their separate existence in every way, except visually. You can also combine scalar and vector signals into a *nonvirtual* vector signal, by using a **Vector Concatenate** block. The signal output by a Vector Concatenate block is an ordinary contiguous vector, inheriting no special properties from the fact that it was created from separate signals.

To create a composite signal whose constituent signals retain their identities and can have different data types, use a **Bus Creator** block rather than a Mux block. For details, see “Composite Signals” on page 61-3. Although you can use a Mux block to create a composite signal in some cases, MathWorks discourages this practice. See “Prevent Bus and Mux Mixtures” on page 61-113 for more information.

### Using Muxes

The Signal Routing library provides two virtual blocks for implementing muxes:

#### **Mux**

Combine several input signals into a mux (virtual vector) signal

#### **Demux**

Extract and output the values in a mux (virtual vector) signal

To implement a mux signal:

- 1 Select a Mux and Demux block from the Signal Routing library.
- 2 Set the Mux block **Number of inputs** and the Demux block **Number of outputs** block parameters to the desired values.
- 3 Connect the Mux, Demux, and other blocks as needed to implement the desired signal.

The next figure shows three signals that are input to a Mux block, transmitted as a mux signal to a Demux block, and output as separate signals.

The Mux and Demux blocks are the left and right vertical bars, respectively. To reduce visual complexity, neither block displays a name. In this example, the line connecting the blocks, representing the mux signal, is wide because the model has been built with **Display > Signals & Ports > Wide Nonscalar Lines** option enabled. See “Display Signal Attributes” on page 60-60 for details.

Signals input to a Mux block can be any combination of scalars, vectors, and muxes. The signals in the output mux appear in the order in which they were input to the Mux block. You can use multiple Mux blocks to create a mux in several stages, but the result is flat, not hierarchical, just as if the constituent signals had been combined using a single mux block.

The values in all signals input to a Mux block must have the same data type.

If a Demux block attempts to output more values than exist in the input signal, an error occurs. A Demux block can output fewer values than exist in the input mux, and can group the values it outputs into different scalars and vectors than were input to the Mux block. However, the Demux block cannot rearrange the order of those values. For details, see Demux.

---

**Note:** MathWorks discourages using Mux and Demux blocks to create and access buses under any circumstances. See “Prevent Bus and Mux Mixtures” on page 61-113 for details.

---

## **More About**

- “Signal Basics” on page 60-2
- “Signal Types” on page 60-8

# Signal Values

**In this section...**

“Signal Data Types” on page 60-15

“Signal Dimensions, Size, and Width” on page 60-15

“Complex Signals” on page 60-15

“Initializing Signal Values” on page 60-16

“Viewing Signal Values” on page 60-16

“Displaying Signal Values in Model Diagrams” on page 60-17

“Exporting Signal Data” on page 60-18

## Signal Data Types

Data type refers to the format used to represent signal values internally. By default, the data type of Simulink signals is double. You can create signals of other data types. Simulink signals support the same range of data types as MATLAB. See “About Data Types in Simulink” on page 55-2 for more information.

## Signal Dimensions, Size, and Width

Simulink blocks can output one-dimensional, two-dimensional, or multidimensional signals. The Simulink user interface and documentation generally refer to 1-D signals as vectors and 2-D or multidimensional signals as matrices. A one-element array is frequently referred to as a scalar.

The size of a signal refers to the number of elements that a signal contains. The size of a matrix (2-D) signal is generally expressed as M-by-N, where M is the number of columns and N is the number of rows making up the signal. The size of a vector signal is referred to as the width of the signal.

For more information, see “Signal Dimensions” on page 60-30.

## Complex Signals

The values of signals can be complex numbers or real numbers. A signal whose values are complex numbers is a complex signal. Create a complex-valued signal using one of the following approaches:

- Load complex-valued signal data from the MATLAB workspace into the model via a root-level Inport block.
- Create a **Constant** block in your model and set its value to a complex number.
- Create real signals corresponding to the real and imaginary parts of a complex signal, then combine the parts into a complex signal, using the **Real - Imag to Complex** conversion block.

Manipulate complex signals via blocks that accept them. If you are not sure whether a block accepts complex signals, see the documentation for the block.

## Initializing Signal Values

If a signal does not have an explicit initial value, the initial value that Simulink uses depends on the data type of the signal.

| Signal Data Type                 | Default Initial Value |
|----------------------------------|-----------------------|
| Numeric (other than fixed-point) | Zero                  |
| Fixed-point                      | Ground value          |
| Boolean                          | False                 |
| Enumerated                       | Default value         |

You can specify the non-default initial values of signals for Simulink to use at the beginning of simulation.

- For any signal, you can define a signal object (`Simulink.Signal`), and use that signal object to specify an initial value for the signal.
- For some blocks, such as **Outport**, **Data Store Memory**, and **Memory**, you can use either a signal object or a block parameter, or both, to specify the initial value of a block state or output.

For details, see “Initialize Signals and Discrete States” on page 60-48.

## Viewing Signal Values

You can use either blocks or the signal viewers (such as the Signal & Scope Manager) to display the values of signals during a simulation. For example, you can use either

the Scope block or the Signal & Scope Manager to graph time-varying signals on an oscilloscope-like display during simulation. For general information about options for viewing signal values, see “Scope Blocks and Scope Viewer Overview” on page 24-2. For detailed information about:

- Blocks that you can use to display signals in a model, see “Sinks”
- Signal viewers, see “Floating Scope and Scope Viewer Tasks” on page 24-48
- The Signal & Scope Manager, see “Signal and Scope Manager” on page 24-57
- Test points, which are signals that Simulink guarantees to be observable when using a Floating Scope block in a model, see “Test Points” on page 60-57.

## Displaying Signal Values in Model Diagrams

To include graphical displays of signal values in a model diagram, use one of the following approaches:

- “Display Data Tips During Simulation” on page 60-17
- “Display Signal Value After Simulation” on page 60-17

### Display Data Tips During Simulation

For many blocks, Simulink can display block output (port values) as data tips on the block diagram while a simulation is running.

- 1 In the Simulink Editor, select **Display > Data Display in Simulation**.
- 2 From the submenu, select either **Show Value Labels When Hovering** or **Show Value Labels When Clicked**.
- 3 To change display options, use the **Options** submenu.

For details, see “Display Port Values for Debugging” on page 31-18.

### Display Signal Value After Simulation

To display, below a specific signal, the signal value after simulation:

- 1 Right-click the signal.
- 2 In the context menu, select **Show Value Label of Selected Port**.

## Exporting Signal Data

You can save signal values to the MATLAB workspace during simulation, for later retrieval and postprocessing. For a summary of different approaches, see “Approaches for Exporting Signal Data” on page 57-4.

## Related Examples

- “Control Signal Data Types” on page 55-7

## Signal Label Propagation

### In this section...

“Propagated Signal Labels” on page 60-19

“Blocks That Support Signal Label Propagation” on page 60-19

“Display Propagated Signal Labels” on page 60-20

“How Simulink Propagates Signal Labels” on page 60-21

### Propagated Signal Labels

When you enable the display of signal label propagation for output signals of the blocks listed in “Blocks That Support Signal Label Propagation” on page 60-19:

- If there is a user-specified signal name that Simulink can propagate, the propagated signal label includes the name in angle brackets (for example, <sig1>).
- If there is no signal name to propagate, Simulink displays an empty set of angle brackets (<>) for the label.

For example, in the following model, the output signal from the Subsystem block is configured for signal label propagation. The propagated signal label (<const>) is based on the name of the upstream output signal of the Constant block (const).

For more information on how Simulink creates propagated signal labels, see “How Simulink Propagates Signal Labels” on page 60-21.

### Blocks That Support Signal Label Propagation

You can use signal label propagation with output signals for several *connection* blocks, which route signals through the model without changing the data. Connection blocks perform no signal transformation.

Also, Model blocks support signal label propagation.

The connection blocks that support signal label propagation are:

- Enable
- From
- Function Call Split
- Goto
- Inport (subsystem only; not root inports)
- Signal Specification
- Subsystem (through subsystem Inport and Outport blocks)
- Trigger
- Two-Way Connection (a Simscape block)

The Bus Creator and Bus Selector blocks do *not* support signal label propagation. However, if you want to view the hierarchy for any bus signal, use the “Signal Hierarchy Viewer” on page 61-7.

The Signal Properties dialog box for a signal indicates whether that signal supports signal label propagation. The **Show propagated signals** parameter is available only for blocks that support signal label propagation. For details, see “Display Propagated Signal Labels” on page 60-20.

## Display Propagated Signal Labels

To display a propagated signal label:

- 1 Set **Model Configuration Parameters** > **Diagnostics** > **Connectivity** > **Mux blocks used to create bus signals** to **error**.
- 2 Right-click the signal for which you want to display a propagated signal label and select **Properties**.
- 3 In the Signal Properties dialog box, select **Show propagated signals**.

The **Show propagated signals** parameter is available only for output signals from blocks that support signal label propagation.

To enable this signal property programmatically, create a handle to the signal line, and specify `signalPropagation` as 'on'. For example, you can use this code to enable or disable the property for all of the signals in a model diagram.

```
% Create an array of handles to every signal line in the diagram
signalLines = find_system(gcs, 'FindAll', 'on', 'type', 'line');

% Enable or disable the property for each signal line
for i = 1:length(signalLines)

    %set(signalLines(i), 'signalPropagation', 'off');
    set(signalLines(i), 'signalPropagation', 'on');
end
```

If a signal already has a label, then an *alternative* approach for displaying a propagated signal label is:

- 1 In the model diagram, click the signal label.
- 2 Remove the label text.
- 3 In the signal label text box, enter an angle bracket (<).
- 4 Click outside the signal label.

Simulink displays the propagated signal label.

## How Simulink Propagates Signal Labels

Understanding how Simulink propagates signal labels helps you to:

- Anticipate the scope of the signal label propagation, from source to final destination
- Configure your model to display signal labels for the signals that you want

For output signals from supported blocks, you can choose to have Simulink display propagated signal labels. For a list of supported blocks, see “Blocks That Support Signal Label Propagation” on page 60-19.

In general, Simulink performs signal label propagation consistently:

- For different modeling constructs (for example, non-bus and bus signals, virtual and nonvirtual buses, subsystem and model variants, model referencing, and libraries)
- In models with or without hidden blocks, which Simulink inserts in certain cases to enable simulation
- At model load, edit, update, and simulation times

For information about some special cases, see:

- “Processing for Referenced Models” on page 60-26
- “Processing for Variants and Configurable Subsystems” on page 60-28

### **General Signal Label Propagation Processing**

In general, when you enable signal label propagation for an output signal of a block (for example, BlockA), Simulink performs the following processing to find the source signal name to propagate:

- 1** Checks the block whose output signal connects to BlockA, and if necessary, continues checking upstream blocks, working backward from the closest block to the farthest block.
- 2** Stops when it encounters a block that either:
  - Supports signal label propagation and has a signal name
  - Does not support signal label propagation
- 3** Obtains the signal name, if any, of the output signal for the block at which Simulink stops.
- 4** Uses that signal name for the propagated signal label of any output signals of downstream blocks for which you enable signal label propagation.

For example, in the following model, suppose that you enable signal label propagation for the output signal for the Subsystem block (that is, the signal connected to the **Out1** port).

Simulink checks inside the subsystem, checks upstream from the From and GoTo blocks (which support signal label propagation and do not have a name), and then checks farther upstream, to the Constant block, which does not support signal label propagation.

Simulink uses the signal name of the Constant block output signal, `const`. The propagated signal label for the Subsystem output signal is `<const>`.

If the output signal from the Constant block did not have a signal name, then the propagated signal label would be an empty set of angle brackets (`<>`).

Suppose that in the Subsystem block you enable signal label propagation for the output signal from the In1 block, and you use the Signal Properties dialog box to specify the signal name `const - from` for the output signal of the From block, as shown below.

The propagated signal label for the Subsystem output signal changes to `<const - from>`, because that is the first named signal that Simulink encounters in its signal label propagation processing.

In the following model, the signal label propagation for the output signal of the Subsystem block uses the signal name `bus1`, which is the name of the output bus signal of the Bus Creator block. The propagated signal label does not include the names of the bus element signals (`a` and `b`).

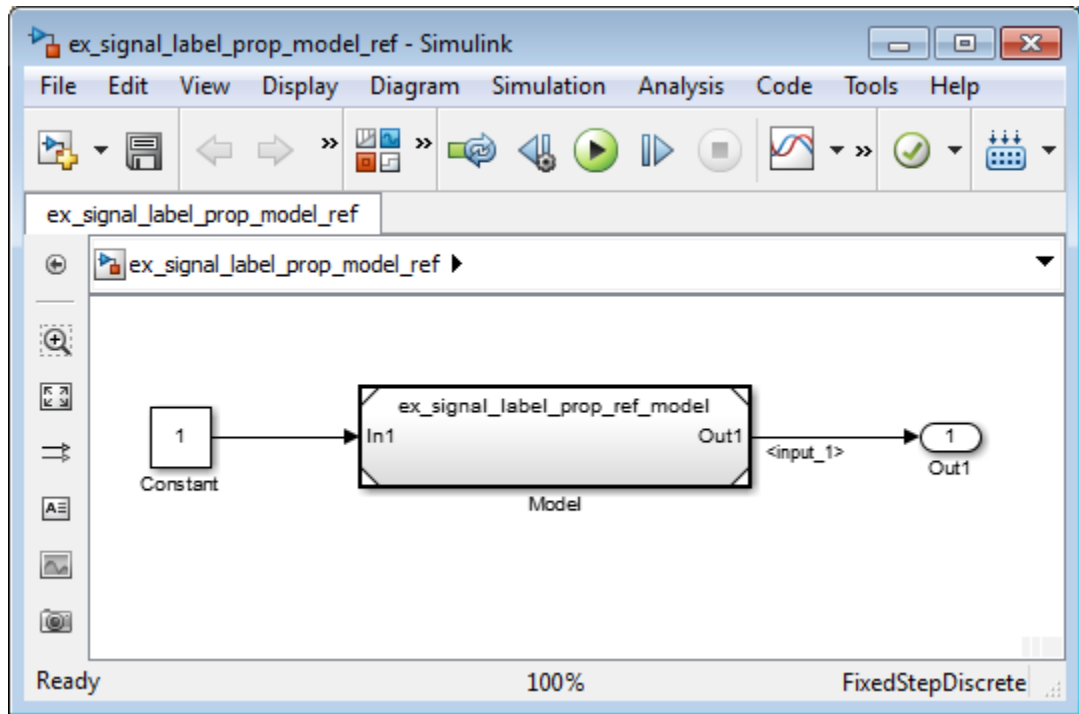

### Processing for Referenced Models

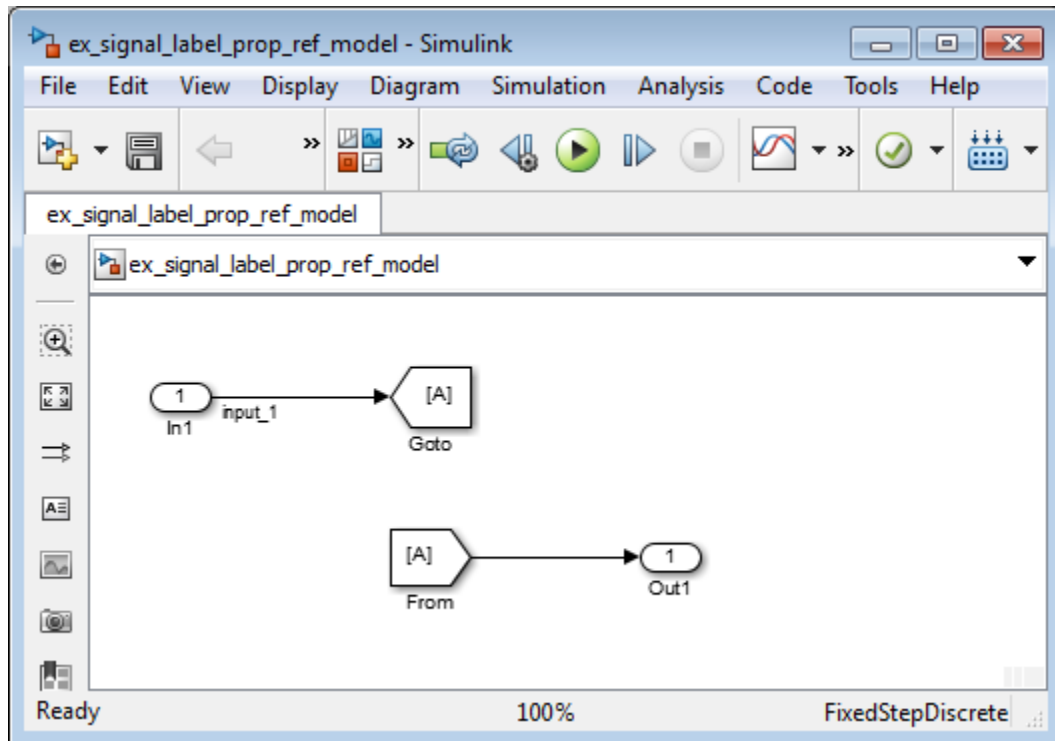

To enable signal label propagation for referenced models, in addition to the steps described in “Display Propagated Signal Labels” on page 60-20, enable the **Model Configuration Parameters > Model Referencing > Propagate all signal labels out of the model** parameter.

If you make a change inside a referenced model that affects signal label propagation, the propagated signal labels outside of the referenced model do not reflect those changes until after you update the diagram or simulate the model.

For example, the model `ex_signal_label_prop_model_ref` has a referenced model that includes an output signal from the In1 block that has a signal name of `input_1`.

If you enable signal label propagation for the signal from the Out1 port of the Model block, that signal does *not* reflect the name `input_1` until after you update the diagram or simulate the model.

### Processing for Variants and Configurable Subsystems

Simulink updates the propagated signal label (if enabled) for the output signal of the Subsystem or Model block, when *both* of these conditions occur:

- The output signals for model reference variants have different signal names.
- You change the active variant model or variant subsystem.

For Subsystem blocks, the signal label updates at edit time. For Model blocks, the update occurs when you update diagram or simulate the model.

## Signal Dimensions

**In this section...**

“About Signal Dimensions” on page 60-30

“Simulink Blocks that Support Multidimensional Signals” on page 60-31

### About Signal Dimensions

Simulink blocks can output one-dimensional, two-dimensional, or multidimensional signals. The Simulink user interface and documentation generally refer to 1-D signals as *vectors* and 2-D or multidimensional signals as *matrices*. A one-element array is frequently referred to as a *scalar*. A *row vector* is a 2-D array that has one row. A *column vector* is a 2-D array that has one column.

- A one-dimensional (1-D) signal consists of a series of one-dimensional arrays output at a frequency of one array (vector) per simulation time step.
- A two-dimensional (2-D) signal consists of a series of two-dimensional arrays output at a frequency of one 2-D array (matrix) per block sample time.
- A multidimensional signal consists of a series of multidimensional (two or more dimensions) arrays output at a frequency of one array per block sample time. You can specify multidimensional arrays with any valid MATLAB multidimensional expression, such as [4 3]. See “Multidimensional Arrays” for information on multidimensional arrays.

Simulink blocks vary in the dimensionality of the signals they can accept or output. Some blocks can accept or output signals of any dimension. Some can accept or output only scalar or vector signals. To determine the signal dimensionality of a particular block, see the block documentation. See “Determine Output Signal Dimensions” on page 60-32 for information on what determines the dimensions of output signals for blocks that can output nonscalar signals.

---

**Note:** Simulink does not support dynamic signal dimensions during a simulation. That is, the dimension of a signal must remain constant while a simulation is executing. However, you can change the size of a signal during a simulation. See “Variable-Size Signal Basics” on page 62-2.

---

## Simulink Blocks that Support Multidimensional Signals

The Simulink Block Data Type Support table includes a column identifying the blocks with multi-dimension signal support.

- 1 In the Simulink editor, from the **Help** menu, click **Simulink > Block Data Types & Code Generation Support > All Tables**.

A separate window with the Simulink Block Data Type Support table opens.

- 2 In the Block column, locate the name of a Simulink block. Columns to the right are data types or features. An **X** in a column indicates support for that feature.

Simulink supports signals with up to 32 dimensions. Do not use signals with more than 32 dimensions.

### Related Examples

## Determine Output Signal Dimensions

### In this section...

“About Signal Dimensions” on page 60-32

“Determining the Output Dimensions of Source Blocks” on page 60-32

“Determining the Output Dimensions of Nonsource Blocks” on page 60-33

“Signal and Parameter Dimension Rules” on page 60-33

“Scalar Expansion of Inputs and Parameters” on page 60-34

### About Signal Dimensions

If a block can emit nonscalar signals, the dimensions of the signals that the block outputs depend on the block parameters, if the block is a source block; otherwise, the output dimensions depend on the dimensions of the block input and parameters.

### Determining the Output Dimensions of Source Blocks

A *source* block is a block that has no inputs. Examples of source blocks include the **Constant** block and the **Sine Wave** block. See “Sources” for a complete listing of Simulink source blocks. The output dimensions of a source block are the same as those of its output value parameters if the block’s **Interpret vector parameters as 1-D** parameter is off (that is, not selected in the block parameter dialog box). If the **Interpret vector parameters as 1-D** parameter is on, the output dimensions equal the output value parameter dimensions unless the parameter dimensions are N-by-1 or 1-by-N. In the latter case, the block outputs a vector signal of width N.

As an example of how a source block’s output value parameter(s) and **Interpret vector parameters as 1-D** parameter determine the dimensionality of its output, consider the **Constant** block. This block outputs a constant signal equal to its **Constant value** parameter. The following table illustrates how the dimensionality of the **Constant value** parameter and the setting of the **Interpret vector parameters as 1-D** parameter determine the dimensionality of the block’s output.

| Constant Value | Interpret vector parameters as 1-D | Output            |
|----------------|------------------------------------|-------------------|
| scalar         | off                                | one-element array |
| scalar         | on                                 | one-element array |

| Constant Value | Interpret vector parameters as 1-D | Output           |
|----------------|------------------------------------|------------------|
| 1-by-N matrix  | off                                | 1-by-N matrix    |
| 1-by-N matrix  | on                                 | N-element vector |
| N-by-1 matrix  | off                                | N-by-1 matrix    |
| N-by-1 matrix  | on                                 | N-element vector |
| M-by-N matrix  | off                                | M-by-N matrix    |
| M-by-N matrix  | on                                 | M-by-N matrix    |

Simulink source blocks allow you either to specify the dimensions of the signals that they output or specify values from which Simulink infers the dimensions. You can therefore use the source blocks to introduce signals of various dimensions into your model.

## Determining the Output Dimensions of Nonsource Blocks

If a block has inputs, the dimensions of its outputs are, after scalar expansion, the same as those of its inputs. (All inputs must have the same dimensions, as discussed in “Signal and Parameter Dimension Rules” on page 60-33).

## Signal and Parameter Dimension Rules

When creating a Simulink model, you must observe the following rules regarding signal and parameter dimensions.

### Input Signal Dimension Rule

All nonscalar inputs to a block must have the same dimensions.

A block can have a mix of scalar and nonscalar inputs as long as all the nonscalar inputs have the same dimensions. Simulink expands the scalar inputs to have the same dimensions as the nonscalar inputs (see “Scalar Expansion of Inputs and Parameters” on page 60-34).

### Block Parameter Dimension Rule

In general, block parameters must have the same dimensions as the dimensions of the inputs to the block. Simulink performs some processing that provides flexibility relating to that general rule.

- A block can have scalar parameters corresponding to nonscalar inputs. In this case, Simulink expands a scalar parameter to have the same dimensions as the corresponding input (see “Scalar Expansion of Inputs and Parameters” on page 60-34).
- If an input is a vector, the corresponding parameter can be either an N-by-1 or a 1-by-N matrix. In this case, Simulink applies the N matrix elements to the corresponding elements of the input vector. This exception allows use of MATLAB row or column vectors, which are actually 1-by-N or N-by-1 matrices, respectively, to specify parameters that apply to vector inputs.

### Vector or Matrix Input Conversion Rules

Simulink converts vectors to row or column matrices and row or column matrices to vectors under the following circumstances:

- If a vector signal is connected to an input that requires a matrix, Simulink converts the vector to a one-row or one-column matrix.
- If a one-column or one-row matrix is connected to an input that requires a vector, Simulink converts the matrix to a vector.
- If the inputs to a block consist of a mixture of vectors and matrices and the matrix inputs all have one column or one row, Simulink converts the vectors to matrices having one column or one row, respectively.

---

**Note** You can configure Simulink to display a warning or error message if a vector or matrix conversion occurs during a simulation. See “Vector/matrix block input conversion” for more information.

---

### Scalar Expansion of Inputs and Parameters

*Scalar expansion* is the conversion of a scalar value into a nonscalar array. Many Simulink blocks support scalar expansion of inputs and parameters. Block-specific descriptions indicate whether Simulink applies scalar expansion to a block's inputs and parameters.

Scalar expansion of inputs refers to the expansion of scalar inputs to match the dimensions of other nonscalar inputs or nonscalar parameters. When the input to a block is a mix of scalar and nonscalar signals, Simulink expands the scalar inputs into nonscalar signals having the same dimensions as the other nonscalar inputs. For

example, a scalar of 4 is expanded to the vector [4 4 4] if the associated nonscalar has a dimension of 3.

Scalar expansion of parameters refers to the expansion of scalar block parameters to match the dimensions of nonscalar inputs.

| Input(s)                            | Associated Block Parameter | Scalar Expansion   |
|-------------------------------------|----------------------------|--|
| Scalar                              | Nonscalar                  | Input expanded to match parameter dimensions.<br><br>See “Scalar Input and Nonscalar Parameter” on page 60-35.   |
| Nonscalar                           | Scalar                     | Scalar parameter expanded to match number of elements of input.<br><br>See “Nonscalar Input and Scalar Parameter” on page 60-36.                           |
| Combination of scalar and nonscalar | No corresponding parameter | Scalar inputs expanded to match dimensions of largest nonscalar input.<br><br>See “Scalar and Nonscalar Inputs and No Associated Parameter” on page 60-36. |

### Scalar Input and Nonscalar Parameter

In this example, the Constant block input to the Gain block is scalar. The Gain block **Gain** parameter is a nonscalar. Simulink expands the scalar input to match the dimensions of a nonscalar **Gain** parameter, as reflected in the simulation results in the Display block.

### Nonscalar Input and Scalar Parameter

In this example, the Constant block input to the Gain block is nonscalar. The Gain block **Gain** parameter is a scalar. Simulink expands the scalar parameter to match the dimensions of a nonscalar input from the Constant block, as reflected in the simulation results in the Display block.

### Scalar and Nonscalar Inputs and No Associated Parameter

In this example, the Constant1 block input to the Sum block is nonscalar, and the Constant2 block input is scalar. The Sum block has no associated parameter. Simulink expands the scalar input from Constant2 to match to the dimensions of the nonscalar Constant1 block input. The input is expanded to the vector [3 3 3].

## **Related Examples**

## Display Signal Sources and Destinations

### In this section...

“About Signal Highlighting” on page 60-38

“Highlighting Signal Sources” on page 60-38

“Highlighting Signal Destinations” on page 60-39

“Removing Highlighting” on page 60-40

“Resolving Incomplete Highlighting to Library Blocks” on page 60-40

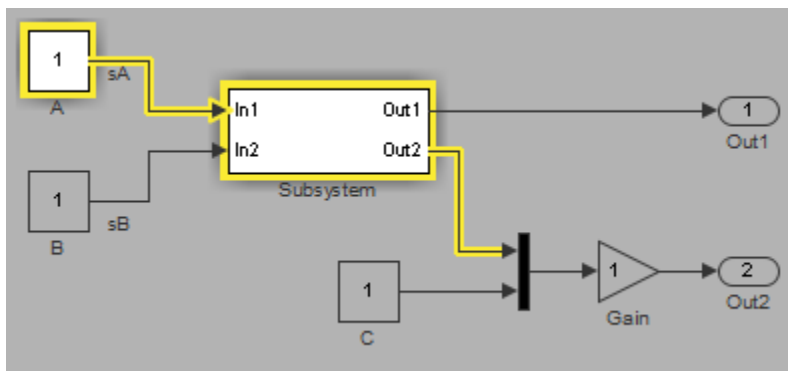

### About Signal Highlighting

You can highlight a signal and its source or destination block(s), then remove the highlighting once it has served its purpose. Signal highlighting crosses subsystem boundaries, allowing you to trace a signal across multiple subsystem levels. Highlighting does not cross the boundary into or out of a referenced model. If a signal is composite, all source or destination blocks are highlighted. (See “Composite Signals” on page 61-3.)

### Highlighting Signal Sources

To display the source block(s) of a signal, select the **Highlight Signal to Source** option from the context menu for the signal. This option highlights:

- All branches of the signal anywhere in the model
- All virtual blocks through which the signal passes
- The nonvirtual block(s) that write the value of the signal

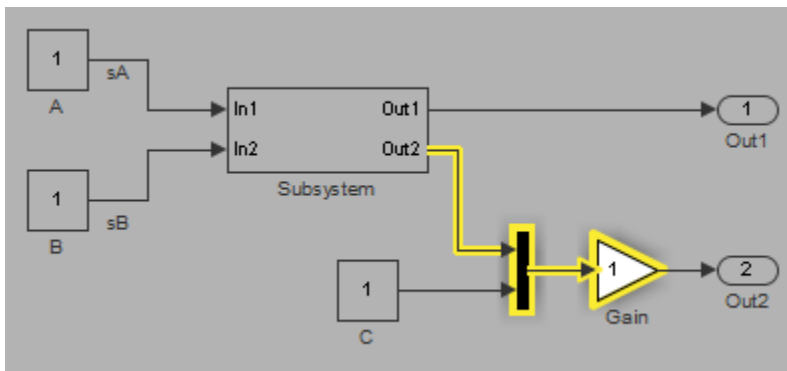

## Highlighting Signal Destinations

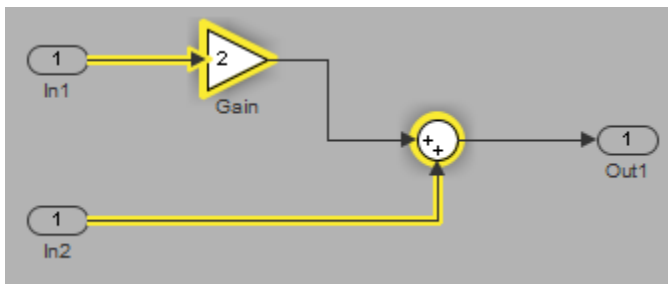

To display the destination blocks of a signal, select the **Highlight Signal to Destination** option from the context menu for the signal. This option highlights:

- All branches of the signal anywhere in the model
- All virtual blocks through which the signal passes
- The nonvirtual block(s) that read the value of the signal
- The signal and destination block for all blocks that are duplicates of the inport block for the line that you select

In this example, the selected signal highlights the Gain block as the destination block.

In the next example, selecting the signal from In2 and choosing the **Highlight Signal to Destination** option highlights the signal and destination block for In2 and In1, because In1 and In2 are duplicate inport blocks.

## Removing Highlighting

To remove all highlighting, select **Remove Highlighting** from the model's context menu, or select **Display > Remove Highlighting**.

## Resolving Incomplete Highlighting to Library Blocks

If the path from a source block or to a destination block includes an unresolved reference to a library block, the highlighting options highlight the path from or to the library block, respectively. To display the complete path, first update the diagram (for example, by pressing **Ctrl+D**). The update of the diagram resolves all library references and displays the complete path to a destination block or from a source block.

# Signal Ranges

**In this section...**

“About Signal Ranges” on page 60-41

“Blocks That Allow Signal Range Specification” on page 60-41

“Specifying Ranges for Signals” on page 60-42

“Checking for Signal Range Errors” on page 60-43

## About Signal Ranges

Many Simulink blocks allow you to specify a range of valid values for their output signals. Simulink provides a diagnostic that you can enable to detect when blocks generate signals that exceed their specified ranges during simulation. See the sections that follow for more information.

## Blocks That Allow Signal Range Specification

The following blocks allow you to specify ranges for their output signals:

- Abs
- Constant
- Data Store Memory
- Data Type Conversion
- Difference
- Discrete Derivative
- Discrete-Time Integrator
- Gain
- Inport
- Interpolation Using Prelookup
- 1-D Lookup Table
- 2-D Lookup Table
- n-D Lookup Table
- Math Function

- MinMax
- Multiport Switch
- Outport
- Product, Divide, Product of Elements
- Relay
- Repeating Sequence Interpolated
- Repeating Sequence Stair
- Saturation
- Saturation Dynamic
- Signal Specification
- Sum, Add, Subtract, Sum of Elements
- Switch

## Specifying Ranges for Signals

In general, use the **Output minimum** and **Output maximum** parameters that appear on a block parameter dialog box to specify a range of valid values for the block output signal. Exceptions include the **Data Store Memory**, **Inport**, **Outport**, and **Signal Specification** blocks, for which you use their **Minimum** and **Maximum** parameters to specify a signal range. See “Blocks That Allow Signal Range Specification” on page 60-41 for a list of applicable blocks.

When specifying minimum and maximum values that constitute a range, enter only expressions that evaluate to a scalar, real number with **double** data type. The default values for the minimum and maximum are [ ] (unspecified). The scalar values that you specify are subject to expansion, for example, when the block inputs are nonscalar or bus signals (see “Scalar Expansion of Inputs and Parameters” on page 60-34).

---

**Note:** You cannot specify the minimum or maximum value as NaN, **inf**, or **-inf**.

---

## Specifying Ranges for Complex Numbers

When you specify an **Output minimum** and/or **Output maximum** for a signal that is a complex number, the specified minimum and maximum values apply separately to the

real part and to the imaginary part of the complex number. If the value of either part of the number is less than the minimum, or greater than the maximum, the complex number is outside the specified range. No range checking occurs against any combination of the real and imaginary parts, such as  $(\text{sqrt}(a^2+b^2))$

## Checking for Signal Range Errors

Simulink provides a diagnostic named **Simulation range checking**, which you can enable to detect when signals exceed their specified ranges during simulation. When enabled, Simulink compares the signal values that a block outputs with both the specified range (see “Specifying Ranges for Signals” on page 60-42) and the block data type. That is, Simulink performs the following check:

$$\text{DataTypeMin} \leq \text{MinValue} \leq \text{VALUE} \leq \text{MaxValue} \leq \text{DataTypeMax}$$

where

- **DataTypeMin** is the minimum value representable by the block data type.
- **MinValue** is the minimum value the block should output, specified by, e.g., **Output minimum**.
- **VALUE** is the signal value that the block outputs.
- **MaxValue** is the maximum value the block should output, specified by, e.g., **Output maximum**.
- **DataTypeMax** is the maximum value representable by the block data type.

---

**Note:** It is possible to overspecify how a block handles signals that exceed particular ranges. For example, you can specify values (other than the default values) for both signal range parameters and enable the **Saturate on integer overflow** parameter. In this case, Simulink displays a warning message that advises you to disable the **Saturate on integer overflow** parameter.

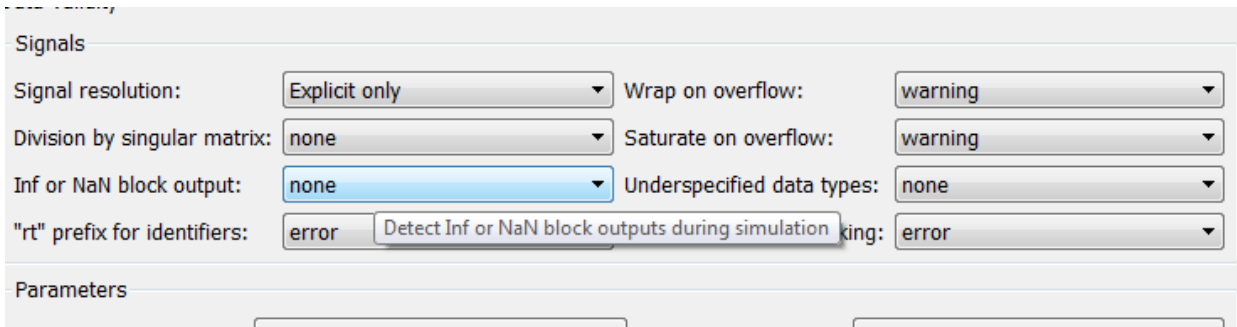

---

## Enabling Simulation Range Checking

To enable the **Simulation range checking** diagnostic:

- 1 In your model window, select **Simulation > Model Configuration Parameters**.  
Simulink displays the Configuration Parameters dialog box.

- 2 In the **Select** tree on the left side of the Configuration Parameters dialog box, click the **Diagnostics > Data Validity** category. On the right side under **Signals**, set the **Simulation range checking** diagnostic to error or warning.

- 3 Click **OK** to apply your changes and close the Configuration Parameters dialog box.

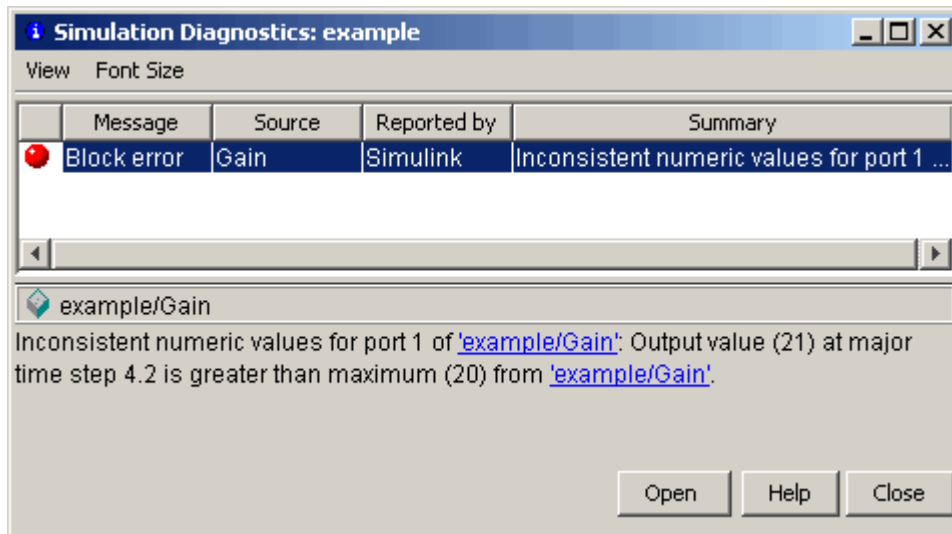

See “Simulation range checking” for more information.

### Simulating Models with Simulation Range Checking

To check for signal range errors or warnings:

- 1 Enable the **Simulation range checking** diagnostic for your model (see “Enabling Simulation Range Checking” on page 60-43).
- 2 In your model window, select **Simulation > Run** to simulate the model.

Simulink simulates your model and performs signal range checking. If a signal exceeds its specified range when the **Simulation range checking** diagnostic specifies **error**, Simulink stops the simulation and displays an error message:

Otherwise, if a signal exceeds its specified range when the **Simulation range checking** diagnostic specifies **warning**, Simulink displays a warning message in the MATLAB Command Window:

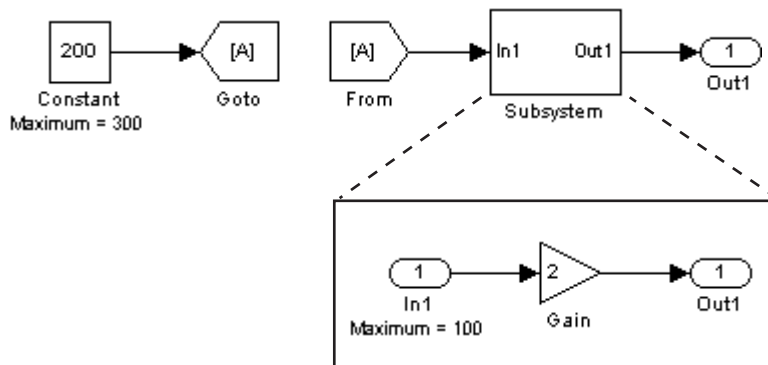

```
Warning: Inconsistent numeric values for port 1
of 'example/Gain': Output value (21) at major
time step 4.2 is greater than maximum (20) from
'example/Gain'.
```

Each message identifies the block whose output signal exceeds its specified range, and the time step at which this violation occurs.

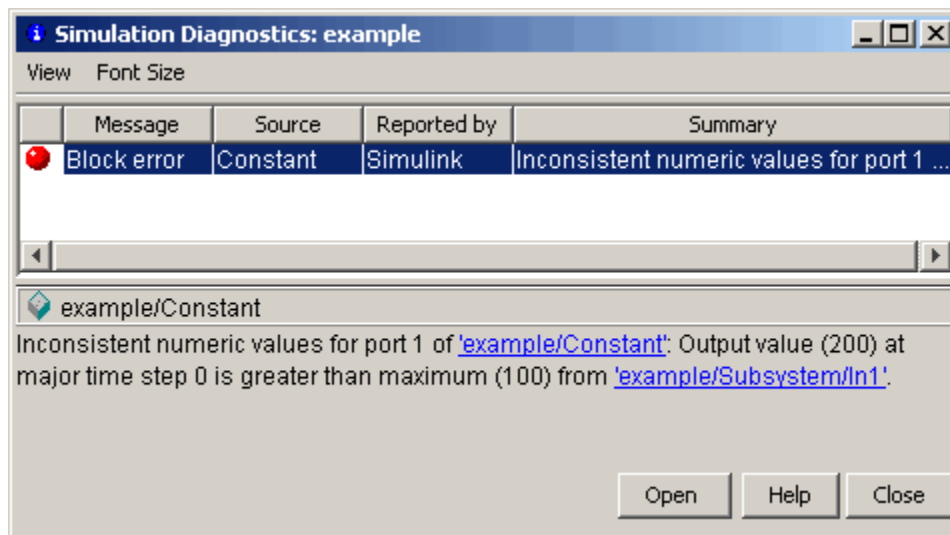

### Signal Range Propagation for Virtual Blocks

Some virtual blocks (see “Nonvirtual and Virtual Blocks” on page 31-2) allow you to specify ranges for their output signals, for example, the **Inport** and **Outport** blocks. When the **Simulation range checking** diagnostic is enabled for a model that contains such blocks, the signal range of the virtual block propagates backward to the first instance of a nonvirtual block whose output signal it receives. If the nonvirtual block specifies different values for its own range, Simulink performs signal range checking with the *tightest* range possible. That is, Simulink checks the signal using the larger minimum value and the smaller maximum value.

For example, consider the following model:

In this model, the Constant block specifies its **Output maximum** parameter as 300, and that of the Inport block is set to 100. Suppose you enable the **Simulation range checking** diagnostic and simulate the model. The Inport block back propagates its maximum value to the nonvirtual block that precedes it, i.e., the Constant block. Simulink then uses the smaller of the two maximum values to check the signal that the Constant block outputs. Because the Constant block outputs a signal whose value (200) exceeds the tightest range, Simulink displays the following error message:

### About Initialization

---

**Note:** For information about initializing bus signals, see “Specify Initial Conditions for Bus Signals” on page 61-65.

---

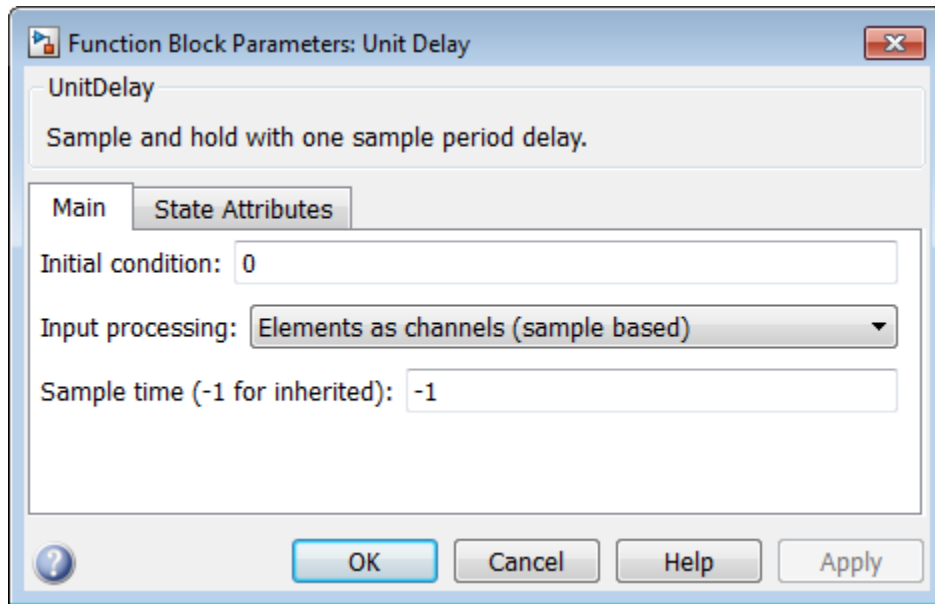

Simulink allows you to specify the initial values of signals and discrete states, i.e., the values of the signals and discrete states at the **Start time** of the simulation. You can use signal objects to specify the initial values of any signal or discrete state in a model. In addition, for some blocks, e.g., **Outport**, **Data Store Memory**, or **Memory**, you can use either a signal object or a block parameter or both to specify the initial value of a block state or output. In such cases, Simulink checks to ensure that the values specified by the signal object and the parameter are consistent.

When you specify a signal object for signal or discrete state initialization, or a variable as the value of a block parameter, Simulink resolves the name that you specify to an appropriate object or variable, as described in “Symbol Resolution” on page 4-95.

A given signal can be associated with at most one signal object under any circumstances. The signal can refer to the object more than once, but every reference must resolve to exactly the same object. A different signal object that has exactly the same properties will not meet the requirement for uniqueness. A compile-time error occurs if a model associates more than one signal object with any signal. For more information, see `Simulink.Signal` and the `Merge` block.

## Using Block Parameters to Initialize Signals and Discrete States

For blocks that have an initial value or initial condition parameter, you can use that parameter to initialize a signal. For example, the following Block Parameters dialog box initializes the signal for a Unit Delay block with an initial condition of 0.

## Use Signal Objects to Initialize Signals and Discrete States

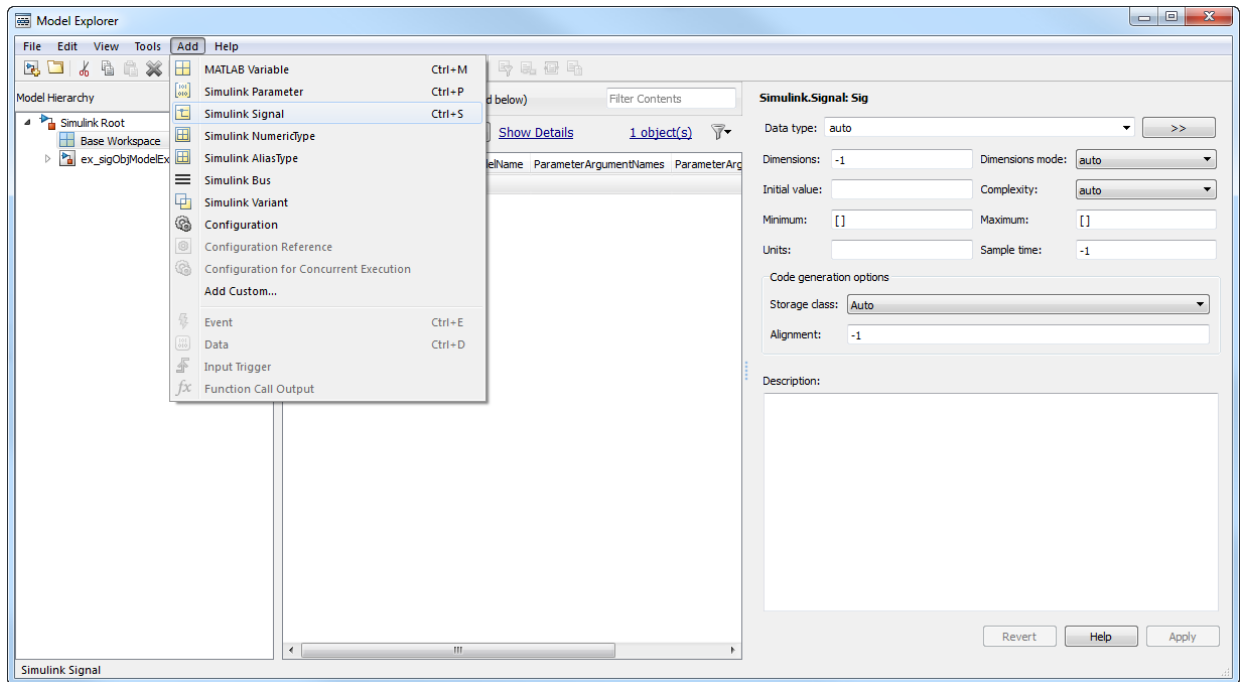

You can use signal objects that have a storage class other than 'auto' or 'SimulinkGlobal' to initialize

- Discrete states with an initial condition parameter
- Signals in a model except bus signals and blocks that output constant value

To specify an initial value, use the Model Explorer or MATLAB commands to do the following:

- 1 Create the signal object.

