Fit Linear Regression Using Data in Table

Load the sample data.

```
load carsmall
```

Store the variables in a table.

```
tbl = table(Weight,Acceleration,MPG,'VariableNames',{'Weight','Acceleration','MPG'});
```

Display the first five rows of the table.

```
tbl(1:5,:)
```

```
ans =
```

Weight	Acceleration	MPG
3504	12	18
3693	11.5	15
3436	11	18
3433	12	16
3449	10.5	17

Fit a linear regression model for miles per gallon (MPG).

```
lm = fitlm(tbl,'MPG-Weight+Acceleration')
```

```
lm =
```

Linear regression model:

MPG ~ 1 + Weight + Acceleration

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	45.155	3.4659	13.028	1.6266e-22

Weight	-0.0082475	0.00059836	-13.783	5.3165e-24
Acceleration	0.19694	0.14743	1.3359	0.18493

Number of observations: 94, Error degrees of freedom: 91
 Root Mean Squared Error: 4.12
 R-squared: 0.743, Adjusted R-Squared 0.738
 F-statistic vs. constant model: 132, p-value = 1.38e-27

This syntax uses Wilkinson notation to specify the `modelspec`.

The model 'MPG~Weight+Acceleration' in this example is equivalent to fitting the model using the string 'linear' as `modelspec`. For example,

```
lm2 = fitlm(tbl, 'linear');
```

When you use a string as `modelspec` and do not specify the response variable, `fitlm` by default accepts the last variable in `tbl` as the response variable and the other variables as the predictor variables. If there are any categorical variables and you use 'linear' as the `modelspec`, then you must explicitly specify those variables as categorical variables using the `CategoricalVars` name-value pair argument.

Fit Linear Regression Using Specified Model Formula

Fit a linear regression model using a model formula specified by Wilkinson notation.

Load the sample data.

```
load carsmall
```

Store the variables in a table.

```
tbl = table(Weight, Acceleration, Model_Year, MPG, 'VariableNames', {'Weight', 'Acceleration
```

Fit a linear regression model for miles per gallon (MPG) with weight and acceleration as the predictor variables.

```
lm = fitlm(tbl, 'MPG~Weight+Acceleration')
```

```
lm =
```

```
Linear regression model:  
MPG ~ 1 + Weight + Acceleration
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	45.155	3.4659	13.028	1.6266e-22
Weight	-0.0082475	0.00059836	-13.783	5.3165e-24
Acceleration	0.19694	0.14743	1.3359	0.18493

Number of observations: 94, Error degrees of freedom: 91

Root Mean Squared Error: 4.12

R-squared: 0.743, Adjusted R-Squared 0.738

F-statistic vs. constant model: 132, p-value = 1.38e-27

The *P*-value of 0.18493 indicates that **Acceleration** does not have a significant impact on MPG.

Remove **Acceleration** from the model, and try improving the model by adding the predictor variable **Model_Year**. First define **Model_Year** as a nominal variable.

```
tbl.Model_Year = categorical(tbl.Model_Year);
lm = fitlm(tbl, 'MPG~Weight+Model_Year')
```

```
lm =
```

Linear regression model:

```
MPG ~ 1 + Weight + Model_Year
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	40.11	1.5418	26.016	1.2024e-43
Weight	-0.0066475	0.00042802	-15.531	3.3639e-27
Model_Year_76	1.9291	0.74761	2.5804	0.011488
Model_Year_82	7.9093	0.84975	9.3078	7.8681e-15

Number of observations: 94, Error degrees of freedom: 90

Root Mean Squared Error: 2.92

R-squared: 0.873, Adjusted R-Squared 0.868

F-statistic vs. constant model: 206, p-value = 3.83e-40

Specifying `modelspec` using Wilkinson notation enables you to update the model without having to change the design matrix. `fitlm` uses only the variables that are specified in the formula. It also creates the necessary two dummy indicator variables for the categorical variable `Model_Year`.

Linear Regression with Categorical Predictor

Fit a model of a table that contains a categorical predictor.

Load the `carsmall` data.

```
load carsmall
```

Construct a table containing continuous predictor variable `Weight`, nominal predictor variable `Year`, and response variable `MPG`.

```
tbl = table(MPG,Weight);
tbl.Year = nominal(Model_Year);
```

Create a fitted model of `MPG` as a function of `Year`, `Weight`, and `Weight^2`. (You don't have to include `Weight` explicitly in your formula because it is a lower-order term of `Weight^2`) and is included automatically.

```
mdl = fitlm(tbl,'MPG ~ Year + Weight^2')
```

```
mdl =
```

Linear regression model:

```
MPG ~ 1 + Weight + Year + Weight^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.78

R-squared: 0.885, Adjusted R-Squared 0.88
 F-statistic vs. constant model: 172, p-value = 5.52e-41

`fitlm` creates two dummy (indicator) variables for the nominal variate, `Year`. The dummy variable `Year_76` takes the value 1 if model year is 1976 and takes the value 0 if it is not. The dummy variable `Year_82` takes the value 1 if model year is 1982 and takes the value 0 if it is not. And the year 1970 is the reference year. The corresponding model is

$$\hat{MPG} = 54.206 - 0.0164(\textit{Weight}) + 2.0887(\textit{Year_76}) + 8.1864(\textit{Year_82}) + 1.557e - 06(\textit{Weight}^2)$$

Specify Response and Predictor Variables for Linear Model

Fit a linear regression model to sample data. Specify the response and predictor variables, and include only pairwise interaction terms in the model.

Load sample data.

```
load hospital
```

Fit a linear model with interaction terms to the data. Specify `weight` as the response variable, and `sex`, `age`, and `smoking status` as the predictor variables. Also, specify that `sex` and `smoking status` are categorical variables.

```
mdl = fitlm(hospital, 'interactions', 'ResponseVar', 'Weight', ...
            'PredictorVars', {'Sex', 'Age', 'Smoker'}, ...
            'CategoricalVar', {'Sex', 'Smoker'})
```

```
mdl =
```

Linear regression model:

```
Weight ~ 1 + Sex*Age + Sex*Smoker + Age*Smoker
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	118.7	7.0718	16.785	6.821e-30
Sex_Male	68.336	9.7153	7.0339	3.3386e-10
Age	0.31068	0.18531	1.6765	0.096991
Smoker_1	3.0425	10.446	0.29127	0.77149
Sex_Male:Age	-0.49094	0.24764	-1.9825	0.050377
Sex_Male:Smoker_1	0.9509	3.8031	0.25003	0.80312

```
Age:Smoker_1      -0.07288    0.26275    -0.27737    0.78211
```

Number of observations: 100, Error degrees of freedom: 93

Root Mean Squared Error: 8.75

R-squared: 0.898, Adjusted R-Squared 0.892

F-statistic vs. constant model: 137, p-value = 6.91e-44

The weight of the patients do not seem to differ significantly according to age, or the status of smoking, or interaction of these factors with patient sex at the 5% significance level.

Fit a Robust Linear Regression Model

Fit a linear regression model using a robust fitting method.

Load the sample data.

```
load hald
```

The `hald` data measures the effect of cement composition on its hardening heat. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The array `heat` contains the heat of hardening after 180 days for each cement sample.

Fit a robust linear model to the data.

```
mdl = fitlm(ingredients,heat,'linear','RobustOpts','on')
```

```
mdl =
```

Linear regression model (robust fit):

```
y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.65
R-squared: 0.979, Adjusted R-Squared 0.969
F-statistic vs. constant model: 94.6, p-value = 9.03e-07

- “Examine Quality and Adjust the Fitted Model” on page 10-20

- “Regression with Categorical Covariates” on page 2-62

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-56). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: single | double | logical

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double`

modelspec — Model specification

'linear' (default) | string naming the model | t -by- $(p + 1)$ terms matrix | string of the form 'Y ~ terms'

Model specification, specified as one of the following.

- A string naming the model.

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- t -by- $(p + 1)$ matrix, namely terms matrix, specifying terms to include in the model, where t is the number of terms and p is the number of predictor variables, and plus 1 is for the response variable.
- A string representing a formula in the form 'Y ~ terms',

where the **terms** are in Wilkinson Notation.

Example: `'quadratic'`

Example: `'y ~ X1 + X2^2 + X1:X2'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example: `'Intercept', false, 'PredictorVars', [1,3], 'ResponseVar', 5, 'RobustOpts', 'logistic'` specifies a robust regression model with no constant term, where the algorithm uses the logistic weighting function with the default tuning constant, first and third variables are the predictor variables, and fifth variable is the response variable.

'CategoricalVars' — Categorical variables

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of 'CategoricalVars' and either a cell array of strings of the names of the categorical variables in the table or dataset array **tbl**, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array **tbl**, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix **X**, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars', [2,3]`

Example: `'CategoricalVars', logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

'Exclude' — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

```
Example: 'Exclude', [2,3]
```

```
Example: 'Exclude', logical([0 1 1 0 0 0])
```

Data Types: `single` | `double` | `logical`

'Intercept' — Indicator for constant term

`true` (default) | `false`

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of `'Intercept'` and either `true` to include or `false` to remove the constant term from the model.

Use `'Intercept'` only when specifying the model using a string, not a formula or matrix.

```
Example: 'Intercept', false
```

'PredictorVars' — Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of `'PredictorVars'` and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the `'VarNames'` name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

```
Example: 'PredictorVars', [2,3]
```

```
Example: 'PredictorVars', logical([0 1 1 0 0 0])
```

Data Types: `single` | `double` | `logical` | `cell`

'ResponseVar' — Response variable

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar', 'yield'`

Example: `'ResponseVar', [4]`

Example: `'ResponseVar', logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char`

'RobustOpts' — Indicator of robust fitting type

'off' (default) | 'on' | string | structure with string or function handle

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of `'RobustOpts'` and one of the following.

- `'off'` — No robust fitting. `fitlm` uses ordinary least squares.
- `'on'` — Robust fitting. When you use robust fitting, `'bisquare'` weight function is the default.
- String — Name of the robust fitting weight function from the following table. `fitlm` uses the corresponding default tuning constant in the table.
- Structure with the string `RobustWgtFun` containing the name of the robust fitting weight function from the following table and optional scalar `Tune` fields — `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. You can choose the name of the robust fitting weight function from this table. If you do not supply a `Tune` field, the fitting function uses the corresponding default tuning constant.

Weight Function	Equation	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339

Weight Function	Equation	Default Tuning Constant
'bisquare' (default)	$w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$	4.685
'cauchy'	$w = 1 ./ (1 + r.^2)$	2.385
'fair'	$w = 1 ./ (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 ./ \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) ./ r$	1.205
'ols'	Ordinary least squares (no weighting function)	None
'talwar'	$w = 1 * (\text{abs}(r) < 1)$	2.795
'welsch'	$w = \exp(-(r.^2))$	2.985

The value r in the weight functions is

$$r = \text{resid}/(\text{tune} * s * \sqrt{1-h}),$$

where `resid` is the vector of residuals from the previous iteration, `h` is the vector of leverage values from a least-squares fit, and `s` is an estimate of the standard deviation of the error term given by

$$s = \text{MAD}/0.6745.$$

MAD is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If there are p columns in X , the smallest p absolute deviations are excluded when computing the median.

Default tuning constants give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

- Structure with the function handle `RobustWgtFun` and optional scalar `Tune` fields — You can specify a custom weight function. `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. Specify `RobustWgtFun` as a function handle that accepts a vector of residuals, and returns a vector of weights the

same size. The fitting function scales the residuals, dividing by the tuning constant (default 1) and by an estimate of the error standard deviation before it calls the weight function.

Example: `'RobustOpts', 'andrews'`

'VarNames' — Names of variables in fit

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of X first, and the name for the response variable y last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}`

Data Types: `cell`

'Weights' — Observation weights

`ones(n, 1)` (default) | n -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an n -by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: `single` | `double`

Output Arguments

mdl — Linear model

`LinearModel` object

Linear model representing a least-squares fit of the response to the data, returned as a `LinearModel` object.

If the value of the `'RobustOpts'` name-value pair is not `[]` or `'ols'`, the model is not a least-squares fit, but uses the robust fitting function.

For properties and methods of the linear model object, `mdl`, see the `LinearModel` class page.

More About

Terms Matrix

A terms matrix is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and plus one is for the response variable.

The value of $T(i, j)$ is the exponent of variable j in term i . Suppose there are three predictor variables A , B , and C :

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model `'BloodPressure ~ 1 + Sex + Age + Smoker'` in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
0    0    0    0
1    0    0    0
0    0    1    0
```

```
0 0 0 1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...  
hospital.Smoker,'VarNames',{ 'BloodPressure', 'Sex', 'Age', 'Smoker' });
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
0 0 0 0  
0 1 0 0  
0 0 1 0  
0 0 0 1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall  
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```
0 0 0  
1 0 0  
0 1 0  
1 1 0  
0 2 0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

```
Linear regression model:
```

```
y ~ 1 + x1*x2 + x2^2
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

```
Number of observations: 94, Error degrees of freedom: 89
```

```
Root Mean Squared Error: 4.1
```

```
R-squared: 0.751, Adjusted R-Squared 0.739
```

```
F-statistic vs. constant model: 67, p-value = 4.99e-26
```

Only the intercept and x2 term, which correspond to the **Weight** variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
```

```
mdl = stepwiselm(X,MPG,[0 0 0], 'upper',T)
```

```
1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28
```

```
mdl =
```

```
Linear regression model:
```

```
y ~ 1 + x2
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

```
Number of observations: 94, Error degrees of freedom: 92
```

```
Root Mean Squared Error: 4.13
```

```
R-squared: 0.738, Adjusted R-Squared 0.735
```

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

Formula

A formula for model specification is a string of the form ' $Y \sim terms$ '

where

- Y is the response name.
- $terms$ contains
 - Variable names
 - $+$ means include the next variable
 - $-$ means do not include the next variable
 - $:$ defines an interaction, a product of terms
 - $*$ defines an interaction **and all lower-order terms**
 - $^$ raises the predictor to a power, exactly as in $*$ repeated, so $^$ includes lower order terms as well
 - $()$ groups terms

Note: Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include -1 in the formula.

For example,

' $Y \sim A + B + C$ ' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.

' $Y \sim A + B + C + B^2$ ' is a three-variable model with intercept and a B^2 term.

' $Y \sim A + B^2 + C$ ' is the same as the previous example because B^2 includes a B term.

' $Y \sim A + B + C + A:B$ ' includes an $A*B$ term.

' $Y \sim A*B + C$ ' is the same as the previous example because $A*B = A + B + A:B$.

' $Y \sim A*B*C - A:B:C$ ' has all interactions among A , B , and C , except the three-way interaction.

' $Y \sim A*(B + C + D)$ ' has all linear terms, plus products of A with each of the other variables.

Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

Introduced in R2013b

fitlme

Fit linear mixed-effects model

Syntax

```
lme = fitlme(tbl,formula)
lme = fitlme(tbl,formula,Name,Value)
```

Description

`lme = fitlme(tbl,formula)` returns a linear mixed-effects model, specified by `formula`, fitted to the variables in the table or dataset array `tbl`.

`lme = fitlme(tbl,formula,Name,Value)` returns a linear mixed-effects model with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.

Examples

Fit Linear Mixed-Effects Model

Load the sample data.

```
load imports-85
```

Store the variables in a table.

```
tbl = table(X(:,12),X(:,14),X(:,24), 'VariableNames', {'Horsepower', 'CityMPG', 'EngineType
```

Display the first five rows of the table.

```
tbl(1:5,:)
```

```
ans =
```

Horsepower	CityMPG	EngineType
111	21	13
111	21	13
154	19	37
102	24	35
115	18	35

Fit a linear mixed-effects model for miles per gallon in the city, with fixed effects for horsepower, and uncorrelated random effect for intercept and horsepower grouped by the engine type.

```
lme = fitlme(tbl, 'CityMPG~Horsepower+(1|EngineType)+(Horsepower-1|EngineType)');
```

In this model, CityMPG is the response variable, horsepower is the predictor variable, and engine type is the grouping variable. The fixed-effects portion of the model corresponds to $1 + \text{Horsepower}$, because the intercept is included by default.

Since the random-effect terms for intercept and horsepower are uncorrelated, these terms are specified separately. Because the second random-effect term is only for horsepower, you must include a -1 to eliminate the intercept from the second random-effect term.

Display the model.

```
lme
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

```
Number of observations      203
Fixed effects coefficients    2
Random effects coefficients  14
Covariance parameters        3
```

```
Formula:
```

```
CityMPG ~ 1 + Horsepower + (1 | EngineType) + (Horsepower | EngineType)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
1099.5	1116	-544.73	1089.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	37.276	2.8556	13.054	201	1.3147e-28
'Horsepower'	-0.12631	0.02284	-5.53	201	9.8848e-08

Lower	Upper
31.645	42.906
-0.17134	-0.081269

Random effects covariance parameters (95% CIs):

Group: EngineType (7 Levels)

Name1	Name2	Type	Estimate	Lower
'(Intercept)'	'(Intercept)'	'std'	5.7338	2.3773

Upper
13.829

Group: EngineType (7 Levels)

Name1	Name2	Type	Estimate	Lower
'Horsepower'	'Horsepower'	'std'	0.050357	0.02307

Upper
0.10992

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.226	2.9078	3.5789

Note that the random-effects covariance parameters for intercept and horsepower are separate in the display.

Now, fit a linear mixed-effects model for miles per gallon in the city, with the same fixed-effects term and potentially correlated random effect for intercept and horsepower grouped by the engine type.

```
lme2 = fitlme(tbl, 'CityMPG~Horsepower+(Horsepower|EngineType)');
```

Because the random-effect term includes the intercept by default, you do not have to add 1, the random effect term is equivalent to (1 + Horsepower | EngineType).

Display the model.

```
lme2
```

```
lme2 =
```

  'Res Std'     3.1845     2.8774   3.5243
```

Note that the random effects covariance parameters for intercept and horsepower are together in the display, and it includes the correlation ('corr') between the intercept and horsepower.

Fit Random Intercept LME Model

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the new response variable `FluRate`, the nominal variable `Region` that shows which region each estimate is from, the nationwide estimate `WtdILI`, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
            'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Display the first six rows of `flu2`.

```
flu2(1:6,:)
```

```
ans =
```

```
    Date    WtdILI    Region    FluRate
10/9/2005    1.182    NE         0.97
10/9/2005    1.182  MidAtl     1.025
10/9/2005    1.182  ENCentral  1.232
```

10/9/2005	1.182	WNCentral	1.286
10/9/2005	1.182	SAt1	1.082
10/9/2005	1.182	ESCentral	1.457

Fit a linear mixed-effects model with a fixed-effects term for the nationwide estimate, `WtdILI`, and a random intercept that varies by `Date`. The model corresponds to

$$y_{im} = \beta_0 + \beta_1 WtdILI_{im} + b_{0m} + \epsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`. b_{0m} is the random effect for level m of the grouping variable `Date` and ϵ_{im} is the observation error for observation i . The random effect has the prior distribution, $b \sim N(0, \sigma_b^2)$ and the error term has the distribution, $\epsilon \sim N(0, \sigma^2)$.

```
lme = fitlme(flu2, 'FluRate ~ 1 + WtdILI + (1|Date)')
```

```
lme =
```

```
Linear mixed-effects model fit by ML

```

```

0.050813    0.27689
0.66028    0.78691

```

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower
'(Intercept)'	'(Intercept)'	'std'	0.17146	0.13227

```

Upper
0.22226

```

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

Estimated covariance parameters are displayed in the section titled "Random effects covariance parameters". The estimated value of σ_b is 0.17146 and its 95% confidence interval is [0.13227, 0.22226]. Since this interval does not include 0, the random-effects term is significant. You can formally test the significance of any random-effects term using a likelihood ratio test via the `compare` (`LinearMixedModel`) method.

The estimated response at an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

$$\begin{aligned}
 \hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005} \\
 &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\
 &= 1.46749,
 \end{aligned}$$

where \hat{b} is the estimated best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```

beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level1);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')

y_hat =

    1.4674

```

You can display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(28)
```

```
ans =
```

```
1.4674
```

LME Model for Randomized Block Design

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'shift.mat'))
```

The data shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift. Use the restricted maximum likelihood method and `'effects'` contrasts.

`'effects'` contrasts mean that the coefficients sum to 0, and `fitlme` creates a matrix called a *fixed effects design matrix*; to describe the effect of shift. This matrix has two columns, *Shift_Evening* and *Shift_Morning*, where

$$\textit{Shift_Evening} = \begin{cases} 0, & \textit{if Morning} \\ 1, & \textit{if Evening} \\ -1, & \textit{if Night} \end{cases}$$

and

$$\textit{Shift_Morning} = \begin{cases} 1, & \textit{if Morning} \\ 0, & \textit{if Evening} \\ -1, & \textit{if Night} \end{cases} .$$

The model corresponds to

$$\begin{aligned} \text{MorningShift : } QCDev_{im} &= \beta_0 + \beta_2 \text{Shift_Morning}_i + b_{0m} + \varepsilon_{im}, & m = 1, 2, \dots, 5, \\ \text{EveningShift : } QCDev_{im} &= \beta_0 + \beta_1 \text{Shift_Evening}_i + b_{0m} + \varepsilon_{im}, \\ \text{NightShift : } QCDev_{im} &= \beta_0 - \beta_1 \text{Shift_Evening}_i - \beta_2 \text{Shift_Morning}_i + b_{0m} + \varepsilon_{im}, \end{aligned}$$

where $b \sim N(0, \sigma_b^2)$ and $\epsilon \sim N(0, \sigma^2)$.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)', ...
'FitMethod', 'REML', 'DummyVarCoding', 'effects')
```

```
lme =
```

```
Linear mixed-effects model fit by REML
```

  'Res Std'     0.85462    0.52357  1.395

```

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

```
B = randomEffects(lme)
```

```
B =
```

```

  0.5775
  1.1757
 -2.1715
  2.3655
 -1.9472

```

The estimated absolute deviation from the target quality characteristics for the third operator working the evening shift is

$$\begin{aligned}
 \hat{y}_{Evening, Operator3} &= \hat{\beta}_0 + \hat{\beta}_1 Shift_Evening + \hat{b}_{03} \\
 &= 3.6525 - 0.53293 - 2.1715 \\
 &= 0.94807.
 \end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')
```

```
ans =
```

```
0.9481
```

Similarly, you can calculate the estimated absolute deviation from the target quality characteristics for the third operator working the morning shift as

$$\begin{aligned}\hat{y}_{Morning,Operator3} &= \hat{\beta}_0 + \hat{\beta}_2 Shift_Morning + \hat{b}_{03} \\ &= 3.6525 - 0.91973 - 2.1715 \\ &= 0.56127.\end{aligned}$$

You can also display this value as follows.

```
F(shift.Shift=='Morning' & shift.Operator=='3')
```

```
ans =
```

```
0.5613
```

The operator tends to make a smaller magnitude of error during the morning shift.

LME Model for Split-Plot Experiment

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'))
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;  
ds.Tomato = nominal(ds.Tomato);  
ds.Soil = nominal(ds.Soil);  
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

This model corresponds to

$$y_{imjk} = \beta_0 + \sum_{m=2}^4 \beta_{1m} I[F]_{im} + \sum_{j=2}^5 \beta_{2j} I[T]_{ij} + \sum_{j=2}^5 \sum_{m=2}^4 \beta_{3mj} I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S * T)_{jk} + \varepsilon_{imjk},$$

where $i = 1, 2, \dots, 60$, index m corresponds to the fertilizer types, j corresponds to the tomato types, and $k = 1, 2, 3$ corresponds to the blocks (soil). S_k represents the k th soil type, and $(S * T)_{jk}$ represents the j th tomato type nested in the k th soil type. $I[F]_{im}$ is the dummy variable representing level m of the fertilizer. Similarly, $I[T]_{ij}$ is the dummy variable representing level j of the tomato type.

The random effects and observation error have these prior distributions: $b_{0k} \sim N(0, \sigma_S^2)$, $b_{0jk} \sim N(0, \sigma_{S*T}^2)$, and $\varepsilon_{imjk} \sim N(0, \sigma^2)$.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)')
```

```
lme =
```

```
Linear mixed-effects model fit by ML

```

The P -values corresponding to the last 12 rows in the fixed-effects coefficients display (0.82701 to 0.47881) indicate that interaction coefficients between the tomato and fertilizer types are not significant. To test for the overall interaction between tomato and fertilizer, use the `anova (LinearMixedModel)` method after refitting the model using `'effects'` contrasts.

The confidence interval for the standard deviations of the random-effects terms (σ_s^2), where the intercept is grouped by soil, is very large. This term does not appear significant.

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term `(1 | Soil)`.

```
lme = fitlme(ds, 'Yield ~ Fertilizer + Tomato + (1|Soil:Tomato)')
```

```
lme =

You can compare the two models using the `compare` (`LinearMixedModel`) method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term are tested.

Longitudinal Study with a Covariate

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'))
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight, Program, Subject, Week, y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`fitlme` uses program A as a reference and creates the necessary dummy variables $I[.]$. Since the model already has an intercept, `fitlme` only creates dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables. This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) \\ + b_{0m} + b_{1m} Week_{im} + \epsilon_{im},$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[.]$ is a dummy variable representing a type of program. For example, $I[PB]_i$ is the dummy variable representing program B. The random effects and observation error have these prior distributions: $b_{0m} \sim N(0, \sigma_0^2)$, $b_{1m} \sim N(0, \sigma_1^2)$, and $\epsilon_{im} \sim N(0, \sigma^2)$.

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)')
```

```
lme =
```

0.88573
0.20537

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.10261	0.087882	0.11981

The *P*-values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include 0, thus they are significant. You can also test the significance of the random effects using the `compare` method.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-56). You must specify the model for the variables using `formula`.

Data Types: single | double | char | cell

formula — Formula for model specification

string of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'

Formula for model specification, specified as a string of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'. The string is case sensitive. For a full description, see “Formula” on page 25-1990.

Example: `'y ~ treatment + (1|block)'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example:

`'CovariancePattern', 'Diagonal', 'Optimizer', 'fminunc', 'OptimizerOptions', opt` specifies a model, where the random-effects terms have a diagonal covariance matrix structure, and `fitlme` uses the `fminunc` optimization algorithm with the custom optimization parameters defined in variable `opt`.

'CovariancePattern' — Pattern of covariance matrix

`'FullCholesky'` (default) | string | square symmetric logical matrix | cell array of strings or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of `'CovariancePattern'` and a string, a square symmetric logical matrix, or a cell array of strings or logical matrices.

If there are R random-effects terms, then the value of `'CovariancePattern'` must be a cell array of length R , where each element r of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

`'FullCholesky'`

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

`'Full'`

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

`'Diagonal'`

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

`'CompSymm'`

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where σ_{b1}^2 is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .

`PAT`

Square symmetric logical matrix. If `'CovariancePattern'` is defined by the matrix `PAT`, and if `PAT(a, b) = false`, then the `(a, b)` element of the corresponding covariance matrix is constrained to be 0.

Example: `'CovariancePattern', 'Diagonal'`

Example: `'CovariancePattern', {'Full', 'Diagonal'}`

'FitMethod' — Method for estimating parameters

`'ML'` (default) | `'REML'`

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of `'FitMethod'` and either of the following.

`'ML'`

Default. Maximum likelihood estimation

`'REML'`

Restricted maximum likelihood estimation

Example: `'FitMethod', 'REML'`

'Weights' — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length n , where n is the number of observations.

Data Types: `single` | `double`**'Exclude' — Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: `'Exclude', [13,67]`Data Types: `single` | `double` | `logical`**'DummyVarCoding' — Coding to use for dummy variables**`'reference'` (default) | `'effects'` | `'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the following.

Value	Description
<code>'reference'</code>	Default. Coefficient for first category set to 0.
<code>'effects'</code>	Coefficients sum to 0.
<code>'full'</code>	One dummy variable for each category.

Example: `'DummyVarCoding', 'effects'`**'Optimizer' — Optimization algorithm**`'quasnewton'` (default) | `'fminunc'`

Optimization algorithm, specified as the comma-separated pair consisting of `'Optimizer'` and either of the following.

<code>'quasinevton'</code>	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
<code>'fminunc'</code>	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> with <code>'Algorithm'</code> set to <code>'quasi-newton'</code> .

Example: `'Optimizer', 'fminunc'`

'OptimizerOptions' — Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of `'OptimizerOptions'` and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If `'Optimizer'` is `'fminunc'`, then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options `'fminunc'` uses. If `'Optimizer'` is `'fminunc'` and you do not supply `'OptimizerOptions'`, then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with `'Algorithm'` set to `'quasi-newton'`.
- If `'Optimizer'` is `'quasinevton'`, then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The `'quasinevton'` optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

'ToIFun' — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

'ToIX' — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

'MaxIter' — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

'Display' — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

'StartMethod' — Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

Value	Description
'default'	An internally defined default value
'random'	A random initial value

Example: 'StartMethod', 'random'

'Verbose' — Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: `'Verbose', true`

'CheckHessian' — Indicator to check positive definiteness of Hessian

`false` (default) | `true`

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of `'CheckHessian'` and either `false` or `true`. Default is `false`.

Specify `'CheckHessian'` as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: `'CheckHessian', true`

Output Arguments

lme — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

Alternatives

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G)`.

More About

Formula

In general, a formula for model specification is a string of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, y
- Predictor variables, X_j , which can be continuous or grouping variables
- Grouping variables, g_1, g_2, \dots, g_R ,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, or cell arrays of strings.

Then, in a formula of the form, ' $y \sim \text{fixed} + (\text{random}_1 | g_1) + \dots + (\text{random}_R | g_R)$ ', the term `fixed` corresponds to a specification of the fixed-effects design matrix X , `random1` is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1 , and similarly `randomR` is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R . You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$)
$X1 : X2$	$X1.*X2$ only
$- X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.
'y ~ -1 + X1 + X2'	No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including - 1.
'y ~ 1 + (1 g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'.
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where D is a q -by- q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ , q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D , is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q^*(q+1)/2$ -by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

LinearMixedModel | `fitlmematrix`

Introduced in R2013b

fitlmematrix

Fit linear mixed-effects model

Syntax

```
lme = fitlmematrix(X,y,Z,[])  
lme = fitlmematrix(X,y,Z,G)  
lme = fitlmematrix( ____,Name,Value)
```

Description

`lme = fitlmematrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`.

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where `n` is the number of observations. Using `fitlmematrix(X,Y,Z,[])` without a specified covariance pattern most likely results in a nonidentifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using the 'CovariancePattern' name-value pair argument.

`lme = fitlmematrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = fitlmematrix(____,Name,Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

Examples

No Grouping Variable Specified

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, where miles per gallon (MPG) is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

```
y = MPG;
X = [ones(size(Weight)), Weight];
Z = ones(size(y));
lme = fitlmematrix(X,y,Z,Model_Year)

lme =
```

Linear mixed-effects model fit by ML

Longitudinal Study with a Covariate

Navigate to a folder containing sample data.

```
cd(matlabroot)
```

```
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

$$\begin{aligned}
 y_{im} = & \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\
 & + \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) \\
 & + b_{0m} + b_{1m} Week_{im} + \varepsilon_{im},
 \end{aligned}$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[PB]_i$ is the dummy variable representing program type B. The random effects and observation error have these prior distributions: $b_{0m} \sim N(0, \sigma^2_0)$, $b_{1m} \sim N(0, \sigma^2_1)$, and $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
Subject = nominal(Subject);
Program = nominal(Program);
D = dummyvar(Program); % Create dummy variables for Program
X = [ones(120,1), InitialWeight, D(:,2:4), Week, ...
     D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];
Z = [ones(120,1), Week];
G = Subject;
```

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept', 'InitWeight', 'PrgB', 'PrgC', 'PrgD', 'Week', 'Week_PrgB', 'Week_PrgC', 'Week_PrgD'}
```

```
'RandomEffectPredictors',{{'Intercept','Week'}},'RandomEffectGroups',{'Subject'})
```

```

'Res Std'	0.10261	0.087882	0.11981

The *p*-values 0.0228 and 0.0115 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects who

are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the `compare` method.

Random Intercept Model

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into a tall array that has a single response variable, `FluRate`, and a nominal variable, `Region`, the nationwide estimate `WtdILI`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10, 'NewDataVarName', 'FluRate', ...  
            'IndVarName', 'Region');  
flu2.Date = nominal(flu2.Date);
```

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by `Date`. The corresponding model is

$$y_{im} = \beta_0 + \beta_1 WtdILI_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`. b_{0m} is the random effect for level m of the grouping variable `Date` and ε_{im} is the observation error for observation i . The random effect has the prior distribution, $b_{0m} \sim N(0, \sigma_{FR}^2)$ and the error term has the distribution, $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
y = flu2.FluRate;  
X = [ones(468,1) flu2.WtdILI];  
Z = [ones(468,1)];  
G = flu2.Date;
```

Fit the linear mixed-effects model.

```
lme = fitlmematrix(X,y,Z,G, 'FixedEffectPredictors', {'Intercept', 'NationalRate'}, ...
  'RandomEffectPredictors', {'Intercept'}, 'RandomEffectGroups', {'Date'})
```

```
lme =
```

```
Linear mixed-effects model fit by ML

Random effects coefficients	52
Covariance parameters	2

```
Formula:
```

```
y ~ Intercept + NationalRate + (Intercept | Date)
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
286.24	302.83	-139.12	278.24

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	pValue	Lower	Upper
'Intercept'	0.16385	0.057525	2.8484	466	0.0045885	0.0508	0.2769
'NationalRate'	0.7236	0.032219	22.459	466	3.0502e-76	0.660	0.7872

```
Random effects covariance parameters (95% CIs):
```

```
Group: Date (52 Levels)
```

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	0.17146	0.13227	0.22226

```
Group: Error
```

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

The confidence limits of the standard deviation of the random-effects term $\sigma_{b_{0m}}^2$, do not include zero (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects using `compare` method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILLI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where \hat{b} is the best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % compute the random effects statistics STATS
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')

y_hat =

    1.4674
```

You can simply display the fitted value using the `fitted(lme)` method.

```
F = fitted(lme);
F(28)

ans =

    1.4674
```

Randomized Block Design

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the 'effects' contrasts. 'effects' contrasts mean that the coefficients sum to 0. You need to create two contrast coded variables in the fixed-effects design matrix, X1 and X2, where

$$Shift_Evening = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} \quad \text{and} \quad Shift_Morning = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} .$$

The model corresponds to

$$\text{Morning Shift: } QCDev_{im} = \beta_0 + \beta_2 Shift_Morning_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 5,$$

$$\text{Evening Shift: } QCDev_{im} = \beta_0 + \beta_1 Shift_Evening_i + b_{0m} + \varepsilon_{im},$$

$$\text{Night Shift: } QCDev_{im} = \beta_0 - \beta_1 Shift_Evening_i - \beta_2 Shift_Morning_i + b_{0m} + \varepsilon_{im},$$

where i represents the observations, and m represents the operators, $i = 1, 2, \dots, 15$, and $m = 1, 2, \dots, 5$. The random effects and the observation error have these distributions: $b_{0m} \sim N(0, \sigma^2_{b_{0m}})$ and $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
S = shift.Shift;
X1 = (S=='Morning') - (S=='Night');
X2 = (S=='Evening') - (S=='Night');
X = [ones(15,1), X1, X2];
y = shift.QCDev;
Z = ones(15,1);
G = shift.Operator;
```

Fit a linear mixed-effects model using the specified design matrices and restricted maximum likelihood method.

The estimated deviation from the target quality characteristics for the third operator working the evening shift is

$$\begin{aligned}
 \hat{y}_{Evening, Operator3} &= \hat{\beta}_0 + \hat{\beta}_1 Shift_Evening + \hat{b}_{03} \\
 &= 3.6525 - 0.53293 - 2.1715 \\
 &= 0.94807.
 \end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')

ans =

    0.9481
```

Correlated and Uncorrelated Random-Effects Terms

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and uncorrelated random effect for intercept and acceleration grouped by the model year. This model corresponds to

$$MPG_{im} = \beta_0 + \beta_1 Acc_i + \beta_2 HP + b_{0m} + b_{1m} Acc_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having these distributions: $b_{0m} \sim N(0, \sigma_0^2)$, and $b_{1m} \sim N(0, \sigma_1^2)$. m represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = {ones(406,1), Acceleration};
G = {Model_Year, Model_Year};
Model_Year = nominal(Model_Year);
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X, MPG, Z, G, 'FixedEffectPredictors', ...
{'Intercept', 'Acceleration', 'Horsepower'}, 'RandomEffectPredictors', ...
{{'Intercept'}, {'Acceleration'}}}, 'RandomEffectGroups', {'Model_Year', 'Model_Year'})

lme =

Linear mixed-effects model fit by ML
```

Model information:

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	3

Formula:

```
y ~ Intercept + Acceleration + Horsepower + (Intercept | Model_Year) + (Acceleration
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2194.5	2218.3	-1091.3	2182.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue	Lower	Upper
'Intercept'	49.839	2.0518	24.291	389	5.6168e-80	44.735	54.943
'Acceleration'	-0.58565	0.10846	-5.3995	389	1.1652e-07	-0.80281	-0.36849
'Horsepower'	-0.16534	0.0071227	-23.213	389	1.9755e-75	-0.17961	-0.15107

Random effects covariance parameters (95% CIs):

Group: Model_Year (13 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	8.0669e-07	NaN	NaN

Group: Model_Year (13 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Acceleration'	'Acceleration'	'std'	0.18783	0.12523	0.25043

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.7258	3.4698	4.0007

Note that the random effects covariance parameters for intercept and acceleration are separate in the display. The standard deviation of the random effect for the intercept does not seem significant.

Refit the model with potentially correlated random effects for intercept and acceleration. In this case, the random-effects terms has this prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N \left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right),$$

where m represents the model year.

First, prepare the random-effects design matrix and grouping variable.

```
Z = [ones(406,1) Acceleration];
G = Model_Year;

lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'})

lme =
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	4

Formula:

```
y ~ Intercept + Acceleration + Horsepower + (Intercept + Acceleration | Model_Year)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2193.5	2221.3	-1089.7	2179.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue	Lower	Upper
'Intercept'	50.133	2.2652	22.132	389	7.7727e-71	45.601	54.665
'Acceleration'	-0.58327	0.13394	-4.3545	389	1.7075e-05	-0.8511	-0.3154

Random effects covariance parameters (95% CIs):

Group: Model_Year (13 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	3.3475	1.2862	5.4088
'Acceleration'	'Intercept'	'corr'	-0.87971	-0.98501	-0.77441
'Acceleration'	'Acceleration'	'std'	0.33789	0.1825	0.51328

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.6874	3.4298	3.9644

Note that the random effects covariance parameters for intercept and acceleration are together in the display, with an addition of the correlation between the intercept and acceleration. The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include 0s, hence they seem significant. You can compare these two models using the `compare` method.

Specify the Covariance Pattern

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables.

```
Subject = nominal(Subject);
Program = nominal(Program);
```

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week as the fixed effects.

```
D = dummyvar(Program);
X = [ones(120,1), InitialWeight, D(:,2:4), Week];
Z = [ones(120,1) Week];
G = Subject;
```

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + b_{0m} + b_{1m} Week2_{im} + b_{2m} Week4_{im} + b_{3m} Week6_{im} + b_{4m} Week8_{im} \\ + b_{5m} Week10_{im} + b_{6m} Week12_{im} + \varepsilon_{im},$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$.

β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{1m} and b_{1m} are random effects. IW stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For

example, $I[PB]_i$ is the dummy variable representing program type B. The random effects and observation error have these prior distributions: $b_{0m} \sim N(0, \sigma_0^2)$, $b_{1m} \sim N(0, \sigma_1^2)$, and $\varepsilon_{im} \sim N(0, \sigma^2)$.

Fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```
lme = fitlmematrix(X,y,Z,G, 'FixedEffectPredictors',...
{'Intercept', 'InitWeight', 'PrgB', 'PrgC', 'PrgD', 'Week'},...
'RandomEffectPredictors', {{'Intercept', 'Week'}},...

'Res Std'	0.10272	0.088014	0.11987

Input Arguments

X — Fixed-effects design matrix

n-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of **X** corresponds to one observation, and each column of **X** corresponds to one variable.

Data Types: `single` | `double`

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single` | `double`

Z — Random-effects design

n-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then **Z** must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then **Z** must be a cell array of length *R*. Each cell of **Z** contains an *n*-by-*q*(*r*) design matrix $Z\{\mathbf{r}\}$, *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, $Z\{\mathbf{r}\}$.

Data Types: `single` | `double` | `cell`

G — Grouping variable or variables

n-by-1 vector | cell array of *R* *n*-by-1 vectors

Grouping variable or variables, specified as either of the following.

- If there is one random-effects term, then **G** must be an n -by-1 vector corresponding to a single grouping variable with M levels or groups.

G can be a categorical vector, numeric vector, character array, or cell array of strings.

- If there are multiple random-effects terms, then **G** must be a cell array of length R . Each cell of **G** contains a grouping variable **G**{ r }, $r = 1, 2, \dots, R$, with $M(r)$ levels.

G{ r } can be a categorical vector, numeric vector, character array, or cell array of strings.

Data Types: `single` | `double` | `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

Example:

`'CovariancePattern', 'Diagonal', 'DummyVarCoding', 'full', 'Optimizer', 'fminunc'` specifies a random-effects covariance pattern with zero off-diagonal elements, creates a dummy variable for each level of a categorical variable, and uses the `fminunc` optimization algorithm.

'FixedEffectPredictors' — Names of columns in fixed-effects design matrix

{'x1', 'x2', ..., 'xP'} (default) | cell array of length p

Names of columns in the fixed-effects design matrix **X**, specified as the comma-separated pair consisting of `'FixedEffectPredictors'` and a cell array of length p .

For example, if you have a constant term and two predictors, say `TimeSpent` and `Gender`, where `Female` is the reference level for `Gender`, as the fixed effects, then you can specify the names of your fixed effects in the following way. `Gender_Male` represents the dummy variable you must create for category `Male`. You can choose different names for these variables.

Example: `'FixedEffectPredictors', {'Intercept', 'TimeSpent', 'Gender_Male'}`,

Data Types: `cell`

'RandomEffectPredictors' — Names of columns in random-effects design matrix or cell array

cell array of length q | cell array of length R with elements of length $q(r)$, $r = 1, 2, \dots, R$

Names of columns in the random-effects design matrix or cell array Z , specified as the comma-separated pair consisting of **'RandomEffectPredictors'** and either of the following:

- A cell array of length q when Z is an n -by- q design matrix. In this case, the default is `{'z1', 'z2', ..., 'zQ'}`.
- A cell array of length R , when Z is a cell array of length R with each element $Z\{r\}$ of length $q(r)$, $r = 1, 2, \dots, R$. In this case, the default is `{'z11', 'z12', ..., 'z1Q(1)'} , ..., {'zr1', 'zr2', ..., 'zrQ(r)'}`.

For example, suppose you have correlated random effects for intercept and a variable named `Acceleration`. Then, you can specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors', {'Intercept', 'Acceleration'}`

If you have two random effects terms, one for the intercept and the variable `Acceleration` grouped by variable `g1`, and the second for the intercept, grouped by the variable `g2`, then you specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors', {{'Intercept', 'Acceleration'} , {'Intercept'}}`

Data Types: `cell`

'ResponseVarName' — Name of response variable

`'y'` (default) | `string`

Name of response variable, specified as the comma-separated pair consisting of **'ResponseVarName'** and a string.

For example, if your response variable name is `score`, then you can specify it as follows.

Example: `'ResponseVarName', 'score'`

Data Types: `char`

'RandomEffectGroups' — Names of random effects grouping variables

`'g'` or `{'g1', 'g2', ..., 'gR'}` (default) | `string` | cell array of strings

Names of random effects grouping variables, specified as the comma-separated pair 'RandomEffectGroups' and either of the following:

- String — If there is only one random-effects term, that is, if \mathbf{G} is a vector, then the value of 'RandomEffectGroups' is a string containing the name for the grouping variable \mathbf{G} . The default is 'g'.
- Cell array of strings — If there are multiple random-effects terms, that is, if \mathbf{G} is a cell array of length R , then the value of 'RandomEffectGroups' is a cell array of length R , where each cell contains the name for the grouping variable $\mathbf{G}\{r\}$. The default is {'g1', 'g2', ..., 'gR'}.

For example, if you have two random-effects terms, \mathbf{z}_1 and \mathbf{z}_2 , grouped by the grouping variables `sex` and `subject`, then you can specify the names of your grouping variables as follows.

Example: 'RandomEffectGroups', {'sex', 'subject'}

Data Types: char | cell

'CovariancePattern' — Pattern of covariance matrix

'FullCholesky' (default) | string | square symmetric logical matrix | cell array of strings or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a string, a square symmetric logical matrix, or a cell array of strings or logical matrices.

If there are R random-effects terms, then the value of 'CovariancePattern' must be a cell array of length R , where each element r of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

'FullCholesky'

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

`'CompSymm'`

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where σ_{b1}^2 is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .

`PAT`

Square symmetric logical matrix. If `'CovariancePattern'` is defined by the matrix `PAT`, and if `PAT(a,b) = false`, then the `(a,b)` element of the corresponding covariance matrix is constrained to be 0.

Example: `'CovariancePattern', 'Diagonal'`

Example: `'CovariancePattern', {'Full', 'Diagonal'}`

'FitMethod' — Method for estimating parameters

`'ML'` (default) | `'REML'`

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of `'FitMethod'` and either of the following.

`'ML'`

Default. Maximum likelihood estimation

`'REML'`

Restricted maximum likelihood estimation

Example: `'FitMethod', 'REML'`

'Weights' — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length n , where n is the number of observations.

Data Types: `single` | `double`**'Exclude' — Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: `'Exclude', [13,67]`Data Types: `single` | `double` | `logical`**'DummyVarCoding' — Coding to use for dummy variables**`'reference'` (default) | `'effects'` | `'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the following.

Value	Description
<code>'reference'</code>	Default. Coefficient for first category set to 0.
<code>'effects'</code>	Coefficients sum to 0.
<code>'full'</code>	One dummy variable for each category.

Example: `'DummyVarCoding', 'effects'`**'Optimizer' — Optimization algorithm**`'quasnewton'` (default) | `'fminunc'`

Optimization algorithm, specified as the comma-separated pair consisting of `'Optimizer'` and either of the following.

'quasinevton'	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
'fminunc'	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer', 'fminunc'

'OptimizerOptions' — Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasinevton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasinevton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

'ToIFun' — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

'ToIX' — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

'MaxIter' — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

'Display' — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

'StartMethod' — Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

Value	Description
'default'	An internally defined default value
'random'	A random initial value

Example: 'StartMethod', 'random'

'Verbose' — Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose', true

'CheckHessian' — Indicator to check positive definiteness of Hessian`false (default) | true`

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either `false` or `true`. Default is `false`.

Specify 'CheckHessian' as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian', `true`

Output Arguments

lme — Linear mixed-effects model`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

Alternative Functionality

You can also fit a linear mixed-effects model using `fitlme(tbl, formula)`, where `tbl` is a table or dataset array containing the response `y`, the predictor variables `X`, and the grouping variables, and `formula` is of the form '`y ~ fixed + (random1 | g1) + ... + (randomR | gR)`'.

More About

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where D is a q -by- q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ , q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D , is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q^*(q+1)/2$ -by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

Introduced in R2013b

fitrgp

Fit a Gaussian process regression (GPR) model

Syntax

```
gprMdl = fitrgp(tbl,ResponseVarName)
gprMdl = fitrgp(tbl,formula)
gprMdl = fitrgp(tbl,y)
```

```
gprMdl = fitrgp(X,y)
```

```
gprMdl = fitrgp( ____,Name,Value)
```

Description

`gprMdl = fitrgp(tbl,ResponseVarName)` returns a Gaussian process regression (GPR) model trained using the sample data in `tbl`, where `ResponseVarName` is the name of the response variable in `tbl`.

`gprMdl = fitrgp(tbl,formula)` returns a Gaussian process regression (GPR) model, trained using the sample data in `tbl`, for the predictor variables and response variables identified by `formula`.

`gprMdl = fitrgp(tbl,y)` returns a GPR model for the predictors in table `tbl` and continuous response vector `y`.

`gprMdl = fitrgp(X,y)` returns a GPR model for predictors `X` and continuous response vector `y`.

`gprMdl = fitrgp(____,Name,Value)` returns a GPR model for any of the input arguments in the previous syntaxes, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the fitting method, the prediction method, the covariance function, or the active set selection method. You can also train a cross-validated model.

`gprMdl` is a `RegressionGP` object. For methods and properties of this class, see `RegressionGP` class page.

If you train a cross-validated model, then `gprMdl` is a `RegressionPartitionedModel` object. For further analysis on the cross-validated object, use the methods of `RegressionPartitionedModel` class. For the methods of this class, see the `RegressionPartitionedModel` class page.

Examples

Train GPR Model Using Data in Table

This example uses the abalone data [1], [2], from the UCI Machine Learning Repository [3]. Download the data and save it in your current folder with the name 'abalone.data'.

Store the data into a `table`. Display the first seven rows.

```
tbl = readtable('abalone.data', 'Filetype', 'text', 'ReadVariableNames', false);tbl.Properties
tbl(1:7,:)
```

```
ans =
```

Sex	Length	Diameter	Height	WWeight	SWeight	VWeight	ShWeight
'M'	0.455	0.365	0.095	0.514	0.2245	0.101	0.15
'M'	0.35	0.265	0.09	0.2255	0.0995	0.0485	0.07
'F'	0.53	0.42	0.135	0.677	0.2565	0.1415	0.21
'M'	0.44	0.365	0.125	0.516	0.2155	0.114	0.155
'I'	0.33	0.255	0.08	0.205	0.0895	0.0395	0.055
'I'	0.425	0.3	0.095	0.3515	0.141	0.0775	0.12
'F'	0.53	0.415	0.15	0.7775	0.237	0.1415	0.33

The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, number of shell rings shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.

Fit a GPR model using the `subset of regressors` method for parameter estimation and `fully independent conditional` method for prediction. Standardize the predictors.

```
gprMdl = fitrgp(tbl,'NoShellRings','KernelFunction','ardsquaredexponential',...  
              'FitMethod','sr','PredictMethod','fic','Standardize',1)
```

```
grMdl =
```

  BCDInformation: []
```

Predict the responses using the trained model.

```
ypred = resubPredict(gprMdl);
```

Plot the true response and the predicted responses.

```
figure();  
plot(tbl.NoShellRings,'r.');
```

```
hold on  
plot(ypred,'b');  
xlabel('x');  
ylabel('y');  
legend({'data','predictions'},'Location','Best');  
axis([0 4300 0 30]);  
hold off;
```

Compute the regression loss on the training data (resubstitution loss) for the trained model.

```
L = resubLoss(gprMd1)
```

```
L =
```

```
4.0064
```

Train GPR Model and Plot Predictions

Generate sample data.

```
rng(0,'twister'); % For reproducibility
n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*5e-2 + sin(x)./x + 0.2*randn(n,1);
```

Fit a GPR model using a linear basis function and the exact fitting method to estimate the parameters. Also use the exact prediction method.

```
gprMdl = fitrgp(x,y,'Basis','linear',...  
              'FitMethod','exact','PredictMethod','exact');
```

Predict the response corresponding to the rows of x (resubstitution predictions) using the trained model.

```
ypred = resubPredict(gprMdl);
```

Plot the true response with the predicted values.

```
plot(x,y,'b. ');  
hold on;  
plot(x,ypred,'r','LineWidth',1.5);  
xlabel('x');  
ylabel('y');  
legend('Data','GPR predictions');  
hold off
```

Impact of Specifying Initial Kernel Parameter Values

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'gprdata2.mat'))
```

The data has one predictor variable and continuous response. This is simulated data.

Fit a GPR model using the squared exponential kernel function with default kernel parameters.

```
gprMd11 = fitrgp(x,y, 'KernelFunction', 'squareexponential');
```

Now, fit a second model, where you specify the initial values for the kernel parameters.

```
sigma0 = 0.2;
kparams0 = [3.5, 6.2];
gprMdl2 = fitrgp(x,y,'KernelFunction','squareexponential',...
    'KernelParameters',kparams0,'Sigma',sigma0);
```

Compute the resubstitution predictions from both models.

```
ypred1 = resubPredict(gprMdl1);
ypred2 = resubPredict(gprMdl2);
```

Plot the response predictions from both models and the responses in training data.

```
figure();
plot(x,y,'r. ');
hold on
plot(x,ypred1,'b');
plot(x,ypred2,'g');
xlabel('x');
ylabel('y');
legend({'data','default kernel parameters',...
    'kparams0 = [3.5,6.2], sigma0 = 0.2'},...
    'Location','Best');
title('Impact of initial kernel parameter values');
hold off
```

The marginal log likelihood that `fitrgp` maximizes to estimate GPR parameters has multiple local solutions; the solution that it converges to depends on the initial point. Each local solution corresponds to a particular interpretation of the data. In this example, the solution with the default initial kernel parameters corresponds to a low frequency signal with high noise whereas the second solution with custom initial kernel parameters corresponds to a high frequency signal with low noise.

Use Separate Length Scales for Predictors

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'gprdata.mat'))
```

There are six continuous predictor variables. There are 500 observations in the training data set and 100 observations in the test data set. This is simulated data.

Fit a GPR model using the squared exponential kernel function with a separate length scale for each predictor. This covariance function is defined as:

$$k(x_i, x_j | \theta) = \sigma_f^2 \exp \left[-\frac{1}{2} \sum_{m=1}^d \frac{(x_{im} - x_{jm})^2}{\sigma_m^2} \right].$$

where σ_m represents the length scale for predictor m , $m = 1, 2, \dots, d$ and σ_f is the signal standard deviation. The unconstrained parametrization θ is

$$\begin{aligned} \theta_m &= \log \sigma_m, \quad \text{for } m = 1, 2, \dots, d \\ \theta_{d+1} &= \log \sigma_f. \end{aligned}$$

Initialize length scales of the kernel function at 10 and signal and noise standard deviations at the standard deviation of the response.

```
sigma0 = std(ytrain);
sigmaF0 = sigma0;
d = size(Xtrain,2);
sigmaM0 = 10*ones(d,1);
```

Fit the GPR model using the initial kernel parameter values. Standardize the predictors in the training data. Use the exact fitting and prediction methods.

```
gprMdl = fitrgp(Xtrain,ytrain,'Basis','constant','FitMethod','exact',...
'PredictMethod','exact','KernelFunction','ardsquaredexponential',...
'KernelParameters',[sigmaM0;sigmaF0],'Sigma',sigma0,'Standardize',1);
```

Compute the regression loss on the test data.

```
L = loss(gprMdl,Xtest,ytest)
```

```
L =
```

```
0.6919
```

Access the kernel information.

```
gprMdl.KernelInformation
```

```
ans =
```

```
                Name: 'ARDSquaredExponential'  
    KernelParameters: [7x1 double]  
    KernelParameterNames: {7x1 cell}
```

Display the kernel parameter names.

```
gprMdl.KernelInformation.KernelParameterNames
```

```
ans =
```

```
'LengthScale1'  
'LengthScale2'  
'LengthScale3'  
'LengthScale4'  
'LengthScale5'  
'LengthScale6'  
'SigmaF'
```

Display the kernel parameters.

```
sigmaM = gprMdl.KernelInformation.KernelParameters(1:end-1,1)  
sigmaF = gprMdl.KernelInformation.KernelParameters(end)  
sigma = gprMdl.Sigma
```

```
sigmaM =
```

```
1.0e+04 *  
  
0.0004  
0.0007  
0.0004  
4.1732  
0.1018  
0.0056
```

```
sigmaF =
```

```
28.1718
```

```
sigma =
```

```
0.8162
```

Plot the log of learned length scales.

```
figure()  
plot((1:d)',log(sigmaM),'ro-');  
xlabel('Length scale number');  
ylabel('Log of length scale');
```

The log of length scale for the 4th and 5th predictor variables are high relative to the others. These predictor variables do not seem to be as influential on the response as the other predictor variables.

Fit the GPR model without using the 4th and 5th variables as the predictor variables.

```
X = [Xtrain(:,1:3) Xtrain(:,6)];
sigma0 = std(ytrain);
sigmaF0 = sigma0;
d = size(X,2);
sigmaM0 = 10*ones(d,1);

gprMdl = fitrgp(X,ytrain,'Basis','constant','FitMethod','exact',...
'PredictMethod','exact','KernelFunction','ardsquaredexponential',...
'KernelParameters',[sigmaM0;sigmaF0],'Sigma',sigma0,'Standardize',1);
```

Compute the regression error on the test data.

```
xtest = [Xtest(:,1:3) Xtest(:,6)];
L = loss(gprMdl,xtest,ytest)
```

```
L =
    0.6928
```

The loss is similar to the one when all variables are used as predictor variables.

Compute the predicted response for the test data.

```
ypred = predict(gprMdl,xtest);
```

Plot the original response along with the fitted values.

```
figure;
plot(ytest,'r');
hold on;
plot(ypred,'b');
legend('True response','GPR predicted values','Location','Best');
hold off
```

Train GPR Model Using Cross Validation

This example uses the abalone data [1], [2], from the UCI Machine Learning Repository [3]. Download the data and save it in your current folder with the name 'abalone.data'.

Store the data into a `table`. Display the first seven rows.

```
tbl = readtable('abalone.data', 'Filetype', 'text', 'ReadVariableNames', false);tbl.Properties
tbl(1:7,:)
```

```
ans =
```

```
Sex      Length      Diameter      Height      WWeight      SWeight      VWeight      ShWeight
```

'M'	0.455	0.365	0.095	0.514	0.2245	0.101	0.15
'M'	0.35	0.265	0.09	0.2255	0.0995	0.0485	0.07
'F'	0.53	0.42	0.135	0.677	0.2565	0.1415	0.21
'M'	0.44	0.365	0.125	0.516	0.2155	0.114	0.155
'I'	0.33	0.255	0.08	0.205	0.0895	0.0395	0.055
'I'	0.425	0.3	0.095	0.3515	0.141	0.0775	0.12
'F'	0.53	0.415	0.15	0.7775	0.237	0.1415	0.33

The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, number of shell rings shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.

Train a cross-validated GPR model using the 25% of the data for validation.

```
rng('default') % For reproducibility
cvgprMdl = fitrgp(tbl, 'NoShellRings', 'Standardize', 1, 'Holdout', 0.25);
```

Compute the average loss on folds using models trained on out-of-fold observations.

```
kfoldLoss(cvgprMdl)
```

```
ans =
    4.6409
```

Predict the responses for out-of-fold data.

```
ypred = kfoldPredict(cvgprMdl);
```

Plot the true responses used for testing and the predictions.

```
figure();
plot(ypred(cvgprMdl.Partition.test));
hold on;
y = table2array(tbl(:,end));
plot(y(cvgprMdl.Partition.test), 'r. ');
axis([0 1050 0 30]);
xlabel('x')
ylabel('y')
hold off;
```

Fit GPR Model Using Custom Kernel Function

Generate the sample data.

```
rng(0,'twister'); % For reproducibility
n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*5e-2 + sin(x)./x + 0.2*randn(n,1);
```

Define the squared exponential kernel function as a custom kernel function.

You can compute the squared exponential kernel function as

$$k(x_i, x_j | \theta) = \sigma_f^2 \exp\left(-\frac{1}{2} \frac{(x_i - x_j)^T (x_i - x_j)}{\sigma_l^2}\right),$$

where σ_f is the signal standard deviation, σ_l is the length scale. Both σ_f and σ_l must be greater than zero. This condition can be enforced by the unconstrained parametrization, $\sigma_l = \exp(\theta(1))$ and $\sigma_f = \exp(\theta(2))$, for some unconstrained parametrization vector θ .

Hence, you can define the squared exponential kernel function as a custom kernel function as follows:

```
kfcn = @(XN, XM, theta) (exp(theta(2))^2)*exp(-(pdist2(XN, XM).^2)/(2*exp(theta(1))^2));
```

Here `pdist2(XN, XM).^2` computes the distance matrix.

Fit a GPR model using the custom kernel function, `kfcn`. Specify the initial values of the kernel parameters (Because you use a custom kernel function, you must provide initial values for the unconstrained parametrization vector, `theta`).

```
theta0 = [1.5, 0.2];
gprMdl = fitrgp(x, y, 'KernelFunction', kfcn, 'KernelParameters', theta0);
```

`fitrgp` uses analytical derivatives to estimate parameters when using a built-in kernel function, whereas when using a custom kernel function it uses numerical derivatives.

Compute the resubstitution loss for this model.

```
L = resubLoss(gprMdl)
```

```
L =
```

```
0.0391
```

Fit the GPR model using the built-in squared exponential kernel function option. Specify the initial values of the kernel parameters (Because you use the built-in custom kernel function and specifying initial parameter values, you must provide the initial values for the signal standard deviation and length scale(s) directly).

```
sigmaL0 = exp(1.5);
sigmaF0 = exp(0.2);
gprMdl2 = fitrgp(x, y, 'KernelFunction', 'squaredexponential', 'KernelParameters', [sigmaL0,
```

Compute the resubstitution loss for this model.

```
L2 = resubLoss(gprMdl2)
```

```
L2 =
```

0.0391

The two loss values are the same as expected.

Input Arguments

tbl — Sample data

table

Sample data used to train the model, specified as a **table**. Each row of **tbl** corresponds to one observation, and each column corresponds to one variable. **tbl** contains the predictor variables, and optionally it can also contain one column for the response variable. Multi-column variables and cell arrays other than cell arrays of strings are not allowed.

- If **tbl** contains the response variable, and you want to use all the remaining variables as predictors, then specify the response variable using **ResponseVarName**.
- If **tbl** contains the response variable, and you want to use only a subset of the predictors in training the model, then specify the response variable and the predictor variables using **formula**.
- If **tbl** does not contain the response variable, then specify a response variable using **y**. The length of the response variable and the number of rows in **tbl** must be equal.

For more information on the **table** data type, please see **table**.

If your predictor data contains categorical variables, then the software uses full dummy coding for these variables. The software creates one dummy variable for each level of the categorical variable.

Data Types: **table**

ResponseVarName — Response variable name

name of a variable in **tbl**

Response variable name, specified as the name of a variable in **tbl**. You must specify **ResponseVarName** as a string. For example, if the response variable **y** is stored in **tbl** (as **tbl.y**), then specify it as **'y'**. Otherwise, the software treats all the columns of **tbl**, including **y**, as predictors when training the model.

Data Types: **double**

formula — Response and predictor variables to use in model training

String in the form of 'y~x1+x2+x3'

Response and predictor variables to use in model training, specified as a string in the form of 'y~x1+x2+x3'. In this form, **y** represents the response variable; **x1**, **x2**, **x3** represent the predictor variables to use in training the model.

Use formula string if you want to specify a subset of variables in **tbl** as predictors to use when training the model. If you specify a formula string, then any variables that do not appear in **formula** are not used to train the model.

The formula does not indicate the form of the **BasisFunction**.

Example: 'PetalLength~PetalWidth+Species' identifies the variable **PetalLength** as the response variable, and **PetalWidth** and **Species** as the predictor variables.

X — Predictor data for the GPR model

n-by-*d* matrix

Predictor data for the GPR model, specified as an *n*-by-*d* matrix. *n* is the number of observations (rows), and *d* is the number of predictors (columns).

The length of **y** and the number of rows of **X** must be equal.

To specify the names of the predictors in the order of their appearance in **X**, use the **PredictorNames** name-value pair argument.

Data Types: double

y — Response data for the GPR model

n-by-1 vector

Response data for the GPR model, specified as an *n*-by-1 vector. You can omit **y** if you provide the **tbl** training data that also includes **y**. In that case, use **ResponseVarName** to identify the response variable or use **formula** to identify the response and predictor variables.

Data Types: double | char

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

```
'FitMethod', 'sr', 'BasisFunction', 'linear', 'ActiveSetMethod', 'sgma', 'PredictMet
```

trains the GPR model using the subset of regressors approximation method for parameter estimation, uses a linear basis function, uses sparse greedy matrix approximation for active selection, and fully independent conditional approximation method for prediction.

Fitting

'FitMethod' — Method to estimate parameters of the GPR model

'none' | 'exact' | 'sd' | 'sr' | 'fic'

Method to estimate parameters of the GPR model, specified as the comma-separated pair consisting of 'FitMethod' and one of the following.

Fit Method	Description
'none'	No estimation, use the initial parameter values as the known parameter values.
'exact'	Exact Gaussian process regression. Default if $n \leq 2000$, where n is the number of observations.
'sd'	Subset of data points approximation. Default if $n > 2000$, where n is the number of observations.
'sr'	Subset of regressors approximation.
'fic'	Fully independent conditional approximation.

Example: `'FitMethod', 'fic'`

'BasisFunction' — Explicit basis in the GPR model

'constant' (default) | 'none' | 'linear' | 'pureQuadratic' | function handle

Explicit basis in the GPR model, specified as the comma-separated pair consisting of 'BasisFunction' and one of the following. If n is the number of observations, the basis function adds the term $\mathbf{H}^* \boldsymbol{\beta}$ to the model, where \mathbf{H} is the basis matrix and $\boldsymbol{\beta}$ is a p -by-1 vector of basis coefficients.

Explicit Basis	Basis Matrix
'none'	Empty matrix.
'constant'	$\mathbf{H} = \mathbf{1}$ <p>(n-by-1 vector of 1s, where n is the number of observations)</p>
'linear'	$\mathbf{H} = [\mathbf{1}, \mathbf{X}]$
'pureQuadratic'	$\mathbf{H} = [\mathbf{1}, \mathbf{X}, \mathbf{X}_2],$ <p>where</p> $\mathbf{X}_2 = \begin{bmatrix} x_{11}^2 & x_{12}^2 & \cdots & x_{1d}^2 \\ x_{21}^2 & x_{22}^2 & \cdots & x_{2d}^2 \\ \vdots & \vdots & \vdots & \vdots \\ x_{n1}^2 & x_{n2}^2 & \cdots & x_{nd}^2 \end{bmatrix}.$
Function handle	<p>Function handle, <code>hfcn</code>, that <code>fitrgp</code> calls as:</p> $\mathbf{H} = \text{hfcn}(\mathbf{X}),$ <p>where \mathbf{X} is an n-by-d matrix of predictors and \mathbf{H} is an n-by-p matrix of basis functions.</p>

Example: 'BasisFunction', 'pureQuadratic'

Data Types: char | function_handle

'Beta' — Initial value of the coefficients

p -by-1 vector

Initial value of the coefficients for the explicit basis, specified as the comma-separated pair consisting of 'Beta' and p -by-1 vector, where p is the number of columns in the basis matrix \mathbf{H} .

The basis matrix depends on the choice of the explicit basis function as follows (also see `BasisFunction`).

`fitrgp` uses the coefficient initial values as the known coefficient values, only when `FitMethod` is `'none'`.

Data Types: `double`

'Sigma' — Initial value for the noise standard deviation of the Gaussian process model

`std(y)/sqrt(2)` (default) | positive scalar value

Initial value for the noise standard deviation of the Gaussian process model, specified as the comma-separated pair consisting of `'Sigma'` and a positive scalar value.

Example: `'Sigma',2`

Data Types: `double`

'SigmaLowerBound' — Lower bound on the noise standard deviation

`1e-2*std(y)` (default) | positive scalar value

Lower bound on the noise standard deviation, specified as the comma-separated pair consisting of `'SigmaLowerBound'` and a positive scalar value.

Example: `'SigmaLowerBound',0.02`

Data Types: `double`

'CategoricalPredictors' — List of categorical predictors

numeric vector | logical vector | `'all'` | cell array of strings

List of categorical predictors, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following.

- A numeric vector with indices from 1 through p , where p is the number of columns in `X` or variables in `tbl`.
- A 1-by- p logical vector, with a `true` entry corresponding to the column of `X` or `tbl` that is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames` values.
- `'all'`, which means all predictors are categorical.

By default, if the predictor data is in a matrix (`X`), `fitrgp` assumes that none of the predictors are categorical unless specified as such using the `CategoricalPredictors`

name-value pair argument. If the predictor data is in a table (tbl), the software assumes that a variable is categorical if it contains logical values, categorical values, or a cell array of strings.

Example: `'CategoricalPredictors',[false true false true false]` specifies the second and the fourth predictors as categorical.

Data Types: `double | logical | cell`

'Standardize' — Indicator to standardize data

`0 (false) (default) | logical value`

Indicator to standardize data, specified as the comma-separated pair consisting of `'Standardize'` and a logical value.

If you set `'Standardize',1`, then the software centers and scales each column of the predictor data, by the column mean and standard deviation, respectively. The software does not standardize the data contained in the dummy variable columns that it generates for categorical predictors.

Example: `'Standardize',1`

Example: `'Standardize',true`

Data Types: `logical`

'Regularization' — Regularization standard deviation

`1e-2*std(y) (default) | positive scalar value`

Regularization standard deviation for sparse methods subset of regressors (`'sr'`) and fully independent conditional (`'fic'`), specified as the comma-separated pair consisting of `'Regularization'` and a positive scalar value.

Example: `'Regularization',0.2`

Data Types: `double`

'ComputationMethod' — Method for computing log likelihood and gradient

`'qr' (default) | 'v'`

Method for computing the log likelihood and gradient for parameter estimation using subset of regressors (`'sr'`) and fully independent conditional (`'fic'`) approximation methods, specified as the comma-separated pair consisting of `'ComputationMethod'` and one of the following.

- 'qr' — Use QR factorization based approach, this option provides better accuracy.
- 'v' — Use V-method-based approach. This option provides faster computation of log likelihood gradients.

Example: 'ComputationMethod', 'v'

Kernel (Covariance) Function

'KernelFunction' — Form of the covariance function

'squaredexponential' (default) | 'matern32' | 'matern52' |
'ardsquaredexponential' | 'ardmatern32' | 'ardmatern52' | function handle

Form of the covariance function, specified as the comma-separated pair consisting of 'KernelFunction' and one of the following.

Function	Description
'squaredexponential'	Squared exponential kernel
'matern32'	Matern kernel with parameter 3/2
'matern52'	Matern kernel with parameter 5/2
'ardsquaredexponential'	Squared exponential kernel with a separate length scale per predictor
'ardmatern32'	Matern kernel with parameter 3/2 and a separate length scale per predictor
'ardmatern52'	Matern kernel with parameter 5/2 and a separate length scale per predictor
Function handle	A function handle that can be called like this: $K_{mn} = kfcn(X_m, X_n, \theta)$ where X_m is an m -by- d matrix, X_n is an n -by- d matrix and K_{mn} is an m -by- n matrix of kernel products such that $K_{mn}(i,j)$ is the kernel product between $X_m(i,:)$ and $X_n(j,:)$. θ is the r -by-1 unconstrained parameter vector for $kfcn$.

For more information on the kernel functions, see “Kernel (Covariance) Function Options” on page 6-6.

Example: 'KernelFunction', 'Matern32'

Data Types: char | function_handle

'KernelParameters' — Initial values for the kernel parameters

vector

Initial values for the kernel parameters, specified as the comma-separated pair consisting of 'KernelParameters' and a vector. The size of the vector and the values depend on the form of the covariance function, specified by the KernelFunction name-value pair argument.

'KernelFunction'	'KernelParameters'
'squaredexponential' or 'matern32' or 'matern52'	2-by-1 vector ϕ , where $\phi(1)$ contains the length scale and $\phi(2)$ contains the noise standard deviation. Default initial value of the length scale parameter is the mean of standard deviations of the predictors, and the noise standard deviation is the standard deviation of the responses divided by square root of 2. That is, $\phi = [\text{mean}(\text{std}(X)), \text{std}(y) / \text{sqrt}(2)]$
'ardsquaredexponential' or 'ardmatern32' or 'ardmatern52'	$(d+1)$ -by-1 vector θ , where $\theta(i)$ contains the length scale for predictor i and $\theta(d+1)$ contains the noise standard deviation. d is the number of predictor variables. Default initial value of the length scale parameters are the standard deviations of the predictors and the noise standard deviation is the standard deviation of the responses divided by square root of 2. That is, $\theta = [\text{std}(X), \text{std}(y) / \text{sqrt}(2)]$
Function handle	r -by-1 vector as the initial value of the unconstrained parameter vector ϕ for the custom kernel function <code>kfcn</code> .

'KernelFunction'	'KernelParameters'
	When <code>KernelFunction</code> is a function handle, you must supply initial values for the kernel parameters.

For more information on the kernel functions, see “Kernel (Covariance) Function Options” on page 6-6.

Example: `'KernelParameters', theta`

Data Types: `double`

'DistanceMethod' — Method for computing inter-point distances

`'fast'` (default) | `'accurate'`

Method for computing inter-point distances to evaluate built-in kernel functions, specified as the comma-separated pair consisting of `'DistanceMethod'` and either `'fast'` or `'accurate'`. `fitrgp` computes $(x - y)^2$ as $x^2 + y^2 - 2 * x * y$ when you choose the `fast` option and as $(x - y)^2$ when you choose the `accurate` option.

Example: `'DistanceMethod', 'accurate'`

Active Set Selection

'ActiveSet' — Observations in the active set

`[]` (default) | m -by-1 vector of integers ranging from 1 to n ($m \leq n$) | logical vector of length n

Observations in the active set, specified as the comma-separated pair consisting of `'ActiveSet'` and an m -by-1 vector of integers ranging from 1 to n ($m \leq n$) or a logical vector of length n with at least one `true` element. n is the total number of observations in the training data.

`fitrgp` uses the observations indicated by `ActiveSet` to train the GPR model. The active set cannot have duplicate elements.

If you supply `ActiveSet`, then:

- `fitrgp` does not use `ActiveSetSize` and `ActiveSetMethod`.
- You cannot perform cross-validation on this model.

Data Types: double | logical

'ActiveSetSize' — Size of the active set for sparse methods

an integer m ($1 \leq m \leq n$)

Size of the active set for sparse methods ('sd', 'sr', 'fic'), specified as the comma-separated pair consisting of 'ActiveSetSize' and an integer m , $1 \leq m \leq n$, where n is the number of observations.

Default is $\min(1000, n)$ when FitMethod is 'sr' or 'fic', and $\min(2000, n)$, otherwise.

Example: 'ActiveSetSize', 100

Data Types: double

'ActiveSetMethod' — Active set selection method

'random' (default) | 'sgma' | 'entropy' | 'likelihood'

Active set selection method, specified as the comma-separated pair consisting of 'ActiveSetMethod' and one of the following.

Method	Description
'random'	Random selection
'sgma'	Sparse greedy matrix approximation
'entropy'	Differential entropy-based selection
'likelihood'	Subset of regressors log likelihood-based selection

All active set selection methods (except 'random') require the storage of an n -by- m matrix, where m is the size of the active set and n is the number of observations.

Example: 'ActiveSetMethod', 'entropy'

'RandomSearchSetSize' — Random search set size

59 (default) | integer value

Random search set size per greedy inclusion for active set selection, specified as the comma-separated pair consisting of 'RandomSearchSetSize' and an integer value.

Example: 'RandomSearchSetSize', 30

Data Types: double

'ToleranceActiveSet' — Relative tolerance for terminating active set selection

1e-06 (default) | positive scalar

Relative tolerance for terminating active set selection, specified as the comma-separated pair consisting of `'ToleranceActiveSet'` and a positive scalar value.

Example: `'ToleranceActiveSet',0.0002`

Data Types: double

'NumActiveSetRepeats' — Number of repetitions

3 (default) | integer value

Number of repetitions for interleaved active set selection and parameter estimation when `ActiveSetMethod` is not `'random'`, specified as the comma-separated pair consisting of `'NumActiveSetRepeats'` and an integer value.

Example: `'NumActiveSetRepeats',5`

Data Types: double

Prediction**'PredictMethod' — Method used to make predictions**`'exact' | 'bcd' | 'sd' | 'sr' | 'fic'`

Method used to make predictions from a Gaussian process model given the parameters, specified as the comma-separated pair consisting of `'PredictMethod'` and one of the following.

Method	Description
<code>'exact'</code>	Exact Gaussian process regression method. Default, if $n \leq 10000$.
<code>'bcd'</code>	Block Coordinate Descent. Default, if $n > 10000$.
<code>'sd'</code>	Subset of Datapoints approximation.
<code>'sr'</code>	Subset of Regressors approximation.
<code>'fic'</code>	Fully Independent Conditional approximation.

Example: 'PredictMethod', 'bcd'

'BlockSizeBCD' — Block size

minimum of 1000 or n (default) | integer in the range from 1 to n

Block size for block coordinate descent method ('bcd'), specified as the comma-separated pair consisting of 'BlockSizeBCD' and an integer in the range from 1 to n , where n is the number of observations.

Example: 'BlockSizeBCD', 1500

Data Types: double

'NumGreedyBCD' — Number of greedy selections

minimum of 100 and BlockSizeBCD (default) | integer value in the range from 1 to BlockSizeBCD

Number of greedy selections for block coordinate descent method ('bcd'), specified as the comma-separated pair consisting of 'NumGreedyBCD' and an integer in the range from 1 to BlockSizeBCD.

Example: 'NumGreedyBCD', 150

Data Types: double

'ToleranceBCD' — Relative tolerance on gradient norm

1e-3 (default) | positive scalar

Relative tolerance on gradient norm for terminating block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'ToleranceBCD' and a positive scalar.

Example: 'ToleranceBCD', 0.002

Data Types: double

'StepToleranceBCD' — Absolute tolerance on step size

1e-3 (default) | positive scalar

Absolute tolerance on step size for terminating block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'StepToleranceBCD' and a positive scalar.

Example: 'StepToleranceBCD', 0.002

Data Types: double

'IterationLimitBCD' — Maximum number of BCD iterations

1000000 (default) | integer value

Maximum number of block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'IterationLimitBCD' and an integer value.

Example: 'IterationLimitBCD',10000

Data Types: double

Optimization**'Optimizer' — Optimizer to use for parameter estimation**

'quasinevton' (default) | 'fminsearch' | 'fminunc' | 'fmincon'

Optimizer to use for parameter estimation, specified as the comma-separated pair consisting of 'Optimizer' and one of quasinevton, fminsearch, fminunc, fmincon.

Use of 'fminunc' and 'fmincon' requires an Optimization Toolbox license.

Example: 'Optimizer', 'fmincon'

'OptimizerOptions' — Options for the optimizer

structure | object

Options for the optimizer you choose using the Optimizer name-value pair argument, specified as the comma-separated pair consisting of 'Optimizer' and a structure or object created by optimset, statset('fitrgp'), or optimoptions.

Optimizer	Create Optimizer Options Using
'fminsearch'	optimset (structure)
'quasinevton'	statset('fitrgp') (structure)
'fminunc' or 'fmincon'	optimoptions (object)

The default options depend on the type of optimizer.

Example: 'OptimizerOptions', opt

Cross-Validation**'CrossVal' — Indicator for cross-validation**

'off' (default) | 'on'

Indicator for cross-validation, specified as the comma-separated pair consisting of 'CrossVal' and either 'off' or 'on'. If it is 'on', then fitrgp returns a GPR model cross-validated with 10 folds.

You can use one of the KFold, Holdout, Leaveout or CVPartition name-value pair arguments to change the default cross-validation settings. You can use only one of these name-value pairs at a time.

As an alternative, you can use the `crossval` method for your model.

Example: 'CrossVal', 'on'

Data Types: double

'CVPartition' — Random partition for a stratified k -fold cross validation
cvpartition object

Random partition for a stratified k -fold cross validation, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition object.

Example: 'CVPartition', cvp uses the random partition defined by cvp.

If you specify CVPartition, then you cannot specify Holdout, KFold, or Leaveout.

'Holdout' — Fraction of data to use for testing
Scalar value in the range from 0 to 1

Fraction of the data to use for testing in holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range from 0 to 1. If you specify 'Holdout', p , then the software:

1. Randomly reserves around $p*100\%$ of the data as validation data, and trains the model using the rest of the data
2. Stores the compact, trained model in `cvgprMdl.Trained`.

Example: 'Holdout', 0.3 uses 30% of the data for testing and 70% of the data for training.

If you specify Holdout, then you cannot specify CVPartition, KFold, or Leaveout.

Data Types: double

'KFold' — Number of folds
10 (default) | positive integer value

Number of folds to use in cross-validated GPR model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value. KFold must be greater than 1. If you specify 'KFold', k then the software:

1. Randomly partitions the data into k sets.
2. For each set, reserves the set as test data, and trains the model using the other $k - 1$ sets.
3. Stores the k compact, trained models in the cells of a k -by-1 cell array in `cvgprMdl.Trained`.

Example: 'KFold', 5 uses 5 folds in cross-validation. That is, for each fold, uses that fold as test data, and trains the model on the remaining 4 folds.

If you specify KFold, then you cannot specify CVPartition, Holdout, or Leaveout.

Data Types: double

'Leaveout' — Indicator for leave-one-out cross-validation

'off' (default) | 'on'

Indicator for leave-one-out cross-validation, specified as the comma-separated pair consisting of 'Leaveout' and either 'off' or 'on'.

If you specify 'Leaveout', 'on', then, for each of the n observations, the software:

1. Reserves the observation as test data, and trains the model using the other $n - 1$ observations.
2. Stores the compact, trained model in a cell in the n -by-1 cell array `cvgprMdl.Trained`.

Example: 'Leaveout', 'on'

If you specify Leaveout, then you cannot specify CVPartition, Holdout, or KFold.

Other

'PredictorNames' — Names for the predictor variables

{'x1', 'x2', ...} (default) | cell array

Names for the predictor variables, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array.

If you specify the predictors in a table (`tbl`), then PredictorNames must be a subset of the variable names in `tbl`. In this case, the software uses only the variables in PredictorNames to train the model.

Example: `'PredictorNames', {'PedalWidth', 'PedalLength'}`

Data Types: `cell`

'ResponseName' — Name of the response variable

`'Y'` (default) | `string`

Name of the response variable, specified as the comma-separated pair consisting of `'ResponseName'` and a string.

This name-value pair argument is not valid when using the `formula` or `ResponseVarName` input arguments.

Example: `'ResponseName', 'Price'`

Data Types: `char`

'Verbose' — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and one of the following.

- `0` — `fitrgp` suppresses diagnostic messages related to active set selection and block coordinate descent but displays the messages related to parameter estimation, depending on the value of `'Display'` in `OptimizerOptions`.
- `1` — `fitrgp` displays the iterative diagnostic messages related to parameter estimation, active set selection, and block coordinate descent.

Example: `'Verbose', 1`

'CacheSize' — Cache size in megabytes

`1000 MB` (default) | `positive scalar`

Cache size in megabytes (MB), specified as the comma-separated pair consisting of `'CacheSize'` and a positive scalar. Cache size is the extra memory that is available in addition to that required for fitting and active set selection. `fitrgp` uses `CacheSize` to:

- Decide whether interpoint distances should be cached when estimating parameters.
- Decide how matrix vector products should be computed for block coordinate descent method and for making predictions.

Example: `'CacheSize', 2000`

Data Types: double

Output Arguments

gprMdl — Gaussian process regression model

RegressionGP object | RegressionPartitionedModel object

Gaussian process regression model, returned as an `RegressionGP` or a `RegressionPartitionedModel` object.

- If you cross validate, that is, if you use one of the `'Crossval'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` name-value pairs, then `gprMdl` is a `RegressionPartitionedModel` object. You cannot use a `RegressionPartitionedModel` object to make predictions using `predict`. For more information on the methods and properties of this object, see `RegressionPartitionedModel`.
- If you do not cross validate, then `gprMdl` is a `RegressionGP` object. You can use this object for predictions using the `predict` method. For more information on the methods and properties of this object, see `RegressionGP`.

More About

Active Set Selection and Parameter Estimation

For subset of data, subset of regressors, or fully independent conditional approximation fitting methods (FitMethod equal to `'sd'`, `'sr'`, or `'fic'`), if you do not provide the active set, `fitrgp` selects the active set and computes the parameter estimates in a series of iterations.

In the first iteration, the software uses the initial parameter values in vector $\eta_0 = [\beta_0, \sigma_0, \theta_0]$ to select an active set A_1 . It maximizes the GPR marginal log likelihood or its approximation using η_0 as the initial values and A_1 to compute the new parameter estimates η_1 . Next, it computes the new log likelihood L_1 using η_1 and A_1 .

In the second iteration, the software selects the active set A_2 using the parameter values in η_1 . Then, using η_1 as the initial values and A_2 , it maximizes the GPR marginal log likelihood or its approximation and estimates the new parameter values η_2 . Then using η_2 and A_2 , computes the new log likelihood value L_2 .

The following table summarizes the iterations and what is computed at each iteration.

Iteration Number	Active Set	Parameter Vector	Log Likelihood
1	A_1	η_1	L_1
2	A_2	η_2	L_2
3	A_3	η_3	L_3
...

The software iterates similarly for a specified number of repetitions. You can specify the number of replications for active set selection using the NumActiveSetRepeats name-value pair argument.

Tips

- `fitrgp` accepts any combination of fitting, prediction, and active set selection methods. In some cases it might not be possible to compute the standard deviations of the predicted responses, hence the prediction intervals. See `predict`. And in some cases, using the exact method might be expensive due to the size of the training data.
- The `PredictorNames` property stores one element for each of the original predictor variable names. For example, if there are three predictors, one of which is a categorical variable with three levels, `PredictorNames` is a 1-by-3 cell array of strings.
- The `ExpandedPredictorNames` property stores one element for each of the predictor variables, including the dummy variables. For example, if there are three predictors, one of which is a categorical variable with three levels, then `ExpandedPredictorNames` is a 1-by-5 cell array of strings.
- Similarly, the `Beta` property stores one beta coefficient for each predictor, including the dummy variables.
- The `X` property stores the training data as originally input. It does not include the dummy variables.

fitrlinear

Fit linear regression model to high-dimensional data

`fitrlinear` efficiently trains linear regression models with high-dimensional, full or sparse predictor data. Available linear regression models include regularized support vector machines (SVM) and least-squares regression methods. `fitrlinear` minimizes the objective function using techniques that reduce computing time (e.g., stochastic gradient descent).

A high-dimensional data set includes many predictor variables. Although such a data set can consume a significant fraction of memory, it must fit in the MATLAB Workspace. For low- through medium-dimensional predictor data sets, see “Alternatives for Lower-Dimensional Data” on page 18-2.

Syntax

```
Mdl = fitrlinear(X,Y)
Mdl = fitrlinear(X,Y,Name,Value)
[Mdl,FitInfo] = fitrlinear( ___ )
```

Description

`Mdl = fitrlinear(X,Y)` returns a trained regression model object that contains the results of fitting a support vector machine regression model to the predictors `X` and response `Y`.

`Mdl = fitrlinear(X,Y,Name,Value)` returns a trained linear regression model with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify implement least-squares regression, specify to cross-validate, or specify the type of regularization. It is good practice to cross-validate using the `KfoldName,Value` pair argument. The cross-validation results determine how well the model generalizes.

`[Mdl,FitInfo] = fitrlinear(___)` also returns optimization details using any of the previous syntaxes. You cannot request `FitInfo` for cross-validated models.

Examples

Train Linear Regression Model

Train a linear regression model using SVM, dual SGD, and ridge regularization.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = x_1, \dots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model. By default, `fitrlinear` uses support vector machines with a ridge penalty, and optimizes using dual SGD for SVM. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

```
[Mdl,FitInfo] = fitrlinear(X,Y)
```

```
Mdl =
```

```
RegressionLinear
  ResponseName: 'Y'
  ResponseTransform: 'none'
           Beta: [1000x1 double]
           Bias: -0.0056
           Lambda: 1.0000e-04
           Learner: 'svm'
```

```

FitInfo =
    Lambda: 1.0000e-04
    Objective: 0.2726
    PassLimit: 10
    NumPasses: 10
    BatchLimit: []
    NumIterations: 100000
    GradientNorm: NaN
    GradientTolerance: 0
    RelativeChangeInBeta: 0.4908
    BetaTolerance: 1.0000e-04
    DeltaGradient: 1.5818
    DeltaGradientTolerance: 0.1000
    TerminationCode: 0
    TerminationStatus: {'Maximal number of iterations has been reached.'}
    Alpha: [10000x1 double]
    History: []
    FitTime: 0.1167
    Solver: {'dual'}

```

`Mdl` is a `RegressionLinear` model. You can pass `Mdl` and the training or new data to `loss` to inspect the in-sample mean-squared error. Or, you can pass `Mdl` and new predictor data to `predict` to predict responses for new observations.

`FitInfo` is a structure array containing, among other things, the termination status (`TerminationStatus`) and how long the solver took to fit the model to the data (`FitTime`). It is good practice to use `FitInfo` to determine whether optimization-termination measurements are satisfactory. In this case, `fitrlinear` reached the maximum number of iterations. Because training time is fast, you can retrain the model, but increase the number of passes through the data. Or, try another solver, such as LBFGS.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear regression model that uses least squares, implement 5-fold cross-validation.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1} .

```
Lambda = logspace(-5,-1,15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Solve the objective function using SpARSA.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');

numCLModels = numel(CVMdl.Trained)
```

```
numCLModels =
```

```
5
```

CVMdl is a `RegressionPartitionedLinear` model. Because `fitrlinear` implements 5-fold cross-validation, CVMdl contains 5 `RegressionLinear` models that the software trains on each fold.

Display the first trained linear regression model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
```

```

RegressionLinear
  ResponseName: 'Y'
  ResponseTransform: 'none'
  Beta: [1000x15 double]
  Bias: [1x15 double]
  Lambda: [1x15 double]
  Learner: 'leastsquares'

```

Mdl1 is a `RegressionLinear` model object. `fitrlinear` constructed Mdl1 by training on the first four folds. Because `Lambda` is a sequence of regularization strengths, you can think of Mdl1 as 11 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated MSE.

```
mse = kfoldLoss(CVMdl);
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```

Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
  'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);

```

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```

figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
  log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} MSE')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off

```

Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, `Lambda(10)`).

```
idxFinal = 10;
```

Extract the model with corresponding to the minimal MSE.

```
MdlFinal = selectModels(Mdl,idxFinal)
idxNZCoeff = find(MdlFinal.Beta~=0)
EstCoeff = Mdl.Beta(idxNZCoeff)
```

```
MdlFinal =
```

```
RegressionLinear
  ResponseName: 'Y'
  ResponseTransform: 'none'
    Beta: [1000x1 double]
    Bias: -0.0050
    Lambda: 0.0037
  Learner: 'leastsquares'
```

```
idxNZCoeff =
```

```
100
200
```

```
EstCoeff =
```

```
1.0051
1.9965
```

`MdlFinal` is a `RegressionLinear` model with one regularization strength. The nonzero coefficients `EstCoeff` are close to the coefficients that simulated the data.

Input Arguments

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix.

The length of `Y` and the number of observations in `X` must be equal.

Note: If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn'`, `'columns'`, then you might experience a significant reduction in optimization-execution time.

Y — Response data

numeric vector

Response data, specified as an n -dimensional numeric vector. The length of Y and the number of observations in X must be equal.

Data Types: `single` | `double`

Note `fitrlinear` removes missing observations, that is, observations with any of these characteristics:

- NaN elements in the response (Y or `ValidationData{2}`)
- At least one NaN value in a predictor observation (row in X or `ValidationData{1}`)
- NaN value or 0 weight (`Weights` or `ValidationData{3}`)

For memory-usage economy, it is best practice to remove observations containing missing values from your training data manually before training.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example:

`'Learner', 'regression', 'CrossVal', 'on', 'Regularization', 'lasso'` specifies to implement least-squares regression, implement 10-fold cross-validation, and specifies to include a lasso regularization term.

Linear Regression Options

'Epsilon' — Half the width of epsilon-insensitive band

`iqr(Y)/1.349` (default) | nonnegative scalar value

Half the width of the epsilon-insensitive band, specified as the comma-separated pair consisting of `'Epsilon'` and a nonnegative scalar value. `'Epsilon'` applies to SVM learners only.

The default `Epsilon` value is `iqr(Y)/1.349`, which is an estimate of standard deviation using the interquartile range of the response variable Y . If `iqr(Y)` is equal to zero, then the default `Epsilon` value is 0.1.

Example: 'Epsilon',0.3

Data Types: single | double

'Lambda' — Regularization term strength

'auto' (default) | nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as the comma-separated pair consisting of 'Lambda' and 'auto', a nonnegative scalar, or a vector of nonnegative values.

- For 'auto', $\text{Lambda} = 1/n$.
 - If you specify a cross-validation, name-value pair argument (e.g., `CrossVal`), then n is the number of in-fold observations.
 - Otherwise, n is the training sample size.
- For a vector of nonnegative values, the software sequentially optimizes the objective function for each distinct value in `Lambda` in ascending order.
 - If `Solver` is 'sgd' or 'asgd' and `Regularization` is 'lasso', then the software does not use the previous coefficient estimates as a warm start for the next optimization iteration. Otherwise, the software uses warm starts.
 - If `Regularization` is 'lasso', then any coefficient estimate of 0 retains its value when the software optimizes using subsequent values in `Lambda`.

Returns coefficient estimates for all optimization iterations.

Example: 'Lambda',10.^(-(10:-2:2))

Data Types: char | double | single

'Learner' — Linear regression model type

'svm' (default) | 'leastsquares'

Linear regression model type, specified as the comma-separated pair consisting of 'Learner' and 'svm' or 'leastsquares'.

In this table, $f(x) = \beta'x + b$.

- β is a vector of p coefficients.
- x is an observation from p predictor variables.
- b is the scalar bias.

Value	Algorithm	Response range	Loss function
'leastsquares'	Linear regression via ordinary least squares	$y \in (-\infty, \infty)$	Mean squared error (MSE): $\ell[y, f(x)] = \frac{1}{2}[y - f(x)]^2$
'svm'	Support vector machine regression	Same as 'leastsquares'	Epsilon-insensitive: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$

Example: 'Learner', 'leastsquares'

Data Types: char

'ObservationsIn' — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

Note: If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Data Types: char

'Regularization' — Complexity penalty type

'lasso' | 'ridge'

Complexity penalty type, specified as the comma-separated pair consisting of 'Regularization' and 'lasso' or 'ridge'.

The software composes the objective function for minimization from the sum of the average loss function (see Learner) and the regularization term in this table.

Value	Description
'lasso'	Lasso (L1) penalty: $\lambda \sum_{j=1}^p \beta_j $

Value	Description
'ridge'	Ridge (L2) penalty: $\frac{\lambda}{2} \sum_{j=1}^p \beta_j^2$

To specify the regularization term strength, which is λ in the expressions, use `Lambda`.

The software excludes the bias term (β_0) from the regularization penalty.

If `Solver` is 'sparsa', then the default value of `Regularization` is 'lasso'. Otherwise, the default is 'ridge'.

Tip

- For predictor variable selection, specify 'lasso'.
 - For optimization accuracy, specify 'ridge'.
-

Example: 'Regularization', 'lasso'

Data Types: char

'Solver' — Objective function minimization technique

'sgd' | 'asgd' | 'dual' | 'bfgs' | 'lbfgs' | 'sparsa' | cell vector of strings

Objective function minimization technique, specified as the comma-separated pair consisting of 'Solver' and a string or cell vector of strings from this table.

Value	Description	Restrictions
'sgd'	Stochastic gradient descent (SGD) [5][3]	
'asgd'	Average stochastic gradient descent (ASGD) [8]	
'dual'	Dual SGD for SVM [2][7]	Regularization must be 'ridge' and Learner must be 'svm'.

Value	Description	Restrictions
'bfgs'	Broyden-Fletcher-Goldfarb-Shanno quasi-Newton algorithm (BFGS) [4]	Inefficient if X is very high-dimensional.
'lbfgs'	Limited-memory BFGS (LBFGS) [4]	Regularization must be 'ridge'.
'sparsa'	Sparse Reconstruction by Separable Approximation (SpaRSA) [6]	Regularization must be 'lasso'.

If you specify:

- A ridge penalty (see **Regularization**) and `size(X,1) <= 100` (100 or fewer predictor variables), then the default solver is 'bfgs'.
- An SVM regression model (see **Learner**), a ridge penalty, and `size(X,1) > 100` (more than 100 predictor variables), then the default solver is 'dual'.
- A lasso penalty and X contains 100 or fewer predictor variables, then the default solver is 'sparsa'.

Otherwise, the default solver is 'sgd'.

If you specify a cell vector of solver names, then the software uses all solvers in the specified order for each `Lambda`.

For more details on which solver to choose, see “Tips” on page 25-2085.

Example: 'Solver', {'sgd', 'lbfgs'}

Data Types: char | cell

'Beta' — Initial linear coefficient estimates

`zeros(p,1)` (default) | numeric vector | numeric matrix

Initial linear coefficient estimates (β), specified as the comma-separated pair consisting of 'Beta' and a p -dimensional numeric vector or a p -by- L numeric matrix. p is the number of predictor variables in X and L is the number of regularization-strength values (for more details, see `Lambda`).

- If you specify a p -dimensional vector, then the software optimizes the objective function L times using this process.

- 1 The software optimizes using **Beta** as the initial value and the minimum value of **Lambda** as the regularization strength.
 - 2 The software optimizes again using the resulting estimate from the previous optimization as a warm start, and the next smallest value in **Lambda** as the regularization strength.
 - 3 The software implements step 2 until it exhausts all values in **Lambda**.
- If you specify a p -by- L matrix, then the software optimizes the objective function L times. At iteration j , the software uses **Beta**($:$, j) as the initial value and, after it sorts **Lambda** in ascending order, uses **Lambda**(j) as the regularization strength.

If you set 'Solver', 'dual', then the software ignores **Beta**.

Data Types: single | double

'Bias' — Initial intercept estimate

numeric scalar | numeric vector

Initial intercept estimate (b), specified as the comma-separated pair consisting of 'Bias' and a numeric scalar or an L -dimensional numeric vector. L is the number of regularization-strength values (for more details, see **Lambda**).

- If you specify a scalar, then the software optimizes the objective function L times using this process.
 - 1 The software optimizes using **Bias** as the initial value and the minimum value of **Lambda** as the regularization strength.
 - 2 The uses the resulting estimate as a warm start to the next optimization iteration, and uses the next smallest value in **Lambda** as the regularization strength.
 - 3 The software implements step 2 until it exhausts all values in **Lambda**.
- If you specify an L -dimensional vector, then the software optimizes the objective function L times. At iteration j , the software uses **Bias**(j) as the initial value and, after it sorts **Lambda** in ascending order, uses **Lambda**(j) as the regularization strength.
- By default:
 - If **Learner** is 'leastquares', then **Bias** is the weighted average of Y for training or, for cross-validation, in-fold responses.

- If `Learner` is `'svm'`, then `Bias` is the weighted median of `Y` for all training or, for cross-validation, in-fold observations that are greater than `Epsilon`.

Data Types: `single` | `double`

'FitBias' — Linear model intercept inclusion flag

`true` (default) | `false`

Linear model intercept inclusion flag, specified as the comma-separated pair consisting of `'FitBias'` and `true` or `false`.

Value	Description
<code>true</code>	The software includes the bias term b in the linear model, and then estimates it.
<code>false</code>	The software sets $b = 0$ during estimation.

Example: `'FitBias', false`

Data Types: `logical`

'PostFitBias' — Flag to fit linear model intercept after optimization

`false` (default) | `true`

Flag to fit the linear model intercept after optimization, specified as the comma-separated pair consisting of `'PostFitBias'` and `true` or `false`.

Value	Description
<code>false</code>	The software estimates the bias term b and the coefficients β during optimization.
<code>true</code>	To estimate b , the software: <ol style="list-style-type: none"> 1 Estimates β and b using the model. 2 Computes residuals. 3 Refits b. For least squares, b is the weighted average of the residuals. For SVM regression, b is the weighted median between all residuals with magnitude greater than <code>Epsilon</code>.

If you specify `true`, then `FitBias` must be true.

Example: `'PostFitBias', true`

Data Types: `logical`

'Verbose' — Verbosity level

0 (default) | nonnegative integer

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and a nonnegative integer. `Verbose` controls the amount of diagnostic information `fitrlinear` displays at the command line.

Value	Description
0	<code>fitrlinear</code> does not display diagnostic information.
1	<code>fitrlinear</code> periodically displays and stores the value of the objective function, gradient magnitude, and other diagnostic information. <code>FitInfo.History</code> contains the diagnostic information.
Any other positive integer	<code>fitrlinear</code> displays and stores diagnostic information at each optimization iteration. <code>FitInfo.History</code> contains the diagnostic information.

Example: `'Verbose', 1`

Data Types: `double` | `single`

SGD and ASGD Solver Options

'BatchSize' — Mini-batch size

positive integer

Mini-batch size, specified as the comma-separated pair consisting of `'BatchSize'` and a positive integer. At each iteration, the software estimates the subgradient using `BatchSize` observations from the training data.

- If X is a numeric matrix, then the default value is 10.

- If X is a sparse matrix, then the default value is $\max([10, \text{ceil}(\text{sqrt}(\text{ff}))])$, where $\text{ff} = \text{numel}(X) / \text{nnz}(X)$ (the *fullness factor* of X).

Example: 'BatchSize', 100

Data Types: single | double

'LearnRate' — Learning rate

positive scalar

Learning rate, specified as the comma-separated pair consisting of 'LearnRate' and a positive scalar. `LearnRate` specifies how many steps to take per iteration. At each iteration, the gradient specifies the direction and magnitude of each step.

- If `Regularization` is 'ridge', then `LearnRate` specifies the initial learning rate γ_0 . The software determines the learning rate for iteration t , γ_t , using

$$\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.$$

- λ is the value of `Lambda`.
- If `Solver` is 'sgd', then $c = 1$.
- If `Solver` is 'asgd', then c is:
 - 2/3 if `Learner` is 'leastquares'
 - 3/4 if `Learner` is 'svm' [8]
- If `Regularization` is 'lasso', then, for all iterations, `LearnRate` is constant.

By default, `LearnRate` is $1/\text{sqrt}(1 + \max(\text{sum}(X.^2, \text{obsDim})))$, where `obsDim` is 1 if the observations compose the columns of X , and 2 otherwise.

Example: 'LearnRate', 0.01

Data Types: single | double

'OptimizeLearnRate' — Flag to decrease learning rate

true (default) | false

Flag to decrease the learning rate when the software detects divergence (that is, over-stepping the minimum), specified as the comma-separated pair consisting of 'OptimizeLearnRate' and true or false.

If `OptimizeLearnRate` is `'true'`, then:

- 1 For the few optimization iterations, the software starts optimization using `LearnRate` as the learning rate.
- 2 If the value of the objective function increases, then the software restarts and uses half of the current value of the learning rate.
- 3 The software iterates step 2 until the objective function decreases.

Example: `'OptimizeLearnRate', true`

Data Types: `logical`

'TruncationPeriod' – Number of mini-batches between lasso truncation runs

10 (default) | `positive integer`

Number of mini-batches between lasso truncation runs, specified as the comma-separated pair consisting of `'TruncationPeriod'` and a positive integer.

After a truncation run, the software applies a soft threshold to the linear coefficients. That is, after processing $k = \text{TruncationPeriod}$ mini-batches, the software truncates the estimated coefficient j using

$$\hat{\beta}_j^* = \begin{cases} \hat{\beta}_j - u_t & \text{if } \hat{\beta}_j > u_t \\ 0 & \text{if } |\hat{\beta}_j| \leq u_t \\ \hat{\beta}_j + u_t & \text{if } \hat{\beta}_j < -u_t \end{cases}$$

- For SGD, $\hat{\beta}_j$ is the estimate of coefficient j after processing k mini-batches. $u_t = k\gamma_t\lambda$. γ_t is the learning rate at iteration t . λ is the value of `Lambda`.
- For ASGD, $\hat{\beta}_j$ is the averaged estimate coefficient j after processing k mini-batches, $u_t = k\lambda$.

If `Regularization` is `'ridge'`, then the software ignores `TruncationPeriod`.

Example: `'TruncationPeriod', 100`

Data Types: `single` | `double`

Other Regression Options

'Weights' — Observation weights

`ones(size(X,2),1)/size(X,2)` (default) | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. `fitrlinear` weighs the observations in `X` with the corresponding value in `Weights`. The size of `Weights` must equal the number of observations in `X`.

`fitrlinear` normalizes `Weights` to sum to 1.

Data Types: `double` | `single`

Cross-Validation Options

'CrossVal' — Flag to train cross-validated classifier

'off' (default) | 'on'

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using one of the 'KFold', 'Holdout', or 'CVPartition' name-value pair arguments. You can only use one cross-validation name-value pair argument at a time to create a cross-validated model.

Example: 'Crossval', 'on'

Data Types: `char`

'CVPartition' — Cross-validation partition

[] (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', ρ , then the software:

- 1 Randomly reserves $\rho*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

Example: 'Holdout',0.1

Data Types: double | single

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', k , then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'KFold'.

Example: 'KFold',8

Data Types: single | double

SGD and ASGD Convergence Controls**'BatchLimit' — Maximal number of batches**

positive integer

Maximal number of batches to process, specified as the comma-separated pair consisting of `'BatchLimit'` and a positive integer. When the software processes `BatchLimit` batches, it terminates optimization.

- By default:
 - The software passes through the data `PassLimit` times.
 - If you specify multiple solvers, and use (A)SGD to get an initial approximation for the next solver, then the default value is `ceil(1e6/BatchSize)`. `BatchSize` is the value of the `'BatchSize'` name-value pair argument.
- If you specify `'BatchLimit'` and `'PassLimit'`, then the software chooses the argument that results in processing the fewest observations.
- If you specify `'BatchLimit'` but not `'PassLimit'`, then the software processes enough batches to complete up to one entire pass through the data.

Example: `'BatchLimit', 100`

Data Types: `single` | `double`

'BetaTolerance' — Relative tolerance on linear coefficients and bias term

`1e-4` (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = \begin{bmatrix} \beta_t' & b_t \end{bmatrix}$, that is, the vector of the coefficients and the bias term at optimization

iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance', 1e-6`

Data Types: `single` | `double`

'NumCheckConvergence' — Number of batches to process before next convergence check

positive integer

Number of batches to process before next convergence check, specified as the comma-separated pair consisting of `'NumCheckConvergence'` and a positive integer.

To specify the batch size, see `BatchSize`.

The software checks for convergence about 10 times per pass through the entire data set by default.

Example: `'NumCheckConvergence',100`

Data Types: `single` | `double`

'PassLimit' — Maximal number of passes

1 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer.

`fitrlinear` processes all observations when it completes one pass through the data.

When `fitrlinear` passes through the data `PassLimit` times, it terminates optimization.

If you specify `'BatchLimit'` and `PassLimit`, then `fitrlinear` chooses the argument that results in processing the fewest observations. For more details, see “Algorithms” on page 25-2086.

Example: `'PassLimit',5`

Data Types: `single` | `double`

'ValidationData' — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of `'ValidationData'` and a cell array.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 25-2086. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- `ValidationData(1)` must contain an m -by- p or p -by- m full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. The number of observations in both sets can vary.

- `ValidationData(2)` must contain an array of m responses with length corresponding to the number of observations in `ValidationData{1}`.
- Optionally, `ValidationData(3)` can contain an m -dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

'GradientTolerance' — Absolute gradient tolerance

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of `'GradientTolerance'` and a nonnegative scalar. `GradientTolerance` applies to these values of `Solver`: `'bfgs'`, `'lbfgs'`, and `'sparsa'`.

Let ∇L_t be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla L\|_{\infty} = \max|\nabla L| < \text{GradientTolerance}$, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when `fitrlinear` satisfies either stopping criterion.

If `fitrlinear` converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, `fitrlinear` uses the next solver specified in `Solver`.

Example: `'GradientTolerance', eps`

Data Types: `single` | `double`

'IterationLimit' — Maximal number of optimization iterations

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer. `IterationLimit` applies to these values of `Solver`: `'bfgs'`, `'lbfgs'`, and `'sparsa'`.

Example: 'IterationLimit',1e7

Data Types: single | double

Dual SGD Optimization Convergence Controls

'BetaTolerance' — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = \begin{bmatrix} \beta_t' & b_t \end{bmatrix}$, that is, the vector of the coefficients and the bias term at optimization

iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify `DeltaGradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: 'BetaTolerance',1e-6

Data Types: single | double

'DeltaGradientTolerance' — Gradient-difference tolerance

0.1 (default) | nonnegative scalar

Gradient-difference tolerance between upper and lower pool Karush-Kuhn-Tucker (KKT) complementarity conditions violators, specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar. `DeltaGradientTolerance` applies to the 'dual' value of `Solver` only.

- If the magnitude of the KKT violators is less than `DeltaGradientTolerance`, then `fitrlinear` terminates optimization.
- If `fitrlinear` converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, `fitrlinear` uses the next solver specified in `Solver`.

Example: 'DeltaGapTolerance',1e-2

Data Types: `double` | `single`

'NumCheckConvergence' — Number of passes through entire data set to process before next convergence check

5 (default) | positive integer

Number of passes through entire data set to process before next convergence check, specified as the comma-separated pair consisting of `'NumCheckConvergence'` and a positive integer.

Example: `'NumCheckConvergence',100`

Data Types: `single` | `double`

'PassLimit' — Maximal number of passes

10 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer.

When the software completes one pass through the data, it has processed all observations.

When the software passes through the data `PassLimit` times, it terminates optimization.

Example: `'PassLimit',5`

Data Types: `single` | `double`

'ValidationData' — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of `'ValidationData'` and a cell array.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 25-2086. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- `ValidationData(1)` must contain an m -by- p or p -by- m full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in

the training data `X` and `ValidationData{1}` must correspond. The number of observations in both sets can vary.

- `ValidationData(2)` must contain an array of m responses with length corresponding to the number of observations in `ValidationData{1}`.
- Optionally, `ValidationData(3)` can contain an m -dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

BFGS, LBFGS, and SpARSA Convergence Controls

'BetaTolerance' — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = \begin{bmatrix} \beta_t' & b_t \end{bmatrix}$, that is, the vector of the coefficients and the bias term at optimization

iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify `GradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: 'BetaTolerance', 1e-6

Data Types: single | double

'GradientTolerance' — Absolute gradient tolerance

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of `'GradientTolerance'` and a nonnegative scalar.

Let ∇_{L_t} be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla_{L_t}\|_{\infty} = \max|\nabla_{L_t}| < \text{GradientTolerance}$, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in the software, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'GradientTolerance', 1e-5`

Data Types: `single` | `double`

'HessianHistorySize' — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of history buffer for Hessian approximation, specified as the comma-separated pair consisting of `'HessianHistorySize'` and a positive integer. That is, at each iteration, the software composes the Hessian using statistics from the latest `HessianHistorySize` iterations.

The software does not support `'HessianHistorySize'` for `SpaRSA`.

Example: `'HessianHistorySize', 10`

Data Types: `single` | `double`

'IterationLimit' — Maximal number of optimization iterations

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer. `IterationLimit` applies to these values of `Solver`: `'bfgs'`, `'lbfgs'`, and `'sparsa'`.

Example: `'IterationLimit', 500`

Data Types: `single` | `double`

'ValidationData' — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 25-2086. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- `ValidationData(1)` must contain an m -by- p or p -by- m full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. The number of observations in both sets can vary.
- `ValidationData(2)` must contain an array of m responses with length corresponding to the number of observations in `ValidationData{1}`.
- Optionally, `ValidationData(3)` can contain an m -dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

Output Arguments

Mdl — Trained linear regression model

`RegressionLinear` model object | `RegressionPartitionedLinear` cross-validated model object

Trained linear regression model, returned as a `RegressionLinear` model object or `RegressionPartitionedLinear` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `RegressionPartitionedLinear` cross-validated model object. Otherwise, `Mdl` is a `RegressionLinear` model object.

To reference properties of `Mdl`, use dot notation. For example, enter `Mdl.Beta` in the Command Window to display the vector or matrix of estimated coefficients.

Note: Unlike other regression models, and for economical memory usage, `RegressionLinear` and `RegressionPartitionedLinear` model objects do not store the training data or optimization details (for example, convergence history).

FitInfo — Optimization details

structure array

Optimization details, returned as a structure array.

Fields specify final values or name-value pair argument specifications, for example, `Objective` is the value of the objective function when optimization terminates. Rows of multidimensional fields correspond to values of `Lambda` and columns correspond to values of `Solver`.

This table describes some notable fields.

Field	Description														
<code>TerminationStatus</code>	<ul style="list-style-type: none"> Reason for optimization termination Corresponds to a value in <code>TerminationCode</code> 														
<code>FitTime</code>	Elapsed, wall-clock time in seconds														
<code>History</code>	<p>A structure array of optimization information for each iteration. The field <code>Solver</code> stores solver types using integer coding.</p> <table border="1"> <thead> <tr> <th>Integer</th> <th>Solver</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>SGD</td> </tr> <tr> <td>2</td> <td>ASGD</td> </tr> <tr> <td>3</td> <td>Dual SGD for SVM</td> </tr> <tr> <td>4</td> <td>LBFSGS</td> </tr> <tr> <td>5</td> <td>BFGS</td> </tr> <tr> <td>6</td> <td>SpaRSA</td> </tr> </tbody> </table>	Integer	Solver	1	SGD	2	ASGD	3	Dual SGD for SVM	4	LBFSGS	5	BFGS	6	SpaRSA
Integer	Solver														
1	SGD														
2	ASGD														
3	Dual SGD for SVM														
4	LBFSGS														
5	BFGS														
6	SpaRSA														

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.History.Objective`.

It is good practice to examine `FitInfo` to assess whether convergence is satisfactory.

Note: If `Learner` is `'leastsquares'`, then the loss term in the objective function is half of the MSE. `loss` returns the MSE by default. Therefore, if you use `loss` to check the resubstitution, or training, error then there is a discrepancy between the MSE returned by `loss` and optimization results in `FitInfo` or returned to the command line by setting a positive verbosity level using `Verbose`.

More About

Warm Start

A *warm start* is initial estimates of the beta coefficients and bias term supplied to an optimization routine for quicker convergence.

Tips

- It is a best practice to orient your predictor matrix so that observations correspond to columns and to specify `'ObservationsIn'`, `'columns'`. As a result, you can experience a significant reduction in optimization-execution time.
- For better optimization accuracy if `X` is high-dimensional and `Regularization` is `'ridge'`, set any of these combinations for `Solver`:
 - `'sgd'`
 - `'asgd'`
 - `'dual'` if `Learner` is `'svm'`
 - `{'sgd', 'lbfgs'}`
 - `{'asgd', 'lbfgs'}`
 - `{'dual', 'lbfgs'}` if `Learner` is `'svm'`

Other combinations can result in poor optimization accuracy.

- For better optimization accuracy if `X` is moderate- through low-dimensional and `Regularization` is `'ridge'`, set `Solver` to `'bfgs'`.
- If `Regularization` is `'lasso'`, set any of these combinations for `Solver`:
 - `'sgd'`
 - `'asgd'`

- 'sparsa'
- {'sgd', 'sparsa'}
- {'asgd', 'sparsa'}
- When choosing between SGD and ASGD, consider that:
 - SGD takes less time per iteration, but requires more iterations to converge.
 - ASGD requires fewer iterations to converge, but takes more time per iteration.
- If X has few observations, but many predictor variables, then:
 - Specify 'PostFitBias', true.
 - For SGD or ASGD solvers, set `PassLimit` to a positive integer that is greater than 1, for example, 5 or 10. This setting often results in better accuracy.
- For SGD and ASGD solvers, `BatchSize` affects the rate of convergence.
 - If `BatchSize` is too small, then `fitrlinear` achieves the minimum in many iterations, but computes the gradient per iteration quickly.
 - If `BatchSize` is too large, then `fitrlinear` achieves the minimum in fewer iterations, but computes the gradient per iteration slowly.
- Large learning rates (see `LearnRate`) speed up convergence to the minimum, but can lead to divergence (that is, over-stepping the minimum). Small learning rates ensure convergence to the minimum, but can lead to slow termination.
- When using lasso penalties, experiment with various values of `TruncationPeriod`. For example, set `TruncationPeriod` to 1, 10, and then 100.
- For efficiency, `fitrlinear` does not standardize predictor data. To standardize X , enter

```
X = bsxfun(@rdivide, bsxfun(@minus, X, mean(X, 2)), std(X, 0, 2));
```

The code requires that you orient the predictors and observations as the rows and columns of X , respectively. Also, for memory-usage economy, the code replaces the original predictor data the standardized data.

Algorithms

- If you specify `ValidationData`, then, during objective-function optimization:
 - `fitrlinear` estimates the validation loss of `ValidationData` periodically using the current model, and tracks the minimal estimate.

- When `fitrlinear` estimates a validation loss, it compares the estimate to the minimal estimate.
- When subsequent, validation loss estimates exceed the minimal estimate five times, `fitrlinear` terminates optimization.
- If you specify `ValidationData` and to implement a cross-validation routine (`CrossVal`, `CVPartition`, `Holdout`, or `KFold`), then:
 - 1 `fitrlinear` randomly partitions X and Y according to the cross-validation routine that you choose.
 - 2 `fitrlinear` trains the model using the training-data partition. During objective-function optimization, `fitrlinear` uses `ValidationData` as another possible way to terminate optimization (for details, see the previous bullet).
 - 3 Once `fitrlinear` satisfies a stopping criterion, it constructs a trained model based on the optimized linear coefficients and intercept.
 - a If you implement k -fold cross-validation, and `fitrlinear` has not exhausted all training-set folds, then `fitrlinear` returns to Step 2 to train using the next training-set fold.
 - b Otherwise, `fitrlinear` terminates training, and then returns the cross-validated model.
 - 4 You can determine the quality of the cross-validated model. For example:
 - To determine the validation loss using the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldLoss`.
 - To predict observations on the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldPredict`.

Introduced in R2016a

fitrm

Fit repeated measures model

Syntax

```
rm = fitrm(t,modelspec)
rm = fitrm(t,modelspec,Name,Value)
```

Description

`rm = fitrm(t,modelspec)` returns a repeated measures model, specified by `modelspec`, fitted to the variables in the table or dataset array `t`.

`rm = fitrm(t,modelspec,Name,Value)` returns a repeated measures model, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the hypothesis for the within-subject factors.

Examples

Fit a Repeated Measures Model

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = table([1 2 3 4]','VariableNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the `species` is the predictor variable.

```

rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas)
rm =
  RepeatedMeasuresModel with properties:
  Between Subjects:
    BetweenDesign: [150x5 table]
    ResponseNames: {'meas1' 'meas2' 'meas3' 'meas4'}
    BetweenFactorNames: {'species'}
    BetweenModel: '1 + species'
  Within Subjects:
    WithinDesign: [4x1 table]
    WithinFactorNames: {'Measurements'}
    WithinModel: 'separatemeans'
  Estimates:
    Coefficients: [3x4 table]
    Covariance: [4x4 table]

```

Display the coefficients.

```
rm.Coefficients
```

```
ans =
```

	meas1	meas2	meas3	meas4
(Intercept)	5.8433	3.0573	3.758	1.1993
species_setosa	-0.83733	0.37067	-2.296	-0.95333
species_versicolor	0.092667	-0.28733	0.502	0.12667

`fitrm` uses the 'effects' contrasts which means that the coefficients sum to 0. The `rm.DesignMatrix` has one column of 1s for the intercept, and two other columns `species_setosa` and `species_versicolor`, which are as follows:

$$\text{species_setosa} = \begin{cases} 1, & \text{if } setosa \\ 0, & \text{if } versicolor \\ -1, & \text{if } virginica \end{cases} \quad \text{and} \quad \text{species_versicolor} = \begin{cases} 0, & \text{if } setosa \\ 1, & \text{if } versicolor \\ -1, & \text{if } virginica \end{cases}$$

Display the covariance matrix.

```
rm.Covariance
```

```
ans =
```

	meas1	meas2	meas3	meas4
meas1	0.26501	0.092721	0.16751	0.038401
meas2	0.092721	0.11539	0.055244	0.03271
meas3	0.16751	0.055244	0.18519	0.042665
meas4	0.038401	0.03271	0.042665	0.041882

Specify the Within-Subject Hypothesis

Navigate to the folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load('longitudinalData')
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];
```

Store the data in a proper table array format to conduct repeated measures analysis.

```
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5),...
'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where blood levels are the responses and gender is the predictor variable. Also define the hypothesis for within-subject factors.

```
rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time,'WithinModel','orthogonalcontrasts')
```

```
rm =  
  
RepeatedMeasuresModel with properties:  
  
Between Subjects:  
  BetweenDesign: [16x6 table]  
  ResponseNames: {'t0' 't2' 't4' 't6' 't8'}  
  BetweenFactorNames: {'Gender'}  
  BetweenModel: '1 + Gender'  
  
Within Subjects:  
  WithinDesign: [5x1 table]  
  WithinFactorNames: {'Time'}  
  WithinModel: 'orthogonalcontrasts'  
  
Estimates:  
  Coefficients: [2x5 table]  
  Covariance: [5x5 table]
```

Fit a Model with Covariates

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the eight repeated measurements `y1–y8` as responses and the between-subject factors `Group`, `Gender`, `IQ`, and `Age`. `IQ` and `Age` as continuous variables. The table `within` includes the within-subject factors `w1` and `w2`.

Fit a repeated measures model, where `age`, `IQ`, and `group`, `gender` are the predictor variables, and the model includes the interaction effect of `group` and `gender`. Also define the within-subject factors.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender+Age+IQ', 'WithinDesign', within)
```

```
rm =

The display shows the coefficients for fitting the repeated measures as a function of the terms in the between-subjects model.

Input Arguments

t — Input data

table

Input data, which includes the values of the response variables and the between-subject factors to use as predictors in the repeated measures model, specified as a table.

Data Types: table

modelspec — Formula for model specification

string of the form 'y1-yk ~ terms'

Formula for model specification, specified as a string of the form `'y1-yk ~ terms'`. The responses and terms are specified using Wilkinson notation. `fitrm` treats the variables used in model terms as categorical if they are categorical (nominal or ordinal), logical, char arrays, or a cell arrays of strings.

For example, if you have four repeated measures as responses and the factors `x1`, `x2`, and `x3` as the predictor variables, then you can define a repeated measures model as follows.

Example: `'y1-y4 ~ x1 + x2 * x3'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'WithinDesign', 'W', 'WithinModel', 'w1+w2'` specifies the matrix `w` as the design matrix for within-subject factors, and the model for within-subject factors `w1` and `w2` is `'w1+w2'`.

'WithinDesign' — Design for within-subject factors

numeric vector of length r (default) | r -by- k numeric matrix | r -by- k table

Design for within-subject factors, specified as the comma-separated pair consisting of `'WithinDesign'` and one of the following:

- Numeric vector of length r , where r is the number of repeated measures.

In this case, `fitrm` treats the values in the vector as continuous, and these are typically time values.

- r -by- k numeric matrix of the values of the k within-subject factors, w_1, w_2, \dots, w_k .

In this case, `fitrm` treats all k variables as continuous.

- r -by- k table that contains the values of the k within-subject factors.

In this case, `fitrm` treats all numeric variables as continuous, and all categorical variables as categorical.

For example, if the table `weeks` contains the values of the within-subject factors, then you can define the design table as follows.

Example: `'WithinDesign', weeks`

Data Types: `single` | `double` | `table`

'WithinModel' — Model specifying within-subject hypothesis test

`'separatemeans'` (default) | `'orthogonalcontrasts'` | string that defines a model

Model specifying the within-subject hypothesis test, specified as the comma-separated pair consisting of `'WithinModel'` and one of the following:

- `'separatemeans'` — Compute a separate mean for each group.
- `'orthogonalcontrasts'` — This is valid only when the within-subject model has a single numeric factor T . Responses are the average, the slope of centered T , and, in general, all orthogonal contrasts for a polynomial up to $T^{(p-1)}$, where p is the number of rows in the within-subject model.
- A string that defines a model specification in the within-subject factors. You can define the model based on the rules for the `terms` in `modelspec`.

For example, if there are three within-subject factors `w1`, `w2`, and `w3`, then you can specify a model for the within-subject factors as follows.

Example: `'WithinModel', 'w1+w2+w2*w3'`

Data Types: `single` | `double`

Output Arguments

rm — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

More About

Model Specification Using Wilkinson Notation

Wilkinson notation describes the factors present in models. It does not describe the multipliers (coefficients) of those factors.

The following rules specify the responses in `modelspec`.

Wilkinson Notation	Meaning
Y1, Y2, Y3	Specific list of variables
Y1 - Y5	All table variables from Y1 through Y5

The following rules specify terms in `modelspec`.

Wilkinson notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1 * X2$
$X1 : X2$	$X1 * X2$ only
$-X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

`RepeatedMeasuresModel`

Introduced in R2014a

fitdist

Fit probability distribution object to data

Syntax

```
pd = fitdist(x,distname)
pd = fitdist(x,distname,Name,Value)

[pdca,gn,gl] = fitdist(x,distname,'By',groupvar)
[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value)
```

Description

`pd = fitdist(x,distname)` creates a probability distribution object by fitting the distribution specified by `distname` to the data in column vector `x`.

`pd = fitdist(x,distname,Name,Value)` creates the probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

`[pdca,gn,gl] = fitdist(x,distname,'By',groupvar)` creates probability distribution objects by fitting the distribution specified by `distname` to the data in `x` based on the grouping variable `groupvar`. It returns a cell array of fitted probability distribution objects, `pdca`, a cell array of group labels, `gn`, and a cell array of grouping variable levels, `gl`.

`[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value)` returns the above output arguments using additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

Examples

Fit a Normal Distribution to Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 154 [148.728, 159.272]
sigma = 26.5714 [23.3299, 30.8674]
```

Plot the pdf of the distribution.

```
x_values = 50:1:250;
y = pdf(pd,x_values);
plot(x_values,y, 'LineWidth',2)
```

Fit a Kernel Distribution to Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create a kernel distribution object by fitting it to the data. Use the Epanechnikov kernel function.

```
pd = fitdist(x, 'Kernel', 'Kernel', 'epanechnikov')
```

```
pd =
```

```
KernelDistribution
```

```
Kernel = epanechnikov  
Bandwidth = 14.3792  
Support = unbounded
```

Plot the pdf of the distribution.

```
x_values = 50:1:250;  
y = pdf(pd,x_values);  
plot(x_values,y)
```

Fit Normal Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create normal distribution objects by fitting them to the data, grouped by patient gender.

```
gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Normal','By',gender)
```

```
pdca =
```

```
        [1x1 prob.NormalDistribution]    [1x1 prob.NormalDistribution]

gn =

    'Female'
    'Male'

gl =

    'Female'
    'Male'
```

The cell array `pdca` contains two probability distribution objects, one for each gender group. The cell array `gn` contains two strings of the group labels. The cell array `gl` contains two strings of the group levels.

View each distribution in the cell array `pdca` to compare the mean, `mu`, and the standard deviation, `sigma`, grouped by patient gender.

```
female = pdca{1} % Distribution for females
```

```
female =

    NormalDistribution

    Normal distribution
        mu = 130.472    [128.183, 132.76]
        sigma = 8.30339    [6.96947, 10.2736]
```

```
male = pdca{2} % Distribution for males
```

```
male =

    NormalDistribution

    Normal distribution
        mu = 180.532    [177.833, 183.231]
```

```
sigma = 9.19322 [7.63933, 11.5466]
```

Compute the pdf of each distribution.

```
x_values = 50:1:250;  
femalepdf = pdf(female,x_values);  
malepdf = pdf(male,x_values);
```

Plot the pdfs for a visual comparison of weight distribution by gender.

```
figure  
plot(x_values,femalepdf,'LineWidth',2)  
hold on  
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)  
legend(gn,'Location','NorthEast')  
hold off
```

Fit Kernel Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create kernel distribution objects by fitting them to the data, grouped by patient gender. Use a triangular kernel function.

```
gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Kernel','By',gender,'Kernel','triangle');
```

View each distribution in the cell array `pdca` to see the kernel distributions for each gender.

```
female = pdca{1} % Distribution for females
```

```
female =
```

```
KernelDistribution  
  
Kernel = triangle  
Bandwidth = 4.25894  
Support = unbounded
```

```
male = pdca{2} % Distribution for males
```

```
male =
```

```
KernelDistribution  
  
Kernel = triangle  
Bandwidth = 5.08961  
Support = unbounded
```

Compute the pdf of each distribution.

```
x_values = 50:1:250;  
femalepdf = pdf(female,x_values);  
malepdf = pdf(male,x_values);
```

Plot the pdfs for a visual comparison of weight distribution by gender.

```
figure  
plot(x_values,femalepdf,'LineWidth',2)  
hold on  
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)  
legend(gn,'Location','NorthEast')  
hold off
```

Input Arguments

x — Input data

column vector

Input data, specified as a column vector. `fitdist` ignores NaN values in `x`. Additionally, any NaN values in the censoring vector or frequency vector causes `fitdist` to ignore the corresponding values in `x`.

Data Types: `single` | `double`

distname — Distribution name

string

Distribution name, specified as one of the following strings. The distribution specified by `distname` determines the class type of the returned probability distribution object.

Distribution Name	Description	Distribution Class
'Beta '	Beta distribution	prob.BetaDistribution
'Binomial '	Binomial distribution	prob.BinomialDistribution
'BirnbauSaunders '	Birnbau-Saunders distribution	prob.BirnbauSaundersDistribution
'Burr '	Burr distribution	prob.BurrDistribution
'Exponential '	Exponential distribution	prob.ExponentialDistribution
'ExtremeValue '	Extreme Value distribution	prob.ExtremeValueDistribution
'Gamma '	Gamma distribution	prob.GammaDistribution
'GeneralizedExtremeVal	Generalized Extreme Value distribution	prob.GeneralizedExtremeValueDistribution
'GeneralizedPareto '	Generalized Pareto distribution	prob.GeneralizedParetoDistribution
'HalfNormal '	Half-normal distribution	prob.HalfNormalDistribution
'InverseGaussian '	Inverse Gaussian distribution	prob.InverseGaussianDistribution
'Kernel '	Kernel distribution	prob.KernelDistribution
'Logistic '	Logistic distribution	prob.LogisticDistribution
'Loglogistic '	Loglogistic distribution	prob.LoglogisticDistribution
'Lognormal '	Lognormal distribution	prob.LognormalDistribution
'Nakagami '	Nakagami distribution	prob.NakagamiDistribution
'NegativeBinomial '	Negative Binomial distribution	prob.NegativeBinomialDistribution
'Normal '	Normal distribution	prob.NormalDistribution
'Poisson '	Poisson distribution	prob.PoissonDistribution
'Rayleigh '	Rayleigh distribution	prob.RayleighDistribution

Distribution Name	Description	Distribution Class
'Rician'	Rician distribution	prob.RicianDistribution
'Stable'	Stable distribution	prob.StableDistribution
'tLocationScale'	t Location-Scale distribution	prob.tLocationScaleDistribution
'Weibull'	Weibull distribution	prob.WeibullDistribution

groupvar — Grouping variable

categorical array | logical or numeric vector | cell array of strings

Grouping variable, specified as a categorical array, logical or numeric vector, or cell array of strings. Each unique value in a grouping variable defines a group.

For example, if `Gender` is a cell array of strings with values 'Male' and 'Female', you can use `Gender` as a grouping variable to fit a distribution to your data by gender.

More than one grouping variable can be used by specifying a cell array of grouping variable names. Observations are placed in the same group if they have common values of all specified grouping variables.

For example, if `Smoker` is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array `{Gender, Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker.

Example: `{Gender, Smoker}`

Data Types: single | double | logical | cell | char

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `fitdist(x, 'Kernel', 'Kernel', 'triangle')` fits a kernel distribution object to the data in `x` using a triangular kernel function.

'Censoring' — Logical flag for censored data

0 (default) | vector of logical values

Logical flag for censored data, specified as the comma-separated pair consisting of `'Censoring'` and a vector of logical values that is the same size as input vector `x`. The value is 1 when the corresponding element in `x` is a right-censored observation and 0 when the corresponding elements is an exact observation. The default is a vector of 0s, indicating that all observations are exact.

`fitdist` ignores any NaN values in this censoring vector. Additionally, any NaN values in `x` or the frequency vector causes `fitdist` to ignore the corresponding values in the censoring vector.

Data Types: `logical`

'Frequency' — Observation frequency

1 (default) | vector of nonnegative integer values

Observation frequency, specified as the comma-separated pair consisting of `'Frequency'` and a vector of nonnegative integer values that is the same size as input vector `x`. Each element of the frequency vector specifies the frequencies for the corresponding elements in `x`. The default is a vector of 1s, indicating that each value in `x` only appears once.

`fitdist` ignores any NaN values in this frequency vector are ignored by the fitting calculations. Additionally, any NaN values in `x` or the censoring vector causes `fitdist` to ignore the corresponding values in the frequency vector.

Data Types: `logical`

'Options' — Control parameters

structure

Control parameters for the iterative fitting algorithm, specified as the comma-separated pair consisting of `'Options'` and a structure you create using `statset`.

Data Types: `struct`

'NTrials' — Number of trials

positive integer value

Number of trials for the binomial distribution, specified as the comma-separated pair consisting of `'NTrials'` and a positive integer value. You must specify `distname` as `'Binomial'` to use this option.

Data Types: `single` | `double`

'Theta' — Threshold parameter

0 (default) | scalar value

Threshold parameter for the generalized Pareto distribution, specified as the comma-separated pair consisting of `'Theta'` and a scalar value. You must specify `distname` as `'GeneralizedPareto'` to use this option.

Data Types: `single` | `double`**'Kernel' — Kernel smoother type**`'normal'` (default) | `'box'` | `'triangle'` | `'epanechnikov'`

Kernel smoother type, specified as the comma-separated pair consisting of `'Kernel'` and one of the following:

- `'normal'`
- `'box'`
- `'triangle'`
- `'epanechnikov'`

You must specify `distname` as `'Kernel'` to use this option.

'Support' — Kernel density support`'unbounded'` (default) | `'positive'` | two-element vector

Kernel density support, specified as the comma-separated pair consisting of `'Support'` and a string or two-element vector. The string must be one of the following.

<code>'unbounded'</code>	Density can extend over the whole real line.
<code>'positive'</code>	Density is restricted to positive values.

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

You must specify `distname` as `'Kernel'` to use this option.

Data Types: `single` | `double`**'Width' — Bandwidth of kernel smoothing window**

scalar value

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of 'Width' and a scalar value. The default value used by `fitdist` is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes. You must specify `distname` as 'Kernel' to use this option.

Data Types: `single` | `double`

Output Arguments

pd — Probability distribution

probability distribution object

Probability distribution, returned as a probability distribution object. The distribution specified by `distname` determines the class type of the returned probability distribution object.

pdca — Probability distribution objects

cell array

Probability distribution objects of the type specified by `distname`, returned as a cell array.

gn — Group labels

cell array of strings

Group labels, returned as a cell array of strings.

g1 — Grouping variable levels

cell array of strings

Grouping variable levels, returned as a cell array of strings containing one column for each grouping variable.

Alternative Functionality

App

The Distribution Fitting app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can

then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitting app using `dfittool`, or click Distribution Fitting on the Apps tab.

More About

Algorithms

The `fitdist` function fits most distributions using maximum likelihood estimation. Two exceptions are the normal and lognormal distributions with uncensored data.

- For the uncensored normal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance.
- For the uncensored lognormal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance of the log of the data.

Introduced in R2009a

fitensemble

Fitted ensemble for classification or regression

Syntax

```
Ensemble = fitensemble(TBL,ResponseVarName,Method,NLearn,Learners)
```

```
Ensemble = fitensemble(TBL,formula,Method,NLearn,Learners)
```

```
Ensemble = fitensemble(TBL,Y,Method,NLearn,Learners)
```

```
Ensemble = fitensemble(X,Y,Method,NLearn,Learners)
```

```
Ensemble = fitensemble( ____,Method,NLearn,Learners,Name,Value)
```

Description

```
Ensemble = fitensemble(TBL,ResponseVarName,Method,NLearn,Learners)
```

creates an ensemble model that predicts responses to data. The ensemble consists of models listed in `Learners`.

```
Ensemble = fitensemble(TBL,formula,Method,NLearn,Learners)
```

creates an ensemble model that predicts responses to data. The ensemble consists of models listed in `Learners`.

```
Ensemble = fitensemble(TBL,Y,Method,NLearn,Learners)
```

creates an ensemble model that predicts responses to data. The ensemble consists of models listed in `Learners`.

```
Ensemble = fitensemble(X,Y,Method,NLearn,Learners)
```

creates an ensemble model that predicts responses to data. The ensemble consists of models listed in `Learners`.

```
Ensemble = fitensemble( ____,Method,NLearn,Learners,Name,Value)
```

creates an ensemble model with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes. You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Input Arguments

TBL

Predictor data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor. Optionally, TBL can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of strings are not allowed.

If TBL contains the response variable, and you want to use all remaining variables in TBL as predictors, then specify the response variable using `ResponseVarName`.

If TBL contains the response variable, and you want to use only a subset of the remaining variables in TBL as predictors, then specify a formula string using `formula`.

If TBL does not contain the response variable, then specify a response variable using `Y`. The length of response variable and the number of rows of TBL must be equal.

ResponseVarName

Response variable name, specified as the name of a variable in TBL.

You must specify `ResponseVarName` as a string. For example, if the response variable `Y` is stored as `TBL.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of TBL, including `Y`, as predictors when training the model.

formula

Response and predictor variables to use in model training, specified as a string in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables.

To specify a subset of variables in TBL as predictors for training the model, use a formula string. If you specify a formula string, then any variables in TBL that do not appear in `formula` are not used to train the model.

X

Matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

Y

For classification, Y is a categorical variable, character array, or cell array of strings. Each row of Y represents the classification of the corresponding row of X.

For regression, Y is a numeric column vector with the same number of rows as X. Each entry in Y is the response to the data in the corresponding row of X.

Method

Case-insensitive string consisting of one of the following.

- For classification with two classes:
 - 'AdaBoostM1'
 - 'LogitBoost'
 - 'GentleBoost'
 - 'RobustBoost' (requires an Optimization Toolbox license)
 - 'LPBoost' (requires an Optimization Toolbox license)
 - 'TotalBoost' (requires an Optimization Toolbox license)
 - 'RUSBoost'
 - 'Subspace'
 - 'Bag'
- For classification with three or more classes:
 - 'AdaBoostM2'
 - 'LPBoost' (requires an Optimization Toolbox license)
 - 'TotalBoost' (requires an Optimization Toolbox license)
 - 'RUSBoost'
 - 'Subspace'
 - 'Bag'
- For regression:
 - 'LSBoost'
 - 'Bag'

'Bag' applies to all methods. So when you use 'Bag', indicate whether you want a classifier or regressor with the `type` name-value pair set to 'classification' or 'regression'.

NLearn

Number of ensemble learning cycles, a positive integer (or the string 'AllPredictorCombinations', see the next paragraph). At every training cycle, `fitensemble` loops over all learner templates in `Learners` and trains one weak learner for every template. The total number of trained learners in `Ensemble` is `NLearn*numel(Learners)`.

If you set `Method` to 'Subspace', you can set `NLearn` to 'AllPredictorCombinations'. With this setting, `fitensemble` constructs learners for all possible combinations of predictors taken `NPredToSample` at a time. This gives a total of `nchoosek(size(X,2),NPredToSample)` learners in the ensemble. You can use only one learner template for this setting.

`NLearn` for ensembles can vary from a few dozen to a few thousand. Usually, an ensemble with a good predictive power needs from a few hundred to a few thousand weak learners. You do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and, if necessary, train more weak learners using the `resume` method of the ensemble.

Learners

One of the following:

- A string with the name of a weak learner:
 - 'Discriminant' (recommended for 'Subspace')
 - 'KNN' (applies only to 'Subspace')
 - 'Tree' (applies to all methods except 'Subspace')
- A single weak learner template you create with `templateTree`, `templateKNN`, or `templateDiscriminant`.
- A cell array of weak learner templates. Usually you should supply only one weak learner template.

Ensemble performance depends on the parameters of the weak learners, and you can get poor performance using weak learners with default parameters. Specify the parameters

for the weak learners in the template. Specify parameters for the ensemble in the `fitensemble` name-value pairs.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

All Ensembles

'CategoricalPredictors'

List of categorical predictors. Pass `CategoricalPredictors` as one of:

- A numeric vector with indices from 1 to `p`, where `p` is the number of columns of `X`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `X` is a categorical variable.
- 'All', meaning all predictors are categorical.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in the `PredictorNames` property.
- A character matrix, where each row of the matrix is the name of a predictor variable. The names must match entries in the `PredictorNames` property. Pad the names with extra blanks so each row of the character matrix has the same length.

You can set `CategoricalPredictors` for these learners:

- 'Tree'
- 'KNN', when all predictors are categorical

By default, if the predictor data is in a matrix (`X`), `fitensemble` assumes that none of the predictors are categorical. If the predictor data is in a table (`TBL`), `fitensemble` assumes that a variable is categorical if it contains logical values, categorical values, or a cell array of strings.

'CrossVal'

If 'On', grows a cross-validated learner with 10 folds. You can use 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' parameters to override this cross-

validation setting. You can only use one of these four parameters ('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated learner.

Default: 'Off'

'CVPartition'

Partition created with `cvpartition` to use in a cross-validated learner. You can only use one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

'FResample'

Fraction of the training set to be selected by resampling for every weak learner. A numeric scalar from 0 through 1. This parameter has no effect unless you grow an ensemble by bagging or set 'Resample' to 'on'. The default setting is the one used most often for an ensemble grown by resampling.

Default: 1

'Holdout'

Holdout validation tests the specified fraction of the data, and uses the remaining data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated learner: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

'KFold'

Number of folds to use in a cross-validated learner, a positive integer greater than 1. You can only use one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Default: 10

'Leaveout'

Use leave-one-out cross validation by setting to 'on'. You can only use one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

'NPredToSample'

Number of predictors in each random subspace learner, a positive integer from 1 to `size(X,2)`.

Default: 1

'NPrint'

Printout frequency, a positive integer scalar. Set to 'Off' for no printout. Use this parameter to track how many weak learners have been trained so far. This is useful when you train ensembles with many learners on large data sets. If you use one of the cross-validation options, this parameter defines the printout frequency per number of cross-validation folds.

Default: 'Off'

'PredictorNames'

Cell array of names for the predictor variables, in the order in which they appear in X .

If you specify the predictors as a table (TBL), `PredictorNames` must be a subset of the variable names in TBL. In this case, the software uses only the variables in `PredictorNames` to train the model. If you use `formula` to specify the model, then you cannot use the `PredictorNames` name-value pair.

Default: {'x1', 'x2', ...}

'Replace'

'On' or 'Off'. If 'On', sample with replacement. If 'Off', sample without replacement. This parameter has no effect unless you grow an ensemble by bagging or set `Resample` to 'On'. If you set `Resample` to 'On' and `Replace` to 'Off', `fitensemble` samples training observations assuming uniform weights, and boosts by reweighting observations.

Default: 'On'

'Resample'

'On' or 'Off'. If 'On', grow an ensemble by resampling, with the resampling fraction given by `FResample`, and sampling with or without replacement given by `Replace`.

- Boosting — When 'Off', the boosting algorithm reweights observations at every learning iteration. When 'On', the algorithm samples training observations using updated weights as the multinomial sampling probabilities.
- Bagging — You can use only the default value of this parameter ('On').

Default: 'Off' for boosting, 'On' for bagging

'ResponseName'

Name of the response variable Y, a string.

Default: 'Y'

'Type'

String, either 'Classification' or 'Regression'. Specify Type when the Method is 'Bag'.

'Weights'

Vector of observation weights, or the name of a variable in the TBL. The length of Weights is the number of rows in X.

If you specify the input data as a table TBL, then Weights can be the name of a variable in TBL that contains a numeric vector. In this case, you must specify Weights as a variable name string. For example, if the weights vector W is stored as TBL.W, then specify it as 'W'. Otherwise, the software treats all columns of TBL, including W, as predictors when training the model.

Default: `ones(size(X,1),1)`

Classification Ensembles

'ClassNames'

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical vector, cell array of strings, character array, logical vector, or numeric vector. ClassNames must be the same data type as Y.

Use ClassNames to:

- Order the classes during training.
- Specify the order of output argument dimensions that correspond to classes. For example, use ClassNames to specify the column order of classification scores returned by `predict`.

- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is $\{ 'a', 'b', 'c' \}$. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames', $\{ 'a', 'c' \}$.

The default is the set of all distinct class names in Y .

Example: 'ClassNames', $\{ 'b', 'g' \}$

Default: Class names that exist in Y

'Cost'

Square matrix C , where $C(i, j)$ is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of $Cost$, additionally specify the **ClassNames** name-value pair argument.

Alternatively, **cost** can be a structure S having two fields:

- $S.ClassNames$ containing the group names as a categorical variable, character array, or cell array of strings
- $S.ClassificationCosts$ containing the cost matrix C

If **Method** is **Bag**, **Type** is **Classification**, and **Cost** is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty. For smaller sample sizes, this might cause a very low relative frequency of out-of-bag observations from the class that has a large penalty. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.

Default: $C(i, j) = 1$ if $i \neq j$, and $C(i, j) = 0$ if $i = j$

'Prior'

Prior probabilities for each class. Specify as one of:

- A string:
 - 'Empirical' determines class probabilities from class frequencies in Y . If you pass observation weights, they are used to compute the class probabilities.
 - 'Uniform' sets all class probabilities equal.
- A vector (one scalar value for each class). To specify the class order for the corresponding elements of **Prior**, additionally specify the **ClassNames** name-value pair argument.

- A structure `S` with two fields:
 - `S.ClassNames` containing the class names as a categorical variable, character array, or cell array of strings
 - `S.ClassProbs` containing a vector of corresponding probabilities

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

If `Method` is `Bag`, `Type` is `Classification`, and `Prior` is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large prior probability. For smaller sample sizes, this might cause a very low relative frequency of out-of-bag observations from the class that has a large prior probability. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.

Default: `'Empirical'`

AdaBoostM1, AdaBoostM2, LogitBoost, GentleBoost, RUSBoost, and LSBoost

'LearnRate'

Learning rate for shrinkage, a numeric scalar from 0 to 1. If you set the learning rate to less than 1, the ensemble requires more learning iterations but often achieves a better accuracy. 0.1 is a popular choice for an ensemble grown with shrinkage.

Default: 1

RUSBoost

'RatioToSmallest'

Either a numeric scalar or vector with `K` elements when there are `K` classes. Every element of this vector is the sampling proportion for this class with respect to the class with fewest observations in `Y`. If you pass a scalar, the software uses this sampling proportion for all classes. For example, suppose you have class `A` with 100 observations and class `B` with 10 observations. If you pass `[2 1]` for `'RatioToSmallest'`, every learner in the ensemble is trained on 20 observations of class `A` and 10 observations of class `B`. If you pass 2 or `[2 2]`, every learner is trained on 20 observations of class `A` and 20 observations of class `B`. If you specify class names by using the `ClassNames` name-

value pair argument of the fitting function, then the software matches elements in the array of class names to elements in this vector.

Default: ones(K,1)

LPBoost and TotalBoost

'MarginPrecision'

Margin precision, a numeric scalar between 0 and 1. **MarginPrecision** affects the number of boosting iterations required for conversion. Use a small value to grow an ensemble with many learners, and use a large value to grow an ensemble with few learners.

Default: 0.01

RobustBoost

'RobustErrorGoal'

Target classification error for **RobustBoost**, a numeric scalar from 0 through 1. Usually there is an optimal range for this parameter for your training data. If you set the error goal too low or too high, **RobustBoost** can produce a model with poor classification accuracy.

Default: 0.1

'RobustMarginSigma'

Spread of the distribution of classification margins over the training set for **RobustBoost**, a numeric positive scalar. You should consult literature on **RobustBoost** before setting this parameter

Default: 0.1

'RobustMaxMargin'

Maximal classification margin for **RobustBoost** in the training set, a nonnegative numeric scalar. **RobustBoost** minimizes the number of observations in the training set with classification margins below **RobustMaxMargin**.

Default: 0

Output Arguments

Ensemble

Ensemble object for predicting characteristics. The class of `Ensemble` depends on settings. In the following table, cross-validation names are `CrossVal`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Settings	Class
Resample name-value pair is <code>'Off'</code> , and you don't set a cross-validation name-value pair argument.	<code>ClassificationEnsemble</code>
Resample name-value pair is <code>'Off'</code> , and you don't set a cross-validation name-value pair argument.	<code>RegressionEnsemble</code>
Resample name-value pair is <code>'On'</code> , type is <code>'classification'</code> , and you don't set a cross-validation name-value pair argument.	<code>ClassificationBaggedEnsemble</code>
Resample name-value pair is <code>'On'</code> , type is <code>'regression'</code> , and you don't set a cross-validation name-value pair argument.	<code>RegressionBaggedEnsemble</code>
Method is a classification method, and you set a cross-validation name-value pair argument.	<code>ClassificationPartitionedEnsemble</code>
Method is a regression method, and you set a cross-validation name-value pair argument.	<code>RegressionPartitionedEnsemble</code>

Examples

Estimate the Resubstitution Loss of a Boosting Ensemble

Estimate the resubstitution loss of a trained, boosting classification ensemble of decision trees.

Load the `ionosphere` data set.