### Model Explorer

## MATLAB Command

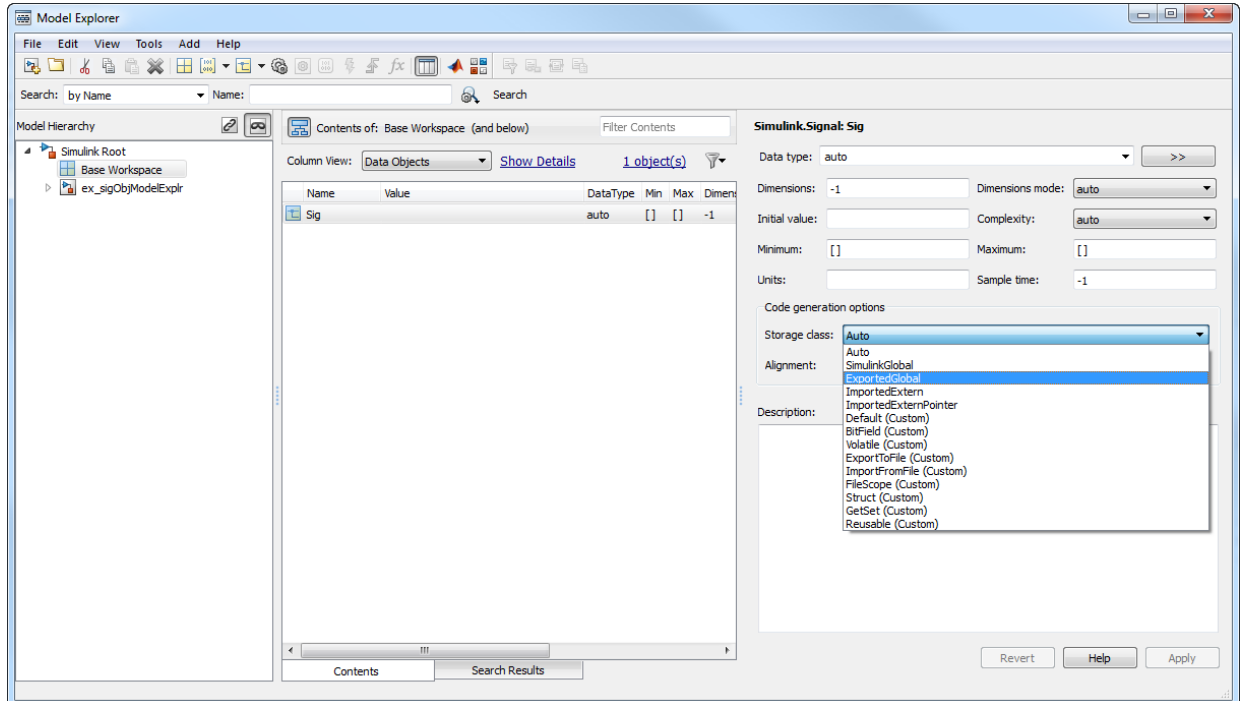

```
S1 = Simulink.Signal;
```

The name of the signal object must be the same as the name of the signal that the object is initializing. Although not required, consider setting the **Signal name must resolve to Simulink signal object** option in the Signal Properties dialog box. This setting makes signal objects in the MATLAB workspace consistent with signals that appear in your model.

Consider using the Data Object Wizard to create signal objects. The Data Object Wizard searches a model for signals for which signal objects do not exist. You can then selectively create signal objects for multiple signals listed in the search results with a single operation. For more information about the Data Object Wizard, see “Create Data Objects for a Model Using Data Object Wizard” on page 55-45 in the Simulink documentation.

- Set the signal object's storage class to a value other than 'auto' or 'SimulinkGlobal'.

## Model Explorer

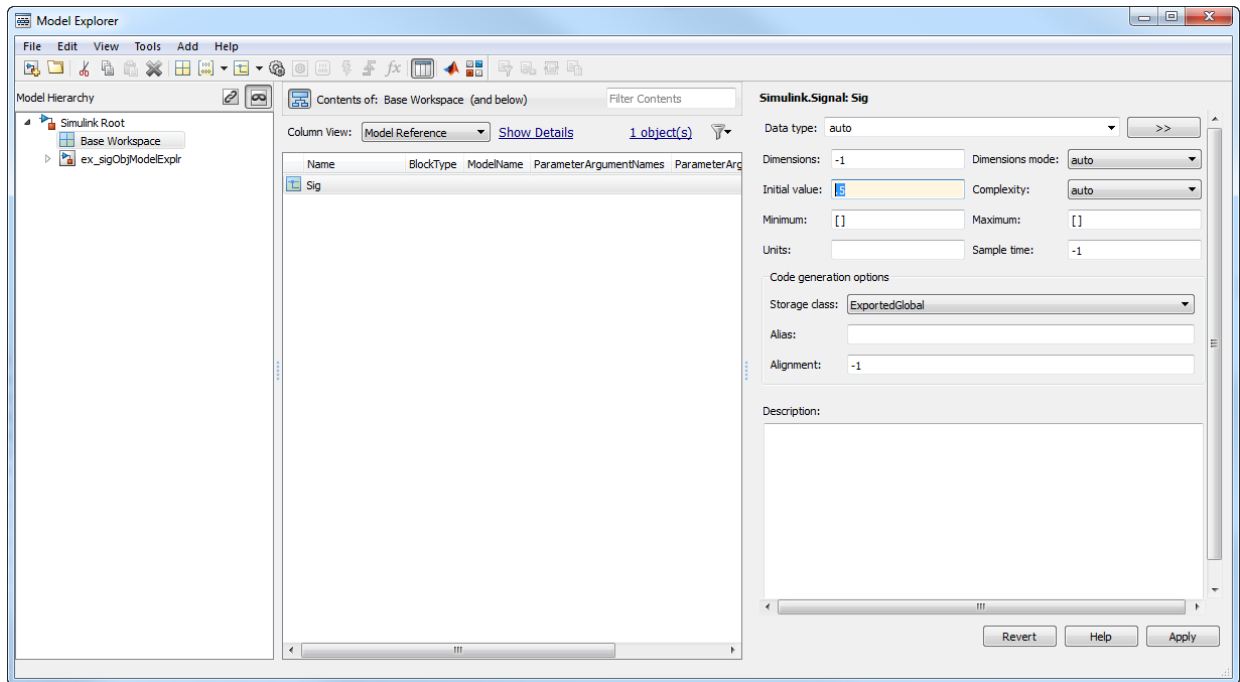

## MATLAB Command

```
S1.CoderInfo.StorageClass='ExportedGlobal';
```

- Set the initial value. You can specify a MATLAB expression, including the name of a workspace variable, that evaluates to a numeric scalar value or array.

The Simulink engine converts the initial value so the type, complexity, and dimension are consistent with the corresponding block parameter value. If you specify an invalid value or expression, an error message appears when you update the model.

## Model Explorer

## MATLAB Command

```
S1.InitialValue = '0.5'
```

If you can also use a block parameter to set the initial value of the signal or state, you should set the parameter either to empty (`[]`) or to the same value as the initial value of the signal object. If you set the parameter value to empty, Simulink uses the value specified by the signal object to initialize the signal or state. If you set the parameter to any other value, Simulink compares the parameter value to the signal object value and displays an error if they differ.

Some initial value settings may depend on the initialization mode. For more information, see “Underspecified initialization detection”.

**Classic initialization mode:** In this mode, initial value settings for signal objects that represent the following signals and states override the corresponding block parameter initial values if undefined (specified as `[]`):

- Output signals of conditionally executed subsystems and Merge blocks
- Block states

**Simplified initialization mode:** In this mode, initial values of signal objects associated with the output of the following blocks are ignored. The initial values of the corresponding blocks are used instead.

- Output signals of conditionally executed subsystems
- Merge blocks

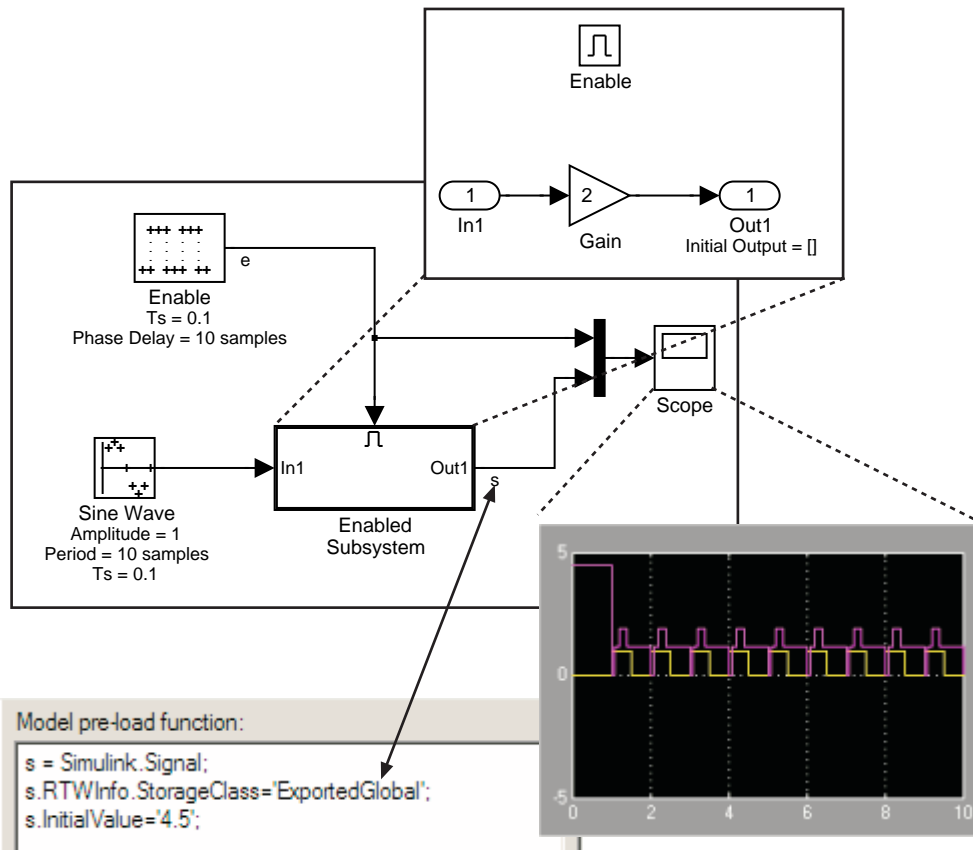

## Using Signal Objects to Tune Initial Values

Simulink allows you to use signal objects as an alternative to parameter objects (see ) to tune the initial values of block outputs and states that can be specified via a tunable parameter. To use a signal object to tune an initial value, create a signal object with the same name as the signal or state and set the signal object's initial value to an expression that includes a variable defined in the MATLAB workspace. You can then tune the initial value by changing the value of the corresponding workspace variable during the simulation.

For example, suppose you want to tune the initial value of a **Memory** block state named **M1**. To do this, you might create a signal object named **M1**, set its storage class to `'ExportedGlobal'`, set its initial value to `K` (`M1.InitialValue='K'`), where `K` is a workspace variable in the MATLAB workspace, and set the corresponding initial condition parameter of the **Memory** block to `[]` to avoid consistency errors. You could then change the initial value of the **Memory** block's state any time during the simulation by changing the value of `K` at the MATLAB command line and updating the block diagram (e.g., by typing **Ctrl+D**).

## Example: Using a Signal Object to Initialize a Subsystem Output

The following example shows a signal object specifying the initial output of an enabled subsystem.

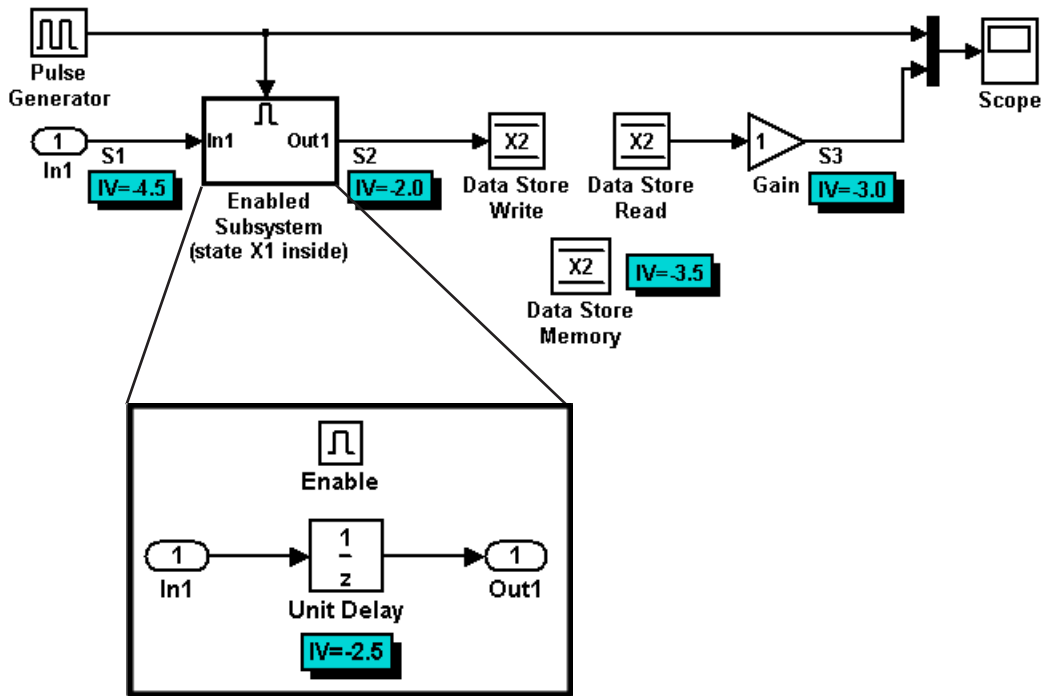

Signal `s` is initialized to 4.5. To avoid a consistency error, the initial value of the enabled subsystem's Output block must be `[]` or 4.5.

If you need a signal object and its initial value setting to persist across Simulink sessions, see “Create Persistent Data Objects” on page 55-55.

## Initialization Behavior Summary for Signal Objects

The following model and table show different types of signals and discrete states that you can initialize and the simulation behavior that results for each.

| Signal or Discrete State | Description  | Behavior  |
|--------------------------|--|---|
| S1                       | Root inport  | <ul style="list-style-type: none"> <li>• Initialized to <code>S1.InitialValue</code>.</li> <li>• If you use the <b>Data Import/Export</b> pane of the Configuration Parameters dialog to specify values for the root inputs, the initial value is overwritten and may differ at each time step. Otherwise, the value remains constant.</li> </ul>   |
| X1                       | Unit Delay block — Block with a discrete state that has an initial condition | <ul style="list-style-type: none"> <li>• Initialized to <code>X1.InitialValue</code>.</li> <li>• Simulink checks whether <code>X1.InitialValue</code> matches the initial condition specified for the block and displays an error if a mismatch occurs.</li> <li>• At first write, the output equals <code>X1.InitialValue</code> and the state equals S1.</li> <li>• At each time step after the first write, the output equals the state and the state is updated to equal S1.</li> </ul> |

| Signal or Discrete State | Description                    | Behavior  |
|--------------------------|--------------------------------|---|
|                          |                                | <ul style="list-style-type: none"> <li>If the block is inside an enabled subsystem, you can use the initial value as a reset value if the subsystem's Enable block parameter <b>States when enabling</b> is set to <b>reset</b>.</li> </ul>   |
| X2                       | Data Store Memory block        | <ul style="list-style-type: none"> <li>Data type work (DWork) vector initialized to <code>X2.InitialValue</code>. For information on work vectors, see “DWork Vector Basics”.</li> <li>Simulink checks whether <code>X2.InitialValue</code> matches the initial condition specified for the block, and displays an error if a mismatch occurs.</li> <li>Data Store Write blocks overwrite the value.</li> </ul>   |
| S2                       | Output of an enabled subsystem | <ul style="list-style-type: none"> <li>Initialized to <code>S2.InitialValue</code> or the value of the Outputport block. If multiple initial values are specified for the same signal, all initial values must be the same.</li> <li>The first write occurs when the subsystem is enabled. The block feeding the subsystem output sets the value.</li> <li>The initial value is also used as a reset value if the subsystem's Enable block parameter <b>States when enabling</b> or Outputport block parameter <b>Output when disabled</b> is set to <b>reset</b>.</li> </ul> |
| S3                       | Persistent signals             | <ul style="list-style-type: none"> <li>Initialized to <code>S3.InitialValue</code>.</li> <li>The output value is reset by the block at each time step.</li> <li>Affects code generation only. For simulation, setting the initial value for <code>S3</code> is irrelevant because the values are overwritten at the model's simulation start time.</li> </ul>   |

## Test Points

### In this section...

“What Is a Test Point?” on page 60-57

“Designating a Signal as a Test Point” on page 60-57

“Displaying Test Point Indicators” on page 60-58

### What Is a Test Point?

A *test point* is a signal that Simulink guarantees to be observable when using a Floating Scope block in a model. Simulink allows you to designate any signal in a model as a test point.

Designating a signal as a test point exempts the signal from model optimizations, such as signal storage reuse (see “Signal storage reuse”) and block reduction (see “Implement logic signals as Boolean data (vs. double)”). These optimizations render signals inaccessible and hence unobservable during simulation.

Signals designated as test points will not have algebraic loops minimized, even if **Minimize algebraic loop occurrences** is selected (for more information about algebraic loops, see “Algebraic Loops” on page 3-37).

Test points are primarily intended for use when generating code from a model with Simulink Coder. For more information about test points in the context of code generation, see “Signals with Test Points”.

Marking a signal as a test point has no impact on signal logging that uses the Dataset logging format. For information about logging signals, see “Export Signal Data Using Signal Logging” on page 57-36.

### Designating a Signal as a Test Point

Use one of the following ways to designate a signal as a test point:

- Open the signal's **Signal Properties** dialog and check **Test Point** in the **Logging and accessibility** section.
- Resolve the signal to a base workspace Simulink.Signal object whose storage class is SimulinkGlobal.

The second method is more convenient when you want to control test pointing without having to alter the model.

### Model Referencing Limitation

Simulink might not log all signals configured for signal logging in a referenced model, if *all* of these conditions exist:

- The referenced model sets the **Model Configuration Parameters > Data Import/Export > Signal logging format** parameter to `ModelDataLogs`.
- The referenced model uses a library and you make a change that affects the set of test points in a library, or that changes the set of models that a library references.

To ensure proper signal logging for the referenced model:

- 1 Open the referenced model.
- 2 Perform an update diagram on the referenced model (for example, by pressing **Ctrl +D**).
- 3 Save the referenced model.

### Displaying Test Point Indicators

By default, Simulink displays an indicator on each signal whose **Signal Properties > Test point** option is enabled. For example, in the following model signals `s2` and `s3` are test points:

---

**Note:** Simulink does not display an indicator on a signal that is specified as a test point by a `Simulink.Signal` object, because such a specification is external to the graphical model.

---

A signal that is a test point can also be logged. See “Export Signal Data Using Signal Logging” on page 57-36 for information about signal logging. The appearance of the indicator changes to indicate signals for which logging is also enabled.

To turn display of test point indicators on or off, in the Simulink Editor, select or clear **Display > Signals & Ports > Testpoint & Logging Indicators**.

### Ports & Signals Menu

The **Display > Signals & Ports** submenu of the Simulink Editor offers the following options for displaying signal properties on the block diagram:

- Linearization Indicators
- Port Data Types (See “Port Data Types” on page 60-61)
- Design Ranges (See “Design Ranges” on page 60-61)
- Signal Dimensions (See “Signal Dimensions” on page 60-62)
- Storage Class
- Testpoint/Logging Indicators
- Signal Resolution Indicators (See “Signal to Object Resolution Indicator” on page 60-62)
- Viewer Indicators
- Wide Nonscalar Lines (See “Wide Nonscalar Lines” on page 60-63)

In addition, you can display sample time information. If you first select **Display > Sample Time**, a submenu provides the choices of **Colors**, **Annotations** and **All**. The **Colors** option allows the block diagram signal lines and blocks to be color-coded based on the sample time types and relative rates. The **Annotations** option provides black codes on the signal lines which indicate the type of sample time. **All** causes both the colors and the annotations to display. All of these options cause a Sample Time Legend to appear. The legend contains a description of the type of sample time and the sample time

rate. If **Colors** is turned 'on', color codes also appear in the legend. The same is true if **Annotations** are turned 'on'.

## Port Data Types

Displays the data type of a signal next to the output port that emits the signal.

The notation (c) following the data type of a signal indicates that the signal is complex.

## Design Ranges

Displays the compiled design range of a signal next to the output port that emits the signal. The ranges are computed during an update diagram.

Ranges are displayed in the format [min..max]. In the above example, the design range at the output port of the Mux block is displayed as [-10..mixed], because the two

signals the Mux block combines have the same design minimum but different design maximums.

You can also use command-line parameters `CompiledPortDesignMin` and `CompiledPortDesignMax` to access the design minimum and maximum of port signals, respectively, at compile time. For more information, see “Common Block Properties”.

## Signal Dimensions

Display the dimensions of nonscalar signals next to the line that carries the signal.

The format of the display depends on whether the line represents a single signal or a bus. If the line represents a single vector signal, Simulink displays the width of the signal. If the line represents a single matrix signal, Simulink displays its dimensions as  $[N_1 \times N_2]$  where  $N_i$  is the size of the  $i$ th dimension of the signal. If the line represents a bus carrying signals of the same data type, Simulink displays  $N\{M\}$  where  $N$  is the number of signals carried by the bus and  $M$  is the total number of signal elements carried by the bus. If the bus carries signals of different data types, Simulink displays only the total number of signal elements  $\{M\}$ .

## Signal to Object Resolution Indicator

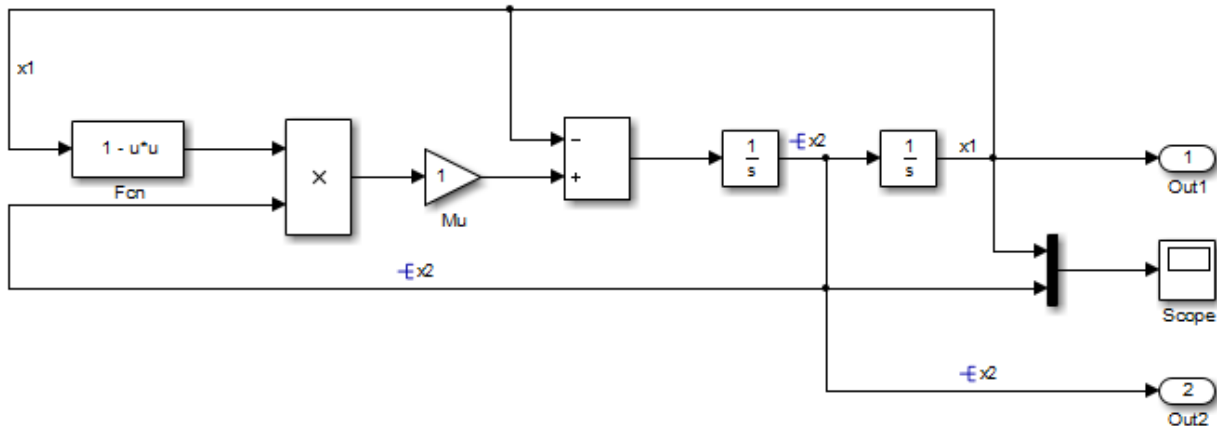

The Simulink Editor by default graphically indicates signals that must resolve to signal objects. For any labeled signal whose **Signal name must resolve to signal object** property is enabled, a signal resolution icon appears to the left of the signal name. The icon looks like this:

A signal resolution icon indicates only that a signal's **Signal name must resolve to signal object** property is enabled. The icon does not indicate whether the signal is actually resolved, and does not appear on a signal that is implicitly resolved without its **Signal name must resolve to signal object** property being enabled.

Where multiple labels exist, each label displays a signal resolution icon. No icon appears on an unlabeled branch. In the next figure, signal `x2` must resolve to a signal object, so a signal resolution icon appears to the left of the signal name in each label:

To suppress the display of signal resolution icons, in the model window deselect **Display > Signals & Ports > Signal to Object Resolution Indicator**, which is selected by default. To restore signal resolution icons, reselect **Signal to Object Resolution Indicator**. Individual signals cannot be set to show or hide signal resolution indicators independently of the setting for the whole model. For additional information, see:

- “Symbol Resolution” on page 4-95
- “Initialize Signals and Discrete States” on page 60-48
- `Simulink.Signal`

## Wide Nonscalar Lines

Draws lines that carry vector or matrix signals wider than lines that carry scalar signals.

See “Composite Signals” on page 61-3 for more information about vector and matrix signals.

“Simulation Options Dialog Box” on page 60-114

## About Signal Groups

The **Signal Builder** block displays and allows you to create or edit interchangeable groups of signal sources and quickly switch the groups into and out of a model.

Signal groups can greatly facilitate testing a model, especially when you use them with conjunction with **Simulink Assertion** blocks and the **Model Coverage Tool** from the **Simulink Verification and Validation**. For a description of the **Model Coverage Tool**, see “**Model Coverage Collection Workflow**”.

**Model Configuration Parameter Solver** pane settings can affect the **Signal Builder** block output. See “**Simulation Phases in Dynamic Systems**” on page 3-17 and “**Solvers**” on page 3-21 for a description of how solvers affect simulation.

## Using the Signal Builder Block with Fast Restart

After you turn on fast restart:

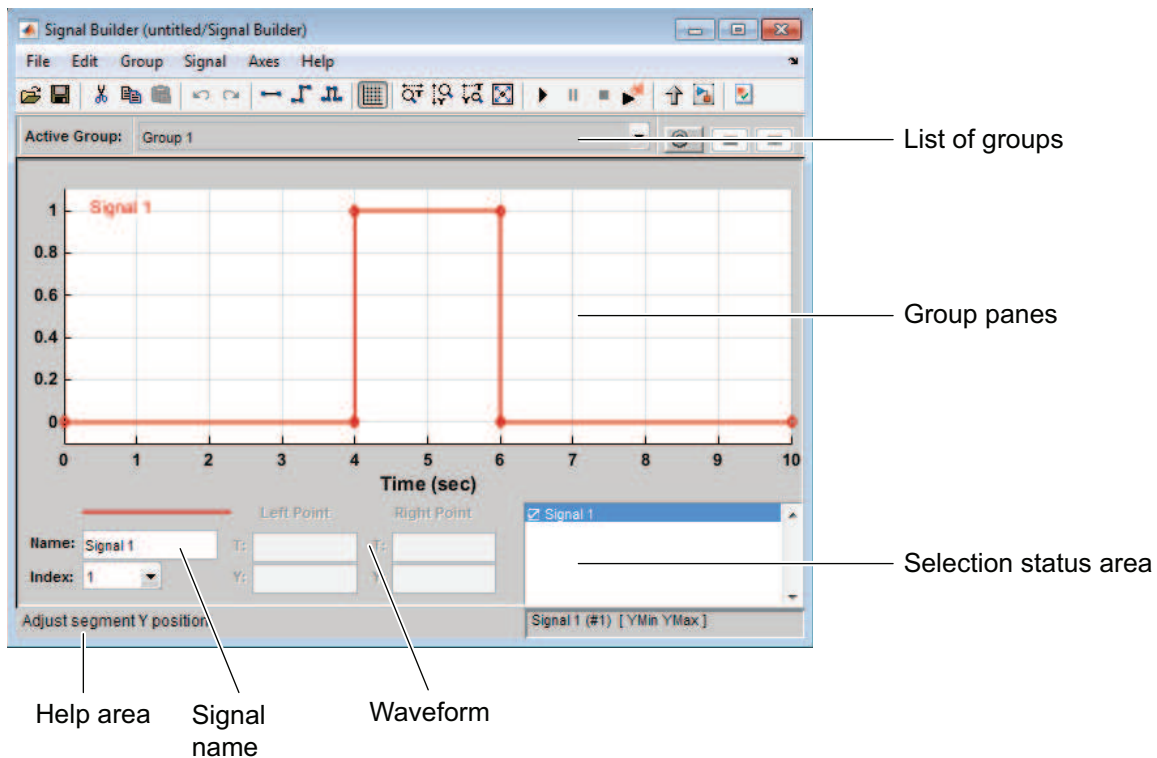

- In between runs, you can change data, rename signals and signal groups, and add new groups. You cannot:
  - Import signals or signal groups

- Change signal output settings
- You can click the **Run all** button once. To reenale the **Run all** button, toggle the fast restart button on the Simulink Editor tool bar. However, **Run all** does not use fast restart.

## Signal Builder Window

The Signal Builder block window allows you to define the shape of the signals (waveform) output by the block. You can specify any waveform that is piecewise linear.

To open the window, double-click the block. The Signal Builder window appears.

The Signal Builder window allows you to create and modify signal groups represented by a Signal Builder block. The Signal Builder window includes the following controls.

**Group Pane**

Displays the set of interchangeable signal source groups represented by the block. The pane for each group displays an editable representation of each waveform in the group. The name of the group appears at the top of the pane. Only one pane is visible at a time. To display a group that is not visible, from the list, select the group name. The block outputs the group of signals whose pane is currently visible. Each pane occupies a pane in the Signal Builder block dialog box.

**Signal Axes**

The signals appear on separate axes that share a common time range (see “Signal Builder Time Range” on page 60-111). This presentation allows you to compare the relative timing of changes in each signal. The Signal Builder automatically scales the range of each axis to accommodate the signal that it displays. Use the Signal Builder **Axes** menu to change the time (T) and amplitude (Y) ranges of the selected axis.

**Signal List**

Displays the names and visibility (see “Editing Signals” on page 60-69) of the signals that belong to the currently selected signal group. Clicking an entry in the list selects the signal. Double-clicking a signal entry in the list hides or displays the waveform on the group pane.

**Selection Status Area**

Displays the name of the currently selected signal and the index of the currently selected waveform segment or point.

**Waveform Coordinates**

Displays the coordinates of the currently selected waveform segment or point. You can change the coordinates by editing the displayed values (see “Editing Waveforms” on page 60-106).

**Name**

Name of the currently selected signal. You can change the name of a signal by editing this field (see “Renaming a Signal” on page 60-75).

**Index**

Index of the currently selected signal. The index indicates the output port at which the signal appears. An index of 1 indicates the topmost output port, 2 indicates the second

port from the top, and so on. You can change the index of a signal by editing this field (see “Changing a Signal Index” on page 60-78).

### **Help Area**

Displays context-sensitive tips on using Signal Builder window features.

### **Editing Signal Groups**

The Signal Builder window allows you to create, rename, move, then delete signal groups from the set of groups represented by a Signal Builder block.

#### **Creating and Deleting Signal Groups**

To create a signal group:

- 1** In Signal Builder, copy an existing signal group.
- 2** Modify it to suit your needs.

To copy an existing signal group:

- 1** In Signal Builder, select the group from the list.
- 2** Select **Group > Copy**.

A new group is created.

To delete a group, select the group from the list, and select **Group > Delete**.

#### **Renaming Signal Groups**

To rename a signal group:

- 1** In Signal Builder, select the group from the list,
- 2** Select **Group > Rename**.

A dialog box appears.

- 3** Edit the existing name in the dialog box or enter a new name. Click **OK**.

#### **Moving Signal Groups**

To reposition a group in the stack of group panes:

- 1** In Signal Builder, select the pane.
- 2** To move the group lower in the stack, select **Group > Move Down**.
- 3** To move the pane higher in the stack, select **Group > Move Up**.

## Editing Signals

Signal Builder allows you to create, cut and paste, hide, and delete signals from signal groups.

### Creating Signals

To create a signal in the currently selected signal group:

- 1 In Signal Builder, from the Active Group list, select the group you want to add the signal to.
- 2 Select **Signal > New**.

The menu lists the waveforms you can add (described in the table).

| Waveform | Description       | Inputs   |
|----------|-------------------|--|
| Constant | Constant waveform | None.  |
| Step     | Step waveform     | None.  |
| Pulse    | Pulse waveform    | None.  |
| Square   | Square waveform   | <ul style="list-style-type: none"> <li>• <b>Frequency</b><br/>Waveform frequency, in hertz</li> <li>• <b>Amplitude</b><br/>Waveform amplitude</li> <li>• <b>Offset</b><br/>Waveform vertical offset</li> <li>• <b>% Duty cycle</b><br/>Percent of the period the signal is positive (a value between 0 and 100)</li> </ul> |
| Triangle | Triangle waveform | <ul style="list-style-type: none"> <li>• <b>Frequency</b><br/>Waveform frequency, in hertz.</li> <li>• <b>Amplitude</b><br/>Waveform amplitude</li> </ul>  |

| Waveform               | Description  | Inputs   |
|------------------------|--|--|
|                        |  | <ul style="list-style-type: none"> <li>• <b>Offset</b><br/>Waveform vertical offset</li> </ul>   |
| Sampled Sin            | Sampled sinewave waveform  | <ul style="list-style-type: none"> <li>• <b>Frequency (Hz)</b><br/>Waveform frequency, in hertz</li> <li>• <b>Amplitude</b><br/>Waveform amplitude</li> <li>• <b>Offset</b><br/>Waveform vertical offset</li> <li>• <b>Samples Per Period</b><br/>Number of samples per waveform period</li> </ul>   |
| Sampled Gaussian Noise | Sampled Gaussian noise waveform based on a Gaussian distribution with input mean and standard deviation at input frequency | <ul style="list-style-type: none"> <li>• <b>Frequency</b><br/>Waveform frequency, in hertz</li> <li>• <b>Mean</b><br/>The mean value of the random variable output</li> <li>• <b>Standard Deviation</b><br/>The standard deviation squared of the random variable output</li> <li>• <b>Seed (empty to use current state)</b><br/>The initial seed value for the random number generator</li> </ul> |

| Waveform             | Description   | Inputs  |
|----------------------|---|---|
| Pseudorandom Noise   | Pseudorandom noise waveform based on a binomial distribution with upper and lower values at input frequency | <ul style="list-style-type: none"> <li>• <b>Frequency</b><br/>Frequency with which waveform fluctuates between <b>Upper value</b> and <b>Lower value</b>, in hertz</li> <li>• <b>Upper value</b><br/>Upper limit of signal</li> <li>• <b>Lower value</b><br/>Lower limit of signal</li> <li>• <b>Seed</b><br/>The initial seed value for the random number generator</li> </ul> |
| Poisson Random Noise | Poisson random noise waveform that alternates between 0 and 1   | <ul style="list-style-type: none"> <li>• <b>Avg rate (1/sec)</b><br/>Average rate of transition between 0 and 1</li> <li>• <b>Seed (empty to use current state)</b><br/>The initial seed value for the random number generator</li> </ul>   |

| Waveform | Description  | Inputs   |
|----------|--|--|
| Custom   | Custom piecewise linear waveform; custom values must fit within the display area | <ul style="list-style-type: none"> <li>• <b>Time values</b><br/>Vector of two or more time coordinates</li> <li>• <b>Y values</b><br/>Vector of two or more signal amplitudes that correspond to the values in <b>Time values</b></li> </ul> <p>The entries in either field can be any MATLAB expression that evaluates to a vector, including the results from the evaluation of a MATLAB workspace variable. The resulting vectors must be of equal length.</p> <hr/> <p><b>Note:</b> Signal Builder displays a warning if you add a custom waveform with a large number of data points (100,000,000 or more).</p> |

- 3 Select the waveform you want to add.
- 4 Specify the inputs (in prompt), and click **OK**.

If you select a standard waveform, Signal Builder adds a signal with that waveform to the group. If you select a custom waveform, you are prompted for **Time values** and **Y values**.

You can also use MATLAB workspace variables to create new signals.

- 1 In the MATLAB Command Window, create data for two variables,  $t$  and  $y$ .

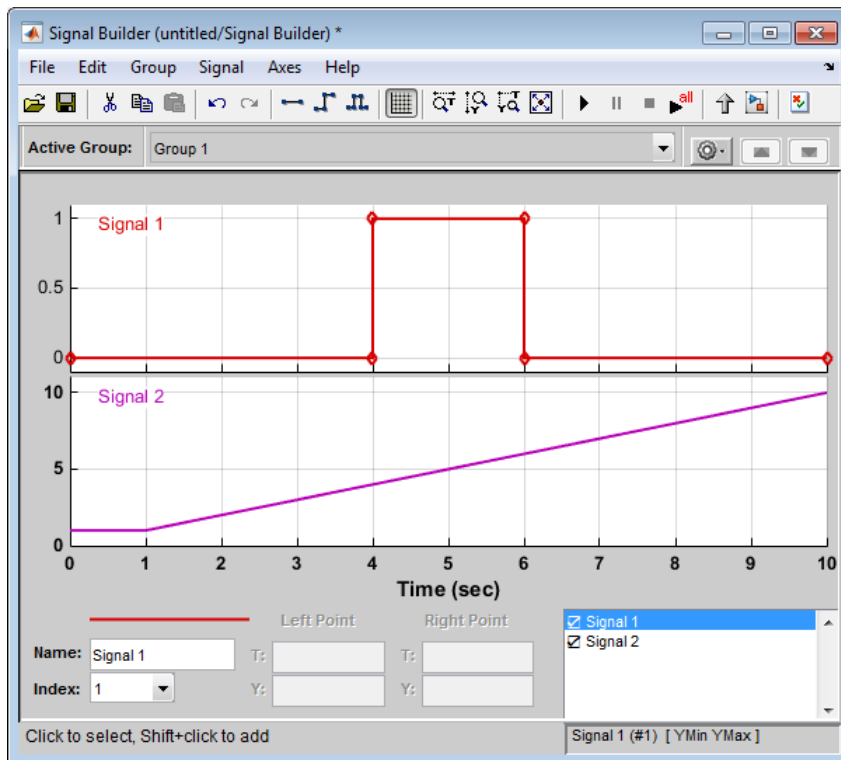

```
t = 1:10
y = 1:10
```

These vectors must be the same size.

- 2 Create a model and add a Signal Builder block.
- 3 Double-click the Signal Builder block.

- 4 Select **Signal > New > Custom**.
- 5 In the Custom Waveform window, enter  $t$  in the **Time values** field and  $y$  in the **Y values** field and then click **OK**.

The Signal Builder block window displays the new signal as Signal 2.

### Defining Signal Output

To specify the type of output to use for sending test signals:

- 1 In Signal Builder, select **Signal > Output**.
- 2 From the list, select:
  - **Ports**

Default. Sends individual signals from the block. An output port named Signal *N* appears for each Signal *N*.

- **Bus**

Sends single, virtual, nonhierarchical bus of signals from the block. An output port named Bus appears.

---

**Tip**

- You cannot use the **Bus** option to create a bus of nonvirtual signals.
  - The **Bus** option enables you to change your model layout without having to reroute Signal Builder block signals. Use the **Bus Selector** block to select the signals from this bus.
  - If you create a Signal Builder block using the Signal & Scope Manager or using the **Create & Connect Generator** option from a signal line context menu, you cannot define signal output. In these cases, the block sends individual signals.
- 

**Copying and Pasting Signals**

To copy a signal from one group and paste it into another group as a new signal:

- 1 In Signal Builder, select the signal you want to copy.
- 2 Select **Edit > Copy**.
- 3 Select the group you want to paste the signal into.
- 4 Select **Edit > Paste**.

To copy a signal from one axis and paste it into another axis to replace its signal:

- 1 Select the signal you want to copy.
- 2 Select **Edit > Copy**.
- 3 Select the signal on the axis that you want to update.
- 4 Select **Edit > Paste**.

**Deleting Signals**

To delete a signal, in Signal Builder, select the signal and choose **Delete** or **Cut** from the **Edit** menu. Signal Builder deletes the signal from the current group. Because each

signal group must contain the same number of signals, Signal Builder also deletes all signals sharing the same index in the other groups.

### Renaming a Signal

To rename a signal:

- 1 In Signal Builder, select **Signal > Rename**.

A dialog box appears with an edit field that displays the current name of the signal.

- 2 Edit or replace the current name with a new name.
- 3 Click **OK**.

You can also edit the signal name in the **Name** field in the lower-left corner of the Signal Builder window.

### Replacing a Signal

To replace a signal:

- 1 In Signal Builder, select the signal, then select **Signal > Replace with**.

A menu of waveforms appears. It includes a set of standard waveforms (**Constant**, **Step**, and so on) and a **Custom** waveform option.

- 2 Select one of the waveforms.

If you select a standard waveform, the Signal Builder replaces a signal in the currently selected group with that waveform. For other waveforms, the Signal Builder displays a dialog to allow you to provide input for the requested waveform.

| Waveform | Description        | Inputs   |
|----------|--------------------|--|
| Constant | Constant waveform. | None.  |
| Step     | Step waveform.     | None.  |
| Pulse    | Pulse waveform.    | None.  |
| Square   | Square waveform.   | <ul style="list-style-type: none"> <li>• <b>Frequency</b><br/>Waveform frequency, in Hertz.</li> <li>• <b>Amplitude</b><br/>Waveform amplitude.</li> </ul> |

| Waveform    | Description                | Inputs  |
|-------------|----------------------------|---|
|             |                            | <ul style="list-style-type: none"> <li>• <b>Offset</b><br/>Waveform vertical offset.</li> <li>• <b>% Duty cycle</b><br/>Percent of the period in which the signal is positive. Enter a value between 0 and 100.</li> </ul>  |
| Triangle    | Triangle waveform.         | <ul style="list-style-type: none"> <li>• <b>Frequency</b><br/>Waveform frequency, in Hertz.</li> <li>• <b>Amplitude</b><br/>Waveform amplitude</li> <li>• <b>Offset</b><br/>Waveform vertical offset.</li> </ul>  |
| Sampled Sin | Sampled sinewave waveform. | <ul style="list-style-type: none"> <li>• <b>Frequency (Hz)</b><br/>Waveform frequency, in Hertz.</li> <li>• <b>Amplitude</b><br/>Waveform amplitude</li> <li>• <b>Offset</b><br/>Waveform vertical offset.</li> <li>• <b>Samples Per Period</b><br/>Number of samples per waveform period.</li> </ul> |

| Waveform               | Description   | Inputs   |
|------------------------|---|--|
| Sampled Gaussian Noise | Sampled Gaussian noise waveform based on a Gaussian distribution with input mean and standard deviation at input frequency. | <ul style="list-style-type: none"> <li>• <b>Frequency</b><br/>Waveform frequency, in Hertz.</li> <li>• <b>Mean</b><br/>The mean value of the random variable output.</li> <li>• <b>Standard Deviation</b><br/>The standard deviation squared of the random variable output.</li> <li>• <b>Seed (empty to use current state)</b><br/>The initial seed value for the random number generator.</li> </ul> |
| Pseudorandom Noise     | Pseudorandom noise waveform based on a binomial distribution with upper and lower values at input frequency.                | <ul style="list-style-type: none"> <li>• <b>Frequency</b><br/>Frequency with which waveform fluctuates between <b>Upper value</b> and <b>Lower value</b>, in Hertz.</li> <li>• <b>Upper value</b><br/>Upper limit of signal.</li> <li>• <b>Lower value</b><br/>Lower limit of signal.</li> <li>• <b>Seed</b><br/>The initial seed value for the random number generator</li> </ul>                     |

| Waveform             | Description   | Inputs  |
|----------------------|---|---|
| Poisson Random Noise | Poisson random noise waveform that alternates between 0 and 1.                    | <ul style="list-style-type: none"> <li>• <b>Avg rate (1/sec)</b><br/>Average rate of transition between 0 and 1.</li> <li>• <b>Seed (empty to use current state)</b><br/>The initial seed value for the random number generator</li> </ul>  |
| Custom               | Custom piecewise linear waveform. Custom values must fit within the display area. | <ul style="list-style-type: none"> <li>• <b>Time values</b><br/>Vector of two or more time coordinates.</li> <li>• <b>Y values</b><br/>Vector of two or more signal amplitudes that correspond to the values in <b>Time values</b>.</li> </ul> <p>The entries in either field can be any MATLAB expression that evaluates to a vector. The resulting vectors must be of equal length.</p> <p><b>Note:</b> Signal Builder returns a warning if you add a custom waveform with a large number of data points (100,000,000 or more). You can then cancel the action.</p> |

You can also edit the signal name in the **Name** field in the lower-left corner of the Signal Builder window.

### Changing a Signal Index

To change a signal index:

- 1 In Signal Builder, select the signal, then select **Signal > Change Index**.

A dialog box appears with a drop-down list field containing the existing index of the signal.

- 2 From the drop-down list, another index and select **OK**. Or select an index from the **Index** list in the lower-left corner of the Signal Builder window.

### Hiding Signals

By default, the Signal Builder window displays the group waveforms in the group pane. To hide a waveform:

- 1 In Signal Builder, select the waveform, then select **Signal > Hide**.
- 2 To redisplay a hidden waveform, select the **Group** pane, then select **Signal > Show**.
- 3 Select the signal from the list. Alternatively, you can hide and redisplay a hidden waveform by double-clicking its name in the Signal Builder signal list (see “Signal List” on page 60-67).

## Creating Signal Group Sets

You can create signal groups in the **Signal Builder** block by:

- “Creating Signal Group Sets Manually” on page 60-79
- “Importing Signal Group Sets” on page 60-80
- “Importing Data with Custom Formats” on page 60-105

You can also use the `signalbuilder` function to populate the Signal Builder block.

### Creating Signal Group Sets Manually

This topic describes how to create signal group sets manually. If you have signal data files, such as those from test cases, consider importing this data as described in “Importing Signal Group Sets” on page 60-80.

To create an interchangeable set of signal groups:

- 1 Drag an instance of the Signal Builder block from the Simulink Sources library and drop it into your model.

By default, the block represents a single signal group containing a single signal source that outputs a square wave pulse.

- 2 Use the block signal editor (see “Signal Builder Window” on page 60-66) to create additional signal groups, add signals to the signal groups, modify existing signals and signal groups, and select the signal group that the block outputs.

---

**Note:** Each signal group must contain the same number of signals.

---

- 3 Connect the output of the block to your diagram.

The block displays an output port for each signal that the block can output.

You can create as many Signal Builder blocks as you like in a model, each representing a distinct set of interchangeable groups of signal sources. When a group has multiple signals, the signals might have different end times. However, **Signal Builder** block requires the end times of signals within a group to match. If a mismatch occurs, **Signal Builder** block matches the end times by holding the last value of the signal with the smaller end time.

See “Simulating with Signal Groups” on page 60-113 for information on using signal groups in a model.

### Importing Signal Group Sets

The topics in this section describe how to import signal data into the Signal Builder block. You should already have a signal data file whose contents you want to import. For example, you might have signal data from previously run test cases. See “Importing

Signal Groups from Existing Data Sets” on page 60-81 for a description of the data formats that the Signal Builder block accepts. The procedures in the following topics use the file `3Grp_3Sig.xls` in the folder `matlabroot\help\toolbox\simulink\ug\examples\signals` (open).

Signal Builder accepts signals only of type double.

### Importing Signal Groups from Existing Data Sets

You might have existing signal data sets that you want to enter into the Signal Builder block. The **File > Import from File** command on the Signal Builder window starts the Import File dialog box. This dialog box is modal, which means that focus cannot change to another MATLAB window while the dialog box is running. If you want to see changes in the Signal Builder window after you import data, do one of the following:

- Close the Import File dialog box.
- Set up the Import File dialog box and Signal Builder window side by side.

---

**Note:** You cannot undo the results of importing a signal data file. In addition, you cannot undo the last action performed before opening the Import File dialog box. When you close the Import File dialog box, the **Undo last edit** and **Redo last edit** buttons on the Signal Builder window are grayed out. These buttons are grayed out regardless of whether you imported a data file.

---

The Import File dialog box accepts the following appropriately formatted file types:

- Microsoft Excel (`.xls`, `.xlsx`)
- Comma-separated value (CSV) text files (`.csv`)
- MAT-files (`.mat`)

---

**Note:** Signal Builder block uses the `xlsread` function. See the `xlsread` documentation for information on supported platforms.

---

You can import your data set file only if it is appropriately formatted.

For Microsoft Excel spreadsheets:

- The Signal Builder block interprets the first row as signal name. If you do not specify a signal name, the Signal Builder block assigns a default one with the format `Imported_Signal #`, where `#` increments with each additional unnamed signal.
- The Signal Builder block interprets the first column as time. In this column, the time values must increase.
- The Signal Builder block interprets the remaining columns as signals.
- If there are multiple sheets:
  - Each sheet must have the same number of signals (columns).
  - Each sheet must have the same set of signal names (if any).
  - Each column on each sheet must have the same number of rows.
- Signal Builder block interprets each worksheet as a signal group.

This example contains an acceptably formatted Microsoft Excel spreadsheet. It has three worksheets named Group1, Group2, and Group3, representing three signal groups.

Time must be first column

| 1  | Time | DC In | Trigger | AC In | ← Signal names (optional) |
|----|------|-------|---------|-------|---------------------------|
| 2  | 0    | 1     | 2       | 3     |                           |
| 3  | 1    | 2     | 3       | 4     |                           |
| 4  | 2    | 3     | 4       | 5     |                           |
| 5  | 3    | 4     | 5       | 6     |                           |
| 6  | 4    | 5     | 6       | 7     |                           |
| 7  | 5    | 6     | 7       | 8     |                           |
| 8  | 6    | 7     | 8       | 9     |                           |
| 9  | 7    | 8     | 9       | 10    |                           |
| 10 | 8    | 9     | 10      | 11    |                           |
| 11 | 9    | 10    | 11      | 12    |                           |
| 12 | 10   | 11    | 12      | 13    |                           |
| 13 | 11   | 12    | 13      | 14    |                           |
| 14 | 12   | 13    | 14      | 15    |                           |
| 15 | 13   | 14    | 15      | 16    |                           |
| 16 | 14   | 15    | 16      | 17    |                           |
| 17 | 15   | 16    | 17      | 18    |                           |
| 18 |      |       |         |       |                           |

Worksheets - equivalent to signal group

For CSV text files:

- Each file contains only numbers. Do not name signals in a CSV file.
- The Signal Builder block interprets the first column as time. In this column, the time values must increase.
- The Signal Builder block interprets the remaining columns as signals.
- Each column must have the same number of entries.
- The Signal Builder block interprets each file as one signal group.
- The Signal Builder block assigns a default signal name to each signal with the format `Imported_Signal #`, where `#` increments with each additional signal.

This example contains an acceptably formatted CSV file. The contents represent one signal group.

```
0,0,0,5,0
1,0,1,5,0
2,0,1,5,0
3,0,1,5,0
4,5,1,5,0
5,5,1,5,0
6,5,1,5,0
7,0,1,5,0
8,0,1,5,1
9,0,1,5,1
10,0,1,5,0
```

For MAT-files:

- The Signal Builder block supports data store logging that the `Simulink.SimulationData.Dataset` object represents and interprets this data as a single group.
- The Signal Builder block supports Simulink output saved as a structure with time.
- The Signal Builder block supports the Signal Builder data format. This format is a group of cell arrays that must be labeled:
  - `time`
  - `data`
  - `sigName`
  - `groupName`

`sigName` and `groupName` are optional.

- For backwards compatibility, the Signal Builder block supports logged data from the `Simulink.ModelDataLogs` object and interprets this data as a single group. The `ModelDataLogs` format will be removed in a future release.
- Signal Builder block does not support:
  - Simulink output as only a structure
  - Simulink output as only an array

---

**Note:** Signal Builder returns a warning if you import a large number of data points (100,000,000 or more). You can then cancel the action.

---

This example contains an acceptably logged MATLAB workspace. Use the MATLAB workspace **Save** command to save the variables to a MAT-file. Import this file to the Signal Builder block.

#### **Signal Builder Block Import File Dialog Box**

The Signal Builder Import File dialog box allows you to import existing signal data files into the Signal Builder block.

Signal data file to import

Repository of data import status messages

Tree view of signal data file contents

Drop-down list of import actions for signal data

### Replacing All Signal Data with Selected Data

Simulink software creates a default Signal Builder block with one signal. To replace this signal and all other signal data that the block might display:

- 1 Create a model and drag a Signal Builder block into that model.
- 2 Double-click the block.

---

The Signal Builder window appears with its default Signal 1.

- 3 In Signal Builder, select **File > Import from File**.

The Import File dialog box appears.

- 4 In the **File to Import** field, enter a signal data file name or click **Browse**.

The file browser appears.

- 5 If you select the file browser, navigate to and select a signal data file. For example, select 3Grp\_3Sig.xls.

---

**Note:** If you try to import an improperly formatted data file, an error message pops up. When you click to dismiss this window, the **Status History** pane displays a more detailed error message (if there is one). For example:

```
File 'signals.mat' format does not  
comply with Signal Builder required format.  
There is no 'time' parameter defined.
```

```
.....
```

---

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.

- 6 Select the signals you want to import. To import all the signals, click **Select All**.
- 7 From the **Placement for Selected Data** list, select the action to take on the signal data. For example, select **Replace existing dataset**.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action. If the signal data selection is not appropriate, **Confirm Selection** remains grayed out. For example, **Confirm Selection** remains grayed out if the number of signals you select is not the same as the number of signals in the Signal Builder group that you want to replace.

- 8 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the status. For example:

Current data in Signal Builder will be replaced  
by new data.

Number of groups: 3

Group name(s):

myGroup1

myGroupB

myGroup\_Three

Number of signals per group: 3

Signal name(s):

Sig1

Sig2

Sig3

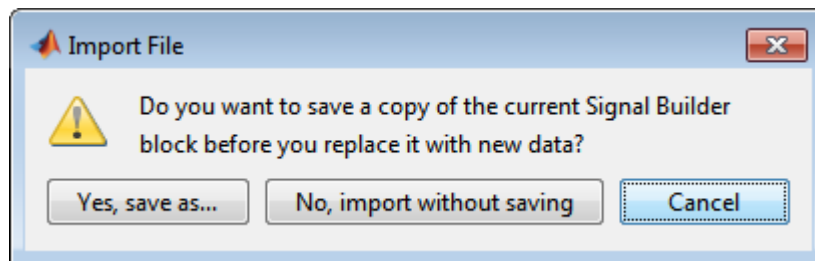

(Names may have been renamed for uniqueness.)

.....

The confirmation also enables the **OK** and **Apply** buttons.

- 9 If you are satisfied with the status message, click **Apply** to replace the existing signal data with the contents of this file.

When selecting **Replace existing dataset**, the software gives you the opportunity to save the existing contents of the Signal Builder block.

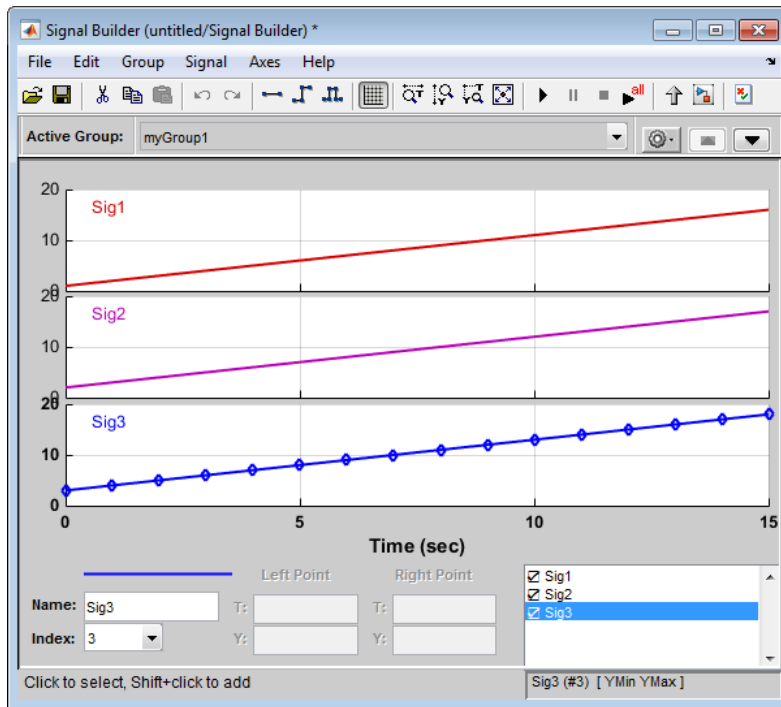

- 10 Click a button, as follows:

| To...   | Click...            |
|---|---------------------|
| Save the contents of the Signal Builder block before replacing it with the new signal data. | <b>Yes, save as</b> |

| To...   | Click...                         |
|---|----------------------------------|
| <b>Note:</b> This selection prompts you to save the Signal Builder block in a model name of your choice. The software saves only the Signal Builder block and no other model content. |                                  |
| Replace the contents of the Signal Builder block without saving them first.   | <b>No, import without saving</b> |
| Stop the replacement process.   | <b>Cancel</b>                    |

For this example, select **No, import without saving** to replace the contents of the Signal Builder block.

- 11 The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the Signal Builder block.

- 12 Click **OK**.
- 13 Inspect the updated Signal Builder window to confirm that your signal data is intact.
- 14 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder1`.

### Appending Selected Signals to All Existing Signal Groups

You can import signals from a signal data file and append selected signals to the end of all existing signal groups. If the signal names to be appended are not unique, the software renames them by incrementing each name by 1 or higher until it is a unique signal name. For example, if the block and data file contain signals named `thermostat`, the software renames the imported signal to `thermostat1` upon appending. If you add another signal named `thermostat`, the software names that latest version `thermostat2`.

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 60-86.

- 1 In the MATLAB Command Window, type `signalbuilder1`.
- 2 Double-click the Signal Builder block.

The Signal Builder window appears.

- 3 In the Signal Builder window, select **File > Import from File**.

The Import File dialog box appears.

- 4 In the **File to Import** field, enter a signal data file name or click **Browse**.

The file browser is displayed.

- 5 If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.

---

**Note:** If you try to import an improperly formatted signal data file, an error message pops up. When you click to dismiss this window, the **Status History** pane displays an error message. For example:

```
File 'signals.mat' format does not  
comply with Signal Builder required format.  
There is no 'time' parameter defined.  
.....
```

---

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.

- 6 Select the signals you want to import. In this example, there are three groups, `myGroup1`, `myGroupB`, and `myGroup_Three`. Select all the signals in `myGroup1`.

- 7 From the **Placement for Selected Data** list, select the action to take on the signal data. For example, select **Append selected signals to all groups**.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action. If the signal data selection is not appropriate, **Confirm Selection** remains grayed out. For example, **Confirm Selection** remains grayed out if the number of signals you select is not the same as the number of signals in the Signal Builder group that you want to replace.

- 8 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the state. For example:

```

3 signal(s) will be appended to each group.
Selected signal name(s):
Before:
  Sig1
  Sig2
  Sig3

After:
  Sig4
  Sig5
  Sig6

Signal name(s) in the block:
Before:
  Sig1
  Sig2
  Sig3

After:
  Sig1
  Sig2
  Sig3
  Sig4
  Sig5
  Sig6

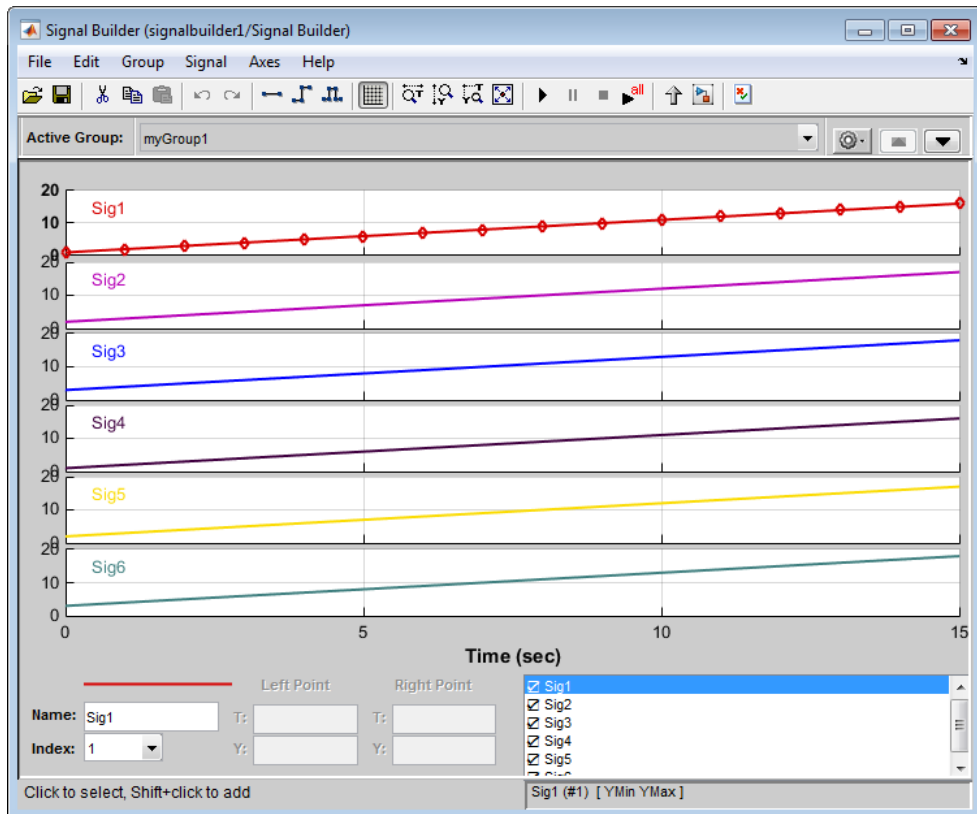

(Name(s) may have been renamed for uniqueness.)
.....

```

The confirmation also enables the **OK** and **Apply** buttons.

Observe the **Before** and **After** headings for the signals. These sections indicate the names of the block and imported data signals before and after the append action.

- 9 If you are satisfied with the status message, click **Apply** to append the selected signals to all the signal groups in the Signal Builder block.
- 10 The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the Signal Builder block.

- 11 Click **OK**.
- 12 Inspect the updated Signal Builder window to confirm that your signal data is intact. Notice that the software has renamed the signals Sig1, Sig2, and Sig3 from the signal data file to Sig4, Sig5, and Sig6 in the Signal Builder block.
- 13 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder2`.

### Appending Selected Signals to Sequential Existing Signal Groups

You can append signals, in the order in which they are selected, to the end of sequential signal groups. This statement means that you select the same number of signals as there are signal groups, and sequentially append each signal to a different group. The software renames each appended signal to the name of the last appended signal.

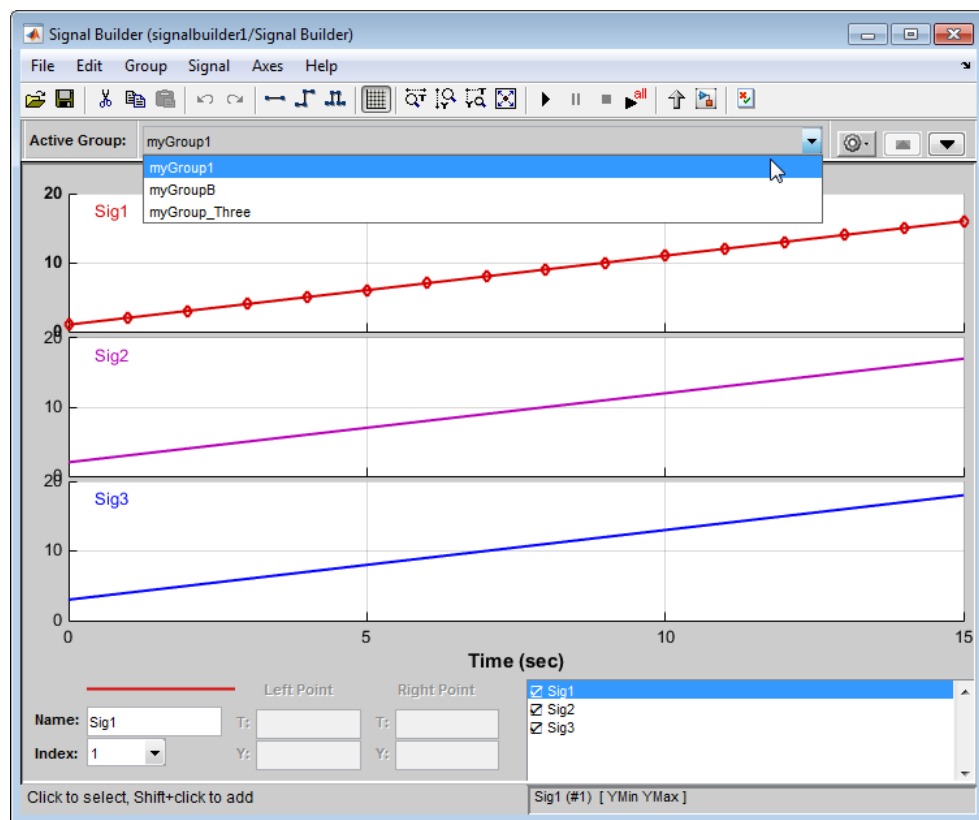

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 60-86.

- 1 In the MATLAB Command Window, type `signalbuilder1`.
- 2 Double-click the Signal Builder block.

The Signal Builder window appears.

- 3 Note how many groups exist in the Signal Builder block. For example, this Signal Builder block has three groups, `myGroup1`, `myGroupB`, and `myGroup_Three`.

- 4 In the Signal Builder window, select **File > Import from File**.

The Import File dialog box appears.

- 5 In the **File to Import** field, enter a signal data file name or click **Browse**.

The file browser appears.

- 6 If you select the file browser, navigate to and select a signal data file. For example, select 3Grp\_3Sig.xls.

---

**Note:** If you try to import an improperly formatted signal data file, an error message popup window. When you click to dismiss this window, the **Status History** pane displays an error message. For example:

```
File 'signals.mat' format does not  
comply with Signal Builder required format.  
There is no 'time' parameter defined.  
.....
```

---

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.

- 7 Select the signals you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup\_Three. Select all the signals in myGroup1.

- 8 From the **Placement for Selected Data** list, select the action to take on the signal data. For example, select **Append selected signals to different groups (in order)**.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action.

- 9 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the state. For example:

1 signal will be appended to each group.

Selected signal names:

Before:

Sig1

Sig2

Sig3

Selected unique signal name:

After:

Sig4

The confirmation also enables the **OK** and **Apply** buttons.

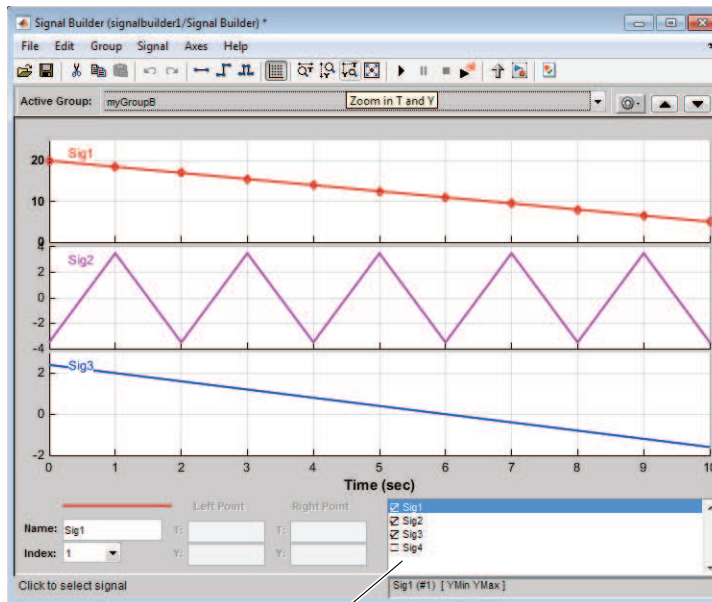

- 10** If you are satisfied with the status message, click **Apply** to append the signals.

The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the three groups of the Signal Builder block.

The topmost signal group, myGroup1, shows all signals by default, including the new Sig4.

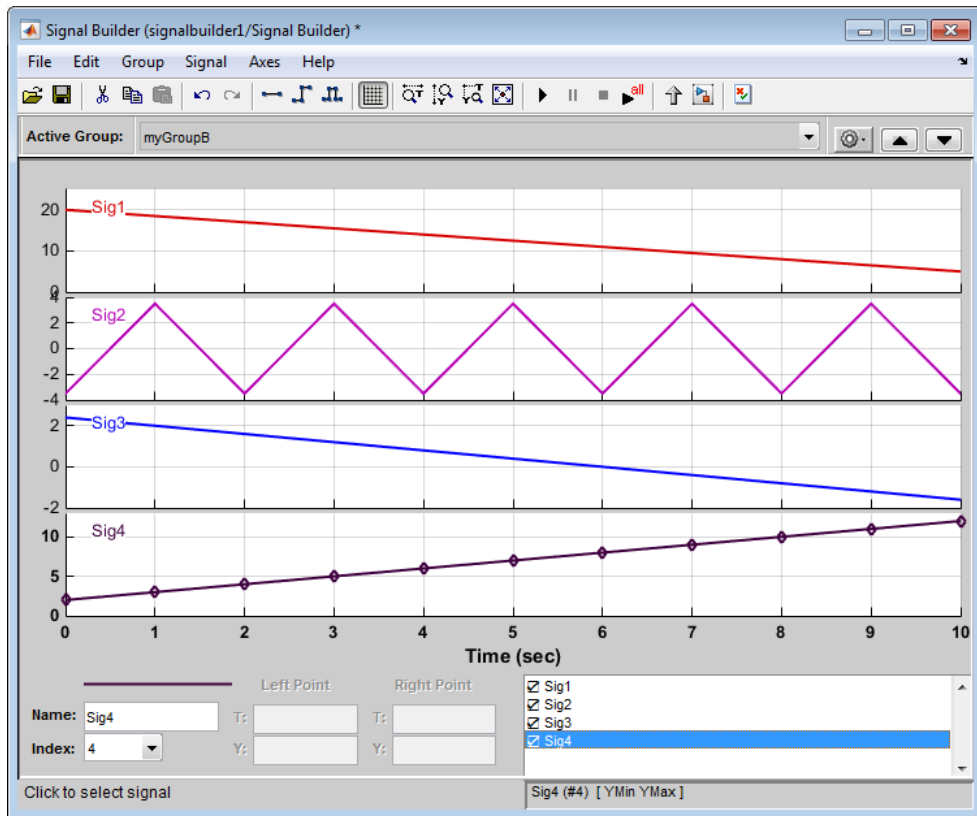

- 11 Click another group name, for example, myGroupB. Notice that Sig4 exists for the group, hidden by default.

Sig4 appears in signal list, but does not appear in group pane

- 12 To show Sig4 on this pane, double-click Sig4 in the Selection Status area of the pane. The graph is updated to reflect Sig4.

- 13** Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder3`.

### Appending Signal Groups to Existing Groups

You can append one or more signal groups to the end of the list of existing signal groups. If the block already has a signal group with the same name as the one you are adding, the software increments the group name by 1 or higher until it is unique before adding it. For example, if the block and data file contain groups named `MyGroup1`, the software renames the imported group to `MyGroup2` upon appending. If you add another group named `MyGroup1`, the software names that latest version `MyGroup3`.

This topic uses `signalbuilder1` from the procedure in “Replacing All Signal Data with Selected Data” on page 60-86.

- 1 In the MATLAB Command Window, type `signalbuilder1`.
- 2 Double-click the Signal Builder block.

The Signal Builder window appears.

- 3 Note how many groups exist in the Signal Builder block, and how many signals exist in each group. The Signal Builder block requires that all groups have the same number of signals. For example, this Signal Builder block has three groups, `myGroup1`, `myGroupB`, and `myGroup_Three`. Three signals exist in each group.

- 4 Double-click the block.
- 5 In the **File to Import** text field, enter a signal data file name or click **Browse**.

The file browser appears.

- 6 If you select the file browser, navigate to and select a signal data file. For example, select `3Grp_3Sig.xls`.

The **Data to Import** pane contains the signal data from the file. Click the expander to display all the signals.

- 7 Evaluate the number of signals in the groups of this data file. If the number of signals in each group equals the number of signals in the groups that exist in the block, you can append one of these groups to the block.
- 8 Select the group you want to import. In this example, there are three groups, myGroup1, myGroupB, and myGroup\_Three. Select myGroupB.

- 9 From the **Placement for Selected Data** list, select the action to take on the signal group. For example, select **Append groups**.

The **Confirm Selection** button is activated. Validate your signal selection before the Signal Builder block performs the specified action.

- 10 Click the **Confirm Selection** button.

If the requested action is a valid one, the Status History pane displays messages to indicate the state. For example:

1 group(s) (each with 3 signal(s)),  
will be appended to the existing block.

Selected group name(s):

Before:

myGroupB

After:

myGroupB1

Signal name(s) in selected group(s):

Before:

Sig1

Sig2

Sig3

Signal name(s) in the block:

Before:

Sig1

Sig2

Sig3

After:

Sig1

Sig2

Sig3

The confirmation also enables the **OK** and **Apply** buttons.

- 11 If you are satisfied with the status message, click **Apply** to append the signals.

The Signal Builder block updates with the new signal data. Click **OK** to close the Import File dialog box and inspect the groups of the Signal Builder block.

Notice the addition of the new signal group as the last pane. Because there is already a signal group named myGroupB, the software automatically increments the new signal group name by 1. Select myGroupB.

- 12 Close the Signal Builder window and save and close the model. For example, save the model as `signalbuilder4`.

### Appending Signals with the Same Name to Existing Signal Groups

If you append a signal whose name is the same as a signal that exists in the Signal Builder block, the software increments the name of the appended signal by 1. The software repeats incrementing until the appended signal name is unique. For example:

- 1 Assume your Signal Builder block has a signal group, `myGroup1`, with the signals `Sig1`, `Sig2`, and `Sig3`.
- 2 Append a signal named `Sig1` to `myGroup1`.
- 3 Observe that the software increments `Sig1` to `Sig4` before appending it to `myGroup1`.

### Appending a Group of Signals with Different Signal Names

If you append a signal group whose signal names differ from those that exist in the Signal Builder block, the software changes the names of the existing signals to be the same as the appended signals. For example,

- 1 Assume your Signal Builder block has a signal group, `myGroup1`, with the signals `Sig1`, `Sig2`, and `Sig3`.
- 2 Append a signal group named `myGroup2` whose signal names are `SigA`, `SigB`, and `SigC`.
- 3 Observe that the software:
  - Appends `myGroup2`.
  - Renames the signals in `myGroup1` to be the same as those in `myGroup2`.

### Importing Data with Custom Formats

This topic describes how to import signal data formatted in a custom format. You should already have a signal data from a file whose contents you want to import. See “Importing Signal Groups from Existing Data Sets” on page 60-81 for a description of the data formats that the Signal Builder block accepts. If your data is not formatted using one of these data formats, use the following workflow to import the custom formatted data. This workflow uses the following files, located in the folder `matlabroot\help\toolbox\simulink\examples` (open), as examples:

- `SigBldCustomFile.xls` — Signal data Microsoft Excel file using a format that Signal Builder block does not accept, for example:

|               |         |     |     |     |     |     |     |     |     |      |      |      |      |      |      |      |      |
|---------------|---------|-----|-----|-----|-----|-----|-----|-----|-----|------|------|------|------|------|------|------|------|
| <b>Group1</b> | Time    | 0   | 1   | 2   | 3   | 4   | 5   | 6   | 7   | 8    | 9    | 10   | 11   | 12   | 13   | 14   | 15   |
|               | Signal1 | 1   | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9    | 10   | 11   | 12   | 13   | 14   | 15   | 16   |
|               | Signal2 | 1   | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9    | 10   | 11   | 12   | 13   | 14   | 15   | 16   |
|               | Signal3 | 1   | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9    | 10   | 11   | 12   | 13   | 14   | 15   | 16   |
|               | Signal4 | 1   | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9    | 10   | 11   | 12   | 13   | 14   | 15   | 16   |
| <b>Group2</b> | Signal1 | 1.6 | 2.6 | 3.6 | 4.6 | 5.6 | 6.6 | 7.6 | 8.6 | 9.6  | 10.6 | 11.6 | 12.6 | 13.6 | 14.6 | 15.6 | 16.6 |
|               | Signal2 | 1.8 | 2.8 | 3.8 | 4.8 | 5.8 | 6.8 | 7.8 | 8.8 | 9.8  | 10.8 | 11.8 | 12.8 | 13.8 | 14.8 | 15.8 | 16.8 |
|               | Signal3 | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9   | 10   | 11   | 12   | 13   | 14   | 15   | 16   | 17   |
|               | Signal4 | 2.2 | 3.2 | 4.2 | 5.2 | 6.2 | 7.2 | 8.2 | 9.2 | 10.2 | 11.2 | 12.2 | 13.2 | 14.2 | 15.2 | 16.2 | 17.2 |

- `createSignalBuilderSupportedFormat.m` — Custom MATLAB function that uses `xlsread` to read Microsoft Excel spreadsheets. This example function reformats the custom data, in a format that the Signal Builder block supports, as follows:
  - `grpNames` — Cell array that contains group name strings with number of rows = 1, number of columns = number of groups.

- *sigNames* — Cell array that contains signal name strings with number of rows = 1, columns = number of signals.
- *time* — Cell array that contains time data with number of rows = number of signals, columns = number of groups.
- *data* — Cell array that contains signal data with number of rows = number of signals, columns = number of groups.

Signal Builder has the following requirements for this custom function:

- Number of signals in each group must be the same.
- Signal names in each group must be the same.
- Number of data points in each signal must be the same.
- Each element in the *time* and *data* cell array holds a matrix of real numbers. This matrix can be  $[1 \times N]$  or  $[N \times 1]$ , where  $N$  is the number of data points in every signal.

- 1 Identify the format of your custom signal data, for example:

```
SigBldCustomFile.xls
```

- 2 Create a custom MATLAB function that:

- a Uses a MATLAB I/O function, such as `xlsread`, to read your custom formatted signal data. For example, `createSignalBuilderSupportedFormat.m`.
- b Formats the custom formatted signal data to one that the Signal Builder block accepts, for example, a MAT-file.

- 3 Use your custom MATLAB function to write your custom formatted signal data to a file that Signal Builder block accepts. For example:

```
createSignalBuilderSupportedFormat('SigBldCustomFile.xls', 'OutputData.mat')
```

- 4 Import the reformatted signal data file, `OutputData.mat`, into the Signal Builder block (see “Importing Signal Group Sets” on page 60-80).

## Editing Waveforms

Signal Builder allows you to change the shape, color, and line style and thickness of the waveforms output by a group.

## Reshaping a Waveform

Signal Builder allows you to change the waveform by selecting and dragging its line segments and points with the mouse or arrow keys or by editing the coordinates of segments or points.

### Selecting a Waveform

To select a waveform, left-click the mouse on any point on the waveform.

The Signal Builder displays the waveform points to indicate that the waveform is selected.

To deselect a waveform, left-click any point on the waveform axis that is not on the waveform itself or press the **Esc** key.

### Selecting Points

To select a point of a waveform, first select the waveform. Then position the mouse cursor over the point. The cursor changes shape to indicate that it is over a point.

Left-click the point with the mouse. The Signal Builder draws a circle around the point to indicate your selection.

To deselect the point, press the **Esc** key.

### Selecting Segments

To select a line segment, first select the waveform that contains it. Then left-click the segment. The Signal Builder thickens the segment to indicate that it is selected.

To deselect the segment, press the **Esc** key.

### Moving Waveforms

To move a waveform, select it and use the arrow keys on your keyboard to move the waveform in the desired direction. Each key stroke moves the waveform to the next location on the snap grid (see “Snap Grid” on page 60-110) or by 0.1 inches if the snap grid is not enabled.

### Dragging Segments

To drag a line segment to a new location, position the mouse cursor over the line segment. The mouse cursor changes shape to show the direction in which you can drag the segment.

Press the left mouse button and drag the segment in the direction indicated to the desired location. You can also use the arrow keys on your keyboard to move the selected line segment.

### **Dragging points**

To drag a point along the signal amplitude (vertical) axis, move the mouse cursor over the point. The cursor changes shape to a circle to indicate that you can drag the point. Drag the point parallel to the *y*-axis to the desired location. To drag the point along the time (horizontal) axis, press the **Shift** key while dragging the point. You can also use the arrow keys on your keyboard to move the selected point.

### **Snap Grid**

Each waveform axis contains an invisible snap grid that facilitates precise positioning of waveform points. The origin of the snap grid coincides with the origin of the waveform axis. When you drop a point or segment that you have been dragging, the Signal Builder moves the point or the segment points to the nearest point or points on the grid, respectively. The Signal Builder **Axes** menu allows you to specify the grid horizontal (time) axis and vertical (amplitude) axis spacing independently. The finer the spacing, the more freedom you have in placing points but the harder it is to position points precisely. By default, the grid spacing is 0, which means that you can place points anywhere on the grid; i.e., the grid is effectively off. Use the **Axes** menu to select the spacing that you prefer.

### **Inserting and Deleting points**

To insert a point, first select the waveform. Then hold down the **Shift** key and left-click the waveform at the point where you want to insert the point. To delete a point, select the point and press the **Del** key.

### **Editing Point Coordinates**

To change the coordinates of a point, first select the point. The Signal Builder displays the current coordinates of the point in the **Left Point** edit fields at the bottom of the Signal Builder window. To change the amplitude of the selected point, edit or replace the value in the **Y** field with the new value and press **Enter**. The Signal Builder moves the point to its new location. Similarly edit the value in the **T** field to change the time of the selected point.

### **Editing Segment Coordinates**

To change the coordinates of a segment, first select the segment. The Signal Builder displays the current coordinates of the endpoints of the segment in the **Left Point**

and **Right Point** edit fields at the bottom of the Signal Builder window. To change a coordinate, edit the value in its corresponding edit field and press **Enter**.

### Changing the Color of a Waveform

To change the color of a waveform, select the waveform and then select **Color** from the Signal Builder **Signal** menu. The Signal Builder displays the MATLAB color chooser. Choose a new color for the waveform. Click **OK**.

### Changing a Waveform Line Style and Thickness

The Signal Builder can display a waveform as a solid, dashed, or dotted line. It uses a solid line by default. To change the line style of a waveform, select the waveform, then select **Line Style** from the Signal Builder **Signal** menu. A menu of line styles pops up. Select a line style from the menu.

To change the line thickness of a waveform, select the waveform, then select **Line Width** from the **Signal** menu. A dialog box appears with the line current thickness. Edit the thickness value and click **OK**.

## Signal Builder Time Range

The Signal Builder time range determines the span of time over which its output is explicitly defined. By default, the time range runs from 0 to 10 seconds. You can change both the beginning and ending times of a block time range (see “Changing a Signal Builder Time Range” on page 60-112).

If the simulation starts before the start time of a block time range, the block extrapolates its initial output from its first two defined outputs. If the simulation runs beyond the block time range, the block by default outputs values extrapolated from the last defined signal values for the remainder of the simulation. The Signal Builder **Simulation Options** dialog box allows you to specify other final output options (see “Signal values after final time” on page 60-115 for more information).

---

**Note:** When you click the **Start simulation** button on the Signal Builder block toolbar, the simulation uses the stop time of the model. The end of the time range specified in the waveform is not the stop time for the model.

---

### Changing a Signal Builder Time Range

To change the time range, select **Change Time Range** from the Signal Builder **Axes** menu. A dialog box appears.

Edit the **Min time** and **Max time** fields as necessary to reflect the beginning and ending times of the new time range, respectively. Click **OK**.

### Exporting Signal Group Data

To export the data that define a Signal Builder block signal groups to the MATLAB workspace, select **Export to Workspace** from the block **File** menu. A dialog box appears.

The Signal Builder exports the data by default to a workspace variable named **channels**. To export to a differently named variable, enter the variable name in the **Variable name** field. Click **OK**. The Signal Builder exports the data to the workspace as the value of the specified variable.

The exported data is an array of structures. The structure **xData** and **yData** fields contain the coordinate points defining signals in the currently selected signal group. You can access the coordinate values defining signals associated with other signal groups from the structure **allXData** and **allYData** fields.

## Printing, Exporting, and Copying Waveforms

Signal Builder allows you to print, export, and copy the waveforms visible in the active signal group.

To print the waveforms to a printer, select **Print** from the block **File** menu.

You can also export the waveforms to other destinations by using the **Export** option from the block **File** menu. From this submenu, select one of the following destinations:

- **To File** — Converts the current view to a graphics file.

Select the format of the graphics file from the **Save as type** drop-down list on the resulting **Export** dialog box.

- **To Figure** — Converts the current view to a MATLAB figure window.

To copy the waveforms to the system clipboard for pasting into other applications, select **Copy Figure To Clipboard** from the block **Edit** menu.

## Simulating with Signal Groups

You can use standard simulation commands to run models containing Signal Builder blocks or you can use the **Run** or **Run all** button in the Signal Builder window (see “Running All Signal Groups” on page 60-114).

If you want to capture inputs and outputs that the **Run all** button generates, consider using the SystemTest™ software.

### Activating a Signal Group

During a simulation, a Signal Builder block always outputs the active signal group. The active signal group is the group selected in the Signal Builder window for that block, if the dialog box is open. Otherwise, the active group is the group that was selected when the dialog box was last closed. To activate a group, open the group Signal Builder window and select the group.

### Running Different Signal Groups in Succession

The Signal Builder toolbar includes the standard Simulink buttons for running a simulation. This facilitates running several different signal groups in succession. For example, you can open the dialog box, select a group, run a simulation, select another group, run a simulation, etc., all from the Signal Builder window.

## Running All Signal Groups

To run all the signal groups defined by a Signal Builder block, open the block dialog box and click the **Run all** button

from the Signal Builder toolbar. The **Run all** button runs a series of simulations, one for each signal group defined by the block. If you installed Simulink Verification and Validation on your system and are using the Model Coverage Tool, the **Run all** button configures the tool to collect and save coverage data for each simulation in the MATLAB workspace and display a report of the combined coverage results at the end of the last simulation. This allows you to quickly determine how well a set of signal groups tests your model.

---

**Note** To stop a series of simulations started by the **Run all** command, enter **Ctrl+C** at the MATLAB command line.

---

## Simulation Options Dialog Box

The **Simulation Options** dialog box allows you to specify simulation options pertaining to the Signal Builder. To display the dialog box, select **Simulation Options** from the **File** menu of the Signal Builder window. The dialog box appears.

The dialog box allows you to specify the following options.

### Signal values after final time

The setting of this control determines the output of the Signal Builder block if a simulation runs longer than the period defined by the block. The options are

- Hold final value

Selecting this option causes the Signal Builder block to output the last defined value of each signal in the currently active group for the remainder of the simulation.

- Extrapolate

Selecting this option causes the Signal Builder block to output values extrapolated from the last defined value of each signal in the currently active group for the remainder of the simulation.

- Set to zero

Selecting this option causes the Signal Builder block to output zero for the remainder of the simulation.

### Sample time

Determines whether the Signal Builder block outputs a continuous (the default) or a discrete signal. If you want the block to output a continuous signal, enter 0 in this field. For example, the following display shows the output of a Signal Builder block set to output a continuous Gaussian waveform over a period of 10 seconds.

If you want the block to output a discrete signal, enter the sample time of the signal in this field. The following example shows the output of a Signal Builder block set to emit a discrete Gaussian waveform having a 0.5 second sample time.

### Enable zero crossing

Specifies whether the Signal Builder block detects zero-crossing events (enabled by default). This block sets the zero-crossing detection on the `From Workspace` block that you use to create the Signal Builder signal groups. For more information, see “Zero-Crossing Detection” on page 3-23.

# Composite Signals

## In this section...

“What is a Composite Signal?” on page 61-3

“Techniques for Combining Signals” on page 61-3

## What is a Composite Signal?

A *composite signal* is a signal that is composed of other signals. The constituent signals originate separately and join to form the composite signal. You can then extract individual signals from the composite signal downstream and use the signal as if it had never been part of a composite signal.

Composite signals can reduce visual complexity in models by grouping signals that run in parallel over some or all of their courses. Composite signals offer other benefits, as described in the documentation for each technique for combining signals.

## Techniques for Combining Signals

Simulink provides several techniques for combining signals into a composite signal, depending on your modeling requirements.

| Composite Signal Technique | When to Use  |
|----------------------------|--|
| Virtual bus                | Combine signals of any type and dimension, without affecting the memory layout. Use for graphical convenience.<br><br>See “Choose Between Virtual and Nonvirtual Buses” on page 61-12.                         |
| Nonvirtual bus             | Combine signals of different types and dimensions such that they are contiguous in memory. Produces a structure in the generated code.<br><br>See “Choose Between Virtual and Nonvirtual Buses” on page 61-12. |

| Composite Signal Technique                      | When to Use  |
|---|--|
| Mux block                                       | Graphically combine signals of same type. See “Buses and Muxes” on page 61-4.  |
| Vector Concatenate and Matrix Concatenate block | Create a vector or matrix, for example to be used in mathematical operations. The resulting vector is stored in contiguous memory.   |
| Array of buses                                  | Combine multiple buses with identical properties. Array of buses is equivalent to an array of structures in MATLAB.<br><br>See “Combine Buses into an Array of Buses” on page 61-82. |

### Buses and Muxes

If all signals in a bus are the same type, you may be able to use a contiguous vector or a virtual vector (mux) instead of a bus. For more information, see “Mux Signals” on page 60-11.

In the context of a model, do not use bus and mux mixtures. A bus and mux mixture occurs when some blocks treat a signal as a mux, while other blocks treat that same signal as a bus. For more information, see “Prevent Bus and Mux Mixtures” on page 61-113.

### Bus Code

The various techniques for defining buses are essentially equivalent for simulation, but the techniques used can make a significant difference in the efficiency, size, and readability of generated code. If you intend to generate production code for a model that uses buses, for information about the best techniques to use, in the Embedded Coder documentation, see “Code Generation with Buses”.

### Function-Call Signals

To combine function-call signals to call a single system, use a Mux block.

If you use a Bus Creator block to group function-call signals into one bus, then use a Bus Selector block to separate out specific function-call signals.

## Buses

### In this section...

“What is a Bus?” on page 61-5

“Types of Simulink Buses” on page 61-6

“Bus Objects” on page 61-6

“View Information about Buses” on page 61-6

---

**Tip** Simulink provides several techniques for combining signals into a composite signal. For a comparison of techniques, see “Techniques for Combining Signals” on page 61-3.

---

### What is a Bus?

A Simulink composite signal is called a *bus signal*, or just a *bus*. A Simulink bus is analogous to a bundle of wires held together by tie wraps. Simulink implements a bus as a name-based hierarchical structure. A Simulink bus should not be confused with a hardware bus, like the bus in the backplane of many computers. It is more like a programmatic structure defined in a language like C.

The signals that constitute a bus are called *elements*. The constituent signals retain their separate identities within the bus and can be of any type or types, including other buses nested to any level. The elements of a bus can be any of the following:

- Mixed data type signals (e.g. double, integer, fixed point)
- Mixture of scalar and vector elements
- Buses as elements
- N-D signals
- Mixture of Real and Complex signals

Some requirements and limitations apply when you connect buses to blocks or to nonvirtual subsystems. See “Bus-Capable Blocks” on page 61-21, “Use Buses for Inports and Outports” on page 61-62, and “Composite Signal Limitations” on page 61-127 for more information.

## Types of Simulink Buses

A bus can be either *virtual* or *nonvirtual*. Both virtual and nonvirtual buses provide the same visual simplification, but their implementations are different.

- Virtual buses exist only graphically. They have no functional effects and do not appear in generated code; only the constituent signals appear. See “Virtual Signals” on page 60-11 for details. Simulink implements virtual buses with pointers, so virtual buses add no data copying overhead and do not affect performance.
- Nonvirtual buses may have functional effects. They appear as structures in generated code, which can simplify the code and clarify its correspondence with the model. Simulink implements nonvirtual buses by copying data from the source signals to the bus, which can affect performance.

The two types of buses are interchangeable for many purposes, but some situations require a nonvirtual bus. See “Virtual and Nonvirtual Buses” on page 61-11 for more information.

## Bus Objects

A bus can have an associated *bus object*, which can both provide and validate bus properties. A bus object is an instance of class `Simulink.Bus` that is defined in the base workspace. The object defines the structure of the bus and the properties of its elements, such as nesting, data type, and size. Bus objects are optional for virtual buses and required for nonvirtual buses. See “Bus Objects” on page 61-23 for more information. You can create bus objects programmatically or by using the Simulink Bus Editor, which facilitates bus object creation and management. See “Manage Bus Objects with the Bus Editor” on page 61-27 for more information.

## View Information about Buses

To view information about buses, use one of the following approaches:

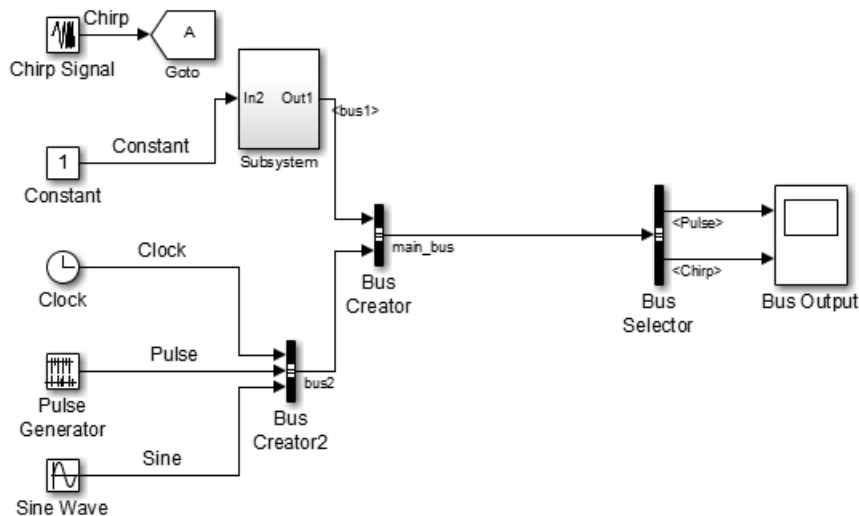

- Use the Signal Hierarchy Viewer to interactively display bus hierarchy (for bus signals)
- From the MATLAB command line, display the type and hierarchy of a bus signal in a compiled model. For details, see “CompiledBusType and SignalHierarchy Parameters” on page 61-9.

## Signal Hierarchy Viewer

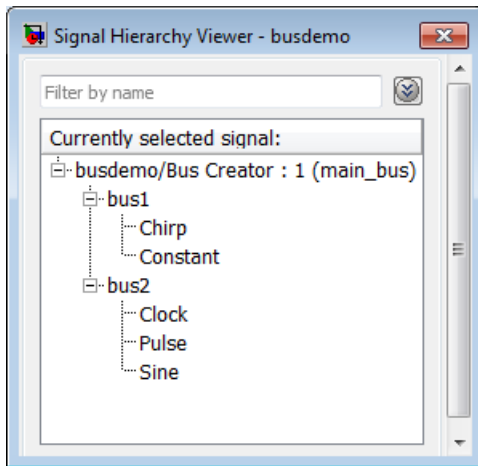

Use the Signal Hierarchy Viewer to interactively display information about a signal. For a bus signal, the Signal Hierarchy Viewer displays the bus hierarchy.

- 1 Check that the **Configuration Parameters > Diagnostics > Connectivity > Mux blocks used to create bus signals** parameter is set to **error**.
- 2 Right-click a signal line.
- 3 Select the **Signal Hierarchy** option. The Signal Hierarchy Viewer dialog box appears.

For example, open the `busdemo` model.

Right-click the `main_bus` signal (output signal for the Bus Creator block), and select **Signal Hierarchy**. The following information appears:

Each Signal Hierarchy Viewer is associated with a specific model. If you edit a model while the associated Signal Hierarchy Viewer is open, the Signal Hierarchy Viewer reflects those updates.

You can also open the Signal Hierarchy Viewer in the Simulink Editor.

- 1 Select **Diagram > Signals & Ports > Signal Hierarchy**.
- 2 Select a signal

---

**Note:** To produce accurate results at edit time, the Signal Hierarchy Viewer requires that the model compiles successfully.

---

To filter the displayed signals, click the **Options** button on the right-hand side of the **Filter by name** edit box (  ).

- To use MATLAB regular expressions for filtering signal names, select **Enable regular expression**. For example, entering `r$` in the **Filter by name** edit box displays all signals whose names end with a lowercase `r` (and their immediate parents). For details, see “Regular Expressions”.
- To use a flat list format to display the list of filtered signals, based on the search text in the **Filter by name** edit box, select **Show filtered results as a flat list**. The flat list format uses dot notation to reflect the hierarchy of bus signals. The following is an example of a flat list format for a filtered set of nested bus signals.

### CompiledBusType and SignalHierarchy Parameters

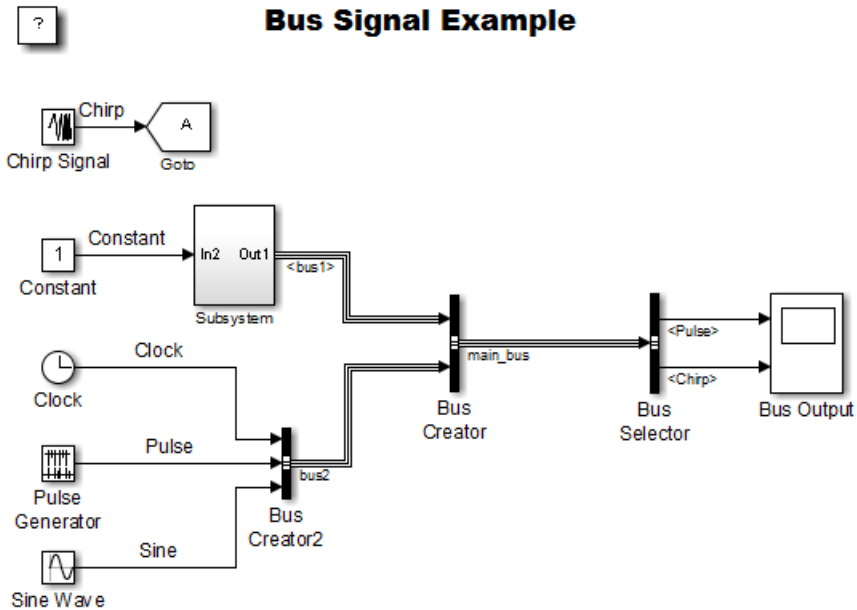

To get information about the type and hierarchy of a bus signal in a compiled model, use these parameters with the `get_param` command:

- **CompiledBusType** — For a compiled model, returns information about whether the signal connected to a port is a bus, and if so, whether the signal is a virtual or nonvirtual bus.
- **SignalHierarchy** — If the signal is a bus, returns the name and hierarchy of the signals in the bus.

Before you use these commands:

- 1 Set the **Configuration Parameters > Diagnostics > Connectivity > Mux blocks used to create bus signals** diagnostic to **error**.
- 2 Update the diagram or simulate the model.

For example, if you open and simulate the `busdemo` model, the model looks as shown below:

The following code illustrates how you can use the `SignalHierarchy` and `CompiledBusType` parameters:

```
mdl = 'busdemo';
open_system(mdl)
% Obtain the handle a port
ph = get_param([mdl '/Bus Creator'], 'PortHandles');
% SignalHierarchy is available at edit time
sh = get_param(ph.Outport, 'SignalHierarchy')
% Compile the model
busdemo([],[],[],'compile');
bt = get_param(ph.Outport, 'CompiledBusType')
% Terminate the model
busdemo([],[],[],'term');
```

## Virtual and Nonvirtual Buses

### In this section...

“About Virtual and Nonvirtual Buses” on page 61-11  
 “Choose Between Virtual and Nonvirtual Buses” on page 61-12  
 “Nonvirtual Bus Sample Times” on page 61-13  
 “Automatic Bus Conversion” on page 61-13  
 “Explicit Bus Conversion” on page 61-13

### About Virtual and Nonvirtual Buses

A bus signal can be *virtual*, meaning that it is just a graphical convenience that has no functional effect, or *nonvirtual*, meaning that the signal occupies its own storage.

#### Bus Signal Lines

When you simulate a model that contains buses, Simulink uses different line styles for virtual and nonvirtual bus signals.

|                |   |
|----------------|---|
| Virtual Bus    |    |
| Nonvirtual Bus |  |

#### Bus Storage

During simulation:

- A block connected to a *virtual* bus reads inputs and writes outputs by accessing the memory allocated to the component signals. These signals are typically noncontiguous, and no intermediate memory exists.
- A block connected to a *nonvirtual* bus reads inputs and writes outputs by accessing copies of the component signals. The copies are maintained in a contiguous area of memory allocated to the bus.

Compared with nonvirtual buses, virtual buses reduce memory requirements because they do not require a separate contiguous storage block, and execute faster because they do not require copying data to and from that block.

A nonvirtual bus is represented by a structure in generated code, which can be helpful when tracing the correspondence between the model and the code.

### Simulation Results and Generated Code

For a *virtual* bus, simulation results and generated code are exactly the same as if the bus did not exist, which functionally it does not.

Generated code for a *nonvirtual* bus represents the bus data with a structure. The use of a structure in the generated code can be helpful when tracing the correspondence between the model and the code. For example, below is the generated code for Bus Creator block in the `ex_bus_logging` model.

```

50
51     /* BusCreator: '<Root>/COUNTERBUSCreator' incorporates:
52      * BusCreator: '<Root>/LIMITBUSCreator'
53      * Constant: '<Root>/lower_saturation_limit'
54      * Constant: '<Root>/upper_saturation_limit'
55      */
56     ex_bus_logging_B.COUNTERBUS_n.data = rtb_data;
57     ex_bus_logging_B.COUNTERBUS_n.limits.upper_saturation_limit = 40;
58     ex_bus_logging_B.COUNTERBUS_n.limits.lower_saturation_limit = 0;
59

```

### Choose Between Virtual and Nonvirtual Buses

Whether to use a virtual or nonvirtual bus depends on your modeling goal. Frequently, a model contains both virtual and nonvirtual buses.

| Modeling Goal   | Type of Bus        |
|---|--------------------|
| Use bus signals within a functional units, such as within a referenced model              | Virtual            |
| Use signals with different sample rates in a bus  | Virtual (required) |
| Have bus data packaged as data structures in the generated code                           | Nonvirtual         |
| Have bus data cross model reference, MATLAB Function block, or Stateflow chart boundaries | Nonvirtual         |

Not all blocks can accept buses. See “Bus-Capable Blocks” on page 61-21 for more about which blocks can handle which types of buses. Virtual buses are the default except where nonvirtual buses are explicitly required. See “Use Buses for Inports and Outports” on page 61-62 for more information.