```
load ionosphere;
```

Train a decision tree ensemble using AdaBoost, 100 learning cycles, and the entire data set.

```
ClassTreeEns = fitensemble(X,Y, 'AdaBoostM1', 100, 'Tree');
```

`ClassTreeEns` is a trained `ClassificationEnsemble` ensemble classifier.

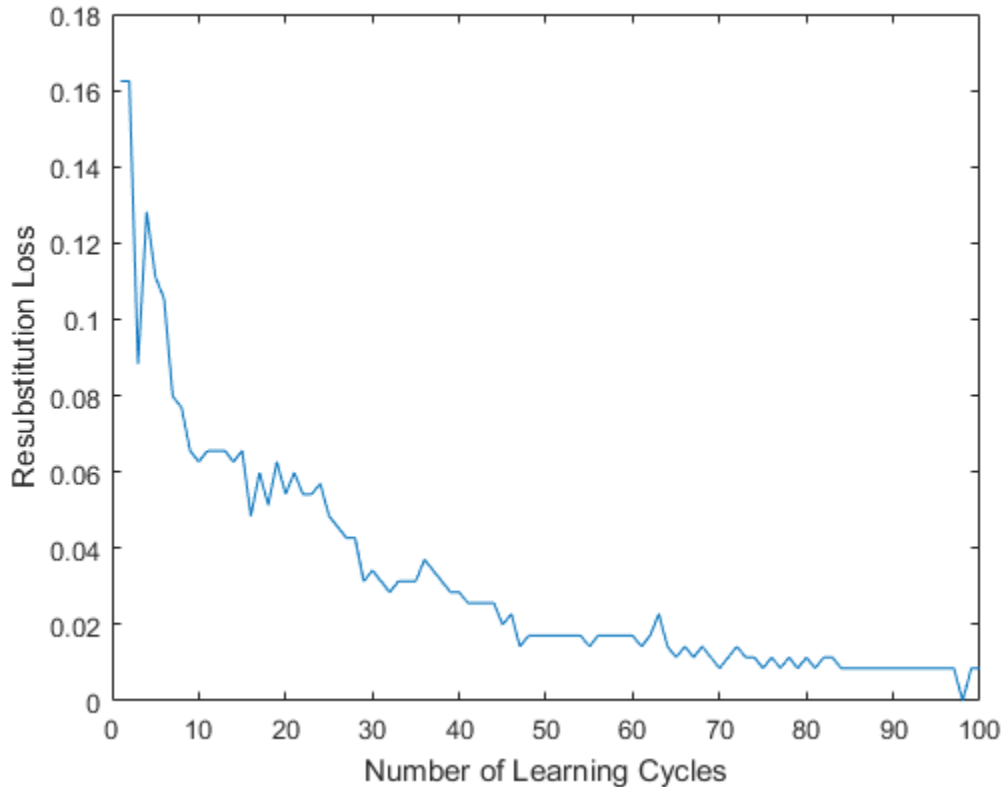

Determine the cumulative resubstitution losses (i.e., the cumulative misclassification error of the labels in the training data).

```
rsLoss = resubLoss(ClassTreeEns, 'Mode', 'Cumulative');
```

`rsLoss` is a 100-by-1 vector, where element k contains the resubstitution loss after the first k learning cycles.

Plot the cumulative resubstitution loss over the number of learning cycles.

```
plot(rsLoss);  
xlabel('Number of Learning Cycles');  
ylabel('Resubstitution Loss');
```

In general, as the number of decision trees in the trained classification ensemble increases, the resubstitution loss decreases.

A decrease in resubstitution loss might indicate that the software trained the ensemble sensibly. However, you cannot infer the predictive power of the ensemble by this decrease. To measure the predictive power of an ensemble, estimate the generalization error by:

- 1 Randomly partitioning the data into training and cross-validation sets. Do this by specifying `'holdout'`, `holdoutProportion` when you train the ensemble using `fitensemble`.

- 2 Passing the trained ensemble to `kfoldLoss`, which estimates the generalization error.

Train a Regression Ensemble

Use a trained, boosted regression tree ensemble to predict the fuel economy of a car. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors.

Load the `carsmall` data set. Set the predictors to `X`.

```
load carsmall
X = [Cylinders,Displacement,Horsepower,Weight];
xnames = {'Cylinders','Displacement','Horsepower','Weight'};
```

Specify a regression tree template that uses surrogate splits to improve predictive accuracy in the presence of NaN values.

```
RegTreeTemp = templateTree('Surrogate','On');
```

Train the regression tree ensemble using `LSBoost` and 100 learning cycles.

```
RegTreeEns = fitensemble(X,MPG,'LSBoost',100,RegTreeTemp,...
    'PredictorNames',xnames);
```

`RegTreeEns` is a trained `RegressionEnsemble` regression ensemble.

Use the trained regression ensemble to predict the fuel economy for a four-cylinder car with a 200-cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

```
predMPG = predict(RegTreeEns,[4 200 150 3000])
```

```
predMPG =
    22.6290
```

The average fuel economy of a car with these specifications is 21.78 mpg.

Estimate the Generalization Error of a Boosting Ensemble

Estimate the generalization error of a trained, boosting classification ensemble of decision trees.

Load the `ionosphere` data set.

```
load ionosphere;
```

Train a decision tree ensemble using `AdaBoostM1`, 100 learning cycles, and half of the data chosen randomly. The software validates the algorithm using the remaining half.

```
rng(2); % For reproducibility
ClassTreeEns = fitensemble(X,Y,'AdaBoostM1',100,'Tree',...
    'Holdout',0.5);
```

`ClassTreeEns` is a trained `ClassificationEnsemble` ensemble classifier.

Determine the cumulative generalization error, i.e., the cumulative misclassification error of the labels in the validation data).

```
genError = kfoldLoss(ClassTreeEns,'Mode','Cumulative');
```

`genError` is a 100-by-1 vector, where element k contains the generalization error after the first k learning cycles.

Plot the generalization error over the number of learning cycles.

```
plot(genError);
xlabel('Number of Learning Cycles');
ylabel('Generalization Error');
```

The cumulative generalization error decreases to approximately 7% when 25 weak learners compose the ensemble classifier.

Find the Optimal Number of Splits and Trees for an Ensemble

You can control the depth of the trees in an ensemble of decision trees. You can also control the tree depth in an ECOC model containing decision tree binary learners using the `MaxNumSplits`, `MinLeafSize`, or `MinParentSize` name-value pair parameters.

- When bagging decision trees, `fitensemble` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.
- When boosting decision trees, `fitensemble` grows stumps (a tree with one split) by default. You can grow deeper trees for better accuracy.

Load the `carsmall` data set. Specify the variables `Acceleration`, `Displacement`, `Horsepower`, and `Weight` as predictors, and `MPG` as the response.

```
load carsmall
X = [Acceleration Displacement Horsepower Weight];
Y = MPG;
```

The default values of the tree depth controllers for boosting regression trees are:

- 1 for `MaxNumSplits`. This option grows stumps.
- 5 for `MinLeafSize`
- 10 for `MinParentSize`

To search for the optimal number of splits:

- 1 Train a set of ensembles. Exponentially increase the maximum number of splits for subsequent ensembles from stump to at most $n - 1$ splits. Also, decrease the learning rate for each ensemble from 1 to 0.1.
- 2 Cross validate the ensembles.
- 3 Estimate the cross-validated mean-squared error (MSE) for each ensemble.
- 4 Compare the cross-validated MSEs. The ensemble with the lowest one performs the best, and indicates the optimal maximum number of splits, number of trees, and learning rate for the data set.

Grow and cross validate a deep classification tree and a stump. Specify to use surrogate splits because the data contain missing values. These serve as benchmarks.

```
MdlDeep = fitrtree(X,Y,'CrossVal','on','MergeLeaves','off',...
    'MinParentSize',1,'Surrogate','on');
MdlStump = fitrtree(X,Y,'MaxNumSplits',1,'CrossVal','on','Surrogate','on');
```

Train the boosting ensembles using 150 regression trees. Cross validate the ensemble using 5-fold cross validation. Vary the maximum number of splits using the values in the sequence $\{2^0, 2^1, \dots, 2^m\}$, where m is such that 2^m is no greater than $n - 1$. For each variant, adjust the learning rate to each value in the set $\{0.1, 0.25, 0.5, 1\}$;

```
n = size(X,1);
m = floor(log2(n - 1));
lr = [0.1 0.25 0.5 1];
maxNumSplits = 2.^(0:m);
```

```

numTrees = 150;
Mdl = cell(numel(maxNumSplits),numel(lr));
rng(1); % For reproducibility
for k = 1:numel(lr);
    for j = 1:numel(maxNumSplits);
        t = templateTree('MaxNumSplits',maxNumSplits(j),'Surrogate','on');
        Mdl{j,k} = fitensemble(X,Y,'LSBoost',numTrees,t,...
            'Type','regression','KFold',5,'LearnRate',lr(k));
    end;
end;

```

Compute the cross-validated MSE for each ensemble.

```

kflAll = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kflAll,Mdl,'Uniform',false);
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(lr)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);

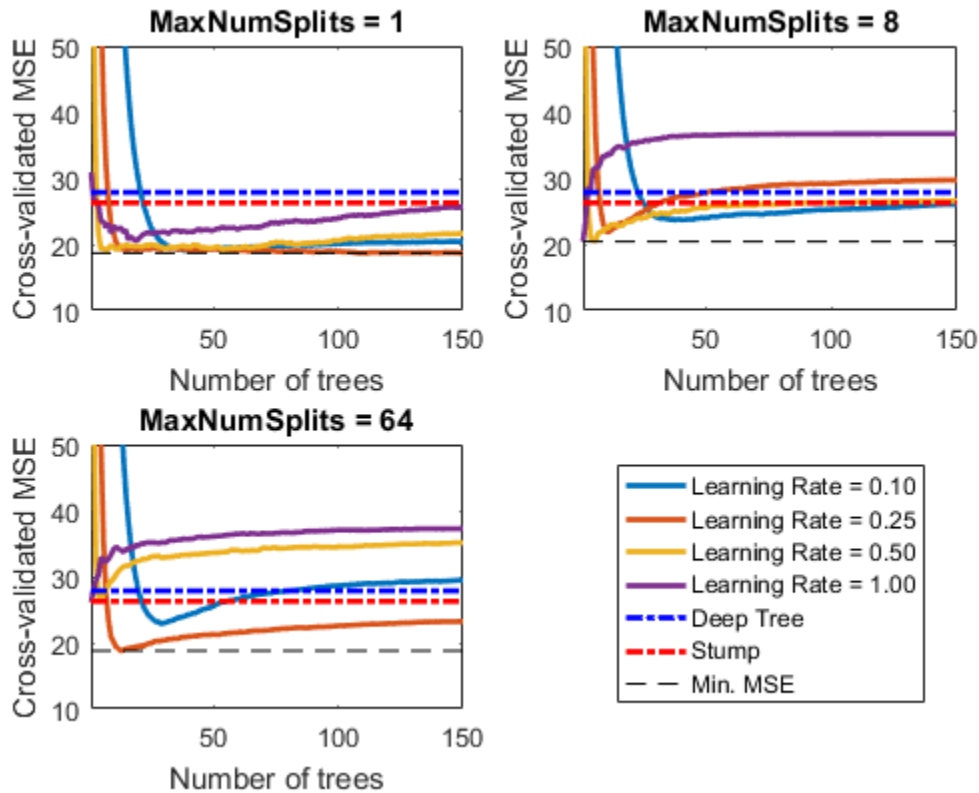

```

Plot how the cross-validated classification error behaves as the number of trees in the ensemble increases for a few of the ensembles, the deep tree, and the stump. Plot the curves with respect to learning rate in the same plot, and plot separate plots for varying tree complexities. Choose a subset of tree complexity levels.

```

mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
for k = 1:3;
    subplot(2,2,k);
    plot(squeeze(error(:,mnsPlot(k),:)), 'LineWidth',2);
    axis tight;
    hold on;
    h = gca;
    plot(h.XLim,[errorDeep errorDeep], '-.b', 'LineWidth',2);
    plot(h.XLim,[errorStump errorStump], '-.r', 'LineWidth',2);
    plot(h.XLim,min(min(error(:,mnsPlot(k),:)).*[1 1], '-.k'));
    h.YLim = [10 50];
    xlabel 'Number of trees';
    ylabel 'Cross-validated MSE';
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))));
    hold off;
end;
hL = legend([cellstr(num2str(lr),'Learning Rate = %0.2f'));...
    'Deep Tree'; 'Stump'; 'Min. MSE']);
hL.Position(1) = 0.6;

```

Each curve contains a minimum cross-validated MSE occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest MSE overall.

```
[minErr minErrIdxLin] = min(error(:));
[idxNumTrees idxMNS idxLR] = ind2sub(size(error),minErrIdxLin);

fprintf('\nMin. MSE = %0.5f',minErr)
fprintf('\nOptimal Parameter Values:\nNum. Trees = %d',idxNumTrees);
fprintf('\nMaxNumSplits = %d\nLearning Rate = %0.2f\n',...
        maxNumSplits(idxMNS),lr(idxLR))
```

```
Min. MSE = 18.38840
Optimal Parameter Values:
Num. Trees = 36
MaxNumSplits = 4
Learning Rate = 0.10
```

More About

Tips

Avoid large estimated out-of-bag error variances by setting a more balanced misclassification cost matrix or a less skewed prior probability vector. This is particularly important if you train using a small sample size.

Algorithms

- For details of boosting and bagging algorithms, see “Ensemble Algorithms” on page 17-159.
- `fitensemble` generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class might be very low. Therefore, the estimated out-of-bag error might have a large variance and might be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.
- For ensembles of decision trees, and for dual-core systems and above, `fitensemble` parallelizes training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.
- “Supervised Learning Workflow and Algorithms” on page 17-2
- “Ensemble Methods” on page 17-69

Introduced in R2011a

fitnlm

Fit nonlinear regression model

Syntax

```
mdl = fitnlm(tbl,modelfun,beta0)
mdl = fitnlm(X,y,modelfun,beta0)
mdl = fitnlm( ___,modelfun,beta0,Name,Value)
```

Description

`mdl = fitnlm(tbl,modelfun,beta0)` fits the model specified by `modelfun` to variables in the table or dataset array `tbl`, and returns the nonlinear model `mdl`.

`fitnlm` estimates model coefficients using an iterative procedure starting from the initial values in `beta0`.

`mdl = fitnlm(X,y,modelfun,beta0)` fits a nonlinear regression model using the column vector `y` as a response variable and the columns of the matrix `X` as predictor variables.

`mdl = fitnlm(___,modelfun,beta0,Name,Value)` fits a nonlinear regression model with additional options specified by one or more `Name,Value` pair arguments.

Examples

Nonlinear Model from a Table

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(tbl,modelfun,beta0)
```

```
mdl =
```

```
Nonlinear regression model:
```

```
MPG ~ b1 + b2*Horsepower^b3 + b4*Weight^b5
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

```
Number of observations: 392, Error degrees of freedom: 387
```

```
Root Mean Squared Error: 3.96
```

```
R-Squared: 0.745, Adjusted R-Squared 0.743
```

```
F-statistic vs. constant model: 283, p-value = 1.79e-113
```

Nonlinear Model from Matrix Data

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)
```

```
mdl =
```

```
Nonlinear regression model:
```

```
y ~ b1 + b2*x1^b3 + b4*x2^b5
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083

b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387
 Root Mean Squared Error: 3.96
 R-Squared: 0.745, Adjusted R-Squared 0.743
 F-statistic vs. constant model: 283, p-value = 1.79e-113

Adjust Fitting Options in the Nonlinear Model

Create a nonlinear model for auto mileage based on the `carbig` data. Strive for more accuracy by lowering the `TolFun` option, and observe the iterations by setting the `Display` option.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
```

Create options to lower `TolFun` and to report iterative display, and create a model using the options.

```
opts = statset('Display','iter','TolFun',1e-10);
mdl = fitnlm(X,y,modelfun,beta0,'Options',opts);
```

Iteration	SSE	Norm of Gradient	Norm of Step
0	1.82248e+06		
1	678600	788810	1691.07
2	616716	6.12739e+06	45.4738
%%% Many iterations deleted %%%			
122	6068.48	1.56393	0.629325
123	6068.48	1.13809	0.432543
124	6068.48	0.295962	0.297511

Iterations terminated: relative change in SSE less than OPTIONS.TolFun

Specify Nonlinear Regression Using Model String Syntax

Specify a nonlinear regression model for estimation using a function handle or model string syntax.

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Use a function handle to specify the Hougen-Watson model for the rate data.

```
mdl = fitnlm(X,y,@hougen,beta0)
```

```
mdl =
```

Nonlinear regression model:

```
y ~ hougen(b,X)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8

Root Mean Squared Error: 0.193

R-Squared: 0.999, Adjusted R-Squared 0.998

F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Alternatively, you can use a string expression to specify the Hougen-Watson model for the rate data.

```
myfun = 'y~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';
mdl2 = fitnlm(X,y,myfun,beta0)
```

```
mdl2 =
```

Nonlinear regression model:

```
y ~ (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)
```

Estimated Coefficients:

Estimate Nonlinear Regression Using Robust Fitting Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where b_1 , b_2 , and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x) (b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options. Here, use a string expression to specify the model.

```
b0 = [2;2;2];
modelstr = 'y ~ b1 + b2*exp(-b3*x)';

mdl = fitnlm(x,y,modelstr,b0,'Options',opts)

mdl =
```

```
Nonlinear regression model (robust fit):  
y ~ b1 + b2*exp( - b3*x)
```

```
Estimated Coefficients:

```

Fit Nonlinear Regression Model Using Weights Function Handle

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;  
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
mdl = fitnlm(X,y,@hougen,beta0,'Weights',weights)
```

```
mdl =
```

```
Nonlinear regression model:  
y ~ hougen(b,X)
```

```
Estimated Coefficients:

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. If you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variable must be numeric.

You specify the response and predictor names in your model string. If you do not provide a model string, you can set a different column as the response variable by using the `ResponseVar` name-value pair argument. You can select a subset of the columns as predictors by using the `PredictorVars` name-value pair argument.

Data Types: single | double | logical

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

Data Types: single | double | logical

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: single | double

modelfun — Functional form of the model

function handle | string of the form ' $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ '

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where

- `b` is a coefficient vector with the same number of elements as `beta0`.
- `x` is a matrix with the same number of columns as `X` or the number of predictor variable columns of `tbl`.

`modelfun(b,x)` returns a column vector that contains the same number of rows as `x`. Each row of the vector is the result of evaluating `modelfun` on the corresponding row of `x`. In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. `modelfun` should return real numbers to obtain meaningful coefficients.

- String of the form `'y ~ f(b1,b2,...,bj,x1,x2,...,xk)'`, where `f` represents a scalar function of the scalar coefficient variables `b1,...,bj` and the scalar data variables `x1,...,xk`.

beta0 – Coefficients

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. `NonLinearModel` starts its search for optimal coefficients from `beta0`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'ErrorModel','combined','Exclude',2,'Options',opt` specifies the error model as the combined model, excludes the second observation from the fit, and uses the options defined in the structure `opt` to control the iterative fitting procedure.

'CoefficientNames' – Names of the model coefficients

{`'b1'`, `'b2'`, ..., `'bk'`} (default) | cell array of strings

Names of the model coefficients, specified as a cell array of strings.

Data Types: `char`

'ErrorModel' – Form of the error variance model

`'constant'` (default) | `'proportional'` | `'combined'`

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f , and one or two parameters a and b

'constant' (default)	$y = f + ae$
'proportional'	$y = f + bfe$
'combined'	$y = f + (a + b f)e$

The only allowed error model when using `Weights` is 'constant'.

Note: `options.RobustWgtFun` must have value [] when using an error model other than 'constant'.

Example: 'ErrorModel', 'proportional'

'ErrorParameters' — Initial estimates of the error model parameters

numeric array

Initial estimates of the error model parameters for the chosen `ErrorModel`, specified as a numeric array.

Error Model	Parameters	Default Values
'constant'	a	1
'proportional'	b	1
'combined'	a, b	[1, 1]

You can only use the 'constant' error model when using `Weights`.

Note: `options.RobustWgtFun` must have value [] when using an error model other than 'constant'.

For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for a and the starting value 2 for b as follows.

Example: 'ErrorParameters',[1,2]

Data Types: single | double

'Exclude' — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude',[2,3]

Example: 'Exclude',logical([0 1 1 0 0 0])

Data Types: single | double | logical

'Options' — Options for controlling the iterative fitting procedure

[] (default) | structure

Options for controlling the iterative fitting procedure, specified as a structure created by `statset`. The relevant fields are the nonempty fields in the structure returned by the call `statset('fitnlm')`.

Option	Meaning	Default
DerivStep	Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics and Machine Learning Toolbox function using the options structure.	$\text{eps}^{(1/3)}$
Display	Amount of information displayed by the fitting algorithm. <ul style="list-style-type: none"> 'off' — Displays no information. 'final' — Displays the final output. 'iter' — Displays iterative output to the Command Window. 	'off'

Option	Meaning	Default
FunValCheck	String indicating to check for invalid values, such as NaN or Inf, from the model function.	'on'
MaxIter	Maximum number of iterations allowed. Positive integer.	200
RobustWgtFun	Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See “Robust Options” on page 25-2148	[]
Tune	Tuning constant used in robust fitting to normalize the residuals before applying the weight function. A positive scalar. Required if the weight function is specified as a function handle.	See “Robust Options” on page 25-2148 for the default, which depends on RobustWgtFun.
TolFun	Termination tolerance for the objective function value. Positive scalar.	1e-8
TolX	Termination tolerance for the parameters. Positive scalar.	1e-8

Data Types: struct

'PredictorVars' — Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars', [2,3]

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `cell`

'ResponseVar' — Response variable

last column of `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable.

If you supply a model string, it specifies the response variable. Otherwise, when fitting a table or dataset array, `'ResponseVar'` indicates which variable `fitnlm` should use as the response.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: `'ResponseVar',[4]`

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char`

'VarNames' — Names of variables in fit

{`'x1'`, `'x2'`, ..., `'xn'`, `'y'`} (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

Data Types: `cell`

'Weights' — Observation weights`ones(n,1)` (default) | vector of nonnegative scalar values | function handle

Observation weights, specified as a vector of nonnegative scalar values or function handle.

- If you specify a vector, then it must have n elements, where n is the number of rows in `tbl` or `y`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, `W`, `NonLinearModel` estimates the error variance at observation `i` by $\text{MSE} * (1/W(i))$, where `MSE` is the mean squared error.

Data Types: `single` | `double` | `function_handle`

Output Arguments

mdl — Nonlinear model`NonLinearModel` object

Nonlinear model representing a least-squares fit of the response to the data, returned as a `NonLinearModel` object.

If the `Options` structure contains a nonempty `RobustWgtFun` field, the model is not a least-squares fit, but uses the `RobustWgtFun` robust fitting function.

For properties and methods of the nonlinear model object, `mdl`, see the `NonLinearModel` class page.

nlinfit | NonLinearModel

Introduced in R2013b

LinearMixedModel.fitmatrix

Class: LinearMixedModel

Fit linear mixed-effects model using design matrices

Compatibility

LinearMixedModel.fitmatrix will be removed in a future release. Use fitlmematrix instead.

Syntax

```
lme = LinearMixedModel.fitmatrix(X,y,Z,[])  
lme = LinearMixedModel.fitmatrix(X,y,Z,G)  
lme = LinearMixedModel.fitmatrix( ____,Name,Value)
```

Description

`lme = LinearMixedModel.fitmatrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`.

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where `n` is the number of observations. Using `LinearMixedModel.fitmatrix(X,Y,Z,[])` without a specified covariance pattern most likely will result in a non-identifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using 'CovariancePattern' name-value pair argument.

`lme = LinearMixedModel.fitmatrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = LinearMixedModel.fitmatrix(____,Name,Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

Tips

- If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix`.

Input Arguments

X — Fixed-effects design matrix

n-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of **X** corresponds to one observation, and each column of **X** corresponds to one variable.

Data Types: `single` | `double`

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single` | `double`

Z — Random-effects design

n-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then **Z** must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then **Z** must be a cell array of length *R*. Each cell of **Z** contains an *n*-by-*q*(*r*) design matrix $Z\{r\}$, *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, $Z\{r\}$.

Data Types: `single` | `double` | `cell`

G — Grouping variable or variables

n -by-1 vector | cell array of R n -by-1 vectors

Grouping variable or variables, specified as either of the following.

- If there is one random-effects term, then **G** must be an n -by-1 vector corresponding to a single grouping variable with M levels or groups.

G can be a categorical vector, numeric vector, character array, or cell array of strings.

- If there are multiple random-effects terms, then **G** must be a cell array of length R . Each cell of **G** contains a grouping variable $G\{r\}$, $r = 1, 2, \dots, R$, with $M(r)$ levels.

$G\{r\}$ can be a categorical vector, numeric vector, character array, or cell array of strings.

Data Types: `single` | `double` | `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

'FixedEffectPredictors' — Names of columns in fixed-effects design matrix

{'x1', 'x2', ..., 'xP'} (default) | cell array of length p

Names of columns in the fixed-effects design matrix X , specified as the comma-separated pair consisting of **'FixedEffectPredictors'** and a cell array of length p .

For example, if you have a constant term and two predictors, say **TimeSpent** and **Gender**, where **Female** is the reference level for **Gender**, as the fixed effects, then you can specify the names of your fixed effects in the following way. **Gender_Male** represents the dummy variable you must create for category **Male**. You can choose different names for these variables.

Example: **'FixedEffectPredictors'**,
{'Intercept', 'TimeSpent', 'Gender_Male'},

Data Types: `cell`

'RandomEffectPredictors' — Names of columns in random-effects design matrix or cell array

cell array of length q | cell array of length R with elements of length $q(r)$, $r = 1, 2, \dots, R$

Names of columns in the random-effects design matrix or cell array Z , specified as the comma-separated pair consisting of **'RandomEffectPredictors'** and either of the following:

- A cell array of length q when Z is an n -by- q design matrix. In this case, the default is `{'z1', 'z2', ..., 'zQ'}`.
- A cell array of length R , when Z is a cell array of length R with each element $Z\{r\}$ of length $q(r)$, $r = 1, 2, \dots, R$. In this case, the default is `{'z11', 'z12', ..., 'z1Q(1)'}, ..., {'zr1', 'zr2', ..., 'zrQ(r)'}`.

For example, suppose you have correlated random effects for intercept and a variable named `Acceleration`. Then, you can specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors', {'Intercept', 'Acceleration'}`

If you have two random effects terms, one for the intercept and the variable `Acceleration` grouped by variable `g1`, and the second for the intercept, grouped by the variable `g2`, then you specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors', {{'Intercept', 'Acceleration'}}, {'Intercept'}}`

Data Types: `cell`

'ResponseVarName' — Name of response variable

`'y'` (default) | `string`

Name of response variable, specified as the comma-separated pair consisting of **'ResponseVarName'** and a string.

For example, if your response variable name is `score`, then you can specify it as follows.

Example: `'ResponseVarName', 'score'`

Data Types: `char`

'RandomEffectGroups' — Names of random effects grouping variables

`'g'` or `{'g1', 'g2', ..., 'gR'}` (default) | `string` | cell array of strings

Names of random effects grouping variables, specified as the comma-separated pair 'RandomEffectGroups' and either of the following:

- String — If there is only one random-effects term, that is, if G is a vector, then the value of 'RandomEffectGroups' is a string containing the name for the grouping variable G . The default is 'g'.
- Cell array of strings — If there are multiple random-effects terms, that is, if G is a cell array of length R , then the value of 'RandomEffectGroups' is a cell array of length R , where each cell contains the name for the grouping variable $G\{r\}$. The default is {'g1', 'g2', ..., 'gR'}.

For example, if you have two random-effects terms, $z1$ and $z2$, grouped by the grouping variables `sex` and `subject`, then you can specify the names of your grouping variables as follows.

Example: 'RandomEffectGroups', {'sex', 'subject'}

Data Types: char | cell

'CovariancePattern' — Pattern of covariance matrix

'FullCholesky' (default) | string | square symmetric logical matrix | cell array of strings or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a string, a square symmetric logical matrix, or a cell array of strings or logical matrices.

If there are R random-effects terms, then the value of 'CovariancePattern' must be a cell array of length R , where each element r of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

'FullCholesky'

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where σ_{b1}^2 is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if `PAT(a, b) = false`, then the (a, b) element of the corresponding covariance matrix is constrained to be 0.

Example: 'CovariancePattern', 'Diagonal'

Example: 'CovariancePattern', {'Full', 'Diagonal'}

'FitMethod' — Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'

Default. Maximum likelihood estimation

'REML'

Restricted maximum likelihood estimation

Example: 'FitMethod', 'REML'

'Weights' — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length n , where n is the number of observations.

Data Types: `single` | `double`**'Exclude' — Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: `'Exclude', [13,67]`Data Types: `single` | `double` | `logical`**'DummyVarCoding' — Coding to use for dummy variables**`'reference'` (default) | `'effects'` | `'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the following.

Value	Description
<code>'reference'</code>	Default. Coefficient for first category set to 0.
<code>'effects'</code>	Coefficients sum to 0.
<code>'full'</code>	One dummy variable for each category.

Example: `'DummyVarCoding', 'effects'`**'Optimizer' — Optimization algorithm**`'quasnewton'` (default) | `'fminunc'`

Optimization algorithm, specified as the comma-separated pair consisting of `'Optimizer'` and either of the following.

<code>'quasinevton'</code>	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
<code>'fminunc'</code>	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> with <code>'Algorithm'</code> set to <code>'quasi-newton'</code> .

Example: `'Optimizer', 'fminunc'`

'OptimizerOptions' — Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of `'OptimizerOptions'` and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If `'Optimizer'` is `'fminunc'`, then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options `'fminunc'` uses. If `'Optimizer'` is `'fminunc'` and you do not supply `'OptimizerOptions'`, then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with `'Algorithm'` set to `'quasi-newton'`.
- If `'Optimizer'` is `'quasinevton'`, then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The `'quasinevton'` optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

'ToIFun' — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

'ToIX' — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

'MaxIter' — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

'Display' — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

'StartMethod' — Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

Value	Description
'default'	An internally defined default value
'random'	A random initial value

Example: 'StartMethod', 'random'

'Verbose' — Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose', true

'CheckHessian' — Indicator to check positive definiteness of Hessian`false (default) | true`

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either `false` or `true`. Default is `false`.

Specify 'CheckHessian' as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian', true

Output Arguments

lme — Linear mixed-effects model`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

Examples

No Grouping Variable Specified

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, where MPG is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

```
y = MPG;  
X = [ones(size(Weight)), Weight];  
Z = ones(size(y));  
lme = LinearMixedModel.fitmatrix(X,y,Z,Model_Year)
```

```
lme =

Longitudinal Study with Covariate

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six two-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

$$\begin{aligned}
y_{im} = & \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\
& + \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) \\
& + b_{0m} + b_{1m} Week_{im} + \varepsilon_{im},
\end{aligned}$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[PB]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions: $b_{0m} \sim N(0, \sigma_0^2)$, $b_{1m} \sim N(0, \sigma_1^2)$, and $\varepsilon_{im} \sim N(0, \sigma^2)$.

```

Subject = nominal(Subject);
Program = nominal(Program);
D = dummyvar(Program); % Create dummy variables for Program
X = [ones(120,1), InitialWeight, D(:,2:4), Week, ...
     D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];
Z = [ones(120,1), Week];
G = Subject;

```

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables.

```

lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week','Week_PrgB','Week_PrgC','Week_PrgD',
'RandomEffectPredictors',{{'Intercept','Week'}},'RandomEffectGroups',{'Subject'})

lme =

```

Linear mixed-effects model fit by ML

Model information:

Number of observations	120

'Week_PrgB'	0.038771	0.095394	0.40644	111	0.68521	-0.
'Week_PrgC'	0.030543	0.095394	0.32018	111	0.74944	-0.
'Week_PrgD'	0.033114	0.095394	0.34713	111	0.72915	-0.

Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	0.18407	0.12281	0.27587
'Week'	'Intercept'	'corr'	0.66841	0.21076	0.88573
'Week'	'Week'	'std'	0.15033	0.11004	0.20537

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.10261	0.087882	0.11981

The *p*-values 0.0228 and 0.0115 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects that are in program B is significantly different relative to the weight loss of subjects that are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the `compare` method.

Random-Intercept Model

Load the sample data.

```
load flu
```

`flu` dataset array has a `Date` variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into a tall array that has a single response variable, `FluRate`, and a nominal variable, `Region`, the nationwide estimate `WtdILI`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10, 'NewDataVarName', 'FluRate', ...
            'IndVarName', 'Region');
flu2.Date = nominal(flu2.Date);
```

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by `Date`. The corresponding model is

$$y_{im} = \beta_0 + \beta_1 WtdILI_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`. b_{0m} is the random effect for level m of the grouping variable `Date` and ε_{im} is the observation error for observation i . The random effect has the prior distribution, $b_{0m} \sim N(0, \sigma_{FR}^2)$ and the error term has the distribution, $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
y = flu2.FluRate;
X = [ones(468,1) flu2.WtdILI];
Z = [ones(468,1)];
G = flu2.Date;
```

Fit the linear mixed-effects model.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G, 'FixedEffectPredictors', {'Intercept', 'NationalRate'},
    'RandomEffectPredictors', {'Intercept'}, 'RandomEffectGroups', {'Date'})
```

```
lme =
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	468
Fixed effects coefficients	2
Random effects coefficients	52
Covariance parameters	2

Formula:

```
y ~ Intercept + NationalRate + (Intercept | Date)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
286.24	302.83	-139.12	278.24

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue	Lower	Upper
'Intercept'	0.16385	0.057525	2.8484	466	0.0045885	0.0500	0.2577
'NationalRate'	0.7236	0.032219	22.459	466	3.0502e-76	0.6600	0.7872

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	0.17146	0.13227	0.22226

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

The confidence limits of the standard deviation of the random-effects term $\sigma_{b_{0m}}$, do not include zero (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects using `compare` method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where \hat{b} is the BLUP of the random effects for the intercept. You can compute this value in the following way.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % compute the random effects statistics STATS
STATS.Level = nominal(STATS.Level1);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
y_hat =
```

```
1.4674
```

You can simply display the fitted value using the `fitted(lme)` method.

```
F = fitted(lme);
F(28)
```

```
ans =
```

```
1.4674
```

Randomized-Block Design

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data set shows the deviations from the target quality characteristic measured from the products each of five operators manufacture over three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the 'effects' contrasts. 'effects' contrasts mean that the coefficients sum to zero. You need to create two contrast coded variables in the fixed-effects design matrix, $X1$ and $X2$, where

$$\text{Shift_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} \quad \text{and} \quad \text{Shift_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} .$$

The model corresponds to

Morning Shift: $QCDev_{im} = \beta_0 + \beta_2 Shift_Morning_i + b_{0m} + \varepsilon_{im}$, $m = 1, 2, \dots, 5$,
 Evening Shift: $QCDev_{im} = \beta_0 + \beta_1 Shift_Evening_i + b_{0m} + \varepsilon_{im}$,
 Night Shift: $QCDev_{im} = \beta_0 - \beta_1 Shift_Evening_i - \beta_2 Shift_Morning_i + b_{0m} + \varepsilon_{im}$,

where i represents the observations, and m represents the operators, $i = 1, 2, \dots, 15$, and $m = 1, 2, \dots, 5$. The random effects and the observation error have the following distributions: $b_{0m} \sim N(0, \sigma_{b_{0m}}^2)$ and $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
S = shift.Shift;
X1 = (S=='Morning') - (S=='Night');
X2 = (S=='Evening') - (S=='Night');
X = [ones(15,1), X1, X2];
y = shift.QCDev;
Z = ones(15,1);
G = shift.Operator;
```

Fit a linear mixed-effects model using the specified design matrices and restricted maximum likelihood method.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FitMethod','REML','FixedEffectPredictors',...
{'Intercept','S_Morning','S_Evening'},'RandomEffectPredictors',{{'Intercept'}},...
'RandomEffectGroups',{'Operator'},'DummyVarCoding','effects')
```

-1.9472

```

The estimated deviation from the target quality characteristics for the third operator working in the evening shift is

$$\begin{aligned}
 \hat{y}_{Evening, Operator3} &= \hat{\beta}_0 + \hat{\beta}_1 Shift_Evening + \hat{b}_{03} \\
 &= 3.6525 - 0.53293 - 2.1715 \\
 &= 0.94807.
 \end{aligned}$$

You can also display this value in the following way.

```
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')
```

```
ans =
```

```
0.9481
```

Correlated and Uncorrelated Random-Effects Terms

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and the cylinders, and uncorrelated random-effect for intercept and acceleration grouped by the model year. This model corresponds to

$$MPG_{im} = \beta_0 + \beta_1 Acc_i + \beta_2 HP + b_{0m} + b_{1m} Acc_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distributions: $b_{0m} \sim N(0, \sigma^2_0)$, and $b_{1m} \sim N(0, \sigma^2_1)$. m represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = {ones(406,1), Acceleration};
G = {Model_Year, Model_Year};
Model_Year = nominal(Model_Year);
```

Now, fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables.

```
lme = LinearMixedModel.fitmatrix(X, MPG, Z, G, 'FixedEffectPredictors', ...
{'Intercept', 'Acceleration', 'Horsepower'}, 'RandomEffectPredictors', ...
{{'Intercept'}}, {'Acceleration'}}, 'RandomEffectGroups', {'Model_Year', 'Model_Year'})
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	3

```
Formula:
```

```
y ~ Intercept + Acceleration + Horsepower + (Intercept | Model_Year) + (Acceleration
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
2194.5	2218.3	-1091.3	2182.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue	Lower	Upper
'Intercept'	49.839	2.0518	24.291	389	5.6168e-80	44.735	54.943

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.7258	3.4698	4.0007

The standard deviation of the random effect for the intercept does not seem significant.

Refit the model with potentially correlated random effects for intercept and acceleration. In this case the random-effects terms have the following prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N \left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right),$$

where m represents the model year.

First prepare the random-effects design matrix and grouping variable.

```
Z = [ones(406,1) Acceleration];
G = Model_Year;
```

```
lme = LinearMixedModel.fitmatrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{'Intercept','Acceleration'}),'RandomEffectGroups',{'Model_Year'})
```

```
lme =
```

Linear mixed-effects model fit by ML

Model information:

'Acceleration'	-0.58327	0.13394	-4.3545	389	1.7075e-05	-0.85115	-0.31539
'Horsepower'	-0.16954	0.0072609	-23.35	389	5.188e-76	-0.20421	-0.13487

Random effects covariance parameters (95% CIs):

Group: Model_Year (13 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	3.3475	1.2862	5.4088
'Acceleration'	'Intercept'	'corr'	-0.87971	-0.98501	-0.77441
'Acceleration'	'Acceleration'	'std'	0.33789	0.1825	0.51328

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.6874	3.4298	3.9644

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. You can compare these two models using the `compare` method.

Specify the Covariance Pattern

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

load `weight`

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six two-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables.

```
Subject = nominal(Subject);
Program = nominal(Program);
```

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week are the fixed effects.

```
D = dummyvar(Program);
X = [ones(120,1), InitialWeight, D(:,2:4), Week];
Z = [ones(120,1) Week];
G = Subject;
```

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + b_{0m} + b_{1m} Week2_{im} + b_{2m} Week4_{im} + b_{3m} Week6_{im} + b_{4m} Week8_{im} \\ + b_{5m} Week10_{im} + b_{6m} Week12_{im} + \varepsilon_{im},$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$.

β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[PB]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions: $b_{0m} \sim N(0, \sigma_0^2)$, $b_{1m} \sim N(0, \sigma_1^2)$, and $\varepsilon_{im} \sim N(0, \sigma^2)$.

Fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week'},...
'RandomEffectPredictors',{{'Intercept','Week'}},...
'RandomEffectGroups',{'Subject'},'CovariancePattern','Isotropic')
```

lme =

Definitions

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where D is a q -by- q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ , q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D , is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q^*(q+1)/2$ -by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

Alternatives

You can also fit a linear mixed-effects model using `fitlme(tbl, formula)`, where `tbl` is a table or dataset array containing the response `y`, the predictor variables `X`, and the grouping variables, and `formula` is of the form `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`.

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X, y, Z, G)`.

`fitlme` | `LinearMixedModel`

fitNaiveBayes

Train naive Bayes classifier

Compatibility

`fitNaiveBayes` will be removed in a future release. Use `fitcnb` instead.

Syntax

```
NBModel = fitNaiveBayes(X,Y)
NBModel = fitNaiveBayes(X,Y,Name,Value)
```

Description

`NBModel = fitNaiveBayes(X,Y)` returns a naive Bayes classifier `NBModel`, trained by predictors `X` and class labels `Y` for K -level classification.

Predict labels for new data by passing the data and `NBModel` to `predict`.

`NBModel = fitNaiveBayes(X,Y,Name,Value)` returns a naive Bayes classifier with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify a distribution to model the data, prior probabilities for the classes, or the kernel smoothing window bandwidth.

Examples

Train a Naive Bayes Classifier

Load Fisher's iris data set.

```
load fisheriris
X = meas(:,3:4);
Y = species;
tabulate(Y)
```

Value	Count	Percent
setosa	50	33.33%
versicolor	50	33.33%
virginica	50	33.33%

The software can classify data with more than two classes using naive Bayes methods.

Train a naive Bayes classifier.

```
NBModel = fitNaiveBayes(X,Y)
```

```
Warning: NaiveBayes will be removed in a future release. Use fitcnb instead.
```

```
NBModel =
```

```
Naive Bayes classifier with 3 classes for 2 dimensions.  
Feature Distribution(s):normal  
Classes:setosa, versicolor, virginica
```

NBModel is a trained NaiveBayes classifier.

By default, the software models the predictor distribution within each class using a Gaussian distribution having some mean and standard deviation. Use dot notation to display the parameters of a particular Gaussian fit, e.g., display the fit for the first feature within `setosa`.

```
setosaIndex = strcmp(NBModel.ClassLevels,'setosa');  
estimates = NBModel.Params{setosaIndex,1}
```

```
estimates =
```

```
1.4620  
0.1737
```

The mean is 1.4620 and the standard deviation is 0.1737.

Plot the Gaussian contours.

```
figure  
gscatter(X(:,1),X(:,2),Y);  
h = gca;  
xlim = [h.XLim h.YLim];
```

```

hold on
Params = cell2mat(NBModel.Params);
Mu = Params(2*(1:3)-1,1:2); % Extracts the means
Sigma = zeros(2,2,3);
for j = 1:3
    Sigma(:,:,j) = diag(Params(2*j,:)); % Extracts the standard deviations
    ezcontour(@(x1,x2)mvnpdf([x1,x2],Mu(j,:),Sigma(:,:,j)),...
        xlim+0.5*[-1,1,-1,1]) ...
        % Draws contours for the multivariate normal distributions
end
title('Naive Bayes Classifier -- Fisher's Iris Data')
xlabel('Petal Length (cm)')
ylabel('Petal Width (cm)')
hold off

```

You can change the default distribution using the name-value pair argument 'Distribution'. For example, If some predictors are count based, then you can specify that they are multinomial random variables using 'Distribution', 'mn' .

Specify Predictor Distributions for Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Train a naive Bayes classifier using every predictor.

```
NBModel1 = fitNaiveBayes(X,Y);
NBModel1.ClassLevels % Display the class order
NBModel1.Params
NBModel1.Params{1,2}
```

Warning: NaiveBayes will be removed in a future release. Use fitcnb instead.

```
ans =
```

```
    'setosa'
    'versicolor'
    'virginica'
```

```
ans =
```

```
    [2x1 double]    [2x1 double]    [2x1 double]    [2x1 double]
    [2x1 double]    [2x1 double]    [2x1 double]    [2x1 double]
    [2x1 double]    [2x1 double]    [2x1 double]    [2x1 double]
```

```
ans =
```

```
    3.4280
    0.3791
```

By default, the software models the predictor distribution within each class as a Gaussian with some mean and standard deviation. There are four predictors and three class levels. Each cell in `NBModel1.Params` corresponds to a numeric vector containing

the mean and standard deviation of each distribution, e.g., the mean and standard deviation for setosa iris sepal widths are 3.4280 and 0.3791, respectively.

Estimate the confusion matrix for NBModel1.

```
predictLabels1 = predict(NBModel1,X);
[ConfusionMat1,labels] = confusionmat(Y,predictLabels1)
```

Warning: NaiveBayes will be removed in a future release. Use the predict method of an object returned by fitcnb instead.

```
ConfusionMat1 =
```

```
    50     0     0
     0    47     3
     0     3    47
```

```
labels =
```

```
    'setosa'
    'versicolor'
    'virginica'
```

Element (j, k) of ConfusionMat1 represents the number of observations that the software classifies as k , but the data show as being in class j .

Retrain the classifier using the Gaussian distribution for predictors 1 and 2 (the sepal lengths and widths), and the default normal kernel density for predictors 3 and 4 (the petal lengths and widths).

```
NBModel2 = fitNaiveBayes(X,Y,...
    'Distribution',{ 'normal', 'kernel', 'normal', 'kernel'});
NBModel2.Params{1,2}
```

Warning: NaiveBayes will be removed in a future release. Use fitcnb instead.

```
ans =
```

```
KernelDistribution
```

```
Kernel = normal
Bandwidth = 0.179536
Support = unbounded
```

The software does not train parameters to the kernel density. Rather, the software chooses an optimal width. However, you can specify a width using the 'KSWidth' name-value pair argument.

Estimate the confusion matrix for NBModel2.

```
predictLabels2 = predict(NBModel2,X);  
ConfusionMat2 = confusionmat(Y,predictLabels2)
```

Warning: NaiveBayes will be removed in a future release. Use the predict method of an object returned by fitcnb instead.

ConfusionMat2 =

```
    50     0     0  
     0    47     3  
     0     3    47
```

Based on the confusion matrices, the two classifiers perform similarly in the training sample.

Train Naive Bayes Classifiers Using Multinomial Predictors

Some spam filters classify an incoming email as spam based on how many times a word or punctuation (called tokens) occurs in an email. The predictors are the frequencies of particular words or punctuations in an email. Therefore, the predictors compose multinomial random variables.

This example illustrates classification using naive Bayes and multinomial predictors.

Suppose you observed 1000 emails and classified them as spam or not spam. Do this by randomly assigning -1 or 1 to y for each email.

```
n = 1000; % Sample size  
rng(1); % For reproducibility  
y = randsample([-1 1],n,true); % Random labels
```

To build the predictor data, suppose that there are five tokens in the vocabulary, and 20 observed tokens per email. Generate predictor data from the five tokens by drawing multinomial deviates. The relative frequencies for tokens corresponding to spam emails should differ from emails that are not spam.

```

tokenProbs = [0.2 0.3 0.1 0.15 0.25;...
              0.4 0.1 0.3 0.05 0.15]; % Token relative frequencies
tokensPerEmail = 20;
X = zeros(n,5);
X(y == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),sum(y == 1));
X(y == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),sum(y == -1));

```

Train a naive Bayes classifier. Specify that the predictors are multinomial.

```
NBModel = fitNaiveBayes(X,y,'Distribution','mn');
```

Warning: NaiveBayes will be removed in a future release. Use fitcnb instead.

NBModel is a trained NaiveBayes classifier.

Assess the in-sample performance of NBModel by estimating the misclassification rate.

```

predSpam = predict(NBModel,X);
misclass = sum(y'~=predSpam)/n

```

Warning: NaiveBayes will be removed in a future release. Use the predict method of an object returned by fitcnb instead.

```

misclass =
    0.0200

```

The in-sample misclassification rate is 2%.

Randomly generate deviates that represent a new batch of emails.

```

nOut = 500;
yOut = randsample([-1 1],nOut,true);
XOut = zeros(nOut,5);
XOut(yOut == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),...
                          sum(yOut == 1));
XOut(yOut == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),...
                          sum(yOut == -1));

```

Classify the new emails using the trained naive Bayes classifier NBModel, and determine whether the algorithm generalizes.

```

predSpamOut = predict(NBModel,XOut);
genRate = sum(yOut'~=predSpamOut)/nOut

```

Warning: NaiveBayes will be removed in a future release. Use the predict method of an object returned by fitcnb instead.

```
genRate =  
    0.0260
```

The out-of-sample misclassification rate is 2.6% indicating that the classifier generalizes fairly well.

Input Arguments

X — Predictor data

matrix of numeric values

Predictor data to which the naive Bayes classifier is trained, specified as a matrix of numeric values.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of Y and the number of rows of X must be equivalent.

Data Types: double

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels to which the naive Bayes classifier is trained, specified as a categorical or character array, logical or numeric vector, or cell array of strings. Each element of Y defines the class membership of the corresponding row of X. Y supports K class levels.

If Y is a character array, then each row must correspond to one class label.

The length of Y and the number of rows of X must be equivalent.

Data Types: cell | char | double | logical

Note: The software treats NaN, empty string (' '), and <undefined> elements as missing values.

- If Y contains missing values, then the software removes them and the corresponding rows of X .
- If X contains any rows composed entirely of missing values, then the software removes those rows and the corresponding elements of Y .
- If X contains missing values and you set `'Distribution', 'mn'`, then the software removes those rows of X and the corresponding elements of Y .
- If a predictor is not represented in a class, that is, if all of its values are NaN within a class, then the software returns an error.

Removing rows of X and corresponding elements of Y decreases the effective training or cross-validation sample size.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Distribution', 'mn', 'Prior', 'uniform', 'KSWidth', 0.5` specifies the following: the data distribution is multinomial, the prior probabilities for all classes are equal, and the kernel smoothing window bandwidth for all classes is 0.5 units.

'Distribution' — Data distributions

`'normal'` (default) | `'kernel'` | `'mn'` | `'mvmn'` | cell array of strings

Data distributions `fitNaiveBayes` uses to model the data, specified as the comma-separated pair consisting of `'Distribution'` and a string or cell array of strings.

This table summarizes the available distributions.

Value	Description
<code>'kernel'</code>	Kernel smoothing density estimate.
<code>'mn'</code>	Multinomial distribution. If you specify <code>mn</code> , then all features are components of a multinomial distribution. Therefore, you cannot include <code>'mn'</code> as an element of a cell array of strings. For details, see “Algorithms” on page 25-2190.

Value	Description
'mvnm'	Multivariate multinomial distribution. For details, see “Algorithms” on page 25-2190.
'normal'	Normal (Gaussian) distribution.

If you specify a string, then the software models all the features using that distribution. If you specify a 1-by- D cell array of strings, then the software models feature j using the distribution in element j of the cell array.

Example: 'Distribution', {'kernel', 'normal'}

Data Types: cell | char

'KSSupport' — Kernel smoothing density support

'unbounded' (default) | 'positive' | cell array | numeric row vector

Kernel smoothing density support, specified as the comma-separated pair consisting of 'KSSupport' and a numeric row vector, a string, or a cell array. The software applies the kernel smoothing density to this region.

If you do not specify 'Distribution', 'kernel', then the software ignores the values of 'KSSupport', 'KSType', and 'KSWidth'.

This table summarizes the available options for setting the kernel smoothing density region.

Value	Description
1-by-2 numeric row vector	For example, [L,U], where L and U are the finite lower and upper bounds, respectively, for the density support.
'positive'	The density support is all positive real values.
'unbounded'	The density support is all real values.

If you specify a 1-by- D cell array, with each cell containing any value in the table, then the software trains the classifier using the kernel support in cell j for feature j in X .

Example: 'KSSupport', {[-10,20], 'unbounded'}

Data Types: cell | char | double

'KSType' — Kernel smoother type

'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | cell array of strings

Kernel smoother type, specified as the comma-separated pair consisting of 'KSType' and a string or cell array of strings.

If you do not specify 'Distribution', 'kernel', then the software ignores the values of 'KSSupport', 'KSType', and 'KSWidth'.

This table summarizes the available options for setting the kernel smoothing density region. Let $I\{u\}$ denote the indicator function.

Value	Kernel	Formula
'box'	Box (uniform)	$f(x) = 0.5I\{ x \leq 1\}$
'epanechni	Epanechnikov	$f(x) = 0.75(1 - x^2)I\{ x \leq 1\}$
'normal'	Gaussian	$f(x) = \frac{1}{\sqrt{2\pi}} \exp(-0.5x^2)$
'triangle'	Triangular	$f(x) = (1 - x)I\{ x \leq 1\}$

If you specify a 1-by- D cell array, with each cell containing any value in the table, then the software trains the classifier using the kernel smoother type in cell j for feature j in X .

Example: 'KSType', {'epanechnikov', 'normal'}

Data Types: cell | char

'KSWidth' — Kernel smoothing window bandwidth

matrix of numeric values (default) | numeric column vector | numeric row vector | scalar | structure array

Kernel smoothing window bandwidth, specified as the comma-separated pair consisting of 'KSWidth' and a matrix of numeric values, numeric row vector, numeric column vector, scalar, or structure array.

If you do not specify 'Distribution', 'kernel', then the software ignores the values of 'KSSupport', 'KSType', and 'KSWidth'.

Suppose there are K class levels and D predictors. This table summarizes the available options for setting the kernel smoothing window bandwidth.

Value	Description
K -by- D matrix of numeric values	Element (k,d) specifies the bandwidth for predictor d in class k .
K -by-1 numeric column vector	Element k specifies the bandwidth for all predictors in class k .
1-by- D numeric row vector	Element d specifies the bandwidth in all class levels for predictor d .
scalar	Specifies the bandwidth for all features in all classes.
structure array	A structure array S containing class levels and their bandwidths. S must have two fields: <ul style="list-style-type: none"> • S.width: A numeric row vector of bandwidths, or a matrix of numeric values with D columns. • S.group: A vector of the same type as Y, containing unique class levels indicating the class for the corresponding element of S.width.

By default, the software selects a default bandwidth automatically for each combination of feature and class by using a value that is optimal for a Gaussian distribution.

Example: `'KSWidth', struct('width', [0.5, 0.25], 'group', {'b'; 'g'})`

Data Types: double | struct

'Prior' — Class prior probabilities

'empirical' (default) | 'uniform' | numeric vector | structure array

Class prior probabilities, specified as the comma-separated pair consisting of 'Prior' and a numeric vector, structure array, or string.

This table summarizes the available options for setting prior probabilities.

Value	Description
'empirical'	The software uses the class relative frequencies distribution for the prior probabilities.

Value	Description
numeric vector	<p>A numeric vector of length K specifying the prior probabilities for each class. The order of the elements of <code>Prior</code> should correspond to the order of the class levels. For details on the order of the classes, see “Algorithms” on page 25-2190.</p> <p>The software normalizes prior probabilities to sum to 1.</p>
structure array	<p>A structure array <code>S</code> containing class levels and their prior probabilities. <code>S</code> must have two fields:</p> <ul style="list-style-type: none"> • <code>S.prob</code>: A numeric vector of prior probabilities. The software normalizes prior probabilities to sum to 1. • <code>S.group</code>: A vector of the same type as <code>Y</code> containing unique class levels indicating the class for the corresponding element of <code>S.prob</code>. <code>S.class</code> must contain all the K levels in <code>Y</code>. It can also contain classes that do not appear in <code>Y</code>. This can be useful if <code>X</code> is a subset of a larger training set. The software ignores any classes that appear in <code>S.group</code> but not in <code>Y</code>.
'uniform'	The prior probabilities are equal for all classes.

Example: `'Prior', struct('prob', [1,2], 'group', {'b'; 'g'})`

Data Types: char | double | struct

Output Arguments

NBModel — Trained naive Bayes classifier

NaiveBayes classifier

Trained naive Bayes classifier, returned as a NaiveBayes classifier.

More About

Bag-of-Tokens Model

In the bag-of-tokens model, the value of predictor j is the nonnegative number of occurrences of token j in this observation. The number of categories (bins) in this multinomial model is the number of distinct tokens, that is, the number of predictors.

Tips

- For classifying count-based data, such as the bag-of-tokens model, use the multinomial distribution (e.g., set `'Distribution', 'mn'`).
- This list defines the order of the classes. It is useful when you specify prior probabilities by setting `'Prior', prior`, where `prior` is a numeric vector.
 - If `Y` is a categorical array, then the order of the class levels matches the output of `categories(Y)`.
 - If `Y` is a numeric or logical vector, then the order of the class levels matches the output of `sort(unique(Y))`.
 - For cell arrays of string and character arrays, the order of the class labels is the order which each label appears in `Y`.

Algorithms

- If you specify `'Distribution', 'mn'`, then the software considers each observation as multiple trials of a multinomial distribution, and considers each occurrence of a token as one trial (see “Bag-of-Tokens Model” on page 25-2189).
- If you specify `'Distribution', 'mvmn'`, then the software assumes each individual predictor follows a multinomial model within a class. The parameters for a predictor include the probabilities of all possible values that the corresponding feature can take.
- “Naive Bayes Classification” on page 16-38
- “Grouping Variables” on page 2-56

NaiveBayes | posterior | predict

Introduced in R2014a

fitPosterior

Class: ClassificationSVM

Fit posterior probabilities

Syntax

```
ScoreSVMModel = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,Name,Value)
```

Description

`ScoreSVMModel = fitPosterior(SVMModel)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier `SVMModel`, and by conducting 10-fold cross validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`) as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the “Sigmoid Function” on page 25-2208.
- If the classes are perfectly separable, then the transformation function is the “Step Function” on page 25-2208.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the “Constant Function” on page 25-2265. `fitPosterior` is not appropriate for one-class learning.
- The software stores the optimal score transformation function in `ScoreSVMModel.ScoreTransform`.

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)` additionally returns the optimal score-to-posterior-probability transformation function parameters (`ScoreTransform`).

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,Name,Value)`
returns the optimal score-to-posterior-probability transformation function and its parameters with additional options specified by one or more `Name,Value` pair arguments.

Tips

Here is one way to predict positive class posterior probabilities.

- 1 Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as, `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.
- 2 Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, for example, `ScoreSVMModel`, is the same, trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.

If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- 3 Pass the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) and predictor data matrix to `predict`. The second column of the second output argument stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

Input Arguments

SVMModel — Trained SVM classifier

ClassificationSVM classifier

Trained SVM classifier, specified as a `ClassificationSVM`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'CVPartition' — Cross-validation partition

`[]` (default) | `cvpartition` partition

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition as created by `cvpartition`. You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

`crossval` splits the data into subsets using `cvpartition`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1.

You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Example: `'KFold', 8`

Data Types: `single` | `double`

'Leaveout' — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross validation to compute the transformation function, specified as the comma-separated

pair consisting of 'Leaveout' and 'on' or 'off'. Use leave-one-out cross validation by using 'on'.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Leaveout', 'on'

Output Arguments

ScoreSVMModel — Trained SVM classifier

ClassificationSVM classifier

Trained SVM classifier containing the estimated score-to-posterior-probability transformation function, returned as a ClassificationSVM classifier.

To estimate posterior probabilities for the training set observations, pass ScoreSVMModel to resubPredict.

To estimate posterior probabilities for new observations, then pass them and ScoreSVMModel to predict. If you set 'Standardize', true in fitcsvm to train SVMModel, then predict standardizes the columns of X using the corresponding means in SVMModel.Mu and standard deviations in SVMModel.Sigma.

ScoreTransform — Optimal score transformation function parameters

structure array

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.

- If field Type is sigmoid, then ScoreTransform has the following other fields:
 - Slope: The value of A in the “Sigmoid Function” on page 25-2208
 - Intercept: The value of B in the sigmoid function
- If field Type is step, then ScoreTransform has the following other fields:
 - PositiveClassProbability: The value of π in the “Step Function” on page 25-2208. It represents the probability that an observation is in the positive class. Also, the posterior probability that an observation is in the positive class given that its score is in the interval (LowerBound,UpperBound).

- **LowerBound:** The value $\max_{y_n=-1} s_n$ in the step function. It represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score less than `LowerBound` has the posterior probability of being the positive class 0.
- **UpperBound:** The value $\min_{y_n=+1} s_n$ in the step function. It represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has the posterior probability of being the positive class 1.
- If field `Type` is constant, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

This result is the same as `SVMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always 1.

Definitions

Sigmoid Function

The sigmoid function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}$$

If the output argument `ScoreTransform.Type` is `sigmoid`, then parameters A and B correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

Step Function

The step function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- s_j the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.

If the output argument `ScoreTransform.Type` is `step`, then the quantities $\max_{y_k=-1} s_k$

and $\min_{y_k=+1} s_k$ correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

Examples

Estimate In-Sample Posterior Probabilities of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

SVMModel is a ClassificationSVM classifier. The positive class is 'g'.

Fit the optimal score-to-posterior-probability transformation function.

```
rng(1); % For reproducibility
ScoreSVMModel = fitPosterior(SVMModel)
```

```
ScoreSVMModel =
```

```
ClassificationSVM
    ResponseName: 'Y'
  CategoricalPredictors: []
        ClassNames: {'b' 'g'}
    ScoreTransform: '@(S) sigmoid(S, -9.481802e-01, -1.218745e-01) '
    NumObservations: 351
                Alpha: [90x1 double]
                Bias: -0.1343
  KernelParameters: [1x1 struct]
                Mu: [1x34 double]
                Sigma: [1x34 double]
    BoxConstraints: [351x1 double]
  ConvergenceInfo: [1x1 struct]
  IsSupportVector: [351x1 logical]
                Solver: 'SMO'
```

Since the classes are inseparable, the score transformation function (ScoreSVMModel.ScoreTransform) is the sigmoid function.

Estimate scores and positive class posterior probabilities for the training data. Display the results for the first 10 observations.

```
[label,scores] = resubPredict(SVMModel);
[~,postProbs] = resubPredict(ScoreSVMModel);
table(Y(1:10),label(1:10),scores(1:10,2),postProbs(1:10,2),'VariableNames',...
      {'TrueLabel','PredictedLabel','Score','PosteriorProbability'})
```

```
ans =
```

TrueLabel	PredictedLabel	Score	PosteriorProbability
'g'	'g'	1.4861	0.82215
'b'	'b'	-1.0004	0.30436
'g'	'g'	1.8685	0.86916
'b'	'b'	-2.6458	0.084183
'g'	'g'	1.2805	0.79184
'b'	'b'	-1.4617	0.22028
'g'	'g'	2.1672	0.89814
'b'	'b'	-5.7085	0.0050122
'g'	'g'	2.4797	0.92223
'b'	'b'	-2.7811	0.074805

Plot Posterior Probability Contours for Multiple Classes Using SVM

This example steps through the process of one-versus-all (OVA) classification to train a multiclass SVM classifier, and then plots probability contours for each class. To implement OVA directly, see `fitcecoc`.

Load Fisher's iris data set. Use the petal lengths and widths.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Examine a scatter plot of the data.

```
figure
gscatter(X(:,1),X(:,2),Y);
title('\bf Scatter Diagram of Iris Measurements');
xlabel('Petal length');
ylabel('Petal width');
legend('Location', 'Northwest');
axis tight
```

Train three binary SVM classifiers that separate each type of iris from the others. Assume that a radial basis function is an appropriate kernel for each, and allow the algorithm to choose a kernel scale. It is good practice to define the class order.

```

classNames = {'setosa'; 'virginica'; 'versicolor'};
numClasses = size(classNames,1);
inds = cell(3,1); % Preallocation
SVMModel = cell(3,1);

rng(1); % For reproducibility
for j = 1:numClasses
    inds{j} = strcmp(Y,classNames{j}); % OVA classification
    SVMModel{j} = fitcsvm(X,inds{j},'ClassNames',[false true],...
        'Standardize',true,'KernelFunction','rbf','KernelScale','auto');

```

end

fitcsvm uses a heuristic procedure that involves subsampling to compute the value of the kernel scale.

Fit the optimal score-to-posterior-probability transformation function for each classifier.

```
for j = 1:numClasses
    SVMModel{j} = fitPosterior(SVMModel{j});
end
```

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step function.

Define a grid to plot the posterior probability contours. Estimate the posterior probabilities over the grid for each classifier.

```
d = 0.02;
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),...
    min(X(:,2)):d:max(X(:,2)));
xGrid = [x1Grid(:),x2Grid(:)];
```

```
posterior = cell(3,1);
for j = 1:numClasses
    [~,posterior{j}] = predict(SVMModel{j},xGrid);
end
```

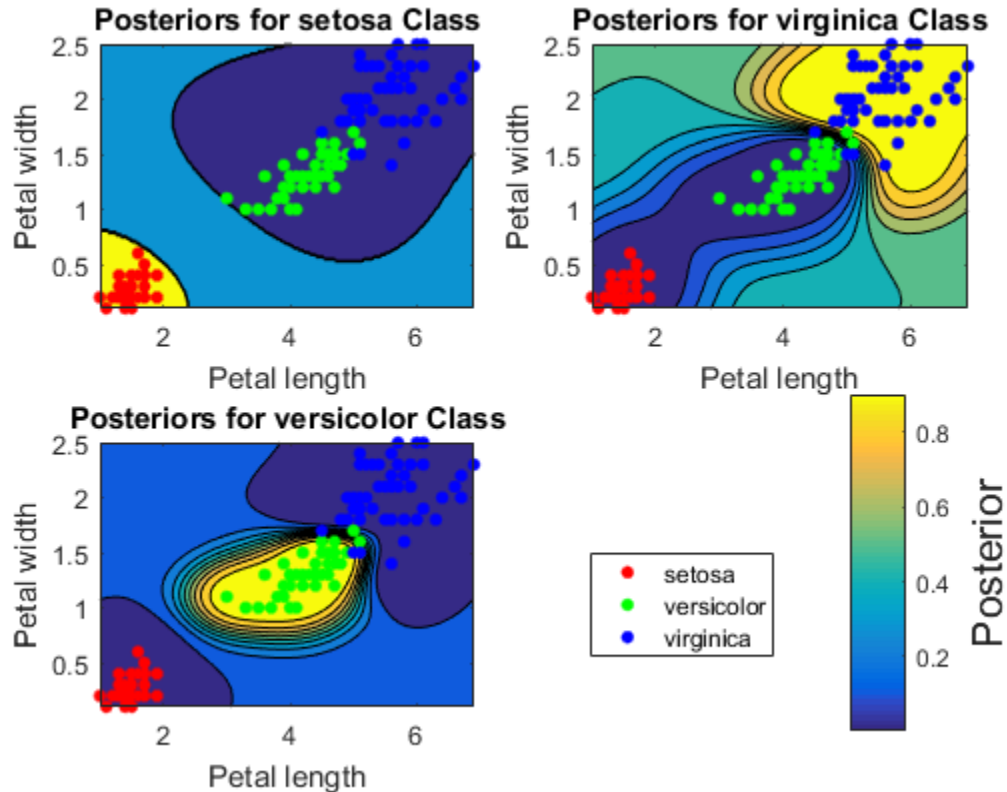

For each SVM classifier, plot the posterior probability contour under the scatter plot of the data.

```
figure
h = zeros(numClasses + 1,1); % Preallocation for graphics handles
for j = 1:numClasses
    subplot(2,2,j)
    contourf(x1Grid,x2Grid,reshape(posterior{j}(:,2),size(x1Grid,1),size(x1Grid,2)));
    hold on
    h(1:numClasses) = gscatter(X(:,1),X(:,2),Y);
    title(sprintf('Posteriors for %s Class',classNames{j}));
    xlabel('Petal length');
    ylabel('Petal width');
    legend off
    axis tight
    hold off
end
h(numClasses + 1) = colorbar('Location','EastOutside',...
```

```

'Position',[0.8,0.1,0.05,0.4]);
set(get(h(numClasses + 1), 'YLabel'), 'String', 'Posterior', 'FontSize', 16);
legend(h(1:numClasses), 'Location', [0.6,0.2,0.1,0.1]);

```

Fit Optimal Posterior Probability Function Using Holdout Cross Validation

Platt (2000) outlines a bias-reducing method of estimating the score-to-posterior-probability transformation function. This method estimates the transformation function after the SVM classifier is trained, and uses cross validation to reduce bias. By default, `fitPosterior` and `fitSVMPosterior` use 10-fold cross validation when they estimate the transformation function. To reduce run time for larger data sets, you can specify to use holdout cross validation instead.

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMMModel = fitcsvm(X,Y,'ClassNames',{ 'b', 'g'},'Standardize',true);
```

SVMMModel is a `ClassificationSVM` classifier. The positive class is 'g'.

Fit the optimal score-to-posterior-probability transformation function. For comparison, use 10-fold cross validation (default) and specify a 10% holdout test sample.

```
rng(1); % For reproducibility

tic; % Start the stopwatch
SVMMModel_10FCV = fitPosterior(SVMMModel);
toc % Stop the stopwatch and display the run time

tic;
SVMMModel_HO = fitPosterior(SVMMModel,'Holdout',0.10);
toc
```

```
Elapsed time is 1.185624 seconds.
```

```
Elapsed time is 0.238108 seconds.
```

Though both runtimes are short because the data set is relatively small, SVMMModel_HO fitted the score transformation function much faster than SVMMModel_10FCV.

Algorithms

If you reestimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning
- Resets the original transformation function to 'none' before estimating the new one

Alternatives

You can also fit the posterior probability function using `fitSVMPosterior`. This function is similar to `fitPosterior`, except it is more broad since it accepts a wider range of SVM classifier types.

`ClassificationSVM` | `fitcsvm` | `fitSVMPosterior` | `predict`

fitPosterior

Class: CompactClassificationSVM

Fit posterior probabilities

Syntax

```
ScoreSVMModel = fitPosterior(SVMModel, TBL, Y)
```

```
ScoreSVMModel = fitPosterior(SVMModel, X, Y)
```

```
[ScoreSVMModel, ScoreTransform] = fitPosterior(SVMModel, X, Y)
```

Description

`ScoreSVMModel = fitPosterior(SVMModel, TBL, Y)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning. If you trained `SVMModel` using a table, then you must use a table as input for `fitPosterior`.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier `SVMModel`, and by conducting 10-fold cross validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`) as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the “Sigmoid Function” on page 25-2208.
- If the classes are perfectly separable, the transformation function is the “Step Function” on page 25-2208.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the “Constant Function” on page 25-2265. `fitPosterior` is not appropriate for one-class learning.
- The software stores the optimal score-to-posterior-probability transformation function in `ScoreSVMModel.ScoreTransform`.

`ScoreSVMModel = fitPosterior(SVMModel, X, Y)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-

probability transformation function for two-class learning. If you trained `SVMModel` using a matrix, then you must use a matrix as input for `fitPosterior`.

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,X,Y)` additionally returns the optimal score-to-posterior-probability transformation function parameters (`ScoreTransform`)

Tips

Here is one way to predict positive class posterior probabilities.

- 1 Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as, `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.
- 2 Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, for example, `ScoreSVMModel`, is the same, trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.

If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- 3 Pass the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) and predictor data matrix to `predict`. The second column of the second output argument stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

Input Arguments

SVMModel — Trained, compact SVM classifier

`CompactClassificationSVM` classifier

Trained, compact SVM classifier, specified as a `CompactClassificationSVM`.

TBL — Sample data

table

Sample data, specified as a table. Each row of `TBL` corresponds to one observation, and each column corresponds to one predictor variable. `TBL` must contain all of the

predictors used to train `SVMMODEL`. Optionally, TBL can contain an additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of strings are not allowed.

If TBL contains the response variable, you do not need to specify Y. If TBL does not include the response variable, then the length of Y must be equal to the number of rows of TBL.

If the sample data used to train `SVMMODEL` is a table, then you must specify the input data for `fitPosterior` as a table.

Data Types: `table`

X — Predictor data

`matrix`

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of Y and the number of rows of X must be equal.

If you set `'Standardize', true` in `fitcsvm` to train `SVMMODEL`, then the software standardizes the columns of X using the corresponding means in `SVMMODEL.Mu` and standard deviations in `SVMMODEL.Sigma`. If the software fits the transformation-function parameter estimates using standardized data, then the estimates might differ from estimation without standardized data.

Data Types: `double` | `single`

Y — Class labels

`categorical array` | `character array` | `logical vector` | `vector of numeric values` | `cell array of strings`

Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical or character array, logical or numeric vector, or cell array of strings.

If Y is a character array, then each element must correspond to one class label.

The length of Y and the number of rows of X must be equal.

Output Arguments

ScoreSVMModel — Trained, compact SVM classifier

CompactClassificationSVM classifier

Trained, compact SVM classifier containing the estimated score-to-posterior-probability transformation function, returned as a CompactClassificationSVM classifier.

To estimate posterior probabilities, pass ScoreSVMModel and predictor data to predict. If you set 'Standardize', true in fitcsvm to train SVMModel, then predict standardizes the columns of X using the corresponding means in SVMModel.Mu and standard deviations in SVMModel.Sigma.

ScoreTransform — Optimal score transformation function parameters

structure array

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.

- If field Type is sigmoid, then ScoreTransform has the following other fields:
 - Slope: The value of A in the “Sigmoid Function” on page 25-2208
 - Intercept: The value of B in the sigmoid function
- If field Type is step, then ScoreTransform has the following other fields:
 - PositiveClassProbability: The value of π in the “Step Function” on page 25-2208. It represents the probability that an observation is in the positive class. Also, the posterior probability that an observation is in the positive class given that its score is in the interval (LowerBound,UpperBound).
 - LowerBound: The value $\max_{y_n=-1} s_n$ in the step function. It represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class PositiveClassProbability. Any observation with a score less than LowerBound has the posterior probability of being the positive class 0.
 - UpperBound: The value $\min_{y_n=+1} s_n$ in the step function. It represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class

PositiveClassProbability. Any observation with a score greater than **UpperBound** has the posterior probability of being the positive class 1.

- If field **Type** is constant, then **ScoreTransform.PredictedClass** contains the name of the class prediction.

This result is the same as **SVMModel.ClassNames**. The posterior probability of an observation being in **ScoreTransform.PredictedClass** is always 1.

Definitions

Sigmoid Function

The sigmoid function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the output argument **ScoreTransform.Type** is **sigmoid**, then parameters A and B correspond to the fields **Scale** and **Intercept** of **ScoreTransform**, respectively.

Step Function

The step function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- s_j the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.

If the output argument `ScoreTransform.Type` is `step`, then the quantities $\max_{y_k=-1} s_k$

and $\min_{y_k=+1} s_k$ correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

Examples

Estimate Posterior Probabilities for New Data When Classes Are Inseparable

Load the `ionosphere` data set. Reserve 20 random observations of the data, and consider this set new data.

```
load ionosphere
n = size(X,1);
rng(1); % For reproducibility

indx = ~ismember([1:n],randsample(n,20)); % Indices for the training data
```

The classes of this data set are inseparable.

Train an SVM classifier using the training data. It is good practice to specify the class order and standardize the data.

```
SVMModel = fitcsvm(X(indx,:),Y(indx),'ClassNames',{'b','g'},...
```

```
'Standardize',true);
```

`SVMMModel` is a `ClassificationSVM` classifier.

Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as `g`. For efficiency, make a compact version of the SVM classifier `SVMMModel`, and pass it and the new data to `fitPosterior`.

```
CompactSVMMModel = compact(SVMMModel);  
[ScoreCSVMMModel,ScoreParameters] = fitPosterior(CompactSVMMModel,...  
    X(~indx,:),Y(~indx));
```

```
ScoreTransform = ScoreCSVMMModel.ScoreTransform  
ScoreParameters
```

```
ScoreTransform =
```

```
@(S)sigmoid(S,-1.098922e+00,4.519963e-01)
```

```
ScoreParameters =
```

```
    Type: 'sigmoid'  
    Slope: -1.0989  
    Intercept: 0.4520
```

`ScoreTransform` is the optimal score transform function. `ScoreParameters` is a structure array having three fields: the score transformation function name (`Type`), the sigmoid slope (`Slope`) and sigmoid intercept (`Intercept`) estimates.

Alternatively, you can pass `SVMMModel` and the new data to `fitSVMPPosterior`, but this does not have the benefit of efficiency.

Estimate the posterior probabilities that the observations in the new data are in class `g`.

```
[labels,postProbs] = predict(ScoreCSVMMModel,X(~indx,:));  
table(Y(~indx),labels,postProbs(:,2),...  
    'VariableNames',{'TrueLabel','PredictedLabel','PosteriorProbability'})
```

```
ans =
```

TrueLabel	PredictedLabel	PosteriorProbability
'g'	'g'	0.78437
'b'	'b'	0.024588
'g'	'g'	0.82399
'b'	'b'	0.0061637
'b'	'b'	3.6118e-06
'b'	'b'	0.15688
'b'	'g'	0.9622
'b'	'b'	6.1348e-09
'b'	'b'	0.0019646
'g'	'g'	0.7251
'g'	'g'	0.70263
'b'	'b'	0.075298
'g'	'g'	0.90691
'g'	'g'	0.82849
'b'	'b'	0.051193
'g'	'g'	0.95331
'b'	'b'	0.0031877
'b'	'b'	0.16015
'g'	'g'	0.92008
'g'	'g'	0.91349

Estimate Posterior Probabilities for New Data When Classes Are Separable

Load Fisher's iris data set. Use the petal lengths and widths, and remove the virginica species from the data. Reserve 10 random observations of the data, and consider this set new data.

```
load fisheriris
classKeep = ~strcmp(species,'virginica');
X = meas(classKeep,3:4);
Y = species(classKeep);

rng(1); % For reproducibility
indx1 = 1:numel(species);
indx2 = indx1(classKeep);
indx = ~ismember(indx2,randsample(indx2,10)); % Indices for the training data

gscatter(X(indx,1),X(indx,2),Y(indx));
title('Scatter Diagram of Iris Measurements')
xlabel('Petal length')
```

```
ylabel('Petal width')
legend('Setosa','Versicolor')
```

The classes are perfectly separable. Therefore, the score-to-posterior-probability transformation function is a step function.

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMModel = fitcsvm(X(indx,:),Y(indx),...
    'ClassNames',{'setosa','versicolor'},'Standardize',true);
```

SVMModel is a ClassificationSVM classifier.

Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as `versicolor`. For efficiency, make a compact version of the SVM classifier `SVMMModel`, and pass it and the new data to `fitPosterior`.

```
CompactSVMMModel = compact(SVMMModel);
[ScoreCSVMMModel,ScoreParameters] = fitPosterior(CompactSVMMModel,...
    X(~indx,:),Y(~indx));
```

```
ScoreTransform = ScoreCSVMMModel.ScoreTransform
```

```
Warning: Classes are perfectly separated. The optimal score-to-posterior
transformation is a step function.
```

```
ScoreTransform =
```

```
@(S)step(S,-1.338450e+00,2.012495e+00,5.333333e-01)
```

`fitPosterior` displays a warning whenever the classes are separable, and stores the step function in `ScoreSVMMModel.ScoreTransform`.

Display the score function type and its estimated values.

```
ScoreParameters
```

```
ScoreParameters =
```

```

                Type: 'step'
    LowerBound: -1.3385
    UpperBound:  2.0125
PositiveClassProbability: 0.5333
```

`ScoreParameters` is a structure array having four fields:

- The score transformation function type (`Type`)
- The score corresponding to negative class boundary (`LowerBound`)
- The score corresponding to positive class boundary (`UpperBound`)
- The positive class probability (`PositiveClassProbability`)

Alternatively, you can pass `SVMMModel` and the new data to `fitSVMPosterior`, but this does not have the benefit of efficiency.

Estimate the posterior probabilities that the observations in the new data are versicolor irises.

```
[labels,postProbs] = predict(ScoreCSVMModel,X(~indx,:));  
table(Y(~indx),labels,postProbs(:,2),...  
      'VariableNames',{ 'TrueLabel' , 'PredictedLabel' , 'PosteriorProbability' })
```

```
ans =
```

TrueLabel	PredictedLabel	PosteriorProbability
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'versicolor'	'versicolor'	1
'versicolor'	'versicolor'	1

Since the classes are separable, the step function transforms the positive-class score to:

- 0, if the score is less than `ScoreParameters.LowerBound`
- 1, if the score is greater than `ScoreParameters.UpperBound`
- `ScoreParameters.PositiveClassProbability`, if the score is in the interval [`ScoreParameters.LowerBound` , `ScoreParameters.LowerBound`]

Algorithms

If you reestimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not none, then the software:

- Displays a warning
- Resets the original transformation function to 'none' before estimating the new one

Alternatives

You can also estimate the optimal score-to-posterior-probability function using `fitSVMPosterior`. This function is similar to `fitPosterior`, except it is more broad since it accepts a wider range of SVM classifier types.

`CompactClassificationSVM` | `fitcsvm` | `fitSVMPosterior` | `predict`

fitrsvm

Fit a support vector machine regression model

Syntax

```
mdl = fitrsvm(tbl,ResponseVarName)
```

```
mdl = fitrsvm(tbl,formula)
```

```
mdl = fitrsvm(tbl,Y)
```

```
mdl = fitrsvm(X,Y)
```

```
mdl = fitrsvm( ____,Name,Value)
```

Description

`mdl = fitrsvm(tbl,ResponseVarName)` returns a full, trained support vector machine (SVM) regression model `mdl` trained using the predictors values in the table `tbl` and the response values in `tbl.ResponseVarName`.

`mdl = fitrsvm(tbl,formula)` returns a full, trained support vector machine (SVM) regression model `mdl` trained using the predictors values in the table `tbl`. `formula` is a formula string that identifies the response and predictor variables in `tbl` used for training.

`mdl = fitrsvm(tbl,Y)` returns a full, trained support vector machine (SVM) regression model `mdl` trained using the predictors values in the table `tbl` and the response values in the vector `Y`.

`mdl = fitrsvm(X,Y)` returns a full, trained support vector machine (SVM) regression model `mdl` trained using the predictors values in the matrix `X` and the response values in the vector `Y`.

`mdl = fitrsvm(____,Name,Value)` returns an SVM regression model with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the kernel function or train a cross-validated model.

Examples

Train a Linear Support Vector Machine Regression Model

This example shows how to train a linear support vector machine (SVM) regression model using sample data stored in matrices.

Load the `carsmall` data set.

```
load carsmall
rng default % for reproducibility
```

Specify `Horsepower` and `Weight` as the predictor variables (X) and `MPG` as the response variable (Y).

```
X = [Horsepower,Weight];
Y = MPG;
```

Train a linear SVM regression model.

```
mdl = fitrsvm(X,Y)
```

```
mdl =
```

```
RegressionSVM
    PredictorNames: {'x1' 'x2'}
    ResponseName: 'Y'
    CategoricalPredictors: []
    ResponseTransform: 'none'
                Alpha: [76x1 double]
                Bias: 43.1920
    KernelParameters: [1x1 struct]
    NumObservations: 93
    BoxConstraints: [93x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [93x1 logical]
                Solver: 'SMO'
```

```
Properties, Methods
```

The Command Window shows that `mdl` is a trained `RegressionSVM` classifier and displays a property list.

Check the model for convergence.

```
mdl.ConvergenceInfo.Converged
```

```
ans =
```

```
0
```

The returned value 0 indicates that the model did not converge.

Retrain the model using standardized data.

```
mdlStd = fitrsvm(X,Y,'Standardize',true)
```

```
mdlStd =
```

```
RegressionSVM
  PredictorNames: {'x1' 'x2'}
  ResponseName: 'Y'
  CategoricalPredictors: []
  ResponseTransform: 'none'
  Alpha: [77x1 double]
  Bias: 22.9131
  KernelParameters: [1x1 struct]
  Mu: [109.3441 2.9625e+03]
  Sigma: [45.3545 805.9668]
  NumObservations: 93
  BoxConstraints: [93x1 double]
  ConvergenceInfo: [1x1 struct]
  IsSupportVector: [93x1 logical]
  Solver: 'SMO'
```

Properties, Methods

Check the model for convergence.

```
mdlStd.ConvergenceInfo.Converged
```

```
ans =
```

```
1
```

The returned value 1 indicates that the model did converge.

Compute the resubstitution loss for the new model.

```
lStd = resubLoss mdlStd)
```

```
lStd =
```

```
17.0256
```

Train a Support Vector Machine Regression Model

This example shows how to train a support vector machine (SVM) regression model using sample data stored in a `table`.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current folder with the name `'abalone.data'`. Read the data into a `table`.

```
tbl = readtable('abalone.data', 'Filetype', 'text', 'ReadVariableNames', false);
rng default % for reproducibility
```

The sample data contains 4177 observations. All the predictor variables are continuous except for `sex`, which is a categorical variable with possible values `'M'` (for males), `'F'` (for females), and `'I'` (for infants). The goal is to predict the number of rings on the abalone and determine its age using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```
mdl = fitrsvm(tbl, 'Var9', 'KernelFunction', 'gaussian', 'KernelScale', 'auto', 'Standardize
```

```
mdl =
```

```
RegressionSVM
    PredictorNames: {1x8 cell}
    ResponseName: 'Var9'
    CategoricalPredictors: 1
    ResponseTransform: 'none'
    Alpha: [3635x1 double]
    Bias: 10.8144
    KernelParameters: [1x1 struct]
    Mu: [1x10 double]
    Sigma: [1x10 double]
    NumObservations: 4177
    BoxConstraints: [4177x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [4177x1 logical]
```

```
Solver: 'SMO'
```

Properties, Methods

The Command Window shows that `mdl` is a trained `RegressionSVM` classifier and displays a property list.

Display the properties of `mdl` using dot notation. For example, check to confirm whether the model converged and how many iterations it completed.

```
conv = mdl.ConvergenceInfo.Converged  
iter = mdl.NumIterations
```

```
conv =
```

```
    1
```

```
iter =
```

```
    2759
```

The returned results indicate that the model converged after 2759 iterations.

Train Cross-Validated SVM Regression Model Using `fitrsvm`

This example shows how to train a cross-validated support vector machine (SVM) regression model using `fitrsvm`.

Load the `carsmall` sample data.

```
load carsmall  
rng default % for reproducibility
```

Specify `Horsepower` and `Weight` as the predictor variables (X), and `MPG` as the response variable (Y).

```
X = [Horsepower,Weight];  
Y = MPG;
```

Train a linear SVM regression model. Specify a 10% holdout sample for testing the model. Standardize the data.

```
mdl = fitrsvm(X,Y,'Standardize',true,'Holdout',0.1)
```

```
mdl =
    classreg.learning.partition.RegressionPartitionedSVM
        CrossValidatedModel: 'SVM'
            PredictorNames: {'x1' 'x2'}
            ResponseName: 'Y'
            NumObservations: 94
            KFold: 1
            Partition: [1x1 cvpartition]
            ResponseTransform: 'none'
```

Properties, Methods

mdl is a RegressionPartitionedSVM model.

Calculate the loss (mean square error) of the partitioned regression model.

```
L = kfoldLoss(mdl)
```

```
L =
```

```
10.6435
```

Input Arguments

tbl — Predictor data

table

Predictor data to which the SVM regression model is fit, specified as a table. Each row of **tbl** corresponds to one observation, and each column corresponds to one predictor. Optionally, **tbl** can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of strings are not allowed.

If **tbl** contains the response variable, and you want to use all remaining variables in **tbl** as predictors, then specify the response variable using **ResponseVarName**.

If **tbl** contains the response variable, and you want to use only a subset of the remaining variables in **tbl** as predictors, then specify a formula string using **formula**.

If **tbl** does not contain the response variable, then specify a response variable using **Y**. The length of response variable and the number of rows of **tbl** must be equal.

If a row of `tbl` or an element of `Y` contains at least one `NaN`, then `fitrsvm` removes those rows and elements from both arguments when training the model.

To specify the names of the predictors in the order of their appearance in `tbl`, use the `PredictorNames` name-value pair argument.

Data Types: `table`

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a string. For example, if the response variable `Y` is stored as `tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `tbl`, including `Y`, as predictors when training the model.

formula — Response and predictor variables to use in model training

string in the form of `'Y~X1+X2+X3'`

Response and predictor variables to use in model training, specified as a string in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables.

To specify a subset of variables in `tbl` as predictors for training the model, use a formula string. If you specify a formula string, then any variables in `tbl` that do not appear in `formula` are not used to train the model.

X — Predictor data

matrix of numeric values

Predictor data to which the SVM regression model is fit, specified as an n -by- p matrix of numeric values. n is the number of observations and p is the number of predictor variables.

The length of `Y` and the number of rows of `X` must be equal.

If a row of `X` or an element of `Y` contains at least one `NaN`, then `fitrsvm` removes those rows and elements from both arguments.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

Y — Response values

vector of numeric values

Response values, specified as an n -by-1 vector of numeric values. The length of `Y` and the number of rows of `tbl` or `X` must be equal.

If a row of `tbl` or `X`, or an element of `Y`, contains at least one NaN, then `ftrsvm` removes those rows and elements from both arguments when training the model.

To specify the response variable name, use the `ResponseName` name-value pair argument.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example:

`'KernelFunction', 'gaussian', 'Standardize', true, 'CrossVal', 'on'` trains a 10-fold cross-validated SVM regression model using a Gaussian kernel and standardized training data.

Kernel Function

'KernelFunction' — Kernel function

`'linear'` (default) | `'gaussian'` | `'rbf'` | `'polynomial'` | function name

Kernel function used to compute the elements of the Gram matrix, specified as the comma-separated pair consisting of `'KernelFunction'` and `'linear'`, `'gaussian'`, `'rbf'`, or `'polynomial'`.

Alternatively, you can pass the name of a function on the MATLAB path. The function must be of the form $G = \text{KFUN}(U, V)$. The returned value `G` must be an m -by- n matrix, where m and n are the number of rows in `U` and `V`, respectively.

Example: `'KernelFunction', 'gaussian'`

'KernelOffset' — Kernel offset

nonnegative scalar value

Kernel offset, specified as the comma-separated pair consisting of `'KernelOffset'` and a nonnegative scalar value. After `fitrsvm` computes an element of the Gram matrix, it adds the value of `KernelOffset` to the computed element.

If `Solver` is specified as `'SMO'`, then the default value of `KernelOffset` is 0. If `Solver` is specified as `'ISDA'`, then the default value of `KernelOffset` is 0.1.

Example: `'KernelOffset',0`

Data Types: `single` | `double`

'KernelScale' — Kernel scale factor1 (default) | `'auto'` | scalar value

Kernel scale factor, specified as the comma-separated pair consisting of `'KernelScale'` and either a scalar value or the string `'auto'`. If `'auto'`, `fitrsvm` selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates obtained by this procedure can vary from one application of `fitrsvm` to another. Set the random number generator seed before calling `fitrsvm` for reproducibility.

To compute the Gram matrix, `fitrsvm` divides each element in predictor matrix `X` by the value of `KernelScale` if `KernelFunction` is specified as `'linear'`, `'gaussian'`, `'rbf'`, or `'polynomial'`.

If you pass your own kernel function, `fitrsvm` errors if you use the `'KernelScale'` name-value pair argument.

Example: `'KernelScale','auto'`

Data Types: `single` | `double`

'PolynomialOrder' — Degree for polynomial kernel

3 (default) | positive integer value

Degree for polynomial kernel, specified as the comma-separated pair consisting of `'PolynomialOrder'` and a positive integer value. This name-value pair is only valid if you specify `'KernelFunction'` as `'polynomial'`.

Example: `'PolynomialOrder',4`

Data Types: `single` | `double`

Algorithm and Tolerance Values

'DeltaGradientTolerance' — Tolerance for gradient difference between upper and lower violators

0 | nonnegative scalar value

Tolerance for gradient difference between upper and lower violators, specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar value.

Example: 'DeltaGradientTolerance',1e-4

Data Types: single | double

'GapTolerance' — Tolerance for feasibility gap

1e-3 (default) | nonnegative scalar value

Tolerance for feasibility gap, specified as the comma-separated pair consisting of 'GapTolerance' and a nonnegative scalar value. This name-value pair applies only if 'Solver' is 'SMO' or 'ISDA'.

If `GapTolerance` is 0, then `firsvm` does not use this parameter to check convergence.

Example: 'GapTolerance',1e-4

Data Types: single | double

'IterationLimit' — Maximum number of iterations

1e6 (default) | positive integer value

Maximum number of iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer value. `firsvm` returns a result when this limit is reached, even if the optimization did not converge.

Example: 'IterationLimit',1000

Data Types: single | double

'KKTolerance' — Tolerance for KKT violation

0 | nonnegative scalar value

Tolerance for Karush-Kuhn-Tucker (KKT) violation, specified as the comma-separated pair consisting of 'KKTolerance' and a nonnegative scalar value.

This name-value pair applies only if 'Solver' is 'SMO' or 'ISDA'.

If `KKTTolerance` is 0, then `fitrsvm` does not use this parameter to check convergence.

Example: `'KKTTolerance', 1e-4`

Data Types: `single` | `double`

'Solver' — Name of solver algorithm

`'SMO'` | `'ISDA'` | `'L1QP'`

Name of solver algorithm, specified as the comma-separated pair consisting of `'Solver'` and one of the following strings.

Value	Description
<code>'SMO'</code>	Sequential Minimal Optimization
<code>'ISDA'</code>	Iterative Single Data Algorithm
<code>'L1QP'</code>	L1 soft-margin minimization by quadratic programming (requires an Optimization Toolbox license).

If you specify a positive value for the `'OutlierFraction'` name-value pair, then the default solver is `'ISDA'`. Otherwise, the default solver is `'SMO'`.

Example: `'Solver', 'ISDA'`

Dual Problem Parameters

'Alpha' — Initial estimates of alpha coefficients

`zeros(n,1)` (default) | n -by-1 vector in the range $[-C, C]$

Initial estimates of alpha coefficients, specified as the comma-separated pair consisting of `'Alpha'` and an n -by-1 vector of scalar values in the range $[-C, C]$. n is the number of rows in the input matrix X , and C is the value of the box constraint. You can set the box constraint using the `BoxConstraint` name-value pair argument.

The alpha coefficients are the estimated Lagrange multipliers for the support vectors, and the coefficients for the dual optimization problem.

You cannot use this name-value pair if X contains NaN values or if you also use one of the cross-validation name-value pair options (`'CrossVal'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`).

Data Types: `single` | `double`

'BoxConstraint' — Box constraint

positive scalar value

Box constraint for the alpha coefficients, specified as the comma-separated pair consisting of `'BoxConstraint'` and a positive scalar value.

The absolute value of the Alpha coefficients cannot exceed the value of `BoxConstraint`.

The default `BoxConstraint` value for the `'gaussian'` or `'rbf'` kernel function is $\text{iqr}(Y)/1.349$, where $\text{iqr}(Y)$ is the interquartile range of response variable Y . For all other kernels, the default `BoxConstraint` value is 1.

Example: `BoxConstraint,10`

Data Types: `single` | `double`

'ClipAlphas' — Flag to clip alpha coefficients

`true` (default) | `false`

Flag to clip alpha coefficients, specified as the comma-separated pair consisting of `'ClipAlphas'` and either `'true'` or `'false'`.

Suppose that the alpha coefficient for observation j is α_j , and the box constraint of j is C_j . $j = 1, \dots, n$ and n is the training sample size.

Value	Description
<code>true</code>	At each iteration, if α_j is near 0 or near C_j , then MATLAB sets α_j to 0 or to C_j , respectively.
<code>false</code>	MATLAB does not change the alpha coefficients during optimization.

MATLAB stores the final values of α in the `Alpha` property of the trained SVM model object.

`ClipAlphas` can affect SMO and ISDA convergence.

Example: `'ClipAlphas',false`

Data Types: `logical`

'Epsilon' — Half the width of epsilon-insensitive band`iqr(Y)/1.349` (default) | nonnegative scalar value

Half the width of the epsilon-insensitive band, specified as the comma-separated pair consisting of `'Epsilon'` and a nonnegative scalar value.

The default `Epsilon` value is `iqr(Y)/1.349`, which is an estimate of standard deviation using the interquartile range of the response variable `Y`. If `iqr(Y)` is equal to zero, then the default `Epsilon` value is 0.1.

Example: `'Epsilon', 0.3`

Data Types: `single` | `double`

Cross-Validation**'CrossVal' — Cross-validation flag**`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'CrossVal'` and either `'on'` or `'off'`.

If `'on'`, `fitrsvm` trains a cross-validated model with 10 folds. You can override this cross-validation setting using one of the `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` name-value pair arguments. You can only use one of these four options (`'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`) at a time when creating a cross-validated model.

Alternatively, you can cross-validate the model later using the `crossval` method.

Example: `'CrossVal', 'on'`

'CVPartition' — Partition for cross-validated model`cvpartition` object

Partition for cross-validated model, specified as the comma-separated pair consisting of `'CVPartition'` and an object created using `cvpartition`.

If you use `'CVPartition'`, you cannot use any of the `'KFold'`, `'Holdout'`, or `'Leaveout'` name-value pair arguments.

'Holdout' — Fraction of data for holdout validation`0` (default) | scalar value in the range `[0,1]`

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation test model using the specified fraction of the data, and uses the rest of the data for training.

If you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout',0.1

Data Types: single | double

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in the cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

If you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'KFold',8

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. To use leave-one-out cross validation, specify 'on'.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout','on'

Other

'CacheSize' — Cache size

1000 (default) | positive scalar value | 'maximal'

Cache size in megabytes (MB), specified as the comma-separated pair consisting of 'CacheSize' and a positive scalar value.

Alternatively, you can specify `'maximal'`. In this case, `fitrsvm` makes the cache large enough to hold the entire Gram matrix of size n -by- n , where n is the number of rows in `X`.

Increasing the cache size can improve the training speed for data with many observations.

Example: `'CacheSize','maximal'`

Data Types: `single` | `double`

'CategoricalPredictors' — Categorical predictors list

numeric or logical vector | cell array of strings | `'all'`

List of categorical predictors, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following:

- A numeric vector with indices from 1 through `p`, where `p` is the number of columns of `X`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `X` is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- `'all'`, meaning all predictors are categorical.

By default, if the predictor data is in a matrix (`X`), `fitrsvm` assumes that none of the predictors are categorical. If the predictor data is in a table (`tbl`), `fitrsvm` assumes that a variable is categorical if it contains logical values, categorical values, or a cell array of strings.

For example, the following syntax specifies that columns 1 and 3 of the input matrix `X` contain categorical variables.

Example: `'CategoricalPredictors',[1,3]`

Data Types: `single` | `double` | `logical` | `cell`

'NumPrint' — Frequency of diagnostic display

1000 (default) | nonnegative scalar value

Frequency of diagnostic display, specified as the comma-separated pair consisting of `'NumPrint'` and a nonnegative scalar value. Diagnostic messages are displayed during optimization by `SMO` or `ISDA` every `'NumPrint'` iterations. `fitrsvm` uses this parameter only if you set the `'Verbose'` name-value pair argument to 1.

Example: 'NumPrint',500

Data Types: single | double

'OutlierFraction' — Expected fraction of outliers

0 (default) | scalar value in the range [0,1]

Expected fraction of outliers in the training set, specified as the comma-separated pair consisting of 'OutlierFraction' and a scalar value in the range [0,1]. `ftrsvm` removes observations with large gradients, ensuring that `ftrsvm` removes the fraction of observations specified by `OutlierFraction` by the time convergence is reached. This name-value pair is only valid when 'Solver' is 'ISDA'.

Example: 'OutlierFraction',0.1

Data Types: single | double

'PredictorNames' — Predictor variable names

{'x1','x2',...} (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in X.

Data Types: cell

'ResponseName' — Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable in Y.

Example: 'ResponseName','response'

Data Types: char

'ShrinkagePeriod' — Shrinkage period

0 (default) | nonnegative integer value

Shrinkage period, specified as the comma-separated pair consisting of 'ShrinkagePeriod' and a nonnegative integer value.

If you specify a value for 'ShrinkagePeriod', then `ftrsvm` moves observations from the active set to the inactive set every `ShrinkagePeriod` number of iterations. If `ShrinkagePeriod` is 0, then `ftrsvm` does not shrink the active set.

Shrinking can speed up convergence significantly when the support vector set is much smaller than the training data set. If you want to apply shrinkage, set `'ShrinkagePeriod'` to 1000 as a suggested starting point.

Example: `'ShrinkagePeriod',1000`

Data Types: `single` | `double`

'Standardize' — Flag to standardize predictor data

`false` (default) | `true`

Flag to standardize predictor data, specified as the comma-separated pair consisting of `'Standardize'` and `false` or `true`. If `true`, `ftrsvm` standardizes the values in the predictor matrix X by centering and dividing each column by its standard deviations.

Example: `'Standardize',true`

Data Types: `logical`

'Verbose' — Verbosity level

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and either 0, 1, or 2. `Verbose` controls the amount of optimization information that the software displays in the Command Window and saves to the structure `mdl.ConvergenceInfo.History`.

The following table summarizes the available verbosity level options.

Value	Description
0	The software does not display or save convergence information.
1	The software displays diagnostic messages and saves convergence criteria every <i>numprint</i> number of iterations. You can set the value of <i>numprint</i> using the <code>'NumPrint'</code> name-value pair argument.
2	The software displays diagnostic messages and saves convergence criteria at every iteration.

Example: `'Verbose',1`

'Weights' — Observation weights

ones(size(X,1),1) (default) | vector of numeric values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of numeric values. The size of `Weights` must equal the number of rows in `X`. `fitrsvm` normalizes the values of `Weights` to sum to 1.

Data Types: `single` | `double`

Output Arguments

mdl — Trained SVM regression model

RegressionSVM model | RegressionPartitionedSVM cross-validated model

Trained SVM regression model, returned as a RegressionSVM model or RegressionPartitionedSVM cross-validated model.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `Leaveout`, `CrossVal`, or `CVPartition`, then `mdl` is a RegressionPartitionedSVM cross-validated model. Otherwise, `mdl` is a RegressionSVM model.

Introduced in R2015b

fitree

Fit binary regression decision tree

Syntax

```
tree = fitrtree(tbl,ResponseVarName)
tree = fitrtree(tbl,formula)
tree = fitrtree(tbl,y)

tree = fitrtree(x,y)

tree = fitrtree( ____,Name,Value)
```

Description

`tree = fitrtree(tbl,ResponseVarName)` returns a regression tree based on the input variables (also known as predictors, features, or attributes) in the table `tbl` and output (response) contained in `tbl.ResponseVarName`. `tree` is a binary tree where each branching node is split based on the values of a column of `tbl`.

`tree = fitrtree(tbl,formula)` returns a regression tree based on the input variables contained in the table `tbl`. `formula` is a formula string that identifies the response and predictor variables in `tbl` used for training.

`tree = fitrtree(tbl,y)` returns a regression tree based on the input variables contained in the table `tbl` and output contained in `y`.

`tree = fitrtree(x,y)` returns a regression tree based on the input variables `x` and output `y`. `tree` is a binary tree where each branching node is split based on the values of a column of `x`.

`tree = fitrtree(____,Name,Value)` fits a tree with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify observation weights or train a cross-validated model.

If you use one of the following five options, `tree` is of class `RegressionPartitionedModel`: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. Otherwise, `tree` is of class `RegressionTree`.

Examples

Construct a Regression Tree

Load the sample data.

```
load carsmall;
```

Construct a regression tree using the sample data.

```
tree = fitrtree([Weight, Cylinders],MPG,...  
               'categoricalpredictors',2,'MinParentSize',20,...  
               'PredictorNames',{'W','C'})
```

```
tree =
```

```
RegressionTree  
    PredictorNames: {'W' 'C'}  
    ResponseName: 'Y'  
    CategoricalPredictors: 2  
    ResponseTransform: 'none'  
    NumObservations: 94
```

Predict the mileage of 4,000-pound cars with 4, 6, and 8 cylinders.

```
mileage4K = predict(tree,[4000 4; 4000 6; 4000 8])
```

```
mileage4K =
```

```
19.2778  
19.2778  
14.3889
```

Control Regression Tree Depth

You can control the depth of trees using the `MaxNumSplits`, `MinLeafSize`, or `MinParentSize` name-value pair parameters. `fitrtree` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

The default values of the tree-depth controllers for growing regression trees are:

- `n - 1` for `MaxNumSplits`. `n` is the training sample size.
- `1` for `MinLeafSize`.
- `10` for `MinParentSize`.

These default values tend to grow deep trees for large training sample sizes.

Train a regression tree using the default values for tree-depth control. Cross validate the model using 10-fold cross validation.

```
rng(1); % For reproducibility
MdlDefault = fitrtree(X,MPG,'CrossVal','on');
```

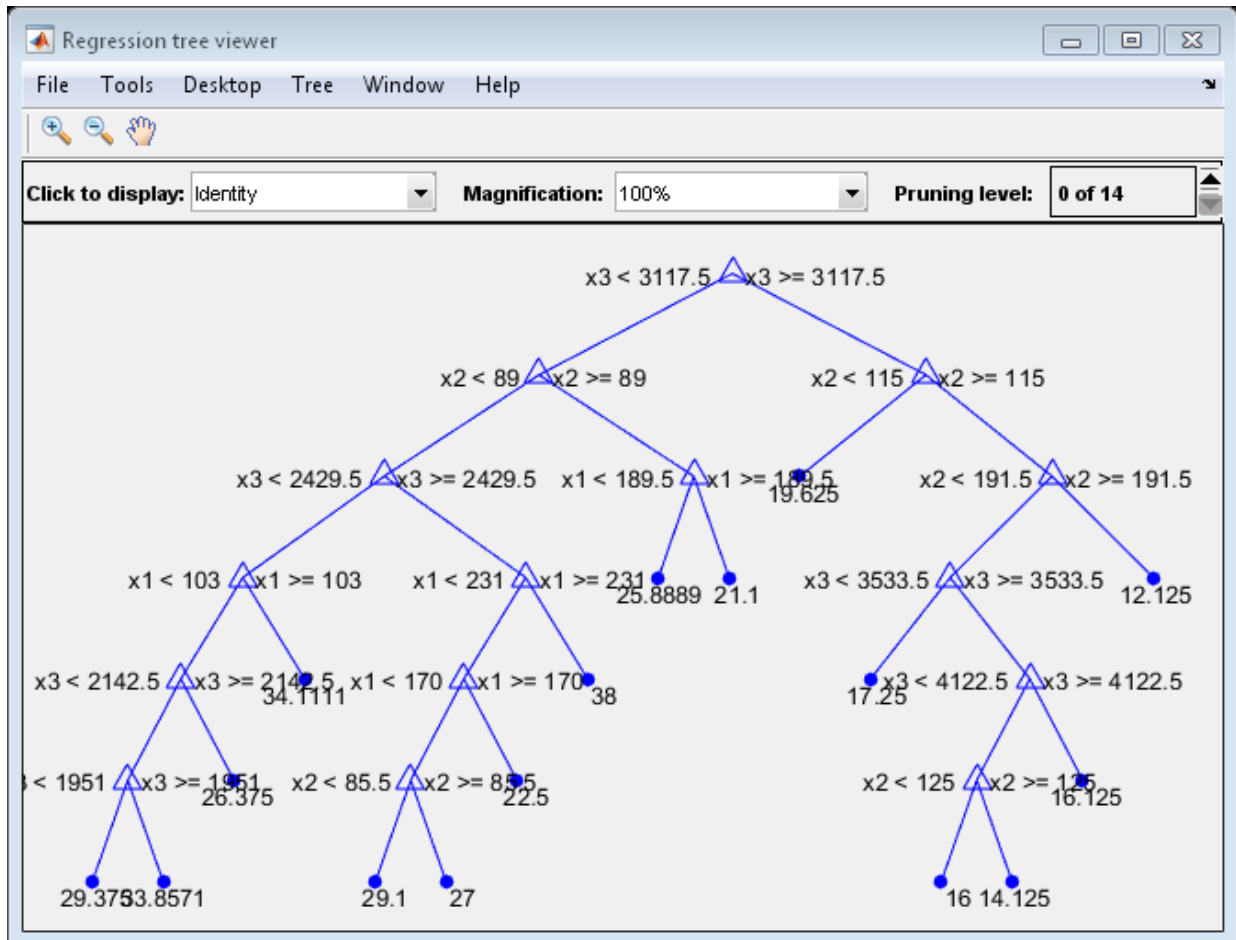

Draw a histogram of the number of imposed on the trees. The number of imposed splits is one less than the number of leaves. Also, view one of the trees.

```
numBranches = @(x)sum(x.IsBranch);
mdlDefaultNumSplits = cellfun(numBranches, MdlDefault.Trained);

figure;
histogram(mdlDefaultNumSplits)

view(MdlDefault.Trained{1}, 'Mode', 'graph')
```

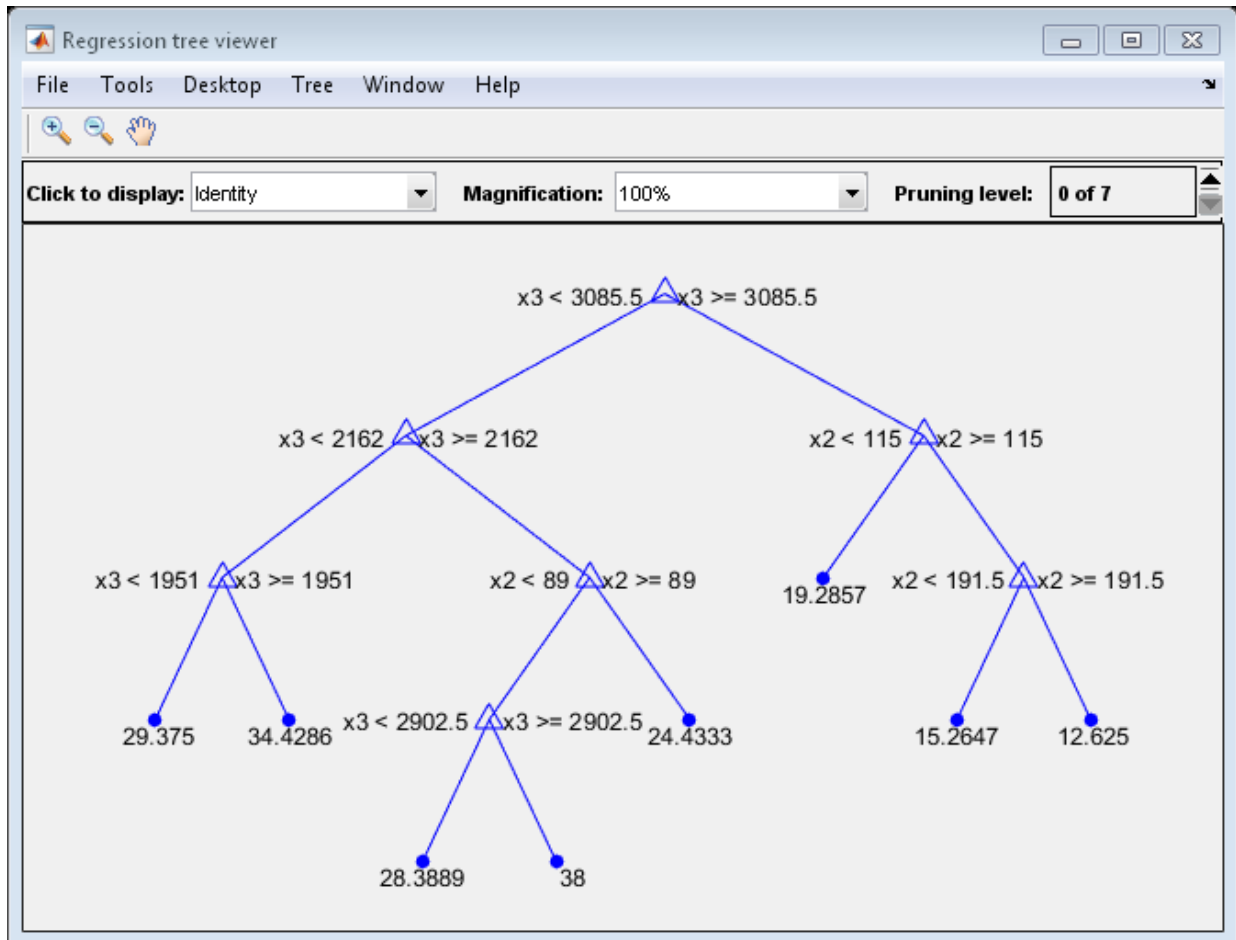

The average number of splits is between 14 and 15.

Suppose that you want a regression tree that is not as complex (deep) as the ones trained using the default number of splits. Train another regression tree, but set the maximum number of splits at 7, which is about half the mean number of splits from the default regression tree. Cross validate the model using 10-fold cross validation.

```
Mdl7 = fitree(X,MPG,'MaxNumSplits',7,'CrossVal','on');
view(Mdl7.Trained{1},'Mode','graph')
```

Compare the cross validation MSEs of the models.

```
mseDefault = kfoldLoss(MdlDefault)
mse7 = kfoldLoss(Mdl7)
```

```
mseDefault =
    27.7277
```

```
mse7 =  
    28.3833
```

Mdl7 is much less complex and performs only slightly worse than MdlDefault.

Input Arguments

tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of **tbl** corresponds to one observation, and each column corresponds to one predictor variable. Optionally, **tbl** can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of strings are not allowed.

If **tbl** contains the response variable, and you want to use all remaining variables in **tbl** as predictors, then specify the response variable using **ResponseVarName**.

If **tbl** contains the response variable, and you want to use only a subset of the remaining variables in **tbl** as predictors, then specify a formula string using **formula**.

If **tbl** does not contain the response variable, then specify a response variable using **y**. The length of response variable and the number of rows of **tbl** must be equal.

Data Types: `table`

x — Predictor values

matrix of floating-point values

Predictor values, specified as matrix of floating-point values. Each column of **x** represents one variable, and each row represents one observation.

`fitree` considers NaN values in **x** as missing values. `fitree` does not use observations with all missing values for **x** the fit. `fitree` uses observations with some missing values for **x** to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

ResponseVarName — Response variable name

name of a variable in **tbl**

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a string. For example, if the response variable `y` is stored as `tbl.y`, then specify it as `'response'`. Otherwise, the software treats all columns of `tbl`, including `y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of strings. If `y` is a character array, then each element must correspond to one row of the array.

It is good practice to specify the order of the classes using the `ClassNames` name-value pair argument.

formula — Response and predictor variables to use in model training

string in the form of `'Y~X1+X2+X3'`

Response and predictor variables to use in model training, specified as a string in the form of `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables.

To specify a subset of variables in `tbl` as predictors for training the model, use a formula string. If you specify a formula string, then any variables in `tbl` that do not appear in `formula` are not used to train the model.

y — Response data

numeric column vector

Response data, specified as a numeric column vector with the same number of rows as `x`. Each entry in `y` is the response to the data in the corresponding row of `x`.

`fitrtree` considers NaN values in `y` to be missing values. `fitrtree` does not use observations with missing values for `y` in the fit.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'CrossVal', 'on', 'MinParentSize', 30` specifies a cross-validated regression tree with a minimum of 30 observations per branch node.

'CategoricalPredictors' — Categorical predictors list

numeric or logical vector | cell array of strings | character matrix | `'all'`

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following.

- A numeric vector with indices from 1 to `p`, where `p` is the number of columns of `x` or `tbl`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `x` or `tbl` is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in the `PredictorNames` property.
- A character matrix, where each row of the matrix is a name of a predictor variable. Pad the names with extra blanks so each row of the character matrix has the same length.
- `'all'`, meaning all predictors are categorical.

By default, if the predictor data is in a matrix (`x`), the software assumes that none of the predictors are categorical. If the predictor data is in a table (`tbl`), the software assumes that a variable is categorical if it contains, logical values, values of the unordered data type `categorical`, or a cell array of strings.

Data Types: `single` | `double` | `logical` | `char` | `cell`

'CrossVal' — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'CrossVal'` and either `'on'` or `'off'`.

If `'on'`, `fitree` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the `'Kfold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` name-value pair arguments. You can only use one of these four options (`'Kfold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`) at a time when creating a cross-validated tree.

Alternatively, cross-validate `tree` later using the `crossval` method.

Example: 'CrossVal', 'on'

'CVPartition' — Partition for cross-validation tree

cvpartition object

Partition for cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object created using cvpartition.

If you use 'CVPartition', you cannot use any of the 'Kfold', 'Holdout', or 'Leaveout' name-value pair arguments.

'Holdout' — Fraction of data for holdout validation

0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use 'Holdout', you cannot use any of the 'CVPartition', 'Kfold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout', 0.1

Data Types: single | double

'Kfold' — Number of folds

10 (default) | positive integer greater than 1

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'Kfold' and a positive integer value greater than 1.

If you use 'Kfold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'Kfold', 8

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout', 'on'

'MergeLeaves' — Leaf merge flag

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and 'on' or 'off'.

If MergeLeaves is 'on', then fitree:

- Merges leaves that originate from the same parent node, and that yields a sum of risk values greater or equal to the risk associated with the parent node
- Estimates the optimal sequence of pruned subtrees, but does not prune the regression tree

Otherwise, fitree does not merge leaves.

Example: 'MergeLeaves', 'off'

'MinLeafSize' — Minimum number of leaf node observations

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeafSize' and a positive integer value. Each leaf has at least MinLeafSize observations per tree leaf. If you supply both MinParentSize and MinLeafSize, fitree uses the setting that gives larger leaves: $\text{MinParentSize} = \max(\text{MinParentSize}, 2 * \text{MinLeafSize})$.

Example: 'MinLeafSize', 3

Data Types: single | double

'MinParentSize' — Minimum number of branch node observations

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParentSize' and a positive integer value. Each branch node in the tree has at least MinParentSize observations. If you supply both MinParentSize and MinLeafSize, fitree uses the setting that gives larger leaves: $\text{MinParentSize} = \max(\text{MinParentSize}, 2 * \text{MinLeafSize})$.

Example: `'MinParentSize',8`

Data Types: `single` | `double`

'NumVariablesToSample' — Number of predictors for split

`'all'` (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of `'NumVariablesToSample'` and a positive integer value. You can also specify `'all'` to use all available predictors.

Example: `'NumVariablesToSample',3`

Data Types: `single` | `double`

'PredictorNames' — Predictor variable names

`{'x1','x2',...}` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of strings containing the names for the predictor variables, in the order in which they appear in `x` or `tbl`.

If you specify the predictors as a table (`tbl`), `PredictorNames` must be a subset of the variable names in `tbl`. In this case, the software uses only the variables in `PredictorNames` to fit the model. If you use formula to specify the model, then you cannot use the `PredictorNames` name-value pair.

Data Types: `cell`

'Prune' — Flag to estimate optimal sequence of pruned subtrees

`'on'` (default) | `'off'`

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of `'Prune'` and `'on'` or `'off'`.

If `Prune` is `'on'`, then `fitrtree` grows the regression tree and estimates the optimal sequence of pruned subtrees, but does not prune the regression tree. Otherwise, `fitrtree` grows the regression tree without estimating the optimal sequence of pruned subtrees.

To prune a trained regression tree, pass the regression tree to `prune`.

Example: `'Prune','off'`

'PruneCriterion' — Pruning criterion`'error'` (default)

Pruning criterion, specified as the comma-separated pair consisting of `'PruneCriterion'` and `'error'`.

Example: `'PruneCriterion', 'error'`

'QuadraticErrorTolerance' — Quadratic error tolerance`1e-6` (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of `'QuadraticErrorTolerance'` and a positive scalar value. Splitting nodes stops when quadratic error per node drops below `QuadraticErrorTolerance*QED`, where QED is the quadratic error for the entire data computed before the decision tree is grown.

Example: `'QuadraticErrorTolerance', 1e-4`

'ResponseName' — Response variable name`'Y'` (default) | string

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a string representing the name of the response variable.

This name-value pair is not valid when using the `ResponseVarName` or `formula` input arguments.

Example: `'ResponseName', 'Response'`

Data Types: char

'ResponseTransform' — Response transform function`'none'` (default) | function handle

Response transform function for transforming the raw response values, specified as the comma-separated pair consisting of `'ResponseTransform'` and either a function handle or `'none'`. The function handle must accept a matrix of response values and return a matrix of the same size. The default string `'none'` means $@(x)x$, or no transformation.

Add or change a `ResponseTransform` function using dot notation:

```
tree.ResponseTransform = @function
```

Data Types: function_handle

'SplitCriterion' — Split criterion`'MSE'` (default)

Split criterion, specified as the comma-separated pair consisting of `'SplitCriterion'` and `'MSE'`, meaning mean squared error.

Example: `'SplitCriterion','MSE'`

'Surrogate' — Surrogate decision splits flag`'off' | 'on' | 'all' | positive integer value`

Surrogate decision splits flag, specified as the comma-separated pair consisting of `'Surrogate'` and `'on'`, `'off'`, `'all'`, or a positive integer value.

- When `'on'`, `fitrtree` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `fitrtree` finds at most the specified number of surrogate splits at each branch node.
- When set to `'all'`, `fitrtree` finds all surrogate splits at each branch node. The `'all'` setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: `'Surrogate','on'`

Data Types: `single` | `double`

'Weights' — Observation weights`ones(size(X,1),1)` (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values. The software weights the observations in each row of `X` or `tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `tbl`.

If you specify the input data as a table `tbl`, then `Weights` can be the name of a variable in `tbl` that contains a numeric vector. In this case, you must specify `Weights` as a variable name string. For example, if weights vector `W` is stored as `TBL.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `tbl`, including `W`, as predictors when training the model.

`fitrtree` normalizes the weights in each class to add up to 1.

Data Types: `single` | `double`

Output Arguments

tree — Regression tree

regression tree object

Regression tree, returned as a regression tree object. Using the `'Crossval'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a tree of class `RegressionPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `RegressionTree`, and you can use the `predict` method to make predictions.

More About

Predictive Measure of Association

The *predictive measure of association* is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k , respectively, and $j \neq k$. At node t , the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_j L_k} - P_{R_j R_k})}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t , such that $x_j < u$. The subscript L stands for the left child of node t .
- P_R is the proportion of observations in node t , such that $x_j \geq u$. The subscript R stands for the right child of node t .

- P_{L_j, L_k} is the proportion of observations at node t , such that $x_j < u$ and $x_k < v$.
- P_{R_j, R_k} is the proportion of observations at node t , such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Surrogate Decision Splits

A *surrogate decision split* is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association.

Tips

By default, Prune is 'on'. However, this specification does not prune the regression tree. To prune a trained regression tree, pass the regression tree to `prune`.

Algorithms

Node Splitting Rules

`fitrtree` follows these steps to determine how to split node t . For all predictors x_i , $i = 1, \dots, p$:

- 1 `fitrtree` computes the weighted, mean-square error (MSE) of the responses in node t using

$$\varepsilon_t = \sum_{j \in T} w_j (y_j - \bar{y}_t)^2.$$

w_j is the weight of observation j , and T is the set of all observation indices in node t . If you do not specify `Weights`, then $w_j = 1/n$, where n is the sample size.

- 2 `fitree` estimates the probability that an observation is in node t using

$$P(T) = \sum_{j \in T} w_j.$$

- 3 `fitree` sorts x_i in ascending order. Each element of the sorted predictor is a splitting candidate or cut point. `fitree` records any indices corresponding to missing values in the set T_U , which is the unsplit set.

- 4 `fitree` determines the best way to split node t using x_i by maximizing the reduction in MSE (ΔI) over all splitting candidates. That is, for all splitting candidates in x_i :

a `fitree` splits the observations in node t into left and right child nodes (t_L and t_R , respectively).

b `fitree` computes ΔI . Suppose that for a particular splitting candidate, t_L and t_R contain observation indices in the sets T_L and T_R , respectively.

- If x_i does not contain any missing values, then the reduction in MSE for the current splitting candidate is

$$\Delta I = P(T)\varepsilon_t - P(T_L)\varepsilon_{t_L} - P(T_R)\varepsilon_{t_R}.$$

- If x_i contains missing values, then, assuming that the observations are missing at random, the reduction in MSE is

$$\Delta I_U = P(T - T_U)\varepsilon_t - P(T_L)\varepsilon_{t_L} - P(T_R)\varepsilon_{t_R}.$$

$T - T_U$ is the set of all observation indices in node t that are not missing.

- If you use surrogate decision splits, then:
 - `fitree` computes the predictive measures of association between the decision split $x_j < u$ and all possible decision splits $x_k < v$, $j \neq k$.
 - `fitree` sorts the possible alternative decision splits in descending order by their predictive measure of association with the optimal split. The surrogate split is the decision split yielding the largest measure.

- iii `fitrtree` decides the child node assignments for observations with a missing value for x_i using the surrogate split. If the surrogate predictor also contains a missing value, then `fitrtree` uses the decision split with the second largest measure, and so on, until there are no other surrogates. It is possible for `fitrtree` to split two different observations at node t using two different surrogate splits. For example, suppose the predictors x_1 and x_2 are the best and second best surrogates, respectively, for the predictor x_i , $i \notin \{1,2\}$, at node t . If observation m of predictor x_i is missing (i.e., x_{mi} is missing), but x_{m1} is not missing, then x_1 is the surrogate predictor for observation x_{mi} . If observations $x_{(m+1),i}$ and $x_{(m+1),1}$ are missing, but $x_{(m+1),2}$ is not missing, then x_2 is the surrogate predictor for observation $m+1$.
 - iv `fitrtree` uses the appropriate MSE reduction formula. That is, if `fitrtree` fails to assign all missing observations in node t to children nodes using surrogate splits, then the MSE reduction is ΔI_U . Otherwise, `fitrtree` uses ΔI for the MSE reduction.
- c `fitrtree` chooses the candidate that yields the largest MSE reduction.

`fitrtree` splits the predictor variable at the cut point that maximizes the MSE reduction.

Tree Depth Control

- If `MergeLeaves` is 'on' and `PruneCriterion` is 'error' (which are the default values for these name-value pair arguments), then the software applies pruning only to the leaves and by using classification error. This specification amounts to merging leaves that share the most popular class per leaf.
- To accommodate `MaxNumSplits`, `fitrtree` splits all nodes in the current *layer*, and then counts the number of branch nodes. A layer is the set of nodes that are equidistant from the root node. If the number of branch nodes exceeds `MaxNumSplits`, `fitrtree` follows this procedure:
 - 1 Determine how many branch nodes in the current layer must be unsplit so that there are at most `MaxNumSplits` branch nodes.
 - 2 Sort the branch nodes by their impurity gains.
 - 3 Unsplit the number of least successful branches.
 - 4 Return the decision tree grown so far.

This procedure produces maximally balanced trees.

- The software splits branch nodes layer by layer until at least one of these events occurs:
 - There are `MaxNumSplits` branch nodes.
 - A proposed split causes the number of observations in at least one branch node to be fewer than `MinParentSize`.
 - A proposed split causes the number of observations in at least one leaf node to be fewer than `MinLeafSize`.
 - The algorithm cannot find a good split within a layer (i.e., the pruning criterion (see `PruneCriterion`), does not improve for all proposed splits in a layer). A special case is when all nodes are pure (i.e., all observations in the node have the same class).

`MaxNumSplits` and `MinLeafSize` do not affect splitting at their default values. Therefore, if you set '`MaxNumSplits`', splitting might stop due to the value of `MinParentSize`, before `MaxNumSplits` splits occur.

Parallelization

For dual-core systems and above, `fitree` parallelizes training decision trees using Intel Threading Building Blocks (TBB). For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

fitSVMPosterior

Fit posterior probabilities

Syntax

```
ScoreSVMModel = fitSVMPosterior(SVMModel)

ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,ResponseVarName)
ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,Y)

ScoreSVMModel = fitSVMPosterior(SVMModel,X,Y)

ScoreSVMModel = fitSVMPosterior( ____,Name,Value)

[ScoreSVMModel,ScoreTransform] = fitSVMPosterior( ____ )
```

Description

`ScoreSVMModel = fitSVMPosterior(SVMModel)` returns `ScoreSVMModel`, which is a trained, support vector machine (SVM) classifier containing the optimal score-to-posterior-probability transformation function for two-class learning.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier `SVMModel`, and by cross validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`). The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function.
- If the classes are perfectly separable, the transformation function is the step function.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function. `fitSVMPosterior` is not appropriate for one-class learning.
- If `SVMModel` is a `ClassificationSVM` classifier, then the software estimates the optimal transformation function by 10-fold cross validation as outlined in [1]. Otherwise, `SVMModel` must be a `ClassificationPartitionedModel` classifier. `SVMModel` specifies the cross-validation method.

- The software stores the optimal transformation function in `ScoreSVMModel.ScoreTransform`.

`ScoreSVMModel = fitSVMPosterior(SVMModel, TBL, ResponseVarName)` returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier `SVMModel`. The software estimates the score transformation function using predictor data in the table `TBL` and class labels `TBL.ResponseVarName`.

`ScoreSVMModel = fitSVMPosterior(SVMModel, TBL, Y)` returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier `SVMModel`. The software estimates the score transformation function using predictor data in the table `TBL` and class labels `Y`.

`ScoreSVMModel = fitSVMPosterior(SVMModel, X, Y)` returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier `SVMModel`. The software estimates the score transformation function using predictor data `X` and class labels `Y`.

`ScoreSVMModel = fitSVMPosterior(____, Name, Value)` uses additional options specified by one or more `Name, Value` pair arguments provided `SVMModel` is a `ClassificationSVM` classifier. For example, you can specify the number of folds to use in k -fold cross validation.

`[ScoreSVMModel, ScoreTransform] = fitSVMPosterior(____)` additionally returns the transformation function parameters (`ScoreTransform`) using any of the input arguments in the previous syntaxes.

Examples

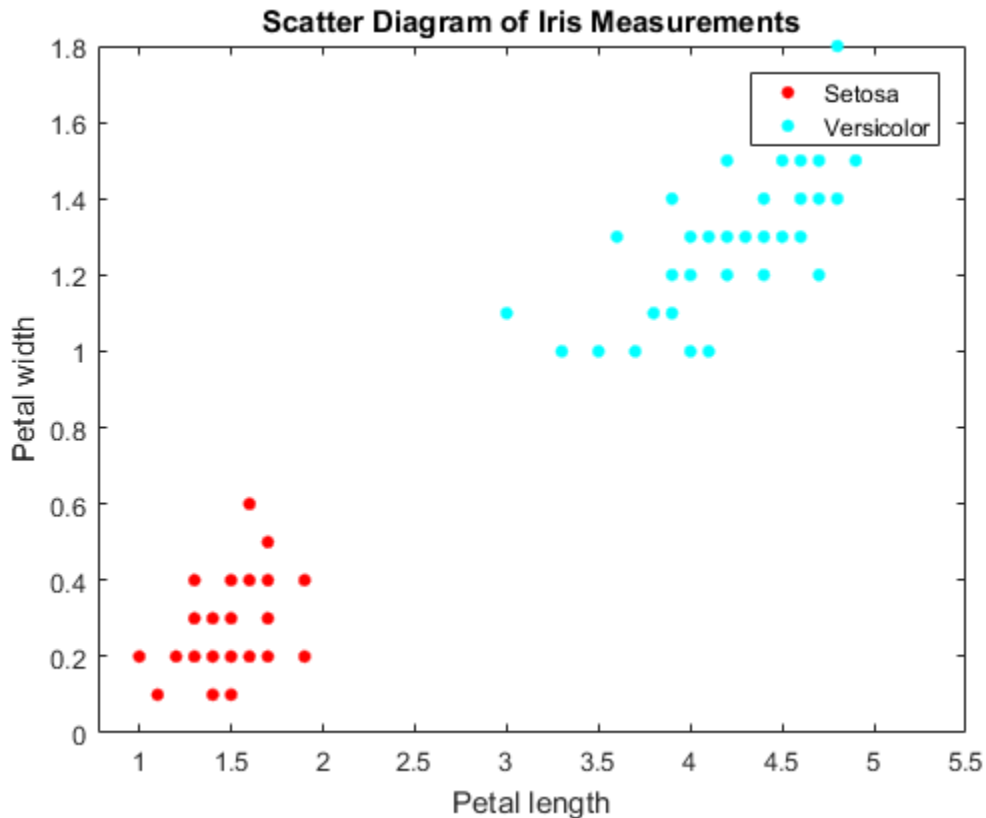

Fit the Score-to-Posterior Probability Function for Separable Classes

Load Fisher's iris data set. Train the classifier using the petal lengths and widths, and remove the virginica species from the data.

```
load fisheriris
classKeep = ~strcmp(species, 'virginica');
X = meas(classKeep, 3:4);
y = species(classKeep);

gscatter(X(:,1), X(:,2), y);
title('Scatter Diagram of Iris Measurements')
```

```
xlabel('Petal length')  
ylabel('Petal width')  
legend('Setosa', 'Versicolor')
```

The classes are perfectly separable. Therefore, the score transformation function is a step function.

Train an SVM classifier using the data. Cross validate the classifier using 10-fold cross validation (the default).

```
rng(1);  
CVSVMModel = fitcsvm(X,y,'CrossVal','on');
```

CVSVMModel is a trained `ClassificationPartitionedModel` SVM classifier.

Estimate the step function that transforms scores to posterior probabilities.

```
[ScoreCVSVMModel,ScoreParameters] = fitSVMPosterior(CVSVMModel);
```

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step function.

`fitSVMPosterior` does the following:

- Uses the data that the software stored in `CVSVMModel` to fit the transformation function
- Warns whenever the classes are separable
- Stores the step function in `ScoreCVSVMModel.ScoreTransform`

Display the score function type and its parameter values.

`ScoreParameters`

```
ScoreParameters =
    Type: 'step'
    LowerBound: -0.8431
    UpperBound: 0.6897
    PositiveClassProbability: 0.5000
```

`ScoreParameters` is a structure array with four fields:

- The score transformation function type (`Type`)
- The score corresponding to the negative class boundary (`LowerBound`)
- The score corresponding to the positive class boundary (`UpperBound`)
- The positive class probability (`PositiveClassProbability`)

Since the classes are separable, the step function transforms the score to either 0 or 1, which is the posterior probability that an observation is a versicolor iris.

Fit the Score-to-Posterior Probability Function for Inseparable Classes

Load the `ionosphere` data set.

```
load ionosphere
```

The classes of this data set are not separable.

Train an SVM classifier. Cross validate using 10-fold cross validation (the default). It is good practice to standardize the predictors and specify the class order.

```
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'ClassNames',{ 'b', 'g'}, 'Standardize', true, ...
    'CrossVal', 'on');
ScoreTransform = CVSVMModel.ScoreTransform
```

```
ScoreTransform =
```

```
none
```

CVSVMModel is a trained ClassificationPartitionedModel SVM classifier. The positive class is 'g'. The ScoreTransform property is none.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```
[ScoreCVSVMModel,ScoreParameters] = fitSVMPosterior(CVSVMModel);
ScoreTransform = ScoreCVSVMModel.ScoreTransform
ScoreParameters
```

```
ScoreTransform =
```

```
@(S)sigmoid(S,-9.481576e-01,-1.218300e-01)
```

```
ScoreParameters =
```

```
    Type: 'sigmoid'
    Slope: -0.9482
    Intercept: -0.1218
```

ScoreTransform is the optimal score transform function. ScoreParameters contains the score transformation function, slope estimate, and the intercept estimate.

You can estimate test-sample, posterior probabilities by passing ScoreCVSVMModel to kfoldPredict.

Estimate Posterior Probabilities for Test Samples

Estimate positive class posterior probabilities for the test set of an SVM algorithm.

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Specify a 20% holdout sample. It is good practice to standardize the predictors and specify the class order.

```
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'Holdout',0.2,'Standardize',true,...
    'ClassNames',{'b','g'});
```

CVSVMModel is a trained `ClassificationPartitionedModel` cross-validated classifier.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```
ScoreCVSVMModel = fitSVMPosterior(CVSVMModel);
```

ScoreSVMModel is a trained `ClassificationPartitionedModel` cross-validated classifier containing the optimal score transformation function estimated from the training data.

Estimate the out-of-sample positive class posterior probabilities. Display the results for the first 10 out-of-sample observations.

```
[~,OOSPostProbs] = kfoldPredict(ScoreCVSVMModel);
indx = ~isnan(OOSPostProbs(:,2));
hoObs = find(indx); % Holdout observation numbers
OOSPostProbs = [hoObs, OOSPostProbs(indx,2)];
table(OOSPostProbs(1:10,1),OOSPostProbs(1:10,2),...
    'VariableNames',{'ObservationIndex','PosteriorProbability'})
```

ans =

ObservationIndex	PosteriorProbability
6	0.17378
7	0.89637
8	0.0076609
9	0.91602
16	0.026718

22	4.6081e-06
23	0.9024
24	2.4129e-06
38	0.00042697
41	0.86427

Input Arguments

SVMMODEL — Trained SVM classifier

ClassificationSVM classifier | CompactClassificationSVM classifier |
ClassificationPartitionedModel classifier

Trained SVM classifier, specified as a ClassificationSVM, CompactClassificationSVM, or ClassificationPartitionedModel classifier.

If SVMMODEL is a ClassificationSVM classifier, then you can set optional name-value pair arguments.

If SVMMODEL is a CompactClassificationSVM classifier, then you must input predictor data X and class labels Y.

TBL — Sample data

table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all of the predictors used to train SVMMODEL. Multi-column variables and cell arrays other than cell arrays of strings are not allowed.

If TBL contains the response variable used to train SVMMODEL, then you do not need to specify ResponseVarName or Y.

If you trained SVMMODEL using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: table

X — Predictor data

matrix

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of `Y` and the number of rows of `X` must be equal.

If you set `'Standardize'`, `true` in `fitcsvm` to train `SVMMODEL`, then the software standardizes the columns of `X` using the corresponding means in `SVMMODEL.MU` and standard deviations in `SVMMODEL.SIGMA`. If the software fits the transformation-function parameter estimates using standardized data, then the estimates might differ from estimation without standardized data.

Data Types: `double` | `single`

ResponseVarName — Response variable name

name of a variable in `TBL`

Response variable name, specified as the name of a variable in `TBL`. If `TBL` contains the response variable used to train `SVMMODEL`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a string. For example, if the response variable is stored as `TBL.Response`, then specify it as `'Response'`. Otherwise, the software treats all columns of `TBL`, including `TBL.Response`, as predictors.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of strings. If the response variable is a character array, then each element must correspond to one row of the array.

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical or character array, logical or numeric vector, or cell array of strings.

If `Y` is a character array, then each element must correspond to one class label.

The length of `Y` and the number of rows of `X` must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'KFold', 8` performs 8-fold cross validation when `SVMModel` is a `ClassificationSVM` classifier.

'CVPartition' — Cross-validation partition

`[]` (default) | `cvpartition` partition

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition as created by `cvpartition`. You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

`crossval` splits the data into subsets using `cvpartition`.

'Holdout' — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

'KFold' — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1.

You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Example: 'KFold',8

Data Types: single | double

'Leaveout' — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross validation to compute the transformation function, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Use leave-one-out cross validation by using 'on'.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Leaveout', 'on'

Output Arguments

ScoreSVMModel — Trained SVM classifier

ClassificationSVM classifier | CompactClassificationSVM classifier |
ClassificationPartitionedModel classifier

Trained SVM classifier containing the estimated score transformation function, returned as a ClassificationSVM, CompactClassificationSVM, or ClassificationPartitionedModel classifier.

The ScoreSVMModel classifier type is the same as the SVMModel classifier type.

To estimate posterior probabilities, pass ScoreSVMModel and predictor data to predict. If you set 'Standardize', true in fitcsvm to train SVMModel, then predict standardizes the columns of X using the corresponding means in SVMModel.Mu and standard deviations in SVMModel.Sigma.

ScoreTransform — Optimal score-to-posterior-probability transformation function parameters

structure array

Optimal score-to-posterior-probability transformation function parameters, specified as a structure array. If field Type is:

- `sigmoid`, then `ScoreTransform` has these fields:
 - `Slope` — The value of A in the sigmoid function
 - `Intercept` — The value of B in the sigmoid function
- `step`, then `ScoreTransform` has these fields:
 - `PositiveClassProbability`: the value of π in the step function. π represents:
 - The probability that an observation is in the positive class.
 - The posterior probability that a score is in the interval `(LowerBound,UpperBound)`.
 - `LowerBound`: the value $\max_{y_n=-1} s_n$ in the step function. It represents the lower bound of the interval that assigns the posterior probability of being in the positive class `PositiveClassProbability` to scores. Any observation with a score less than `LowerBound` has posterior probability of being the positive class `0`.
 - `UpperBound`: the value $\min_{y_n=+1} s_n$ in the step function. It represents the upper bound of the interval that assigns the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has posterior probability of being the positive class `1`.
- `constant`, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

This result is the same as `SVMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always `1`.

More About

Sigmoid Function

The sigmoid function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the output argument `ScoreTransform.Type` is `sigmoid`, then parameters A and B correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

Step Function

The step function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s_j < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- s_j the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.

If the output argument `ScoreTransform.Type` is `step`, then the quantities $\max_{y_k=-1} s_k$ and $\min_{y_k=+1} s_k$ correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

Tips

Here is one way to predict positive class posterior probabilities.

- 1 Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as, `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.
- 2 Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, for example, `ScoreSVMModel`, is the same, trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.

If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- 3 Pass the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) and predictor data matrix to `predict`. The second column of the second output argument stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

Algorithms

If you reestimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning
- Resets the original transformation function to 'none' before estimating the new one

Introduced in R2014a

fitted

Class: GeneralizedLinearMixedModel

Fitted responses from generalized linear mixed-effects model

Syntax

```
mufit = fitted(glme)
mufit = fitted(glme, Name, Value)
```

Description

`mufit = fitted(glme)` returns the fitted conditional response of the generalized linear mixed-effects model `glme`.

`mufit = fitted(glme, Name, Value)` returns the fitted response with additional options specified by one or more name-value pair arguments. For example, you can specify to compute the marginal fitted response.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Conditional' — Indicator for conditional response

true (default) | false

Indicator for conditional response, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

Value	Description
true	Contributions from both fixed effects and random effects (conditional)
false	Contribution from only fixed effects (marginal)

To obtain fitted marginal response values, `fitted` computes the conditional mean of the response with the empirical Bayes predictor vector of random effects b set equal to 0. For more information, see “Conditional and Marginal Response” on page 25-2268

Example: 'Conditional', false

Output Arguments

mufit — Fitted response values n -by-1 vector

Fitted response values, returned as an n -by-1 vector, where n is the number of observations.

Definitions

Conditional and Marginal Response

A *conditional response* includes contributions from both fixed- and random-effects predictors. A *marginal response* includes contribution from only fixed effects.

Suppose the generalized linear mixed-effects model `glme` has an n -by- p fixed-effects design matrix X and an n -by- q random-effects design matrix Z . Also, suppose the

estimated p -by-1 fixed-effects vector is $\hat{\beta}$, and the q -by-1 empirical Bayes predictor vector of random effects is \hat{b} .

The fitted conditional response corresponds to the 'Conditional', true name-value pair argument, and is defined as

$$\hat{\mu}_{cond} = g^{-1}(\hat{\eta}_{ME}),$$

where $\hat{\eta}_{ME}$ is the linear predictor including the fixed- and random-effects of the generalized linear mixed-effects model

$$\hat{\eta}_{ME} = X\hat{\beta} + Z\hat{b} + \delta.$$

The fitted marginal response corresponds to the 'Conditional', false name-value pair argument, and is defined as

$$\hat{\mu}_{mar} = g^{-1}(\hat{\eta}_{FE}),$$

where $\hat{\eta}_{FE}$ is the linear predictor including only the fixed-effects portion of the generalized linear mixed-effects model

$$\hat{\eta}_{FE} = X\hat{\beta} + \delta.$$

Examples

Plot Observed Versus Fitted Values

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\begin{aligned} \log(\mu_{ij}) = & \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time_dev_{ij} \\ & + \beta_3 temp_dev_{ij} + \beta_4 supplier_C_{ij} + \beta_5 supplier_B_{ij} + b_i, \end{aligned}$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- $newprocess_{ij}$, $time_dev_{ij}$, and $temp_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j . For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier_C_{ij}$ and $supplier_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|fact
```

Generate the fitted conditional mean values for the model.

```
mufit = fitted(glme);
```

Create a scatterplot of the observed values versus fitted values.