For additional guidelines for generated code for buses, see “About Buses and Code Generation”.

## Nonvirtual Bus Sample Times

All signals in a nonvirtual bus must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that would result in a nonvirtual bus that violates this requirement generates an error.

All buses and signals input to a Bus Creator block that outputs a nonvirtual bus must therefore have the same sample time. You can use a **Rate Transition** block to change the sample time of an individual signal, or of all signals in a bus, to allow the signal or bus to be included in a nonvirtual bus.

## Automatic Bus Conversion

When updating a diagram prior to simulation or code generation, Simulink automatically converts a virtual bus to a nonvirtual bus (or vice versa) in cases such as when the virtual bus is an input to, or output from:

- A referenced model
- An S-Function block
- A Stateflow chart

The conversion consists of inserting hidden **Signal Conversion** blocks into the model where needed. Conversion to a nonvirtual bus fails if no bus object is specified at the port to which the virtual bus connects.

## Explicit Bus Conversion

You can eliminate the need for the automatic conversion by using one of these approaches:

- Specify a nonvirtual bus in the block where the bus originates. For example, if you use a Bus Creator block to create a bus, then to specify a nonvirtual bus, set the **Bus Creator** block **Data type** parameter to use a `Simulink.Bus` object.

- Manually insert a Signal Conversion block. Using a Signal Conversion block can reduce memory usage, support modeling constructs such as Model blocks that require that input buses be nonvirtual, and reduce generated code. For details, see the `Signal Conversion` documentation.

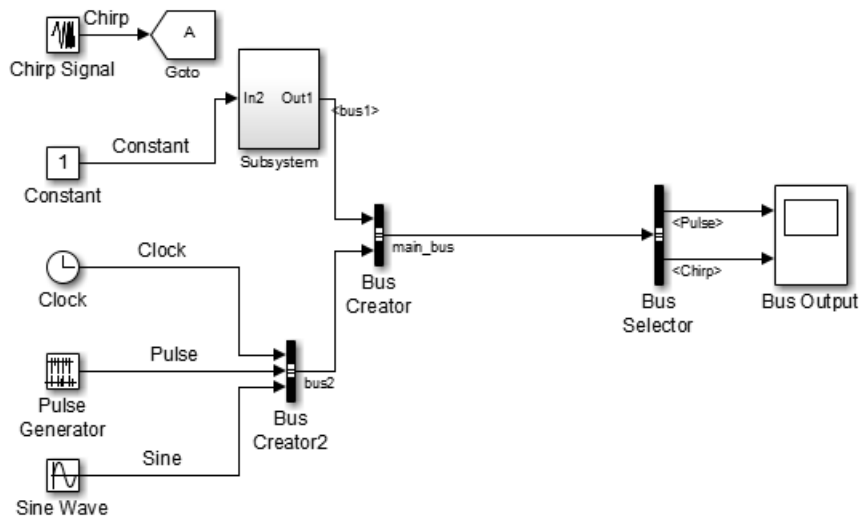

### **Related Examples**

- “Create Bus Signals” on page 61-15

## Create Bus Signals

You can combine signals into a bus signal and then access the bus as a whole or select specific signals from the bus.

The `busdemo` top-level model uses a Bus Creator block to combine the `Clock`, `Pulse`, and `Sine` signals into the `bus2` bus signal. The model combines the `bus2` signal and the subsystem signal to form the `main_bus` signal. The model uses a Bus Selector to select two signals (bus elements) from the bus and output the signals to a Scope block.

### Create a Bus

- 1 In the Simulink Editor, drag to select multiple blocks or signals that you want to create a bus for.
- 2 In the action bar that appears, click **Create Bus**.

Using the **Create Bus** button to create a bus automatically performs these actions:

- Creates a Bus Creator block with the right number of inputs
- Resizes the Bus Creator block to an appropriate size for the number of input signals
- Orients the Bus Creator block to the direction of the input signals
- Connects the signals to the Bus Creator block

As an alternative, you can add a Bus Creator block to a model and manually connect signals to that block to create a bus.

## Create a Nonvirtual Bus

Bus signals do not specify whether they are virtual or nonvirtual; they inherit that specification from the block in which they originate. Every block that creates or requires a nonvirtual bus must have an associated bus object. Those blocks are:

- Bus Creator
- Inport

- Output
- Constant
- Data Store Memory

To specify that a bus is nonvirtual:

- 1 Associate the block with a bus object, as described in “Associating Bus Objects with Simulink Blocks” on page 61-24.
- 2 For the block that creates the bus, open the Block Parameters dialog box.
- 3 Set the data type to **Bus: <object name>** and replace <object name> with the bus object name.
  - For Inport, Output, and Data Store Memory blocks, use the **Data type** parameter to set the data type.
  - For Bus Creator and Constant blocks, use the **Output data type** parameter to set the data type.
- 4 For any Bus Creator, Inport, or Output blocks that have an associated bus object, enable the output as a nonvirtual bus.
  - For Bus Creator and Inport blocks, use the **Output as nonvirtual bus** parameter.
  - For Output blocks, use the **Output as nonvirtual bus in parent model** parameter.
- 5 Click **OK** or **Apply**.

The **Signal Attributes** parameter is applicable only to root Inport and Output blocks. It does not appear in the parameters of a subsystem Inport or Output block. In a root Output block, setting **Signal Attributes > Output as nonvirtual bus in parent model** specifies that the bus emerging in the parent model is nonvirtual. The input bus of the root Output can be virtual or nonvirtual.

### Blocks

Bus Creator | Bus Selector

## Related Examples

- “Nest Buses” on page 61-19

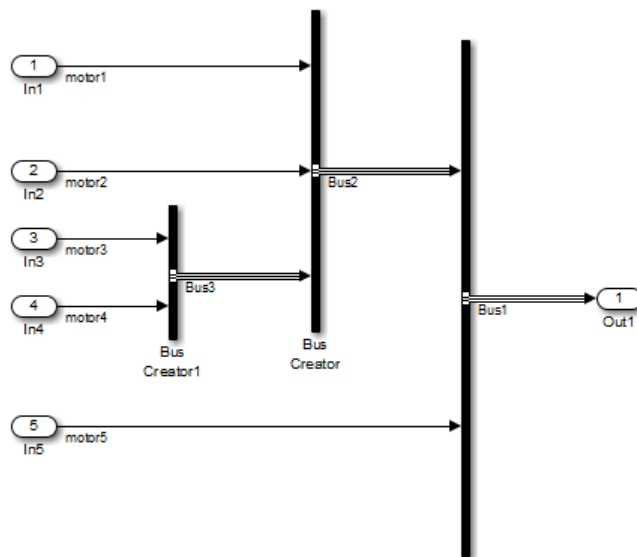

### **More About**

- “Buses” on page 61-5
- “Virtual and Nonvirtual Buses” on page 61-11

## Nest Buses

You can nest buses to any depth. To create a nested bus, use a **Bus Creator** block. If one of the inputs to the Bus Creator block is a bus, then the output is a nested bus. To select a signal within a nested bus, use a **Bus Selector** block.

For example, in the next model, the **Bus3** bus signal combines two signals, **motor3** and **motor4**. The **Bus2** signal combines the **Bus3** bus signal and the **motor1** and **motor2** signals. The **Bus1** signal combines the **Bus2** bus signal and the **motor5** signal.

All of the signals retain their separate identities, just as if no bus creation and selection occurred. You can use Bus Selector blocks to select individual signals from a nested bus.

The Simulink software automatically handles most of the complexities involved. For example, you can specify to have Simulink repair broken selections in the Bus Selector and Bus Assignment block parameter dialog boxes due to upstream bus hierarchy changes. To enable these automatic repairs, in the **Configuration Parameters > Diagnostics > Connectivity** pane, set the **Repair bus selections** diagnostic to Warn and repair. The repairs occur when you update a model. To save the repairs, save the model.

## Circular Bus Definitions

The ability to nest a bus as an element of another bus creates the possibility of a loop of Bus Creator blocks, Bus Selector blocks, and bus-capable blocks that inadvertently includes a bus as an element of itself. The resulting circular definition cannot be resolved and therefore causes an error.

The error message that appears specifies the location at which the Simulink software determined that the circular structure exists. The error is not really at any one location: the structure as a whole is in error. Nonetheless, the location cited in the error message can be useful for beginning to trace the definition cycle; its structure may not be obvious on visual inspection.

- 1** Begin by selecting a signal line associated with the location cited in the error message.
- 2** Choose **Highlight to Signal to Source** or **Highlight Signal to Destination** from the signal's context menu. (See “Display Signal Sources and Destinations” on page 60-38 for more information.)
- 3** Continue choosing signals and highlighting their sources and destinations until the cycle becomes clear.
- 4** Restructure the model as needed to eliminate the circular bus definition.

Because the problem is a circular definition rather than a circular computation, the cycle cannot be broken by inserting additional blocks, in the way that an algebraic loop can be broken by inserting a Unit Delay block. No alternative exists but to restructure the model to eliminate the circular bus definition.

## Bus-Capable Blocks

All virtual blocks are bus-capable. The following blocks are also bus-capable. Some blocks only support nonvirtual buses.

- Bus Assignment
- Bus Creator
- Bus Selector
- Constant (nonvirtual buses)
- Data Store Memory (nonvirtual buses)
- Data Store Read (nonvirtual buses)
- Data Store Write (nonvirtual buses)
- From Workspace (nonvirtual buses)
- Memory
- Merge
- Multiport Switch
- Rate Transition
- Signal Conversion
- Signal Specification
- Switch
- To Workspace
- Unit Delay
- Zero-Order Hold

All signals in a nonvirtual bus input to a bus-capable block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a **Rate Transition** block to change the sample time of an individual signal, or of all signals in a bus.

Some bus-capable blocks impose other constraints on bus propagation through them. See the documentation for specific blocks for more information.

Subsystems, model referencing and S-functions support the use of buses. See the documentation for those features for any special considerations relating to the use of buses.

# Bus Objects

## In this section...

“About Bus Objects” on page 61-23

“Bus Object Capabilities” on page 61-24

“Associating Bus Objects with Simulink Blocks” on page 61-24

## About Bus Objects

The properties that you specify for a bus signal by using Bus Creator block parameters are inherited by all downstream blocks that use the bus. Using Bus Creator block parameters is adequate for defining virtual buses and performing limited error checking. However, to define a nonvirtual bus, or to perform complete error checking on any bus, use a *bus object* to specify additional information.

Creating a bus object establishes a composite data type whose name is the name of the bus object and whose properties are given by the object. A bus object specifies only the architectural properties of a bus, as distinct from the values of the signals it contains. For example, a bus object can specify the number of elements in a bus, the order of those elements, whether and how elements are nested, and the data types of constituent signals; but not the signal values.

A bus object is analogous to a structure definition in C: it defines the members of the bus but does not create a bus. A bus object is an instance of class `Simulink.Bus` that is defined in the base workspace. A bus object serves as the root of an ordered hierarchy of *bus elements*, which are instances of class `Simulink.BusElement`. Each element completely specifies the properties of one signal in a bus: its name, data type, dimensionality, etc. The order of the elements contained in the bus object defines the order of the signals in the bus.

Referenced models, Stateflow charts, and MATLAB Function blocks that input and output buses require those buses to be defined with bus objects. Inport and Outport blocks can use bus objects to specify the structure of the bus passing through them. Root inport blocks use bus objects to specify the structure of the bus. Root output blocks use bus objects to check the structure of the incoming bus and to specify the structure of the bus in the parent model, if any.

## Bus Object Capabilities

You can associate a bus object with several blocks. For details, see “Associating Bus Objects with Simulink Blocks” on page 61-24.

When a bus object governs a signal output by a block, the signal is a bus that has exactly the properties specified by the object. When a bus object governs a signal input by a block, the signal must be a bus that has exactly the properties specified by the object; any variance causes an error.

A bus object can also specify properties that were not defined by constituent signals, but were left to be inherited. A property specification in a bus object can either validate or provide the corresponding property in the bus. If the bus specifies a different property, an error occurs. If the bus does not specify the property, but leaves it to be inherited, the bus inherits the property from the bus object. Note again that such inheritance never includes signal values.

You can use the Simulink Bus Editor to create and manage bus objects, as described in “Manage Bus Objects with the Bus Editor” on page 61-27, or you can use the Simulink API, as described in “Bus Object API” on page 61-26. After you create a bus object and specify its attributes, you can associate it with any block that needs to use the bus definition that the object provides.

## Associating Bus Objects with Simulink Blocks

You can associate a bus object with the following blocks:

- Bus Creator
- Data Store Memory
- Data Store Read
- Data Store Write
- From File
- From Workspace
- Inport
- Outport
- Permute Dimensions
- Probe

- Reshape
- Signal Conversion
- Signal Specification

In the Block Parameters dialog box for the block that you want to associate with a bus, set **Data type** to **Bus: <object name>** and replace <object name> with the bus object name.

---

**Note:** Do not set the minimum and maximum values for bus data on blocks with bus object data type. Simulink ignores these settings. Instead, set the minimum and maximum values for bus elements of the bus object specified as the data type. The values should be finite real double scalar.

For information on the Minimum and Maximum properties of a bus element, see `Simulink.BusElement`.

---

## Bus Object API

The Simulink software provides all Bus Editor capabilities programmatically. Many of these capabilities, like importing and exporting MATLAB code files and MAT-files, are not specific to bus objects, and are described elsewhere in the MATLAB and Simulink documentation.

The classes that implement bus objects are:

`Simulink.Bus`

Specify the properties of a signal bus

`Simulink.BusElement`

Describe an element of a signal bus

The functions that create and save bus objects are:

`Simulink.Bus.createObject`

Create bus objects for blocks, optionally saving them in a MATLAB file in a specified format

`Simulink.Bus.cellToObject`

Convert a cell array containing bus information to bus objects in the base workspace

`Simulink.Bus.objectToCell`

Convert bus objects in the base workspace to a cell array containing bus information

`Simulink.Bus.save`

Export specified bus objects or all bus objects from the base workspace to a MATLAB file in a specified format

`Simulink.Bus.createMATLABStruct`

Create MATLAB structure with same hierarchy, names, and attributes as the bus signal

In addition, when you use `Simulink.SubSystem.convertToModelReference` to convert an atomic subsystem to a referenced model, you can save any bus objects created during the conversion to a MATLAB file.

# Manage Bus Objects with the Bus Editor

**In this section...**

“Introduction” on page 61-27

“Open the Bus Editor” on page 61-28

“Display Bus Objects” on page 61-29

“Create Bus Objects” on page 61-31

“Create Bus Elements” on page 61-34

“Nest Bus Definitions” on page 61-37

“Change Bus Entities” on page 61-40

“Export Bus Objects” on page 61-44

“Import Bus Objects” on page 61-45

“Close the Bus Editor” on page 61-46

## Introduction

The Simulink Bus Editor is a tool similar to the Model Explorer, but is customized for use with bus objects. You can use the Simulink Bus Editor to:

- Create new bus objects and elements
- Navigate, change, and nest bus objects
- Import existing bus objects from a MATLAB code file or MAT-file
- Export bus objects to a MATLAB code file or MAT-file

For a description of bus objects and their use, see “Bus Objects” on page 61-23.

## Base Workspace Bus Objects

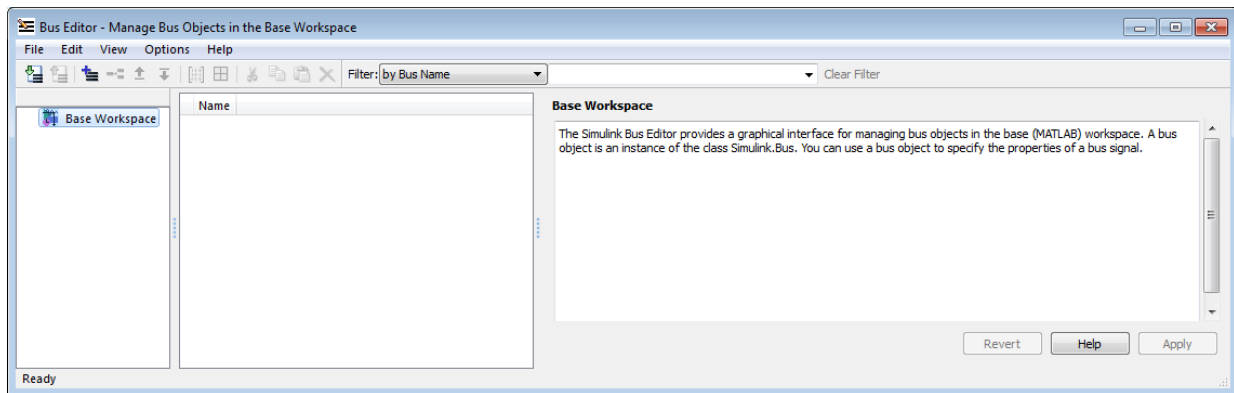

All bus objects exist in the MATLAB base workspace. Bus Editor actions take effect in the base workspace immediately, and can be used by Simulink models as soon as each action is complete. The Bus Editor does not have a workspace of its own: it acts only on the base workspace. Bus Editor actions do not directly affect bus object definitions in saved MATLAB code files or MAT-files. To save changed bus object definitions, export them from the base workspace into MATLAB code files or MAT-files, as described in “Export Bus Objects” on page 61-44.

## Open the Bus Editor

You can open the Bus Editor in any of these ways:

- In the Simulink Editor, select **Edit > Bus Editor**.
- In a bus object's dialog box in the Model Explorer, click the **Launch Bus Editor** button.
- Enter `buseditor` at the command line of the MATLAB software.

If no bus objects exist, the Bus Editor looks like the one shown here:

### Bus Editor Commands

The Bus Editor provides menu choices that you can use to execute all Bus Editor commands. The editor also provides toolbar icons and keyboard shortcuts for all commonly used commands, including the standard MATLAB shortcuts for Cut, Copy, Paste, and Delete. The Toolbar Tip for each icon describes the command, and the menu entry for each command shows any shortcut. The icons for commands that are specific to the Bus Editor are:

| Command       | Icon  | Description  |
|---------------|---|--|
| <b>Import</b> |  | Import the contents of a MATLAB code file or MAT-file into the base workspace. |
| <b>Export</b> |  | Export all bus objects and elements to a MATLAB code file or MAT-file.         |

| Command  | Icon  | Description   |
|--|---|---|
| <b>Create</b>                                  |  | Create a new bus object in the base workspace.                          |
| <b>Insert</b>                                  |  | Add a bus element below the currently selected bus entity.              |
| <b>Move Up</b>                                 |  | Move the selected element up in the list of a bus object's elements.    |
| <b>Move Down</b>                               |  | Move the selected element down in the list of bus object elements.      |
| <b>Create/Edit a Simulink.Parameter object</b> |  | Create or edit a Simulink.Parameter object for the selected bus object. |
| <b>Create a MATLAB structure</b>               |  | Create a MATLAB structure for the selected bus object.                  |

You can use toolbar icons and keyboard shortcuts instead of menu commands whenever you prefer.

## Display Bus Objects

The Bus Editor is similar to the Model Explorer (which can display bus objects but cannot edit them) and uses the same three panes to display bus objects:

- **Hierarchy pane** (left) — Displays the bus objects defined in the base workspace
- **Contents pane** (center) — Displays the elements of the bus object selected in the Hierarchy pane
- **Dialog pane** (right) — Displays for editing the current selection in the Contents or Hierarchy pane

Items that appear in the Hierarchy pane or the Contents pane have Context menus that provide immediate access to the capabilities most likely to be useful with that item. The contents of an item's Context menu depend on the item and the current state within the Bus Editor. All Context menu options are also available from the menu bar and/or the toolbar. Right-click any item in the Hierarchy or Contents pane to see its Context menu.

## Hierarchy Pane

If no bus objects exist in the base workspace, the Hierarchy pane shows only **Base Workspace**, which is the root of the hierarchy of bus objects. The Bus Editor then looks as shown in the previous figure. As you create or import bus objects, they appear in the Hierarchy Pane as nodes subordinate to **Base Workspace**. The bus objects appear in alphabetical order. The next figure shows the Bus Editor with two bus objects, **control** and **main**, defined in the base workspace:

The Hierarchy pane displays each bus object as an expandable node. The root of the node displays the name of the bus object, and (if the bus contains any elements) a button for expanding and collapsing the node. Expanding a bus node displays named subnodes that represent the bus's top-level elements. In the preceding figure, both bus objects are fully expanded, and **control** is selected.

## Contents Pane

Selecting any top-level bus object in the Hierarchy Pane displays the object's elements in the Contents pane. In the previous figure, the elements of bus object **control**, **valve1** and **valve2**, appear. Each element's properties appear to the right of the element's

name. These properties are editable, and you can edit the properties of multiple elements in one operation, as described in “Editing in the Contents Pane” on page 61-40.

## Dialog Pane

When a bus object is selected in the Hierarchy pane, or a bus object or element is selected in the Contents pane, the properties of the selected item appear in the Dialog pane. In the previous figure, `valve1` is selected in the Contents pane, so the Dialog pane shows its properties. These properties are editable, and changes can be reverted or applied using the buttons below the Dialog pane, as described in “Editing in the Dialog Pane” on page 61-42.

## Filter Boxes

By default, the Bus Editor displays all bus objects that exist in the base workspace. Where a model contains large numbers of bus objects, seeing them all at the same time can be inconvenient. To facilitate working efficiently with large collections of bus objects, you can use the **Filter** boxes, to the right of the iconic tools in the toolbar, to show a selected subset of bus objects. See “Filter Displayed Bus Objects” on page 61-51 for details.

## Create Bus Objects

To use the Bus Editor to create a new bus object in the base workspace:

- 1 Choose **File > Add Bus**.

A new bus object with a default name and properties is created immediately in the base workspace. The object appears in the Hierarchy pane, and its default properties appear in the Dialog pane:

- 2 To specify the bus object name and other properties, in the Dialog pane:
  - a Specify the **Name** of the of the new bus object (or you can retain the default name). The name must be unique in the base workspace. See “Signal Names and Labels” on page 60-5 for guidelines for signal names.
  - b Optionally, specify a **C Header file** that defines a user-defined type corresponding to this bus object. This header file has no effect on Simulink simulation; it is used only by Simulink Coder software to generate code.
  - c Optionally, specify a **Description** that provides information about the bus object to human readers. This description has no effect on Simulink simulation; it exists only for human convenience.
- 3 Click **Apply**.

The properties of the bus object on the base workspace change as specified. If you rename `BusObject` to `main`, the Bus Editor looks like this:

You can use **Add Bus** at any time to create a new bus object in the base workspace, then set the name and properties of the object as needed. You can intersperse creating bus objects and specifying their properties in any order. The hierarchy pane reorders as needed to display all bus objects in alphabetical order. If you add an additional bus object named `control`, the Bus Editor looks like this:

You can also use capabilities outside the Bus Editor to create new bus objects. Such objects do not appear in the Bus Editor until the next time its window is selected.

## Create Bus Elements

Every bus element belongs to a specific bus. To create a new bus element:

- 1 In the Hierarchy pane, select the entity below which to create the new element. The entity can be a bus or a bus element. The new element will belong to the selected bus object, or to the bus object that contains the selected element. The previous figure shows the `control` bus object selected.
- 2 Choose **File > Add/Insert BusElement**.

A new bus element with a default name and properties is created immediately in the applicable bus object. The object appears in the Hierarchy pane immediately below the previously selected entity, and its default properties appear in the Dialog pane:

- 3 To specify the bus element name and other properties, in the Dialog pane:
  - a Specify the **Name** of the of the new bus element (or you can retain the default name). The name must be unique among the elements of the bus object. See “Signal Names and Labels” on page 60-5 for guidelines for signal names.
  - b Specify the other properties of the element. The properties must match the properties of the corresponding signal within the bus exactly, and can be anything that a legal signal might have. The Data Type Assistant appears in the Dialog pane to help specify the element's data type. You can specify any available data type, including a user-defined data type.
- 4 Click **Apply**.

The properties of the bus element of the bus object in the base workspace change as specified. If you rename the new element **a** to **valve1**, the Bus Editor looks like this:

You can use **Add/Insert BusElement** at any time to create a new bus element in any bus object. You can intersperse creating bus objects and specifying their properties in any order. The order of the other bus elements in the bus object does not change when a new element is added. If you add element `valve2` to `control`, and `secondary` and `primary` to `main`, the Bus Editor looks like this:

You can also use capabilities outside the Bus Editor to add new bus elements to a bus object. Such an addition changes an existing bus object, so any new bus element appears immediately in the Bus Editor.

## Nest Bus Definitions

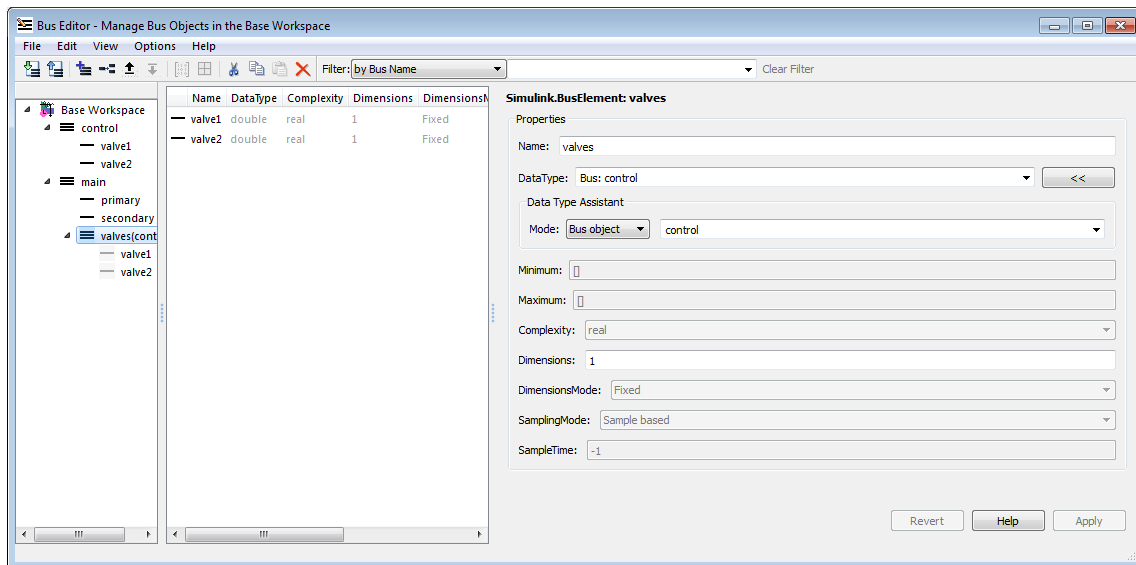

As described in “Nest Buses” on page 61-19, any signal in a bus can be another bus, which can in turn contain subordinate buses, and so on to any depth. Describing nested buses with bus objects requires nesting the bus definitions that the objects provide.

Every bus object inherently defines a data type whose properties are those specified by the object. To nest one bus definition in another, you assign to an element of one bus object a data type that is defined by another bus object. The element then represents a nested bus whose structure is given by the bus object that provides its data type.

A data type defined by a bus object is called a *bus type*. Nesting buses by assigning bus types to elements, rather than by subordinating the bus objects that define the types, allows the same bus definition to be used conveniently in multiple contexts without unwanted interactions. To specify that an element of a bus object represents a nested bus definition:

- 1 Create a bus element to represent the nested bus definition, in the appropriate position under the containing bus object, and give the element the desired name. (You can also use an existing element.)
- 2 Use the Dialog pane to set the data type of the element to the name of a bus object. The Data Type Assistant shows the names of all available bus types. (You can also specify a nonexistent bus type and define the object later.)

In the preceding figure, if you add to bus object `main` a third element named `valves`, set the data type of `valves` to be `control` (the name of the other defined bus object) and expand the new element `valves`, the Bus Editor looks like this:

The bus object `main` shown in the Bus Editor now defines the same structure used by the bus signal `main` in the next figure:

The distinction between a bus object and the bus type that it defines can be useful for initially understanding how nested bus objects work and how the Bus Editor handles them. In other contexts, the distinction is mostly an implementation detail, and describing bus objects themselves as being nested is more convenient. The rest of this chapter follows that convention.

You can nest a bus object in as many different bus objects as desired, and as many times in the same bus object as desired. You can nest bus objects to any depth, but you cannot define a circular structure by directly or indirectly nesting a bus object within itself.

If you try to define a circular structure, the Bus Editor posts a warning and sets the data type of the element that would have completed the cycle to **double**. Click **OK** to dismiss the Notice and continue using the editor.

You can use the Hierarchy pane to explore nested bus objects by expanding the objects, but you cannot change any property of a bus object anywhere that it appears in nested form. To change the properties of a nested bus object, you must change the source object, which is accessible at the top level in the Hierarchy pane. You can jump from a nested bus object to its source object by selecting the nested object and choosing **Go to 'element'** from its Context menu.

## Change Bus Entities

You can use the Bus Editor to change and delete existing bus objects and elements at any time. All three panes allow you to change the entities that they display. Changes that create, reorder, or delete entities take effect immediately in the base workspace. Changes to properties take effect when you apply them, or can be canceled, leaving the properties unchanged. The Bus Editor does not provide an Undo capability.

The Bus Editor provides comprehensive GUI capabilities for changing bus entities. You can Cut, Copy, and Paste within and between panes in any way that has a legal result. The Hierarchy and Dialog panes provide a Context menu for the current selection. Pasting a Copied entity always creates a copy, as distinct from a pointer to the original. The Bus Editor automatically changes names when needed to avoid duplication.

Changes made outside the bus editor can affect the information on display within it. Any change to an existing bus object or bus element is visible immediately in the editor. Any change that creates or deletes a bus object becomes visible in the bus editor next time its window is selected.

### Editing in the Hierarchy pane

You can select the root node **Base Workspace** and perform various operations, like export, cut, copy, paste, and delete. The operation simultaneously affects all bus objects displayed in the Hierarchy pane, but does not affect any that are invisible because a filter is in effect. See “Filter Displayed Bus Objects” on page 61-51 for details.

As you use the Bus Editor, the Hierarchy pane automatically reorders the bus objects it displays to maintain alphabetical order. This behavior cannot be changed. However, the elements under a bus object can appear in any order. To change that order, cut and paste elements as needed, or move elements up and down as follows:

- 1 Select the element to be moved.
- 2 Choose **Edit > Move Element Up** or **Edit > Move Element Down**.

You cannot Paste one bus object under another to create a nested bus object specification. To specify a nested bus, you must change the data type of a bus element to be the type of an existing bus object, as described in “Nest Buses” on page 61-19.

### Editing in the Contents Pane

Selecting any top-level bus object in the Hierarchy pane displays the object's elements in the Contents pane. Each element's properties appear to the right of the element's name,

and can be edited. To change a property displayed in the Contents pane, click the value, enter a new value, then press **Return**.

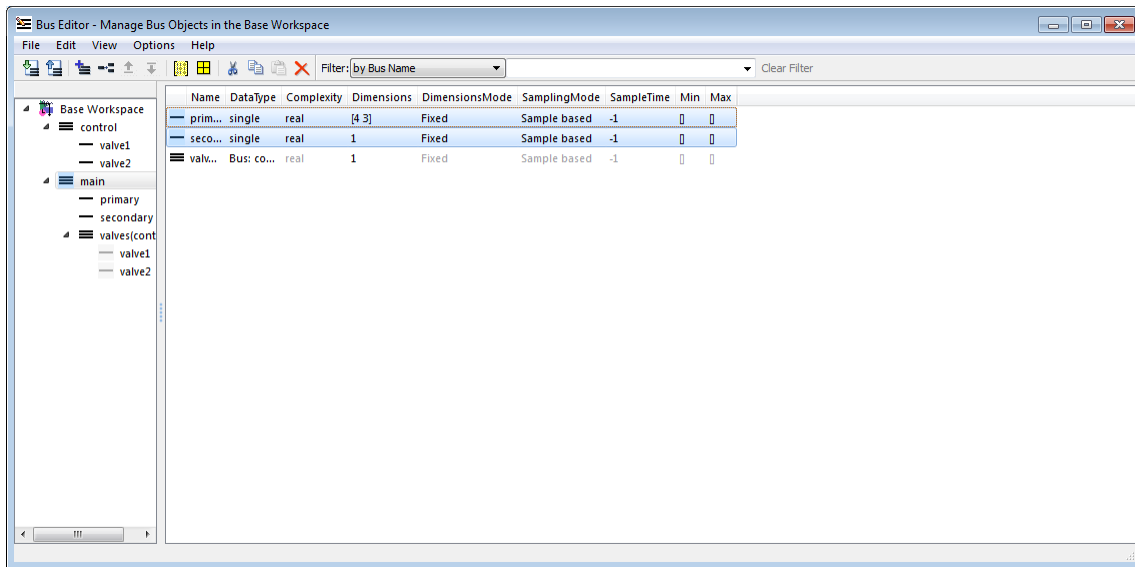

Choose **View > Dialog View** to hide the Dialog pane to provide more room to display properties in the Contents pane. Choose the command again to redisplay the Dialog pane.

You can use the mouse and keyboard to select multiple elements in the Contents pane. The selected entities need not be contiguous. You can then perform any operation that you could on a single entity selected in the pane, including operations performed with the Context menu. Clicking and editing a value in any selected element changes that value in them all.

The next figure shows the Bus Editor with **Dialog View** enabled, two elements selected in the Contents pane, and the **Data Type** property selected for editing in the second element:

If you change the value of **Data Type** to **single** and press Return, the value changes for both elements. The effect is the same no matter which element you edit in a multiple selection:

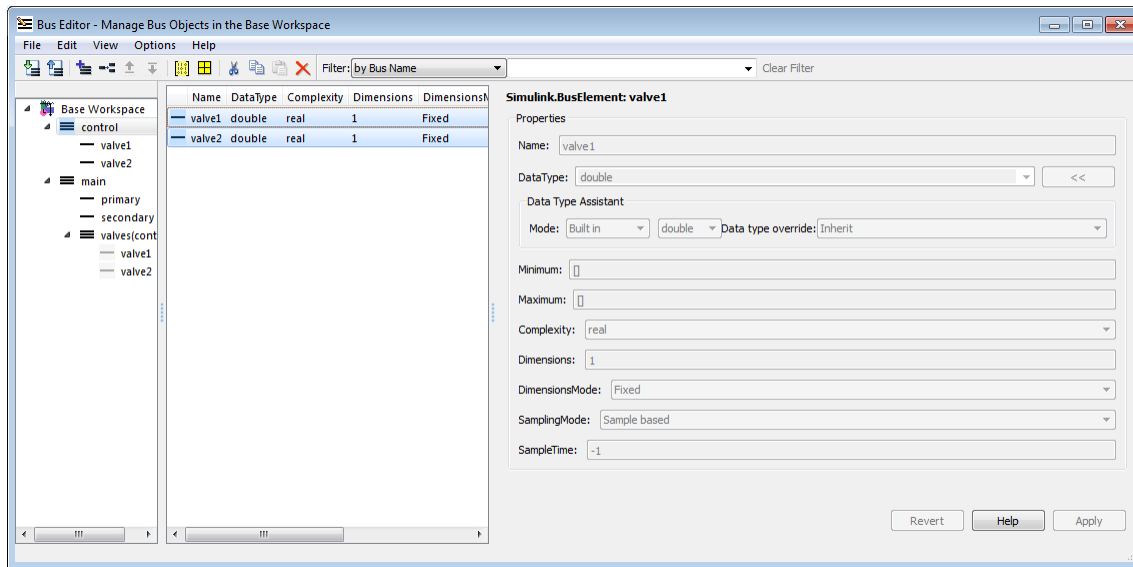

### Editing in the Dialog Pane

When a bus object is selected in the Hierarchy pane, or a bus object or element is selected in the Contents pane, the properties of the selected item appear in the Dialog pane. In the next figure, `valve1` is selected in the Contents pane, so the Dialog pane shows its properties:

The properties shown in the Dialog pane are editable, and the pane includes the Data Type Assistant. Click **Apply** to save changes, or **Revert** to cancel them and restore the values that existed before any unapplied changes. You can edit only one element at a time in the Dialog pane. If multiple entities are selected in the Contents pane, all fields in the Dialog pane are grayed out:

If you use the Dialog pane to change any property of a bus entity, then navigate elsewhere without clicking either **Apply** or **Revert**, a query box appears by default. The query box asks whether to apply changes, ignore changes, or continue as if the navigation had not been tried. You can suppress this query for future operations by checking **Never ask me again** in the box, or by selecting **Options > Auto Apply/Ignore Dialog Changes**.

If you suppress the query, and thereafter navigate away from a change without clicking **Apply** or **Revert**, the Bus Editor automatically applies or discards changes, depending on which action you most recently chose in the box. You can re-enable the query box for future operations by deselecting **Options > Auto Apply/Ignore Dialog Changes**.

## Export Bus Objects

Like all base workspace objects, bus objects are not saved with a model that uses them, but exist separately in a MATLAB code file or MAT-file. You can use the Bus Editor to export some or all bus objects to either type of file.

- If you export bus objects to a MATLAB code file, the Bus Editor asks whether to store them in object format or cell format (the default). Specify the desired format.

- If exporting would overwrite an existing MATLAB code file or MAT-file, a confirmation dialog box appears. Confirm the export or cancel it and try a different filename.

To export all bus objects from the base workspace to a file:

- 1 In the Bus Editor, choose **File > Export to File**.

The Export dialog box appears.

- 2 Specify the desired name and format of the export file.
- 3 Click **Save**.

All bus objects, and nothing else, are exported to the specified file in the specified format.

To export only selected bus objects from the base workspace to a file:

- 1 Select a bus object in the Hierarchy pane, or one or more bus objects in the Contents pane.
- 2 Right-click to display the Context menu.
- 3 Choose **Export to File** to export only the selected bus objects, or **Export with Related Bus Objects to File** to also export any nested bus objects used by the selected objects.
- 4 Use the Export dialog box to export the selected bus object(s).

Clicking the **Export** icon in the toolbar is equivalent to choosing **File > Export**, which exports all bus objects whether or not any are selected.

### Customizing Bus Object Export

You can customize bus object export by providing a custom function that writes the exported objects to something other than the default destination, a MATLAB code file or MAT-file stored in the file system. For example, the exported bus objects could be saved as records in a corporate database. See “Customize Bus Object Import and Export” on page 61-57 for details.

## Import Bus Objects

You can use the Bus Editor to import the definitions in a MATLAB code file or MAT-file to the base workspace. Importing the file imports the complete contents of the file, not

just any bus objects that it contains. If you import a file not exported by the Bus Editor, be careful that it does not contain unwanted definitions previously exported from the base workspace or created programmatically.

To import bus objects from a file to the base workspace:

- 1 Choose **File > Import into Base Workspace**.
- 2 Use the Open File dialog box to navigate to and import the desired file.

Before importing the file, the Bus Editor posts a warning that importing the file will overwrite any variable in the base workspace that has the same name as an entity in the file. Click **Yes** or **No** as appropriate. The imported bus objects appear immediately in the editor. You can also use capabilities outside the Bus Editor to import bus objects. Such objects do not appear in the Bus Editor until the next time its window becomes the current window.

### **Customizing Bus Object Import**

You can customize bus object import by providing a custom function that imports the objects from something other than the default source, a MATLAB code file or MAT-file stored in the file system. For example, the bus objects could be retrieved from records in a corporate database. See “Customize Bus Object Import and Export” on page 61-57 for details.

### **Close the Bus Editor**

To close the Bus Editor, choose **File > Close**. Closing the Bus Editor neither saves nor discards changes to bus objects, which remain unaffected in the base workspace. However, if you also close MATLAB without saving changes to bus objects, the changes will be lost. To save bus objects without saving other base workspace contents, use the techniques described in “Export Bus Objects” on page 61-44. You can also save bus objects using any MATLAB technique that saves the contents of the base workspace, but the resulting file will contain everything in the base workspace, not just bus objects.

You can configure the Bus Editor so that closing it posts a reminder to save bus objects. To enable the reminder, select **Options > Always Warn Before Closing**. When this option is selected and you try to close the Bus Editor, a reminder appears that asks whether the editor should save bus objects before closing. Click **Yes** to save bus objects and close, **No** to close without saving bus objects, or **Cancel** to dismiss the reminder and continue in the Bus Editor. You can disable the reminder by deselecting **Options > Always Warn Before Closing**.

## Store and Load Bus Objects

### In this section...

“Data Dictionary” on page 61-47

“MATLAB Code Files” on page 61-47

“MATLAB Data Files (MAT-Files)” on page 61-48

“Database or Other External Source Files” on page 61-48

You can store bus object objects in a variety of ways.

| Format                                      | When to Use  |
|---|--|
| In a data dictionary                        | For large model componentization   |
| As a MATLAB code file                       | For traceability and model differencing using MATLAB code  |
| As a MATLAB data file (MAT-file)            | For faster bus loading and saving  |
| In a database or other external data source | For comparing bus interface information with design documents stored in an external data source. |

### Data Dictionary

You can use the Model Explorer to create a new data dictionary that includes bus objects and link it to a model. For details, see “Migrate Single Model to Use Dictionary” on page 59-17.

### MATLAB Code Files

You can read and save bus data with MATLAB code files.

To save all bus objects (instances of the `Simulink.Bus` class) in the MATLAB base workspace to a MATLAB code file, use *one* of the following approaches:

- Use the Bus Editor (see “Export Bus Objects” on page 61-44 and “Import Bus Objects” on page 61-45).
- From the MATLAB command line, use the `Simulink.Bus.save` command.

To save variables from the base workspace to a MATLAB code file, use the `Simulink.saveVars` command. The file containing the variables is formatted to be easily understood and editable. Running the file restores the saved variables to the base workspace.

For traceability, consider using a clearly named separate file for each model.

## **MATLAB Data Files (MAT-Files)**

You can load bus objects in MATLAB data files (MAT-files), using *one* of the following approaches:

- Use the Bus Editor (see “Export Bus Objects” on page 61-44 and “Import Bus Objects” on page 61-45).
- From the MATLAB command line, use the `load` command.

Loading large data from MAT-files is faster than loading from MATLAB code files.

## **Database or Other External Source Files**

You can capture bus interface information in a database or other external source, and use scripts and Database Toolbox™ functionality to read that information into MATLAB.

You can use `sl_customization.m` to customize the Bus Editor to import bus data from a database or other external source. For details, see “Customize Bus Object Import and Export” on page 61-57.

## **Related Examples**

- “Map Bus Objects to Models” on page 61-49

## Map Bus Objects to Models

As models become complex, you need to keep track of which models use which bus objects. From any model or bus object, you should be able to tell what component it needs or is needed by.

A model must load all of its bus objects before you execute the model. For automation and consistency across models, it is important to map bus objects to models.

- By identifying all of the bus objects a model needs, you can ensure that those objects are loaded before model execution.
- By identifying all models that use a bus object, you can ensure that changes to a bus object do not cause unexpected changes in any of the models that use that bus object.

To map bus objects to models, consider:

- Including the bus objects in a data dictionary. You can link the data dictionary to one or more models. For details, see “Migrate Single Model to Use Dictionary” on page 59-17.
- Using Simulink Projects by:
  - 1 Serializing the files that contain the bus objects as part of a project
  - 2 Loading that data upon project open

For details, see “Project Management”.

- Capturing the mapping information in an external data source, such as a database.

### Use a Rigorous Naming Convention

Using a rigorous and standard naming convention for bus mapping information is a straightforward approach. For example, consider the model and data required for an actuator control function. You could name the model **Actuator** and name the input and output ports **Actuator\_bus\_in** and **Actuator\_bus\_out**, respectively. This naming convention makes it clear to what models a particular bus object is related, and vice versa.

Note that this approach can cause issues if the output from one model reference is fed directly to another model reference. In this case, the naming mismatch results in an error.

## **Related Examples**

- “Store and Load Bus Objects” on page 61-47

## Filter Displayed Bus Objects

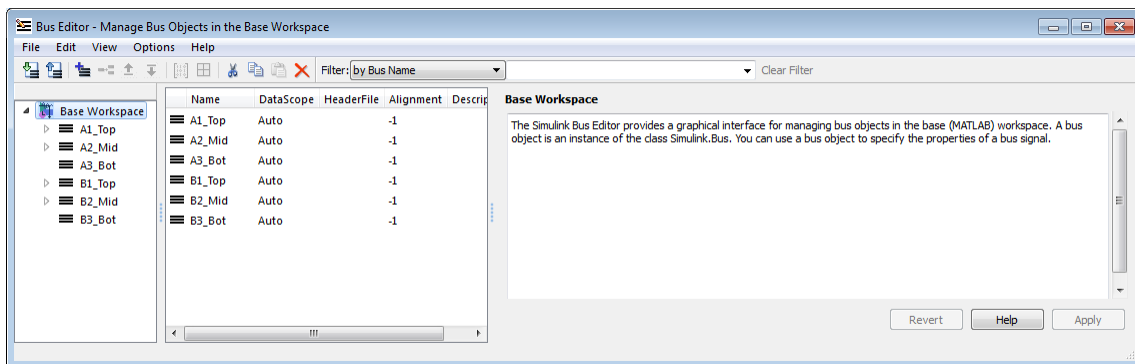

### In this section...

- “Filter by Name” on page 61-52
- “Filter by Relationship” on page 61-53
- “Change Filtered Objects” on page 61-55
- “Clear the Filter” on page 61-56

By default, the Bus Editor displays all bus objects that exist in the base workspace, always in alphabetical order. When a model contains large numbers of bus objects, seeing them all at the same time can be inconvenient. To facilitate working efficiently with large collections of bus objects, you can set the Bus Editor to display only bus objects that:

- Have names that match a given string or regular expression
- Have a specified relationship to a bus object specified by name

To set a filter, you specify values in the **Filter** boxes to the right of the tools in the toolbar. The left **Filter** box specifies the type of filtering. This box always appears, and is called the **Filter Type** box. Depending on the specified type of filtering, one or two boxes appear to the right of the **Filter Type** box. The next figure includes the **Filter** boxes (near the top of the dialog box) and shows that six bus objects exist in the Base Workspace:

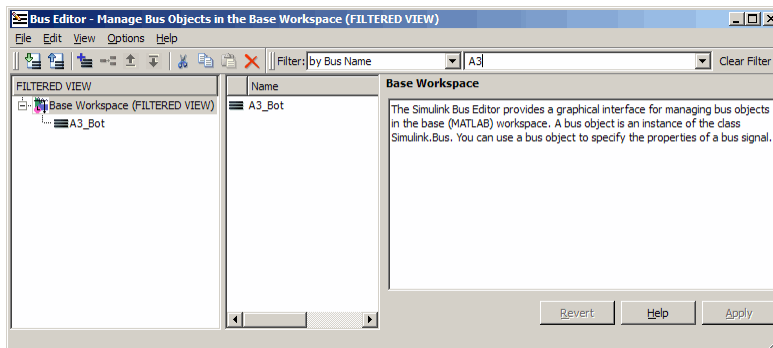

The bus objects shown form two disjoint hierarchies. A1\_Top is the parent of A2\_Mid, which is the parent of A3\_Bot. Similarly, B1\_Top > B2\_Mid > B3\_Bot. See “Nest Buses” on page 61-19 for information about bus object hierarchies.

## Filter by Name

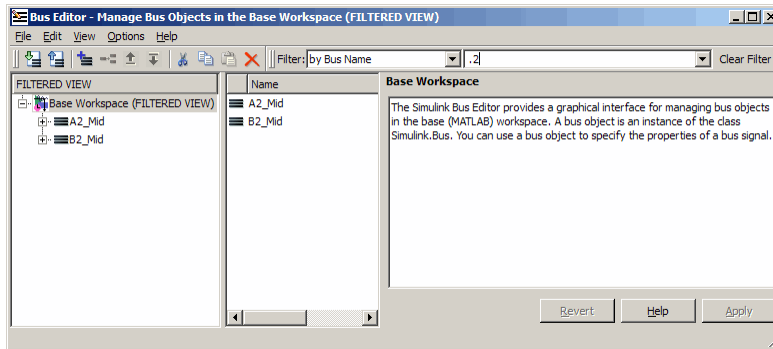

To filter bus objects by name, set the **Filter Type** box to **by Bus Name** (which is the default). The right **Filter** box is the **Object Name** box. Type any MATLAB regular expression (which can just be a string) into the **Object Name** box. As you type, the Bus Editor updates dynamically to show only bus objects whose names match the expression you have typed. The comparison is case-sensitive. For example, entering **A** displays:

Note that **FILTERED VIEW** appears in three locations, as shown in the preceding figure. This indicator appears whenever any filter is in effect. Entering the additional character **3** into the **Object Name** box displays:

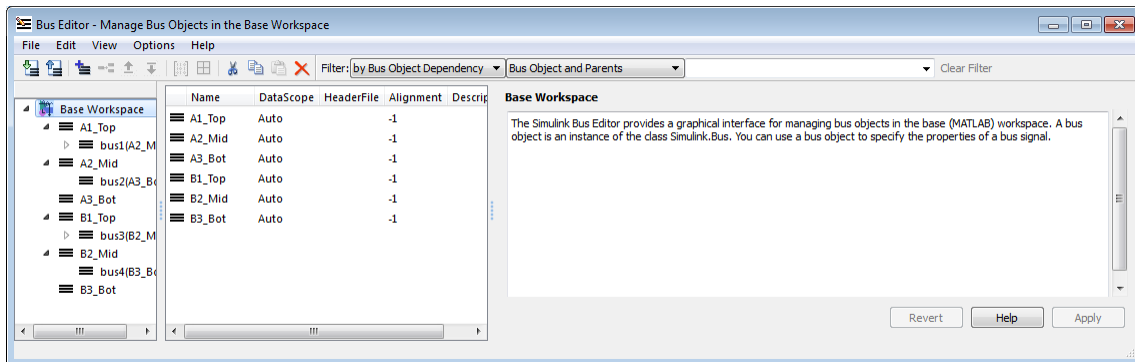

In a MATLAB regular expression, the metacharacter **dot** (**.**) matches any character, so entering **.2** displays:

See “Regular Expressions” for complete information about MATLAB regular expression syntax.

## Filter by Relationship

To filter bus objects by relationship, set the **Filter Type** box to **by Bus Object Dependency**. A third **Filter** box, called the **Relationship** box, appears between the **Filter Type** box and the **Object Name** box. You may have to widen the Bus Editor to see all three boxes:

In the **Relationship** box, select the type of relationship to display. The options are:

- **Bus Object and Parents** — Show a specified bus object and all superior bus objects in the hierarchy (default)
- **Bus Object and Dependents** — Show a specified bus object and all subordinate bus objects in the hierarchy

- **Bus Object and Related Objects** — Show a specified bus object and all superior and subordinate bus objects

In the **Object Name** box, specify a bus object by name. You can use the list to select any existing bus object name, or you can type a name. As you type, the editor:

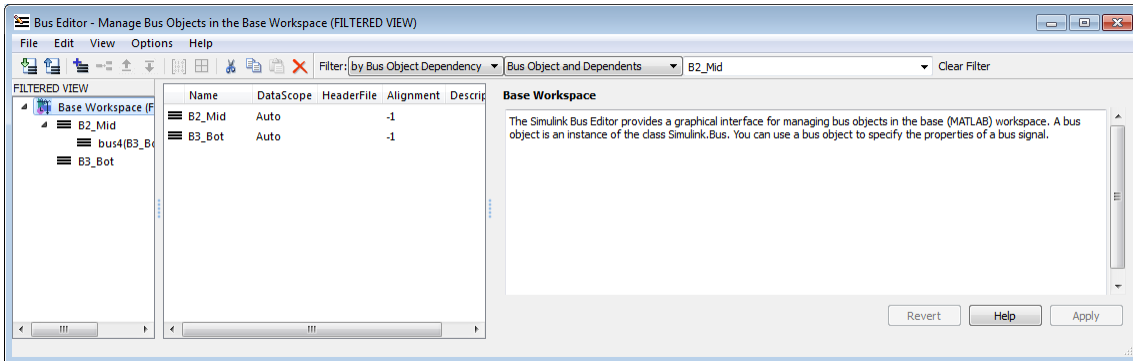

- Dynamically completes the field to indicate the first bus object that alphabetically matches what you have typed.
- Updates the display panes to show only that object and any objects that have the specified relationship to it.

When filtering by relationship, you must enter a string, not a regular expression, in the **Object Name** box. The match is case-sensitive. For example, assuming that **A1\_Top** is the parent of **A2\_Mid**, which is the parent of **A3\_Bot** (as previously described) if you enter **B2** (or any leftmost substring that matches only **B2\_Mid**) in the **Object Name** box, the Bus Editor displays the following for each of the three choices of relationship type:

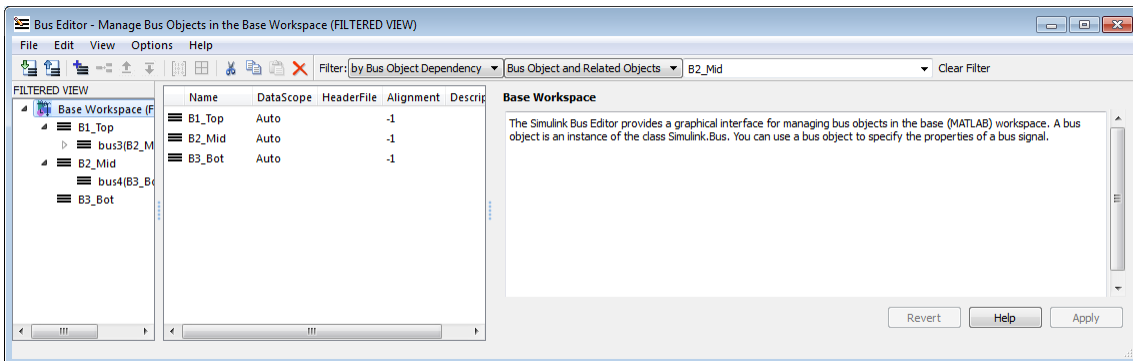

### Bus Object and Parents

### Bus Object and Dependents

## Bus Object and Related Objects

Note that **FILTERED VIEW** appears in each the preceding figures, as it does when any filter is in effect.

## Change Filtered Objects

You can work with any bus object that is visible in a filtered display exactly as you could in an unfiltered display. If you change the name or dependency of an object so that it no longer passes the current filter, the object vanishes from the display. Conversely, if some activity outside the Bus Editor changes a filtered object so that it passes the current filter, the object immediately becomes visible.

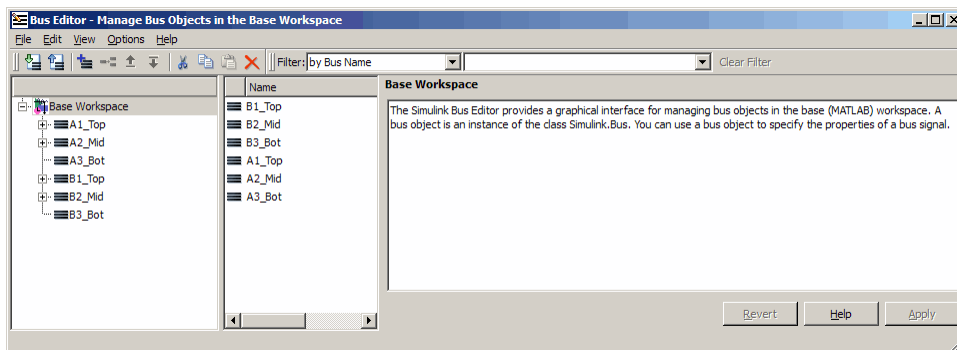

A new bus object created within the Bus Editor with a filter in effect may or may not appear, depending on the filter. If you create a new bus object but do not see it in the

editor, check the filter. The new object (whose name always begins with `BusObject`) may exist but be invisible. Bus objects created or imported using capabilities outside the Bus Editor are not visible until the Bus Editor window is next selected, regardless of whether a filter is in effect.

Operations performed on the root node **Base Workspace** in the Hierarchy pane, such as exporting bus objects, affect only visible objects. An object that is invisible because a filter is in effect is unaffected by the operation. If you want to export all existing bus objects, be sure to clear any filter that may be in effect before performing the export.

## Clear the Filter

To clear any filter currently in effect, click the **Clear Filter** button at the right of the Filter subpane, or press the **F5** key. The subpane reverts to its default state, in which all bus objects appear:

If you jump from a nested bus object to its source object by selecting the nested object and choosing **Go to 'element'** from its Context menu, and the source object is invisible due to a filter, the Bus Editor automatically clears the filter and selects the source object. Jumping to an object that is already visible leaves the filter unchanged.

## Customize Bus Object Import and Export

### In this section...

“Prerequisites for Customization” on page 61-58

“Writing a Bus Object Import Function” on page 61-58

“Writing a Bus Object Export Function” on page 61-59

“Registering Customizations” on page 61-59

“Changing Customizations” on page 61-61

You can use the Bus Editor to import bus objects to the base workspace, as described in “Import Bus Objects” on page 61-45, and to export bus objects from the base workspace, as described in “Export Bus Objects” on page 61-44. By default, the Bus Editor can import bus objects only from a MATLAB code file or MAT-file, and can export bus objects only to a MATLAB code file or MAT-file, with the files stored somewhere that is accessible using an ordinary **Open** or **Save** dialog.

Alternatively, you can customize the Bus Editor's import and export commands by writing MATLAB functions that provide the desired capabilities, and registering these functions using the Simulink Customization Manager. When a custom bus object import or export function exists, and you use the Bus Editor to import or export bus objects, the editor calls the custom import or export function rather than using its default capabilities.

A customized import or export function can have any desired effect and use any available technique. For example, rather than storing bus objects in MATLAB code files or MAT-files in the file system, you could provide customized functions that store the objects as records in a corporate database, perhaps in a format that also meets other corporate data management requirements.

This section describes techniques for designing and implementing a custom bus object import or export function, and for using the Simulink Customization Manager to register such a custom function. The registration process establishes the custom import and export functions as callbacks for the Bus Editor **Import to Base Workspace** and **Export to File** commands, replacing the default capabilities of the editor.

Customizing the Bus Editor's import and export capabilities has no effect on any MATLAB or Simulink API function: it affects only the behavior of the Bus Editor. You can customize bus object import, export, or both. You can establish, change, and cancel

import or export customization at any time. Canceling import or export customization restores the default Bus Editor capabilities for that operation without affecting the other.

## Prerequisites for Customization

To perform bus object import or export customization, you must understand:

- The MATLAB language and programming techniques that you will need.
- Simulink bus object syntax. See “About Bus Objects” on page 61-23, `Simulink.Bus`, `Simulink.BusElement`, and “Nest Bus Definitions” on page 61-37.
- The proprietary format into which you will translate bus objects, and all techniques necessary to access the facility that stores the objects.
- Any platform-specific techniques needed to obtain data from the user, such as the name of the location in which to store or access bus objects.

The rest of the information that you will need, including all necessary information about the Simulink Customization Manager appears in this section. For complete information about the Customization Manager, see “Simulink Environment Customization”.

## Writing a Bus Object Import Function

A function that customizes bus import can use any MATLAB programming construct or technique. The function can take zero or more arguments, which can be anything that the function needs to perform its task. You can use functions, global variables, or any other MATLAB technique to provide argument values. The function can also poll the user for information, such as a designation of where to obtain bus object information. The general algorithm of a custom bus object import function is:

- 1 Obtain bus object information from the local repository.
- 2 Translate each bus object definition to a Simulink bus object.
- 3 Save each bus object to the MATLAB base workspace.

An example of the syntactic shell of an import callback function is:

```
function myImportCallback
disp('Custom import was called!');
```

Although this function does not import any bus objects, it is syntactically valid and could be registered with the Simulink Customization Manager. A real import function would

somehow obtain a designation of where to obtain the bus object(s) to import; convert each one to a Simulink bus object; and store the object in the base workspace. The additional logic needed is enterprise-specific.

## Writing a Bus Object Export Function

A callback function that customizes bus export can use any MATLAB programming construct or technique. The function must take one argument, and can take zero or more additional arguments, which can be anything that the function needs to perform its task. When the Bus Editor calls the function, the value of the first argument is a cell array containing the names of all bus objects selected within the editor to be exported. You can use functions, global variables, or any other MATLAB technique to provide values for any additional arguments. The general algorithm of a customized export function is:

- 1 Iterate over the list of object names in the first argument.
- 2 Obtain the bus object corresponding to each name.
- 3 Translate the bus object to the proprietary syntax.
- 4 Save the translated bus object in the local repository.

An example of the syntactic shell of such an export callback function is:

```
function myExportCallback(selectedBusObjects)
disp('Custom export was called!');
for idx = 1:length(selectedBusObjects)
    disp([selectedBusObjects{idx} ' was selected for export.']);
end
```

Although this function does not export any bus objects, it is syntactically valid and could be registered. It accepts a cell array of bus object names, iterates over them, and prints each name. A real export function would use each name to retrieve the corresponding bus object from the base workspace; convert the object to proprietary format; and store the converted object somewhere. The additional logic needed is enterprise-specific.

## Registering Customizations

To customize bus object import or export, you provide a *customization registration function* that inputs and configures the Customization Manager whenever you start the Simulink software or subsequently refresh Simulink customizations. The steps for using a customization registration function are:

- 1 Create a file named `sl_customization.m` to contain the customization registration function (or use an existing customization file).
- 2 At the top of the file, create a function named `sl_customization` that takes a single argument (or use the customization function in an existing file). When the function is invoked, the value of this argument will be the Customization Manager.
- 3 Configure the `sl_customization` function to set `importCallbackFcn` and `exportCallbackFcn` to be function handles that specify your customized bus object import and export functions.
- 4 If `sl_customization.m` is a new customization file, put it anywhere on the MATLAB search path. Two frequently-used locations are `matlabroot` and the current working directory; or you may want to extend the search path.

A simple example of a customization registration function is:

```
function sl_customization(cm)
disp('My customization file was loaded. ');
cm.BusEditorCustomizer.importCallbackFcn = @myImportCallback;
cm.BusEditorCustomizer.exportCallbackFcn = @(x)myExportCallback(x);
```

When the Simulink software starts up, it traverses the MATLAB search path looking for files named `sl_customization.m`. The software loads each such file that it finds (not just the first file) and executes the `sl_customization` function at its top, establishing the customizations that the function specifies.

Executing the previous customization function will display a message (which an actual function probably would not) and establish that the Bus Editor uses a function named `myImportCallback()` to import bus objects, and a function named `myExportCallback(x)` to export bus objects.

The function corresponding to a handle that appears in a callback registration need not be defined when the registration occurs, but it must be defined when the Bus Editor later calls the function. The same latitude and requirement applies to any functions or global variables used to provide the values of any additional arguments.

Other functions can also exist in the `sl_customization.m` file. However, the Simulink software ignores files named `sl_customization.m` except when it starts up or refreshes customizations, so any changes to functions in the customization file will be ignored until one of those events occurs. By contrast, changes to other MATLAB code files on the MATLAB path take effect immediately.

## Changing Customizations

You can change the handles established in the `sl_customization` function by changing the function to specify the changed handles, saving the function, then refreshing customizations by executing:

```
sl_refresh_customizations
```

The Simulink software then traverses the MATLAB path and reloads all `sl_customization.m` files that it finds, executing the first function in each one, just as it did on Simulink startup.

You can revert to default import or export behavior by setting the appropriate `BusEditorCustomizer` element to `[]` in the `sl_customization` function, then refreshing customizations. Alternatively, you can eliminate both customizations in one operation by executing:

```
cm.BusEditorCustomizer.clear
```

where `cm` was previously set to a customization manager object (see “Registering Customizations” on page 61-59).

Changes to the import and export callback functions themselves, as distinct from changes to the handles that register them as customizations, take effect immediately unless they are in the `sl_customization.m` file itself, in which case they take effect next time you refresh customizations. Keeping the callback functions in separate files usually provides more flexible and modular results.

## Use Buses for Inports and Outports

| In this section...                                 |
|--|
| “Use Buses with Root Level Inports” on page 61-62  |
| “Use Buses with Root Level Outports” on page 61-62 |
| “Use Buses with Nonvirtual Inports” on page 61-62  |

This topic describes how to use buses with Inport and Outport blocks in a model.

For information about using buses as inputs to, or outputs from, a referenced model, see “Bus Data Crossing Model Reference Boundaries” on page 61-110.

### Use Buses with Root Level Inports

If you want a root level Inport of a model to produce a bus signal, in the Inport block parameters dialog box, set **Data type** to **Bus: <object name>** and replace <object name> with the name of the bus object name that defines the bus that the Inport produces. See “Bus Objects” on page 61-23 for more information.

### Use Buses with Root Level Outports

A root level Outport of a model can accept a virtual bus only if all elements of the bus have the same data type. The Outport block automatically unifies the bus to a vector having the same number of elements as the bus, and outputs that vector.

If you want a root level Outport of a model to accept a bus signal that contains mixed types, in the Outport block parameters dialog box, set **Data type** to **Bus: <object name>** and replace <object name> with the name of the bus object name that defines the bus that the Inport produces. If the bus signal is virtual, it will be converted to nonvirtual, as described in “Automatic Bus Conversion” on page 61-13. See “Bus Objects” on page 61-23 more information.

### Use Buses with Nonvirtual Inports

By default, an Inport block is a virtual block and accepts a bus as input. However, an Inport block is nonvirtual if:

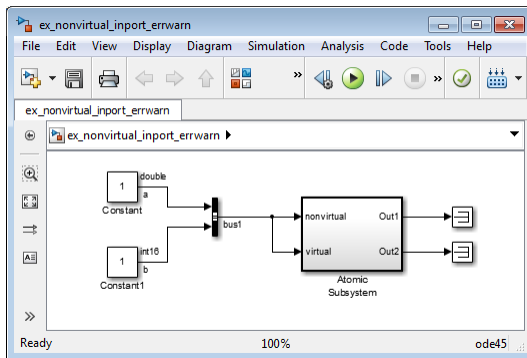

- The Inport block is in a conditionally executed or atomic subsystem, or in a referenced model.

- The bus or any of its elements are directly connected to the output of the subsystem or referenced model.

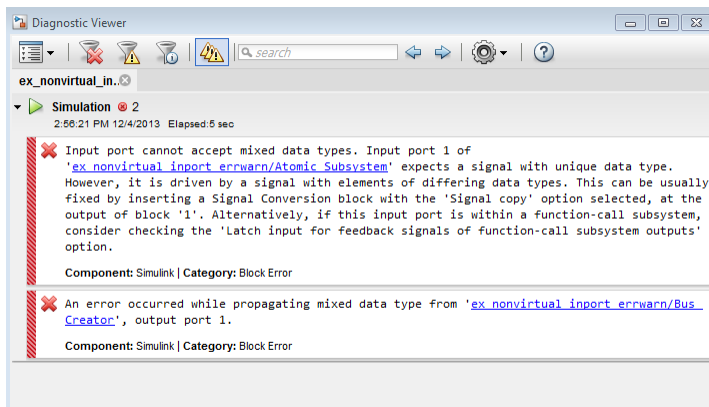

In such a case, the Inport block can accept a bus only if all elements of the bus have the same data type or the bus is a nonvirtual bus.

If the bus elements are of differing data types, attempting to simulate the model causes the Simulink software to halt the simulation and display an error message. You can avoid this problem, without changing the semantics of your model, by inserting a **Signal Conversion** block between the Inport block and the Outport block to which it was originally connected.

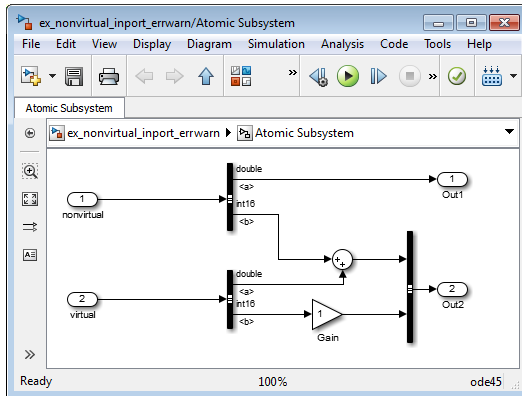

For example, the following model, which includes an atomic subsystem, does not simulate.

Starting the simulation generates the following error messages:

Opening the subsystem reveals that in this model, the Inport block labeled `nonvirtual` is nonvirtual because it resides in an atomic subsystem and one of its bus elements (labeled `a`) is directly connected to one of the subsystem's outputs. Further, the bus (`bus1`) connected to the subsystem's inputs has elements of differing data types. As a result, you cannot simulate this model.

To break the direct connection to the subsystem's output, insert a Signal Conversion block. Set the Signal Conversion block **Output** parameter to `Signal copy`. Inserting the Signal Conversion block enables the Simulink software to simulate the model.

## Specify Initial Conditions for Bus Signals

### In this section...

“Bus Signal Initialization” on page 61-65

“Create Initial Condition (IC) Structures” on page 61-66

“Three Ways to Initialize Bus Signals Using Block Parameters” on page 61-74

“Initialize Arrays of Buses” on page 61-78

“Setting Diagnostics to Support Bus Signal Initialization” on page 61-80

### Bus Signal Initialization

Bus signal initialization is a special kind of signal initialization. For general information about initializing signals, see “Initialize Signals and Discrete States” on page 60-48.

Bus signal initialization specifies the bus element values that Simulink uses for the first execution of a block that uses that bus signal. By default, the initial value for a bus element is the ground value (represented by 0). Bus initialization, as described in this section, involves specifying nonzero initial conditions (ICs).

You can use bus signal initialization features to:

- Specify initial conditions for signals that have different data types
- Apply a different initial condition for each signal in the bus
- Specify initial conditions for a subset of signals in a bus without specifying initial conditions for all the signals
- Use the same initial conditions for multiple blocks, signals, or models

### Blocks that Support Bus Signal Initialization

You can initialize bus signal values that input to a block, if that block meets both of these conditions:

- It has an initial value or initial condition block parameter
- It supports bus signals

The following blocks support bus signal initialization:

- Data Store Memory
- Memory
- Merge
- Output (when the block is inside a conditionally executed context)
- Rate Transition
- Unit Delay

For example, the Unit Delay block is a bus-capable block and the Block Parameters dialog box for the Unit Delay block has an **Initial conditions** parameter.

### **Initialization Is Not Supported for Bus Signals with Variable-Size or Frame-Based Elements**

You cannot initialize a bus that has:

- Variable-size signals
- Frame-based signals

### **Workflow for Initializing Bus Signals Using Initial Condition Structures**

You need to set up your model properly to use initial condition structures to initialize bus signals. The general workflow involves the tasks listed in the following table. You can vary the order of the tasks, but before you update the diagram or run a simulation, you need to ensure your model is set up properly.

| <b>Task</b>   | <b>Documentation</b>  |
|---|---|
| Define an IC structure                                      | “Create Initial Condition (IC) Structures” on page 61-66                    |
| Use an IC structure to specify a nonzero initial condition. | “Three Ways to Initialize Bus Signals Using Block Parameters” on page 61-74 |
| Set Configuration Parameters dialog box diagnostics         | “Setting Diagnostics to Support Bus Signal Initialization” on page 61-80    |

### **Create Initial Condition (IC) Structures**

You can create partial or full IC structures to represent initial values for a bus signal. Create an IC structure by either:

- Defining a MATLAB structure in the MATLAB base or Simulink model workspace
- Specifying an expression that evaluates to a structure for the initial condition parameter in the Block Parameters dialog box for a block that supports bus signal initialization

For information about defining MATLAB structures, see “Create a Structure Array” in the MATLAB documentation.

### **Full and Partial IC Structures**

A full IC structure provides an initial value for every element of a bus signal. This IC structure mirrors the bus hierarchy and reflects the attributes of the bus elements.

A partial IC structure provides initial values for a subset of the elements of a bus signal. If you use a partial IC structure, during simulation, Simulink creates a full IC structure to represent all of the bus signal elements, assigning the respective ground value to each element for which the partial IC structure does not explicitly assign a value.

Specifying partial structures for block parameter values can be useful during the iterative process of creating a model. Partial structures enable you to focus on a subset of signals in a bus. When you use partial structures, Simulink initializes unspecified signals implicitly.

Specifying full structures during code generation offers these advantages:

- Generates more readable code
- Supports a modeling style that explicitly initializes all signals

### **Match IC Structure Values to Corresponding Bus Element Data Characteristics**

The field that you specify in an IC structure must match the following data attributes of the bus element exactly:

- Name
- Dimension
- Complexity

For example, if you define a bus element to be a real [2x2] double array, then in the IC structure, define the value to initialize that bus element to be a real [2x2] double array.

You must explicitly specify fields in the IC structure for every bus element that has an enumerated (enum) data type.

When you define a partial IC structure:

- Include only fields that are in the bus.
- You can omit fields that are in the bus.
- Make the field in the IC structure correspond to the nesting level of the bus element.
- Within the same nesting level in both the structure and the bus, you can specify the structure fields in a different order than the order of the elements in the bus.

---

**Note:** The value of an IC structure must lie within the design minimum and maximum range of the corresponding bus element. Simulink performs this range checking during an update diagram and when you run the model.

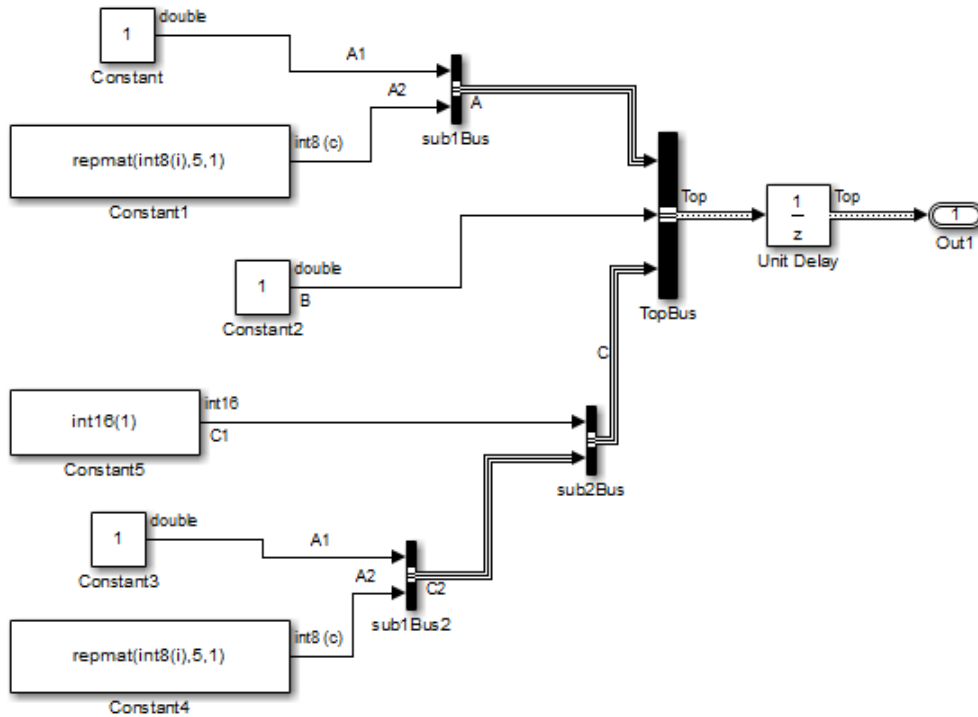

---

### Examples of Partial Structures

Suppose you have a bus, `Top`, composed of three elements: `A`, `B`, and `C`, with these characteristics:

- `A` is a nested bus, with two signal elements.
- `B` is a single signal.
- `C` is a nested bus that includes bus `A` as a nested bus.

The following model, `ex_busic` includes the nested `Top` bus. The screen capture below shows the model after it has been updated. .

The following diagram summarizes the Top bus hierarchy and the data type, dimension, and complexity of the bus elements .

Top

```

A (sub1)
  A1 (double)
  A2 (int8, 5x1, complex)
B (double)
C (sub2)
  C1 (int16)
  C2 (sub1)
    A1 (double)
    A2 (int8, 5x1, complex)

```

#### Valid partial IC structures

In the following examples, K is an IC structure specified for the initial value of the Unit Delay block. The IC structure corresponds to the Top bus in the ex\_busic model.

The following table shows valid initial condition specifications.

| Valid Syntax                                       | Description  |
|--|--|
| <code>K.A.A1 = 3</code>                            | Initializes the bus element <code>Top.A.A1</code> using the value 3.   |
| <code>K = struct('C',struct('C1',int16(4)))</code> | The bus element <code>Top.C.C1</code> is <code>int16</code> . The corresponding structure field explicitly specifies <code>int16(4)</code> . Alternatively, you could specify the field value as 4 without specifying an explicit data type. |
| <code>K = struct('B',3,'A',struct('A1',4))</code>  | Bus element <code>Top.B</code> and <code>Top.A</code> are at the same nesting level in the bus. For bus elements at the same nesting level, the order of corresponding structure fields does not matter.                                     |

#### Invalid partial IC structures

In the following examples, `K` is an IC structure specified for the initial value of the Unit Delay block. The IC structure corresponds to the `Top` bus in the `ex_busic` model.

These three initial condition specifications are *not* valid:

| Invalid Syntax                       | Reason the Syntax Is Invalid  |
|--------------------------------------|---|
| <code>K.A.A2 = 3</code>              | Value dimension and complexity do not match. The bus element <code>Top.A.A2</code> is <code>5x1</code> , but <code>K.A.A2</code> is <code>1x1</code> ; <code>Top.A.A2</code> is complex, but <code>K.A.A2</code> is real. |
| <code>K.C.C2 = 3</code>              | You cannot use a scalar value to initialize IC substructures.   |
| <code>K = struct('B',3,'X',4)</code> | You cannot specify fields that are not in the bus ( <code>X</code> does not exist in the bus).  |

#### Creating Full IC Structures Using `Simulink.Bus.createMATLABStruct`

Use the `Simulink.Bus.createMATLABStruct` function to streamline the process of creating a full MATLAB initial condition structure with the same hierarchy, names, and data attributes as a bus signal. This function fills all the elements that you do not specify with the ground values for those elements.

You can use several different kinds of input with the `Simulink.Bus.createMATLABStruct` function, including

- A bus object name
- An array of port handles

You can invoke the `Simulink.Bus.createMATLABStruct` function from the Bus Editor, using one of these approaches:

- Select the **File > Create a MATLAB structure** menu item.
- Select the bus object for which you want to create a full MATLAB structure and click the **Create a MATLAB structure** icon () from the toolbar.

You can then edit the MATLAB structure in the MATLAB Editor.

See the `Simulink.Bus.createMATLABStruct` documentation for details.

### Decide Whether to Specify Data Types for Structure Fields

To specify a field value, you can use either of these techniques:

- Use an untyped expression such as `4`. The field implicitly uses the data type `double`. If the corresponding bus signal elements use data types other than `double`, the bus elements cast the values of the structure fields prior to simulation. This technique allows you to avoid explicitly specifying a data type for each structure field.

If you have a Simulink Coder license, and if you set **Configuration Parameters > Optimization > Signals and Parameters > Default parameter behavior** to **Inlined**, you can use this technique to create the structure. The structure appears nontunable in the generated code. However, it is a best practice for code generation to match the structure field types with the bus element types.

- Use a typed expression such as `int16(4)`. If you use this technique, match the data type of the structure field with the data type of the corresponding bus element.

If you have a Simulink Coder license, this technique allows you to:

- Eliminate unnecessary runtime casts from the structure field type to the bus element type.
- Create tunable initial condition structures.

For examples and more information about initial conditions in the generated code, see “Control Signal and State Initialization in the Generated Code”.

Whether you use typed or untyped expressions, you can use a `Simulink.Bus` object to specify the data type of the entire initial condition structure. This technique allows you to manage the field values and data types independently. If you have a Simulink Coder license, this technique allows you to more easily match the structure field types with the bus element types for code generation. If you have a Fixed-Point Designer license, this technique helps you to avoid data type mismatches when you perform data type override on a system that contains bus signals.

For basic information about bus objects, see “Bus Objects” on page 61-23. For information about using bus objects in the fixed-point workflow, see “Bus Objects in the Fixed-Point Workflow”.

### Use Untyped Expressions

You can use untyped expressions to specify the structure field values. Use the structure fields to represent the ideal real-world initialization values. Use the bus signal elements to control the data types. If you use this technique, you do not need to change the data types of the structure fields if you later change the data types of the bus elements.

Suppose that you create a bus signal `myBus` with these signal elements. Each element uses a specific data type.

```
myBus
    signalElement1 (int32)
    signalElement2 (boolean)
    signalElement3 (single)
```

Create an initial condition structure `initStruct`. Use untyped expressions to specify the field values. To enhance readability of the Boolean field `signalElement2`, use the value `false`.

```
initStruct.signalElement1 = 3;
initStruct.signalElement2 = false;
initStruct.signalElement3 = 17.35;
```

All of the structure fields, except `signalElement2`, implicitly use the data type `double`. Prior to simulation, the bus signal elements cast the values of the structure fields.

### Use Typed Expressions

Suppose that you create a bus signal `myBus` with this hierarchy of signal elements. Each element uses a specific data type.

```
myBus
    signalElement1 (int32)
```

```

signalElement2 (boolean)
signalElement3 (single)

```

Create an initial condition structure `initStruct`. Match the data types of the structure fields with the data types of the corresponding bus elements.

```

initStruct.signalElement1 = int32(3);
initStruct.signalElement2 = false;
initStruct.signalElement3 = single(17.35);

```

If you later change the data type of a bus element and forget to change the data type of the corresponding structure field, the bus element casts the value of the structure field prior to simulation. To detect quantization effects, downcasts, and losses of precision due to this cast, adjust the settings on the **Diagnostics > Data Validity** pane of the Configuration Parameters dialog box.

### Use Bus Object as Data Type for Initial Condition Structure

To control the data types that the structure fields and the signal elements use during simulation and in the generated code, you can create a `Simulink.Bus` object.

Suppose that you use a Bus Creator block to create a bus signal `myBus` with these signal elements.

```

myBus
  signalElement1 (int32)
  signalElement2 (boolean)
  signalElement3 (single)

```

- 1 Open the Bus Editor.

```
buseditor
```

- 2 Create a bus object `myBus` that corresponds to the bus signal.

- 3 Create an initial condition structure `initStruct`.

```
initStruct.signalElement1 = 3;
```

```
initStruct.signalElement2 = false;  
initStruct.signalElement3 = 17.35;
```

- 4 Create a `Simulink.Parameter` object to represent the structure.

```
initStruct = Simulink.Parameter(initStruct);
```

- 5 Use the parameter object to specify an initial condition for the bus signal. For example, in a Unit Delay block dialog box, set **Initial condition** to `initStruct`.

- 6 Use the bus object to specify the data type of the parameter object.

```
initStruct.DataType = 'Bus: myBus';
```

- 7 Use the bus object to specify the data type of the bus signal. For example, in the Bus Creator block dialog box, set **Output data type** to `Bus: myBus`.

During simulation and in the generated code, the structure fields and the signal elements use the data types that you specify in the bus object. Prior to simulation and code generation, the parameter object casts the structure fields to the data types that you specify in the bus object.

### Convert Between Untyped and Typed Expressions

To convert all of the fields of an initial condition structure from typed expressions to doubles, you can write a custom function. Use the example function `castStructToDbl` as a template.

To convert a structure that uses doubles to one that uses typed expressions, you can create a reference structure using the function `Simulink.Bus.createMATLABStruct`. You can then write a custom function to perform the type conversions. Use the example function `castStructFromDbl` as a template.

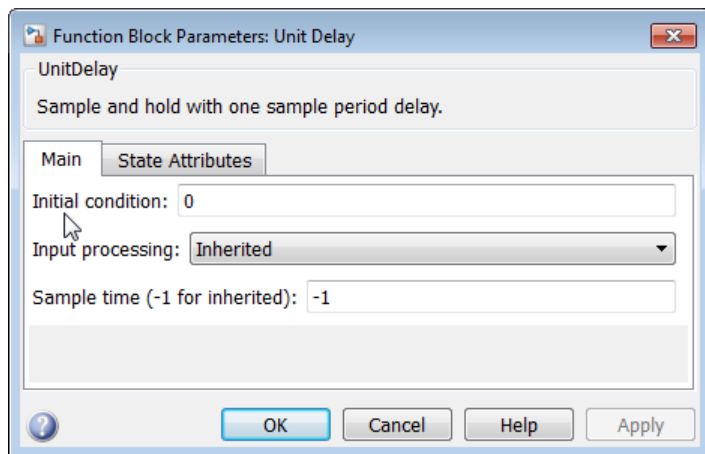

### Using Model Advisor to Check for Partial Structures

To detect when structure parameters are not consistent in shape (hierarchy and names) with the associated bus signal, in the Simulink Editor, use the **Analysis > Model Advisor > By Product > Simulink** “**Check for partial structure parameter usage with bus signals**” check. This check identifies partial IC structures.

### Three Ways to Initialize Bus Signals Using Block Parameters

Initialize a bus signal by setting the initial condition parameter for a block that receives a bus signal as input and that supports bus initialization (see “Blocks that Support Bus Signal Initialization” on page 61-65).

For example, the Block Parameters dialog box for the Unit Delay block has an **Initial conditions** parameter.

For a block that supports bus signal initialization, you can replace the default value of 0 using one of these approaches:

- “MATLAB Structure for Initialization” on page 61-75
- “MATLAB Variable for Initialization” on page 61-76
- “Simulink.Parameter for Initialization” on page 61-77

All three approaches require that you define an IC structure (see “Create Initial Condition (IC) Structures” on page 61-66). You cannot specify a nonzero scalar value or any other type of value other than 0, an IC structure, or `Simulink.Parameter` object to initialize a bus signal.

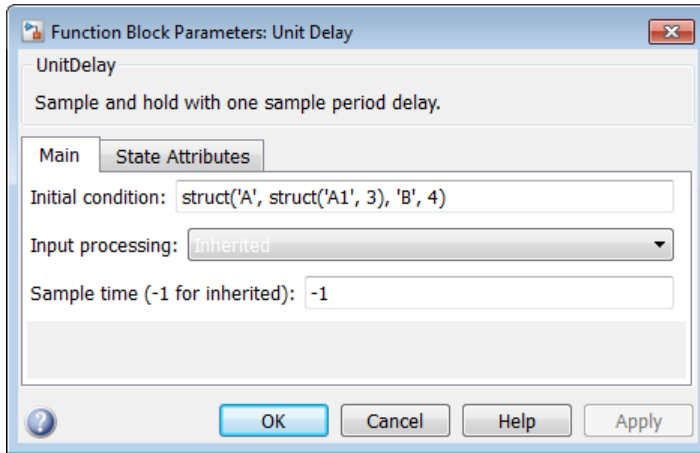

Defining an IC structure as a MATLAB variable, rather than specifying the IC structure directly in the block parameters dialog box offers several advantages, including:

- Reuse of the IC structure for multiple blocks
- Using the IC structure as a tunable parameter in the generated code

### **MATLAB Structure for Initialization**

You can initialize a bus signal using a MATLAB structure that explicitly defines the initial conditions for the bus signal.

For example, in the **Initial conditions** parameter of the Unit Delay block, you could type in a structure such as shown below:

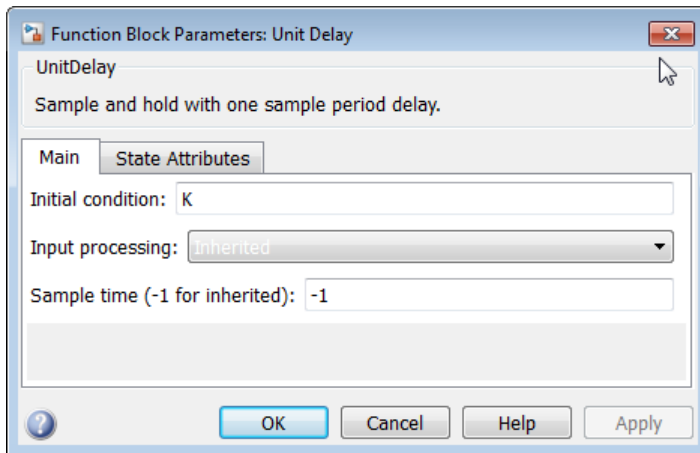

### MATLAB Variable for Initialization

You can initialize a bus signal using a MATLAB variable that you define as an IC structure with the appropriate values.

For example, you could define the following partial structure in the base workspace:

```
K = struct('A', struct('A1', 3), 'B', 4);
```

You can then specify the K structure as the **Initial conditions** parameter of the Unit Delay block:

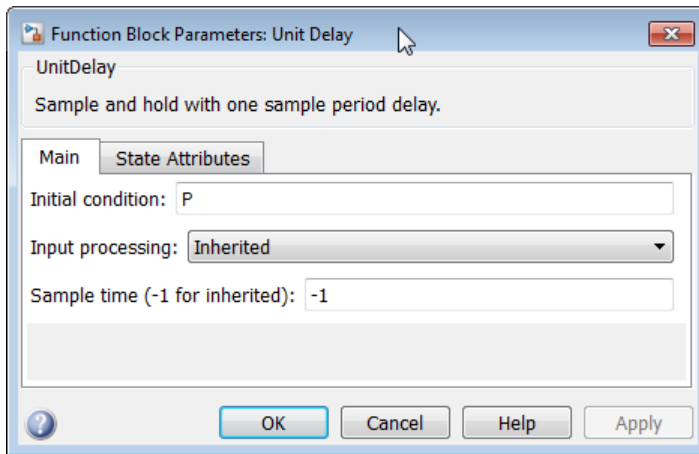

### Simulink.Parameter for Initialization

You can initialize a bus signal using a `Simulink.Parameter` object that uses an IC structure for the `Value` property.

For example, you could define the partial structure `P` in the base workspace (reflecting the `ex_busic` model discussed in the previous section):

```
P = Simulink.Parameter;
P.DataType = 'Bus: Top';
P.Value = Simulink.Bus.createMATLABStruct('Top');
P.Value.A.A1 = 3;
P.Value.B = 5;
```

You can then specify the `P` structure as the **Initial conditions** parameter of the Unit Delay block:

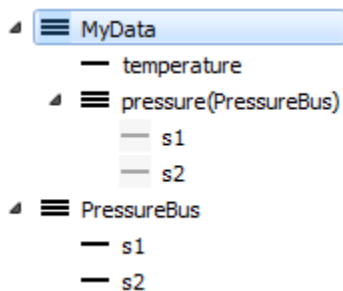

## Initialize Arrays of Buses

To specify a unique initial value for each of the individual signals in an array of buses, you can use an array of initial condition structures. Each structure in the array initializes one of the buses.

### Initialize an Array of Buses

Suppose that you define the bus types `MyData` and `PressureBus`.

Suppose that you set the data type of the signal element `temperature` to `int16`, and the data type of the elements `s1` and `s2` to `double`.

To specify initial conditions for an array of buses, you can create a variable whose value is an array of initial condition structures.

```
initValues(1).temperature = int16(5);  
initValues(1).pressure.s1 = 9.87;  
initValues(1).pressure.s2 = 8.71;  
  
initValues(2).temperature = int16(20);  
initValues(2).pressure.s1 = 10.21;  
initValues(2).pressure.s2 = 9.56;  
  
initValues(3).temperature = int16(35);  
initValues(3).pressure.s1 = 8.98;  
initValues(3).pressure.s2 = 9.17;
```

The variable `initValues` provides initial conditions for a signal that is an array of three buses. You can use `initValues` to specify the **Initial condition** parameter of a block such as Unit Delay.

Alternatively, you can use a single scalar structure to specify the same initial conditions for all of the buses in the array.

```
initStruct.temperature = int16(15);  
initStruct.pressure.s1 = 10.32;  
initStruct.pressure.s2 = 9.46;
```

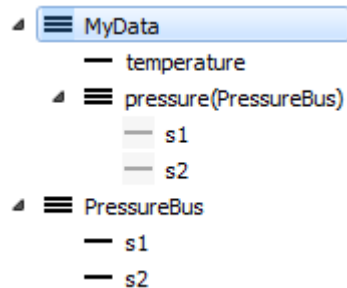

If you specify `initStruct` in the **Initial condition** parameter of a block, each bus in the array uses the same initial value, 15, for the signal element `temperature`. Similarly, the buses use the initial value 10.32 for the element `pressure.s1` and the value 9.46 for the element `pressure.s2`.

To create an array of structures for a bus that uses a large hierarchy of signal elements, consider using the function `Simulink.Bus.createMATLABStruct`.

### Initialize Nested Arrays of Buses

Create an initial condition structure for a complicated signal hierarchy that includes nested arrays of buses.

- 1 In the Bus Editor, create the bus objects `MyData` and `PressureBus`.

- 2 In the hierarchy pane, select the bus element **pressure**. Set the **Dimensions** property to [1 3].
- 3 Create an array of four initialization structures by using the function `Simulink.Bus.createMATLABStruct`. Store the array in the variable `initStruct`. Initialize all of the individual signals to the ground value, 0.

```
initStruct=Simulink.Bus.createMATLABStruct('MyData',[],[1 4]);
```

- 4 In the base workspace, double-click the variable `initStruct` to view it in the variable editor.

The four structures in the array each have the fields `temperature` and `pressure`.

- 5 Double-click one of the `pressure` fields to inspect it.

The value of each of the four `pressure` fields is an array of three substructures. Each substructure has the fields `s1` and `s2`.

- 6 To provide unique initialization values for the signals in an array of buses, you can specify the values manually using the variable editor.

Alternatively, you can write a script. For example, to access the field `s1` of the second substructure `pressure` in the third structure of `initStruct`, use this code:

```
initStruct(3).pressure(2).s1 = 15.35;
```

## Setting Diagnostics to Support Bus Signal Initialization

To enable bus signal initialization, before you start a simulation, set the following two Configuration Parameter diagnostics as indicated:

- In the **Configuration Parameters > Diagnostics > Connectivity** pane, set **“Mux blocks used to create bus signals”** to error.
- **Configuration Parameters > Diagnostics > Data Validity** pane, set **“Underspecified initialization detection”** to simplified.

The documentation for these diagnostics explains how convert your model to handle error messages the diagnostics generate.

## Combine Buses into an Array of Buses

---

**Tip** Simulink provides several techniques for combining signals into a composite signal. For a comparison of techniques, see “Techniques for Combining Signals” on page 61-3.

---

### What Is an Array of Buses?

An array of buses is an array whose elements are buses. Each element in an array of buses must be nonvirtual and must have the same bus type. Each bus object has the same signal name, hierarchy, and attributes for its bus elements.

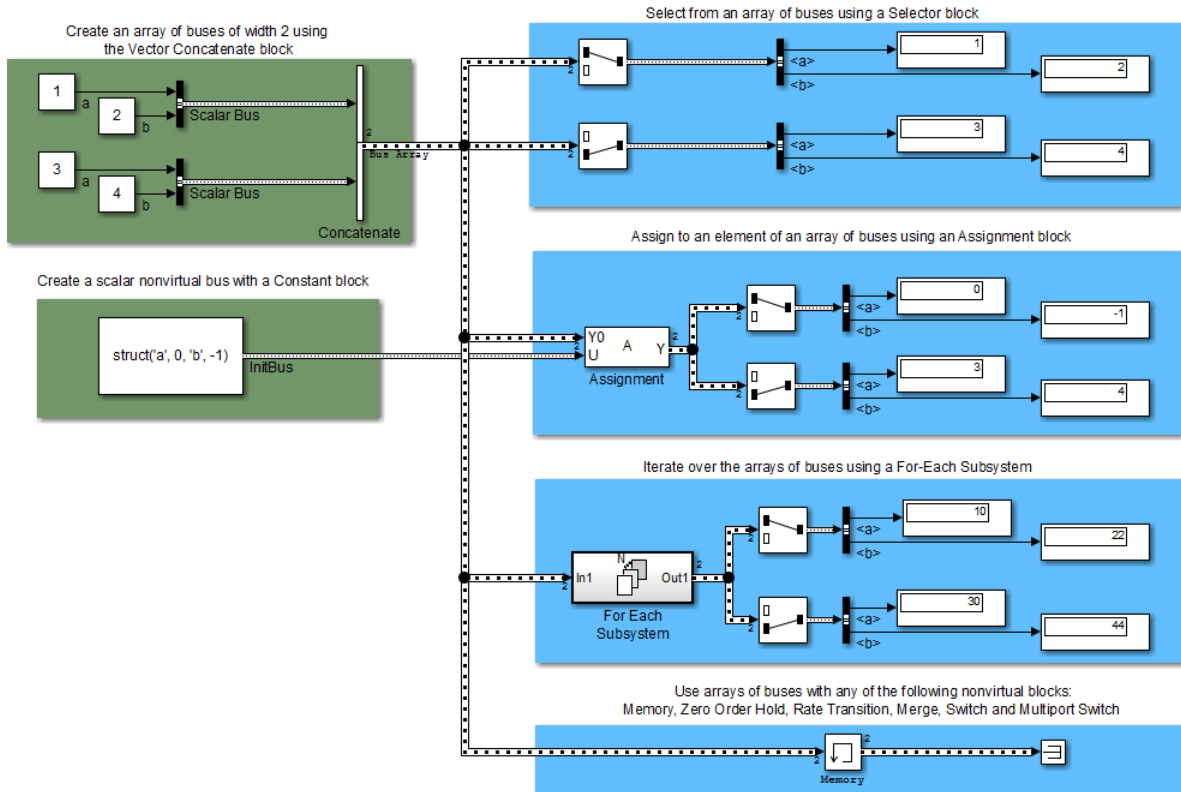

An example of using an array of buses is to model a multi-channel communication system. You can model all of the channels using the same bus object, although each of the channels could have a different value.

Using arrays of buses involves:

- Using a bus object as a data type (see “Specify a Bus Object Data Type” on page 55-34)
- Specifying dimensions for the bus and bus elements

For an example of a model that uses an array of buses, open the `sldemo_bus_arrays` model. In this example, the nonvirtual bus input signals connect to a Vector Concatenate or Matrix Concatenate block that creates an array of bus signals. When you update the diagram, the model looks like the following figure:

## Modeling Arrays of Bus Signals

The model uses the array of buses with:

- An Assignment block, to assign a bus in the array
- A For Each Subsystem block, to perform iterative processing over each bus in the array
- A Memory block, to output the array of buses input from the previous time step

## Benefits of an Array of Buses

Using an array of buses:

- Represents structured data compactly

- Reduces model complexity
- Reduces maintenance by centralizing algorithms used for processing multiple buses
- Streamlines iterative processing of multiple buses of the same type, for example, by using a For Each Subsystem with the array of buses
- Simplifies changing the number of buses, without your having to restructure the rest of the model or make updates in multiple places in the model
- Allows models to use built-in blocks, such as the Assignment or Selector blocks, to manipulate arrays of buses just like arrays of any other type, rather than your creating custom S-functions to manage packing and unpacking structure signals
- Supports using the combined bus data across subsystem boundaries, model reference boundaries, and into or out of a MATLAB Function block
- Allows you to keep all the logic in the Simulink model, rather than splitting the logic between C code and the Simulink model
  - Supports integrated consistency and correctness checking, maintaining metadata in the model, and avoids your keeping track of model components in two different environments
- Generates code that has an array of C structures, which you can integrate with legacy C code that uses arrays of structures
  - Simplifies indexing into an array for Simulink computations, using a `for` loop on indexed structures

## Array of Buses Limitations

### Bus Limitations

The buses combined into an array must all:

- Be nonvirtual
- Have the same bus type (that is, same name, hierarchies, and attributes for the bus elements)
- Have no variable-size signals or frame-based signals

### Supported Blocks

You can use arrays of buses with the following blocks:

- Virtual blocks
- Several nonvirtual blocks, such as:
  - Some signal routing blocks (for example, Data Store Memory, Merge, and Switch)
  - Rate Transition and Zero-Order Hold blocks
- Several additional blocks, such as Assignment, MATLAB Function, and Signal Conversion

For a complete list, see “Blocks That Support Arrays of Buses” on page 61-88. That section describes requirements for using the supported blocks.

### **Structure Parameter Limitations**

To initialize an array of buses with structure parameters, you can use:

- The number `0`. In this case, all of the individual signals in the array of buses use the initial value `0`.
- A scalar `struct` that represents the same hierarchy of fields and field names as the bus type. In this case, the scalar structure expands to initialize each of the individual signals in the array of buses.
- An array of structures that specifies an initial value for each of the individual signals in the array of buses.

You cannot use partial structures.

If you use an array of structures, all of the structures in the array must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics across the array:

- Field name
- Numeric data type, such as `single` or `int32`
- Complexity
- Dimensions

For more information about specifying initial conditions for bus signals, see “Specify Initial Conditions for Bus Signals” on page 61-65.

### **Signal Logging Limitation**

Simulink does not log signals inside referenced models in Rapid Accelerator mode.

## Stateflow Limitations

Stateflow action language does not support arrays of buses.

## Define an Array of Buses

For information about the kinds of buses that you can combine into an array of buses, see “Bus Limitations” on page 61-84.