```
figure
scatter(mfr.defects, mufit)
title('Residuals versus Fitted Values')
xlabel('Fitted Values')
ylabel('Residuals')
```

fitted

Class: LinearMixedModel

Fitted responses from a linear mixed-effects model

Syntax

```
yfit = fitted(lme)
yfit = fitted(lme,Name,Value)
```

Description

`yfit = fitted(lme)` returns the fitted conditional response from the linear mixed-effects model `lme`.

`yfit = fitted(lme,Name,Value)` returns the fitted response from the linear mixed-effects model `lme` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify if you want to compute the fitted marginal response.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Conditional' — Indicator for conditional response

True (default) | False

Indicator for conditional response, specified as the comma-separated pair consisting of 'Conditional' and either of the following.

True	Contribution from both fixed effects and random effects (conditional)
False	Contribution from only fixed effects (marginal)

Example: `'Conditional, 'False'`

Output Arguments

yfit — Fitted response values

n-by-1 vector

Fitted response values, returned as an *n*-by-1 vector, where *n* is the number of observations.

Examples

Compute Fitted Conditional and Marginal Responses

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
            'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by `Date`.

`Region` is a categorical variable. You can specify the contrasts for categorical variables using the `DummyVarCoding` name-value pair argument when fitting the model. When you do not specify the contrasts, `fitlme` uses the 'reference' contrast by default. Because the model has an intercept, `fitlme` takes the first region, NE, as the reference and creates eight dummy variables representing the other eight regions. For example, `I[MidAtl]` is the dummy variable representing the region `MidAtl`. For details, see “Dummy Indicator Variables” on page 2-59.

The corresponding model is

$$y_{im} = \beta_0 + \beta_1 I[\text{MidAtl}]_i + \beta_2 I[\text{ENCentral}]_i + \beta_3 I[\text{WNCentral}]_i + \beta_4 I[\text{SAtl}]_i \\ + \beta_5 I[\text{ESCentral}]_i + \beta_6 I[\text{WSCentral}]_i + \beta_7 I[\text{Mtn}]_i + \beta_8 I[\text{Pac}]_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`, β_j , $j = 0, 1, \dots, 8$, are the fixed-effects coefficients, with β_0 being the coefficient for region NE. b_{0m} is the random effect for level m of the grouping variable `Date`, and ε_{im} is the observation error for observation i . The random effect has the prior distribution, $b_{0m} \sim N(0, \sigma_b^2)$ and the error term has the distribution, $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
lme = fitlme(flu2,'FluRate ~ 1 + Region + (1|Date)')
```

Linear mixed-effects model fit by ML

Model information:

```

Number of observations      468
Fixed effects coefficients  9
Random effects coefficients 52
Covariance parameters      2

```

Formula:

```

'Region_Pac'	-0.16013	0.052221	-3.0665	459	0.0022936

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'(Intercept)'	'(Intercept)'	'std'	0.6443	0.5297	0.78368

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.26627	0.24878	0.285

The p -values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions `WNCentral` and `ESCentral` are significantly different relative to the flu rates in region `NE`.

The confidence limits for the standard deviation of the random-effects term, σ_b^2 , do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The conditional fitted response from the model at a given observation includes contributions from fixed and random effects. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region `WNCentral` in week 10/9/2005 is

$$\begin{aligned}\hat{y}_{WNCentral,10/9/2005} &= \hat{\beta}_0 + \hat{\beta}_3 I[WNCentral] + \hat{b}_{10/9/2005} \\ &= 1.2233 + 0.23687 - 0.1718 \\ &= 1.28837.\end{aligned}$$

This is the fitted conditional response, since it includes contributions to the estimate from both the fixed and random effects. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')

y_hat =

    1.2884
```

In the previous calculation, `beta(1)` corresponds to the estimate for β_0 and `beta(4)` corresponds to the estimate for β_3 . You can simply display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')

ans =

    1.2884
```

The estimated marginal response for region `WNCentral` in week `10/9/2005` is

$$\begin{aligned}\hat{y}_{WNCentral,10/9/2005}^{(\text{marginal})} &= \hat{\beta}_0 + \hat{\beta}_3 I[WNCentral] \\ &= 1.2233 + 0.23687 \\ &= 1.46017.\end{aligned}$$

Compute the fitted marginal response.

```
F = fitted(lme,'Conditional',false);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans =  
  
    1.4602
```

Plot Residuals vs. Fitted Values

Navigate to a folder containing sample data.

```
cd(matlabroot)  
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);  
tbl.Subject = nominal(tbl.Subject);  
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and raw residuals.

```
F = fitted(lme);  
R = residuals(lme);
```

Plot the residuals versus the fitted values.

```
plot(F,R,'bx')  
xlabel('Fitted Values')  
ylabel('Residuals')
```

Now, plot the residuals versus the fitted values, grouped by program.

```
figure();  
gscatter(F,R,Program)
```

Definitions

Fitted Conditional and Marginal Response

A conditional response includes contributions from both fixed and random effects, whereas a marginal response includes contribution from only fixed effects.

Suppose the linear mixed-effects model, lme , has an n -by- p fixed-effects design matrix X and an n -by- q random-effects design matrix Z . Also, suppose the p -by-1 estimated

fixed-effects vector is $\hat{\beta}$, and the q -by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is \hat{b} . The fitted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

and the fitted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta},$$

fixedEffects

Class: GeneralizedLinearMixedModel

Estimates of fixed effects and related statistics

Syntax

```
beta = fixedEffects(glme)
[beta,betaname] = fixedEffects(glme)
[beta,betaname,stats] = fixedEffects(glme)
[ ___ ] = fixedEffects(glme,Name,Value)
```

Description

`beta = fixedEffects(glme)` returns the estimated fixed-effects coefficients, `beta`, of the generalized linear mixed-effects model `glme`.

`[beta,betaname] = fixedEffects(glme)` also returns the names of estimated fixed-effects coefficients in `betaname`. Each name corresponds to a fixed-effects coefficient in `beta`.

`[beta,betaname,stats] = fixedEffects(glme)` also returns a table of statistics, `stats`, related to the estimated fixed-effects coefficients of `glme`.

`[___] = fixedEffects(glme,Name,Value)` returns any of the output arguments in previous syntaxes using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence level, or the method for computing the approximate degrees of freedom for the *t*-statistic.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Alpha' — Confidence level

0.05 (default) | scalar value in the range [0,1]

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range [0,1]. For a value α , the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha', 0.01

Data Types: single | double

'DFMethod' — Method for computing approximate degrees of freedom

'residual' (default) | 'none'

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

Value	Description
'residual'	The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
'none'	All degrees of freedom are set to infinity.

Example: 'DFMethod', 'none'

Output Arguments

beta — Estimated fixed-effects coefficients

vector

Estimated fixed-effects coefficients of the fitted generalized linear mixed-effects model `glme`, returned as a vector.

betanames — Names of fixed-effects coefficients

table

Names of fixed-effects coefficients in `beta`, returned as a table.

stats — Fixed-effects estimates and related statistics

dataset array

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

Column Name	Description
Name	Name of the fixed-effects coefficient
Estimate	Estimated coefficient value
SE	Standard error of the estimate
tStat	<i>t</i> -statistic for a test that the coefficient is 0
DF	Estimated degrees of freedom for the <i>t</i> -statistic
pValue	<i>p</i> -value for the <i>t</i> -statistic
Lower	Lower limit of a 95% confidence interval for the fixed-effects coefficient
Upper	Upper limit of a 95% confidence interval for the fixed-effects coefficient

When fitting a model using `fitglme` and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), if you specify the 'CovarianceMethod' name-value pair argument as 'conditional', then SE does not account for the uncertainty in estimating the covariance parameters. To account for this uncertainty, specify 'CovarianceMethod' as 'JointHessian'.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REMP'), `fixedEffects` bases the fixed effects estimates and related statistics on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Examples

Estimate Fixed-Effects Coefficients

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time_dev** and **temp_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time_dev**, **temp_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as **'effects'**, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\begin{aligned} \log(\mu_{ij}) = & \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time_dev_{ij} \\ & + \beta_3 temp_dev_{ij} + \beta_4 supplier_C_{ij} + \beta_5 supplier_B_{ij} + b_i, \end{aligned}$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- $newprocess_{ij}$, $time_dev_{ij}$, and $temp_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j . For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier_C_{ij}$ and $supplier_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|fact
```

Compute and display the estimated fixed-effects coefficient values and related statistics.

```
[beta, betanames, stats] = fixedEffects(glme);
stats
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'residual', Alpha = 0.05
```

Name	Estimate	SE	tStat	DF
'(Intercept)'	1.4689	0.15988	9.1875	94
'newprocess'	-0.36766	0.17755	-2.0708	94
'time_dev'	-0.094521	0.82849	-0.11409	94

'temp_dev'	-0.28317	0.9617	-0.29444	94
'supplier_C'	-0.071868	0.078024	-0.9211	94
'supplier_B'	0.071072	0.07739	0.91836	94

pValue	Lower	Upper
9.8194e-15	1.1515	1.7864
0.041122	-0.72019	-0.015134
0.90941	-1.7395	1.5505
0.76907	-2.1926	1.6263
0.35936	-0.22679	0.083051
0.36078	-0.082588	0.22473

The returned results indicate, for example, that the estimated coefficient for `temp_dev` is -0.28317 . Its large p -value, 0.76907 , indicates that it is not a statistically significant predictor at the 5% significance level. Additionally, the confidence interval boundaries `Lower` and `Upper` indicate that the 95% confidence interval for the coefficient for `temp_dev` is $[-0.2.1926, 1.6263]$. This interval contains 0, which supports the conclusion that `temp_dev` is not statistically significant at the 5% significance level.

fixedEffects

Class: LinearMixedModel

Estimates of fixed effects and related statistics

Syntax

```
beta = fixedEffects(lme)
[beta,betanames] = fixedEffects(lme)
[beta,betanames,stats] = fixedEffects(lme)
[beta,betanames,stats] = fixedEffects(lme,Name,Value)
```

Description

`beta = fixedEffects(lme)` returns the estimated fixed-effects coefficients, `beta`, of the linear mixed-effects model `lme`.

`[beta,betanames] = fixedEffects(lme)` also returns the names of estimated fixed-effects coefficients in `betanames`. Each name corresponds to a fixed-effects coefficient in `beta`.

`[beta,betanames,stats] = fixedEffects(lme)` also returns the estimated fixed-effects coefficients of the linear mixed-effects model `lme` and related statistics in `stats`.

`[beta,betanames,stats] = fixedEffects(lme,Name,Value)` also returns the estimated fixed-effects coefficients of the linear mixed-effects model `lme` and related statistics with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'Alpha' — Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha', 0.01

Data Types: single | double

'DFMethod' — Method for computing approximate degrees of freedom

'residual' (default) | 'satterthwaite' | 'none'

Method for computing approximate degrees of freedom for the t -statistic that tests the fixed-effects coefficients against 0, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

'residual'

Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.

'satterthwaite'

Satterthwaite approximation.

'none'

All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: 'DFMethod', 'satterthwaite'

Output Arguments

beta — Fixed-effects coefficients estimates

vector

Fixed-effects coefficients estimates of the fitted linear mixed-effects model `lme`, returned as a vector.

betanames — Names of fixed-effects coefficients

table

Names of fixed-effects coefficients in `beta`, returned as a table.

stats — Fixed-effects estimates and related statistics

dataset array

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

Name	Name of the fixed effect coefficient
Estimate	Estimated coefficient value
SE	Standard error of the estimate
tStat	<i>t</i> -statistic for a test that the coefficient is zero
DF	Estimated degrees of freedom for the <i>t</i> -statistic
pValue	<i>p</i> -value for the <i>t</i> -statistic
Lower	Lower limit of a 95% confidence interval for the fixed-effect coefficient
Upper	Upper limit of a 95% confidence interval for the fixed-effect coefficient

Examples

Display Fixed-Effects Coefficient Estimates and Names

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

The data set `weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = tbl(InitWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between week and program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl,'y ~ InitWeight + Program*Week + (Week|Subject)');
```

Display the fixed-effects coefficient estimates and corresponding fixed-effects names.

```
[beta,betaname] = fixedEffects(lme);
```

```

    0.6610
    0.0032
    0.3608
   -0.0333
    0.1132
    0.1732
    0.0388
    0.0305
    0.0331
```

```
betaname =
```

```
    Name
    '(Intercept) '
    'InitWeight '
    'Program_B '
    'Program_C '
    'Program_D '
    'Week '
    'Program_B:Week '
```

```
'Program_C:Week'  
'Program_D:Week'
```

Compute Coefficient Estimates and Related Statistics

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and potentially correlated random effects for intercept and acceleration grouped by model year. First, store the data in a table.

```
tbl = table(Acceleration,Horsepower,Model_Year,MPG);
```

Fit the model.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Compute the fixed-effects coefficients estimates and related statistics.

```
[~,~,stats] = fixedEffects(lme)
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.05
```

Name	Estimate	SE	tStat	DF	pValue	Lower
'(Intercept)'	50.133	2.2652	22.132	389	7.7727e-71	44.5
'Acceleration'	-0.58327	0.13394	-4.3545	389	1.7075e-05	-0.85
'Horsepower'	-0.16954	0.0072609	-23.35	389	5.188e-76	-0.18

The small p -values (under `pValue`) indicate that all fixed-effects coefficients are significant.

Compute Confidence Intervals with Specified Options

Navigate to a folder containing sample data.

```
cd(matlabroot)  
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Compute the 99% confidence intervals for fixed-effects coefficients, using the residual method to compute the degrees of freedom. This is the default method.

```
[~,~,stats] = fixedEffects(lme, 'alpha', 0.01)
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.01
```

Name	Estimate	SE	tStat	DF	pValue	Lower
'(Intercept)'	3.1196	0.88681	3.5178	12	0.0042407	0.4108
'Shift_Morning'	-0.3868	0.48344	-0.80009	12	0.43921	-1.863
'Shift_Night'	1.9856	0.48344	4.1072	12	0.0014535	0.508

Compute the 99% confidence intervals for fixed-effects coefficients, using the Satterthwaite approximation to compute the degrees of freedom.

```
[~,~,stats] = fixedEffects(lme, 'DFMethod', 'satterthwaite', 'alpha', 0.01)
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'Satterthwaite', Alpha = 0.01
```

Name	Estimate	SE	tStat	DF	pValue	Lower
'(Intercept)'	3.1196	0.88681	3.5178	6.123	0.01214	-0.14
'Shift_Morning'	-0.3868	0.48344	-0.80009	10	0.44225	-1

'Shift_Night'	1.9856	0.48344	4.1072	10	0.00212	0.4
---------------	--------	---------	--------	----	---------	-----

The Satterthwaite approximation usually produces smaller DF values than the residual method. That is why it produces larger p -values (`pValue`) and larger confidence intervals (see `Lower` and `Upper`).

fpdf

F probability density function

Syntax

`Y = fpdf(X, V1, V2)`

Description

`Y = fpdf(X, V1, V2)` computes the F pdf at each of the values in `X` using the corresponding numerator degrees of freedom `V1` and denominator degrees of freedom `V2`. `X`, `V1`, and `V2` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. `V1` and `V2` parameters must contain real positive values, and the values in `X` must lie on the interval $[0, \infty)$.

The probability density function for the F distribution is

$$y = f(x | v_1, v_2) = \frac{\Gamma\left(\frac{v_1 + v_2}{2}\right)}{\Gamma\left(\frac{v_1}{2}\right)\Gamma\left(\frac{v_2}{2}\right)} \left(\frac{v_1}{v_2}\right)^{\frac{v_1}{2}} \frac{x^{\frac{v_1}{2} - 1}}{\left[1 + \left(\frac{v_1}{v_2}\right)x\right]^{\frac{v_1 + v_2}{2}}}$$

Examples

```
y = fpdf(1:6,2,2)
y =
    0.2500    0.1111    0.0625    0.0400    0.0278    0.0204

z = fpdf(3,5:10,5:10)
z =
    0.0689    0.0659    0.0620    0.0577    0.0532    0.0487
```

fracfact

Fractional factorial design

Syntax

```
X = fracfact(gen)
[X,conf] = fracfact(gen)
[X,conf] = fracfact(gen,Name,Value)
```

Description

`X = fracfact(gen)` creates the two-level fractional factorial design defined by the generator string `gen`.

`[X,conf] = fracfact(gen)` returns a cell array of strings containing the confounding pattern for the design.

`[X,conf] = fracfact(gen,Name,Value)` creates a fractional factorial designs with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

gen

Either a cell array of strings where each cell contains one “word,” or a string consisting of “words” separated by spaces. “Words” consist of case-sensitive letters or groups of letters, where 'a' represents string 1, 'b' represents string 2, ..., 'A' represents string 27, ..., 'Z' represents string 52.

Each word defines how the corresponding factor’s levels are defined as products of generators from a 2^K full-factorial design. K is the number of letters of the alphabet in `gen`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

'FactorNames'

Cell array specifying the name for each factor.

Default: { 'X1', 'X2', . . . }

'MaxInt'

Positive integer setting the maximum level of interaction to include in the confounding output.

Default: 2

Output Arguments

X

The two-level fractional factorial design. X is a matrix of size N-by-P, where

- $N = 2^K$, where K is the number of letters of the alphabet in `gen`.
- P is the number of words in `gen`.

Because X is a two-level design, the components of X are ± 1 . For the meaning of X, see “Fractional Factorial Designs” on page 22-5.

conf

Cell array of strings containing the confounding pattern for the design.

Examples

Generate a fractional factorial design for four variables, where the fourth variable is the product of the first three:

```
x = fracfact('a b c abc')
```

```
x =  
    -1    -1    -1    -1  
    -1    -1     1     1
```

```

-1    1    -1    1
-1    1    1    -1
 1    -1   -1    1
 1    -1    1    -1
 1    1    -1   -1
 1    1    1    1

```

Find generators for a six-factor design that uses four factors and achieves resolution IV using `fracfactgen`. Use the result to specify the design:

```

generators = fracfactgen('a b c d e f',4, ... % 4 factors
4) % resolution 4

```

```

generators =
  'a'
  'b'
  'c'
  'd'
  'bcd'
  'acd'

```

```

x = fracfact(generators)

```

```

x =
-1    -1    -1    -1    -1    -1
-1    -1    -1    1    1    1
-1    -1    1    -1    1    1
-1    -1    1    1    -1    -1
-1    1    -1    -1    1    -1
-1    1    -1    1    -1    1
-1    1    1    -1    -1    1
-1    1    1    1    1    -1
 1    -1    -1    -1    -1    1
 1    -1    -1    1    1    -1
 1    -1    1    -1    1    -1
 1    -1    1    1    -1    1
 1    1    -1    -1    1    1
 1    1    -1    1    -1    -1
 1    1    1    -1    -1    -1
 1    1    1    1    1    1

```

fracfactgen

Fractional factorial design generators

Syntax

```
generators = fracfactgen(terms)
generators = fracfactgen(terms,k)
generators = fracfactgen(terms,k,R)
generators = fracfactgen(terms,k,R,basic)
```

Description

`generators = fracfactgen(terms)` uses the Franklin-Bailey algorithm to find generators for the smallest two-level fractional-factorial design for estimating linear model terms specified by `terms`. `terms` is a string consisting of words formed from the 52 case-sensitive letters a-Z, separated by spaces. Use 'a' - 'z' for the first 26 factors, and, if necessary, 'A' - 'Z' for the remaining factors. For example, `terms = 'a b c ab ac'`. Single-character words indicate main effects to be estimated; multiple-character words indicate interactions. Alternatively, `terms` is an m -by- n matrix of 0s and 1s where m is the number of model terms to be estimated and n is the number of factors. For example, if `terms` contains rows `[0 1 0 0]` and `[1 0 0 1]`, then the factor `b` and the interaction between factors `a` and `d` are included in the model. `generators` is a cell array of strings with one generator per cell. Pass `generators` to `fracfact` to produce the fractional-factorial design and corresponding confounding pattern.

`generators = fracfactgen(terms,k)` returns generators for a two-level fractional-factorial design with 2^k -runs, if possible. If `k` is `[]`, `fracfactgen` finds the smallest design.

`generators = fracfactgen(terms,k,R)` finds a design with resolution `R`, if possible. The default resolution is 3.

A design of *resolution R* is one in which no n -factor interaction is confounded with any other effect containing less than $R - n$ factors. Thus a resolution III design does not confound main effects with one another but may confound them with two-way interactions, while a resolution IV design does not confound either main effects or two-way interactions but may confound two-way interactions with each other.

If `fracfactgen` is unable to find a design at the requested resolution, it tries to find a lower-resolution design sufficient to calibrate the model. If it is successful, it returns the generators for the lower-resolution design along with a warning. If it fails, it returns an error.

`generators = fracfactgen(terms,k,R,basic)` also accepts a vector `basic` specifying the indices of factors that are to be treated as basic. These factors receive full-factorial treatments in the design. The default includes factors that are part of the highest-order interaction in `terms`.

Examples

Suppose you wish to determine the effects of four two-level factors, for which there may be two-way interactions. A full-factorial design would require $2^4 = 16$ runs. The `fracfactgen` function finds generators for a resolution IV (separating main effects) fractional-factorial design that requires only $2^3 = 8$ runs:

```
generators = fracfactgen('a b c d',3,4)
generators =
  'a'
  'b'
  'c'
  'abc'
```

The more economical design and the corresponding confounding pattern are returned by `fracfact`:

```
[dfF,confounding] = fracfact(generators)
dfF =
  -1  -1  -1  -1
  -1  -1   1   1
  -1   1  -1   1
  -1   1   1  -1
   1  -1  -1   1
   1  -1   1  -1
   1   1  -1  -1
   1   1   1   1
confounding =
  'Term'      'Generator'      'Confounding'
  'X1'        'a'                'X1'
  'X2'        'b'                'X2'
```

'X3'	'c'	'X3'
'X4'	'abc'	'X4'
'X1*X2'	'ab'	'X1*X2 + X3*X4'
'X1*X3'	'ac'	'X1*X3 + X2*X4'
'X1*X4'	'bc'	'X1*X4 + X2*X3'
'X2*X3'	'bc'	'X1*X4 + X2*X3'
'X2*X4'	'ac'	'X1*X3 + X2*X4'
'X3*X4'	'ab'	'X1*X2 + X3*X4'

The confounding pattern shows, for example, that the two-way interaction between X1 and X2 is confounded by the two-way interaction between X3 and X4.

Introduced in R2006a

friedman

Friedman's test

Syntax

```
p = friedman(x, reps)
p = friedman(x, reps, displayopt)
[p, tbl] = friedman( ___ )
[p, tbl, stats] = friedman( ___ )
```

Description

`p = friedman(x, reps)` returns the p -value for the nonparametric Friedman's test to compare column effects in a two-way layout. `friedman` tests the null hypothesis that the column effects are all the same against the alternative that they are not all the same.

`p = friedman(x, reps, displayopt)` enables the ANOVA table display when `displayopt` is 'on' (default) and suppresses the display when `displayopt` is 'off'.

`[p, tbl] = friedman(___)` returns the ANOVA table (including column and row labels) in cell array `tbl`.

`[p, tbl, stats] = friedman(___)` also returns a structure `stats` that you can use to perform a follow-up multiple comparison test.

Examples

Test For Column Effects Using Friedman's Test

This example shows how to test for column effects in a two-way layout using Friedman's test.

Load the sample data.

```
load popcorn
```

```
popcorn
```

```
popcorn =
```

```
  5.5000  4.5000  3.5000
  5.5000  4.5000  4.0000
  6.0000  4.0000  3.0000
  6.5000  5.0000  4.0000
  7.0000  5.5000  5.0000
  7.0000  5.0000  4.5000
```

This data comes from a study of popcorn brands and popper type (Hogg 1987). The columns of the matrix `popcorn` are brands (Gourmet, National, and Generic). The rows are popper type (Oil and Air). The study popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Use Friedman's test to determine whether the popcorn brand affects the yield of popcorn.

```
p = friedman(popcorn,3)
```

```
p =
```

```
  0.0010
```

Friedman's ANOVA Table					
Source	SS	df	MS	Chi-sq	Prob>Chi-sq
Columns	99.75	2	49.875	13.76	0.001
Interaction	0.0833	2	0.0417		
Error	16.1667	12	1.3472		
Total	116	17			

Test for column effects after row effects are removed

The small value of $p = 0.001$ indicates the popcorn brand affects the yield of popcorn.

Input Arguments

x — Sample data
matrix

Sample data for the hypothesis test, specified as a matrix. The columns of **x** represent changes in a factor A. The rows represent changes in a blocking factor B. If there is more than one observation for each combination of factors, input **reps** indicates the number of replicates in each “cell,” which must be constant.

Data Types: `single` | `double`

reps — Number of replicates per cell

1 (default) | positive integer value

Number of replicates per cell, specified as a positive integer value.

Data Types: `single` | `double`

displayopt — ANOVA table display option

'off' (default) | 'on'

ANOVA table display option, specified as 'off' or 'on'.

If `displayopt` is 'on', then `friedman` displays a figure showing an ANOVA table, which divides the variability of the ranks into two or three parts:

- The variability due to the differences among the column effects
- The variability due to the interaction between rows and columns (if `reps` is greater than its default value of 1)
- The remaining variability not explained by any systematic source

The ANOVA table has six columns:

- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df.
- The fifth shows Friedman's chi-square statistic.
- The sixth shows the p value for the chi-square statistic.

You can copy a text version of the ANOVA table to the clipboard by selecting **Copy Text** from the **Edit** menu.

Output Arguments

p — p -value

scalar value in the range [0, 1]

p -value of the test, returned as a scalar value in the range $[0, 1]$. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

tb1 — ANOVA table

cell array

ANOVA table, including column and row labels, returned as a cell array. The ANOVA table has six columns:

- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df.
- The fifth shows Friedman's chi-square statistic.
- The sixth shows the p value for the chi-square statistic.

You can copy a text version of the ANOVA table to the clipboard by selecting **Copy Text** from the **Edit** menu.

stats — Test data

structure

Test data, returned as a structure. `friedman` evaluates the hypothesis that the column effects are all the same against the alternative that they are not all the same. However, sometimes it is preferable to perform a test to determine which pairs of column effects are significantly different, and which are not. You can use the `multcompare` function to perform such tests by supplying `stats` as the input value.

More About

Friedman's Test

Friedman's test is similar to classical balanced two-way ANOVA, but it tests only for column effects after adjusting for possible row effects. It does not test for row effects or interaction effects. Friedman's test is appropriate when columns represent treatments that are under study, and rows represent nuisance effects (blocks) that need to be taken into account but are not of any interest.

The different columns of X represent changes in a factor A. The different rows represent changes in a blocking factor B. If there is more than one observation for each combination of factors, input `reps` indicates the number of replicates in each “cell,” which must be constant.

The matrix below illustrates the format for a set-up where column factor A has three levels, row factor B has two levels, and there are two replicates (`reps=2`). The subscripts indicate row, column, and replicate, respectively.

$$\begin{bmatrix} x_{111} & x_{121} & x_{131} \\ x_{112} & x_{122} & x_{132} \\ x_{211} & x_{221} & x_{231} \\ x_{212} & x_{222} & x_{232} \end{bmatrix}$$

Friedman's test assumes a model of the form

$$x_{ijk} = \mu + \alpha_i + \beta_j + \varepsilon_{ijk}$$

where μ is an overall location parameter, α_i represents the column effect, β_j represents the row effect, and ε_{ijk} represents the error. This test ranks the data within each level of B, and tests for a difference across levels of A. The p that `friedman` returns is the p value for the null hypothesis that $\alpha_i = 0$. If the p value is near zero, this casts doubt on the null hypothesis. A sufficiently small p value suggests that at least one column-sample median is significantly different than the others; i.e., there is a main effect due to factor A. The choice of a critical p value to determine whether a result is “statistically significant” is left to the researcher. It is common to declare a result significant if the p value is less than 0.05 or 0.01.

Friedman's test makes the following assumptions about the data in X :

- All data come from populations having the same continuous distribution, apart from possibly different locations due to column and row effects.
- All observations are mutually independent.

The classical two-way ANOVA replaces the first assumption with the stronger assumption that data come from normal distributions.

Introduced before R2006a

frnd

F random numbers

Syntax

```
R = frnd(V1,V2)
R = frnd(V1,V2,m,n,...)
R = frnd(V1,V2,[m,n,...])
```

Description

`R = frnd(V1,V2)` generates random numbers from the *F* distribution with numerator degrees of freedom *V1* and denominator degrees of freedom *V2*. *V1* and *V2* can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for *V1* or *V2* is expanded to a constant array with the same dimensions as the other input.

`R = frnd(V1,V2,m,n,...)` or `R = frnd(V1,V2,[m,n,...])` generates an *m*-by-*n*-by-... array containing random numbers from the *F* distribution with parameters *V1* and *V2*. *V1* and *V2* can each be scalars or arrays of the same size as *R*.

Examples

```
n1 = frnd(1:6,1:6)
n1 =
    0.0022    0.3121    3.0528    0.3189    0.2715    0.9539
```

```
n2 = frnd(2,2,[2 3])
n2 =
    0.3186    0.9727    3.0268
    0.2052   148.5816    0.2191
```

```
n3 = frnd([1 2 3;4 5 6],1,2,3)
n3 =
    0.6233    0.2322   31.5458
    2.5848    0.2121    4.4955
```

More About

See Also

random | fpdf | fcdf | finv | fstat

Introduced before R2006a

fstat

F mean and variance

Syntax

`[M,V] = fstat(V1,V2)`

Description

`[M,V] = fstat(V1,V2)` returns the mean of and variance for the *F* distribution with numerator degrees of freedom *V1* and denominator degrees of freedom *V2*. *V1* and *V2* can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of *M* and *V*. A scalar input for *V1* or *V2* is expanded to a constant arrays with the same dimensions as the other input.

The mean of the *F* distribution for values of v_2 greater than 2 is

$$\frac{v_2}{v_2 - 2}$$

The variance of the *F* distribution for values of v_2 greater than 4 is

$$\frac{2v_2^2(v_1 + v_2 - 2)}{v_1(v_2 - 2)^2(v_2 - 4)}$$

The mean of the *F* distribution is undefined if v_2 is less than 3. The variance is undefined for v_2 less than 5.

Examples

`fstat` returns NaN when the mean and variance are undefined.

```
[m,v] = fstat(1:5,1:5)
```

```
m =  
  NaN  NaN  3.0000  2.0000  1.6667  
v =  
  NaN  NaN  NaN  NaN  8.8889
```

`fpdf` | `fcdf` | `finv` | `frnd`

Introduced before R2006a

fsurfht

Interactive contour plot

Syntax

```
fsurfht(fun,xlims,ylims)
fsurfht(fun,xlims,ylims,p1,p2,p3,p4,p5)
```

Description

`fsurfht(fun,xlims,ylims)` is an interactive contour plot of the function specified by the text variable `fun`. The x -axis limits are specified by `xlims` in the form `[xmin xmax]`, and the y -axis limits are specified by `ylims` in the form `[ymin ymax]`.

`fsurfht(fun,xlims,ylims,p1,p2,p3,p4,p5)` allows for five optional parameters that you can supply to the function `fun`.

The intersection of the vertical and horizontal reference lines on the plot defines the current x value and y value. You can drag these reference lines and watch the calculated z -values (at the top of the plot) update simultaneously. Alternatively, you can type the x value and y value into editable text fields on the x -axis and y -axis.

Examples

Plot the Gaussian likelihood function for the `gas.mat` data.

```
load gas
```

Create a function containing the following commands, and name it `gauslike.m`.

```
function z = gauslike(mu,sigma,p1)
n = length(p1);
z = ones(size(mu));
for i = 1:n
z = z .* (normpdf(p1(i),mu,sigma));
end
```

The `gauslike` function calls `normpdf`, treating the data sample as fixed and the parameters μ and σ as variables. Assume that the gas prices are normally distributed, and plot the likelihood surface of the sample.

```
fsurfht('gauslike',[112 118],[3 5],price1)
```

The sample mean is the x value at the maximum, but the sample standard deviation is *not* the y value at the maximum.

```
mumax = mean(price1)
mumax =
    115.1500
sigmamax = std(price1)*sqrt(19/20)
sigmamax =
```

3.7719

Introduced before R2006a

fullfact

Full factorial design

Syntax

```
dFF = fullfact(levels)
```

Description

`dFF = fullfact(levels)` gives factor settings `dFF` for a full factorial design with n factors, where the number of levels for each factor is given by the vector `levels` of length n . `dFF` is m -by- n , where m is the number of treatments in the full-factorial design. Each row of `dFF` corresponds to a single treatment. Each column contains the settings for a single factor, with integer values from one to the number of levels.

Examples

The following generates an eight-run full-factorial design with two levels in the first factor and four levels in the second factor:

```
dFF = fullfact([2 4])
dFF =
  1  1
  2  1
  1  2
  2  2
  1  3
  2  3
  1  4
  2  4
```

`ff2n`

Introduced before R2006a

gagerr

Gage repeatability and reproducibility study

Syntax

```
gagerr(y, {part, operator})  
gagerr(y, GROUP)  
gagerr(y, part)  
gagerr(..., param1, val1, param2, val2, ...)  
[TABLE, stats] = gagerr(...)
```

Description

`gagerr(y, {part, operator})` performs a gage repeatability and reproducibility study on measurements in `y` collected by `operator` on `part`. `y` is a column vector containing the measurements on different parts. `part` and `operator` are categorical variables, numeric vectors, character matrices, or cell arrays of strings. The number of elements in `part` and `operator` should be the same as in `y`.

`gagerr` prints a table in the command window in which the decomposition of variance, standard deviation, study var (5.15 x standard deviation) are listed with respective percentages for different sources. Summary statistics are printed below the table giving the number of distinct categories (NDC) and the percentage of Gage R&R of total variations (PRR).

`gagerr` also plots a bar graph showing the percentage of different components of variations. Gage R&R, repeatability, reproducibility, and part-to-part variations are plotted as four vertical bars. Variance and study var are plotted as two groups.

To determine the capability of a measurement system using NDC, use the following guidelines:

- If $NDC > 5$, the measurement system is capable.
- If $NDC < 2$, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

To determine the capability of a measurement system using PRR, use the following guidelines:

- If $PRR < 10\%$, the measurement system is capable.
- If $PRR > 30\%$, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

`gagerr(y, GROUP)` performs a gage R&R study on measurements in `y` with `part` and `operator` represented in `GROUP`. `GROUP` is a numeric matrix whose first and second columns specify different parts and operators, respectively. The number of rows in `GROUP` should be the same as the number of elements in `y`.

`gagerr(y, part)` performs a gage R&R study on measurements in `y` without operator information. The assumption is that all variability is contributed by `part`.

`gagerr(..., param1, val1, param2, val2, ...)` performs a gage R&R study using one or more of the following parameter name/value pairs:

- `'spec'` — A two-element vector that defines the lower and upper limit of the process, respectively. In this case, summary statistics printed in the command window include Precision-to-Tolerance Ratio (PTR). Also, the bar graph includes an additional group, the percentage of tolerance.

To determine the capability of a measurement system using PTR, use the following guidelines:

- If $PTR < 0.1$, the measurement system is capable.
- If $PTR > 0.3$, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.
- `'printtable'` — A string with a value `'on'` or `'off'` that indicates whether the tabular output should be printed in the command window or not. The default value is `'on'`.
- `'printgraph'` — A string with a value `'on'` or `'off'` that indicates whether the bar graph should be plotted or not. The default value is `'on'`.
- `'randomoperator'` — A logical value, `true` or `false`, that indicates whether the effect of `operator` is random or not. The default value is `true`.
- `'model'` — The model to use, specified by one of:
 - `'linear'` — Main effects only (default)
 - `'interaction'` — Main effects plus two-factor interactions
 - `'nested'` — Nest operator in part

The default value is 'linear'.

[TABLE, stats] = gagerr(...) returns a 6-by-5 matrix TABLE and a structure stats. The columns of TABLE, from left to right, represent variance, percentage of variance, standard deviations, study var, and percentage of study var. The rows of TABLE, from top to bottom, represent different sources of variations: gage R&R, repeatability, reproducibility, operator, operator and part interactions, and part. stats is a structure containing summary statistics for the performance of the measurement system. The fields of stats are:

- ndc — Number of distinct categories
- prr — Percentage of gage R&R of total variations
- ptr — Precision-to-tolerance ratio. The value is NaN if the parameter 'spec' is not given.

Examples

Gage R&R Study

Simulate a measurement system by randomly generating the operators, parts, and the measurements, y, operators do on the parts.

```
rng(1234, 'twister')           % for reproducibility
y = randn(100,1);             % measurements
part = ceil(3*rand(100,1));    % parts
operator = ceil(4*rand(100,1)); % operators
```

Conduct a gage R&R study for this system using a mixed ANOVA model without interactions.

```
gagerr(y, {part, operator}, 'randomoperator', true)
```

Introduced in R2006b

gamcdf

Gamma cumulative distribution function

Syntax

```
gamcdf(x, a, b)
[p, plo, pup] = gamcdf(x, a, b, pcov, alpha)
[p, plo, pup] = gamcdf( ____, 'upper' )
```

Description

`gamcdf(x, a, b)` returns the gamma cdf at each of the values in `x` using the corresponding shape parameters in `a` and scale parameters in `b`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `a` and `b` must be positive.

`[p, plo, pup] = gamcdf(x, a, b, pcov, alpha)` produces confidence bounds for `p` when the input parameters `a` and `b` are estimates. `pcov` is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies `100(1-alpha)%` confidence bounds. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p, plo, pup] = gamcdf(____, 'upper')` returns the complement of the gamma cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the `'upper'` argument with any of the previous syntaxes.

The gamma cdf is

$$p = F(x | a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} dt$$

The result, p , is the probability that a single observation from a gamma distribution with parameters a and b will fall in the interval $[0, x]$.

`gammainc` is the gamma distribution with b fixed at 1.

Examples

Compute Gamma Distribution CDF

The mean of the gamma distribution is the product of the parameters, ab . In this example, the mean approaches the median as it increases (i.e., the distribution becomes more symmetric).

```
a = 1:6;
b = 5:10;
prob = gamcdf(a.*b,a,b)

prob =
    0.6321    0.5940    0.5768    0.5665    0.5595    0.5543
```

Introduced before R2006a

gamfit

Gamma parameter estimates

Syntax

```
phat = gamfit(data)
[phat,pci] = gamfit(data)
[phat,pci] = gamfit(data,alpha)
[...] = gamfit(data,alpha,censoring,freq,options)
```

Description

`phat = gamfit(data)` returns the maximum likelihood estimates (MLEs) for the parameters of the gamma distribution given the data in vector `data`.

`[phat,pci] = gamfit(data)` returns MLEs and 95% percent confidence intervals. The first row of `pci` is the lower bound of the confidence intervals; the last row is the upper bound.

`[phat,pci] = gamfit(data,alpha)` returns $100(1 - \alpha)\%$ confidence intervals. For example, `alpha = 0.01` yields 99% confidence intervals.

`[...] = gamfit(data,alpha,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = gamfit(data,alpha,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any nonnegative values.

`[...] = gamfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The gamma fit function accepts an `options` structure which can be created using the function `statset`. Enter `statset('gamfit')` to see the names and default values of the parameters that `gamfit` accepts in the `options` structure.

Examples

Fit a gamma distribution to random data generated from a specified gamma distribution:

```
a = 2; b = 4;  
data = gamrnd(a,b,100,1);
```

```
[p,ci] = gamfit(data)
```

```
p =  
 2.1990  3.7426
```

```
ci =  
 1.6840  2.8298  
 2.7141  4.6554
```

prob.GammaDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Gamma probability distribution object

Description

`prob.GammaDistribution` is an object consisting of parameters, a model description, and sample data for a gamma probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Gamma')` creates a gamma probability distribution object using the default parameter values.

`pd = makedist('Gamma', 'a', a, 'b', b)` creates a gamma probability distribution object using the specified parameter values.

Input Arguments

a — Shape parameter

1 (default) | positive scalar value

Shape parameter for the gamma distribution, specified as a positive scalar value.

Data Types: `single` | `double`

b — Scale parameter

1 (default) | nonnegative scalar value

Scale parameter for the gamma distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Properties

a — Shape parameter

positive scalar value

Shape parameter for the gamma distribution, stored as a positive scalar value.

Data Types: `single` | `double`

b — Scale parameter

nonnegative scalar value

Scale parameter for the gamma distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: single | double

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i, j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i, i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i, i) elements of the covariance matrix are 0. This property is read-only.

Data Types: single | double

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: char

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: logical

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single` | `double`

Definitions

Gamma Distribution

The gamma distribution is a two-parameter family of distributions used to model sums of exponentially distributed random variables. The chi-square and the exponential distributions, which are children of the gamma distribution, are one-parameter distributions that fix one of the two gamma parameters.

The gamma distribution uses the following parameters.

Parameter	Description	Support
a	Shape parameter	$a > 0$
b	Scale parameter	$b \geq 0$

The probability density function (pdf) is

$$f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}} \quad ; \quad x > 0,$$

where $\Gamma(\cdot)$ is the Gamma function.

Examples

Create a Gamma Distribution Object Using Default Parameters

Create a gamma distribution object using the default parameter values.

```
pd = makedist('Gamma')  
pd =  
GammaDistribution  
  
Gamma distribution  
a = 1  
b = 1
```

Create a Gamma Distribution Object Using Specified Parameters

Create a gamma distribution object by specifying the parameter values.

```
pd = makedist('Gamma', 'a',2,'b',4)  
pd =  
GammaDistribution  
  
Gamma distribution  
a = 2  
b = 4
```

Compute the mean of the distribution.

```
m = mean(pd)  
m =  
8
```

- Property Attributes

gaminv

Gamma inverse cumulative distribution function

Syntax

```
X = gaminv(P,A,B)
[X,XLO,XUP] = gamcdf(P,A,B,pcov,alpha)
```

Description

`X = gaminv(P,A,B)` computes the inverse of the gamma cdf with shape parameters in **A** and scale parameters in **B** for the corresponding probabilities in **P**. **P**, **A**, and **B** can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in **A** and **B** must all be positive, and the values in **P** must lie on the interval [0 1].

The gamma inverse function in terms of the gamma cdf is

$$x = F^{-1}(p | a, b) = \{x : F(x | a, b) = p\}$$

where

$$p = F(x | a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} dt$$

`[X,XLO,XUP] = gamcdf(P,A,B,pcov,alpha)` produces confidence bounds for **P** when the input parameters **A** and **B** are estimates. **pcov** is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. **alpha** has a default value of 0.05, and specifies 100(1 - **alpha**)% confidence bounds. **PLO** and **PUP** are arrays of the same size as **P** containing the lower and upper confidence bounds.

Examples

This example shows the relationship between the gamma cdf and its inverse function.

```
a = 1:5;
b = 6:10;
x = gaminv(gamcdf(1:5, a, b), a, b)
x =
  1.0000  2.0000  3.0000  4.0000  5.0000
```

More About

Algorithms

There is no known analytical solution to the integral equation above. `gaminv` uses an iterative approach (Newton's method) to converge on the solution.

- “Gamma Distribution” on page B-47

`icdf` | `gamcdf` | `gampdf` | `gamstat` | `gamfit` | `gamlike` | `gamrnd`

Introduced before R2006a

gamlike

Gamma negative log-likelihood

Syntax

```
nlogL = gamlike(params,data)
[nlogL,AVAR] = gamlike(params,data)
```

Description

`nlogL = gamlike(params,data)` returns the negative of the gamma log-likelihood of the parameters, `params`, given `data`. `params(1)=A`, shape parameters, and `params(2)=B`, scale parameters.

`[nlogL,AVAR] = gamlike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates when the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`[...] = gamlike(params,data,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = gamfit(params,data,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any non-negative values.

`gamlike` is a utility function for maximum likelihood estimation of the gamma distribution. Since `gamlike` returns the negative gamma log-likelihood function, minimizing `gamlike` using `fminsearch` is the same as maximizing the likelihood.

Examples

Compute the negative log-likelihood of parameter estimates computed by the `gamfit` function:

```
a = 2; b = 3;
r = gamrnd(a,b,100,1);

[nlogL,AVAR] = gamlike(gamfit(r),r)
nlogL =
    267.5648
AVAR =
    0.0788  -0.1104
   -0.1104  0.1955
```

gamfit | gampdf | gamcdf | gaminv | gamstat | gamrnd

Introduced before R2006a

gampdf

Gamma probability density function

Syntax

```
Y = gampdf(X,A,B)
```

Description

`Y = gampdf(X,A,B)` computes the gamma pdf at each of the values in `X` using the corresponding shape parameters in `A` and scale parameters in `B`. `X`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `A` and `B` must all be positive, and the values in `X` must lie on the interval $[0 \infty)$.

The gamma pdf is

$$y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

The gamma probability density function is useful in reliability models of lifetimes. The gamma distribution is more flexible than the exponential distribution in that the probability of a product surviving an additional period may depend on its current age. The exponential and χ^2 functions are special cases of the gamma function.

Examples

The exponential distribution is a special case of the gamma distribution.

```
mu = 1:5;
```

```
y = gampdf(1,1,mu)  
y =
```

```
0.3679 0.3033 0.2388 0.1947 0.1637
```

```
y1 = exppdf(1,mu)
```

```
y1 =
```

```
0.3679 0.3033 0.2388 0.1947 0.1637
```

gamrnd

Gamma random numbers

Syntax

```
R = gamrnd(A,B)
R = gamrnd(A,B,m,n,...)
R = gamrnd(A,B,[m,n,...])
```

Description

`R = gamrnd(A,B)` generates random numbers from the gamma distribution with shape parameters in `A` and scale parameters in `B`. `A` and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `A` or `B` is expanded to a constant array with the same dimensions as the other input.

`R = gamrnd(A,B,m,n,...)` or `R = gamrnd(A,B,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the gamma distribution with parameters `A` and `B`. `A` and `B` can each be scalars or arrays of the same size as `R`.

Examples

```
n1 = gamrnd(1:5,6:10)
n1 =
    9.1132  12.8431  24.8025  38.5960 106.4164
```

```
n2 = gamrnd(5,10,[1 5])
n2 =
    30.9486  33.5667  33.6837  55.2014  46.8265
```

```
n3 = gamrnd(2:6,3,1,5)
n3 =
    12.8715  11.3068  3.0982  15.6012  21.6739
```

Introduced before R2006a

gamstat

Gamma mean and variance

Syntax

```
[M,V] = gamstat(A,B)
```

Description

`[M,V] = gamstat(A,B)` returns the mean of and variance for the gamma distribution with shape parameters in **A** and scale parameters in **B**. **A** and **B** can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of **M** and **V**. A scalar input for **A** or **B** is expanded to a constant array with the same dimensions as the other input.

The mean of the gamma distribution with parameters a and b is ab . The variance is ab^2 .

Examples

```
[m,v] = gamstat(1:5,1:5)
```

```
m =  
    1    4    9   16   25  
v =  
    1    8   27   64  125
```

```
[m,v] = gamstat(1:5,1./(1:5))
```

```
m =  
    1    1    1    1    1  
v =  
    1.0000    0.5000    0.3333    0.2500    0.2000
```

Introduced before R2006a

ge

Class: grandstream

Greater than or equal relation for handles

Syntax

`h1 >= h2`

Description

`h1 >= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `>=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = ge(h1, h2)` stores the result in a logical array of the same dimensions.

prob.GeneralizedExtremeValueDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Generalized extreme value probability distribution object

Description

`prob.GeneralizedExtremeValueDistribution` is an object consisting of parameters, a model description, and sample data for a generalized extreme value probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('GeneralizedExtremeValue')` creates a generalized extreme value probability distribution object using the default parameter values.

`pd = makedist('GeneralizedExtremeValue', 'k', k, 'sigma', sigma, 'mu', mu)` creates a generalized extreme value probability distribution object using the specified parameter values.

Input Arguments

k — Shape parameter

0 (default) | scalar value

Shape parameter for the generalized extreme value distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

1 (default) | nonnegative scalar value

Scale parameter for the generalized extreme value distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

mu — Location parameter

0 (default) | scalar value

Location parameter for the generalized extreme value distribution, specified as a scalar value.

Data Types: `single` | `double`

Properties

k — Shape parameter

scalar value

Shape parameter of the generalized extreme value distribution, stored as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter of the generalized extreme value distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

mu — Location parameter

scalar value

Location parameter of the generalized extreme value distribution, stored as a scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If **IsTruncated** equals 0, the distribution is not truncated. If **IsTruncated** equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i, j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i, i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i, i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: char

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: logical

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Definitions

Generalized Extreme Value Distribution

The generalized extreme value distribution is often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. It combines three simpler distributions into a single form, allowing a continuous range of possible shapes that include all three of the simpler distributions.

The three distribution types correspond to the limiting distribution of block maxima from different classes of underlying distributions:

- Type 1 — Distributions whose tails decrease exponentially, such as the normal distribution
- Type 2 — Distributions whose tails decrease as a polynomial, such as Student's t distribution
- Type 3 — Distributions whose tails are finite, such as the beta distribution

The generalized extreme value distribution uses the following parameters.

Parameter	Description	Support
k	Shape parameter	$-\infty \leq k \leq \infty$
σ	Scale parameter	$\sigma \geq 0$
μ	Location parameter	$-\infty \leq \mu \leq \infty$

The probability density function (pdf) for a Type 1 distribution, where shape parameter $k = 0$, is

$$f(x | 0, \mu, \sigma) = \left(\frac{1}{\sigma}\right) \exp\left(-\exp\left(-\frac{(x-\mu)}{\sigma}\right) - \frac{(x-\mu)}{\sigma}\right); \quad -\infty < x < \infty.$$

When $k \neq 0$, the pdf is

$$f(x | k, \mu, \sigma) = \left(\frac{1}{\sigma}\right) \exp\left(-\left(1+k\frac{(x-\mu)}{\sigma}\right)^{-\frac{1}{k}}\right) \left(1+k\frac{(x-\mu)}{\sigma}\right)^{-1-\frac{1}{k}}$$

for

$$1+k\frac{(x-\mu)}{\sigma} > 0.$$

For the Type 2 case, $k > 0$ and $x \geq \mu - \frac{\sigma}{k}$. For the Type 3 case, $k < 0$ and $x < \mu - \frac{\sigma}{k}$.

Examples

Create a Generalized Extreme Value Distribution Object Using Default Parameters

Create a generalized extreme value distribution object using the default parameter values.

```
pd = makedist('GeneralizedExtremeValue')  
  
pd =  
  
GeneralizedExtremeValueDistribution  
  
Generalized Extreme Value distribution  
    k = 0  
    sigma = 1  
    mu = 0
```

Create a Generalized Extreme Value Distribution Object Using Specified Parameters

Create a generalized extreme value distribution object by specifying values for the parameters.

```
pd = makedist('GeneralizedExtremeValue', 'k',0, 'sigma',2, 'mu',1)  
  
pd =  
  
GeneralizedExtremeValueDistribution  
  
Generalized Extreme Value distribution  
    k = 0  
    sigma = 2  
    mu = 1
```

Compute the mean of the distribution.

```
m = mean(pd)  
  
m =  
  
    2.1544
```

GeneralizedLinearMixedModel class

Generalized linear mixed-effects model class

Description

A `GeneralizedLinearMixedModel` object represents a regression model of a response variable that contains both fixed and random effects. The object comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a generalized linear mixed-effects (GLME) model. You can predict model responses with the `predict` function and generate random data at new design points using the `random` function.

Construction

You can fit a generalized linear mixed-effects (GLME) model to sample data using `fitglme(tbl, formula)`. For more information, see `fitglme`.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-56). You must specify the model for the variables using `formula`.

Data Types: `table`

formula — Formula for model specification

string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For a full description, see `Formula`.

Example: `'y ~ treatment +(1|block)'`

Properties

Coefficients — Estimates of fixed-effects coefficients

dataset array

Estimates of fixed-effects coefficients and related statistics, stored as a dataset array that has one row for each coefficient and the following columns:

- **Name** — Name of the coefficient
- **Estimate** — Estimated coefficient value
- **SE** — Standard error of the estimate
- **tStat** — *t*-statistic for a test that the coefficient is equal to 0
- **DF** — Degrees of freedom associated with the *t* statistic
- **pValue** — *p*-value for the *t*-statistic
- **Lower** — Lower confidence limit
- **Upper** — Upper confidence limit

To obtain any of these columns as a vector, index into the property using dot notation.

Use the `coefTest` method to perform other tests on the coefficients.

CoefficientCovariance — Covariance of estimated fixed-effects vector

matrix

Covariance of estimated fixed-effects vector, stored as a matrix.

Data Types: `single` | `double`

CoefficientNames — Names of fixed-effects coefficients

cell array of strings

Names of fixed-effects coefficients, stored as a cell array of strings. The label for the coefficient of the constant term is (`Intercept`). The labels for other coefficients indicate the terms that they multiply. When the term includes a categorical predictor, the label also indicates the level of that predictor.

Data Types: `cell`

DFE — Degrees of freedom for error

positive integer value

Degrees of freedom for error, stored as a positive integer value. DFE is the number of observations minus the number of estimated coefficients.

DFE contains the degrees of freedom corresponding to the 'Residual' method of calculating denominator degrees of freedom for hypothesis tests on fixed-effects coefficients. If n is the number of observations and p is the number of fixed-effects coefficients, then DFE is equal to $n - p$.

Data Types: double

Dispersion — Model dispersion parameter

scalar value

Model dispersion parameter, stored as a scalar value. The dispersion parameter defines the conditional variance of the response.

For observation i , the conditional variance of the response y_i , given the conditional mean μ_i and the dispersion parameter σ^2 , in a generalized linear mixed-effects model is

$$\text{var}(y_i | \mu_i, \sigma^2) = \frac{\sigma^2}{w_i} v(\mu_i),$$

where w_i is the i th observation weight and v is the variance function for the specified conditional distribution of the response. The **Dispersion** property contains an estimate of σ^2 for the specified GLME model. The value of **Dispersion** depends on the specified conditional distribution of the response. For binomial and Poisson distributions, the theoretical value of **Dispersion** is equal to $\sigma^2 = 1.0$.

- If **FitMethod** is **MPL** or **REMP**L and the '**DispersionFlag**' name-value pair argument in **fitglme** is **true**, then a dispersion parameter is estimated from data for all distributions, including binomial and Poisson distributions.
- If **FitMethod** is **ApproximateLaplace** or **Laplace**, then the '**DispersionFlag**' name-value pair argument in **fitglme** does not apply, and the dispersion parameter is fixed at 1.0 for binomial and Poisson distributions. For all other distributions, **Dispersion** is estimated from data.

Data Types: double

DispersionEstimated — Flag indicating if dispersion parameter was estimated

true | false

Flag indicating estimated dispersion parameter, stored as a logical value.

- If `FitMethod` is `ApproximateLaplace` or `Laplace`, then the dispersion parameter is fixed at its theoretical value of 1.0 for binomial and Poisson distributions, and `DispersionEstimated` is `false`. For other distributions, the dispersion parameter is estimated from the data, and `DispersionEstimated` is `true`.
- If `FitMethod` is `MPL` or `REMP`, and the `'DispersionFlag'` name-value pair argument in `fitglm` is specified as `true`, then the dispersion parameter is estimated for all distributions, including binomial and Poisson distributions, and `DispersionEstimated` is `true`.
- If `FitMethod` is `MPL` or `REMP`, and the `'DispersionFlag'` name-value pair argument in `fitglm` is specified as `false`, then the dispersion parameter is fixed at its theoretical value for binomial and Poisson distributions, and `DispersionEstimated` is `false`. For distributions other than binomial and Poisson, the dispersion parameter is estimated from the data, and `DispersionEstimated` is `true`.

Data Types: logical

Distribution — Response distribution name

'Normal' | 'Binomial' | 'Poisson' | 'Gamma' | 'InverseGaussian'

Response distribution name, stored as one of the following:

- `'Normal'` — Normal distribution
- `'Binomial'` — Binomial distribution
- `'Poisson'` — Poisson distribution
- `'Gamma'` — Gamma distribution
- `'InverseGaussian'` — Inverse Gaussian distribution

FitMethod — Method used to fit the model

'MPL' | 'REMP' | 'ApproximateLaplace' | 'Laplace'

Method used to fit the model, stored as one of the following.

- `'MPL'` — Maximum pseudo likelihood
- `'REMP'` — Restricted maximum pseudo likelihood

- 'ApproximateLaplace' — Maximum likelihood using the approximate Laplace method, with fixed effects profiled out
- 'Laplace' — Maximum likelihood using the Laplace method

Formula — Model specification formula

object

Model specification formula, stored as an object. The model specification formula uses Wilkinson's notation to describe the relationship between the fixed-effects terms, random-effects terms, and grouping variables in the GLME model. For more information see Formula.

Link — Link function characteristics

structure

Link function characteristics, stored as a structure containing the following fields. The link is a function G that links the distribution parameter μ to the linear predictor η as follows: $G(\mu) = \eta$.

Field	Description
Name	Name of the link function
Link	Function that defines G
Derivative	Derivative of G
SecondDerivative	Second derivative of G
Inverse	Inverse of G

Data Types: struct

LogLikelihood — Log of likelihood function

scalar value

Log of likelihood function evaluated at the estimated coefficient values, stored as a scalar value. LogLikelihood depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then LogLikelihood is the maximized log likelihood.
- If you use 'MPL', then LogLikelihood is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.

- If you use 'REML', then `LogLikelihood` is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

Data Types: `double`

ModelCriterion — Model criterion

table

Model criterion to compare fitted generalized linear mixed-effects models, stored as a table with the following fields.

Field	Description
AIC	Akaike information criterion
BIC	Bayesian information criterion
LogLikelihood	<ul style="list-style-type: none"> • For a model fit using 'Laplace' or 'ApproximateLaplace', <code>LogLikelihood</code> is the maximized log likelihood. • For a model fit using 'MPL', <code>LogLikelihood</code> is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration. • For a model fit using 'REML', <code>LogLikelihood</code> is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.
Deviance	-2 times <code>LogLikelihood</code>

NumCoefficients — Number of fixed-effects coefficients

positive integer value

Number of fixed-effects coefficients in the fitted generalized linear mixed-effects model, stored as a positive integer value.

Data Types: `double`

NumEstimatedCoefficients — Number of estimated fixed-effects coefficients

positive integer value

Number of estimated fixed-effects coefficients in the fitted generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumObservations — Number of observations

positive integer value

Number of observations used in the fit, stored as a positive integer value. `NumObservations` is the number of rows in the table or dataset array `tbl`, minus rows excluded using the 'Exclude' name-value pair of `fitglme` or rows containing NaN values.

Data Types: double

NumPredictors — Number of predictors

positive integer value

Number of variables used as predictors in the generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumVariables — Total number of variables

positive integer value

Total number of variables, including the response and predictors, stored as a positive integer value. If the sample data is in a table or dataset array `tbl`, then `NumVariables` is the total number of variables in `tbl`, including the response variable. `NumVariables` includes variables, if any, that are not used as predictors or as the response.

Data Types: double

ObservationInfo — Information about the observations

table

Information about the observations used in the fit, stored as a table.

`ObservationInfo` has one row for each observation and the following columns.

Name	Description
Weights	The weight value for the observation. The default value is 1.

Name	Description
Excluded	If the observation was excluded from the fit using the 'Exclude' name-value pair argument in <code>fitglm</code> , then <code>Excluded</code> is <code>true</code> , or 1. Otherwise, <code>Excluded</code> is <code>false</code> , or 0.
Missing	If the observation was excluded from the fit because any response or predictor value is missing, then <code>Missing</code> is <code>true</code> . Otherwise, <code>Missing</code> is <code>false</code> . Missing values include NaN for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the <code><undefined></code> value for categorical arrays.
Subset	If the observation was used in the fit, then <code>Subset</code> is <code>true</code> . If the observation was not used in the fit because it is missing or excluded, then <code>Subset</code> is <code>false</code> .
BinomSize	Binomial size for each observation. This column only applies when fitting a binomial distribution.

Data Types: `table`

ObservationNames — Names of observations

cell array of strings

Names of observations used in the fit, stored as a cell array of strings.

- If the data is in a table or dataset array `tbl` that contains observation names, then `ObservationNames` uses those names.
- If the data is provided in matrices, or in a table or dataset array without observation names, then `ObservationNames` is an empty cell array.

Data Types: `cell`

PredictorNames — Names of predictors

cell array of strings

Names of the variables used as predictors in the fit, stored as a cell array of strings that has the same length as NumPredictors.

Data Types: `cell`

ResponseName — Name of response variable

character string

Name of the variable used as the response variable in the fit, stored as a character string.

Data Types: `char`

Rsquared — Proportion of variability in the response explained by the fitted model

structure

Proportion of variability in the response explained by the fitted model, stored as a structure. **Rsquared** contains the *R*-squared value of the fitted model, also known as the multiple correlation coefficient. **Rsquared** contains the following fields.

Field	Description
Ordinary	R-squared value, stored as a scalar value in a structure. $\text{Rsquared.Ordinary} = 1 - \text{SSE./SST}$
Adjusted	R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure. $\text{Rsquared.Adjusted} = 1 - (\text{SSE./SST}) * (\text{DFT./DFE}),$ where $\text{DFE} = n - p$, $\text{DFT} = n - 1$, n is the total number of observations, and p is the number of fixed-effects coefficients.

Data Types: `struct`

SSE — Error sum of squares

positive scalar value

Error sum of squares, stored as a positive scalar value. **SSE** is the weighted sum of the squared conditional residuals, and is calculated as

$$SSE = \sum_{i=1}^n w_i^{eff} (y_i - f_i)^2,$$

where n is the number of observations, w_i^{eff} is the i th effective weight, y_i is the i th response, and f_i is the i th fitted value.

The i th effective weight is calculated as

$$w_i^{eff} = \left\{ \frac{w_i}{v_i(\mu_i(\hat{\beta}, \hat{b}))} \right\},$$

where v_i is the variance term for the i th observation, $\hat{\beta}$ and \hat{b} are estimated values of β and b , respectively.

The i th fitted value is calculated as

$$f_i = g^{-1}(x_i^T \hat{\beta} + z_i^T \hat{b} + \delta_i),$$

where x_i^T is the i th row of the fixed-effects design matrix X , and z_i^T is the i th row of the random-effects design matrix Z . δ_i is the i th offset value.

Data Types: double

SSR — Regression sum of squares

positive scalar value

Regression sum of squares, stored as a positive scalar value. **SSR** is the sum of squares explained by the generalized linear mixed-effects regression, or equivalently the weighted sum of the squared deviations of the conditional fitted values from their weighted mean. **SSR** is calculated as

$$SSR = \sum_{i=1}^N w_i^{eff} (f_i - \bar{f})^2,$$

where n is the number of observations, w_i^{eff} is the i th effective weight, f_i is the i th fitted value, and \bar{f} is a weighted average of the fitted values.

The i th effective weight is calculated as

$$w_i^{\text{eff}} = \left\{ \frac{w_i}{v_i(\mu_i(\hat{\beta}, \hat{b}))} \right\},$$

where $\hat{\beta}$ and \hat{b} are estimated values of β and b , respectively.

The i th fitted value is calculated as

$$f_i = g^{-1}(x_i^T \hat{\beta} + z_i^T \hat{b} + \delta_i),$$

where x_i^T is the i th row of the fixed-effects design matrix X , and z_i^T is the i th row of the random-effects design matrix Z . δ_i is the i th offset value.

The weighted average of fitted values is calculated as

$$\bar{f} = \frac{\left[\sum_{i=1}^n w_i^{\text{eff}} f_i \right]}{\sum_{i=1}^n w_i^{\text{eff}}}.$$

Data Types: double

SST — Total sum of squares

positive scalar value

Total sum of squares, stored as a positive scalar value. For a GLME model, SST is defined as $\text{SST} = \text{SSE} + \text{SSR}$.

Data Types: double

VariableInfo — Information about the variables

table

Information about the variables used in the fit, stored as a table. `VariableInfo` has one row for each variable and contains the following columns.

Column Name	Description
Class	Class of the variable ('double', 'cell', 'nominal', and so on).
Range	Value range of the variable. <ul style="list-style-type: none"> For a numerical variable, <code>Range</code> is a two-element vector of the form <code>[min,max]</code>. For a cell or categorical variable, <code>Range</code> is a cell or categorical array containing all unique values of the variable.
InModel	If the variable is a predictor in the fitted model, <code>InModel</code> is <code>true</code> . If the variable is not in the fitted model, <code>InModel</code> is <code>false</code> .
IsCategorical	If the variable type is treated as a categorical predictor (such as cell, logical, or categorical), then <code>IsCategorical</code> is <code>true</code> . If the variable is a continuous predictor, then <code>IsCategorical</code> is <code>false</code> .

Data Types: `table`

VariableNames — Names of the variables

cell array of strings

Names of all the variables contained in the table or dataset array `tbl`, stored as a cell array of strings.

Data Types: `cell`

Variables — Variables

table

Variables, stored as a table. If the fit is based on a table or dataset array `tbl`, then `Variables` is identical to `tbl`.

Data Types: `table`

Methods

<code>anova</code>	Analysis of variance for generalized linear mixed-effects model
<code>coefCI</code>	Confidence intervals for coefficients of generalized linear mixed-effects model
<code>coefTest</code>	Hypothesis test on fixed and random effects of generalized linear mixed-effects model
<code>compare</code>	Compare generalized linear mixed-effects models
<code>covarianceParameters</code>	Extract covariance parameters of generalized linear mixed-effects model
<code>designMatrix</code>	Fixed- and random-effects design matrices
<code>fitted</code>	Fitted responses from generalized linear mixed-effects model
<code>fixedEffects</code>	Estimates of fixed effects and related statistics
<code>plotResiduals</code>	Plot residuals of generalized linear mixed-effects model
<code>predict</code>	Predict response of generalized linear mixed-effects model
<code>random</code>	Generate random responses from fitted generalized linear mixed-effects model
<code>randomEffects</code>	Estimates of random effects and related statistics
<code>refit</code>	Refit generalized linear mixed-effects model
<code>residuals</code>	Residuals of fitted generalized linear mixed-effects model

response

Response vector of generalized linear mixed-effects model

Definitions

Formula

In general, a formula for model specification is a string of the form 'y ~ terms'. For generalized linear mixed-effects models, this formula is in the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)', where `fixed` and `random` contain the fixed-effects and the random-effects terms, respectively, and R is the number of grouping variables in the model.

Suppose a table `tbl` contains the following:

- A response variable, y
- Predictor variables, X_j , which can be continuous or grouping variables
- Grouping variables, g_1, g_2, \dots, g_R ,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, or cell arrays of strings.

Then, in a formula of the form, 'y ~ fixed + (random₁|g₁) + ... + (random_R|g_R)', the term `fixed` corresponds to a specification of the fixed-effects design matrix X , `random1` is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1 , and similarly `randomR` is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R . You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$

Wilkinson Notation	Factors in Standard Notation
X1*X2	X1, X2, X1.*X2 (elementwise multiplication of X1 and X2)
X1:X2	X1.*X2 only
- X2	Do not include X2
X1*X2 + X3	X1, X2, X3, X1*X2
X1 + X2 + X3 + X1:X2	X1, X2, X3, X1*X2
X1*X2*X3 - X1:X2:X3	X1, X2, X3, X1*X2, X1*X3, X2*X3
X1*(X2 + X3)	X1, X2, X3, X1*X2, X1*X3

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.
'y ~ -1 + X1 + X2'	No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.
'y ~ 1 + (1 g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'.
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

Examples

Fit a Generalized Linear Mixed-Effects Model

Navigate to the folder containing the sample data. Load the sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier of the chemical used in the batch (**supplier**)
- Number of defects in the batch (**defects**)

The data also includes **time_dev** and **temp_dev**, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using **newprocess**, **time_dev**, **temp_dev**, and **supplier** as fixed-effects predictors. Include a random-effects term for intercept grouped by **factory**, to account for quality differences that might exist due to factory-specific variations. The response variable **defects** has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as **'effects'**, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$defects_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 newprocess_{ij} + \beta_2 time_dev_{ij} + \beta_3 temp_dev_{ij} + \beta_4 supplier_C_{ij} + \beta_5 supplier_B_{ij} + b_i,$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- $newprocess_{ij}$, $time_dev_{ij}$, and $temp_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j . For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier_C_{ij}$ and $supplier_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)
```

Display the model.

```
disp(glme)

-2.1926	1.6263
-0.22679	0.083051
-0.082588	0.22473

Random effects covariance parameters:

Group: factory (20 Levels)

Name1	Name2	Type	Estimate
'(Intercept)'	'(Intercept)'	'std'	0.31381

Group: Error

Name	Estimate
'sqrt(Dispersion)'	1

The **Model information** table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a **Poisson** distribution, the link function is **Log**, and the fit method is **Laplace**.

Formula indicates the model specification using Wilkinson's notation.

The `Model fit statistics` table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (AIC), Bayesian information criterion (BIC) values, log likelihood (`LogLikelihood`), and deviance (`Deviance`) values.

The `Fixed effects coefficients` table indicates that `fitglm` returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (`Name`) contains the name of each fixed-effects coefficient, column 2 (`Estimate`) contains its estimated value, and column 3 (`SE`) contains the standard error of the coefficient. Column 4 (`tStat`) contains the *t*-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (`DF`) and column 6 (`pValue`) contain the degrees of freedom and *p*-value that correspond to the *t*-statistic, respectively. The last two columns (`Lower` and `Upper`) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

`Random effects covariance parameters` displays a table for each grouping variable (here, only `factory`), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, `std` indicates that `fitglm` returns the standard deviation of the random effect associated with the `factory` predictor, which has an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by `fitglm` does not provide confidence intervals for the random-effects parameters. To compute and display these values, use `covarianceParameters`.

- “Generalized Linear Mixed-Effects Models” on page 11-65

GeneralizedLinearModel class

Generalized linear regression model class

Description

An object comprising training data, model description, diagnostic information, and fitted coefficients for a generalized linear regression. Predict model responses with the `predict` or `feval` methods.

Construction

`mdl = fitglm(tbl)` or `mdl = fitglm(X,y)` creates a generalized linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`. For details, see `fitglm`.

`mdl = stepwiseglm(tbl)` or `mdl = stepwiseglm(X,y)` creates a generalized linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`, with unimportant predictors excluded. For details, see `stepwiseglm`.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-56). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X .

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double`

Properties

CoefficientCovariance — Covariance matrix of coefficient estimates

numeric matrix

Covariance matrix of coefficient estimates, stored as a p -by- p matrix of numeric values. p is the number of coefficients in the fitted model.

CoefficientNames — Coefficient names

cell array of strings

Coefficient names, stored as a cell array of strings containing a label for each coefficient.

Coefficients — Coefficient values

table

Coefficient values, stored as a table. `Coefficients` has one row for each coefficient and the following columns:

- `Estimate` — Estimated coefficient value
- `SE` — Standard error of the estimate

- `tStat` — t statistic for a test that the coefficient is zero
- `pValue` — p -value for the t statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

Deviance — Deviance of the fit

numeric value

Deviance of the fit, stored as a numeric value. Deviance is useful for comparing two models when one is a special case of the other. The difference between the deviance of the two models has a chi-square distribution with degrees of freedom equal to the difference in the number of estimated parameters between the two models. For more information on deviance, see “Deviance” on page 25-2387.

DFE — Degrees of freedom for error

positive integer value

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients, stored as a positive integer value.

Diagnostics — Diagnostic information

table

Diagnostic information for the model, stored as a table. Diagnostics can help identify outliers and influential observations. `Diagnostics` contains the following fields:

Field	Meaning	Utility
Leverage	Diagonal elements of <code>HatMatrix</code>	Leverage indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with p coefficients and n observations, the average value of <code>Leverage</code> is p/n . An observation with <code>Leverage</code> larger than $2*p/n$ can be an outlier.

Field	Meaning	Utility
CooksDistance	Cook's measure of scaled change in fitted values	CooksDistance is a measure of scaled change in fitted values. An observation with CooksDistance larger than three times the mean Cook's distance can be an outlier.
HatMatrix	Projection matrix to compute fitted from observed responses	HatMatrix is an n -by- n matrix such that $\text{Fitted} = \text{HatMatrix} * Y$, where Y is the response vector and Fitted is the vector of fitted response values.

All of these quantities are computed on the scale of the linear predictor. So, for example, in the equation that defines the hat matrix,

```
Yfit = glm.Fitted.LinearPredictor
Y = glm.Fitted.LinearPredictor + glm.Residuals.LinearPredictor
```

Dispersion — Scale factor of the variance of the response

structure

Scale factor of the variance of the response, stored as a structure. **Dispersion** multiplies the variance function for the distribution.

For example, the variance function for the binomial distribution is $p(1-p)/n$, where p is the probability parameter and n is the sample size parameter. If **Dispersion** is near 1, the variance of the data appears to agree with the theoretical variance of the binomial distribution. If **Dispersion** is larger than 1, the data are “overdispersed” relative to the binomial distribution.

DispersionEstimated — Flag to indicate use of dispersion scale factor

logical value

Flag to indicate whether `fitglm` used the **Dispersion** scale factor to compute standard errors for the coefficients in `Coefficients.SE`, stored as a logical value. If **DispersionEstimated** is `false`, `fitglm` used the theoretical value of the variance.

- **DispersionEstimated** can be `false` only for 'binomial' or 'poisson' distributions.
- Set **DispersionEstimated** by setting the **DispersionFlag** name-value pair in `fitglm`.

Distribution — Generalized distribution information

structure

Generalized distribution information, stored as a structure with the following fields relating to the generalized distribution:

Field	Description
Name	Name of the distribution, one of 'normal', 'binomial', 'poisson', 'gamma', or 'inverse gamma'.
DevianceFunction	Function that computes the components of the deviance as a function of the fitted parameter values and the response values.
VarianceFunction	Function that computes the theoretical variance for the distribution as a function of the fitted parameter values. When <code>DispersionEstimated</code> is true, <code>Dispersion</code> multiplies the variance function in the computation of the coefficient standard errors.

Fitted — Fitted response values based on input data

table

Fitted (predicted) values based on the input data, stored as a table with one row for each observation and the following columns.

Field	Description
Response	Predicted values on the scale of the response.
LinearPredictor	Predicted values on the scale of the linear predictor. These are the same as the link function applied to the <code>Response</code> fitted values.
Probability	Fitted probabilities (this column is included only with the binomial distribution).

To obtain any of the columns as a vector, index into the property using dot notation. For example, in the model `mdl`, the vector `f` of fitted values on the response scale is

```
f = mdl.Fitted.Response
```

Use `predict` to compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

Formula — Model information

`LinearFormula` object | `NonLinearFormula` object

Model information, stored as a `LinearFormula` object or `NonLinearFormula` object. If you fit a linear or generalized linear regression model, then `Formula` is a `LinearFormula` object. If you fit a nonlinear regression model, then `Formula` is a `NonLinearFormula` object.

Link — Link function

structure

Link function, stored as a structure with the following fields:

Field	Description
Name	Name of the link function, or '' if you specified the link as a function handle rather than a string.
LinkFunction	The function that defines f , a function handle.
DevianceFunction	Derivative of f , a function handle.
VarianceFunction	Inverse of f , a function handle.

The link is a function f that links the distribution parameter μ to the fitted linear combination Xb of the predictors:

$$f(\mu) = Xb.$$

LogLikelihood — Log likelihood

numeric value

Log likelihood of the model distribution at the response values, stored as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.

ModelCriterion — Criterion for model comparison

structure

Criterion for model comparison, stored as a structure with the following fields:

- **AIC** — Akaike information criterion
- **AICc** — Akaike information criterion corrected for sample size
- **BIC** — Bayesian information criterion
- **CAIC** — Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

NumCoefficients — Number of model coefficients

positive integer

Number of model coefficients, stored as a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

NumEstimatedCoefficients — Number of estimated coefficients

positive integer

Number of estimated coefficients in the model, stored as a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

NumObservations — Number of observations

positive integer

Number of observations the fitting function used in fitting, stored as a positive integer. This is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the `Excluded` name-value pair) or rows with missing values.

NumPredictors — Number of predictor variables

positive integer

Number of predictor variables used to fit the model, stored as a positive integer.

NumVariables — Number of variables

positive integer

Number of variables in the input data, stored as a positive integer. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

ObservationInfo — Observation information

table

Observation information, stored as a n -by-4 table, where n is equal to the number of rows of input data. The four columns of `ObservationInfo` contain the following:

Field	Description
Weights	Observation weights. Default is all 1.
Excluded	Logical value, 1 indicates an observation that you excluded from the fit with the <code>Exclude</code> name-value pair.
Missing	Logical value, 1 indicates a missing value in the input. Missing values are not used in the fit.
Subset	Logical value, 1 indicates the observation is not excluded or missing, so is used in the fit.

ObservationNames — Observation names

cell array

Observation names, stored as a cell array of strings containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array

Offset — Offset variable

numeric vector

, stored as a numeric vector with the same length as the number of rows in the data. `Offset` is passed from `fitglm` or `stepwiseglm` in the `Offset` name-value pair. The fitting function used `Offset` as a predictor variable, but with the coefficient set to exactly 1. In other words, the formula for fitting was $\mu \sim \text{Offset} + (\text{terms involving real predictors})$

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor A. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

PredictorNames — Names of predictors used to fit the model

cell array

Names of predictors used to fit the model, stored as a cell array of strings.

Residuals — Residuals for fitted model

table

Residuals for the fitted model, stored as a table with one row for each observation and the following columns.

Field	Description
Raw	Observed minus fitted values.
LinearPredictor	Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors.
Pearson	Raw residuals divided by the estimated standard deviation of the response.
Anscombe	Residuals defined on transformed data with the transformation chosen to remove skewness.
Deviance	Residuals based on the contribution of each observation to the deviance.

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

ResponseName — Response variable name

string

Response variable name, stored as a string.

Rsquared — R-squared value for the model

structure

R-squared value for the model, stored as a structure.

For a linear or nonlinear model, **Rsquared** is a structure with two fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients

For a generalized linear model, **Rsquared** is a structure with five fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients
- **LLR** — Log-likelihood ratio
- **Deviance** — Deviance
- **AdjGeneralized** — Adjusted generalized R-squared

The R-squared value is the proportion of total sum of squares explained by the model.

The ordinary R-squared value relates to the **SSR** and **SST** properties:

$\text{Rsquared} = \text{SSR}/\text{SST} = 1 - \text{SSE}/\text{SST}$.

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

SSE — Sum of squared errors

numeric value

Sum of squared errors (residuals), stored as a numeric value.

The Pythagorean theorem implies

$\text{SST} = \text{SSE} + \text{SSR}$.

SSR — Regression sum of squares

numeric value

Regression sum of squares, stored as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies
 $SST = SSE + SSR$.

SST — Total sum of squares

numeric value

Total sum of squares, stored as a numeric value. The total sum of squares is equal to the sum of squared deviations of y from $\text{mean}(y)$.

The Pythagorean theorem implies
 $SST = SSE + SSR$.

Steps — Stepwise fitting information

structure

Stepwise fitting information, stored as a structure with the following fields.

Field	Description
Start	Formula representing the starting model
Lower	Formula representing the lower bound model, these terms that must remain in the model
Upper	Formula representing the upper bound model, model cannot contain more terms than Upper
Criterion	Criterion used for the stepwise algorithm, such as 'sse'
PEnter	Value of the parameter, such as 0.05
PRemove	Value of the parameter, such as 0.10
History	Table representing the steps taken in the fit

The **History** table has one row for each step including the initial fit, and the following variables (columns).

Field	Description
Action	Action taken during this step, one of: <ul style="list-style-type: none"> 'Start' — First step 'Add' — A term is added 'Remove' — A term is removed

Field	Description
TermName	<ul style="list-style-type: none"> 'Start' step: The starting model specification 'Add' or 'Remove' steps: The term moved in that step
Terms	Terms matrix (see <code>modelspec</code> of <code>fitlm</code>)
DF	Regression degrees of freedom after this step
delDF	Change in regression degrees of freedom from previous step (negative for steps that remove a term)
Deviance	Deviance (residual sum of squares) at that step
FStat	F statistic that led to this step
PValue	p -value of the F statistic

The structure is empty unless you use `stepwiselm` or `stepwiseglm` to fit the model.

VariableInfo — Information about input variables

table

Information about input variables contained in `Variables`, stored as a table with one row for each model term and the following columns.

Field	Description
Class	String giving variable class, such as 'double'
Range	Cell array giving variable range: <ul style="list-style-type: none"> Continuous variable — Two-element vector $[min, max]$, the minimum and maximum values Categorical variable — Cell array of distinct variable values
InModel	Logical vector, where <code>true</code> indicates the variable is in the model
IsCategorical	Logical vector, where <code>true</code> indicates a categorical variable

VariableNames — Names of variables used in fit

cell array

Names of variables used in fit, stored as a cell array of strings.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.

- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

Variables — Data used to fit the model

table

Data used to fit the model, stored as a table. `Variables` contains both observation and response values. If the fit is based on a table or dataset array, `Variables` contains all of the data from that table or dataset array. Otherwise, `Variables` is a table created from the input data matrix X and response vector y .

Methods

<code>addTerms</code>	Add terms to generalized linear model
<code>coefCI</code>	Confidence intervals of coefficient estimates of generalized linear model
<code>coefTest</code>	Linear hypothesis test on generalized linear regression model coefficients
<code>devianceTest</code>	Analysis of deviance
<code>disp</code>	Display generalized linear regression model
<code>feval</code>	Evaluate generalized linear regression model prediction
<code>fit</code>	Create generalized linear regression model
<code>plotDiagnostics</code>	Plot diagnostics of generalized linear regression model
<code>plotResiduals</code>	Plot residuals of generalized linear regression model
<code>plotSlice</code>	Plot of slices through fitted generalized linear regression surface
<code>predict</code>	Predict response of generalized linear regression model
<code>random</code>	Simulate responses for generalized linear regression model

removeTerms	Remove terms from generalized linear model
step	Improve generalized linear regression model by adding or removing terms
stepwise	Create generalized linear regression model by stepwise regression

Definitions

Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Hat Matrix

The *hat matrix* H is defined in terms of the data matrix X and a diagonal weight matrix W :

$$H = X(X^T W X)^{-1} X^T W^T.$$

W has diagonal elements w_i :

$$w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}},$$

where

- g is the link function mapping y_i to $x_i b$.
- g' is the derivative of the link function g .
- V is the variance function.
- μ_i is the i th mean.

The diagonal elements H_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$
$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

The *leverage* of observation i is the value of the i th diagonal term, h_{ii} , of the hat matrix H . Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered to be an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = w_i \frac{e_i^2}{p \hat{\phi} (1 - h_{ii})^2},$$

where

- $\hat{\phi}$ is the dispersion parameter (estimated or theoretical).
- e_i is the linear predictor residual, $g(y_i) - x_i \hat{\beta}$, where

- g is the link function.
- y_i is the observed response.
- x_i is the observation.
- $\hat{\beta}$ is the estimated coefficient vector.
- p is the number of coefficients in the regression model.
- h_{ii} is the i th diagonal element of the Hat Matrix H .

Deviance

Deviance of a model M_1 is twice the difference between the loglikelihood of that model and the saturated model, M_S . The saturated model is the model with the maximum number of parameters that can be estimated. For example, if there are n observations y_i , $i = 1, 2, \dots, n$, with potentially different values for $X_i^T\beta$, then you can define a saturated model with n parameters. Let $L(b,y)$ denote the maximum value of the likelihood function for a model. Then the deviance of model M_1 is

$$-2(\log L(b_1, y) - \log L(b_S, y)),$$

where b_1 are the estimated parameters for model M_1 and b_S are the estimated parameters for the saturated model. The deviance has a chi-square distribution with $n - p$ degrees of freedom, where n is the number of parameters in the saturated model and p is the number of parameters in model M_1 .

If M_1 and M_2 are two different generalized linear models, then the fit of the models can be assessed by comparing the deviances D_1 and D_2 of these models. The difference of the deviances is

$$\begin{aligned} D &= D_2 - D_1 = -2(\log L(b_2, y) - \log L(b_S, y)) + 2(\log L(b_1, y) - \log L(b_S, y)) \\ &= -2(\log L(b_2, y) - \log L(b_1, y)). \end{aligned}$$

Asymptotically, this difference has a chi-square distribution with degrees of freedom v equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters

estimated in M_1 and M_2 . You can get the p -value for this test using `1 - chi2cdf(D,V)`, where $D = D_2 - D_1$.

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

Examples

Fit a Generalized Linear Model

Fit a logistic regression model of probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the `hospital` dataset array.

```
load hospital
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Create the generalized linear model.

```
mdl = fitglm(ds,modelspec,'Distribution','binomial')
```

```
mdl =
```

Generalized Linear regression model:

```
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
Distribution = Binomial
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	-6.0492	19.749	-0.3063	0.75938

Sex_Male	-2.2859	12.424	-0.18399	0.85402
Age	0.11691	0.50977	0.22934	0.81861
Weight	0.031109	0.15208	0.20455	0.83792
Sex_Male:Age	0.020734	0.20681	0.10025	0.92014
Sex_Male:Weight	0.01216	0.053168	0.22871	0.8191
Age:Weight	-0.00071959	0.0038964	-0.18468	0.85348

100 observations, 93 error degrees of freedom
 Dispersion: 1
 Chi^2-statistic vs. constant model: 5.07, p-value = 0.535

The large *P*-value indicates the model might not differ statistically from a constant.

Create a Generalized Linear Model Stepwise

Create response data using just three of 20 predictors, and create a generalized linear model stepwise to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng default % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = stepwiseglm(X,y,...
    'constant','upper','linear','Distribution','poisson')
```

1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

```
mdl =
```

```
Generalized Linear regression model:
log(y) ~ 1 + x5 + x10 + x15
Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
--	----------	----	-------	--------

(Intercept)	1.0115	0.064275	15.737	8.4217e-56
x5	0.39508	0.066665	5.9263	3.0977e-09
x10	0.18863	0.05534	3.4085	0.0006532
x15	0.29295	0.053269	5.4995	3.8089e-08

100 observations, 96 error degrees of freedom

Dispersion: 1

Chi²-statistic vs. constant model: 91.7, p-value = 9.61e-20

prob.GeneralizedParetoDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Generalized Pareto probability distribution object

Description

`prob.GeneralizedParetoDistribution` is an object consisting of parameters, a model description, and sample data for a generalized Pareto probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('GeneralizedPareto')` creates a generalized Pareto probability distribution object using default parameter values.

`pd = makedist('GeneralizedPareto','k',k,'sigma',sigma,'theta',theta)` creates a generalized Pareto probability distribution object using the specified parameter values.

Input Arguments

k — Shape parameter

1 (default) | scalar value

Shape parameter for the generalized Pareto distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

1 (default) | nonnegative scalar value

Scale parameter for the generalized Pareto distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

theta — Location parameter

1 (default) | scalar value

Location parameter for the generalized Pareto distribution, specified as a scalar value.

Data Types: single | double

Properties

k — Shape parameter

scalar value

Shape parameter for the generalized Pareto distribution, stored as a scalar value.

Data Types: single | double

sigma — Scale parameter

nonnegative scalar value

Scale parameter for the generalized Pareto distribution, stored as a nonnegative scalar value.

Data Types: single | double

theta — Location parameter

scalar value

Location parameter for the generalized Pareto distribution, stored as a scalar value.

Data Types: single | double

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: char

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i, j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i, i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i, i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: logical

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

cdf

Cumulative distribution function of probability distribution object

icdf

Inverse cumulative distribution function of probability distribution object

iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative log likelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Generalized Pareto Distribution

The generalized Pareto distribution is used to model the tails of another distribution. It allows a continuous range of possible shapes that include both the exponential and Pareto distributions as special cases. It has three basic forms, each corresponding to a limiting distribution of exceedence data from a different class of underlying distributions.

- Distributions whose tails decrease exponentially, such as the normal, lead to a generalized Pareto shape parameter of zero.
- Distributions whose tails decrease polynomially, such as the Student's t , lead to a positive shape parameter.
- Distributions whose tails are finite, such as the beta, lead to a negative shape parameter.

The generalized Pareto distribution uses the following parameters.

Parameter	Description	Support
<code>k</code>	Shape parameter	$-\infty < k < \infty$
<code>sigma</code>	Scale parameter	$\sigma \geq 0$
<code>theta</code>	Location parameter	$-\infty < \theta < \infty$

The probability density function (pdf) of the generalized Pareto distribution with shape parameter $k \neq 0$ is

$$f(x | k, \sigma, \theta) = \left(\frac{1}{\sigma}\right) \left(1 + k \frac{(x - \theta)}{\sigma}\right)^{-1 - \frac{1}{k}}$$

for $x > \theta$, when $k > 0$, or for $\theta < x < -\frac{\sigma}{k}$, when $k < 0$.

For $k = 0$, the pdf is

$$y = f(x | 0, \sigma, \theta) = \left(\frac{1}{\sigma}\right) \exp\left(-\frac{(x - \theta)}{\sigma}\right)$$

for $x > \theta$.

If $k = 0$ and $\theta = 0$, the generalized Pareto distribution is equivalent to the exponential

distribution. If $k > 0$ and $\theta = \frac{\sigma}{k}$, the generalized Pareto distribution is equivalent to the Pareto distribution.

Examples

Create a Generalized Pareto Distribution Object Using Default Parameters

Create a generalized Pareto distribution object using the default parameter values.

```
pd = makedist('GeneralizedPareto')
pd =
    GeneralizedParetoDistribution
    Generalized Pareto distribution
        k = 1
        sigma = 1
        theta = 1
```

Create a Generalized Pareto Distribution Object Using Specified Parameters

Create a generalized Pareto distribution object by specifying parameter values.

```
pd = makedist('GeneralizedPareto','k',0,'sigma',2,'theta',1)
pd =
    GeneralizedParetoDistribution
    Generalized Pareto distribution
        k = 0
        sigma = 2
        theta = 1
```

Compute the mean of the distribution.

```
m = mean(pd)
m =

geocdf

Geometric cumulative distribution function

Syntax

```
y = geocdf(x,p)
y = geocdf(x,p,'upper')
```

Description

`y = geocdf(x,p)` returns the cumulative distribution function (cdf) of the geometric distribution at each value in `x` using the corresponding probabilities in `p`. `x` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `p` must lie on the interval `[0, 1]`.

`y = geocdf(x,p,'upper')` returns the complement of the geometric distribution cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Examples

Compute Geometric Distribution cdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing three or fewer tails ("failures") before tossing a heads?

To solve, determine the value of the cumulative distribution function (cdf) for the geometric distribution at `x` equal to 3. The probability of success (tossing a heads) `p` in any given trial is 0.5.

```
x = 3;
p = 0.5;
y = geocdf(x,p)
```

$y =$

0.9375

The returned value of y indicates that the probability of observing three or fewer tails before tossing a heads is 0.9375.

More About

Geometric Distribution cdf

The cumulative distribution function (cdf) of the geometric distribution is

$$y = F(x | p) = 1 - (1 - p)^{x+1} ; x = 0, 1, 2, \dots,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing up to x trials before a success, when the probability of success in any given trial is p .

Introduced before R2006a

geoinv

Geometric inverse cumulative distribution function

Syntax

```
x = geoinv(y,p)
```

Description

`x = geoinv(y,p)` returns the inverse cumulative distribution function (icdf) of the geometric distribution at each value in `y` using the corresponding probabilities in `p`.

`geoinv` returns the smallest positive integer `x` such that the geometric cdf evaluated at `x` is equal to or exceeds `y`. You can think of `y` as the probability of observing `x` successes in a row in independent trials, where `p` is the probability of success in each trial.

`y` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `p` or `y` is expanded to a constant array with the same dimensions as the other input. The values in `p` and `y` must lie on the interval `[0, 1]`.

Examples

Compute Geometric Distribution icdf

Suppose the probability of a five-year-old car battery not starting in cold weather is 0.03. If we want no more than a ten percent chance that the car does not start, what is the maximum number of days in a row that we should try to start the car?

To solve, compute the inverse cdf of the geometric distribution. In this example, a "success" means the car does not start, while a "failure" means the car does start. The probability of success for each trial `p` equals 0.03, while the probability of observing `x` failures in a row before observing a success `y` equals 0.1.

```
y = 0.1;  
p = 0.03;  
x = geoinv(y,p)
```

```
x =  
    3
```

The returned result indicates that if we start the car three times, there is at least a ten percent chance that it will not start on one of those tries. Therefore, if we want no greater than a ten percent chance that the car will not start, we should only attempt to start it for a maximum of two days in a row.

We can confirm this result by evaluating the cdf at values of x equal to 2 and 3, given the probability of success for each trial p equal to 0.03.

```
y2 = geocdf(2,p) % cdf for x = 2  
y3 = geocdf(3,p) % cdf for x = 3
```

```
y2 =  
    0.0873
```

```
y3 =  
    0.1147
```

The returned results indicate an 8.7% chance of the car not starting if we try two days in a row, and an 11.5% chance of not starting if we try three days in a row.

geomean

Geometric mean

Syntax

```
m = geomean(x)
geomean(X,dim)
```

Description

`m = geomean(x)` calculates the geometric mean of a sample. For vectors, `geomean(x)` is the geometric mean of the elements in `x`. For matrices, `geomean(X)` is a row vector containing the geometric means of each column. For N-dimensional arrays, `geomean` operates along the first nonsingleton dimension of `X`.

`geomean(X,dim)` takes the geometric mean along the dimension `dim` of `X`.

The geometric mean is

$$m = \left[\prod_{i=1}^n x_i \right]^{\frac{1}{n}}$$

Examples

The arithmetic mean is greater than or equal to the geometric mean.

```
x = exprnd(1,10,6);
```

```
geometric = geomean(x)
```

```
geometric =
```

```
0.7466 0.6061 0.6038 0.2569 0.7539 0.3478
```

```
average = mean(x)
```

```
average =

mean | median | harmmean | trimmean

Introduced before R2006a

geopdf

Geometric probability density function

Syntax

```
y = geopdf(x,p)
```

Description

`y = geopdf(x,p)` returns the probability density function (pdf) of the geometric distribution at each value in `x` using the corresponding probabilities in `p`. `x` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `p` must lie on the interval $[0, 1]$.

Examples

Compute Geometric Distribution pdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing exactly three tails ("failures") before tossing a heads?

To solve, determine the value of the probability density function (pdf) for the geometric distributon at x equal to 3. The probability of success (tossing a heads) p in any given trial is 0.5.

```
x = 3;  
p = 0.5;  
y = geopdf(x,p)
```

```
y =
```

```
0.0625
```

The returned value of y indicates that the probability of observing exactly three tails before tossing a heads is 0.0625.

More About

Geometric Distribution pdf

The probability distribution function (pdf) of the geometric distribution is

$$y = f(x | p) = p(1 - p)^x \quad ; \quad x = 0, 1, 2, \dots,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing exactly x trials before a success, when the probability of success in any given trial is p . For discrete distributions, the probability distribution function is also known as the probability mass function (pmf).

Introduced before R2006a

geornd

Geometric random numbers

Syntax

```
r = geornd(p)
r = geornd(p,m,n,...)
r = geornd(p,[m,n,...])
```

Description

`r = geornd(p)` generates random numbers from a geometric distribution with probability parameter `p`. `p` can be a vector, a matrix, or a multidimensional array. The size of `r` is equal to the size of `p`. The parameters in `p` must lie in the interval `[0,1]`.

`r = geornd(p,m,n,...)` or `r = geornd(p,[m,n,...])` generates a multidimensional `m`-by-`n`-by-... array containing random numbers from the geometric distribution with probability parameter `p`. `p` can be a scalar or an array of the same size as `r`.

The geometric distribution is useful to model the number of failures before one success in a series of independent trials, where each trial results in either success or failure, and the probability of success in any individual trial is the constant `p`.

Examples

Generate Random Numbers from Geometric Distribution

Generate a single random number from a geometric distribution with probability parameter `p` equal to 0.01.

```
rng default % For reproducibility
p = 0.01;
r1 = geornd(0.01)
```

```
r1 =  
    20
```

The returned random number represents a single experiment in which 20 failures were observed before a success, where each independent trial has a probability of success p equal to 0.01.

Generate a 1-by-5 array of random numbers from a geometric distribution with probability parameter p equal to 0.01.

```
r2 = geornd(p,1,5)  
  
r2 =  
     9    205     9    45    231
```

Each random number in the returned array represents the result of an experiment to determine the number of failures observed before a success, where each independent trial has a probability of success p equal to 0.01.

Generate a 1-by-3 array containing one random number from each of the three geometric distributions corresponding to the parameters in the 1-by-3 array of probabilities p .

```
p = [0.01 0.1 0.5];  
r3 = geornd(p,[1 3])
```

```
r3 =  
    127     5     0
```

Each element of the returned 1-by-3 array **r3** contains one random number generated from the geometric distribution described by the corresponding parameter in **P**. For example, the first element in **r3** represents an experiment in which 127 failures were observed before a success, where each independent trial has a probability of success p equal to 0.01. The second element in **r3** represents an experiment in which 5 failures were observed before a success, where each independent trial has a probability of success p equal to 0.1. The third element in **r3** represents an experiment in which zero failures

were observed before a success - in other words, the first attempt was a success - where each independent trial has a probability of success p equal to 0.5.

Introduced before R2006a

geostat

Geometric mean and variance

Syntax

```
[m,v] = geostat(p)
```

Description

`[m,v] = geostat(p)` returns the mean `m` and variance `v` of a geometric distribution with corresponding probability parameters in `p`. `p` can be a vector, a matrix, or a multidimensional array. The parameters in `p` must lie in the interval `[0,1]`.

Examples

Compute Mean and Variance of Geometric Distribution

Define a probability vector that contains six different parameter values.

```
p = 1./(1:6)
```

```
p =
```

```
    1.0000    0.5000    0.3333    0.2500    0.2000    0.1667
```

Compute the mean and variance of the geometric distribution that corresponds to each value contained in probability vector.

```
[m,v] = geostat(1./(1:6))
```

```
m =
```

```
    0    1.0000    2.0000    3.0000    4.0000    5.0000
```

v =

0 2.0000 6.0000 12.0000 20.0000 30.0000

The returned values indicate that, for example, the mean of a geometric distribution with probability parameter p equal to 1/3 is 2, and its variance is 6.

More About

Geometric Distribution Mean and Variance

The mean of the geometric distribution is

$$\text{mean} = \frac{1-p}{p},$$

and the variance of the geometric distribution is

$$\text{var} = \frac{1-p}{p^2},$$

where p is the probability of success.

Introduced before R2006a

clustering.evaluation.GapEvaluation class

Package: clustering.evaluation

Superclasses: clustering.evaluation.ClusterCriterion

Gap criterion clustering evaluation object

Description

`clustering.evaluation.GapEvaluation` is an object consisting of sample data, clustering data, and gap criterion values used to evaluate the optimal number of clusters. Create a gap criterion clustering evaluation object using `evalclusters`.

Construction

`eva = evalclusters(x, clust, 'Gap')` creates a gap criterion clustering evaluation object.

`eva = evalclusters(x, clust, 'Gap', Name, Value)` creates a gap criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data

matrix

Input data, specified as an N -by- P matrix. N is the number of observations, and P is the number of variables.

Data Types: single | double

clust — Clustering algorithm

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

'kmeans'	Cluster the data in <code>x</code> using the <code>kmeans</code> clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.
'linkage'	Cluster the data in <code>x</code> using the <code>clusterdata</code> agglomerative clustering algorithm, with 'Linkage' set to 'ward'.
'gmdistribution'	Cluster the data in <code>x</code> using the <code>gmdistribution</code> Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If `Criterion` is 'CalinskHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle. The function must be of the form `C = clustfun(DATA,K)`, where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric n -by- K matrix of score for n observations and K classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `Criterion` is 'CalinskHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify `clust` as a n -by- K matrix containing the proposed clustering solutions. n is the number of observations in the sample data, and K is the number of proposed clustering solutions. Column j contains the cluster indices for each of the N points in the j th clustering solution.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: 'KList',[1:5],'Distance','cityblock' specifies to test 1, 2, 3, 4, and 5 clusters using the sum of absolute differences distance measure.

'B' — Number of reference data sets

100 (default) | positive integer value

Number of reference data sets generated from the reference distribution `ReferenceDistribution`, specified as the comma-separated pair consisting of `'B'` and a positive integer value.

Example: `'B', 150`

'Distance' — Distance metric

`'sqEuclidean'` (default) | `'Euclidean'` | `'cityblock'` | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of `'Distance'` and one of the following.

<code>'sqEuclidean'</code>	Squared Euclidean distance
<code>'Euclidean'</code>	Euclidean distance
<code>'cityblock'</code>	Sum of absolute differences
<code>'cosine'</code>	One minus the cosine of the included angle between points (treated as vectors)
<code>'correlation'</code>	One minus the sample correlation between points (treated as sequences of values)

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric by using a function handle. The distance function must be of the form

```
d2 = distfun(XI,XJ),
```

where `XI` is a 1-by- n vector corresponding to a single row of the input matrix `X`, and `XJ` is an m_2 -by- n matrix corresponding to multiple rows of `X`. `distfun` must return an m_2 -by-1 vector of distances `d2`, whose k th element is the distance between `XI` and `XJ(k,:)`.

If `Criterion` is `'silhouette'`, you can also specify `Distance` as the output vector output created by the function `pdist`.

When `Clust` a string representing a built-in clustering algorithm, `evalclusters` uses the distance metric specified for `Distance` to cluster the data, except for the following:

- If `Clust` is `'linkage'`, and `Distance` is either `'sqEuclidean'` or `'Euclidean'`, then the clustering algorithm uses Euclidean distance and Ward linkage.
- If `Clust` is `'linkage'` and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.

In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

Example: `'Distance', 'Euclidean'`

'KList' — List of number of clusters to evaluate

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of `'KList'` and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name string or a function handle. When `criterion` is `'gap'`, `clust` must be a string or a function handle, and you must specify `KList`.

Example: `'KList', [1:6]`

'ReferenceDistribution' — Reference data generation method

`'PCA'` (default) | `'uniform'`

Reference data generation method, specified as the comma-separated pair consisting of `'ReferenceDistributions'` and one of the following.

<code>'PCA'</code>	Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix x .
<code>'uniform'</code>	Generate reference data uniformly over the range of each feature in the data matrix x .

Example: `'ReferenceDistribution', 'uniform'`

'SearchMethod' — Method for selecting optimal number of clusters

`'globalMaxSE'` (default) | `'firstMaxSE'`

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of `'SearchMethod'` and one of the following.

<code>'globalMaxSE'</code>	Evaluate each proposed number of clusters in <code>KList</code> and select the smallest number of clusters satisfying
----------------------------	---

$$\text{Gap}(K) \geq \text{GAPMAX} - \text{SE}(\text{GAPMAX}),$$

where K is the number of clusters, $\text{Gap}(K)$ is the gap value for the clustering solution with K clusters, GAPMAX is the largest gap value, and $\text{SE}(\text{GAPMAX})$ is the standard error corresponding to the largest gap value.

'firstMaxSE'

Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{Gap}(K + 1) - \text{SE}(K + 1),$$

where K is the number of clusters, $\text{Gap}(K)$ is the gap value for the clustering solution with K clusters, and $\text{SE}(K + 1)$ is the standard error of the clustering solution with $K + 1$ clusters.

Example: 'SearchMethod', 'globalMaxSE'

Properties

B

Number of data sets generated from the reference distribution, stored as a positive integer value.

ClusteringFunction

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name string or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

CriterionName

Name of the criterion used for clustering evaluation, stored as a valid criterion name string.

CriterionValues

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

Distance

Distance measure used for clustering data, stored as a valid distance measure name string.

ExpectedLogW

Expectation of the natural logarithm of W based on the generated reference data, stored as a vector of scalar values. W is the within-cluster dispersion computed using the distance measurement **Distance**.

InspectedK

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

LogW

Natural logarithm of W based on the input data, stored as a vector of scalar values. W is the within-cluster dispersion computed using the distance measurement **Distance**.

Missing

Logical flag for excluded data, stored as a column vector of logical values. If **Missing** equals **true**, then the corresponding value in the data matrix X is not used in the clustering solution.

NumObservations

Number of observations in the data matrix X , minus the number of missing (NaN) values in X , stored as a positive integer value.

OptimalK

Optimal number of clusters, stored as a positive integer value.

OptimalY

Optimal clustering solution corresponding to **OptimalK**, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, **OptimalY** is empty.

ReferenceDistribution

Reference data generation method, stored as a valid reference distribution name string.

SE

Standard error of the natural logarithm of W with respect to the reference data for each number of clusters in `InspectedK`, stored as a vector of scalar values. W is the within-cluster dispersion computed using the distance measurement `Distance`.

SearchMethod

Method for determining the optimal number of clusters, stored as a valid search method name string.

StdLogW

Standard deviation of the natural logarithm of W with respect to the reference data for each number of clusters in `InspectedK`. W is the within-cluster dispersion computed using the distance measurement `Distance`.

X

Data used for clustering, stored as a matrix of numerical values.

Methods

increaseB	Increase reference data sets
-----------	------------------------------

Inherited Methods

addK	Evaluate additional numbers of clusters
plot	Plot clustering evaluation object criterion values
compact	Compact clustering evaluation object

Definitions

Gap Value

A common graphical approach to cluster evaluation involves plotting an error measurement versus several proposed numbers of clusters, and locating the “elbow” of this plot. The “elbow” occurs at the most dramatic decrease in error measurement. The gap criterion formalizes this approach by estimating the “elbow” location as the number of clusters with the largest gap value. Therefore, under the gap criterion, the optimal number of clusters occurs at the solution with the largest local or global gap value within a tolerance range.

The gap value is defined as

$$\text{Gap}_n(k) = E_n^* \{ \log(W_k) \} - \log(W_k),$$

where n is the sample size, k is the number of clusters being evaluated, and W_k is the pooled within-cluster dispersion measurement

$$W_k = \sum_{r=1}^k \frac{1}{2n_r} D_r,$$

where n_r is the number of data points in cluster r , and D_r is the sum of the pairwise distances for all points in cluster r .

The expected value $E_n^* \{ \log(W_k) \}$ is determined by Monte Carlo sampling from a reference distribution, and $\log(W_k)$ is computed from the sample data.

The gap value is defined even for clustering solutions that contain only one cluster, and can be used with any distance metric. However, the gap criterion is more computationally expensive than other cluster evaluation criteria, because the clustering algorithm must be applied to the reference data for each proposed clustering solution.

Examples

Evaluate the Clustering Solution Using Gap Criterion

Evaluate the optimal number of clusters using the gap clustering evaluation criterion.

Load the sample data.

```
load fisheriris;
```

The data contains sepal and petal measurements from three species of iris flowers.

Evaluate the number of clusters based on the gap criterion values. Cluster the data using `kmeans`.

```
rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','gap','KList',[1:6])
```

```
eva =
```

```
GapEvaluation with properties:
```

```
NumObservations: 150
InspectecedK: [1 2 3 4 5 6]
CriterionValues: [1x6 double]
OptimalK: 4
```

The `OptimalK` value indicates that, based on the gap criterion, the optimal number of clusters is four.

Plot the gap criterion values for each number of clusters tested.

```
figure;
plot(eva);
```

Based on the plot, the maximum value of the gap criterion occurs at five clusters. However, the value at four clusters is within one standard error of the maximum, so the suggested optimal number of clusters is four.

Create a grouped scatter plot to examine the relationship between petal length and width. Group the data by suggested clusters.

```
figure;  
PetalLength = meas(:,3);  
PetalWidth = meas(:,4);  
ClusterGroup = eva.OptimalY;  
figure;  
gscatter(PetalLength,PetalWidth,ClusterGroup,'rbgk','xod^');
```

The plot shows cluster 1 in the lower-left corner, completely separated from the other three clusters. Cluster 1 contains flowers with the smallest petal widths and lengths. Cluster 4 is in the upper-right corner, and contains flowers with the largest petal widths and lengths. Clusters 2 and 3 are near the center of the plot, and contain flowers with measurements between the two extremes.

- [Property Attributes](#)

get

Class: dataset

Access dataset array properties

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
get(A)
s = get(A)
p = get(A,PropertyName)
p = get(A,{PropertyName1,PropertyName2,...})
```

Description

`get(A)` displays a list of property/value pairs for the dataset array `A`.

`s = get(A)` returns the values in a scalar structure `s` with field names given by the properties.

`p = get(A,PropertyName)` returns the value of the property specified by the string `PropertyName`.

`p = get(A,{PropertyName1,PropertyName2,...})` allows multiple property names to be specified and returns their values in a cell array.

Examples

Create a dataset array from Fisher's iris data and access the information.

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)', '%-d'));
iris = dataset({nominal(species), 'species'},...
              {meas, 'SL', 'SW', 'PL', 'PW'},...
              'ObsNames', NameObs);

get(iris)
  Description: ''
  Units: {}
  DimNames: {'Observations' 'Variables'}
  UserData: []
  ObsNames: {150x1 cell}
  VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}

ON = get(iris, 'ObsNames');
ON(1:3)
ans =
  'Obs1'
  'Obs2'
  'Obs3'
```

set | summary

getlabels

Access categorical array labels

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
labels = getlabels(A)
```

Description

`labels = getlabels(A)` returns the labels of the levels in the nominal or ordinal array `A` as a cell array of strings, `labels`. If `A` is an ordinal array, `getlabels` returns the labels in the order of the levels.

Examples

- “Change Category Labels” on page 2-10

Input Arguments

A — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

More About

- Using nominal Objects

- Using ordinal Objects

getlevels | nominal | ordinal

Introduced in R2007a

getlevels

Access categorical array levels

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
L = getlevels(A)
```

Description

`L = getlevels(A)` returns the levels in the nominal or ordinal array `A` in `L`, a vector with the same type as `A`.

Examples

- “Add and Drop Category Levels” on page 2-24
- “Merge Category Levels” on page 2-22
- “Reorder Category Levels” on page 2-12

Input Arguments

A — Nominal or ordinal array

nominal array | ordinal array

gevcdf

Generalized extreme value cumulative distribution function

Syntax

```
p = gevcdf(x,k,sigma,mu)
p = gevcdf(x,k,sigma,mu,'upper')
```

Description

`p = gevcdf(x,k,sigma,mu)` returns the cdf of the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

`p = gevcdf(x,k,sigma,mu,'upper')` returns the complement of the cdf of the GEV distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblcdf` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evcdf` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-mu)/sigma > -1$.

Introduced before R2006a

gevfit

Generalized extreme value parameter estimates

Syntax

```
parmhat = gevfit(X)
[parmhat,parmci] = gevfit(X)
[parmhat,parmci] = gevfit(X,alpha)
[...] = gevfit(X,alpha,options)
```

Description

`parmhat = gevfit(X)` returns maximum likelihood estimates of the parameters for the generalized extreme value (GEV) distribution given the data in `X`. `parmhat(1)` is the shape parameter, `k`, `parmhat(2)` is the scale parameter, `sigma`, and `parmhat(3)` is the location parameter, `mu`.

`[parmhat,parmci] = gevfit(X)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gevfit(X,alpha)` returns $100(1-\text{alpha})\%$ confidence intervals for the parameter estimates.

`[...] = gevfit(X,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gevfit')` for parameter names and default values. Pass in `[]` for `alpha` to use the default values.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblfit` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evfit` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution is defined for $k*(X-\text{mu})/\text{sigma} > -1$.

Introduced before R2006a

gevinv

Generalized extreme value inverse cumulative distribution function

Syntax

```
X = gevinv(P,k,sigma,mu)
```

Description

`X = gevinv(P,k,sigma,mu)` returns the inverse cdf of the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter `mu`, evaluated at the values in `P`. The size of `X` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblinv` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evinv` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\sigma > -1$.

Introduced before R2006a

gevlike

Generalized extreme value negative log-likelihood

Syntax

```
nlogL = gevlike(params,data)
[nlogL,ACOV] = gevlike(params,data)
```

Description

`nlogL = gevlike(params,data)` returns the negative of the log-likelihood `nlogL` for the generalized extreme value (GEV) distribution, evaluated at parameters `params`. `params(1)` is the shape parameter, `k`, `params(2)` is the scale parameter, `sigma`, and `params(3)` is the location parameter, `mu`.

`[nlogL,ACOV] = gevlike(params,data)` returns the inverse of Fisher's information matrix, `ACOV`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `ACOV` are their asymptotic variances. `ACOV` is based on the observed Fisher's information, not the expected information.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wbllike` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evlike` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\sigma > -1$.

Introduced before R2006a

gevpdf

Generalized extreme value probability density function

Syntax

$Y = \text{gevpdf}(X, k, \text{sigma}, \mu)$

Description

$Y = \text{gevpdf}(X, k, \text{sigma}, \mu)$ returns the pdf of the generalized extreme value (GEV) distribution with shape parameter k , scale parameter sigma , and location parameter, μ , evaluated at the values in X . The size of Y is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for k , sigma , and μ are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblpdf` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evcdf` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\text{sigma} > -1$.

Introduced before R2006a

gevrnd

Generalized extreme value random numbers

Syntax

```
R = gevrnd(k, sigma, mu)
R = gevrnd(k, sigma, mu, m, n, ...)
R = gevrnd(k, sigma, mu, [m, n, ...])
```

Description

`R = gevrnd(k, sigma, mu)` returns an array of random numbers chosen from the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`. The size of `R` is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of `R` is the size of the other parameters.

`R = gevrnd(k, sigma, mu, m, n, ...)` or `R = gevrnd(k, sigma, mu, [m, n, ...])` generates an `m`-by-`n`-by-... array containing random numbers from the GEV distribution with parameters `k`, `sigma`, and `mu`. The `k`, `sigma`, `mu` parameters can each be scalars or arrays of the same size as `R`.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblrnd` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evrnd` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-mu)/sigma > -1$.

Introduced before R2006a

gevstat

Generalized extreme value mean and variance

Syntax

```
[M,V] = gevstat(k,sigma,mu)
```

Description

`[M,V] = gevstat(k,sigma,mu)` returns the mean of and variance for the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`. The sizes of `M` and `V` are the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblstat` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evstat` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-mu)/sigma > -1$.

Introduced before R2006a

gline

Interactively add line to plot

Syntax

```
gline(h)
gline
hline = gline(...)
```

Description

`gline(h)` allows you to draw a line segment in the figure with handle `h` by clicking the pointer at the two endpoints. A rubber-band line tracks the pointer movement.

`gline` with no input arguments defaults to `h = gcf` and draws in the current figure.

`hline = gline(...)` returns the handle `hline` to the line.

Examples

Use `gline` to connect two points in a plot:

```
x = 1:10;
y = x + randn(1,10);
scatter(x,y,25,'b','*')

lsline

mu = mean(y);
hold on
plot([1 10],[mu mu],'ro')

hline = gline; % Connect circles
set(hline,'Color','r')
```

`refline` | `refcurve` | `lsline`

Introduced before R2006a

glmfit

Generalized linear model regression

Syntax

```
b = glmfit(X,y,distr)
b = glmfit(X,y,distr,param1,val1,param2,val2,...)
[b,dev] = glmfit(...)
[b,dev,stats] = glmfit(...)
```

Description

`b = glmfit(X,y,distr)` returns a $(p + 1)$ -by-1 vector **b** of coefficient estimates for a generalized linear regression of the responses in **y** on the predictors in **X**, using the distribution *distr*. **X** is an n -by- p matrix of p predictors at each of n observations. *distr* can be any of the following strings: 'binomial', 'gamma', 'inverse gaussian', 'normal' (the default), and 'poisson'.

In most cases, **y** is an n -by-1 vector of observed responses. For the binomial distribution, **y** can be a binary vector indicating success or failure at each observation, or a two column matrix with the first column indicating the number of successes for each observation and the second column indicating the number of trials for each observation.

This syntax uses the canonical link (see below) to relate the distribution to the predictors.

Note: By default, `glmfit` adds a first column of 1s to **X**, corresponding to a constant term in the model. Do not enter a column of 1s directly into **X**. You can change the default behavior of `glmfit` using the 'constant' parameter, below.

`glmfit` treats NaNs in either **X** or **y** as missing values, and ignores them.

`b = glmfit(X,y,distr,param1,val1,param2,val2,...)` additionally allows you to specify optional parameter name/value pairs to control the model fit. Acceptable parameters are as follows.

Parameter	Value	Description
'link'	'identity', default for the distribution 'normal'	$\mu = Xb$
	'log', default for the distribution 'poisson'	$\log(\mu) = Xb$
	'logit', default for the distribution 'binomial'	$\log(\mu/(1 - \mu)) = Xb$
	'probit'	$\text{norminv}(\mu) = Xb$
	'comploglog'	$\log(-\log(1 - \mu)) = Xb$
	'reciprocal', default for the distribution 'gamma'	$1/\mu = Xb$
	'loglog'	$\log(-\log(\mu)) = Xb$
	p (a number), default for the distribution 'inverse gaussian' (with $p = -2$)	$\mu^p = Xb$
	cell array of the form {FL FD FI}, containing three function handles, created using @, that define the link (FL), the derivative of the link (FD), and the inverse link (FI).	<p>Custom-defined link function. You must provide</p> <ul style="list-style-type: none"> • FL(mu) • FD = dFL(mu) / dmu • FI = FL^(-1)
'estdisp'	'on'	Estimates a dispersion parameter for the binomial or Poisson distribution.
	'off' (Default for binomial or Poisson distribution)	Uses the theoretical value of 1.0 for those distributions.
'offset'	Vector	Used as an additional predictor variable, but with a coefficient value fixed at 1.0.
'weights'	Vector of prior weights, such as the inverses of the relative variance of each observation	

Parameter	Value	Description
'constant'	'on' (default)	Includes a constant term in the model. The coefficient of the constant term is the first element of b .
	'off'	Omit the constant term.

`[b,dev] = glmfit(...)` returns `dev`, the deviance of the fit at the solution vector. The deviance is a generalization of the residual sum of squares. It is possible to perform an analysis of deviance to compare several models, each a subset of the other, and to test whether the model with more terms is significantly better than the model with fewer terms.

`[b,dev,stats] = glmfit(...)` returns `dev` and `stats`.

`stats` is a structure with the following fields:

- `beta` — Coefficient estimates **b**
- `dfe` — Degrees of freedom for error
- `sfit` — Estimated dispersion parameter
- `s` — Theoretical or estimated dispersion parameter
- `estdisp` — 0 when the `'estdisp'` name-value pair argument value is `'off'` and 1 when the `'estdisp'` name-value pair argument value is `'on'`.
- `covb` — Estimated covariance matrix for **B**
- `se` — Vector of standard errors of the coefficient estimates **b**
- `coeffcorr` — Correlation matrix for **b**
- `t` — *t* statistics for **b**
- `p` — *p*-values for **b**
- `resid` — Vector of residuals
- `residp` — Vector of Pearson residuals
- `residd` — Vector of deviance residuals
- `resida` — Vector of Anscombe residuals

If you estimate a dispersion parameter for the binomial or Poisson distribution, then `stats.s` is set equal to `stats.sfit`. Also, the elements of `stats.se` differ by the factor `stats.s` from their theoretical values.

Examples

Fit Generalized Linear Model with Probit Link

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...  
     3300 3500 3700 3900 4100 4300]';  
n = [48 42 31 34 31 21 23 23 21 16 17 21]';  
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each y value is the number of successes in corresponding number of trials in n , and x contains the predictor variable values.

Fit a probit regression model for y on x .

```
b = glmfit(x,[y n], 'binomial', 'link', 'probit');
```

Compute the estimated number of successes and plot the percent observed and estimated percent success versus the x values.

```
yfit = glmval(b,x, 'probit', 'size', n);  
plot(x, y./n, 'o', x, yfit./n, '-', 'LineWidth', 2)
```

Use Custom-defined Link Function

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the response and predictor variables.

```
X = meas(51:end,:);
y = strcmp('versicolor',species(51:end));
```

Define three function handles, created using `@`, that define the link, the derivative of the link, and the inverse link for a logit link function, and store them in a cell array.

```
link = @(mu) log(mu ./ (1-mu));
```

```
derlink = @(mu) 1 ./ (mu .* (1-mu));  
invlink = @(resp) 1 ./ (1 + exp(-resp));  
F = {link, derlink, invlink};
```

Fit a logistic regression using `glmfit` with the link function you defined.

```
b = glmfit(X,y,'binomial','link',F)
```

```
b =
```

```
42.6378  
2.4652  
6.6809  
-9.4294  
-18.2861
```

Now, fit a generalized linear model using the `logit` link function and compare the results.

```
b = glmfit(X,y,'binomial','link','logit')
```

```
b =
```

```
42.6378  
2.4652  
6.6809  
-9.4294  
-18.2861
```

glmval

Generalized linear model values

Syntax

```
yhat = glmval(b,X,link)
[yhat,dylo,dyhi] = glmval(b,X,link,stats)
[...] = glmval(...,param1,val1,param2,val2,...)
```

Description

`yhat = glmval(b,X,link)` computes predicted values for the generalized linear model with link function `link` and predictors `X`. Distinct predictor variables should appear in different columns of `X`. `b` is a vector of coefficient estimates as returned by the `glmfit` function. `link` can be any of the strings or the custom-defined link functions used as values for the 'link' name-value pair argument in the `glmfit` function.

Note: By default, `glmval` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`. You can change the default behavior of `glmval` using the 'constant' parameter, below.

`[yhat,dylo,dyhi] = glmval(b,X,link,stats)` also computes 95% confidence bounds for the predicted values. When the `stats` structure output of the `glmfit` function is specified, `dylo` and `dyhi` are also returned. `dylo` and `dyhi` define a lower confidence bound of `yhat-dylo`, and an upper confidence bound of `yhat+dyhi`. Confidence bounds are nonsimultaneous, and apply to the fitted curve, not to a new observation.

`[...] = glmval(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs to control the predicted values. Acceptable parameters are:

Parameter	Value
'confidence' — the confidence level for the confidence bounds	A scalar between 0 and 1

Parameter	Value
'size' — the size parameter (N) for a binomial model	A scalar, or a vector with one value for each row of X
'offset' — used as an additional predictor variable, but with a coefficient value fixed at 1.0	A vector
'constant'	<ul style="list-style-type: none"> 'on' — Includes a constant term in the model. The coefficient of the constant term is the first element of b. 'off' — Omit the constant term
'simultaneous' — Compute simultaneous confidence intervals (true), or compute non-simultaneous confidence intervals (default false)	true or false

Examples

Fit Generalized Linear Model with Probit Link

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
      3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each **y** value is the number of successes in corresponding number of trials in **n**, and **x** contains the predictor variable values.

Fit a generalized linear model for **y** on **x** using a probit link function.

```
b = glmfit(x,[y n], 'binomial', 'link', 'probit');
```

Compute the estimated number of successes and plot the observed and estimated percent success versus the **x** values.

```
yfit = glmval(b,x,'probit','size',n);
plot(x, y./n, 'o', x, yfit./n, '-', 'LineWidth', 2)
```

Use Custom-defined Link Function

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
      3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each y value is the number of successes in corresponding number of trials in n , and x contains the predictor variable values.

Now define three function handles, created using `@`, that define the link, the derivative of the link, and the inverse link for a probit link function, and store them in a cell array.

```
link = @(mu) norminv(mu);
derlink = @(mu) 1 ./ normpdf(norminv(mu));
invlink = @(resp) normcdf(resp);
```

```
F = {link, derlink, invlink};
```

Fit a generalized linear model for y on x using the link function you defined.

```
b = glmfit(x,[y n], 'binomial', 'link',F);
```

Compute the estimated number of successes and plot the observed and estimated percent success versus the x values.

```
yfit = glmval(b,x,F, 'size',n);  
plot(x, y./n, 'o',x,yfit./n, '-','LineWidth',2)
```

glyphplot

Glyph plot

Syntax

```
glyphplot(X)
glyphplot(X, 'glyph', 'face')
glyphplot(X, 'glyph', 'face', 'features', f)
glyphplot(X, ..., 'grid', [rows, cols])
glyphplot(X, ..., 'grid', [rows, cols], 'page', p)
glyphplot(X, ..., 'centers', C)
glyphplot(X, ..., 'centers', C, 'radius', r)
glyphplot(X, ..., 'obslabels', labels)
glyphplot(X, ..., 'standardize', method)
glyphplot(X, ..., prop1, val1, ...)
h = glyphplot(X, ...)
```

Description

`glyphplot(X)` creates a star plot from the multivariate data in the n -by- p matrix X . Rows of X correspond to observations, columns to variables. A star plot represents each observation as a “star” whose i th spoke is proportional in length to the i th coordinate of that observation. `glyphplot` standardizes X by shifting and scaling each column separately onto the interval $[0, 1]$ before making the plot, and centers the glyphs on a rectangular grid that is as close to square as possible. `glyphplot` treats NaNs in X as missing values, and does not plot the corresponding rows of X . `glyphplot(X, 'glyph', 'star')` is a synonym for `glyphplot(X)`.

`glyphplot(X, 'glyph', 'face')` creates a face plot from X . A face plot represents each observation as a “face,” whose i th facial feature is drawn with a characteristic proportional to the i th coordinate of that observation. The features are described in “Face Features” on page 25-2459.

`glyphplot(X, 'glyph', 'face', 'features', f)` creates a face plot where the i th element of the index vector f defines which facial feature will represent the i th column of

`X`. `f` must contain integers from 0 to 17, where 0 indicate that the corresponding column of `X` should not be plotted. See “Face Features” on page 25-2459 for more information.

`glyphplot(X, ..., 'grid', [rows, cols])` organizes the glyphs into a rows-by-cols grid.

`glyphplot(X, ..., 'grid', [rows, cols], 'page', p)` organizes the glyph into one or more pages of a rows-by-cols grid, and displays the page `p`. If `p` is a vector, `glyphplot` displays multiple pages in succession. If `p` is 'all', `glyphplot` displays all pages. If `p` is 'scroll', `glyphplot` displays a single plot with a scrollbar.

`glyphplot(X, ..., 'centers', C)` creates a plot with each glyph centered at the locations in the n -by-2 matrix `C`.

`glyphplot(X, ..., 'centers', C, 'radius', r)` creates a plot with glyphs positioned using `C`, and scale the glyphs so the largest has radius `r`.

`glyphplot(X, ..., 'obslabels', labels)` labels each glyph with the text in the character array or cell array of strings `labels`. By default, the glyphs are labelled 1:N. Use '' for blank labels.

`glyphplot(X, ..., 'standardize', method)` standardizes `X` before making the plot. Choices for *method* are

- 'column' — Maps each column of `X` separately onto the interval [0,1]. This is the default.
- 'matrix' — Maps the entire matrix `X` onto the interval [0, 1].
- 'PCA' — Transforms `X` to its principal component scores, in order of decreasing eigenvalue, and maps each one onto the interval [0, 1].
- 'off' — No standardization. Negative values in `X` may make a star plot uninterpretable.

`glyphplot(X, ..., prop1, val1, ...)` sets properties to the specified property values for all line graphics objects created by `glyphplot`.

`h = glyphplot(X, ...)` returns a matrix of handles to the graphics objects created by `glyphplot`. For a star plot, `h(:, 1)` and `h(:, 2)` contain handles to the line objects for each star's perimeter and spokes, respectively. For a face plot, `h(:, 1)` and `h(:, 2)` contain object handles to the lines making up each face and to the pupils, respectively. `h(:, 3)` contains handles to the text objects for the labels, if present.

Face Features

The following table describes the correspondence between the columns of the vector f , the value of the 'Features' input parameter, and the facial features of the glyph plot. If X has fewer than 17 columns, unused features are displayed at their default value.

Column	Facial Feature
1	Size of face
2	Forehead/jaw relative arc length
3	Shape of forehead
4	Shape of jaw
5	Width between eyes
6	Vertical position of eyes
7	Height of eyes
8	Width of eyes (this also affects eyebrow width)
9	Angle of eyes (this also affects eyebrow angle)
10	Vertical position of eyebrows
11	Width of eyebrows (relative to eyes)
12	Angle of eyebrows (relative to eyes)
13	Direction of pupils
14	Length of nose
15	Vertical position of mouth
16	Shape of mouth
17	Mouth arc length

Examples

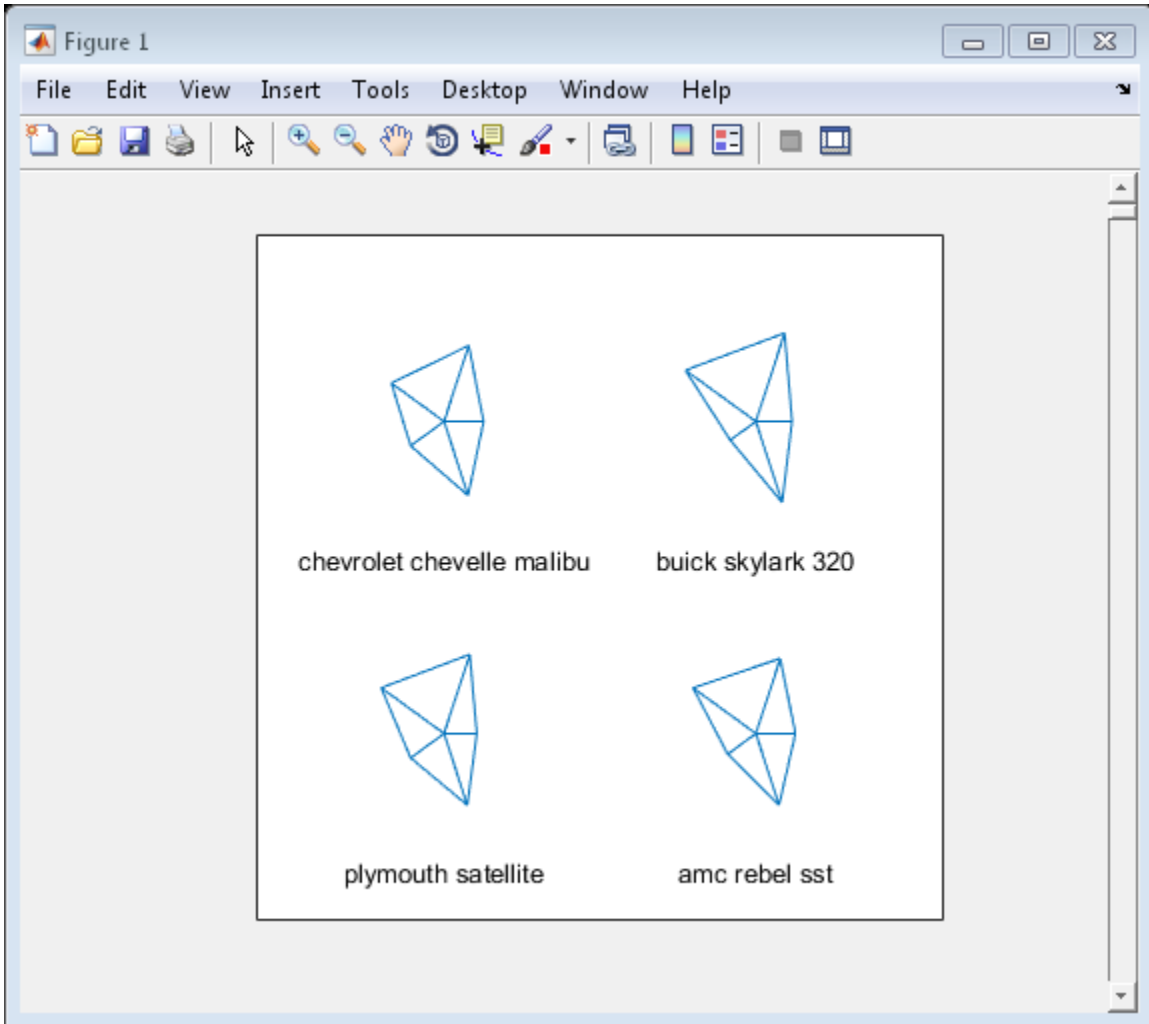

Star and Face Plots of Multivariate Data

Load the sample data.

```
load carsmall
X = [Acceleration Displacement Horsepower MPG Weight];
```

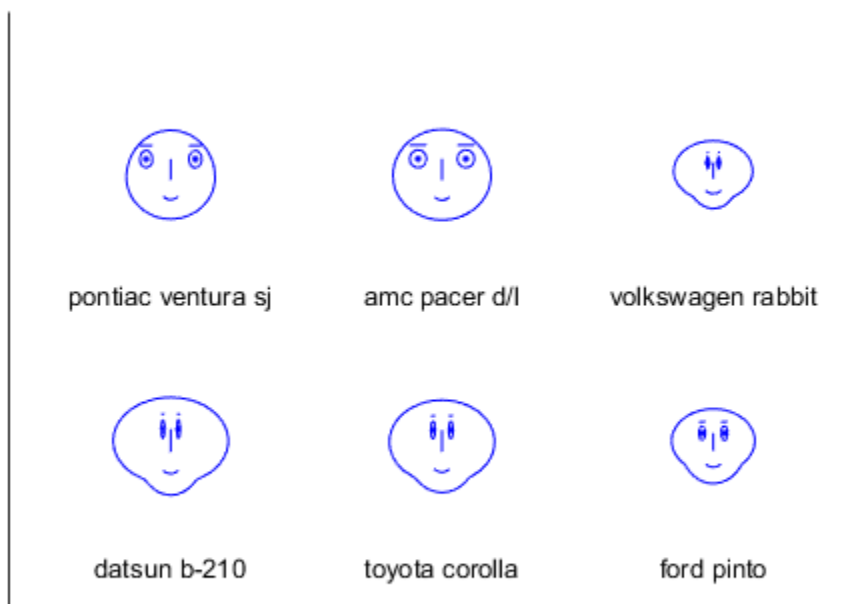

Create a star plot of the data in X . Standardize the data before plotting.

```
glyphplot(X, 'standardize', 'column', 'obslabels', Model, 'grid', [2 2], ...  
          'page', 'scroll');
```

Create a faceplot of the data in X .

```
glyphplot(X, 'glyph', 'face', 'obslabels', Model, 'grid', [2 3], 'page', 9);
```

gmdistribution class

Gaussian mixture models

Description

An object of the `gmdistribution` class defines a Gaussian mixture distribution, which is a multivariate distribution that consists of a mixture of one or more multivariate Gaussian distribution components. The number of components for a given `gmdistribution` object is fixed. Each multivariate Gaussian component is defined by its mean and covariance, and the mixture is defined by a vector of mixing proportions.

Construction

To create a Gaussian mixture distribution by specifying the distribution parameters, use the `gmdistribution` constructor. To fit a Gaussian mixture distribution model to data, use `fitgmdist`.

<code>fit</code>	Gaussian mixture parameter estimates
<code>.gmdistribution</code>	Construct Gaussian mixture distribution

Properties

All objects of the class have the properties listed in the following table.

<code>CovarianceType</code>	Type of covariance matrices
<code>DistributionName</code>	Type of distribution
<code>mu</code>	Input matrix of means μ
<code>NumComponents</code>	Number k of mixture components
<code>NumVariables</code>	Dimension d of multivariate Gaussian distributions
<code>ComponentProportion</code>	Input vector of mixing proportions
<code>SharedCovariance</code>	<code>true</code> if all covariance matrices are restricted to be the same

Sigma	Input array of covariances
-------	----------------------------

Objects constructed with `fitgmdist` have the additional properties listed in the following table.

AIC	Akaike Information Criterion
BIC	Bayes Information Criterion
Converged	Determine if algorithm converged
NumIterations	Number of iterations
NegativeLogLikelihood	Negative of log-likelihood
RegularizationValue	Value of 'Regularize' parameter

Methods

cdf	Cumulative distribution function for Gaussian mixture distribution
cluster	Construct clusters from Gaussian mixture distribution
disp	Display Gaussian mixture distribution object
display	Display Gaussian mixture distribution object
fit	Gaussian mixture parameter estimates
mahal	Mahalanobis distance to component means
pdf	Probability density function for Gaussian mixture distribution
posterior	Posterior probabilities of components
random	Random numbers from Gaussian mixture distribution
subsasgn	Subscripted reference for Gaussian mixture distribution object
subsref	Subscripted reference for Gaussian mixture distribution object

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Fit a Gaussian Mixture Model

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function. Fit the resulting data.

Generate the data using 1000 points from each distribution.

```
rng(1); % For reproducibility
MU1 = [1 2];
SIGMA1 = [2 0; 0 .5];
MU2 = [-3 -5];
SIGMA2 = [1 0; 0 1];
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];

scatter(X(:,1),X(:,2),10,'.')
hold on
```

Fit a two-component Gaussian mixture model.

```
options = statset('Display','final');  
obj = fitgmdist(X,2,'Options',options);
```

```
10 iterations, log-likelihood = -7105.71
```

Plot the fit.

```
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

See Also

`fitgmdist`

gmdistribution

Class: gmdistribution

Construct Gaussian mixture distribution

Syntax

```
obj = gmdistribution(mu,sigma,p)
```

Description

`obj = gmdistribution(mu,sigma,p)` constructs an object `obj` of the `gmdistribution` class defining a Gaussian mixture distribution.

`mu` is a k -by- d matrix specifying the d -dimensional mean of each of the k components.

`sigma` specifies the covariance of each component. The size of `sigma` is:

- d -by- d -by- k if there are no restrictions on the form of the covariance. In this case, `sigma(:, :, I)` is the covariance of component `I`.
- 1-by- d -by- k if the covariance matrices are restricted to be diagonal, but not restricted to be same across components. In this case, `sigma(:, :, I)` contains the diagonal elements of the covariance of component `I`.
- d -by- d matrix if the covariance matrices are restricted to be the same across components, but not restricted to be diagonal. In this case, `sigma` is the pooled estimate of covariance.
- 1-by- d if the covariance matrices are restricted to be diagonal and the same across components. In this case, `sigma` contains the diagonal elements of the pooled estimate of covariance.

`p` is an optional 1-by- k vector specifying the mixing proportions of each component. If `p` does not sum to 1, `gmdistribution` normalizes it. The default is equal proportions.

Examples

Construct a Gaussian Mixture Distribution

Create a `gmdistribution` distribution defining a two-component mixture of bivariate Gaussian distributions.

```
mu = [1 2;-3 -5];  
sigma = cat(3,[2 0;0 .5],[1 0;0 1]);  
p = ones(1,2)/2;  
obj = gmdistribution(mu,sigma,p);  
  
ezsurf(@(x,y)pdf(obj,[x y]),[-10 10],[-10 10])
```

Introduced in R2007b

gname

Add case names to plot

Syntax

```
gname(cases)
gname
h = gname(cases, line_handle)
```

Description

`gname(cases)` displays a figure window and waits for you to press a mouse button or a keyboard key. The input argument `cases` is a character array or a cell array of strings, in which each row of the character array or each element of the cell array contains the case name of a point. Moving the mouse over the graph displays a pair of cross-hairs. If you position the cross-hairs near a point with the mouse and click once, the graph displays the label corresponding to that point. Alternatively, you can click and drag the mouse to create a rectangle around several points. When you release the mouse button, the graph displays the labels for all points in the rectangle. Right-click a point to remove its label. When you are done labelling points, press the **Enter** or **Escape** key to stop labeling.

`gname` with no arguments labels each case with its case number.

`cases` typically contains unique case names for each point, and is a cell array of strings or a character matrix with each row representing a name. `cases` can also be any grouping variable, which `gname` converts to labels.

`h = gname(cases, line_handle)` returns a vector of handles to the text objects on the plot. Use the scalar `line_handle` to identify the correct line if there is more than one line object on the plot.

You can use `gname` to label plots created by the `plot`, `scatter`, `gscatter`, `plotmatrix`, and `gplotmatrix` functions.

Examples

This example uses the city ratings data sets to find out which cities are the best and worst for education and the arts.

```
load cities
education = ratings(:,6);
arts = ratings(:,7);
plot(education,arts,'+')
gname(names)
```

Click the point at the top of the graph to display its label, "New York."

gpcdf

Generalized Pareto cumulative distribution function

Syntax

```
p = gpcdf(x,k,sigma,theta)
p = gpcdf(x,k,sigma,theta,'upper')
```

Description

`p = gpcdf(x,k,sigma,theta)` returns the cdf of the generalized Pareto (GP) distribution with the tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

`p = gpcdf(x,k,sigma,theta,'upper')` returns the complement of the cdf of the generalized Pareto (GP) distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for `k`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

$$k < 0, 0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}.$$

`cdf` | `gppdf` | `gpinv` | `gpstat` | `gpfit` | `gplike` | `gprnd`

Introduced before R2006a

gpf_{it}

Generalized Pareto parameter estimates

Syntax

```
parmhat = gpfit(x)  
[parmhat,parmci] = gpfit(x)  
[parmhat,parmci] = gpfit(x,alpha)  
[...] = gpfit(x,alpha,options)
```

Description

`parmhat = gpfit(x)` returns maximum likelihood estimates of the parameters for the two-parameter generalized Pareto (GP) distribution given the data in `x`. `parmhat(1)` is the tail index (shape) parameter, `k` and `parmhat(2)` is the scale parameter, `sigma`. `gpfit` does not fit a threshold (location) parameter.

`[parmhat,parmci] = gpfit(x)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gpfit(x,alpha)` returns $100(1 - \alpha)\%$ confidence intervals for the parameter estimates.

`[...] = gpfit(x,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gpfit')` for parameter names and default values.

Other functions for the generalized Pareto, such as `gpcdf` allow a threshold parameter, `theta`. However, `gpfit` does not estimate `theta`. It is assumed to be known, and subtracted from `x` before calling `gpfit`.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to $1/k$. The mean of the GP is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. When $k \geq 0$, the GP has positive density for

$k > \theta$, or, when $k < 0$, for

$$0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}$$

Introduced before R2006a

gpinv

Generalized Pareto inverse cumulative distribution function

Syntax

```
x = gpinv(p,k,sigma,theta)
```

Description

`x = gpinv(p,k,sigma,theta)` returns the inverse cdf for a generalized Pareto (GP) distribution with tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter `theta`, evaluated at the values in `p`. The size of `x` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

$$k < 0, 0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}.$$

Introduced before R2006a

gplike

Generalized Pareto negative log-likelihood

Syntax

```
nlogL = gplike(params,data)
[nlogL,acov] = gplike(params,data)
```

Description

`nlogL = gplike(params,data)` returns the negative of the log-likelihood `nlogL` for the two-parameter generalized Pareto (GP) distribution, evaluated at parameters `params`. `params(1)` is the tail index (shape) parameter, `k`, and `params(2)` is the scale parameter. `gplike` does not allow a threshold (location) parameter.

`[nlogL,acov] = gplike(params,data)` returns the inverse of Fisher's information matrix, `acov`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `acov` are their asymptotic variances. `acov` is based on the observed Fisher's information, not the expected information.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

$$k < 0, 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}.$$

pdf | gpcdf | gpinv | gpstat | gpfit | gplike | gprnd

Introduced before R2006a

gplotmatrix

Matrix of scatter plots by group

Syntax

```
gplotmatrix(x,y,group)
gplotmatrix(x,y,group,clr,sym,siz)
gplotmatrix(x,y,group,clr,sym,siz,doleg)
gplotmatrix(x,y,group,clr,sym,siz,doleg,disopt)
gplotmatrix(x,y,group,clr,sym,siz,doleg,disopt,xnam,ynam)
[h,ax,bigax] = gplotmatrix(...)
```

Description

`gplotmatrix(x,y,group)` creates a matrix of scatter plots. Each individual set of axes in the resulting figure contains a scatter plot of a column of `x` against a column of `y`. All plots are grouped by the grouping variable `group`.

`x` and `y` are matrices with the same number of rows. If `x` has p columns and `y` has q columns, the figure contains a p -by- q matrix of scatter plots. If you omit `y` or specify it as the empty matrix, `[]`, `gplotmatrix` creates a square matrix of scatter plots of columns of `x` against each other.

`group` is a grouping variable that can be a categorical variable, vector, string array, or cell array of strings. `group` must have the same number of rows as `x` and `y`. Points with the same value of `group` are placed in the same group, and appear on the graph with the same marker and color. Alternatively, `group` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`); in that case, observations are in the same group if they have common values of all grouping variables.

`gplotmatrix(x,y,group,clr,sym,siz)` specifies the color, marker type, and size for each group. `clr` is a string array of colors recognized by the `plot` function. `sym` is a string array of symbols recognized by the `plot` command, with the default value `'.'`. `siz` is a vector of sizes, with the default determined by the `DefaultLineMarkerSize` property. If you do not specify enough values for all groups, `gplotmatrix` cycles through the specified values as needed.

`gplotmatrix(x,y,group,clr,sym,siz,doleg)` controls whether a legend is displayed on the graph (*doleg* is 'on', the default) or not (*doleg* is 'off').

`gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt)` controls what appears along the diagonal of a plot matrix of *y* versus *x*. Allowable values are 'none', to leave the diagonals blank, 'hist', to plot histograms, 'stairs' to display the outlines of grouped histograms (default if there is more than one group), 'grpbars' to plot grouped histogram bars. or 'variable', to write the variable names. `gplotmatrix` displays histograms along the diagonal only when there is only one variable (i.e., `gplotmatrix(x,[],[],[],[],[],[],[], 'hist')`).

`gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt,xnam,yname)` specifies the names of the columns in the *x* and *y* arrays. These names are used to label the *x*- and *y*-axes. *xnam* and *yname* must be character arrays or cell arrays of strings, with one name for each column of *x* and *y*, respectively.

`[h,ax,bigax] = gplotmatrix(...)` returns three arrays of handles. *h* is an array of handles to the lines on the graphs. The array's third dimension corresponds to groups in the input argument *group*. *ax* is a matrix of handles to the axes of the individual plots. If *dispopt* is 'hist', 'stairs', or 'grpbars', *ax* contains one extra row of handles to invisible axes in which the histograms are plotted. *bigax* is a handle to big (invisible) axes framing the entire plot matrix. *bigax* is fixed to point to the current axes, so a subsequent `title`, `xlabel`, or `ylabel` command will produce labels that are centered with respect to the entire plot matrix.

Examples

Create Grouped Data Scatter Plot Matrix

Load the sample data.

```
load discrim;
```

The `ratings` array contains rating values for 329 U.S. cities in the nine different categories listed in the `categories` array. The `group` array contains a city size code that is equal to 2 for the 26 largest cities, and 1 otherwise.

Create a matrix of scatter plots to compare the first two categories, `climate` and `housing`, with categories 4 (`crime`) and 7 (`arts`). Specify `group` as the grouping variable to visually distinguish the data for large and small cities.

```
figure;
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group);
```

The figure displays a matrix of scatter plots for the specified comparisons, with each city size group represented by a different color.

For better clarity, you can adjust the appearance of the graphs by specifying colors and plotting symbols, and labeling the axes with the rating categories.

```
figure;
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group,...
    'br','o',[],'on',' ',categories(1:2,:),...
    categories([4 7],:));
```

gprnd

Generalized Pareto random numbers

Syntax

```
r = gprnd(k,sigma,theta)
r = gprnd(k,sigma,theta,m,n,...)
R = gprnd(K,sigma,theta,[m,n,...])
```

Description

`r = gprnd(k,sigma,theta)` returns an array of random numbers chosen from the generalized Pareto (GP) distribution with tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`. The size of `r` is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of `r` is the size of the other parameters.

`r = gprnd(k,sigma,theta,m,n,...)` or `R = gprnd(K,sigma,theta,[m,n,...])` generates an `m`-by-`n`-by-... array. The `k`, `sigma`, `theta` parameters can each be scalars or arrays of the same size as `r`.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

$$0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}$$

gpstat

Generalized Pareto mean and variance

Syntax

```
[m,v] = gpstat(k,sigma,theta)
```

Description

`[m,v] = gpstat(k,sigma,theta)` returns the mean of and variance for the generalized Pareto (GP) distribution with the tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`.

The default value for `theta` is 0.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for `x > theta`, or when

$$k < 0, 0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}.$$

growTrees

Class: TreeBagger

Train additional trees and add to ensemble

Syntax

`B = growTrees(B,ntrees)`

`B = growTrees(B,ntrees, 'param1',val1, 'param2',val2, ...)`

Description

`B = growTrees(B,ntrees)` grows `ntrees` new trees and appends them to those trees already stored in the ensemble `B`.