To define an array of buses, use a **Concatenate** block. The table describes the array of buses input requirements and output for each of the **Vector Concatenate** and the **Matrix Concatenate** versions of the **Concatenate** block.

| Block              | Bus Signal Input Requirement                                   | Output  |
|--------------------|--|---|
| Vector Concatenate | Vectors, row vectors, or columns vectors                       | If any of the inputs are row or column vectors, output is a row or column vector.   |
| Matrix Concatenate | Signals of any dimensionality (scalars, vectors, and matrices) | Trailing dimensions are assumed to be 1 for lower dimensionality inputs.<br><br>Concatenation is on the dimension that you specify with the <b>Concatenate dimension</b> parameter. |

---

**Note:** Do not use a **Mux** block or a **Bus Creator** block to define an array of buses. Instead, use a **Bus Creator** block to create scalar bus signals.

---

- 1 Define *one* bus object to use for *all* of the buses that you want to combine into an array of buses. For information about defining bus objects, see “Create Bus Objects” on page 61-31.

The `sldemo_bus_arrays` model defines an `sldemo_bus_arrays_busobject` bus object, which both of the **Bus Creator** blocks use for the input bus signals (**Scalar Bus**) for the array of buses.

- 2 Add a **Vector Concatenate** or **Matrix Concatenate** block to the model and open the block’s parameters dialog box.

The `sldemo_bus_arrays_busobject` model uses a Vector Concatenate block, because the inputs are scalars.

- 3 Set the **Number of inputs** parameter to be the number of buses that you want to be in the array of buses.

The block icon displays the number of input ports that you specify.

- 4 Set the **Mode** parameter to match the type of the input bus data.

In the `sldemo_bus_arrays` model, the input bus data is scalar, so the **Mode** setting is **Vector**.

- 5 If you use a Matrix Concatenation block, set the **Concatenate dimension** parameter to specify the output dimension along which to concatenate the input arrays. Enter one of the following values:
  - 1 — concatenate input arrays vertically
  - 2 — concatenate input arrays horizontally
  - A higher dimension than 2 — perform multidimensional concatenation on the inputs
- 6 Connect to the Concatenate block all of the buses that you want to be in the array of buses.

### Blocks That Support Arrays of Buses

The following blocks support arrays of buses:

- Virtual blocks (see “Nonvirtual and Virtual Blocks” on page 31-2)
- These nonvirtual blocks:
  - Data Store Memory
  - Data Store Read
  - Data Store Write
  - Memory
  - Merge
  - Multiport Switch
  - Rate Transition
  - Switch
  - Unit Delay
  - Zero-Order Hold
- Assignment
- MATLAB Function
- Matrix Concatenate
- Selector
- Signal Conversion
- Vector Concatenate
- Width

- Two-Way Connection (a Simscape block)

### Block Parameter Settings

The following table describes the block parameter settings for blocks that support arrays of buses. This information is also in the reference pages for each of these blocks.

For usage information for bus-related blocks, see “Arrays of Buses with Bus-Related Blocks” on page 61-90.

| Block  | Block Parameters Settings  |
|--------|--|
| Memory | <p><b>Initial condition</b> — You can specify this parameter with:</p> <ul style="list-style-type: none"> <li>• The value 0. In this case, all of the individual signals in the array of buses use the initial value 0.</li> <li>• An array of structures that specifies an initial condition for each of the individual signals in the array of buses.</li> <li>• A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.</li> </ul>  |
| Merge  | <ul style="list-style-type: none"> <li>• <b>Allow unequal port widths</b> — Clear this parameter.</li> <li>• <b>Number of inputs</b> — Set to a value of 2 or greater.</li> <li>• <b>Initial condition</b> — You can specify this parameter with: <ul style="list-style-type: none"> <li>• The value 0. In this case, all of the individual signals in the array of buses use the initial value 0.</li> <li>• An array of structures that specifies an initial condition for each of the individual signals in the array of buses.</li> <li>• A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the bus signals in the array.</li> </ul> </li> </ul> |

| Block             | Block Parameters Settings                                     |
|-------------------|---|
| Multiport Switch  | <b>Number of data ports</b> — Set to a value of 2 or greater. |
| Signal Conversion | <b>Output</b> — Set to Signal copy.                           |
| Switch            | <b>Threshold</b> — Specify a scalar threshold.                |

## Arrays of Buses with Bus-Related Blocks

To select a signal within an array of buses:

- 1 Use a Selector block to find the appropriate bus within the array of buses.
- 2 Use a Bus Selector block to select the signal.

To assign a value to a signal within an array of buses:

- 1 Use a Bus Assignment block to assign a value to a bus element.
- 2 Use the Assignment block to assign the bus to the array of buses.

Bus Selector and Bus Assignment blocks can only accept scalar buses, not arrays of buses.

A `Bus Creator` block can accept an array of buses as input, but cannot have an array of buses as output.

For details, see “Set Up a Model to Use Arrays of Buses” on page 61-90.

## Set Up a Model to Use Arrays of Buses

Setting up a model to use an array of buses usually involves basic tasks similar to these:

- 1 Define the array of buses (see “Define an Array of Buses” on page 61-86).
- 2 Add a subsystem for performing iterative processing on each element of the array of buses. For example, use a `For Each Subsystem` block or an `Iterator` block.

### Perform Iterative Processing

You can perform iterative processing on the bus signal data of an array of buses using blocks such as a `For Each Subsystem` block, a `While Iterator`

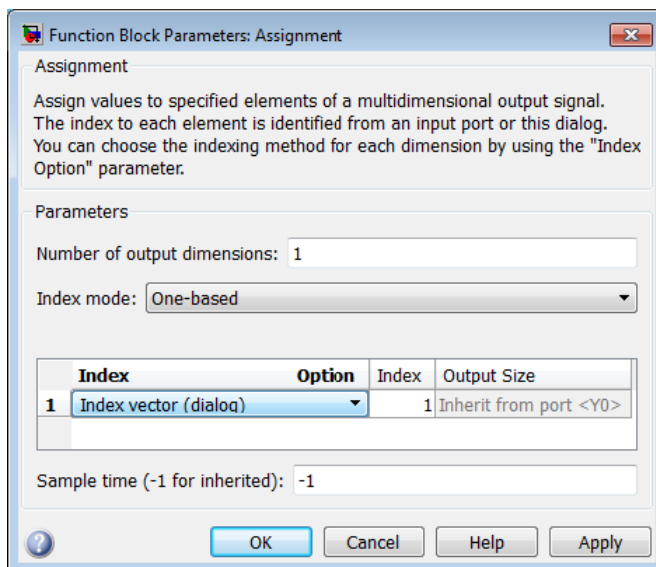

Subsystem block, or a For Iterator Subsystem block. You can use one of these blocks to perform the same kind of processing on each bus in the array of buses, or on a selected subset of buses in the array of buses.

- 3 Connect the array of buses signal from the Concatenate block to the iterative processing subsystem.
- 4 Model your scalar algorithm within the iterative processing subsystem (for example, a For Each subsystem).
  - a Operate on the array of buses (using Selector and Assignment blocks).
  - b Use the Bus Selector and Bus Assignment blocks to select elements from, or assign elements to, a scalar bus within the subsystem.

### Assign values into an array of buses

Use an Assignment block to assign values to specified elements in a bus array.

For example, in the `sldemo_bus_arrays` model, the Assignment block assigns the value to the first element of the array of buses.

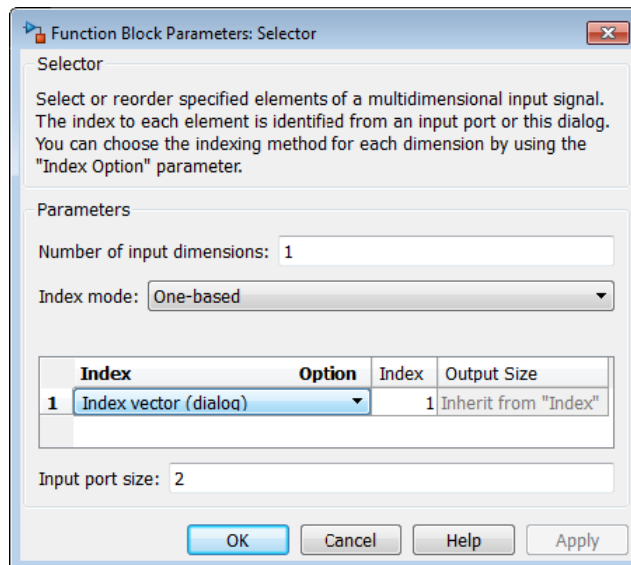

To assign bus elements within a bus signal, use the Bus Assignment block. The input for the Bus Assignment block must be a scalar bus signal.

### Select bus elements from an array of buses

Use a **Selector** block to select elements of an array of buses. The input array of buses can have any dimension. The output bus signal of the Selector block is a selected or reordered set of elements from the input array of buses.

For example, the `sldemo_bus_arrays` model uses Selector blocks to select elements from the array of buses signal that the Assignment and For Each Subsystem blocks outputs. In this example, the block parameters dialog box for the Selector block that selects the first element looks like this:

To select bus elements within a bus signal, use the **Bus Selector** block. The input for the Bus Selector block must be a scalar bus signal.

- Optionally, import or log array of buses data.

### Import array of buses data

Use a root **Inport** block to import (load) an array of structures of MATLAB `timeseries` objects for an array of buses. You can import partial data into the array of buses.

For details, see “Import Array of Buses Data” on page 57-94.

You cannot use a From Workspace or From File block to import data for an array of buses.

### Log Array of Buses Signals

To export an array of buses signal, you must log the signal, using the Signal Properties dialog box.

Set the **Configuration Parameters > Data Import/Export > Signal logging format** to **Dataset**. For more information, see “Save Runtime Data from Simulation”.

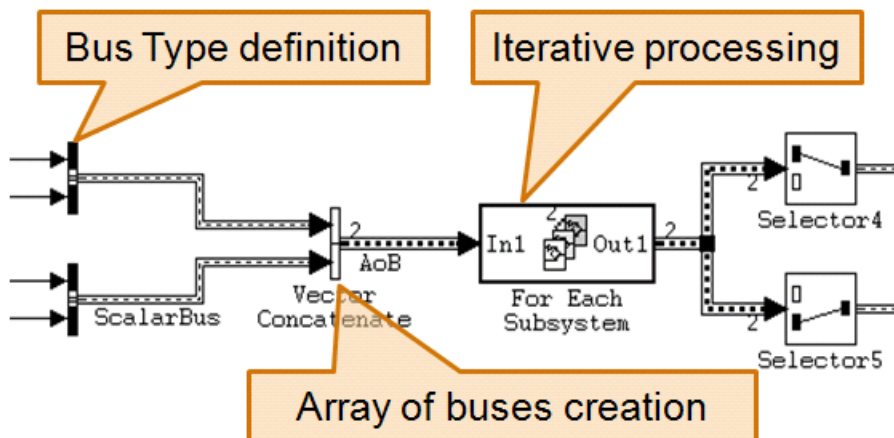

---

**Note:** Simulink does not log signals inside referenced models in Rapid Accelerator mode.

---

To access the signal logging data for a specific signal in an array of buses, navigate through the structure hierarchy and specify the index to the specific signal. For details, see “Access Array of Buses Signal Logging Data” on page 57-25.

The resulting model includes these components.

## Set Diagnostic

Before you run a simulation on a model that uses an array of buses, in the **Configuration Parameters > Diagnostics > Connectivity** pane, check that the **Mux blocks used to create bus signals** parameter uses the default setting of **error**.

## Signal Line Style

After you create an array of buses and update the diagram, the line style for the array of buses signal is a thicker version of the signal line style for a nonvirtual bus signal.

For example, in the `sldemo_bus_arrays` model, the **Scalar Bus** signal is a nonvirtual bus signal, and the **Bus Array** output signal of the **Concatenate** block is an array of buses signal.

## Convert Models to Use Arrays of Buses

There are several reasons to convert a model to use an array of buses (see “Benefits of an Array of Buses” on page 61-83). For example:

- The model was developed before Simulink supported arrays of buses (introduced in R2010b), and the model contains many subsystems that perform the same kind of processing.
- The model that has grown in complexity.

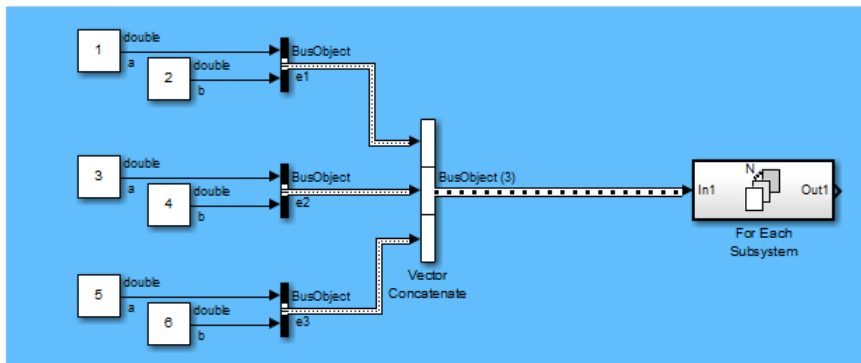

### General Conversion Approach

This section presents a general approach for converting a model that contains buses to a model that uses an array of buses. The method that you use depends on your model. For details about these techniques, see “Combine Buses into an Array of Buses” on page 61-82 and “Arrays of Buses in Models” on page 61-88.

This workflow refers to a stylized example model. The example shows the original modeling pattern and a new modeling pattern that uses an array of buses.

Original modeling pattern

New modeling pattern

In the original modeling pattern:

- The target bus signal to be converted is named **MainBus**, and it has three elements, each of type **BusObject**.
- The **ScalarAlgorithm1**, **ScalarAlgorithm2**, and **ScalarAlgorithm3** subsystems encapsulate the algorithms that operate on each of the bus elements. The subsystems all have the same content.
- A **Bus Selector** block picks out each element of **MainBus** to drive the subsystems.

The construction in the original modeling pattern is inefficient for two reasons:

- A copy of the subsystem that encapsulates the algorithm is made for each element of the bus that is to be processed.
- Adding another element to `MainBus` involves changing the bus object definition and the Bus Selector block, and adding a new subsystem. Each of these changes is a potential source of error.

To convert the original modeling pattern to use an array of buses:

- 1** Identify the target bus and associated algorithm that you want to convert. Typically, the target bus signal is a bus of buses, where each element bus signal is of the same type.
  - The bus that you convert must be a nonvirtual bus. You can convert a virtual bus to a nonvirtual bus if all elements of the target bus have the same sample time (or if the sample time is inherited).
  - The target bus cannot have variable-dimensioned and frame-based elements.
- 2** Use a Concatenate block to convert the original bus of buses signal to an array of buses.

In the example, the new modeling pattern uses a Vector Concatenate block to replace the Bus Creator block that creates the `MainBus` signal. The output of the Vector Concatenate block is an array of buses, where the type of the bus signal is `BusObject`. The new model eliminates the wrapper bus signal (`MainBus`).

- 3** Replace all identical copies of the algorithm subsystem with a single For-Each subsystem that encapsulates the scalar algorithm. Connect the array of buses signal to the For-Each subsystem.

The new model eliminates the Bus Selector blocks that separate out the elements of the `MainBus` signal in the original model.

- 4** Configure the For Each Subsystem block to iterate over the input array of buses signal and concatenate the output bus signal.

The scalar algorithm within the For-Each subsystem cannot have continuous states. For additional limitations, see the `FOR Each Subsystem` block documentation.

## Repeat an Algorithm Using a For Each Subsystem

If you repeat algorithms in a diagram by copying and pasting blocks and subsystems, maintaining the model can become difficult. Individual signal lines and subsystems can crowd the diagram, reducing readability and making simple changes difficult. At the same time, many variables can crowd workspaces, reducing model portability. A model can develop these efficiency issues as you add to the design over time.

To repeat an algorithm, you can iterate the algorithm over signals, subsystems, and parameters that are grouped into arrays and structures. This example shows how to convert an inefficiently complex repetitive algorithm into a compact form that is easier to manage.

### In this section...

“Explore Example Model” on page 61-98

“Reduce Signal Line Density with Buses” on page 61-99

“Repeat Algorithm Using For Each Subsystem Blocks and Arrays of Buses” on page 61-102

“Organize Parameters into Arrays of Structures” on page 61-105

“Inspect the Converted Model” on page 61-107

### Explore Example Model

- 1 Open the example model `ex_repeat_algorithm`. The model creates about 30 variables in the base workspace.
- 2 Inspect the subsystem `Burner_1_Analysis`. This subsystem executes an algorithm by using the base workspace variables as parameters in blocks such as Constant and Discrete-Time Integrator.
- 3 Inspect the subsystems `Burner_2_Analysis` and `Burner_3_Analysis`. All three subsystems execute the same algorithm but use different workspace variables to parameterize the blocks.
- 4 Inspect the three `Analysis_Delay` subsystems. These subsystems repeat a different algorithm from the one in the Analysis subsystems.
- 5 Return to the top level of the model. The Memory blocks delay the input signals before they enter the `Analysis_Delay` subsystems.

- 6 Look at the **Data Import/Export** pane of the Configuration Parameters dialog box. The model uses the variables `SensorsInput` and `t` as simulation inputs.

During simulation, each of the nine columns in the matrix variable `SensorsInput` provides input data for an Inport block at the top level of the model.

## Reduce Signal Line Density with Buses

You can use buses to group related signals into a single structured signal, reducing line density and improving model readability.

Each subsystem in the example model requires three signal inputs. You can combine each group of three signals into a single bus.

You could modify all of the subsystems in the example model to use buses. However, because some of the subsystems are identical, you can delete them and later replace them with For Each Subsystem blocks.

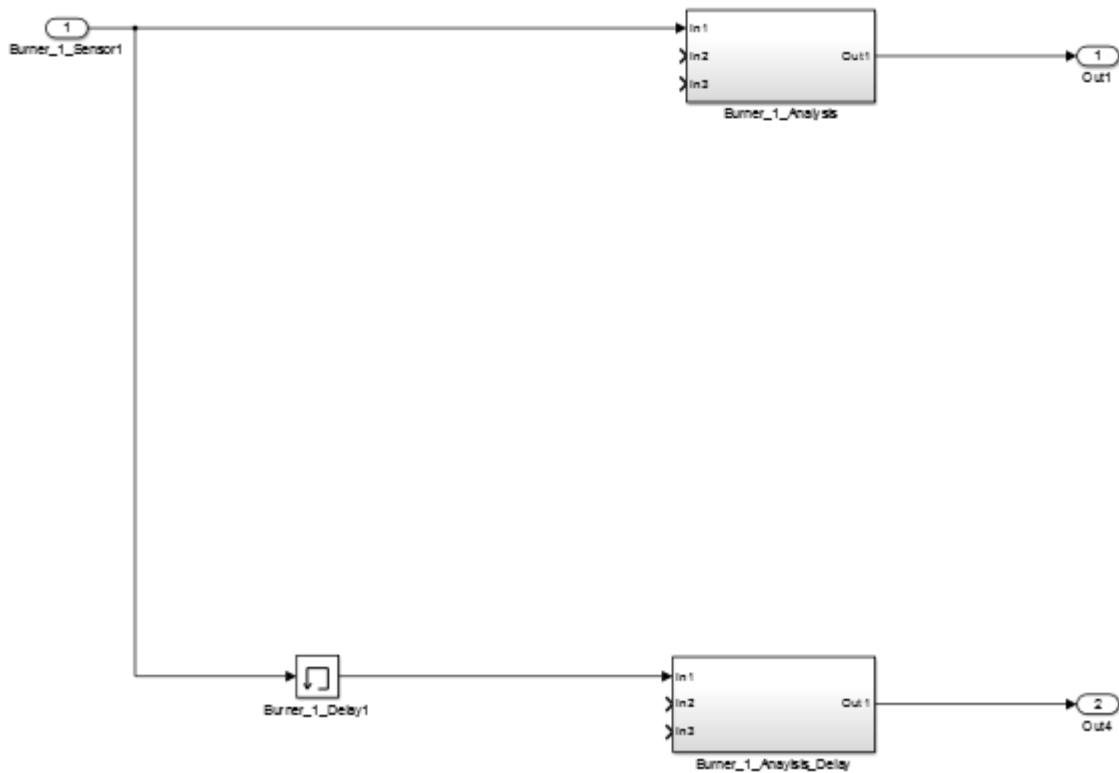

- 1 Open the Bus Editor.

```
buseditor
```

- 2 Create a bus type `SensorData` with three signal elements: `sensor1`, `sensor2`, and `sensor3`.

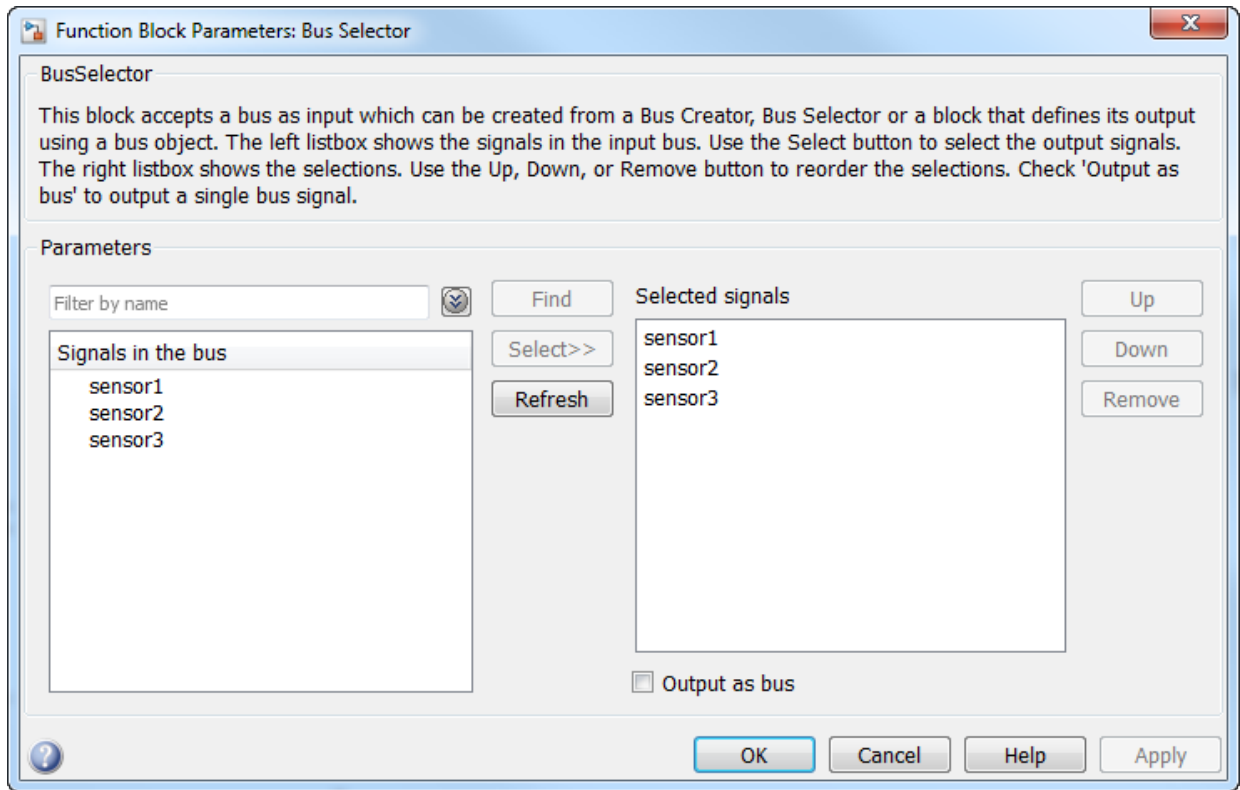

- 3 Delete the blocks as shown in the figure, leaving only the `Burner_1_Sensor1` and `Burner_1_Delay1` blocks as inputs to the two remaining subsystems.

- 4 On the **Signal Attributes** tab of the Burner\_1\_Sensor1 Inport block dialog box, set **Data type** to Bus: SensorData.

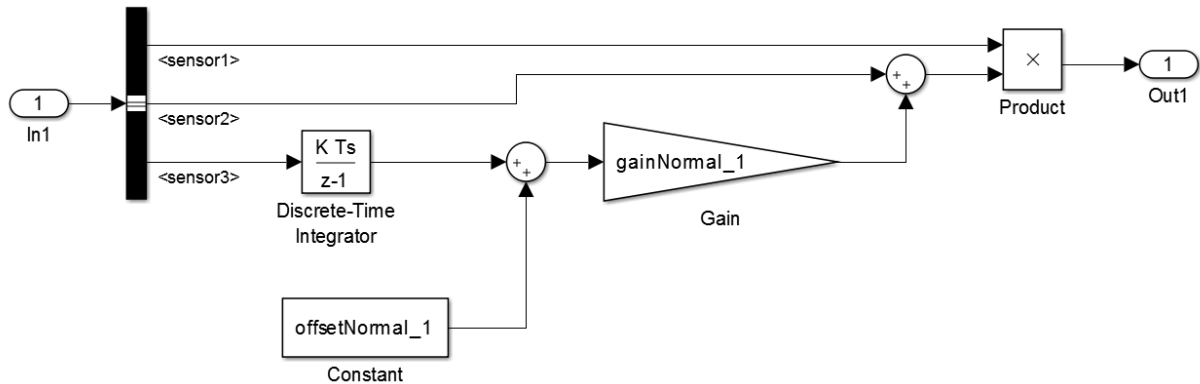

The output of the block is a bus signal that contains the three signal elements sensor1, sensor2, and sensor3.

- 5 Open the subsystem Burner\_1\_Analysis. Delete the signal output lines of the three Inport blocks. Delete the In2 and In3 Inport blocks.
- 6 Add a Bus Selector block to the right of the In1 Inport block. Connect the Inport block output to the Bus Selector block.
- 7 In the Bus Selector block dialog box, select the signals sensor1, sensor2, and sensor3.

The Bus Selector block extracts the three signal elements from the input bus. Other blocks in the model can use the extracted signal elements.

- 8 In the subsystem, connect the blocks as shown.

- 9 In the subsystem `Burner_1_Analysis_Delay`, use a Bus Selector block to extract the signals in the bus. Use the same technique as you did in the subsystem `Burner_1_Analysis`.

## Repeat Algorithm Using For Each Subsystem Blocks and Arrays of Buses

A For Each Subsystem block partitions an input signal, and sequentially executes an algorithm on each partition. For example, if the input to the subsystem is an array of six signals, you can configure the subsystem to execute the same algorithm on each of the six signals.

You can use For Each subsystems to repeat an algorithm in an iterative fashion. This approach improves model readability and allows you to easily change the repeated algorithm.

- 1 Add two For Each Subsystem blocks to the model. Name one of the subsystems `Burner_Analysis`. Name the other subsystem `Burner_Analysis_Delay`.
- 2 Copy the contents of the subsystem `Burner_1_Analysis` into the subsystem `Burner_Analysis`. Before you paste the blocks, delete the Inport and Outport blocks in the For Each subsystem.
- 3 In the For Each block dialog box in the `Burner_Analysis` subsystem, select the check box to partition the input `In1`.
- 4 Copy the contents of the subsystem `Burner_1_Analysis_Delay` into the subsystem `Burner_Analysis_Delay`.

- 5 In the For Each block dialog box in the Burner\_Analysis\_Delay subsystem, select the check box to partition the input In1.
- 6 At the top level of the model, delete the subsystems Burner\_1\_Analysis and Burner\_1\_Analysis\_Delay. Connect the new For Each Subsystem blocks in their place.
- 7 On the **Signal Attributes** tab of the Burner\_1\_Sensor1 Inport block dialog box, set **Port dimensions** to 3.

The block output is a three-element array of buses. The For Each subsystems in the model repeat an algorithm for each of the three buses in the array.

- 8 Create a Simulink.SimulationData.Dataset object that the Inport block can use to import the simulation data. You can use this code to create the object and store it in the variable SensorsInput.

```
% First, create an array of structures whose field values are
% timeseries objects.

for i = 1:3 % Burner number

    % Sensor 1
    eval(['tempInput(1,' num2str(i) ').sensor1 = ' ...
          'timeseries(t,SensorsInput(:, ' num2str(3*(i-1)+1) ');'])

    % Sensor 2
    eval(['tempInput(1,' num2str(i) ').sensor2 = ' ...
          'timeseries(t,SensorsInput(:, ' num2str(3*(i-1)+2) ');'])

    % Sensor 3
    eval(['tempInput(1,' num2str(i) ').sensor3 = ' ...
          'timeseries(t,SensorsInput(:, ' num2str(3*(i-1)+3) ');'])

end

% Create the Dataset object.

SensorsInput = Simulink.SimulationData.Dataset;
SensorsInput = addElement(SensorsInput,tempInput,'element1');

clear tempInput t i
```

The code first creates a variable `tempInput` that contains an array of three structures. Each structure has three fields that correspond to the signal elements

in the bus type `SensorData`, and each field stores a MATLAB `timeseries` object. Each `timeseries` object stores one of the nine columns of data from the variable `SensorsInput`, which stored the simulation input data for each of the sensors.

The code then overwrites `SensorsInput` with a new `Simulink.SimulationData.Dataset` object, and adds `tempInput` as an element of the object.

- 9 On the **Data Import/Export** pane of the Configuration Parameters dialog box, set **Input** to `SensorsInput`.

Since `SensorsInput` provides simulation input data in the form of `timeseries` objects, you do not need to specify a variable that contains time data.

- 10 Create an array of structures to initialize the remaining Memory block, and store the array in the variable `initForDelay`. Specify the structure fields with the values of the existing initialization variables such as `initDelay_1_sensor1`.

```
for i = 1:3 % Burner number

    % Sensor 1
    eval(['initForDelay(' num2str(i) ').sensor1 = ' ...
          'initDelay_' num2str(i) '_sensor1;'])

    % Sensor 2
    eval(['initForDelay(' num2str(i) ').sensor2 = ' ...
          'initDelay_' num2str(i) '_sensor2;'])

    % Sensor 3
    eval(['initForDelay(' num2str(i) ').sensor3 = ' ...
          'initDelay_' num2str(i) '_sensor3;'])
end
```

To view the contents of the new variable `initForDelay`, double-click the variable name in the base workspace. The variable contains an array of three structures that each has three fields: `sensor1`, `sensor2`, and `sensor3`.

| Fields | sensor1 | sensor2 | sensor3 |
|--------|---------|---------|---------|
| 1      | 17.5000 | 13.2000 | 27.8000 |
| 2      | 5.2000  | 6.9000  | 1.7000  |
| 3      | 19.4000 | 14.9000 | 22.3000 |

- 11 In the Memory block dialog box, set **Initial condition** to `initForDelay`.

The Memory block output is an array of buses that requires initialization. Each signal element in the array of buses acquires an initial value from the corresponding field in the array of structures.

## Organize Parameters into Arrays of Structures

The base workspace contains many variables that the example model uses for block parameters. To reduce the number of workspace variables, package them into arrays of structures, and use the individual structure fields to specify block parameters.

A For Each Subsystem block can partition an array of values that you specify as a mask parameter. Each iteration of the subsystem uses a single partition of the array to specify block parameters. If you specify the parameter as an array of structures, each iteration of the subsystem can use one of the structures in the array.

- 1 Create an array of structures to parameterize the Burner\_Analysis For Each subsystem, and store the array in the variable `paramsNormal`. Specify the structure fields by using the values of existing parameter variables such as `gainNormal_1`, `offsetNormal_1`, and `initDelayed_1`.

```
for i = 1:3
    eval(['paramsNormal(' num2str(i) ').gain = gainNormal_' num2str(i) ';' ])
    eval(['paramsNormal(' num2str(i) ').offset = offsetNormal_' num2str(i) ';' ])
    eval(['paramsNormal(' num2str(i) ').init = initNormal_' num2str(i) ';' ])
end
```

The variable contains an array of three structures that each has three fields: `gain`, `offset`, and `init`.

- 2 In the model, right-click the Burner\_Analysis For Each subsystem and select **Mask > Create Mask**.
- 3 On the **Parameters & Dialog** pane of the dialog box, under **Controls**, click **Edit**. For the new mask parameter, set **Prompt** to `Parameter structure` and **Name** to `paramStruct`. Click **OK**.
- 4 In the mask for the Burner\_Analysis subsystem, set **Parameter structure** to `paramsNormal`.
- 5 Open the subsystem. In the For Each block dialog box, on the **Parameter Partition** pane, select the check box to partition the parameter `paramStruct`. Set **Partition dimension** to 2.
- 6 For the blocks in the subsystem, set these parameters.

| Block                    | Parameter Name           | Parameter Value                 |
|--------------------------|--------------------------|---------------------------------|
| Gain                     | <b>Gain</b>              | <code>paramStruct.gain</code>   |
| Discrete-Time Integrator | <b>Initial condition</b> | <code>paramStruct.init</code>   |
| Constant                 | <b>Constant value</b>    | <code>paramStruct.offset</code> |

- 7 Create an array of structures to parameterize the Burner\_Analysis\_Delay For Each subsystem, and store the array in the variable `paramsForDelay`.

```

for i = 1:3
    eval(['paramsForDelay(' num2str(i) ').gain = gainDelayed_' num2str(i) ';' ])
    eval(['paramsForDelay(' num2str(i) ').offset = offsetDelayed_' num2str(i) ';' ])
    eval(['paramsForDelay(' num2str(i) ').init = initDelayed_' num2str(i) ';' ])
end

```

- 8 At the top level of the model, right-click the Burner\_Analysis\_Delay For Each subsystem and select **Mask > Create Mask**.
- 9 On the **Parameters & Dialog** pane of the dialog box, under **Controls**, click **Edit**. For the new mask parameter, set **Prompt** to `Parameter structure` and **Name** to `paramStruct`. Click **OK**.
- 10 In the mask for the For Each Subsystem block, set **Parameter structure** to `paramsForDelay`.
- 11 Open the subsystem. In the For Each block dialog box, on the **Parameter Partition** pane, select the check box to partition the parameter `paramStruct`. Set **Partition dimension** to 2.
- 12 For the blocks in the subsystem, set these parameters.

| Block                    | Parameter Name    | Parameter Value    |
|--------------------------|-------------------|--------------------|
| Gain                     | Gain              | paramStruct.gain   |
| Discrete-Time Integrator | Initial condition | paramStruct.init   |
| Constant                 | Constant value    | paramStruct.offset |

- 13** Clear the unnecessary variables from the base workspace.

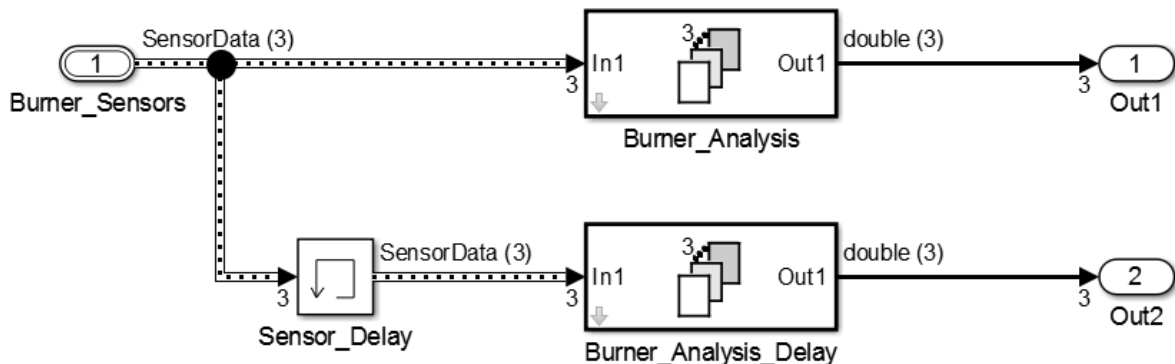

```
% Clear the old parameter variables that you replaced
% with arrays of structures
clear -regexp _

% Clear the iteration variables
clear i
```

The model requires very few variables in the base workspace.

## Inspect the Converted Model

Update the diagram to view the new signal and subsystem organization.

The model input is an array of three bus signals. The model uses two For Each subsystems to execute the two algorithms on each of the three bus signals in the input array.

In the base workspace, arrays of structures replace the many variables that the model used. Mathematically, the modified model behaves the same way it did when you started because the arrays of structures contain the values of all of the old variables.

To view the completed model, open the example model `ex_repeat_algorithm_complete`.

- “Bus Objects” on page 61-23

## Code Generation for Arrays of Buses

When you generate code for a model that includes an array of buses, a `typedef` that represents the underlying bus type appears in the `*_types.h` file.

Code generation produces an array of C structures that you can integrate with legacy C code that uses arrays of structures. As necessary, code for bus variables (arrays) are generated in the following structures:

- Block IO
- States
- External inputs
- External outputs

Here is a simplified example of some generated code for an array of buses.

```
typedef struct {  
    real_T a;  
    real_T b;  
} BusObject;  
/* Block signals (auto storage) */  
typedef struct {  
    BusObject ForEachSubsystem_IterInp_0[2];  
} BlockIO_aob1;
```

## Bus Data Crossing Model Reference Boundaries

A model reference boundary refers to the boundary between a model that contains a Model block and the referenced model. If you have bus data in a model that is passed to a Model block, then that data crosses the boundary to the referenced model.

To have bus data cross model reference boundaries:

- 1 Use a bus object (`Simulink.Bus`) to define the bus. For details, see “Create a Nonvirtual Bus” on page 61-16.

You can use a nonvirtual or a virtual bus as an input to a referenced model. If you use a virtual bus, Simulink automatically converts it to a nonvirtual bus (for details, see “Automatic Bus Conversion” on page 61-13). Simulink requires that each model reference inport use contiguous memory, which nonvirtual buses provide. Using a nonvirtual bus provides a well-defined data interface for code generation.

- 2 Consider stripping out unneeded data from bus objects crossing model reference boundaries.

In large models, bus objects can become quite large and have several levels of hierarchy. Often referenced models need some, but not all, of the data contained in large buses. Passing unneeded data across model reference boundaries impacts performance negatively. The interface definition for a model should specify exactly what data the model uses.

## Connect Multi-Rate Buses to Referenced Models

In a model that uses a fixed-rate solver, referenced models can input only single-rate buses. However, you can input the signals in a multi-rate bus to a referenced model by inserting blocks into the parent and referenced model as follows:

- 1 **In the parent model:** Insert a **Rate Transition** block to convert the multi-rate bus to a single-rate bus. The **Rate Transition** block must specify a rate in its **Block Parameters > Output port sample time** field unless one of the following is true:
  - The **Configuration Parameters > Solver** pane specifies a rate:
    - **Periodic sample time constraint** is Specified
    - **Sample time properties** contains the specified rate.

- The Inport that accepts the bus in the referenced model specifies a rate in its **Block Properties > Signal Attributes > Sample time** field.
- 2 In the referenced model:** Use a **Bus Selector** block to pick out signals of interest, and use **Rate Transition** blocks to convert the signals to the desired rates.

## Buses and Libraries

When you define a library block, the block can input, process, and output buses just as an ordinary subsystem can.

You need to provide the appropriate input bus signal if:

- You have a bus routing block (Bus Creator, Bus Selector, or Bus Assignment) block that is in a library.
- That block depends on signals that are input to the library.

To change that block in a library, perform these steps. For details about modifying library links, see “Work with Library Links” on page 36-8.

- 1** Copy the library block that uses that block to a model that connects an input bus.
- 2** Disable the link to the library block in this model.
- 3** Edit the bus routing block within the context of the outside model.
- 4** Resolve the link to the library.
- 5** In the Link Tool, in **Push/Restore Mode**, select **PUSH** to place the edited content into the library.
- 6** Save the library.

Alternatively, to configure the library to supply an appropriate bus signal, use a bus object to lock in the data type at the interface of a library subsystem block .

## Prevent Bus and Mux Mixtures

### In this section...

“What Are Bus and Mux Signal Mixtures?” on page 61-113

“Why Avoid Mixing Bus and Mux Signals?” on page 61-114

“When to Configure a Model to Prevent Bus and Mux Mixtures?” on page 61-115

“Two Upgrade Procedures” on page 61-115

### What Are Bus and Mux Signal Mixtures?

A Simulink mux signal is a virtual signal that graphically combines two or more scalar or vector signals into one signal line. All of the signals in a mux signal must have the same data type and complexity. For more information, see “Mux Signals” on page 60-11.

Bus signals can contain signals of different data types and complexities.

A bus and mux mixture occurs when some blocks treat a signal as a mux, while other blocks treat that same signal as a bus, as described below.

#### Mux Block That Creates a Virtual Bus

One way that a model can mix bus and mux signals is when a Mux block creates a virtual bus. For example:

- A signal from a Mux block connects to a Bus Selector block.

- Mux and Demux blocks combine a signal with different attributes (for example, data type or complexity).

### Bus Signal Treated as a Mux Signal

A second way that a model can mix bus and mux signals is when the model treats a bus signal as if it is a mux signal. For example:

- Bus Creator block that creates a signal to be used as a vector.

- Bus Creator block that creates a signal to be used as a vector.

### Why Avoid Mixing Bus and Mux Signals?

Mixing bus and mux signals in a model causes your model to be less robust. Configuring your model to prevent bus and mux mixtures:

- Improves loop handling
- Produces clear error messages

- Contributes to consistent edit and compile time behavior

Configuring your model to prevent bus and mux mixtures not only makes your model more robust, it also allows you to update your model to take advantage of several features that you could not otherwise use, including:

- Nonzero initialization of bus signals
- Bus support for blocks such as Constant, Data Store Memory, From File, From Workspace, To File, and To Workspace
- Signal Hierarchy Viewer
- Signal label propagation enhancements
- Arrays of buses

## When to Configure a Model to Prevent Bus and Mux Mixtures?

Configure a model to prevent bus and mux mixtures if *all* of the following conditions apply — the model:

- Was created before R2013b
- Contains one of the following: Bus Creator, Bus Selector, or Bus Assignment block, or a bus object
- Has **Configuration Parameters > Diagnostics > Connectivity > Mux blocks used to create bus signals** set to none or warning

Even if a model created before R2013b does not require that you configure it to prevent bus and mux mixtures, you may want to update it anyway. Doing so facilitates making future modifications to the model to use buses or features that require that the model is configured to prevent bus and mux mixtures.

Starting in R2013b, when you create a new model, Simulink automatically configures the model to avoid bus and mux mixtures. Simulink sets the **Mux blocks used to create bus signals** parameter to **error**. Then, when you do a model update or simulate the model, Simulink reports an error if you introduce a bus and mux mixture.

## Two Upgrade Procedures

Configuring a model to prevent bus and mux mixtures involves performing these procedures:

- “Correct Mux Blocks That Create Bus Signals” on page 61-117
- “Correct Buses Used as Muxes” on page 61-122

The procedure to correct muxes that create bus signals not only configures your model to identify when you introduce a bus and mux mixture, it also automatically changes your model to correct many of the instances of such mixtures.

## Correct Mux Blocks That Create Bus Signals

### In this section...

- “Choose the Appropriate Procedure” on page 61-117
- “Models Without Model Referencing” on page 61-117
- “Models With Model Referencing” on page 61-118
- “Address Compatibility Issues After Running Upgrade Advisor” on page 61-119

### Choose the Appropriate Procedure

The procedure that you perform depends on whether or not a model uses model referencing. Use the appropriate procedure, as described in:

- “Models Without Model Referencing” on page 61-117
- “Models With Model Referencing” on page 61-118

### Models Without Model Referencing

- 1 Save a copy of the existing model and simulation results for the model.

Because you might need to make several changes to your model during the conversion process, it can help to have the original model for reference and for comparing simulation results.

- 2 Open the Upgrade Advisor. In the Simulink Editor, select **Analysis > Model Advisor > Upgrade Advisor**.
- 3 Select **Check for Mux blocks used to create bus signals**.
- 4 Click **Run this check**.
- 5 Click **Modify**. The Upgrade Advisor replaces Mux blocks with Bus Creator blocks and sets the **Mux blocks used to create bus signals** configuration parameter to error.

The Upgrade Advisor closes any models that it checks that contain library links.

- 6 If necessary, reopen the model. Rerun the check to confirm that the model passes.

If the check fails, go to step 7.

- 7 Update your model to address the applicable modeling patterns described in “Address Compatibility Issues After Running Upgrade Advisor” on page 61-119 and rerun the check.

## Models With Model Referencing

In a model that uses model referencing, the Upgrade Advisor upgrades the top model, but not the referenced model. To make the upgrade process more efficient for models that use model referencing, use *one* of the following approaches:

- For models that reference a small number of models (for example, five), in the Upgrade Advisor, run the **Analyze model hierarchy for upgrade issues** check. This check addresses bus and mux signal mixture issues for each referenced model.

The steps for using the Upgrade Advisor are the same as described in “Models Without Model Referencing” on page 61-117.

- For models that have many referenced models (for example, more than five), use `find_mdlsrefs` and `sreplace_mux` to find Mux blocks and replace them with Bus Creator blocks. You can create a script based on the following pattern.

```
[refMdls,~] = find_mdlsrefs mdl, true);

% run through reference models and top model
for i = 1:length(refMdls)
    load_system(refMdls{i});

    % Add code if any model uses referenced configuration sets

    sreplace_mux(refMdls{i},false) % reportonly = false;

    save_system(refMdls{i});
    close_system(refMdls{i});
end
```

If a model does not compile, address the applicable modeling patterns described in “Address Compatibility Issues After Running Upgrade Advisor” on page 61-119 and rerun the **Analyze model hierarchy for upgrade issues** check or, for models with many referenced models, the script.

## Address Compatibility Issues After Running Upgrade Advisor

For many models, running the Upgrade Advisor modifies your model so that Mux blocks no longer create bus signals. However, for some models you might encounter compatibility issues even after running the check. You need to modify your model manually to address those issues.

Also, after you compile the model using Upgrade Advisor, the Simulink Editor sometimes indicates that the model needs to be saved (that is, that the model is dirty), even though you did not make any changes. Save the model to prevent this issue from reoccurring for this model.

| Modeling Pattern  | Issue  | Solution   |
|---|--|--|
| Demux block with <b>Bus selection mode</b> enabled                        | You cannot use a Demux block to select bus signals.  | Replace the Demux block with a Bus Selector block.<br><br>If a Demux block has input from a Mux block, change the Mux block to a Bus Creator.  |
| Data Store Memory block with <b>Data Type</b> set to <b>Inherit: auto</b> | A Data Store Memory block whose associated Data Store Read or Data Store Write blocks read or write bus signal data must use a bus object.   | In the Data Store Memory block, set the <b>Data Type</b> signal attribute to <b>Bus: &lt;BusObject&gt;</b> .                                   |
| Signal Conversion block <b>Output</b> parameter matches input bus type    | A Signal Conversion block whose <b>Output</b> parameter is set to <b>Nonvirtual</b> bus requires a virtual bus input.<br><br>A Signal Conversion block whose <b>Output</b> parameter is set to <b>Virtual</b> bus requires a nonvirtual bus input. | To create a copy of the input signal, set <b>Output</b> to <b>Signal copy</b> .  |
| Merge, Switch, or Multiport Switch block with multiple bus inputs         | Merge, Switch, and Multiport Switch blocks with multiple bus inputs require all of those inputs to have the same names and hierarchy.  | Reconfigure the model so that the bus inputs all have the same names and hierarchy.<br><br>To view the names and hierarchy of the bus signals, |

| Modeling Pattern   | Issue   | Solution   |
|--|---|--|
|  |   | use the “Signal Hierarchy Viewer” on page 61-7 .   |
| Root Inport block outputting a virtual bus and specifying a value for <b>Port dimensions</b> | A root Inport block that outputs to a virtual bus must inherit the dimensions.  | Set the Inport block <b>Port dimensions</b> signal attribute to 1 or -1 ( <i>inherit</i> ).  |
| Mux block with nonvirtual bus inputs   | A Mux block cannot accept nonvirtual bus signals.   | To treat the output as an array, replace the Mux block with a Vector Concatenate block.<br><br>If you want a virtual bus output, use a Bus Creator block to combine the signals. |
| Bus to Vector block without a virtual bus signal input                                       | A nonbus signal does not need a Bus to Vector block.  | Remove the Bus to Vector block.  |
| Assignment block with virtual bus inputs   | The Upgrade Advisor converts the Assignment block Y0 port bus input to a vector.  | Add a Bus to Vector block before the Assignment block.   |
| S-function using a nonvirtual bus  | An S-function that is not a Level-2 C S-function does not support nonvirtual bus signals.   | Change the S-function to be a Level-2 C S-function.<br><br>Consider using an S-Function Builder block to create a Level-2 C S-function.  |
| Stateflow chart with parameterized data type   | In a Stateflow chart, you cannot parameterize the data type of an input or output in terms of another input or output if the data type is a bus object. | For the parameterized port, set <b>Data Type</b> to <b>Bus: &lt;object name&gt;</b> .  |
| Subsystem with bus operations in a Stateflow chart   | An Inport block inside a subsystem in a Stateflow chart requires a bus object data type if its signal is a bus.   | In the Inport block, set <b>Data type</b> to <b>Bus: &lt;object name&gt;</b> .   |

| <b>Modeling Pattern</b>                                       | <b>Issue</b>  | <b>Solution</b>  |
|---|---|--|
| Ground block used as a bus source                             | The output signal of a Ground block cannot be a source for a bus.                           | Use a Constant block with <b>Constant value</b> set to 0 and the <b>Output data type</b> signal attribute set to <b>Bus: &lt;object name&gt;</b> . |
| Root Outport block with a single-element bus object data type | The input to the Outport block must be a bus if it specifies a bus object as its data type. | In the Outport block, set <b>Data type</b> to <b>Inherit: auto</b> .   |

## Correct Buses Used as Muxes

### In this section...

“Three Approaches” on page 61-122

“Use the Model Advisor” on page 61-122

“Explicitly Add Bus to Vector Blocks” on page 61-122

“Reorganize the Model” on page 61-124

“Bus to Vector Block Compatibility Issues” on page 61-125

### Three Approaches

The three approaches that you can use to correct bus signals used as muxes are:

- “Use the Model Advisor” on page 61-122
- “Explicitly Add Bus to Vector Blocks” on page 61-122
- “Reorganize the Model” on page 61-124

Generally, using the Model Advisor is the most efficient approach.

### Use the Model Advisor

Before you use the Model Advisor to correct bus signals used as a muxes, perform the steps described in “Correct Mux Blocks That Create Bus Signals” on page 61-117.

- 1 Open the Model Advisor from the Upgrade Advisor, or in the Simulink Editor, select **Analysis > Model Advisor > Model Advisor**.
- 2 Select and run the **Simulink > Check bus usage** check.

The Model Advisor reports any cases of bus signals treated as muxes.

- 3 Follow the Model Advisor suggestions to correct any errors reported by the check.

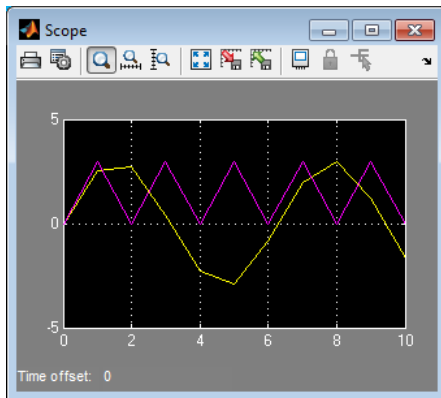

For additional information about using the Model Advisor, see “Consulting the Model Advisor” on page 5-2.

### Explicitly Add Bus to Vector Blocks

You can explicitly add **Bus to Vector** blocks to convert the bus signal to a mux (vector), using one of these approaches:

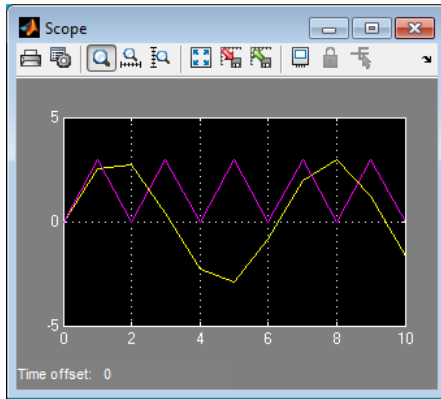

- Insert the Bus to Vector block into any bus used implicitly as a mux to explicitly convert the bus to a mux (vector).
- Use the `Simulink.BlockDiagram.addBusToVector` function, which automatically inserts Bus to Vector blocks wherever needed.

For example, this model uses a bus signal as a mux signal by using the bus as an input to a Gain block. The Scope block shows the simulation results.

This figure shows the same model, rebuilt after inserting a Bus to Vector block after the Bus Creator block.

The results of simulation are the same in either case. The Bus to Vector block is virtual, and does not affect simulation results, code generation, or performance.

## Reorganize the Model

You can replace blocks manually to avoid using bus signals as muxes. Change the sources for a block that require vector inputs to avoid feeding a bus signal into a block that requires vector input.

For example, in the following model, the Gain block requires a vector signal. However, the input signal is a bus signal created by a Bus Creator block.

Change the Bus Creator block to a Mux block to provide the required vector signal for the Gain block.

Challenges with reorganizing the model manually include:

- Identifying all of the occurrences in a model. (The Model Advisor check identifies all occurrences in the model and helps you to correct them.)
- Dealing with many occurrences in a model is time-consuming and error-prone.
- Reorganizing the model to address this issue can interfere with other aspects of the model.

## Bus to Vector Block Compatibility Issues

If you use **Save As** to save a model in a version of the Simulink product before R2007a (V6.6), Simulink:

- Sets the `StrictBusMsg` parameter to error if its value is `WarnOnBusTreatedAsVector` or `ErrorOnBusTreatedAsVector`.
- Replaces each Bus to Vector block in the model with a null subsystem that outputs nothing.

The resulting model specifies strong type checking for Mux blocks used to create buses. Before you can use the model, you must reconnect or otherwise correct each signal that contained a Bus to Vector block but is now interrupted by a null subsystem.

## Buses in Generated Code

If you have a Simulink Coder license, the various techniques for defining buses are essentially equivalent for simulation, but the techniques used can make a significant difference in the efficiency, size, and readability of generated code. For example, a nonvirtual bus appears as a structure in generated code, and only one copy exists of any algorithm that uses the bus. The use of a structure in the generated code can be helpful when tracing the correspondence between the model and the code. For example, below is the generated code for Bus Creator block in the `ex_bus_logging` model.

```
50
51     /* BusCreator: '<Root>/COUNTERBUSCreator' incorporates:
52      * BusCreator: '<Root>/LIMITBUSCreator'
53      * Constant: '<Root>/lower_saturation_limit'
54      * Constant: '<Root>/upper_saturation_limit'
55      */
56     ex_bus_logging_B.COUNTERBUS_n.data = rtb_data;
57     ex_bus_logging_B.COUNTERBUS_n.limits.upper_saturation_limit = 40;
58     ex_bus_logging_B.COUNTERBUS_n.limits.lower_saturation_limit = 0;
59
```

A virtual bus does not appear as a structure or any other coherent unit in generated code, and a separate copy of any algorithm that manipulates the bus exists for each element.

Using buses properly results in efficient code and visually clean models. If you intend to generate production code for a model that uses buses, see “Code Generation with Buses” for information about the best techniques to use.

## Composite Signal Limitations

- Buses that contain signals of enumerated data types cannot pass through a block that requires a nonzero scalar initial value (such as a `Unit Delay` block).
- Root level bus outputs cannot be logged using the **Configuration Parameters > Data Import/Export > Save to Workspace > Output** option. Use standard signal logging instead, as described in “Export Signal Data Using Signal Logging” on page 57-36.
- Inputs to a Bus Creator block must have unique names. If there are duplicate names, the Bus Creator block appends (`signal#`) to all input signal names, where # is the input port index.

# Working with Variable-Size Signals

## Variable-Size Signal Basics

### In this section...

“About Variable-Size Signals” on page 62-2

“Creating Variable-Size Signals” on page 62-2

“How Variable-Size Signals Propagate” on page 62-3

“Empty Signals” on page 62-4

“Subsystem Initialization of Variable-Size Signals” on page 62-4

“See Also” on page 62-5

### About Variable-Size Signals

A Simulink signal can be a scalar, vector (1-D), matrix (2-D), or N-D. For information about these types of signals, see “Signal Basics” on page 60-2 in the *Simulink User's Guide*.

A Simulink variable-size signal is a signal whose size (the number of elements in a dimension), in addition to its values, can change during a model simulation. However, during a simulation, the number of dimensions cannot change. This capability allows you to model systems with varying resources, constraints, and environments.

### Creating Variable-Size Signals

You can create variable-size signals in your Simulink model by using:

- Switch or Multiplex blocks with different input ports having fixed-size signals with different sizes. The output is a variable-size signal.
- A selector block and the **Starting and ending indices (port)** indexing option. The index port signal can specify different subregions of the input data signal which produce an output signal of variable size as the simulation progresses.
- The S-function block with the output port configured for a variable-size signal. The output includes not only the values but also the dimension of the signal.

## How Variable-Size Signals Propagate

In the Simulink environment, variable-size signals can change their size during model execution in one of two ways:

- **At every step of model execution.**

Various blocks in the model modify the sizes of the signals during execution of the output method.

- **Only during initialization of conditionally executed subsystems.**

Size changes occur during distinct mode-switching events in subsystems such as Action, Enable, and Function-Call subsystems.

You can see the key difference by considering a Discrete 2-Tap Filter block with states.

### Discrete 2-Tap Filter

Assume that the input signal dimension to this filter changes from 4 to 1 during simulation. It is ambiguous when and how the states of the Unit Delay blocks should adapt from 4 to 1 to continue processing the input. To ensure consistency, both Unit Delay blocks must change their state behavior synchronously. To prevent ambiguity, Simulink generally disallows blocks whose number of states depends on input signal sizes in contexts where signal sizes change at any point during execution.

In contrast, consider the same Discrete 2-Tap Filter block in a Function-Call subsystem. Assume that this subsystem is using the second way to propagate variable-size signals. In this case, the size of the input signal changes from 4 to 1 only at the initialization of the subsystem. At initialization, the subsystem resets all of its states (including the

states of the two Unit Delay blocks) to their initial values. Resetting the subsystem ensures no ambiguity on the assignment of states to the input signal of the filter.

“Mode-Dependent Variable-Size Signals” on page 62-14 shows how you can use the two ways of propagating variable-size signals in a complementary fashion to model complex systems.

## Empty Signals

An empty signal is a signal with a length of 0. For example, signals with size [0], [0x3], [2x0], and [2x0x3] are all empty signals. Simulink allows empty signals with variable-size signals and supports most element-wise operations. However, Simulink does not support empty signals for blocks that modify signal dimensions. Unsupported blocks include Reshape, Permute, and Sum along a specified dimension.

## Subsystem Initialization of Variable-Size Signals

The initial signal size from an Output block in a conditionally executed subsystem varies depending on the parameters you select.

If you set the **Propagate sizes of variable-size signals** parameter in the parent subsystem to **During execution**, the **Initial output** parameter for the Output block must not exceed the maximum size of the input port. If the **Initial output** parameter value is:

| Initial output parameter | Initial output signal size   |
|--------------------------|--|
| A nonscalar matrix       | The initial output signal size is the size of the <b>Initial output</b> parameter. |
| A scalar                 | The initial output signal size is a scalar.  |
| The default []           | The initial output size is an empty signal (dimensions are all zeros).             |

If you set the **Propagate sizes of variable-size signals** parameter in the parent subsystem to **Only when enabling**, the **Initial output** parameter for the Output block must be a scalar value.

- When size is repropagated for the input of the Output block, the initial output value is set using scalar expansion from the scalar parameter value.

- If the **Initial output** parameter is the default value [ ], Simulink treats the initial output as a grounded value.
- If the model does not activate the parent subsystem at start time ( $t = 0$ ), the current size of the subsystem output corresponding to the Outport block is set to maximum size.
- When its parent subsystem repropagates signal sizes, the values of the subsystem variable-size output signals are also reset to their initial output parameter values.

## Simulink Models Using Variable-Size Signals

### In this section...

“Variable-Size Signal Generation and Operations” on page 62-6

“Variable-Size Signal Length Adaptation” on page 62-10

“Mode-Dependent Variable-Size Signals” on page 62-14

“See Also” on page 62-19

### Variable-Size Signal Generation and Operations

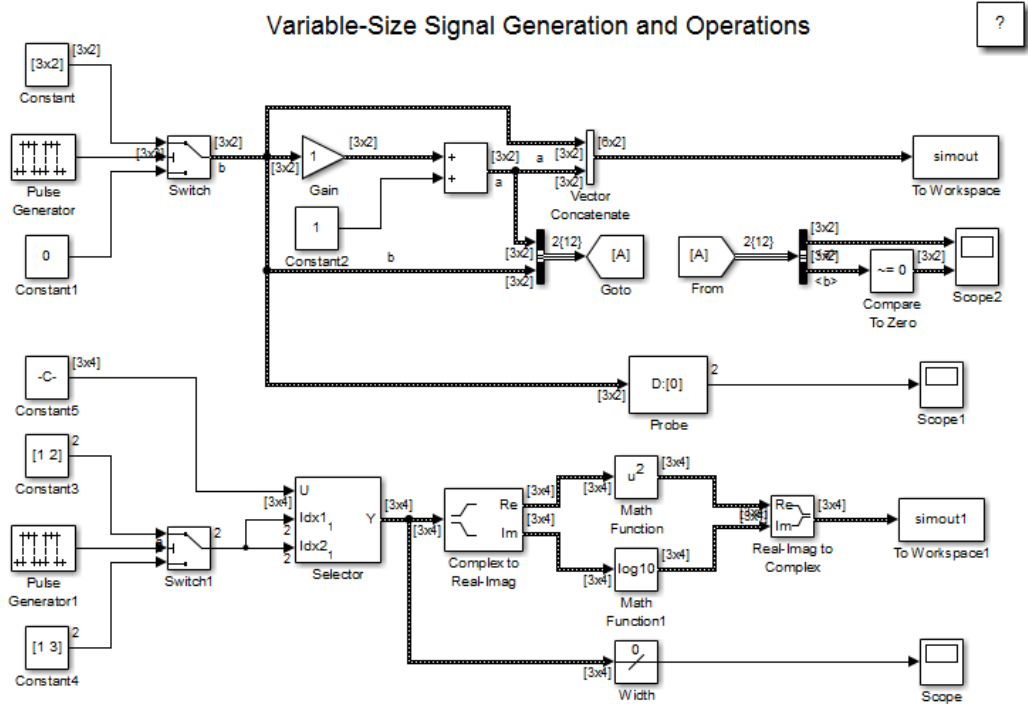

This example model shows how to create a variable-size signal from multiple fixed-size signals and from a single data signal. It also shows some of the operations you can apply to variable-size signals.

For a complete list of blocks that support variable-size signals, see “Simulink Block Support for Variable-Size Signals” on page 62-23.

- 1 In the MATLAB Command Window, type  

```
sldemo_varsize_basic
```
- 2 In the Simulink Editor, select **Display > Signals & Ports > Signal Dimensions**. Run a simulation or press **Ctrl-D**.

The Simulink Editor displays the signal dimensions and line styles. See “Signal Basics” on page 60-2 for an interpretation of signal line styles.

### Creating a Variable-Size Signal from Fixed-Size Signals

One way to create a variable-size signal is to use the Switch block. The input signals to the Switch block can differ in their number of dimensions and in their size.

Output from the Switch block is a 2-D variable-size signal with a maximum size of  $3 \times 2$ . When you select the **Allow different data input sizes** parameter on the Switch block, Simulink does not expand the scalar value from the Constant1 block.

### Saving Variable-Size Signal Data

You could add a To Workspace block to the output from the Switch block. Since the model already has a To Workspace block, the second To Workspace block would save data to a signal array named `simout2`. The `values` field logs the actual signal values. If logged signal data is smaller than the maximum size, values are padded with NaNs or appropriate values. To obtain these signal values, type:

```
simout2.signals.values
```

```
ans(:,:,1) =
```

```
    1    -1
   -2     2
   -3     3
```

```
ans(:,:,2) =
```

```
    1    -1
   -2     2
   -3     3
```

```
ans(:,:,3) =
```

```

0    NaN
NaN  NaN
NaN  NaN

```

The `valueDimensions` field logs the dimensions of a variable-size signal. To obtain the dimensions, type:

```
simout2.signals.valueDimensions
```

The signal dimensions for the first three time steps are shown.

```
ans =
```

```

3    2
3    2
1    1

```

### Creating a Variable-Size Signal from a Single Data Signal

The data signal (Constant5) is a 3x4 matrix. The Pulse Generator represents a control signal that selects a starting and ending index value ( [ 1 2] or [ 1 3]). The Selector block then uses the index values to select different parts of the data signal at each time step and output a variable-size signal.

### Viewing Changes in Signal Size

The output from the Selector block is either a 2x2 or 3x3 matrix. Because the maximum dimension for a variable-size signal is the 3x4 matrix from the data signal, the logged output signals are padded with NaNs.

Use the Probe or Width blocks to inspect the current dimensions and width of a variable-size signal. In addition, you can display variable-size signals on Scope blocks and save variable-size signals to the workspace using the To Workspace block.

### Processing Variable-Size Signals

The remainder of the model shows various operations that are possible with variable-size signals. Operations include using the Gain block, the Sum block, the Math Function block, the Matrix Concatenate block. You can connect variable-size signals with the From, Goto, Bus Assignment, Bus Creator, and Bus Selector blocks.

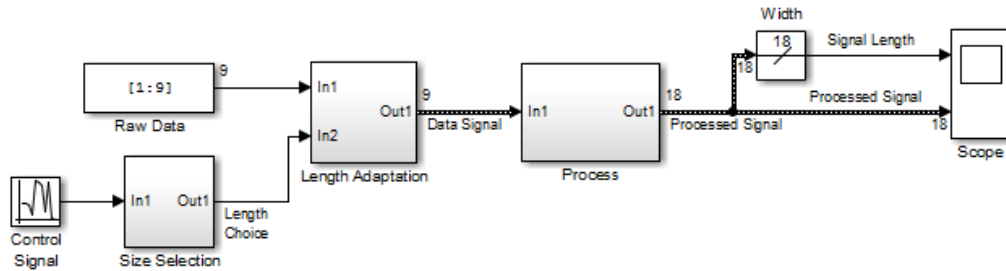

### Variable-Size Signal Length Adaptation

This example model corresponds to a hypothetical system where the model adapts the length of a signal over time. Length adaptation is based on the value of a control signal. When the control signal falls within one of three predefined ranges, the fixed-size raw data signal changes to a variable-size data signal.

The variable-size signal connects to a processing block, where blocks that support variable-size signals operate on it. A MATLAB Function block with both input and output signals of variable size allow more flexibility than other blocks supporting variable-size signals. See “Simulink Block Support for Variable-Size Signals” on page 62-23.

To open the example model, in the MATLAB Command Window, type:

```
sldemo_varsize_dataLengthAdapt
```

### Creating a Variable-Size Signal by Adapting the Length of a Data Signal

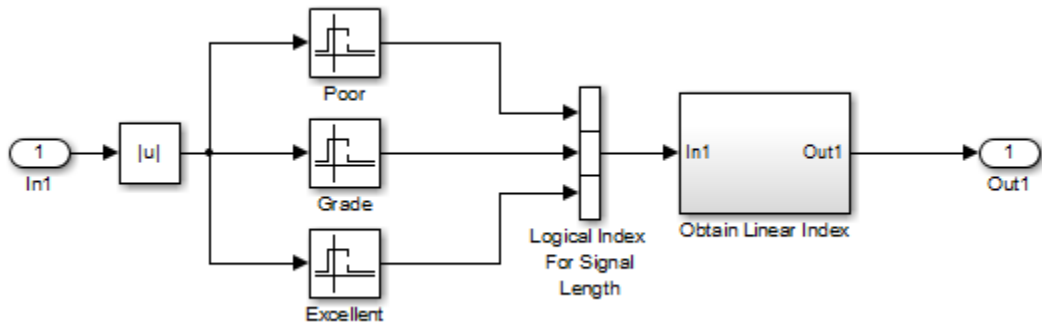

This model generates a data signal and converts the signal to a variable-size signal. The size of the signal depends on the value of a control signal. The raw data signal is a column vector with values from 1 to 9.

```
[1:9].'
```

```
ans =
```

- 1
- 2
- 3
- 4
- 5
- 6
- 7
- 8
- 9

The Size Selection subsystem determines the quality of the data signal and outputs a quality value ( 1, 2, or 3). This value helps to select the length of the data signal in the Length Adaptation subsystem.

In the Length Adaptation subsystem, the Signal Size subsystem generates an index based on the quality value from the Size Selection subsystem (In2). The Data Selector block uses the starting and ending indices to adapt the length of the data signal (In1) and output a variable-size signal.

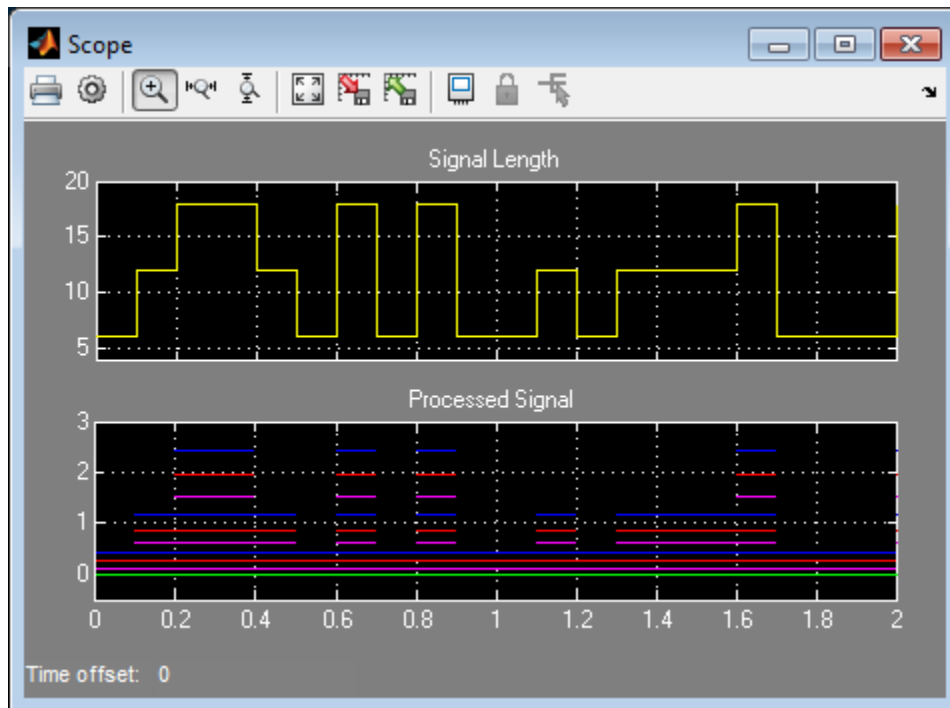

### Processing a Variable-Size Signal

The center section of the model processes the variable-size signal. The MATLAB Function block adds zeros between the data values in a way that is similar to upsampling a signal. The dimension of the signal changes from 9 to 18. The Math Function blocks shows various manipulations you can do with variable-size signals.

### Visualizing a Variable-Size Signal

The right section of the model determines the signal width (size) and uses a scope to visualize the width and the processed data signal.

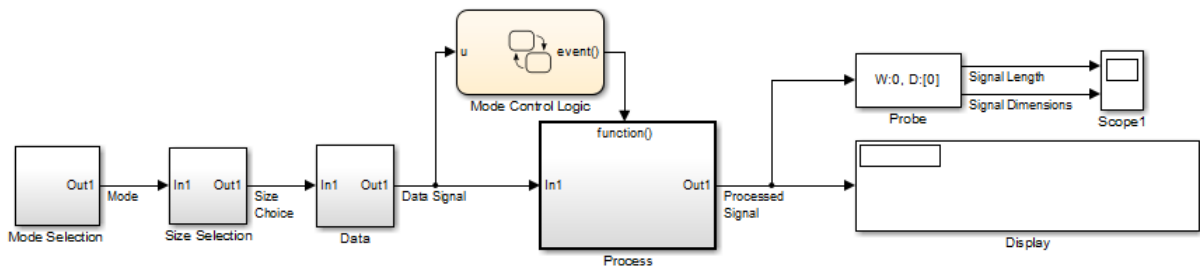

## Mode-Dependent Variable-Size Signals

This example model represents a system that has three operation modes. For each mode, the data signal to process has a different size.

The Process subsystem in this model receives a variable-size signal where the size of the signal depends on the operation mode of the system. For each mode change, the Stateflow chart, Mode Control Logic, detects when the data signal size changes. It then generates a function call to reset the blocks in the Process subsystem.

To open the model, In the MATLAB Command Window, type:

```
sldemo_varsize_multimode
```

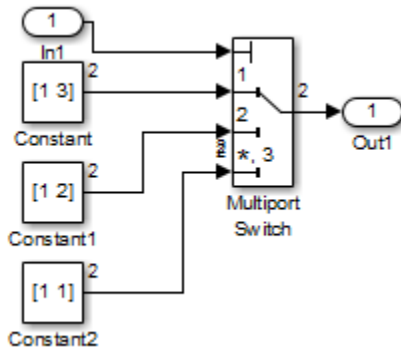

### Creating a Variable-Size Signal Based on Mode

The Mode Selection subsystem determines the mode for processing a data signal and outputs a mode value ( 1, 2, or 3). This value helps to select the length of the data signal using the Size Selection and Data subsystems.

The Size Selection subsystem creates an index value from the mode value. In this example, the index values are [1 3], [1 2], and [1 1].

The Data subsystem takes a data signal (Constant block) and selects part of the data signal dependent on the mode. The output is a variable-size signal with a matrix size of 3x3, 2x2, and 1x1.

The dimensions of the raw data signal (Constant block) is a 3x3. After connecting a To Workspace block to a signal line, you can view the signal in the MATLAB Command Window by typing:

```
simout.signals.values
```

```
ans(:,:,1) =
```

|   |   |   |
|---|---|---|
| 1 | 4 | 7 |
| 2 | 5 | 8 |
| 3 | 6 | 9 |

The variable-size signal generated from the Data subsystem is also a 3x3 matrix. For shorter signals, the matrix is padded with NaNs.

```
simout.signals.values
```

```
ans(:,:,1) =
```

```
    1   NaN   NaN  
   NaN   NaN   NaN  
   NaN   NaN   NaN
```

```
ans(:,:,2) =
```

```
    1    4   NaN  
    2    5   NaN  
   NaN   NaN   NaN
```

```
ans(:,:,3) =
```

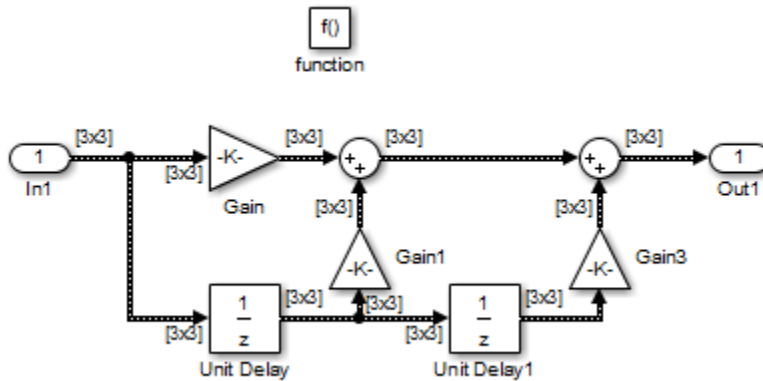

```
    1    4    7  
    2    5    8  
    3    6    9
```

### Processing a Variable-Size Signal with a Conditionally Executed Subsystem

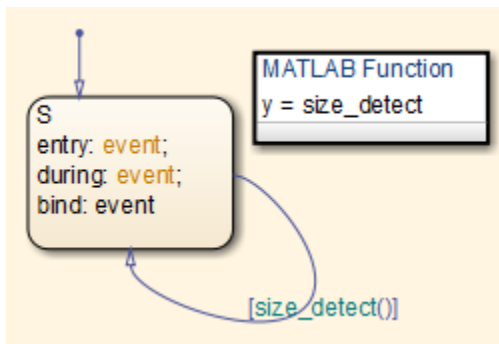

Because the Process subsystem contains a Delay block, the subsystem resets and repropagates the signal at each time step. This model uses a Stateflow chart to detect a signal size change and reset the Process subsystem.

In the function block dialog, and from the **Propagate sizes of variable-size signals** list, choose **Only when enabling**. When the model enables this subsystem, selecting this option directs the Simulink software to propagate sizes for variable-size signals inside the conditionally executed subsystem. Signal sizes can change only when they transition from disabled to enabled. For an explanation of handling signal-size changes with blocks containing states, see “How Variable-Size Signals Propagate” on page 62-3.

The Stateflow chart determines if there is a change in the size of the signal. The function `size_detect` calculates the width of the variable-size signal at each time step, and compares the current width to the previous width. If there is a change in signal size, the chart outputs a function-call output event that resets and repropagates the signal sizes within the Process subsystem.

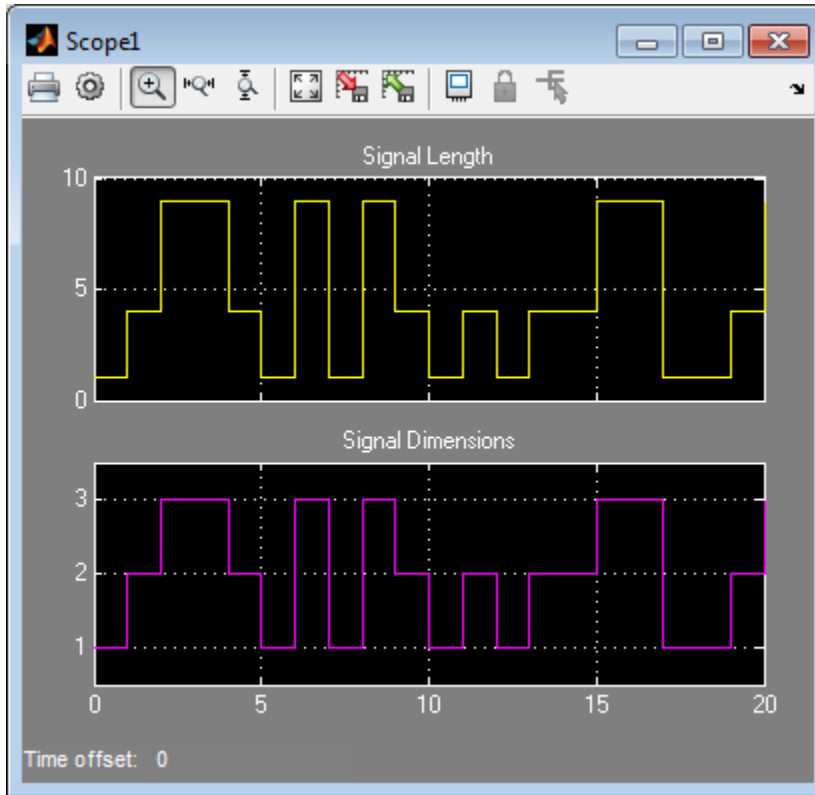

### Visualizing Data

Use the Probe block to visualize signal size and signal dimension.

Since the signals are  $n \times n$  matrices, the signal dimension lines overlap in the Scope display.

You can use a Display block and the Simulink Debugger to visualize signal values at each time step.

## S-Functions Using Variable-Size Signals

### In this section...

“Level-2 MATLAB S-Function with Variable-Size Signals” on page 62-20

“C S-Function with Variable-Size Signals” on page 62-21

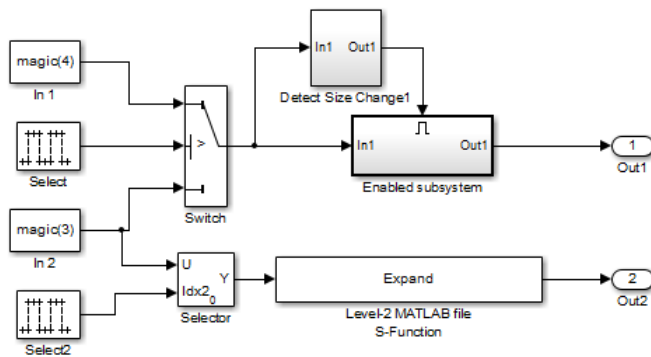

“See Also” on page 62-22

### Level-2 MATLAB S-Function with Variable-Size Signals

Both Level-2 MATLAB S-Functions and C S-Functions support variable-size signals when you set the **DimensionMode** for the output port to **Variable**. You also need to consider the current dimension of the input and output signals in the input and output update methods.

To open this example model, in the MATLAB Command Window, type:

```
msfcdemo_varsize
```

```
matlabroot\toolbox\simulink\simdemos\simfeatures\msfcn_varsize_expand.m
```

```
matlabroot\toolbox\simulink\simdemos\simfeatures\tlc_c\msfcn_varsize_expand.tlc
```

```
matlabroot\toolbox\simulink\simdemos\simfeatures\msfcn_varsize_holdStatesUntilReset.m
```

```
matlabroot\toolbox\simulink\simdemos\simfeatures\tlc_c\msfcn_varsize_holdStatesUntilReset.tlc
```

The Enabled subsystem includes a Level-2 MATLAB S-Function which shows how to implement a block that holds its states until reset. Because this block contains states and delays the input signal, the input size can change only when a reset occurs.

The Expand block is a Level-2 MATLAB S-Function that takes a scalar input and outputs a vector of length indicated by its input value. The output is by  $1:n$  where  $n$  is the input value.

## C S-Function with Variable-Size Signals

To open this example model, in the MATLAB Command Window, type:

```
sfcn_demo_varsize
```

The enabled subsystems have two S-Functions:

- `sfun_varsize_holdStatesUntilReset` is a C S-Function that has states and requires its DWorks vector to reset whenever the sizes of the input signal changes.

- `sfun_varsize_concat1D` is a C S-function that implements the concatenation of two unoriented vectors. You can use this function within an enabled subsystem by itself.

## Simulink Block Support for Variable-Size Signals

### In this section...

“Simulink Block Data Type Support” on page 62-23

“Conditionally Executed Subsystem Blocks” on page 62-23

“Switching Blocks” on page 62-24

“See Also” on page 62-26

### Simulink Block Data Type Support

The Simulink Block Data Type Support table includes a complete list of blocks that support variable-size signals.

To view the table:

- 1 Open a Simulink model.
- 2 Select **Help > Simulink > Block Data Types & Code Generation Support > Simulink**.

An X in the **Variable-Size Support** column indicates support for that block.

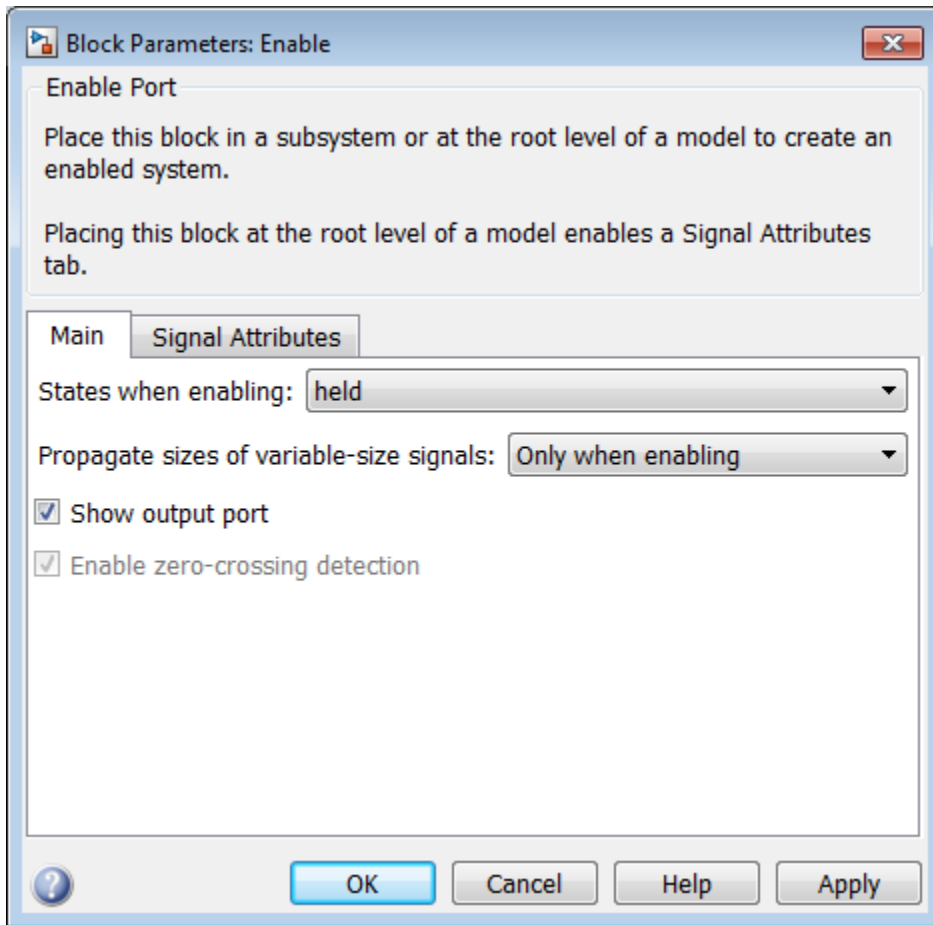

---

**Tip** You can also view the table by entering `showblockdatatypetable` at the command prompt.

---

### Conditionally Executed Subsystem Blocks

Control port blocks are in conditionally executed subsystems. You can set the **Propagate sizes of variable-size signals** parameter for these blocks to **During execution, Only when execution is resumed (Action Port)**, and **Only when enabling (Enable and Trigger or Function-Call)**.

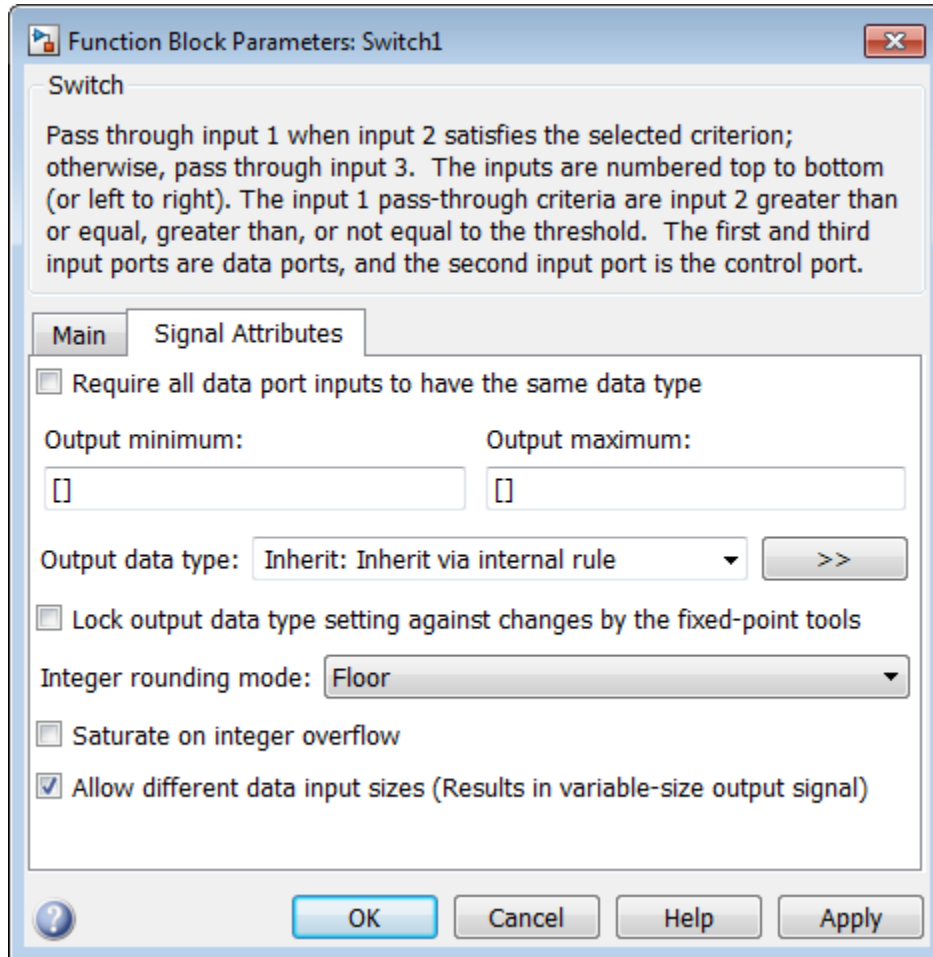

- Action Port
- Enable
- Trigger — **Trigger type** set to function-call

## Switching Blocks

Switching blocks support variable-size signals by allowing input signals with different sizes and propagating the size of the input signal to the output signal. You can set the

**Allow different data input sizes** parameter for these blocks on the Signal Attributes pane to either on or off.

- Switch
- Multiport Switch
- Manual Switch

- “Variable-Size Signal Limitations” on page 62-27

## Variable-Size Signal Limitations

The following table is a list of known limitations and workarounds.

| Limitation  | Workaround   |
|---|--|
| Array format logging does not support variable-size signals.  | Use a <b>Structure</b> or <b>Structure With Time</b> format for logging variable-size signals.   |
| Right-click signal logging does not support variable-size signals.  | Use a <b>To Workspace</b> block (with <b>Structure</b> or <b>Structure With Time</b> format) or a root <b>Outport</b> block for logging variable-size signals. |
| A frame-based variable-size signal cannot change the frame length (first dimension size), but it can change the second dimension size (number of channels). Using frame-based signals requires DSP System Toolbox software. | Use the <b>Frame Conversion</b> block to convert a signal into sample-based signal.  |
| Variable-size signals must have a discrete sample time.   | —  |
| Embedded Coder does not support variable-size signals with ERT S-functions, custom storage classes, function prototype control, the AUTOSAR, C++ interface, and the ERT reusable code interface.                            | —  |
| Simulink does not support variable-size parameter or <b>DWork</b> vectors.  | —  |
| Rapid accelerator mode does not support models having root-level input ports with variable-size signals.  | —  |

## Add Items to Model Editor Menus

### In this section...

“About Adding Items” on page 63-2  
“Code for Adding Menu Items” on page 63-2  
“Define Menu Items” on page 63-4  
“Register Menu Customizations” on page 63-9  
“Callback Info Object” on page 63-10  
“Debugging Custom Menu Callbacks” on page 63-10  
“Menu Tags” on page 63-11

### About Adding Items

You can add commands and submenus to the following menu locations for the Simulink Editor and Stateflow Editor:

- The end of top-level menus
- The menu bar
- The beginning or end of a context menu

To add an item to an editor menu:

- For each item, create a function, called a *schema function*, that defines the item (see “Define Menu Items” on page 63-4).
- Register the menu customizations with the Simulink customization manager at startup, e.g., in an `sl_customization.m` file on the MATLAB path (see “Register Menu Customizations” on page 63-9).
- Create callback functions that implement the commands triggered by the items that you add to the menus.

### Code for Adding Menu Items

The following `sl_customization.m` file adds four items to the Simulink Editor’s **Tools** menu.

```
function sl_customization(cm)
```

```

%% Register custom menu function.
cm.addCustomMenuFcn('Simulink:ToolsMenu', @getMyMenuItems);
end

%% Define the custom menu function.
function schemaFcns = getMyMenuItems(callbackInfo)
    schemaFcns = {@getItem1,...
                 @getItem2,...
                 {@getItem3,3}... %% Pass 3 as user data to getItem3.
                 @getItem4};
end

%% Define the schema function for first menu item.
function schema = getItem1(callbackInfo)
    schema = sl_action_schema;
    schema.label = 'Item One';
    schema.userdata = 'item one';
    schema.callback = @myCallback1;
end

function myCallback1(callbackInfo)
    disp(['Callback for item ' callbackInfo.userdata ' was called']);
end

function schema = getItem2(callbackInfo)
    % Make a submenu label 'Item Two' with
    % the menu item above three times.
    schema = sl_container_schema;
    schema.label = 'Item Two';
    schema.childrenFcns = {@getItem1, @getItem1, @getItem1};
end

function schema = getItem3(callbackInfo)
    % Create a menu item whose label is
    % 'Item Three: 3', with the 3 being passed
    % from getMyItems above.

    schema = sl_action_schema;
    schema.label = ['Item Three: ' num2str(callbackInfo.userdata)];
end

function myToggleCallback(callbackInfo)
    if strcmp(get_param(gcs, 'ScreenColor'), 'red') == 0
        set_param(gcs, 'ScreenColor', 'red');
    else
        set_param(gcs, 'ScreenColor', 'white');
    end
end

%% Define the schema function for a toggle menu item.
function schema = getItem4(callbackInfo)
    schema = sl_toggle_schema;
    schema.label = 'Red Screen';
    if strcmp(get_param(gcs, 'ScreenColor'), 'red') == 1
        schema.checked = 'checked';
    end
end

```

```
else
    schema.checked = 'unchecked';
end
schema.callback = @myToggleCallback;
end
```

## Define Menu Items

You define a menu item by creating a function that returns an object, called a *schema* object, that specifies the information needed to create the menu item. The menu item that you define may trigger a custom action or display a custom submenu. See the following sections for more information.

- “Defining Menu Items That Trigger Custom Commands” on page 63-4
- “Defining Custom Submenus” on page 63-7

### Defining Menu Items That Trigger Custom Commands

To define an item that triggers a custom command, your schema function must accept a callback info object (see “Callback Info Object” on page 63-10) and create and return an action schema object (see “Action Schema Object” on page 63-5) that specifies the item's label and a function, called a *callback*, to be invoked when the user selects the item. For example, the following schema function defines a menu item that displays a message when selected by the user.

```
function schema = getItem1(callbackInfo)

    %% Create an instance of an action schema.
    schema = sl_action_schema;

    %% Specify the menu item's label.
    schema.label = 'My Item 1';
    schema.userdata = 'item1';
    %% Specify the menu item's callback function.
    schema.callback = @myCallback1;

end

function myCallback1(callbackInfo)
    disp(['Callback for item ' callbackInfo.userdata
        ' was called']);
end
```

### Action Schema Object

This object specifies information about menu items that trigger commands that you define, including the label that appears on the menu item and the function to be invoked when the user selects the menu item. Use the function `sl_action_schema` to create instances of this object in your schema functions. Its properties include

- **tag**

Optional string that identifies this action, for example, so that it can be referenced by a filter function.

- **label**

String specifying the label that appears on a menu item that triggers this action.

- **state**

Property that specifies the state of this action. Valid values are 'Enabled' (the default), 'Disabled', and 'Hidden'.

- **statustip**

String specifying text to appear in the editor's status bar when the user selects the menu item that triggers this action.

- **userdata**

Data that you specify. May be of any type.

- **accelerator**

String specifying a keyboard shortcut that a user may use to trigger this action. The string must be of the form 'Ctrl+K', where *K* is the shortcut key. For example, 'Ctrl+T' specifies that the user may invoke this action by holding down the **Ctrl** key and pressing the **T** key.

- **callback**

String specifying a MATLAB expression to be evaluated or a handle to a function to be invoked when a user selects the menu item that triggers this action. This function must accept one argument: a callback info object.

- **autoDisableWhen**

Property that controls when a menu item is automatically disabled.

| Setting  | When Menu Items Are Disabled   |
|----------|--|
| 'Locked' | (default) When the active editor is locked or when the model is busy |
| 'Busy'   | Only if the model is busy  |
| 'Never'  | Never  |

### Toggle Schema Object

This object specifies information about a menu item that toggles some object on or off. Use the function `sl_toggle_schema` to create instances of this object in your schema functions. Its properties include

- `tag`

Optional string that identifies this toggle action, for example, so that it can be referenced by a filter function.

- `label`

String specifying the label that appears on a menu item that triggers this toggle action.

- `checked`

Specify whether the menu item displays a check mark. Valid values are 'unchecked' (default) and 'checked'

- `state`

String that specifies the state of this toggle action. Valid values are 'Enabled' (default), 'Disabled', and 'Hidden'.

- `statustip`

String specifying text to appear in the editor's status bar when the user selects the menu item that triggers this toggle action.

- `userdata`

Data that you specify. May be of any type.

- `accelerator`

String specifying a keyboard shortcut that a user may use to trigger this action. The string must be of the form 'Ctrl+K', where *K* is the shortcut key. For example, 'Ctrl+T' specifies that the user may invoke this action by holding down the **Ctrl** key and pressing the **T** key.

- `callback`

String specifying a MATLAB expression to be evaluated or a handle to a function to be invoked when a user selects the menu item that triggers this action. This function must accept one argument: a callback info object.

- `autoDisableWhen`

Property that controls when a menu item is automatically disabled.

| Setting  | When Menu Items Are Disabled   |
|----------|--|
| 'Locked' | (default) When the active editor is locked or when the model is busy |
| 'Busy'   | Only if the model is busy  |
| 'Never'  | Never  |

## Defining Custom Submenus

To define a submenu, create a schema function that accepts a callback info object and returns a container schema object (see “Container Schema Object” on page 63-7) that specifies the schemas that define the items on the submenu. For example, the following schema function defines a submenu that contains three instances of the menu item defined in the example in “Defining Menu Items That Trigger Custom Commands” on page 63-4.

```
function schema = getItem2( callbackInfo )
    schema = sl_container_schema;
    schema.label = 'Item Two';
    schema.childrenFcns = {@getItem1, @getItem1, @getItem1};
end
```

## Container Schema Object

A container schema object specifies a submenu’s label and its contents. Use the function `sl_container_schema` to create instances of this object in your schema functions. Properties of the object include

- **tag**

Optional string that identifies this submenu.

- **label**

String specifying the submenu's label.

- **state**

String that specifies the state of this submenu. Valid values are 'Enabled' (the default), 'Disabled', and 'Hidden'.

- **statustip**

String specifying text to appear in the editor's status bar when the user selects this submenu.

- **childrenFcns**

Cell array that specifies the contents of the submenu. Each entry in the cell array can be

- A pointer to a schema function that defines an item on the submenu (see “Define Menu Items” on page 63-4)
- A two-element cell array whose first element is a pointer to a schema function that defines an item entry and whose second element is data to be inserted as user data in the callback info object (see “Callback Info Object” on page 63-10) passed to the schema function
- 'separator', which causes a separator to appear between the item defined by the preceding entry in the cell array and the item defined in the following entry. The case is ignored for this entry (for example, 'SEPARATOR' and 'Separator' are both valid entries). A separator is also suppressed if it appears at the beginning or end of the submenu and separators that would appear successively are combined into a single separator (for example, as a result of an item being hidden).

For example, the following cell array specifies two submenu entries:

```
{@getItem1, 'separator', {@getItem2, 1}}
```

In this example, a 1 is passed to `getItem2` via a callback info object.

- **generateFcn**

Pointer to a function that returns a cell array defining the contents of the submenu. The cell array must have the same format as that specified for the container schema objects `childrenFcns` property.

---

**Note:** The `generateFcn` property takes precedence over the `childrenFcns` property. If you set both, the `childrenFcns` property is ignored and the cell array returned by the `generateFcn` is used to create the submenu.

---

- `userdata`

Data of any type that is passed to `generateFcn`.

- `autoDisableWhen`

Property that controls when a menu item is automatically disabled.

| Setting  | When Menu Items Are Disabled   |
|----------|--|
| 'Locked' | (default) When the active editor is locked or when the model is busy |
| 'Busy'   | Only if the model is busy  |
| 'Never'  | Never  |

## Register Menu Customizations

You must register custom items to be included on a Simulink menu with the customization manager. Use the `sl_customization.m` file for a Simulink installation (see “Registering Customizations” on page 63-25) to perform this task. In particular, for each menu that you want to customize, your system's `sl_customization` function must invoke the customization manager's `addCustomMenuFcn` method (see “Customization Manager” on page 63-25). Each invocation should pass the tag of the menu (see “Menu Tags” on page 63-11) to be customized and a custom menu function that specifies the items to be added to the menu (see “Creating the Custom Menu Function” on page 63-10). For example, the following `sl_customization` function adds custom items to the Simulink Tools menu.

```
function sl_customization(cm)
    %% Register custom menu function.
    cm.addCustomMenuFcn('Simulink:ToolsMenu', @getMyItems);
```

## Creating the Custom Menu Function

The custom menu function returns a cell array of schema functions that define custom items that you want to appear on the model editor menus (see “Define Menu Items” on page 63-4 ). The custom menu function returns a cell array similar to that returned by the `generateFcn` function.

Your custom menu function should accept a callback info object (see “Callback Info Object” on page 63-10) and return a cell array that lists the schema functions. Each element of the cell array can be either a handle to a schema function or a two-element cell array whose first element is a handle to a schema function and whose second element is user-defined data to be passed to the schema function. For example, the following custom menu function returns a cell array that lists three schema functions.

```
function schemas = getMyItems(callbackInfo)
    schemas = {@getItem1, ...
              @getItem2, ...
              {@getItem3,3} }; % Pass 3 as userdata to getItem3.
end
```

## Callback Info Object

Instances of these objects are passed to menu customization functions. Methods and properties of these objects include:

- `uiObject`

Method to get the handle to the owner of the menu for which this is the callback. The owner can be the Simulink Editor or the Stateflow Editor.