`B = growTrees(B,ntrees, 'param1',val1, 'param2',val2, ...)` specifies optional parameter name/value pairs:

'NumPrint'

Specifies that a diagnostic message showing training progress should display after every `value` training cycles (grown trees). Default is no diagnostic messages.

'Options'

A `struct` that specifies options that govern computation when growing the ensemble of decision trees. One option requests that the computation of decision trees on multiple bootstrap replicates uses multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to use in selecting bootstrap replicates. You can create this argument with a call to `statset`. You can retrieve values of the individual fields with a call to `statget`. Applicable `statset` parameters are:

- 'UseParallel' — If `true` and if a `parpool` of the Parallel Computing Toolbox is open, compute decision trees drawn on separate bootstrap replicates in parallel. If the Parallel Computing Toolbox is not installed, or a `parpool`

is not open, computation occurs in serial mode. Default is `false`, or serial computation.

- **UseSubstreams** — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set **Streams** to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
- **Streams** — A `RandStream` object or cell array of such objects. If you do not specify **Streams**, `growTrees` uses the default stream or streams. If you choose to specify **Streams**, use a single object except in the case
 - You have an open Parallel pool
 - `UseParallel` is `true`
 - `UseSubstreams` is `false`

In that case, use a cell array the same size as the Parallel pool.

grp2idx

Create index vector from grouping variable

Syntax

```
[G,GN]=grp2idx(S)
[G,GN,GL] = grp2idx(S)
```

Description

`[G,GN]=grp2idx(S)` creates an index vector **G** from the grouping variable **S**. **S** can be a categorical, numeric, logical, datetime, or duration vector; a cell vector of strings; or a character matrix with each row representing a group label. The result **G** is a vector taking integer values from 1 up to the number **K** of distinct groups. **GN** is a cell array of strings representing group labels. **GN(G)** reproduces **S** (aside from any differences in type).

The order of **GN** depends on the grouping variable:

- For numeric and logical grouping variables, the order is the sorted order of **S**.
- For categorical grouping variables, the order is the order of `getlabels(S)`.
- For string grouping variables, the order is the order of first appearance in **S**.

`[G,GN,GL] = grp2idx(S)` returns a column vector **GL** representing the group levels. The set of groups and their order in **GL** and **GN** are the same, except that **GL** has the same type as **S**. If **S** is a character matrix, `GL(G, :)` reproduces **S**, otherwise `GL(G)` reproduces **S**.

`grp2idx` treats NaNs (numeric, duration, or logical), empty strings (char or cell array of strings), or `<undefined>` values (categorical) or NaTs (datetime) in **S** as missing values and returns NaNs in the corresponding rows of **G**. **GN** and **GL** don't include entries for missing values.

Examples

Load the data in `hospital.mat` and create a categorical grouping variable:

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)', '%d'), {'s'});
AgeGroup = ordinal(hospital.Age, labels, [], edges);

ages = hospital.Age(1:5)

ages =
    38
    43
    38
    40
    49

group = AgeGroup(1:5)

group =
    30s
    40s
    30s
    40s
    40s

indices = grp2idx(group)

indices =
     4
     5
     4
     5
     5
```

Introduced before R2006a

grpstats

Summary statistics organized by group

Syntax

```
statarray = grpstats(tbl,groupvar)
statarray = grpstats(tbl,groupvar,whichstats)
statarray = grpstats(tbl,groupvar,whichstats,Name,Value)

means = grpstats(X,group)
[stats1,...,statsN] = grpstats(X,group,whichstats)
[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha)

grpstats(X,group,alpha)
```

Description

`statarray = grpstats(tbl,groupvar)` returns a table or dataset array with the means for the data groups specified in `tbl` determined by the values of the grouping variable or variables specified in `groupvar`.

- If there is a single grouping variable, then there is a row in `statarray` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character array), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `groupvar` is a cell array of strings containing multiple grouping variable names, or a vector of column numbers, then there is a row in `statarray` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If any variables in `tbl` (other than those specified in `groupvar`) are not numeric or logical arrays, then you must specify the names or column numbers of the numeric and logical variables for which you want to calculate means using the name-value pair argument, `DataVars`.

`statarray = grpstats(tbl,groupvar,whichstats)` returns the group values for the summary statistics types specified in `whichstats`.

`statarray = grpstats(tbl,groupvar,whichstats,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`means = grpstats(X,group)` returns a column vector or matrix with the means of the groups of the data in the matrix or vector `X` determined by the values of the grouping variable or variables, `group`. The rows of `means` correspond to the grouping variable values.

- If there is a single grouping variable, then there is a row in `means` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character array), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `group` is a cell array of grouping variables, then there is a row in `means` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If `X` is a matrix, then `means` is a matrix with the same number of columns as `X`. Each column of `means` has the group means for the corresponding column of `X`.

`[stats1,...,statsN] = grpstats(X,group,whichstats)` returns column vectors or arrays with group values for the summary statistic types specified in `whichstats`.

`[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha)` specifies the significance level for confidence and prediction intervals.

`grpstats(X,group,alpha)` plots the means of the groups of data in the vector or matrix `X` determined by the values of the grouping variable, `group`. The grouping variable values are on the horizontal plot axis. Each group mean has $100 \times (1 - \alpha)\%$ confidence intervals.

- If `X` is a matrix, then `grpstats` plots the means and confidence intervals for each column of `X`.
- If `group` is a cell array of grouping variables, then `grpstats` plots the means and confidence intervals for the groups of data in `X` determined by the unique combinations of values of the grouping variables. For example, if there are two grouping variables, each with two values, there are four possible combinations of grouping variable values. The plot includes only the combinations of values that exist in the input grouping variables (not all possible combinations).

Examples

Dataset Array Summary Statistics Organized by Group

Load the sample data.

```
load('hospital')
```

The dataset array `hospital` has 100 observations and 7 variables.

Create a dataset array with only the variables `Sex`, `Age`, `Weight`, and `Smoker`.

```
ds = hospital(:, {'Sex', 'Age', 'Weight', 'Smoker'});
```

`Sex` is a nominal array, with levels `Male` and `Female`. The variables `Age` and `Weight` have numeric values, and `Smoker` has logical values.

Compute the mean for the numeric and logical arrays, `Age`, `Weight`, and `Smoker`, grouped by the levels in `Sex`.

```
statarray = grpstats(ds, 'Sex')
```

```
statarray =
```

	Sex	GroupCount	mean_Age	mean_Weight	mean_Smoker
Female	Female	53	37.717	130.47	0.24528
Male	Male	47	38.915	180.53	0.44681

`statarray` is a dataset array with two rows, corresponding to the levels in `Sex`.

`GroupCount` is the number of observations in each group. The means of `Age`, `Weight`, and `Smoker`, grouped by `Sex`, are given in `mean_Age`, `mean_Weight`, and `mean_Smoker`.

Compute the mean for `Age` and `Weight`, grouped by the values in `Smoker`.

```
statarray = grpstats(ds, 'Smoker', 'mean', 'DataVars', {'Age', 'Weight'})
```

```
statarray =
```

	Smoker	GroupCount	mean_Age	mean_Weight
0	false	66	37.97	149.91
1	true	34	38.882	161.94

In this case, not all variables in `ds` (excluding the grouping variable, `Smoker`) are numeric or logical arrays; the variable `Sex` is a nominal array. When not all variables in

the input dataset array are numeric or logical arrays, you must specify the variables for which you want to calculate summary statistics using `DataVars`.

Compute the minimum and maximum weight, grouped by the combinations of values in `Sex` and `Smoker`.

```
statarray = grpstats(ds, {'Sex', 'Smoker'}, {'min', 'max'}, ...
                    'DataVars', 'Weight')
```

```
statarray =
```

	Sex	Smoker	GroupCount	min_Weight	max_Weight
Female_0	Female	false	40	111	147
Female_1	Female	true	13	115	146
Male_0	Male	false	26	158	194
Male_1	Male	true	21	164	202

There are two unique values in `Smoker` and two levels in `Sex`, for a total of four possible combinations of values: Female Nonsmoker (`Female_0`), Female Smoker (`Female_1`), Male Nonsmoker (`Male_0`), and Male Smoker (`Male_1`).

Specify the names for the columns in the output.

```
statarray = grpstats(ds, {'Sex', 'Smoker'}, {'min', 'max'}, ...
                    'DataVars', 'Weight', 'VarNames', {'Gender', 'Smoker'}, ...
                    'GroupCount', 'LowestWeight', 'HighestWeight')
```

```
statarray =
```

	Gender	Smoker	GroupCount	LowestWeight	HighestWeight
Female_0	Female	false	40	111	147
Female_1	Female	true	13	115	146
Male_0	Male	false	26	158	194
Male_1	Male	true	21	164	202

Summary Statistics for a Dataset Array Without Grouping

Load the sample data.

```
load('hospital')
```

The dataset array `hospital` has 100 observations and 7 variables.

Create a dataset array with only the variables `Age`, `Weight`, and `Smoker`.

```
ds = hospital(:, {'Age', 'Weight', 'Smoker'});
```

The variables `Age` and `Weight` have numeric values, and `Smoker` has logical values.

Compute the mean, minimum, and maximum for the numeric and logical arrays, `Age`, `Weight`, and `Smoker`, with no grouping.

```
statarray = grpstats(ds, [], {'mean', 'min', 'max'})
```

```
statarray =
```

	GroupCount	mean_Age	min_Age	max_Age	mean_Weight
All	100	38.28	25	50	154

	min_Weight	max_Weight	mean_Smoker	min_Smoker	max_Smoker
All	111	202	0.34	false	true

The observation name `All` indicates that all observations in `ds` were used to compute the summary statistics.

Group Means for a Matrix Using One or More Grouping Variables

Load the sample data.

```
load('carsmall')
```

All variables are measured for 100 cars. `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA). `Cylinders` has three unique values, 4, 6, and 8, indicating the number of cylinders in each car.

Calculate the mean acceleration, grouped by country of origin.

```
means = grpstats(Acceleration, Origin)
```

```
means =
```

```
14.4377
18.0500
15.8867
16.3778
16.6000
15.5000
```

`means` is a 6-by-1 vector of mean accelerations, where each value corresponds to a country of origin.

Calculate the mean acceleration, grouped by both country of origin and number of cylinders.

```
means = grpstats(Acceleration,{Origin,Cylinders})
```

```
means =  
    17.0818  
    16.5267  
    11.6406  
    18.0500  
    15.9143  
    15.5000  
    16.3375  
    16.7000  
    16.6000  
    15.5000
```

There are 18 possible combinations of grouping variable values because `Origin` has 6 unique values and `Cylinders` has 3 unique values. Only 10 of the possible combinations appear in the data, so `means` is a 10-by-1 vector of group means corresponding to the observed combinations of values.

Return the group names along with the mean acceleration for each group.

```
[means,grps] = grpstats(Acceleration,{Origin,Cylinders},...  
                        {'mean','gname'})
```

```
means =  
    17.0818  
    16.5267  
    11.6406  
    18.0500  
    15.9143  
    15.5000  
    16.3375  
    16.7000  
    16.6000  
    15.5000
```

```
grps =  
    'USA'    '4'
```

```
'USA'      '6'
'USA'      '8'
'France'   '4'
'Japan'    '4'
'Japan'    '6'
'Germany'  '4'
'Germany'  '6'
'Sweden'   '4'
'Italy'    '4'
```

The output `grpstats` shows the 10 observed combinations of grouping variable values. For example, the mean acceleration of 4-cylinder cars made in France is 18.05.

Multiple Summary Statistics for a Matrix Organized by Group

Load the sample data.

```
load('carsmall')
```

The variable `Acceleration` was measured for 100 cars. The variable `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA).

Return the minimum, median, and maximum acceleration, grouped by country of origin.

```
[grpMin,grpMed,grpMax,grp] = grpstats(Acceleration,Origin,...
                                     {'min','median','max','gname'})
```

```
grpMin =
```

```
8.0000
15.3000
13.9000
12.2000
15.7000
15.5000
```

```
grpMed =
```

```
14.7000
17.5000
15.7000
15.3000
16.6000
```

```
15.5000

grpMax =

22.2000
21.9000
18.2000
24.6000
17.5000
15.5000

grp =

'USA'
'France'
'Japan'
'Germany'
'Sweden'
'Italy'
```

The sample car with the lowest acceleration is made in the USA, and the sample car with the highest acceleration is made in Germany.

Plot Prediction Intervals for a New Observation in Each Group

Load the sample data.

```
load('carsmall')
```

The variable `Weight` was measured for 100 cars. The variable `Model_Year` has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Calculate the mean weight and 90% prediction intervals for each model year.

```
[means,pred,grp] = grpstats(Weight,Model_Year,...
    {'mean','predci','gname'},'Alpha',0.1);
```

Plot error bars showing the mean weight and 90% prediction intervals, grouped by model year. Label the horizontal axis with the group names.

```
ngrps = length(grp); % Number of groups
```

```
figure()
errorbar(1:ngrps)',means,pred(:,2)-means)
set(gca,'xtick',1:ngrps,'xticklabel',grp)
title('90% Prediction Intervals for Weight by Year')
```

Plot Group Means and Confidence Intervals

Load the sample data.

```
load('carsmall')
```

The variables **Acceleration** and **Weight** are the acceleration and weight values measured for 100 cars. The variable **Cylinders** is the number of cylinders in each car. The variable **Model_Year** has three unique values, **70**, **76**, and **82**, which correspond to model years 1970, 1976, and 1982.

Plot mean acceleration, grouped by **Cylinders**, with 95% confidence intervals.

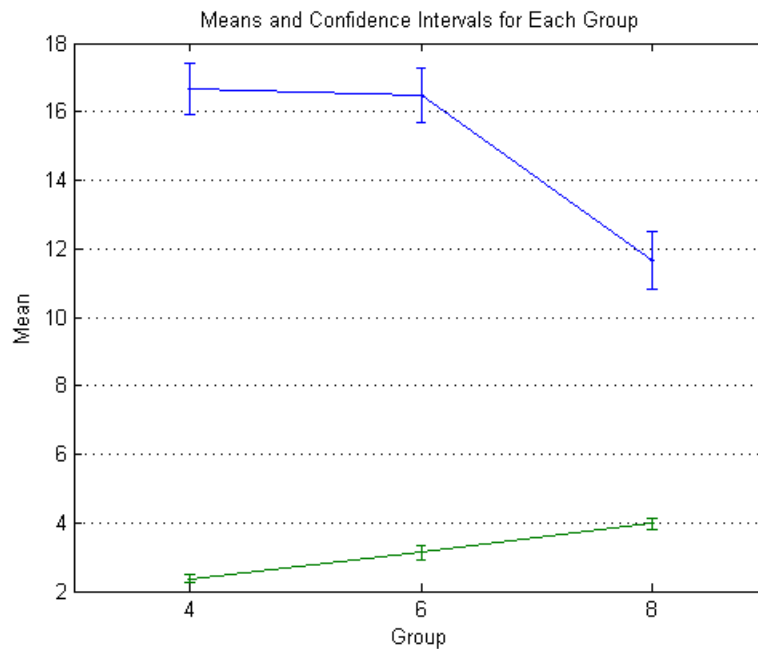

```
grpstats(Acceleration,Cylinders,0.05)
```

The mean acceleration for cars with 8 cylinders is significantly lower than for cars with 4 or 6 cylinders.

Plot mean acceleration and weight, grouped by `Cylinders`, and 95% confidence intervals. Scale the `Weight` values by 1000 so the means of `Weight` and `Acceleration` are the same order of magnitude.

```
grpstats([Acceleration,Weight/1000],Cylinders,0.05)
```

The average weight of cars increases with the number of cylinders, and the average acceleration decreases with the number of cylinders.

Plot mean acceleration, grouped by both `Cylinders` and `Model_Year`. Specify 95% confidence intervals.

```
grpstats(Acceleration, {Cylinders, Model_Year}, 0.05)
```

There are nine possible combinations of grouping variable values because there are three unique values in `Cylinders` and three unique values in `Model_Year`. The plot does not show 8-cylinder cars with model year 1982 because the data did not include this combination.

The mean acceleration of 8-cylinder cars made in 1976 is significantly larger than the mean acceleration of 8-cylinder cars made in 1970.

- “Summary Statistics Grouped by Category” on page 2-42
- “Test Differences Between Category Means” on page 2-33
- “Plot Data Grouped by Category” on page 2-28
- “Calculations on Dataset Arrays” on page 2-113

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. **tbl** must include at least one variable that is a grouping variable.

Summary statistics can only be calculated for variables that have a numeric or logical data type. If any variables in **tbl** (other than the grouping variables) are not numeric or logical arrays, then use the name-value pair argument **DataVars** to specify the names or column numbers of the numeric and logical variables for which to calculate summary statistics.

groupvar — Identifiers for the grouping variables

cell array of strings | vector of positive integers | logical vector | []

Identifiers for the grouping variables in the input data, **tbl**, specified as one of the following:

String or cell array of strings	Names of the grouping variables
Positive integer or vector of positive integers	Variable numbers of the grouping variables
Vector of logical values with number of elements equal to the number of variables in tbl	Logical indicator with value true for grouping variables and false otherwise
[]	No groups (returns summary statistics for all data)

Any variable that is identified by **groupvar** as a grouping variable must have a valid grouping variable data type: categorical array, logical or numeric vector, datetime or duration vector, or cell array of strings.

For example, consider an input table, **tbl**, with six variables. The fourth variable is named **Gender**. To be a valid grouping variable, the data type of **Gender** might be a cell array of strings or a nominal array, with the unique values **Male** and **Female**. To specify the variable **Gender** as the grouping variable, you can use any of these syntaxes:

- `statarray = grpstats(tbl,'Gender')`
- `statarray = grpstats(tbl,4)`
- `statarray = grpstats(tbl,logical([0 0 0 1 0 0]))`

Data Types: double | logical | cell | char

whichstats — Types of summary statistics

string | function handle

Types of summary statistics to compute, specified as a string or function handle, or a cell array of strings and function handles. Use a cell array to specify multiple types of summary statistics.

Possible string values are:

'mean'	Mean
'sem'	Standard error of the mean
'numel'	Count, or number, of non-NaN elements
'gname'	Group name
'std'	Standard deviation
'var'	Variance
'min'	Minimum
'max'	Maximum
'range'	Range
'meanci'	95% confidence interval for the mean
'predci'	95% prediction interval for a new observation

Example: `[stat1,stat2] = grpstats(X,group,{'mean','sem'})`

You can specify different significance levels for the 'meanci' and 'predci' options using the name-value pair argument, `Alpha`.

To specify other types of summary statistics, you can use function handles. You can use the handle to any function that accepts a column or matrix of data, and returns the same size output each time `grpstats` calls it (even if the output for some groups is empty).

If the function accepts a column of data, then the function can return either a scalar value, or an *nvals*-by-1 column vector for descriptive statistics of length *nvals* (for example, confidence intervals have length two). If the function accepts a matrix, it must either return a 1-by-*ncols* row vector, or an *nvals*-by-*ncols* matrix, where *ncols* is the number of columns in the input data matrix.

Example: `[stat1,stat2,stat3] = grpstats(X,group,{'mean','std',@skewness})`

For functions that do not compute column-wise statistics, specify the computation direction while specifying the function.

```
Example: stat1 = grpstats(X,group,@(x)sum(x,1))
```

Data Types: char | function_handle

alpha — Significance level

scalar value in the range (0,1)

Significance level, specified as a scalar value in the range (0,1).

- When you specify 'meanci' or 'predci' in `whichstats`, you can use `alpha` to specify the significance level for the confidence or prediction intervals. If you specify `alpha`, then `grpstats` returns $100 \times (1 - \text{alpha})\%$ confidence or prediction intervals. If you do not specify `alpha`, then `grpstats` returns 95% intervals (`alpha = 0.05`).
- Use `alpha` with the `grpstats(X,group,alpha)` syntax to plot group means and corresponding $100 \times (1 - \text{alpha})\%$ confidence intervals.

Data Types: double

X — Input data

vector | matrix

Input data, specified as a vector or a matrix. If `X` is a matrix, then `grpstats` returns summary statistics for each column of `X`.

Data Types: double | single

group — Grouping variable

categorical array | logical or numeric vector | datetime or duration vector | cell array of strings | []

Grouping variable, specified as a categorical array, logical or numeric vector, or cell array of strings. Each unique value in a grouping variable defines a group. `grpstats` groups data for summary statistics using the grouping variable values.

There must be a grouping variable value for each row of the input data `X`. Observations (rows) with the same value of the grouping variable are in the same group. Use `[]` to compute summary statistics for all data, without using groups.

For example, if `Gender` is a cell array of strings with values 'Male' and 'Female', you can use `Gender` as a grouping variable to summarize your data by gender.

You can also use more than one grouping variable to group data for summary statistics. In this case, specify a cell array of grouping variables.

For example, if `Smoker` is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array `{Gender,Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker. `grpstats` returns summary statistics only for the combinations of values that exist in the input grouping variables (not all possible combinations).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DataVars',[1,3,4],'Alpha',0.01` specifies that summary statistics be calculated for the 1st, 3rd, and 4th variables in a dataset array, with 99% confidence intervals.

'Alpha' — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level for confidence and prediction intervals, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

When you include `'meanci'` or `'predci'` in `whichstats`, you can use `Alpha` to specify the significance level for confidence or prediction intervals. If you specify the value a , then `grpstats` returns $100 \times (1 - a)\%$ confidence or prediction intervals.

If you do not specify a value for `Alpha`, then `grpstats` returns 95% intervals ($a = 0.05$).

Example: `'Alpha',0.1`

Data Types: `double`

'DataVars' — Variable names or columns

cell array of strings | vector of positive integers | logical vector

Variable names or columns indicating which variables in the input data `tbl` you want to compute summary statistics for, specified as the comma-separated pair consisting of `'DataVars'` and a cell array of strings, vector of positive integers, or a logical vector. Use a string to specify a variable name, a positive integer to specify a variable column

number, or logical values to indicate which variables to include (`true` if you want to compute summary statistics, `false` otherwise).

You must specify `DataVars` if there are any variables in `tbl` (other than the grouping variables specified in `groupvar`) that are not numeric or logical arrays. Summary statistics can only be calculated for variables that have a numeric or logical data type.

Example: `'DataVars', {'Height', 'Weight'}`

Data Types: `double | cell | char`

'VarNames' — Variable names for output

cell array of strings

Variable names for the output `statarray`, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings. By default, `grpstats` constructs output variable names by appending a prefix to the variable names from the input data `tbl`. This prefix corresponds to the summary statistic name.

Example: `'VarNames', {'Gender', 'GroupCount', 'MaleMean', 'FemaleMean'}`

Data Types: `cell`

Output Arguments

statarray — Group summary statistics

table | dataset array

Group summary statistics, returned as a table or a dataset array. If `tbl` is a table, `grpstats` returns `statarray` as a table. If `tbl` is a dataset array, `grpstats` returns `statarray` as a dataset array.

`statarray` contains summary statistic values for the groups of data in `tbl` determined by the levels of the grouping variables specified by `groupvar`. There is a row in `statarray` for each observed value or combination of values in the variables specified by `groupvar`. The output `statarray` contains:

- All grouping variables specified by `groupvar`.
- The variable `GroupCount`, containing the number of observations in each group.
- Group summary statistic values for all variables in `tbl` (other than those specified by `groupvar`), or for only the variables specified using `DataVars`.

The total number of variables in `statarray` is $n\text{groupvars} + 1 + n\text{datavars} \times n\text{stats}$, where *n*groupvars is the number of variables in `groupvar`, *n*datavars is the number of variables for which summary statistics are computed, and *n*stats is the number of summary statistic types specified in `whichstats`.

`grpstats` assigns default names to the variables in `statarray`, unless you specify variable names using the name-value pair argument `VarNames`.

means — Group means

column vector | array

Group means for the groups of data in the vector or matrix *X* determined by the levels of `group`, returned as an *n*groups-by-*n*cols array. Here, *n*groups is the number of unique values in the grouping variable, and *n*cols is the number of columns in *X*. If *X* is a vector, then `means` is a column vector.

stats1, ..., statsN — Group summary statistics

column vectors | arrays

Group summary statistics for the groups of data in the vector or matrix *X* determined by the levels of `group`, returned as *n*groups-by-*n*cols arrays. Here, *n*groups is the number of unique values in the grouping variable, and *n*cols is the number of columns in *X*. You must specify an output argument for each type of summary statistic specified in `whichstats`.

If a summary statistic type in `whichstats` returns a value of length *n*vals (for example, a confidence interval is a descriptive statistic of length two), then the corresponding output argument is an *n*groups-by-*n*cols-by-*n*vals array.

More About

Algorithms

- `grpstats` treats NaNs as missing values, and removes them from the input data before calculating summary statistics.
- `grpstats` ignores empty group names.

Introduced before R2006a

grpstats

Class: RepeatedMeasuresModel

Compute descriptive statistics of repeated measures data by group

Syntax

```
statstbl = grpstats(rm,g)
statstbl = grpstats(rm,g,stats)
```

Description

`statstbl = grpstats(rm,g)` returns the count, mean, and variance for the data used to fit the repeated measures model `rm`, grouped by the factors, `g`.

`statstbl = grpstats(rm,g,stats)` returns the statistics specified by `stats` for the data used to fit the repeated measures model `rm`, grouped by the factors, `g`.

Tips

- `grpstats` computes results separately for each group. The results do not depend on the fitted repeated measures model. It computes the results on all available data, without omitting entire rows that contain NaNs.

Input Arguments

rm — Repeated measures model
RepeatedMeasuresModel object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

g — Name of grouping factor or factors

string | cell array of strings

Name of grouping factor or factors, specified as a string or cell array of strings.

Example: 'Drug'

Example: {'Drug', 'Sex'}

Data Types: char

stats — Statistics to compute

string | function handle | cell array of multiple strings and function handles

Statistics to compute, specified as one of the following:

- String specifying the name of the statistics to compute. Names can be one of the following.

Name	Description
'mean'	Mean
'sem'	Standard error of the mean
'numel'	Count or number of elements
'gname'	Group name
'std'	Standard deviation
'var'	Variance
'min'	Minimum
'max'	Maximum
'range'	Maximum minus minimum
'meanci'	95% confidence interval for the mean
'predci'	95% prediction interval for a new observation

- Function handle — The function you specify must accept a vector of response values for a single group, and compute descriptive statistics for it. A function should typically return a value that has one row. A function must return the same size output each time `grpstats` calls it, even if the input for some groups is empty.
- A cell array of strings and function handles.

Example: @median

Example: @skewness

Example: 'gname'

Example: {'gname', 'range', 'predci'}

Data Types: char | function_handle | cell

Output Arguments

statstb1 — Statistics values for each group

table

Statistics values for each group, returned as a table.

Examples

Compute Group Statistics

Load the sample data.

```
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the `species` is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Compute group counts, mean, and standard deviation with respect to `species`.

```
grpstats(rm,'species')
```

```
ans =
```

species	GroupCount	mean	std
'setosa'	200	2.5355	1.8483
'versicolor'	200	3.573	1.7624
'virginica'	200	4.285	1.9154

Now, compute the range of data and 95% confidence intervals for the group means for the factor species. Also display the group name.

```
grpstats(rm, 'species', {'gname', 'range', 'predci'})
```

```
ans =
```

species	gname	GroupCount	range	predci	
'setosa'	'setosa'	200	5.7	-1.1185	6.1895
'versicolor'	'versicolor'	200	6	0.088976	7.057
'virginica'	'virginica'	200	6.5	0.4985	8.0715

Statistics for Data Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables age, IQ, group, gender, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Compute group counts, mean, standard deviation, skewness, and kurtosis of data grouped by the factors Group and Gender.

```
GS = grpstats(rm, {'Group', 'Gender'}, {'mean', 'std', @skewness, @kurtosis})
```

```
GS =
```

Group	Gender	GroupCount	mean	std	skewness	kurtosis
A	Female	40	16.554	21.498	0.35324	3.7807
A	Male	40	9.8335	20.602	-0.38722	2.7834
B	Female	40	11.261	25.779	-0.49177	4.1484
B	Male	40	3.6078	24.646	0.55447	2.7966
C	Female	40	-11.335	27.186	1.7499	6.1429
C	Male	40	-14.028	31.984	1.7362	5.141

See Also`fitrm | plot`

gscatter

Scatter plot by group

Syntax

```
gscatter(x,y,group)
gscatter(x,y,group,clr,sym,siz)
gscatter(x,y,group,clr,sym,siz,doleg)
gscatter(x,y,group,clr,sym,siz,doleg,xnam,ynam)
h = gscatter(...)
```

Description

`gscatter(x,y,group)` creates a scatter plot of `x` and `y`, grouped by `group`. `x` and `y` are vectors of the same size. `group` is a grouping variable in the form of a categorical variable, vector, string array, or cell array of strings. Alternatively, `group` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`), in which case observations are in the same group if they have common values of all grouping variables. Points in the same group and appear on the graph with the same marker and color.

`gscatter(x,y,group,clr,sym,siz)` specifies the color, marker type, and size for each group. `clr` is either a string array of colors recognized by the `plot` function or a three-column matrix of color specifications. `sym` is a string array of symbols recognized by the `plot` command, with the default value `'.'`. `siz` is a vector of sizes, with the default determined by the `'DefaultLineMarkerSize'` property. If you do not specify enough values for all groups, `gscatter` cycles through the specified values as needed.

`gscatter(x,y,group,clr,sym,siz,doleg)` controls whether a legend is displayed on the graph (`doleg` is `'on'`, the default) or not (`doleg` is `'off'`).

`gscatter(x,y,group,clr,sym,siz,doleg,xnam,ynam)` specifies the name to use for the `x`-axis and `y`-axis labels. If the `x` and `y` inputs are simple variable names and `xnam` and `yname` are omitted, `gscatter` labels the axes with the variable names.

`h = gscatter(...)` returns an array of handles to the lines on the graph.

Examples

Scatter Plot of Climate and Housing Ratings

Load the sample data.

```
load discrim
```

The sample data contains ratings of cities according to nine factors such as climate, housing, education, and health in the matrix `ratings` .

Plot the relationship between the ratings for climate (first column) and housing (second column) grouped by city size in the matrix `group`. Choose different colors and plotting symbols for each group.

```
figure;  
gscatter(ratings(:,1),ratings(:,2),group,'br','xo')  
xlabel('climate');  
ylabel('housing');
```

Introduced before R2006a

gt

Class: grandstream

Greater than relation for handles

Syntax

`h1 > h2`

Description

`h1 > h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `>` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = gt(h1, h2)` stores the result in a logical array of the same dimensions.

prob.HalfNormalDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Half-normal probability distribution object

Description

`prob.HalfNormalDistribution` is an object consisting of parameters, a model description, and sample data for a half-normal probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('HalfNormal')` creates a half-normal probability distribution object using the default parameter values $\mu = 0$ and $\sigma = 1$.

`pd = makedist('HalfNormal', 'mu', mu, 'sigma', sigma)` creates a half-normal distribution object using the parameter values specified for `mu` and `sigma`.

Input Arguments

mu — Location parameter

0 (default) | scalar value

Location parameter of the half-normal distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

1 (default) | positive scalar value

Scale parameter of the half-normal distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Properties

mu — Location parameter

scalar value

Location parameter of the half-normal distribution, stored as a scalar value. The `mu` parameter is also the lower limit of the half-normal distribution.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter of the half-normal distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative log likelihood of probability distribution object

paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

The half-normal distribution is a special case of the folded normal and truncated normal distributions. Applications of the half-normal distribution include modeling measurement data and lifetime data.

The half-normal distribution uses the following parameters.

Parameter	Description	Support
mu	Location parameter	$-\infty < \mu < \infty$
sigma	Scale parameter	$\sigma \geq 0$

For more information, see “Half-Normal Distribution” on page B-73.

Examples

Create a Half-Normal Distribution Object Using Default Parameters

```
pd = makedist('HalfNormal')
```

```
pd =
```

```
HalfNormalDistribution
```

```
Half Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Create a Half-Normal Distribution Object Using Specified Parameters

Create a half-normal distribution object. Specify `mu` equal to 0 and `sigma` equal to 1.5.

```
pd = makedist('HalfNormal','mu',0,'sigma',1.5)
```

```
pd =  
  
HalfNormalDistribution  
  
Half Normal distribution  
    mu =    0  
    sigma = 1.5
```

Compute the mean and standard deviation of the distribution.

```
m = mean(pd)  
s = std(pd)
```

```
m =  
  
    1.1968
```

```
s =  
  
    0.9042
```

Fit a Half-Normal Distribution Object

Generate 100 random numbers from a standard normal distribution and compute their absolute value.

```
rng default % For reproducibility  
x = abs(random(makedist('Normal'),100,1));
```

Fit a half-normal distribution object to the sample data.

```
pd = fitdist(x,'HalfNormal')
```

```
pd =
  HalfNormalDistribution
  Half Normal distribution
  mu = 0
  sigma = 1.1631 [1.02184, 1.35006]
```

Calculate the mean of the fitted half-normal distribution using the probability distribution object.

```
m = mean(pd)
```

```
m =
  0.9280
```

Calculate the mean of the half-normal distribution by substituting the fitted μ and σ parameter values into the formula

$$mean = \mu + \sigma \sqrt{\frac{2}{\pi}}.$$

```
mcalc = pd.mu + pd.sigma*(sqrt(2/pi))
```

```
mcalc =
  0.9280
```

Introduced in R2016a

haltonset class

Superclasses: grandset

Halton quasi-random point sets

Description

haltonset is a quasi-random point set class that produces points from the Halton sequence.

Construction

<code>.haltonset</code>	Construct Halton quasi-random point set
-------------------------	---

Methods

Inherited Methods

Methods in the following table are inherited from grandset.

<code>disp</code>	Display grandset object
<code>end</code>	Last index in indexing expression for point set
<code>length</code>	Length of point set
<code>ndims</code>	Number of dimensions in matrix
<code>net</code>	Generate quasi-random point set
<code>scramble</code>	Scramble quasi-random point set
<code>size</code>	Number of dimensions in matrix
<code>suboref</code>	Subscripted reference for grandset

Properties

Inherited Properties

Properties in the following table are inherited from `grandset`.

Dimensions	Number of dimensions
Leap	Interval between points
ScrambleMethod	Settings that control scrambling
Skip	Number of initial points to omit from sequence
Type	Name of sequence on which point set P is based

Copy Semantics

Handle. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

`sobolset`

How To

- "Quasi-Random Point Sets" on page 7-17

haltonset

Class: haltonset

Construct Halton quasi-random point set

Syntax

```
p = haltonset(d)
p = haltonset(d,prop1,va11,prop2,va12,...)
```

Description

`p = haltonset(d)` constructs a d -dimensional point set `p` of the `haltonset` class, with default property settings.

`p = haltonset(d,prop1,va11,prop2,va12,...)` specifies property name/value pairs used to construct `p`.

The object `p` returned by `haltonset` encapsulates properties of a specified quasi-random sequence. The point set is finite, with a length determined by the `Skip` and `Leap` properties and by limits on the size of point set indices (maximum value of 2^{53}). Values of the point set are not generated and stored in memory until you access `p` using `net` or parenthesis indexing.

Examples

Generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:

```
p = haltonset(3,'Skip',1e3,'Leap',1e2)
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : 1000
        Leap : 100
        ScrambleMethod : none
```

Use `scramble` to apply reverse-radix scrambling:

```
p = scramble(p, 'RR2')
p =
  Halton point set in 3 dimensions (8.918019e+013 points)
  Properties:
    Skip : 1000
    Leap : 100
    ScrambleMethod : RR2
```

Use `net` to generate the first four points:

```
X0 = net(p,4)
X0 =
  0.0928    0.6950    0.0029
  0.6958    0.2958    0.8269
  0.3013    0.6497    0.4141
  0.9087    0.7883    0.2166
```

Use parenthesis indexing to generate every third point, up to the 11th point:

```
X = p(1:3:11,:)
X =
  0.0928    0.6950    0.0029
  0.9087    0.7883    0.2166
  0.3843    0.9840    0.9878
  0.6831    0.7357    0.7923
```

See Also

`net` | `scramble` | `sobolset`

Introduced in R2008a

harmmean

Harmonic mean

Syntax

```
m = harmmean(X)
harmmean(X,dim)
```

Description

`m = harmmean(X)` calculates the harmonic mean of a sample. For vectors, `harmmean(x)` is the harmonic mean of the elements in `x`. For matrices, `harmmean(X)` is a row vector containing the harmonic means of each column. For N -dimensional arrays, `harmmean` operates along the first nonsingleton dimension of `X`.

`harmmean(X,dim)` takes the harmonic mean along dimension `dim` of `X`.

The harmonic mean is

$$m = \frac{n}{\sum_{i=1}^n \frac{1}{x_i}}$$

Examples

The arithmetic mean is greater than or equal to the harmonic mean.

```
x = exprnd(1,10,6);
```

```
harmonic = harmmean(x)
```

```
harmonic =
```

```
0.3382 0.3200 0.3710 0.0540 0.4936 0.0907
```

```
average = mean(x)
```

```
average =
```

1.3509 1.1583 0.9741 0.5319 1.0088 0.8122

mean | median | geomean | trimmean

Introduced before R2006a

hist3

Bivariate histogram

Syntax

```
hist3(X)
hist3(X,nbins)
hist3(X,ctrs)
hist3(X,'Edges',edges)
N = hist3(X,...)
[N,C] = hist3(X,...)
hist3(...,param1,val1,param2,val2,...)
```

Description

`hist3(X)` bins the elements of the m -by-2 matrix X into a 10-by-10 grid of equally spaced containers, and plots a histogram. Each column of X corresponds to one dimension in the bin grid.

`hist3(X,nbins)` plots a histogram using an `nbins(1)`-by-`nbins(2)` grid of bins. `hist3(X,'Nbins',nbins)` is equivalent to `hist3(X,nbins)`.

`hist3(X,ctrs)`, where `ctrs` is a two-element cell array of numeric vectors with monotonically non-decreasing values, uses a 2-D grid of bins centered on `ctrs{1}` in the first dimension and on `ctrs{2}` in the second. `hist3` assigns rows of X falling outside the range of that grid to the bins along the outer edges of the grid, and ignores rows of X containing NaNs. `hist3(X,'Ctrs',ctrs)` is equivalent to `hist3(X,ctrs)`.

`hist3(X,'Edges',edges)`, where `edges` is a two-element cell array of numeric vectors with monotonically non-decreasing values, uses a 2-D grid of bins with edges at `edges{1}` in the first dimension and at `edges{2}` in the second. The (i,j) th bin includes the value $X(k,:)$ if

```
edges{1}(i) <= X(k,1) < edges{1}(i+1)
edges{2}(j) <= X(k,2) < edges{2}(j+1)
```

Rows of X that fall on the upper edges of the grid, `edges{1}(end)` or `edges{2}(end)`, are counted in the (I, j) th or (i, J) th bins, where I and J are the lengths of `edges{1}` and `edges{2}`. `hist3` does not count rows of X falling outside the range of the grid. Use `-Inf` and `Inf` in `edges` to include all non-`NaN` values.

`N = hist3(X, ...)` returns a matrix containing the number of elements of X that fall in each bin of the grid, and does not plot the histogram.

`[N,C] = hist3(X, ...)` returns the positions of the bin centers in a 1-by-2 cell array of numeric vectors, and does not plot the histogram. `hist3(ax,X, ...)` plots onto an `axes` with handle `ax` instead of the current `axes`. See the `axes` reference page for more information about handles to plots.

`hist3(...,param1,val1,param2,val2,...)` allows you to specify graphics parameter name/value pairs to fine-tune the plot.

Examples

Plot Density Histogram with Intensity Map

Load the sample data.

```
load seamount
```

Correct grid for negative y-values and draw histogram in 2D.

```
hold on
dat = [-y,x];
hist3(dat)
```

Extract histogram data.

```
n = hist3(dat); % default is to 10x10 bins
n1 = n';
n1(size(n,1) + 1, size(n,2) + 1) = 0;
```

Generate grid for 2-D projected view of intensities.

```
xb = linspace(min(dat(:,1)),max(dat(:,1)),size(n,1)+1);
yb = linspace(min(dat(:,2)),max(dat(:,2)),size(n,1)+1);
```

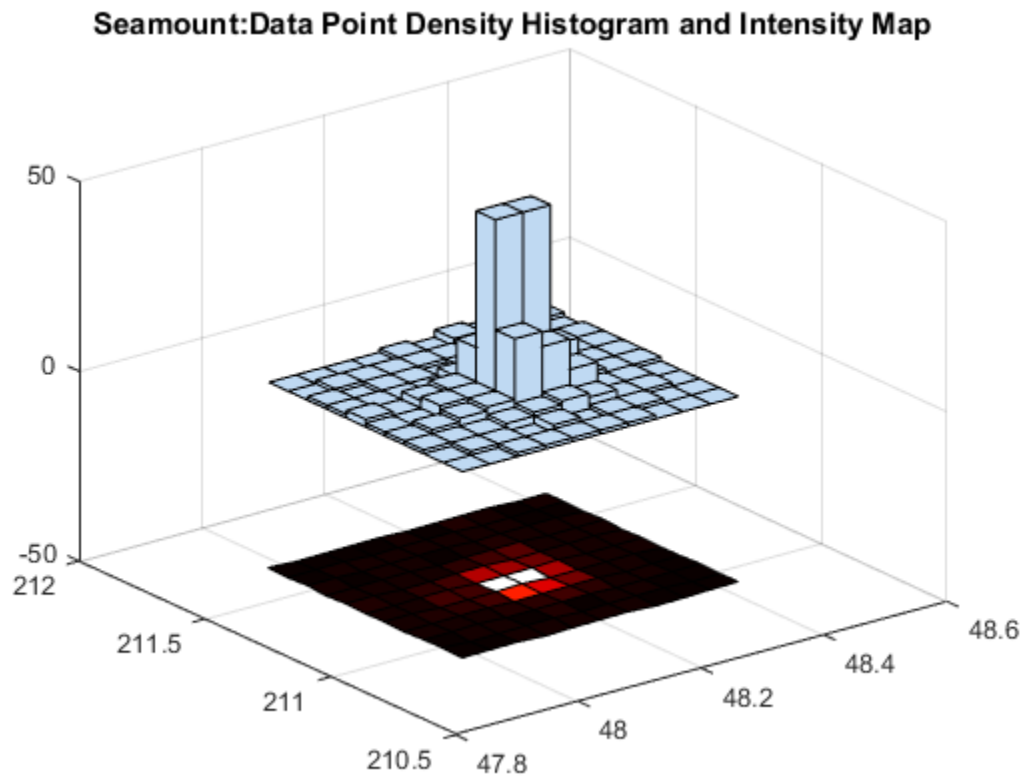

Make a pseudocolor plot.

```
h = pcolor(xb,yb,n1);
```

Set the z-level and colormap of the displayed grid, and display the default 3-D perspective view.

```
h.ZData = ones(size(n1)) * -max(max(n));
colormap(hot) % heat map
title('Seamount:Data Point Density Histogram and Intensity Map');
grid on
view(3);
```

Histogram with Semi-Transparent Bars

Load the sample data.

```
load carbig
```

Use the data to make histogram on a 7-by-7 grid of bins.

```
X = [MPG,Weight];
hist3(X,[7 7]);
xlabel('MPG'); ylabel('Weight');
```

Make a histogram with semi-transparent bars.

```
hist3(X,[7 7], 'FaceAlpha', .65);  
xlabel('MPG'); ylabel('Weight');  
set(gcf, 'renderer', 'opengl');
```

Specify bin centers, different in each direction; get back counts, but don't make the plot.

```
cnt = hist3(X, {0:10:50 2000:500:5000});
```

Histogram Bars Colored According to Height

Load the sample data.

```
load carbig
```

Make a histogram on a 7-by-7 grid of bins.

```
X = [MPG,Weight];
hist3(X,[7 7]);
```

```
xlabel('MPG'); ylabel('Weight');  
set(gcf, 'renderer', 'opengl');
```

Color the bars based on the frequency of the observations, i.e. according to the height of the bars.

```
set(get(gca, 'child'), 'FaceColor', 'interp', 'CDataMode', 'auto');
```

histfit

Histogram with a distribution fit

Syntax

```
histfit(data)
histfit(data,nbins)
histfit(data,nbins,dist)
```

```
h = histfit(____)
```

Description

`histfit(data)` plots a histogram of values in `data` using the number of bins equal to the square root of the number of elements in `data` and fits a normal density function.

`histfit(data,nbins)` plots a histogram using `nbins` bins and fits a normal density function.

`histfit(data,nbins,dist)` plots a histogram with `nbins` bins and fits a density function from the distribution specified by `dist`.

`h = histfit(____)` returns a vector of handles `h`, where `h(1)` is the handle to the histogram and `h(2)` is the handle to the density curve. It can include any of the input arguments in previous syntaxes.

Examples

Histogram with a Normal Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default; % For reproducibility
r = normrnd(10,1,100,1);
```

Construct a histogram with a normal distribution fit.

```
histfit(r)
```

Histogram for a Given Number of Bins

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default; % For reproducibility  
r = normrnd(10,1,100,1);
```

Construct a histogram using six bins with a normal distribution fit.

```
histfit(r,6)
```

Histogram with a Specified Distribution Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng default; % For reproducibility  
b = betarnd(3,10,100,1);
```

Construct a histogram using 10 bins with a beta distribution fit.

```
histfit(b,10,'beta')
```

Histogram with a Kernel Smoothing Function Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng default; % For reproducibility  
b = betarnd(3,10,[100,1]);
```

Construct a histogram using 10 bins with a smoothing function fit.

```
histfit(b,10,'kernel')
```

Handle for a Histogram with a Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default % for reproducibility  
r = normrnd(10,1,100,1);
```

Construct a histogram with a normal distribution fit.

```
h = histfit(r,10,'normal')
```

```
h =
```

2x1 graphics array:

Bar
Line

Change the bar colors of the histogram.

```
h(1).FaceColor = [.8 .8 1];
```

Change the color of the density curve.

```
h(2).Color = [.2 .2 .2];
```

Input Arguments

data — Input data

vector

Input data, specified as a vector.

Example: `data = [1.5 2.5 4.6 1.2 3.4]`

Example: `data = [1.5 2.5 4.6 1.2 3.4]'`

Data Types: `double` | `single`

nbins — Number of bins

positive integer | []

Number of bins for the histogram, specified as a positive integer. Default value is the square root of the number of elements in `data`, rounded up. Use [] for the default number of bins when fitting a distribution.

Example: `y = histfit(x,8)`

Example: `y = histfit(x,10,'gamma')`

Example: `y = histfit(x,[],'weibull')`

Data Types: `double` | `single`

dist — Distribution to fit

'normal' (default) | string

Distribution to fit to the histogram, specified as a string. The following table shows the supported distributions.

dist	Description
'beta'	Beta
'birnbaumsaunders'	Birnbaum-Saunders
'burr'	Burr Type XII
'exponential'	Exponential
'extreme value' or 'ev'	Extreme value
'gamma'	Gamma
'generalized extreme value' or 'gev'	Generalized extreme value
'generalized pareto' or 'gp'	Generalized Pareto (threshold 0)
'inversegaussian'	Inverse Gaussian
'logistic'	Logistic
'loglogistic'	Loglogistic
'lognormal'	Lognormal
'nakagami'	Nakagami
'negative binomial' or 'nbin'	Negative binomial

dist	Description
'normal'	Normal
'poisson'	Poisson
'rayleigh'	Rayleigh
'rician'	Rician
'tlocationscale'	t location-scale
'weibull' or 'wbl'	Weibull
'kernel'	Nonparametric kernel-smoothing distribution. The density is evaluated at 100 equally spaced points that cover the range of the data in <code>data</code> . It works best with continuously distributed samples.

Data Types: char

Output Arguments

h — Handles for the plot

plot handle

Handles for the plot, returned as a vector, where `h(1)` is the handle to the histogram, and `h(2)` is the handle to the density curve.

hmmdecode

Hidden Markov model posterior state probabilities

Syntax

```
PSTATES = hmmdecode(seq, TRANS, EMIS)
[PSTATES, logpseq] = hmmdecode(...)
[PSTATES, logpseq, FORWARD, BACKWARD, S] = hmmdecode(...)
hmmdecode(..., 'Symbols', SYMBOLS)
```

Description

`PSTATES = hmmdecode(seq, TRANS, EMIS)` calculates the posterior state probabilities, `PSTATES`, of the sequence `seq`, from a hidden Markov model. The posterior state probabilities are the conditional probabilities of being at state k at step i , given the observed sequence of symbols, `sym`. You specify the model by a transition probability matrix, `TRANS`, and an emissions probability matrix, `EMIS`. `TRANS(i, j)` is the probability of transition from state i to state j . `EMIS(k, seq)` is the probability that symbol `seq` is emitted from state k .

`PSTATES` is an array with the same length as `seq` and one row for each state in the model. The (i, j) th element of `PSTATES` gives the probability that the model is in state i at the j th step, given the sequence `seq`.

Note The function `hmmdecode` begins with the model in state 1 at step 0, prior to the first emission. `hmmdecode` computes the probabilities in `PSTATES` based on the fact that the model begins in state 1.

`[PSTATES, logpseq] = hmmdecode(...)` returns `logpseq`, the logarithm of the probability of sequence `seq`, given transition matrix `TRANS` and emission matrix `EMIS`.

`[PSTATES, logpseq, FORWARD, BACKWARD, S] = hmmdecode(...)` returns the forward and backward probabilities of the sequence scaled by `S`.

`hmmdecode(..., 'Symbols', SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

Examples

```
trans = [0.95,0.05;  
         0.10,0.90];  
emis = [1/6 1/6 1/6 1/6 1/6 1/6;  
        1/10 1/10 1/10 1/10 1/10 1/2];  
  
[seq,states] = hmmgenerate(100,trans,emis);  
pStates = hmmdecode(seq,trans,emis);  
[seq,states] = hmmgenerate(100,trans,emis,...  
    'Symbols',{'one','two','three','four','five','six'})  
pStates = hmmdecode(seq,trans,emis,...  
    'Symbols',{'one','two','three','four','five','six'});
```

See Also

`hmmgenerate` | `hmmestimate` | `hmmviterbi` | `hmmtrain`

Introduced before R2006a

hmmestimate

Hidden Markov model parameter estimates from emissions and states

Syntax

```
[TRANS,EMIS] = hmmestimate(seq,states)
hmmestimate(...,'Symbols',SYMBOLS)
hmmestimate(...,'Statenames',STATENAMES)
hmmestimate(...,'Pseudoemissions',PSEUDOE)
hmmestimate(...,'Pseudotransitions',PSEUDOTR)
```

Description

`[TRANS,EMIS] = hmmestimate(seq,states)` calculates the maximum likelihood estimate of the transition, `TRANS`, and emission, `EMIS`, probabilities of a hidden Markov model for sequence, `seq`, with known states, `states`.

`hmmestimate(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

`hmmestimate(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be a numeric array or a cell array of the names of the states. The default state names are 1 through `M`, where `M` is the number of states.

`hmmestimate(...,'Pseudoemissions',PSEUDOE)` specifies pseudocount emission values in the matrix `PSEUDOE`. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. `PSEUDOE` should be a matrix of size m -by- n , where m is the number of states in the hidden Markov model and n is the number of possible emissions. If the $i \rightarrow k$ emission does not occur in `seq`, you can set `PSEUDOE(i,k)` to be a positive number representing an estimate of the expected number of such emissions in the sequence `seq`.

`hmmestimate(...,'Pseudotransitions',PSEUDOTR)` specifies pseudocount transition values. You can use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. `PSEUDOTR` should be a matrix of size m -by- m , where m is the number of states

in the hidden Markov model. If the $i \rightarrow j$ transition does not occur in `states`, you can set `PSEUDOTR(i, j)` to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

Pseudotransitions and Pseudoemissions

If the probability of a specific transition or emission is very low, the transition might never occur in the sequence `states`, or the emission might never occur in the sequence `seq`. In either case, the algorithm returns a probability of 0 for the given transition or emission in `TRANS` or `EMIS`. You can compensate for the absence of transition with the 'Pseudotransitions' and 'Pseudoemissions' arguments. The simplest way to do this is to set the corresponding entry of `PSEUDOE` or `PSEUDOTR` to 1. For example, if the transition $i \rightarrow j$ does not occur in `states`, set `PSEUDOTR(i, j) = 1`. This forces `TRANS(i, j)` to be positive. If you have an estimate for the expected number of transitions $i \rightarrow j$ in a sequence of the same length as `states`, and the actual number of transitions $i \rightarrow j$ that occur in `seq` is substantially less than what you expect, you can set `PSEUDOTR(i, j)` to the expected number. This increases the value of `TRANS(i, j)`. For transitions that do occur in `states` with the frequency you expect, set the corresponding entry of `PSEUDOTR` to 0, which does not increase the corresponding entry of `TRANS`.

If you do not know the sequence of states, use `hmmtrain` to estimate the model parameters.

Examples

```
trans = [0.95,0.05; 0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(1000,trans,emis);
[estimateTR,estimateE] = hmmestimate(seq,states);
```

hmmgenerate | hmmdecode | hmmviterbi | hmmtrain

Introduced before R2006a

hmmgenerate

Hidden Markov model states and emissions

Syntax

```
[seq,states] = hmmgenerate(len,TRANS,EMIS)
hmmgenerate(...,'Symbols',SYMBOLS)
hmmgenerate(...,'Statenames',STATENAMES)
```

Description

[seq,states] = hmmgenerate(len,TRANS,EMIS) takes a known Markov model, specified by transition probability matrix TRANS and emission probability matrix EMIS, and uses it to generate

- A random sequence **seq** of emission symbols
- A random sequence **states** of states

The length of both **seq** and **states** is **len**. TRANS(*i*, *j*) is the probability of transition from state *i* to state *j*. EMIS(*k*, *l*) is the probability that symbol *l* is emitted from state *k*.

Note The function `hmmgenerate` begins with the model in state 1 at step 0, prior to the first emission. The model then makes a transition to state i_1 , with probability T_{1i_1} , and generates an emission a_{k_1} with probability $E_{i_1k_1}$. `hmmgenerate` returns i_1 as the first entry of **states**, and a_{k_1} as the first entry of **seq**.

`hmmgenerate(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. SYMBOLS can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

`hmmgenerate(...,'Statenames',STATENAMES)` specifies the names of the states. STATENAMES can be a numeric array or a cell array of the names of the states. The default state names are 1 through M, where M is the number of states.

Since the model always begins at state 1, whose transition probabilities are in the first row of TRANS, in the following example, the first entry of the output `states` is be 1 with probability 0.95 and 2 with probability 0.05.

Examples

```
trans = [0.95,0.05;
         0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis)
[seq,states] = hmmgenerate(100,trans,emis,...
    'Symbols',{'one','two','three','four','five','six'},...
    'Statenames',{'fair';'loaded'})
```

See Also

`hmmviterbi` | `hmmdecode` | `hmmestimate` | `hmmtrain`

Introduced before R2006a

hmmtrain

Hidden Markov model parameter estimates from emissions

Syntax

```
[ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS)
hmmtrain(...,'Algorithm',algorithm)
hmmtrain(...,'Symbols',SYMBOLS)
hmmtrain(...,'Tolerance',tol)
hmmtrain(...,'Maxiterations',maxiter)
hmmtrain(...,'Verbose',true)
hmmtrain(...,'Pseudoemissions',PSEUDOE)
hmmtrain(...,'Pseudotransitions',PSEUDOTR)
```

Description

[ESTTR,ESTEMIT] = `hmmtrain(seq,TRGUESS,EMITGUESS)` estimates the transition and emission probabilities for a hidden Markov model using the Baum-Welch algorithm. `seq` can be a row vector containing a single sequence, a matrix with one row per sequence, or a cell array with each cell containing a sequence. `TRGUESS` and `EMITGUESS` are initial estimates of the transition and emission probability matrices. `TRGUESS(i,j)` is the estimated probability of transition from state `i` to state `j`. `EMITGUESS(i,k)` is the estimated probability that symbol `k` is emitted from state `i`.

`hmmtrain(...,'Algorithm',algorithm)` specifies the training algorithm. *algorithm* can be either 'BaumWelch' or 'Viterbi'. The default algorithm is 'BaumWelch'.

`hmmtrain(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

`hmmtrain(...,'Tolerance',tol)` specifies the tolerance used for testing convergence of the iterative estimation process. The default tolerance is `1e-4`.

`hmmtrain(...,'Maxiterations',maxiter)` specifies the maximum number of iterations for the estimation process. The default maximum is `100`.

`hmmtrain(..., 'Verbose', true)` returns the status of the algorithm at each iteration.

`hmmtrain(..., 'Pseudoemissions', PSEUDOE)` specifies pseudocount emission values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. `PSEUDOE` should be a matrix of size m -by- n , where m is the number of states in the hidden Markov model and n is the number of possible emissions. If the $i \rightarrow k$ emission does not occur in `seq`, you can set `PSEUDOE(i, k)` to be a positive number representing an estimate of the expected number of such emissions in the sequence `seq`.

`hmmtrain(..., 'Pseudotransitions', PSEUDOTR)` specifies pseudocount transition values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. `PSEUDOTR` should be a matrix of size m -by- m , where m is the number of states in the hidden Markov model. If the $i \rightarrow j$ transition does not occur in `states`, you can set `PSEUDOTR(i, j)` to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

If you know the states corresponding to the sequences, use `hmmestimate` to estimate the model parameters.

Tolerance

The input argument `'tolerance'` controls how many steps the `hmmtrain` algorithm executes before the function returns an answer. The algorithm terminates when all of the following three quantities are less than the value that you specify for `tolerance`:

- The log likelihood that the input sequence `seq` is generated by the currently estimated values of the transition and emission matrices
- The change in the norm of the transition matrix, normalized by the size of the matrix
- The change in the norm of the emission matrix, normalized by the size of the matrix

The default value of `'tolerance'` is `.0001`. Increasing the tolerance decreases the number of steps the `hmmtrain` algorithm executes before it terminates.

maxiterations

The maximum number of iterations, `'maxiterations'`, controls the maximum number of steps the algorithm executes before it terminates. If the algorithm

executes `maxiter` iterations before reaching the specified tolerance, the algorithm terminates and the function returns a warning. If this occurs, you can increase the value of `'maxiterations'` to make the algorithm reach the desired tolerance before terminating.

Examples

```
trans = [0.95,0.05;  
         0.10,0.90];  
emis = [1/6, 1/6, 1/6, 1/6, 1/6, 1/6;  
        1/10, 1/10, 1/10, 1/10, 1/10, 1/2];  
  
seq1 = hmmgenerate(100,trans,emis);  
seq2 = hmmgenerate(200,trans,emis);  
seqs = {seq1,seq2};  
[estTR,estE] = hmmtrain(seqs,trans,emis);
```

hmmviterbi

Hidden Markov model most probable state path

Syntax

```
STATES = hmmviterbi(seq,TRANS,EMIS)
hmmviterbi(...,'Symbols',SYMBOLS)
hmmviterbi(...,'Statenames',STATENAMES)
```

Description

`STATES = hmmviterbi(seq,TRANS,EMIS)` given a sequence, `seq`, calculates the most likely path through the hidden Markov model specified by transition probability matrix, `TRANS`, and emission probability matrix `EMIS`. `TRANS(i,j)` is the probability of transition from state `i` to state `j`. `EMIS(i,k)` is the probability that symbol `k` is emitted from state `i`.

Note The function `hmmviterbi` begins with the model in state 1 at step 0, prior to the first emission. `hmmviterbi` computes the most likely path based on the fact that the model begins in state 1.

`hmmviterbi(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

`hmmviterbi(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be a numeric array or a cell array of the names of the states. The default state names are 1 through `M`, where `M` is the number of states.

Examples

```
trans = [0.95,0.05;
         0.10,0.90];
```

```
emis = [1/6 1/6 1/6 1/6 1/6 1/6;  
        1/10 1/10 1/10 1/10 1/10 1/2];  
  
[seq,states] = hmmgenerate(100,trans,emis);  
estimatedStates = hmmviterbi(seq,trans,emis);  
  
[seq,states] = ...  
    hmmgenerate(100,trans,emis,...  
                'Statenames',{'fair';'loaded'});  
estimatedStates = ...  
    hmmviterbi(seq,trans,emis,...  
                'Statenames',{'fair';'loaded'});
```

[hmmgenerate](#) | [hmmdecode](#) | [hmmestimate](#) | [hmmtrain](#)

Introduced before R2006a

horzcat

Class: dataset

Horizontal concatenation for dataset arrays

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = horzcat(ds1, ds2, ...)
```

Description

`ds = horzcat(ds1, ds2, ...)` horizontally concatenates the dataset arrays `ds1`, `ds2`, You may concatenate dataset arrays that have duplicate variable names, however, the variables must contain identical data, and `horzcat` includes only one copy of the variable in the output dataset.

Observation names for all dataset arrays that have them must be identical except for order. `horzcat` concatenates by matching observation names when present, or by position for datasets that do not have observation names.

See Also

`cat` | `vertcat`

hougen

Hougen-Watson model

Syntax

```
yhat = hougen(beta, x)
```

Description

`yhat = hougen(beta, x)` returns the predicted values of the reaction rate, `yhat`, as a function of the vector of parameters, `beta`, and the matrix of data, `X`. `beta` must have 5 elements and `X` must have three columns.

`hougen` is a utility function for `rsmdemo`.

The model form is:

$$\hat{y} = \frac{\beta_1 x_2 - x_3 / \beta_5}{1 + \beta_2 x_1 + \beta_3 x_2 + \beta_4 x_3}$$

References

`rsmdemo`

Introduced before R2006a

hygecdf

Hypergeometric cumulative distribution function

Syntax

```
hygecdf(x, M, K, N)  
hygecdf(x, M, K, N, 'upper')
```

Description

`hygecdf(x, M, K, N)` computes the hypergeometric cdf at each of the values in `x` using the corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. Vector or matrix inputs for `x`, `M`, `K`, and `N` must all have the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.

`hygecdf(x, M, K, N, 'upper')` returns the complement of the hypergeometric cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The hypergeometric cdf is

$$p = F(x | M, K, N) = \sum_{i=0}^x \frac{\binom{K}{i} \binom{M-K}{N-i}}{\binom{M}{N}}$$

The result, p , is the probability of drawing up to x of a possible K items in N drawings without replacement from a group of M objects.

Examples

Compute Hypergeometric Distribution CDF

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing zero to two defective floppies if you select 10 at random?

```
p = hygecdf(2, 100, 20, 10)
```

```
p =  
0.6812
```

See Also

[cdf](#) | [hygepdf](#) | [hygeinv](#) | [hygestat](#) | [hygernd](#)

Introduced before R2006a

hygeinv

Hypergeometric inverse cumulative distribution function

Syntax

`hygeinv(P,M,K,N)`

Description

`hygeinv(P,M,K,N)` returns the smallest integer X such that the hypergeometric cdf evaluated at X equals or exceeds P . You can think of P as the probability of observing X defective items in N drawings without replacement from a group of M items where K are defective.

Examples

Suppose you are the Quality Assurance manager for a floppy disk manufacturer. The production line turns out floppy disks in batches of 1,000. You want to sample 50 disks from each batch to see if they have defects. You want to accept 99% of the batches if there are no more than 10 defective disks in the batch. What is the maximum number of defective disks should you allow in your sample of 50?

```
x = hygeinv(0.99,1000,10,50)
x =
    3
```

What is the median number of defective floppy disks in samples of 50 disks from batches with 10 defective disks?

```
x = hygeinv(0.50,1000,10,50)
x =
    0
```

`icdf` | `hygecdf` | `hygepdf` | `hygestat` | `hygernd`

Introduced before R2006a

hygepdf

Hypergeometric probability density function

Syntax

$Y = \text{hygepdf}(X, M, K, N)$

Description

$Y = \text{hygepdf}(X, M, K, N)$ computes the hypergeometric pdf at each of the values in X using the corresponding size of the population, M , number of items with the desired characteristic in the population, K , and number of samples drawn, N . X , M , K , and N can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

The parameters in M , K , and N must all be positive integers, with $N \leq M$. The values in X must be less than or equal to all the parameter values.

The hypergeometric pdf is

$$y = f(x | M, K, N) = \frac{\binom{K}{x} \binom{M-K}{N-x}}{\binom{M}{N}}$$

The result, y , is the probability of drawing exactly x of a possible K items in n drawings without replacement from a group of M objects.

Examples

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing 0 through 5 defective floppy disks if you select 10 at random?

```
p = hygepdf(0:5,100,20,10)
p =
  0.0951  0.2679  0.3182  0.2092  0.0841  0.0215
```

pdf | hygecdf | hygeinv | hygestat | hygernd

Introduced before R2006a

hygernd

Hypergeometric random numbers

Syntax

```
R = hygernd(M,K,N)
R = hygernd(M,K,N,m,n,...)
R = hygernd(M,K,N,[m,n,...])
```

Description

`R = hygernd(M,K,N)` generates random numbers from the hypergeometric distribution with corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. `M`, `K`, and `N` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `R`. A scalar input for `M`, `K`, or `N` is expanded to a constant array with the same dimensions as the other inputs.

`R = hygernd(M,K,N,m,n,...)` or `R = hygernd(M,K,N,[m,n,...])` generates an `m-by-n-by-...` array. The `M`, `K`, `N` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
numbers = hygernd(1000,40,50)
numbers =
    1
```

`random` | `hygepdf` | `hygecdf` | `hygeinv` | `hygestat`

Introduced before R2006a

hygestat

Hypergeometric mean and variance

Syntax

```
[MN,V] = hygestat(M,K,N)
```

Description

[MN,V] = hygestat(M,K,N) returns the mean of and variance for the hypergeometric distribution with corresponding size of the population, M, number of items with the desired characteristic in the population, K, and number of samples drawn, N. Vector or matrix inputs for M, K, and N must have the same size, which is also the size of MN and V. A scalar input for M, K, or N is expanded to a constant matrix with the same dimensions as the other inputs.

The mean of the hypergeometric distribution with parameters M, K, and N is NK/M , and the variance is $NK(M-K)(M-N) / [M^2(M-1)]$.

Examples

The hypergeometric distribution approaches the binomial distribution, where $p = K/M$, as M goes to infinity.

```
[m,v] = hygestat(10.^(1:4),10.^(0:3),9)
m =
    0.9000    0.9000    0.9000    0.9000
v =
    0.0900    0.7445    0.8035    0.8094
```

```
[m,v] = binostat(9,0.1)
m =
    0.9000
v =
    0.8100
```

hygepdf | hygecdf | hygeinv | hygernd

Introduced before R2006a

icdf

Inverse cumulative distribution functions

Syntax

```
x = icdf('name',y,A)
x = icdf('name',y,A,B)
x = icdf('name',y,A,B,C)
x = icdf('name',y,A,B,C,D)

x = icdf(pd,y)
```

Description

`x = icdf('name',y,A)` returns the inverse cumulative distribution function (icdf) for the one-parameter distribution family specified by `'name'`, evaluated at the probability values in `y`. `A` contains the parameter value for the distribution.

`x = icdf('name',y,A,B)` returns the icdf for the two-parameter distribution family specified by `'name'`, evaluated at the probability values in `y`. `A` and `B` contain the parameter values for the distribution.

`x = icdf('name',y,A,B,C)` returns the icdf for the three-parameter distribution family specified by `'name'`, evaluated at the probability values in `y`. `A`, `B`, and `C` contain the parameter values for the distribution.

`x = icdf('name',y,A,B,C,D)` returns the icdf for the four-parameter distribution family specified by `'name'`, evaluated at the probability values in `y`. `A`, `B`, `C`, and `D` contain the parameter values for the distribution.

`x = icdf(pd,y)` returns the inverse cumulative distribution function of the probability distribution object, `pd`, evaluated at the probability values in `y`.

Examples

Compute the Normal Distribution icdf

Create a standard normal distribution object with the mean, μ , equal to 0 and the standard deviation, σ , equal to 1.

```
mu = 0;  
sigma = 1;  
pd = makedist('Normal',mu,sigma);
```

Define the input vector y to contain the probability values at which to calculate the icdf.

```
y = [0.1,0.25,0.5,0.75,0.9];
```

Compute the icdf values for the standard normal distribution at the values in y .

```
x = icdf(pd,y)
```

```
x =
```

```
-1.2816    -0.6745         0     0.6745     1.2816
```

Each value in x corresponds to a value in the input vector y . For example, at the value y equal to 0.9, the corresponding icdf value x is equal to 1.2816.

Alternatively, you can compute the same icdf values without creating a probability distribution object. Use the `icdf` function and specify a standard normal distribution using the same parameter values for μ and σ .

```
x2 = icdf('Normal',y,mu,sigma)
```

```
x2 =
```

```
-1.2816    -0.6745         0     0.6745     1.2816
```

The icdf values are the same as those computed using the probability distribution object.

Compute the Poisson Distribution icdf

Create a Poisson distribution object with the rate parameter, λ , equal to 2.

```
lambda = 2;  
pd = makedist('Poisson',lambda);
```

Define the input vector y to contain the probability values at which to calculate the icdf.

```
y = [0.1,0.25,0.5,0.75,0.9];
```

Compute the icdf values for the Poisson distribution at the values in y .

```
x = icdf(pd,y)
```

```
x =
```

```
    0    1    2    3    4
```

Each value in x corresponds to a value in the input vector y . For example, at the value y equal to 0.9, the corresponding icdf value x is equal to 4.

Alternatively, you can compute the same icdf values without creating a probability distribution object. Use the `icdf` function and specify a Poisson distribution using the same value for the rate parameter λ .

```
x2 = icdf('Poisson',y,lambda)
```

```
x2 =
```

```
    0    1    2    3    4
```

The icdf values are the same as those computed using the probability distribution object.

Input Arguments

'name' — Probability distribution name

probability distribution name string

Probability distribution name, specified as one of the following probability distribution name strings.

name	Distribution	Input Parameter A	Input Parameter B	Input Parameter C	Input Parameter D
'Beta '	“Beta Distribution” on page B-4	α : first shape parameter	b : second shape parameter	—	—

y — Probability values at which to evaluate icdf

scalar value | array of scalar values

Probability values at which to evaluate the `icdf`, specified as a scalar value, or an array of scalar values.

- If `x` is a scalar value, and if you specify distribution parameters `A`, `B`, `C`, or `D` as arrays, then `cdf` expands `x` into a constant array of the same size as the parameters.
- If `x` is an array, and if you specify distribution parameters `A`, `B`, `C`, or `D` as arrays, then `x`, `A`, `B`, `C`, and `D` must all be the same size.

Example: `[0.1,0.25,0.5,0.75,0.9]`Data Types: `single` | `double`**A — First probability distribution parameter**

scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value, or an array of scalar values.

If `x` and `A` are arrays, they must be the same size. If `x` is a scalar, then `cdf` expands it into a constant matrix the same size as `A`. If `A` is a scalar, then `cdf` expands it into a constant matrix the same size as `x`.

Data Types: `single` | `double`**B — Second probability distribution parameter**

scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value, or an array of scalar values.

If `x`, `A`, and `B` are arrays, they must be the same size. If `x` is a scalar, then `cdf` expands it into a constant matrix the same size as `A` and `B`. If `A` or `B` are scalars, then `cdf` expands them into constant matrices the same size as `x`.

Data Types: `single` | `double`**C — Third probability distribution parameter**

scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value, or an array of scalar values.

If x , A , B , and C are arrays, they must be the same size. If x is a scalar, then `cdf` expands it into a constant matrix the same size as A , B , and C . If any of A , B or C are scalars, then `cdf` expands them into constant matrices the same size as x .

Data Types: `single` | `double`

D — Fourth probability distribution parameter

scalar value | array of scalar values

Fourth probability distribution parameter, specified as a scalar value, or an array of scalar values.

If x , A , B , C , and D are arrays, they must be the same size. If x is a scalar, then `cdf` expands it into a constant array the same size as A , B , C , and D . If any of A , B , C , or D are scalars, then `cdf` expands them into constant matrices the same size as x .

Data Types: `single` | `double`

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
<code>dfittool</code>	Fit a probability distribution object to sample data using the interactive Distribution Fitting app.
<code>paretotails</code>	Create a Pareto tails object.

Output Arguments

x — Inverse cumulative distribution function

array

Inverse cumulative distribution function of the specified probability distribution, returned as an array.

- If you specify distribution parameters A, B, C, or D, then `x` is the common size of `y`, A, B, C, and D, after any necessary scalar expansion.
- If you specify a probability distribution object, `pd`, then `x` has the same dimensions as `y`.

More About

- “Working with Probability Distributions” on page 5-3

Introduced before R2006a

icdf

Class: `piecewisedistribution`

Inverse cumulative distribution function for piecewise distribution

Syntax

```
X = icdf(obj,P)
```

Description

`X = icdf(obj,P)` returns an array `X` of values of the inverse cumulative distribution function for the piecewise distribution object `obj`, evaluated at the values in the array `P`.

Examples

Fit Pareto tails to a *t* distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj)
p =
    0.1000
    0.9000
q =
   -1.7766
    1.8432

icdf(obj,p)
ans =
   -1.7766
    1.8432
```

See Also

`paretotails` | `cdf`

icdf

Class: ProbDistUnivKernel

Return inverse cumulative distribution function (ICDF) for ProbDistUnivKernel object

Syntax

$Y = \text{icdf}(PD, P)$

Description

$Y = \text{icdf}(PD, P)$ returns Y , an array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivKernel object PD , evaluated at values in P .

Input Arguments

PD	An object of the class ProbDistUnivKernel.
P	A numeric array of values from 0 to 1 where you want to evaluate the ICDF.

Output Arguments

Y	An array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivKernel object PD .
-----	--

See Also

icdf

icdf

Class: ProbDistUnivParam

Return inverse cumulative distribution function (ICDF) for ProbDistUnivParam object

Syntax

$Y = \text{icdf}(PD, P)$

Description

$Y = \text{icdf}(PD, P)$ returns Y , an array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivParam object PD , evaluated at values in P .

Input Arguments

PD	An object of the class ProbDistUnivParam.
P	A numeric array of values from 0 to 1 where you want to evaluate the ICDF.

Output Arguments

Y	An array containing the inverse cumulative distribution function (ICDF) for the ProbDistUnivParam object PD .
-----	---

See Also

icdf

icdf

Class: prob.TruncatableDistribution

Package: prob

Inverse cumulative distribution function of probability distribution object

Syntax

```
y = icdf(pd,prob)
```

Description

`y = icdf(pd,prob)` returns the inverse cumulative distribution function (icdf) values of the probability distribution `pd` at the probabilities in `prob`.

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

prob — Probabilities

array of scalar values in the range [0,1]

Probabilities at which to compute the icdf, specified as an array of scalar values in the range [0,1]. For example, specifying `[.25 .5 .75]` returns a vector containing three icdf values corresponding to these probabilities.

Data Types: `single` | `double`

Output Arguments

y — Inverse cumulative distribution function

array

Inverse cumulative distribution function (icdf) values of the specified probability distribution, evaluated at the probabilities in **prob**, returned as an array. **y** has the same dimensions as **x**.

Examples

Compute Standard Normal Critical Values

Create a standard normal distribution object.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Determine the critical values at the 5% significance level for a test statistic with a standard normal distribution, by computing the upper and lower 2.5% values.

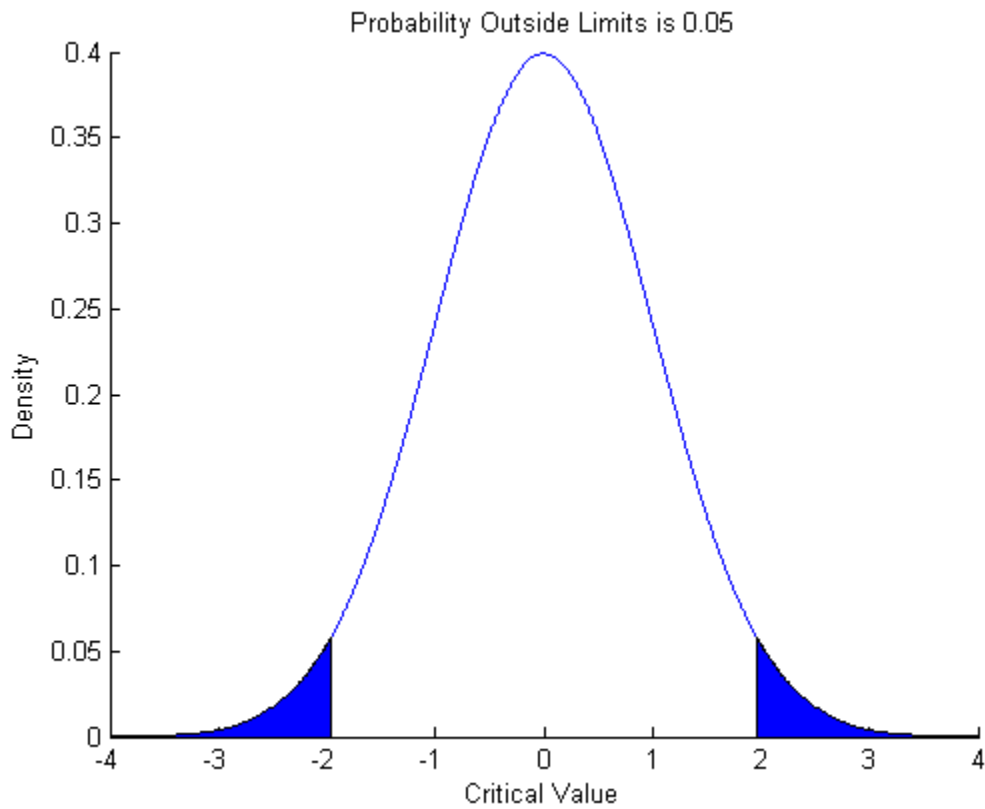

```
y = icdf(pd, [.025, .975])
```

```
y =
```

```
-1.9600    1.9600
```

Plot the cdf and shade the critical regions.

```
p = normspec(y,0,1,'outside')
```

inconsistent

Inconsistency coefficient

Syntax

```
Y = inconsistent(Z)
Y = inconsistent(Z,d)
```

Description

`Y = inconsistent(Z)` computes the inconsistency coefficient for each link of the hierarchical cluster tree `Z`, where `Z` is an $(m-1)$ -by-3 matrix generated by the `linkage` function. The inconsistency coefficient characterizes each link in a cluster tree by comparing its height with the average height of other links at the same level of the hierarchy. The higher the value of this coefficient, the less similar the objects connected by the link.

`Y = inconsistent(Z,d)` computes the inconsistency coefficient for each link in the hierarchical cluster tree `Z` to depth `d`, where `d` is an integer denoting the number of levels of the cluster tree that are included in the calculation. By default, `d=2`.

The output, `Y`, is an $(m-1)$ -by-4 matrix formatted as follows.

Column	Description
1	Mean of the heights of all the links included in the calculation.
2	Standard deviation of the heights of all the links included in the calculation.
3	Number of links included in the calculation.
4	Inconsistency coefficient.

For each link, k , the inconsistency coefficient is calculated as:

$$Y(k,4) = (z(k,3) - Y(k,1)) / Y(k,2)$$

For leaf nodes, nodes that have no further nodes under them, the inconsistency coefficient is set to 0.

Examples

Compute Inconsistency Coefficient

Create the sample data.

```
X = gallery('uniformdata',[10 2],12);  
Y = pdist(X);
```

Generate the hierarchical cluster tree.

```
Z = linkage(Y,'single');
```

Generate a dendrogram plot of the hierarchical cluster tree.

```
dendrogram(Z)
```

Compute the inconsistency coefficient for each link in the cluster tree Z to depth 3.

`W = inconsistent(Z,3)`

`W =`

Introduced before R2006a

increaseB

Class: clustering.evaluation.GapEvaluation

Package: clustering.evaluation

Increase reference data sets

Syntax

```
eva_out = increaseB(eva,nref)
```

Description

`eva_out = increaseB(eva,nref)` returns a gap criterion clustering evaluation object `eva_out` that uses the same evaluation criteria as the input object `eva` and an additional number of reference data sets as specified by `nref`.

Input Arguments

eva — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

nref — Number of additional reference data sets

positive integer value

Number of additional reference data sets, specified as a positive integer value.

Output Arguments

eva_out — Updated clustering evaluation data

clustering evaluation object

Updated clustering evaluation data, returned as a gap criterion clustering evaluation object. `eva_out` contains evaluation data obtained using the reference data sets from the input object `eva` plus a number of additional reference data sets as specified in `nref`.

`increaseB` updates the `B` property of the input object `eva` to reflect the increase in the number of reference data sets used to compute the gap criterion values. `increaseB` also updates the `CriterionValues` property with gap criterion values computed using the total number of reference data sets. `increaseB` might also update the `OptimalK` and `OptimalY` properties to reflect the optimal number of clusters and optimal clustering solution as determined using the total number of reference data sets. Additionally, `increaseB` might also update the `LogW`, `ExpectedLogW`, `StdLogW`, and `SE` properties.

Examples

Evaluate Clustering Solutions Using Additional Reference Data

Create a gap clustering evaluation object using `evalclusters`, then use `increaseB` to increase the number of reference data sets used to compute the gap criterion values.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Cluster the flower measurement data using `kmeans`, and use the gap criterion to evaluate proposed solutions of one through five clusters. Use 50 reference data sets.

```
eva = evalclusters(meas, 'kmeans', 'gap', 'klist', 1:5, 'B', 50)
```

```
eva =
```

```
GapEvaluation with properties:
```

```
NumObservations: 150
InspectedK: [1 2 3 4 5]
CriterionValues: [0.0848 0.5920 0.8750 1.0044 1.0462]
OptimalK: 5
```

The clustering evaluation object `eva` contains data on each proposed clustering solution. The returned results indicate that the optimal number of clusters is five.

The value of the **B** property of `eva` shows 50 reference data sets.

```
eva.B
```

```
ans =
```

```
    50
```

Increase the number of reference data sets by 50, for a total of 100 sets.

```
eva = increaseB(eva,50)
```

```
eva =
```

```
GapEvaluation with properties:
```

```
    NumObservations: 150
```

```
    InspectedK: [1 2 3 4 5]
```

```
    CriterionValues: [0.0824 0.5899 0.8742 1.0044 1.0463]
```

```
    OptimalK: 4
```

The returned results now indicate that the optimal number of clusters is four.

The value of the **B** property of `eva` now shows 100 reference data sets.

```
eva.B
```

```
ans =
```

```
   100
```

`evalclusters`

InputData property

Class: ProbDist

Read-only structure containing information about input data to ProbDist object

Description

`InputData` is a read-only property of the ProbDist class. `InputData` is a structure containing information about input data to a ProbDist object. It includes the following fields:

- `data`
- `cens`
- `freq`

Values

Possible values for the three fields in the structure are any data supplied to the `fitdist` function:

- `data` — Data passed to the `fitdist` function when creating the ProbDist object. This field is empty if the ProbDist object was created without fitting to data, that is by using the ProbDistUnivParam constructor.
- `cens` — The vector supplied with the `'censoring'` parameter when creating the ProbDist object using the `fitdist` function. This field is empty if the ProbDist object was created without fitting to data, that is by using the ProbDistUnivParam constructor.
- `freq` — The vector supplied with the `'frequency'` parameter when creating the ProbDist object using the `fitdist` function. This field is empty if the ProbDist object was created without fitting to data, that is by using the ProbDistUnivParam constructor.

Use this information to view and compare the data supplied to create distributions.

interactionplot

Interaction plot for grouped data

Syntax

```
interactionplot(Y,GROUP)
interactionplot(Y,GROUP,'varnames',VARNAMES)
[h,AX,bigax] = interactionplot(...)
```

Description

`interactionplot(Y,GROUP)` displays the two-factor interaction plot for the group means of matrix `Y` with groups defined by entries in the cell array `GROUP`. `Y` is a numeric matrix or vector. If `Y` is a matrix, the rows represent different observations and the columns represent replications of each observation. If `Y` is a vector, the rows give the means of each entry in the cell array `GROUP`. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or a single-column cell array of strings. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of rows as `Y`. The number of grouping variables must be greater than 1.

The interaction plot is a matrix plot, with the number of rows and columns both equal to the number of grouping variables. The grouping variable names are printed on the diagonal of the plot matrix. The plot at off-diagonal position (i,j) is the interaction of the two variables whose names are given at row diagonal (i,i) and column diagonal (j,j) , respectively.

`interactionplot(Y,GROUP,'varnames',VARNAMES)` displays the interaction plot with user-specified grouping variable names `VARNAMES`. `VARNAMES` is a character matrix or a cell array of strings, one per grouping variable. Default names are 'X1', 'X2',

`[h,AX,bigax] = interactionplot(...)` returns a handle `h` to the figure window, a matrix `AX` of handles to the subplot axes, and a handle `bigax` to the big (invisible) axes framing the subplots.

Examples

Display Interaction Plots

Randomly generate data for a response variable y .

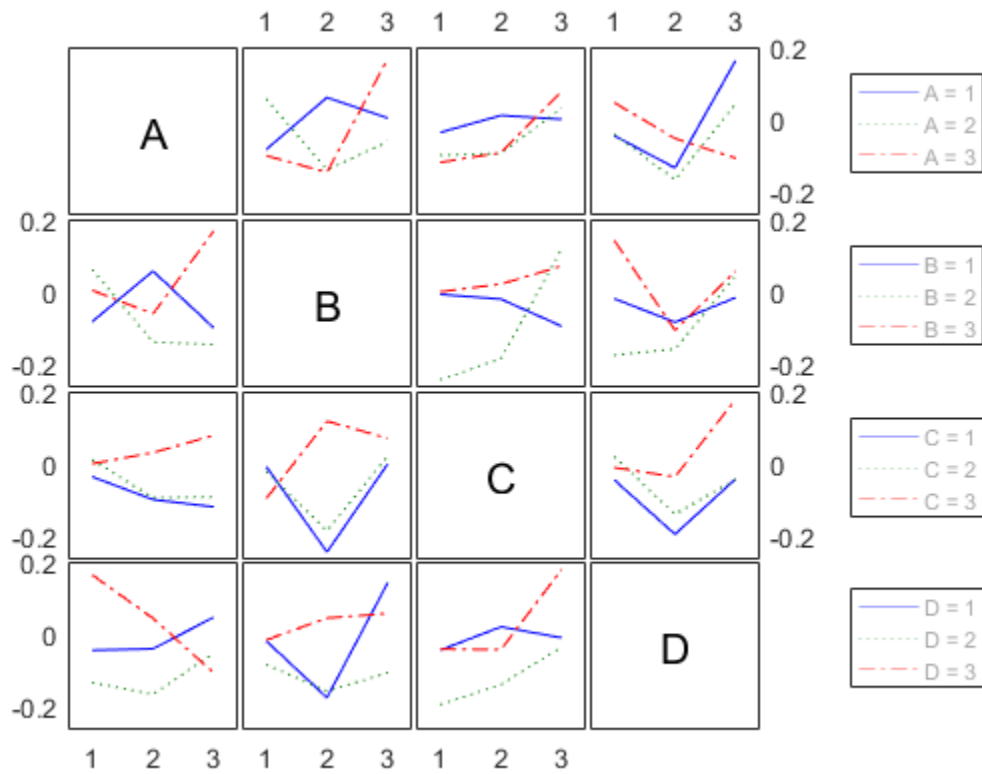

```
rng default; % For reproducibility  
y = randn(1000,1);
```

Randomly generate data for four three-level factors.

```
group = ceil(3*rand(1000,4));
```

Display the interaction plots for the factors and name the factors 'A', 'B', 'C', 'D'.

```
interactionplot(y,group,'varnames',{'A','B','C','D'})
```

Introduced in R2006b

intersect

Class: dataset

Set intersection for dataset array observations

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = intersect(A,B)
C = intersect(A,B,vars)
C = intersect(A,B,vars,setOrder)
[C,iA,iB] = intersect( __ )
```

Description

`C = intersect(A,B)` for dataset arrays **A** and **B** returns the common set of observations from the two arrays, with repetitions removed. The observations in the dataset array **C** are in sorted order.

`C = intersect(A,B,vars)` returns the set of common observations from the two arrays, considering only the variables specified in **vars**, with repetitions removed. The observations in the dataset array **C** are sorted by those variables.

The values for variables not specified in **vars** for each observation in **C** are taken from the corresponding observations in **A**. If there are multiple observations in **A** that correspond to an observation in **C**, then those values are taken from the first occurrence.

`C = intersect(A,B,vars,setOrder)` returns the observations in **C** in the order specified by **setOrder**.

`[C,iA,iB] = intersect(____)` also returns index vectors `iA` and `iB` such that `C = A(iA,:)` and `C = B(iB,:)`. If there are repeated observations in `A` or `B`, then `intersect` returns the index of the first occurrence. You can use any of the previous input arguments.

Input Arguments

A,B

Input dataset arrays.

vars

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating the variables in `A` and `B` that `intersect` considers.

Specify `vars` as `[]` to use its default value of all variables.

setOrder

Flag indicating the sorting order for the observations in `C`. The possible values of `setOrder` are:

- | | |
|----------|---|
| 'sorted' | Observations in <code>C</code> are in sorted order (default). |
| 'stable' | Observations in <code>C</code> are in the same order that they appear in <code>A</code> . |

Output Arguments

C

Dataset array with the common set of observations in `A` and `B`, with repetitions removed. `C` is in sorted order (by default), or the order specified by `setOrder`.

iA

Index vector, indicating the observations in `A` that are common to `B`. The vector `iA` contains the index to the first occurrence of any repeated observations in `A`.

iB

Index vector, indicating the observations in **B** that are common to **A**. The vector **iB** contains the index to the first occurrence of any repeated observations in **B**.

Examples

Intersection of Two Dataset Arrays

Navigate to the folder containing sample data, and load sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

```
A = dataset('XLSFile','hospitalSmall.xlsx');
B = dataset('XLSFile','hospitalSmall.xlsx','Sheet',2);
```

Return the intersection and index vectors.

```
[C,iA,iB] = intersect(A,B);
```

C =

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

There is one observation in common between **A** and **B**.

Find the observation in the original dataset arrays.

```
A(iA,:)
```

ans =

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

```
B(iB,:)
```

ans =

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

prob.InverseGaussianDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Inverse Gaussian probability distribution object

Description

`prob.InverseGaussianDistribution` is an object consisting of parameters, a model description, and sample data for an inverse Gaussian probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('InverseGaussian')` creates an inverse Gaussian probability distribution object using the default parameter values.

`pd = makedist('InverseGaussian','mu',mu,'lambda',lambda)` creates an inverse Gaussian probability distribution object using the specified parameter values.

Input Arguments

mu — Scale parameter

1 (default) | positive scalar value

Scale parameter for the inverse Gaussian distribution, specified as a positive scalar value.

Data Types: `single` | `double`

lambda — Shape parameter

1 (default) | positive scalar value

Shape parameter for the inverse Gaussian distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Properties

mu — Scale parameter

positive scalar value

Scale parameter for the inverse Gaussian distribution, stored as a positive scalar value.

Data Types: `single` | `double`

lambda — Shape parameter

positive scalar value

Shape parameter for the inverse Gaussian distribution, stored as a positive scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If **IsTruncated** equals 0, the distribution is not truncated. If **IsTruncated** equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative log likelihood of probability distribution object

paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Inverse Gaussian Distribution

Also known as the Wald distribution, the inverse Gaussian is used to model nonnegative positively skewed data. Inverse Gaussian distributions have many similarities to standard Gaussian (normal) distributions, which lead to applications in inferential statistics.

The inverse Gaussian distribution uses the following parameters.

Parameter	Description	Support
mu	Scale parameter	$\mu > 0$
lambda	Shape parameter	$\lambda > 0$

The probability density function (pdf) is

$$f(x | \mu, \lambda) = \sqrt{\frac{\lambda}{2\pi x^3}} \exp\left\{-\frac{\lambda}{2\mu^2 x}(x - \mu)^2\right\} ; \quad x > 0.$$

Examples

Create an Inverse Gaussian Distribution Object Using Default Parameters

Create an inverse Gaussian distribution object using the default parameter values.

```
pd = makedist('InverseGaussian')
```

```
pd =  
  
InverseGaussianDistribution  
  
Inverse Gaussian distribution  
    mu = 1  
    lambda = 1
```

Create an Inverse Gaussian Distribution Object Using Specified Parameters

Create an inverse Gaussian distribution object by specifying parameter values.

```
pd = makedist('InverseGaussian', 'mu', 2, 'lambda', 4)
```

```
pd =  
  
InverseGaussianDistribution  
  
Inverse Gaussian distribution  
    mu = 2  
    lambda = 4
```

Compute the standard deviation of the distribution.

```
s = std(pd)
```

```
s =  
  
1.4142
```

More About

- “Inverse Gaussian Distribution” on page B-82

- Class Attributes
- Property Attributes

invpred

Inverse prediction

Syntax

```
X0 = invpred(X,Y,Y0)
[X0,DXLO,DXUP] = invpred(X,Y,Y0)
[X0,DXLO,DXUP] = invpred(X,Y,Y0,name1,val1,name2,val2,...)
```

Description

`X0 = invpred(X,Y,Y0)` accepts vectors `X` and `Y` of the same length, fits a simple regression, and returns the estimated value `X0` for which the height of the line is equal to `Y0`. The output, `X0`, has the same size as `Y0`, and `Y0` can be an array of any size.

`[X0,DXLO,DXUP] = invpred(X,Y,Y0)` also computes 95% inverse prediction intervals. `DXLO` and `DXUP` define intervals with lower bound `X0-DXLO` and upper bound `X0+DXUP`. Both `DXLO` and `DXUP` have the same size as `Y0`.

The intervals are not simultaneous and are not necessarily finite. Some intervals may extend from a finite value to `-Inf` or `+Inf`, and some may extend over the entire real line.

`[X0,DXLO,DXUP] = invpred(X,Y,Y0,name1,val1,name2,val2,...)` specifies optional argument name/value pairs chosen from the following list. Argument names are case insensitive and partial matches are allowed.

Name	Value
'alpha'	A value between 0 and 1 specifying a confidence level of $100 \cdot (1 - \text{alpha})\%$. Default is <code>alpha=0.05</code> for 95% confidence.
'predopt'	Either 'observation', the default value to compute the intervals for <code>X0</code> at which a new observation could equal <code>Y0</code> , or 'curve' to compute intervals for the <code>X0</code> value at which the curve is equal to <code>Y0</code> .

Examples

Inverse Prediction

Generate sample data.

```
x = 4*rand(25,1);  
y = 10 + 5*x + randn(size(x));
```

Make a scatterplot of the data.

```
scatter(x,y)
```

Predict the x value for a given y value of 20.

```
x0 = invpred(x,y,20)
```

```
x0 =
```

```
1.9967
```

Introduced before R2006a

iqr

Interquartile range

Syntax

```
r = iqr(x)
r = iqr(x,dim)

r = iqr(pd)
```

Description

`r = iqr(x)` returns the interquartile range of the values in `x`.

`r = iqr(x,dim)` returns the interquartile range along the dimension of `x` specified by `dim`.

`r = iqr(pd)` returns the interquartile range of the probability distribution, `pd`.

Examples

Compute the Interquartile Range

Generate a 4-by-4 matrix of random data from a normal distribution with parameter values μ equal to 10 and σ equal to 1.

```
rng default % For reproducibility
x = normrnd(10,1,4)
```

`x =`

```
10.5377    10.3188    13.5784    10.7254
11.8339     8.6923    12.7694     9.9369
 7.7412     9.5664     8.6501    10.7147
10.8622    10.3426    13.0349     9.7950
```

Compute the interquartile range for each column of data.

```
r = iqr(x)
```

```
r =
```

```
    2.2086    1.2013    2.5969    0.8541
```

Compute the interquartile range for each row of data.

```
r2 = iqr(x,2)
```

```
r2 =
```

```
    1.7237  
    2.9870  
    1.9449  
    1.8797
```

Compute the Normal Distribution Interquartile Range

Create a standard normal distribution object with the mean, μ , equal to 0 and the standard deviation, σ , equal to 1.

```
pd = makedist('Normal',0,1);
```

Compute the interquartile range of the standard normal distribution.

```
r = iqr(pd)
```

```
r =
```

```
    1.3490
```

The returned value is the difference between the 75th and the 25th percentile values for the distribution. This is equivalent to computing the difference between the inverse cumulative distribution function (icdf) values at the probabilities y equal to 0.75 and 0.25.

```
r2 = icdf(pd,0.75) - icdf(pd,0.25)
```

```
r2 =
```

```
1.3490
```

Input Arguments

x — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `single` | `double`

dim — Dimension

1 (default) | positive integer value

Dimension along which the interquartile range is calculated, specified as a positive integer. For example, for a matrix `x`, when `dim` is equal to 1, `iqr` returns the interquartile range for the columns of `x`. When `dim` is equal to 2, `iqr` returns the interquartile range for the rows of `x`. For n -dimensional arrays, `iqr` operates along the first nonsingleton dimension of `X`.

Data Types: `single` | `double`

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
<code>dfittool</code>	Fit a probability distribution object to sample data using the interactive Distribution Fitting app.

Output Arguments

r — Interquartile range

scalar value

Interquartile range, returned as a scalar value.

- If you input a vector for **x**, then **r** is the difference between the 75th and the 25th percentiles of the sample data contained in **x**.
- If you input a matrix for **x**, then **r** is a row vector containing the difference between the 75th and the 25th percentiles of the sample data contained each column of **x**.
- If you input a probability distribution, **pd**, then the value of **r** is the difference between the values of the 75th and 25th percentile of the probability distribution.

iqr

Class: ProbDistUnivKernel

Return interquartile range (IQR) for ProbDistUnivKernel object

Syntax

$Y = \text{iqr}(PD)$

Description

$Y = \text{iqr}(PD)$ returns Y , the interquartile range for the ProbDistUnivKernel object PD . The interquartile range is the distance between the 75th and 25th percentiles.

Input Arguments

PD An object of the class ProbDistUnivKernel.

Output Arguments

Y The value of the interquartile range for the ProbDistUnivKernel object PD .

See Also

[iqr](#) | [ProbDistUnivKernel.icdf](#)

iqr

Class: ProbDistUnivParam

Return interquartile range (IQR) for ProbDistUnivParam object

Syntax

$Y = \text{iqr}(PD)$

Description

$Y = \text{iqr}(PD)$ returns Y , the interquartile range for the ProbDistUnivParam object PD . The interquartile range is the distance between the 75th and 25th percentiles.

Input Arguments

PD An object of the class ProbDistUnivParam.

Output Arguments

Y The value of the interquartile range for the ProbDistUnivParam object PD .

See Also

iqr | ProbDistUnivParam.icdf

iqr

Class: prob.TruncatableDistribution

Package: prob

Interquartile range of probability distribution object

Syntax

```
r = iqr(pd)
```

Description

`r = iqr(pd)` returns the interquartile range `r` of the probability distribution `pd`.

Input Arguments

pd — **Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Output Arguments

r — **Interquartile range**

scalar value

Interquartile range of the probability distribution, returned as a scalar value. The value of `r` is the difference between the values of the 75th and 25th percentile of the probability distribution.

Examples

Interquartile Range of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')

pd =

    NormalDistribution

    Normal distribution
      mu = 75.0083    [73.4321, 76.5846]
     sigma =  8.7202    [7.7391, 9.98843]
```

Compute the interquartile range of the fitted distribution.

```
r = iqr(pd)

r =

    11.7634
```

The returned result indicates that the difference between the 75th and 25th percentile of the students' grades is 11.7634.

Use `icdf` to determine the 75th and 25th percentiles of the students' grades.

```
y = icdf(pd,[0.25,0.75])

y =
    69.1266    80.8900
```

Calculate the difference between the 75th and 25th percentiles. This yields the same result as `iqr`.

```
y(2)-y(1)
```

```
ans =  
    11.7634
```

Use `boxplot` to visualize the interquartile range.

```
boxplot(x)
```

The top line of the box shows the 75th percentile, and the bottom line shows the 25th percentile. The center line shows the median, which is the 50th percentile.

isbranch

Class: classregtree

Test node for branch

Compatibility

`classregtree` will be removed in a future release. See `fitctree`, `fitrtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

```
ib = isbranch(t)
ib = isbranch(t,nodes)
```

Description

`ib = isbranch(t)` returns an n -element logical vector `ib` that is `true` for each branch node and `false` for each leaf node.

`ib = isbranch(t,nodes)` takes a vector `nodes` of node numbers and returns a vector of logical values for the specified nodes.

Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
```

```

4 if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5 class = virginica
6 if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7 class = virginica
8 class = versicolor
9 class = virginica

```

```
view(t)
```

Click to display: Magnification: Pruning level:

```

ib = isbranch(t)
ib =
  1
  0
  1

`classregtree` | `numnodes` | `cutvar`

isempty

Class: dataset

True for empty dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
tf = isempty(A)
```

Description

`tf = isempty(A)` returns true (1) if `A` is an empty dataset and false (0) otherwise. An empty array has no elements, that is `prod(size(A))==0`.

See Also

`size`

islevel

Determine if levels are in nominal or ordinal array

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
tf = islevel(levels,A)
```

Description

`tf = islevel(levels,A)` returns a logical array indicating which of the levels in `levels` correspond to a level in the nominal or ordinal array `A`.

Input Arguments

A — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

levels — Levels to test

string | cell array of strings | 2-D character matrix

Levels to test, specified as a string, cell array of strings, or 2-D character matrix.

Data Types: `char` | `cell`

Output Arguments

tf — Logical array

array the same size as `levels`

Logical array, returned as an array the same size as `levels`. `tf` has value `1` (true) where the corresponding element of `levels` is the label of a level in the nominal or ordinal array `A`, even if the level contains no elements. `tf` has value `0` (false) otherwise.

More About

- Using nominal Objects
- Using ordinal Objects

`isequal` | `ismember` | `nominal` | `ordinal`

Introduced in R2007a

ismember

Class: dataset

Dataset array elements that are members of set

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
LiA = ismember(A,B)  
LiA = ismember(A,B,vars)  
[LiA,LocB] = ismember( ___ )
```

Description

`LiA = ismember(A,B)` for dataset arrays `A` and `B` returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value 1 (true) in the elements that correspond to observations in `A` that are also present in `B`, and 0 (false) otherwise.

`LiA = ismember(A,B,vars)` returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value 1 (true) in the elements that correspond to observations in `A` that are also present in `B` for the variables specified in `vars` only, and 0 (false) otherwise.

`[LiA,LocB] = ismember(___)` also returns a vector the same length as `A` containing the index to the first observation in `B` that corresponds to each observation in `A`, or 0 if there is no such observation. You can use any of the previous input arguments.

Input Arguments

A

Query dataset array, containing the observations to be found in B.

B

Set dataset array. When an observation in A is found in B, for all variables or only those variables specified in `vars`, the corresponding element of `LiA` is 1.

vars

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating which variables to match observations on in A and B.

Output Arguments

LiA

Vector of logical values the same length as A. `LiA` has value 1 (true) when the corresponding observation in A is present in B. Otherwise, `LiA` has value 0 (false).

If you specify `vars`, `LiA` has value 1 when the corresponding observation in A is present in B for the variables in `vars` only.

LocB

Vector the same length as A containing the index to the first observation in B that corresponds to each observation in A, for all variables or only those variables specified in `vars`.

Examples

Find Observations That Are Members of a Dataset Array

Load sample data.

```
load('hospital')
```

```
B = hospital(1:50,1:5);
```

This set dataset array, **B**, has 50 observations on 5 variables.

Specify a query dataset array.

```
rng('default')
rIx = randsample(100,10);
A = hospital(rIx,1:5)
```

```
A =
```

ismissing

Class: dataset

Find dataset array elements with missing values

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
I = ismissing(ds)
I = ismissing(ds,Name,Value)
```

Description

`I = ismissing(ds)` returns a logical array that indicates which elements in the dataset array, `ds`, contain a missing value. By default, `ismissing` recognizes NaN as a missing value in numeric variables, '' as a missing value in string variables, and <undefined> as a missing value in categorical arrays.

- `ds2 = ds(~any(I,2),:)` creates a new dataset array containing only the complete observations in `ds`.
- `ds2 = ds(:,~any(I,1))` creates a new dataset array containing only the variables from `ds` with no missing values.

`I = ismissing(ds,Name,Value)` returns missing value indices with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ds

dataset array

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'`NumericTreatAsMissing`'

Vector of numeric values to treat as missing value indicators in floating point `ds` variables. `ismissing` always treats a NaN value as a missing value.

Default:

'`StringTreatAsMissing`'

String or cell array of strings to treat as missing value indicators in string `ds` variables. `ismissing` always treats the empty string ' ' as a missing value.

Output Arguments

`I`

Logical array indicating which elements in `ds` contain a missing value. `I` is the same size as `ds`, with value 1 for elements that contain a missing value.

See Also

`dataset` | `isempty` | `isnan` | `isundefined` | `replaceWithMissing`

isvalid

Class: grandstream

Test handle validity

Syntax

```
tf = isvalid(h)
```

Description

`tf = isvalid(h)` performs an element-wise check for validity on the handle elements of `h`. The result is a logical array of the same dimensions as `h`, where each element is the element-wise validity result.

A handle is invalid if it has been deleted or if it is an element of a handle array and has not yet been initialized.

See Also

`delete` | `grandstream`

NumIterations property

Class: `gmdistribution`

Number of iterations

Description

The number of iterations of the algorithm.

Note: This property applies only to `gmdistribution` objects constructed with `fitgmdist`.

iwishrnd

Inverse Wishart random numbers

Syntax

```
W = iwishrnd(Tau,df)
W = iwishrnd(Tau,df,DI)
[W,DI] = iwishrnd(Tau,df)
```

Description

`W = iwishrnd(Tau,df)` generates a random matrix `W` from the inverse Wishart distribution with parameters `Tau` and `df`. The inverse of `W` has the Wishart distribution with covariance matrix `Sigma = inv(Tau)` and with `df` degrees of freedom. `Tau` is a symmetric and positive definite matrix.

`W = iwishrnd(Tau,df,DI)` expects `DI` to be the transpose of the inverse of the Cholesky factor of `Tau`, so that `DI' * DI = inv(Tau)`, where `inv` is the MATLAB inverse function. `DI` is lower-triangular and the same size as `Tau`. If you call `iwishrnd` multiple times using the same value of `Tau`, it is more efficient to supply `DI` instead of computing it each time.

`[W,DI] = iwishrnd(Tau,df)` returns `DI` so you can use it as an input in future calls to `iwishrnd`.

Note that different sources use different parametrizations for the inverse Wishart distribution. This function defines the parameter `tau` so that the mean of the output matrix is `Tau / (df - d - 1)` where `d` is the dimension of `Tau`.

Introduced before R2006a

jackknife

Jackknife sampling

Syntax

```
jackstat = jackknife(jackfun,X)
jackstat = jackknife(jackfun,X,Y,...)
jackstat = jackknife(jackfun,...,'Options',option)
```

Description

`jackstat = jackknife(jackfun,X)` draws jackknife data samples from the n -by- p data array `X`, computes statistics on each sample using the function `jackfun`, and returns the results in the matrix `jackstat`. `jackknife` regards each row of `X` as one data sample, so there are n data samples. Each of the n rows of `jackstat` contains the results of applying `jackfun` to one jackknife sample. `jackfun` is a function handle specified with `@`. Row i of `jackstat` contains the results for the sample consisting of `X` with the i th row omitted:

```
s = x;
s(i,:) = [];
jackstat(i,:) = jackfun(s);
```

If `jackfun` returns a matrix or array, then this output is converted to a row vector for storage in `jackstat`. If `X` is a row vector, it is converted to a column vector.

`jackstat = jackknife(jackfun,X,Y,...)` accepts additional arguments to be supplied as inputs to `jackfun`. They may be scalars, column vectors, or matrices. `jackknife` creates each jackknife sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). Scalar data are passed to `jackfun` unchanged. Non-scalar arguments must have the same number of rows, and each jackknife sample omits the same row from these arguments.

`jackstat = jackknife(jackfun,...,'Options',option)` provides an option to perform jackknife iterations in parallel, if the Parallel Computing Toolbox is available. Set `'Options'` as a structure you create with `statset`. `jackknife` uses the following field in the structure:

`'UseParallel'` If `true` and if a `parpool` of the Parallel Computing Toolbox is open, use multiple processors to compute jackknife iterations. If the Parallel Computing Toolbox is not installed, or a `parpool` is not open, computation occurs in serial mode. Default is `false`, or serial computation.

Examples

Estimate the bias of the MLE variance estimator of random samples taken from the vector `y` using `jackknife`. The bias has a known formula in this problem, so you can compare the `jackknife` value to this formula.

```
sigma = 5;
y = normrnd(0,sigma,100,1);
m = jackknife(@var, y, 1);
n = length(y);
bias = -sigma^2 / n % known bias formula
jbias = (n - 1)*(mean(m)-var(y,1)) % jackknife bias estimate

bias =
    -0.2500

jbias =
    -0.3378
```

Introduced in R2006a

jbtest

Jarque-Bera test

Syntax

```
h = jbtest(x)
h = jbtest(x,alpha)
h = jbtest(x,alpha,mctol)
[h,p] = jbtest(____)
[h,p,jbstat,critval] = jbtest(____)
```

Description

`h = jbtest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a normal distribution with an unknown mean and variance, using the Jarque-Bera test. The alternative hypothesis is that it does not come from such a distribution. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = jbtest(x,alpha)` returns a test decision for the null hypothesis at the significance level specified by `alpha`.

`h = jbtest(x,alpha,mctol)` returns a test decision based on a p -value computed using a Monte Carlo simulation with a maximum Monte Carlo standard error less than or equal to `mctol`.

`[h,p] = jbtest(____)` also returns the p -value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,jbstat,critval] = jbtest(____)` also returns the test statistic `jbstat` and the critical value `critval` for the test.

Examples

Test for a Normal Distribution

Load the data set.

```
load carbig;
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.

```
h = jbtest(MPG)
```

```
h =
```

```
1
```

The returned value of $h = 1$ indicates that `jbtest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at a Different Significance Level

Load the data set.

```
load carbig;
```

Test the null hypothesis that car mileage in miles per gallon (MPG) follows a normal distribution across different makes of cars at the 1% significance level.

```
[h,p] = jbtest(MPG,0.01)
```

```
h =
```

```
1
```

```
p =
```

```
0.0022
```

The returned value of $h = 1$, and the returned p -value less than $\alpha = 0.01$ indicate that `jbtest` rejects the null hypothesis.

Test for a Normal Distribution Using Monte Carlo Simulation

Load the data set.

```
load carbig;
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Use a Monte Carlo simulation to obtain an exact p -value.

```
[h,p,jbstat,critval] = jbtest(MPG,[],0.0001)
h =
    1
p =
    0.0022
jbstat =
    18.2275
critval =
    5.8461
```

The returned value of `h = 1` indicates that `jbtest` rejects the null hypothesis at the default 5% significance level. Additionally, the test statistic, `jbstat`, is larger than the critical value, `critval`, which indicates rejection of the null hypothesis.

Input Arguments

x — Sample data

vector

Sample data for the hypothesis test, specified as a vector. `jbtest` treats NaN values in `x` as missing values and ignores them.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as a scalar value in the range (0,1). If `alpha` is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, `jbtest` looks up the critical value for the test in a table of precomputed values. To conduct the test at a significance level outside of these specifications, use `mctol`.

Example: 0.01

Data Types: `single` | `double`

mctol — Maximum Monte Carlo standard error

nonnegative scalar value

Maximum Monte Carlo standard error for the p -value, p , specified as a nonnegative scalar value. If you specify a value for `mctol`, `jbtest` computes a Monte Carlo approximation for p directly, rather than interpolating into a table of precomputed values. `jbtest` chooses the number of Monte Carlo replications large enough to make the Monte Carlo standard error for p less than `mctol`.

If you specify a value for `mctol`, you must also specify a value for `alpha`. You can specify `alpha` as `[]` to use the default value of 0.05.

Example: 0.0001

Data Types: `single` | `double`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If $h = 1$, this indicates the rejection of the null hypothesis at the `alpha` significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the `alpha` significance level.

p — p -value

scalar value in the range (0,1)

p -value of the test, returned as a scalar value in the range (0,1). p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

`jbtest` warns when p is not found within the tabulated range of [0.001,0.50], and returns either the smallest or largest tabulated value. In this case, you can use `mctol` to compute a more accurate p -value.

jbstat — Test statistic

nonnegative scalar value

Test statistic for the Jarque-Bera test, returned as a nonnegative scalar value.

critval — Critical value

nonnegative scalar value

Critical value for the Jarque-Bera test at the `alpha` significance level, returned as a nonnegative scalar value. If `alpha` is in the range `[0.001,0.50]`, and if the sample size is less than or equal to 2000, `jbstest` looks up the critical value for the test in a table of precomputed values. If you use `mctol`, `jbstest` determines the critical value of the test using a Monte Carlo simulation. The null hypothesis is rejected when `jbstat` > `critval`.

More About

Jarque-Bera Test

The Jarque-Bera test is a two-sided goodness-of-fit test suitable when a fully specified null distribution is unknown and its parameters must be estimated.

The test is specifically designed for alternatives in the Pearson system of distributions. The test statistic is

$$JB = \frac{n}{6} \left(s^2 + \frac{(k-3)^2}{4} \right),$$

where n is the sample size, s is the sample skewness, and k is the sample kurtosis. For large sample sizes, the test statistic has a chi-square distribution with two degrees of freedom.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the p -value.

The Monte Carlo standard error is calculated as

$$SE = \sqrt{\frac{(\hat{p})(1 - \hat{p})}{\text{mcreps}}},$$

where \hat{p} is the estimated p -value of the hypothesis test, and `mcreps` is the number of Monte Carlo replications performed. `jbtest` chooses the number of Monte Carlo replications, `mcreps`, large enough to make the Monte Carlo standard error for \hat{p} less than the value specified for `mctol`.

Algorithms

Jarque-Bera tests often use the chi-square distribution to estimate critical values for large samples, deferring to the Lilliefors test (see `lillietest`) for small samples. `jbtest`, by contrast, uses a table of critical values computed using Monte Carlo simulation for sample sizes less than 2000 and significance levels from 0.001 to 0.50. Critical values for a test are computed by interpolating into the table, using the analytic chi-square approximation only when extrapolating for larger sample sizes.

Introduced before R2006a

johnsrnd

Johnson system random numbers

Syntax

```
r = johnsrnd(quantiles,m,n)
r = johnsrnd(quantiles)
[r,type] = johnsrnd(...)
[r,type,coefs] = johnsrnd(...)
```

Description

`r = johnsrnd(quantiles,m,n)` returns an m -by- n matrix of random numbers drawn from the distribution in the Johnson system that satisfies the quantile specification given by `quantiles`. `quantiles` is a four-element vector of quantiles for the desired distribution that correspond to the standard normal quantiles $[-1.5 -0.5 0.5 1.5]$. In other words, you specify a distribution from which to draw random values by designating quantiles that correspond to the cumulative probabilities $[0.067 0.309 0.691 0.933]$. `quantiles` may also be a 2-by-4 matrix whose first row contains four standard normal quantiles, and whose second row contains the corresponding quantiles of the desired distribution. The standard normal quantiles must be spaced evenly.

Note: Because `r` is a random sample, its sample quantiles typically differ somewhat from the specified distribution quantiles.

`r = johnsrnd(quantiles)` returns a scalar value.

`r = johnsrnd(quantiles,m,n,...)` or `r = johnsrnd(quantiles,[m,n,...])` returns an m -by- n -by-... array.

`[r,type] = johnsrnd(...)` returns the type of the specified distribution within the Johnson system. `type` is 'SN', 'SL', 'SB', or 'SU'. Set `m` and `n` to zero to identify the distribution type without generating any random values.

The four distribution types in the Johnson system correspond to the following transformations of a normal random variate:

- 'SN' — Identity transformation (normal distribution)
- 'SL' — Exponential transformation (lognormal distribution)
- 'SB' — Logistic transformation (bounded)
- 'SU' — Hyperbolic sine transformation (unbounded)

`[r,type,coefs] = johnsrnd(...)` returns coefficients `coefs` of the transformation that defines the distribution. `coefs` is `[gamma, eta, epsilon, lambda]`. If `z` is a standard normal random variable and `h` is one of the transformations defined above, $r = \lambda * h((z - \text{gamma}) / \text{eta}) + \text{epsilon}$ is a random variate from the distribution `type` corresponding to `h`.

Examples

Generate Random Samples Using the Johnson System

This example shows several different approaches to using the Johnson system of flexible distribution families to generate random numbers and fit a distribution to sample data.

Generate random values with longer tails than a standard normal.

```
rng default; % For reproducibility
r = johnsrnd([-1.7 -.5 .5 1.7],1000,1);
figure;
qqplot(r);
```

Generate random values skewed to the right.

```
r = johnsrnd([-1.3 -.5 .5 1.7],1000,1);  
figure;  
qqplot(r);
```

Generate random values that match some sample data well in the right-hand tail.

```
load carbig;
qnorm = [.5 1 1.5 2];
q = quantile(Acceleration, normcdf(qnorm));
r = johnsrnd([qnorm;q],1000,1);
[q;quantile(r,normcdf(qnorm))]
```

ans =

```
16.7000    18.2086    19.5376    21.7263
16.6986    18.2220    19.9078    22.0918
```

Determine the distribution type and the coefficients.

```
[r,type,coefs] = johnsrnd([qnorm;q],0)
```

```
r =
```

```
    []
```

```
type =
```

```
SU
```

```
coefs =
```

```
    1.0920    0.5829   18.4382    1.4494

Introduced in R2006a

join

Class: dataset

Merge observations

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = join(A,B)
C = join(A,B,keys)
C = join(A,B,param1,va11,param2,va12,...)
[C,IB] = join(...)
C = join(A,B,'Type',TYPE,...)
C = join(A,B,'Type',TYPE,'MergeKeys',true,...)
[C,IA,IB] = join(A,B,'Type',TYPE,...)
```

Description

`C = join(A,B)` creates a dataset array `C` by merging observations from the two dataset arrays `A` and `B`. `join` performs the merge by first finding *key variables*, that is, pairs of dataset variables, one in `A` and one in `B`, that share the same name. Each observation in `B` must contain a unique combination of values in the key variables, and must contain all combinations of values that are present in the keys from `A`. `join` then uses these key variables to define a many-to-one correspondence between observations in `A` and those in `B`. `join` uses this correspondence to replicate the observations in `B` and combine them with the observations in `A` to create `C`.

`C = join(A,B,keys)` performs the merge using the variables specified by `keys` as the key variables in both `A` and `B`. `keys` is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

C contains one observation for each observation in **A**. Variables in **C** include all of the variables from **A**, as well as one variable corresponding to each variable in **B** (except for the keys from **B**). If **A** and **B** contain variables with identical names, `join` adds the suffix `'_left'` and `'_right'` to the corresponding variables in **C**.

`C = join(A,B,param1,va11,param2,va12,...)` specifies optional parameter name/value pairs to control how the dataset variables in **A** and **B** are used in the merge. Parameters are:

- `'Keys'` — Specifies the variables to use as keys in both **A** and **B**.
- `'LeftKeys'` — Specifies the variables to use as keys in **A**.
- `'RightKeys'` — Specifies the variables to use as keys in **B**.

You may provide either the `'Keys'` parameter, or both the `'LeftKeys'` and `'RightKeys'` parameters. The value for these parameters is a positive integer, a vector of positive integers, a variable name, a cell array containing variable names, or a logical vector. `'LeftKeys'` or `'RightKeys'` must both specify the same number of key variables, and `join` pairs the left and right keys in the order specified.

- `'LeftVars'` — Specifies which variables from **A** to include in **C**. By default, `join` includes all variables from **A**.
- `'RightVars'` — Specifies which variables from **B** to include in **C**. By default, `join` includes all variables from **B** except the key variables.

You can use `'LeftVars'` or `'RightVars'` to include or exclude key variables as well as data variables. The value for these parameters is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

`[C,IB] = join(...)` returns an index vector **IB**, where `join` constructs **C** by horizontally concatenating `A(:,LeftVars)` and `B(IB,RightVars)`. `join` can also perform more complicated inner and outer join operations that allow a many-to-many correspondence between **A** and **B**, and allow unmatched observations in either **A** or **B**.

`C = join(A,B,'Type',TYPE,...)` performs the join operation specified by **TYPE**. **TYPE** is one of `'inner'`, `'leftouter'`, `'rightouter'`, `'fullouter'`, or `'outer'` (which is a synonym for `'fullouter'`). For an inner join, **C** only contains observations corresponding to a combination of key values that occurred in both **A** and **B**. For a left (or right) outer join, **C** also contains observations corresponding to keys in **A** (or **B**) that did not match any in **B** (or **A**). Variables in **C** taken from **A** (or **B**) contain null values in those observations. A full outer join is equivalent to a left and right outer join. **C** contains

variables corresponding to the key variables from both A and B, and `join` sorts the observations in C by the key values.

For inner and outer joins, C contains variables corresponding to the key variables from both A and B by default, as well as all the remaining variables. `join` sorts the observations in the result C by the key values.

`C = join(A,B, 'Type', TYPE, 'MergeKeys', true, ...)` includes a single variable in C for each key variable pair from A and B, rather than including two separate variables. For outer joins, `join` creates the single variable by merging the key values from A and B, taking values from A where a corresponding observation exists in A, and from B otherwise. Setting the 'MergeKeys' parameter to `true` overrides inclusion or exclusion of any key variables specified via the 'LeftVars' or 'RightVars' parameter. Setting the 'MergeKeys' parameter to `false` is equivalent to not passing in the 'MergeKeys' parameter.

`[C, IA, IB] = join(A,B, 'Type', TYPE, ...)` returns index vectors IA and IB indicating the correspondence between observations in C and those in A and B. For an inner join, `join` constructs C by horizontally concatenating A(IA, LeftVars) and B(IB, RightVars). For an outer join, IA or IB may also contain zeros, indicating the observations in C that do not correspond to observations in A or B, respectively.

Examples

Create a dataset array from Fisher's iris data:

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'}, num2str((1:NumObs)', '%-d'));
iris = dataset({nominal(species), 'species'}, ...
              {meas, 'SL', 'SW', 'PL', 'PW'}, ...
              'ObsNames', NameObs);
```

Create a separate dataset array with the diploid chromosome counts for each species of iris:

```
snames = nominal({'setosa'; 'versicolor'; 'virginica'});
CC = dataset({snames, 'species'}, {[38; 108; 70], 'cc'})
CC =
    species      cc
    setosa       38
    versicolor   108
```

```
virginica      70
```

Broadcast the data in `CC` to the rows of `iris` using the key variable `species` in each dataset:

```
iris2 = join(iris,CC);
iris2([1 2 51 52 101 102],:)
ans =
```

	species	SL	SW	PL	PW	cc
Obs1	setosa	5.1	3.5	1.4	0.2	38
Obs2	setosa	4.9	3	1.4	0.2	38
Obs51	versicolor	7	3.2	4.7	1.4	108
Obs52	versicolor	6.4	3.2	4.5	1.5	108
Obs101	virginica	6.3	3.3	6	2.5	70
Obs102	virginica	5.8	2.7	5.1	1.9	70

Create two datasets and join them using the `'MergeKeys'` flag:

```
% Create two data sets that both contain the key variable
% 'Key1'. The two arrays contain observations with common
% values of Key1, but each array also contains observations
% with values of Key1 not present in the other.
a = dataset({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...
    'VarNames',{'Key1' 'Var1'})
b = dataset({'a' 'b' 'd' 'e'},[4 5 6 7]',...
    'VarNames',{'Key1' 'Var2'})

% Combine a and b with an outer join, which matches up
% observations with common key values, but also retains
% observations whose key values don't have a match.
% Keep the key values as separate variables in the result.
couter = join(a,b,'key','Key1','Type','outer')

% Join a and b, merging the key values as a single variable
% in the result.
coutermerge = join(a,b,'key','Key1','Type','outer',...
    'MergeKeys',true)

% Join a and b, retaining only observations whose key
% values match.
cinner = join(a,b,'key','Key1','Type','inner',...

KDTreeSearcher

Grow *Kd*-tree

Syntax

```
Mdl = KDTreeSearcher(X)
Mdl = KDTreeSearcher(X,Name,Value)
```

Description

`Mdl = KDTreeSearcher(X)` grows a default *Kd*-tree (`Mdl`) using the n -by- K numeric matrix of training data (`X`). `Mdl` is a `KDTreeSearcher` model object that stores the results of the grown *Kd*-tree. You can use `Mdl` to search the training data (`X`) for the nearest neighbors to the query data.

`Mdl = KDTreeSearcher(X,Name,Value)` grows a *Kd*-tree (`Mdl`) with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify a distance metric or the maximum number of observations in each leaf node (i.e., the bucket size).

Examples

Grow a Default *K d*-Tree

Load Fisher's iris data set.

```
load fisheriris
X = meas;
[n,k] = size(X)
```

```
n =
```

```
150
```

```
k =
    4
```

X has 150 observations and 4 predictors.

Grow a 4-dimensional K d-tree using the entire data set as training data.

```
Mdl = KDTreeSearcher(X)
```

```
Mdl =
```

```
KDTreeSearcher with properties:
```

```
    BucketSize: 50
    Distance: 'euclidean'
    DistParameter: []
    X: [150x4 double]
```

Mdl is a KDTreeSearcher model object, and its properties appear in the Command Window. It contains information about the grown 4-dimensional K d-tree, such as the distance metric. You can alter property values using dot notation

To find the nearest neighbors in X to a batch of query data, pass Mdl and the query data to knnsearch or rangesearch.

Specify the Minkowski Distance for Nearest Neighbor Search

Load Fisher's iris data. Focus on the petal dimensions.

```
load fisheriris
X = meas(:, [3 4]); % Predictors
```

Grow a two-dimensional K d-tree using createns and the training data. Specify the Minkowski distance metric.

```
Mdl = createns(X, 'NSMethod', 'kdtree', 'Distance', 'Minkowski')
```

```
Mdl =
```

KDTreeSearcher with properties:

```
    BucketSize: 50
      Distance: 'minkowski'
  DistParameter: 2
           X: [150x2 double]
```

Mdl is a KDTreeSearcher model object. Access properties of Mdl using dot notation. For example, use Mdl.DistParameter to access the Minkowski distance exponent.

```
Mdl.DistParameter
```

```
ans =
```

```
    2
```

You can pass query data and Mdl to:

- knnsearch to find indices and distances of nearest neighbors.
- rangearch to find indices of all nearest neighbors within a distance that you specify.

Search for Nearest Neighbors of Query Data Using the Minkowski Distance

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
tIdx = ~ismember(1:n,qIdx); % Indices of training data
Q = meas(qIdx,:);
X = meas(tIdx,:);
```

Grow a four-dimensional K d-tree using the training data. Specify to use the Minkowski distance for finding nearest neighbors later.

```
Mdl = createns(X, 'NSMethod', 'kdtree', 'Distance', 'minkowski')
```

```

Mdl =
    KDTreearcher with properties:
        BucketSize: 50
        Distance: 'minkowski'
        DistParameter: 2
        X: [145x4 double]

```

Mdl is a `KDTreearcher` model object. By default, the Minkowski distance exponent is 2.

Find the indices of the training data (X) that are the two nearest neighbors of each point in the query data (Q).

```
IdxNN = knnsearch(Mdl,Q,'K',2)
```

```

IdxNN =
     17     4
     6     2
     1    12
    89    66
   124   100

```

Each row of NN corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors. For example, using the Minkowski distance, the second nearest neighbor of $Q(3, :)$ is $X(12, :)$.

Input Arguments

X — Training data

numeric matrix

Training data that grows the Kd -tree, specified as a numeric matrix. X has n rows, each corresponding to an observation (i.e., an instance or example), and K columns, each corresponding to a predictor or feature.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Distance', 'minkowski', 'P', 3, 'BucketSize', 10` specifies to use the Minkowski distance when searching for nearest neighbors, to use 3 for the Minkowski distance metric exponent, and to use 10 for the bucket size.

'Distance' — Distance metric

`'euclidean'` (default) | `'chebychev'` | `'cityblock'` | `'minkowski'`

Distance metric used to find nearest neighbors of query points, specified as the comma-separated pair consisting of `'Distance'` and one of these strings.

Value	Description
<code>'chebychev'</code>	Chebychev distance (maximum coordinate difference)
<code>'cityblock'</code>	City block distance
<code>'euclidean'</code>	Euclidean distance
<code>'minkowski'</code>	Minkowski distance

For more details, see “Distance Metrics” on page 17-10.

The software does not use the distance metric for training the *Kd*-tree, so you can alter it after training using dot notation.

Example: `'Distance', 'minkowski'`

Data Types: char

'P' — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of `'P'` and a positive scalar. If you specify `P` and do not specify `'Distance', 'minkowski'`, then the software throws an error.

Example: `'P', 3`

Data Types: `double` | `single`

'BucketSize' – Maximum number of data points in each leaf node

50 (default) | positive integer

Maximum number of data points in each leaf node of the *Kd*-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer.

Example: `'BucketSize',10`

Data Types: `double` | `single`

Output Arguments

Md1 – Grown *Kd*-tree

KDTreeSearcher model object

Grown *Kd*-tree, returned as a KDTreeSearcher model object. To search the training data for the nearest neighbors of the query data, pass the query data and `Md1` to `knnsearch` or `rangearch`.

Introduced in R2010a

Using KDTreeSearcher Objects

Nearest neighbor search using *Kd*-tree

Description

`KDTreeSearcher` model objects store results of a nearest neighbors search using the *Kd*-tree algorithm. Results that you can store include the training data, the distance metric and its parameters, and the maximal number of data points in each leaf node (i.e., the bucket size). The *Kd*-tree algorithm partitions an n -by- K data set by recursively splitting n points in K -dimensional space into a binary tree. To find the nearest neighbors of a query observation, `KDTreeSearcher` restricts the training data space to the training observations in the leaf node that the query observation belongs to.

Once you create or train a `KDTreeSearcher` model object, you can search the stored tree to find all neighboring points to the query data by performing a nearest neighbors search using `knnsearch` or radius search using `rangesearch`. The *Kd*-tree algorithm is particularly useful when:

- K is relatively small (i.e., $K < 10$).
- The training and query sets are not sparse.
- The training and query sets have many observations.

Examples

Grow a Default K d-Tree

Load Fisher's iris data set.

```
load fisheriris
X = meas;
[n,k] = size(X)
```

```
n =
```

```
150
```

```
k =  
    4
```

X has 150 observations and 4 predictors.

Grow a 4-dimensional K d-tree using the entire data set as training data.

```
Mdl = KDTreeSearcher(X)
```

```
Mdl =  
    KDTreeSearcher with properties:  
        BucketSize: 50  
        Distance: 'euclidean'  
        DistParameter: []  
        X: [150x4 double]
```

Mdl is a KDTreeSearcher model object, and its properties appear in the Command Window. It contains information about the grown 4-dimensional K d-tree, such as the distance metric. You can alter property values using dot notation

To find the nearest neighbors in X to a batch of query data, pass Mdl and the query data to knnsearch or rangesearch.

Alter Properties of KDTreeSearcher Model

Load Fisher's iris data set.

```
load fisheriris  
X = meas;
```

Grow a default four-dimensional K d-tree using the entire data set as training data.

```
Mdl = KDTreeSearcher(X)
```

```
Mdl =  
    KDTreeSearcher with properties:  
        BucketSize: 50
```

```
Distance: 'euclidean'  
DistParameter: []  
X: [150x4 double]
```

Specify that the neighbor searcher use the Minkowski metric to compute the distances between the training and query data.

```
Mdl.Distance = 'minkowski'
```

```
Mdl =
```

```
KDTreeSearcher with properties:
```

```
BucketSize: 50  
Distance: 'minkowski'  
DistParameter: 2  
X: [150x4 double]
```

Pass `Mdl` and the query data to either `knnsearch` or `rangesearch` to find the nearest neighbors to the points in the query data using the Minkowski distance.

Search for Nearest Neighbors of Query Data Using the Minkowski Distance

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1); % For reproducibility  
n = size(meas,1); % Sample size  
qIdx = randsample(n,5); % Indices of query data  
tIdx = ~ismember(1:n,qIdx); % Indices of training data  
Q = meas(qIdx,:);  
X = meas(tIdx,:);
```

Grow a four-dimensional K d-tree using the training data. Specify to use the Minkowski distance for finding nearest neighbors later.

```
Mdl = createns(X, 'NSMethod', 'kdtree', 'Distance', 'minkowski')
```

```
Mdl =
```

KDTreeSearcher with properties:

```

    BucketSize: 50
      Distance: 'minkowski'
    DistParameter: 2
          X: [145x4 double]

```

Mdl is a KDTreeSearcher model object. By default, the Minkowski distance exponent is 2.

Find the indices of the training data (X) that are the two nearest neighbors of each point in the query data (Q).

```
IdxNN = knnsearch(Mdl,Q,'K',2)
```

IdxNN =

```

    17     4
     6     2
     1    12
    89    66
   124   100

```

Each row of NN corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors. For example, using the Minkowski distance, the second nearest neighbor of Q(3, :) is X(12, :).

Properties

Distance — Distance metric

'chebychev' | 'cityblock' | 'euclidean' | 'minkowski'

Distance metric used to find nearest neighbors of query points, specified as one of these strings.

Value	Description
'chebychev'	Chebychev distance (maximum coordinate difference)

Value	Description
'cityblock'	City block distance
'euclidean'	Euclidean distance
'minkowski'	Minkowski distance

For more details, see “Distance Metrics” on page 17-10.

The software does not use the distance metric for training the *Kd*-tree, so you can alter it after training using dot notation.

Data Types: char

DistParameter — Distance metric parameter values

[] | positive scalar

Distance metric parameter values, specified as empty ([]) or as a positive scalar.

If `Distance` is 'minkowski', then:

- `DistParameter` is the exponent in the Minkowski distance formula.
- You can alter `DistParameter` of a trained `KDTreeSearcher` model.

Otherwise, `DistParameter` is [], indicating that the specified distance metric formula has no parameters.

Data Types: single | double

X — Training data

numeric matrix

This property is read only.

Training data that grows the *Kd*-tree, specified as a numeric matrix. `X` has n rows, each corresponding to an observation (i.e., an instance or example), and K columns, each corresponding to a predictor or feature.

Data Types: single | double

Object Functions

`knnsearch`

k-nearest neighbors search using *Kd*-tree or exhaustive search

rangesearch

Find all neighbors within specified distance using exhaustive search or Kd-tree

Create Object

Train a KDTreeSearcher model object using KDTreeSearcher or createns.

Kernel property

Class: ProbDistKernel

Read-only string specifying name of kernel smoothing function for ProbDistKernel object

Description

`Kernel` is a read-only property of the ProbDistKernel class. `Kernel` is a string specifying the name of the kernel smoothing function used to create a ProbDistKernel object.

Values

'normal'
'box'
'triangle'
'epanechnikov'

Use this information to view and compare the kernel smoothing function used to create distributions.

See Also

`ksdensity`

prob.KernelDistribution class

Package: prob

Superclasses: prob.TruncatableDistribution

Kernel probability distribution object

Description

prob.KernelDistribution is an object consisting of parameters, a model description, and sample data for a nonparametric kernel-smoothing distribution. Create a prob.KernelDistribution object using `fitdist` or `dfittool`.

Construction

`pd = fitdist(x, 'Kernel')` creates a probability distribution object by fitting a kernel-smoothing distribution to the data in `x`.

`pd = fitdist(x, 'Kernel', Name, Value)` creates a probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can change the kernel function or specify the kernel bandwidth.

Input Arguments

x — Input data

column vector

Input data to fit with a kernel-smoothing distribution, specified as a column vector of scalar values. `fitdist` ignores NaN values in `x`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Kernel' — Kernel smoother type`'normal' (default) | 'box' | 'triangle' | 'epanechnikov'`

Kernel smoother type, specified as the comma-separated pair consisting of `'Kernel'` and one of the following kernel smoothing function types:

- `'normal'`
- `'box'`
- `'triangle'`
- `'epanechnikov'`

'Support' — Kernel density support`'unbounded' (default) | 'positive' | two-element vector`

Kernel density support, specified as the comma-separated pair consisting of `'Support'` and a string or two-element vector. The string must be one of the following.

<code>'unbounded'</code>	Density can extend over the whole real line.
<code>'positive'</code>	Density is restricted to positive values.

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

Data Types: `single` | `double`

'Width' — Bandwidth of kernel smoothing window`scalar value`

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of `'Width'` and a scalar value. The default value used by `fitdist` is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes.

Data Types: `single` | `double`

Properties

Kernel — Kernel smoother type`'normal' | 'box' | 'triangle' | 'epanechnikov'`

Kernel function type, stored as a valid kernel function type name.

BandWidth — Bandwidth of kernel smoothing window

positive scalar value

Bandwidth of the kernel smoothing window, stored as a positive scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single` | `double`

Methods

<code>mean</code>	Mean of probability distribution object
<code>negloglik</code>	Negative loglikelihood
<code>std</code>	Standard deviation of probability distribution object
<code>var</code>	Variance of probability distribution object

Inherited Methods

<code>cdf</code>	Cumulative distribution function of probability distribution object
<code>icdf</code>	Inverse cumulative distribution function of probability distribution object
<code>iqr</code>	Interquartile range of probability distribution object
<code>median</code>	Median of probability distribution object
<code>pdf</code>	Probability density function of probability distribution object
<code>random</code>	Generate random numbers from probability distribution object
<code>truncate</code>	Truncate probability distribution object

Definitions

Kernel Distribution

The kernel distribution is a nonparametric estimation of the probability density function (pdf) of a random variable.

The kernel distribution uses the following options.

Option	Description	Possible Values
Kernel	Kernel function type	normal, box, triangle, epanechnikov
BandWidth	Kernel smoothing parameter	BandWidth > 0

The kernel density estimator is

$$\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x-x_i}{h}\right) ; \quad -\infty < x < \infty ,$$

where n is the sample size, $K(\cdot)$ is the kernel function, and h is the bandwidth.

Examples

Fit a Kernel Distribution Object to Data

Load the sample data. Visualize the patient weight data using a histogram.

```
load hospital
histogram(hospital.Weight)
```

The histogram shows that the data has two modes, one for female patients and one for male patients.

Create a probability distribution object by fitting a kernel distribution to the patient weight data.

```
pd_kernel = fitdist(hospital.Weight, 'Kernel')
```

```
pd_kernel =
```

```
KernelDistribution
```

```
Kernel = normal
```

```
Bandwidth = 14.3792  
Support = unbounded
```

For comparison, create another probability distribution object by fitting a normal distribution to the patient weight data.

```
pd_normal = fitdist(hospital.Weight, 'Normal')
```

```
pd_normal =  
  
NormalDistribution  
  
Normal distribution  
    mu =    154    [148.728, 159.272]  
    sigma = 26.5714 [23.3299, 30.8674]
```

Define the x values and compute the pdf of each distribution.

```
x = 50:1:250;  
pdf_kernel = pdf(pd_kernel,x);  
pdf_normal = pdf(pd_normal,x);
```

Plot the pdf of each distribution.

```
plot(x,pdf_kernel, 'Color', 'b', 'LineWidth',2);  
hold on;  
plot(x,pdf_normal, 'Color', 'r', 'LineStyle', ':', 'LineWidth',2);  
legend('Kernel Distribution', 'Normal Distribution', 'Location', 'SouthEast');  
hold off;
```

Fitting a kernel distribution instead of a unimodal distribution such as the normal reveals the separate modes for the female and male patients.

kfoldEdge

Class: ClassificationPartitionedECOC

Classification edge for observations not used for training

Syntax

```
edge = kfoldEdge(CVMdl)
edge = kfoldEdge(CVMdl,Name,Value)
```

Description

`edge = kfoldEdge(CVMdl)` returns the classification edge obtained by the cross-validated ECOC model (ClassificationPartitionedECOC) `CVMdl`. For every fold, `kfoldEdge` computes the classification edge for in-fold observations using an ECOC model trained on out-of-fold observations. `CVMdl.X` contains both sets of observations.

`edge = kfoldEdge(CVMdl,Name,Value)` returns the classification edge with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the number of folds, decoding scheme, or verbosity level.

Input Arguments

CVMdl — Cross-validated ECOC model

ClassificationPartitionedECOC model

Cross-validated ECOC model, specified as a ClassificationPartitionedECOC model. You can create a ClassificationPartitionedECOC model by:

- Passing a trained ECOC model (ClassificationECOC) to `crossval`
- Training an ECOC model using `fitcecoc` and setting any one of these cross-validation name-value pair arguments: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge'
| 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
where:
```

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 25-4317.

By default, if all binary learners are:

- SVMs or linear classification models of SVM learners, then `BinaryLoss` is 'hinge'
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is 'exponential'
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is 'binodeviance'
- Linear classification models of logistic regression learners, or you specify to predict class posterior probabilities (i.e., set 'FitPosterior', 1 in `fitcecoc`), then `BinaryLoss` is 'quadratic'

Otherwise, the default `BinaryLoss` is 'hamming'. To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | function_handle

'Decoding' — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the “Binary Loss” on page 25-4314, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'.

Example: 'Decoding', 'lossbased'

Data Types: char

'Folds' — Fold indices for prediction

1:Mdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from 1 through `Mdl.KFold`.

The software only uses the folds specified in `Folds` for prediction.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

'Mode' — Edge aggregation level

'average' (default) | 'individual'

Edge meaning, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

This table describes the values.

Value	Description
'average'	edge is the scalar average over all folds.
'individual'	edge is a vector of length k containing one edge per fold. k is the number of folds.

Example: `'Mode','individual'`

Data Types: `char`

'Options' — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments

edge — Classification edge

numeric scalar | numeric row vector

Classification edge, returned as a numeric scalar or numeric row vector.

If `Mode` is 'average', then `edge` is the average classification edge among all binary learners. Otherwise, `edge` is a 1-by-L numeric row vector containing the classification edge for each, respective binary learner, where L is the number of binary learners (`size(CVMdl.CodingMatrix,2)`).

Data Types: single | double

Definitions

Classification Edge

The *classification edge* is the weighted mean of the *classification margins*.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the true class and maximal negative loss among the false classes. If the margins

are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_i, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of predict and loss), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Estimate k -Fold Cross-Validation Edge of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize', 1);
CVMdl = fitcecoc(X, Y, 'CrossVal', 'on', 'Learners', t, 'ClassNames', classOrder);
```

CVMD1 is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the out-of-fold edges.

```
edge = kfoldEdge(CVMD1)
```

```
edge =
```

```
    0.4825
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode', 'individual' in `kfoldEdge`.

Display Individual Edges for Each Cross-Validation Fold

The classification edge is a relative measure of classifier quality. You can determine ill-performing folds by displaying the edges for each fold.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to use 8-fold cross validation. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMD1 = fitcecoc(X,Y,'KFold',8,'Learners',t,'ClassNames',classOrder);
```

Estimate the classification edge for each fold.

```
edges = kfoldEdge(CVMD1,'Mode','individual')
```

```
edges =
```

```
    0.4790
```

```
0.4872
0.4260
0.5301
0.5064
0.4575
0.4860
0.4687
```

The edges have similar magnitudes across folds. Ill-performing folds have low edges relative to the other folds.

You can return the classification edge for the entire model by specifying the well-performing folds using the 'Folds' name-value pair argument.

Select ECOC Model Features by Comparing Cross-Validation Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare cross-validation edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the petal dimensions.

```
fullX = X;
partX = X(:,3:4);
```

Train an ECOC model using SVM binary classifiers for each predictor set, and specify to cross validate. It is good practice to define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

```
PCVMdl = fitcecoc(partX,Y,'CrossVal','on','Learners',t,...  
    'ClassNames',classOrder);
```

CVMDL and PCVMdl are ClassificationPartitionedECOC models. By default, the software implements 10-fold cross validation.

Estimate the test-sample edge for each classifier.

```
fullEdge = kfoldEdge(CVMDL)  
partEdge = kfoldEdge(PCVMdl)
```

```
fullEdge =
```

```
    0.4825
```

```
partEdge =
```

```
    0.4951
```

PCVMdl achieves an edge that is similar to the more complex model CVMDL.

kfoldEdge

Class: ClassificationPartitionedEnsemble

Classification edge for observations not used for training

Syntax

```
E = kfoldEdge(obj)
E = kfoldEdge(obj, Name, Value)
```

Description

`E = kfoldEdge(obj)` returns classification edge (average classification margin) obtained by cross-validated classification ensemble `obj`. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

`E = kfoldEdge(obj, Name, Value)` calculates edge with additional options specified by one or more `Name, Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Input Arguments

ens

Object of class `ClassificationPartitionedEnsemble`. Create `ens` with `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `ens` from a classification ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'folds'

Indices of folds ranging from 1 to `ens.KFold`. Use only these folds for predictions.

Default: `1:ens.KFold`

'mode'

String representing the meaning of the output `edge`:

- `'average'` — `edge` is a scalar value, the average over all folds.
- `'individual'` — `edge` is a vector of length `ens.KFold` with one element per fold.
- `'cumulative'` — `edge` is a vector of length `min(ens.NTrainedPerFold)` in which element `J` is obtained by averaging values across all folds for weak learners `1:J` in each fold.

Default: `'average'`

Output Arguments

E

The average classification margin. `E` is a scalar or vector, depending on the setting of the `mode` name-value pair.

Definitions

Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `obj.Prior`.

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. `Margin` is a column vector with the same number of rows as in the matrix `obj.X`.

Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

Examples

Compute the k-fold edge for an ensemble trained on the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
cvens = crossval(ens);
E = kfoldEdge(cvens)
```

```
E =
    3.2078
```

kfoldEdge

Class: ClassificationPartitionedLinear

Classification edge for observations not used for training

Syntax

```
e = kfoldEdge(CVMd1)
e = kfoldEdge(CVMd1,Name,Value)
```

Description

`e = kfoldEdge(CVMd1)` returns the cross-validated classification edges obtained by the cross-validated, binary, linear classification model `CVMd1`. That is, for every fold, `kfoldEdge` estimates the classification edge for observations that it holds out when it trains using all other observations.

`e` contains a classification edge for each regularization strength in the linear classification models that comprise `CVMd1`.

`e = kfoldEdge(CVMd1,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, indicate which folds to use for the edge calculation.

Input Arguments

CVMd1 — Cross-validated, binary, linear classification model

ClassificationPartitionedLinear model object

Cross-validated, binary, linear classification model, specified as a ClassificationPartitionedLinear model object. You can create a ClassificationPartitionedLinear model using `fitlinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, ClassificationPartitionedLinear.kfoldEdge applies the same data used to cross-validate the linear classification model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Folds' — Fold indices to use for classification-score prediction

1:CVMD1.KFold (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from 1 through `CVMD1.KFold`.

Example: `'Folds', [1 4 10]`

Data Types: `single` | `double`

'Mode' — Edge aggregation level

'average' (default) | 'individual'

Edge aggregation level, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

Value	Description
'average'	Returns classification edges averaged over all folds
'individual'	Returns classification edges for each fold

Example: `'Mode', 'individual'`

Data Types: `char`

Output Arguments

e — Cross-validated classification edges

numeric scalar | numeric vector | numeric matrix

Cross-validated classification edges, returned as a numeric scalar, vector, or matrix.

Let L be the number of regularization strengths in the cross-validated models (stored in `numel(CVMdl.Trained{1}.Lambda)`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is 'average', then \mathbf{e} is a 1-by- L vector. $\mathbf{e}(j)$ is the average classification edge over all folds of the cross-validated model that uses regularization strength j .
- Otherwise, \mathbf{e} is an F -by- L matrix. $\mathbf{e}(i, j)$ is the classification edge for fold i of the cross-validated model that uses regularization strength j .

To estimate \mathbf{e} , `kfoldEdge` uses the data that created `CVMdl` (see X and Y).

Definitions

Classification Edge

The *classification edge* is the weighted mean of the *classification margins*.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The *classification margins* for binary classification are, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The literature commonly defines the margin as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Classification Score

For linear classification models, the raw *classification score* for classifying the observation x , a row vector, into the positive class is

$$f(x_j) = x\beta_j + b_j.$$

For the model with regularization strength j , β_j is the estimated column vector of coefficients (the model property `Beta(:,j)`) and b_j be the estimated, scalar bias (the model property `Bias(j)`).

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Examples

Estimate k -Fold Cross-Validation Edge

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility  
CVMdl = fitlinear(X,Ystats,'CrossVal','on');
```

CVMD1 is a `ClassificationPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the out-of-fold edges.

```
e = kfoldEdge(CVMD1)
```

```
e =
```

```
8.1243
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode', 'individual' in `kfoldEdge`.

Feature Selection Using *k*-fold Edges

One way to perform feature selection is to compare *k*-fold edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the NLP data set. Preprocess the data as in “Estimate *k*-Fold Cross-Validation Edge”.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Cross-validate two binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Solve the objective function using `SparSA`, and indicate that observations correspond to columns.

```
CVMD1 = fitlinear(fullX,Ystats,'CrossVal','on','Solver','sparsa',...
    'ObservationsIn','columns');
```

```
PCVMdl = fitlinear(partX,Ystats,'CrossVal','on','Solver','sparsa',...  
    'ObservationsIn','columns');
```

CVMD1 and PCVMD1 are ClassificationPartitionedLinear models.

Estimate the k -fold edge for each classifier.

```
fullEdge = kfoldEdge(CVMD1)  
partEdge = kfoldEdge(PCVMD1)
```

```
fullEdge =  
  
    16.5629
```

```
partEdge =  
  
    13.9030
```

Based on the k -fold edges, the classifier that uses all of the predictors is the better model.

Find Good Lasso Penalty Using k -fold Edge

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare k -fold edges.

Load the NLP data set. Preprocess the data as in “Estimate k -Fold Cross-Validation Edge”.

```
load nlpdata  
Ystats = Y == 'stats';  
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-8} through 10^1 .

```
Lambda = logspace(-8,1,11);
```

Cross-validate a binary, linear classification model using 5-fold cross-validation and that uses each of the regularization strengths. Solve the objective function using SpARSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
rng(10); % For reproducibility  
CVMD1 = fitlinear(X,Ystats,'ObservationsIn','columns','KFold',5,...  
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
```

```
'Lambda', Lambda, 'GradientTolerance', 1e-8)
```

```
CVMd1 =
```

```
classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 5
  Partition: [1x1 cvpartition]
  ClassNames: [0 1]
  ScoreTransform: 'none'
```

CVMd1 is a `ClassificationPartitionedLinear` model. Because `fitlinear` implements 5-fold cross-validation, CVMd1 contains 5 `ClassificationLinear` models that the software trains on each fold.

Estimate the edges for each fold and regularization strength.

```
eFolds = kfoldEdge(CVMd1, 'Mode', 'individual')
```

```
eFolds =
```

```
Columns 1 through 7
```

0.9958	0.9958	0.9958	0.9958	0.9958	0.9923	0.9770
0.9990	0.9990	0.9990	0.9990	0.9990	0.9937	0.9780
0.9992	0.9992	0.9992	0.9992	0.9992	0.9943	0.9781
0.9974	0.9974	0.9974	0.9974	0.9974	0.9931	0.9772
0.9977	0.9977	0.9977	0.9977	0.9977	0.9942	0.9781

```
Columns 8 through 11
```

0.9167	0.8444	0.8127	0.8127
0.9181	0.8262	0.8128	0.8128
0.9141	0.8253	0.8128	0.8128
0.9203	0.8460	0.8130	0.8130
0.9199	0.8415	0.8127	0.8127

`eFolds` is a 5-by-11 matrix of edges. Rows correspond to folds and columns correspond to regularization strengths in `Lambda`. You can use `eFolds` to identify ill-performing folds, that is, unusually low edges.

Estimate the average edge over all folds for each regularization strength.

```
e = kfoldEdge(CVMdl)
```

```
e =
```

```
Columns 1 through 7
```

```
    0.9978    0.9978    0.9978    0.9978    0.9978    0.9935    0.9777
```

```
Columns 8 through 11
```

```
    0.9178    0.8367    0.8128    0.8128
```

Determine how well the models generalize by plotting the averages of the 5-fold edge for each regularization strength. Identify the regularization strength that maximizes the 5-fold edge over the grid.

```
figure;  
plot(log10(Lambda),log10(e),'-o')  
[~, maxEIdx] = max(e);  
maxLambda = Lambda(maxEIdx);  
hold on  
plot(log10(maxLambda),log10(e(maxEIdx)),'ro');  
ylabel('log_{10} 5-fold edge')  
xlabel('log_{10} Lambda')  
legend('Edge','Max edge')  
hold off
```

Several values of Lambda yield similarly high edges. Higher values of lambda lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the edge starts decreasing.

```
LambdaFinal = Lambda(5);
```

Train a linear classification model using the entire data set and specify the regularization strength LambdaFinal .

```
MdlFinal = fitlinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',LambdaFinal);
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

`ClassificationLinear` | `ClassificationPartitionedLinear` | `edge` | `kfoldMargin` | `kfoldPredict`

Introduced in R2016a

kfoldEdge

Class: ClassificationPartitionedLinearECOC

Classification edge for observations not used for training

Syntax

```
e = kfoldEdge(CVMdl)
e = kfoldEdge(CVMdl,Name,Value)
```

Description

`e = kfoldEdge(CVMdl)` returns the cross-validated classification edges obtained by the cross-validated, error-correcting output codes (ECOC) model composed of linear classification models `CVMdl`. That is, for every fold, `kfoldEdge` estimates the classification edge for observations that it holds out when it trains using all other observations.

`e` contains a classification edge for each regularization strength in the linear classification models that comprise `CVMdl`.

`e = kfoldEdge(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify a decoding scheme, which folds to use for the edge calculation, or verbosity level.

Input Arguments

CVMdl — Cross-validated, ECOC model composed of linear classification models

ClassificationPartitionedLinearECOC model object

Cross-validated, ECOC model composed of linear classification models, specified as a ClassificationPartitionedLinearECOC model object. You can create a ClassificationPartitionedLinearECOC model using `fitcecoc` and by:

- 1 Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`

- 2 Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, `ClassificationPartitionedLinearECOC.kfoldEdge` applies the same data used to cross-validate the ECOC model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'`
| `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
<code>'binodeviance'</code>	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
<code>'exponential'</code>	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
<code>'hamming'</code>	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
<code>'hinge'</code>	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
<code>'linear'</code>	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
<code>'logit'</code>	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
<code>'quadratic'</code>	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
where:
```

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 25-4317.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is `'hinge'`
- Logistic regression, then `BinaryLoss` is `'quadratic'`

Example: `'BinaryLoss','binodeviance'`

Data Types: char | function_handle

'Decoding' — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the “Binary Loss” on page 25-4314, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: char

'Folds' — Fold indices to use for classification-score prediction

1:CVMDL.KFold (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must range from 1 through CVMDL.KFold.

Example: 'Folds', [1 4 10]

Data Types: single | double

'Mode' — Edge aggregation level

'average' (default) | 'individual'

Edge aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

Value	Description
'average'	Returns classification edges averaged over all folds
'individual'	Returns classification edges for each fold

Example: 'Mode', 'individual'

Data Types: char

'Options' — Estimation options[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments

e — Cross-validated classification edges

numeric scalar | numeric vector | numeric matrix

Cross-validated classification edges, returned as a numeric scalar, vector, or matrix.

Let L be the number of regularization strengths in the cross-validated models (stored in `numel(CVMdl.Trained{1}.BinaryLearners{1}.Lambda)`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is 'average', then \mathbf{e} is a 1-by- L vector. $\mathbf{e}(j)$ is the average classification edge over all folds of the cross-validated model that uses regularization strength j .
- Otherwise, \mathbf{e} is a F -by- L matrix. $\mathbf{e}(i, j)$ is the classification edge for fold i of the cross-validated model that uses regularization strength j .

Definitions

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k, j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the `LossFun` name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Classification Edge

The *classification edge* is the weighted mean of the *classification margins*.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the true class and maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Examples

Estimate *k*-Fold Cross-Validation Edge

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Cross-validate a multiclass, linear classification model.

```
rng(1); % For reproducibility
```

```
CVMD1 = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

CVMD1 is a `ClassificationPartitionedLinearECOC` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Estimate the average of the out-of-fold edges.

```
e = kfoldEdge(CVMD1)
```

```
e =
```

```
0.7232
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair `'Mode','individual'` in `kfoldEdge`.

Feature Selection Using k -fold Edges

One way to perform feature selection is to compare k -fold edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the NLP data set. Preprocess the data as in “Estimate k -Fold Cross-Validation Edge”, and orient the predictor data so that observations correspond to columns.

```
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains a 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Create a linear classification model template that specifies to solve the objective function using `SpaRSA`.

```
t = templateLinear('Solver','sparsa');
```

Cross-validate two ECOC models composed of binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Indicate that observations correspond to columns.

```
CVMD1 = fitcecoc(fullX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
PCVMD1 = fitcecoc(partX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
```

CVMD1 and PCVMD1 are ClassificationPartitionedLinearECOC models.

Estimate the k -fold edge for each classifier.

```
fullEdge = kfoldEdge(CVMD1)
partEdge = kfoldEdge(PCVMD1)
```

```
fullEdge =
    0.3090
```

```
partEdge =
    0.2617
```

Based on the k -fold edges, the classifier that uses all of the predictors is the better model.

Find Good Lasso Penalty Using k -fold Edge

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare k -fold edges.

Load the NLP data set. Preprocess the data as in “Feature Selection Using k -fold Edges”.

```
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-8} through 10^1 .

```
Lambda = logspace(-8,1,11);
```

Create a linear classification model template that specifies to use logistic regression with a lasso penalty, use each of the regularization strengths, solve the objective function using SpaRSA, and reduce the tolerance on the gradient of the objective function to $1e-8$.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...  
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate an ECOC model composed of binary, linear classification models using 5-fold cross-validation and that

```
rng(10); % For reproducibility  
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5)
```

```
CVMdl =
```

```
classreg.learning.partition.ClassificationPartitionedLinearECOC  
  CrossValidatedModel: 'Linear'  
    ResponseName: 'Y'  
  NumObservations: 31572  
         KFold: 5  
    Partition: [1x1 cvpartition]  
    ClassNames: [comm    dsp    simulink    others]  
  ScoreTransform: 'none'
```

CVMdl is a ClassificationPartitionedLinearECOC model.

Estimate the edges for each fold and regularization strength.

```
eFolds = kfoldEdge(CVMdl,'Mode','individual')
```

```
eFolds =
```

```
Columns 1 through 7
```

0.5558	0.5557	0.5562	0.5561	0.5557	0.5403	0.4620
0.5248	0.5257	0.5260	0.5265	0.5271	0.5162	0.4507
0.5263	0.5280	0.5287	0.5291	0.5298	0.5134	0.4490
0.5429	0.5443	0.5448	0.5449	0.5433	0.5265	0.4552

```

    0.5505    0.5552    0.5559    0.5572    0.5586    0.5415    0.4668

Columns 8 through 11

    0.3148    0.1506    0.0889    0.0889
    0.3119    0.1527    0.0922    0.0922
    0.3071    0.1466    0.0893    0.0854
    0.3072    0.1503    0.0882    0.0882
    0.3101    0.1505    0.0861    0.0861

```

`eFolds` is a 5-by-11 matrix of edges. Rows correspond to folds and columns correspond to regularization strengths in `Lambda`. You can use `eFolds` to identify ill-performing folds, that is, unusually low edges.

Estimate the average edge over all folds for each regularization strength.

```
e = kfoldEdge(CVMdl)
```

```

e =

Columns 1 through 7

    0.5401    0.5418    0.5423    0.5428    0.5429    0.5276    0.4567

Columns 8 through 11

    0.3102    0.1501    0.0889    0.0882

```

Determine how well the models generalize by plotting the averages of the 5-fold edge for each regularization strength. Identify the regularization strength that minimizes the 5-fold edge over the grid.

```

figure;
plot(log10(Lambda),log10(e),'-o')
[~, maxEIdx] = max(e);
maxLambda = Lambda(maxEIdx);
hold on
plot(log10(maxLambda),log10(e(maxEIdx)),'ro');
ylabel('log_{10} 5-fold edge')
xlabel('log_{10} Lambda')
legend('Edge','Max edge')

```

```
hold off
```

Several values of `Lambda` yield similarly high edges. Higher values of lambda lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the edge starts decreasing.

```
LambdaFinal = Lambda(5);
```

Train an ECOC model composed of linear classification model using the entire data set and specify the regularization strength `LambdaFinal`.

```
t = templateLinear('Learner', 'logistic', 'Solver', 'sparsa', ...
    'Regularization', 'lasso', 'Lambda', Lambda(5), 'GradientTolerance', 1e-8);
```

```
MdlFinal = fitcecoc(X,Y, 'Learners',t, 'ObservationsIn', 'columns');
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Introduced in R2016a

kfoldEdge

Class: ClassificationPartitionedModel

Classification edge for observations not used for training

Syntax

```
E = kfoldEdge(obj)
E = kfoldEdge(obj, Name, Value)
```

Description

`E = kfoldEdge(obj)` returns classification edge (average classification margin) obtained by cross-validated classification model `obj`. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

`E = kfoldEdge(obj, Name, Value)` calculates edge with additional options specified by one or more `Name, Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Input Arguments

obj

Object of class `ClassificationPartitionedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'folds'

Indices of folds ranging from 1 to `obj.KFold`. Use only these folds for predictions.

Default: 1:obj.KFold

'mode'

String representing the meaning of the output `edge`:

- `'average'` — `edge` is a scalar value, the average over all folds.
- `'individual'` — `edge` is a vector of length `obj.KFold` with one element per fold.

Default: `'average'`

Output Arguments

E

The average classification margin. `E` is a scalar or vector, depending on the setting of the `mode` name-value pair.

Definitions

Edge

The *edge* is the weighted mean value of the classification *margin*. The weights are class prior probabilities. If you supply additional weights, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix `X`. A high value of margin indicates a more reliable prediction than a low value.

Score

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 16-7.

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as `true` when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

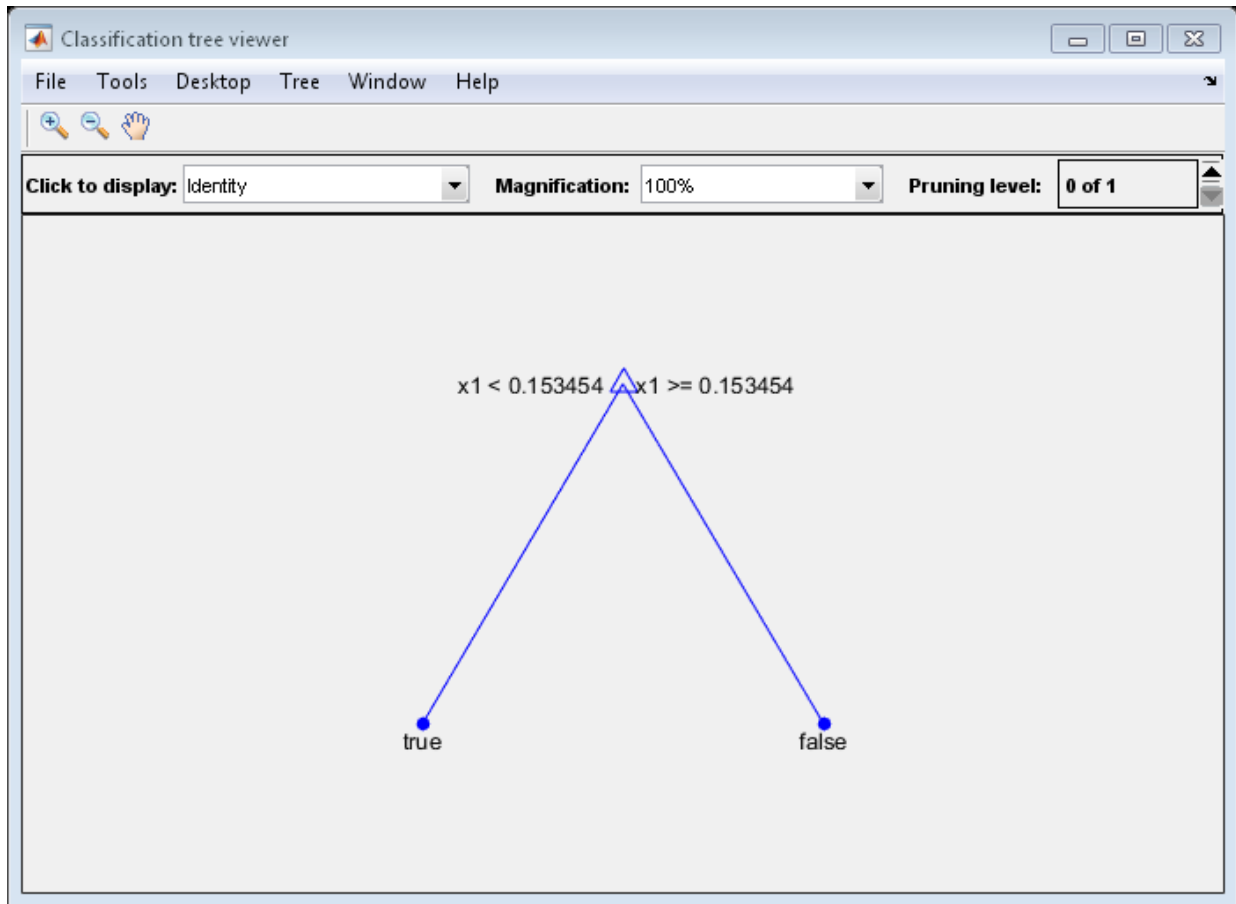

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for **true**, and about $.8/.85=.94$ for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range $(.95, 1)$ instead of the expected 5 observations.

Examples

Estimate the k -fold Edge of a Classifier

Compute the k -fold edge for a model trained on Fisher's iris data.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree classifier.

```
tree = fitctree(meas,species);
```

Cross validate the classifier using 10-fold cross validation.

```
cvtree = crossval(tree);
```

Compute the k -fold edge.

```
edge = kfoldEdge(cvtree)
```

edge =

0.8578

kfoldfun

Class: ClassificationPartitionedECOC

Cross validate function

Syntax

```
vals = kfoldfun(CVMdl, fun)
```

Description

`vals = kfoldfun(CVMdl, fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `CVMdl`. You must pass `fun` as a function handle.

Input Arguments

CVMdl — Cross-validated model

ClassificationPartitionedECOC model |
ClassificationPartitionedEnsemble model |
ClassificationPartitionedModel model

Cross-validated model, specified as a ClassificationPartitionedECOC model, ClassificationPartitionedEnsemble model, or a ClassificationPartitionedModel model.

fun — Cross-validated function

function handle

Cross-validated function, specified as a function handle. `fun` has the syntax

```
testvals = fun(CMP, Xtrain, Ytrain, Wtrain, Xtest, Ytest, Wtest)
```

- `CMP` is a compact model stored in one element of the `CVMdl.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.

- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.
- The returned value `testvals` needs the same size across all folds.

Data Types: `function_handle`

Output Arguments

vals — Cross-validation results

numeric matrix

Cross-validation results, returned as an numeric matrix. `vals` is the arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold`-by-`N` numeric matrix with one row per fold.

Data Types: `double`

Examples

Estimate Classification Error Using a Custom Loss Function

Train an ECOC multiclass classifier, and then cross validate it using a custom k -fold loss function.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers for each predictor set, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

CVMdl is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross validation.

Compute the classification error (proportion of misclassified observations) for the out-of-fold observations.

```
L = kfoldLoss(CVMdl)
```

```
L =
```

```
0.0400
```

Examine the result when the cost of misclassifying a flower as 'versicolor' is 10, and any other error is 1. Write a function called `noversicolor.m` that attributes a cost of 1 for misclassification, but 10 for misclassifying a flower as `versicolor`, and save it on your MATLAB path.

```
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
%noversicolor Example custom cross-validation function
% Attributes a cost of 10 for misclassifying versicolor irises, and 1 for
% the other irises. This example function requires the |fisheriris| data
% set.
Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % Different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions
cost = sum(misclassified) + ...
    9*sum(misclassified & classifiedAsVersicolor); % Total differences
averageCost = cost/numel(Ytest); % Average error
end
```

Compute the mean misclassification error with the `noversicolor` cost.

```
foldLoss = kfoldfun(CVMdl,@noversicolor);
mean(foldLoss)
```

```
ans =
```

```
0.0667
```

kfoldfun

Class: ClassificationPartitionedModel

Cross validate function

Syntax

```
vals = kfoldfun(CVMd1, fun)
```

Description

`vals = kfoldfun(CVMd1, fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `CVMd1`. You must pass `fun` as a function handle.

Input Arguments

CVMd1 — Cross-validated model

ClassificationPartitionedECOC model |
ClassificationPartitionedEnsemble model |
ClassificationPartitionedModel model

Cross-validated model, specified as a ClassificationPartitionedECOC model, ClassificationPartitionedEnsemble model, or a ClassificationPartitionedModel model.

fun — Cross-validated function

function handle

Cross-validated function, specified as a function handle. `fun` has the syntax

```
testvals = fun(CMP, Xtrain, Ytrain, Wtrain, Xtest, Ytest, Wtest)
```

- `CMP` is a compact model stored in one element of the `CVMd1.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.

- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.
- The returned value `testvals` needs the same size across all folds.

Data Types: `function_handle`

Output Arguments

vals — Cross-validation results

numeric matrix

Cross-validation results, returned as an numeric matrix. `vals` is the arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold`-by-`N` numeric matrix with one row per fold.

Data Types: `double`

Examples

Estimate Classification Error Using a Custom Loss Function

Train a classification tree classifier, and then cross validate it using a custom k -fold loss function.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree classifier.

```
Mdl = fitctree(meas,species);
```

`Mdl` is a `ClassificationTree` model.

Cross validate `Mdl` using the default 10-fold cross validation. Compute the classification error (proportion of misclassified observations) for the out-of-fold observations.

```
rng(1); % For reproducibility  
CVMdl = crossval(Mdl);  
L = kfoldLoss(CVMdl)
```

```
L =  
  
    0.0467
```

Examine the result when the cost of misclassifying a flower as 'versicolor' is 10, and any other error is 1. Write a function called `noversicolor.m` that attributes a cost of 1 for misclassification, but 10 for misclassifying a flower as `versicolor`, and save it on your MATLAB path.

```
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)  
%noversicolor Example custom cross-validation function  
% Attributes a cost of 10 for misclassifying versicolor irises, and 1 for  
% the other irises. This example function requires the |fisheriris| data  
% set.  
Ypredict = predict(CMP,Xtest);  
misclassified = not(strcmp(Ypredict,Ytest)); % Different result  
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions  
cost = sum(misclassified) + ...  
    9*sum(misclassified & classifiedAsVersicolor); % Total differences  
averageCost = cost/numel(Ytest); % Average error  
end
```

Compute the mean misclassification error with the `noversicolor` cost.

```
mean(kfoldfun(CVMdl,@noversicolor))  
  
ans =  
  
    0.2267
```

kfoldfun

Class: RegressionPartitionedModel

Cross validate function

Syntax

```
vals = kfoldfun(obj, fun)
```

Description

`vals = kfoldfun(obj, fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `obj`. You must pass `fun` as a function handle.

Input Arguments

obj

Object of class `RegressionPartitionedModel` or `RegressionPartitionedEnsemble`. Create `obj` with `fitrtree` or `fitensemble` along with one of the cross-validation options: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. Alternatively, create `obj` from a regression tree or regression ensemble with `crossval`.

fun

A function handle for a cross-validation function. `fun` has the syntax

```
testvals = fun(CMP, Xtrain, Ytrain, Wtrain, Xtest, Ytest, Wtest)
```

- `CMP` is a compact model stored in one element of the `obj.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.
- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.

- The returned value `testvals` must have the same size across all folds.

Output Arguments

`vals`

The arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold`-by-`N` numeric matrix with one row per fold.

Examples

Cross validate a regression tree, and obtain the mean squared error (see `kfoldLoss`):

```
load imports-85
t = fitrtree(X(:,[4 5]),X(:,16),...
    'predictorNames',{'length' 'width'},...
    'responseName','price');
cv = crossval(t);
L = kfoldLoss(cv)
```

```
L =
    1.5489e+007
```

Examine the result of simple averaging of responses instead of using predictions:

```
f = @(cmp,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)...
    mean((Ytest-mean(Ytrain)).^2)
mean(kfoldfun(cv,f))
```

```
ans =
    6.3497e+007
```

kfoldLoss

Class: ClassificationPartitionedECOC

Classification loss for observations not used for training

Syntax

```
loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)
```

Description

`loss = kfoldLoss(CVMdl)` returns the classification loss obtained by the cross-validated ECOC model (ClassificationPartitionedECOC) `CVMdl`. For every fold, this function computes the classification loss for in-fold observations using a model trained on out-of-fold observations. `CVMdl.X` contains both sets of observations.

`loss = kfoldLoss(CVMdl,Name,Value)` returns the classification loss with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the number of folds, decoding scheme, or verbosity level.

Input Arguments

CVMdl — Cross-validated ECOC model

ClassificationPartitionedECOC model

Cross-validated ECOC model, specified as a ClassificationPartitionedECOC model. You can create a ClassificationPartitionedECOC model by:

- Passing a trained ECOC model (ClassificationECOC) to `crossval`
- Training an ECOC model using `fitcecoc` and setting any one of these cross-validation name-value pair arguments: 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition'

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge'
| 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
where:
```

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 25-4317.

By default, if all binary learners are:

- SVMs or linear classification models of SVM learners, then `BinaryLoss` is 'hinge'
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is 'exponential'
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is 'binodeviance'
- Linear classification models of logistic regression learners, or you specify to predict class posterior probabilities (i.e., set 'FitPosterior', 1 in `fitcecoc`), then `BinaryLoss` is 'quadratic'

Otherwise, the default `BinaryLoss` is 'hamming'. To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | function_handle

'Decoding' — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the “Binary Loss” on page 25-4314, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'.

Example: 'Decoding', 'lossbased'

Data Types: char

'Folds' — Fold indices for prediction

1:Mdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of **'Folds'** and a numeric vector of positive integers. The elements of **Folds** must range from 1 through `Mdl.KFold`.

The software only uses the folds specified in **Folds** for prediction.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

'LossFun' — Loss function

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of **'LossFun'** and a function handle or **'classiferror'**.

You can:

- Specify the built-in function **'classiferror'**, then the loss function is the classification error
- Specify your own function using function handle notation.

For what follows, n is the number of observations in the training data (`CVMD1.NumObservations`) and K is the number of classes (`numel(CVMD1.ClassNames)`). Your function needs the signature `lossvalue = Lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*Lossfun*).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `CVMD1.ClassNames`.

Construct C by setting $C(p,q) = 1$ if observation p is in class q , for each row. Set every element of row p to 0.

- S is an n -by- K numeric matrix of negated loss values for classes. Each row corresponds to an observation. The column order corresponds to the class order in `CVMD1.ClassNames`. S resembles the output argument `NegLoss` of `kfoldPredict`.

- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes its elements to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = ones(K) - eye(K)$ specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

Data Types: `function_handle` | `char`

'Mode' — Edge aggregation level

'average' (default) | 'individual'

Edge meaning, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

Value	Description
'average'	edge is the scalar average over all folds.
'individual'	edge is a vector of length k containing one edge per fold. k is the number of folds.

Example: `'Mode', 'individual'`

Data Types: `char`

'Options' — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options', statset('UseParallel', 1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

loss — Classification loss

numeric scalar | numeric row vector

Classification loss, returned as a numeric scalar or numeric row vector.

If `Mode` is `'average'`, then `loss` is the average classification loss among all binary learners. Otherwise, `loss` is a 1-by-L numeric row vector containing the classification loss for each, respective binary learner, where L is the number of binary learners (`size(CVMdl.CodingMatrix,2)`).

Data Types: `single` | `double`

Definitions

Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- w_j is the weight for observation j . The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of predict and loss), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Determine k -Fold Cross-Validation Loss of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMD1 = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMD1 is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average out-of-fold classification error.

```
L = kfoldLoss(CVMD1)
```

```
L =
```

```
0.0400
```

The average classification error for the folds is 4%.

Alternatively, you can obtain the per-fold losses by specifying the name-value pair 'Mode','individual' in kfoldLoss.

Display Individual Losses for Each Cross-Validation Fold

The classification loss is a measure of classifier quality. You can determine ill-performing folds by displaying the losses for each fold.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to use 8-fold cross validation. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMD1 = fitcecoc(X,Y,'KFold',8,'Learners',t,'ClassNames',classOrder);
```

Estimate the average classification loss across folds, and the losses for each fold.

```
loss = kfoldLoss(CVMD1)
```

```
losses = kfoldLoss(CVMdl, 'Mode', 'individual')

loss =

    0.0333

losses =

    0.0556
    0.0526
    0.1579
         0
         0
         0
         0
         0
```

The third fold misclassifies a much higher portion of observations than any other fold.

Return the classification loss for the entire model by specifying the well-performing folds using the 'Folds' name-value pair argument.

```
loss = kfoldLoss(CVMdl, 'Folds', [1:2 4:8])

loss =

    0.0153
```

The total classification loss decreased by approximately half its original size.

Consider adjusting parameters of the binary classifiers or the coding design to see if performance for all folds improves.

Determine ECOC Model Quality Using a Custom Cross-Validation Loss

Suppose that it is interesting to know how well a model classifies a particular class. This example shows how to pass such a custom loss function to `kfoldLoss`.

Load Fisher's iris data set.

```

load fisheriris
X = meas;
Y = categorical(species);
n = numel(Y); % Sample size
classOrder = unique(Y) % Class order
K = numel(classOrder); % Number of classes
rng(1) % For reproducibility

```

```

classOrder =

    setosa
    versicolor
    virginica

```

Train an ECOC model using SVM binary classifiers, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```

t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);

```

CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Compute the negated losses for the out-of-fold observations.

```

[~,negLoss] = kfoldPredict(CVMdl);

```

Create a function that takes the minimal loss for each observation, and then averages the minimal losses across all observations.

```

lossfun = @(C,S,~,~)mean(min(-negLoss,[],2));

```

Compute the cross-validated custom loss.

```

kfoldLoss(CVMdl,'LossFun',lossfun)

```

```

ans =

```

```

    0.0101

```

The average, minimal, binary loss for the out-of-fold observations is 0.0101.

kfoldLoss

Class: ClassificationPartitionedEnsemble

Classification loss for observations not used for training

Syntax

```
L = kfoldLoss(ens)
L = kfoldLoss(ens,Name,Value)
```

Description

`L = kfoldLoss(ens)` returns loss obtained by cross-validated classification model `ens`. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

`L = kfoldLoss(ens,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

Object of class `ClassificationPartitionedEnsemble`. Create `ens` with `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `ens` from a classification ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'folds'

Indices of folds ranging from 1 to `ens.KFold`. Use only these folds for predictions.

Default: `1:ens.KFold`

'lossfun'

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector.

Value	Description
<code>'binodeviance'</code>	Binomial deviance
<code>'classiferror'</code>	Classification error
<code>'exponential'</code>	Exponential
<code>'hinge'</code>	Hinge
<code>'logit'</code>	Logistic
<code>'mincost'</code>	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
<code>'quadratic'</code>	Quadratic

`'mincost'` is appropriate for classification scores that are posterior probabilities.

- Bagged and subspace ensembles return posterior probabilities by default (`ens.Method` is `'Bag'` or `'Subspace'`).
- If the ensemble method is `'AdaBoostM1'`, `'AdaBoostM2'`, `GentleBoost`, or `'LogitBoost'`, then, to use posterior probabilities as classification scores, you must specify the double-logit score transform by entering

```
ens.ScoreTransform = 'doublelogit';
```
- For all other ensemble methods, the software does not support posterior probabilities as classification scores.
- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(ens.ClassNames)`), `ens` is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- `C` is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `ens.ClassNames`.

Construct `C` by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- `S` is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `ens.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
- `W` is an n -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to 1.
- `Cost` is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 25-2750.

Default: `'classiferror'`

'mode'

A character vector for determining the output of `kfoldLoss`:

- `'average'` — `L` is a scalar, the loss averaged over all folds.
- `'individual'` — `L` is a vector of length `ens.KFold`, where each entry is the loss for a fold.
- `'cumulative'` — `L` is a vector in which element J is obtained by using learners $1:J$ from the input list of learners.

Default: 'average'

Output Arguments

L

Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When comparing the same type of loss among many models, lower loss indicates a better predictive model.

Suppose that:

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, and a 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.

- $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
- $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

The supported loss functions are:

- Binomial deviance, specified using `'LossFun', 'binodeviance'`. Its equation is

$$L = \sum_{j=1}^n w_j \log \{1 + \exp[-2m_j]\}.$$

- Exponential loss, specified using `'LossFun', 'exponential'`. Its equation is

$$L = \sum_{j=1}^n w_j \exp(-m_j).$$

- Classification error, specified using `'LossFun', 'classiferror'`. It is the weighted fraction of misclassified observations, with equation

$$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$$

\hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.

- Hinge loss, specified using `'LossFun', 'hinge'`. Its equation is

$$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$$

- Logit loss, specified using 'LossFun', 'logit'. Its equation is

$$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$$

- Minimal cost, specified using 'LossFun', 'mincost'. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$:

- 1 Estimate the 1-by- K vector of expected classification costs for observation j

$$\gamma_j = f(X_j)'C.$$

$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix the input model stores in the property `Cost`.

- 2 For observation j , predict the class label corresponding to the minimum, expected classification cost:

$$\hat{y}_j = \min_{j=1, \dots, K} (\gamma_j).$$

- 3 Using C , identify the cost incurred (c_j) for making the prediction.

The weighted, average, minimum cost loss is

$$L = \sum_{j=1}^n w_j c_j.$$

- Quadratic loss, specified using 'LossFun', 'quadratic'. Its equation is

$$L = \sum_{j=1}^n w_j (1 - m_j)^2.$$

This figure compares some of the loss functions for one observation over m (some functions are normalized to pass through $[0,1]$).

Examples

Estimate Cross-Validated Classification Error

Load the ionosphere data set.

```
load ionosphere
```

Boost 100 trees using AdaBoostM1.

```
ens = fitensemble(X,Y, 'AdaBoostM1',100, 'Tree');
```

Cross-validate the ensemble using 10-fold cross-validation.

```
cvens = crossval(ens);
```

Estimate the cross-validated classification error.

```
L = kfoldLoss(cvens)
```

```
L =
```

```
    0.0655
```

kfoldLoss

Class: ClassificationPartitionedLinear

Classification loss for observations not used in training

Syntax

```
L = kfoldLoss(CVMd1)
L = kfoldLoss(CVMd1,Name,Value)
```

Description

`L = kfoldLoss(CVMd1)` returns the cross-validated classification losses obtained by the cross-validated, binary, linear classification model `CVMd1`. That is, for every fold, `kfoldLoss` estimates the classification loss for observations that it holds out when it trains using all other observations.

`L` contains a classification loss for each regularization strength in the linear classification models that compose `CVMd1`.

`L = kfoldLoss(CVMd1,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, indicate which folds to use for the loss calculation or specify the classification-loss function.

Input Arguments

CVMd1 — Cross-validated, binary, linear classification model

ClassificationPartitionedLinear model object

Cross-validated, binary, linear classification model, specified as a ClassificationPartitionedLinear model object. You can create a ClassificationPartitionedLinear model using `fitlinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, ClassificationPartitionedLinear.kfoldLoss applies the same data used to cross-validate the linear classification model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Folds' — Fold indices to use for classification-score prediction

1: `CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of `Folds` must range from 1 through `CVMdl.KFold`.

Example: 'Folds', [1 4 10]

Data Types: single | double

'LossFun' — Loss function

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. For linear classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see predict).

- Specify your own function using function handle notation.

Let n be the number of observations in X and K be the number of distinct classes (`numel(Mdl.ClassNames)`, Mdl is the input model). Your function must have this signature

`lossvalue = lossfun(C,S,W,Cost)`

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct C by setting $C(p,q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

Data Types: char | function_handle

'Mode' — Loss aggregation level

'average' (default) | 'individual'

Loss aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

Value	Description
'average'	Returns losses averaged over all folds
'individual'	Returns losses for each fold

Example: 'Mode', 'individual'

Data Types: char

Output Arguments

L — Cross-validated classification losses

numeric scalar | numeric vector | numeric matrix

Cross-validated classification losses, returned as a numeric scalar, vector, or matrix. The interpretation of L depends on `LOSSFun`.

Let R be the number of regularizations strengths is the cross-validated models (stored in `numel(CVMdl.Trained{1}.Lambda)`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is 'average', then L is a 1-by- R vector. $L(j)$ is the average classification loss over all folds of the cross-validated model that uses regularization strength j .
- Otherwise, L is an F -by- R matrix. $L(i, j)$ is the classification loss for fold i of the cross-validated model that uses regularization strength j .

To estimate L, `kfoldLoss` uses the data that created `CVMdl` (see X and Y).

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When comparing the same type of loss among many models, lower loss indicates a better predictive model.

Suppose that:

- L is the weighted average classification loss.
- n is the sample size.

- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, and a 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

The supported loss functions are:

- Binomial deviance, specified using `'LossFun', 'binodeviance'`. Its equation is

$$L = \sum_{j=1}^n w_j \log \{1 + \exp[-2m_j]\}.$$

- Exponential loss, specified using `'LossFun', 'exponential'`. Its equation is

$$L = \sum_{j=1}^n w_j \exp(-m_j).$$

- Classification error, specified using 'LossFun', 'classiferror'. It is the weighted fraction of misclassified observations, with equation

$$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$$

\hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.

- Hinge loss, specified using 'LossFun', 'hinge'. Its equation is

$$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$$

- Logit loss, specified using 'LossFun', 'logit'. Its equation is

$$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$$

- Minimal cost, specified using 'LossFun', 'mincost'. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$:

- 1 Estimate the 1-by- K vector of expected classification costs for observation j

$$\gamma_j = f(X_j)'C.$$

$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix the input model stores in the property **Cost**.

- 2 For observation j , predict the class label corresponding to the minimum, expected classification cost:

$$\hat{y}_j = \min_{j=1,\dots,K} (\gamma_j).$$

3 Using C , identify the cost incurred (c_j) for making the prediction.

The weighted, average, minimum cost loss is

$$L = \sum_{j=1}^n w_j c_j.$$

- Quadratic loss, specified using 'LossFun', 'quadratic'. Its equation is

$$L = \sum_{j=1}^n w_j (1 - m_j)^2.$$

This figure compares some of the loss functions for one observation over m (some functions are normalized to pass through $[0,1]$).

Examples

Estimate k -Fold Cross-Validation Classification Error

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'CrossVal','on');
```

CVMdl is a `ClassificationPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the out-of-fold, classification error rates.

```
ce = kfoldLoss(CVMdl)
```

```
ce =
```

```
7.6017e-04
```

Alternatively, you can obtain the per-fold classification error rates by specifying the name-value pair 'Mode', 'individual' in `kfoldLoss`.

Specify Custom Classification Loss

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Classification Error”, and transpose the predictor data.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Cross-validate a binary, linear classification model using 5-fold cross-validation. Solve the objective function using `SpARSA`. Specify that the predictor observations correspond to columns.

```
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'Solver','sparsa','KFold',5,...
    'ObservationsIn','columns');
CMD1 = CVMdl.Trained{1};
```

CVMdl is a `ClassificationPartitionedLinear` model. It contains the property `Trained`, which is a 5-by-1 cell array holding a `ClassificationLinear` models that the software trained using the training set of each fold.

Create an anonymous function that measures linear loss, that is,

$$L = \frac{\sum_j -w_j y_j f_j}{\sum_j w_j}.$$

w_j is the weight for observation j , y_j is response j (-1 for the negative class, and 1 otherwise), and f_j is the raw classification score of observation j . Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the `LossFun` name-value pair argument. Because the function does not use classification cost, use `~` to have `kfoldLoss` ignore its position.

```
linearloss = @(C,S,W,~)sum(-W.*sum(S.*C,2))/sum(W);
```

Estimate the average cross-validated classification loss using the linear loss function. Also, obtain the loss for each fold.

```
ce = kfoldLoss(CVMdl,'LossFun',linearloss)
ceFold = kfoldLoss(CVMdl,'LossFun',linearloss,'Mode','individual')
```

```
ce =
    -8.0982
```

```
ceFold =
    -8.3165
    -8.7633
    -7.4342
    -8.0423
    -7.9347
```

Find Good Lasso Penalty Using k -fold Classification Loss

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample classification error rates.

Load the NLP data set. Preprocess the data as in “Specify Custom Classification Loss”.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{0.5}$.

```
Lambda = logspace(-6, -0.5, 11);
```

Cross-validate binary, linear classification models using 5-fold cross-validation, and that use each of the regularization strengths. Solve the objective function using SpARSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
rng(10); % For reproducibility
CVMdl = fitlinear(X, Ystats, 'ObservationsIn', 'columns', ...
    'KFold', 5, 'Learner', 'logistic', 'Solver', 'sparsa', ...
    'Regularization', 'lasso', 'Lambda', Lambda, 'GradientTolerance', 1e-8)
```

```
CVMdl =
```

```
classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 5
  Partition: [1x1 cvpartition]
  ClassNames: [0 1]
  ScoreTransform: 'none'
```

Extract a trained linear classification model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =  
  
ClassificationLinear  
    ResponseName: 'Y'  
    ClassNames: [0 1]  
    ScoreTransform: 'logit'  
        Beta: [34023x11 double]  
        Bias: [1x11 double]  
        Lambda: [1x11 double]  
    Learner: 'logistic'
```

Mdl1 is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of Mdl as 11 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated classification error.

```
ce = kfoldLoss(CVMdl);
```

Because there are 11 regularization strengths, `ce` is a 1-by-11 vector of classification error rates.

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model for each regularization strength using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitlinear(X,Ystats,'ObservationsIn','columns',...  
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...  
    'Lambda',Lambda,'GradientTolerance',1e-8);  
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated, classification error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;  
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...  
    log10(Lambda),log10(numNZCoeff));  
hL1.Marker = 'o';  
hL2.Marker = 'o';  
ylabel(h(1),'log10 classification error')
```

```

ylabel(h(2), 'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
title('Test-Sample Statistics')
hold off

```

Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between 10^{-4} to 10^{-1} should suffice.

```
idxFinal = 7;
```

Select the model from Mdl with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

`ClassificationLinear` | `ClassificationPartitionedLinear` | `kfoldPredict` | `loss`

Introduced in R2016a

kfoldLoss

Class: ClassificationPartitionedLinearECOC

Classification loss for observations not used in training

Syntax

`L = kfoldLoss(CVMdl)`

`L = kfoldLoss(CVMdl,Name,Value)`

Description

`L = kfoldLoss(CVMdl)` returns the cross-validated classification error rates estimated by the cross-validated, error-correcting output codes (ECOC) model composed of linear classification models `CVMdl`. That is, for every fold, `kfoldLoss` estimates the classification error rate for observations that it holds out when it trains using all other observations. `kfoldLoss` applies the same data used create `CVMdl` (see `fitcecoc`).

`L` contains a classification loss for each regularization strength in the linear classification models that compose `CVMdl`.

`L = kfoldLoss(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify a decoding scheme, which folds to use for the loss calculation, or verbosity level.

Input Arguments

CVMdl — Cross-validated, ECOC model composed of linear classification models

ClassificationPartitionedLinearECOC model object

Cross-validated, ECOC model composed of linear classification models, specified as a ClassificationPartitionedLinearECOC model object. You can create a ClassificationPartitionedLinearECOC model using `fitcecoc` and by:

- 1 Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`

- 2 Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, `ClassificationPartitionedLinearECOC.kfoldLoss` applies the same data used to cross-validate the ECOC model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'`
| `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
<code>'binodeviance'</code>	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
<code>'exponential'</code>	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
<code>'hamming'</code>	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
<code>'hinge'</code>	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
<code>'linear'</code>	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
<code>'logit'</code>	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
<code>'quadratic'</code>	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
where:
```

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 25-4317.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is `'hinge'`
- Logistic regression, then `BinaryLoss` is `'quadratic'`

Example: `'BinaryLoss','binodeviance'`

Data Types: char | function_handle

'Decoding' — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the “Binary Loss” on page 25-4314, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: char

'Folds' — Fold indices to use for classification-score prediction`1:CVMD1.KFold` (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from 1 through `CVMD1.KFold`.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

'LossFun' — Loss function`'classiferror'` (default) | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a function handle or `'classiferror'`.

You can:

- Specify the built-in function `'classiferror'`, then the loss function is the classification error.
- Specify your own function using function handle notation.

For what follows, n is the number of observations in the training data (`CVMD1.NumObservations`) and K is the number of classes (`numel(CVMD1.ClassNames)`). Your function needs the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `CVMD1.ClassNames`.

Construct C by setting $C(p,q) = 1$ if observation p is in class q , for each row. Set every element of row p to 0.

- S is an n -by- K numeric matrix of negated loss values for classes. Each row corresponds to an observation. The column order corresponds to the class order in `CVMD1.ClassNames`. S resembles the output argument `NegLoss` of `kfoldPredict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes its elements to sum to 1.

- **Cost** is a K-by-K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

Data Types: `function_handle` | `char`

'Mode' — Loss aggregation level

`'average'` (default) | `'individual'`

Loss aggregation level, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

Value	Description
<code>'average'</code>	Returns losses averaged over all folds
<code>'individual'</code>	Returns losses for each fold

Example: `'Mode', 'individual'`

Data Types: `char`

'Options' — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options', statset('UseParallel', 1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0 or 1. **Verbose** controls the amount of diagnostic messages that the software displays in the Command Window.

If **Verbose** is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments

L — Cross-validated classification losses

numeric scalar | numeric vector | numeric matrix

Cross-validated classification losses, returned as a numeric scalar, vector, or matrix. The interpretation of **L** depends on **LOSSFun**.

Let R be the number of regularizations strengths is the cross-validated models (`CVMdl.Trained{1}.BinaryLearners{1}.Lambda`) and F be the number of folds (stored in `CVMdl.KFold`).

- If **Mode** is 'average', then **L** is a 1-by- R vector. $L(j)$ is the average classification loss over all folds of the cross-validated model that uses regularization strength j .
- Otherwise, **L** is a F -by- R matrix. $L(i, j)$ is the classification loss for fold i of the cross-validated model that uses regularization strength j .

Definitions

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the `LossFun` name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- w_j is the weight for observation j . The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

Examples

Estimate k -Fold Cross-Validation Classification Error

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels.

Cross-validate an ECOC model of linear classification models.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

`CVMdl` is a `ClassificationPartitionedLinearECOC` model. By default, the software implements 10-fold cross validation.

Estimate the average of the out-of-fold classification error rates.

```
ce = kfoldLoss(CVMdl)
```

```
ce =  
    0.0958
```

Alternatively, you can obtain the per-fold classification error rates by specifying the name-value pair 'Mode', 'individual' in kfoldLoss.

Specify Custom Classification Loss

Load the NLP data set. Transpose the predictor data.

```
load nlpdata  
X = X';
```

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a linear classification model template that specifies to solve the objective function using SpaRSA.

```
t = templateLinear('Solver','sparsa');
```

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Solve the objective function using SpaRSA. Specify that the predictor observations correspond to columns.

```
rng(1); % For reproducibility  
CVMdl = fitcecoc(X,Y,'Learners',t,'KFold',5,'ObservationsIn','columns');  
CMdl1 = CVMdl.Trained{1}
```

```
CMdl1 =  
  
classreg.learning.classif.CompactClassificationECOC  
    ResponseName: 'Y'  
    ClassNames: [comm    dsp    simulink    others]  
    ScoreTransform: 'none'
```

```
BinaryLearners: {6x1 cell}
CodingMatrix: [4x6 double]
```

CVMD1 is a `ClassificationPartitionedLinearECOC` model. It contains the property `Trained`, which is a 5-by-1 cell array holding a `CompactClassificationECOC` models that the software trained using the training set of each fold.

Create a function that takes the minimal loss for each observation, and then averages the minimal losses across all observations. Because the function does not use the class-identifier matrix (`C`), observation weights (`W`), and classification cost (`Cost`), use `~` to have `kfoldLoss` ignore its their positions.

```
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Estimate the average cross-validated classification loss using the minimal loss per observation function. Also, obtain the loss for each fold.

```
ce = kfoldLoss(CVMD1, 'LossFun', lossfun)
ceFold = kfoldLoss(CVMD1, 'LossFun', lossfun, 'Mode', 'individual')
```

```
ce =
```

```
0.0243
```

```
ceFold =
```

```
0.0244
0.0255
0.0248
0.0240
0.0226
```

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for an ECOC model composed of linear classification models that use logistic regression learners, implement 5-fold cross-validation.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-7} through 10^{-2} .

```
Lambda = logspace(-7,-2,11);
```

Create a linear classification model template that specifies to use logistic regression learners, use lasso penalties with strengths in Lambda, train using SpARSA, and lower the tolerance on the gradient of the objective function to $1e-8$.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```
X = X';
rng(10); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5);
```

CVMdl is a ClassificationPartitionedLinearECOC model.

Dissect CVMdl, and each model within it.

```
numECOCModels = numel(CVMdl.Trained)
ECOCmdl1 = CVMdl.Trained{1}
numCLModels = numel(ECOCmdl1.BinaryLearners)
CLmdl1 = ECOCmdl1.BinaryLearners{1}
```

```
numECOCModels =
```

```
5
```

```
ECOCmdl1 =
```

```
classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: [comm    dsp    simulink    others]
    ScoreTransform: 'none'
    BinaryLearners: {6x1 cell}
    CodingMatrix: [4x6 double]

numCLModels =

    6

CLMd11 =

    ClassificationLinear
        ResponseName: 'Y'
        ClassNames: [-1 1]
        ScoreTransform: 'logit'
            Beta: [34023x11 double]
            Bias: [1x11 double]
            Lambda: [1x11 double]
            Learner: 'logistic'
```

Because `fitcecoc` implements 5-fold cross-validation, `CVMd1` contains a 5-by-1 cell array of `CompactClassificationECOC` models that the software trains on each fold. The `BinaryLearners` property of each `CompactClassificationECOC` model contains the `ClassificationLinear` models. The number of `ClassificationLinear` models within each compact ECOC model depends on the number of distinct labels and coding design. Because `Lambda` is a sequence of regularization strengths, you can think of `CLMd11` as 11 models, one for each regularization strength in `Lambda`.

Determine how well the models generalize by plotting the averages of the 5-fold classification error for each regularization strength. Identify the regularization strength that minimizes the generalization error over the grid.

```
ce = kfoldLoss(CVMd1);
figure;
plot(log10(Lambda), log10(ce))
[~, minCEIdx] = min(ce);
```

```

minLambda = Lambda(minCEIdx);
hold on
plot(log10(minLambda),log10(ce(minCEIdx)),'ro');
ylabel('log_{10} 5-fold classification error')
xlabel('log_{10} Lambda')
legend('MSE','Min classification error')
hold off

```

Train an ECOC model composed of linear classification model using the entire data set, and specify the minimal regularization strength.

```

t = templateLinear('Learner','logistic','Solver','sparsa',...
'Regularization','lasso','Lambda',minLambda,'GradientTolerance',1e-8);
Md1Final = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns');

```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

kfoldLoss

Class: ClassificationPartitionedModel

Classification loss for observations not used for training

Syntax

```
L = kfoldLoss(obj)
L = kfoldLoss(obj,Name,Value)
```

Description

`L = kfoldLoss(obj)` returns loss obtained by cross-validated classification model `obj`. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

`L = kfoldLoss(obj,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

obj

Object of class `ClassificationPartitionedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'folds'

Indices of folds ranging from 1 to `obj.KFold`. Use only these folds for predictions.

Default: 1:obj.KFold

'lossfun'

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. All models use posterior probabilities as classification scores by default except SVM models. You can specify to use posterior probabilities as classification scores for SVM models by setting 'FitPosterior', true when you cross-validate the model using `fitcsvm`.

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(obj.ClassNames)`, `obj` is the input model). Your function must have this signature

`lossvalue = lossfun(C,S,W,Cost)`

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).

- **C** is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `obj.ClassNames`.

Construct **C** by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- **S** is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `obj.ClassNames`. **S** is a matrix of classification scores, similar to the output of `predict`.
- **W** is an n -by-1 numeric vector of observation weights. If you pass **W**, the software normalizes them to sum to 1.
- **Cost** is a K -by- K numeric matrix of misclassification costs. For example, **Cost** = `ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 25-2786.

Default: `'classiferror'`

'mode'

A character vector for determining the output of `kfoldLoss`:

- `'average'` — **L** is a scalar, the loss averaged over all folds.
- `'individual'` — **L** is a vector of length `obj.KFold`, where each entry is the loss for a fold.

Default: `'average'`

Output Arguments

L

Loss, by default the fraction of misclassified data. **L** can be a vector, and can mean different things, depending on the name-value pair settings.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When comparing the same type of loss among many models, lower loss indicates a better predictive model.

Suppose that:

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, and a 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

The supported loss functions are:

- Binomial deviance, specified using 'LossFun', 'binodeviance'. Its equation is

$$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$$

- Exponential loss, specified using 'LossFun', 'exponential'. Its equation is

$$L = \sum_{j=1}^n w_j \exp(-m_j).$$

- Classification error, specified using 'LossFun', 'classiferror'. It is the weighted fraction of misclassified observations, with equation

$$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$$

\hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.

- Hinge loss, specified using 'LossFun', 'hinge'. Its equation is

$$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$$

- Logit loss, specified using 'LossFun', 'logit'. Its equation is

$$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$$

- Minimal cost, specified using 'LossFun', 'mincost'. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$:

- 1 Estimate the 1-by- K vector of expected classification costs for observation j

$$\gamma_j = f(X_j)'C.$$

$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix the input model stores in the property **Cost**.

- 2 For observation j , predict the class label corresponding to the minimum, expected classification cost:

$$\hat{y}_j = \min_{j=1, \dots, K}(\gamma_j).$$

- 3 Using C , identify the cost incurred (c_j) for making the prediction.

The weighted, average, minimum cost loss is

$$L = \sum_{j=1}^n w_j c_j.$$

- Quadratic loss, specified using 'LossFun', 'quadratic'. Its equation is

$$L = \sum_{j=1}^n w_j (1 - m_j)^2.$$

This figure compares some of the loss functions for one observation over m (some functions are normalized to pass through $[0,1]$).

Examples

Estimate Cross-Validated Classification Error

Load the ionosphere data set.

```
load ionosphere
```

Grow a classification tree.

```
tree = fitctree(X,Y);
```

Cross-validate the classification tree using 10-fold cross-validation.

```
cvtree = crossval(tree);
```

Estimate the cross-validated classification error.

```
L = kfoldLoss(cvtree)
```

```
L =
```

```
    0.1111
```

How To

- “Examine Quality of KNN Classifier” on page 17-31

kfoldLoss

Class: RegressionPartitionedEnsemble

Cross-validation loss of partitioned regression ensemble

Syntax

```
L = kfoldLoss(cvens)
L = kfoldLoss(cvens,Name,Value)
```

Description

`L = kfoldLoss(cvens)` returns the cross-validation loss of `cvens`.

`L = kfoldLoss(cvens,Name,Value)` returns cross-validation loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

cvens

Object of class `RegressionPartitionedEnsemble`. Create `obj` with `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `obj` from a regression ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'folds'

Indices of folds ranging from 1 to `cvens.KFold`. Use only these folds for predictions.

Default: `1:cvens.KFold`

'lossfun'

Function handle for loss function, or the string `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `loss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

Default: `'mse'`

'mode'

String representing the meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

Output Arguments

L

The loss (mean squared error) between the observations in a fold when compared against predictions made with an ensemble trained on the out-of-fold data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Find the cross-validation loss for a regression ensemble of the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
rens = fitensemble(X,MPG,'LSboost',100,'Tree');
cvrens = crossval(rens);
L = kfoldLoss(cvrens)
```

```
L =
    25.6935
```

See Also

[RegressionPartitionedEnsemble](#) | [loss](#) | [kfoldPredict](#)

kfoldLoss

Class: RegressionPartitionedLinear

Regression loss for observations not used in training

Syntax

```
L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl, Name, Value)
```

Description

Description

`L = kfoldLoss(CVMdl)` returns the cross-validated mean squared error (MSE) obtained by the cross-validated, linear regression model `CVMdl`. That is, for every fold, `kfoldLoss` estimates the regression loss for observations that it holds out when it trains using all other observations.

`L` contains a regression loss for each regularization strength in the linear regression models that compose `CVMdl`.

`L = kfoldLoss(CVMdl, Name, Value)` uses additional options specified by one or more `Name, Value` pair arguments. For example, indicate which folds to use for the loss calculation or specify the regression-loss function.

Input Arguments

CVMdl — Cross-validated, linear regression model

RegressionPartitionedLinear model object

Cross-validated, linear regression model, specified as a `RegressionPartitionedLinear` model object. You can create a `RegressionPartitionedLinear` model using `fitrlinear` and specifying any of the one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, `RegressionPartitionedLinear.kfoldLoss` applies the same data used to cross-validate the linear regression model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Folds' — Fold indices to use for response prediction

1: `CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices to use for response prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of `Folds` must range from 1 through `CVMdl.KFold`.

Example: 'Folds', [1 4 10]

Data Types: `single` | `double`

'LossFun' — Loss function

'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector. Also, in the table, $f(x) = \beta'x + b$.
 - β is a vector of p coefficients.
 - x is an observation from p predictor variables.
 - b is the scalar bias.

Value	Description
'epsiloninsensitive'	Epsilon-insensitive loss: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$
'mse'	MSE: $\ell[y, f(x)] = [y - f(x)]^2$

'epsiloninsensitive' is appropriate for SVM learners only.

- Specify your own function using function handle notation.

Let n be the number of observations in X . Your function must have this signature

```
lossvalue = lossfun(Y,Yhat,W)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).
- Y is an n -dimensional vector of observed responses. `RegressionPartitionedLinear.kfoldLoss` passes the input argument Y in for Y .
- $Yhat$ is an n -dimensional vector of predicted responses, which is similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights.

Specify your function using 'LossFun', @*lossfun*.

Data Types: char | function_handle

'Mode' — Loss aggregation level

'average' (default) | 'individual'

Loss aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

Value	Description
'average'	Returns losses averaged over all folds
'individual'	Returns losses for each fold

Example: 'Mode','individual'

Data Types: char

Output Arguments

L — Cross-validated regression losses

numeric scalar | numeric vector | numeric matrix

Cross-validated regression losses, returned as a numeric scalar, vector, or matrix. The interpretation of L depends on LossFun.

Let R be the number of regularizations strengths is the cross-validated models (stored in `numel(CVMdl.Trained{1}.Lambda)`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is `'average'`, then L is a 1-by- R vector. $L(j)$ is the average regression loss over all folds of the cross-validated model that uses regularization strength j .
- Otherwise, L is an F -by- R matrix. $L(i, j)$ is the regression loss for fold i of the cross-validated model that uses regularization strength j .

To estimate L, `kfoldLoss` uses the data that created `CVMdl` (see X and Y).

Examples

Estimate k -Fold Mean Squared Error

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Cross-validate a linear regression model using SVM learners.

```
rng(1); % For reproducibility
CVMdl = fitrlinear(X,Y,'CrossVal','on');
```

CVMdl is a `RegressionPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the test-sample MSEs.

```
mse = kfoldLoss(CVMdl)
```

```
mse =
    0.1735
```

Alternatively, you can obtain the per-fold MSEs by specifying the name-value pair 'Mode', 'individual' in `kfoldLoss`.

Specify Custom Regression Loss

Simulate data as in “Estimate k-Fold Mean Squared Error”.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
X = X'; % Put observations in columns for faster training
```

Cross-validate a linear regression model using 10-fold cross-validation. Solve the objective function using `Sparse`.

```
CVMdl = fitrlinear(X,Y,'CrossVal','on','ObservationsIn','columns',...
    'Solver','sparsa');
```

CVMdl is a `RegressionPartitionedLinear` model. It contains the property `Trained`, which is a 10-by-1 cell array holding `RegressionLinear` models that the software trained using the training set.

Create an anonymous function that measures Huber loss ($\delta = 1$), that is,

$$L = \frac{1}{\sum w_j} \sum_{j=1}^n w_j \ell_j, \text{ where}$$

$$\ell_j = \begin{cases} 0.5\hat{e}^2 & \text{for } |\hat{e}| \leq 1 \\ |\hat{e}| - 0.5 & \text{otherwise} \end{cases} .$$

\hat{e}_j is the residual for observation j . Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the `LOSSFUN` name-value pair argument.

```
huberloss = @(Y,Yhat,W) sum(W.*((0.5*(abs(Y-Yhat)<=1).*(Y-Yhat).^2) + ...
    ((abs(Y-Yhat)>1).*abs(Y-Yhat)-0.5)))/sum(W);
```

Estimate the average Huber loss over the folds. Also, obtain the Huber loss for each fold.

```
mseAve = kfoldLoss(CVMdl, 'LossFun', huberloss)
mseFold = kfoldLoss(CVMdl, 'LossFun', huberloss, 'Mode', 'individual')
```

```
mseAve =
    -0.4447
```

```
mseFold =
    -0.4454
    -0.4479
    -0.4454
    -0.4468
    -0.4435
    -0.4429
    -0.4461
    -0.4422
    -0.4440
    -0.4427
```

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear regression model that uses least squares, implement 5-fold cross-validation.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1} .

```
Lambda = logspace(-5, -1, 15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Solve the objective function using SpaRSA.

```
X = X';
CVMdl = fitrlinear(X,Y, 'ObservationsIn', 'columns', 'KFold', 5, 'Lambda', Lambda, ...
    'Learner', 'leastsquares', 'Solver', 'sparsa', 'Regularization', 'lasso');
```

```
numCLModels = numel(CVMdl.Trained)
```

```
numCLModels =
```

```
5
```

CVMdl is a `RegressionPartitionedLinear` model. Because `fitrlinear` implements 5-fold cross-validation, CVMdl contains 5 `RegressionLinear` models that the software trains on each fold.

Display the first trained linear regression model.

```
Mdl1 = CVMdl.Trained{1}

Mdl1 =
  RegressionLinear
    ResponseName: 'Y'
    ResponseTransform: 'none'
    Beta: [1000x15 double]
    Bias: [1x15 double]
    Lambda: [1x15 double]
    Learner: 'leastsquares'
```

Mdl1 is a `RegressionLinear` model object. `fitrlinear` constructed Mdl1 by training on the first four folds. Because `Lambda` is a sequence of regularization strengths, you can think of Mdl1 as 11 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated MSE.

```
mse = kfoldLoss(CVMdl);
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log10 MSE')
ylabel(h(2),'log10 nonzero-coefficient frequency')
xlabel('log10 Lambda')
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, $\text{Lambda}(10)$).

```
idxFinal = 10;
```

Extract the model with corresponding to the minimal MSE.

```
MdlFinal = selectModels(Mdl,idxFinal)
idxNZCoeff = find(MdlFinal.Beta==0)
EstCoeff = Mdl.Beta(idxNZCoeff)
```

```
MdlFinal =
```

```
RegressionLinear
  ResponseName: 'Y'
  ResponseTransform: 'none'
    Beta: [1000x1 double]
    Bias: -0.0050
    Lambda: 0.0037
  Learner: 'leastquares'
```

```
idxNZCoeff =
```

```
100
200
```

```
EstCoeff =
```

```
1.0051
1.9965
```

`MdlFinal` is a `RegressionLinear` model with one regularization strength. The nonzero coefficients `EstCoeff` are close to the coefficients that simulated the data.

See Also

`kfoldPredict` | `loss` | `RegressionLinear` | `RegressionPartitionedLinear`

Introduced in R2016a

kfoldLoss

Class: RegressionPartitionedModel

Cross-validation loss of partitioned regression model

Syntax

```
L = kfoldLoss(cvmodel)
L = kfoldLoss(cvmodel, Name, Value)
```

Description

`L = kfoldLoss(cvmodel)` returns the cross-validation loss of `cvmodel`.

`L = kfoldLoss(cvmodel, Name, Value)` returns cross-validation loss with additional options specified by one or more `Name, Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Input Arguments

cvmodel

Object of class `RegressionPartitionedModel`. Create `obj` with `fitrtree` along with one of the cross-validation options: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. Alternatively, create `obj` from a regression tree with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'folds'

Indices of folds ranging from 1 to `obj.KFold`. Use only these folds for predictions.

Default: 1:obj.KFold

'lossfun'

Function handle for loss function, or the string 'mse', meaning mean squared error. If you pass a function handle `fun`, `kfoldLoss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

Default: 'mse'

'mode'

One of the following strings:

- 'average' — `L` is the average loss over all folds.
- 'individual' — `L` is a vector of the individual losses of in-fold observations trained on out-of-fold data.

Default: 'average'

Output Arguments

L

The loss (mean squared error) between the observations in a fold when compared against predictions made with a tree trained on the out-of-fold data. If `mode` is 'individual', `L` is a vector of the losses. If `mode` is 'average', `L` is the average loss.

Examples

Construct a partitioned regression model, and examine the cross-validation losses for the folds:

```
load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
cvmodel = fitrtree(XX,YY,'crossval','on');
L = kfoldLoss(cvmodel,'mode','individual')
```

```
L =
    44.9635
    11.8525
    18.2046
     9.2965
    29.4329
    54.8659
    24.6446
     8.2085
    19.7593
    16.7394
```

Alternatives

You can avoid constructing a cross-validated tree model by calling `cvLoss` instead of `kfoldLoss`. The cross-validated tree can save time if you are going to examine it more than once.

See Also

`loss` | `kfoldPredict` | `fitrtree`

kfoldMargin

Class: ClassificationPartitionedECOC

Classification margins for observations not used for training

Syntax

```
margin = kfoldMargin(CVMdl)
margin = kfoldMargin(CVMdl,Name,Value)
```

Description

`margin = kfoldMargin(CVMdl)` returns classification margins obtained by the cross-validated ECOC model (ClassificationPartitionedECOC) `CVMdl`. For every fold, this method computes classification margins for in-fold observations using a model trained on out-of-fold observations. `CVMdl.X` contains both sets of observations.

`margin = kfoldMargin(CVMdl,Name,Value)` returns classification margins with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the binary learner loss function, decoding scheme, or verbosity level.

Input Arguments

CVMdl — Cross-validated ECOC model

ClassificationPartitionedECOC model

Cross-validated ECOC model, specified as a ClassificationPartitionedECOC model. You can create a ClassificationPartitionedECOC model by:

- Passing a trained ECOC model (ClassificationECOC) to `crossval`
- Training an ECOC model using `fitcecoc` and setting any one of these cross-validation name-value pair arguments: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge'
| 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 25-4317.

By default, if all binary learners are:

- SVMs or linear classification models of SVM learners, then `BinaryLoss` is 'hinge'
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is 'exponential'
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is 'binodeviance'
- Linear classification models of logistic regression learners, or you specify to predict class posterior probabilities (i.e., set 'FitPosterior', 1 in `fitcecoc`), then `BinaryLoss` is 'quadratic'

Otherwise, the default `BinaryLoss` is 'hamming'. To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | function_handle

'Decoding' — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the “Binary Loss” on page 25-4314, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'.

Example: 'Decoding', 'lossbased'

Data Types: char

'Options' — Estimation options[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`margin` — Classification margins

numeric vector

Classification margins, returned as a numeric vector. `margin` is an n -by-1 vector, where each row is the margin of the corresponding observation, and n is the number of observations (i.e., `size(CVMdl.X,1)`).

Data Types: `single` | `double`

Definitions

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the true class and maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the `LossFun` name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Estimate k -Fold Cross-Validated Margins of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);  
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the out-of-fold margins. Display the distribution of the margins using a boxplot.

```
margin = kfoldMargin(CVMdl);  
  
figure;  
boxplot(margin);  
title('Cross-Validated Margins')
```

An observation margin is the positive-class, negated loss minus the maximum negative-class, negated loss. Classifiers that yield relatively large margins are desirable.

Select ECOC Model Features by Comparing Cross-Validation Margins

The classifier margin measures the average of the classifier margins. One way to perform feature selection is to compare cross-validation margins from multiple models. Based solely on this criterion, the classifier with the greater margins is the best classifier.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
```

```
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the petal dimensions.

```
fullX = X;
partX = X(:,3:4);
```

Train an ECOC model using SVM binary classifiers for each predictor set, and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
PCVMdl = fitcecoc(partX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedECOC` models. By default, the software implements 10-fold cross validation.

Estimate the test sample margin for each classifier. Specify to use loss-based decoding for aggregating the binary learner results. For each model, display the distribution of the margins using a boxplot.

```
fullMargins = kfoldMargin(CVMdl,'Decoding','lossbased');
partMargins = kfoldMargin(PCVMdl,'Decoding','lossbased');

figure;
boxplot([fullMargins partMargins],'Labels',{'All Predictors','Two Predictors'});
title('Boxplots of Cross-Validated Margins')
```

The margin distributions are approximately the same, but PCVMd1 is a less complex model, which might make it more desirable.

kfoldMargin

Class: ClassificationPartitionedLinear

Classification margins for observations not used in training

Syntax

```
m = kfoldMargin(CVMdl)
```

Description

`m = kfoldMargin(CVMdl)` returns the cross-validated classification margins obtained by the cross-validated, binary, linear classification model `CVMdl`. That is, for every fold, `kfoldMargin` estimates the classification margins for observations that it holds out when it trains using all other observations.

`m` contains classification margins for each regularization strength in the linear classification models that comprise `CVMdl`.

Input Arguments

CVMdl — Cross-validated, binary, linear classification model

ClassificationPartitionedLinear model object

Cross-validated, binary, linear classification model, specified as a ClassificationPartitionedLinear model object. You can create a ClassificationPartitionedLinear model using `fitclinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, ClassificationPartitionedLinear.kfoldMargin applies the same data used to cross-validate the linear classification model (X and Y).

Output Arguments

m — Cross-validated classification margins

numeric vector | numeric matrix

Cross-validated classification margins, returned as a numeric vector or matrix.

m is n -by- L , where n is the number of observations in the data that created `CVMD1` (see `X` and `Y`) and L is the number of regularization strengths in `CVMD1` (that is, `numel(CVMD1.Trained{1}.Lambda)`).

$m(i, j)$ is the cross-validated classification margin of observation i using the linear classification model that has regularization strength `CVMD1.Trained{1}.Lambda(j)`.

Data Types: `single` | `double`

Definitions

Classification Margin

The *classification margins* for binary classification are, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The literature commonly defines the margin as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Classification Score

For linear classification models, the raw *classification score* for classifying the observation x , a row vector, into the positive class is

$$f(x_j) = x\beta_j + b_j.$$

For the model with regularization strength j , β_j is the estimated column vector of coefficients (the model property `Beta(:,j)`) and b_j be the estimated, scalar bias (the model property `Bias(j)`).

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Examples

Estimate k -Fold Cross-Validation Margins

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility  
CVMdl = fitlinear(X,Ystats,'CrossVal','on');
```

`CVMdl` is a `ClassificationPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the cross-validated margins.

```
m = kfoldMargin(CVMdl);  
size(m)
```

```
ans =
```

```
    31572         1
```

m is a 31572-by-1 vector. $m(j)$ is the average of the out-of-fold margins for observation j .

Plot the k -fold margins using box plots.

```
figure;  
boxplot(m);  
h = gca;  
h.YLim = [-5 30];  
title('Distribution of Cross-Validated Margins')
```

Feature Selection Using k -fold Margins

One way to perform feature selection is to compare k -fold margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the NLP data set. Preprocess the data as in “Estimate k -Fold Cross-Validation Margins”.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Cross-validate two binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Solve the objective function using SparSA, and indicate that observations correspond to columns.

```
CVMD1 = fitlinear(fullX,Ystats,'CrossVal','on','Solver','sparsa',...
    'ObservationsIn','columns');
PCVMD1 = fitlinear(partX,Ystats,'CrossVal','on','Solver','sparsa',...
    'ObservationsIn','columns');
```

`CVMD1` and `PCVMD1` are `ClassificationPartitionedLinear` models.

Estimate the k -fold margins for each classifier. Plot the distribution of the k -fold margins sets using box plots.

```
fullMargins = kfoldMargin(CVMD1);
partMargins = kfoldMargin(PCVMD1);

figure;
boxplot([fullMargins partMargins],'Labels',...
    {'All Predictors','Half of the Predictors'});
h = gca;
h.YLim = [-30 60];
title('Distribution of Cross-Validated Margins')
```

The distributions of the margins of the two classifiers are similar.

Find Good Lasso Penalty Using k -fold Margins

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare distributions of k -fold margins.

Load the NLP data set. Preprocess the data as in “Estimate k -Fold Cross-Validation Margins”.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-8} through 10^1 .

```
Lambda = logspace(-8,1,11);
```

Cross-validate a binary, linear classification model using 5-fold cross-validation and that uses each of the regularization strengths. Solve the objective function using SpARSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
rng(10); % For reproducibility
CVMdl = fitlinear(X,Ystats,'ObservationsIn','columns','KFold',5,...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8)
```

```
CVMdl =
```

```
classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
    ResponseName: 'Y'
  NumObservations: 31572
    KFold: 5
    Partition: [1x1 cvpartition]
    ClassNames: [0 1]
  ScoreTransform: 'none'
```

CVMdl is a `ClassificationPartitionedLinear` model. Because `fitlinear` implements 5-fold cross-validation, CVMdl contains 5 `ClassificationLinear` models that the software trains on each fold.

Estimate the k -fold margins for each regularization strength.

```
m = kfoldMargin(CVMdl);
size(m)
```

```
ans =
```

```
31572    11
```

`m` is a 31572-by-11 matrix of cross-validated margins for each observation. The columns correspond to the regularization strengths.

Plot the k -fold margins for each regularization strength. Because logistic regression scores are in $[0,1]$, margins are in $[-1,1]$. Rescale the margins to help identify the regularization strength that maximizes the margins over the grid.

```
figure;
boxplot(10000.^m)
ylabel('Exponentiated test-sample margins')
xlabel('Lambda indices')
```

Several values of `Lambda` yield k -fold margin distributions that are compacted near 10000^1 . Higher values of `lambda` lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the centers of the k -fold margin distributions start decreasing.

```
LambdaFinal = Lambda(5);
```

Train a linear classification model using the entire data set and specify the desired regularization strength.

```
MdlFinal = fitclinear(X,Ystats,'ObservationsIn','columns',...  
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...  
    'Lambda',LambdaFinal);
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Introduced in R2016a

kfoldMargin

Class: ClassificationPartitionedLinearECOC

Classification margins for observations not used in training

Syntax

```
m = kfoldMargin(CVMdl)
m = kfoldMargin(CVMdl,Name,Value)
```

Description

`m = kfoldMargin(CVMdl)` returns the cross-validated classification margins obtained by `CVMdl`, which is a cross-validated, error-correcting output codes (ECOC) model composed of linear classification models. That is, for every fold, `kfoldMargin` estimates the classification margins for observations that it holds out when it trains using all other observations.

`m` contains classification margins for each regularization strength in the linear classification models that comprise `CVMdl`.

`m = kfoldMargin(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify a decoding scheme or verbosity level.

Input Arguments

CVMdl — Cross-validated, ECOC model composed of linear classification models

ClassificationPartitionedLinearECOC model object

Cross-validated, ECOC model composed of linear classification models, specified as a ClassificationPartitionedLinearECOC model object. You can create a ClassificationPartitionedLinearECOC model using `fitcecoc` and by:

- 1 Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`

- 2 Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, `ClassificationPartitionedLinearECOC.kfoldMargin` applies the same data used to cross-validate the ECOC model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'`
| `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
<code>'binodeviance'</code>	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
<code>'exponential'</code>	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
<code>'hamming'</code>	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
<code>'hinge'</code>	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
<code>'linear'</code>	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
<code>'logit'</code>	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
<code>'quadratic'</code>	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
where:
```

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 25-4317.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is `'hinge'`
- Logistic regression, then `BinaryLoss` is `'quadratic'`

Example: `'BinaryLoss','binodeviance'`

Data Types: char | function_handle

'Decoding' — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the “Binary Loss” on page 25-4314, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding','lossbased'`

Data Types: char

'Options' — Estimation options[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`m` — Cross-validated classification margins

numeric vector | numeric matrix

Cross-validated classification margins, returned as a numeric vector or matrix.

`m` is n -by- L , where n is the number of observations in `X` and L is the number of regularization strengths in `Mdl` (that is, `numel(Mdl.Lambda)`).

`m(i,j)` is the cross-validated classification margin of observation i using the ECOC model, composed of linear classification models, that has regularization strength `Mdl.Lambda(j)`.

Definitions

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of predict and loss), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the true class and maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Examples

Estimate k -Fold Cross-Validation Margins

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Cross-validate a multiclass, linear classification model.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

CVMdl is a `ClassificationPartitionedLinearECOC` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the k -fold margins.

```
m = kfoldMargin(CVMdl);
size(m)
```

```
ans =
```

```
    31572         1
```

m is a 31572-by-1 vector. $m(j)$ is the average of the out-of-fold margins for observation j .

Plot the k -fold margins using box plots.

```
figure;
boxplot(m);
h = gca;
h.YLim = [-5 5];
title('Distribution of Cross-Validated Margins')
```

Feature Selection Using k -fold Margins

One way to perform feature selection is to compare k -fold margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the NLP data set. Preprocess the data as in “Estimate k -Fold Cross-Validation Margins”, and orient the predictor data so that observations correspond to columns.

```
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Create a linear classification model template that specifies to solve the objective function using SpaRSA.

```
t = templateLinear('Solver','sparsa');
```

Cross-validate two ECOC models composed of binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Indicate that observations correspond to columns.

```
CVMD1 = fitcecoc(fullX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
PCVMD1 = fitcecoc(partX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
```

`CVMD1` and `PCVMD1` are `ClassificationPartitionedLinearECOC` models.

Estimate the k -fold margins for each classifier. Plot the distribution of the k -fold margins sets using box plots.

```
fullMargins = kfoldMargin(CVMD1);
partMargins = kfoldMargin(PCVMD1);

figure;
boxplot([fullMargins partMargins],'Labels',...
    {'All Predictors','Half of the Predictors'});
h = gca;
h.YLim = [-1 1];
title('Distribution of Cross-Validated Margins')
```

The distributions of the k -fold margins of the two classifiers are similar.

Find Good Lasso Penalty Using k -fold Margins

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare distributions of k -fold margins.

Load the NLP data set. Preprocess the data as in “Feature Selection Using k -fold Margins”.

```
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-8} through 10^1 .

```
Lambda = logspace(-8,1,11);
```

Create a linear classification model template that specifies to use logistic regression with a lasso penalty, use each of the regularization strengths, solve the objective function using SpaRSA, and reduce the tolerance on the gradient of the objective function to $1e-8$.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...  
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate an ECOC model composed of binary, linear classification models using 5-fold cross-validation and that

```
rng(10); % For reproducibility  
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5)
```

```
CVMdl =
```

```
classreg.learning.partition.ClassificationPartitionedLinearECOC  
  CrossValidatedModel: 'Linear'  
    ResponseName: 'Y'  
  NumObservations: 31572  
        KFold: 5  
    Partition: [1x1 cvpartition]  
    ClassNames: [comm dsp simulink others]  
  ScoreTransform: 'none'
```

CVMdl is a ClassificationPartitionedLinearECOC model.

Estimate the k -fold margins for each regularization strength. The scores for logistic regression are in $[0,1]$. Apply the quadratic binary loss.

```
m = kfoldMargin(CVMdl,'BinaryLoss','quadratic');  
size(m)
```

```
ans =
```

```
31572    11
```

m is a 31572-by-11 matrix of cross-validated margins for each observation. The columns correspond to the regularization strengths.

Plot the k -fold margins for each regularization strength.

```
figure;  
boxplot(m)  
ylabel('Cross-validated margins')  
xlabel('Lambda indices')
```

Several values of **Lambda** yield similarly high margin distribution centers with low spreads. Higher values of **Lambda** lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the margin distribution center starts decreasing and spread starts increasing.

```
LambdaFinal = Lambda(5);
```

Train an ECOC model composed of linear classification model using the entire data set and specify the regularization strength `LambdaFinal`.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...  
    'Regularization','lasso','Lambda',Lambda(5),'GradientTolerance',1e-8);  
MdlFinal = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns');
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Introduced in R2016a

kfoldMargin

Class: ClassificationPartitionedModel

Classification margins for observations not used for training

Syntax

```
M = kfoldMargin(obj)
```

Description

`M = kfoldMargin(obj)` returns classification margins obtained by cross-validated classification model `obj`. For every fold, this method computes classification margins for in-fold observations using a model trained on out-of-fold observations.

Input Arguments

obj

A partitioned classification model of type `ClassificationPartitionedModel` or `ClassificationPartitionedEnsemble`.

Output Arguments

M

The classification margin.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X . A high value of margin indicates a more reliable prediction than a low value.

Score

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 16-7.

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

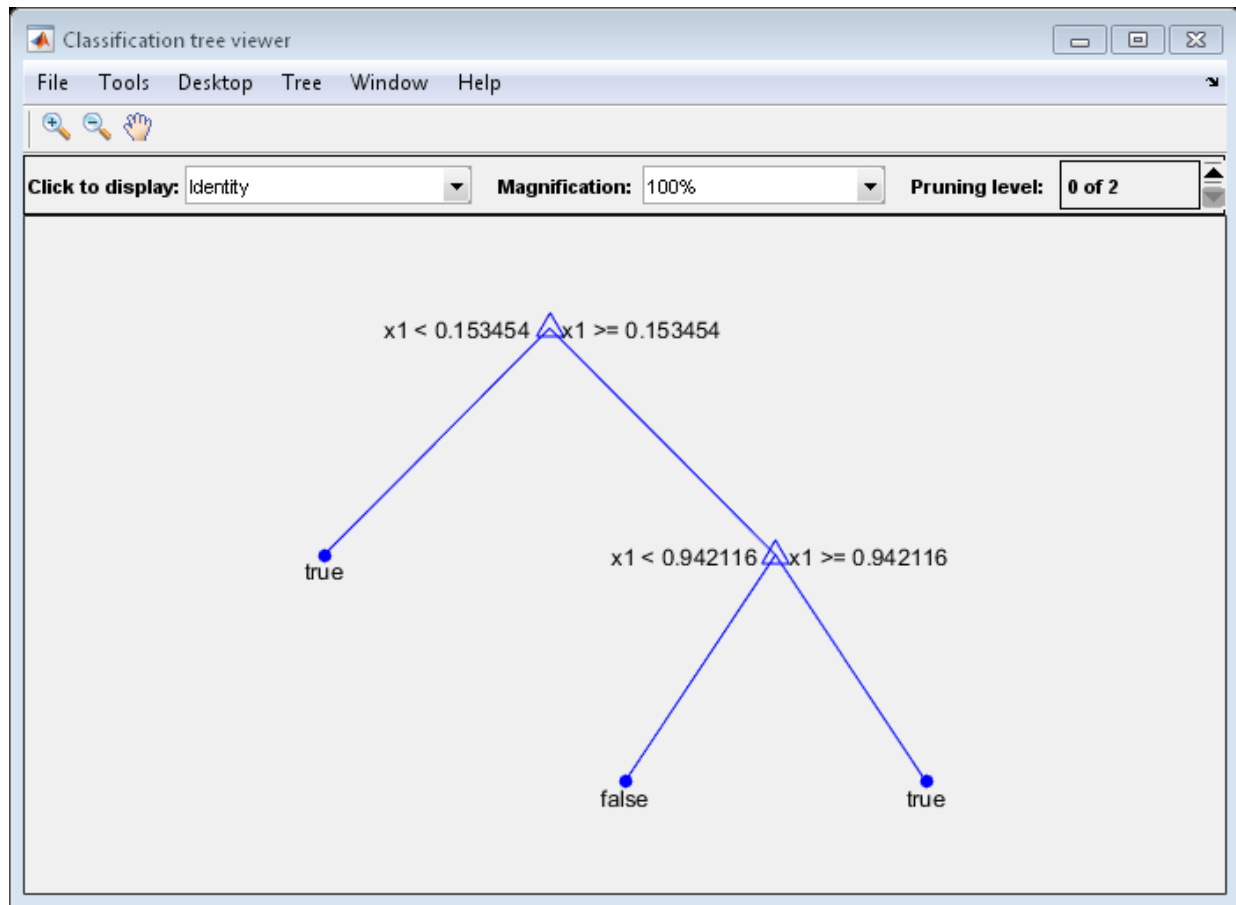

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as true when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

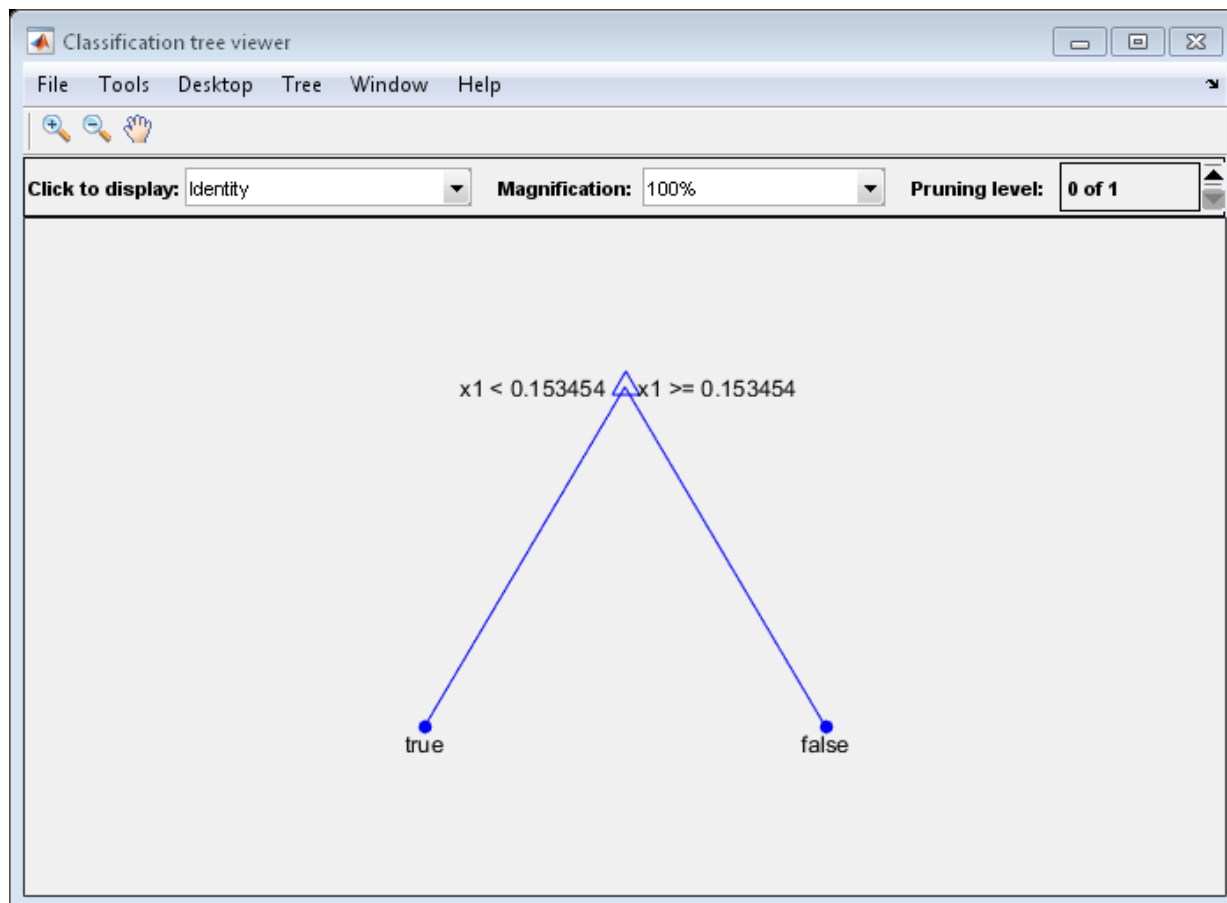

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for **true**, and about $.8/.85=.94$ for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =  
  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0     1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0     1.0000    0.0975  
    0.9059    0.0941    0.2785  
    0.9059    0.0941    0.5469  
    0.9059    0.0941    0.9575  
    0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range $(.95, 1)$ instead of the expected 5 observations.

Examples

Estimate the k -fold Margins of a Classifier

Find the k -fold margins for an ensemble that classifies the ionosphere data.

Load the ionosphere data set.

```
load ionosphere
```

Train a classification ensemble of decision trees.

```
Mdl = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
```

Cross validate the classifier using 10-fold cross validation.

```
cvens = crossval(Mdl);
```

Compute the `_k_fold` margins. Display summary statistics for the margins.

```
m = kfoldMargin(cvens);  
marginStats = table(min(m),mean(m),max(m),...  
    'VariableNames',{'Min','Mean','Max'})
```

```
marginStats =
```

Min	Mean	Max
-11.312	7.3236	23.517

kfoldPredict

Class: ClassificationPartitionedECOC

Predict responses for observations not used for training

Syntax

```
label = kfoldPredict(CVMdl)
label = kfoldPredict(CVMdl,Name,Value)
[label,NegLoss,PBScore] = kfoldPredict(____)
[label,NegLoss,PBScore,Posterior] = kfoldPredict(____)
```

Description

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated ECOC model (ClassificationPartitionedECOC) `CVMdl`. That is, for every fold, `kfoldPredict` predicts class labels for observations that it holds out when it trains. `CVMdl.X` contains both sets of observations.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = kfoldPredict(CVMdl,Name,Value)` returns predicted class labels with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label,NegLoss,PBScore] = kfoldPredict(____)` additionally returns negated values of the average binary loss per class (`NegLoss`) for in-fold observations, and positive-class scores (`PBScore`) for in-fold observations classified by each binary learner.

If the coding matrix varies across folds (that is, if the coding scheme is `sparsrandom` or `denserandom`), then `PBScore` is empty (`[]`).

`[label,NegLoss,PBScore,Posterior] = kfoldPredict(____)` additionally returns posterior class probability estimates for in-fold observations (`Posterior`).

To obtain posterior class probabilities, you must set `'FitPosterior', 1` when training the ECOC model using `fitcecoc`. Otherwise, `kfoldPredict` throws an error.

Input Arguments

CVMd1 — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model by:

- Passing a trained ECOC model (`ClassificationECOC`) to `crossval`
- Training an ECOC model using `fitcecoc` and setting any one of these cross-validation name-value pair arguments: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'`
| `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
<code>'binodeviance'</code>	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$

Value	Description	Score Domain	$g(y_i, s_i)$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_i s_i)/2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_i s_i)]/2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_i s_i)/2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_i s_i)/2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_i s_i)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_i(2s_i - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss', @customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 25-4317.

By default, if all binary learners are:

- SVMs or linear classification models of SVM learners, then `BinaryLoss` is `'hinge'`
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is `'exponential'`
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is `'binodeviance'`

- Linear classification models of logistic regression learners, or you specify to predict class posterior probabilities (i.e., set 'FitPosterior', 1 in fitcecoc), then BinaryLoss is 'quadratic'

Otherwise, the default BinaryLoss is 'hamming'. To check the default value, use dot notation to display the BinaryLoss property of the trained model at the command line.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | function_handle

'Decoding' — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the “Binary Loss” on page 25-4314, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'.

Example: 'Decoding', 'lossbased'

Data Types: char

'NumKLInitializations' — Number of random initial values

0 (default) | nonnegative integer

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of 'NumKLInitializations' and a nonnegative integer.

If you do not request the fourth output argument (Posterior) and set 'PosteriorMethod', 'kl' (the default), then the software ignores the value of NumKLInitializations.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 25-4325.

Example: 'NumKLInitializations', 5

Data Types: single | double

'Options' — Estimation options

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',1)`.

'PosteriorMethod' — Posterior probability estimation method

`'k1'` (default) | `'qp'`

Posterior probability estimation method, specified as the comma-separated pair consisting of `'PosteriorMethod'` and `'k1'` or `'qp'`.

- If `PosteriorMethod` is `'k1'`, then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 25-4325.
- If `PosteriorMethod` is `'qp'`, then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 25-4327.
- If you do not request the fourth output argument (`Posterior`), then the software ignores the value of `PosteriorMethod`.

Example: `'PosteriorMethod','qp'`

Data Types: char

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: single | double

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

label:

- Is the same data type as `CVMD1.Y`
- Has length equal to the number of rows of `CVMD1.X`

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

NegLoss — Negated average binary losses

numeric matrix

Negated average binary losses, returned as a numeric matrix. `NegLoss` is an n -by- K matrix, where n is the number of observations (`size(CVMD1.X,1)`) and K is the number of unique classes (`size(CVMD1.ClassNames,1)`).

PBScore — Positive-class scores

numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. `PBScore` is an n -by- L matrix, where n is the number of observations (`size(CVMD1.X,1)`) and L is the number of binary learners (`size(CVMD1.CodingMatrix,2)`).

If the coding matrix varies across folds (that is, if the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty (`[]`).

Posterior — Posterior class probabilities

numeric matrix

Posterior class probabilities, returned as a numeric matrix. `Posterior` is an n -by- K matrix, where n is the number of observations (`size(CVMD1.X,1)`) and K is the number of unique classes (`size(CVMD1.ClassNames,1)`).

You must set 'FitPosterior', 1 when training the ECOC model using `fitcecoc` to request Posterior. Otherwise, the software throws an error.

Definitions

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of predict and loss), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Predict k -Fold Cross-Validation Labels of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Predict the out-of-fold labels. Print a random subset of true and predicted labels.

```
labels = kfoldPredict(CVMdl);
idx = randsample(numel(labels),10);
table(Y(idx),labels(idx),...
      'VariableNames',{'TrueLabels','PredictedLabels'})
```

ans =

TrueLabels	PredictedLabels
setosa	setosa
versicolor	versicolor
setosa	setosa
virginica	virginica
versicolor	versicolor
setosa	setosa
virginica	virginica
virginica	virginica
setosa	setosa
setosa	setosa

CVMdl correctly labeled the out-of-fold observations with indices `idx`.

Predict Cross-Validation Labels of ECOC Models Using Custom Binary Loss Function

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
K = numel(classOrder); % Number of classes
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers and specify to cross validate. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a `ClassificationPartitionedModel` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

SVM scores are signed distances from the observation to the decision boundary.

Therefore, the domain is $(-\infty, \infty)$. Create a custom binary loss function that:

- Maps the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 out-of-fold observations.

```
[label,NegLoss] = kfoldPredict(CVMdl,'BinaryLoss',customBL);
```

```
idx = randsample(numel(label),10);
classOrder
table(Y(idx),label(idx),NegLoss(idx,:), 'VariableNames',...
      {'TrueLabel','PredictedLabel','NegLoss'})
```

```
classOrder =
    setosa
  versicolor
  virginica
```

```
ans =
```

TrueLabel	PredictedLabel	NegLoss		
setosa	versicolor	0.37141	2.1292	-4.0006
versicolor	versicolor	-1.2169	0.36685	-0.64995
setosa	versicolor	0.23914	2.0795	-3.8187
virginica	virginica	-1.915	-0.19952	0.61451
versicolor	versicolor	-1.3744	0.45537	-0.58093
setosa	versicolor	0.20073	2.2777	-3.9784
virginica	versicolor	-1.4926	0.09073	-0.098159
virginica	virginica	-1.7667	-0.13462	0.40134
setosa	versicolor	0.20006	1.9112	-3.6112
setosa	versicolor	0.16108	1.9684	-3.6294

The order of the columns corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results seem to indicate that the median of the linear losses might not perform as well as other losses.

Estimate Cross-Validation Posterior Probabilities of ECOC Models

Load Fisher's iris data set. Train the classifier using the petal dimensions as predictors.

```
load fisheriris
X = meas(:,3:4);
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Create an SVM template, and specify the Gaussian kernel. It is good practice to standardize the predictors.

```
t = templateSVM('Standardize',1,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template, and specify to cross validate. Transform classification scores to class posterior probabilities (returned by `kfoldPredict`) using the `'FitPosterior'` name-value pair argument. It is good practice to specify the class order.

```
CVMD1 = fitcecoc(X,Y,'Learners',t,'CrossVal','on','FitPosterior',true,...
```

```
'ClassNames',classOrder);
```

CVMdl is a `ClassificationPartitionedECOC` model. By default, the software uses 10-fold cross validation.

Predict the out-of-fold class posterior probabilities. Specify to use 10 random initial values for the Kullback-Leibler algorithm.

```
[label,~,~,Posterior] = kfoldPredict(CVMdl,'NumKLInitializations',10);
```

The software assigns an observation to the class that yields the smallest average binary loss. Since all binary learners are computing posterior probabilities, the binary loss function is quadratic.

Display a random set of results.

```
idx = randsample(size(X,1),10);
CVMdl.ClassNames
table(Y(idx),label(idx),Posterior(idx,:),...
      'VariableNames',{'TrueLabel','PredLabel','Posterior'})
```

```
ans =
```

```
setosa
versicolor
virginica
```

```
ans =
```

TrueLabel	PredLabel	Posterior		
versicolor	versicolor	0.0086394	0.98243	0.0089291
versicolor	virginica	2.2197e-14	0.12447	0.87553
setosa	setosa	0.999	0.00022837	0.00076884
versicolor	versicolor	2.2194e-14	0.98916	0.010839
virginica	virginica	0.012318	0.012925	0.97476
virginica	virginica	0.0015571	0.0015638	0.99688
virginica	virginica	0.0042895	0.0043556	0.99135
setosa	setosa	0.999	0.00028329	0.00071382
virginica	virginica	0.0094721	0.0098231	0.9807
setosa	setosa	0.999	0.00013562	0.00086192

The columns of `Posterior` correspond to the class order of `Mdl.ClassNames`.

Estimate Cross-Validation Posterior Probabilities Using Parallel Computing

Train an error-correcting output codes, multiclass model and estimate posterior probabilities using parallel computing.

Load the `arrhythmia` data set.

```
load arrhythmia
Y = categorical(Y);
tabulate(Y)
n = numel(Y);
K = numel(unique(Y));
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

Several classes are not represented in the data, and many of the other classes have low relative frequencies.

Specify an ensemble learning template that uses the `GentleBoost` method, and 50 weak, classification tree learners.

```
t = templateEnsemble('GentleBoost',50,'Tree');
```

`t` is a template object. Most of the options are empty (`[]`). The software uses default values for all empty options during training.

Since there are many classes, specify a sparse random coding design.

```
rng(1); % For reproducibility
```

```
Coding = designecoc(K, 'sparserandom');
```

Train an ECOC model using parallel computing, and specify to cross validate and fit posterior probabilities (returned by `kfoldPredict`).

```
pool = parpool; % Invokes workers
options = statset('UseParallel',1);
CVMdl = fitcecoc(X,Y,'Learner',t,'Options',options,'Coding',Coding,...
    'FitPosterior',1,'CrossVal','on');
```

Starting parallel pool (parpool) using the 'local' profile ... connected to 4 workers.
Warning: One or more folds do not contain points from all the groups.

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

The pool invokes four workers. The number of workers might vary among systems. Also, there is a good chance that one or more folds do not contain observations from all classes since some classes have low relative frequency.

Estimate posterior probabilities, and display the posterior probability of being classified as not having arrhythmia (class 1) given the data for a random set of out-of-fold observations.

```
[~,~,~,posterior] = kfoldPredict(CVMdl,'Options',options);
idx = randsample(n,10);
table(idx,Y(idx),posterior(idx,1),...
    'VariableNames',{'OOFSampleIndex','TrueLabel','PosteriorNoArrhythmia'})
```

```
ans =
```

OOFSampleIndex	TrueLabel	PosteriorNoArrhythmia
171	1	0.33654
221	1	0.85135
72	16	0.9174
3	10	0.025649
202	1	0.8438
243	1	0.94338
18	1	0.81789
49	6	0.090153
234	1	0.61626

- “Quick Start Parallel Computing for Statistics and Machine Learning Toolbox” on page 24-2

Algorithms

- The software can estimate class posterior probabilities using quadratic programming or by minimizing the Kullback-Leibler divergence. For the following descriptions of the posterior estimation algorithms, let:
 - m_{kj} be the element (k,j) of the coding design matrix M .
 - I be the indicator function.
 - \hat{p}_k be the class posterior probability estimate for class k of an observation, $k = 1, \dots, K$.
 - r_j be the positive-class posterior probability for binary learner j . That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r, r) = \sum_{j=1}^L w_j \left[r_j \log \frac{r_j}{r_j} + (1 - r_j) \log \frac{1 - r_j}{1 - r_j} \right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j with S_j the set of observation

indices that binary learner j is trained on and w_i^* is the weight of observation i . The software minimizes the divergence iteratively. The first step is to choose initial values $\hat{p}_k^{(0)}$; $k = 1, \dots, K$ for the class posterior probabilities.

- If you do not specify `NumKLIterations`, then the software uses both sets of deterministic initial values described next, and uses the one that minimizes Δ .
 - $\hat{p}_k^{(0)} = 1 / K$; $k = 1, \dots, K$.
 - $\hat{p}_k^{(0)}$; $k = 1, \dots, K$ is the solution of the system

$$M_{01} \hat{p}^{(0)} = r,$$

where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [14]. The software uses `lsqnonneg` to solve the system.

- If you specify `'NumKLIterations', c`, where c is a natural number, then the software does the following to choose $\hat{p}_k^{(0)}$; $k = 1, \dots, K$, and uses the one that minimizes Δ .
 - The software chooses both sets of deterministic initial values as described previously.
 - The software randomly generates c vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t , the software:

- 1 Computes

$$\hat{r}_j^{(t)} = \frac{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

- 2 Estimates the next class posterior probability using

$$\hat{p}_k^{(t+1)} = \hat{p}_k^{(t)} \frac{\sum_{j=1}^L w_j [r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1)]}{\sum_{j=1}^L w_j [\hat{r}_j^{(t)} I(m_{kj} = +1) + (1 - \hat{r}_j^{(t)}) I(m_{kj} = -1)]}.$$

- 3 Normalizes $\hat{p}_k^{(t+1)}$; $k = 1, \dots, K$ so that they sum to 1.
- 4 Checks for convergence.

For more details, see [23] and [46].

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software:

- 1 Estimates the positive-class posterior probabilities, r_j , for binary learners $j = 1, \dots, L$.
- 2 Using the relationship between r_j and \hat{p}_k [42], minimizes

$$\sum_{j=1}^L \left[-r_j \sum_{k=1}^K \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^K \hat{p}_k I(m_{kj} = +1) \right]^2$$

with respect to \hat{p}_k and the restrictions

$$\begin{aligned} 0 &\leq \hat{p}_k \leq 1 \\ \sum_k \hat{p}_k &= 1. \end{aligned}$$

The software performs minimization using `quadprog`.

kfoldPredict

Class: ClassificationPartitionedLinear

Predict labels for observations not used for training

Syntax

```
Label = kfoldPredict(CVMdl)
[Label,Score] = kfoldPredict(CVMdl)
```

Description

`Label = kfoldPredict(CVMdl)` returns cross-validated class labels predicted by the cross-validated, binary, linear classification model `CVMdl`. That is, for every fold, `kfoldPredict` predicts class labels for observations that it holds out when it trains using all other observations.

`Label` contains predicted class labels for each regularization strength in the linear classification models that compose `CVMdl`.

`[Label,Score] = kfoldPredict(CVMdl)` also returns cross-validated classification scores for both classes. `Score` contains classification scores for each regularization strength in `CVMdl`.

Input Arguments

CVMdl — Cross-validated, binary, linear classification model

`ClassificationPartitionedLinear` model object

Cross-validated, binary, linear classification model, specified as a `ClassificationPartitionedLinear` model object. You can create a `ClassificationPartitionedLinear` model using `fitlinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, `ClassificationPartitionedLinear.kfoldPredict` applies the same data used to cross-validate the linear classification model (X and Y).

Output Arguments

Label — Cross-validated, predicted class labels

categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

Cross-validated, predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

In most cases, `Label` is an n -by- L array of the same data type as the observed class labels (see `Y`) used to create `CVMD1`. n is the number of observations in the predictor data (see `X`) and L is the number of regularization strengths in `CVMD1.Trained{1}.Lambda`. That is, `Label(i,j)` is the predicted class label for observation i using the linear classification model that has regularization strength `CVMD1.Trained{1}.Lambda(j)`.

If `Y` is a character array and $L > 1$, then `Label` is a cell array of class labels.

Score — Cross-validated classification scores

numeric array

Cross-validated classification scores, returned as an n -by-2-by- L numeric array. n is the number of observations in the predictor data that created `CVMD1` (see `X`) and L is the number of regularization strengths in `CVMD1.Trained{1}.Lambda`. `Score(i,k,j)` is the score for classifying observation i into class k using the linear classification model that has regularization strength `CVMD1.Trained{1}.Lambda(j)`. `CVMD1.ClassNames` stores the order of the classes.

If `CVMD1.Trained{1}.Learner` is 'logistic', then classification scores are posterior probabilities.

Definitions

Classification Score

For linear classification models, the raw *classification score* for classifying the observation x , a row vector, into the positive class is

$$f(x_j) = x\beta_j + b_j.$$

For the model with regularization strength j , β_j is the estimated column vector of coefficients (the model property `Beta(:, j)`) and b_j be the estimated, scalar bias (the model property `Bias(j)`).

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Examples

Predict k -fold Cross-Validation Labels

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model using the entire data set, which can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility
CVMdl = fitlinear(X, Ystats, 'CrossVal', 'on');
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
```

```
ClassificationLinear
ResponseName: 'Y'
```

```

    ClassNames: [0 1]
  ScoreTransform: 'none'
        Beta: [34023x1 double]
        Bias: -1.0008
        Lambda: 3.5193e-05
    Learner: 'svm'

```

CVMD1 is a `ClassificationPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Predict labels for the observations that `fitclinear` did not use in training the folds.

```
label = kfoldPredict(CVMD1);
```

Because there is one regularization strength in `Mdl1`, `label` is a column vector of predictions containing as many rows as observations in `X`.

Construct a confusion matrix.

```
ConfusionTrain = confusionmat(Ystats,label)
```

```
ConfusionTrain =
```

```

    30009         9
         15    1539

```

The model misclassifies 15 `'stats'` documentation pages as being outside of the Statistics and Machine Learning Toolbox documentation, and misclassifies nine pages as `'stats'` pages.

Estimate *k*-fold Cross-Validation Posterior Class Probabilities

Linear classification models return posterior probabilities for logistic regression learners only.

Load the NLP data set and preprocess it as in “Predict *k*-fold Cross-Validation Labels”. Transpose the predictor data matrix.

```
load nlpdata
```

```
Ystats = Y == 'stats';  
X = X';
```

Cross-validate binary, linear classification models using 5-fold cross-validation. Solve the objective function using SpARSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
rng(10); % For reproducibility  
CVMdl = fitlinear(X,Ystats,'ObservationsIn','columns',...  
    'KFold',5,'Learner','logistic','Solver','sparsa',...  
    'Regularization','lasso','GradientTolerance',1e-8);
```

Predict the posterior class probabilities for observations not used to train each fold.

```
[~,posterior] = kfoldPredict(CVMdl);  
CVMdl.ClassNames
```

```
ans =
```

```
    0  
    1
```

Because there is one regularization strength in `CVMdl`, `posterior` is a matrix with 2 columns and rows equal to the number of observations. Column i contains posterior probabilities of `Mdl.ClassNames(i)` given a particular observation.

Obtain false and true positive rates, and estimate the AUC. Specify that the second class is the positive class.

```
[fpr,tpr,~,auc] = perfcurve(Ystats,posterior(:,2),CVMdl.ClassNames(2));  
auc
```

```
auc =
```

```
    0.9990
```

The AUC is **0.9990**, which indicates a model that predicts well.

Plot an ROC curve.

```
figure;
```

```
plot(fpr, tpr)
h = gca;
h.XLim(1) = -0.1;
h.YLim(2) = 1.1;
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve')
```

The ROC curve indicates that the model classifies almost perfectly.

Find Good Lasso Penalty Using Cross-Validated AUC

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare cross-validated AUC values.

Load the NLP data set. Preprocess the data as in “Estimate k-fold Cross-Validation Posterior Class Probabilities”.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

There are 9471 observations in the test sample.

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6, -0.5, 11);
```

Cross-validate a binary, linear classification models that use each of the regularization strengths and 5-fold cross-validation. Solve the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
rng(10); % For reproducibility
CVMdl = fitlinear(X, Ystats, 'ObservationsIn', 'columns', ...
    'KFold', 5, 'Learner', 'logistic', 'Solver', 'sparsa', ...
    'Regularization', 'lasso', 'Lambda', Lambda, 'GradientTolerance', 1e-8)
Mdl1 = CVMdl.Trained{1}
```

```
CVMdl =
```

```
classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 5
  Partition: [1x1 cvpartition]
  ClassNames: [0 1]
  ScoreTransform: 'none'
```

```
Mdl1 =
```

```
ClassificationLinear
  ResponseName: 'Y'
  ClassNames: [0 1]
```

```
ScoreTransform: 'logit'  
    Beta: [34023x11 double]  
    Bias: [1x11 double]  
    Lambda: [1x11 double]  
    Learner: 'logistic'
```

`Mdl1` is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl1` as 11 models, one for each regularization strength in `Lambda`.

Predict the cross-validated labels and posterior class probabilities.

```
[label,posterior] = kfoldPredict(CVMdl);  
CVMdl.ClassNames;  
[n,K,L] = size(posterior)  
posterior(3,1,5)
```

```
n =  
  
    31572
```

```
K =  
  
     2
```

```
L =  
  
    11
```

```
ans =  
  
    1.0000
```

`label` is a 31572-by-11 matrix of predicted labels. Each column corresponds to the predicted labels of the model trained using the corresponding regularization strength. `posterior` is a 31572-by-2-by-11 matrix of posterior class probabilities. Columns correspond to classes and pages correspond to regularization strengths. For example,

`posterior(3,2,5)` indicates that the posterior probability that the first class (label 0) is assigned to observation 3 by the model that uses `Lambda(5)` as a regularization strength is 1.0000.

For each model, compute the AUC. Designate the second class as the positive class.

```
auc = 1:numel(Lambda); % Preallocation
for j = 1:numel(Lambda)
    [~,~,~,auc(j)] = perfcurve(Ystats,posterior(:,2,j),CVMdl.ClassNames(2));
end
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model for each regularization strength using the entire data set and the same options as when you trained the model. Determine the number of nonzero coefficients per model.

```
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the test-sample error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(auc),...
    log10(Lambda),log10(numNZCoeff + 1));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} AUC')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
title('Cross-Validated Statistics')
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and high AUC. In this case, a value between 10^{-3} to 10^{-1} should suffice.

```
idxFinal = 9;
```

Select the model from Md1 with the chosen regularization strength.

```
Md1Final = selectModels(Md1,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Introduced in R2016a

kfoldPredict

Class: ClassificationPartitionedLinearECOC

Predict labels for observations not used for training

Syntax

```
Label = kfoldPredict(CVMdl)
Label = kfoldPredict(CVMdl,Name,Value)
[Label,NegLoss,PBScore] = kfoldPredict( ___ )
[Label,NegLoss,PBScore,Posterior] = kfoldPredict( ___ )
```

Description

`Label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated ECOC model composed of linear classification models `CVMdl`. That is, for every fold, `kfoldPredict` predicts class labels for observations that it holds out when it trains using all other observations. `kfoldPredict` applies the same data used create `CVMdl` (see `fitcecoc`).

Also, `Label` contains class labels for each regularization strength in the linear classification models that compose `CVMdl`.

`Label = kfoldPredict(CVMdl,Name,Value)` returns predicted class labels with additional options specified by one or more `Name,Value` pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[Label,NegLoss,PBScore] = kfoldPredict(___)` additionally returns, for held-out observations and each regularization strength:

- Negated values of the average binary loss per class (**NegLoss**).
- Positive-class scores (**PBScore**) for each binary learner.

`[Label,NegLoss,PBScore,Posterior] = kfoldPredict(___)` additionally returns posterior class probability estimates for held-out observations and for each regularization strength. To return posterior probabilities, the linear classification model learners must be logistic regression models.

Input Arguments

CVMd1 — Cross-validated, ECOC model composed of linear classification models

ClassificationPartitionedLinearECOC model object

Cross-validated, ECOC model composed of linear classification models, specified as a ClassificationPartitionedLinearECOC model object. You can create a ClassificationPartitionedLinearECOC model using `fitcecoc` and by:

- 1 Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`
- 2 Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, `ClassificationPartitionedLinearECOC.kfoldPredict` applies the same data used to cross-validate the ECOC model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge'
| 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$

Value	Description	Score Domain	$g(y_i, s_j)$
'hamming'	Hamming	[0,1] or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)]/2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j)/2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j)/2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss', @customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 25-4317.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is `'hinge'`
- Logistic regression, then `BinaryLoss` is `'quadratic'`

Example: `'BinaryLoss', 'binodeviance'`

Data Types: char | function_handle

'Decoding' — Decoding scheme`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the “Binary Loss” on page 25-4314, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding', 'lossbased'`

Data Types: `char`

'NumKLInitializations' — Number of random initial values`0` (default) | nonnegative integer

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of `'NumKLInitializations'` and a nonnegative integer.

To use this option, you must:

- Return the fourth output argument (`Posterior`).
- The linear classification models that compose the ECOC models must use logistic regression learners (that is, `CVMdl.Trained{1}.BinaryLearners{1}.Learner` must be `'logistic'`).
- `PosteriorMethod` must be `'kl'`.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 25-4325.

Example: `'NumKLInitializations', 5`

Data Types: `single` | `double`

'Options' — Estimation options`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options', statset('UseParallel', 1)`.

'PosteriorMethod' — Posterior probability estimation method

'k1' (default) | 'qp'

Posterior probability estimation method, specified as the comma-separated pair consisting of 'PosteriorMethod' and 'k1' or 'qp'.

- To use this option, you must return the fourth output argument (**Posterior**) and the linear classification models that compose the ECOC models must use logistic regression learners (that is, `CVMDL.Trained{1}.BinaryLearners{1}.Learner` must be 'logistic').
- If **PosteriorMethod** is 'k1', then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 25-4325.
- If **PosteriorMethod** is 'qp', then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 25-4327.

Example: 'PosteriorMethod', 'qp'

Data Types: char

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. **Verbose** controls the amount of diagnostic messages that the software displays in the Command Window.

If **Verbose** is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments

Label1 — Cross-validated, predicted class labels

categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

Cross-validated, predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

In most cases, `Label` is an n -by- L array of the same data type as the observed class labels (`Y`) used to create `CVMdl`. n is the number of observations in the predictor data (`X`) and L is the number of regularization strengths in the linear classification models that compose the cross-validated ECOC model. That is, `Label(i, j)` is the predicted class label for observation i using the ECOC model of linear classification models that has regularization strength `CVMdl.Trained{1}.BinaryLearners{1}.Lambda(j)`.

If `Y` is a character array and $L > 1$, then `Label` is a cell array of class labels.

The software assigns the predicted label corresponding to the class with the largest, negated, average binary loss (`NegLoss`), or, equivalently, the smallest average binary loss.

NegLoss — Cross-validated, negated, average binary losses

numeric array

Cross-validated, negated, average binary losses, returned as an n -by- K -by- L numeric matrix or array. K is the number of distinct classes in the training data and columns correspond to the classes in `CVMdl.ClassNames`. For n and L , see `Label`. `NegLoss(i, k, j)` is the negated, average binary loss for classifying observation i into class k using the linear classification model that has regularization strength `CVMdl.Trained{1}.BinaryLoss{1}.Lambda(j)`.

PBScore — Cross-validated, positive-class scores

numeric array

Cross-validated, positive-class scores, returned as an n -by- B -by- L numeric array. B is the number of binary learners in the cross-validated ECOC model and columns correspond to the binary learners in `CVMdl.Trained{1}.BinaryLearners`. For n and L , see `Label`. `PBScore(i, b, j)` is the positive-class score of binary learner b for classifying observation i into its positive class, using the linear classification model that has regularization strength `CVMdl.Trained{1}.BinaryLearners{1}.Lambda(j)`.

If the coding matrix varies across folds (that is, if the coding scheme is `sparsrandom` or `denserandom`), then `PBScore` is empty (`[]`).

Posterior — Cross-validated posterior class probabilities

numeric array

Cross-validated posterior class probabilities, returned as an n -by- K -by- L numeric array. For dimension definitions, see `NegLoss.Posterior` is an n -by- K matrix, where n is the number of observations (`size(CVMdl.X,1)`) and K is the number of unique classes (`size(CVMdl.ClassNames,1)`). `Posterior(i,k,j)` is the posterior probability for classifying observation i into class K using the linear classification model that has regularization strength `CVMdl.Trained{1}.BinaryLearners{1}.Lambda(j)`.

To return posterior probabilities, `CVMdl.Trained{1}.BinaryLearner{1}.Learner` must be `'logistic'`.

Definitions

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the `LossFun` name-value pair argument of `predict` and `loss`), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Predict k -fold Cross-Validation Labels

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

Cross-validate an ECOC model of linear classification models.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

CVMdl is a ClassificationPartitionedLinearECOC model. By default, the software implements 10-fold cross validation.

Predict labels for the observations that fitcecoc did not use in training the folds.

```
label = kfoldPredict(CVMdl);
```

Because there is one regularization strength in CVMdl, label is a column vector of predictions containing as many rows as observations in X.

Construct a confusion matrix.

```
ConfusionTrain = confusionmat(Y,label)
CVMdl.ClassNames
```

```
ConfusionTrain =
```

```
Columns 1 through 6
```

vision

```

```
xpc
```

Rows correspond to the true class and columns to the predicted class. The dimensions correspond to the order in `CVMD1.ClassNames`.

Specify Custom Binary Loss

Load the NLP data set. Transpose the predictor data.

```
load nlpdata
X = X';
```

For simplicity, use the label 'others' for all observations in `Y` that are not 'simulink', 'dsp', or 'comm'.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a linear classification model template that specifies to solve the objective function using SpaRSA.

```
t = templateLinear('Solver','sparsa');
```

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Solve the objective function using SpaRSA. Specify that the predictor observations correspond to columns.

```
rng(1); % For reproducibility
CVMD1 = fitcecoc(X,Y,'Learners',t,'KFold',5,'ObservationsIn','columns');
CMd11 = CVMD1.Trained{1}
```

```
CMd11 =
```

```
classreg.learning.classif.CompactClassificationECOC
  ResponseName: 'Y'
  ClassNames: [comm dsp simulink others]
  ScoreTransform: 'none'
  BinaryLearners: {6x1 cell}
  CodingMatrix: [4x6 double]
```

`CVMD1` is a `ClassificationPartitionedLinearECOC` model. It contains the property `Trained`, which is a 5-by-1 cell array holding a `CompactClassificationECOC` models that the software trained using the training set of each fold.

By default, the linear classification models that compose the ECOC models use SVMs. SVM scores are signed distances from the observation to the decision boundary.

Therefore, the domain is $(-\infty, \infty)$. Create a custom binary loss function that:

- Maps the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 out-of-fold observations.

```
[label,NegLoss] = kfoldPredict(CVMdl,'BinaryLoss',customBL);
idx = randsample(numel(label),10);
table(Y(idx),label(idx),NegLoss(idx,1),NegLoss(idx,2),NegLoss(idx,3),...
      NegLoss(idx,4),'VariableNames',{'True';'Predicted'};...
      categories(CVMdl.ClassNames))
```

```
ans =
```

True	Predicted	comm	dsp	simulink	others

The software predicts the label based on the maximum negated loss.

Estimate Posterior Class Probabilities

ECOC models composed of linear classification models return posterior probabilities for logistic regression learners only. This example requires the Parallel Computing Toolbox™ and the Optimization Toolbox™.

Load the NLP data set and preprocess the data as in “Specify Custom Binary Loss”.

```
load nlpdata
X = X';
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a set of 5 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6, -0.5, 5);
```

Create a linear classification model template that specifies to solve the objective function using SpaRSA and to use logistic regression learners.

```
t = templateLinear('Solver','sparsa','Learner','logistic','Lambda',Lambda);
```

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Specify that the predictor observations correspond to columns, and to use parallel computing.

```
rng(1); % For reproducibility
Options = statset('UseParallel',true);
CVMdl = fitcecoc(X,Y,'Learners',t,'Kfold',5,'ObservationsIn','columns',...
    'Options',Options);
```

Predict the cross-validated posterior class probabilities. Specify to use parallel computing and to estimate posterior probabilities using quadratic programming.

```
[label,~,~,Posterior] = kfoldPredict(CVMdl,'Options',Options,...
    'PosteriorMethod','qp');
size(label)
label(3,4)
size(Posterior)
Posterior(3,:,4)
```

```
ans =  
  
    31572         5  
  
ans =  
  
    others  
  
ans =  
  
    31572         4         5  
  
ans =  
  
    0.0294    0.0374    0.1691    0.7641
```

Because there is are five regularization strengths:

- `label` is a 31572-by-5 categorical array. `label(3,4)` is the predicted, cross-validated label for observation 3 using the model trained with regularization strength `Lambda(4)`.
- `Posterior` is a 31572-by-4-by-5 matrix. `Posterior(3, :, 4)` is the vector of all estimated, posterior class probabilities for observation 3 using the model trained with regularization strength `Lambda(4)`. The order of the second dimension corresponds to `CVMDL.ClassNames`. Display a random set of 10 posterior class probabilities.

Display a random sample of cross-validated labels and posterior probabilities for the model trained using `Lambda(4)`.

```
idx = randsample(size(label,1),10);  
table(Y(idx),label(idx,4),Posterior(idx,1,4),Posterior(idx,2,4),...  
    Posterior(idx,3,4),Posterior(idx,4,4),...  
    'VariableNames',{'True'};{'Predicted'};categories(CVMDL.ClassNames)))
```

```
ans =  
  
    True    Predicted    comm    dsp    simulink    others  
_____  
_____
```

- “Quick Start Parallel Computing for Statistics and Machine Learning Toolbox” on page 24-2

Algorithms

- The software can estimate class posterior probabilities using quadratic programming or by minimizing the Kullback-Leibler divergence. For the following descriptions of the posterior estimation algorithms, let:
 - m_{kj} be the element (k,j) of the coding design matrix M .
 - I be the indicator function.
 - \hat{p}_k be the class posterior probability estimate for class k of an observation, $k = 1, \dots, K$.
 - r_j be the positive-class posterior probability for binary learner j . That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r, r) = \sum_{j=1}^L w_j \left[r_j \log \frac{r_j}{r_j} + (1 - r_j) \log \frac{1 - r_j}{1 - r_j} \right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j with S_j the set of observation

indices that binary learner j is trained on and w_i^* is the weight of observation i . The software minimizes the divergence iteratively. The first step is to choose initial values $\hat{p}_k^{(0)}$; $k = 1, \dots, K$ for the class posterior probabilities.

- If you do not specify `NumKLIterations`, then the software uses both sets of deterministic initial values described next, and uses the one that minimizes Δ .
 - $\hat{p}_k^{(0)} = 1 / K$; $k = 1, \dots, K$.
 - $\hat{p}_k^{(0)}$; $k = 1, \dots, K$ is the solution of the system

$$M_{01} \hat{p}^{(0)} = r,$$

where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [14]. The software uses `lsqnonneg` to solve the system.

- If you specify '`NumKLIterations`', `c`, where `c` is a natural number, then the software does the following to choose $\hat{p}_k^{(0)}$; $k = 1, \dots, K$, and uses the one that minimizes Δ .
 - The software chooses both sets of deterministic initial values as described previously.
 - The software randomly generates `c` vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t , the software:

- 1 Computes

$$\hat{r}_j^{(t)} = \frac{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

- 2 Estimates the next class posterior probability using

$$\hat{p}_k^{(t+1)} = \hat{p}_k^{(t)} \frac{\sum_{j=1}^L w_j [r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1)]}{\sum_{j=1}^L w_j [\hat{r}_j^{(t)} I(m_{kj} = +1) + (1 - \hat{r}_j^{(t)}) I(m_{kj} = -1)]}.$$

- 3 Normalizes $\hat{p}_k^{(t+1)}$; $k = 1, \dots, K$ so that they sum to 1.
- 4 Checks for convergence.

For more details, see [23] and [46].

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software:

- 1 Estimates the positive-class posterior probabilities, r_j , for binary learners $j = 1, \dots, L$.
- 2 Using the relationship between r_j and \hat{p}_k [42], minimizes

$$\sum_{j=1}^L \left[-r_j \sum_{k=1}^K \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^K \hat{p}_k I(m_{kj} = +1) \right]^2$$

with respect to \hat{p}_k and the restrictions

$$0 \leq \hat{p}_k \leq 1$$
$$\sum_k \hat{p}_k = 1.$$

The software performs minimization using `quadprog`.

Introduced in R2016a

kfoldPredict

Class: ClassificationPartitionedModel

Predict response for observations not used for training

Syntax

```
label = kfoldPredict(obj)
[label, score] = kfoldPredict(obj)
[label, score, cost] = kfoldPredict(obj)
```

Description

`label = kfoldPredict(obj)` returns class labels predicted by `obj`, a cross-validated classification. For every fold, `kfoldPredict` predicts class labels for in-fold observations using a model trained on out-of-fold observations.

`[label, score] = kfoldPredict(obj)` returns the predicted classification scores for in-fold observations using a model trained on out-of-fold observations.

`[label, score, cost] = kfoldPredict(obj)` returns misclassification costs.

Input Arguments

obj

Object of class `ClassificationPartitionedModel` or `ClassificationPartitionedEnsemble`.

Output Arguments

label

Vector of class labels of the same type as the response data used in training `obj`. Each entry of `label` corresponds to a predicted class label for the corresponding row of `X`.

score

Numeric matrix of size N-by-K, where N is the number of observations (rows) in `obj.X`, and K is the number of classes (in `obj.ClassNames`). `score(i, j)` represents the confidence that row `i` of `obj.X` is of class `j`. For details, see “Definitions” on page 25-2897.

cost

Numeric matrix of misclassification costs of size N-by-K. `cost(i, j)` is the average misclassification cost of predicting that row `i` of `obj.X` is of class `j`.

Definitions

Cost (discriminant analysis)

The *average misclassification cost* is the mean misclassification cost for predictions made by the cross-validated classifiers trained on out-of-fold observations. The matrix of expected costs per observation is defined in “Cost” on page 16-8.

Score

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 16-7.

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

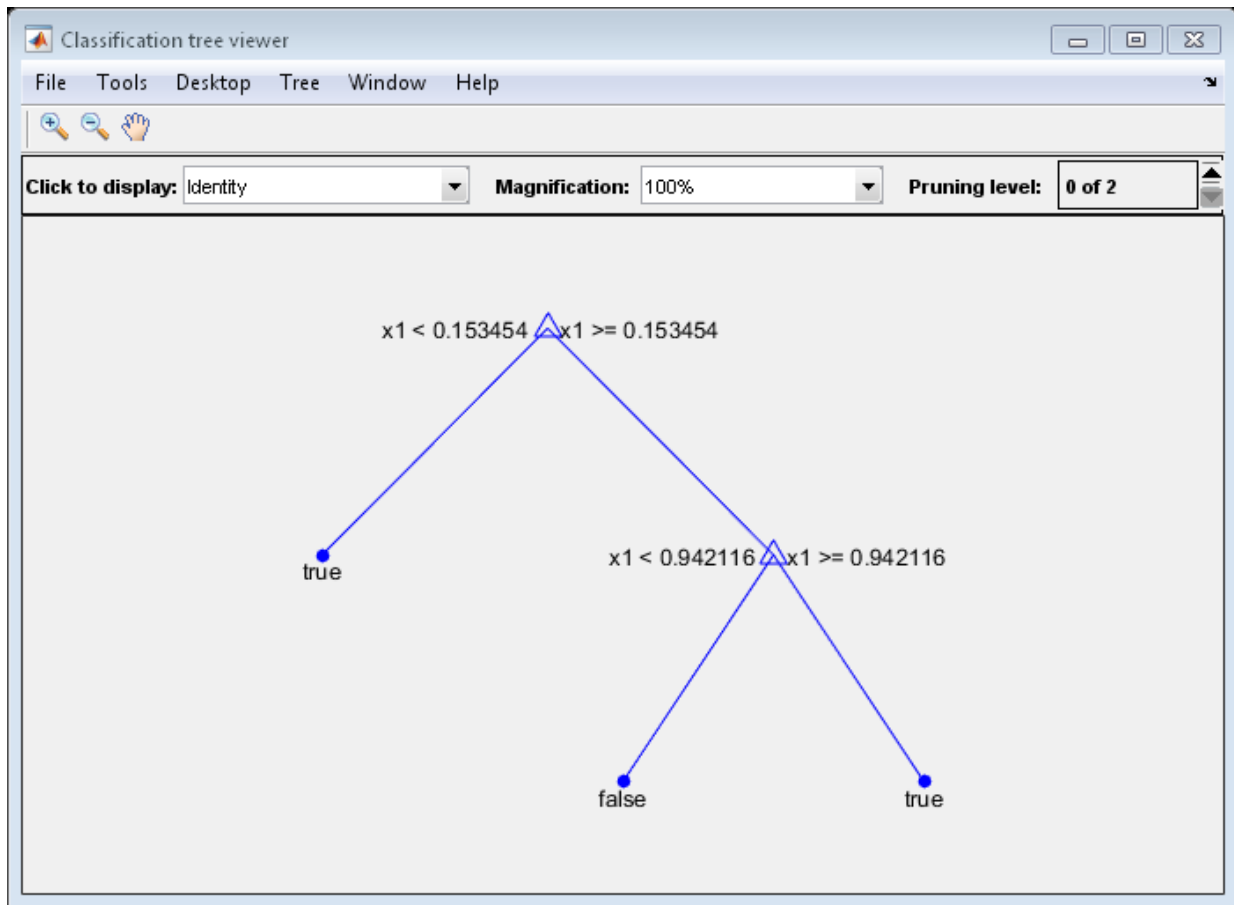

- `AdaBoostM1` scores range from $-\infty$ to ∞ .
- `Bag` scores range from 0 to 1.

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as true when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

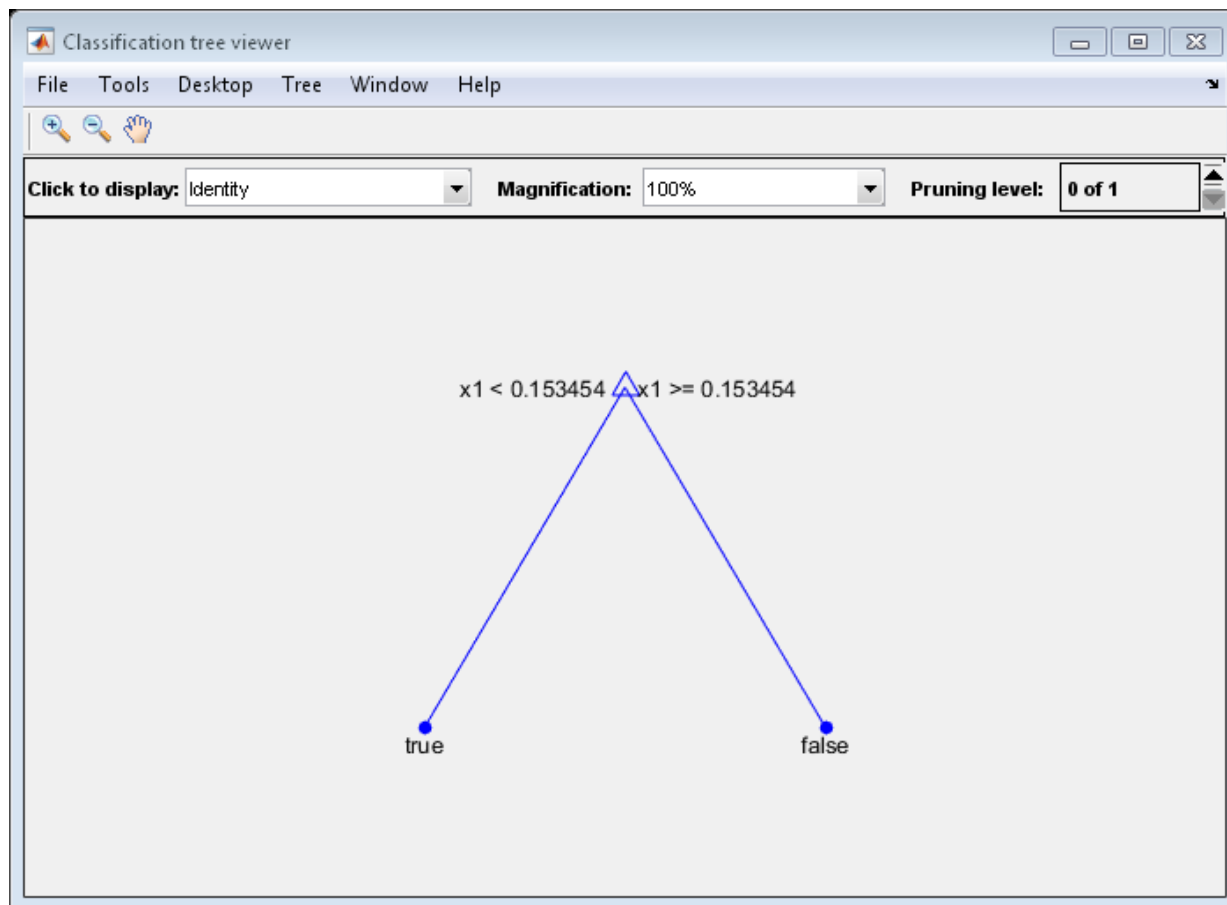

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for **true**, and about $.8/.85=.94$ for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
```

```
[score X(1:10,:)]  
  
ans =  
  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0    1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0    1.0000    0.0975  
    0.9059    0.0941    0.2785  
    0.9059    0.0941    0.5469  
    0.9059    0.0941    0.9575  
    0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

Examples

Estimate Cross-Validation Predictions from an Ensemble

Find the cross-validation predictions for a model based on Fisher's iris data.

Load Fisher's iris data set.

```
load fisheriris
```

Train an ensemble of classification trees.

```
rng(1); % For reproducibility  
Mdl = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
```

Cross validate the trained ensemble using 10-fold cross validation.

```
CVMdl = crossval(Mdl);
```

Estimate cross-validation predicted labels and scores.

```
[elabel escore] = kfoldPredict(CVMdl);
```

Display the maximum and minimum scores of each class.

```
max(escore)  
min(escore)
```

```
ans =
```

```
    9.3862    8.9871   10.1866
```

```
ans =
```

```
    0.0017    3.8359    0.8981
```

kfoldPredict

Class: RegressionPartitionedLinear

Predict responses for observations not used for training

Syntax

```
YHat = kfoldPredict(CVMdl)
```

Description

`YHat = kfoldPredict(CVMdl)` returns cross-validated predicted responses by the cross-validated linear regression model `CVMdl`. That is, for every fold, `kfoldPredict` predicts responses for observations that it holds out when it trains using all other observations.

`YHat` contains predicted responses for each regularization strength in the linear regression models that compose `CVMdl`.

Input Arguments

CVMdl — Cross-validated, linear regression model

RegressionPartitionedLinear model object

Cross-validated, linear regression model, specified as a `RegressionPartitionedLinear` model object. You can create a `RegressionPartitionedLinear` model using `fitrlinear` and specifying any of the one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, `RegressionPartitionedLinear.kfoldPredict` applies the same data used to cross-validate the linear regression model (X and Y).

Output Arguments

YHat — Cross-validated predicted responses

numeric array

Cross-validated predicted responses, returned as an n -by- L numeric array. n is the number of observations in the predictor data that created `CVMdl` (see `X`) and L is the number of regularization strengths in `CVMdl.Trained{1}.Lambda`. `YHat(i,j)` is the predicted response for observation i using the linear regression model that has regularization strength `CVMdl.Trained{1}.Lambda(j)`.

The predicted response using the model with regularization strength j is $\hat{y}_j = x\beta_j + b_j$.

- x is an observation from the predictor data matrix `X`, and is row vector.
- β_j is the estimated column vector of coefficients. The software stores this vector in `Mdl.Beta(:,j)`.
- b_j is the estimated, scalar bias, which the software stores in `Mdl.Bias(j)`.

Examples

Predict Cross-Validated Responses

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = x_1, \dots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Cross-validate a linear regression model.

```
CVMdl = fitrlinear(X,Y,'CrossVal','on')
Mdl1 = CVMdl.Trained{1}
```

```
CVMdl =  
  
classreg.learning.partition.RegressionPartitionedLinear  
    CrossValidatedModel: 'Linear'  
        ResponseName: 'Y'  
        NumObservations: 10000  
        KFold: 10  
        Partition: [1x1 cvpartition]  
        ResponseTransform: 'none'
```

```
Mdl1 =  
  
RegressionLinear  
    ResponseName: 'Y'  
    ResponseTransform: 'none'  
        Beta: [1000x1 double]  
        Bias: 0.0107  
        Lambda: 1.1111e-04  
    Learner: 'svm'
```

By default, `fitrlinear` implements 10-fold cross-validation. `CVMdl` is a `RegressionPartitionedLinear` model. It contains the property `Trained`, which is a 10-by-1 cell array holding 10 `RegressionLinear` models that the software trained using the training set.

Predict responses for observations that `fitrlinear` did not use in training the folds.

```
yHat = kfoldPredict(CVMdl);
```

Because there is one regularization strength in `Mdl`, `yHat` is a numeric vector.

Predict for Models Containing Several Regularization Strengths

Simulate 10000 observations as in “Predict Cross-Validated Responses”.

```
rng(1) % For reproducibility  
n = 1e4;  
d = 1e3;  
nz = 0.1;  
X = sprandn(n,d,nz);
```

```
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1} .

```
Lambda = logspace(-5, -1, 15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Specify to use least squares with a lasso penalty, and solve the objective function using SpaRSA.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
```

CVMdl is a `RegressionPartitionedLinear` model. Its `Trained` property contains a 5-by-1 cell array of trained `RegressionLinear` models, each one holds out a different fold during training. Because `fitrlinear` trained using 15 regularization strengths, you can think of each `RegressionLinear` model as 15 models.

Predict cross-validated responses.

```
YHat = kfoldPredict(CVMdl);
size(YHat)
YHat(2,:)
```

```
ans =
```

```
    10000         15
```

```
ans =
```

```
Columns 1 through 7
```

```
-1.7338  -1.7332  -1.7319  -1.7299  -1.7266  -1.7239  -1.7135
```

```
Columns 8 through 14
```

```
-1.7210  -1.7324  -1.7063  -1.6397  -1.5112  -1.2631  -0.7841
```

```
Column 15
```

-0.0096

YHat is a 10000-by-15 matrix. YHat(2,:) is the cross-validated response for observation 2 using the model regularized with all 15 regularization values.

Introduced in R2016a

kfoldPredict

Class: RegressionPartitionedModel

Predict response for observations not used for training.

Syntax

```
yfit = kfoldPredict(obj)
```

Description

`yfit = kfoldPredict(obj)` returns the predicted values for the responses of the training data based on `obj`, an object trained on out-of-fold observations.

Input Arguments

obj

Object of class `RegressionPartitionedModel`. Create `obj` with `fitrtree` or `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `obj` from a regression tree or regression ensemble with `crossval`.

Output Arguments

yfit

A vector of predicted values for the response data based on a model trained on out-of-fold observations.

Examples

Construct a partitioned regression model, and examine the cross-validation loss. The cross-validation loss is the mean squared error between `yfit` and the true response data:

```
load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
tree = fitrtree(XX,YY);
cvmodel = crossval(tree);
L = kfoldLoss(cvmodel)
```

```
L =
    26.5271
```

```
yfit = kfoldPredict(cvmodel);
mean( (yfit - tree.Y).^2 )
```

```
ans =
    26.5271
```

See Also

`kfoldLoss` | `fitrtree`

kmeans

k-means clustering

Syntax

```
idx = kmeans(X,k)
idx = kmeans(X,k,Name,Value)
[idx,C] = kmeans( ___ )
[idx,C,sumd] = kmeans( ___ )
[idx,C,sumd,D] = kmeans( ___ )
```

Description

`idx = kmeans(X,k)` performs *k*-means clustering to partition the observations of the *n*-by-*p* data matrix *X* into *k* clusters, and returns an *n*-by-1 vector (**idx**) containing cluster indices of each observation. Rows of *X* correspond to points and columns correspond to variables.

By default, `kmeans` uses the squared Euclidean distance measure and the *k*-means++ algorithm for cluster center initialization.

`idx = kmeans(X,k,Name,Value)` returns the cluster indices with additional options specified by one or more **Name,Value** pair arguments.

For example, specify the cosine distance, the number of times to repeat the clustering using new initial values, or to use parallel computing.

`[idx,C] = kmeans(___)` returns the *k* cluster centroid locations in the *k*-by-*p* matrix **C**.

`[idx,C,sumd] = kmeans(___)` returns the within-cluster sums of point-to-centroid distances in the *k*-by-1 vector **sumd**.

`[idx,C,sumd,D] = kmeans(___)` returns distances from each point to every centroid in the *n*-by-*k* matrix **D**.

Examples

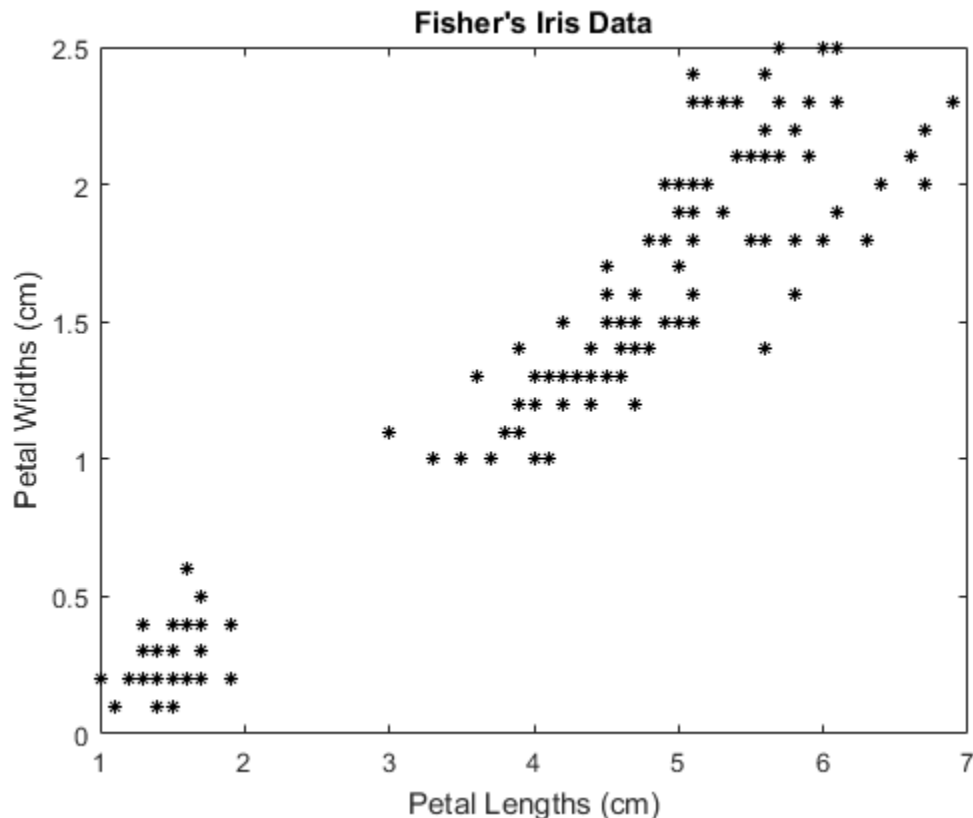

Train a *k*-Means Clustering Algorithm

Cluster data using *k*-means clustering, then plot the cluster regions.

Load Fisher's iris data set. Use the petal lengths and widths as predictors.

```
load fisheriris
X = meas(:,3:4);

figure;
plot(X(:,1),X(:,2),'k*','MarkerSize',5);
title 'Fisher''s Iris Data';
xlabel 'Petal Lengths (cm)';
ylabel 'Petal Widths (cm)';
```

The larger cluster seems to be split into a lower variance region and a higher variance region. This might indicate that the larger cluster is two, overlapping clusters.

Cluster the data. Specify $k = 3$ clusters.

```
rng(1); % For reproducibility
[idx,C] = kmeans(X,3);
```

`kmeans` uses the k -means++ algorithm for centroid initialization and squared Euclidean distance by default. It is good practice to search for lower, local minima by setting the 'Replicates' name-value pair argument.

`idx` is a vector of predicted cluster indices corresponding to the observations in `X`. `C` is a 3-by-2 matrix containing the final centroid locations.

Use `kmeans` to compute the distance from each centroid to points on a grid. To do this, pass the centroids (`C`) and points on a grid to `kmeans`, and implement one iteration of the algorithm.

```
x1 = min(X(:,1)):0.01:max(X(:,1));
x2 = min(X(:,2)):0.01:max(X(:,2));
[x1G,x2G] = meshgrid(x1,x2);
XGrid = [x1G(:),x2G(:)]; % Defines a fine grid on the plot

idx2Region = kmeans(XGrid,3,'MaxIter',1,'Start',C);
% Assigns each node in the grid to the closest centroid
```

```
Warning: Failed to converge in 1 iterations.
```

`kmeans` displays a warning stating that the algorithm did not converge, which you should expect since the software only implemented one iteration.