- `model`

Method to get the handle to the model being displayed in the editor window.

- `userdata`

User data property. The value of this property can be any type of data.

## Debugging Custom Menu Callbacks

On systems using the Microsoft Windows operating system, selecting a custom menu item whose callback contains a breakpoint can cause the mouse to become unresponsive

or the menu to remain open and on top of other windows. To fix these problems, use the MATLAB code debugger keyboard commands to continue execution of the callback.

## Menu Tags

A menu tag is a string that identifies a Simulink Editor or the Stateflow Editor menu bar or menu. You need to know a menu's tag to add custom items to it (see “Register Menu Customizations” on page 63-9). You can configure the editor to display all (see “Displaying Menu Tags” on page 63-12) but the following tags:

| Tag                     | Add...  |
|-------------------------|---|
| Simulink tags           |   |
| Simulink:MenuBar        | Menu to Simulink Editor's menu bar  |
| Simulink:PreContextMenu | Item to the beginning of Simulink Editor's context menu   |
| Simulink:ContextMenu    | Item to the end of Simulink Editor's context menu   |
| Simulink:FileMenu       | Item near the end of the Simulink Editor's <b>File</b> menu, but before the <b>Exit MATLAB</b> item |
| Simulink>EditMenu       | Item to the end of the Simulink Editor's <b>Edit</b> menu   |
| Simulink:ViewMenu       | Item to the end of the Simulink Editor's <b>View</b> menu   |
| Simulink:DisplayMenu    | Item to the end of the Simulink Editor's <b>Display</b> menu  |
| Simulink:DiagramMenu    | Item to the end of the Simulink Editor's <b>Diagram</b> menu  |
| Simulink:SimulationMenu | Item to the end of the Simulink Editor's <b>Simulation</b> menu                                     |
| Simulink:AnalysisMenu   | Item to the end of the Simulink Editor's <b>Analysis</b> menu                                       |
| Simulink:CodeMenu       | Item to the end of the Simulink Editor's <b>Code</b> menu   |
| Simulink:ToolsMenu      | Item to the end of the Simulink Editor's <b>Tools</b> menu  |
| Simulink:HelpMenu       | Item to the end of Simulink Editor's <b>Help</b> menu   |

| Tag                      | Add...   |
|--------------------------|--|
| Stateflow tags           |  |
| Stateflow:MenuBar        | Menu to Stateflow Editor's menu bar  |
| Stateflow:PreContextMenu | Item to the beginning of Stateflow Editor's context menu.  |
| Stateflow:ContextMenu    | Items to the end of Stateflow Editor's context menu.   |
| Stateflow:FileMenu       | Item near the end of the Stateflow Editor's <b>File</b> menu, but before the <b>Exit MATLAB</b> item |
| Stateflow>EditMenu       | Item to the end of Stateflow Editor's <b>Edit</b> menu   |
| Stateflow:ViewMenu       | Item to the end of the Stateflow Editor's <b>View</b> menu   |
| Stateflow:DisplayMenu    | Item to the end of the Stateflow Editor's <b>Display</b> menu  |
| Stateflow:ChartMenu      | Item to the end of the Stateflow Editor's <b>Chart</b> menu  |
| Stateflow:SimulationMenu | Item to the end of the Stateflow Editor's <b>Simulation</b> menu                                     |
| Stateflow:AnalysisMenu   | Item to the end of the Stateflow Editor's <b>Analysis</b> menu                                       |
| Stateflow:CodeMenu       | Item to the end of the Stateflow Editor's <b>Code</b> menu   |
| Stateflow:ToolsMenu      | Item to the end of the Stateflow Editor's <b>Tools</b> menu  |
| Stateflow:HelpMenu       | Item to the end of the Stateflow Editor's <b>Help</b> menu   |

### Displaying Menu Tags

You can configure the Simulink and Stateflow software to display the tag for a menu item next to the item's label, allowing you to determine at a glance the tag for a menu. The `Simulink:TagName` customizations appear only if the current editor is the Simulink Editor. The `Stateflow:TagName` customizations appear only if the current editor is the Stateflow Editor.

To configure the editor to display menu tags, at the MATLAB command line, set the customization manager's `showWidgetIdAsToolTip` property to `true`. For example:

```
cm = sl_customization_manager;
cm.showWidgetIdAsToolTip=true;
```

The tag of each menu item appears next to the item's label on the menu:

To turn off tag display, enter the following command at the command line:

```
cm.showWidgetIdAsToolTip=false;
```

---

**Note:** Some menu items may not work while menu tag display is enabled. To ensure that all items work, turn off menu tag display before using the menus.

---

### **Simulink and Stateflow Editor Menu Customization**

Use the same general procedures to customize Stateflow Editor menus as you use for Simulink Editor. The addition of custom menu functions to the ends of top-level menus depends on the active editor:

- Menus bound to `Simulink:FileMenu` only appear when the Simulink Editor is active.
- Menus bound to `Stateflow:FileMenu` only appear when the Stateflow Editor is active.
- To have a menu to appear in both of the editors, call `addCustomMenuFcn` twice, once for each tag. Check that the code works in both editors.

## Disable and Hide Model Editor Menu Items

### In this section...

“About Disabling and Hiding Model Editor Menu Items” on page 63-15

“Example: Disabling the New Model Command on the Simulink Editor's File Menu” on page 63-15

“Creating a Filter Function” on page 63-15

“Registering a Filter Function” on page 63-16

### About Disabling and Hiding Model Editor Menu Items

You can disable or hide items that appear on the Simulink model editor menus. To disable or hide a menu item, you must:

- Create a filter function that disables or hides the menu item (see “Creating a Filter Function” on page 63-15).
- Register the filter function with the customization manager (see “Registering a Filter Function” on page 63-16).

For more information on Model Editor menu items, see:

### Example: Disabling the New Model Command on the Simulink Editor's File Menu

```
function sl_customization(cm)
    cm.addCustomFilterFcn('Simulink:NewModel',@myFilter);
end

function state = myFilter(callbackInfo)
    state = 'Disabled';
end
```

### Creating a Filter Function

Your filter function must accept a callback info object and return a string that specifies the state that you want to assign to the menu item. Valid states are

- 'Hidden'

- 'Disabled'
- 'Enabled'

Your filter function may have to compete with other filter functions and with Simulink itself to assign a state to an item. Who succeeds depends on the strength of the state that each assigns to the item. 'Hidden' is the strongest state. If any filter function or Simulink assigns 'Hidden' to the item, it is hidden. 'Enabled' is the weakest state. For an item to be enabled, all filter functions and the Simulink or Stateflow products must assign 'Enabled' to the item. The 'Disabled' state is of middling strength. It overrides 'Enabled' but is itself overridden by 'Hidden'. For example, if any filter function or Simulink or Stateflow assigns 'Disabled' to a menu item and none assigns 'Hidden' to the item, the item is disabled.

---

**Note:** The Simulink software does not allow you to filter some menu items, for example, the **Exit MATLAB** item on the Simulink **File** menu. An error message is displayed if you attempt to filter a menu item that you are not allowed to filter.

---

## Registering a Filter Function

Use the customization manager's `addCustomFilterFcn` method to register a filter function. The `addCustomFilterFcn` method takes two arguments: a tag that identifies the menu or menu item to be filtered (see “Displaying Menu Tags” on page 63-12) and a pointer to the filter function itself. For example, the following code registers a filter function for the **New Model** item on the Simulink **File** menu.

```
function sl_customization(cm)
    cm.addCustomFilterFcn('Simulink:NewModel',@myFilter);
end
```

## Disable and Hide Dialog Box Controls

### In this section...

“About Disabling and Hiding Controls” on page 63-17

“Disable a Button on a Dialog Box” on page 63-18

“Write Control Customization Callback Functions” on page 63-18

“Dialog Box Methods” on page 63-19

“Dialog Box and Widget IDs” on page 63-19

“Register Control Customization Callback Functions” on page 63-20

### About Disabling and Hiding Controls

The Simulink product includes a customization API that allows you to disable and hide controls (also referred to as *widgets*), such as text fields and buttons, on most of its dialog boxes. The customization API allows you to disable or hide controls on an entire class of dialog boxes, for example, parameter dialog boxes via a single method call.

Before attempting to customize a Simulink dialog box or class of dialog boxes, you must first ensure that the dialog box or class of dialog boxes is customizable. Any dialog box that appears in the dialog pane of Model Explorer is customizable. In addition, any dialog box that has dialog and widget IDs is customizable. To determine whether a standalone dialog box (i.e., one that does not appear in Model Explorer) is customizable, open the dialog box, enable dialog and widget ID display (see “Dialog Box and Widget IDs” on page 63-19), and position the mouse over a widget. If a widget ID appears, the dialog box is customizable.

Once you have determined that a dialog box or class of dialog boxes is customizable, you must write MATLAB code to customize the dialog boxes. This entails writing callback functions that disable or hide controls for a specific dialog box or class of dialog boxes (see “Write Control Customization Callback Functions” on page 63-18) and registering the callback functions via an object called the customization manager (see “Register Control Customization Callback Functions” on page 63-20). Simulink then invokes the callback functions to disable or hide the controls whenever a user opens the dialog boxes.

For more information on Dialog Box controls, see:

## Disable a Button on a Dialog Box

The following `sl_customization.m` file disables the **Build** button on the **Code Generation** pane of the Configuration Parameters dialog box for any model whose name contains “engine.”

```
function sl_customization(cm)

% Disable for standalone Configuration Parameters dialog box.
cm.addDlgPreOpenFcn('Simulink.ConfigSet',@disableRTWBuildButton)
% Disable for Configuration Parameters dialog box that appears in
% the Model Explorer.
cm.addDlgPreOpenFcn('Simulink.RTWCC',@disableRTWBuildButton)

end

function disableRTWBuildButton(dialogH)
    hSrc = dialogH.getSource; % Simulink.RTWCC
    hModel = hSrc.getModel;
    modelName = get_param(hModel, 'Name');

    if ~isempty(strfind(modelName, 'engine'))
        % Takes a cell array of widget Factory ID.
        dialogH.disableWidgets({'Simulink.RTWCC.Build'})
    end
end

end
```

To test this customization:

- 1 Put the preceding `sl_customization.m` file on the path.
- 2 Register the customization by entering `sl_refresh_customizations` at the command line or by restarting the MATLAB software (see “Registering Customizations” on page 63-25).
- 3 Open the `sldemo_engine` model, for example, by entering the command `sldemo_engine` at the command line.

## Write Control Customization Callback Functions

A callback function for disabling or hiding controls on a dialog box should accept one argument: a handle to the dialog box object that contains the controls you want to disable or hide. The dialog box object provides methods that the callback function can use to disable or hide the controls that the dialog box contains.

The dialog box object also provides access to objects containing information about the current model. Your callback function can use these objects to determine whether

to disable or hide controls. For example, the following callback function uses these objects to disable the **Build** button on the **Code Generation** pane of the Configuration Parameters dialog box displayed in Model Explorer for any model whose name contains “engine.”

```
function disableRTWBuildButton(dialogH)

    hSrc    = dialogH.getSource; % Simulink.RTWCC
    hModel  = hSrc.getModel;
    modelName = get_param(hModel, 'Name');

    if ~isempty(strfind(modelName, 'engine'))
        % Takes a cell array of widget Factory ID.
        dialogH.disableWidgets({'Simulink.RTWCC.Build'})
    end
end
```

## Dialog Box Methods

Dialog box objects provide the following methods for enabling, disabling, and hiding controls:

- `disableWidgets(widgetIDs)`
- `hideWidgets(widgetIDs)`

where `widgetIDs` is a cell array of widget identifiers (see “Dialog Box and Widget IDs” on page 63-19) that specify the widgets to be disabled or hidden.

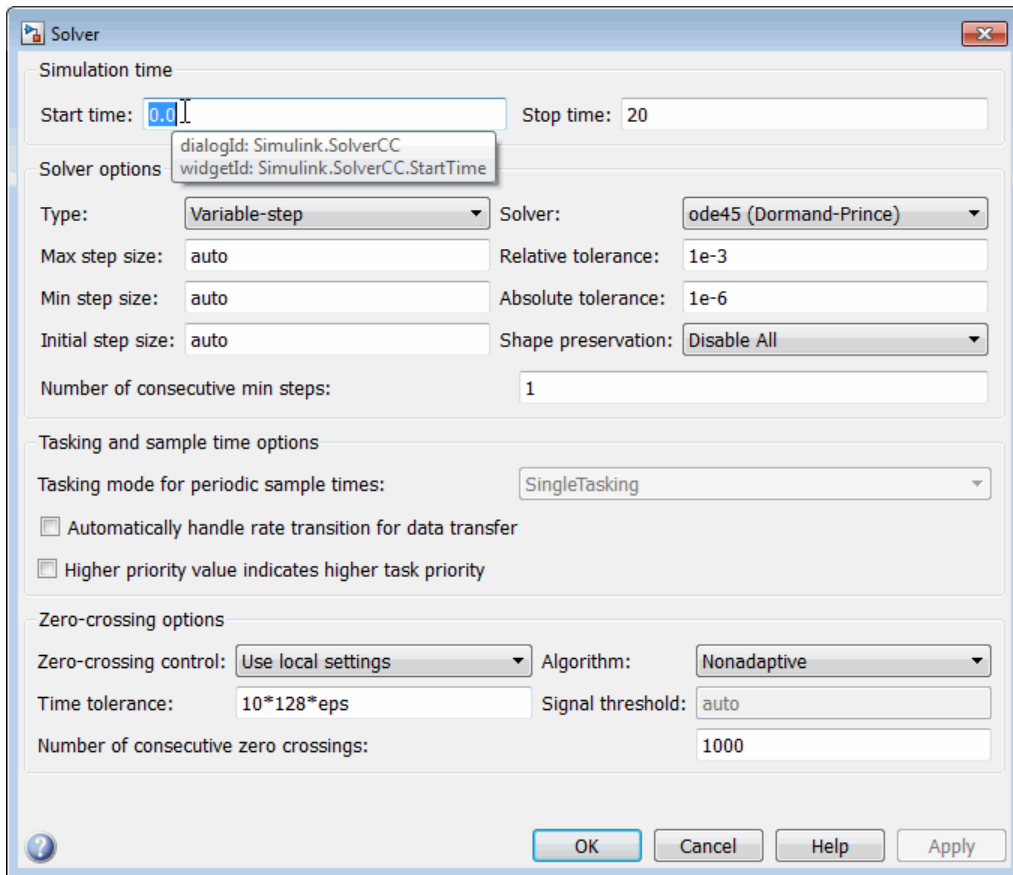

## Dialog Box and Widget IDs

Dialog box and widget IDs are strings that identify a control on a Simulink dialog box. To determine the dialog box and widget ID for a particular control, execute the following code at the command line:

```
cm = sl_customization_manager;
cm.showWidgetIdAsToolTip = true
```

Then, open the dialog box that contains the control and move the mouse cursor over the control to display a tooltip listing the dialog box and the widget IDs for the control. For example, moving the cursor over the **Start time** field on the **Solver** pane of the Configuration Parameters dialog box reveals that the dialog box ID for the

**Solver** pane is `Simulink.SolverCC` and the widget ID for the **Start time** field is `Simulink.SolverCC.StartTime`.

**Note:** The tooltip displays “not customizable” for controls that are not customizable.

## Register Control Customization Callback Functions

To register control customization callback functions for a particular installation of the Simulink product, include code in the installation’s `sl_customization.m` file

(see “Registering Customizations” on page 63-25) that invokes the customization manager’s `addDlgPreOpenFcn` on the callbacks.

The `addDlgPreOpenFcn` takes two arguments. The first argument is a dialog box ID (see “Dialog Box and Widget IDs” on page 63-19) and the second is a pointer to the callback function to be registered. Invoking this method causes the registered function to be invoked for each dialog box of the type specified by the dialog box ID. The function is invoked before the dialog box is opened, allowing the function to perform the customizations before they become visible to the user.

The following example registers a callback that disables the **Build** button on the **Code Generation** pane of the Configuration Parameters dialog box (see “Write Control Customization Callback Functions” on page 63-18).

```
function sl_customization(cm)

    % Disable for standalone Configuration Parameters dialog box.
    cm.addDlgPreOpenFcn('Simulink.ConfigSet',@disableRTWBuildButton)

    % Disable for Configuration Parameters dialog box that appears in
    % the Model Explorer
    cm.addDlgPreOpenFcn('Simulink.RTWCC',@disableRTWBuildButton)

end
```

---

**Note:** Registering a customization callback causes the Simulink software to invoke the callback for every instance of the class of dialog boxes specified by the method’s dialog box ID argument. This allows you to use a single callback to disable or hide a control for an entire class of dialog boxes. In particular, you can use a single callback to disable or hide the control for a parameter that is common to most built-in blocks. This is because most built-in block dialog boxes are instances of the same dialog box super class.

---

## Customize the Library Browser

### In this section...

“Reorder Libraries” on page 63-22

“Disable and Hide Libraries” on page 63-22

“Reorder Blocks in Libraries” on page 63-23

### Reorder Libraries

The order in which a library appears in the Library Browser is determined by its name and its sort priority. Libraries appear in the Library Browser's tree view in ascending order of priority, with all blocks having the same priority sorted alphabetically. The Simulink library has a sort priority of -1 by default; all other libraries, a sort priority of 0. This guarantees that the Simulink library is by default the first library displayed in the Library Browser. You can reorder libraries by changing their sort priorities. To change library sort priorities, insert a line of code of the following form in an `sl_customization.m` file (see “Registering Customizations” on page 63-25) on the MATLAB path:

```
cm.LibraryBrowserCustomizer.applyOrder( {'LIBNAME1', PRIORITY1, ...
                                         'LIBNAME2', 'PRIORITY2, ...
                                         .
                                         .
                                         'LIBNAMEN', PRIORITYN} );
```

where `LIBNAMEN` is the name of the library or its model file and `PRIORITYn` is an integer indicating the library's sort priority. For example, the following code moves the Simulink Extras library to the top of the Library Browser's tree view.

```
cm.LibraryBrowserCustomizer.applyOrder( {'Simulink Extras', -2} );
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

### Disable and Hide Libraries

To disable or hide libraries, sublibraries, or library blocks, insert code of the following form in an `sl_customization.m` file (see “Registering Customizations” on page 63-25) on the MATLAB path:

```
cm.LibraryBrowserCustomizer.applyFilter( {'PATH1', 'STATE1', ...
                                           'PATH2', 'STATE2', ...
                                           .
                                           'PATHn', 'STATEN'} );
```

where `PATHn` is the path of the library, sublibrary, or block to be disabled or hidden and `'STATEN'` is `'Disabled'` or `'Hidden'`. For example, the following code hides the Simulink Sources sublibrary and disables the Sinks sublibrary.

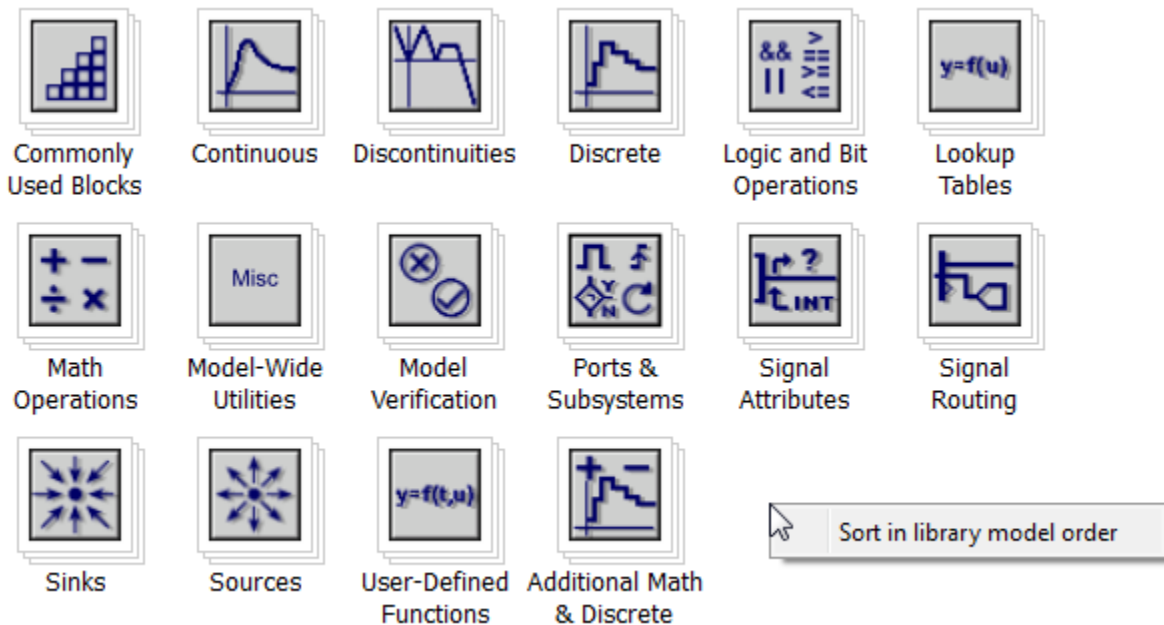

```
cm.LibraryBrowserCustomizer.applyFilter({'Simulink/Sources', 'Hidden'});
cm.LibraryBrowserCustomizer.applyFilter({'Simulink/Sinks', 'Disabled'});
```

After adding or modifying the `sl_customization.m` file, enter `sl_refresh_customizations` at the MATLAB command prompt to see the customizations take effect.

## Reorder Blocks in Libraries

You can order blocks in the Library Browser alphabetically or based on their layout in the underlying library model. This library model can be a built-in block library or your custom library model.

To reorder the display of blocks in all libraries in the Library Browser, right-click in the blocks pane and select **Sort in library model order** or **Sort in alphabetical order**. This setting stays in effect from session to session.

**Note:** Customized sorting in the Library Browser takes precedence over library model order or alphabetical order sorting. In the figure, the blocks pane for the Simulink library shows the Additional Math & Discrete sublibrary last because of custom sorting rules applied to this sublibrary.

## Registering Customizations

### In this section...

“About Registering User Interface Customizations” on page 63-25

“Customization Manager” on page 63-25

### About Registering User Interface Customizations

You must register your user interface customizations using a MATLAB function called `sl_customization.m`. This is located on the MATLAB path of the Simulink installation that you want to customize. The `sl_customization` function should accept one argument: a handle to a customization manager object. For example:

```
function sl_customization(cm)
```

The customization manager object includes methods for registering menu and control customizations (see “Customization Manager” on page 63-25). Your instance of the `sl_customization` function should use these methods to register customizations specific to your application. For more information, see the following sections on performing customizations.

- “Add Items to Model Editor Menus” on page 63-2
- “Disable and Hide Model Editor Menu Items” on page 63-15
- “Disable and Hide Dialog Box Controls” on page 63-17

The `sl_customization.m` file is read when the Simulink software starts. If you subsequently change the `sl_customization.m` file, you must restart the Simulink software or enter the following command at the command line to effect the changes:

```
sl_refresh_customizations
```

### Customization Manager

The customization manager includes the following methods:

- `addCustomMenuFcn(stdMenuTag, menuSpecsFcn)`

Adds the menus specified by `menuSpecsFcn` to the end of the standard Simulink menu specified by `stdMenuTag`. The `stdMenuTag` argument is a string that specifies

the menu to be customized. For example, the `stdMenuTag` for the Simulink editor's **Tools** menu is `'Simulink:ToolsMenu'` (see “Displaying Menu Tags” on page 63-12 for more information). The `menuSpecsFcn` argument is a handle to a function that returns a list of functions that specify the items to be added to the specified menu. See “Add Items to Model Editor Menus” on page 63-2 for more information.

- `addCustomFilterFcn(stdMenuItemID, filterFcn)`

Adds a custom filter function specified by `filterFcn` for the standard Simulink model editor menu item specified by `stdMenuItemID`. The `stdMenuItemID` argument is a string that identifies the menu item. For example, the ID for the **New Model** item on the Simulink editor's **File** menu is `'Simulink:NewModel'` (see “Displaying Menu Tags” on page 63-12 for more information). The `filterFcn` argument is a pointer to a function that hides or disables the specified menu item. See “Disable and Hide Model Editor Menu Items” on page 63-15 for more information.

# Frames for Printed Models

---

- “Print Frames” on page 64-2
- “Create a Print Frame” on page 64-6
- “Add Rows and Cells to Print Frames” on page 64-7
- “Add Content to Print Frame Cells” on page 64-9
- “Print Using Print Frames” on page 64-13

## Print Frames

### In this section...

“What are Print Frames?” on page 64-2

“PrintFrame Editor” on page 64-3

“Single Use or Multiple Use Print Frames” on page 64-4

“Text and Variable Content” on page 64-5

### What are Print Frames?

Print frames are borders of a printed page that contain information about a block diagram, such as the model name or the date of printing. After you create a print frame, use the Simulink or Stateflow Editor to print a block diagram or chart with that print frame.

The default print frame has two rows:

Rows contain one or more cells. You can add content entries to cells. You can also add new rows and cells.

For example, the print frame below includes:

- An additional row at the top of the frame for a title

- A middle row, which includes the block diagram
- A bottom row, in which one cell has the path to the subsystem and another cell has the page number

## PrintFrame Editor

Use the PrintFrame Editor to create and edit print frames.

To open the PrintFrame Editor, at the MATLAB command line, enter the `frameedit` command.

Use the PrintFrame Editor to:

- Set up the printed page
- Add or remove rows and cells in the print frame
- Add content to cells, such as text, the date, and page numbers
- Format cell content

To open an existing print frame, use `frameedit` command with the `filename` parameter, where `filename` is an existing print frame (a `.fig` file).

## Single Use or Multiple Use Print Frames

You can design a print frame for one particular block diagram, or you can design a more generic print frame for printing multiple block diagrams.

## **Text and Variable Content**

In cells, you can include text (such as the name and address of your organization) and variable content (such as the current date).

## Create a Print Frame

- 1 At the MATLAB prompt, type `frameedit` to open the PrintFrame Editor.
- 2 In the PrintFrame Editor, select **File > Page Setup**.

If necessary, change default page setup for the print frame, which is:

- Paper type — usletter
- Orientation — landscape

---

**Note:** The paper orientation you specify does not control the paper orientation used for printing. For example, assume you specify a landscape-oriented print frame in the PrintFrame Editor. If you want the printed page to have a landscape orientation, you must specify that using the Print Model dialog box.

---

- Margins — .75 inches on all sides
- 3 Set up the layout of the print frame and add content. See:
    - “Add Rows and Cells to Print Frames” on page 64-7
    - “Add Content to Print Frame Cells” on page 64-9
  - 4 Save the print frame as a `.fig` file. Select **File > Save As**.

## Add Rows and Cells to Print Frames

### In this section...

“Add and Remove Rows” on page 64-7

“Add and Remove Cells” on page 64-7

“Resize Rows and Cells” on page 64-7

---

**Tip** Specify the print frame page setup before you create rows and cells or add content (see “Create a Print Frame” on page 64-6).

---

### Add and Remove Rows

You can add a row above the row that you select.

- 1 Click in a cell to select a row.

When you select a row, handles appear on all four corners. If you select only a line, handles appear on two corners.

- 2 Click **Add Row**.

The new row appears above the row that you selected.

To remove a row, select the row and click **Delete Row**.

### Add and Remove Cells

You can add cells within a row.

- 1 Select the cell that you want to split.

- 2 Click **Split Cell**.

The cell splits into two cells.

To remove a cell, select the cell and click **Delete Cell**.

### Resize Rows and Cells

You can change the dimensions of a row or cell by selecting the bordering line.

- 1** Click the line you want to move.  
A handle appears on both ends of the line.
- 2** Drag the line to resize the row or cell.

For example, to make a row taller, click on the top line that forms the row. Then drag the line up and the height of the row increases.

To change the overall dimensions of the print frame, see “Create a Print Frame” on page 64-6.

## Add Content to Print Frame Cells

### In this section...

- “Types of Content” on page 64-9
- “Add Content to Cells” on page 64-9
- “Block Diagram” on page 64-10
- “Variables” on page 64-10
- “Text” on page 64-11
- “Format Content in Cells” on page 64-12

### Types of Content

You can add text or variables, or both, to a cell.

You must add a **Block Diagram** variable to one of the cells.

For details about the types of content, see:

- “Block Diagram” on page 64-10
- “Variables” on page 64-10
- “Text” on page 64-11

### Add Content to Cells

- 1 Select the cell that you want to add content to.
- 2 From the list, select the type of content that you want to add.
- 3 Click **Add**.

The type of content that you added appears in the cell.

---

**Tip** If you click **Add** and nothing happens, it might be because you did not select a cell first.

---

- 4 If you add text, select the edit box and type in the text. For details, see “Text” on page 64-11.

---

**Tip** To make it easier to read and edit the content that you add, you can click the **Zoom in +** button.

---

### **Include Multiple Entries in a Cell**

- 1 Select a cell that has a content entry.
- 2 Add another content type item from the list.

The new entry is added after the last entry in that cell.

You can also add descriptive text to any of the variable entries without using the **Text** item.

- 1 Double-click in the cell.
- 2 Type text in the edit box before or after the entry.
- 3 To end editing mode, click outside of the cell.

---

**Note:** You cannot include multiple entries or text in the cell that contains the **Block Diagram** variable. `%<blockdiagram>` must be the only content in that cell.

---

## **Block Diagram**

Use the **Block Diagram** variable to indicate the cell in which to print the block diagram. Every print frame must include one **Block Diagram** variable. If you do not specify a **Block Diagram** in one of the cells, you cannot save the print frame and cannot print a block diagram with it.

Do not add any other content in a cell that contains a **Block Diagram** variable.

## **Variables**

In addition to the **Block Diagram** variable, you can add other variables, such as the current date, to cells. Simulink supplies variable content at the time of printing.

Variable entries include:

- **Block Diagram** — Add this variable in the cell in which you want the block diagram to print. For details, see “Block Diagram” on page 64-10.

- **Date** — The date that the block diagram and print frame are printed, in `dd-mmm-yyyy` format.
- **Time** — The time that the block diagram and print frame are printed, in `hh:mm` format.
- **Page Number** — The page of the block diagram being printed.
- **Total Pages** — The total number of pages being printed for the block diagram, which depends on the printing options specified.
- **System Name** — The name of the block diagram being printed.
- **Full System Name** — The name of the block diagram being printed, including its position from the root system through the current system, for example, `engine/Throttle & Manifold`.
- **File Name** — The file name of the block diagram, for example, `sldemo_engine.mdl`.
- **Full File Name** — The full path and file name for the block diagram, for example, `\matlab\toolbox\simulink\simdemos\automotive\sldemo_engine.mdl`.

When you enter a variable, the cell displays the type of content in brackets, `<>`, preceded by a percent sign, `%`. For example, if you add a **Page Number** variable, it appears as `%<page>`.

---

**Note:** Do not edit the text of a variable entry, because then the variable content does not print. For example, if you accidentally remove the `%` from the `%<page>` entry, the text `<page>` prints, instead of the actual page number.

---

## Text

For **Text** content, type the text that you want to include in that cell (for example, the name of your organization). To type additional text on a new line, press the **Enter** key. When you are finished editing, click outside of the edit box.

You can copy and paste text from another document into a cell. Any formatting of the copied text is lost.

To type special characters (for example, superscripts and subscripts, Greek letters, and mathematical symbols), use embedded TeX sequences. For a list of allowable sequences, see the `text` command **String** property (in **Text Properties**).

## **Format Content in Cells**

You can align cell contents using the left, center, and right alignment buttons. (Block diagrams are always center aligned.)

You can change font properties, such as size or style (for example, italics or bold). To change font properties, select the cell, then right-click the contents and use the context menu to format the text.

## Print Using Print Frames

To print using a print frame, you specify an existing print frame. If you want to build a print frame, see “Create a Print Frame” on page 64-6.

---

**Note:** If you enable the print frame option, then Simulink does not use tiled printing.

---

- 1 In the Simulink Editor or Stateflow Editor, select **File > Print > Print**.
- 2 In the Print Model dialog box, select the **Frame** check box.

- 3 Supply the file name for the print frame you want to use. Either type the path and file name directly in the edit box, or click the ... button and select a print frame file you saved using the PrintFrame Editor. The default print frame file name, `sldefaultframe.fig`, appears in the file name edit box until you specify a different file name.
- 4 Specify other printing options in the Print Model dialog box.

---

**Note:** The paper orientation you specify with the PrintFrame Editor does not control the paper orientation used for printing. For example, assume you specify a landscape-oriented print frame in the PrintFrame Editor. If you want the printed page to have a landscape orientation, you must specify that using the Print Model dialog box.

---

**5** Click **OK**.

The block diagram prints with the print frame that you specify.

# Running Models on Target Hardware

# About Run on Target Hardware Feature

- “Tune and Monitor Models Running on Target Hardware” on page 65-3
- “Block Produces Zeros or Does Nothing in Simulation” on page 65-7

## Simulink Supported Hardware

As of this release, Simulink supports the following hardware.

| Support Package                | Vendor       | Earliest Release Available | Last Release Available |
|--------------------------------|--------------|----------------------------|------------------------|
| Apple iOS Devices              | Apple        | R2015a                     | Current                |
| Arduino Hardware               | Arduino      | R2012a                     | Current                |
| BeagleBoard Hardware           | BeagleBoard  | R2012a                     | Current                |
| LEGO MINDSTORMS NXT Hardware   | LEGO         | R2012a                     | Current                |
| LEGO MINDSTORMS EV3 Hardware   | LEGO         | R2014a                     | Current                |
| Raspberry Pi Hardware          | Raspberry Pi | R2013a                     | Current                |
| Samsung GALAXY Android Devices | Android      | R2014a                     | Current                |

For a complete list of supported hardware, see [Hardware Support](#).

## Tune and Monitor Models Running on Target Hardware

### In this section...

“Overview of Using External Mode” on page 65-3

“Run Your Simulink Model in External Mode” on page 65-4

“Stop External Mode” on page 65-5

“External Mode Control Panel” on page 65-5

### Overview of Using External Mode

You can use External mode to tune parameters and monitor a model running on your target hardware.

External mode enables you to tune model parameters and evaluate the effects of different parameter values on model results in real time. Doing so helps you find the optimal values to achieve desired performance. This process is called *parameter tuning*.

External mode accelerates parameter tuning because you do not have to rerun the model each time you change parameters. You can also use External mode to develop and validate your model using the actual data and hardware for which it is designed. This software-hardware interaction is not available solely by simulating a model.

This workflow lists the tasks usually required to tune parameters with External mode:

- 1 In the model on your host computer, enable External mode.
- 2 (Optional) Place one or more sink blocks in your model. For example, use **Display** or **Scope** blocks to visualize data, or use a **To File** block to log signal data.
- 3 Give the Simulink software command to run the model on the target hardware.
- 4 (Optional) Observe the data External mode sends from the target hardware to sink blocks in the model on the host computer.
- 5 Change and apply parameter values in the model on your host computer.
- 6 Find the optimal parameter values by making adjustments and observing the results.
- 7 Save the new parameter values, disable External mode, and save the model.

## Run Your Simulink Model in External Mode

---

**Note:** If you have the Embedded Coder or Simulink Coder software, you can use External mode with a model that contains Model blocks (uses the “Model reference”).

---

- 1 Connect the target hardware to your host computer.

Different types of target hardware can use different types of connections. Check the External mode topic for your target hardware to determine which type of connection to use.

- 2 On the model toolbar, set **Simulation mode** to External.

- 3 Set the **Simulation stop time** parameter, located to the left of **Simulation mode** on the model toolbar. The default value is 10.0 seconds. To run the model for an indefinite period, enter `inf`.
- 4 Click the **Run** button.

If your model does not contain a sink block, the MATLAB Command Window displays a warning message. For example:

```
Warning: No data has been selected for uploading.
> In C:\Program Files (x86)\MATLAB\R2013a Student1\toolbox\
realtime\realtime\+realtime\extModeAutoConnect.p>
extModeAutoConnect at 17
In C:\Program Files (x86)\MATLAB\R2013a Student1\toolbox\
realtime\realtime\sl_customization.p>myRunCallback at 149
```

You can disregard this warning or add a sink block to the model.

After several minutes, Simulink starts running your model on the board.

- 5 Change parameter values in the model on your host computer.

Observe the corresponding changes in the model running on the hardware.

Any Simulink Sinks blocks in your model receive data from the hardware and display it on your host computer.

---

**Note:** External mode increases the processing burden of the model running on the board, and can cause overruns.

---

## Stop External Mode

To stop the model running in External mode, click the black square Stop button located on the model toolbar, as shown here.

This action stops the process for the model running on the target hardware, and stops the model simulation running on your host computer.

If the **Simulation stop time** parameter is set to a specific number of seconds, External mode stops when that time elapses.

When you are finished using External mode, set **Simulation mode** back to Normal.

## External Mode Control Panel

Using External Mode Control Panel provides additional control of External mode operations, including:

- Connect or disconnect the model on the host computer to/from the model running on the target hardware.
- Start and stop the model running on the target hardware.
- Gather changes to parameter values in a batch before applying them concurrently to the model running on the target hardware.

To open the External Mode Control Panel dialog box, in the model window, select **Code > External Mode Control Panel**.

The **Connect/Disconnect** button connects or disconnects the model on your host computer to/from the model running on the target hardware. If the model is not running on the target hardware, clicking **Connect** automatically deploys and runs the model on the target hardware.

- The **Start Real-Time Code/Stop Real-Time Code** button starts or stops the model running on the target hardware.
- **Batch download** enables you to gather changes before using the **Download** button to simultaneously apply those changes to the model running on the hardware:
  - While **Batch download** is disabled, clicking **OK** or **Apply** in a block dialog box sends updated block parameter values from the block to the model running on the target hardware.
  - When you enable **Batch download**, clicking **OK** or **Apply** in a block dialog box stores updated block parameter values on the host computer. You can complete a set of changes before clicking **Download** to simultaneously send all of the updated values to the model running on the target hardware. This feature is useful for avoiding error conditions when a model contains blocks whose parameter values must be changed concurrently.

External Mode Control Panel displays **Parameter changes pending...** to the right of the **Download** button until the model running on the target hardware has applied the new parameter values.

## Block Produces Zeros or Does Nothing in Simulation

If you simulate a model on your host computer without running it on your target hardware:

- Input blocks produce zeros.
- Output blocks do nothing.

This is the expected behavior.

For example, in a model, if you select **Simulation > Mode > Normal** and then select **Simulation > Run**, the following happens:

- The sensor block and Digital Input block send zeros to the model.
- The Digital Output block does nothing.

To see the blocks work normally, run your model on target hardware or use External mode.

To run the model on target hardware, select **Tools > Run on Target Hardware > Prepare to Run**. Then, click the Deploy to Hardware button.

To use External mode, select **Simulation > Mode > External**. Then, select **Simulation > Run**.

# Running Simulations in Fast Restart

---

- “Stop Simulation and Exit Fast Restart” on page 66-10
- “Fast Restart Methodology” on page 66-11
- “Factors Affecting Fast Restart” on page 66-14

## How Fast Restart Improves Iterative Simulations

In the classic Simulink workflow, when you simulate a model, Simulink:

- 1 Compiles the model
- 2 Simulates the model
- 3 Terminates the simulation

While developing a model, you typically simulate a model repeatedly as you iterate the design. For example, you might calibrate input values or block parameters for a particular response. Changing these values or parameters does not always require compiling the model before simulating again. However, in the classic workflow, each simulation compiles the model, even if the changes do not alter the model structurally. Each compile slows down the process and increases overall simulation time.

Fast restart allows you to perform iterative simulations without compiling a model or terminating the simulation each time. Using fast restart, you compile a model only once. You can then tune parameters and root inputs and simulate the model again without spending time on compiling. Fast restart associates multiple simulation phases to a single compile phase to make iterative simulations more efficient.

Use fast restart when your workflow does not require structural changes to the model. Also, fast restart is better suited if the workflow involves any of these factors:

- The model requires multiple simulations in which simulation inputs or parameters change in every iteration.
- The compile time of the model is several seconds or longer.

You can use fast restart in normal and accelerator simulation modes. When you use fast restart in accelerator mode, you reduce simulation time and perform only a single compilation.

### Related Examples

- “Tunable Block Parameters” on page 32-18
- “Choosing a Simulation Mode” on page 30-11
- “Factors Affecting Fast Restart” on page 66-14

## Fast Restart Workflow

When you need to simulate a model iteratively to tune parameters, achieve a desired response, or automate testing, use fast restart to avoid compiling again.

- 1 Turn on fast restart using the **Fast restart** button on the Simulink Editor toolbar or from the command line.
- 2 Simulate the model. The first simulation requires the model to compile, initialize and save a `SimState`. Once the simulation is complete, it does not terminate. Instead, the model is initialized again in fast restart.
- 3 Perform any of these actions:
  - Change tunable parameters.
  - Tune root-level inputs.
  - Modify base workspace, model workspace variables and data dictionary entries that are referenced by tunable parameters.
  - Change inputs to From File and From Workspace blocks.

Once you have initialized a model in fast restart, you cannot

- Change the dimension, type, or complexity of a signal or variable.
- Make changes to a nontunable parameter such as sample time.
- Make structural changes such as adding or deleting blocks or connections.

These changes require you to compile the model again. To make changes like these, turn off fast restart, make your changes, and repeat this procedure.

- 4 Simulate the model. The model uses the new values of parameters and inputs that you provided but does not compile again.
- 5 Once you have achieved the desired response, turn off fast restart.

---

**Note:** When you turn off fast restart, Simulink does not store any compile information for the model. The model compiles when you next simulate the model.

---

### Related Examples

## **More About**

- “How Fast Restart Improves Iterative Simulations” on page 66-2
- “Factors Affecting Fast Restart” on page 66-14
- “Save and Restore Simulation State as SimState” on page 22-36

## Get Started with Fast Restart

### In this section...

“Prepare a Model to Use Fast Restart” on page 66-6

“Enable Fast Restart” on page 66-6

### Prepare a Model to Use Fast Restart

Before you simulate a model in fast restart, ensure that the model meets these requirements:

- If you have enabled callbacks in the model, make sure they do not attempt to make structural changes when the model is reinitialized. For example, callbacks such as mask initialization commands get called at the beginning of each simulation. Therefore, avoid using mask initialization code that makes structural changes to the model.
- All blocks in the model must support `SimState`.
- The simulation mode is Normal or Accelerator mode.

---

**Caution** When fast restart is on, you cannot save changes to the model after it compiles. Saving changes requires Simulink to discard information about the compiled state. To save any changes to the model, turn off fast restart first.

---

### Enable Fast Restart

Use one of these methods to enable fast restart:

- Click the **Fast restart** button  on the Simulink Editor toolbar.
- At the MATLAB Command prompt, use `set_param` to enable fast restart. Type 

```
set_param(model, 'FastRestart', 'on')
```

### Related Examples

- “Simulate a Model Using Fast Restart” on page 66-8

### **More About**

- “Fast Restart Methodology” on page 66-11
- “Factors Affecting Fast Restart” on page 66-14

## Simulate a Model Using Fast Restart

After you load your model and turn on fast restart, simulate the model.

- 1 Simulate the model by calling `sim` or clicking the **Play** button  in the Simulink Editor toolstrip. The first simulation in fast restart requires the model to compile and save a `SimState`.

Once the simulation is complete, the status bar shows that the model is initialized in fast restart.

- 2 Adjust tunable parameters in the model, such as the gain value of a Gain block, or tune root-level input values. You can also make changes to base workspace variables. You cannot adjust nontunable parameters such as sample time, because doing so requires the model to compile once more.
- 3 Simulate the model again. This time, the model does not compile. When you click the **Play** button or step forward, Simulink updates blocks that have new values as well as blocks that reference workspace variables.
- 4 When you are satisfied with your results, turn off fast restart by clicking the **Fast restart** button off.
- 5 To keep your changes, save the model.

---

**Note:** After a model is initialized in fast restart, Simulink displays a warning if you attempt to make a structural change to the model. To make such changes, you must turn off fast restart.

---

### Related Examples

## **More About**

- “Stop Simulation and Exit Fast Restart” on page 66-10
- “Fast Restart Methodology” on page 66-11

## Stop Simulation and Exit Fast Restart

### In this section...

“Stop a Simulation” on page 66-10

“Exit Fast Restart” on page 66-10

### Stop a Simulation

When you click **Stop** in the middle of a fast restart simulation:

- Simulation does not terminate.
- The model is in the initialized state.
- You can now change tunable parameters in the model
- You can terminate the simulation and exit fast restart by clicking the **Fast restart** button off.

### Exit Fast Restart

You can exit fast restart only when the model is in the initialized state. After simulating, click the **Fast restart** button off. To do this programmatically, type:

```
set_param(model, 'FastRestart', 'off')
```

- Simulink terminates simulation.
- Simulink discards any compiled information about the model.
- The model must compile again the next time you simulate.

# Fast Restart Methodology

## In this section...

“Simulation Modes” on page 66-11

“Tuning Parameters Between Simulations” on page 66-11

“Model Methods and Callbacks in Fast Restart” on page 66-11

“SimState and Initial State Values” on page 66-13

“Analyze Data Using the Simulation Data Inspector” on page 66-13

“Custom Code in the Initialize Function” on page 66-13

## Simulation Modes

You can use fast restart in Normal and Accelerator simulation modes.

## Tuning Parameters Between Simulations

- When a model is initialized in fast restart, in addition to block values and base workspace variables, you can tune parameters in the **Data Import/Export** and **Solver** panes in the **Simulation > Model Configuration Parameters** dialog box.
- Certain parameters are tunable between simulations only when the model is initialized in fast restart. They include:
  - **Initial Value** parameter of the IC block
  - **Initial Output** parameter of the Merge block
  - **Data** parameter of the From Workspace block
  - **Signal** parameter and signal groups of the Signal Builder block.

## Model Methods and Callbacks in Fast Restart

When fast restart is on, Simulink calls model and block methods and callbacks as follows:

- 1 Call model Start method.
  - a Call mdlStart S-function method.

- 2 Call model `InitFcn` callback.
- 3 Call model `Initialize` method.
  - a Call `mdlInitializeConditions` S-function method.

---

**Note:** Use the `ssIsFirstInitCond` flag to guard code that should run only in the first and subsequent initializations in fast restart.

---

- 4 Call model and block `StartFcn` callbacks.

---

**Note:** Steps 1–4 apply to all simulations in Simulink (with or without fast restart).

---

- 5 For the first simulation in fast restart, capture a simulation snapshot. A simulation snapshot contains simulation state (`SimState`) and information related to logged data and visualization blocks. As part of the snapshot capture, call `mdlGetSimState` S-function method.
- 6 This is a standard execution phase of any simulation, with or without fast restart.
  - Call model `Outputs`.
  - Call model `Update`.
  - Call model `Derivatives`.
  - Repeat these steps in a loop until stop time or a stop is requested.
- 7 After simulation ends, call model and block `StopFcn` callbacks. This is a standard phase of any simulation, with or without fast restart.
- 8 Restore the simulation snapshot taken for fast restart. As part of the restore, call `mdlSetSimState` S-function method.
- 9 Wait in a reinitialized state until one of these actions:
  - To run another simulation in fast restart, return to step 3 but skip step 5.
  - To terminate the simulation, call the model terminate method.
    - a Call `mdlTerminate` S-function method.
    - b Do not call `StopFcn` callbacks again at this point.

For more information on model callbacks, see “Callbacks for Customized Model Behavior” on page 4-68.

## SimState and Initial State Values

You can change initial state values, including `SimState`, in between fast restart simulations.

When a `SimState` object for initial state is used in fast restart, every new simulation resets to the start time of the model and not the snapshot time of each `SimState` object. Thereafter, on the first step forward, Simulink checks to see if a `SimState` has been specified. If yes, Simulink restores it before computing the next step. Thus, the first simulation step effectively fast forwards to the snapshot time of the specified `SimState` object.

## Analyze Data Using the Simulation Data Inspector

Fast restart supports data logging using the Simulation Data Inspector. Every simulation in fast restart creates an SDI object with the name `<modelname> fast restart run <number>`. The value of `number` increments for each simulation.

## Custom Code in the Initialize Function

When you place custom code in the **Configuration Parameters > Simulation Target > Custom Code > Initialize function** pane in the **Model Configuration Parameters** dialog box, this gets called only during the first simulation in fast restart.

## Related Examples

- “Fast Restart Workflow” on page 66-4

## More About

- “Factors Affecting Fast Restart” on page 66-14
- “What Is a SimState?”

## Factors Affecting Fast Restart

There are some limitations to simulating in fast restart.

- Fast restart does not support these modes:
  - Rapid Accelerator
  - External
- When a model is in the reinitialized state, you cannot:
  - Make structural changes.
  - Make changes to nontunable parameters such as sample time.
  - Save changes to the model. You must turn off fast restart to save any changes to the model.
- You cannot turn on fast restart in a model if it contains blocks that do not support `SimState`. These blocks include:
  - `SimEvents` blocks
  - `SimMechanics First Generation` blocks
  - MATLAB function blocks that contain system objects
  - S-functions that do not implement `SimState` `get` and `set` methods but have `Pwork` vectors declared
  - From Multimedia File
  - To Multimedia File
  - From Audio Device
  - To Audio Device
  - Multipath Rician Fading Channel
  - Multipath Rayleigh Fading Channel
  - Derepeat
  - DC Blocker
  - Stack
  - Queue
  - Read Binary File
  - Write Binary File

- Video Viewer
- Frame Rate Display
- Video From Workspace
- Video To Workspace
- Between simulations, fast restart does not handle changes to design data, such as bus properties.
- When you use fast restart for model references in Accelerator mode, you cannot tune block parameters.
- The Fixed-Point Tool provides limited support when a model is simulated in fast restart. You must exit fast restart to collect simulation and derived ranges, and propose data types.
- When fast restart is on, you cannot change the variant that a variant subsystem or variant model uses. This is because the inactive subsystems are not compiled in the first simulation.
- When there are multiple model references to the same submodel, you cannot change the model visibility when the model is in the reinitialized state.
- Fast restart does not support signal logging in the `ModelDataLogs` format.
- Fast restart is not compatible with these tools:
  - Simulink Profiler
  - Simulink Debugger
- When simulating a model in fast restart, you cannot run checks using Model Advisor.
- When you enable fast restart, the `sim` command supports only the single output `Simulink.SimulationOutput` form, regardless of the syntax you use in the command.
- When you enable fast restart, you cannot pass non-tunable parameters as arguments to `sim`.

## Related Examples

- “Fast Restart Workflow” on page 66-4

## More About

- “How Fast Restart Improves Iterative Simulations” on page 66-2