Plot the cluster regions.

```
figure;
gscatter(XGrid(:,1),XGrid(:,2),idx2Region,...
        [0,0.75,0.75;0.75,0,0.75;0.75,0.75,0],'.');
hold on;
plot(X(:,1),X(:,2),'k*','MarkerSize',5);
title 'Fisher''s Iris Data';
xlabel 'Petal Lengths (cm)';
ylabel 'Petal Widths (cm)';
legend('Region 1','Region 2','Region 3','Data','Location','SouthEast');
hold off;
```

Partition Data into Two Clusters

Randomly generate the sample data.

```
rng default; % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
     randn(100,2)*0.5-ones(100,2)];
```

```
figure;
plot(X(:,1),X(:,2),'.');
title 'Randomly Generated Data';
```

There appears to be two clusters in the data.

Partition the data into two clusters, and choose the best arrangement out of five initializations. Display the final output.

```
opts = statset('Display','final');  
[idx,C] = kmeans(X,2,'Distance','cityblock',...  
    'Replicates',5,'Options',opts);
```

```
Replicate 1, 3 iterations, total sum of distances = 201.533.  
Replicate 2, 5 iterations, total sum of distances = 201.533.  
Replicate 3, 3 iterations, total sum of distances = 201.533.  
Replicate 4, 3 iterations, total sum of distances = 201.533.  
Replicate 5, 2 iterations, total sum of distances = 201.533.
```

Best total sum of distances = 201.533

By default, the software initializes the replicates separately using *k*-means++.

Plot the clusters and the cluster centroids.

```
figure;
plot(X(idx==1,1),X(idx==1,2), 'r.', 'MarkerSize', 12)
hold on
plot(X(idx==2,1),X(idx==2,2), 'b.', 'MarkerSize', 12)
plot(C(:,1),C(:,2), 'kx', ...
     'MarkerSize', 15, 'LineWidth', 3)
legend('Cluster 1', 'Cluster 2', 'Centroids', ...
     'Location', 'NW')
title 'Cluster Assignments and Centroids'
hold off
```

You can determine how well separated the clusters are by passing `idx` to `silhouette`.

Cluster Data Using Parallel Computing

Clustering large data sets might take time, particularly if you use online updates (set by default). If you have a Parallel Computing Toolbox license and you invoke a pool of workers, then `kmeans` runs each clustering task (or replicate) in parallel. Therefore, if `Replicates > 1`, then the parallel computing decreases time to convergence.

Randomly generate a large data set from a Gaussian mixture model.

```
Mu = bsxfun(@times,ones(20,30),(1:20)'); % Gaussian mixture mean
rn30 = randn(30,30);
Sigma = rn30'*rn30; % Symmetric and positive-definite covariance
```

```
Mdl = gmdistribution(Mu,Sigma);
```

```
rng(1); % For reproducibility
X = random(Mdl,10000);
```

Mdl is a 30-dimensional gmdistribution model with 20 components. X is a 10000-by-30 matrix of data generated from Mdl.

Invoke a parallel pool of workers. Specify options for parallel computing.

```
pool = parpool; % Invokes workers
stream = RandStream('mlfg6331_64'); % Random number stream
options = statset('UseParallel',1,'UseSubstreams',1,...
    'Streams',stream);
```

Starting parallel pool (parpool) using the 'local' profile ... connected to 4 workers.

The input argument 'mlfg6331_64' of RandStream specifies to use the multiplicative lagged Fibonacci generator algorithm. options is a structure array containing fields that specify options for controlling estimation.

The Command Window indicates that four workers are available. The number of workers might vary on your system.

Cluster the data using k -means clustering. Specify that there are $k = 20$ clusters in the data and increase the number of iterations. Typically, the objective function contains local minima. Specify 10 replicates to help find a lower, local minimum.

```
tic; % Start stopwatch timer
[idx,C,sumd,D] = kmeans(X,20,'Options',options,'MaxIter',10000,...
    'Display','final','Replicates',10);
toc % Terminate stopwatch timer
```

```
Replicate 7, 44 iterations, total sum of distances = 7.55218e+06.
Replicate 4, 95 iterations, total sum of distances = 7.53848e+06.
Replicate 2, 104 iterations, total sum of distances = 7.54232e+06.
Replicate 6, 80 iterations, total sum of distances = 7.54237e+06.
Replicate 8, 111 iterations, total sum of distances = 7.54445e+06.
Replicate 1, 52 iterations, total sum of distances = 7.55817e+06.
Replicate 5, 70 iterations, total sum of distances = 7.55278e+06.
Replicate 3, 94 iterations, total sum of distances = 7.54858e+06.
Replicate 10, 56 iterations, total sum of distances = 7.54547e+06.
Replicate 9, 83 iterations, total sum of distances = 7.53701e+06.
Best total sum of distances = 7.53701e+06
Elapsed time is 3.239232 seconds.
```

The Command Window displays the number of iterations and the terminal objective function value for each replicate. The output arguments contain the results of replicate 9 because it has the lowest total sum of distances.

- “Avoid Local Minima” on page 15-26

Input Arguments

X — Data

numeric matrix

Data, specified as a numeric matrix. The rows of **X** correspond to observations, and the columns correspond to variables.

If **X** is a numeric vector, then `kmeans` treats it as an n -by-1 data matrix, regardless of its orientation.

Data Types: `single` | `double`

k — Number of clusters

positive integer

Number of clusters in the data, specified as a positive integer.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

```
'Distance', 'cosine', 'Replicates', 10, 'Options', statset('UseParallel', 1)
```

specifies the cosine distance, 10 replicate clusters at different starting values, and to use parallel computing.

'Display' — Level of output to display

`'off'` (default) | `'final'` | `'iter'`

Level of output to display in the Command Window, specified as the comma-separated pair consisting of 'Display' and a string. Available options are:

- 'final' — Displays results of the final iteration
- 'iter' — Displays results of each iteration
- 'off' — Displays nothing

Example: 'Display', 'final'

Data Types: char

'Distance' — Distance measure

'sqeuclidean' (default) | 'cityblock' | 'cosine' | 'correlation' | 'hamming'

Distance measure, in p -dimensional space, used for minimization, specified as the comma-separated pair consisting of 'Distance' and a string.

kmeans computes centroid clusters differently for the different, supported distance measures. This table summarizes the available distance measures. In the formulae, x is an observation (that is, a row of X) and c is a centroid (a row vector).

Distance Measure	Description	Formula
'sqeuclidean'	Squared Euclidean distance (default). Each centroid is the mean of the points in that cluster.	$d(x, c) = (x - c)(x - c)'$
'cityblock'	Sum of absolute differences, i.e., the $L1$ distance. Each centroid is the component-wise median of the points in that cluster.	$d(x, c) = \sum_{j=1}^p x_j - c_j $
'cosine'	One minus the cosine of the included angle between points (treated as vectors). Each centroid is the mean of the points in that cluster, after normalizing those points to unit Euclidean length.	$d(x, c) = 1 - \frac{xc'}{\sqrt{(xx')(cc')}}$

Distance Measure	Description	Formula
'correlation'	One minus the sample correlation between points (treated as sequences of values). Each centroid is the component-wise mean of the points in that cluster, after centering and normalizing those points to zero mean and unit standard deviation.	$d(x, c) = 1 - \frac{(x - \bar{x})(c - \bar{c})'}{\sqrt{(x - \bar{x})(x - \bar{x})'} \sqrt{(c - \bar{c})(c - \bar{c})'}}$ <p>where</p> <ul style="list-style-type: none"> • $\bar{x} = \frac{1}{p} \left(\sum_{j=1}^p x_j \right) \bar{1}_p$ • $\bar{c} = \frac{1}{p} \left(\sum_{j=1}^p c_j \right) \bar{1}_p$ • $\bar{1}_p$ is a row vector of p ones.
'hamming'	This measure is only suitable for binary data. It is the proportion of bits that differ. Each centroid is the component-wise median of points in that cluster.	$d(x, y) = \frac{1}{p} \sum_{j=1}^p I\{x_j \neq y_j\},$ <p>where I is the indicator function.</p>

Example: 'Distance', 'cityblock'

Data Types: char

'EmptyAction' — Action to take if cluster loses all member observations

'singleton' (default) | 'error' | 'drop'

Action to take if a cluster loses all its member observations, specified as the comma-separated pair consisting of 'EmptyAction' and a string. This table summarizes the available options.

Value	Description
'error'	Treat an empty cluster as an error.

Value	Description
'drop'	Remove any clusters that become empty. <code>kmeans</code> sets the corresponding return values in <code>C</code> and <code>D</code> to <code>NaN</code> .
'singleton'	Create a new cluster consisting of the one point furthest from its centroid (default).

Example: 'EmptyAction', 'error'

Data Types: char

'MaxIter' — Maximum number of iterations

100 (default) | positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer.

Example: 'MaxIter', 1000

Data Types: double | single

'OnlinePhase' — Online update flag

'off' (default) | 'on'

Online update flag, specified as the comma-separated pair consisting of 'OnlinePhase' and 'off' or 'on'.

If `OnlinePhase` is `on`, then `kmeans` performs an online update phase in addition to a batch update phase. The online phase can be time consuming for large data sets, but guarantees a solution that is a local minimum of the distance criterion. In other words, the software finds a partition of the data in which moving any single point to a different cluster increases the total sum of distances.

Example: 'OnlinePhase', 'on'

Data Types: char

'Options' — Options for controlling iterative algorithm for minimizing fitting criteria

[] (default) | structure array returned by `statset`

Options for controlling the iterative algorithm for minimizing the fitting criteria, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`. These options require Parallel Computing Toolbox.

This table summarizes the available options.

Option	Description
'Streams'	<p>A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>kmeans</code> uses the default stream or streams. If you specify <code>Streams</code>, use a single object except when:</p> <ul style="list-style-type: none"> • You have an open parallel pool • <code>UseParallel</code> is <code>true</code>. • <code>UseSubstreams</code> is <code>false</code>. <p>In that case, use a cell array the same size as the parallel pool. If a parallel pool is not open, then <code>Streams</code> must supply a single random number stream.</p>
'UseParallel'	<ul style="list-style-type: none"> • If <code>true</code>, <code>Replicates</code> > 1, and if a parallel pool of workers from the Parallel Computing Toolbox is open, then the software implements <i>k</i>-means on each replicate in parallel. • If the Parallel Computing Toolbox is not installed, or a parallel pool of workers is not open, computation occurs in serial mode. Default is <code>default</code>, meaning serial computation.
'UseSubstreams'	<p>Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'m1fg6331_64'</code> or <code>'mrg32k3a'</code>.</p>

To ensure more predictable results, use `parpool` and explicitly create a parallel pool before invoking `kmeans` and setting `'Options', statset('UseParallel', 1)`.

Example: `'Options', statset('UseParallel', 1)`

Data Types: `struct`

'Replicates' — Number of times to repeat clustering using new initial cluster centroid positions

1 (default) | positive integer

Number of times to repeat clustering using new initial cluster centroid positions, specified as the comma-separated pair consisting of 'Replicates' and an integer. `kmeans` returns the solution with the lowest `sumd`.

You can set 'Replicates' implicitly by supplying a 3-D array as the value for the 'Start' name-value pair argument.

Example: 'Replicates',5

Data Types: double | single

'Start' — Method for choosing initial cluster centroid positions

'plus' (default) | 'cluster' | 'sample' | 'uniform' | numeric matrix | numeric array

Method for choosing initial cluster centroid positions (or *seeds*), specified as the comma-separated pair consisting of 'Start' and a string, a numeric matrix, or a numeric array. This table summarizes the available options for choosing seeds.

Value	Description
'cluster'	Perform a preliminary clustering phase on a random 10% subsample of X . This preliminary phase is itself initialized using 'sample'.
'plus' (default)	Select k seeds by implementing the k -means++ algorithm for cluster center initialization.
'sample'	Select k observations from X at random.
'uniform'	Select k points uniformly at random from the range of X . Not valid with the Hamming distance.
numeric matrix	k -by- p matrix of centroid starting locations. The rows of <code>Start</code> correspond to seeds. The software infers k from the first dimension of <code>Start</code> , so you can pass in <code>[]</code> for k .

Value	Description
numeric array	k-by-p-r array of centroid starting locations. The rows of each page correspond to seeds. The third dimension invokes replication of the clustering routine. Page j contains the set of seeds for replicate j . The software infers the number of replicates (specified by the 'Replicates' name-value pair argument) from the size of the third dimension.

Example: 'Start', 'sample'

Data Types: char | double | single

Note: The software treats NaNs as missing data, and removes any row of X containing at least one NaN. Removing rows of X reduces the sample size.

Output Arguments

idx — Cluster indices

numeric column vector

Cluster indices, returned as a numeric column vector. **idx** has as many rows as X , and each row indicates the cluster assignment of the corresponding observation.

C — Cluster centroid locations

numeric matrix

Cluster centroid locations, returned as a numeric matrix. **C** is a k-by-p matrix, where row j is the centroid of cluster j .

sumd — Within-cluster sums of point-to-centroid distances

numeric column vector

Within-cluster sums of point-to-centroid distances, returned as a numeric column vector. **sumd** is a k-by-1 vector, where element j is the sum of point-to-centroid distances within cluster j .

D — Distances from each point to every centroid

numeric matrix

Distances from each point to every centroid, returned as a numeric matrix. **D** is an n -by- k matrix, where element (j,m) is the distance from observation j to centroid m .

More About

***k*-Means Clustering**

k-means clustering, or Lloyd’s algorithm [2], is an iterative, data-partitioning algorithm that assigns n observations to exactly one of k clusters defined by centroids, where k is chosen before the algorithm starts.

The algorithm proceeds as follows:

- 1 Choose k initial cluster centers (*centroid*). For example, choose k observations at random (by using 'Start', 'sample') or use the *k*-means ++ algorithm for cluster center initialization (the default).
- 2 Compute point-to-cluster-centroid distances of all observations to each centroid.
- 3 There are two ways to proceed (specified by **OnlinePhase**):
 - Batch update — Assign each observation to the cluster with the closest centroid.
 - Online update — Individually assign observations to a different centroid if the reassignment decreases the sum of the within-cluster, sum-of-squares point-to-cluster-centroid distances.

For more details, see “Algorithms” on page 25-2926.

- 4 Compute the average of the observations in each cluster to obtain k new centroid locations.
- 5 Repeat steps 2 through 4 until cluster assignments do not change, or the maximum number of iterations is reached.

***k*-means++ Algorithm**

The *k*-means++ algorithm uses an heuristic to find centroid seeds for *k*-means clustering. According to Arthur and Vassilvitskii [1], *k*-means++ improves the running time of Lloyd’s algorithm, and the quality of the final solution.

The *k*-means++ algorithm chooses seeds as follows, assuming the number of clusters is k .

- 1 Select an observation uniformly at random from the data set, X . The chosen observation is the first centroid, and is denoted c_1 .
- 2 Compute distances from each observation to c_1 . Denote the distance between c_j and the observation m as $d(x_m, c_j)$.
- 3 Select the next centroid, c_2 at random from X with probability

$$\frac{d^2(x_m, c_1)}{\sum_{j=1}^n d^2(x_j, c_1)}.$$

- 4 To choose center j :
 - a Compute the distances from each observation to each centroid, and assign each observation to its closest centroid.
 - b For $m = 1, \dots, n$ and $p = 1, \dots, j - 1$, select centroid j at random from X with probability

$$\frac{d^2(x_m, c_p)}{\sum_{\{h; x_h \in C_p\}} d^2(x_h, c_p)},$$

where C_p is the set of all observations closest to centroid c_p and x_m belongs to C_p .

That is, select each subsequent center with a probability proportional to the distance from itself to the closest center that you already chose.

- 5 Repeat step 4 until k centroids are chosen.

Arthur and Vassilvitskii [1] demonstrate, using a simulation study for several cluster orientations, that *k*-means++ achieves faster convergence to a lower sum of within-cluster, sum-of-squares point-to-cluster-centroid distances than Lloyd's algorithm.

Algorithms

- `kmeans` uses a two-phase iterative algorithm to minimize the sum of point-to-centroid distances, summed over all k clusters.

- 1 This first phase uses *batch updates*, where each iteration consists of reassigning points to their nearest cluster centroid, all at once, followed by recalculation of cluster centroids. This phase occasionally does not converge to solution that is a local minimum. That is, a partition of the data where moving any single point to a different cluster increases the total sum of distances. This is more likely for small data sets. The batch phase is fast, but potentially only approximates a solution as a starting point for the second phase.
 - 2 This second phase uses *online updates*, where points are individually reassigned if doing so reduces the sum of distances, and cluster centroids are recomputed after each reassignment. Each iteration during this phase consists of one pass though all the points. This phase converges to a local minimum, although there might be other local minima with lower total sum of distances. In general, finding the global minimum is solved by an exhaustive choice of starting points, but using several replicates with random starting points typically results in a solution that is a global minimum.
- If `Replicates = r > 1` and `Start` is `plus` (the default), then the software selects r possibly different sets of seeds according to the k -means++ algorithm.
 - If you enable the `UseParallel` option in `Options` and `Replicates > 1`, then each worker selects seeds and clusters in parallel.

kmedoids

k-medoids clustering

Syntax

```
[idx,C] = kmedoids( ___ )
[idx,C,sumd] = kmedoids( ___ )
[idx,C,sumd,D] = kmedoids( ___ )
[idx,C,sumd,D,midx] = kmedoids( ___ )
[idx,C,sumd,D,midx,info] = kmedoids( ___ )
```

Description

`idx = kmedoids(X,k)` performs “*k*-medoids Clustering” on page 25-2944 to partition the observations of the *n*-by-*p* matrix *X* into *k* clusters, and returns an *n*-by-1 vector `idx` containing cluster indices of each observation. Rows of *X* correspond to points and columns correspond to variables. By default, `kmedoids` uses squared Euclidean distance measure and the *k*-means++ algorithm for choosing initial cluster medoid positions.

`idx = kmedoids(X,k,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[idx,C] = kmedoids(___)` returns the *k* cluster medoid locations in the *k*-by-*p* matrix *C*.

`[idx,C,sumd] = kmedoids(___)` returns the within-cluster sums of point-to-medoid distances in the *k*-by-1 vector `sumd`.

`[idx,C,sumd,D] = kmedoids(___)` returns distances from each point to every medoid in the *n*-by-*k* matrix *D*.

`[idx,C,sumd,D,midx] = kmedoids(___)` returns the indices `midx` such that `C = X(midx,:)`. `midx` is a *k*-by-1 vector.

`[idx,C,sumd,D,midx,info] = kmedoids(___)` returns a structure `info` with information about the options used by the algorithm when executed.

Examples

Group Data into Two Clusters

Randomly generate data.

```
rng('default'); % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
     randn(100,2)*0.55-ones(100,2)];
figure;
plot(X(:,1),X(:,2),'.');
title('Randomly Generated Data');
```

Group data into two clusters using `kmedoids`. Use the `cityblock` distance measure.

```
opts = statset('Display','iter');
[idx,C,sumd,d,midx,info] = kmedoids(X,2,'Distance','cityblock','Options',opts);
```

```
    rep    iter      sum
     1      1    209.856
     1      2    209.856
```

```
Best total sum of distances = 209.856
```

`info` is a struct that contains information about how the algorithm was executed. For example, `bestReplicate` field indicates the replicate that was used to produce the final solution. In this example, the replicate number 1 was used since the default number of replicates is 1 for the default algorithm, which is `pam` in this case.

```
info
```

```
info =
```

```
    algorithm: 'pam'
         start: 'plus'
         distance: 'cityblock'
    iterations: 2
    bestReplicate: 1
```

Plot the clusters and the cluster medoids.

```
figure;
plot(X(idx==1,1),X(idx==1,2),'r.','MarkerSize',7)
hold on
plot(X(idx==2,1),X(idx==2,2),'b.','MarkerSize',7)
plot(C(:,1),C(:,2),'co',...
     'MarkerSize',7,'LineWidth',1.5)
legend('Cluster 1','Cluster 2','Medoids',...
     'Location','NW');
title('Cluster Assignments and Medoids');
hold off
```

Cluster Categorical Data Using k -Medoids

This example uses "Mushroom" data set [3][4][5] [6][7] from the UCI machine learning archive [7], described in <http://archive.ics.uci.edu/ml/datasets/Mushroom>. The data set includes 22 predictors for 8,124 observations of various mushrooms. The predictors are categorical data types. For example, cap shape is categorized with features of 'b' for bell-shaped cap and 'c' for conical. Mushroom color is also categorized with features of 'n' for brown, and 'p' for pink. The data set also includes a classification for each mushroom of either edible or poisonous.

Since the features of the mushroom data set are categorical, it is not possible to define the mean of several data points, and therefore the widely-used k -means clustering algorithm cannot be meaningfully applied to this data set. k -medoids is a related

algorithm that partitions data into k distinct clusters, by finding medoids that minimize the sum of dissimilarities between points in the data and their nearest medoid.

The medoid of a set is a member of that set whose average dissimilarity with the other members of the set is the smallest. Similarity can be defined for many types of data that do not allow a mean to be calculated, allowing k -medoids to be used for a broader range of problems than k -means.

Using k -medoids, this example clusters the mushrooms into two groups, based on the predictors provided. It then explores the relationship between those clusters and the classifications of the mushrooms as either edible or poisonous.

This example assumes that you have downloaded the "Mushroom" data set [3][4][5][6][7] from the UCI database (<http://archive.ics.uci.edu/ml/machine-learning-databases/mushroom/>) and saved it in your current directory as a text file named `agaricus-lepiota.txt`. There is no column headers in the data, so `readtable` uses the default variable names.

```
clear all
data = readtable('agaricus-lepiota.txt', 'ReadVariableNames', false);
```

Display the first 5 mushrooms with their first few features.

```
data(1:5, 1:10)
```

```
ans =
```

Var1	Var2	Var3	Var4	Var5	Var6	Var7	Var8	Var9	Var10
'p'	'x'	's'	'n'	't'	'p'	'f'	'c'	'n'	'k'
'e'	'x'	's'	'y'	't'	'a'	'f'	'c'	'b'	'k'
'e'	'b'	's'	'w'	't'	'l'	'f'	'c'	'b'	'n'
'p'	'x'	'y'	'w'	't'	'p'	'f'	'c'	'n'	'n'
'e'	'x'	's'	'g'	'f'	'n'	'f'	'w'	'b'	'k'

Extract the first column, labeled data for edible and poisonous groups. Then delete the column.

```
labels = data(:, 1);
labels = categorical(labels{:,:});
data(:, 1) = [];
```

Store the names of predictors (features), which are described in <http://archive.ics.uci.edu/ml/machine-learning-databases/mushroom/agaricus-lepiota.names>.

```
VarNames = {'cap_shape' 'cap_surface' 'cap_color' 'bruises' 'odor' ...  
           'gill_attachment' 'gill_spacing' 'gill_size' 'gill_color' ...  
           'stalk_shape' 'stalk_root' 'stalk_surface_above_ring' ...  
           'stalk_surface_below_ring' 'stalk_color_above_ring' ...  
           'stalk_color_below_ring' 'veil_type' 'veil_color' 'ring_number' ....  
           'ring_type' 'spore_print_color' 'population' 'habitat'};
```

Set the variable names.

```
data.Properties.VariableNames = VarNames;
```

There are a total of 2480 missing values denoted as '?'.
sum(char(data{:, :}) == '?')

```
ans =
```

```
2480
```

Based on the inspection of the data set and its description, the missing values belong only to the 11th variable (`stalk_root`). Remove the column from the table.

```
data(:,11) = [];
```

`kmedoids` only accepts numeric data. You need to cast the categories you have into numeric type. The distance function you will use to define the dissimilarity of the data will be based on the double representation of the categorical data.

```
cats = categorical(data{:, :});  
data = double(cats);
```

`kmedoids` can use any distance metric supported by `pdist2` to cluster. For this example you will cluster the data using the Hamming distance because this is an appropriate distance metric for categorical data as illustrated below. The Hamming distance between two vectors is the percentage of the vector components that differ. For instance, consider these two vectors.

```
v1 = [1 0 2 1];
```

```
v2 = [1 1 2 1];
```

They are equal in the 1st, 3rd and 4th coordinate. Since 1 of the 4 coordinates differ, the Hamming distance between these two vectors is .25.

You can use the function `pdist2` to measure the Hamming distance between the first and second row of data, the numerical representation of the categorical mushroom data. The value `.2857` means that 6 of the 21 features of the mushroom differ.

```
pdist2(data(1,:),data(2:,:), 'hamming')
ans =
    0.2857
```

In this example, you're clustering the mushroom data into two clusters based on features to see if the clustering corresponds to edibility. The `kmedoids` function is guaranteed to converge to a local minima of the clustering criterion; however, this may not be a global minimum for the problem. It is a good idea to cluster the problem a few times using the `'replicates'` parameter. When `'replicates'` is set to a value, n , greater than 1, the `k-medoids` algorithm is run n times, and the best result is returned.

To run `kmedoids` to cluster data into 2 clusters, based on the Hamming distance and to return the best result of 3 replicates, you run the following.

```
rng('default'); %For reproducibility
[IDX, C, SUMD, D, MIDX, INFO] = kmedoids(data,2,'distance','hamming','replicates',3);
```

Let's assume that mushrooms in the predicted group 1 are poisonous and group 2 are all edible. To determine the performance of clustering results, calculate how many mushrooms in group 1 are indeed poisonous and group 2 are edible based on the known labels. In other words, calculate the number of false positives, false negatives, as well as true positives and true negatives.

Construct a confusion matrix (or matching matrix), where the diagonal elements represent the number of true positives and true negatives, respectively. The off-diagonal elements represent false negatives and false positives, respectively. For convenience, use the `confusionmat` function, which calculates a confusion matrix given known labels and predicted labels. Get the predicted label information from the `IDX` variable. `IDX` contains values of 1 and 2 for each data point, representing poisonous and edible groups, respectively.

```
predLabels = labels; %Initialize a vector for predicted labels.
predLabels(IDX==1) = categorical({'p'}); %Assign group 1 to be poisonous.
predLabels(IDX==2) = categorical({'e'}); %Assign group 2 to be edible.
confMatrix = confusionmat(labels,predLabels)

confMatrix =
```

```
      4176      32
      816     3100
```

Out of 4208 edible mushrooms, 4176 were correctly predicted to be in group 2 (edible group), and 32 were incorrectly predicted to be in group 1 (poisonous group). Similarly, out of 3916 poisonous mushrooms, 3100 were correctly predicted to be in group 1 (poisonous group), and 816 were incorrectly predicted to be in group 2 (edible group).

Given this confusion matrix, calculate the accuracy, which is the proportion of true results (both true positives and true negatives) against the overall data, and precision, which is the proportion of the true positives against all the positive results (true positives and false positives).

```
accuracy = (confMatrix(1,1)+confMatrix(2,2))/(sum(sum(confMatrix)))
```

```
accuracy =
```

```
0.8956
```

```
precision = confMatrix(1,1) / (confMatrix(1,1)+confMatrix(2,1))
```

```
precision =
```

```
0.8365
```

The results indicated that applying the k-medoids algorithm to the categorical features of mushrooms resulted in clusters that were associated with edibility.

Input Arguments

X — Data

numeric matrix

Data, specified as a numeric matrix. The rows of X correspond to observations, and the columns correspond to variables.

k — Number of medoids

positive integer

Number of medoids in the data, specified as a positive integer.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

```
'Distance', 'euclidean', 'Replicates', 3, 'Options', statset('UseParallel', 1)
```

specifies Euclidean distance, three replicate medoids at different starting values, and to use parallel computing.

'Algorithm' — Algorithm to find medoids

```
'pam' | 'small' | 'clara' | 'large'
```

Algorithm to find medoids, specified as the comma-separated pair consisting of 'Algorithm' and a string. The default algorithm depends on the number of rows of X .

- If the number of rows of X is less than 3000, 'pam' is the default algorithm.
- If the number of rows is between 3000 and 10000, 'small' is the default algorithm.
- For all other cases, 'large' is the default algorithm.

You can override the default choice by explicitly stating the algorithm. This table summarizes the available algorithms.

Algorithm	Description
'pam'	<p>Partitioning Around Medoids (PAM) is the classical algorithm for solving the k-medoids problem described in [1]. After applying the initialization function to select initial medoid positions, the program performs the swap-step of the PAM algorithm, that is, it searches over all possible swaps between medoids and non-medoids to see if the sum of medoid to cluster member distances goes down. You can specify which initialization function to use via the 'Start' name-value pair argument.</p> <p>The algorithm proceeds as follows.</p> <ol style="list-style-type: none"> 1 Build-step: Each of k clusters is associated with a potential medoid. This assignment is performed using a technique specified by the 'Start' name-value pair argument.

Algorithm	Description
	<p>2 Swap-step: Within each cluster, each point is tested as a potential medoid by checking if the sum of within-cluster distances gets smaller using that point as the medoid. If so, the point is defined as a new medoid. Every point is then assigned to the cluster with the closest medoid.</p> <p>The algorithm iterates the build- and swap-steps until the medoids do not change, or other termination criteria are met.</p> <p>The algorithm can produce better solutions than the other algorithms in some situations, but it can be prohibitively long running.</p>
'small'	<p>Use an algorithm similar to the k-means algorithm to find k medoids. This option employs a variant of the Lloyd's iterations based on [2].</p> <p>The algorithm proceeds as follows.</p> <ol style="list-style-type: none"> 1 For each point in each cluster, calculate the sum of distances from the point to every other point in the cluster. Choose the point that minimizes the sum as the new medoid. 2 Update the cluster membership for each data point to reflect the new medoid. <p>The algorithm repeats these steps until no further updates occur or other termination criteria are met. The algorithm has an optional PAM-like online update phase (specified by the 'OnlinePhase' name-value pair argument) that improves cluster quality. It tends to return higher quality solutions than the clara or large algorithms, but it may not be the best choice for very large data.</p>

Algorithm	Description
'clara'	<p>Clustering LARge Applications (CLARA) [1] repeatedly performs the PAM algorithm on random subsets of the data. It aims to overcome scaling challenges posed by the PAM algorithm through sampling.</p> <p>The algorithm proceeds as follows.</p> <ol style="list-style-type: none"> 1 Select a subset of the data and apply the PAM algorithm to the subset. 2 Assign points of the full data set to clusters by picking the closest medoid. <p>The algorithm repeats these steps until the medoids do not change, or other termination criteria are met.</p> <p>For the best performance, it is recommended that you perform multiple replicates. By default, the program performs five replicates. Each replicate samples s rows from X (specified by 'NumSamples' name-value pair argument) to perform clustering on. By default, $40+2*k$ samples are selected.</p>
'large'	<p>This is similar to the <code>small</code> scale algorithm and repeatedly performs searches using a k-means like update. However, the algorithm examines only a random sample of cluster members during each iteration. The user-adjustable parameter, 'PercentNeighbors', controls the number of neighbors to examine. If there is no improvement after the neighbors are examined, the algorithm terminates the local search. The algorithm performs a total of r replicates (specified by 'Replicates' name-value pair argument) and returns the best clustering result. The algorithm has an optional PAM-like online phase (specified by the 'OnlinePhase' name-value pair argument) that improves cluster quality.</p>

Example: 'Algorithm', 'pam'

'OnlinePhase' — Flag to perform PAM-like online update phase

'on' (default) | 'off'

A flag to perform PAM-like online update phase, specified as a comma-separated pair consisting of 'OnlinePhase' and 'on' or 'off'.

If it is on, then `kmedoids` performs a PAM-like update to the medoids after the Lloyd iterations in the `small` and `large` algorithms. During this online update phase, the algorithm chooses a small subset of data points in each cluster that are the furthest from and nearest to medoid. For each chosen point, it reassigns the clustering of the entire data set and check if this creates a smaller sum of distances than the best known.

In other words, the swap considerations are limited to the points near the medoids and far from the medoids. The near points are considered in order to refine the clustering. The far points are considered in order to escape local minima. Turning on this feature tends to improve the quality of solutions generated by both algorithms. Total run time tends to increase as well, but the increase typically is less than one iteration of PAM.

Example: `OnlinePhase, 'off'`

'Distance' — Distance measure

'squeclidean' (default) | 'euclidean' | 'seuclidean' | 'cityblock' | 'minkowski' | 'chebychev' | 'mahalanobis' | 'cosine' | 'correlation' | 'spearman' | 'hamming' | 'jaccard' | custom distance function

Distance measure, in p-dimensional space, specified as the comma-separated pair consisting of 'Distance' and a string. `kmedoids` minimizes the sum of medoid to cluster member distances. See `pdist` for the definition of each distance measure. `kmedoids` supports all distance measures supported by `pdist`.

Example: `'Distance', 'hamming'`

'Options' — Options to control iterative algorithm to minimize fitting criteria

[] (default) | structure array returned by `statset`

Options to control the iterative algorithm to minimize fitting criteria, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`. This table summarizes these options.

Option	Description
Display	Level of display output. Choices are 'off' (default) and 'iter'.
MaxIter	Maximum number of iterations allowed. The default is 100.
UseParallel	If true and a <code>parpool</code> is open, compute in parallel. If Parallel Computing Toolbox is not available, or a <code>parpool</code> is not open,

Option	Description
	computation occurs in serial mode. The default is <code>false</code> , meaning serial computation.
<code>UseSubstreams</code>	Set to <code>true</code> to compute in parallel in a reproducible fashion. The default is <code>false</code> . To compute reproducibly, you must also set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code> .
<code>Streams</code>	A <code>RandStream</code> object or cell array of such objects. For details about these options and parallel computing in Statistics and Machine Learning Toolbox, see “Speed Up Statistical Computations” or enter <code>help parallelstats</code> at the command line.

Example: `'Options',statset('Display','off')`

'Replicates' — Number of times to repeat clustering using new initial cluster medoid positions

positive integer

Number of times to repeat clustering using new initial cluster medoid positions, specified as a positive integer. The default value depends on the choice of algorithm. For `pam` and `small`, the default is 1. For `clara`, the default is 5. For `large`, the default is 3.

Example: `'Replicates',4`

'NumSamples' — Number of samples to take from data when executing clara algorithm

$40+2*k$ (default) | positive integer

Number of samples to take from the data when executing the `clara` algorithm, specified as a positive integer. The default number of samples is calculated as $40+2*k$.

Example: `'NumSamples',160`

'PercentNeighbors' — Percent of data set to examine using large algorithm

0.001 (default) | scalar value between 0 and 1

Percent of the data set to examine using the `large` algorithm, specified as a positive number.

The program examines `percentneighbors*size(X,1)` number of neighbors for the medoids. If there is no improvement in the within-cluster sum of distances, then the algorithm terminates.

The value of this parameter between 0 and 1, where a value closer to 1 tends to give higher quality solutions, but the algorithm takes longer to run, and a value closer to 0 tends to give lower quality solutions, but finishes faster.

Example: `'PercentNeighbors', 0.01`

'Start' — Method for choosing initial cluster medoid positions

'plus' (default) | 'sample' | 'cluster' | matrix

Method for choosing initial cluster medoid positions, specified as the comma-separated pair consisting of 'Start' and a string or a matrix. This table summarizes the available methods.

Method	Description
'plus' (default)	Select k observations from X according to the k -means++ algorithm for cluster center initialization.
'sample'	Select k observations from X at random.
'cluster'	Perform preliminary clustering phase on a random subsample (10%) of X . This preliminary phase is itself initialized using <code>sample</code> , that is, the observations are selected at random.
matrix	A custom k -by- p matrix of starting locations. In this case, you can pass in <code>[]</code> for the k input argument, and <code>kmedoids</code> infers k from the first dimension of the matrix. You can also supply a 3-D array, implying a value for 'Replicates' from the array's third dimension.

Example: `'Start', 'sample'`

Output Arguments

`idx` — Medoid indices

numeric column vector

Medoid indices, returned as a numeric column vector. `idx` has as many rows as `X`, and each row indicates the medoid assignment of the corresponding observation.

C — Cluster medoid locations

numeric matrix

Cluster medoid locations, returned as a numeric matrix. `C` is a k -by- p matrix, where row j is the medoid of cluster j

sumd — Within-cluster sums of point-to-medoid distances

numeric column vector

Within-cluster sums of point-to-medoid distances, returned as a numeric column vector. `sumd` is a k -by-1 vector, where element j is the sum of point-to-medoid distances within cluster j .

D — Distances from each point to every medoid

numeric matrix

Distances from each point to every medoid, returned as a numeric matrix. `D` is an n -by- k matrix, where element (j,m) is the distance from observation j to medoid m .

midx — Index to X

column vector

Index to `X`, returned as a column vector of indices. `midx` is a k -by-1 vector and the indices satisfy `C = X(midx, :)`.

info — Algorithm information

struct

Algorithm information, returned as a struct. `info` contains options used by the function when executed such as k -medoid clustering algorithm (`algorithm`), method used to choose initial cluster medoid positions (`start`), distance measure (`distance`), number of iterations taken in the best replicate (`iterations`) and the replicate number of the returned results (`bestReplicate`).

More About

***k*-medoids Clustering**

k-medoids clustering is a partitioning method commonly used in domains that require robustness to outlier data, arbitrary distance metrics, or ones for which the mean or median does not have a clear definition.

It is similar to *k*-means, and the goal of both methods is to divide a set of measurements or observations into *k* subsets or clusters so that the subsets minimize the sum of distances between a measurement and a center of the measurement's cluster. In the *k*-means algorithm, the center of the subset is the mean of measurements in the subset, often called a centroid. In the *k*-medoids algorithm, the center of the subset is a member of the subset, called a medoid.

The *k*-medoids algorithm returns medoids which are the actual data points in the data set. This allows you to use the algorithm in situations where the mean of the data does not exist within the data set. This is the main difference between *k*-medoids and *k*-means where the centroids returned by *k*-means may not be within the data set. Hence *k*-medoids is useful for clustering categorical data where a mean is impossible to define or interpret.

The function `kmedoids` provides several iterative algorithms that minimize the sum of distances from each object to its cluster medoid, over all clusters. One of the algorithms is called partitioning around medoids (PAM) [1] which proceeds in two steps.

- 1 Build-step: Each of *k* clusters is associated with a potential medoid. This assignment is performed using a technique specified by the 'Start' name-value pair argument.
- 2 Swap-step: Within each cluster, each point is tested as a potential medoid by checking if the sum of within-cluster distances gets smaller using that point as the medoid. If so, the point is defined as a new medoid. Every point is then assigned to the cluster with the closest medoid.

The algorithm iterates the build- and swap-steps until the medoids do not change, or other termination criteria are met.

You can control the details of the minimization using several optional input parameters to `kmedoids`, including ones for the initial values of the cluster medoids, and for the maximum number of iterations. By default, `kmedoids` uses the *k*-means++ algorithm for cluster medoid initialization and the squared Euclidean metric to determine distances.

Introduced in R2014b

knnsearch

k-nearest neighbors search using *Kd*-tree or exhaustive search

Syntax

```
Idx = knnsearch(Mdl,Y)
Idx = knnsearch(Mdl,Y,Name,Value)
[Idx,D] = knnsearch( ___ )
```

Description

`Idx = knnsearch(Mdl,Y)` searches for the nearest neighbor (i.e., the closest point, row, or observation) in `Mdl.X` to each point (i.e., row or observation) in the query data `Y` using an exhaustive search or a *Kd*-tree. `knnsearch` returns `Idx`, which is a column vector of the indices in `Mdl.X` representing the nearest neighbors.

`Idx = knnsearch(Mdl,Y,Name,Value)` returns the indices of the closest points in `Mdl.X` to `Y` with additional options specified by one or more `Name,Value` pair arguments. For example, specify the number of nearest neighbors to search for, distance metric different from the one stored in `Mdl.Distance`. You can also specify which action to take if the closest distances are tied.

`[Idx,D] = knnsearch(___)` additionally returns the matrix `D` using any of the input arguments in the previous syntaxes. `D` contains the distances between each observation in `Y` that correspond to the closest observations in `Mdl.X`. The function arranges the columns of `D` in ascending order by closeness, with respect to the distance metric.

Examples

Search for Nearest Neighbors Using a *K d*-tree and Exhaustive Search

`knnsearch` accepts `ExhaustiveSearcher` or `KDTreeSearcher` model objects to search the training data for the nearest neighbors to the query data. An `ExhaustiveSearcher`

model invokes the exhaustive searcher algorithm, and a `KDTreeSearcher` model defines a K d-tree, which `knnsearch` uses to search for nearest neighbors.

Load Fisher's iris data set. Randomly reserve five observations from the data for query data.

```
load fisheriris
rng(1); % For reproducibility
n = size(meas,1);
idx = randsample(n,5);
X = meas(~ismember(1:n,idx),:); % Training data
Y = meas(idx,:); % Query data
```

The variable `meas` contains 4 predictors.

Grow a default four-dimensional K d-tree.

```
MdlKDT = KDTreeSearcher(X)
```

```
MdlKDT =
```

```
    KDTreeSearcher with properties:
```

```
        BucketSize: 50
        Distance: 'euclidean'
        DistParameter: []
           X: [145x4 double]
```

`MdlKDT` is a `KDTreeSearcher` model object. You can alter its writable properties using dot notation.

Prepare an exhaustive nearest neighbors searcher.

```
MdlES = ExhaustiveSearcher(X)
```

```
MdlES =
```

```
    ExhaustiveSearcher with properties:
```

```
        Distance: 'euclidean'
        DistParameter: []
           X: [145x4 double]
```

MdlKDT is an `ExhaustiveSearcher` model object. It contains the options, such as the distance metric, to use to find nearest neighbors.

Alternatively, you can grow a K d-tree or prepare an exhaustive nearest neighbors searcher using `createns`.

Search the training data for the nearest neighbors indices that correspond to each query observation. Conduct both types of searches using the default settings. By default, the number of neighbors to search for per query observation is 1.

```
IdxKDT = knnsearch(MdlKDT,Y);
IdxES = knnsearch(MdlES,Y);
[IdxKDT IdxES]
```

```
ans =
```

```
    17    17
     6     6
     1     1
    89    89
   124   124
```

In this case, the results of the search are the same.

Search for Nearest Neighbors of Query Data Using the Minkowski Distance

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Grow a four-dimensional K d-tree using the training data. Specify to use the Minkowski distance for finding nearest neighbors later.

```
Mdl = KDTreeSearcher(X, 'Distance', 'minkowski')
```

```
Mdl =
    KDTreeSearcher with properties:
        BucketSize: 50
        Distance: 'minkowski'
        DistParameter: 2
        X: [145x4 double]
```

`Mdl` is a `KDTreeSearcher` model object. By default, the Minkowski distance exponent is 2.

Find the indices of the training data (`X`) that are the two nearest neighbors of each point in the query data (`Y`).

```
Idx = knnsearch(Mdl,Y,'K',2)
```

```
Idx =
    17     4
     6     2
     1    12
    89    66
   124   100
```

Each row of `Idx` corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors, with respect to ascending distance. For example, using the Minkowski distance, the second nearest neighbor of `Y(3, :)` is `X(12, :)`.

Include Ties in Nearest Neighbors Search

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(4); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
```

```
X = meas(~ismember(1:n,qIdx),:);  
Y = meas(qIdx,:);
```

Grow a four-dimensional K d-tree using the training data. Specify to use the Minkowski distance for finding nearest neighbors later.

```
Mdl = KDTreeSearcher(X);
```

`Mdl` is a `KDTreeSearcher` model object. By default, the distance metric for finding nearest neighbors is the Euclidean metric.

Find the indices of the training data (`X`) that are the seven nearest neighbors of each point in the query data (`Y`).

```
[Idx,D] = knnsearch(Mdl,Y,'K',7,'IncludeTies',true);
```

`Idx` and `D` are five-element cell arrays of vectors, with each vector having at least seven elements.

Display the lengths of the vectors in `Idx`.

```
cellfun('length',Idx)
```

```
ans =
```

```
8  
7  
7  
7  
7
```

Because cell 1 contains a vector with length greater than $k = 7$, query observation 1 (`Y(1,:)`) is equally close to at least two observations in `X`.

Display the indices of the nearest neighbors to `Y(1,:)` and their distances.

```
nn5 = Idx{1}  
nn5d = D{1}
```

```
nn5 =
```

```
91 98 67 69 71 93 88 95
```

```

nn5d =
    Columns 1 through 7
    0.1414    0.2646    0.2828    0.3000    0.3464    0.3742    0.3873
    Column 8
    0.3873

```

Training observations **88** and **95** are 0.3873 cm away from query observation **1**.

Input Arguments

Mdl — Nearest neighbors searcher

ExhaustiveSearcher model object | KDTreeSearcher model object

Nearest neighbors searcher, specified as an `ExhaustiveSearcher` or `KDTreeSearcher` model object, respectively. To create `Mdl`, with the appropriate mode creator. You can also use `createns`.

If `Mdl` is an `ExhaustiveSearcher` model, then `knnsearch` searches for nearest neighbors using an exhaustive search. Otherwise, `knnsearch` uses the grown *Kd*-tree to search for nearest neighbors.

Y — Query data

numeric matrix

Query data, specified as a numeric matrix.

`Y` is an m -by- K matrix. Rows of `Y` correspond to observations (i.e., examples), and columns correspond to predictors (i.e., variables or features). `Y` must have the same number of columns as the training data stored in `Mdl.X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'K', 2, 'Distance', 'minkowski'` specifies to find the two nearest neighbors of `Mdl.X` to each point in `Y` and to use the Minkowski distance metric.

For Both Nearest Neighbor Searchers

'Distance' — Distance metric

`Mdl.Distance` (default) | 'cityblock' | 'euclidean' | 'mahalanobis' | 'minkowski' | 'seuclidean' | function handle | ...

Distance metric used to find neighbors of the training data to the query observations, specified as the comma-separated pair consisting of 'Distance' and a string or function handle.

For both types of nearest neighbor searchers, `Mdl` supports these distance metrics.

Value	Description
'chebychev'	Chebychev distance (maximum coordinate difference)
'cityblock'	City block distance
'euclidean'	Euclidean distance
'minkowski'	Minkowski distance

If `Mdl` is an `ExhaustiveSearcher` model object, then `knnsearch` supports these distance metrics.

Value	Description
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values)
'cosine'	One minus the cosine of the included angle between observations (row vectors)
'hamming'	Hamming distance, which is the percentage of coordinates that differ.

Value	Description
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ
'mahalanobis'	Mahalanobis distance
'seuclidean'	Standardized Euclidean distance
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values)

If `Mdl` is an `ExhaustiveSearcher` model object, then you can also specify a function handle for a custom distance metric using `@` (for example, `@distfun`). The custom distance function must:

- Have the form `function D2 = distfun(ZI, ZJ)`.
- Take as arguments:
 - A 1-by- K vector `ZI` containing a single row from X or from the query points Y
 - An m -by- K matrix `ZJ` containing multiple rows of X or Y
- Return an m -by-1 vector of distances `D2`. `D2(j)` is the distance between the observations `ZI` and `ZJ(j, :)`.

For more details, see “Distance Metrics” on page 17-10.

Example: 'Distance', 'minkowski'

Data Types: char | function_handle

'IncludeTies' — Flag to include nearest neighbors that have the same distance from query observations

false (0) (default) | true (1)

Flag to include nearest neighbors that have the same distance from query observations, specified as the comma-separated pair consisting of 'IncludeTies' and false (0) or true (1).

If `IncludeTies` is true, then:

- `knnsearch` includes all nearest neighbors whose distances are equal to the K th smallest distance in the output arguments.

- `Idx` and `D` are m -by-1 cell arrays such that each cell contains a vector of at least K indices and distances, respectively. Each vector in `D` contains arranged distances in ascending order. Each row in `Idx` contains the indices of the nearest neighbors corresponding to these smallest distances in `D`.

If `IncludeTies` is `false`, then `knnsearch` chooses the observation with the smallest index among the observations that have the same distance from a query point.

Example: `'IncludeTies', true`

'K' — Number of nearest neighbors to search for in the training data per query observation
1 (default) | positive integer

Number of nearest neighbors to search for in the training data per query observation, specified as the comma-separated pair consisting of `'IncludeTies'` and a positive integer.

Example: `'K', 2`

Data Types: `single` | `double`

'P' — Exponent for Minkowski distance metric
2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of `'P'` and a positive scalar. If you specify `P` and do not specify `'Distance', 'minkowski'`, then the software throws an error.

Example: `'P', 3`

Data Types: `double` | `single`

For Exhaustive Nearest Neighbor Searchers

'Cov' — Covariance matrix for Mahalanobis distance metric
`nancov(X)` (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of `'Cov'` and a positive definite matrix. `COV` is a K -by- K matrix, where K is the number of columns of `X`. If you specify `COV` and do not specify `'Distance', 'mahalanobis'`, then `knnsearch` throws an error.

Example: `'Cov', eye(3)`

Data Types: `double` | `single`

'Scale' — Scale parameter value for standard Euclidean distance metric

nanstd(*X*) (default) | nonnegative numeric vector

Scale parameter value for the standard Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector. Scale has length *K*, where *K* is the number of columns of *X*.

The software scales each difference between the training and query data using the corresponding element of Scale. If you specify Scale and do not specify 'Distance', 'seuclidean', then knnsearch throws an error.

Example: 'Scale', quantile(*X*,0.75) - quantile(*X*,0.25)

Data Types: double | single

Note: If you specify 'Distance', 'Cov', 'P', or 'Scale', then `Mdl.Distance` and `Mdl.DistanceParameter` do not change value.

Output Arguments

Idx — Training data indices of nearest neighbors

numeric matrix | cell array of numeric vectors

Training data indices of nearest neighbors, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify `IncludeTies` (`false` by default), then `Idx` is an *m*-by-*K* numeric matrix, where *m* is the number of rows in *Y* and *K* is the number of searched nearest neighbors. `Idx(j,k)` indicates that `Mdl.X(Idx(j,k),:)` is the observation with the *k*th smallest distance to the query observation `Y(j,:)`.
- If you specify 'IncludeTies', `true`, then `Idx` is an *m*-by-1 cell array such that cell `j` (`Idx{j}`) contains a vector of at least *K* indices of the closest observations in `Mdl.X` to the query observation `Y(j,:)`. The function arranges the elements of the vectors in ascending order by distance.

D — Distances of nearest neighbors to the query data

numeric matrix | cell array of numeric vectors

Distances of the nearest neighbors to the query data, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify `IncludeTies` (`false` by default), then `D` is an m -by- K numeric matrix, where m is the number of rows in `Y` and K is the number of searched nearest neighbors. `D(j,k)` is the distance `Mdl.X(Idx(j,k),:)` is from the query observation `Y(j,:)` with respect to the distance metric, and it represents the k th smallest distance.
- If you specify `'IncludeTies',true`, then `D` is an m -by-1 cell array such that cell `j` (`D{j}`) contains a vector of at least K distances of the closest observations in `Mdl.X` to the query observation `Y(j,:)`. The function arranges the elements of the vectors in ascending order by distance.

Alternatives

- `knnsearch` is an object function that requires an `ExhaustiveSearcher` or a `KDTreeSearcher` model object and query data. Under equivalent conditions, `knnsearch` returns the same results as `knnsearch` when you specify the name-value pair argument `'NSMethod','exhaustive'` or `'NSMethod','kdtree'`, respectively.
- For k -nearest neighbors classification, see `fitcknn` and `ClassificationKNN`.

More About

Algorithms

For positive integer K , `knnsearch` finds the K points in `Mdl.X` that are nearest each `Y` point. In contrast, for positive scalar r , `rangesearch` finds all the points in `Mdl.X` that are within a distance r of each `Y` point.

Introduced in R2010a

knnsearch

Find k -nearest neighbors using data

Syntax

```
IDX = knnsearch(X,Y)
[IDX,D] = knnsearch(X,Y)
[IDX,D] = knnsearch(X,Y, 'Name', Value)
```

Description

`IDX = knnsearch(X,Y)` finds the nearest neighbor in X for each point in Y . IDX is a column vector with my rows. Each row in IDX contains the index of nearest neighbor in X for the corresponding row in Y .

`[IDX,D] = knnsearch(X,Y)` returns an my -by-1 vector D containing the distances between each observation in Y and the corresponding closest observation in X . That is, $D(i)$ is the distance between $X(Idx(i), :)$ and $Y(i, :)$.

`[IDX,D] = knnsearch(X,Y, 'Name', Value)` accepts one or more optional comma-separated name-value pair arguments. Specify *Name* inside single quotes.

`knnsearch` does not save a search object. To create a search object, use `createns`.

Input Arguments

X

An $m \times n$ -by- n numeric matrix. Rows of X correspond to observations and columns correspond to variables.

Y

An $m \times n$ -by- n numeric matrix of query points. Rows of Y correspond to observations and columns correspond to variables.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, . . . , `NameN`, `ValueN`.

'K'

Positive integer specifying the number of nearest neighbors in `X` for each point in `Y`. Default is 1. `IDX` and `D` are *m_y-by-K* matrices. `D` sorts the distances in each row in ascending order. Each row in `IDX` contains the indices of the `K` closest neighbors in `X` corresponding to the `K` smallest distances in `D`.

'IncludeTies'

A logical value indicating whether `knnsearch` includes all the neighbors whose distance values are equal to the `K`th smallest distance. If `IncludeTies` is `true`, `knnsearch` includes all these neighbors. In this case, `IDX` and `D` are *m_y-by-1* cell arrays. Each row in `IDX` and `D` contains a vector with at least `K` numeric numbers. `D` sorts the distances in each vector in ascending order. Each row in `IDX` contains the indices of the closest neighbors corresponding to these smallest distances in `D`.

Default: `false`

'NSMethod'

Nearest neighbors search method. Value is either:

- `'kdtree'` — Creates and uses a Kd-tree to find nearest neighbors. This is the default value when the number of columns of `X` is less than 10, `X` is not sparse, and the distance measure is one of the following measures. `'kdtree'` is only valid when the distance measure is one of the following:
 - `'euclidean'`
 - `'cityblock'`
 - `'minkowski'`
 - `'chebychev'`
- `'exhaustive'` — Uses the exhaustive search algorithm by computing the distance values from all the points in `X` to each point in `Y` to find nearest neighbors.

'Distance'

A string or a function handle specifying the distance metric. The value can be one of the following:

- `'euclidean'` — Euclidean distance (default).
- `'seuclidean'` — Standardized Euclidean distance. Each coordinate difference between rows in `X` and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from `X`, `S=nanstd(X)`. To specify another value for `S`, use the `Scale` argument.
- `'cityblock'` — City block distance.
- `'chebychev'` — Chebychev distance (maximum coordinate difference).
- `'minkowski'` — Minkowski distance. The default exponent is 2. To specify a different exponent, use the `'P'` argument.
- `'mahalanobis'` — Mahalanobis distance, computed using a positive definite covariance matrix `C`. The default value of `C` is `nancov(X)`. To change the value of `C`, use the `Cov` parameter.
- `'cosine'` — 1 minus the cosine of the included angle between observations (treated as vectors).
- `'correlation'` — One minus the sample linear correlation between observations (treated as sequences of values).
- `'spearman'` — One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
- `'hamming'` — Hamming distance, which is the percentage of coordinates that differ.
- `'jaccard'` — One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
- custom distance function — A distance function specified using `@` (for example, `@distfun`). A custom distance function must
 - Have the form `function D2 = distfun(ZI,ZJ)`
 - Take as arguments:
 - A 1-by- n vector `ZI` containing a single row from `X` or from the query points `Y`
 - An $m2$ -by- n matrix `ZJ` containing multiple rows of `X` or `Y`
 - Return an $m2$ -by-1 vector of distances `D2`, whose j th element is the distance between the observations `ZI` and `ZJ(j,:)`

For more information on these distance metrics, see “Distance Metrics” on page 17-10.

'P'

A positive scalar, p , indicating the exponent of the Minkowski distance. This parameter is only valid if the `Distance` is `'minkowski'`. Default is 2.

'Cov'

A positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This parameter is only valid when `Distance` is `'mahalanobis'`. Default is `nancov(X)`.

'Scale'

A vector `S` containing nonnegative values, with length equal to the number of columns in `X`. Each coordinate of `X` and each query point is scaled by the corresponding element of `S` when computing the standardized Euclidean distance. This argument is only valid when `Distance` is `'seuclidean'`. Default is `nanstd(X)`.

'BucketSize'

The maximum number of data points in the leaf node of the *kd*-tree. This argument is only meaningful when using the *kd*-tree search method. Default is 50.

Examples

Classify Using k-Nearest Neighbors

Find the 10 nearest neighbors in `x` to each point in `y` using first the `'minkowski'` distance metric with a p value of 5, and then using the `'chebychev'` distance metric.

Load Fisher's iris data set

```
load fisheriris
x = meas(:,3:4);
y = [5 1.45;6 2;2.75 .75];
```

Perform a `knnsearch` between `x` and the query points in `y`, using first Minkowski then Chebychev distance metrics.

```
[n,d]=knnsearch(x,y,'k',10,'distance','minkowski','p',5);  
[ncb,dcb] = knnsearch(x,y,'k',10,...  
    'distance','chebychev');
```

Visualize the results of the two different nearest neighbors searches. Plot the training data. Plot an X for the query points. Use circles to denote the Minkowski nearest neighbors. Use pentagrams to denote the Chebychev nearest neighbors.

```
gscatter(x(:,1),x(:,2),species)  
line(y(:,1),y(:,2),'marker','x','color','k',...  
    'markersize',10,'linewidth',2,'linestyle','none')  
line(x(n,1),x(n,2),'color',[.5 .5 .5],'marker','o',...  
    'linestyle','none','markersize',10)  
line(x(ncb,1),x(ncb,2),'color',[.5 .5 .5],'marker','p',...  
    'linestyle','none','markersize',10)  
legend('setosa','versicolor','virginica','query point',...  
    'minkowski','chebychev','Location','best')
```

Alternatives

knnsearch is the object function of ExhaustiveSearcher and KDTreeSearcher models for a k -nearest neighbors search. If you set the NSMethod name-value pair argument to the appropriate value ('exhaustive' for an exhaustive search or 'kdtree' for a Kd -tree), then the search results are equivalent to conducting a distance search using knnsearch and without using model objects.

More About

Tips

- For a fixed positive integer K , `knnsearch` finds the K points in X that are nearest each point in Y . In contrast, for a fixed positive real value r , `rangesearch` finds all the points in X that are within a distance r of each point in Y .

Algorithms

For information on a specific search algorithm, see “Distance Metrics” on page 17-10.

Introduced in R2010a

kruskalwallis

Kruskal-Wallis test

Syntax

```
p = kruskalwallis(x)
p = kruskalwallis(x,group)
p = kruskalwallis(x,group,displayopt)
[p,tbl,stats] = kruskalwallis( ___ )
```

Description

`p = kruskalwallis(x)` returns the p -value for the null hypothesis that the data in each column of the matrix `x` comes from the same distribution, using a Kruskal-Wallis test. The alternative hypothesis is that not all samples come from the same distribution. `kruskalwallis` also returns an ANOVA table and a box plot.

`p = kruskalwallis(x,group)` returns the p -value for a test of the null hypothesis that the data in each categorical group, as specified by the grouping variable `group` comes from the same distribution. The alternative hypothesis is that not all groups come from the same distribution.

`p = kruskalwallis(x,group,displayopt)` returns the p -value of the test and lets you display or suppress the ANOVA table and box plot.

`[p,tbl,stats] = kruskalwallis(___)` also returns the ANOVA table as the cell array `tbl` and the structure `stats` containing information about the test statistics.

Examples

Test Data Samples for the Same Distribution

Create two different normal probability distribution objects. The first distribution has `mu = 0` and `sigma = 1`, and the second distribution has `mu = 2` and `sigma = 1`.

```
pd1 = makedist('Normal');
pd2 = makedist('Normal','mu',2,'sigma',1);
```

Create a matrix of sample data by generating random numbers from these two distributions.

```
rng('default'); % for reproducibility
x = [random(pd1,20,2),random(pd2,20,1)];
```

The first two columns of `x` contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in `x` comes from the same distribution.

```
p = kruskalwallis(x)
```

```
p =
```

```
3.6896e-06
```

Kruskal-Wallis ANOVA Table					
Source	SS	df	MS	Chi-sq	Prob>Chi-sq
Columns	7631.1	2	3815.55	25.02	3.68957e-06
Error	10363.9	57	181.82		
Total	17995	59			

The returned value of `p` indicates that `kruskalwallis` rejects the null hypothesis that all three data samples come from the same distribution at a 1% significance level. The ANOVA table provides additional test results, and the box plot visually presents the summary statistics for each column in `x`.

Conduct Followup Tests for Unequal Medians

Create two different normal probability distribution objects. The first distribution has `mu = 0` and `sigma = 1`. The second distribution has `mu = 2` and `sigma = 1`.

```
pd1 = makedist('Normal');  
pd2 = makedist('Normal','mu',2,'sigma',1);
```

Create a matrix of sample data by generating random numbers from these two distributions.

```
rng('default'); % for reproducibility
x = [random(pd1,20,2),random(pd2,20,1)];
```

The first two columns of `x` contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in `x` comes from the same distribution. Suppress the output displays, and generate the structure `stats` to use in further testing.

```
[p,tbl,stats] = kruskalwallis(x,[],'off')
```

```
p =
```

```
3.6896e-06
```

```
tbl =
```

```
Columns 1 through 4
```

'Source'	'SS'	'df'	'MS'
'Columns'	[7.6311e+03]	[2]	[3.8155e+03]
'Error'	[1.0364e+04]	[57]	[181.8228]
'Total'	[17995]	[59]	[]

```
Columns 5 through 6
```

'Chi-sq'	'Prob>Chi-sq'
[25.0200]	[3.6896e-06]
[]	[]
[]	[]

```
stats =
```

```
gnames: [3x1 char]
n: [20 20 20]
source: 'kruskalwallis'
meanranks: [26.7500 18.9500 45.8000]
sumt: 0
```

The returned value of `p` indicates that the test rejects the null hypothesis at the 1% significance level. You can use the structure `stats` to perform additional followup testing. The cell array `tbl` contains the same data as the graphical ANOVA table, including column and row labels.

Conduct a followup test to identify which data sample comes from a different distribution.

```
c = multcompare(stats)
```

Note: Intervals can be used for testing but are not simultaneous confidence intervals.

```
c =
```

```
1.0000    2.0000   -5.1435    7.8000   20.7435
1.0000    3.0000  -31.9935  -19.0500   -6.1065
2.0000    3.0000  -39.7935  -26.8500  -13.9065
```

The results indicate that there is a significant difference between groups 1 and 3, so the test rejects the null hypothesis that the data in these two groups comes from the same distribution. The same is true for groups 2 and 3. However, there is not a significant difference between groups 1 and 2, so the test does not reject the null hypothesis that these two groups come from the same distribution. Therefore, these results suggest that the data in groups 1 and 2 come from the same distribution, and the data in group 3 comes from a different distribution.

Test for the Same Distribution Across Groups

Create a vector, `strength`, containing measurements of the strength of metal beams. Create a second vector, `alloy`, containing strings indicating the type of metal alloy from which the corresponding beam is made.

```

strength = [82 86 79 83 84 85 86 87 74 82 ...
            78 75 76 77 79 79 77 78 82 79];

alloy = {'st', 'st', 'st', 'st', 'st', 'st', 'st', 'st', ...
         'al1', 'al1', 'al1', 'al1', 'al1', 'al1', ...
         'al2', 'al2', 'al2', 'al2', 'al2', 'al2'};

```

Test the null hypothesis that the beam strength measurements have the same distribution across all three alloys.

```

p = kruskalwallis(strength, alloy, 'off')

p =

    0.0018

```

The returned value of `p` indicates that the test rejects the null hypothesis at the 1% significance level.

Input Arguments

x — Sample data

vector | matrix

Sample data for the hypothesis test, specified as a vector or an m -by- n matrix. If `x` is an m -by- n matrix, each of the n columns represents an independent sample containing m mutually independent observations.

Data Types: `single` | `double`

group — Grouping variable

categorical variable | vector | character array | cell array

Grouping variable, specified as a categorical variable, vector, character array, or cell array.

- If `x` is a vector, then each element in `group` identifies the group to which the corresponding element in `x` belongs, and `group` must be a vector of the same length as `x`. If a row of `group` contains an empty cell or empty string, that row and the corresponding observation in `x` are disregarded. NaN values in either `x` or `group` are similarly ignored.

- If `x` is a matrix, then each column in `x` represents a different group, and you can use `group` to specify labels for these columns. The number of elements in `group` and the number of columns in `x` must be equal.

The labels contained in `group` also annotate the box plot.

Example:

```
{'red', 'blue', 'green', 'blue', 'red', 'blue', 'green', 'green', 'red'}
```

Data Types: `single` | `double` | `char`

displayopt — Display option

'on' (default) | 'off'

Display option, specified as 'on' or 'off'. If `displayopt` is 'on', `kruskalwallis` displays the following figures:

- An ANOVA table containing the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in `x`.
- A box plot of the data in each column of the data matrix `x`. The box plots are based on the actual data values, rather than on the ranks.

If `displayopt` is 'off', `kruskalwallis` does not display these figures.

If you specify a value for `displayopt`, you must also specify a value for `group`. If you do not have a grouping variable, specify `group` as `[]`.

Example: 'off'

Output Arguments

p — *p*-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. `p` is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of `p` cast doubt on the validity of the null hypothesis.

tb1 — ANOVA table

cell array

ANOVA table of test results, returned as a cell array. `tbl` includes the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in `x`, as well as column and row labels.

stats — Test data

structure

Test data, returned as a structure. You can perform followup multiple comparison tests on pairs of sample medians by using `multcompare`, with `stats` as the input value.

More About

Kruskal-Wallis Test

The Kruskal-Wallis test is a nonparametric version of classical one-way ANOVA, and an extension of the Wilcoxon rank sum test to more than two groups. It compares the medians of the groups of data in `x` to determine if the samples come from the same population (or, equivalently, from different populations with the same distribution).

The Kruskal-Wallis test uses ranks of the data, rather than numeric values, to compute the test statistics. It finds ranks by ordering the data from smallest to largest across all groups, and taking the numeric index of this ordering. The rank for a tied observation is equal to the average rank of all observations tied with it. The F -statistic used in classical one-way ANOVA is replaced by a chi-square statistic, and the p -value measures the significance of the chi-square statistic.

The Kruskal-Wallis test assumes that all samples come from populations having the same continuous distribution, apart from possibly different locations due to group effects, and that all observations are mutually independent. By contrast, classical one-way ANOVA replaces the first assumption with the stronger assumption that the populations have normal distributions.

Introduced before R2006a

ksdensity

Kernel smoothing function estimate for univariate and bivariate data

Syntax

```
[f,xi] = ksdensity(x)
[f,xi] = ksdensity(x,pts)
[f,xi] = ksdensity(x,pts,Name,Value)
[f,xi,bw] = ksdensity( ___ )

ksdensity( ___ )
ksdensity(ax, ___ )
```

Description

`[f,xi] = ksdensity(x)` returns a probability density estimate, `f`, for the sample data in the vector or two-column matrix `x`. The estimate is based on a normal kernel function, and is evaluated at equally-spaced points, `xi`, that cover the range of the data in `x`. `ksdensity` estimates the density at 100 points for univariate data, or 900 points for bivariate data.

`ksdensity` works best with continuously distributed samples.

`[f,xi] = ksdensity(x,pts)` returns a probability density estimate, `f`, for the data sample in the vector or two-column matrix `x`, evaluated at the specified values in vector `pts`. Here, `xi` and `pts` contain identical values.

`[f,xi] = ksdensity(x,pts,Name,Value)` returns a probability density estimate, `f`, for the sample in the vector or two-column matrix `x`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can define the function type `ksdensity` evaluates, such as probability density, cumulative probability, survivor function, and so on. Or you can specify the bandwidth of the smoothing window.

`[f,xi,bw] = ksdensity(___)` also returns the bandwidth of the kernel smoothing window, `bw`. The default bandwidth is the optimal for normal densities.

`ksdensity(___)` plots the kernel smoothing function estimate.

`ksdensity(ax, ___)` plots the results using axes with the handle, `ax`, instead of the current axes returned by `gca`.

Examples

Estimate Density

Generate a sample data set from a mixture of two normal distributions.

```
rng default % for reproducibility
x = [randn(30,1); 5+randn(30,1)];
```

Plot the estimated density.

```
[f,xi] = ksdensity(x);
figure
plot(xi,f);
```

The density estimate shows the bimodality of the sample.

Estimate Cumulative Distribution Function at Specified Values

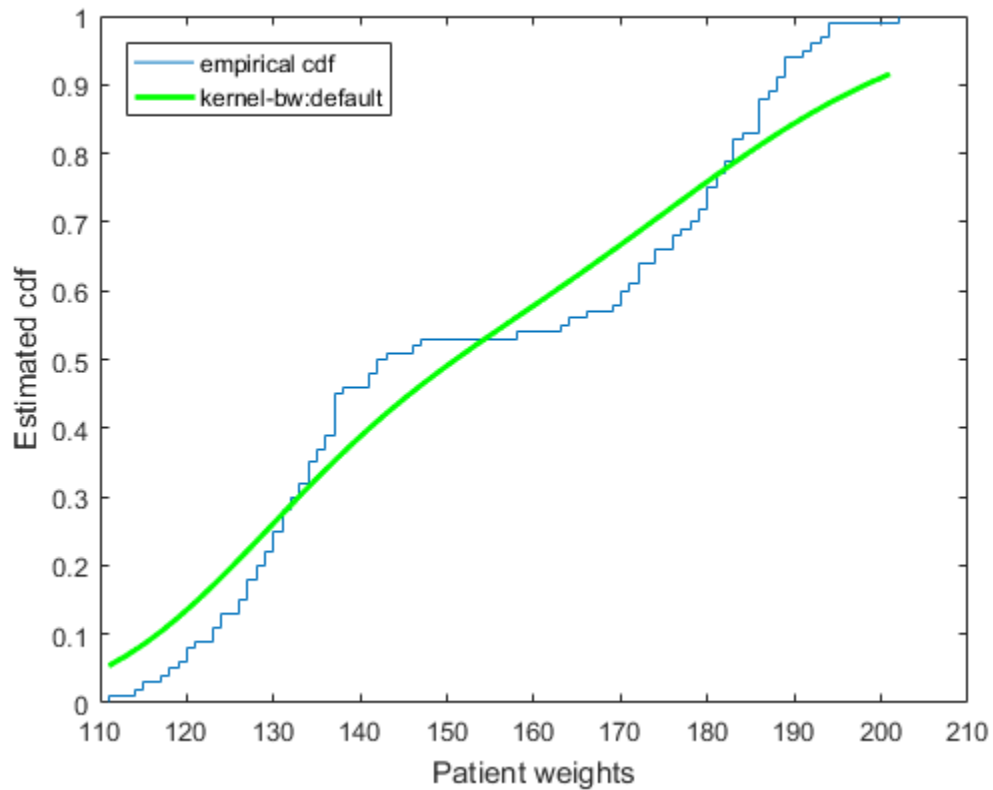

Load the sample data.

```
load hospital
```

Compute and plot the estimated cdf evaluated at a specified set of values.

```
pts = (min(hospital.Weight):2:max(hospital.Weight));  
figure()  
ecdf(hospital.Weight)  
hold on
```

```
[f,xi,bw] = ksdensity(hospital.Weight,pts,'support','positive',...  
    'function','cdf');  
plot(xi,f,'-g','LineWidth',2)  
legend('empirical cdf','kernel-bw:default','Location','NorthWest')  
xlabel('Patient weights')  
ylabel('Estimated cdf')
```

`ksdensity` seems to smooth the cumulative distribution function estimate too much. An estimate with a smaller bandwidth might produce a closer estimate to the empirical cumulative distribution function.

Return the bandwidth of the smoothing window.

`bw`

```
bw =  
  
0.1070
```

Plot the cumulative distribution function estimate using a smaller bandwidth.

```
[f,xi] = ksdensity(hospital.Weight,pts,'support','positive',...  
    'function','cdf','bandwidth',0.05);  
plot(xi,f,'--r','LineWidth',2)  
legend('empirical cdf','kernel-bw:default','kernel-bw:0.05',...  
    'Location','NorthWest')  
hold off
```

The `ksdensity` estimate with a smaller bandwidth matches the empirical cumulative distribution function better.

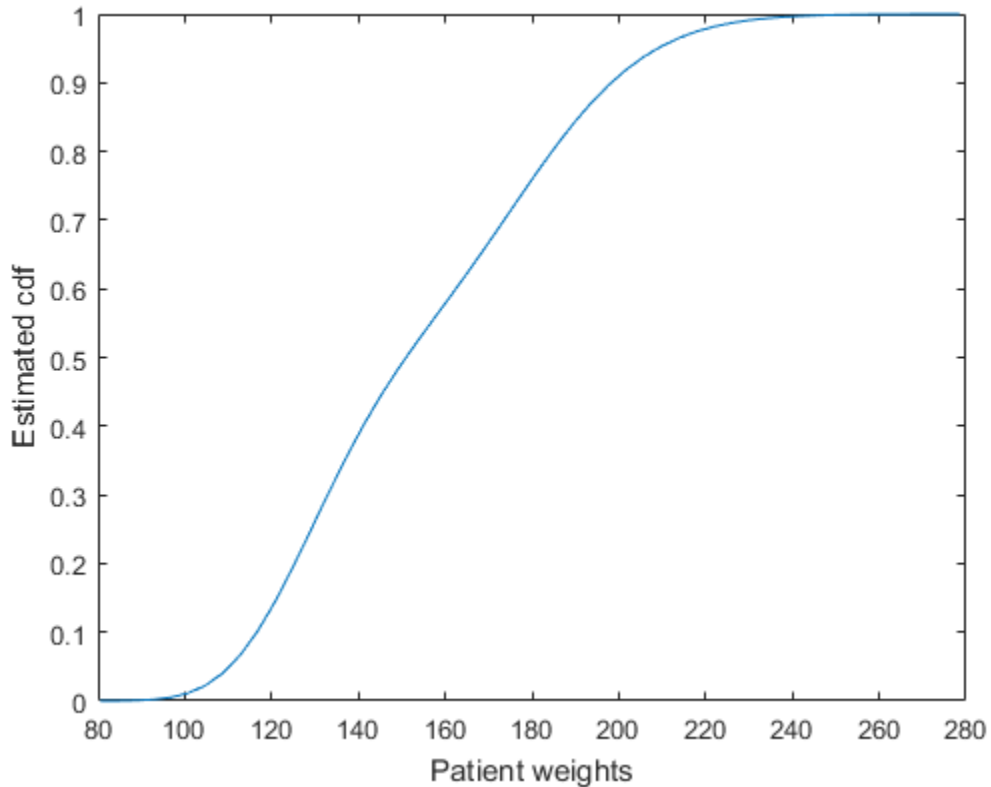

Plot Estimated Cumulative Density Function for Given Number of Points

Load the sample data.

```
load hospital
```

Plot the estimated cdf evaluated at 50 equally spaced points.

```
figure()  
ksdensity(hospital.Weight, 'support', 'positive', 'function', 'cdf', ...  
          'npoints', 50)  
xlabel('Patient weights')  
ylabel('Estimated cdf')
```

Estimate Survivor and Cumulative Hazard for Censored Failure Data

Generate sample data from an exponential distribution with mean 3.

```
rng default % for reproducibility  
x = random('exp',3,100,1);
```

Create a logical vector that indicates censoring. Here, observations with lifetimes longer than 10 are censored.

```
T = 10;  
cens = (x>10);
```

Compute and plot the estimated density function.

```
figure  
ksdensity(x, 'support', 'positive', 'censoring', cens);
```

Compute and plot the survivor function.

```
figure  
ksdensity(x, 'support', 'positive', 'censoring', cens, ...  
          'function', 'survivor');
```

Compute and plot the cumulative hazard function.

```
figure  
ksdensity(x, 'support', 'positive', 'censoring', cens, ...  
          'function', 'cumhazard');
```

Estimate Inverse Cumulative Distribution Function for Specified Probability Values

Generate a mixture of two normal distributions, and plot the estimated inverse cumulative distribution function at a specified set of probability values.

```
rng default % for reproducibility
x = [randn(30,1); 5+randn(30,1)];
pi = linspace(.01,.99,99);
figure
ksdensity(x,pi,'function','icdf');
```

Return Bandwidth of Smoothing Window

Generate a mixture of two normal distributions.

```
rng default % For reproducibility
x = [randn(30,1); 5+randn(30,1)];
```

Return the bandwidth of the smoothing window for the probability density estimate.

```
[f,xi,bw] = ksdensity(x);
bw
```

```
bw =
```

1.5141

The default bandwidth is optimal for normal densities.

Plot the estimated density.

```
figure  
plot(xi,f);  
xlabel('xi')  
ylabel('f')  
hold on
```

Plot the density using an increased bandwidth value.

```
[f,xi] = ksdensity(x,'width',1.8);  
plot(xi,f,'--r','LineWidth',1.5)
```

A higher bandwidth further smooths the density estimate, which might mask some characteristics of the distribution.

Now, plot the density using a decreased bandwidth value.

```
[f,xi] = ksdensity(x,'width',0.8);  
plot(xi,f,'-.k','LineWidth',1.5)  
legend('bw = default','bw = 1.8','bw = 0.8')
```

```
hold off
```

A smaller bandwidth smooths the density estimate less, which exaggerates some characteristics of the sample.

Plot Kernel Density Estimate of Bivariate Data

Create a two-column vector of points at which to evaluate the density.

```
gridx1 = -0.25:.05:1.25;  
gridx2 = 0:.1:15;  
[x1,x2] = meshgrid(gridx1, gridx2);  
x1 = x1(:);  
x2 = x2(:);
```

```
xi = [x1 x2];
```

Generate a 30-by-2 matrix containing random numbers from a mixture of bivariate normal distributions.

```
rng default % For reproducibility
x = [0+.5*rand(20,1) 5+2.5*rand(20,1);
     .75+.25*rand(10,1) 8.75+1.25*rand(10,1)];
```

Plot the estimated density of the sample data.

```
figure
ksdensity(x,xi);
```

- “Fit Kernel Distribution Using `ksdensity`” on page 5-54

- “Fit Distributions to Grouped Data Using `ksdensity`” on page 5-57

Input Arguments

x — Sample data

column vector | two-column matrix

Sample data for which `ksdensity` returns `f` values, specified as a column vector or two-column matrix. Use a column vector for univariate data, and a two-column matrix for bivariate data.

Example: `[f,xi] = ksdensity(x)`

Data Types: `single` | `double`

pts — Points to evaluate `f`

vector | two-column matrix

Points to evaluate `f` at, specified as a vector or two-column matrix. For univariate data, `pts` can be a row or column vector. The returned output `f` has the same dimensions as `pts`.

Example: `pts = (0:1:25); ksdensity(x,pts);`

Data Types: `single` | `double`

ax — Axes handle

handle

Axes handle for the figure `ksdensity` plots to, specified as a handle.

For example, if `h` is a handle for a figure, then `ksdensity` can plot to that figure as follows.

Example: `ksdensity(h,x)`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

'censoring',cens,'kernel','triangle','npoints',20,'function','cdf' specifies that `ksdensity` estimates the cdf by evaluating at 20 equally spaced points that covers the range of data, using the triangle kernel smoothing function and accounting for the censored data information in vector `cens`.

'Bandwidth' — Bandwidth of the kernel smoothing window

optimal value for normal densities (default) | scalar value | two-element vector

The bandwidth of the kernel-smoothing window, which is a function of the number of points in `x`, specified as the comma-separated pair consisting of 'Bandwidth' and a scalar value. If the sample data is bivariate, `Bandwidth` can also be a two-element vector. The default is optimal for estimating normal densities, but you might want to choose a larger or smaller value to smooth more or less.

Example: 'Bandwidth',0.8

Data Types: single | double

'Censoring' — Logical vector

vector of 0s (default) | vector of 0s and 1s

Logical vector indicating which entries are censored, specified as the comma-separated pair consisting of 'Censoring' and a vector of binary values. A value of 0 indicates there is no censoring, 1 indicates that observation is censored. Default is there is no censoring. This name-value pair is only valid for univariate data.

Example: 'Censoring',censdata

Data Types: logical

'Function' — Function to estimate

'pdf' (default) | 'cdf' | 'icdf' | 'survivor' | 'cumhazard'

Function to estimate, specified as the comma-separated pair consisting of 'Function' and one of the following.

'pdf'	Probability density function.
'cdf'	Cumulative distribution function.
'icdf'	Inverse cumulative distribution function. For 'icdf', <code>f = ksdensity(x,pi,'function','icdf')</code> computes the estimated inverse cdf of the values in <code>x</code> , and evaluates it at the probability values specified in <code>pi</code> .

'survivor'	Survivor function.
'cumhazard'	Cumulative hazard function.

Example: 'Function','icdf'

Data Types: char

'Kernel' — Type of kernel smoother

'normal' (default) | 'box' | 'triangle' | 'epanechnikov' | function handle | string

Type of kernel smoother, specified as the comma-separated pair consisting of 'Kernel' and one of the following.

- 'normal' (default)
- 'box'
- 'triangle'
- 'epanechnikov'
- You can also specify a custom kernel function, as a function handle or as a string, e.g., `@normpdf` or `'normpdf'`. This calls the function with one argument that is an array of distances between data values and locations where the density is evaluated. The function must return an array of the same size containing corresponding values of the kernel function.

When 'Function' is 'pdf', this kernel function returns density values. Otherwise, it returns cumulative probability values.

Specifying a custom kernel when 'Function' is 'icdf' returns an error.

For bivariate data, `ksdensity` applies the same kernel to each dimension.

Example: 'Kernel','box'

Data Types: char | function_handle

'NumPoints' — Number of equally spaced points

100 (default) | scalar value

Number of equally spaced points in `xi`, specified as the comma-separated pair consisting of 'NumPoints' and a scalar value. This name-value pair is only valid for univariate data.

For example, for a kernel smooth estimate of a specified function at 80 equally spaced points within the range of sample data, input:

Example: 'NumPoints',80

Data Types: single | double

'Support' — Support for the density

'unbounded' (default) | 'positive' | two-element vector, [L U] | two-by-two matrix, [L1 L2 ; U1 U2]

Support for the density, specified as the comma-separated pair consisting of 'support' and one of the following.

'unbounded'	Default. Allow the density to extend over the whole real line.
'positive'	Restrict the density to positive values.
Two-element vector, [L U]	Give the finite lower and upper bounds for the support of the density. This option is only valid for univariate sample data.
Two-by-two matrix, [L1 L2 ; U1 U2]	Give the finite lower and upper bounds for the support of the density. The first row contains the lower limits and the second row contains the upper limits. This option is only valid for bivariate sample data.

For univariate data, if 'Support' is 'positive', then `ksdensity` transforms x using a log function, estimates the density of the transformed values, and transforms back to the original scale. If 'Support' is a vector [L U], then `ksdensity` uses the transformation $\log((X-L)/(U-X))$. The `Bandwidth` parameter and `bw` outputs are on the scale of the transformed values.

For bivariate data, 'Support' can be a combination of positive, unbounded, or bounded variables specified as [0 -Inf ; Inf Inf] or [0 L ; Inf U]. `ksdensity` transforms each dimension of x in the same way as the univariate data. The 'Bandwidth' parameter and `bw` outputs are on the scale of the transformed values.

Example: 'Support', 'positive'

Example: 'Support', [0 10]

Data Types: single | double | char

'PlotFcn' — Function used to create kernel density plot

'surf' (default) | 'contour' | 'plot3' | 'surfc'

Function used to create kernel density plot, specified as the comma-separated pair consisting of 'PlotFcn' and one of the following.

Name	Value
'surf'	3-D shaded surface plot, created using <code>surf</code>
'contour'	Contour plot, created using <code>contour</code>
'plot3'	3-D line plot, created using <code>plot3</code>
'surfc'	Contour plot under a 3-D shaded surface plot, created using <code>surfc</code>

This name-value pair is only valid for bivariate sample data.

Example: 'PlotFcn', 'contour'

'Weights' — Weights for each x value

vector

Weights for each x value, specified as the comma-separated pair consisting of 'Weights' and a vector of the same length as x .

For instance, if the weights for the data values are in vector xw , then you can specify the weights as follows.

Example: 'Weights', xw

Data Types: `single` | `double`

Output Arguments

f — Estimated function values

vector

Estimated function values, returned as a vector of the same dimension as x_i or pts .

xi — Evaluation points

100 equally spaced points | 900 equally spaced points | vector

Evaluation points at which `ksdensity` calculates f , returned as a vector. For univariate data, the default is 100 equally-spaced points that cover the range of data in x . For

bivariate data, the default is 900 equally-spaced points created using `meshgrid` from 30 equally-spaced points in each dimension.

bw — Bandwidth of smoothing window

scalar value

Bandwidth of smoothing window, returned as a scalar value.

kstest

One-sample Kolmogorov-Smirnov test

Syntax

```
h = kstest(x)
h = kstest(x,Name,Value)
[h,p] = kstest( ___ )
[h,p,ksstat,cv] = kstest( ___ )
```

Description

`h = kstest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a standard normal distribution, against the alternative that it does not come from such a distribution, using the one-sample Kolmogorov-Smirnov test. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

`h = kstest(x,Name,Value)` returns a test decision for the one-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can test for a distribution other than standard normal, change the significance level, or conduct a one-sided test.

`[h,p] = kstest(___)` also returns the p -value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,ksstat,cv] = kstest(___)` also returns the value of the test statistic `ksstat` and the approximate critical value `cv` of the test.

Examples

Test for a Standard Normal Distribution

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
test1 = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with a mean of 75 and a standard deviation of 10. Use these parameters to center and scale each element of the data vector since, by default, `kstest` tests for a standard normal distribution.

```
x = (test1-75)/10;  
h = kstest(x)
```

```
h =  
0
```

The returned value of `h = 0` indicates that `kstest` fails to reject the null hypothesis at the default 5% significance level.

Plot the empirical cumulative distribution function (cdf) and the standard normal cdf for a visual comparison.

```
[f,x_values] = ecdf(x);  
F = plot(x_values,f);  
set(F,'LineWidth',2);  
hold on;  
G = plot(x_values,normcdf(x_values,0,1),'r-');  
set(G,'LineWidth',2);  
legend([F G],...  
       'Empirical CDF', 'Standard Normal CDF',...  
       'Location', 'SE');
```

The plot shows the similarity between the empirical cdf of the centered and scaled data vector and the cdf of the standard normal distribution.

Specify the Hypothesized Distribution Using a Two-Column Matrix

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Specify the hypothesized distribution as a two-column matrix. Column 1 contains the data vector x . Column 2 contains cdf values evaluated at each value in x for a

hypothesized Student's t distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = [x,cdf('tlocation',x,75,10,1)];
```

Test if the data are from the hypothesized distribution.

```
h = kstest(x, 'CDF',test_cdf)
```

```
h =  
1
```

The returned value of $h = 1$ indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

Specify the Hypothesized Distribution Using a Probability Distribution Object

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's t distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = makedist('tlocation','mu',75,'sigma',10,'nu',1);
```

Test the null hypothesis that the data comes from the hypothesized distribution.

```
h = kstest(x, 'CDF',test_cdf)
```

```
h =  
1
```

The returned value of $h = 1$ indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at Different Significance Levels

Load the sample data. Create a vector containing the first column of the students' exam grades.

```
load examgrades;
test1 = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's t distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = makedist('tlocation', 'mu', 75, 'sigma', 10, 'nu', 1);
```

Test the null hypothesis that data comes from the hypothesized distribution at the 1% significance level.

```
[h,p] = kstest(x, 'CDF', test_cdf, 'Alpha', 0.01)
```

```
h =
     1
p =
 0.0021
```

The returned value of $h = 1$ indicates that `kstest` rejects the null hypothesis at the 1% significance level.

Conduct a One-Sided Hypothesis Test

Load the sample data. Create a vector containing the third column of the stock return data matrix.

```
load stockreturns;
x = stocks(:,3);
```

Test the null hypothesis that the data comes from a standard normal distribution, against the alternative hypothesis that the population cdf of the data is larger than the standard normal cdf.

```
[h,p,k,c] = kstest(x, 'Tail', 'larger')
```

```
h =
     1
p =
 5.0854e-05
k =
 0.2197
c =
```

0.1207

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis in favor of the alternative hypothesis at the default 5% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

```
[f,x_values] = ecdf(x);  
J = plot(x_values,f);  
hold on;  
K = plot(x_values,normcdf(x_values),'r--');  
set(J,'LineWidth',2);  
set(K,'LineWidth',2);  
legend([J K], 'Empirical CDF', 'Standard Normal CDF', 'Location', 'SE');
```

The plot shows the difference between the empirical cdf of the data vector x and the cdf of the standard normal distribution.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'Tail', 'larger', 'Alpha', 0.01` specifies a test using the alternative hypothesis that the cdf of the population from which the sample data is drawn is greater than the cdf of the hypothesized distribution, conducted at the 1% significance level.

'Alpha' — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

'CDF' — cdf of hypothesized continuous distribution

matrix | probability distribution object

cdf of hypothesized continuous distribution, specified the comma-separated pair consisting of `'CDF'` and either a two-column matrix or a continuous probability distribution object. When `CDF` is a matrix, column 1 contains a set of possible x values, and column 2 contains the corresponding hypothesized cumulative distribution function values $G(x)$. The calculation is most efficient if `CDF` is specified such that column 1

contains the values in the data vector x . If there are values in x not found in column 1 of CDF, `kstest` approximates $G(x)$ by interpolation. All values in x must lie in the interval between the smallest and largest values in the first column of CDF. By default, `kstest` tests for a standard normal distribution.

The one-sample Kolmogorov-Smirnov test is only valid for continuous cumulative distribution functions, and requires CDF to be predetermined. The result is not accurate if CDF is estimated from the data. To test x against the normal, lognormal, extreme value, Weibull, or exponential distribution without specifying distribution parameters, use `lillietest` instead.

Data Types: `single` | `double`

'Tail' — Type of alternative hypothesis

'unequal' (default) | 'larger' | 'smaller'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'unequal'	Test the alternative hypothesis that the cdf of the population from which x is drawn is not equal to the cdf of the hypothesized distribution.
'larger'	Test the alternative hypothesis that the cdf of the population from which x is drawn is greater than the cdf of the hypothesized distribution.
'smaller'	Test the alternative hypothesis that the cdf of the population from which x is drawn is less than the cdf of the hypothesized distribution.

If the values in the data vector x tend to be larger than expected from the hypothesized distribution, the empirical distribution function of x tends to be smaller, and vice versa.

Example: 'Tail', 'larger'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p – p-value

scalar value in the range [0,1]

p -value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

ksstat – Test statistic

nonnegative scalar value

Test statistic of the hypothesis test, returned as a nonnegative scalar value.

cv – Critical value

nonnegative scalar value

Critical value, returned as a nonnegative scalar value.

More About

One-Sample Kolmogorov-Smirnov Test

The one-sample Kolmogorov-Smirnov test is a nonparametric test of the null hypothesis that the population cdf of the data is equal to the hypothesized cdf.

The two-sided test for “unequal” cdf functions tests the null hypothesis against the alternative that the population cdf of the data is not equal to the hypothesized cdf. The test statistic is the maximum absolute difference between the empirical cdf calculated from x and the hypothesized cdf:

$$D^* = \max_x \left(\left| \hat{F}(x) - G(x) \right| \right),$$

where $\hat{F}(x)$ is the empirical cdf and $G(x)$ is the cdf of the hypothesized distribution.

The one-sided test for a “larger” cdf function tests the null hypothesis against the alternative that the population cdf of the data is greater than the hypothesized cdf. The test statistic is the maximum amount by which the empirical cdf calculated from x exceeds the hypothesized cdf:

$$D^* = \max_x \left(\hat{F}(x) - G(x) \right).$$

The one-sided test for a “smaller” cdf function tests the null hypothesis against the alternative that the population cdf of the data is less than the hypothesized cdf. The test statistic is the maximum amount by which the hypothesized cdf exceeds the empirical cdf calculated from x :

$$D^* = \max_x \left(G(x) - \hat{F}(x) \right).$$

`kstest` computes the critical value `cv` using an approximate formula or by interpolation in a table. The formula and table cover the range $0.01 \leq \alpha \leq 0.2$ for two-sided tests and $0.005 \leq \alpha \leq 0.1$ for one-sided tests. `cv` is returned as `NaN` if `alpha` is outside this range.

Algorithms

`kstest` decides to reject the null hypothesis by comparing the p -value `p` with the significance level `Alpha`, not by comparing the test statistic `ksstat` with the critical value `cv`. Since `cv` is approximate, comparing `ksstat` with `cv` occasionally leads to a different conclusion than comparing `p` with `Alpha`.

adtest | kstest2 | lillietest

Introduced before R2006a

kstest2

Two-sample Kolmogorov-Smirnov test

Syntax

```
h = kstest2(x1,x2)
h = kstest2(x1,x2,Name,Value)
[h,p] = kstest2(____)
[h,p,ks2stat] = kstest2(____)
```

Description

`h = kstest2(x1,x2)` returns a test decision for the null hypothesis that the data in vectors `x1` and `x2` are from the same continuous distribution, using the two-sample Kolmogorov-Smirnov test. The alternative hypothesis is that `x1` and `x2` are from different continuous distributions. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = kstest2(x1,x2,Name,Value)` returns a test decision for a two-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = kstest2(____)` also returns the asymptotic p -value `p`, using any of the input arguments from the previous syntaxes.

`[h,p,ks2stat] = kstest2(____)` also returns the test statistic `ks2stat`.

Examples

Test Two Samples for the Same Distribution

Generate sample data from two different Weibull distributions.

```
rng(1); % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors `x1` and `x2` comes from populations with the same distribution.

```
h = kstest2(x1,x2)
```

```
h =  
1
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at Different Significance Levels

Generate sample data from two different Weibull distributions.

```
rng(1); % For reproducibility  
x1 = wblrnd(1,1,1,50);  
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data vectors `x1` and `x2` are from populations with the same distribution at the 1% significance level.

```
[h,p] = kstest2(x1,x2,'Alpha',0.01)
```

```
h =  
0  
p =  
0.0317
```

The returned value of `h = 0` indicates that `kstest` does not reject the null hypothesis at the 1% significance level.

One-Sided Hypothesis Test

Generate sample data from two different Weibull distributions.

```
rng(1); % For reproducibility  
x1 = wblrnd(1,1,1,50);  
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors `x1` and `x2` comes from populations with the same distribution, against the alternative hypothesis that the cdf of the distribution of `x1` is larger than the cdf of the distribution of `x2`.

```
[h,p,k] = kstest2(x1,x2,'Tail','larger')
```

```
h =  
  1  
p =  
  0.0158  
k =  
  0.2800
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis, in favor of the alternative hypothesis that the cdf of the distribution of `x1` is larger than the cdf of the distribution of `x2`, at the default 5% significance level. The returned value of `k` is the test statistic for the two-sample Kolmogorov-Smirnov test.

Input Arguments

x1 — Sample data

vector

Sample data from the first sample, specified as a vector. Data vectors `x1` and `x2` do not need to be the same size.

Data Types: `single` | `double`

x2 — Sample data

vector

Sample data from the second sample, specified as a vector. Data vectors `x1` and `x2` do not need to be the same size.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

'Alpha' — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

Example: 'Alpha',0.01

Data Types: single | double

'Tail' — Type of alternative hypothesis

'unequal' (default) | 'larger' | 'smaller'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

- 'unequal' Test the alternative hypothesis that the empirical cdf of x1 is unequal to the empirical cdf of x2.
- 'larger' Test the alternative hypothesis that the empirical cdf of x1 is larger than the empirical cdf of x2.
- 'smaller' Test the alternative hypothesis that the empirical cdf of x1 is smaller than the empirical cdf of x2.

If the data values in x1 tend to be larger than those in x2, the empirical distribution function of x1 tends to be smaller than that of x2, and vice versa.

Example: 'Tail', 'larger'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — Asymptotic p-value

scalar value in the range (0,1)

Asymptotic p -value of the test, returned as a scalar value in the range (0,1). p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. The asymptotic p -value becomes very accurate for large sample sizes, and is believed to be reasonably accurate for sample sizes $n1$ and $n2$, such that $(n1*n2)/(n1 + n2) \geq 4$.

ks2stat — Test statistic

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

More About

Two-Sample Kolmogorov-Smirnov Test

The two-sample Kolmogorov-Smirnov test is a nonparametric hypothesis test that evaluates the difference between the cdfs of the distributions of the two sample data vectors over the range of x in each data set.

The two-sided test uses the maximum absolute difference between the cdfs of the distributions of the two data vectors. The test statistic is

$$D^* = \max_x (|F_1(x) - F_2(x)|),$$

where $\hat{F}_1(x)$ is the proportion of $x1$ values less than or equal to x and $\hat{F}_2(x)$ is the proportion of $x2$ values less than or equal to x .

The one-sided test uses the actual value of the difference between the cdfs of the distributions of the two data vectors rather than the absolute value. The test statistic is

$$D^* = \max_x (F_1(x) - F_2(x)).$$

Algorithms

In `kstest2`, the decision to reject the null hypothesis is based on comparing the p -value p with the significance level `Alpha`, not by comparing the test statistic `ks2stat` with a critical value.

adtest | kstest | lillietest

Introduced before R2006a

kurtosis

Kurtosis

Syntax

```
k = kurtosis(X)
k = kurtosis(X,flag)
k = kurtosis(X,flag,dim)
```

Description

`k = kurtosis(X)` returns the sample kurtosis of `X`. For vectors, `kurtosis(x)` is the kurtosis of the elements in the vector `x`. For matrices `kurtosis(X)` returns the sample kurtosis for each column of `X`. For `N`-dimensional arrays, `kurtosis` operates along the first nonsingleton dimension of `X`.

`k = kurtosis(X,flag)` specifies whether to correct for bias (`flag` is 0) or not (`flag` is 1, the default). When `X` represents a sample from a population, the kurtosis of `X` is biased, that is, it will tend to differ from the population kurtosis by a systematic amount that depends on the size of the sample. You can set `flag` to 0 to correct for this systematic bias.

`k = kurtosis(X,flag,dim)` takes the kurtosis along dimension `dim` of `X`.

`kurtosis` treats NaNs as missing values and removes them.

Examples

```
X = randn([5 4])
X =
    1.1650    1.6961   -1.4462   -0.3600
    0.6268    0.0591   -0.7012   -0.1356
    0.0751    1.7971    1.2460   -1.3493
    0.3516    0.2641   -0.6390   -1.2704
   -0.6965    0.8717    0.5774    0.9846
```

```
k = kurtosis(X)
k =
    2.1658    1.2967    1.6378    1.9589
```

More About

Algorithms

Kurtosis is a measure of how outlier-prone a distribution is. The kurtosis of the normal distribution is 3. Distributions that are more outlier-prone than the normal distribution have kurtosis greater than 3; distributions that are less outlier-prone have kurtosis less than 3.

The kurtosis of a distribution is defined as

$$k = \frac{E(x - \mu)^4}{\sigma^4}$$

where μ is the mean of x , σ is the standard deviation of x , and $E(t)$ represents the expected value of the quantity t . `kurtosis` computes a sample version of this population value.

Note Some definitions of kurtosis subtract 3 from the computed value, so that the normal distribution has kurtosis of 0. The `kurtosis` function does not use this convention.

When you set `flag` to 1, the following equation applies:

$$k_1 = \frac{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^4}{\left(\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2 \right)^2}$$

When you set `flag` to 0, the following equation applies:

$$k_0 = \frac{n-1}{(n-2)(n-3)}((n+1)k_1 - 3(n-1)) + 3$$

This bias-corrected formula requires that X contain at least four elements.

Introduced before R2006a

lasso

Regularized least-squares regression using lasso or elastic net algorithms

Syntax

```
B = lasso(X,Y)
[B,FitInfo] = lasso(X,Y)
[B,FitInfo] = lasso(X,Y,Name,Value)
```

Description

`B = lasso(X,Y)` returns fitted least-squares regression coefficients for a set of regularization coefficients `Lambda`.

`[B,FitInfo] = lasso(X,Y)` returns a structure containing information about the fits.

`[B,FitInfo] = lasso(X,Y,Name,Value)` fits regularized regressions with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

X

Numeric matrix with `n` rows and `p` columns. Each row represents one observation, and each column represents one predictor (variable).

Y

Numeric vector of length `n`, where `n` is the number of rows of `X`. `Y(i)` is the response to row `i` of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

'Alpha'

Scalar value from 0 to 1 (excluding 0) representing the weight of lasso (L^1) versus ridge (L^2) optimization. Alpha = 1 represents lasso regression, Alpha close to 0 approaches ridge regression, and other values represent elastic net optimization. See “Definitions” on page 25-3021.

Default: 1

'CV'

Method `lasso` uses to estimate mean squared error:

- K, a positive integer — `lasso` uses K-fold cross validation.
- `cvp`, a `cvpartition` object — `lasso` uses the cross-validation method expressed in `cvp`. You cannot use a 'leaveout' partition with `lasso`.
- 'resubstitution' — `lasso` uses X and Y to fit the model and to estimate the mean squared error, without cross validation.

Default: 'resubstitution'

'DFmax'

Maximum number of nonzero coefficients in the model. `lasso` returns results only for Lambda values that satisfy this criterion.

Default: Inf

'Lambda'

Vector of nonnegative Lambda values. See “Definitions” on page 25-3021.

- If you do not supply Lambda, `lasso` calculates the largest value of Lambda that gives a nonnull model. In this case, `LambdaRatio` gives the ratio of the smallest to the largest value of the sequence, and `NumLambda` gives the length of the vector.
- If you supply Lambda, `lasso` ignores `LambdaRatio` and `NumLambda`.

Default: Geometric sequence of `NumLambda` values, the largest just sufficient to produce $B = 0$

'`LambdaRatio`'

Positive scalar, the ratio of the smallest to the largest `Lambda` value when you do not set `Lambda`.

If you set `LambdaRatio = 0`, `lasso` generates a default sequence of `Lambda` values, and replaces the smallest one with 0.

Default: `1e-4`

'`MCREps`'

Positive integer, the number of Monte Carlo repetitions for cross validation.

- If CV is '`resubstitution`' or a `cvpartition` of type '`resubstitution`', `MCREps` must be 1.
- If CV is a `cvpartition` of type '`holdout`', `MCREps` must be greater than 1.

Default: 1

'`NumLambda`'

Positive integer, the number of `Lambda` values `lasso` uses when you do not set `Lambda`. `lasso` can return fewer than `NumLambda` fits if the residual error of the fits drops below a threshold fraction of the variance of `Y`.

Default: 100

'`Options`'

Structure that specifies whether to cross validate in parallel, and specifies the random stream or streams. Create the `Options` structure with `statset`. Option fields:

- `UseParallel` — Set to `true` to compute in parallel. Default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. To compute reproducibly, set `Streams` to a type allowing substreams: '`mlfg6331_64`' or '`mrg32k3a`'. Default is `false`.

- **Streams** — A `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, `lasso` uses the default stream.

'PredictorNames'

Cell array of strings representing names of the predictor variables, in the order in which they appear in `X`.

Default: {}

'RelTol'

Convergence threshold for the coordinate descent algorithm (see Friedman, Tibshirani, and Hastie [3]). The algorithm terminates when successive estimates of the coefficient vector differ in the L^2 norm by a relative amount less than `RelTol`.

Default: 1e-4

'Standardize'

Boolean value specifying whether `lasso` scales `X` before fitting the models. This affects whether the regularization is applied to the coefficients on the standardized scale or original scale. The results are always presented on the original data scale.

`X` and `Y` are always centered.

Default: true

'Weights'

Observation weights, a nonnegative vector of length `n`, where `n` is the number of rows of `X`. `lasso` scales `Weights` to sum to 1.

Default: `1/n * ones(n,1)`

Output Arguments

B

Fitted coefficients, a `p`-by-`L` matrix, where `p` is the number of predictors (columns) in `X`, and `L` is the number of `Lambda` values.

FitInfo

Structure containing information about the model fits.

Field in FitInfo	Description
Intercept	Intercept term β_0 for each linear model, a 1-by-L vector
Lambda	Lambda parameters in ascending order, a 1-by-L vector
Alpha	Value of Alpha parameter, a scalar
DF	Number of nonzero coefficients in B for each value of Lambda, a 1-by-L vector
MSE	Mean squared error (MSE), a 1-by-L vector

If you set the CV name-value pair to cross validate, the `FitInfo` structure contains additional fields.

Field in FitInfo	Description
SE	The standard error of MSE for each Lambda, as calculated during cross validation, a 1-by-L vector
LambdaMinMSE	The Lambda value with minimum MSE, a scalar
Lambda1SE	The largest Lambda such that MSE is within one standard error of the minimum, a scalar
IndexMinMSE	The index of Lambda with value LambdaMinMSE, a scalar
Index1SE	The index of Lambda with value Lambda1SE, a scalar

Examples

Remove Redundant Predictors

Construct a data set with redundant predictors, and identify those predictors using cross-validated `lasso`.

Create a matrix X of 100 five-dimensional normal variables and a response vector Y from just two components of X, with small added noise.

```
X = randn(100,5);  
r = [0;2;0;-3;0]; % only two nonzero coefficients  
Y = X*r + randn(100,1)*.1; % small added noise
```

Construct the default lasso fit.

```
B = lasso(X,Y);
```

Find the coefficient vector for the 25th value in B.

```
B(:,25)
```

```
ans =
```

```
    0  
  1.6093  
    0  
 -2.5865  
    0
```

lasso identifies and removes the redundant predictors.

Plot a Regularized Fit with Cross Validation

Visually examine the cross-validated error of various levels of regularization.

Load the `acetylene` data and prepare the data with interactions for fitting.

```
load acetylene  
Xs = [x1 x2 x3];  
X = x2fx(Xs, 'interaction');  
X(:,1) = []; % No constant term
```

Construct the lasso fit using ten-fold cross validation. Include the `FitInfo` output so you can plot the result.

```
[B FitInfo] = lasso(X,y, 'CV', 10);
```

Plot the cross-validated fits.

```
lassoPlot(B,FitInfo, 'PlotType', 'CV');
```

More About

Lasso

For a given value of λ , a nonnegative parameter, **lasso** solves the problem

$$\min_{\beta_0, \beta} \left(\frac{1}{2N} \sum_{i=1}^N (y_i - \beta_0 - x_i^T \beta)^2 + \lambda \sum_{j=1}^p |\beta_j| \right),$$

where

- N is the number of observations.
- y_i is the response at observation i .
- x_i is data, a vector of p values at observation i .

- λ is a nonnegative regularization parameter corresponding to one value of Λ .
- The parameters β_0 and β are scalar and p -vector respectively.

As λ increases, the number of nonzero components of β decreases.

The lasso problem involves the L^1 norm of β , as contrasted with the elastic net algorithm.

Elastic Net

For an α strictly between 0 and 1, and a nonnegative λ , elastic net solves the problem

$$\min_{\beta_0, \beta} \left(\frac{1}{2N} \sum_{i=1}^N (y_i - \beta_0 - x_i^T \beta)^2 + \lambda P_\alpha(\beta) \right),$$

where

$$P_\alpha(\beta) = \frac{(1-\alpha)}{2} \|\beta\|_2^2 + \alpha \|\beta\|_1 = \sum_{j=1}^p \left(\frac{(1-\alpha)}{2} \beta_j^2 + \alpha |\beta_j| \right).$$

Elastic net is the same as lasso when $\alpha = 1$. As α shrinks toward 0, elastic net approaches ridge regression. For other values of α , the penalty term $P_\alpha(\beta)$ interpolates between the L^1 norm of β and the squared L^2 norm of β .

Introduced in R2011b

lassoglm

Lasso or elastic net regularization for generalized linear model regression

Syntax

```
B = lassoglm(X,Y)
[B,FitInfo] = lassoglm(X,Y)
[B,FitInfo] = lassoglm(X,Y,distr)
[B,FitInfo] = lassoglm(X,Y,distr,Name,Value)
```

Description

`B = lassoglm(X,Y)` returns penalized maximum-likelihood fitted coefficients for a generalized linear model of the response `Y` to the data matrix `X`. `Y` are assumed to have a Gaussian probability distribution.

`[B,FitInfo] = lassoglm(X,Y)` returns a structure containing information about the fits.

`[B,FitInfo] = lassoglm(X,Y,distr)` fits the model using the probability distribution type for `Y` as specified in `distr`.

`[B,FitInfo] = lassoglm(X,Y,distr,Name,Value)` fits regularized generalized linear regressions with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

X

Numeric matrix with `n` rows and `p` columns. Each row represents one observation, and each column represents one predictor (variable).

Y

When `distr` is not `'binomial'`, `Y` is a numeric vector or categorical array of length `n`, where `n` is the number of rows of `X`. `Y(i)` is the response to row `i` of `X`.

When `distr` is `'binomial'`, `Y` is either a:

- Numeric vector of length `n`, where each entry represents success (1) or failure (0)
- Logical vector of length `n`, where each entry represents success or failure
- Categorical array of length `n`, where each entry represents success or failure
- Two column numeric matrix, where the first column contains the number of successes for each observation, and the second column contains the total number of trials

distr

Distributional family for the nonsystematic variation in the responses, a string. Choices:

- `'normal'`
- `'binomial'`
- `'poisson'`
- `'gamma'`
- `'inverse gaussian'`

By default, `lassoglm` uses the canonical link function corresponding to `distr`. Specify another link function using the `'link'` name-value pair.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'Alpha'

Scalar value from 0 to 1 (excluding 0) representing the weight of lasso (L^1) versus ridge (L^2) optimization. `Alpha = 1` represents lasso regression, and other values represent elastic net optimization. `Alpha` close to 0 approaches ridge regression. See “Definitions” on page 25-3021.

Default: 1

'CV'

Method `lassoglm` uses to estimate deviance:

- `K`, a positive integer — `lassoglm` uses `K`-fold cross validation.
- `cvp`, a `cvpartition` object — `lassoglm` uses the cross-validation method expressed in `cvp`. You cannot use a 'leaveout' partition with `lassoglm`.
- 'resubstitution' — `lassoglm` uses `X` and `Y` to fit the model and to estimate the deviance, without cross validation.

Default: 'resubstitution'

'DFmax'

Maximum number of nonzero coefficients in the model. `lassoglm` returns results for `Lambda` values that satisfy this criterion.

Default: Inf

'Lambda'

Vector of nonnegative `Lambda` values. See “Lasso” on page 25-3033.

- If you do not supply `Lambda`, `lassoglm` estimates the largest value of `Lambda` that gives a nonnull model. In this case, `LambdaRatio` gives the ratio of the smallest to the largest value of the sequence, and `NumLambda` gives the length of the vector.
- If you supply `Lambda`, `lassoglm` ignores `LambdaRatio` and `NumLambda`.

Default: Geometric sequence of `NumLambda` values, the largest just sufficient to produce `B = 0`

'LambdaRatio'

Positive scalar, the ratio of the smallest to the largest `Lambda` value when you do not explicitly set `Lambda`.

If you set `LambdaRatio = 0`, `lassoglm` generates a default sequence of `Lambda` values, and replaces the smallest one with 0.

Default: 1e-4

'Link'

Specify the mapping between the mean μ of the response and the linear predictor Xb .

Value	Description
'comploglog'	$\log(-\log((1-\mu))) = Xb$
'identity', default for the distribution 'normal'	$\mu = Xb$
'log', default for the distribution 'poisson'	$\log(\mu) = Xb$
'logit', default for the distribution 'binomial'	$\log(\mu/(1-\mu)) = Xb$
'loglog'	$\log(-\log(\mu)) = Xb$
'probit'	$\Phi^{-1}(\mu) = Xb$, where Φ is the normal (Gaussian) CDF function
'reciprocal', default for the distribution 'gamma'	$\mu^{-1} = Xb$
p (a number), default for the distribution 'inverse gaussian' (with $p = -2$)	$\mu^p = Xb$
Cell array of the form {FL FD FI}, containing three function handles, created using @, that define the link (FL), the derivative of the link (FD), and the inverse link (FI). Equivalently, can be a structure of function handles with field Link containing FL, field Derivative containing FD, and field Inverse containing FI.	User-specified link function (see “Custom Link Function” on page 11-16)

'MCReps'

Positive integer, the number of Monte Carlo repetitions for cross validation.

- If CV is 'resubstitution' or a cvpartition of type 'resubstitution', MCReps must be 1.
- If CV is a cvpartition of type 'holdout', MCReps must be greater than 1.

Default: 1

'NumLambda'

Positive integer, the number of `Lambda` values `lassoglm` uses when you do not set `Lambda`. `lassoglm` can return fewer than `NumLambda` fits if the deviance of the fits drops below a threshold fraction of the null deviance (deviance of the fit without any predictors `X`).

Default: 100

'Offset'

Numeric vector with the same number of rows as `X`. `lassoglm` uses `Offset` as an additional predictor variable, but keeps its coefficient value fixed at 1.0.

'Options'

Structure that specifies whether to cross validate in parallel, and specifies the random stream or streams. Create the `Options` structure with `statset`. Option fields:

- `UseParallel` — Set to `true` to compute in parallel. Default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`. Default is `false`.
- `Streams` — `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, `lassoglm` uses the default stream.

'PredictorNames'

Cell array of strings representing names of the predictor variables, in the order in which they appear in `X`.

Default: {}

'RelTol'

Convergence threshold for the coordinate descent algorithm (see Friedman, Tibshirani, and Hastie [3]). The algorithm terminates when successive estimates of the coefficient vector differ in the L^2 norm by a relative amount less than `RelTol`.

Default: 1e-4

'Standardize'

Boolean value specifying whether `lassoglm` scales X before fitting the models. This affects whether the regularization is applied to the coefficients on the standardized scale or original scale. The results are always presented on the original scale.

Default: `true`

'Weights'

Observation weights, a nonnegative vector of length n , where n is the number of rows of X . At least two values must be positive.

Default: `1/n * ones(n,1)`

Output Arguments

B

Fitted coefficients, a p -by- L matrix, where p is the number of predictors (columns) in X , and L is the number of `Lambda` values.

FitInfo

Structure containing information about the model fits.

Field in FitInfo	Description
Alpha	Value of <code>Alpha</code> parameter, a scalar.
Deviance	Deviance of the fitted model for each value of <code>Lambda</code> , a 1-by- L vector. If cross validation was performed, the values for <code>Deviance</code> represent the estimated expected deviance of the model applied to new data, as calculated by cross validation. Otherwise, <code>Deviance</code> is the deviance of the fitted model applied to the data used to perform the fit.
DF	Number of nonzero coefficients in <code>B</code> for each <code>Lambda</code> value, a 1-by- L vector.
Intercept	Intercept term β_0 for each linear model, a 1-by- L vector.

Field in FitInfo	Description
Lambda	Lambda parameters in ascending order, a 1-by-L vector.

If you set the CV name-value pair to cross validate, the `FitInfo` structure contains additional fields.

Field in FitInfo	Description
IndexMinDeviance	Index of Lambda with value <code>LambdaMinDeviance</code> , a scalar.
Index1SE	Index of Lambda with value <code>Lambda1SE</code> , a scalar.
LambdaMinDeviance	Lambda value with minimum expected deviance, as calculated by cross validation, a scalar.
Lambda1SE	Largest Lambda such that Deviance is within one standard error of the minimum, a scalar.
SE	Standard error of Deviance for each Lambda, as calculated during cross validation, a 1-by-L vector.

Examples

Lasso Regularization of a Generalized Linear Model

Construct data from a Poisson model, and identify the important predictors using `lassoglm`.

Create data with 20 predictors, and Poisson responses using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Construct a cross-validated lasso regularization of a Poisson regression model of the data.

```
[B FitInfo] = lassoglm(X,y, 'poisson', 'CV', 10);
```

Examine the cross-validation plot to see the effect of the `Lambda` regularization parameter.

```
lassoPlot(B,FitInfo,'plottype','CV');
```

The green circle and dashed line locate the Lambda with minimal cross-validation error. The blue circle and dashed line locate the point with minimal cross-validation error plus one standard deviation.

Find the nonzero model coefficients corresponding to the two identified points.

```
minpts = find(B(:,FitInfo.IndexMinDeviance))
```

```
minpts =
```

```
3
5
```

```
        6
       10
       11
       15
       16

min1pts = find(B(:,FitInfo.Index1SE))

min1pts =

        5
       10
       15
```

The coefficients from the minimal plus one standard error point are exactly those coefficients used to create the data.

- “Regularize Logistic Regression” on page 11-51
- “Regularize Wide Data in Parallel” on page 11-59

More About

Link Function

A link function $f(\mu)$ maps a distribution with mean μ to a linear model with data X and coefficient vector b using the formula

$$f(\mu) = Xb.$$

Find the formulas for the link functions in the `Link` name-value pair description. Here, “typical” means a link function that is typically used for the listed distribution.

Distributional Family	Link Function (typical, {default})
'normal'	{'identity'}
'binomial'	'comploglog', 'loglog', 'probit', {'logit'}
'poisson'	{'log'}
'gamma'	{'reciprocal'}
'inverse gaussian'	{-2}

Lasso

For a nonnegative value of λ , **lasso** solves the problem

$$\min_{\beta_0, \beta} \left(\frac{1}{N} \text{Deviance}(\beta_0, \beta) + \lambda \sum_{j=1}^p |\beta_j| \right),$$

where

- Deviance is the deviance of the model fit to the responses using intercept β_0 and predictor coefficients β . The formula for Deviance depends on the **distr** parameter you supply to **lassoglm**. Minimizing the λ -penalized deviance is equivalent to maximizing the λ -penalized log likelihood.
- N is the number of observations.
- λ is a nonnegative regularization parameter corresponding to one value of **Lambda**.
- Parameters β_0 and β are scalar and p -vector respectively.

As λ increases, the number of nonzero components of β decreases.

The lasso problem involves the L^1 norm of β , as contrasted with the elastic net algorithm.

Elastic Net

For an α strictly between 0 and 1, and a nonnegative λ , elastic net solves the problem

$$\min_{\beta_0, \beta} \left(\frac{1}{N} \text{Deviance}(\beta_0, \beta) + \lambda P_\alpha(\beta) \right),$$

where

$$P_\alpha(\beta) = \frac{(1-\alpha)}{2} \|\beta\|_2^2 + \alpha \|\beta\|_1 = \sum_{j=1}^p \left(\frac{(1-\alpha)}{2} \beta_j^2 + \alpha |\beta_j| \right).$$

Elastic net is the same as lasso when $\alpha = 1$. For other values of α , the penalty term $P_\alpha(\beta)$ interpolates between the L^1 norm of β and the squared L^2 norm of β . As α shrinks toward 0, elastic net approaches **ridge** regression.

Introduced in R2012a

lassoPlot

Trace plot of lasso fit

Syntax

```
ax = lassoPlot(B)
ax = lassoPlot(B,FitInfo)
ax = lassoPlot(B,FitInfo,Name,Value)
[ax,figh] = lassoPlot(B,...)
```

Description

`ax = lassoPlot(B)` creates a trace plot of the values in **B** against the L^1 norm of **B**. `ax` is a handle to the plot axis.

`ax = lassoPlot(B,FitInfo)` creates a plot with type depending on the data type of `FitInfo` and the value, if any, of the `plotType` name-value pair.

`ax = lassoPlot(B,FitInfo,Name,Value)` creates a plot with additional options specified by one or more `Name,Value` pair arguments.

`[ax,figh] = lassoPlot(B,...)` returns a handle to the figure window.

Input Arguments

B

Coefficients of a sequence of regression fits, as returned from the `lasso` or `lassoglm` functions. **B** is a `p`-by-`NLambda` matrix, where `p` is the number of predictors, and each column of **B** is a set of coefficients `lasso` calculates using one `Lambda` penalty value.

FitInfo

Information controlling the plot:

- `FitInfo` is a structure, especially as returned from `lasso` or `lassoglm` — `lassoPlot` creates a plot based on the `PlotType` name-value pair.

- `FitInfo` is a vector — `lassoPlot` forms the x -axis of the plot from the values in `FitInfo`. The length of `FitInfo` must equal the number of columns of `B`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

'Parent'

Axis in which to draw the plot.

Default: New plot

'PlotType'

Choose the plot type when you give a `FitInfo` vector or structure:

FitInfo Type	PlotType	Plot
Vector or Structure	'L1'	<code>plotLasso</code> creates the x -axis from the L^1 norm of the coefficients in <code>B</code> . The x -axis at the top of the plot contains the degrees of freedom (df), meaning the number of nonzero coefficients of <code>B</code> .
Structure	'Lambda'	<code>plotLasso</code> creates the x -axis from the <code>Lambda</code> field of <code>FitInfo</code> . The x -axis at the top of the plot contains the degrees of freedom (df), meaning the number of nonzero coefficients of <code>B</code> .
Cross-Validated Structure	'CV'	<ul style="list-style-type: none"> • For each <code>Lambda</code>, plots an estimate of the mean squared prediction error on new data for the model fitted by <code>lasso</code> with that value of <code>Lambda</code>. • Plots error bars for the estimates. • Plots the value of <code>Lambda</code> with minimum cross-validated MSE. • Plots the greatest <code>Lambda</code> that is within one standard error of minimum MSE (so makes the sparsest model within that region).

Default: 'L1'

'PredictorNames'

Cell array of strings to label each coefficient of **B**. If the length of **PredictorNames** is less than the number of rows of **B**, the remaining labels are padded with default values.

`lassoPlot` uses the predictor names in `FitInfo` only if:

- You created `FitInfo` with a call to `lasso` that included a `PredictorNames` name-value pair.
- You call `lassoPlot` *without* a `PredictorNames` name-value pair.
- You include `FitInfo` in your `lassoPlot` call.

Default: {'B1', 'B2', ...}

'XScale'

- 'linear' for linear x-axis
- 'log' for logarithmic scaled x-axis

Default: 'linear', except 'log' for the 'CV' plot type

Output Arguments

ax

Handle to the axis of the plot (see “Coordinate System”).

figh

Handle to the figure window (see “Special Object Identifiers”).

Examples

Lasso Plot with Default Plot Type

Load the sample data

```
load acetylene
```

Prepare the design matrix for lasso fit with interactions.

```
X = [x1 x2 x3];
D = x2fx(X, 'interaction');
D(:,1) = []; % No constant term
```

Fit a regularized model of the data using `lasso` .

```
B = lasso(D,y);
```

Plot the fits with the default plot type.

```
lassoPlot(B);
```

Lasso Plot with Lambda Plot Type

Load the sample data.

```
load acetylene
```

Prepare the data for lasso fit with interactions.

```
X = [x1 x2 x3];  
D = x2fx(X, 'interaction');  
D(:,1) = []; % No constant term
```

Fit a regularized model of the data with lasso .

```
[B FitInfo] = lasso(D,y);
```

Plot the fits with the Lambda plot type and logarithmic scaling.

```
lassoPlot(B,FitInfo, 'PlotType', 'Lambda', 'XScale', 'log');
```

Lasso Plot with Cross-Validated Fits

Load the sample data.

```
load acetylene
```

Prepare the design matrix for a lasso fit with interactions.

```
X = [x1 x2 x3];
D = x2fx(X, 'interaction');
D(:,1) = []; % No constant term
```

Fit a regularized model of the data with lasso and cross validation.

```
[B FitInfo] = lasso(D,y,'CV',10);
```

Plot the cross-validated fits.

```
lassoPlot(B,FitInfo,'PlotType','CV');
```

lasso | lassoglm

Introduced in R2011b

le

Class: grandstream

Less than or equal relation for handles

Syntax

`h1 <= h2`

Description

Handles are equal if they are handles for the same object. All comparisons use a number associated with each handle object. Nothing can be assumed about the result of a handle comparison except that the repeated comparison of two handles in the same MATLAB session will yield the same result. The order of handle values is purely arbitrary and has no connection to the state of the handle objects being compared.

`h1 <= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `<=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = le(h1, h2)` stores the result in a logical array of the same dimensions.

See Also

`grandstream` | `ge` | `gt` | `ne` | `eq` | `lt`

Leap property

Class: grandset

Interval between points

Description

Number of points to leap over and omit for each point taken from the sequence. The **Leap** property of a point set contains a positive integer which specifies the number of points in the sequence to leap over and omit for every point taken. The default **Leap** value is 0, which corresponds to taking every point from the sequence.

Leaping is a technique used to improve the quality of a point set. However, you must choose the **Leap** values with care; many **Leap** values create sequences that fail to touch on large sub-hyper-rectangles of the unit hypercube, and so fail to be a uniform quasi-random point set.

Choosing Leap Values for Halton Sets

A known rule for choosing **Leap** values for Halton sets is to set it to $(P-1)$ where P is a prime number that has not been used to generate one of the dimensions, i.e. for a k -dimensional point set P would be the $(k+1)$ th or greater prime.

Examples

Experiment with different leap values:

```
% No leaping produces the standard Halton sequence.
```

```
P = haltonset(5);
```

```
P(1:5,:)
```

```
% Set a leap of 1. The point set now includes every other
```

```
% point from the sequence.
```

```
P.Leap = 1;
```

```
P(1:5,:)
```

net | grandset | subsref | haltonset | Skip

length

Class: dataset

Length of dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
n = length(A)
```

Description

`n = length(A)` returns the number of observations in the dataset A. `length` is equivalent to `size(A,1)`.

See Also

`size`

length

Class: grandset

Length of point set

Syntax

`length(p)`

Description

`length(p)` returns the number of points in the point set `p`. It is equivalent to `size(p, 1)`.

See Also

`grandset` | `size`

levelcounts

Element counts by level of a nominal or ordinal array

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
C = levelcounts(A)
C = levelcounts(A,dim)
```

Description

`C = levelcounts(A)` returns counts of the number of elements in the nominal or ordinal array `A` equal to each of the possible levels in `A` into the vector `C`, which has as many elements as `A` has levels.

- If `A` is a matrix, then `C` is a matrix of column counts.
- If `A` is an N -dimensional array, `levelcounts` operates along the first nonsingleton dimension.

`C = levelcounts(A,dim)` operates along the dimension `dim`.

Examples

Count Observations in Each Level

Create a nominal array from string data in a cell array.

```
colors = nominal({'r','b','g','g','r','b','b','r','g'},...
                 {'blue','green','red'})
```

```
colors =  
  
   red     blue     green  
green     red     blue  
blue      red     green
```

Count the number of observations of each level in each column.

```
levelcounts(colors)
```

```
ans =  
  
   1     1     1  
   1     0     2  
   1     2     0
```

Count the number of observations of each level in each row.

```
levelcounts(colors,2)
```

```
ans =  
  
   1     1     1  
   1     1     1  
   1     1     1
```

Alternatively, you can use `summary` to display the counts with their labels. The default is to count elements in each column.

```
summary(colors)  
  
   blue     1     1     1  
   green    1     0     2  
   red      1     2     0
```

You can also count elements in each row.

```
summary(colors,2)
```

blue	green	red
1	1	1
1	1	1
1	1	1

Input Arguments

A — Nominal or ordinal array

`nominal array` | `ordinal array`

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

dim — Dimension along which to count

positive integer value

Dimension along which to count the number of elements in each level, specified as a positive integer value. For example, if the dimension is `1`, then `levelcounts` counts along each column, while if the dimension is `2`, then `levelcounts` counts along each row.

Data Types: `double` | `single`

Introduced in R2007a

leverage

Leverage

Syntax

```
h = leverage(data)
h = leverage(data,model)
```

Description

`h = leverage(data)` finds the leverage of each row (point) in the matrix `data` for a linear additive regression model.

`h = leverage(data,model)` finds the leverage on a regression, using a specified model type, where `model` can be one of these strings:

- 'linear' - includes constant and linear terms
- 'interaction' - includes constant, linear, and cross product terms
- 'quadratic' - includes interactions and squared terms
- 'purequadratic' - includes constant, linear, and squared terms

Leverage is a measure of the influence of a given observation on a regression due to its location in the space of the inputs.

Examples

One rule of thumb is to compare the leverage to $2p/n$ where n is the number of observations and p is the number of parameters in the model. For the Hald data set this value is 0.7692.

```
load hald
h = max(leverage(ingredients,'linear'))
h =
    0.7004
```

Since $0.7004 < 0.7692$, there are no high leverage points using this rule.

More About

Algorithms

```
[Q,R] = qr(x2fx(data, 'model'));
```

```
leverage = (sum(Q' .* Q'))'
```

lhsdesign

Latin hypercube sample

Syntax

```
X = lhsdesign(n,p)
X = lhsdesign(...,'smooth','off')
X = lhsdesign(...,'criterion',criterion)
X = lhsdesign(...,'iterations',k)
```

Description

`X = lhsdesign(n,p)` returns an n -by- p matrix, X , containing a latin hypercube sample of n values on each of p variables. For each column of X , the n values are randomly distributed with one from each interval $(0, 1/n)$, $(1/n, 2/n)$, ..., $(1-1/n, 1)$, and they are randomly permuted.

`X = lhsdesign(...,'smooth','off')` produces points at the midpoints of the above intervals: $0.5/n$, $1.5/n$, ..., $1-0.5/n$. The default is 'on'.

`X = lhsdesign(...,'criterion',criterion)` iteratively generates latin hypercube samples to find the best one according to the criterion *criterion*, which can be one of the following strings.

Criterion	Description
'none'	No iteration.
'maximin'	Maximize minimum distance between points. This is the default.
'correlation'	Reduce correlation.

`X = lhsdesign(...,'iterations',k)` iterates up to k times in an attempt to improve the design according to the specified criterion. The default is $k = 5$.

haltonset | sobolset | lhsnorm | unifrnd

Introduced before R2006a

lhsnorm

Latin hypercube sample from normal distribution

Syntax

```
X = lhsnorm(mu, sigma, n)
X = lhsnorm(mu, sigma, n, flag)
[X, Z] = lhsnorm(...)
```

Description

`X = lhsnorm(mu, sigma, n)` returns an n -by- p matrix, X , containing a latin hypercube sample of size n from a p -dimensional multivariate normal distribution with mean vector, μ , and covariance matrix, σ .

X is similar to a random sample from the multivariate normal distribution, but the marginal distribution of each column is adjusted so that its sample marginal distribution is close to its theoretical normal distribution.

`X = lhsnorm(mu, sigma, n, flag)` controls the amount of smoothing in the sample. If `flag` is 'off', each column has points equally spaced on the probability scale. In other words, each column is a permutation of the values $G(0.5/n)$, $G(1.5/n)$, ..., $G(1-0.5/n)$, where G is the inverse normal cumulative distribution for that column's marginal distribution. If `flag` is 'on' (the default), each column has points uniformly distributed on the probability scale. For example, in place of $0.5/n$ you use a value having a uniform distribution on the interval $(0/n, 1/n)$.

`[X, Z] = lhsnorm(...)` also returns Z , the original multivariate normal sample before the marginals are adjusted to obtain X .

lhsdesign | mvnrnd

Introduced before R2006a

lillietest

Lilliefors test

Syntax

```
h = lillietest(x)
h = lillietest(x,Name,Value)
[h,p] = lillietest( ___ )
[h,p,kstat,critval] = lillietest( ___ )
```

Description

`h = lillietest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a distribution in the normal family, against the alternative that it does not come from such a distribution, using a Lilliefors test. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = lillietest(x,Name,Value)` returns a test decision with additional options specified by one or more name-value pair arguments. For example, you can test the data against a different distribution family, change the significance level, or calculate the p -value using a Monte Carlo approximation.

`[h,p] = lillietest(___)` also returns the p -value `p`, using any of the input arguments from the previous syntaxes.

`[h,p,kstat,critval] = lillietest(___)` also returns the test statistic `kstat` and the critical value `critval` for the test.

Examples

Test for a Normal Distribution

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.

```
load carbig.mat;
```

```
[h,p,k,c] = lillietest(MPG)
```

```
Warning: P is less than the smallest tabulated value, returning 0.001.
```

```
h =  
  1  
p =  
  1.0000e-003  
k =  
  0.0789  
c =  
  0.0451
```

The test statistic k is greater than the critical value c , so `lillietest` returns a result of $h = 1$ to indicate rejection of the null hypothesis at the default 5% significance level. The warning indicates that the returned p -value is the smallest value in the table of precomputed values. To find a more accurate p -value, use `MCTol` to run a Monte Carlo approximation.

Test the Hypothesis at Different Significance Levels

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Test the null hypothesis that the sample data comes from a normal distribution at the 1% significance level.

```
[h,p] = lillietest(x, 'Alpha', 0.01)  
  
h =  
  0  
p =  
  0.0348
```

The returned value of $h = 0$ indicates that `lillietest` does not reject the null hypothesis at the 1% significance level.

Test for an Exponential Distribution

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows an exponential distribution across different makes of cars.

```
load carbig.mat;
```

```
h = lillietest(MPG, 'Distr', 'exp')
```

```
h =  
    1
```

The returned value of $h = 1$ indicates that `lillietest` rejects the null hypothesis at the default 5% significance level.

Determine the p -value Using Monte Carlo Approximation

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Determine the p -value using a Monte Carlo approximation with a maximum Monte Carlo standard error of $1e-4$.

```
load carbig.mat;  
[h,p] = lillietest(MPG, 'MCTol', 1e-4)
```

```
h =  
    1  
p =  
    0
```

The returned value of $h = 1$ indicates that `lillietest` rejects the null hypothesis that the data comes from a normal distribution at the 5% significance level.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Distr', 'exp', 'Alpha', 0.01` tests the null hypothesis that the population distribution belongs to the exponential distribution family at the 1% significance level.

'Alpha' — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

- If `MCTol` is not used, `Alpha` must be in the range [0.001,0.50].
- If `MCTol` is used, `Alpha` must be in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

'Distr' — Distribution family

`'norm'` (default) | `'exp'` | `'ev'`

Distribution family for the hypothesis test, specified as the comma-separated pair consisting of `'Distr'` and one of the following.

<code>'norm'</code>	Normal distribution
<code>'exp'</code>	Exponential distribution
<code>'ev'</code>	Extreme value distribution

Example: `'Distr', 'exp'`

'MCTol' — Maximum Monte Carlo standard error

scalar value in the range (0,1)

Maximum Monte Carlo standard error for p , the p -value of the test, specified as the comma-separated pair consisting of `'MCTol'` and a scalar value in the range (0,1).

Example: `'MCTol', 0.001`

Data Types: `single` | `double`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — *p*-value

scalar value in the range (0,1)

p-value of the test, returned as a scalar value in the range (0,1). *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

- If `MCTol` is not used, *p* is computed using inverse interpolation into the table of critical values, and is returned as a scalar value in the range [0.001,0.50]. `lillietest` warns when *p* is not found within the tabulated range and returns either the smallest or largest tabulated value.
- If `MCTol` is used, `lillietest` conducts a Monte Carlo simulation to compute a more accurate *p*-value, and *p* is returned as a scalar value in the range (0,1).

kstat — Test statistic

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

critval — Critical value

nonnegative scalar value

Critical value for the hypothesis test, returned as a nonnegative scalar value.

More About

Lilliefors Test

The Lilliefors test is a two-sided goodness-of-fit test suitable when the parameters of the null distribution are unknown and must be estimated. This is in contrast to the one-sample Kolmogorov-Smirnov test, which requires the null distribution to be completely specified.

The Lilliefors test statistic is:

$$D^* = \max_x |F(x) - G(x)|,$$

where $\hat{F}(x)$ is the empirical cdf of the sample data and $G(x)$ is the cdf of the hypothesized distribution with estimated parameters equal to the sample parameters.

`lillietest` can be used to test whether the data vector `x` has a lognormal or Weibull distribution by applying a transformation to the data vector and running the appropriate Lilliefors test:

- To test `x` for a lognormal distribution, test if `log(x)` has a normal distribution.
- To test `x` for a Weibull distribution, test if `log(x)` has an extreme value distribution.

The Lilliefors test cannot be used when the null hypothesis is not a location-scale family of distributions.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the p -value.

The Monte Carlo standard error is calculated as:

$$SE = \sqrt{\frac{(\hat{p})(1 - \hat{p})}{\text{mcreps}}},$$

where \hat{p} is the estimated p -value of the hypothesis test, and `mcreps` is the number of Monte Carlo replications performed.

The number of Monte Carlo replications, `mcreps`, is determined such that the Monte Carlo standard error for \hat{p} less than the value specified for `MCTol`.

Algorithms

To compute the critical value for the hypothesis test, `lillietest` interpolates into a table of critical values pre-computed using Monte Carlo simulation for sample sizes less than 1000 and significance levels between 0.001 and 0.50. The table used by `lillietest` is larger and more accurate than the table originally introduced by

Lilliefors. If a more accurate p -value is desired, or if the desired significance level is less than 0.001 or greater than 0.50, the `MCTol` input argument can be used to run a Monte Carlo simulation to calculate the p -value more exactly.

When the computed value of the test statistic is greater than the critical value, `lillietest` rejects the null hypothesis at significance level `Alpha`.

`lillietest` treats NaN values in `x` as missing values and ignores them.

Introduced before R2006a

LinearModel class

Superclasses: CompactLinearModel

Linear regression model class

Description

An object comprising training data, model description, diagnostic information, and fitted coefficients for a linear regression. Predict model responses with the `predict` or `feval` methods.

Construction

`mdl = fitlm(tbl)` or `mdl = fitlm(X,y)` create a linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`. For details, see `fitlm`.

`mdl = stepwiselm(tbl)` or `mdl = stepwiselm(X,y)` create a linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`, with unimportant predictors excluded. For details, see `stepwiselm`.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-56). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X .

Data Types: `single` | `double` | `logical`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double`

Properties

CoefficientCovariance — Covariance matrix of coefficient estimates

numeric matrix

Covariance matrix of coefficient estimates, stored as a p -by- p matrix of numeric values. p is the number of coefficients in the fitted model.

CoefficientNames — Coefficient names

cell array of strings

Coefficient names, stored as a cell array of strings containing a label for each coefficient.

Coefficients — Coefficient values

table

Coefficient values, stored as a table. `Coefficients` has one row for each coefficient and the following columns:

- `Estimate` — Estimated coefficient value
- `SE` — Standard error of the estimate

- `tStat` — t statistic for a test that the coefficient is zero
- `pValue` — p -value for the t statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

DFE — Degrees of freedom for error

positive integer value

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients, stored as a positive integer value.

Diagnostics — Diagnostic values

table

Diagnostic values, stored as a table with the same number of rows as the input data (`tbl` or `X`). `Diagnostics` contains diagnostics helpful in finding outliers and influential observations. Many diagnostics describe the effect on the fit of deleting single observations. `Diagnostics` contains the following fields.

Field	Meaning	Utility
<code>Leverage</code>	Diagonal elements of <code>HatMatrix</code>	<code>Leverage</code> indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with P coefficients and N observations, the average value of <code>Leverage</code> is P/N . An observation with <code>Leverage</code> larger than $2 \cdot P/N$ can be regarded as having high leverage.
<code>CooksDistance</code>	Cook's measure of scaled change in fitted values	<code>CooksDistance</code> is a measure of scaled change in fitted values. An observation with <code>CooksDistance</code> larger than three times the mean Cook's distance can be an outlier.

Field	Meaning	Utility
Dffits	Delete-1 scaled differences in fitted values vs. observation number	Dffits is the scaled change in the fitted values for each observation that would result from excluding that observation from the fit. Values with an absolute value larger than $2 \cdot \sqrt{P/N}$ may be considered influential.
S2_i	Delete-1 variance vs. observation number	S2_i is a set of residual variance estimates obtained by deleting each observation in turn. These can be compared with the value of the MSE property.
CovRatio	Delete-1 ratio of determinant of covariance vs. observation number	CovRatio is the ratio of the determinant of the coefficient covariance matrix with each observation deleted in turn to the determinant of the covariance matrix for the full model. Values larger than $1 + 3 \cdot P/N$ or smaller than $1 - 3 \cdot P/N$ indicate influential points.
Dfbetas	Delete-1 scaled differences in covariance estimates vs. observation number	Dfbetas is an N-by-P matrix of the scaled change in the coefficient estimates that would result from excluding each observation in turn. Values larger than $3/\sqrt{N}$ in absolute value indicate that the observation has a large influence on the corresponding coefficient.
HatMatrix	Projection matrix to compute fitted from observed responses	HatMatrix is an N-by-N matrix such that $\text{Fitted} = \text{HatMatrix} \cdot Y$, where Y is the response vector and Fitted is the vector of fitted response values.

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exception: Delete-1 diagnostics refer to the statistic with and without that observation (row) included in the fit. These diagnostics help identify important observations.

Fitted — Fitted response values based on input data
vector of numeric values

Fitted (predicted) response values based on input data, stored as an n -by-1 vector of numeric values. n is the number of observations in the input data. Use `predict` to

compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

Formula — Model information

`LinearFormula` object | `NonLinearFormula` object

Model information, stored as a `LinearFormula` object or `NonLinearFormula` object. If you fit a linear or generalized linear regression model, then `Formula` is a `LinearFormula` object. If you fit a nonlinear regression model, then `Formula` is a `NonLinearFormula` object.

LogLikelihood — Log likelihood

numeric value

Log likelihood of the model distribution at the response values, stored as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.

ModelCriterion — Criterion for model comparison

structure

Criterion for model comparison, stored as a structure with the following fields:

- `AIC` — Akaike information criterion
- `AICc` — Akaike information criterion corrected for sample size
- `BIC` — Bayesian information criterion
- `CAIC` — Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model `mdl`, the `AIC` value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

MSE — Mean squared error

numeric value

Mean squared error (residuals), stored as a numeric value. Mean square error is calculated as $MSE = SSE / DFE$, where MSE is the mean square error, SSE is the sum of squared errors, and DFE is the degrees of freedom.

NumCoefficients — Number of model coefficients

positive integer

Number of model coefficients, stored as a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

NumEstimatedCoefficients – Number of estimated coefficients

positive integer

Number of estimated coefficients in the model, stored as a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

NumObservations – Number of observations

positive integer

Number of observations the fitting function used in fitting, stored as a positive integer. This is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the `EXCLUDED` name-value pair) or rows with missing values.

NumPredictors – Number of predictor variables

positive integer

Number of predictor variables used to fit the model, stored as a positive integer.

NumVariables – Number of variables

positive integer

Number of variables in the input data, stored as a positive integer. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

ObservationInfo – Observation information

table

Observation information, stored as a n -by-4 table, where n is equal to the number of rows of input data. The four columns of `ObservationInfo` contain the following:

Field	Description
Weights	Observation weights. Default is all 1.
Excluded	Logical value, 1 indicates an observation that you excluded from the fit with the <code>EXCLUDE</code> name-value pair.

Field	Description
Missing	Logical value, 1 indicates a missing value in the input. Missing values are not used in the fit.
Subset	Logical value, 1 indicates the observation is not excluded or missing, so is used in the fit.

ObservationNames — Observation names

cell array

Observation names, stored as a cell array of strings containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array

PredictorNames — Names of predictors used to fit the model

cell array

Names of predictors used to fit the model, stored as a cell array of strings.

Residuals — Residuals for fitted model

table

Residuals for fitted model, stored as a table that contains one row for each observation and the following columns.

Field	Description
Raw	Observed minus fitted values.
Pearson	Raw residuals divided by RMSE.
Standardized	Raw residuals divided by their estimated standard deviation.
Studentized	Residual divided by an independent estimate of the residual standard deviation. The residual for observation i is divided by an estimate of the error standard deviation based on all observations except for observation i .

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

ResponseName — Response variable name

string

Response variable name, stored as a string.

RMSE — Root mean squared error

numeric value

Root mean squared error (residuals), stored as a numeric value. The root mean squared error (RMSE) is equal to $RMSE = \sqrt{MSE}$, where MSE is the mean squared error.

Robust — Robust fit information

structure

Robust fit information, stored as a structure with the following fields:

Field	Description
<code>WgtFun</code>	Robust weighting function, such as 'bisquare' (see <code>robustfit</code>)
<code>Tune</code>	Value specified for tuning parameter (can be <code>[]</code>)
<code>Weights</code>	Vector of weights used in final iteration of robust fit. This field is empty for compacted <code>CompactLinearModel</code> models.

This structure is empty unless `fitlm` constructed the model using robust regression.

Rsquared — R-squared value for the model

structure

R-squared value for the model, stored as a structure.

For a linear or nonlinear model, `Rsquared` is a structure with two fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients

For a generalized linear model, **Rsquared** is a structure with five fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients
- **LLR** — Log-likelihood ratio
- **Deviance** — Deviance
- **AdjGeneralized** — Adjusted generalized R-squared

The R-squared value is the proportion of total sum of squares explained by the model.

The ordinary R-squared value relates to the **SSR** and **SST** properties:

$\text{Rsquared} = \text{SSR}/\text{SST} = 1 - \text{SSE}/\text{SST}$.

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

SSE — Sum of squared errors

numeric value

Sum of squared errors (residuals), stored as a numeric value.

The Pythagorean theorem implies

$\text{SST} = \text{SSE} + \text{SSR}$.

SSR — Regression sum of squares

numeric value

Regression sum of squares, stored as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$\text{SST} = \text{SSE} + \text{SSR}$.

SST — Total sum of squares

numeric value

Total sum of squares, stored as a numeric value. The total sum of squares is equal to the sum of squared deviations of y from $\text{mean}(y)$.

The Pythagorean theorem implies
 $SST = SSE + SSR$.

Steps — Stepwise fitting information

structure

Stepwise fitting information, stored as a structure with the following fields.

Field	Description
Start	Formula representing the starting model
Lower	Formula representing the lower bound model, these terms that must remain in the model
Upper	Formula representing the upper bound model, model cannot contain more terms than Upper
Criterion	Criterion used for the stepwise algorithm, such as 'sse'
PEnter	Value of the parameter, such as 0.05
PRemove	Value of the parameter, such as 0.10
History	Table representing the steps taken in the fit

The **History** table has one row for each step including the initial fit, and the following variables (columns).

Field	Description
Action	Action taken during this step, one of: <ul style="list-style-type: none"> 'Start' — First step 'Add' — A term is added 'Remove' — A term is removed
TermName	<ul style="list-style-type: none"> 'Start' step: The starting model specification 'Add' or 'Remove' steps: The term moved in that step
Terms	Terms matrix (see <code>modelspec</code> of <code>fitlm</code>)
DF	Regression degrees of freedom after this step
delDF	Change in regression degrees of freedom from previous step (negative for steps that remove a term)
Deviance	Deviance (residual sum of squares) at that step

Field	Description
FStat	F statistic that led to this step
PValue	p -value of the F statistic

The structure is empty unless you use `stepwiselm` or `stepwiseglm` to fit the model.

VariableInfo — Information about input variables

table

Information about input variables contained in `Variables`, stored as a table with one row for each model term and the following columns.

Field	Description
Class	String giving variable class, such as 'double'
Range	Cell array giving variable range: <ul style="list-style-type: none"> • Continuous variable — Two-element vector [min, max], the minimum and maximum values • Categorical variable — Cell array of distinct variable values
InModel	Logical vector, where <code>true</code> indicates the variable is in the model
IsCategorical	Logical vector, where <code>true</code> indicates a categorical variable

VariableNames — Names of variables used in fit

cell array

Names of variables used in fit, stored as a cell array of strings.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

Variables — Data used to fit the model

table

Data used to fit the model, stored as a table. `Variables` contains both observation and response values. If the fit is based on a table or dataset array, `Variables` contains all of

the data from that table or dataset array. Otherwise, `Variables` is a table created from the input data matrix X and response vector y .

Methods

<code>addTerms</code>	Add terms to linear regression model
<code>compact</code>	Compact linear regression model
<code>dwtest</code>	Durbin-Watson test of linear model
<code>fit</code>	Create linear regression model
<code>plot</code>	Scatter plot or added variable plot of linear model
<code>plotAdded</code>	Added variable plot or leverage plot for linear model
<code>plotAdjustedResponse</code>	Adjusted response plot for linear regression model
<code>plotDiagnostics</code>	Plot diagnostics of linear regression model
<code>plotResiduals</code>	Plot residuals of linear regression model
<code>removeTerms</code>	Remove terms from linear model
<code>step</code>	Improve linear regression model by adding or removing terms
<code>stepwise</code>	Create linear regression model by stepwise regression

Inherited Methods

<code>anova</code>	Analysis of variance for linear model
<code>coefCI</code>	Confidence intervals of coefficient estimates of linear model
<code>coeffTest</code>	Linear hypothesis test on linear regression model coefficients
<code>disp</code>	Display linear regression model
<code>feval</code>	Evaluate linear regression model prediction

plotEffects	Plot main effects of each predictor in linear regression model
plotInteraction	Plot interaction effects of two predictors in linear regression model
plotSlice	Plot of slices through fitted linear regression surface
predict	Predict response of linear regression model
random	Simulate responses for linear regression model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Definitions

Hat Matrix

The *hat matrix* H is defined in terms of the data matrix X :

$$H = X(X^T X)^{-1} X^T.$$

The diagonal elements h_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

The *leverage* of observation i is the value of the i th diagonal term, h_{ii} , of the hat matrix H . Because the sum of the leverage values is p (the number of coefficients in the regression

model), an observation i can be considered to be an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

Cook's Distance

Cook's distance is the scaled change in fitted values. Each element in `CooksDistance` is the normalized change in the vector of coefficients due to the deletion of an observation. The Cook's distance, D_i , of observation i is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

- \hat{y}_j is the j th fitted response value.
- $\hat{y}_{j(i)}$ is the j th fitted response value, where the fit does not include observation i .
- MSE is the mean squared error.
- p is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \text{MSE}} \left(\frac{h_{ii}}{(1-h_{ii})^2} \right),$$

where r_i is the i th residual, and h_{ii} is the i th leverage value.

`CooksDistance` is an n -by-1 column vector in the `Diagnostics` table of the `LinearModel` object.

Examples

Linear Regression Model of Matrix Data

Fit a linear model of the Hald data.

Load the data.

```
load hald
X = ingredients; % Predictor variables
y = heat; % Response
```

Fit a default linear model to the data.

```
mdl = fitlm(X,y)
```

```
mdl =
```

```
Linear regression model:
y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	62.405	70.071	0.8906	0.39913
x1	1.5511	0.74477	2.0827	0.070822
x2	0.51017	0.72379	0.70486	0.5009
x3	0.10191	0.75471	0.13503	0.89592
x4	-0.14406	0.70905	-0.20317	0.84407

```
Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.45
R-squared: 0.982, Adjusted R-Squared 0.974
F-statistic vs. constant model: 111, p-value = 4.76e-07
```

Linear Regression with Categorical Predictor

Fit a model of a table that contains a categorical predictor.

Load the `carsmall` data.

```
load carsmall
```

Construct a table containing continuous predictor variable `Weight`, nominal predictor variable `Year`, and response variable `MPG`.

```
tbl = table(MPG,Weight);
```

```
tbl.Year = nominal(Model_Year);
```

Create a fitted model of MPG as a function of Year, Weight, and Weight². (You don't have to include Weight explicitly in your formula because it is a lower-order term of Weight²) and is included automatically.

```
mdl = fitlm(tbl, 'MPG ~ Year + Weight^2')
```

```
mdl =
```

Linear regression model:

```
MPG ~ 1 + Weight + Year + Weight^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 2.78

R-squared: 0.885, Adjusted R-Squared 0.88

F-statistic vs. constant model: 172, p-value = 5.52e-41

`fitlm` creates two dummy (indicator) variables for the nominal variate, Year. The dummy variable Year_76 takes the value 1 if model year is 1976 and takes the value 0 if it is not. The dummy variable Year_82 takes the value 1 if model year is 1982 and takes the value 0 if it is not. And the year 1970 is the reference year. The corresponding model is

$$\hat{MPG} = 54.206 - 0.0164(\text{Weight}) + 2.0887(\text{Year}_76) + 8.1864(\text{Year}_82) + 1.557e - 06(\text{Weight}^2)$$

Fit a Robust Linear Regression Model

Fit a linear regression model using a robust fitting method.

Load the sample data.

```
load hald
```

The `hald` data measures the effect of cement composition on its hardening heat. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The array `heat` contains the heat of hardening after 180 days for each cement sample.

Fit a robust linear model to the data.

```
mdl = fitlm(ingredients,heat,'linear','RobustOpts','on')
```

```
mdl =
```

```
Linear regression model (robust fit):
```

```
  y ~ 1 + x1 + x2 + x3 + x4
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

```
Number of observations: 13, Error degrees of freedom: 8
```

```
Root Mean Squared Error: 2.65
```

```
R-squared: 0.979, Adjusted R-Squared 0.969
```

```
F-statistic vs. constant model: 94.6, p-value = 9.03e-07
```

- “Linear Regression Workflow” on page 10-42
- “Robust Regression versus Standard Least-Squares Fit” on page 10-129

Algorithms

The main fitting algorithm is QR decomposition. For robust fitting, the algorithm is `robustfit`.

Alternatives

To remove redundant predictors in linear regression using lasso or elastic net, use the `lasso` function.

To regularize a regression with correlated terms using ridge regression, use the `ridge` or `lasso` functions.

To regularize a regression with correlated terms using partial least squares, use the `plsregress` function.

More About

- “Linear Regression” on page 10-11

LinearMixedModel class

Linear mixed-effects model class

Description

A `LinearMixedModel` object represents a model of a response variable with fixed and random effects. It comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a linear mixed-effects model. You can predict model responses with the `predict` function and generate random data at new design points using the `random` function.

Construction

You can fit a linear mixed-effects model using `fitlme(tbl, formula)` if your data is in a table or dataset array. Alternatively, if your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X, y, Z, G)`.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-56). You must specify the model for the variables using `formula`.

Data Types: `single` | `double` | `char` | `cell`

formula — Formula for model specification

string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For a full description, see “Formula” on page 25-3091.

Example: 'y ~ treatment +(1|block)'

X — Fixed-effects design matrix

n-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of **X** corresponds to one observation, and each column of **X** corresponds to one variable.

Data Types: single | double

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: single | double

Z — Random-effects design

n-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then **Z** must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then **Z** must be a cell array of length *R*. Each cell of **Z** contains an *n*-by-*q*(*r*) design matrix $Z\{r\}$, *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, $Z\{r\}$.

Data Types: single | double | cell

G — Grouping variable or variables

n-by-1 vector | cell array of *R* *n*-by-1 vectors

Grouping variable or variables, specified as either of the following.

- If there is one random-effects term, then **G** must be an *n*-by-1 vector corresponding to a single grouping variable with *M* levels or groups.

G can be a categorical vector, numeric vector, character array, or cell array of strings.

- If there are multiple random-effects terms, then **G** must be a cell array of length R . Each cell of **G** contains a grouping variable $G\{r\}$, $r = 1, 2, \dots, R$, with $M(r)$ levels.

$G\{r\}$ can be a categorical vector, numeric vector, character array, or cell array of strings.

Data Types: `single` | `double` | `char` | `cell`

Properties

Coefficients — Fixed-effects coefficient estimates

dataset array

Fixed-effects coefficient estimates and related statistics, stored as a dataset array containing the following fields.

Name	Name of the term.
Estimate	Estimated value of the coefficient.
SE	Standard error of the coefficient.
tStat	t -statistics for testing the null hypothesis that the coefficient is equal to zero.
DF	Degrees of freedom for the t -test. Method to compute DF is specified by the 'DFMethod' name-value pair argument. Coefficients always uses the 'Residual' method for 'DFMethod'.
pValue	p -value for the t -test.
Lower	Lower limit of the confidence interval for coefficient. Coefficients always uses the 95% confidence level, i.e. 'alpha' is 0.05.
Upper	Upper limit of confidence interval for coefficient. Coefficients always uses the 95% confidence level, i.e. 'alpha' is 0.05.

You can change 'DFMethod' and 'alpha' while computing confidence intervals for or testing hypotheses involving fixed- and random-effects, using the `coefCI` and `coefTest` methods.

CoefficientCovariance — Covariance of the estimated fixed-effects coefficients

p -by- p matrix

Covariance of the estimated fixed-effects coefficients of the linear mixed-effects model, stored as a p -by- p matrix, where p is the number of fixed-effects coefficients.

You can display the covariance parameters associated with the random effects using the `covarianceParameters` method.

Data Types: `double`

CoefficientNames — Names of the fixed-effects coefficients

1-by- p cell array of strings

Names of the fixed-effects coefficients of a linear mixed-effects model, stored as a 1-by- p cell array of strings.

Data Types: `cell`

DFE — Residual degrees of freedom

positive integer value

Residual degrees of freedom, stored as a positive integer value. $DFE = n - p$, where n is the number of observations, and p is the number of fixed-effects coefficients.

This corresponds to the 'Residual' method of calculating degrees of freedom in the `fixedEffects` and `randomEffects` methods.

Data Types: `double`

FitMethod — Method used to fit the linear mixed-effects model

ML | REML

Method used to fit the linear mixed-effects model, stored as either of the following strings.

- ML, if the fitting method is maximum likelihood
- REML, if the fitting method is restricted maximum likelihood

Data Types: `char`

Formula — Specification of the fixed- and random-effects terms, and grouping variables

object

Specification of the fixed-effects terms, random-effects terms, and grouping variables that define the linear mixed-effects model, stored as an object.

For more information on how to specify the model to fit using a formula, see “Formula” on page 25-3091.

LogLikelihood — Maximized log or restricted log likelihood

scalar value

Maximized log likelihood or maximized restricted log likelihood of the fitted linear mixed-effects model depending on the fitting method you choose, stored as a scalar value.

Data Types: double

ModelCriterion — Model criterion

dataset array

Model criterion to compare fitted linear mixed-effects models, stored as a dataset array with the following columns.

AIC	Akaike Information Criterion
BIC	Bayesian Information Criterion
Loglikelihood	Log likelihood value of the model
Deviance	-2 times the log likelihood of the model

If n is the number of observations used in fitting the model, and p is the number of fixed-effects coefficients, then for calculating AIC and BIC,

- The total number of parameters is $nc + p + 1$, where nc is the total number of parameters in the random-effects covariance excluding the residual variance
- The effective number of observations is
 - n , when the fitting method is maximum likelihood (ML)
 - $n - p$, when the fitting method is restricted maximum likelihood (REML)

MSE — ML or REML estimate

positive scalar value

ML or REML estimate, based on the fitting method used for estimating σ^2 , stored as a positive scalar value. σ^2 is the residual variance or variance of the observation error term of the linear mixed-effects model.

Data Types: double

NumCoefficients — Number of fixed-effects coefficients

positive integer value

Number of fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumEstimatedCoefficients — Number of estimated fixed-effects coefficients

positive integer value

Number of estimated fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumObservations — Number of observations

positive integer value

Number of observations used in the fit, stored as a positive integer value. This is the number of rows in the table or dataset array, or the design matrices minus the excluded rows or rows with NaN values.

Data Types: double

NumPredictors — Number of predictors

positive integer value

Number of variables used as predictors in the linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumVariables — Total number of variables

positive integer value

Total number of variables including the response and predictors, stored as a positive integer value.

- If the sample data is in a table or dataset array `tbl`, `NumVariables` is the total number of variables in `tbl` including the response variable.

- If the fit is based on matrix input, `NumVariables` is the total number of columns in the predictor matrix or matrices, and response vector.

`NumVariables` includes variables, if there are any, that are not used as predictors or as the response.

Data Types: `double`

ObservationInfo — Information about the observations

table

Information about the observations used in the fit, stored as a table.

`ObservationInfo` has one row for each observation and the following four columns.

<code>Weights</code>	The value of the weighted variable for that observation. Default value is 1.
<code>Excluded</code>	<code>true</code> , if the observation was excluded from the fit using the ' <code>Exclude</code> ' name-value pair argument, <code>false</code> , otherwise. 1 stands for <code>true</code> and 0 stands for <code>false</code> .
<code>Missing</code>	<code>true</code> , if the observation was excluded from the fit because any response or predictor value is missing, <code>false</code> , otherwise. Missing values include <code>NaN</code> for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the <code><undefined></code> value for categorical arrays.
<code>Subset</code>	<code>true</code> , if the observation was used in the fit, <code>false</code> , if it was not used because it is missing or excluded.

Data Types: `table`

ObservationNames — Names of observations

cell array of strings

Names of observations used in the fit, stored as a cell array of strings.

- If the data is in a table or dataset array, `tbl`, containing observation names, `ObservationNames` has those names.
- If the data is provided in matrices, or a table or dataset array without observation names, then `ObservationNames` is an empty cell array.

Data Types: `cell`

PredictorNames — Names of predictors

cell array of strings

Names of the variables that you use as predictors in the fit, stored as a cell array of strings that has the same length as `NumPredictors`.

Data Types: `cell`

ResponseName — Names of response variable

character string

Name of the variable used as the response variable in the fit, stored as a character string.

Data Types: `char`

Rsquared — Proportion of variability in the response explained by the fitted model

structure

Proportion of variability in the response explained by the fitted model, stored as a structure. It is the multiple correlation coefficient or R-squared. `Rsquared` has two fields.

Ordinary

R-squared value, stored as a scalar value in a structure. `Rsquared.Ordinary = 1 - SSE./SST`

Adjusted

R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure.

`Rsquared.Adjusted = 1 - (SSE./SST)*(DFT./DFE)`,

where $DFE = n - p$, $DFT = n - 1$, and n is the total number of observations, p is the number of fixed-effects coefficients.

Data Types: `struct`

SSE — Error sum of squares

positive scalar value

Error sum of squares, that is, sum of the squared conditional residuals, stored as a positive scalar value.

$SSE = \text{sum}((y - F).^2)$, where y is the response vector, and F is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

Data Types: `double`

SSR — Regression sum of squares

positive scalar value

Regression sum of squares, that is, the sum of squares explained by the linear mixed-effects regression, stored as a positive scalar value. It is the sum of squared deviations of the conditional fitted values from their mean.

$SSR = \text{sum}((F - \text{mean}(F)).^2)$, where F is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

Data Types: `double`

SST — Total sum of squares

positive scalar value

Total sum of squares, that is, the sum of the squared deviations of the observed response values from their mean, stored as a positive scalar value.

$SST = \text{sum}((y - \text{mean}(y)).^2) = SSR + SSE$, where y is the response vector.

Data Types: `double`

Variables — Variables

table

Variables, stored as a table.

- If the fit is based on a table or dataset array `tbl`, then `Variables` is identical to `tbl`.

- If the fit is based on matrix input, then `Variables` is a table containing all the variables in the predictor matrix or matrices, and response variable.

Data Types: `table`

VariableInfo — Information about the variables

`table`

Information about the variables used in the fit, stored as a table.

`VariableInfo` has one row for each variable and contains the following four columns.

<code>Class</code>	Class of the variable ('double', 'cell', 'nominal', and so on).
<code>Range</code>	Value range of the variable. <ul style="list-style-type: none"> • For a numerical variable, it is a two-element vector of the form <code>[min,max]</code>. • For a cell or categorical variable, it is a cell or categorical array containing all unique values of the variable.
<code>InModel</code>	<code>true</code> , if the variable is a predictor in the fitted model. <code>false</code> , if the variable is not in the fitted model.
<code>IsCategorical</code>	<code>true</code> , if the variable has a type that is treated as a categorical predictor, such as cell, logical, or categorical, or if it is specified as categorical by the 'Categorical' name-value pair argument of the <code>fit</code> method. <code>false</code> , if it is a continuous predictor.

Data Types: `table`

VariableNames — Names of the variables

cell array of strings

Names of the variables used in the fit, stored as a cell array of strings.

- If sample data is in a table or dataset array `tbl`, `VariableNames` contains the names of the variables in `tbl`.
- If sample data is in matrix format, then `VariableInfo` includes variable names you supply while fitting the model. If you do not supply the variable names, then `VariableInfo` contains the default names.

Data Types: `cell`

Methods

<code>anova</code>	Analysis of variance for linear mixed-effects model
<code>coefCI</code>	Confidence intervals for coefficients of linear mixed-effects model
<code>coefTest</code>	Hypothesis test on fixed and random effects of linear mixed-effects model
<code>compare</code>	Compare linear mixed-effects models
<code>covarianceParameters</code>	Extract covariance parameters of linear mixed-effects model
<code>designMatrix</code>	Fixed- and random-effects design matrices
<code>disp</code>	Display linear mixed-effects model
<code>fit</code>	Fit linear mixed-effects model using tables
<code>fitmatrix</code>	Fit linear mixed-effects model using design matrices
<code>fitted</code>	Fitted responses from a linear mixed-effects model
<code>fixedEffects</code>	Estimates of fixed effects and related statistics
<code>plotResiduals</code>	Plot residuals of linear mixed-effects model
<code>predict</code>	Predict response of linear mixed-effects model
<code>random</code>	Generate random responses from fitted linear mixed-effects model

randomEffects	Estimates of random effects and related statistics
residuals	Residuals of fitted linear mixed-effects model
response	Response vector of the linear mixed-effects model

Definitions

Formula

In general, a formula for model specification is a string of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, `y`
- Predictor variables, `Xj`, which can be continuous or grouping variables
- Grouping variables, `g1`, `g2`, ..., `gR`,

where the grouping variables in `Xj` and `gr` can be categorical, logical, character arrays, or cell arrays of strings.

Then, in a formula of the form, `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix `X`, `random1` is a specification of the random-effects design matrix `Z1` corresponding to grouping variable `g1`, and similarly `randomR` is a specification of the random-effects design matrix `ZR` corresponding to grouping variable `gR`. You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term

Wilkinson Notation	Factors in Standard Notation
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$)
$X1 : X2$	$X1.*X2$ only
$- X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
' $y \sim X1 + X2$ '	Fixed effects for the intercept, $X1$ and $X2$. This is equivalent to ' $y \sim 1 + X1 + X2$ '.
' $y \sim -1 + X1 + X2$ '	No intercept and fixed effects for $X1$ and $X2$. The implicit intercept term is suppressed by including <code>-1</code> .
' $y \sim 1 + (1 g1)$ '	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable $g1$.
' $y \sim X1 + (1 g1)$ '	Random intercept model with a fixed slope.
' $y \sim X1 + (X1 g1)$ '	Random intercept and slope, with possible correlation between them. This is equivalent to ' $y \sim 1 + X1 + (1 + X1 g1)$ '.
' $y \sim X1 + (1 g1) + (-1 + X1 g1)$ '	Independent random effects terms for intercept and slope.

Formula	Description
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2 , plus an independent interaction effect.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Random Intercept Model with Categorical Predictor

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
    'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by `Date`.

Because region is a nominal variable, `fitlme` takes the first region, NE, as the reference and creates eight dummy variables representing the other eight regions. For example,

$I[MidAtl]$ is the dummy variable representing the region MidAtl. For details, see “Dummy Indicator Variables” on page 2-59.

The corresponding model is

$$y_{im} = \beta_0 + \beta_1 I[MidAtl]_i + \beta_2 I[ENCentral]_i + \beta_3 I[WNCentral]_i + \beta_4 I[SAtl]_i + \beta_5 I[ESCentral]_i + \beta_6 I[WSCentral]_i + \beta_7 I[Mtn]_i + \beta_8 I[Pac]_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable Date, β_j , $j = 0, 1, \dots, 8$, are the fixed-effects coefficients, b_{0m} is the random effect for level m of the grouping variable Date, and ε_{im} is the observation error for observation i . The random effect has the prior distribution, $b \sim N(0, \sigma_b^2)$ and the error term has the distribution, $\varepsilon \sim N(0, \sigma^2)$.

```
lme = fitlme(flu2, 'FluRate ~ 1 + Region + (1|Date)')
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	468
Fixed effects coefficients	9
Random effects coefficients	52
Covariance parameters	2

Formula:

```
FluRate ~ 1 + Region + (1|Date)
```

Model fit statistics:

318.71	364.35	-148.36	296.71

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	1.2233	0.096678	12.654	459	1.085e-31
'Region_MidAtl'	0.010192	0.052221	0.19518	459	0.84534
'Region_ENCentral'	0.051923	0.052221	0.9943	459	0.3206
'Region_WNCentral'	0.23687	0.052221	4.5359	459	7.3324e-06
'Region_SAtl'	0.075481	0.052221	1.4454	459	0.14902
'Region_ESCentral'	0.33917	0.052221	6.495	459	2.1623e-10
'Region_WSCentral'	0.069	0.052221	1.3213	459	0.18705
'Region_Mtn'	0.046673	0.052221	0.89377	459	0.37191
'Region_Pac'	-0.16013	0.052221	-3.0665	459	0.0022936

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'(Intercept)'	'(Intercept)'	'std'	0.6443	0.5297	0.7836

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.26627	0.24878	0.285

The p -values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions `WNCentral` and `ESCentral` are significantly different relative to the flu rates in region `NE`.

The confidence limits for the standard deviation of the random-effects term, σ_b^2 , do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region `WNCentral` in week 10/9/2005 is

$$\begin{aligned}\hat{y}_{WNCentral,10/9/2005} &= \hat{\beta}_0 + \hat{\beta}_3 I[WNCentral] + \hat{b}_{10/9/2005} \\ &= 1.2233 + 0.23687 - 0.1718 \\ &= 1.28837.\end{aligned}$$

This is the fitted conditional response, since it includes contribution to the estimate from both the fixed and random effects. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level1);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')

y_hat =

    1.2884
```

You can simply display the fitted value using the `fitted` method.

```
F = fitted(lme);  
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')  
  
ans =  
  
1.2884
```

Compute the fitted marginal response for region WNCentral in week 10/9/2005.

```
F = fitted(lme, 'Conditional', false);  
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')  
  
ans =  
  
1.4602
```

Linear Mixed-Effects Model with a Random Slope

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and cylinders, and potentially correlated random effect for intercept and acceleration grouped by model year. This model corresponds to

$$MPG_{im} = \beta_0 + \beta_1 Acc_i + \beta_2 HP + b_{0m} + b_{1m} Acc_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N \left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right),$$

where $D(\theta)$ is the covariance matrix.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];  
Z = [ones(406,1) Acceleration];
```

```
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Use the 'fminunc' optimization algorithm.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'},...
'FitMethod','REML')
```

```
lme =
```

Linear mixed-effects model fit by REML

Model information:

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	4

Formula:

```
y ~ Intercept + Acceleration + Horsepower + (Intercept + Acceleration | Model_Year)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2202.9	2230.7	-1094.5	2188.9

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue	Lower	Upper
'Intercept'	50.064	2.3176	21.602	389	1.4185e-68	45.439	54.689
'Acceleration'	-0.57897	0.13843	-4.1825	389	3.5654e-05	-0.8562	-0.3017
'Horsepower'	-0.16958	0.0073242	-23.153	389	3.5289e-75	-0.1848	-0.1543

Random effects covariance parameters (95% CIs):

Group: Model_Year (13 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	3.72	1.5215	5.9185
'Acceleration'	'Intercept'	'corr'	-0.8769	-0.98275	-0.77105
'Acceleration'	'Acceleration'	'std'	0.3593	0.19418	0.52442

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.6913	3.4331	3.9688

The fixed effects coefficients display includes the estimate, standard errors (SE), and the 95% confidence interval limits (**Lower** and **Upper**). The *p*-values for (**pValue**) indicate that all three fixed-effects coefficients are significant.

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. Use the **compare** method to test for the random effects.

Display the covariance matrix of the estimated fixed-effects coefficients.

```
lme.CoefficientCovariance
```

```
ans =
```

```
  5.3711  -0.2809  -0.0126
 -0.2809   0.0192   0.0005
 -0.0126   0.0005   0.0001
```

The diagonal elements show the variances of the fixed-effects coefficient estimates. For example, the variance of the estimate of the intercept is 5.3711. Note that the standard errors of the estimates are the square roots of the variances. For example, the standard error of the intercept is 2.3176, which is `sqrt(5.3711)`.

The off-diagonal elements show the correlation between the fixed-effects coefficient estimates. For example, the correlation between the intercept and acceleration is -0.2809 and the correlation between acceleration and horsepower is 0.0005.

Display the coefficient of determination for the model.

```
lme.Rsquared
```

```
ans =
```

```
  Ordinary: 0.7826
  Adjusted: 0.7815
```

The adjusted value is the R-squared value adjusted for the number of predictors in the model.

`fitlme` | `fitlmematrix`

linhpytest

Linear hypothesis test

Syntax

```
p = linhpytest(beta,COVB,c,H,dfe)
[p,t,r] = linhpytest(...)
```

Description

`p = linhpytest(beta,COVB,c,H,dfe)` returns the p value p of a hypothesis test on a vector of parameters. `beta` is a vector of k parameter estimates. `COVB` is the k -by- k estimated covariance matrix of the parameter estimates. `c` and `H` specify the null hypothesis in the form $H*\mathbf{b} = \mathbf{c}$, where \mathbf{b} is the vector of unknown parameters estimated by `beta`. `dfe` is the degrees of freedom for the `COVB` estimate, or `Inf` if `COVB` is known rather than estimated.

`beta` is required. The remaining arguments have default values:

- `COVB = eye(k)`
- `c = zeros(k,1)`
- `H = eye(K)`
- `dfe = Inf`

If `H` is omitted, `c` must have k elements and it specifies the null hypothesis values for the entire parameter vector.

Note: The following functions return outputs suitable for use as the `COVB` input argument to `linhpytest`: `nlinfit`, `coxphfit`, `glmfit`, `mnrfit`, `regstats`, `robustfit`. `nlinfit` returns `COVB` directly; the other functions return `COVB` in `stats.covb`.

`[p,t,r] = linhpytest(...)` also returns the test statistic `t` and the rank `r` of the hypothesis matrix `H`. If `dfe` is `Inf` or is not given, `t*r` is a chi-square statistic with `r`

degrees of freedom . If `dfe` is specified as a finite value, `t` is an F statistic with `r` and `dfe` degrees of freedom.

`linhptest` performs a test based on an asymptotic normal distribution for the parameter estimates. It can be used after any estimation procedure for which the parameter covariances are available, such as `regstats` or `glmfit`. For linear regression, the p -values are exact. For other procedures, the p -values are approximate, and may be less accurate than other procedures such as those based on a likelihood ratio.

Examples

Fit a multiple linear model to the data in `hald.mat`:

```
load hald
stats = regstats(heat,ingredients,'linear');
beta = stats.beta
beta =
    62.4054
     1.5511
     0.5102
     0.1019
    -0.1441
```

Perform an F -test that the last two coefficients are both 0:

```
SIGMA = stats.covb;
dfe = stats.fstat.dfe;
H = [0 0 0 1 0;0 0 0 0 1];
c = [0;0];
[p,F] = linhptest(beta,SIGMA,c,H,dfe)
p =
    0.4668
F =
    0.8391
```

Introduced in R2007a

linkage

Agglomerative hierarchical cluster tree

Syntax

```
Z = linkage(X)
Z = linkage(X,method)
Z = linkage(X,method,metric)
Z = linkage(X,method,pdist_inputs)
Z = linkage(X,method,metric,'savememory',value)
Z = linkage(Y)
Z = linkage(Y,method)
```

Description

`Z = linkage(X)` returns a matrix `Z` that encodes a tree of hierarchical clusters of the rows of the real matrix `X`.

`Z = linkage(X,method)` creates the tree using the specified *method*, where *method* describes how to measure the distance between clusters.

`Z = linkage(X,method,metric)` performs clustering using the distance measure *metric* to compute distances between the rows of `X`.

`Z = linkage(X,method,pdist_inputs)` passes parameters to the `pdist` function, which is the function that computes the distance between rows of `X`.

`Z = linkage(X,method,metric,'savememory',value)` uses a memory-saving algorithm when *value* is 'true', and uses the standard algorithm when *value* is 'false'.

`Z = linkage(Y)` uses a vector representation `Y` of a distance matrix. `Y` can be a distance matrix as computed by `pdist`, or a more general dissimilarity matrix conforming to the output format of `pdist`.

`Z = linkage(Y,method)` creates the tree using the specified *method*, where *method* describes how to measure the distance between clusters.

Input Arguments

X

Matrix with two or more rows. The rows represent observations, the columns represent categories or dimensions.

method

Algorithm for computing distance between clusters.

Method	Description
'average'	Unweighted average distance (UPGMA)
'centroid'	Centroid distance (UPGMC), appropriate for Euclidean distances only
'complete'	Furthest distance
'median'	Weighted center of mass distance (WPGMC), appropriate for Euclidean distances only
'single'	Shortest distance
'ward'	Inner squared distance (minimum variance algorithm), appropriate for Euclidean distances only
'weighted'	Weighted average distance (WPGMA)

Default: 'single'

metric

Any distance metric that the `pdist` function accepts.

Metric	Description
'euclidean'	Euclidean distance (default).
'squaredeuclidean'	Squared Euclidean distance. (This option is provided for efficiency only. It does not satisfy the triangle inequality.)
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in X is scaled by dividing by the corresponding

Metric	Description
	element of the standard deviation $S = \text{nanstd}(X)$. To specify another value for S , use $D = \text{pdist}(X, 'seuclidean', S)$.
'cityblock'	City block metric.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use $D = \text{pdist}(X, 'minkowski', P)$, where P is a scalar positive value of the exponent.
'chebychev'	Chebychev distance (maximum coordinate difference).
'mahalanobis'	Mahalanobis distance, using the sample covariance of X as computed by <code>nancov</code> . To compute the distance with a different covariance, use $D = \text{pdist}(X, 'mahalanobis', C)$, where the matrix C is symmetric and positive definite.
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
custom distance function	A distance function specified using @: $D = \text{pdist}(X, @\text{distfun})$ A distance function must be of form $d2 = \text{distfun}(XI, XJ)$ taking as arguments a 1-by- n vector XI , corresponding to a single row of X , and an $m2$ -by- n matrix XJ , corresponding to multiple rows of X . <code>distfun</code> must accept a matrix XJ with an arbitrary number of rows. <code>distfun</code> must return an $m2$ -by-1 vector of distances $d2$, whose k th element is the distance between XI and $XJ(k, :)$.

Default: 'euclidean'

pdist_inputs

A cell array of parameters accepted by the `pdist` function. For example, to set the *metric* to `minkowski` and use an exponent of 5, set `pdist_inputs` to `{'minkowski',5}`.

savememory

A string, either `'on'` or `'off'`. When applicable, the `'on'` setting causes `linkage` to construct clusters without computing the distance matrix. `savememory` is applicable when:

- `linkage` is `'centroid'`, `'median'`, or `'ward'`
- `distance` is `'euclidean'` (default)

When `savememory` is `'on'`, `linkage` run time is proportional to the number of dimensions (number of columns of `X`). When `savememory` is `'off'`, `linkage` memory requirement is proportional to N^2 , where `N` is the number of observations. So choosing the best (least-time) setting for `savememory` depends on the problem dimensions, number of observations, and available memory. The default `savememory` setting is a rough approximation of an optimal setting.

Default: `'on'` when `X` has 20 columns or fewer, or the computer does not have enough memory to store the distance matrix; otherwise `'off'`

Y

A vector of distances with the same format as the output of the `pdist` function:

- A row vector of length $m(m-1)/2$, corresponding to pairs of observations in a matrix `X` with `m` rows
- Distances arranged in the order $(2,1), (3,1), \dots, (m,1), (3,2), \dots, (m,2), \dots, (m,m-1)$

`Y` can be a more general dissimilarity matrix conforming to the output format of `pdist`.

Output Arguments

Z

`Z` is a $(m-1)$ -by-3 matrix, where `m` is the number of observations in the original data. Columns 1 and 2 of `Z` contain cluster indices linked in pairs to form a binary tree. The

leaf nodes are numbered from 1 to m . Leaf nodes are the singleton clusters from which all higher clusters are built. Each newly-formed cluster, corresponding to row $Z(I, :)$, is assigned the index $m+I$. $Z(I, 1:2)$ contains the indices of the two component clusters that form cluster $m+I$. There are $m-1$ higher clusters which correspond to the interior nodes of the clustering tree. $Z(I, 3)$ contains the linkage distances between the two clusters merged in row $Z(I, :)$.

For example, suppose there are 30 initial nodes and at step 12 cluster 5 and cluster 7 are combined. Suppose their distance at that time is 1.5. Then $Z(12, :)$ will be $[5, 7, 1.5]$. The newly formed cluster will have index $12 + 30 = 42$. If cluster 42 appears in a later row, it means the cluster created at step 12 is being combined into some larger cluster.

Examples

Compare Cluster Assignments to Clusters

Load the sample data.

```
load fisheriris
```

Compute four clusters of the Fisher iris data using Ward linkage and ignoring species information.

```
Z = linkage(meas, 'ward', 'euclidean');
c = cluster(Z, 'maxclust', 4);
```

See how the cluster assignments correspond to the three species.

```
crosstab(c, species)
```

```
ans =
```

0	25	1
0	24	14
0	1	35
50	0	0

Display the first five rows of Z .

```
firstfive = Z(1:5, :)
```

```

firstfive =
  102.0000  143.0000      0
    8.0000  40.0000  0.1000
    1.0000  18.0000  0.1000
   10.0000  35.0000  0.1000
  129.0000  133.0000  0.1000

```

Create a dendrogram plot of Z .

```
dendrogram(Z)
```

Cluster Data and Plot the Result

Randomly generate the sample data with 20000 observations.

```
rng default; % For reproducibility
X = rand(20000,3);
```

Create a hierarchical cluster tree using Ward's linkage.

```
Z = linkage(X, 'ward', 'euclidean', 'savememory', 'on');
```

If you set `savememory` to `'off'`, you can get an out-of-memory error if your machine doesn't have enough memory to hold the distance matrix.

Cluster data into four groups and plot the result.

```
c = cluster(Z, 'maxclust', 4);
scatter3(X(:,1), X(:,2), X(:,3), 10, c)
```

More About

Linkages

The following notation is used to describe the linkages used by the various methods:

- Cluster r is formed from clusters p and q .
- n_r is the number of objects in cluster r .
- x_{ri} is the i th object in cluster r .
- *Single linkage*, also called *nearest neighbor*, uses the smallest distance between objects in the two clusters:

$$d(r, s) = \min(\text{dist}(x_{ri}, x_{sj}), i \in (1, \dots, n_r), j \in (1, \dots, n_s))$$

- *Complete linkage*, also called *furthest neighbor*, uses the largest distance between objects in the two clusters:

$$d(r, s) = \max(\text{dist}(x_{ri}, x_{sj}), i \in (1, \dots, n_r), j \in (1, \dots, n_s))$$

- *Average linkage* uses the average distance between all pairs of objects in any two clusters:

$$d(r, s) = \frac{1}{n_r n_s} \sum_{i=1}^{n_r} \sum_{j=1}^{n_s} \text{dist}(x_{ri}, x_{sj})$$

- *Centroid linkage* uses the Euclidean distance between the centroids of the two clusters:

$$d(r, s) = \|\bar{x}_r - \bar{x}_s\|_2$$

where

$$\bar{x}_r = \frac{1}{n_r} \sum_{i=1}^{n_r} x_{ri}$$

- *Median linkage* uses the Euclidean distance between weighted centroids of the two clusters,

$$d(r, s) = \|\tilde{x}_r - \tilde{x}_s\|_2$$

where \tilde{x}_r and \tilde{x}_s are weighted centroids for the clusters r and s . If cluster r was created by combining clusters p and q , \tilde{x}_r is defined recursively as

$$\tilde{x}_r = \frac{1}{2}(\tilde{x}_p + \tilde{x}_q)$$

- *Ward's linkage* uses the incremental sum of squares; that is, the increase in the total within-cluster sum of squares as a result of joining two clusters. The within-cluster

sum of squares is defined as the sum of the squares of the distances between all objects in the cluster and the centroid of the cluster. The sum of squares measure is equivalent to the following distance measure $d(r,s)$, which is the formula linkage uses:

$$d(r,s) = \sqrt{\frac{2n_r n_s}{n_r + n_s}} \|\bar{x}_r - \bar{x}_s\|_2,$$

where

- $\|\cdot\|_2$ is Euclidean distance
- \bar{x}_r and \bar{x}_s are the centroids of clusters r and s
- n_r and n_s are the number of elements in clusters r and s

In some references the Ward linkage does not use the factor of 2 multiplying $n_r n_s$. The linkage function uses this factor so the distance between two singleton clusters is the same as the Euclidean distance.

- *Weighted average linkage* uses a recursive definition for the distance between two clusters. If cluster r was created by combining clusters p and q , the distance between r and another cluster s is defined as the average of the distance between p and s and the distance between q and s :

$$d(r,s) = \frac{(d(p,s) + d(q,s))}{2}$$

Tips

- Computing `linkage(Y)` can be slow when Y is a vector representation of the distance matrix. For the 'centroid', 'median', and 'ward' methods, `linkage` checks whether Y is a Euclidean distance. Avoid this time-consuming check by passing in X instead of Y .
- The `centroid` and `median` methods can produce a cluster tree that is not monotonic. This occurs when the distance from the union of two clusters, r and s , to a third cluster is less than the distance between r and s . In this case, in a dendrogram drawn with the default orientation, the path from a leaf to the root node takes some downward steps. To avoid this, use another method. The following image shows a nonmonotonic cluster tree.

In this case, cluster 1 and cluster 3 are joined into a new cluster, while the distance between this new cluster and cluster 2 is less than the distance between cluster 1 and cluster 3. This leads to a nonmonotonic tree.

- You can provide the output `Z` to other functions including `dendrogram` to display the tree, `cluster` to assign points to clusters, `inconsistent` to compute inconsistent measures, and `cophenet` to compute the cophenetic correlation coefficient.

prob.LogisticDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Logistic probability distribution object

Description

`prob.LogisticDistribution` is an object consisting of parameters, a model description, and sample data for a logistic probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Logistic')` creates a logistic probability distribution object using the default parameter values.

`pd = makedist('Logistic', 'mu', mu, 'sigma', sigma)` creates a logistic probability distribution object using the specified parameter values.

Input Arguments

mu — Mean

0 (default) | scalar value

Mean of the logistic distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

1 (default) | nonnegative scalar value

Scale parameter of the logistic distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Properties

mu — Mean

scalar value

Mean of the logistic distribution, stored as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter of the logistic distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Definitions

Logistic Distribution

The logistic distribution is used for growth models and in logistic regression. It has longer tails and a higher kurtosis than the normal distribution.

The logistic distribution uses the following parameters.

Parameter	Description	Support
mu	Mean	$-\infty < \mu < \infty$
sigma	Scale parameter	$\sigma \geq 0$

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{\exp\left\{\frac{x - \mu}{\sigma}\right\}}{\sigma \left(1 + \exp\left\{\frac{x - \mu}{\sigma}\right\}\right)^2} ; \quad -\infty < x < \infty.$$

Examples

Create a Logistic Distribution Object Using Default Parameters

Create a logistic distribution object using the default parameter values.

```
pd = makedist('Logistic')  
pd =  
    LogisticDistribution  
  
    Logistic distribution  
        mu = 0  
        sigma = 1
```

Create a Logistic Distribution Object Using Specified Parameters

Create a logistic distribution object by specifying parameter values.

```
pd = makedist('Logistic', 'mu',2,'sigma',4)  
pd =  
    LogisticDistribution  
  
    Logistic distribution  
        mu = 2  
        sigma = 4
```

Compute the standard deviation of the distribution.

```
s = std(pd)  
s =  
    7.2552
```

prob.LoglogisticDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Loglogistic probability distribution object

Description

`prob.LoglogisticDistribution` is an object consisting of parameters, a model description, and sample data for a loglogistic probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Loglogistic')` creates a loglogistic probability distribution object using the default parameter values.

`pd = makedist('Loglogistic', 'mu', mu, 'sigma', sigma)` creates a loglogistic probability distribution object using the specified parameter values .

Input Arguments

mu — Log mean

0 (default) | positive scalar value

Log mean for the loglogistic distribution, specified as a positive scalar value.

Data Types: `single` | `double`

sigma — Log scale parameter

1 (default) | positive scalar value

Log scale parameter for the loglogistic distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Properties

mu — Log mean

positive scalar value

Log mean for the loglogistic distribution, stored as a positive scalar value.

Data Types: `single` | `double`

sigma — Log scale parameter

positive scalar value

Log scale parameter for the loglogistic distribution, stored as a positive scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: single | double

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i, j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i, i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i, i) elements of the covariance matrix are 0. This property is read-only.

Data Types: single | double

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: char

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: logical

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single` | `double`**Truncation — Truncation interval**

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single` | `double`

Definitions

Loglogistic Distribution

The loglogistic distribution is closely related to the logistic distribution. If x is distributed loglogistically with parameters μ and σ , then $\log(x)$ is distributed logistically with mean and standard deviation. This distribution is often used in survival analysis to model events that experience an initial rate increase, followed by a rate decrease.

The loglogistic distribution uses the following parameters.

Parameter	Description	Support
mu	Log mean	$\mu > 0$
sigma	Log scale parameter	$\sigma > 0$

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{1}{\sigma} \frac{1}{x} \frac{e^z}{(1 + e^z)^2} ; \quad x \geq 0,$$

where $z = \frac{\log(x) - \mu}{\sigma}$.

Examples

Create a Loglogistic Distribution Object Using Default Parameters

Create a loglogistic distribution object using the default parameter values.

```
pd = makedist('Loglogistic')
```

```
pd =  
LoglogisticDistribution  
  
Log-Logistic distribution  
mu = 0  
sigma = 1
```

Create a Loglogistic Distribution Object Using Specified Parameters

Create a loglogistic distribution object by specifying the parameter values.

```
pd = makedist('Loglogistic','mu',5,'sigma',2)
```

```
pd =  
LoglogisticDistribution  
  
Log-Logistic distribution  
mu = 5  
sigma = 2
```

Generate random numbers from the loglogistic distribution and compute their log values.

```
rng(19) % for reproducibility  
x = random(pd,10000,1);  
logx = log(x);
```

Compute the mean of the log values.

```
m = mean(logx)
```

```
m =  
  
4.9828
```

The mean of the log of x is equal to the μ parameter of x , since x has a loglogistic distribution.

Plot `logx`.

```
histogram(logx,50)
```

The plot shows that the log values of x have a logistic distribution.

logncdf

Lognormal cumulative distribution function

Syntax

```
p = logncdf(x,mu,sigma)
[p,plo,pup] = logncdf(x,mu,sigma,pcov,alpha)
[p,plo,pup] = logncdf( __ , 'upper' )
```

Description

`p = logncdf(x,mu,sigma)` returns values at `x` of the lognormal cdf with distribution parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `x`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `x`, `mu`, or `sigma` is expanded to a constant array with the same dimensions as the other inputs.

`[p,plo,pup] = logncdf(x,mu,sigma,pcov,alpha)` returns confidence bounds for `p` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies $100(1 - \alpha)\%$ confidence bounds. The default value of `alpha` is 0.05. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p,plo,pup] = logncdf(__ , 'upper')` returns the complement of the lognormal cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use `'upper'` with any of the previous syntaxes.

`logncdf` computes confidence bounds for `p` using a normal approximation to the distribution of the estimate

$$\frac{x - \hat{\mu}}{\hat{\sigma}}$$

and then transforming those bounds to the scale of the output `p`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov`

from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The lognormal cdf is

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x \frac{e^{-\frac{(\ln(t)-\mu)^2}{2\sigma^2}}}{t} dt$$

Examples

Compute the Lognormal Distribution cdf

Compute the cdf of a lognormal distribution with `mu = 0` and `sigma = 1`.

```
x = (0:0.2:10);  
y = logncdf(x,0,1);
```

Plot the cdf.

```
plot(x,y);  
grid;  
xlabel('x');  
ylabel('p');
```

Introduced before R2006a

lognfit

Lognormal parameter estimates

Syntax

```
parmhat = lognfit(data)
[parmhat,parmci] = lognfit(data)
[parmhat,parmci] = lognfit(data,alpha)
[...] = lognfit(data,alpha,censoring)
[...] = lognfit(data,alpha,censoring,freq)
[...] = lognfit(data,alpha,censoring,freq,options)
```

Description

`parmhat = lognfit(data)` returns a vector of maximum likelihood estimates `parmhat(1) = mu` and `parmhat(2) = sigma` of parameters for a lognormal distribution fitting `data`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution.

`[parmhat,parmci] = lognfit(data)` returns 95% confidence intervals for the parameter estimates `mu` and `sigma` in the 2-by-2 matrix `parmci`. The first column of the matrix contains the lower and upper confidence bounds for parameter `mu`, and the second column contains the confidence bounds for parameter `sigma`.

`[parmhat,parmci] = lognfit(data,alpha)` returns $100(1 - \text{alpha})\%$ confidence intervals for the parameter estimates, where `alpha` is a value in the range (0 1) specifying the width of the confidence intervals. By default, `alpha` is 0.05, which corresponds to 95% confidence intervals.

`[...] = lognfit(data,alpha,censoring)` accepts a Boolean vector `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = lognfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

[...] = `lognfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates when there is censoring. The lognormal fit function accepts an `options` structure which can be created using the function `statset`. Enter `statset('lognfit')` to see the names and default values of the parameters that `lognfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

Note: With no censoring, `lognfit` computes `sigma` using the square root of the unbiased estimator of the variance. With censoring, `sigma` is the maximum likelihood estimate.

Examples

This example generates 100 independent samples of lognormally distributed data with $\mu = 0$ and $\sigma = 3$. `parmhat` estimates μ and σ and `parmci` gives 99% confidence intervals around `parmhat`. Notice that `parmci` contains the true values of μ and σ .

```
data = lognrnd(0,3,100,1);
[parmhat,parmci] = lognfit(data,0.01)
parmhat =
    -0.2480    2.8902
parmci =
    -1.0071    2.4393
     0.5111    3.5262
```

More About

- “Lognormal Distribution” on page B-100

`mle` | `lognlike` | `lognpdf` | `logncdf` | `logninv` | `lognstat` | `lognrnd`

Introduced before R2006a

logninv

Lognormal inverse cumulative distribution function

Syntax

```
X = logninv(P,mu,sigma)
[X,XLO,XUP] = logninv(P,mu,sigma,pcov,alpha)
```

Description

`X = logninv(P,mu,sigma)` returns values at `P` of the inverse lognormal cdf with distribution parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `P`, `mu`, or `sigma` is expanded to a constant array with the same dimensions as the other inputs.

`[X,XLO,XUP] = logninv(P,mu,sigma,pcov,alpha)` returns confidence bounds for `X` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies 100(1 - `alpha`)% confidence bounds. The default value of `alpha` is 0.05. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

`logninv` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\hat{\mu} + \hat{\sigma}q$$

where q is the P th quantile from a normal distribution with mean 0 and standard deviation 1. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The lognormal inverse function is defined in terms of the lognormal cdf as

$$x = F^{-1}(p | \mu, \sigma) = \{x : F(x | \mu, \sigma) = p\}$$

where

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x \frac{e^{-\frac{(\ln(t)-\mu)^2}{2\sigma^2}}}{t} dt$$

Examples

Compute the Lognormal Distribution Inverse cdf

Compute the inverse cdf of a lognormal distribution with $\mu = 0$ and $\sigma = 0.5$.

```
p = (0.005:0.01:0.995);  
crit = logninv(p,1,0.5);
```

Plot the inverse cdf.

```
figure;  
plot(p,crit)  
xlabel('Probability');  
ylabel('Critical Value');  
grid
```

More About

- “Lognormal Distribution” on page B-100

References

- [1] Evans, M., N. Hastings, and B. Peacock. *Statistical Distributions*. Hoboken, NJ: Wiley-Interscience, 2000. pp. 102–105.

See Also

`icdf` | `logncdf` | `lognpdf` | `lognstat` | `lognfit` | `lognlike` | `lognrnd`

Introduced before R2006a

lognlike

Lognormal negative log-likelihood

Syntax

```
nlogL = lognlike(params,data)
[nlogL,avar] = lognlike(params,data)
[...] = lognlike(params,data,censoring)
[...] = lognlike(params,data,censoring,freq)
```

Description

`nlogL = lognlike(params,data)` returns the negative log-likelihood of `data` for the lognormal distribution with parameters `params`. `params(1)` is the mean of the associated normal distribution, `mu`, and `params(2)` is the standard deviation of the associated normal distribution, `sigma`. The values of `mu` and `sigma` are scalars, and the output `nlogL` is a scalar.

`[nlogL,avar] = lognlike(params,data)` returns the inverse of Fisher's information matrix. If the input parameter value in `params` is the maximum likelihood estimate, `avar` is its asymptotic variance. `avar` is based on the observed Fisher's information, not the expected information.

`[...] = lognlike(params,data,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = lognlike(params,data,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. The vector `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `censoring` to use its default value.

prob.LognormalDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Lognormal probability distribution object

Description

`prob.LognormalDistribution` is an object consisting of parameters, a model description, and sample data for a lognormal probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Lognormal')` creates a lognormal probability distribution object using the default parameter values.

`pd = makedist('Lognormal', 'mu', mu, 'sigma', sigma)` creates a lognormal probability distribution object using the specified parameter values.

Input Arguments

mu — Log mean

0 (default) | scalar value

Log mean for the lognormal distribution, specified as a scalar value. `mu` is the mean of the log of x , when x has a lognormal distribution.

Data Types: `single` | `double`

sigma — Log standard deviation

1 (default) | nonnegative scalar value

Log standard deviation for the lognormal distribution, specified as a nonnegative scalar value. `sigma` is the standard deviation of the log of x , when x has a lognormal distribution.

Data Types: `single` | `double`

Properties

mu — Log mean

scalar value

Log mean for the lognormal distribution, stored as a scalar value.

Data Types: `single` | `double`

sigma — Log standard deviation

nonnegative scalar value

Log standard deviation for the lognormal distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i, j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i, i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i, i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Definitions

Lognormal Distribution

The lognormal distribution is closely related to the normal distribution. If x is distributed lognormally with parameters μ and σ , then $\log(x)$ is distributed normally with mean μ and standard deviation σ . The lognormal distribution is applicable when the quantity of interest must be positive, since $\log(x)$ exists only when x is positive.

The lognormal distribution uses the following parameters.

Parameter	Description	Support
mu	Log mean	$-\infty < \mu < \infty$
sigma	Log standard deviation	$\sigma \geq 0$

The probability density function (pdf) of the lognormal distribution is

$$f(x | \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} \exp\left\{-\frac{(\ln x - \mu)^2}{2\sigma^2}\right\} ; \quad x > 0.$$

Examples

Create a Lognormal Distribution Object Using Default Parameters

Create a lognormal distribution object using the default parameter values.

```
pd = makedist('Lognormal')
```

```
pd =  
  
LognormalDistribution  
  
Lognormal distribution  
  mu = 0  
  sigma = 1
```

Create a Lognormal Distribution Object Using Specified Parameters

Create a lognormal distribution object by specifying the parameter values.

```
pd = makedist('Lognormal', 'mu', 5, 'sigma', 2)
```

```
pd =  
  
LognormalDistribution  
  
Lognormal distribution  
  mu = 5  
  sigma = 2
```

Compute the mean of the lognormal distribution.

```
mean(pd)
```

```
ans =  
  
1.0966e+03
```

The mean of the lognormal distribution is not equal to the `mu` parameter.

Generate random numbers from the lognormal distribution and compute their log values.

```
rng(47); % for reproducibility
x = random(pd,10000,1);
logx = log(x);
```

Compute the mean of the log values.

```
m = mean(logx)
```

```
m =
```

```
5.0156
```

The mean of the log of `x` is equal to the `mu` parameter of `x`, since `x` has a lognormal distribution.

Plot `logx`.

```
histogram(logx,50)
```

The plot shows that the log values of x are normally distributed with a mean equal to 5 and a standard deviation equal to 2.

lognpdf

Lognormal probability density function

Syntax

`Y = lognpdf(X,mu,sigma)`

Description

`Y = lognpdf(X,mu,sigma)` returns values at `X` of the lognormal pdf with distribution parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `X`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X`, `mu`, or `sigma` is expanded to a constant array with the same dimensions as the other inputs.

The lognormal pdf is

$$y = f(x | \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{(\ln x - \mu)^2}{2\sigma^2}}$$

The normal and lognormal distributions are closely related. If X is distributed lognormally with parameters μ and σ , then $\log(X)$ is distributed normally with mean μ and standard deviation σ .

The mean m and variance v of a lognormal random variable are functions of μ and σ that can be calculated with the `lognstat` function. They are:

$$m = \exp\left(\mu + \sigma^2 / 2\right)$$
$$v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)$$

So, a lognormal distribution with mean m and variance v has parameters

$$\mu = \log\left(m^2 / \sqrt{v + m^2}\right)$$
$$\sigma = \sqrt{\log(v / m^2 + 1)}$$

If you do not know the population mean and variance, m and v , for the lognormal distribution, you can estimate μ and σ in the following way:

```
mu = mean(log(X))  
sigma = std(log(X))
```

The lognormal distribution is applicable when the quantity of interest must be positive, since $\log(X)$ exists only when X is positive.

Examples

Compute the Lognormal Distribution pdf

Compute the pdf of a lognormal distribution with `mu = 0` and `sigma = 1`.

```
x = (0:0.02:10);  
y = lognpdf(x,0,1);
```

Plot the pdf.

```
plot(x,y); grid;  
xlabel('x'); ylabel('p')
```

Introduced before R2006a

lognrnd

Lognormal random numbers

Syntax

```
R = lognrnd(mu, sigma)
R = lognrnd(mu, sigma, m, n, ...)
R = lognrnd(mu, sigma, [m, n, ...])
```

Description

`R = lognrnd(mu, sigma)` returns an array of random numbers generated from the lognormal distribution with parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

`R = lognrnd(mu, sigma, m, n, ...)` or `R = lognrnd(mu, sigma, [m, n, ...])` generates an `m`-by-`n`-by-... array. The `mu`, `sigma` parameters can each be scalars or arrays of the same size as `R`.

The normal and lognormal distributions are closely related. If X is distributed lognormally with parameters μ and σ , then $\log(X)$ is distributed normally with mean μ and standard deviation σ .

The mean m and variance v of a lognormal random variable are functions of μ and σ that can be calculated with the `lognstat` function. They are:

$$m = \exp\left(\mu + \frac{\sigma^2}{2}\right)$$
$$v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)$$

A lognormal distribution with mean m and variance v has parameters

$$\mu = \log\left(m^2 / \sqrt{v + m^2}\right)$$

$$\sigma = \sqrt{\log(v / m^2 + 1)}$$

Examples

Generate one million lognormally distributed random numbers with mean 1 and variance 2:

```
m = 1;
v = 2;
mu = log((m^2)/sqrt(v+m^2));
sigma = sqrt(log(v/(m^2)+1));

[M,V]= lognstat(mu,sigma)
M =
    1
V =
    2.0000

X = lognrnd(mu,sigma,1,1e6);

MX = mean(X)
MX =
    0.9974
VX = var(X)
VX =
    1.9776
```

lognstat

Lognormal mean and variance

Syntax

```
[M,V] = lognstat(mu,sigma)
```

Description

`[M,V] = lognstat(mu,sigma)` returns the mean of and variance of the lognormal distribution with parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

The normal and lognormal distributions are closely related. If X is distributed lognormally with parameters μ and σ , then $\log(X)$ is distributed normally with mean μ and standard deviation σ .

The mean m and variance v of a lognormal random variable are functions of μ and σ that can be calculated with the `lognstat` function. They are:

$$m = \exp(\mu + \sigma^2 / 2)$$
$$v = \exp(2\mu + \sigma^2)(\exp(\sigma^2) - 1)$$

A lognormal distribution with mean m and variance v has parameters

$$\mu = \log\left(m^2 / \sqrt{v + m^2}\right)$$
$$\sigma = \sqrt{\log(v / m^2 + 1)}$$

Examples

Generate one million lognormally distributed random numbers with mean 1 and variance 2:

```
m = 1;
v = 2;
mu = log((m^2)/sqrt(v+m^2));
sigma = sqrt(log(v/(m^2)+1));

logP

Class: CompactClassificationDiscriminant

Log unconditional probability density for discriminant analysis classifier

Syntax

$lp = \text{logP}(\text{obj}, X_{\text{new}})$

Description

$lp = \text{logP}(\text{obj}, X_{\text{new}})$ returns the log of the unconditional probability density of each row of X_{new} , computed using the discriminant analysis model obj .

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

X_{new}

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in X_{new} must equal the number of predictors in obj .

Output Arguments

lp

Column vector with the same number of rows as X_{new} . Each entry is the logarithm of the unconditional probability density of the corresponding row of X_{new} .

Definitions

Unconditional Probability Density

The unconditional probability density of a point x of a discriminant analysis model is

$$P(x) = \sum_{k=1}^K P(x, k),$$

where $P(x, k)$ is the conditional density of the model at x for class k , when the total number of classes is K .

The conditional density $P(x, k)$ is

$$P(x, k) = P(k)P(x | k),$$

where $P(k)$ is the prior probability of class k , and $P(x | k)$ is the conditional density of x given class k . The conditional density function of the multivariate normal with mean μ_k and covariance Σ_k at a point x is

$$P(x | k) = \frac{1}{(2\pi|\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^T \Sigma_k^{-1}(x - \mu_k)\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k , and Σ_k^{-1} is the inverse matrix.

Examples

Compute the Log Unconditional Probability Density of an Observation

Construct a discriminant analysis classifier for Fisher's iris data, and examine its prediction for an average measurement.

Load Fisher's iris data and construct a default discriminant analysis classifier.

```
load fisheriris
Mdl = fitcdiscr(meas, species);
```

Find the log probability of the discriminant model applied to an average iris.

```
logPAverage = logP(Mdl,mean(meas))
```

```
logPAverage =
```

```
-1.7254
```

logP

Class: CompactClassificationNaiveBayes

Log unconditional probability density for naive Bayes classifier

Syntax

```
lp = logP(Mdl, tbl)
```

```
lp = logP(Mdl, X)
```

Description

`lp = logP(Mdl, tbl)` returns the log unconditional probability density of the observations (rows) in `tbl` using the naive Bayes model `Mdl`.

You can use `lp` to identify outliers in the training data.

`lp = logP(Mdl, X)` returns the log unconditional probability density of the observations (rows) in `X` using the naive Bayes model `Mdl`.

Input Arguments

Mdl — Naive Bayes classifier

ClassificationNaiveBayes model | CompactClassificationNaiveBayes model

Naive Bayes classifier, specified as a ClassificationNaiveBayes model or CompactClassificationNaiveBayes model returned by `fitcnb` or `compact`, respectively.

tbl — Sample data

table

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain

all the predictors used to train Md1. Multi-column variables and cell arrays other than cell arrays of strings are not allowed.

If you trained Md1 using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: table

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of X must be the same as the variables that trained Md1.

Data Types: double | single

Output Arguments

lp — Log of unconditional probability density

numeric column vector

Log of the unconditional probability density of the predictors, returned as a numeric column vector. lp has as many elements as rows in X, and each element is the log probability density of the corresponding row in X.

If any rows in X contain at least one NaN, then the corresponding element of lp is NaN.

Definitions

Unconditional Probability Density

The *unconditional probability density* of the predictors is its distribution marginalized over the classes.

In other words, the unconditional probability density is

$$P(X_1, \dots, X_P) = \sum_{k=1}^K P(X_1, \dots, X_P, Y = k) = \sum_{k=1}^K P(X_1, \dots, X_P | y = k) \pi(Y = k),$$

where $\pi(Y = k)$ is the class prior probability. The conditional distribution of the data given the class ($P(X_1, \dots, X_P | y = k)$) and the class prior probability distributions are training options (i.e., are specified when training the classifier).

Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

Examples

Compute Unconditional Probability Densities of Observations

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```
Mdl = fitcnb(X, Y, 'ClassNames', {'setosa', 'versicolor', 'virginica'});
```

Mdl is a trained `ClassificationNaiveBayes` classifier.

Compute the unconditional probability densities of the in-sample observations.

```
lp = logP(Mdl, X);
histogram(lp)
xlabel 'Log-unconditional probability'
ylabel 'Frequency'
title 'Histogram: Log-Unconditional Probability'
```

Identify indices of observations having log-unconditional probability less than -7.

```
idx = find(lp < -7)
```

```
idx =
```

```
    61  
   118  
   132
```

loss

Class: ClassificationKNN

Loss of k -nearest neighbor classifier

Syntax

```
L = loss mdl, tbl, ResponseVarName
L = loss mdl, tbl, Y
L = loss mdl, X, Y
L = loss( ____, Name, Value)
```

Description

`L = loss(mdl, tbl, ResponseVarName)` returns a scalar representing how well `mdl` classifies the data in `tbl`, when `tbl.ResponseVarName` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `tbl.ResponseVarNames` to the class probabilities used for training, stored in the `Prior` property of `mdl`.

`L = loss(mdl, tbl, Y)` returns a scalar representing how well `mdl` classifies the data in `tbl`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `mdl`.

`L = loss(mdl, X, Y)` returns a scalar representing how well `mdl` classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `mdl`.

`L = loss(____, Name, Value)` returns the loss with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes.

Input Arguments

mdl — Classifier model

classifier model object

k -nearest neighbor classifier model, returned as a classifier model object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `mdl` is of class ClassificationKNN, and you can use the `predict` method to make predictions.

tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If `tbl` contains the response variable used to train `mdl`, then you do not need to specify `ResponseVarName` or `Y`.

If you trained `mdl` using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: table

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. If `tbl` contains the response variable used to train `mdl`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector. For example, if the response variable is stored as `tbl.response`, then specify it as `'response'`. Otherwise, the software treats all columns of `tbl`, including `tbl.response`, as predictors.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

X — Matrix of predictor values

matrix

Matrix of predictor values. Each column of **X** represents one variable, and each row represents one observation.

Y — Categorical variables

categorical array | cell array of character vectors | character array | logical vector | numeric vector

A categorical array, cell array of character vectors, character array, logical vector, or a numeric vector with the same number of rows as **X**. Each row of **Y** represents the classification of the corresponding row of **X**.

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

'LossFun' — Loss function

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of '**LOSSFUN**' and a built-in, loss-function name or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge

Value	Description
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. k -nearest neighbor models return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel mdl.ClassNames`). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `mdl.ClassNames`.

Construct C by setting $C(p,q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `mdl.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = ones(K) - eye(K)$ specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 25-3167.

Data Types: char | function_handle

'Weights' — Observation weights

ones(size(X,1),1) (default) | numeric vector | name of a variable in tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in `tbl`.

If you specify `Weights` as a vector, then the size of `Weights` must be equal to the number of rows of `X` or `tbl`.

If you specify `Weights` as the name of a variable in `tbl`, you must do so as a character vector, such as 'W'. For example, if the weights are stored as `tbl.w`, then specify it as 'w'. Otherwise, the software treats all columns of `tbl`, including `tbl.w`, as predictors.

`loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `Weights`, `loss` computes weighted classification loss.

Data Types: single | double

Output Arguments

L — Classification loss

scalar value

Classification loss, returned as a scalar value. The meaning of the error depends on the values in `weights` and `lossfun`.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When comparing the same type of loss among many models, lower loss indicates a better predictive model.

Suppose that:

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, and a 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^{*'} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

The supported loss functions are:

- Binomial deviance, specified using `'LossFun', 'binodeviance'`. Its equation is

$$L = \sum_{j=1}^n w_j \log \{1 + \exp[-2m_j]\}.$$

- Exponential loss, specified using 'LossFun', 'exponential'. Its equation is

$$L = \sum_{j=1}^n w_j \exp(-m_j).$$

- Classification error, specified using 'LossFun', 'classiferror'. It is the weighted fraction of misclassified observations, with equation

$$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$$

\hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.

- Hinge loss, specified using 'LossFun', 'hinge'. Its equation is

$$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$$

- Logit loss, specified using 'LossFun', 'logit'. Its equation is

$$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$$

- Minimal cost, specified using 'LossFun', 'mincost'. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$:

- 1 Estimate the 1-by- K vector of expected classification costs for observation j

$$\gamma_j = f(X_j)' C.$$

$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix the input model stores in the property **Cost**.

- 2 For observation j , predict the class label corresponding to the minimum, expected classification cost:

$$\hat{y}_j = \min_{j=1,\dots,K} (\gamma_j).$$

3 Using C , identify the cost incurred (c_j) for making the prediction.

The weighted, average, minimum cost loss is

$$L = \sum_{j=1}^n w_j c_j.$$

- Quadratic loss, specified using 'LossFun', 'quadratic'. Its equation is

$$L = \sum_{j=1}^n w_j (1 - m_j)^2.$$

This figure compares some of the loss functions for one observation over m (some functions are normalized to pass through $[0,1]$).

True Misclassification Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you run `fitcknn`. `Cost(i, j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i, j) = 1` if $i \neq j$, and `Cost(i, j) = 0` if $i = j$. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

Expected Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `Noobs` observations that you want to classify with a trained classifier `mdl`. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row. The command

```
[label,score,cost] = predict(mdl,Xnew)
```

returns, among other outputs, a `cost` matrix of size `Noobs`-by-`K`. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n,k)` is

$$\sum_{i=1}^K \hat{P}(i | Xnew(n))C(k | i),$$

where

- K is the number of classes.
- $\hat{P}(i | Xnew(n))$ is the posterior probability of class i for observation $Xnew(n)$.
- $C(k | i)$ is the true misclassification cost of classifying an observation as k when its true class is i .

Examples

Loss Calculation

Construct a k -nearest neighbor classifier for the Fisher iris data, where $k = 5$.

Load the data.

```
load fisheriris
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(meas,species,'NumNeighbors',5);
```

Examine the loss of the classifier for a mean observation classified 'versicolor'.

```
X = mean(meas);  
Y = {'versicolor'};  
L = loss(mdl,X,Y)
```

```
L =
```

```
0
```

The classifier has no doubt that 'versicolor' is the correct classification (all five nearest neighbors classify as 'versicolor').

loss

Class: ClassificationLinear

Classification loss for linear classification models

Syntax

```
L = loss(Mdl,X,Y)
```

```
L = loss( ___,Name,Value)
```

Description

`L = loss(Mdl,X,Y)` returns the classification losses for the binary, linear classification model `Mdl` using predictor data in `X` and corresponding class labels in `Y`. `L` contains classification error rates for each regularization strength in `Mdl`.

`L = loss(___,Name,Value)` uses any of the previous syntaxes and additional options specified by one or more `Name,Value` pair arguments. For example, you can specify that columns in the predictor data correspond to observations or specify the classification loss function.

Input Arguments

Mdl — Binary, linear classification model

ClassificationLinear model object

Binary, linear classification model, specified as a ClassificationLinear model object. You can create a ClassificationLinear model object using `fitclinear`.

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix. This orientation of `X` indicates that rows correspond to individual observations and columns correspond to individual predictor variables.

The length of `Y` and the number of observations in `X` must be equal.

Note: If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn'`, `'columns'`, then you might experience a significant reduction in computation time.

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

- The data type of `Y` must be the same `Mdl.ClassNames`.
- The distinct classes in `Y` must be a subset of `Mdl.ClassNames`.
- If `Y` is a character array, then each element must correspond to one row of the array.
- The length of `Y` and the number of observations in `X` must be equal.

Data Types: `categorical` | `cell` | `char` | `double` | `logical` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'LossFun' — Loss function

`'classiferror'` (default) | `'binodeviance'` | `'exponential'` | `'hinge'` | `'logit'` | `'mincost'` | `'quadratic'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector.

Value	Description
<code>'binodeviance'</code>	Binomial deviance

Value	Description
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. For linear classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see `predict`).

- Specify your own function using function handle notation.

Let n be the number of observations in X and K be the number of distinct classes (`numel(Mdl.ClassNames)`, Mdl is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.

- **Cost** is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

Data Types: char | function_handle

'ObservationsIn' — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of `'ObservationsIn'` and `'columns'` or `'rows'`.

Note: If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn', 'columns'`, then you might experience a significant reduction in optimization-execution time.

Data Types: char

'Weights' — Observation weights

numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values. If you supply weights, `loss` computes the weighted classification loss.

Let n be the number of observations in X .

- `numel(Weights)` must be n .
- By default, `Weights` is `ones(n,1)`.

`ClassificationLinear.loss` normalizes `Weights` to sum up to the value of the prior probability in the respective class.

Data Types: double | single

Output Arguments

L — Classification losses

numeric scalar | numeric row vector

Classification losses, returned as a numeric scalar or row vector. The interpretation of L depends on `Weights` and `LossFun`.

L is the same size as `Mdl.Lambda`. $L(j)$ is the classification loss of the linear classification model trained using the regularization strength `Mdl.Lambda(j)`.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When comparing the same type of loss among many models, lower loss indicates a better predictive model.

Suppose that:

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, and a 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.

- $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
- $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

The supported loss functions are:

- Binomial deviance, specified using `'LossFun', 'binodeviance'`. Its equation is

$$L = \sum_{j=1}^n w_j \log \{1 + \exp[-2m_j]\}.$$

- Exponential loss, specified using `'LossFun', 'exponential'`. Its equation is

$$L = \sum_{j=1}^n w_j \exp(-m_j).$$

- Classification error, specified using `'LossFun', 'classiferror'`. It is the weighted fraction of misclassified observations, with equation

$$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$$

\hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.

- Hinge loss, specified using `'LossFun', 'hinge'`. Its equation is

$$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$$

- Logit loss, specified using 'LossFun', 'logit'. Its equation is

$$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$$

- Minimal cost, specified using 'LossFun', 'mincost'. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$:

- 1 Estimate the 1-by- K vector of expected classification costs for observation j

$$\gamma_j = f(X_j)'C.$$

$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix the input model stores in the property `Cost`.

- 2 For observation j , predict the class label corresponding to the minimum, expected classification cost:

$$\hat{y}_j = \min_{j=1, \dots, K} (\gamma_j).$$

- 3 Using C , identify the cost incurred (c_j) for making the prediction.

The weighted, average, minimum cost loss is

$$L = \sum_{j=1}^n w_j c_j.$$

- Quadratic loss, specified using 'LossFun', 'quadratic'. Its equation is

$$L = \sum_{j=1}^n w_j (1 - m_j)^2.$$

This figure compares some of the loss functions for one observation over m (some functions are normalized to pass through $[0,1]$).

Examples

Estimate Test-Sample Classification Loss

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Specify to hold out 30% of the observations. Solve the objective function using SpaRSA.

```
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'Solver','sparsa','Holdout',0.30);
CMdl = CVMdl.Trained{1};
```

CVMdl is a `ClassificationPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `ClassificationLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Estimate the training- and test-sample classification error.

```
ceTrain = loss(CMdl,X(trainIdx,:),Ystats(trainIdx))
ceTest = loss(CMdl,X(testIdx,:),Ystats(testIdx))
```

```
ceTrain =
    1.3572e-04
```

```
ceTest =
    5.2804e-04
```

Because there is one regularization strength in `CMdl`, `ceTrain` and `ceTest` are numeric scalars.

Specify Custom Classification Loss

Load the NLP data set. Preprocess the data as in “Estimate Test-Sample Classification Loss”, and transpose the predictor data.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Train a binary, linear classification model. Specify to hold out 30% of the observations. Solve the objective function using `SparSA`. Specify that the predictor observations correspond to columns.

```
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'Solver','sparsa','Holdout',0.30,...
    'ObservationsIn','columns');
CMdl = CVMdl.Trained{1};
```

`CVMdl` is a `ClassificationPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `ClassificationLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Create an anonymous function that measures linear loss, that is,

$$L = \frac{\sum_j -w_j y_j f_j}{\sum_j w_j}.$$

w_j is the weight for observation j , y_j is response j (-1 for the negative class, and 1 otherwise), and f_j is the raw classification score of observation j . Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the `LossFun` name-value pair argument.

```
linearloss = @(C,S,W,Cost)sum(-W.*sum(S.*C,2))/sum(W);
```

Estimate the training- and test-sample classification loss using the linear loss function.

```
ceTrain = loss(CMd1,X(:,trainIdx),Ystats(trainIdx),'LossFun',linearloss,...  
              'ObservationsIn','columns')  
ceTest = loss(CMd1,X(:,testIdx),Ystats(testIdx),'LossFun',linearloss,...  
              'ObservationsIn','columns')
```

```
ceTrain =  
-7.8330
```

```
ceTest =  
-7.7383
```

Find Good Lasso Penalty Using Classification Loss

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample classification error rates.

Load the NLP data set. Preprocess the data as in “Specify Custom Classification Loss”.

```
load nlpdata  
Ystats = Y == 'stats';  
X = X';  
  
rng(10); % For reproducibility  
Partition = cvpartition(Ystats,'Holdout',0.30);  
testIdx = test(Partition);  
XTest = X(:,testIdx);  
YTest = Ystats(testIdx);
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6,-0.5,11);
```

Train binary, linear classification models that use each of the regularization strengths. Solve the objective function using SpARSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
CVMd1 = fitlinear(X,Ystats,'ObservationsIn','columns',...
```

```
'CVPartition',Partition,'Learner','logistic','Solver','sparsa',...
'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)
```

```
CVMD1 =
```

```
classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 1
  Partition: [1x1 cvpartition]
  ClassNames: [0 1]
  ScoreTransform: 'none'
```

Extract the trained linear classification model.

```
Mdl = CVMD1.Trained{1}
```

```
Mdl =
```

```
ClassificationLinear
  ResponseName: 'Y'
  ClassNames: [0 1]
  ScoreTransform: 'logit'
  Beta: [34023x11 double]
  Bias: [1x11 double]
  Lambda: [1x11 double]
  Learner: 'logistic'
```

`Mdl` is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl` as 11 models, one for each regularization strength in `Lambda`.

Estimate the test-sample classification error.

```
ce = loss(Mdl,X(:,testIdx),Ystats(testIdx),'ObservationsIn','columns');
```

Because there are 11 regularization strengths, `ce` is a 1-by-11 vector of classification error rates.

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model for each regularization strength using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...  
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...  
    'Lambda',Lambda,'GradientTolerance',1e-8);  
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the test-sample error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;  
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...  
    log10(Lambda),log10(numNZCoeff + 1));  
hL1.Marker = 'o';  
hL2.Marker = 'o';  
ylabel(h(1),'log_{10} classification error')  
ylabel(h(2),'log_{10} nonzero-coefficient frequency')  
xlabel('log_{10} Lambda')  
title('Test-Sample Statistics')  
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between 10^{-4} to 10^{-1} should suffice.

```
idxFinal = 7;
```

Select the model from Mdl with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Algorithms

By default, observation weights are prior class probabilities. If you supply weights using `Weights`, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to estimate the weighted classification loss.

`ClassificationLinear` | `fitclinear` | `predict`

Introduced in R2016a

loss

Class: CompactClassificationDiscriminant

Classification error

Syntax

`L = loss(obj,X,Y)`

`L = loss(obj,X,Y,Name,Value)`

Description

`L = loss(obj,X,Y)` returns the classification loss, which is a scalar representing how well `obj` classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `obj`.

`L = loss(obj,X,Y,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

obj

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

X

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `obj`.

Y

Class labels, with the same data type as exists in `obj`. The number of elements of `Y` must equal the number of rows of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'lossfun'

Built-in, loss-function name (character vector in the table) or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. Discriminant analysis models return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(Mdl.ClassNames)`). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).

- **C** is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct **C** by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- **S** is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. **S** is a matrix of classification scores, similar to the output of `predict`.
- **W** is an n -by-1 numeric vector of observation weights. If you pass **W**, the software normalizes them to sum to 1.
- **Cost** is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 25-3192.

Default: `'mincost'`

'weights'

Numeric vector of length N , where N is the number of rows of **X**. **weights** are nonnegative. `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply **weights**, `loss` computes weighted classification loss.

Default: `ones(N, 1)`

Output Arguments

L

Classification loss, a scalar. The interpretation of **L** depends on the values in **weights** and `lossfun`.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When comparing the same type of loss among many models, lower loss indicates a better predictive model.

Suppose that:

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, and a 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

The supported loss functions are:

- Binomial deviance, specified using 'LossFun', 'binodeviance'. Its equation is

$$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$$

- Exponential loss, specified using 'LossFun', 'exponential'. Its equation is

$$L = \sum_{j=1}^n w_j \exp(-m_j).$$

- Classification error, specified using 'LossFun', 'classiferror'. It is the weighted fraction of misclassified observations, with equation

$$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$$

\hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.

- Hinge loss, specified using 'LossFun', 'hinge'. Its equation is

$$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$$

- Logit loss, specified using 'LossFun', 'logit'. Its equation is

$$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$$

- Minimal cost, specified using 'LossFun', 'mincost'. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$:

- 1 Estimate the 1-by- K vector of expected classification costs for observation j

$$\gamma_j = f(X_j)'C.$$

$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix the input model stores in the property **Cost**.

- 2 For observation j , predict the class label corresponding to the minimum, expected classification cost:

$$\hat{y}_j = \min_{j=1, \dots, K}(\gamma_j).$$

- 3 Using C , identify the cost incurred (c_j) for making the prediction.

The weighted, average, minimum cost loss is

$$L = \sum_{j=1}^n w_j c_j.$$

- Quadratic loss, specified using 'LossFun', 'quadratic'. Its equation is

$$L = \sum_{j=1}^n w_j (1 - m_j)^2.$$

This figure compares some of the loss functions for one observation over m (some functions are normalized to pass through $[0,1]$).

Posterior Probability

The posterior probability that a point z belongs to class j is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean μ_j and covariance Σ_j at a point z is

$$P(x | k) = \frac{1}{(2\pi|\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^T \Sigma_k^{-1}(x - \mu_k)\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k , and Σ_k^{-1} is the inverse matrix.

Let $P(k)$ represent the prior probability of class k . Then the posterior probability that an observation x is of class k is

$$\hat{P}(k | x) = \frac{P(x | k)P(k)}{P(x)},$$

where $P(x)$ is a normalization constant, the sum over k of $P(x | k)P(k)$.

Prior Probability

The prior probability is one of three choices:

- 'uniform' — The prior probability of class k is one over the total number of classes.
- 'empirical' — The prior probability of class k is the number of training samples of class k divided by the total number of training samples.
- Custom — The prior probability of class k is the k th element of the `prior` vector. See `fitcdiscr`.

After creating a classifier `obj`, you can set the prior using dot notation:

```
obj.Prior = v;
```

where `v` is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

Cost

The matrix of expected costs per observation is defined in “Cost” on page 16-8.

Examples

Estimate Classification Error

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis model using all observations in the data.

```
Mdl = fitcdiscr(meas,species);
```

Estimate the classification error of the model using the training observations.

```
L = loss(Mdl,meas,species)
```

```
L =
```

```
    0.0200
```

Alternatively, if `Mdl` is not compact, then you can estimate the training-sample classification error by passing `Mdl` to `resubLoss`.

How To

- “Discriminant Analysis” on page 16-3

loss

Class: CompactClassificationECOC

Classification loss for error-correcting output code multiclass classifiers

Syntax

`L = loss(Mdl,tbl,ResponseVarName)`

`L = loss(Mdl,tbl,Y)`

`L = loss(Mdl,X,Y)`

`L = loss(____,Name,Value)`

Description

`L = loss(Mdl,tbl,ResponseVarName)` returns the classification loss (L), a scalar representing how well the trained error-correcting output code (ECOC) multiclass classifier `Mdl` classifies the predictor data (`tbl`) as compared to the true class labels (`ResponseVarName`). Each row of `tbl` and `ResponseVarName` is an observation.

`L = loss(Mdl,tbl,Y)` returns the classification loss (L), a scalar representing how well the trained error-correcting output code (ECOC) multiclass classifier `Mdl` classifies the predictor data (`tbl`) as compared to the true class labels (`Y`). Each row of `tbl` and `Y` is an observation.

`L = loss(Mdl,X,Y)` returns the classification loss (L), a scalar representing how well the trained error-correcting output code (ECOC) multiclass classifier `Mdl` classifies the predictor data (`X`) as compared to the true class labels (`Y`). Each row of `X` and `Y` is an observation.

`L = loss(____,Name,Value)` returns the classification loss with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can specify a decoding scheme, classification loss function, or verbosity level.

Input Arguments

Mdl — ECOC multiclass classifier

ClassificationECOC model object | CompactClassificationECOC model object

ECOC multiclass classifier, specified as a `ClassificationECOC` or `CompactClassificationECOC` model object.

To create a full or compact ECOC model, see `ClassificationECOC` or `CompactClassificationECOC`.

tbl — Sample data

table

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all the predictors used to train `Mdl`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `Mdl` using sample data contained in a `table`, then the input data for this method must also be in a table.

Note: If `Mdl.BinaryLearners` contains linear classification models (that is, `ClassificationLinear` model objects), then you cannot specify sample data in a `table`. Instead, pass a full or sparse matrix (`X`) and class labels (`Y`).

Data Types: `table`

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a character vector. For example, if the response variable `y` is stored as `tbl.y`, then specify it as `'y'`. Otherwise, the software treats all columns of `tbl`, including `y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation, and each column corresponds to one variable. The variables composing the columns of X should be the same as the variables that trained the `Mdl` classifier.

The length of Y and the number of rows of X must be equal.

Data Types: double | single

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Y must be the same as the data type of `Mdl.ClassNames`.

The length of Y and the number of rows of X must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'BinaryLoss' — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge'
| 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_i, s_i)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_i s_i)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_i s_i) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_i s_i)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_i s_i) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_i s_i) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_i s_i)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_i (2s_i - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss', @customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 25-4317.

By default, if all binary learners are:

- SVMs or linear classification models of SVM learners, then `BinaryLoss` is `'hinge'`

- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is `'exponential'`
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is `'binodeviance'`
- Linear classification models of logistic regression learners, or you specify to predict class posterior probabilities (i.e., set `'FitPosterior', 1` in `fitcecoc`), then `BinaryLoss` is `'quadratic'`

Otherwise, the default `BinaryLoss` is `'hamming'`. To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss', 'binodeviance'`

Data Types: `char` | `function_handle`

'Decoding' — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the “Binary Loss” on page 25-4314, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`.

Example: `'Decoding', 'lossbased'`

Data Types: `char`

'LossFun' — Loss function

`'classiferror'` (default) | `function handle`

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a function handle or `'classiferror'`.

You can:

- Specify the built-in function `'classiferror'` for classification error, i.e., the proportion of misclassified observations.
- Specify your own function using function handle notation.

Suppose that $n = \text{size}(X, 1)$ is the sample size and k is the number of classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).

- **C** is an n -by- k logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct **C** by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- **S** is an n -by- k numeric matrix of negated loss values for classes. Each row corresponds to an observation. The column order corresponds to the class order in `Mdl.ClassNames`. **S** resembles the output argument `NegLoss` of `predict`.
- **W** is an n -by-1 numeric vector of observation weights. If you pass **W**, the software normalizes its elements to sum to 1.
- **Cost** is a k -by- k numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

Data Types: `function_handle` | `char`

'ObservationsIn' — Predictor data observation dimension

`'rows'` (default) | `'columns'`

Predictor data observation dimension, specified as the comma-separated pair consisting of `'ObservationsIn'` and `'columns'` or `'rows'`. `Mdl.BinaryLearners` must contain linear classification models.

Note: If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn', 'columns'`, then you might experience a significant reduction in execution time.

Data Types: `char`

'Options' — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. `Verbose` controls the amount of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

'Weights' — Observation weights`ones(size(X,1))` (default) | numeric vector | name of a variable in `tbl`

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in `tbl`. If you supply weights, then `loss` computes the weighted loss.

`Weights` requires the same length as the number of observations in `X` or `tbl`.

If you specify `Weights` as the name of a variable in `tbl`, you must do so as a character vector. For example, if the weights are stored as `tbl.w`, then specify it as 'w'. Otherwise, the software treats all columns of `tbl`, including `tbl.w`, as predictors.

If you do not specify your own loss function (using `LossFun`), then the software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

If `Mdl.BinaryLearners` contains linear classification models, then you must specify a vector.

Output Arguments

L — Classification loss

numeric scalar | numeric row vector

Classification loss, returned as a numeric scalar or row vector. L is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

If `Mdl.BinaryLearners` contains linear classification models, then L is a 1-by- ℓ vector, where ℓ is the number of regularization strengths in the linear classification models (i.e., `numel(Mdl.BinaryLearners{1}.Lambda)`). $L(j)$ is the loss for the model trained using regularization strength `Mdl.BinaryLearners{1}.Lambda(j)`.

Otherwise, L is a scalar.

Definitions

Classification Error

The *classification error* is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- w_j is the weight for observation j . The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, it is the proportion of observations that the classifier misclassifies.

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$

Value	Description	Score Domain	$g(y_j, s_j)$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j)/2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of predict and loss), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Examples

Determine the Test Sample Loss of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers, and specify a 15% holdout sample. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'Holdout',0.15,'Learners',t,'ClassNames',classOrder);
CMdl = CVMdl.Trained{1}; % Extract trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVMdl is a ClassificationPartitionedECOC model. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationECOC model that the software trained using the training set.

Estimate the test-sample loss.

```
L = loss(CMdl,XTest,YTest)
```

```
L =  
    0
```

The ECOC model correctly classifies all out-of-sample irises.

Determine ECOC Model Quality Using a Custom Loss

Suppose that it is interesting to know how well a model classifies a particular class. This example shows how to pass such a custom loss function to `loss`.

Load Fisher's iris data set.

```
load fisheriris  
X = meas;  
Y = categorical(species);  
n = numel(Y); % Sample size  
classOrder = unique(Y) % Class order  
K = numel(classOrder); % Number of classes  
rng(1) % For reproducibility
```

```
classOrder =  
  
    setosa  
    versicolor  
    virginica
```

Train an ECOC model using SVM binary classifiers and specifying a 15% holdout sample. It is good practice to define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);  
CVMdl = fitcecoc(X,Y,'Holdout',0.15,'Learners',t,'ClassNames',classOrder);  
CMdl = CVMdl.Trained{1}; % Extract trained, compact classifier  
testInds = test(CVMdl.Partition); % Extract the test indices  
XTest = X(testInds,:);  
YTest = Y(testInds,:);
```

`CVMD1` is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

Compute the negated losses for the test-sample observations.

```
[~,negLoss] = predict(CMD1,XTest);
```

Create a function that takes the minimal loss for each observation, and then averages the minimal losses across all observations.

```
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Compute the test-sample custom loss.

```
loss(CMD1,XTest,YTest,'LossFun',lossfun)
```

```
ans =
```

```
0.0033
```

The average, minimal, binary loss in the test sample is 0.0033.

- “Quick Start Parallel Computing for Statistics and Machine Learning Toolbox” on page 24-2

Algorithms

If you trained `Mdl` specifying to standardize the predictor data, then the software standardizes the columns of `X` using the corresponding means and standard deviations that the software stored in `Mdl.BinaryLearner{j}.Mu` and `Mdl.BinaryLearner{j}.Sigma` for learner `j`.

loss

Class: CompactClassificationEnsemble

Classification error

Syntax

`L = loss(ens, tbl, ResponseVarName)`

`L = loss(ens, tbl, Y)`

`L = loss(ens, X, Y)`

`L = loss(____, Name, Value)`

Description

`L = loss(ens, tbl, ResponseVarName)` returns the classification error for ensemble `ens` computed using table of predictors `tbl` and true class labels `tbl.ResponseVarName`.

`L = loss(ens, tbl, Y)` returns the classification error for ensemble `ens` computed using table of predictors `tbl` and true class labels `Y`.

`L = loss(ens, X, Y)` returns the classification error for ensemble `ens` computed using matrix of predictors `X` and true class labels `Y`.

`L = loss(____, Name, Value)` computes classification error with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes.

When computing the loss, `loss` normalizes the class probabilities in `ResponseVarName` or `Y` to the class probabilities used for training, stored in the `Prior` property of `ens`.

Input Arguments

ens

Classification ensemble created with `fitensemble`, or a compact classification ensemble created with `compact`.

tbl

Sample data, specified as a table. Each row of **tbl** corresponds to one observation, and each column corresponds to one predictor variable. **tbl** must contain all of the predictors used to train the model. Multi-column variables and cell arrays other than cell arrays of strings are not allowed.

If you trained **ens** using sample data contained in a **table**, then the input data for this method must also be in a table.

ResponseVarName

Response variable name, specified as the name of a variable in **tbl**. The response variable must be a numeric vector.

You must specify **ResponseVarName** as a string. For example, if the response variable **Y** is stored as **tbl.Y**, then specify it as **'Y'**. Otherwise, the software treats all columns of **tbl**, including **Y**, as predictors when training the model.

X

Matrix of data to classify. Each row of **X** represents one observation, and each column represents one predictor. **X** must have the same number of columns as the data used to train **ens**. **X** should have the same number of rows as the number of elements in **Y**.

If you trained **ens** using sample data contained in a matrix, then the input data for this method must also be in a matrix.

Y

Classification of **tbl** or **X**. **Y** should be of the same type as the classification used to train **ens**, and its number of elements should equal the number of rows of **tbl** or **X**.

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

'learners'

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `loss` uses only these learners for calculating loss.

Default: `1:NumTrained`

'lossfun'

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities.

- Bagged and subspace ensembles return posterior probabilities by default (`ens.Method` is `'Bag'` or `'Subspace'`).
- If the ensemble method is `'AdaBoostM1'`, `'AdaBoostM2'`, `GentleBoost`, or `'LogitBoost'`, then, to use posterior probabilities as classification scores, you must specify the double-logit score transform by entering

```
ens.ScoreTransform = 'doublelogit';
```
- For all other ensemble methods, the software does not support posterior probabilities as classification scores.
- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(ens.ClassNames)`), `ens` is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- `C` is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `ens.ClassNames`.

Construct `C` by setting $C(p,q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- `S` is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `ens.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
- `W` is an n -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to 1.
- `Cost` is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun',@lossfun`.

For more details on loss functions, see “Classification Loss” on page 25-3215.

Default: `'classiferror'`

'mode'

String representing the meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element J is obtained by using learners $1:J$ from the input list of learners.

Default: 'ensemble'

'UseObsForLearner'

A logical matrix of size N-by-T, where:

- N is the number of rows of X.
- T is the number of weak learners in `ens`.

When `UseObsForLearner(i, j)` is true, learner `j` is used in predicting the class of row `i` of X.

Default: `true(N, T)`

'weights'

Vector of observation weights, with nonnegative entries. The length of `weights` must equal the number of rows in X. When you specify `weights`, `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class.

Default: `ones(size(X, 1), 1)`

Output Arguments

L

Classification loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When comparing the same type of loss among many models, lower loss indicates a better predictive model.

Suppose that:

- L is the weighted average classification loss.
- n is the sample size.

- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, and a 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

The supported loss functions are:

- Binomial deviance, specified using `'LossFun', 'binodeviance'`. Its equation is

$$L = \sum_{j=1}^n w_j \log \{1 + \exp[-2m_j]\}.$$

- Exponential loss, specified using `'LossFun', 'exponential'`. Its equation is

$$L = \sum_{j=1}^n w_j \exp(-m_j).$$

- Classification error, specified using 'LossFun', 'classiferror'. It is the weighted fraction of misclassified observations, with equation

$$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$$

\hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.

- Hinge loss, specified using 'LossFun', 'hinge'. Its equation is

$$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$$

- Logit loss, specified using 'LossFun', 'logit'. Its equation is

$$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$$

- Minimal cost, specified using 'LossFun', 'mincost'. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$:

- 1 Estimate the 1-by- K vector of expected classification costs for observation j

$$\gamma_j = f(X_j)'C.$$

$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix the input model stores in the property **Cost**.

- 2 For observation j , predict the class label corresponding to the minimum, expected classification cost:

$$\hat{y}_j = \min_{j=1,\dots,K} (\gamma_j).$$

3 Using C , identify the cost incurred (c_j) for making the prediction.

The weighted, average, minimum cost loss is

$$L = \sum_{j=1}^n w_j c_j.$$

- Quadratic loss, specified using 'LossFun', 'quadratic'. Its equation is

$$L = \sum_{j=1}^n w_j (1 - m_j)^2.$$

This figure compares some of the loss functions for one observation over m (some functions are normalized to pass through $[0,1]$).

Examples

Estimate Classification Error

Load Fisher's iris data set.

```
load fisheriris
```

Boost 100 classification trees using AdaBoostM2.

```
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
```

Estimate the classification error of the model using the training observations.

```
L = loss(ens, meas, species)
```

```
L =
```

```
0.0333
```

Alternatively, if `ens` is not compact, then you can estimate the training-sample classification error by passing `ens` to `resubLoss`.

loss

Class: CompactClassificationNaiveBayes

Classification error for naive Bayes classifier

Syntax

`L = loss(Mdl, tbl, ResponseVarName)`

`L = loss(Mdl, tbl, Y)`

`L = loss(Mdl, X, Y)`

`L = loss(____, Name, Value)`

Description

`L = loss(Mdl, tbl, ResponseVarName)` returns the minimum misclassification cost (see “Classification Loss” on page 25-3225), a scalar representing how well the trained naive Bayes classifier `Mdl` classifies the predictor data in table `tbl` as compared to the true class labels in `tbl.ResponseVarName`.

`loss` normalizes the class probabilities in `tbl.ResponseVarName` to the prior class probabilities `fitcnb` used for training, stored in the `Prior` property of `Mdl`.

`L = loss(Mdl, tbl, Y)` returns the minimum misclassification cost loss (L), a scalar representing how well the trained naive Bayes classifier `Mdl` classifies the predictor data in table `tbl` as compared to the true class labels in `Y`.

`loss` normalizes the class probabilities in `Y` to the prior class probabilities `fitcnb` used for training, stored in the `Prior` property of `Mdl`.

`L = loss(Mdl, X, Y)` returns the minimum misclassification cost loss (L), a scalar representing how well the trained naive Bayes classifier `Mdl` classifies the predictor data (X) as compared to the true class labels (Y).

`loss` normalizes the class probabilities in `Y` to the prior class probabilities `fitcnb` used for training, stored in the `Prior` property of `Mdl`.

`L = loss(____, Name, Value)` returns the classification loss with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes.

Input Arguments

Mdl — Naive Bayes classifier

`ClassificationNaiveBayes model` | `CompactClassificationNaiveBayes model`

Naive Bayes classifier, specified as a `ClassificationNaiveBayes model` or `CompactClassificationNaiveBayes model` returned by `fitcnb` or `compact`, respectively.

tbl — Sample data

`table`

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all the predictors used to train `Mdl`. Multi-column variables and cell arrays other than cell arrays of strings are not allowed.

If you trained `Mdl` using sample data contained in a `table`, then the input data for this method must also be in a table.

Data Types: `table`

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a string. For example, if the response variable `y` is stored as `tbl.y`, then specify it as `'y'`. Otherwise, the software treats all columns of `tbl`, including `y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of strings. If the response variable is a character array, then each element must correspond to one row of the array.

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of X should be the same as the variables that trained `Mdl`.

The length of Y and the number of rows of X must be equal.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. Y must be the same as the data type of `Mdl.ClassNames`.

The length of Y and the number of rows of `tbl` or X must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'LossFun' — Loss function

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LOSSFUN' and a built-in, loss-function name or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge

Value	Description
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. Naive Bayes models return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(Mdl.ClassNames)`, Mdl is the input model). Your function must have this signature

`lossvalue = lossfun(C,S,W,Cost)`

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct C by setting $C(p,q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun',@lossfun`.

For more details on loss functions, see “Classification Loss” on page 25-3225.

Data Types: char | function_handle

'Weights' — Observation weights

ones(size(X,1),1) (default) | numeric vector | name of a variable in tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in `tbl`. The software weighs the observations in each row of `X` or `tbl` with the corresponding weight in `Weights`.

If you specify `Weights` as a vector, then the size of `Weights` must be equal to the number of rows of `X` or `tbl`.

If you specify `Weights` as the name of a variable in `tbl`, you must do so as a string. For example, if the weights are stored as `tbl.w`, then specify it as 'w'. Otherwise, the software treats all columns of `tbl`, including `tbl.w`, as predictors.

If you do not specify your own loss function, then the software normalizes `Weights` to add up to 1.

Data Types: double

Output Arguments

L — Classification loss

scalar

Classification loss, returned as a scalar. `L` is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When comparing the same type of loss among many models, lower loss indicates a better predictive model.

Suppose that:

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, and a 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^{*'} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

The supported loss functions are:

- Binomial deviance, specified using `'LossFun', 'binodeviance'`. Its equation is

$$L = \sum_{j=1}^n w_j \log \{1 + \exp[-2m_j]\}.$$

- Exponential loss, specified using 'LossFun', 'exponential'. Its equation is

$$L = \sum_{j=1}^n w_j \exp(-m_j).$$

- Classification error, specified using 'LossFun', 'classiferror'. It is the weighted fraction of misclassified observations, with equation

$$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$$

\hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.

- Hinge loss, specified using 'LossFun', 'hinge'. Its equation is

$$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$$

- Logit loss, specified using 'LossFun', 'logit'. Its equation is

$$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$$

- Minimal cost, specified using 'LossFun', 'mincost'. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$:

- 1 Estimate the 1-by- K vector of expected classification costs for observation j

$$\gamma_j = f(X_j)' C.$$

$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix the input model stores in the property `Cost`.

- 2 For observation j , predict the class label corresponding to the minimum, expected classification cost:

$$\hat{y}_j = \min_{j=1,\dots,K} (\gamma_j).$$

3 Using C , identify the cost incurred (c_j) for making the prediction.

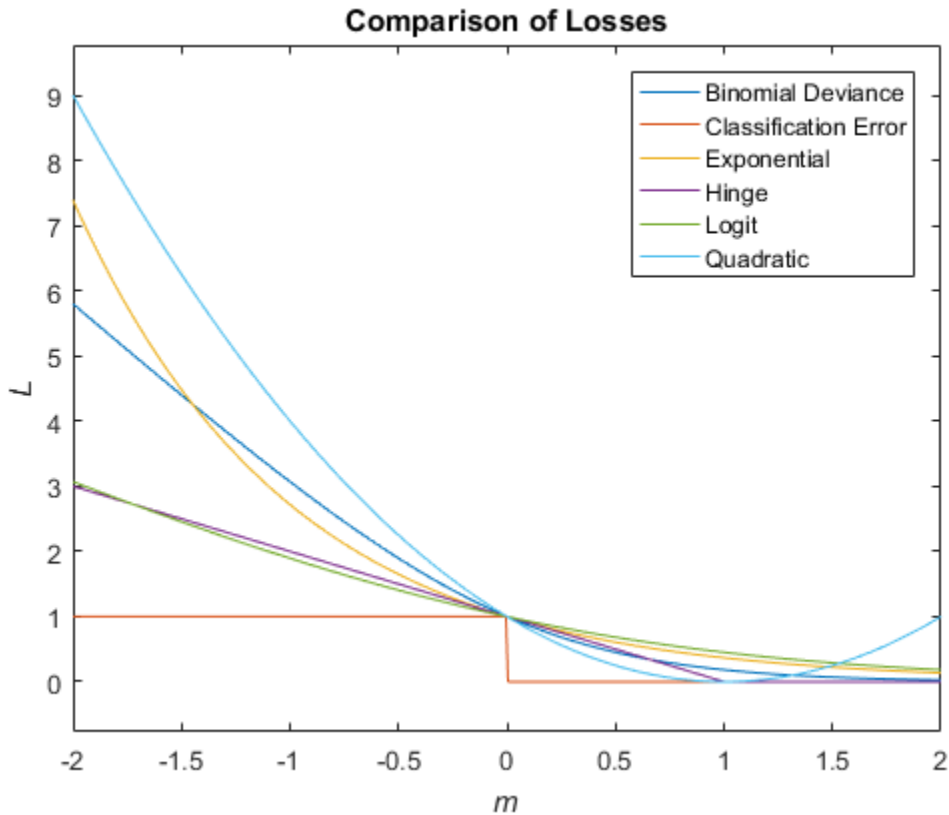

The weighted, average, minimum cost loss is

$$L = \sum_{j=1}^n w_j c_j.$$

- Quadratic loss, specified using 'LossFun', 'quadratic'. Its equation is

$$L = \sum_{j=1}^n w_j (1 - m_j)^2.$$

This figure compares some of the loss functions for one observation over m (some functions are normalized to pass through $[0,1]$).

Misclassification Cost

A *misclassification cost* is the relative severity of a classifier labeling an observation into the wrong class.

There are two types of misclassification costs: true and expected. Let K be the number of classes.

- *True misclassification cost* — A K -by- K matrix, where element (i,j) indicates the misclassification cost of predicting an observation into class j if its true class is i . The software stores the misclassification cost in the property `Mdl.Cost`, and used in computations. By default, `Mdl.Cost(i, j) = 1` if $i \neq j$, and `Mdl.Cost(i, j) = 0` if

$i = j$. In other words, the cost is 0 for correct classification, and 1 for any incorrect classification.

- *Expected misclassification cost* — A K -dimensional vector, where element k is the weighted average misclassification cost of classifying an observation into class k , weighted by the class posterior probabilities. In other words,

$$c_k = \sum_{j=1}^K \hat{P}(Y = j | x_1, \dots, x_P) \text{Cost}_{jk}.$$

the software classifies observations to the class corresponding with the lowest expected misclassification cost.

Posterior Probability

The *posterior probability* is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_P) is

$$\hat{P}(Y = k | x_1, \dots, x_P) = \frac{P(X_1, \dots, X_P | y = k) \pi(Y = k)}{P(X_1, \dots, X_P)},$$

where:

- $P(X_1, \dots, X_P | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_P)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_P) = \sum_{k=1}^K P(X_1, \dots, X_P | y = k) \pi(Y = k).$$

Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

Examples

Determine Test Sample Minimum Cost Loss of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;      % Predictors
Y = species;  % Response
rng(1);       % For reproducibility
```

Train a naive Bayes classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```
CVMdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'},...
    'Holdout',0.15);
CMD1 = CVMdl.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
```

CVMdl is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample minimum cost loss.

```
L = loss(CMD1,XTest,YTest)
```

```
L =
```

```
0.0476
```

The test sample average classification cost is approximately 0.05.

You might improve the classification error by specifying better predictor distributions when you train the classifier.

Determine the Test Sample Classification Error of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1); % For reproducibility
```

Train a naive Bayes classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```
CVMD1 = fitcnb(X,Y, 'ClassNames', {'setosa', 'versicolor', 'virginica'}, ...
    'Holdout', 0.15);
CMdl = CVMD1.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVMD1.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
```

CVMD1 is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample classification error.

```
L = loss(CMdl,XTest,YTest, 'LossFun', 'classiferror')
```

```
L =
    0.0476
```

The classifier misclassified approximately 5% of the test sample observations.

loss

Class: CompactClassificationSVM

Classification error for support vector machine classifiers

Syntax

`L = loss(SVMModel, TBL, ResponseVarName)`

`L = loss(SVMModel, TBL, Y)`

`L = loss(SVMModel, X, Y)`

`L = loss(____, Name, Value)`

Description

`L = loss(SVMModel, TBL, ResponseVarName)` returns the classification error (see “Classification Loss” on page 25-3239), a scalar representing how well the trained support vector machine (SVM) classifier `SVMModel` classifies the predictor data in table `TBL` as compared to the true class labels in `TBL.ResponseVarName`.

`loss` normalizes the class probabilities in `TBL.ResponseVarName` to the prior class probabilities `fitcsvm` used for training, stored in the `Prior` property of `SVMModel`.

`L = loss(SVMModel, TBL, Y)` returns the classification error for the predictor data in table `TBL` and the true class labels in `Y`.

`loss` normalizes the class probabilities in `Y` to the prior class probabilities `fitcsvm` used for training, stored in the `Prior` property of `SVMModel`.

`L = loss(SVMModel, X, Y)` returns the classification error based on the predictor data in matrix `X` as compared to the true class labels in `Y`.

`L = loss(____, Name, Value)` returns the classification error with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes. For example, you can specify the loss function or classification weights.

Input Arguments

SVMMODEL — SVM classifier

`ClassificationSVM classifier` | `CompactClassificationSVM classifier`

SVM classifier, specified as a `ClassificationSVM classifier` or `CompactClassificationSVM classifier` returned by `fitCSVM` or `compact`, respectively.

TBL — Sample data

`table`

Sample data, specified as a table. Each row of `TBL` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `TBL` can contain additional columns for the response variable and observation weights. `TBL` must contain all of the predictors used to train `SVMMODEL`. Multi-column variables and cell arrays other than cell arrays of strings are not allowed.

If `TBL` contains the response variable used to train `SVMMODEL`, then you do not need to specify `ResponseVarName` or `Y`.

If you trained `SVMMODEL` using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: `table`

ResponseVarName — Response variable name

name of a variable in `TBL`

Response variable name, specified as the name of a variable in `TBL`.

You must specify `ResponseVarName` as a string. For example, if the response variable `Y` is stored as `TBL.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `TBL`, including `Y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of strings. If the response variable is a character array, then each element must correspond to one row of the array.

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` must be the same as the variables that trained the `SVMModel` classifier.

The length of `Y` and the number of rows of `X` must be equal.

If you set `'Standardize', true` in `fitcsvm` to train `SVMModel`, then the software standardizes the columns of `X` using the corresponding means in `SVMModel.Mu` and standard deviations in `SVMModel.Sigma`.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. `Y` must be the same as the data type of `SVMModel.ClassNames`.

The length of `Y` must equal the number of rows of `TBL` or `X` must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'LossFun' — Loss function

`'classiferror'` (default) | `'binodeviance'` | `'exponential'` | `'hinge'` | `'logit'` | `'mincost'` | `'quadratic'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector.

Value	Description
<code>'binodeviance'</code>	Binomial deviance

Value	Description
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. You can specify to use posterior probabilities as classification scores for SVM models by setting 'FitPosterior', true when you cross-validate the model using `fitcsvm`.

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(SVMModel.ClassNames)`, `SVMModel` is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
where:
```

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `SVMModel.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `SVMModel.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.

- `Cost` is a K-by-K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 25-3239.

Data Types: `char` | `function_handle`

'Weights' — Observation weights

`ones(size(X,1),1)` (default) | numeric vector | name of a variable in TBL

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector or the name of a variable in TBL. The software weighs the observations in each row of `X` or TBL with the corresponding weight in `Weights`.

If you specify `Weights` as a vector, then the size of `Weights` must be equal to the number of rows of `X` or TBL.

If you specify `Weights` as the name of a variable in TBL, you must do so as a string. For example, if the weights are stored as `TBL.W`, then specify it as `'W'`. Otherwise, the software treats all columns of TBL, including `TBL.W`, as predictors.

If you do not specify your own loss function, then the software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

Data Types: `single` | `double`

Output Arguments

L — Classification loss

scalar

Classification loss, returned as a scalar. `L` is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When comparing the same type of loss among many models, lower loss indicates a better predictive model.

Suppose that:

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, and a 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

The supported loss functions are:

- Binomial deviance, specified using 'LossFun', 'binodeviance'. Its equation is

$$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$$

- Exponential loss, specified using 'LossFun', 'exponential'. Its equation is

$$L = \sum_{j=1}^n w_j \exp(-m_j).$$

- Classification error, specified using 'LossFun', 'classiferror'. It is the weighted fraction of misclassified observations, with equation

$$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$$

\hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.

- Hinge loss, specified using 'LossFun', 'hinge'. Its equation is

$$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$$

- Logit loss, specified using 'LossFun', 'logit'. Its equation is

$$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$$

- Minimal cost, specified using 'LossFun', 'mincost'. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$:

- 1 Estimate the 1-by- K vector of expected classification costs for observation j

$$\gamma_j = f(X_j)'C.$$

$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix the input model stores in the property **Cost**.

- 2 For observation j , predict the class label corresponding to the minimum, expected classification cost:

$$\hat{y}_j = \min_{j=1, \dots, K}(\gamma_j).$$

- 3 Using C , identify the cost incurred (c_j) for making the prediction.

The weighted, average, minimum cost loss is

$$L = \sum_{j=1}^n w_j c_j.$$

- Quadratic loss, specified using 'LossFun', 'quadratic'. Its equation is

$$L = \sum_{j=1}^n w_j (1 - m_j)^2.$$

This figure compares some of the loss functions for one observation over m (some functions are normalized to pass through [0,1]).

Score

The SVM *classification score* for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class, a negative score indicates otherwise.

The score for predicting x into the positive class, also the numerical, predicted response for x , $f(x)$, is the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The score for predicting x into the negative class is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x / s)' \beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

Examples

Determine the Test Sample Classification Error of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVSVMModel` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample classification error.

```
L = loss(CompactSVMModel,XTest,YTest)
```

```
L =
```

```
0.0787
```

The SVM classifier misclassifies approximately 8% of the test sample radar returns.

Determine the Test Sample Hinge Loss of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVSVMModel` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample hinge loss.

```
L = loss(CompactSVMModel,XTest,YTest,'LossFun','Hinge')
```

```
L =
```

```
0.2998
```

The hinge loss is approximately 0.3. Classifiers with hinge losses close to 0 are desirable.

loss

Class: CompactClassificationTree

Classification error

Syntax

```
L = loss(tree, TBL, ResponseVarName)
```

```
L = loss(tree, TBL, Y)
```

```
L = loss(tree, X, Y)
```

```
L = loss( ____, Name, Value)
```

```
[L, se, NLeaf, bestlevel] = loss( ____ )
```

Description

`L = loss(tree, TBL, ResponseVarName)` returns a scalar representing how well `tree` classifies the data in `TBL`, when `TBL.ResponseVarName` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `tree`.

`L = loss(tree, TBL, Y)` returns a scalar representing how well `tree` classifies the data in `TBL`, when `Y` contains the true classifications.

`L = loss(tree, X, Y)` returns a scalar representing how well `tree` classifies the data in `X`, when `Y` contains the true classifications.

`L = loss(____, Name, Value)` returns the loss with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes. For example, you can specify the loss function or observation weights.

`[L, se, NLeaf, bestlevel] = loss(____)` also returns the vector of standard errors of the classification errors (`se`), the vector of numbers of leaf nodes in the trees of the

pruning sequence (`NLeaf`), and the best pruning level as defined in the `TreeSize` name-value pair (`bestlevel`).

Note: `loss` returns `se` and further outputs only when the `LossFun` name-value pair is the default `'classiferror'`.

Input Arguments

tree — Trained classification tree

`ClassificationTree` model object | `CompactClassificationTree` model object

Trained classification tree, specified as a `ClassificationTree` or `CompactClassificationTree` model object. That is, `tree` is a trained classification model returned by `fitctree` or `compact`.

TBL — Sample data

`table`

Sample data, specified as a table. Each row of `TBL` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `TBL` can contain additional columns for the response variable and observation weights. `TBL` must contain all the predictors used to train `tree`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If `TBL` contains the response variable used to train `tree`, then you do not need to specify `ResponseVarName` or `Y`.

If you train `tree` using sample data contained in a `table`, then the input data for this method must also be in a table.

Data Types: `table`

X — Data to classify

numeric matrix

Data to classify, specified as a numeric matrix. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `tree`. `X` must have the same number of rows as the number of elements in `Y`.

Data Types: `single` | `double`

ResponseVarName — Response variable name

name of a variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train `tree`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector. For example, if the response variable is stored as `TBL.Response`, then specify it as `'Response'`. Otherwise, the software treats all columns of TBL, including `TBL.ResponseVarName`, as predictors.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical or character array, a logical or numeric vector, or a cell array of character vectors. Y must be of the same type as the classification used to train `tree`, and its number of elements must equal the number of rows of X.

Data Types: `single` | `double` | `categorical` | `char` | `logical` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'LossFun' — Loss function

`'mincost'` (default) | `'binodeviance'` | `'classiferror'` | `'exponential'` | `'hinge'` | `'logit'` | `'quadratic'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. Classification trees return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(tree.ClassNames)`). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `tree.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `tree.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.

- `Cost` is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 25-3252.

'Weights' — Observation weights

`ones(size(X,1))` (default) | name of a variable in TBL | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or the name of a variable in TBL.

If you specify `Weights` as a numeric vector, then the size of `Weights` must be equal to the number of rows in `X` or TBL.

If you specify `Weights` as the name of a variable in TBL, you must do so as a character vector. For example, if the weights are stored as `TBL.W`, then specify it as `'W'`. Otherwise, the software treats all columns of TBL, including `TBL.W`, as predictors.

`loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `Weights`, `loss` computes weighted classification loss.

Data Types: `single` | `double`

Name, Value arguments associated with pruning subtrees:

'Subtrees' — Pruning level

0 (default) | vector of nonnegative integers | `'all'`

Pruning level, specified as the comma-separated pair consisting of `'Subtrees'` and a vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `CompactClassificationTree.loss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`CompactClassificationTree.loss` prunes tree to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of tree must be nonempty. In other words, grow tree by setting `'Prune'`, `'on'`, or by pruning tree using `prune`.

Example: `'Subtrees','all'`

'TreeSize' — Tree size

`'se'` (default) | `'min'`

Tree size, specified as the comma-separated pair consisting of `'TreeSize'` and one of the following character vectors:

- `'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ($L+se$, where L and se relate to the smallest value in `Subtrees`).
- `'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Output Arguments

L — Classification loss

vector of scalar values

Classification loss, returned as a vector the length of `Subtrees`. The meaning of the error depends on the values in `Weights` and `LossFun`.

se — Standard error of loss

vector of scalar values

Standard error of loss, returned as a vector the length of `Subtrees`.

NLeaf — Number of leaf nodes

vector of integer values

Number of leaves (terminal nodes) in the pruned subtrees, returned as a vector the length of `Subtrees`.

bestlevel — Best pruning level

scalar value

Best pruning level as defined in the `TreeSize` name-value pair, returned as a scalar whose value depends on `TreeSize`:

- `TreeSize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ($L+se$, where L and se relate to the smallest value in `Subtrees`).
- `TreeSize = 'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

By default, `bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When comparing the same type of loss among many models, lower loss indicates a better predictive model.

Suppose that:

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.

- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, and a 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

The supported loss functions are:

- Binomial deviance, specified using `'LossFun', 'binodeviance'`. Its equation is

$$L = \sum_{j=1}^n w_j \log \{1 + \exp[-2m_j]\}.$$

- Exponential loss, specified using `'LossFun', 'exponential'`. Its equation is

$$L = \sum_{j=1}^n w_j \exp(-m_j).$$

- Classification error, specified using `'LossFun', 'classiferror'`. It is the weighted fraction of misclassified observations, with equation

$$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$$

\hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.

- Hinge loss, specified using 'LossFun', 'hinge'. Its equation is

$$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$$

- Logit loss, specified using 'LossFun', 'logit'. Its equation is

$$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$$

- Minimal cost, specified using 'LossFun', 'mincost'. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$:

- 1 Estimate the 1-by- K vector of expected classification costs for observation j

$$\gamma_j = f(X_j)'C.$$

$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix the input model stores in the property **Cost**.

- 2 For observation j , predict the class label corresponding to the minimum, expected classification cost:

$$\hat{y}_j = \min_{j=1, \dots, K} (\gamma_j).$$

- 3 Using C , identify the cost incurred (c_j) for making the prediction.

The weighted, average, minimum cost loss is

$$L = \sum_{j=1}^n w_j c_j.$$

25-3254

- Quadratic loss, specified using 'LossFun', 'quadratic'. Its equation is

$$L = \sum_{j=1}^n w_j (1 - m_j)^2.$$

This figure compares some of the loss functions for one observation over m (some functions are normalized to pass through $[0,1]$).

True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `fitctree` method. `Cost(i, j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i, j) = 1` if `i ≠ j`, and `Cost(i, j) = 0` if `i = j`. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

Expected Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row.

The expected cost matrix `CE` has size `Nobs`-by-`K`. Each row of `CE` contains the expected (average) cost of classifying the observation into each of the `K` classes. `CE(n, k)` is

$$\sum_{i=1}^K \hat{P}(i | Xnew(n)) C(k | i),$$

where

- `K` is the number of classes.
- $\hat{P}(i | Xnew(n))$ is the posterior probability of class `i` for observation `Xnew(n)`.
- $C(k | i)$ is the true misclassification cost of classifying an observation as `k` when its true class is `i`.

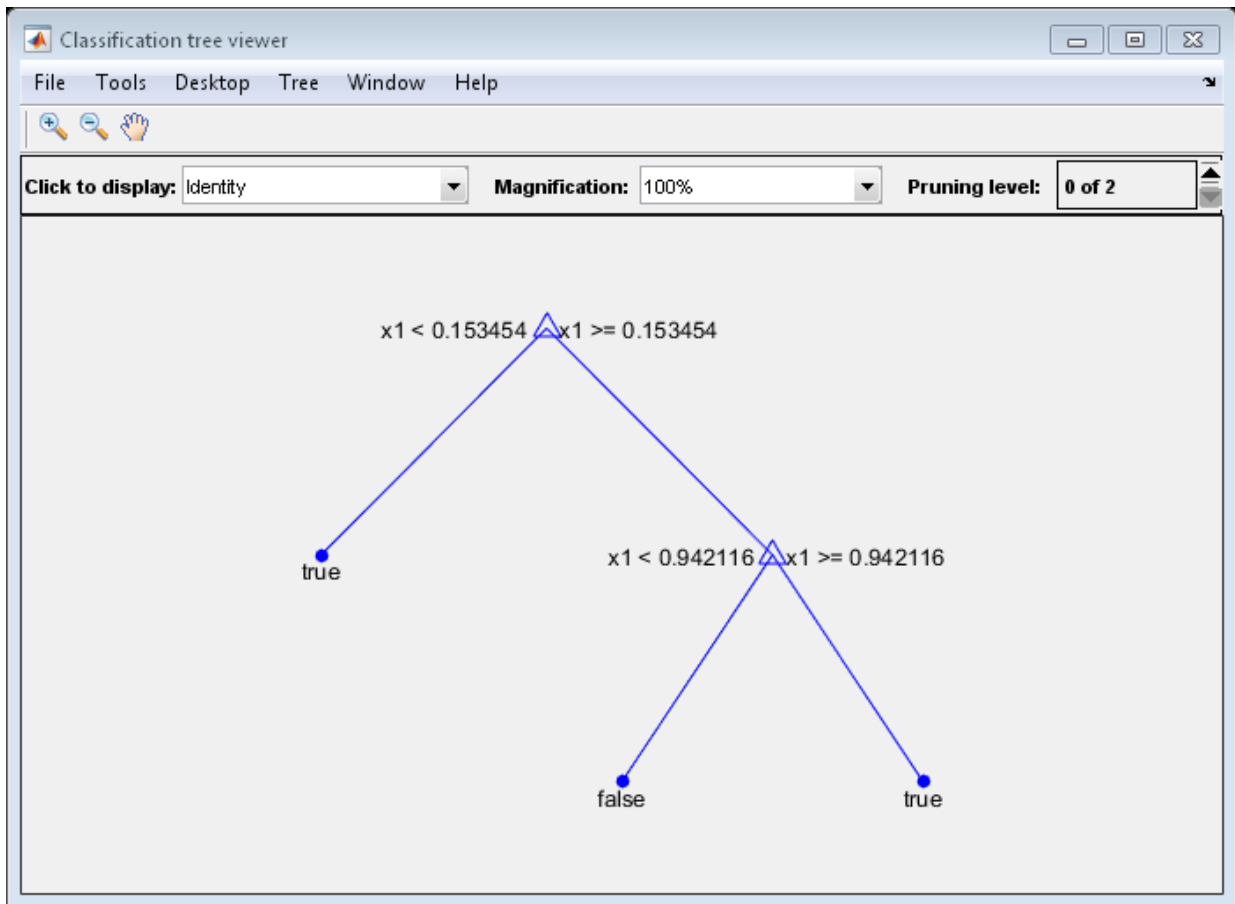

Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for **true**, and about $.8/.85=.94$ for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

Examples

Compute the In-sample Classification Error

Compute the resubstituted classification error for the `ionosphere` data set.

```
load ionosphere
tree = fitctree(X,Y);
L = loss(tree,X,Y)
```

```
L =
    0.0114
```

Examine the Classification Error for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load Fisher's iris data set. Partition the data into training (50%) and validation (50%) sets.

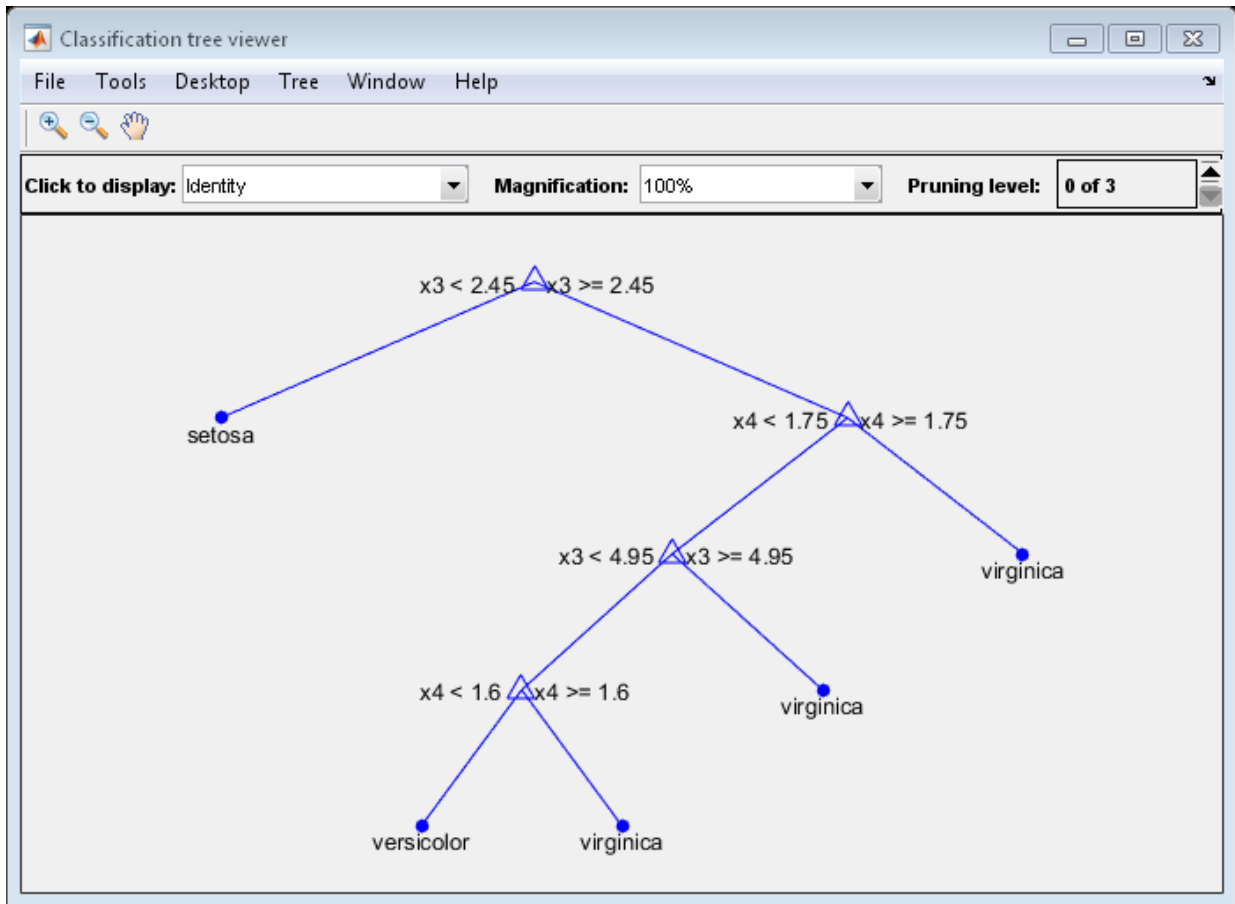

```
load fisheriris
n = size(meas,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false; % Validation set logical indices
```

Grow a classification tree using the training set.

```
Mdl = fitctree(meas(idxTrn,:),species(idxTrn));
```

View the classification tree.

```
view(Mdl, 'Mode', 'graph');
```

The classification tree has four pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 3 is just the root node (i.e., no splits).

Examine the training sample classification error for each subtree (or pruning level) excluding the highest level.

```
m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl, 'SubTrees', 0:m)
```

```
trnLoss =
```

```
0.0267
0.0533
0.3067
```

- The full, unpruned tree misclassifies about 2.7% of the training observations.
- The tree pruned to level 1 misclassifies about 5.3% of the training observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.6% of the training observations.

Examine the validation sample classification error at each level excluding the highest level.

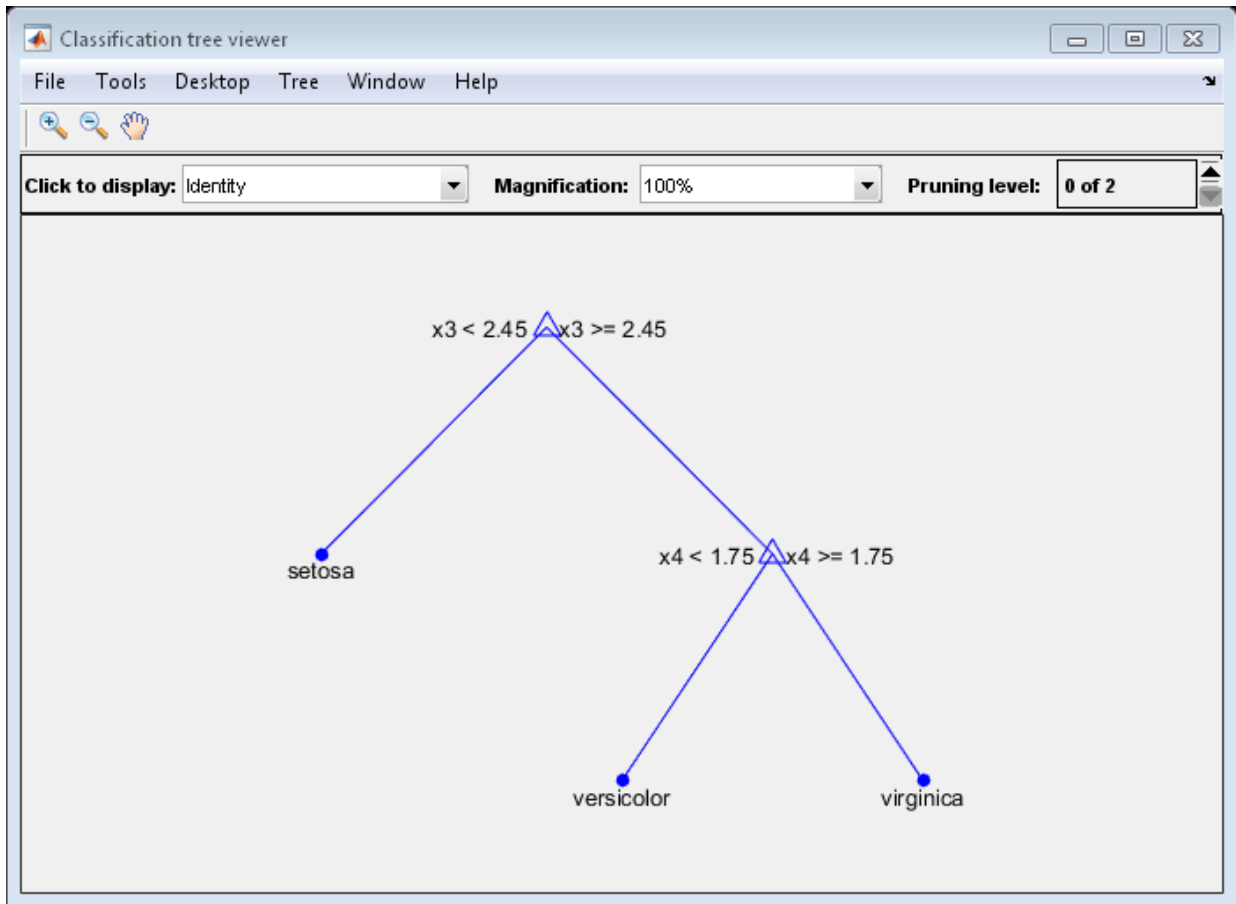

```
valLoss = loss(Mdl, meas(idxVal, :), species(idxVal), 'SubTrees', 0:m)
```

```
valLoss =
    0.0369
    0.0237
    0.3067
```

- The full, unpruned tree misclassifies about 3.7% of the validation observations.
- The tree pruned to level 1 misclassifies about 2.4% of the validation observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.7% of the validation observations.

To balance model complexity and out-of-sample performance, consider pruning `Mdl` to level 1.

```
pruneMdl = prune(Mdl, 'Level', 1);
view(pruneMdl, 'Mode', 'graph')
```

loss

Class: CompactRegressionEnsemble

Regression error

Syntax

```
L = loss(ens, tbl, ResponseVarName)
L = loss(ens, tbl, Y)
L = loss(ens, X, Y)
L = loss( ____, Name, Value)
```

Description

`L = loss(ens, tbl, ResponseVarName)` returns the mean squared error between the predictions of `ens` to the data in `tbl`, compared to the true responses `tbl.ResponseVarName`.

`L = loss(ens, tbl, Y)` returns the mean squared error between the predictions of `ens` to the data in `tbl`, compared to the true responses `Y`.

`L = loss(ens, X, Y)` returns the mean squared error between the predictions of `ens` to the data in `X`, compared to the true responses `Y`.

`L = loss(____, Name, Value)` computes the error in prediction with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes.

Input Arguments

ens

A regression ensemble created with `fitensemble`, or the compact method.

tbl

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. `tbl` must contain all of the predictors

used to train the model. Multi-column variables and cell arrays other than cell arrays of strings are not allowed.

If you trained `ens` using sample data contained in a `table`, then the input data for this method must also be in a `table`.

ResponseVarName

Response variable name, specified as the name of a variable in `tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a string. For example, if the response variable `Y` is stored as `tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `tbl`, including `Y`, as predictors when training the model.

X

A matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

NaN values in `X` are taken to be missing values. Observations with all missing values for `X` are not used in the calculation of loss.

If you trained `ens` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

Y

A numeric column vector with the same number of rows as `tbl` or `X`. Each entry in `Y` is the response to the data in the corresponding row of `tbl` or `X`.

NaN values in `Y` are taken to be missing values. Observations with missing values for `Y` are not used in the calculation of loss.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'learners'

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

'lossfun'

Function handle for loss function, or the string `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `loss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

Default: `'mse'`

'mode'

String representing the meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

'UseObsForLearner'

A logical matrix of size `N`-by-`NumTrained`, where `N` is the number of observations in `ens.X`, and `NumTrained` is the number of weak learners. When `UseObsForLearner(I,J)` is true, `predict` uses learner `J` in predicting observation `I`.

Default: `true(N,NumTrained)`

'weights'

Numeric vector of observation weights with the same number of elements as `Y`. The formula for `loss` with `weights` is in “Weighted Mean Squared Error” on page 25-3267.

Default: `ones(size(Y))`

Output Arguments**L**

Weighted mean squared error of predictions. The formula for `loss` is in “Weighted Mean Squared Error” on page 25-3267.

Definitions**Weighted Mean Squared Error**

Let n be the number of rows of data, x_j be the j th row of data, y_j be the true response to x_j , and let $f(x_j)$ be the response prediction of `ens` to x_j . Let w be the vector of weights (all one by default).

First the weights are divided by their sum so they add to one: $w \rightarrow w/\sum w$. The mean squared error L is

$$L = \sum_{j=1}^n w_j (f(x_j) - y_j)^2.$$

Examples

Find the loss of an ensemble predictor of the `carsmall` data to find MPG as a function of engine displacement, horsepower, and vehicle weight:

```
load carsmall
X = [Displacement Horsepower Weight];
```

```
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');

loss

Class: CompactRegressionGP

Regression error for Gaussian process regression model

Syntax

```
L = loss(gprMdl, Xnew, Ynew)
L = loss(gprMdl, Xnew, Ynew, Name, Value)
```

Description

`L = loss(gprMdl, Xnew, Ynew)` returns the mean squared error for the Gaussian process regression (GPR) model `gpr`, using the predictors in `Xnew` and observed response in `Ynew`.

`L = loss(gprMdl, Xnew, Ynew, Name, Value)` returns the mean squared error for the GPR model, `gpr`, with additional options specified by one or more `Name, Value` pair arguments. For example, you can specify a custom loss function or the observation weights.

Input Arguments

gprMdl — Gaussian process regression model

RegressionGP object | CompactRegressionGP object

Gaussian process regression model, specified as a RegressionGP (full) or CompactRegressionGP (compact) object.

Xnew — New observed data

table | *m*-by-*d* matrix

New data, specified as a table or an *n*-by-*d* matrix, where *m* is the number of observations, and *d* is the number of predictor variables in the training data.

If you trained `gprMdl` on a table, then `Xnew` must be a table that contains all the predictor variables used to train `gprMdl`.

If `Xnew` is a table, then it can also contain `Ynew`. And if it does, then you do not have to specify `Ynew`.

If you trained `gprMdl` on a matrix, then `Xnew` must be a numeric matrix with d columns, and can only contain values for the predictor variables.

Data Types: `single` | `double` | `table`

Ynew — New response values

n -by-1 vector

New observed response values, that correspond to the predictor values in `Xnew`, specified as an n -by-1 vector. n is the number of rows in `Xnew`. Each entry in `Ynew` is the observed response based on the predictor data in the corresponding row of `Xnew`.

If `Xnew` is a table containing new response values, you do not have to specify `Ynew`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

'lossfun' — Loss function

'mse' (default) | function handle

Loss function, specified as 'mse' (mean squared error) or a function handle.

If you pass a function handle, say `fun`, `loss` calls it as shown below: `fun(Y, Ypred, W)`, where `Y`, `Ypred` and `W` are numeric vectors of length n , and n is the number of rows in `Xnew`. `Y` is the observed response, `Ypred` is the predicted response, and `W` is the observation weights.

Example: 'lossfun', `Fct` calls the loss function `Fct`.

Data Types: `char` | `function_handle`

'weights' — Observation weights

vector of 1s (default) | n -by-1 vector

Observation weights, specified as n -by-1 vector, where n is the number of rows in X_{new} . By default, the weight of each observation is 1.

Example: 'weights', W uses the observation weights in vector W .

Data Types: double | single

Output Arguments

L — Regression error

scalar value

Regression error for the trained Gaussian process regression model, `gprMdl`, returned as a scalar value.

Examples

Compute Regression Loss for Test Data

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'gprdata.mat'))
```

The data has 8 predictor variables and contains 500 observations in training data and 100 observations in test data. This is simulated data.

Fit a GPR model using the squared exponential kernel function with separate length scales for each predictor. Standardize the predictor values in the training data. Use the exact method for fitting and prediction.

```
gprMdl = fitrgp(Xtrain,ytrain,'FitMethod','exact',...  
'PredictMethod','exact','KernelFunction','ardsquaredexponential',...  
'Standardize',1);
```

Compute the regression error for the test data.

```
L = loss(gprMdl,Xtest,ytest)
```

```
L =
```

```
0.6928
```

Predict the responses for test data.

```
ypredtest = predict(gprMdl,Xtest);
```

Plot the test response along with the predictions.

```
figure;  
plot(ytest, 'r');  
hold on;  
plot(ypredtest, 'b');  
legend('Data', 'Predictions', 'Location', 'Best');
```

Manually compute the regression loss.

```
L = (ytest - ypredtest)'*(ytest - ypredtest)/length(ytest)
```

```
L =
```

```
    0.6928
```

Specify Custom Loss Function

Load the sample data and store in a table.

```
load fisheriris
tbl = table(meas(:,1),meas(:,2),meas(:,3),meas(:,4),species,...
'VariableNames',{'meas1','meas2','meas3','meas4','species'});
```

Fit a GPR model using the first measurement as the response and the other variables as the predictors.

```
mdl = fitrgp(tbl,'meas1');
```

Predict the responses using the trained model.

```
ypred = predict(mdl,tbl);
```

Compute the mean absolute error.

```
n = height(tbl);
y = tbl.meas1;
fun = @(y,ypred,w) sum(abs(y-ypred))/n;
L = loss(mdl,tbl,'lossfun',fun)
```

```
L =
```

```
    0.2345
```

Alternatives

You can use `resubLoss` to compute the regression error for the trained GPR model at the observations in the training data.

Introduced in R2015b

loss

Class: CompactRegressionSVM

Regression error for support vector machine regression model

Syntax

```
L = loss(md1, tbl, ResponseVarName)
L = loss(md1, tbl, Y)
L = loss(md1, X, Y)
L = loss( ____, Name, Value)
```

Description

`L = loss(md1, tbl, ResponseVarName)` returns the loss for the predictions of the support vector machine (SVM) regression model, `md1`, based on the predictor data in the table `tbl` and the true response values in `tbl.ResponseVarName`.

`L = loss(md1, tbl, Y)` returns the loss for the predictions of the support vector machine (SVM) regression model, `md1`, based on the predictor data in the table `X` and the true response values in the vector `Y`.

`L = loss(md1, X, Y)` returns the loss for the predictions of the support vector machine (SVM) regression model, `md1`, based on the predictor data in `X` and the true responses in `Y`.

`L = loss(____, Name, Value)` returns the loss with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes. For example, you can specify the loss function or observation weights.

Input Arguments

md1 — SVM regression model

RegressionSVM model | CompactRegressionSVM model

SVM regression model, specified as a `RegressionSVM` model or `CompactRegressionSVM` model returned by `fitrsvm` or `compact`, respectively.

tbl — Sample data

table

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all of the predictors used to train `mdl`. Multi-column variables and cell arrays other than cell arrays of strings are not allowed.

If you trained `mdl` using sample data contained in a `table`, then the input data for this method must also be in a table.

Data Types: `table`

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a string. For example, if the response variable `Y` is stored as `tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `tbl`, including `Y`, as predictors when training the model.

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix or table. Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

If you trained `mdl` using a matrix of predictor values, then `X` must be a numeric matrix with p columns. p is the number of predictors used to train `mdl`.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `single` | `double`

Y — Observed response values

vector of numeric values

Observed response values, specified as a vector of length n containing numeric values. Each entry in Y is the observed response based on the predictor data in the corresponding row of X .

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'LossFun' — Loss function

'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a function handle or string.

- The following lists available loss functions. Specify one using its corresponding string.

Value	Loss Function
'mse'	“Weighted Mean Squared Error” on page 25-3278
'epsiloninsensitive'	“Epsilon-Insensitive Loss Function” on page 25-3279

- Specify your own function using function handle notation.

Your function must have the signature `lossvalue = lossfun(Y, Yfit, W)`, where:

- The output argument `lossvalue` is a scalar value.
- You choose the function name (*lossfun*).
- Y is an n -by-1 numeric vector of observed response values.
- $Yfit$ is an n -by-1 numeric vector of predicted response values, calculated using the corresponding predictor values in X (similar to the output of `predict`).
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.

Specify your function using 'LossFun', @*lossfun*.

Example: 'LossFun', 'epsiloninsensitive'

Data Types: char | function_handle

'Weights' — Observation weights

ones(size(X,1)) (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector. **Weights** must be the same length as the number of rows in **X**. The software weighs the observations in each row of **X** using the corresponding weight value in **Weights**.

Weights are normalized to sum to 1.

Data Types: single | double

Output Arguments

L — Regression loss

scalar value

Regression loss, returned as a scalar value.

Definitions

Weighted Mean Squared Error

The weighted mean squared error is calculated as follows:

$$\text{mse} = \frac{\sum_{j=1}^n w_j (f(x_j) - y_j)^2}{\sum_{j=1}^n w_j},$$

where:

- n is the number of rows of data

- x_j is the j th row of data
- y_j is the true response to x_j
- $f(x_j)$ is the response prediction of the SVM regression model `mdl` to x_j
- w is the vector of weights.

The weights in w are all equal to one by default. You can specify different values for weights using the 'Weights' name-value pair argument. If you specify weights, each value is divided by the sum of all weights, such that the normalized weights add to one.

Epsilon-Insensitive Loss Function

The epsilon-insensitive loss function ignores errors that are within the distance epsilon (ϵ) of the function value. It is formally described as:

$$Loss_{\epsilon} = \begin{cases} 0, & \text{if } |y - f(x)| \leq \epsilon \\ |y - f(x)| - \epsilon, & \text{otherwise.} \end{cases}$$

The mean epsilon-insensitive loss is calculated as follows:

$$Loss = \frac{\sum_{j=1}^n w_j \max(0, |y_j - f(x_j)| - \epsilon)}{\sum_{j=1}^n w_j},$$

where:

- n is the number of rows of data
- x_j is the j th row of data
- y_j is the true response to x_j
- $f(x_j)$ is the response prediction of the SVM regression model `mdl` to x_j
- w is the vector of weights.

The weights in w are all equal to one by default. You can specify different values for weights using the 'Weights' name-value pair argument. If you specify weights, each value is divided by the sum of all weights, such that the normalized weights add to one.

Examples

Calculate Test Sample Loss for SVM Regression Model

This example shows how to train an SVM regression model, then calculate the resubstitution mean square error and epsilon-insensitive error.

Load the `carsmall` sample data.

```
load carsmall
rng default % for reproducibility
```

Specify `Horsepower` and `Weight` as the predictor variables (X), and `MPG` as the response variable (Y).

```
X = [Horsepower,Weight];
Y = MPG;
```

Train a linear SVM regression model. Standardize the data.

```
mdl = fitrsvm(X,Y,'Standardize',true);
```

`mdl` is a `RegressionSVM` model.

Determine how well the trained model generalizes to new predictor values by estimating the test sample mean square error and epsilon-insensitive error.

```
lossMSE = loss(mdl,X,Y)
lossEI = loss(mdl,X,Y,'LossFun','epsiloninsensitive')
```

```
lossMSE =
```

```
    17.0256
```

```
lossEI =
```

```
     2.2506
```

Tips

- If `mdl` is a cross-validated `RegressionPartitionedSVM` model, use `kfoldloss` instead of `loss` to calculate the regression error.

`CompactRegressionSVM` | `fitrsvm` | `kfoldloss` | `RegressionSVM`

Introduced in R2015b

loss

Class: CompactRegressionTree

Regression error

Syntax

```
L = loss(tree,tbl,ResponseVarName)
L = loss(tree,x,y)
L = loss( ____,Name,Value)
[L,se,NLeaf,bestlevel] = loss( ____ )
```

Description

`L = loss(tree,tbl,ResponseVarName)` returns the mean squared error between the predictions of `tree` to the data in `tbl`, compared to the true responses `tbl.ResponseVarName`.

`L = loss(tree,x,y)` returns the mean squared error between the predictions of `tree` to the data in `x`, compared to the true responses `y`.

`L = loss(____,Name,Value)` computes the error in prediction with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes.

`[L,se,NLeaf,bestlevel] = loss(____)` also returns the standard error of the loss (`se`), the number of leaves (terminal nodes) in the tree (`NLeaf`), and the optimal pruning level for `tree` (`bestlevel`).

Input Arguments

tree — Trained regression tree

RegressionTree object | CompactRegressionTree object

Trained regression tree, specified as a RegressionTree object constructed by `fitrtree` or a CompactRegressionTree object constructed by `compact`.

x — Predictor values

matrix of floating-point values

Predictor values, specified as matrix of floating-point values. Each column of `x` represents one variable, and each row represents one observation.

Data Types: `single` | `double`

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a string. For example, if the response variable `y` is stored as `tbl.y`, then specify it as `'response'`. Otherwise, the software treats all columns of `tbl`, including `y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of strings. If `y` is a character array, then each element must correspond to one row of the array.

It is good practice to specify the order of the classes using the `ClassNames` name-value pair argument.

y — Response data

numeric column vector

Response data, specified as a numeric column vector with the same number of rows as `x`. Each entry in `y` is the response to the data in the corresponding row of `x`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'LossFun' — Loss function

`'mse'` (default) | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a function handle for loss, or the string `'mse'` representing mean-squared error. If you pass a function handle `fun`, `loss` calls `fun` as:

```
fun(Y,Yfit,W)
```

- `Y` is the vector of true responses.
- `Yfit` is the vector of predicted responses.
- `W` is the observation weights. If you pass `W`, the elements are normalized to sum to 1.

All the vectors have the same number of rows as `Y`.

Example: `'LossFun'`, `'mse'`

Data Types: `function_handle`

'Subtrees' — Pruning level

0 (default) | vector of nonnegative integers | `'all'`

Pruning level, specified as the comma-separated pair consisting of `'Subtrees'` and a vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `CompactRegressionTree.loss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`CompactRegressionTree.loss` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting `'Prune'`, `'on'`, or by pruning `tree` using `prune`.

Example: `'Subtrees'`, `'all'`

'TreeSize' — Tree size

`'se'` (default) | `'min'`

Tree size, specified as the comma-separated pair consisting of `'TreeSize'` and one of the following:

- `'se'` — `loss` returns `bestlevel` that corresponds to the smallest tree whose mean squared error (MSE) is within one standard error of the minimum MSE.
- `'min'` — `loss` returns `bestlevel` that corresponds to the minimal MSE tree.

Example: `'TreeSize','min'`

'Weights' — Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values. The software weights the observations in each row of `x` or `tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `x` or `tbl`.

If you specify the input data as a table `tbl`, then `Weights` can be the name of a variable in `tbl` that contains a numeric vector. In this case, you must specify `Weights` as a variable name string. For example, if weights vector `W` is stored as `tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `tbl`, including `W`, as predictors when training the model.

Data Types: `single` | `double`

Output Arguments

L — Classification error

vector of scalar values

Classification error, returned as a vector the length of `Subtrees`. The error for each tree is the mean squared error, weighted with `Weights`. If you include `LossFun`, `L` reflects the loss calculated with `LossFun`.

se — Standard error of loss

vector of scalar values

Standard error of loss, returned as a vector the length of `Subtrees`.

NLeaf — Number of leaf nodes

vector of integer values

Number of leaves (terminal nodes) in the pruned subtrees, returned as a vector the length of `Subtrees`.

bestlevel — Best pruning level

scalar value

Best pruning level as defined in the `TreeSize` name-value pair, returned as a scalar whose value depends on `TreeSize`:

- `TreeSize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum (`L+se`, where `L` and `se` relate to the smallest value in `Subtrees`).
- `TreeSize = 'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Definitions

Mean Squared Error

The mean squared error m of the predictions $f(X_n)$ with weight vector w is

$$m = \frac{\sum w_n (f(X_n) - Y_n)^2}{\sum w_n}.$$

Examples

Compute the In-Sample MSE

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.

```
tree = fitrtree(X,MPG);
```

Estimate the in-sample MSE.

```
L = loss(tree,X,MPG)
```

```
L =
```

```
4.8952
```

Find the Pruning Level Yielding the Optimal In-sample Loss

Load the `carsmall` data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

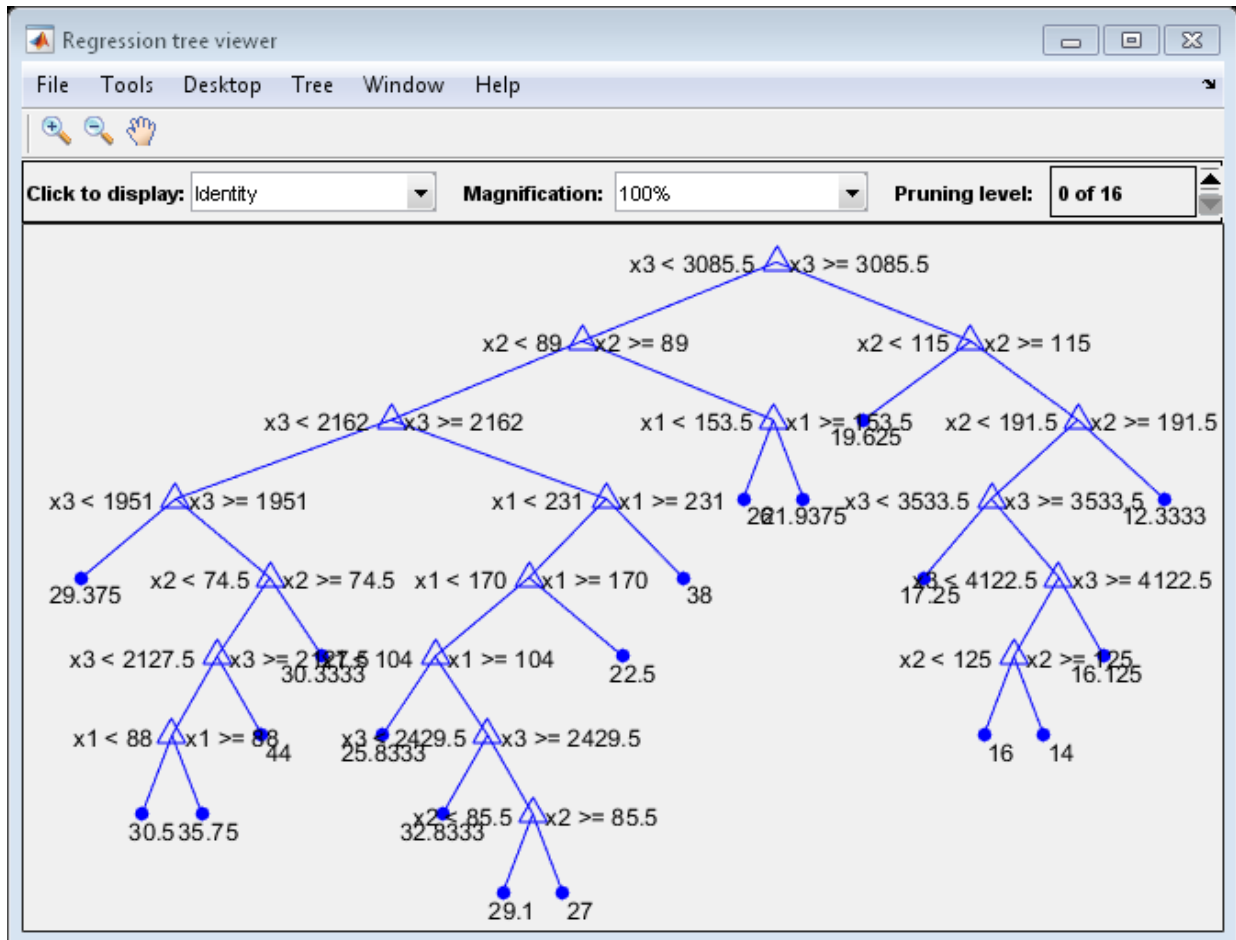

```
load carsmall  
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.

```
Mdl = fitrtree(X,MPG);
```

View the regression tree.

```
view(Mdl, 'Mode', 'graph');
```

Find the best pruning level that yields the optimal in-sample loss.

```
[L,se,NLeaf,bestLevel] = loss(Mdl,X,MPG,'Subtrees','all');
bestLevel
```

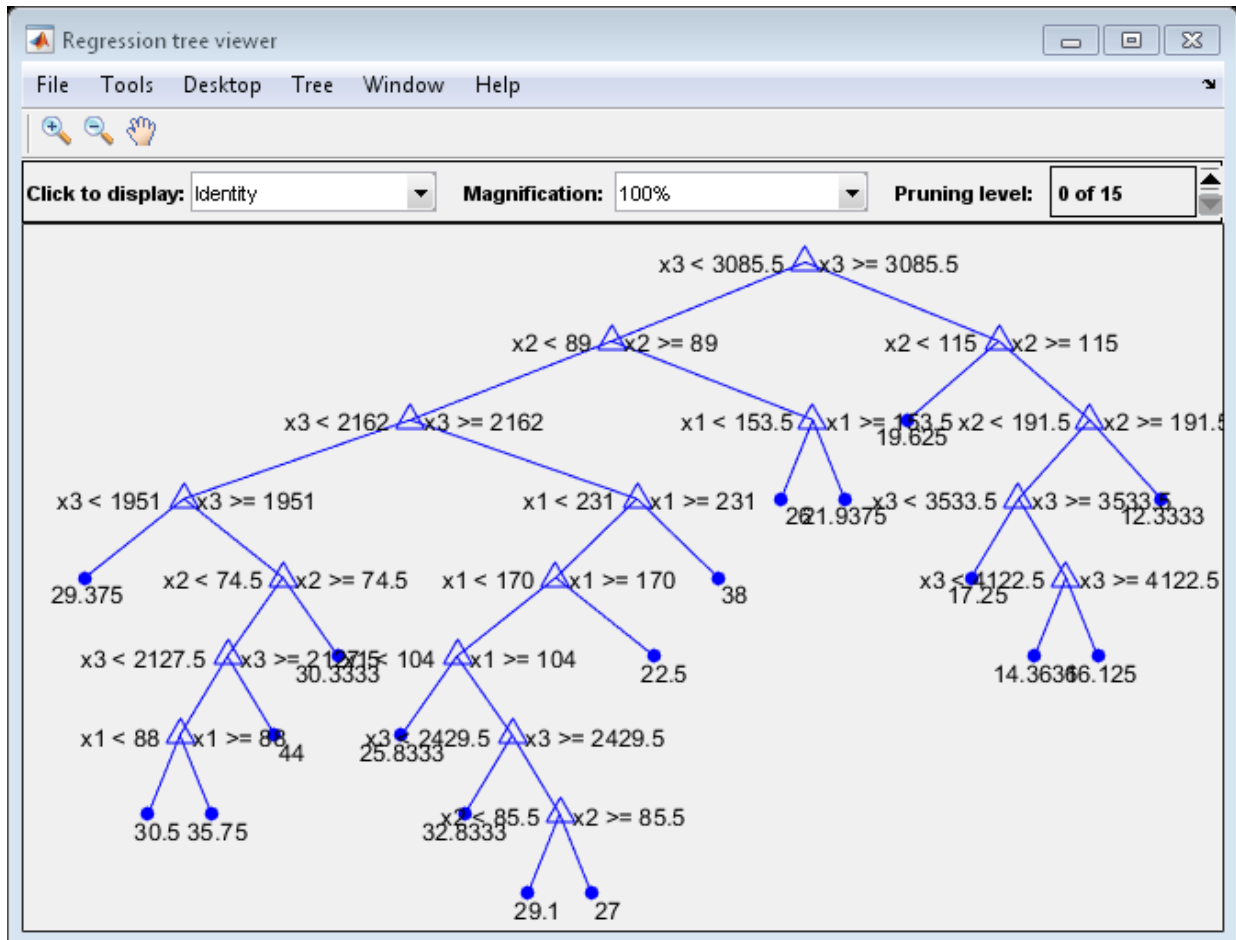

```
bestLevel =
```

```
1
```

The best pruning level is level 1.

Prune the tree to level 1.

```
pruneMdl = prune(Mdl, 'Level', bestLevel);  
view(pruneMdl, 'Mode', 'graph');
```

Examine the MSE for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load the `carsmall` data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

```
load carsmall
```

```
X = [Displacement Horsepower Weight];  
Y = MPG;
```

Partition the data into training (50%) and validation (50%) sets.

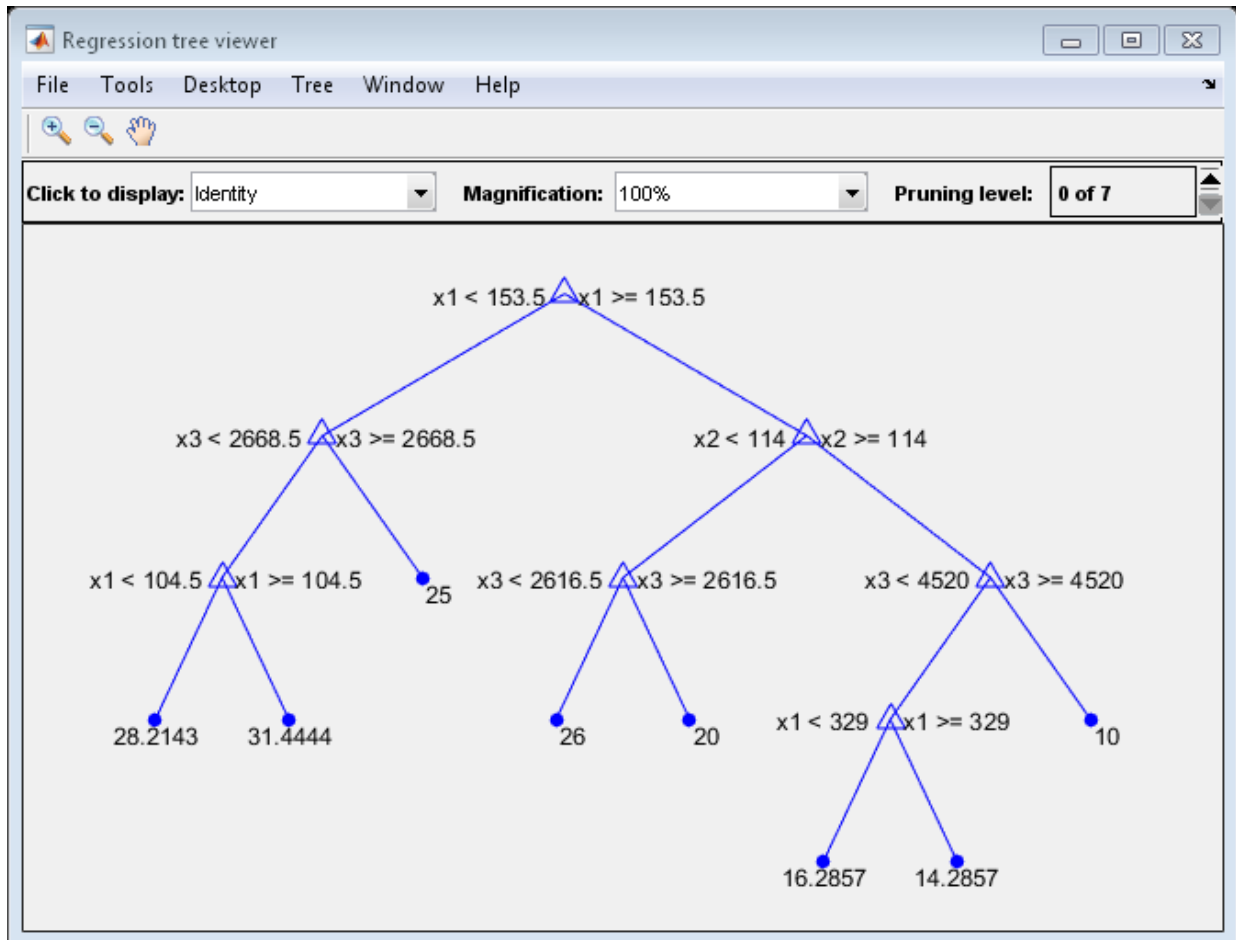

```
n = size(X,1);  
rng(1) % For reproducibility  
idxTrn = false(n,1);  
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices  
idxVal = idxTrn == false; % Validation set logical indices
```

Grow a regression tree using the training set.

```
Mdl = fitrtree(X(idxTrn,:),Y(idxTrn));
```

View the regression tree.

```
view(Mdl, 'Mode', 'graph');
```

The regression tree has seven pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 7 is just the root node (i.e., no splits).

Examine the training sample MSE for each subtree (or pruning level) excluding the highest level.

```
m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl, 'SubTrees', 0:m)
```

```
trnLoss =
    5.9789
    6.2768
    6.8316
    7.5209
    8.3951
   10.7452
   14.8445
```

- The MSE for the full, unpruned tree is about 6 units.
- The MSE for the tree pruned to level 1 is about 6.3 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 14.8 units.

Examine the validation sample MSE at each level excluding the highest level.

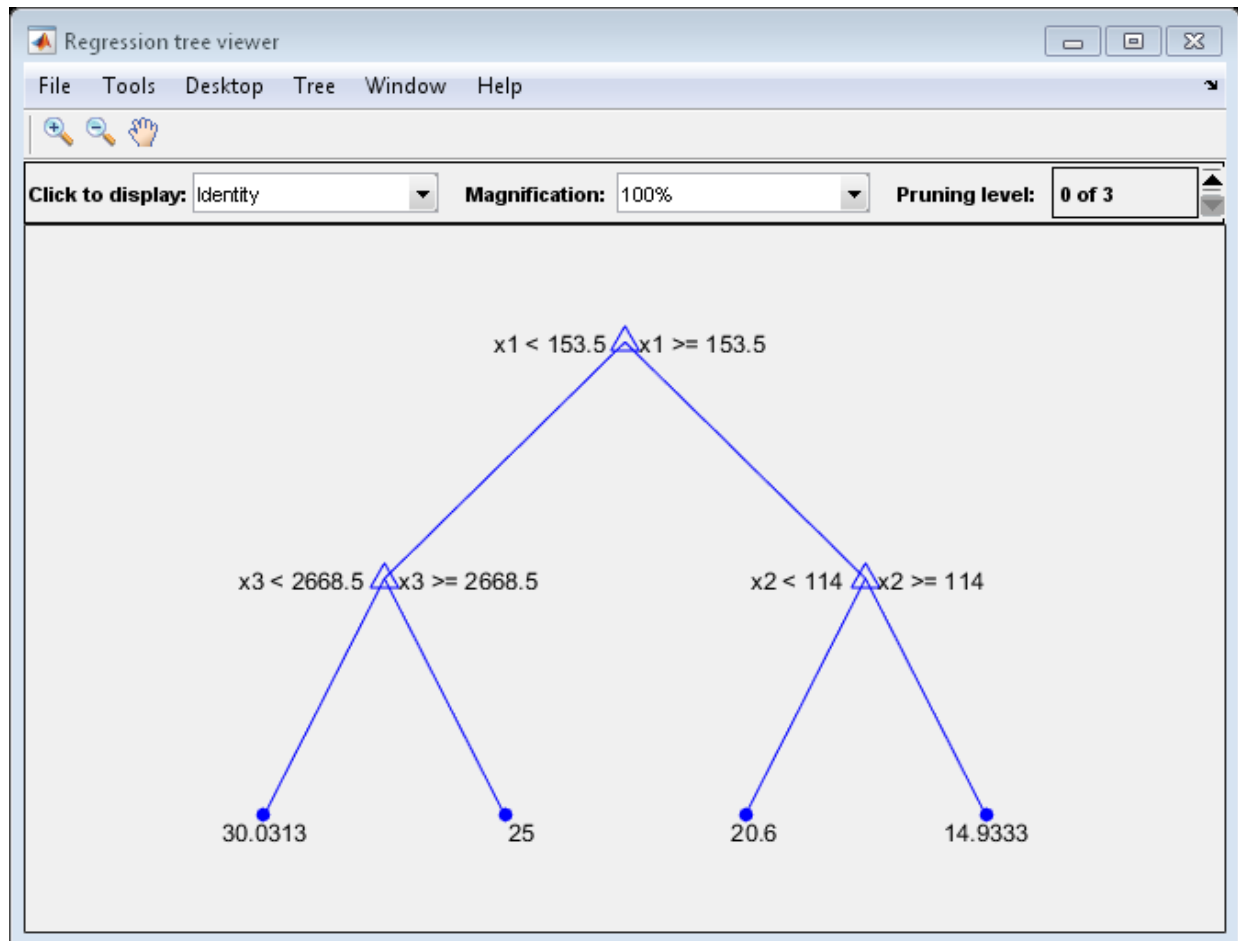

```
valLoss = loss(Mdl,X(idxVal,:),Y(idxVal),'SubTrees',0:m)
```

```
valLoss =
    32.1205
    31.5035
    32.0541
    30.8183
    26.3535
    30.0137
    38.4695
```

- The MSE for the full, unpruned tree (level 0) is about 32.1 units.
- The MSE for the tree pruned to level 4 is about 26.4 units.
- The MSE for the tree pruned to level 5 is about 30.0 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 38.5 units.

To balance model complexity and out-of-sample performance, consider pruning `Mdl` to level 4.

```
pruneMdl = prune(Mdl,'Level',4);
view(pruneMdl,'Mode','graph')
```

See Also

`predict` | `fitrtree`

loss

Class: RegressionLinear

Regression loss for linear regression models

Syntax

`L = loss(Mdl,X,Y)`

`L = loss(____,Name,Value)`

Description

`L = loss(Mdl,X,Y)` returns the mean squared error (MSE) for the linear regression model `Mdl` using predictor data in `X` and corresponding responses in `Y`. `L` contains an MSE for each regularization strength in `Mdl`.

`L = loss(____,Name,Value)` uses any of the previous syntaxes and additional options specified by one or more `Name,Value` pair arguments. For example, specify that columns in the predictor data correspond to observations or specify the regression loss function.

Input Arguments

Mdl — Linear regression model

RegressionLinear model object

Linear regression model, specified as a RegressionLinear model object. You can create a RegressionLinear model object using `fitrlinear`.

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix. This orientation of `X` indicates that rows correspond to individual observations and columns correspond to individual predictor variables.

The length of `Y` and the number of observations in `X` must be equal.

Note: If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in computation time.

Y — Response data

numeric vector

Response data, specified as an n -dimensional numeric vector. The length of Y and the number of observations in X must be equal.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

'LossFun' — Loss function

'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following lists available loss functions. Specify one using its corresponding character vector. Also, in the table, $f(x) = \beta'x + b$.
 - β is a vector of p coefficients.
 - x is an observation from p predictor variables.
 - b is the scalar bias.

Value	Description
'epsiloninsensitive'	Epsilon-insensitive loss: $\ell[y, f(x)] = \max[0, y - f(x) - \epsilon]$
'mse'	MSE: $\ell[y, f(x)] = [y - f(x)]^2$

'epsiloninsensitive' is appropriate for SVM learners only.

- Specify your own function using function handle notation.

Let n be the number of observations in X . Your function must have this signature

```
lossvalue = lossfun(Y,Yhat,W)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- Y is an n -dimensional vector of observed responses. `RegressionLinear.loss` passes the input argument Y in for Y .
- $Yhat$ is an n -dimensional vector of predicted responses, which is similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights.

Specify your function using 'LossFun', @`lossfun`.

Data Types: char | function_handle

'ObservationsIn' — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

Note: If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Data Types: char

'Weights' — Observation weights

numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. If you supply weights, `loss` computes the weighted classification loss.

Let n be the number of observations in X .

- `numel(Weights)` must be n .
- By default, `Weights` is `ones(n,1)`.

Data Types: `double` | `single`

Output Arguments

L — Regression losses

numeric scalar | numeric row vector

Regression losses, returned as a numeric scalar or row vector. The interpretation of `L` depends on `Weights` and `LossFun`.

`L` is the same size as `Mdl.Lambda`. `L(j)` is the regression loss of the linear regression model trained using the regularization strength `Mdl.Lambda(j)`.

Note: If `Mdl.FittedLoss` is `'mse'`, then the loss term in the objective function is half of the MSE. `loss` returns the MSE by default. Therefore, if you use `loss` to check the resubstitution (training) error, then there is a discrepancy between the MSE and optimization results that `fitrlinear` returns.

Examples

Estimate Test-Sample Mean Squared Error

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = x_1, \dots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
```

```
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model. Reserve 30% of the observations as a holdout sample.

```
CVMD1 = fitrlinear(X,Y,'Holdout',0.3);
Mdl = CVMD1.Trained{1}
```

```
Mdl =
```

```
RegressionLinear
  ResponseName: 'Y'
  ResponseTransform: 'none'
      Beta: [1000x1 double]
      Bias: -0.0066
      Lambda: 1.4286e-04
      Learner: 'svm'
```

CVMD1 is a `RegressionPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `RegressionLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```
trainIdx = training(CVMD1.Partition);
testIdx = test(CVMD1.Partition);
```

Estimate the training- and test-sample MSE.

```
mseTrain = loss(Mdl,X(trainIdx,:),Y(trainIdx))
mseTest = loss(Mdl,X(testIdx,:),Y(testIdx))
```

```
mseTrain =
```

```
0.1496
```

```
mseTest =
```

```
0.1799
```

Because there is one regularization strength in `Mdl`, `mseTrain` and `mseTest` are numeric scalars.

Specify Custom Regression Loss

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = x_1, \dots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
X = X'; % Put observations in columns for faster training
```

Train a linear regression model. Reserve 30% of the observations as a holdout sample.

```
CVMdl = fitrlinear(X,Y,'Holdout',0.3,'ObservationsIn','columns');
Mdl = CVMdl.Trained{1}
```

```
Mdl =
  RegressionLinear
    ResponseName: 'Y'
  ResponseTransform: 'none'
           Beta: [1000x1 double]
           Bias: -0.0066
    Lambda: 1.4286e-04
    Learner: 'svm'
```

`CVMdl` is a `RegressionPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `RegressionLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Create an anonymous function that measures Huber loss ($\delta = 1$), that is,

$$L = \frac{1}{\sum w_j} \sum_{j=1}^n w_j \ell_j, \text{ where}$$

$$\ell_j = \begin{cases} 0.5\hat{e}^2 & \text{for } |\hat{e}| \leq 1 \\ |\hat{e}| - 0.5 & \text{otherwise} \end{cases} .$$

\hat{e}_j is the residual for observation j . Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the `LOSSFUN` name-value pair argument.

```
huberloss = @(Y,Yhat,W) sum(W.*((0.5*(abs(Y-Yhat)<=1).*(Y-Yhat).^2) + ...
    ((abs(Y-Yhat)>1).*abs(Y-Yhat)-0.5)))/sum(W);
```

Estimate the training- and test-sample regression loss using the Huber loss function.

```
eTrain = loss(Mdl,X(:,trainIdx),Y(trainIdx),'LossFun',huberloss,...
    'ObservationsIn','columns')
eTest = loss(Mdl,X(:,testIdx),Y(testIdx),'LossFun',huberloss,...
    'ObservationsIn','columns')
```

```
eTrain =
    -0.4186
```

```
eTest =
    -0.4012
```

Find Good Lasso Penalty Using Regression Loss

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-4} through 10^{-1} .

```
Lambda = logspace(-4, -1, 15);
```

Hold out 30% of the data for testing. Identify the test-sample indices.

```
cvp = cvpartition(numel(Y), 'Holdout', 0.30);
idxTest = test(cvp);
```

Train a linear regression model using lasso penalties with the strengths in `Lambda`. Specify the regularization strengths, solve the objective function using `Sparse`, and the data partition. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```
X = X';
CVMdl = fitrlinear(X,Y, 'ObservationsIn', 'columns', 'Lambda', Lambda, ...
    'Solver', 'sparse', 'Regularization', 'lasso', 'CVPartition', cvp);
Mdl1 = CVMdl.Trained{1};
numel(Mdl1.Lambda)
```

```
ans =
```

```
15
```

`Mdl1` is a `RegressionLinear` model. Because `Lambda` is a 15-dimensional vector of regularization strengths, you can think of `Mdl1` as 15 trained models, one for each regularization strength.

Estimate the test-sample mean squared error for each regularized model.

```
mse = loss(Mdl1,X(:,idxTest),Y(idxTest), 'ObservationsIn', 'columns');
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. Retrain the model using the entire data set and all options used

previously, except the data-partition specification. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...  
    'Solver','sparsa','Regularization','lasso');  
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;  
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...  
    log10(Lambda),log10(numNZCoeff));  
hL1.Marker = 'o';  
hL2.Marker = 'o';  
ylabel(h(1),'log_{10} MSE')  
ylabel(h(2),'log_{10} nonzero-coefficient frequency')  
xlabel('log_{10} Lambda')  
hold off
```

Select the index or indices of `Lambda` that balance minimal classification error and predictor-variable sparsity (for example, `Lambda(11)`).

```
idx = 11;
MdlFinal = selectModels(Mdl,idx);
```

`MdlFinal` is a trained `RegressionLinear` model object that uses `Lambda(11)` as a regularization strength.

Introduced in R2016a

lowerparams

Class: paretotails

Lower Pareto tails parameters

Syntax

```
params = lowerparams(obj)
```

Description

`params = lowerparams(obj)` returns the 2-element vector `params` of shape and scale parameters, respectively, of the lower tail of the Pareto tails object `obj`. `lowerparams` does not return a location parameter.

Examples

Fit Pareto tails to a t distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);  
obj = paretotails(t,0.1,0.9);
```

```
lowerparams(obj)  
ans =  
    -0.1901    1.1898  
upperparams(obj)  
ans =  
    0.3646    0.5103
```

See Also

paretotails | upperparams

lt

Class: grandstream

Less than relation for handles

Syntax

`h1 < h2`

Description

`h1 < h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `<` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = lt(h1, h2)` stores the result in a logical array of the same dimensions.

`grandstream` | `ge` | `gt` | `ne` | `eq` | `le`

lsline

Add least-squares line to scatter plot

Syntax

```
lsline  
lsline(ax)  
h = lsline( ___ )
```

Description

`lsline` superimposes a least-squares line on each scatter plot in the current axes. Scatter plots are produced by the MATLAB `scatter` and `plot` functions. Data points connected with solid, dashed, or dash-dot lines (' - ' , ' - - ' , or ' . - ') are not considered to be scatter plots by `lsline`, and are ignored.

`lsline(ax)` superimposes a least-squares line on the scatter plot in axis `ax`.

`h = lsline(___)` returns a column vector of handles `h` to the least-squares lines, using any of the previous syntaxes.

Examples

Plot a Least-Squares Line

Generate three sets of sample data and plot on the same figure.

```
x = 1:10;  
rng default; % For reproducibility  
figure;  
  
y1 = x + randn(1,10);  
scatter(x,y1,25,'b','*')  
hold on
```

```
y2 = 2*x + randn(1,10);  
plot(x,y2, 'mo')
```

```
y3 = 3*x + randn(1,10);  
plot(x,y3, 'rx')
```

Add a least-squares line for each set of sample data.

```
lsline
```

Specify Axes for Least-Squares and Reference Lines

Define the x-variable and two different y-variables to use for the plots.

```
rng default % For reproducibility
x = 1:10;
y1 = x + randn(1,10);
y2 = 2*x + randn(1,10);
```

Define `ax1` as the top half of the figure, and `ax2` as the bottom half of the figure. Create the first scatter plot on the top axis using `y1`, and the second scatter plot on the bottom axis using `y2`.

```
figure
```

```
ax1 = subplot(2,1,1);  
ax2 = subplot(2,1,2);  
  
scatter(ax1,x,y1)  
scatter(ax2,x,y2)
```

Superimpose a least-squares line on the top plot, and a reference line at the mean of the y_2 values in the bottom plot.

```
lsline(ax1)  
  
mu = mean(y2);  
refline(ax2,[0 mu])
```

See Also

`scatter` | `plot` | `refline` | `refcurve` | `gline`

Introduced before R2006a

mad

Mean or median absolute deviation

Syntax

```
y = mad(X)
Y = mad(X,1)
Y = mad(X,0)
```

Description

`y = mad(X)` returns the mean absolute deviation of the values in `X`. For vector input, `y` is `mean(abs(X-mean(X)))`. For a matrix input, `y` is a row vector containing the mean absolute deviation of each column of `X`. For N -dimensional arrays, `mad` operates along the first nonsingleton dimension of `X`.

`Y = mad(X,1)` returns the median absolute deviation of the values in `X`. For vector input, `y` is `median(abs(X-median(X)))`. For a matrix input, `y` is a row vector containing the median absolute deviation of each column of `X`. For N -dimensional arrays, `mad` operates along the first nonsingleton dimension of `X`.

`Y = mad(X,0)` is the same as `mad(X)`, and returns the mean absolute deviation of the values in `X`.

`mad(X,flag,dim)` computes absolute deviations along the dimension `dim` of `X`. `flag` is 0 or 1 to indicate mean or median absolute deviation, respectively.

`mad` treats NaNs as missing values and removes them.

For normally distributed data, multiply `mad` by one of the following factors to obtain an estimate of the normal scale parameter σ :

- `sigma = 1.253*mad(X,0)` — For mean absolute deviation
- `sigma = 1.4826*mad(X,1)` — For median absolute deviation

Examples

The following compares the robustness of different scale estimates for normally distributed data in the presence of outliers:

```
x = normrnd(0,1,1,50);  
xo = [x 10]; % Add outlier
```

```
r1 = std(xo)/std(x)  
r1 =  
    1.7385
```

```
r2 = mad(xo,0)/mad(x,0)  
r2 =  
    1.2306
```

```
r3 = mad(xo,1)/mad(x,1)  
r3 =  
    1.0602
```

Introduced before R2006a

mahal

Mahalanobis distance

Syntax

```
d = mahal(Y,X)
```

Description

`d = mahal(Y,X)` computes the Mahalanobis distance (in squared units) of each observation in `Y` from the reference sample in matrix `X`. If `Y` is n -by- m , where n is the number of observations and m is the dimension of the data, `d` is n -by-1. `X` and `Y` must have the same number of columns, but can have different numbers of rows. `X` must have more rows than columns.

For observation `I`, the Mahalanobis distance is defined by $d(I) = (Y(I,:) - \mu) * \text{inv}(\text{SIGMA}) * (Y(I,:) - \mu)'$, where `mu` and `SIGMA` are the sample mean and covariance of the data in `X`. `mahal` performs an equivalent, but more efficient, computation.

Examples

Compare Mahalanobis and Squared Euclidean Distances

Generate correlated bivariate data.

```
X = mvnrnd([0;0],[1 .9;.9 1],100);
```

Input observations.

```
Y = [1 1;1 -1;-1 1;-1 -1];
```

Compute the Mahalanobis distance of observations in `Y` from the reference sample in `X`.

```
d1 = mahal(Y,X)
```

```
d1 =  
    0.6288  
   19.3520  
   21.1384  
    0.9404
```

Compute their squared Euclidean distances from the mean of X .

```
d2 = sum((Y-repmat(mean(X),4,1)).^2, 2)
```

```
d2 =  
    1.6170  
    1.9334  
    2.1094  
    2.4258
```

Plot the observations with Y values colored according to the Mahalanobis distance.

```
scatter(X(:,1),X(:,2))  
hold on  
scatter(Y(:,1),Y(:,2),100,d1,'*', 'LineWidth',2)  
hb = colorbar;  
ylabel(hb,'Mahalanobis Distance')  
legend('X', 'Y', 'Location', 'NW')
```

The observations in Y with equal coordinate values are much closer to X in Mahalanobis distance than observations with opposite coordinate values, even though all observations are approximately equidistant from the mean of X in Euclidean distance. The Mahalanobis distance, by considering the covariance of the data and the scales of the different variables, is useful for detecting outliers in such cases.

`pdist` | `mahal`

Introduced before R2006a

mahal

Class: CompactClassificationDiscriminant

Mahalanobis distance to class means

Syntax

`M = mahal(obj,X)`

`M = mahal(obj,X,Name,Value)`

Description

`M = mahal(obj,X)` returns the squared Mahalanobis distances from observations in `X` to the class means in `obj`.

`M = mahal(obj,X,Name,Value)` computes the squared Mahalanobis distance with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

obj

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

X

Numeric matrix of size `n`-by-`p`, where `p` is the number of predictors in `obj`, and `n` is any positive integer. `mahal` computes the Mahalanobis distances from the rows of `X` to each of the `K` means of the classes in `obj`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'ClassLabels'

Class labels consisting of `n` elements of `obj.Y`, where `n` is the number of rows of `X`.

Output Arguments

M

Size and meaning of output `M` depends on whether the `ClassLabels` name-value pair is present:

- No `ClassLabels` — `M` is a numeric matrix of size `n`-by-`K`, where `K` is the number of classes in `obj`, and `n` is the number of rows in `X`. `M(i, j)` is the squared Mahalanobis distance from the `i`th row of `X` to the mean of class `j`.
- `ClassLabels` exists — `M` is a column vector with `n` elements. `M(i)` is the squared Mahalanobis distance from the `i`th row of `X` to the mean for the class of the `i`th element of `ClassLabels`.

Definitions

Mahalanobis Distance

The Mahalanobis distance $d(x,y)$ between n -dimensional points x and y , with respect to a given n -by- n covariance matrix S , is

$$d(x, y) = \sqrt{(x - y)^T S^{-1} (x - y)}.$$

Examples

Find the Mahalanobis distances from the mean of the Fisher iris data to the class means, using distinct covariance matrices for each class:

```
load fisheriris
obj = fitcdiscr(meas,species,...
  'DiscrimType','quadratic');
mahadist = mahal(obj,mean(meas))
```

```
mahadist =
  220.0667    5.0254    30.5804
```

See Also

How To

- “Discriminant Analysis” on page 16-3

mahal

Class: gmdistribution

Mahalanobis distance to component means

Syntax

```
D = mahal(obj,X)
```

Description

`D = mahal(obj,X)` computes the Mahalanobis distance (in squared units) of each observation in `X` to the mean of each of the k components of the Gaussian mixture distribution defined by `obj`. `obj` is an object created by `gmdistribution` or `fitgmdist`. `X` is an n -by- d matrix, where n is the number of observations and d is the dimension of the data. `D` is n -by- k , with `D(I,J)` the distance of observation `I` from the mean of component `J`.

Examples

Measure Mahalanobis Distances in Gaussian Mixture Data

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function.

```
MU1 = [1 2];  
SIGMA1 = [2 0; 0 .5];  
MU2 = [-3 -5];  
SIGMA2 = [1 0; 0 1];  
rng(1); % For reproducibility  
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];  
  
scatter(X(:,1),X(:,2),10,'.')  
hold on
```

Fit a two-component Gaussian mixture model.

```
obj = fitgmdist(X,2);  
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

Compute the Mahalanobis distance of each point in X to the mean of each component of obj .

```
D = mahal(obj,X);
```

```
delete(h)  
scatter(X(:,1),X(:,2),10,D(:,1),'.')  
hb = colorbar;  
ylabel(hb,'Mahalanobis Distance to Component 1')
```

See Also

gmdistribution | posterior | cluster | mahal

maineffectsplot

Main effects plot for grouped data

Syntax

```
maineffectsplot(Y, GROUP)
maineffectsplot(Y, GROUP, param1, val1, param2, val2, ...)
[figh, AXESH] = maineffectsplot(...)
```

Description

`maineffectsplot(Y, GROUP)` displays main effects plots for the group means of matrix `Y` with groups defined by entries in the cell array `GROUP`. `Y` is a numeric matrix or vector. If `Y` is a matrix, the rows represent different observations and the columns represent replications of each observation. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or single-column cell array of strings. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of rows as `Y`. The number of grouping variables must be greater than 1.

The display has one subplot per grouping variable, with each subplot showing the group means of `Y` as a function of one grouping variable.

`maineffectsplot(Y, GROUP, param1, val1, param2, val2, ...)` specifies one or more of the following name/value pairs:

- `'varnames'` — Grouping variable names in a character matrix or a cell array of strings, one per grouping variable. Default names are `'X1'`, `'X2'`, ...
- `'statistic'` — String values that indicate whether the group mean or the group standard deviation should be plotted. Use `'mean'` or `'std'`. The default is `'mean'`. If the value is `'std'`, `Y` is required to have multiple columns.
- `'parent'` — A handle to the figure window for the plots. The default is the current figure window.

`[figh, AXESH] = maineffectsplot(...)` returns the handle `figh` to the figure window and an array of handles `AXESH` to the subplot axes.

Examples

Main Effects Plot

Load the sample data.

```
load carsmall;
```

Display main effects plots for car weight with two grouping variables, model year and number of cylinders.

```
maineffectsplot(Weight,{Model_Year,Cylinders}, ...  
                'varnames',{'Model Year',' # of Cylinders'})
```

More About

- “Grouping Variables” on page 2-56

Introduced in R2006b

ClassificationDiscriminant.make

Class: ClassificationDiscriminant

Construct discriminant analysis classifier from parameters (to be removed)

Compatibility

ClassificationDiscriminant.make will be removed in a future release. Use `makecdiscr` instead.

Syntax

```
cobj = ClassificationDiscriminant.make(Mu, Sigma)
cobj = ClassificationDiscriminant.make(Mu, Sigma, Name, Value)
```

Description

`cobj = ClassificationDiscriminant.make(Mu, Sigma)` constructs a compact discriminant analysis classifier from the class means `MU` and covariance matrix `Sigma`.

`cobj = ClassificationDiscriminant.make(Mu, Sigma, Name, Value)` constructs a compact classifier with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

Mu — Class means

matrix of scalar values

Class means, specified as a K -by- p matrix of scalar values class means of size. K is the number of classes, and p is the number of predictors. Each row of `MU` represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the `ClassNames` attribute.

Data Types: `single` | `double`

Sigma — Within-class covariance

matrix of scalar values

Within-class covariance, specified as a matrix of scalar values.

- For a linear discriminant, **Sigma** is a symmetric, positive semidefinite matrix of size p -by- p , where p is the number of predictors.
- For a quadratic discriminant, **Sigma** is an array of size p -by- p -by- K , where K is the number of classes. For each i , **Sigma**($:$, $:$, i) is a symmetric, positive semidefinite matrix.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

'ClassNames' — Class names

numeric vector | categorical vector | logical vector | character array | cell array of strings

Class names as ordered in **Mu**, specified as the comma-separated pair consisting of **'ClassNames'** and an array containing grouping variables. Use any data type for a grouping variable, including numeric vector, categorical vector, logical vector, character array, or cell array of strings.

ClassNames names the classes, as ordered in **Mu**.

Default is $1:K$, where K is the number of classes (the number of rows of **Mu**).

Data Types: `single` | `double` | `logical` | `char` | `cell`

'Cost' — Cost of misclassification

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of **'Cost'** and a square matrix, where **Cost**(i , j) is the cost of classifying a point into class

j if its true class is i . Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Data Types: `single` | `double` | `struct`

'PredictorNames' — Predictor variable names

`{'X1', 'X2', ...}` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of strings containing the names for the predictor variables, in the order in which they appear in `X`.

Data Types: `cell`

'Prior' — Prior probabilities

`'uniform'` (default) | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following.

- `'uniform'`, a string meaning all class prior probabilities are equal.
- A vector containing one scalar value for each class.
- A structure `S` with two fields:
 - `S.ClassNames` containing the class names as a variable of the same type as `ClassNames`.
 - `S.ClassProbs` containing a vector of corresponding probabilities.

Data Types: `single` | `double` | `struct`

'ResponseName' — Response variable name

`'Y'` (default) | string

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a string containing the name of the response variable `y`.

Example: `'ResponseName', 'Response'`

Data Types: `char`

Output Arguments

cobj — Discriminant analysis classifier
discriminant analysis classifier object

Discriminant analysis classifier, returned as a discriminant analysis classifier object of class `CompactClassificationDiscriminant`. You can use the `predict` method to predict classification labels for new data.

Examples

Construct a Compact Linear Discriminant Analysis Classifier

Construct a compact linear discriminant analysis classifier from the means and covariances of the Fisher iris data.

```
load fisheriris
mu(1,:) = mean(meas(1:50,:));
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147; % unbiased estimator of sigma
cpct = ClassificationDiscriminant.make(mu,sigstar,...
    'ClassNames',{ 'setosa', 'versicolor', 'virginica' })

cpct =
classreg.learning.classif.CompactClassificationDiscriminant:
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}
  ResponseName: 'Y'
  ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
  DiscrimType: 'linear'
  Mu: [3x4 double]
```

Coeffs: [3x3 struct]

How To

- “Discriminant Analysis” on page 16-3

makecdiscr

Construct discriminant analysis classifier from parameters

Syntax

```
cobj = makecdiscr(Mu,Sigma)
cobj = makecdiscr(Mu,Sigma,Name,Value)
```

Description

`cobj = makecdiscr(Mu,Sigma)` constructs a compact discriminant analysis classifier from the class means `Mu` and covariance matrix `Sigma`.

`cobj = makecdiscr(Mu,Sigma,Name,Value)` constructs a compact classifier with additional options specified by one or more name-value pair arguments. For example, you can specify the cost of misclassification or the prior probabilities for each class.

Examples

Construct a Compact Linear Discriminant Analysis Classifier

Construct a compact linear discriminant analysis classifier from the means and covariances of the Fisher iris data.

```
load fisheriris
mu(1,:) = mean(meas(1:50,:));
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147; % unbiased estimator of sigma
```

```

cpct = makecdiscr(mu,sigstar,...
    'ClassNames',{ 'setosa', 'versicolor', 'virginica' })

cpct =
classreg.learning.classif.CompactClassificationDiscriminant:
    PredictorNames: {'x1' 'x2' 'x3' 'x4'}
    ResponseName: 'Y'
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
    DiscrimType: 'linear'
    Mu: [3x4 double]
    Coeffs: [3x3 struct]

```

Input Arguments

Mu — Class means

matrix of scalar values

Class means, specified as a K -by- p matrix of scalar values class means of size. K is the number of classes, and p is the number of predictors. Each row of **Mu** represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the **ClassNames** attribute.

Data Types: single | double

Sigma — Within-class covariance

matrix of scalar values

Within-class covariance, specified as a matrix of scalar values.

- For a linear discriminant, **Sigma** is a symmetric, positive semidefinite matrix of size p -by- p , where p is the number of predictors.
- For a quadratic discriminant, **Sigma** is an array of size p -by- p -by- K , where K is the number of classes. For each i , **Sigma**(:, :, i) is a symmetric, positive semidefinite matrix.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'ClassNames', {'setosa' 'versicolor' 'virginica'}` specifies a discriminant analysis classifier that uses 'setosa', 'versicolor', and 'virginica' as the grouping variables.

'ClassNames' — Class names

numeric vector | categorical vector | logical vector | character array | cell array of strings

Class names as ordered in `Mu`, specified as the comma-separated pair consisting of 'ClassNames' and an array containing grouping variables. Use any data type for a grouping variable, including numeric vector, categorical vector, logical vector, character array, or cell array of strings.

The default is `1:K`, where `K` is the number of classes (the number of rows of `Mu`).

Example: `'ClassNames', {'setosa' 'versicolor' 'virginica'}`

Data Types: `single` | `double` | `logical` | `char` | `cell`

'Cost' — Cost of misclassification

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of 'Cost' and a square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i, j)=1` if `i~=j`, and `Cost(i, j)=0` if `i=j`.

Data Types: `single` | `double` | `struct`

'PredictorNames' — Predictor variable names

`{'X1', 'X2', ...}` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in `X`.

Data Types: `cell`

'Prior' — Prior probabilities

'uniform' (default) | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following:

- 'uniform', a string meaning all class prior probabilities are equal
- A vector containing one scalar value for each class
- A structure **S** with two fields:
 - **S.ClassNames** containing the class names as a variable of the same type as **ClassNames**
 - **S.ClassProbs** containing a vector of corresponding probabilities

Data Types: single | double | struct

'ResponseName' — Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable **y**.

Example: 'ResponseName', 'Response'

Data Types: char

Output Arguments

cobj — Discriminant analysis classifier

discriminant analysis classifier object

Discriminant analysis classifier, returned as a discriminant analysis classifier object of class `CompactClassificationDiscriminant`. You can use the `predict` method to predict classification labels for new data.

More About

Tips

- You can change the discriminant type using dot notation after constructing `cobj`:

```
cobj.DiscrimType = 'discrimType'
```

where *discrimType* is one of 'linear', 'quadratic', 'diagLinear', 'diagQuadratic', 'pseudoLinear', or 'pseudoQuadratic'. You can change between linear types or between quadratic types, but cannot change between a linear and a quadratic type.

- `cobj` is a linear classifier when `Sigma` is a matrix. `cobj` is a quadratic classifier when `Sigma` is a three-dimensional array.
- “Discriminant Analysis” on page 16-3

Introduced in R2014a

makedist

Create probability distribution object

Syntax

```
pd = makedist(distname)
pd = makedist(distname,Name,Value)
```

Description

`pd = makedist(distname)` creates a probability distribution object for the distribution `distname`, using the default parameter values.

`pd = makedist(distname,Name,Value)` creates a probability distribution object with one or more distribution parameter values specified by name-value pair arguments.

Examples

Create a Normal Distribution Object

Create a normal distribution object using the default parameter values.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Compute the interquartile range of the distribution.

```
r = iqr(pd)
```

```
r =
```

```
1.3490
```

Create a Gamma Distribution Object

Create a gamma distribution object using the default parameter values.

```
pd = makedist('Gamma')
```

```
pd =
```

```
GammaDistribution
```

```
Gamma distribution
```

```
  a = 1
```

```
  b = 1
```

Compute the mean of the gamma distribution.

```
mean = mean(pd)
```

```
mean =
```

```
1
```

Specify Parameters for a Normal Distribution Object

Create a normal distribution object with parameter values $\mu = 75$ and $\sigma = 10$.

```
pd = makedist('Normal','mu',75,'sigma',10)
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
  mu = 75
```

```
  sigma = 10
```

Specify Parameters for a Gamma Distribution Object

Create a gamma distribution object with the parameter value $a = 3$ and the default value $b = 1$.

```
pd = makedist('Gamma', 'a', 3)
```

```
pd =
```

```
GammaDistribution
```

```
Gamma distribution
```

```
  a = 3
```

```
  b = 1
```

Input Arguments

distname — Distribution name

string

Distribution name, specified as one of the following strings. The distribution specified by **distname** determines the class type of the returned probability distribution object.

Distribution Name	Description	Distribution Class
'Beta'	Beta distribution	prob.BetaDistribution
'Binomial'	Binomial distribution	prob.BinomialDistribution
'BirnbbaumSaunders'	Birnbbaum-Saunders distribution	prob.BirnbbaumSaundersDistribution
'Burr'	Burr distribution	prob.BurrDistribution
'Exponential'	Exponential distribution	prob.ExponentialDistribution
'ExtremeValue'	Extreme Value distribution	prob.ExtremeValueDistribution
'Gamma'	Gamma distribution	prob.GammaDistribution
'GeneralizedExtremeValue'	Generalized Extreme Value distribution	prob.GeneralizedExtremeValueDistribution
'GeneralizedPareto'	Generalized Pareto distribution	prob.GeneralizedParetoDistribution
'HalfNormal'	Half-normal distribution	prob.HalfNormalDistribution
'InverseGaussian'	Inverse Gaussian distribution	prob.InverseGaussianDistribution
'Logistic'	Logistic distribution	prob.LogisticDistribution

Distribution Name	Description	Distribution Class
'Loglogistic'	Loglogistic distribution	prob.LoglogisticDistribution
'Lognormal'	Lognormal distribution	prob.LognormalDistribution
'Multinomial'	Multinomial distribution	prob.MultinomialDistribution
'Nakagami'	Nakagami distribution	prob.NakagamiDistribution
'NegativeBinomial'	Negative Binomial distribution	prob.NegativeBinomialDistribution
'Normal'	Normal distribution	prob.NormalDistribution
'PiecewiseLinear'	Piecewise Linear distribution	prob.PiecewiseLinearDistribution
'Poisson'	Poisson distribution	prob.PoissonDistribution
'Rayleigh'	Rayleigh distribution	prob.RayleighDistribution
'Rician'	Rician distribution	prob.RicianDistribution
'Stable'	Stable distribution	prob.StableDistribution
'tLocationScale'	<i>t</i> Location-Scale distribution	prob.tLocationScaleDistribution
'Triangular'	Triangular distribution	prob.TriangularDistribution
'Uniform'	Uniform distribution	prob.UniformDistribution
'Weibull'	Weibull distribution	prob.WeibullDistribution

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

Example: `makedist('Normal', 'mu', 10)` specifies a normal distribution with parameter `mu` equal to 10, and parameter `sigma` equal to the default value of 1.

Beta Distribution

'a' — First shape parameter

1 (default) | nonnegative scalar value

Example: 'a', 3

Data Types: single | double

'b' — Second shape parameter

1 (default) | nonnegative scalar value

Example: 'b',5

Data Types: single | double

Binomial Distribution

'N' — Number of trials

1 (default) | positive integer value

Example: 'N',25

Data Types: single | double

'p' — Probability of success

0.5 (default) | scalar value in the range [0,1]

Example: 'p',0.25

Data Types: single | double

Birnbaum-Saunders Distribution

'beta' — Scale parameter

1 (default) | positive scalar value

Example: 'beta',2

Data Types: single | double

'gamma' — Shape parameter

1 (default) | nonnegative scalar value

Example: 'gamma',0

Data Types: single | double

Burr Distribution

'alpha' — Scale parameter

1 (default) | positive scalar value

Example: 'alpha',2

Data Types: single | double

'c' — First shape parameter

1 (default) | positive scalar value

Example: 'c', 2

Data Types: single | double

'k' — Second shape parameter

1 (default) | positive scalar value

Example: 'k', 5

Data Types: single | double

Exponential Distribution

'mu' — Mean parameter

1 (default) | positive scalar value

Example: 'mu', 5

Data Types: single | double

Extreme Value Distribution

'mu' — Location parameter

0 (default) | scalar value

Example: 'mu', -2

Data Types: single | double

'sigma' — Scale parameter

1 (default) | nonnegative scalar value

Example: 'sigma', 2

Data Types: single | double

Gamma Distribution

'a' — Shape parameter

1 (default) | positive scalar value

Example: 'a', 2

Data Types: single | double

'b' — Scale parameter

1 (default) | nonnegative scalar value

Example: 'b',0

Data Types: single | double

Generalized Extreme Value Distribution

'k' — Shape parameter

0 (default) | scalar value

Example: 'k',0

Data Types: single | double

'sigma' — Scale parameter

1 (default) | nonnegative scalar value

Example: 'sigma',2

Data Types: single | double

'mu' — Location parameter

0 (default) | scalar value

Example: 'mu',1

Data Types: single | double

Generalized Pareto Distribution

'k' — Shape parameter

1 (default) | scalar value

Example: 'k',0

Data Types: single | double

'sigma' — Scale parameter

1 (default) | nonnegative scalar value

Example: 'sigma',2

Data Types: single | double

'theta' — Location parameter

1 (default) | scalar value

Example: 'theta',2

Data Types: single | double

Half-Normal Distribution

'mu' — Location parameter

0 (default) | positive scalar value

Example: 'mu',1

Data Types: single | double

'sigma' — Shape parameter

1 (default) | positive scalar value

Example: 'sigma',2

Data Types: single | double

Inverse Gaussian Distribution

'mu' — Scale parameter

1 (default) | positive scalar value

Example: 'mu',2

Data Types: single | double

'lambda' — Shape parameter

1 (default) | positive scalar value

Example: 'lambda',4

Data Types: single | double

Logistic Distribution

'mu' — Mean

0 (default) | scalar value

Example: 'mu',2

Data Types: single | double

'sigma' — Scale parameter

1 (default) | nonnegative scalar value

Example: 'sigma',4

Data Types: single | double

Loglogistic Distribution**'mu' — Log mean**

0 (default) | scalar value

Example: 'mu',2

Data Types: single | double

'sigma' — Log scale parameter

1 (default) | nonnegative scalar value

Example: 'sigma',4

Data Types: single | double

Lognormal Distribution**'mu' — Log mean**

0 (default) | scalar value

Example: 'mu',2

Data Types: single | double

'sigma' — Log standard deviation

1 (default) | nonnegative scalar value

Example: 'sigma',2

Data Types: single | double

Multinomial Distribution**'probabilities' — Outcome probabilities**

[0.500 0.500] (default) | vector of scalar values in the range [0,1]

Example: 'probabilities',[0.1 0.2 0.5 0.2]

Data Types: single | double

Nakagami Distribution

'mu' — Shape parameter

1 (default) | positive scalar value

Example: 'mu',5

Data Types: single | double

'omega' — Scale parameter

1 (default) | positive scalar value

Example: 'omega',5

Data Types: single | double

Negative Binomial Distribution

'R' — Number of successes

1 (default) | positive scalar value

Example: 'R',5

Data Types: single | double

'p' — Probability of success

0.5 (default) | scalar value in the range (0,1]

Example: 'p',0.1

Data Types: single | double

Normal Distribution

'mu' — Mean

0 (default) | scalar value

Example: 'mu',2

Data Types: single | double

'sigma' — Standard deviation

1 (default) | nonnegative scalar value

Example: 'sigma',2

Data Types: single | double

Piecewise Linear Distribution

'x' — Data values

1 (default) | vector of scalar values

Example: 'x', [1 2 3]

Data Types: single | double

'Fx' — cdf values

1 (default) | vector of scalar values

Example: 'Fx', [.2 .5 1]

Data Types: single | double

Poisson Distribution

'lambda' — Mean

1 (default) | nonnegative scalar value

Example: 'lambda', 5

Data Types: single | double

Rayleigh Distribution

'b' — Defining parameter

1 (default) | positive scalar value

Example: 'b', 3

Data Types: single | double

Rician Distribution

's' — Noncentrality parameter

1 (default) | nonnegative scalar value

Example: 's', 0

Data Types: single | double

'sigma' — Scale parameter

1 (default) | positive scalar value

Example: 'sigma', 2

Data Types: `single` | `double`

Stable Distribution

'alpha' — First shape parameter

2 (default) | scalar value in the range (0,2]

Example: `'alpha', 1`

Data Types: `single` | `double`

'beta' — Second shape parameter

0 (default) | scalar value in the range [-1,1]

Example: `'beta', 0.5`

Data Types: `single` | `double`

'gam' — Scale parameter

1 (default) | scalar value in the range (0,∞)

Example: `'gam', 2`

Data Types: `single` | `double`

'delta' — Location parameter

0 (default) | scalar value

Example: `'delta', 5`

Data Types: `single` | `double`

***t* Location-Scale Distribution**

'mu' — Location parameter

0 (default) | scalar value

Example: `'mu', -2`

Data Types: `single` | `double`

'sigma' — Scale parameter

1 (default) | positive scalar value

Example: `'sigma', 2`

Data Types: `single` | `double`

'nu' — Degrees of freedom

5 (default) | positive scalar value

Example: 'nu', 20

Data Types: single | double

Triangular Distribution**'a' — Lower limit**

0 (default) | scalar value

Example: 'a', -2

Data Types: single | double

'b' — Peak location

0.5 (default) | scalar value greater than or equal to a

Example: 'b', 1

Data Types: single | double

'c' — Upper limit

1 (default) | scalar value greater than or equal to b

Example: 'c', 5

Data Types: single | double

Uniform Distribution**'lower' — Lower parameter**

0 (default) | scalar value

Example: 'lower', -4

Data Types: single | double

'upper' — Upper parameter

1 (default) | scalar value greater than lower

Example: 'upper', 2

Data Types: single | double

Weibull Distribution

'a' — Scale parameter

1 (default) | positive scalar value

Example: 'a',2

Data Types: single | double

'b' — Shape parameter

1 (default) | positive scalar value

Example: 'b',5

Data Types: single | double

Output Arguments

pd — Probability distribution

probability distribution object

Probability distribution, returned as a probability distribution object of the type specified by `distname`.

Alternative Functionality

App

The Distribution Fitting app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitting app using `dfittool`, or click Distribution Fitting on the Apps tab.

`dfittool` | `fitdist`

Introduced in R2013a

manova

Class: RepeatedMeasuresModel

Multivariate analysis of variance

Syntax

```
manovatbl = manova(rm)
manovatbl = manova(rm,Name,Value)
[manovatbl,A,C,D] = manova( ___ )
```

Description

`manovatbl = manova(rm)` returns the results of multivariate analysis of variance (`manova`) for the repeated measures model `rm`.

`manovatbl = manova(rm,Name,Value)` also returns `manova` results with additional options, specified by one or more `Name,Value` pair arguments.

`[manovatbl,A,C,D] = manova(___)` also returns arrays `A`, `C`, and `D` for the hypotheses tests of the form $A*B*C = D$, where `D` is zero.

Tips

- The multivariate response for each observation (subject) is the vector of repeated measures.
- To test a more general hypothesis $A*B*C = D$, use `coefstest`.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'WithinModel' — Model specifying within-subjects hypothesis test

'separatemeans' (default) | model specification using formula

Model specifying the within-subjects hypothesis test, specified as one of the following:

- 'separatemeans' — Compute a separate mean for each group, and test for equality among the means.
- Model specification — This is a model specification in the within-subject factors. Test each term in the model. In this case, `tbl` contains a separate manova for each term in the formula, with the multivariate response equal to the vector of coefficients of that term.
- An r -by- nc matrix, C , specifying nc contrasts among the r repeated measures. If Y represents the matrix of repeated measures you use in the repeated measures model `rm`, then the output `tbl` contains a separate manova for each column of $Y*C$.

Example: 'WithinModel', 'separatemeans'

'By' — Single between-subjects factor

string

Single between-subjects factor, specified as the comma-separated pair consisting of 'By' and a string. `manova` performs a separate test of the within-subjects model for each value of this factor.

For example, if you have a between-subjects factor, `Drug`, then you can specify that factor to perform manova as follows.

Example: 'By', 'Drug'

Output Arguments

`manova` `tbl` — Results of multivariate analysis of variance

table

Results of multivariate analysis of variance for the repeated measures model `rm`, returned as a `table`.

`manova` uses these methods to measure the contributions of the model terms to the overall covariance:

- Wilks' Lambda
- Pillai's trace
- Hotelling-Lawley trace
- Roy's maximum root statistic

For details, see "Multivariate Analysis of Variance for Repeated Measures" on page 9-84.

`manova` returns the results for these tests for each group. `manovatbl` contains the following columns.

Column Name	Definition
Within	Within-subject terms
Between	Between-subject terms
Statistic	Name of the statistic computed
Value	Value of the corresponding statistic
F	<i>F</i> -statistic value
RSquare	Measure for variance explained
df1	Numerator degrees of freedom
df2	Denominator degrees of freedom
pValue	<i>p</i> -value for the corresponding <i>F</i> -statistic value

Data Types: `table`

A — Specification based on between-subjects model

`matrix` | `cell array`

Specification based on the between-subjects model, returned as a matrix or a cell array. It permits the hypothesis on the elements within given columns of **B** (within time hypothesis). If `manovatbl` contains multiple hypothesis tests, **A** might be a cell array.

Data Types: `single` | `double` | `cell`

C — Specification based on within-subjects model

`matrix` | `cell array`

Specification based on the within-subjects model, returned as a matrix or a cell array. It permits the hypotheses on the elements within given rows of **B** (between time hypotheses). If `manovatbl` contains multiple hypothesis tests, **C** might be a cell array.

Data Types: `single` | `double` | `cell`

D — Hypothesis value

0

Hypothesis value, returned as 0.

Examples

Perform Multivariate Analysis of Variance

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = table([1 2 3 4]','VariableNames',{'Measurements'});
```

Fit a repeated measures model where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform multivariate analysis of variance.

```
manova(rm)
```

```
ans =
```

Constant	species=virginica	Roy	35.505	1716.1	0.97261	3	11

Return Arrays of the Hypothesis Test

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4'],'VarNames',{'Measurements'});
```

Fit a repeated measures model where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform multivariate analysis of variance. Also return the arrays for constructing the hypothesis test.

```
[manovatbl,A,C,D] = manova(rm)
```

```
manovatbl =
```

More About

- “Model Specification for Repeated Measures Models” on page 9-78
- “Multivariate Analysis of Variance for Repeated Measures” on page 9-84

manova1

One-way multivariate analysis of variance

Syntax

```
d = manova1(X,group)
d = manova1(X,group,alpha)
[d,p] = manova1(...)
[d,p,stats] = manova1(...)
```

Description

`d = manova1(X,group)` performs a one-way Multivariate Analysis of Variance (MANOVA) for comparing the multivariate means of the columns of `X`, grouped by `group`. `X` is an m -by- n matrix of data values, and each row is a vector of measurements on n variables for a single observation. `group` is a grouping variable defined as a categorical variable, vector, string array, or cell array of strings. Two observations are in the same group if they have the same value in the `group` array. The observations in each group represent a sample from a population.

The function returns `d`, an estimate of the dimension of the space containing the group means. `manova1` tests the null hypothesis that the means of each group are the same n -dimensional multivariate vector, and that any difference observed in the sample `X` is due to random chance. If `d = 0`, there is no evidence to reject that hypothesis. If `d = 1`, then you can reject the null hypothesis at the 5% level, but you cannot reject the hypothesis that the multivariate means lie on the same line. Similarly, if `d = 2` the multivariate means may lie on the same plane in n -dimensional space, but not on the same line.

`d = manova1(X,group,alpha)` gives control of the significance level, `alpha`. The return value `d` will be the smallest dimension having `p > alpha`, where `p` is a p -value for testing whether the means lie in a space of that dimension.

`[d,p] = manova1(...)` also returns a `p`, a vector of p -values for testing whether the means lie in a space of dimension 0, 1, and so on. The largest possible dimension is either the dimension of the space, or one less than the number of groups. There is one element of `p` for each dimension up to, but not including, the largest.

If the i th p -value is near zero, this casts doubt on the hypothesis that the group means lie on a space of $i-1$ dimensions. The choice of a critical p -value to determine whether the result is judged statistically significant is left to the researcher and is specified by the value of the input argument `alpha`. It is common to declare a result significant if the p -value is less than 0.05 or 0.01.

`[d,p,stats] = manova1(...)` also returns `stats`, a structure containing additional MANOVA results. The structure contains the following fields.

Field	Contents
<code>W</code>	Within-groups sum of squares and cross-products matrix
<code>B</code>	Between-groups sum of squares and cross-products matrix
<code>T</code>	Total sum of squares and cross-products matrix
<code>dfW</code>	Degrees of freedom for <code>W</code>
<code>dfB</code>	Degrees of freedom for <code>B</code>
<code>dfT</code>	Degrees of freedom for <code>T</code>
<code>lambda</code>	Vector of values of Wilk's lambda test statistic for testing whether the means have dimension 0, 1, etc.
<code>chisq</code>	Transformation of <code>lambda</code> to an approximate chi-square distribution
<code>chisqdf</code>	Degrees of freedom for <code>chisq</code>
<code>eigenval</code>	Eigenvalues of W^1B
<code>eigenvec</code>	Eigenvectors of W^1B ; these are the coefficients for the canonical variables <code>C</code> , and they are scaled so the within-group variance of the canonical variables is 1
<code>canon</code>	Canonical variables <code>C</code> , equal to $XC * \text{eigenvec}$, where XC is X with columns centered by subtracting their means
<code>mdist</code>	A vector of Mahalanobis distances from each point to the mean of its group
<code>gmdist</code>	A matrix of Mahalanobis distances between each pair of group means

The canonical variables `C` are linear combinations of the original variables, chosen to maximize the separation between groups. Specifically, `C(:, 1)` is the linear combination of the X columns that has the maximum separation between groups. This means that among all possible linear combinations, it is the one with the most significant F statistic

in a one-way analysis of variance. $C(:, 2)$ has the maximum separation subject to it being orthogonal to $C(:, 1)$, and so on.

You may find it useful to use the outputs from `manova1` along with other functions to supplement your analysis. For example, you may want to start with a grouped scatter plot matrix of the original variables using `gplotmatrix`. You can use `gscatter` to visualize the group separation using the first two canonical variables. You can use `manovacluster` to graph a dendrogram showing the clusters among the group means.

Assumptions

The MANOVA test makes the following assumptions about the data in X :

- The populations for each group are normally distributed.
- The variance-covariance matrix is the same for each population.
- All observations are mutually independent.

Examples

you can use `manova1` to determine whether there are differences in the averages of four car characteristics, among groups defined by the country where the cars were made.

```
load carbig
[d,p] = manova1([MPG Acceleration Weight Displacement],...
                Origin)
d =
     3
p =
     0
    0.0000
    0.0075
    0.1934
```

There are four dimensions in the input matrix, so the group means must lie in a four-dimensional space. `manova1` shows that you cannot reject the hypothesis that the means lie in a 3-D subspace.

manovacluster

Dendrogram of group mean clusters following MANOVA

Syntax

```
manovacluster(stats)  
manovacluster(stats,method)  
H = manovacluster(stats,method)
```

Description

`manovacluster(stats)` generates a dendrogram plot of the group means after a multivariate analysis of variance (MANOVA). `stats` is the output `stats` structure from `manova1`. The clusters are computed by applying the single linkage method to the matrix of Mahalanobis distances between group means.

See `dendrogram` for more information on the graphical output from this function. The dendrogram is most useful when the number of groups is large.

`manovacluster(stats,method)` uses the specified method in place of single linkage. `method` can be any of the following character strings that identify ways to create the cluster hierarchy. (See `linkage` for additional information.)

Method	Description
'single'	Shortest distance (default)
'complete'	Largest distance
'average'	Average distance
'centroid'	Centroid distance
'ward'	Incremental sum of squares

`H = manovacluster(stats,method)` returns a vector of handles to the lines in the figure.

Examples

Dendrogram of Group Means After MANOVA

Load the sample data.

```
load carbig
```

Define the variable matrix.

```
X = [MPG Acceleration Weight Displacement];
```

Perform one-way MANOVA to compare the means of MPG, Acceleration, Weight, and Displacement grouped by Origin.

```
[d,p,stats] = manova1(X,Origin);
```

Create a dendrogram plot of the group means.

```
manovacluster(stats)
```

margin

Class: ClassificationKNN

Margin of k -nearest neighbor classifier

Syntax

```
m = margin(md1,tbl,ResponseVarName)
```

```
m = margin(md1,tbl,Y)
```

```
m = margin(md1,X,Y)
```

Description

`m = margin(md1,tbl,ResponseVarName)` returns the classification margins for the matrix of predictors X and class labels Y . For the definition, see “Margin” on page 25-3367.

`m = margin(md1,tbl,Y)` returns the classification margins for the matrix of predictors X and class labels Y .

`m = margin(md1,X,Y)` returns the classification margins for the matrix of predictors X and class labels Y .

Input Arguments

md1 — Classifier model

classifier model object

k -nearest neighbor classifier model, returned as a classifier model object.

Note that using the 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `mdl` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If `tbl` contains the response variable used to train `mdl`, then you do not need to specify `ResponseVarName` or `Y`.

If you trained `mdl` using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: table

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. If `tbl` contains the response variable used to train `mdl`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector. For example, if the response variable is stored as `tbl.response`, then specify it as `'response'`. Otherwise, the software treats all columns of `tbl`, including `tbl.response`, as predictors.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

X — Matrix of predictor values

matrix

Matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

Y — Categorical variables

categorical array | cell array of character vectors | character array | logical vector | numeric vector

A categorical array, cell array of character vectors, character array, logical vector, or a numeric vector with the same number of rows as X . Each row of Y represents the classification of the corresponding row of X .

Output Arguments

m — Classification margins

numeric vector

Numeric column vector of length `size(X,1)`. Each entry in m represents the margin for the corresponding rows of X and (true class) Y , computed using `mdl`.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

Score

The *score* of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors that have that classification, divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 25-4285.

Examples

Margin Calculation

Construct a k -nearest neighbor classifier for the Fisher iris data, where $k = 5$.

Load the data.

```
load fisheriris
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(meas,species,'NumNeighbors',5);
```

Examine the margin of the classifier for a mean observation classified 'versicolor'.

```
X = mean(meas);  
Y = {'versicolor'};  
m = margin(mdl,X,Y)
```

```
m =
```

```
1
```

The classifier has no doubt that 'versicolor' is the correct classification (all five nearest neighbors classify as 'versicolor').

margin

Class: ClassificationLinear

Classification margins for linear classification models

Syntax

```
m = margin(Mdl,X,Y)
```

```
m = margin( ____,Name,Value)
```

Description

`m = margin(Mdl,X,Y)` returns the classification margins for the binary, linear classification model `Mdl` using predictor data in `X` and corresponding class labels in `Y`. `m` contains classification margins for each regularization strength in `Mdl`.

`m = margin(____,Name,Value)` uses any of the previous syntaxes and additional options specified by one or more `Name,Value` pair arguments. For example, you can specify that columns in the predictor data correspond to observations.

Input Arguments

Mdl — Binary, linear classification model

ClassificationLinear model object

Binary, linear classification model, specified as a ClassificationLinear model object. You can create a ClassificationLinear model object using `fitclinear`.

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix. This orientation of `X` indicates that rows correspond to individual observations and columns correspond to individual predictor variables.

The length of `Y` and the number of observations in `X` must be equal.

Note: If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn'`, `'columns'`, then you might experience a significant reduction in computation time.

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

- The data type of `Y` must be the same `Mdl.ClassNames`.
- The distinct classes in `Y` must be a subset of `Mdl.ClassNames`.
- If `Y` is a character array, then each element must correspond to one row of the array.
- The length of `Y` and the number of observations in `X` must be equal.

Data Types: `categorical` | `cell` | `char` | `double` | `logical` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'ObservationsIn' — Predictor data observation dimension

`'rows'` (default) | `'columns'`

Predictor data observation dimension, specified as the comma-separated pair consisting of `'ObservationsIn'` and `'columns'` or `'rows'`.

Note: If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn'`, `'columns'`, then you might experience a significant reduction in optimization-execution time.

Data Types: char

Output Arguments

m — Classification margins

numeric column vector | numeric matrix

Classification margins, returned as a numeric column vector or matrix.

m is n -by- L , where n is the number of observations in X and L is the number of regularization strengths in Mdl (that is, `numel(Mdl.Lambda)`).

$m(i, j)$ is the classification margin of observation i using the trained linear classification model that has regularization strength $Mdl.Lambda(j)$.

Definitions

Classification Margin

The *classification margins* for binary classification are, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The literature commonly defines the margin as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Classification Score

For linear classification models, the raw *classification score* for classifying the observation x , a row vector, into the positive class is

$$f(x_j) = x\beta_j + b_j.$$

For the model with regularization strength j , β_j is the estimated column vector of coefficients (the model property `Beta(:, j)`) and b_j be the estimated, scalar bias (the model property `Bias(j)`).

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Examples

Estimate Test-Sample Margins

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Specify to hold out 30% of the observations. Solve the objective function using `SpaRSA`.

```
rng(1); % For reproducibility
```

```
CVMD1 = fitclinear(X,Ystats,'Solver','sparsa','Holdout',0.30);  
CMD1 = CVMD1.Trained{1};
```

CVMD1 is a `ClassificationPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `ClassificationLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```
trainIdx = training(CVMD1.Partition);  
testIdx = test(CVMD1.Partition);
```

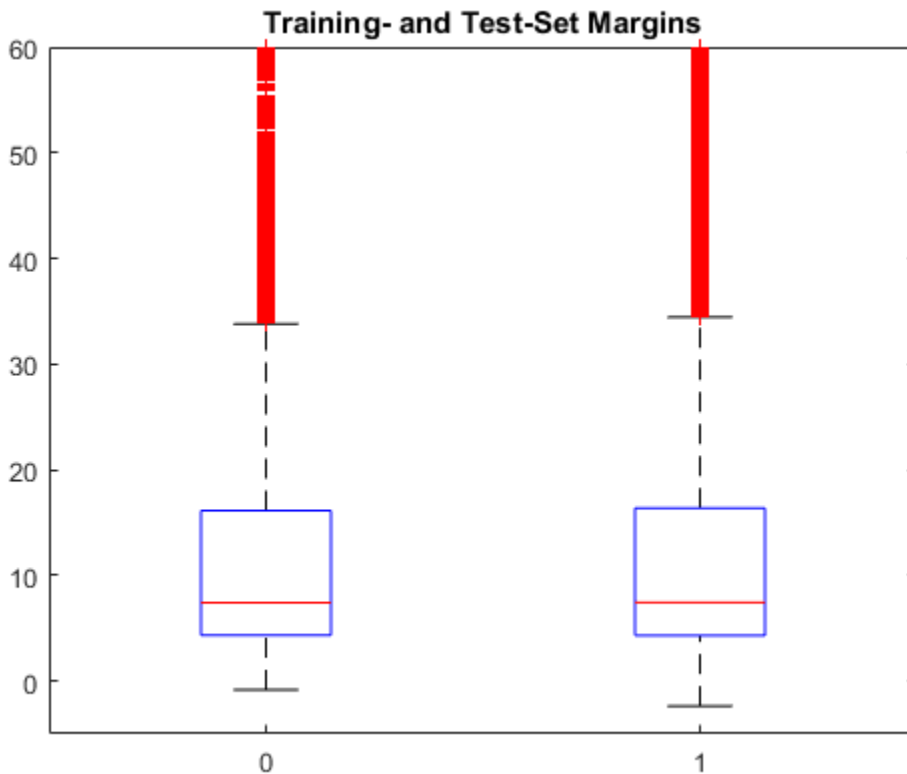

Estimate the training- and test-sample margins.

```
mTrain = margin(CMD1,X(trainIdx,:),Ystats(trainIdx));  
mTest = margin(CMD1,X(testIdx,:),Ystats(testIdx));
```

Because there is one regularization strength in `CMD1`, `mTrain` and `mTest` are column vectors with lengths equal to the number of training and test observations, respectively.

Plot both sets of margins using box plots.

```
figure;  
boxplot([mTrain; mTest],trainIdx);  
h = gca;  
h.YLim = [-5 60];  
title 'Training- and Test-Set Margins'
```

The distributions of the margins between the training and test sets appear similar.

Feature Selection Using Test-Sample Margins

One way to perform feature selection is to compare test-sample margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the NLP data set. Preprocess the data as in “Estimate Test-Sample Margins”.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

```
rng(1); % For reproducibility
```

Create a data partition which holds out 30% of the observations for testing.

```
Partition = cvpartition(Ystats,'Holdout',0.30);
testIdx = test(Partition); % Test-set indices
XTest = X(:,testIdx);
YTest = Ystats(testIdx);
```

Partition is a `cvpartition` object that defines the data set partition.

Randomly choose 10% of the predictor variables.

```
p = size(X,1); % Number of predictors
idxPart = randsample(p,ceil(0.1*p));
```

Train two binary, linear classification models: one that uses the all of the predictors and one that uses the random 10%. Solve the objective function using `SparSA`, and indicate that observations correspond to columns.

```
CVMD1 = fitlinear(X,Ystats,'CVPartition',Partition,'Solver','sparsa',...
    'ObservationsIn','columns');
PCVMD1 = fitlinear(X(idxPart,:),Ystats,'CVPartition',Partition,'Solver','sparsa',...
    'ObservationsIn','columns');
```

CVMD1 and PCVMD1 are `ClassificationPartitionedLinear` models.

Extract the trained `ClassificationLinear` models from the cross-validated models.

```
CMd1 = CVMD1.Trained{1};
PCMd1 = PCVMD1.Trained{1};
```

Estimate the test sample margins for each classifier. Plot the distribution of the margins sets using box plots.

```
fullMargins = margin(CMd1,XTest,YTest,'ObservationsIn','columns');
partMargins = margin(PCMd1,XTest(idxPart,:),YTest,...
    'ObservationsIn','columns');
```

```
figure;
boxplot([fullMargins partMargins],'Labels',...
    {'All Predictors','10% of the Predictors'});
h = gca;
h.YLim = [-20 60];
```

```
title('Test-Sample Margins')
```

The margin distribution of `CMd1` is situated higher than the margin distribution of `PCMd1`.

Find Good Lasso Penalty Using Margins

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare distributions of test-sample margins.

Load the NLP data set. Preprocess the data as in “Estimate Test-Sample Margins”.

```
load nlpdata
```

```

Ystats = Y == 'stats';
X = X';

Partition = cvpartition(Ystats,'Holdout',0.30);
testIdx = test(Partition);
XTest = X(:,testIdx);
YTest = Ystats(testIdx);

```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-8} through 10^1 .

```
Lambda = logspace(-8,1,11);
```

Train binary, linear classification models that use each of the regularization strengths. Solve the objective function using SpARSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```

rng(10); % For reproducibility
CVMdl = fitlinear(X,Ystats,'ObservationsIn','columns',...
    'CVPartition',Partition,'Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)

```

```
CVMdl =
```

```

classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 1
  Partition: [1x1 cvpartition]
  ClassNames: [0 1]
  ScoreTransform: 'none'

```

Extract the trained linear classification model.

```
Mdl = CVMdl.Trained{1}
```

```
Mdl =
```

```

ClassificationLinear
  ResponseName: 'Y'

```

```
ClassNames: [0 1]
ScoreTransform: 'logit'
    Beta: [34023x11 double]
    Bias: [1x11 double]
    Lambda: [1x11 double]
Learner: 'logistic'
```

`Mdl` is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl` as 11 models, one for each regularization strength in `Lambda`.

Estimate the test-sample margins.

```
m = margin(Mdl,X(:,testIdx),Ystats(testIdx),'ObservationsIn','columns');
size(m)
```

```
ans =
```

```
    9471         11
```

Because there are 11 regularization strengths, `m` has 11 columns.

Plot the test-sample margins for each regularization strength. Because logistic regression scores are in $[0,1]$, margins are in $[-1,1]$. Rescale the margins to help identify the regularization strength that maximizes the margins over the grid.

```
figure;
boxplot(10000.^m)
ylabel('Exponentiated test-sample margins')
xlabel('Lambda indices')
```

Several values of **Lambda** yield margin distributions that are compacted near **10000**¹. Higher values of lambda lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the centers of the margin distributions start decreasing.

```
LambdaFinal = Lambda(5);
```

Train a linear classification model using the entire data set and specify the desired regularization strength.

```
MdlFinal = fitlinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
```

```
'Lambda', LambdaFinal);
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Introduced in R2016a

margin

Class: CompactClassificationDiscriminant

Classification margins

Syntax

```
m = margin(obj,X,Y)
```

Description

`m = margin(obj,X,Y)` returns the classification margins for the matrix of predictors `X` and class labels `Y`. For the definition, see “Definitions” on page 25-3382.

Input Arguments

obj

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

X

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `obj`.

Y

Class labels, with the same data type as exists in `obj`. The number of elements of `Y` must equal the number of rows of `X`.

Output Arguments

m

Numeric column vector of length `size(X,1)`. Each entry in `m` represents the margin for the corresponding rows of `X` and (true class) `Y`, computed using `obj`.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X . A high value of margin indicates a more reliable prediction than a low value.

Score (discriminant analysis)

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 16-7.

Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris
X = meas(:,1:2);
obj = fitcdiscr(X,species);
M = margin(obj,X,species);
M(end-10:end)
```

```
ans =
    0.6551
    0.4838
    0.6551
   -0.5127
    0.5659
    0.4611
    0.4949
    0.1024
    0.2787
   -0.1439
   -0.4444
```

The classifier trained on all the data is better:

```
obj = fitcdiscr(meas,species);  
M = margin(obj,meas,species);  
M(end-10:end)
```

```
ans =  
    0.9983  
    1.0000  
    0.9991  
    0.9978

How To

- “Discriminant Analysis” on page 16-3

margin

Class: CompactClassificationECOC

Classification margins for error-correcting output code multiclass classifiers

Syntax

```
m = margin(Mdl,tbl,ResponseVarName)
m = margin(Mdl,tbl,Y)
m = margin(Mdl,X,Y)
m = margin(Mdl, ___,Name,Value)
```

Description

`m = margin(Mdl,tbl,ResponseVarName)` returns the classification margins (`m`) for the trained error-correcting output code (ECOC) multiclass classifier `Mdl` using the predictor data in table `tbl` and the class labels in `tbl.ResponseVarName`. Each row of `tbl` and `ResponseVarName` is an observation.

`m = margin(Mdl,tbl,Y)` returns the classification margins for the trained classifier `Mdl` using the predictor data in table `tbl` and the class labels in vector `Y`. Each row of `tbl` and `Y` is an observation.

`m = margin(Mdl,X,Y)` returns the classification margins for the trained classifier `Mdl` using the predictor data `X` and class labels `Y`. Each row of `X` and `Y` is an observation.

`m = margin(Mdl, ___,Name,Value)` returns the classification margins with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can specify a decoding scheme, binary learner loss function, or verbosity level.

Input Arguments

Mdl — ECOC multiclass classifier

ClassificationECOC model object | CompactClassificationECOC model object

ECOC multiclass classifier, specified as a `ClassificationECOC` or `CompactClassificationECOC` model object.

To create a full or compact ECOC model, see `ClassificationECOC` or `CompactClassificationECOC`.

tbl — Sample data

table

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all the predictors used to train `Mdl`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `Mdl` using sample data contained in a `table`, then the input data for this method must also be in a `table`.

Note: If `Mdl.BinaryLearners` contains linear classification models (that is, `ClassificationLinear` model objects), then you cannot specify sample data in a `table`. Instead, pass a full or sparse matrix (`X`) and class labels (`Y`).

Data Types: `table`

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a character vector. For example, if the response variable `y` is stored as `tbl.y`, then specify it as `'y'`. Otherwise, the software treats all columns of `tbl`, including `y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation, and each column corresponds to one variable. The variables composing the columns of X should be the same as the variables that trained the `Mdl` classifier.

The length of Y and the number of rows of X must be equal.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. Y must be the same as the data type of `Mdl.ClassNames`.

The length of Y and the number of rows of X must be equal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

'BinaryLoss' — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$

Value	Description	Score Domain	$g(y_i, s_i)$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_i s_i)/2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_i s_i)]/2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_i s_i)/2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_i s_i)/2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_i s_i)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_i(2s_i - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss', @customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Models Using Custom Binary Loss Function” on page 25-4317.

By default, if all binary learners are:

- SVMs or linear classification models of SVM learners, then `BinaryLoss` is `'hinge'`
- Ensembles trained by `AdaboostM1` or `GentleBoost`, then `BinaryLoss` is `'exponential'`
- Ensembles trained by `LogitBoost`, then `BinaryLoss` is `'binodeviance'`

- Linear classification models of logistic regression learners, or you specify to predict class posterior probabilities (i.e., set 'FitPosterior', 1 in fitcecoc), then BinaryLoss is 'quadratic'

Otherwise, the default BinaryLoss is 'hamming'. To check the default value, use dot notation to display the BinaryLoss property of the trained model at the command line.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | function_handle

'Decoding' — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the “Binary Loss” on page 25-4314, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'.

Example: 'Decoding', 'lossbased'

Data Types: char

'ObservationsIn' — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'. Mdl.BinaryLearners must contain linear classification models.

Note: If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in execution time.

Data Types: char

'Options' — Estimation options

[] (default) | structure array returned by statset

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',1)`.

'Verbose' — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. **Verbose** controls the amount of diagnostic messages that the software displays in the Command Window.

If **Verbose** is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: `single` | `double`

Output Arguments

m — Classification margins

numeric column vector | numeric matrix

Classification margins, returned as a numeric column vector.

m has the same length as **Y**. The software estimates each entry of **m** using the trained ECOC model **Mdl**, the corresponding row of **X**, and the true class label **Y**.

If **Mdl.BinaryLearners** contains linear classification models, then **m** is an n -by- L vector, where n is the number of observations in **X** and L is the number of regularization strengths in the linear classification models (i.e., `numel(Mdl.BinaryLearners{1}.Lambda)`). $m(i,j)$ is the margin of observation i for the model trained using regularization strength `Mdl.BinaryLearners{1}.Lambda(j)`.

Otherwise, **m** is a column vector of length n .

Definitions

Binary Loss

A *binary loss* is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Let:

- m_{kj} be element (k,j) of the coding design matrix M (i.e., the code corresponding to class k of binary learner j)
- s_j be the score of binary learner j for an observation
- g be the binary loss function
- \hat{k} be the predicted class for the observation

In *loss-based decoding* [15], the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In *loss-weighted decoding* [15], the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. [2] suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [2].

Do not confuse the binary loss with the overall classification loss (specified by the LossFun name-value pair argument of predict and loss), e.g., classification error, which measures how well an ECOC classifier performs as a whole.

Classification Margin

The *classification margins* are, for each observation, the difference between the negative loss for the true class and maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Examples

Estimate Test-Sample Classification Margins of ECOC Models

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers, and specify a 30% holdout sample. It is good practice to standardize the predictors and define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,'ClassNames',classOrder);
CMdl = CVMdl.Trained{1}; % Extract trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVMdl is a `ClassificationPartitionedECOC` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationECOC` model that the software trained using the training set.

Estimate the test-sample classification margins. Display the distribution of the margins using a boxplot.

```
m = margin(CMdl,XTest,YTest);

figure;
boxplot(m);
title 'Test-Sample Margins'
```

An observation margin is the positive-class, negated loss minus the maximum negative-class, negated loss. Classifiers that yield relatively large margins are desirable.

Select ECOC Model Features by Examining Test-Sample Margins

The classifier margins measure, for each observation, the difference between the positive-class, negated loss score and the maximal negative-class, negated loss. One way to perform feature selection is to compare test-sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load Fisher's iris data set.

```
load fisheriris
```

```
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```
Partition = cvpartition(Y, 'Holdout', 0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Define these two data sets:

- `fullX` contains all four predictors.
- `partX` contains the sepal measurements.

```
fullX = X;
partX = X(:,1:2);
```

Train an ECOC model using SVM binary classifiers for each predictor set, and specify the partition definition. It is good practice to define the class order. Specify to standardize the predictors using an SVM template.

```
t = templateSVM('Standardize', 1);
CVMdl = fitcecoc(fullX, Y, 'CVPartition', Partition, 'Learners', t, ...
    'ClassNames', classOrder);
PCVMdl = fitcecoc(partX, Y, 'CVPartition', Partition, 'Learners', t, ...
    'ClassNames', classOrder);
CMdl = CVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};
```

Estimate the test-sample margins for each classifier. For each model, display the distribution of the margins using a boxplot.

```
fullMargins = margin(CMdl, XTest, YTest);
partMargins = margin(PCMdl, XTest(:,3:4), YTest);

figure;
boxplot([fullMargins partMargins], 'Labels', {'All Predictors', 'Two Predictors'});
title('Boxplots of Test-Sample Margins')
```

The margin distribution of `CMdl` is situated higher, and with less variability than the margin distribution of `PCMdl`.

- “Quick Start Parallel Computing for Statistics and Machine Learning Toolbox” on page 24-2

Tip

To compare margins or edges of several classifiers, use template objects to specify a common score transform function among the classifiers when you train them using `fitcecoc`.

Algorithms

If you trained `Mdl` specifying to standardize the predictor data, then the software standardizes the columns of `X` using the corresponding means and standard deviations that the software stored in `Mdl.BinaryLearner{j}.Mu` and `Mdl.BinaryLearner{j}.Sigma` for learner `j`.

margin

Class: CompactClassificationEnsemble

Classification margins

Syntax

```
M = margin(ens,tbl,ResponseVarName)
M = margin(ens,tbl,Y)
M = margin(ens,X,Y)
M = margin( ___ Name,Value)
```

Description

`M = margin(ens,tbl,ResponseVarName)` returns the classification margin for the predictions of `ens` on data `tbl`, when the true classifications are `tbl.ResponseVarName`.

`M = margin(ens,tbl,Y)` returns the classification margin for the predictions of `ens` on data `tbl`, when the true classifications are `Y`.

`M = margin(ens,X,Y)` returns the classification margin for the predictions of `ens` on data `X`, when the true classifications are `Y`.

`M = margin(___ Name,Value)` calculates margin with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes.

Input Arguments

ens

Classification ensemble created with `fitensemble`, or a compact classification ensemble created with `compact`.

tbl

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. `tbl` must contain all of the predictors

used to train the model. Multi-column variables and cell arrays other than cell arrays of strings are not allowed.

If you trained `ens` using sample data contained in a `table`, then the input data for this method must also be in a table.

ResponseVarName

Response variable name, specified as the name of a variable in `tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a string. For example, if the response variable `Y` is stored as `tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `tbl`, including `Y`, as predictors when training the model.

X

Matrix of data to classify. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `ens`. `X` should have the same number of rows as the number of elements in `Y`.

If you trained `ens` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

Y

Classification of `X`. `Y` should be of the same type as the classification used to train `ens`, and its number of elements should equal the number of rows of `tbl` or `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

'learners'

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

'UseObsForLearner'

A logical matrix of size N-by-T, where:

- N is the number of rows of X.
- T is the number of weak learners in ens.

When `UseObsForLearner(i, j)` is true, learner j is used in predicting the class of row i of X.

Default: true(N,T)

Output Arguments

M

A numeric column vector with the same number of rows as `tbl` or X. Each row of M gives the classification margin for that row of `tbl` or X.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix X.

Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

Examples

Find the margin for classifying an average flower from the Fisheriris data as 'versicolor':

```
load fisheriris % X = meas, Y = species
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
flower = mean(meas);
predict(ens,flower)
```

```
ans =
    'versicolor'
```

```
margin(ens,mean(meas),'versicolor')
```

```
ans =
    3.2140
```

margin

Class: CompactClassificationNaiveBayes

Classification margins for naive Bayes classifiers

Syntax

```
m = margin(Mdl, tbl, ResponseVarName)
m = margin(Mdl, tbl, Y)
m = margin(Mdl, X, Y)
```

Description

`m = margin(Mdl, tbl, ResponseVarName)` returns the classification margins (`m`) for the trained naive Bayes classifier `Mdl` using the predictor data in table `tbl` and the class labels in `tbl.ResponseVarName`.

`m = margin(Mdl, tbl, Y)` returns the classification margins (`m`) for the trained naive Bayes classifier `Mdl` using the predictor data in table `tbl` and the class labels in vector `Y`.

`m = margin(Mdl, X, Y)` returns the classification margins (`m`) for the trained naive Bayes classifier `Mdl` using the predictor data `X` and class labels `Y`.

Input Arguments

Mdl — Naive Bayes classifier

ClassificationNaiveBayes model | CompactClassificationNaiveBayes model

Naive Bayes classifier, specified as a ClassificationNaiveBayes model or CompactClassificationNaiveBayes model returned by `fitcnb` or `compact`, respectively.

tbl — Sample data

table

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain

additional columns for the response variable and observation weights. `tbl` must contain all the predictors used to train `Mdl`. Multi-column variables and cell arrays other than cell arrays of strings are not allowed.

If you trained `Mdl` using sample data contained in a `table`, then the input data for this method must also be in a `table`.

Data Types: `table`

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a string. For example, if the response variable `y` is stored as `tbl.y`, then specify it as `'y'`. Otherwise, the software treats all columns of `tbl`, including `y`, as predictors when training the model.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of strings. If the response variable is a character array, then each element must correspond to one row of the array.

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained `Mdl`.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. `Y` must be the same as the data type of `Mdl.ClassNames`.

The length of `Y` and the number of rows of `tbl` or `X` must be equal.

Output Arguments

m — Classification margins

numeric vector

Classification margins, returned as a numeric vector.

m has the same length equal to `size(X, 1)`. Each entry of **m** is the classification margin of the corresponding observation (row) of **X** and element of **Y**.

Definitions

Classification Edge

The *classification edge* is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The *classification margins* are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Posterior Probability

The *posterior probability* is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is *k* for a given observation (x_1, \dots, x_p) is

$$\hat{P}(Y = k | x_1, \dots, x_P) = \frac{P(X_1, \dots, X_P | y = k)\pi(Y = k)}{P(X_1, \dots, X_P)},$$

where:

- $P(X_1, \dots, X_P | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_P)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_P) = \sum_{k=1}^K P(X_1, \dots, X_P | y = k)\pi(Y = k).$$

Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population for each class.

Score

The naive Bayes *score* is the class posterior probability given the observation.

Examples

Estimate Test-Sample Classification Margins of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Train a naive Bayes classifier. Specify a 30% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```
CVMD1 = fitcnb(X,Y,'Holdout',0.30,...  
    'ClassNames',{'setosa','versicolor','virginica'});  
CMD1 = CVMD1.Trained{1}; ...  
    % Extract the trained, compact classifier  
testInds = test(CVMD1.Partition); % Extract the test indices  
XTest = X(testInds,:);  
YTest = Y(testInds);
```

CVMD1 is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample classification margins. Display the distribution of the margins using a boxplot.

```
m = margin(CMD1,XTest,YTest);  
  
figure;  
boxplot(m);  
title 'Distribution of the Test-Sample Margins';
```

An observation margin is the observed true class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are desirable.

Select Naive Bayes Classifier Features by Examining Test Sample Margins

The classifier margins measure, for each observation, the difference between the true class observed score and the maximal false class score for a particular class. One way to perform feature selection is to compare test sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load Fisher's iris data set.

```
load fisheriris
```

```
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```
Partition = cvpartition(Y, 'Holdout', 0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds);
```

Partition defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the last 2 predictors.

```
fullX = X;
partX = X(:,3:4);
```

Train naive Bayes classifiers for each predictor set. Specify the partition definition.

```
FCVMdl = fitcnb(fullX,Y, 'CVPartition', Partition);
PCVMdl = fitcnb(partX,Y, 'CVPartition', Partition);
FCMdl = FCVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};
```

`FullCVMdl` and `PartCVMdl` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample margins for each classifier. Display the distributions of the margins for each model using boxplots.

```
fullM = margin(FCMdl,XTest,YTest);
partM = margin(PCMdl,XTest(:,3:4),YTest);

figure;
boxplot([fullM partM], 'Labels', {'All Predictors', 'Two Predictors'})
h = gca;
h.YLim = [0.98 1.01]; % Modify axis to see boxes.
```

```
title 'Boxplots of Test-Sample Margins';
```

The margins have a similar distribution, but PCMd1 is less complex.

margin

Class: CompactClassificationSVM

Classification margins for support vector machine classifiers

Syntax

```
m = margin(SVMModel, TBL, ResponseVarName)
```

```
m = margin(SVMModel, TBL, Y)
```

```
m = margin(SVMModel, X, Y)
```

Description

`m = margin(SVMModel, TBL, ResponseVarName)` returns the classification margins (`m`) for the trained support vector machine (SVM) classifier `SVMModel` using the sample data in table `TBL` and class labels in `TBL.ResponseVarName`.

`m = margin(SVMModel, TBL, Y)` returns the classification margins (`m`) for the trained support vector machine (SVM) classifier `SVMModel` using the sample data in table `TBL` and class labels in `Y`.

`m = margin(SVMModel, X, Y)` returns the classification margins for `SVMModel` using the predictor data in matrix `X` and class labels `Y`.

Input Arguments

SVMModel — SVM classifier

ClassificationSVM classifier | CompactClassificationSVM classifier

SVM classifier, specified as a ClassificationSVM classifier or CompactClassificationSVM classifier returned by `fitcsvm` or `compact`, respectively.

TBL — Sample data

table

Sample data, specified as a table. Each row of `TBL` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `TBL` can contain

additional columns for the response variable and observation weights. `TBL` must contain all of the predictors used to train `SVMModel`. Multi-column variables and cell arrays other than cell arrays of strings are not allowed.

If `TBL` contains the response variable used to train `SVMModel`, then you do not need to specify `ResponseVarName` or `Y`.

If you trained `SVMModel` using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: `table`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` must be the same as the variables that trained the `SVMModel` classifier.

The length of `Y` and the number of rows of `X` must be equal.

If you set `'Standardize', true` in `fitcsvm` to train `SVMModel`, then the software standardizes the columns of `X` using the corresponding means in `SVMModel.Mu` and standard deviations in `SVMModel.Sigma`.

Data Types: `double` | `single`

ResponseVarName — Response variable name

name of a variable in `TBL`

Response variable name, specified as the name of a variable in `TBL`. If `TBL` contains the response variable used to train `SVMModel`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a string. For example, if the response variable is stored as `TBL.Response`, then specify it as `'Response'`. Otherwise, the software treats all columns of `TBL`, including `TBL.Response`, as predictors.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of strings. If the response variable is a character array, then each element must correspond to one row of the array.

Y – Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. Y must be the same as the data type of `SVMModel.ClassNames`.

The length of Y must equal the number of rows of TBL or X must be equal.

Output Arguments

m – Classification margins

numeric vector

Classification margins, returned as a numeric vector.

m has the same length as Y. The software estimates each entry of m using the trained SVM classifier `SVMModel`, the corresponding row of X, and the true class label Y.

Definitions

Classification Edge

The *edge* is the weighted mean of the *classification margins*.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The *classification margins* for binary classification are, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The literature commonly defines the margin as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Classification Score

The SVM *classification score* for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class, a negative score indicates otherwise.

The score for predicting x into the positive class, also the numerical, predicted response for x , $f(x)$, is the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The score for predicting x into the negative class is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)' \beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

Examples

Estimate Test Sample Classification Margins of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; ...
    % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVSVMModel is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample classification margins.

```
m = margin(CompactSVMModel,XTest,YTest);
m(10:20)
```

```
ans =
```

```
3.5461
5.5939
4.9948
4.5611
-4.7963
5.5127
-2.8776
1.8673
9.4986
9.5018
20.9954
```

An observation margin is the observed true class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are desirable.

Select SVM Classifier Features by Examining Test Sample Margins

The classifier margins measure, for each observation, the difference between the true class observed score and the maximal false class score for a particular class. One way to

perform feature selection is to compare test sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 15% holdout sample for testing.

```
Partition = cvpartition(Y, 'Holdout', 0.15);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set. Specify the partition definition.

```
FullCVSVMModel = fitcsvm(fullX, Y, 'CVPartition', Partition);
PartCVSVMModel = fitcsvm(partX, Y, 'CVPartition', Partition);
FCSVMModel = FullCVSVMModel.Trained{1};
PCSVMModel = PartCVSVMModel.Trained{1};
```

`FullCVSVMModel` and `PartCVSVMModel` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample margins for each classifier.

```
fullM = margin(FCSVMModel, XTest, YTest);
partM = margin(PCSVMModel, XTest(:,end-20:end), YTest);
n = size(XTest, 1);
p = sum(fullM < partM)/n
```

p =
0.2500

Approximately 25% of the margins from the full model are less than those from the model with fewer predictors. This suggests that the model trained using all of the predictors is better.

Algorithms

For binary classification, the software defines the margin for observation j , m_j , as

$$m_j = 2y_j f(x_j),$$

where $y_j \in \{-1, 1\}$, and $f(x_j)$ is the predicted score of observation j for the positive class. However, the literature commonly uses $m_j = y_j f(x_j)$ to define the margin.

margin

Class: CompactClassificationTree

Classification margins

Syntax

```
m = margin(tree, TBL, ResponseVarName)
m = margin(tree, TBL, Y)
m = margin(tree, X, Y)
```

Description

`m = margin(tree, TBL, ResponseVarName)` returns the classification margins for the table of predictors `TBL` and class labels `TBL.ResponseVarName`. For the definition, see “Margin” on page 25-3418.

`m = margin(tree, TBL, Y)` returns the classification margins for the table of predictors `TBL` and class labels `Y`.

`m = margin(tree, X, Y)` returns the classification margins for the matrix of predictors `X` and class labels `Y`.

Input Arguments

tree — Trained classification tree

ClassificationTree model object | CompactClassificationTree model object

Trained classification tree, specified as a ClassificationTree or CompactClassificationTree model object. That is, `tree` is a trained classification model returned by `fitctree` or `compact`.

TBL — Sample data

table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all the predictors used to train `tree`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train `tree`, then you do not need to specify `ResponseVarName` or `Y`.

If you train `tree` using sample data contained in a `table`, then the input data for this method must also be in a table.

Data Types: `table`

X — Data to classify

numeric matrix

Data to classify, specified as a numeric matrix. Each row of X represents one observation, and each column represents one predictor. X must have the same number of columns as the data used to train `tree`. X must have the same number of rows as the number of elements in Y.

Data Types: `single` | `double`

ResponseVarName — Response variable name

name of a variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train `tree`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector. For example, if the response variable is stored as `TBL.Response`, then specify it as `'Response'`. Otherwise, the software treats all columns of TBL, including `TBL.ResponseVarName`, as predictors.

The response variable must be a categorical or character array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Y — Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical or character array, a logical or numeric vector, or a cell array of character vectors. `Y` must be of the same type as the classification used to train `tree`, and its number of elements must equal the number of rows of `X`.

Data Types: `single` | `double` | `categorical` | `char` | `logical` | `cell`

Output Arguments

`m` — Margin

numeric column vector

Margin, returned as a numeric column vector of length `size(X,1)`. Each entry in `m` represents the margin for the corresponding rows of `X` and (true class) `Y`, computed using `tree`.

Definitions

Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `X`.

Score (tree)

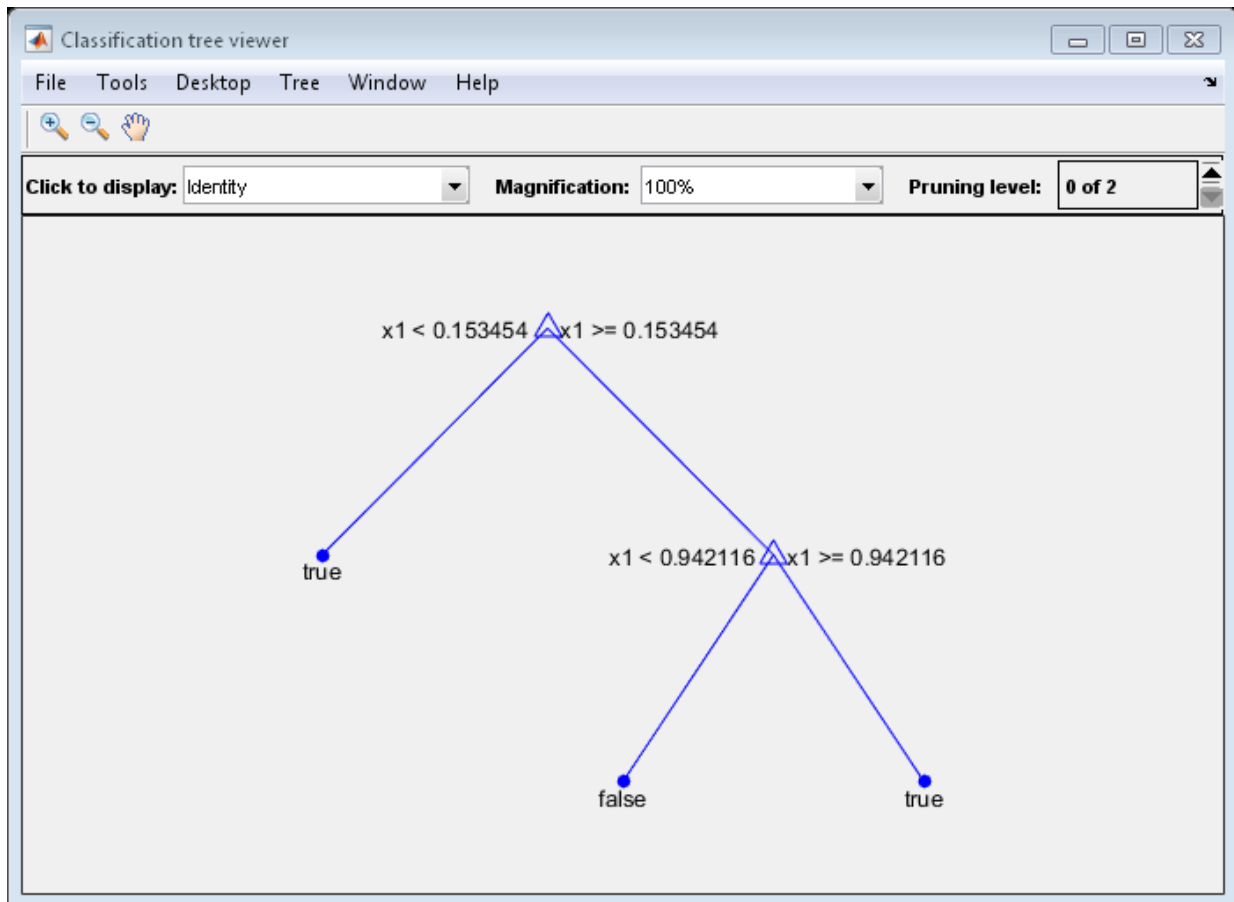

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

Generate 100 random points and classify them:

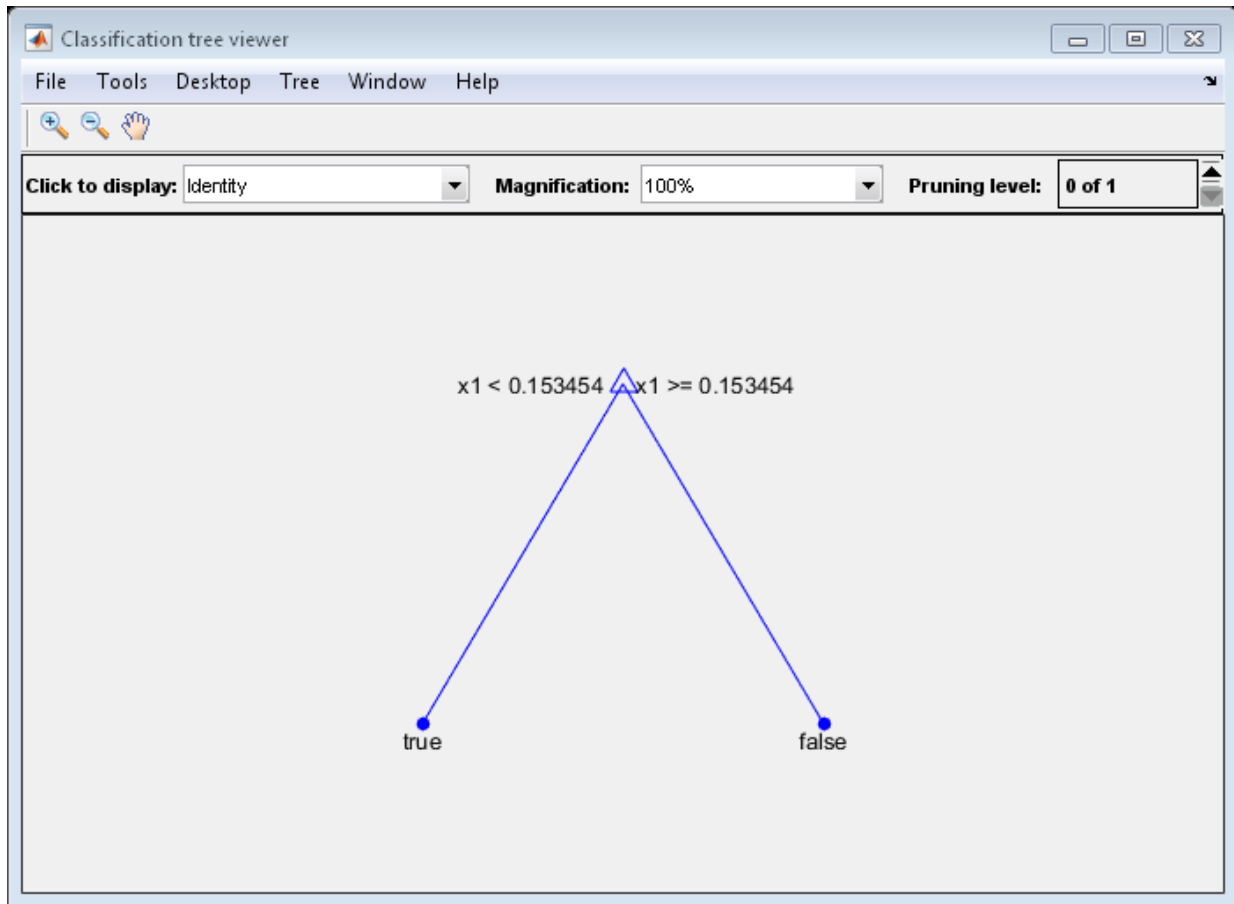

```
rng(0,'twister') % for reproducibility
```

```
X = rand(100,1);  
Y = (abs(X - .55) > .4);  
tree = fitctree(X,Y);  
view(tree,'Mode','Graph')
```

Prune the tree:

```
tree1 = prune(tree,'Level',1);  
view(tree1,'Mode','Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as **true**. It also correctly classifies observations from .15 to .94 as **false**. However, it incorrectly classifies observations that are greater than .94 as **false**. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for **true**, and about $.8/.85=.94$ for **false**.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries.

```
load fisheriris
X = meas(:,1:2);
tree = fitctree(X,species);
M = margin(tree,X,species);
M(end-10:end)
```

```
ans =
    0.1111
    0.1111
    0.1111
   -0.2857
    0.6364
    0.6364
    0.1111
    0.7500
    1.0000
    0.6364
```

```
0.2000
```

The classification tree trained on all the data is better.

```
tree = fitctree(meas,species);  
M = margin(tree,meas,species);  
M(end-10:end)
```

```
ans =  
0.9565  
0.9565  
0.9565  
0.9565  
0.9565  
0.9565  
0.9565  
0.9565  
0.9565  
0.9565  
0.9565
```

[predict](#) | [edge](#) | [loss](#) | [fitctree](#)

margin

Class: CompactTreeBagger

Classification margin

Syntax

```
mar = margin(B, TBLnew, Ynew)
mar = margin(B, Xnew, Ynew)
mar = margin(B, TBLnew, Ynew, 'param1', val1, 'param2', val2, ...)
mar = margin(B, Xnew, Ynew, 'param1', val1, 'param2', val2, ...)
```

Description

`mar = margin(B, TBLnew, Ynew)` computes the classification margins for the predictors contained in the table `TBLnew` given true response `Ynew`. You can omit `Ynew` if `TBLnew` contains the response variable. If you trained `B` using sample data contained in a table, then the input data for this method must also be in a table.

`mar = margin(B, Xnew, Ynew)` computes the classification margins for the predictors contained in the matrix `Xnew` given true response `Ynew`.

`Ynew` can be a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. `mar` is a numeric array of size `Nobs-by-NTrees`, where `Nobs` is the number of rows of `TBLnew` and `Ynew`, and `NTrees` is the number of trees in the ensemble `B`. For observation `I` and tree `J`, `mar(I, J)` is the difference between the score for the true class and the largest score for other classes. This method is available for classification ensembles only.

`mar = margin(B, TBLnew, Ynew, 'param1', val1, 'param2', val2, ...)` or `mar = margin(B, Xnew, Ynew, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name-value pairs:

'Mode'	String indicating how the method computes errors. If set to 'cumulative' (default), <code>margin</code> computes cumulative errors and <code>mar</code> is an <code>Nobs-by-NTrees</code> matrix, where the first column gives
--------	--

	error from <code>trees(1)</code> , second column gives error from <code>trees(1:2)</code> etc., up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>mar</code> is a <code>Nobs-by-NTrees</code> matrix, where each element is an error from each tree in the ensemble. If set to <code>'ensemble'</code> , <code>mar</code> a single column of length <code>Nobs</code> showing the cumulative margins for the entire ensemble.
<code>'Trees'</code>	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to <code>'all'</code> and the method uses all trees. If <code>'Trees'</code> is a numeric vector, the method returns a vector of length <code>NTrees</code> for <code>'cumulative'</code> and <code>'individual'</code> modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for <code>'ensemble'</code> mode. For example, in the <code>'cumulative'</code> mode, the first element gives error from <code>trees(1)</code> , the second element gives error from <code>trees(1:2)</code> etc.
<code>'TreeWeights'</code>	Vector of tree weights. This vector must have the same length as the <code>'Trees'</code> vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the <code>'individual'</code> mode.
<code>'UseInstanceFor'</code>	Logical matrix of size <code>Nobs-by-NTrees</code> indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

See Also

`TreeBagger.margin`

margin

Class: TreeBagger

Classification margin

Syntax

```
mar = margin(B,TBLnew,Ynew)
mar = margin(B,Xnew,Ynew)
mar = margin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)
mar = margin(B,Xnew,Ynew,'param1',val1,'param2',val2,...)
```

Description

`mar = margin(B,TBLnew,Ynew)` computes the classification margins for the predictors contained in the table `TBLnew` given true response `Ynew`. You can omit `Ynew` if `TBLnew` contains the response variable. If you trained `B` using sample data contained in a table, then the input data for this method must also be in a table.

`mar = margin(B,Xnew,Ynew)` computes the classification margins for the predictors contained in the matrix `Xnew` given true response `Ynew`. If you trained `B` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

`Ynew` can be a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. `mar` is a numeric array of size `Nobs-by-NTrees`, where `Nobs` is the number of rows of `TBLnew` and `Ynew`, and `NTrees` is the number of trees in the ensemble `B`. For observation `I` and tree `J`, `mar(I,J)` is the difference between the score for the true class and the largest score for other classes. This method is available for classification ensembles only.

`mar = margin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)` or `mar = margin(B,Xnew,Ynew,'param1',val1,'param2',val2,...)` specifies optional parameter name-value pairs:

'Mode'	String indicating how the method computes errors. If set to 'cumulative' (default), <code>margin</code> computes cumulative errors and
--------	--

	<code>mar</code> is an <code>Nobs-by-NTrees</code> matrix, where the first column gives error from <code>trees(1)</code> , second column gives error from <code>trees(1:2)</code> etc., up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>mar</code> is a <code>Nobs-by-NTrees</code> matrix, where each element is an error from each tree in the ensemble. `CompactTreeBagger.margin`

margmean

Class: RepeatedMeasuresModel

Estimate marginal means

Syntax

```
tbl = margmean(rm, vars)
tbl = margmean(rm, vars, 'alpha', alpha)
```

Description

`tbl = margmean(rm, vars)` returns the estimated marginal means for the variables `vars`, in the table `tbl`.

`tbl = margmean(rm, vars, 'alpha', alpha)` returns the $100 \times (1 - \alpha)\%$ confidence intervals for the marginal means.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

vars — Variables for which to compute the marginal means

string | cell array of strings

Variables for which to compute the marginal means, specified as a string representing the name of a between or within-subjects factor in `rm`, or a cell array of strings representing the names of multiple variables. Each between-subjects factor must be categorical.

For example, if you want to compute the marginal means for the variables `Drug` and `Gender`, then you can specify as follows.

Example: { 'Drug' , 'Gender' }

Data Types: char | cell

alpha — Confidence level

0.05 (default) | scalar value in the range of 0 to 1

Confidence level of the confidence intervals for population marginal means, specified as a scalar value in the range of 0 to 1. The confidence level is $100*(1-\alpha)\%$.

For example, you can specify a 99% confidence level as follows.

Example: 'alpha', 0.01

Data Types: double | single

Output Arguments

tbl — Estimated marginal means

table

Estimated marginal means, returned as a table. **tbl** contains one row for each combination of the groups of the variables you specify in **vars**, one column for each variable, and the following columns.

Column name	Description
Mean	Estimated marginal means
StdErr	Standard errors of the estimates
Lower	Lower limit of a 95% confidence interval for the true population mean
Upper	Upper limit of a 95% confidence interval for the true population mean

Examples

Compute Marginal Means Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` to `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` to `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Compute the marginal means grouped by the between-subjects factor `Group` and the within-subject factor `Time`.

```
M = margmean(rm, {'Group' 'Time'})
```

M =

Group	Time	Mean	StdErr	Lower	Upper
A	1	20.03	11.966	-4.7859	44.846

Display the description for table M.

```
M.Properties.Description
```

```
ans =
```

```
Estimated marginal means  
Means computed with Age=13.7, IQ=98.2667
```

Compute Estimated Marginal Means and Confidence Intervals

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the `species` is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Compute the marginal means grouped by the factor `species`.

```
margmean(rm,'species')
```

```
ans =
```

species	Mean	StdErr	Lower	Upper
'setosa'	2.5355	0.042807	2.4509	2.6201
'versicolor'	3.573	0.042807	3.4884	3.6576
'virginica'	4.285	0.042807	4.2004	4.3696

`StdError` field shows the standard errors of the estimated marginal means. The `Lower` and `Upper` fields show the lower and upper bounds for the 95% confidence intervals

of the group marginal means, respectively. None of the confidence intervals overlap, which indicates that marginal means differ with species. You can also plot the estimated marginal means using the `plotprofile` method.

Compute the 99% confidence intervals for the marginal means.

```
margmean(rm, 'species', 'alpha', 0.01)
```

```
ans =
```

species	Mean	StdErr	Lower	Upper
'setosa'	2.5355	0.042807	2.4238	2.6472
'versicolor'	3.573	0.042807	3.4613	3.6847
'virginica'	4.285	0.042807	4.1733	4.3967

mauchly

Class: RepeatedMeasuresModel

Mauchly's test for sphericity

Syntax

```
tbl = mauchly(rm)
tbl = mauchly(rm,C)
```

Description

`tbl = mauchly(rm)` returns the result of the Mauchly's test for sphericity for the repeated measures model `rm`.

It tests the null hypothesis that the sphericity assumption is true for the response variables in `rm`.

For more information, see “Mauchly's Test of Sphericity” on page 9-82.

`tbl = mauchly(rm,C)` returns the result of the Mauchly's test based on the contrast matrix `C`.

Input Arguments

rm — Repeated measures model
RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

C — Contrasts
matrix

Contrasts, specified as a matrix. The default value of **C** is the **Q** factor in a **QR** decomposition of the matrix **M**, where **M** is defined so that **Y*M** is the difference between all successive pairs of columns of the repeated measures matrix **Y**.

Data Types: `single` | `double`

Output Arguments

tbl — Results of Mauchly's test of sphericity

table

Results of Mauchly's test for sphericity for the repeated measures model **rm**, returned as a **table**.

tbl contains the following columns.

Column Name	Definition
W	Value of Mauchly's <i>W</i> statistic
ChiStat	Chi-square statistic value
DF	Degrees of freedom of the Chi-square statistic
pValue	<i>p</i> -value corresponding to the Chi-square statistic

Data Types: `table`

Examples

Perform Mauchly's Test

Load the sample data.

```
load fisheriris
```

The column vector **species** consists of iris flowers of three different species: *setosa*, *versicolor*, and *virginica*. The double matrix **meas** consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform Mauchly's test to assess the sphericity assumption.

```
mauchly(rm)
```

```
ans =
```

W	ChiStat	DF	pValue
0.55814	84.976	5	1.1102e-16

The small p -value (in the `pValue` field) indicates that the sphericity, hence the compound symmetry assumption, does not hold. You should use epsilon corrections to compute the p -values for a repeated measures anova. You can compute the epsilon corrections using the `epsilon` method and perform the repeated measures anova with the corrected p -values using the `ranova` method.

mat2dataset

Convert matrix to dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = mat2dataset(X)
ds = mat2dataset(X,Name,Value)
```

Description

`ds = mat2dataset(X)` converts a matrix to a dataset array.

`ds = mat2dataset(X,Name,Value)` performs the conversion using additional options specified by one or more `Name,Value` pair arguments.

Examples

Convert Matrix to Dataset Array

Convert a matrix to a dataset array using the default options.

Load sample data.

```
load('fisheriris')
X = meas;
size(X)
```

```
ans =
```

```
150      4
```

Convert the matrix to a dataset array.

```
ds = mat2dataset(X);  
size(ds)
```

```
ans =
```

```
150      4
```

```
ds(1:5,:) 
```

```
ans =
```

```
    X1    X2    X3    X4  
    5.1    3.5    1.4    0.2  
    4.9     3    1.4    0.2  
    4.7    3.2    1.3    0.2  
    4.6    3.1    1.5    0.2  
     5    3.6    1.4    0.2
```

When you do not specify variable names, `mat2dataset` uses the matrix name and column numbers to create default variable names.

Convert Matrix to Dataset Array with Variable Names

Load sample data.

```
load('fisheriris')  
X = meas;  
size(X)
```

```
ans =
```

```
150      4
```

Convert the matrix to a dataset array, providing a variable name for each of the four column of X.

```
ds = mat2dataset(X, 'VarNames', {'SLength', ...  
    'SWidth', 'PLength', 'PWidth'});  
size(ds)
```

```
ans =
```

```

150      4
ds(1:5,:)
ans =
    SWidth    SLength    PWidth    PLength
    5.1        3.5        1.4        0.2
    4.9         3        1.4        0.2
    4.7        3.2        1.3        0.2
    4.6        3.1        1.5        0.2
    5          3.6        1.4        0.2

```

Create a Dataset Array with Multicolumn Variables

Convert a matrix to a dataset array containing multicolumn variables.

Load sample data.

```

load('fisheriris')
X = meas;
size(X)

```

```
ans =
```

```
150      4
```

Convert the matrix to a dataset array, combining the sepal measurements (the first two columns) into one variable named `SepalMeas`, and the petal measurements (third and fourth columns) into one variable names `PetalMeas`.

```

ds = mat2dataset(X,'NumCols',[2,2],...
'VarNames',{'SepalMeas','PetalMeas'});
ds(1:5,:)

```

```
ans =
```

```

SepalMeas      PetalMeas
    5.1         3.5        1.4        0.2
    4.9          3        1.4        0.2
    4.7         3.2        1.3        0.2
    4.6         3.1        1.5        0.2
    5          3.6        1.4        0.2

```

The output dataset array has 150 observations and 2 variables.

```
size(ds)
```

```
ans =
```

```
    150     2
```

- “Create a Dataset Array from a File” on page 2-74

Input Arguments

X — Input matrix

matrix

Input matrix to convert to a dataset array, specified as an M -by- N numeric matrix. Each column of X becomes a variable in the output M -by- N dataset array.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, . . . , **NameN**, **ValueN**.

Example: `'NumCols', [1,1,2,1]` specifies that the 3rd and 4th columns of the input matrix should be combined into a single variable.

'VarNames' — Variable names for output dataset array

cell array of strings

Variable names for the output dataset array, specified as the comma-separated pair consisting of **'VarNames'** and a cell array of strings. You must provide a variable name for each variable in **ds**. The names must be valid MATLAB identifiers, and must be unique.

Example: `'VarNames', {'myVar1', 'myVar2', 'myVar3'}`

'ObsNames' — Observation names for output dataset array

cell array of strings

Observation names for the output dataset array, specified as the comma-separated pair consisting of 'ObsNames' and a cell array of strings. The names do not need to be valid MATLAB identifiers, but they must be unique.

'NumCols' — Number of columns for each variable

vector of nonnegative integers

Number of columns for each variable in `ds`, specified as the comma-separated pair consisting of 'NumCols' and a vector of nonnegative integers. When the number of columns for a variable is greater than one, `mat2dataset` combines multiple columns in `X` into a single variable in `ds`. The vector you assign to `NumCols` must sum to `size(X,2)`.

For example, to convert a matrix with eight columns into a dataset array with five variables, specify a vector with five elements that sum to eight, such as 'NumCols', `[1,1,3,1,2]`.

Output Arguments

`ds` — Output dataset array

dataset array

Output dataset array, returned by default with a variable for each column of `X`, and an observation for each row of `X`. If you specify `NumCols`, then the number of variables in `ds` is equal to the length of the specified vector of column numbers.

mdscale

Nonclassical multidimensional scaling

Syntax

```
Y = mdscale(D,p)
[Y, stress] = mdscale(D,p)
[Y, stress, disparities] = mdscale(D,p)
[...] = mdscale(D,p, 'Name', value)
```

Description

`Y = mdscale(D,p)` performs nonmetric multidimensional scaling on the n -by- n dissimilarity matrix `D`, and returns `Y`, a configuration of n points (rows) in p dimensions (columns). The Euclidean distances between points in `Y` approximate a monotonic transformation of the corresponding dissimilarities in `D`. By default, `mdscale` uses Kruskal's normalized stress1 criterion.

You can specify `D` as either a full n -by- n matrix, or in upper triangle form such as is output by `pdist`. A full dissimilarity matrix must be real and symmetric, and have zeros along the diagonal and non-negative elements everywhere else. A dissimilarity matrix in upper triangle form must have real, non-negative entries. `mdscale` treats NaNs in `D` as missing values, and ignores those elements. `Inf` is not accepted.

You can also specify `D` as a full similarity matrix, with ones along the diagonal and all other elements less than one. `mdscale` transforms a similarity matrix to a dissimilarity matrix in such a way that distances between the points returned in `Y` approximate $\sqrt{1-D}$. To use a different transformation, transform the similarities prior to calling `mdscale`.

`[Y, stress] = mdscale(D,p)` returns the minimized stress, i.e., the stress evaluated at `Y`.

`[Y, stress, disparities] = mdscale(D,p)` returns the disparities, that is, the monotonic transformation of the dissimilarities `D`.

[...] = `mdscale(D,p,'Name',value)` specifies one or more optional parameter name/value pairs that control further details of `mdscale`. Specify *Name* in single quotes. Available parameters are

- **Criterion**— The goodness-of-fit criterion to minimize. This also determines the type of scaling, either non-metric or metric, that `mdscale` performs. Choices for non-metric scaling are:
 - `'stress'` — Stress normalized by the sum of squares of the inter-point distances, also known as stress1. This is the default.
 - `'sstress'` — Squared stress, normalized with the sum of 4th powers of the inter-point distances.

Choices for metric scaling are:

- `'metricstress'` — Stress, normalized with the sum of squares of the dissimilarities.
- `'metricsstress'` — Squared stress, normalized with the sum of 4th powers of the dissimilarities.
- `'sammon'` — Sammon's nonlinear mapping criterion. Off-diagonal dissimilarities must be strictly positive with this criterion.
- `'strain'` — A criterion equivalent to that used in classical multidimensional scaling.
- **Weights** — A matrix or vector the same size as `D`, containing nonnegative dissimilarity weights. You can use these to weight the contribution of the corresponding elements of `D` in computing and minimizing stress. Elements of `D` corresponding to zero weights are effectively ignored.

Note: When you specify weights as a full matrix, its diagonal elements are ignored and have no effect, since the corresponding diagonal elements of `D` do not enter into the stress calculation.

- **Start** — Method used to choose the initial configuration of points for `Y`. The choices are
 - `'cmdscale'` — Use the classical multidimensional scaling solution. This is the default. `'cmdscale'` is not valid when there are zero weights.
 - `'random'` — Choose locations randomly from an appropriately scaled `p`-dimensional normal distribution with uncorrelated coordinates.

- An n -by- p matrix of initial locations, where n is the size of the matrix D and p is the number of columns of the output matrix Y . In this case, you can pass in `[]` for p and `mdscale` infers p from the second dimension of the matrix. You can also supply a 3-D array, implying a value for 'Replicates' from the array's third dimension.
- **Replicates** — Number of times to repeat the scaling, each with a new initial configuration. The default is 1.
- **Options** — Options for the iterative algorithm used to minimize the fitting criterion. Pass in an options structure created by `statset`. For example,

```
opts = statset(param1,val1,param2,val2, ...);  
[...] = mdscale(...,'Options',opts)
```

The choices of `statset` parameters are

- 'Display' — Level of display output. The choices are 'off' (the default), 'iter', and 'final'.
- 'MaxIter' — Maximum number of iterations allowed. The default is 200.
- 'TolFun' — Termination tolerance for the stress criterion and its gradient. The default is $1e-4$.
- 'TolX' — Termination tolerance for the configuration location step size. The default is $1e-4$.

Examples

```
load cereal.mat  
X = [Calories Protein Fat Sodium Fiber ...  
     Carbo Sugars Shelf Potass Vitamins];  
  
% Take a subset from a single manufacturer.  
X = X(strcmp('K',cellstr(Mfg)),:);  
  
% Create a dissimilarity matrix.  
dissimilarities = pdist(X);  
  
% Use non-metric scaling to recreate the data in 2D,  
% and make a Shepard plot of the results.  
[Y,stress,disparities] = mdscale(dissimilarities,2);  
distances = pdist(Y);
```

```
[dum,ord] = sortrows([disparities(:) dissimilarities(:)]);
plot(dissimilarities(distances,'bo', ...
dissimilarities(ord),disparities(ord),'r.-');
xlabel('Dissimilarities'); ylabel('Distances/Disparities')
legend({'Distances' 'Disparities'},'Location','NW');
```

```
% Do metric scaling on the same dissimilarities.
figure
[Y,stress] = ...
mdscale(dissimilarities,2,'criterion','metricsstress');
distances = pdist(Y);
plot(dissimilarities,distances,'bo', ...
[0 max(dissimilarities)],[0 max(dissimilarities)],'r.-');
xlabel('Dissimilarities'); ylabel('Distances')
```

Introduced before R2006a

mdsprox

Class: CompactTreeBagger

Multidimensional scaling of proximity matrix

Syntax

```
[SC,EIGEN] = mdsprox(B,X)
[SC,EIGEN] = mdsprox(B,X, 'param1 ',val1, 'param2 ',val2, ...)
```

Description

[SC,EIGEN] = mdsprox(B,X) applies classical multidimensional scaling to the proximity matrix computed for the data in the matrix X, and returns scaled coordinates SC and eigenvalues EIGEN of the scaling transformation. The method applies multidimensional scaling to the matrix of distances defined as 1-prox, where prox is the proximity matrix returned by the proximity method.

You can supply the proximity matrix directly by using the 'Data' parameter.

[SC,EIGEN] = mdsprox(B,X, 'param1 ',val1, 'param2 ',val2, ...) specifies optional parameter name/value pairs:

- | | |
|----------|--|
| 'Data' | Flag indicating how the method treats the X input argument. If set to 'predictors' (default), mdsprox assumes X to be a matrix of predictors and used for computation of the proximity matrix. If set to 'proximity', the method treats X as a proximity matrix returned by the proximity method. |
| 'Colors' | If you supply this argument, mdsprox makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a string with one character for each color. If there are more classes in the data than characters in the supplied string, mdsprox only plots the first C classes, where C is the length of the string. For regression or if you do not provide the vector of true class labels, the method uses the first color for all observations in X. |

- 'Labels' Vector of true class labels for a classification ensemble. True class labels can be either a numeric vector, character matrix, or cell array of strings. If supplied, this vector must have as many elements as there are observations (rows) in X . This argument has no effect unless you also supply the 'Colors' argument.
- 'MDSCoordinates' Indices of the two scaled coordinates to plot. By default, `mdsprox` makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the 'Colors' argument.

mdsprox

Class: TreeBagger

Multidimensional scaling of proximity matrix

Syntax

```
[S,E] = mdsprox(B)
[S,E] = mdsprox(B, 'param1',val1, 'param2',val2, ...)
```

Description

[S,E] = mdsprox(B) returns scaled coordinates, S, and eigenvalues, E, for the proximity matrix in the ensemble B. An earlier call to `fillprox(B)` must create the proximity matrix.

[S,E] = mdsprox(B, 'param1',val1, 'param2',val2, ...) specifies optional parameter name/value pairs:

- 'Keep' Array of indices of observations in the training data to use for multidimensional scaling. By default, this argument is set to 'all'. If you provide numeric or logical indices, the method uses only the subset of the training data specified by these indices to compute the scaled coordinates and eigenvalues.
- 'Colors' If you supply this argument, `mdsprox` makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a string with one character for each color. If there are more classes in the data than characters in the supplied string, `mdsprox` only plots the first C classes, where C is the length of the string. For regression or if you do not provide the vector of true class labels, the method uses the first color for all observations in X.
- 'MDSCoordinates' Indices of the two scaled coordinates to plot. By default, `mdsprox` makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any

other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the 'Colors' argument.

mean

Mean of probability distribution

Syntax

```
m = mean(pd)
```

Description

`m = mean(pd)` returns the mean `m` of the probability distribution `pd`.

Examples

Mean of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades  
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 75.0083 [73.4321, 76.5846]  
sigma = 8.7202 [7.7391, 9.98843]
```

Compute the mean of the fitted distribution.

```
m = mean(pd)
```

```
m =  
75.0083
```

The mean of the normal distribution is equal to the parameter `mu`.

Mean of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =  
WeibullDistribution  
  
Weibull distribution  
A = 5  
B = 2
```

Compute the mean of the distribution.

```
mean = mean(pd)
```

```
mean =  
4.4311
```

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Output Arguments

m – Mean

scalar value

Mean of the probability distribution, returned as a scalar value.

mean

Class: prob.KernelDistribution

Package: prob

Mean of probability distribution object

Syntax

```
m = mean(pd)
```

Description

`m = mean(pd)` returns the mean `m` of the probability distribution `pd`.

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Fit a probability distribution object to data using `fitdist` or the Distribution Fitting app.

Output Arguments

m — Mean

scalar value

Mean of the probability distribution, returned as a scalar value.

Examples

Mean of a Kernel Distribution

Load the sample data. Create a probability distribution object by fitting a kernel distribution to the miles per gallon (MPG) data.

```
load carsmall;  
pd = fitdist(MPG, 'Kernel')
```

```
pd =
```

```
KernelDistribution
```

```
Kernel = normal  
Bandwidth = 4.11428  
Support = unbounded
```

Compute the mean of the distribution.

```

mean

Class: ProbDistUnivParam

Return mean of ProbDistUnivParam object

Syntax

$M = \text{mean}(PD)$

Description

$M = \text{mean}(PD)$ returns M , the mean of the ProbDistUnivParam object PD .

Input Arguments

PD An object of the class ProbDistUnivParam.

Output Arguments

M The mean of the ProbDistUnivParam object PD .

See Also

Package: prob

Mean of probability distribution object

Syntax

```
m = mean(pd)
```

Description

`m = mean(pd)` returns the mean `m` of the probability distribution `pd`.

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`.

Output Arguments

m — Mean

scalar value

Mean of the probability distribution, returned as a scalar value.

Examples

Mean of a Uniform Distribution

Create a uniform distribution object

```
pd = makedist('Uniform', 'lower', -3, 'upper', 5)
```

```
pd =
```

```
UniformDistribution
```

```
Uniform distribution
```

```
Lower = -3
```

```
Upper = 5
```

Compute the mean of the distribution.

Description

`m = mean(pd)` returns the mean `m` of the probability distribution `pd`.

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Output Arguments

m — Mean

scalar value

Mean of the probability distribution, returned as a scalar value.

Examples

Mean of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')  
  
pd =  
  
NormalDistribution  
  
Normal distribution  
mu = 75.0083 [73.4321, 76.5846]  
sigma = 8.7202 [7.7391, 9.98843]
```

Compute the mean of the fitted distribution.

```
m = mean(pd)  
  
m =  
  
75.0083
```

The mean of the normal distribution is equal to the parameter μ .

Mean of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)  
  
pd =  
  
WeibullDistribution  
  
Weibull distribution  
A = 5  
B = 2
```

Compute the mean of the distribution.

```
mean = mean(pd)
```

```
mean =  
    4.4311
```

meanMargin

Class: CompactTreeBagger

Mean classification margin

Syntax

```
mar = meanMargin(B, TBLnew, Ynew)
mar = meanMargin(B, Xnew, Ynew)
mar = meanMargin(B, TBLnew, Ynew, 'param1', val1, 'param2', val2, ...)
mar = meanMargin(B, Xnew, Ynew, 'param1', val1, 'param2', val2, ...)
```

Description

`mar = meanMargin(B, TBLnew, Ynew)` computes average classification margins for the predictors contained in the table `TBLnew` given the true response `Ynew`. You can omit `Ynew` if `TBLnew` contains the response variable. If you trained `B` using sample data contained in a table, then the input data for this method must also be in a table.

`mar = meanMargin(B, Xnew, Ynew)` computes average classification margins for the predictors contained in the matrix `Xnew` given true response `Ynew`. If you trained `B` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

`Ynew` can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. `meanMargin` averages the margins over all observations (rows) in `TBLnew` or `Xnew` for each tree. `mar` is a matrix of size 1-by-`NTrees`, where `NTrees` is the number of trees in the ensemble `B`. This method is available for classification ensembles only.

`mar = meanMargin(B, TBLnew, Ynew, 'param1', val1, 'param2', val2, ...)` or `mar = meanMargin(B, Xnew, Ynew, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name-value pairs:

'Mode'	String indicating how <code>meanMargin</code> computes errors. If set to 'cumulative' (default), is a vector of length <code>NTrees</code> where
--------	--

	the first element gives mean margin from <code>trees(1)</code> , second column gives mean margins from <code>trees(1:2)</code> etc., up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>mar</code> is a vector of length <code>NTrees</code> , where each element is a mean margin from each tree in the ensemble. If set to <code>'ensemble'</code> , <code>mar</code> is a scalar showing the cumulative mean margin for the entire ensemble.
<code>'Trees'</code>	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to <code>'all'</code> and the method uses all trees. If <code>'Trees'</code> is a numeric vector, the method returns a vector of length <code>NTrees</code> for <code>'cumulative'</code> and <code>'individual'</code> modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for <code>'ensemble'</code> mode. For example, in the <code>'cumulative'</code> mode, the first element gives mean margin from <code>trees(1)</code> , the second element gives mean margin from <code>trees(1:2)</code> etc.
<code>'TreeWeights'</code>	Vector of tree weights. This vector must have the same length as the <code>'Trees'</code> vector. <code>meanMargin</code> uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the <code>'individual'</code> mode.

meansurrvarassoc

Class: classregtree

Mean predictive measure of association for surrogate splits in decision tree

Compatibility

`classregtree` will be removed in a future release. See `fitctree`, `fitrtree`, `ClassificationTree`, or `RegressionTree` instead.

Syntax

`MA` = `meansurrvarassoc(T)`

`MA` = `meansurrvarassoc(T,N)`

Description

`MA` = `meansurrvarassoc(T)` returns a p -by- p matrix, `MA`, with predictive measures of association for p predictors. Element `MA(i,j)` is the predictive measure of association averaged over surrogate splits on predictor j for which predictor i is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor j and dividing by the total number of optimal splits on predictor i , including splits for which the predictive measure of association between predictors i and j is negative.

`MA` = `meansurrvarassoc(T,N)` takes an array `N` of node numbers and returns the predictive measure of association averaged over the specified nodes.

surrogateAssociation

Class: CompactClassificationTree

Mean predictive measure of association for surrogate splits in decision tree

Syntax

```
ma = surrogateAssociation(tree)
ma = surrogateAssociation(tree,N)
```

Description

`ma = surrogateAssociation(tree)` returns a matrix of predictive measures of association for the predictors in `tree`.

`ma = surrogateAssociation(tree,N)` returns a matrix of predictive measures of association averaged over the nodes in vector `N`.

Input Arguments

tree

A classification tree constructed with `fitctree`, or a compact regression tree constructed with `compact`.

N

Vector of node numbers in `tree`.

Output Arguments

ma

- `ma = surrogateAssociation(tree)` returns a P-by-P matrix, where P is the number of predictors in `tree`. `ma(i,j)` is the predictive measure of association

between the optimal split on variable i and a surrogate split on variable j . For more details, see “Algorithms” on page 25-3467.

- `ma = surrogateAssociation(tree,N)` returns a P-by-P representing the predictive measure of association between variables averaged over nodes in the vector N . N contains node numbers from 1 to `max(tree.NumNodes)`.

Definitions

Predictive Measure of Association

The *predictive measure of association* is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k , respectively, and $j \neq k$. At node t , the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_j L_k} - P_{R_j R_k})}{\min(P_L, P_R)}$$

- P_L is the proportion of observations in node t , such that $x_j < u$. The subscript L stands for the left child of node t .
- P_R is the proportion of observations in node t , such that $x_j \geq u$. The subscript R stands for the right child of node t .
- $P_{L_j L_k}$ is the proportion of observations at node t , such that $x_j < u$ and $x_k < v$.
- $P_{R_j R_k}$ is the proportion of observations at node t , such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Surrogate Decision Splits

A *surrogate decision split* is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association.

Algorithms

Element $ma(i, j)$ is the predictive measure of association averaged over surrogate splits on predictor j for which predictor i is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor j and dividing by the total number of optimal splits on predictor i , including splits for which the predictive measure of association between predictors i and j is negative.

Examples

Estimate Predictive Measures of Association for Surrogate Splits

Load Fisher's iris data set.

```
load fisheriris
```

Grow a classification tree using `species` as the response. Specify to use surrogate splits for missing values.

```
tree = fitctree(meas,species, 'surrogate', 'on');
```

Find the mean predictive measure of association between the predictor variables.

```
ma = surrogateAssociation(tree)
```

```
ma =

Examples

Estimate Predictive Measures of Association for Surrogate Splits

Load the `carsmall` data set. Specify `Displacement`, `Horsepower`, and `Weight` as predictor variables.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using `MPG` as the response. Specify to use surrogate splits for missing values.

```
tree = fitrtree(X,MPG,'surrogate','on');
```

Find the mean predictive measure of association between the predictor variables.

```
ma = surrogateAssociation(tree)
```

```
ma =  
  
    1.0000    0.2333    0.5444

median

Median of probability distribution

Syntax

```
m = median(pd)
```

Description

`m = median(pd)` returns the median `m` for the probability distribution `pd`

Examples

Median of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades  
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 75.0083 [73.4321, 76.5846]  
sigma = 8.7202 [7.7391, 9.98843]
```

Compute the median of the fitted distribution.

```
m = median(pd)
```

```
m =  
75.0083
```

For a symmetrical distribution such as the normal distribution, the median is equal to the mean, μ .

Median of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull', 'a', 5, 'b', 2)
```

```
pd =  
WeibullDistribution  
  
Weibull distribution  
A = 5  
B = 2
```

Compute the median of the distribution.

```
m = median(pd)
```

```
m =  
4.1628
```

For a skewed distribution such as the Weibull distribution, the median and the mean may not be equal.

Calculate the mean of the Weibull distribution and compare it to the median.

```
mean = mean(pd)
```

```
mean =  
4.4311
```

The mean of the distribution is greater than the median.

Plot the pdf to visualize the distribution.

```
x = [0:.1:15];  
pdf = pdf(pd,x);  
plot(x,pdf)
```

Input Arguments

pd — Probability distribution
probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Output Arguments

m — Median

scalar value

Median of the probability distribution, returned as a scalar value. The value of `m` is the 50th percentile of the probability distribution.

More About

- “Working with Probability Distributions” on page 5-3

Introduced before R2006a

median

Class: ProbDistUnivKernel

Return median of ProbDistUnivKernel object

Syntax

$M = \text{median}(PD)$

Description

$M = \text{median}(PD)$ returns M , the median of the ProbDistUnivKernel object PD .

Input Arguments

PD An object of the class ProbDistUnivKernel.

Output Arguments

M The median of the ProbDistUnivKernel object PD .

See Also

median

median

Class: ProbDistUnivParam

Return median of ProbDistUnivParam object

Syntax

$M = \text{median}(PD)$

Description

$M = \text{median}(PD)$ returns M , the median of the ProbDistUnivParam object PD .

Input Arguments

PD An object of the class ProbDistUnivParam.

Output Arguments

M The median of the ProbDistUnivParam object PD .

See Also

median

Normal distribution  
mu = 75.0083 [73.4321, 76.5846]  
sigma = 8.7202 [7.7391, 9.98843]
```

Compute the median of the fitted distribution.

```
m = median(pd)  
  
m =  
  
75.0083
```

For a symmetrical distribution such as the normal distribution, the median will be equal to the mean, μ .

Median of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull', 'a', 5, 'b', 2)  
  
pd =  
  
WeibullDistribution
```

```
Weibull distribution
A = 5
B = 2
```

Compute the median of the distribution.

```
m = median(pd)
```

```
m =
    4.1628
```

For a skewed distribution such as the Weibull distribution, the median and the mean may not be equal.

Calculate the mean of the Weibull distribution and compare it to the median.

```
mean = mean(pd)
```

```
mean =
    4.4311
```

The mean of the distribution is greater than the median.

Plot the pdf to visualize the distribution.

```
x = [0:.1:15];
pdf = pdf(pd,x);
plot(x,pdf)
```

MergeLeaves property

Class: TreeBagger

Flag to merge leaves that do not improve risk

Description

The `MergeLeaves` property is true if decision trees have their leaves with the same parent merged for splits that do not decrease the total risk, and false otherwise. The default value is false.

See Also

`ClassificationTree` | `RegressionTree` | `TreeBagger` | `fitctree` | `fitrtree`

mergelevels

Merge levels of nominal or ordinal arrays

Compatibility

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

Syntax

```
B = mergelevels(A,oldlevels)
B = mergelevels(A,oldlevels,newlevel)
```

Description

`B = mergelevels(A,oldlevels)` merges two or more levels of `A`.

- If `A` is a nominal array, `mergelevels` uses the first label in `oldlevels` as the new level.
- If `A` is an ordinal array, the levels specified by `oldlevels` must be consecutive, and `mergelevels` uses the label corresponding to the lowest level in `oldlevels` as the label for the new level.

`B = mergelevels(A,oldlevels,newlevel)` merges two or more levels into the new level with label `newlevel`.

Examples

Create New Category From Merged Levels

Create a nominal array from string data in a cell array.

```
colors = nominal({'r','b','g';'g','r','b';'b','r','g'},...
```

```
{'blue', 'green', 'red'})
```

```
colors =
```

```
   red      blue      green
   green    red       blue
   blue     red       green
```

Merge the elements of the 'red' and 'blue' levels into a new level labeled 'purple'.

```
colors = mergelevels(colors, {'red', 'blue'}, 'purple')
```

```
colors =
```

```
   purple    purple    green
   green    purple    purple
   purple    purple    green
```

Display the levels of colors.

```
getlevels(colors)
```

```
ans =
```

```
   purple      green
```

- “Merge Category Levels” on page 2-22

Input Arguments

A — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created using `nominal` or `ordinal`.

oldlevels — Levels to merge

cell array of strings | 2-D character matrix

Levels to merge, specified as a cell array of strings or 2-D character matrix. For ordinal arrays, the levels in `oldlevels` must be consecutive.

Data Types: `char` | `cell`

newlevel — Level to create

string

Level to create from the merged levels, specified as a string that gives the label for the new level.

Data Types: `char`

Output Arguments

B — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, returned as a `nominal` or `ordinal` array object.

More About

- Using nominal Objects
- Using ordinal Objects

See Also

`addlevels` | `droplevels` | `nominal` | `ordinal` | `reorderlevels`

Introduced in R2007a

Method property

Class: TreeBagger

Method used by trees (classification or regression)

Description

The Method property is 'classification' for classification ensembles and 'regression' for regression ensembles.

mhsample

Metropolis-Hastings sample

Syntax

```
smp1 = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf,  
'proprnd',proprnd)  
smp1 = mhsample(...,'symmetric',sym)  
smp1 = mhsample(...,'burnin',K)  
smp1 = mhsample(...,'thin',m)  
smp1 = mhsample(...,'nchain',n)  
[smp1,accept] = mhsample(...)
```

Description

`smp1 = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf,'proprnd',proprnd)` draws `nsamples` random samples from a target stationary distribution `pdf` using the Metropolis-Hastings algorithm.

`start` is a row vector containing the start value of the Markov Chain, `nsamples` is an integer specifying the number of samples to be generated, and `pdf`, `proppdf`, and `proprnd` are function handles created using `@`. `proppdf` defines the proposal distribution density, and `proprnd` defines the random number generator for the proposal distribution. `pdf` and `proprnd` take one argument as an input with the same type and size as `start`. `proppdf` takes two arguments as inputs with the same type and size as `start`.

`smp1` is a column vector or matrix containing the samples. If the log density function is preferred, `'pdf'` and `'proppdf'` can be replaced with `'logpdf'` and `'logproppdf'`. The density functions used in Metropolis-Hastings algorithm are not necessarily normalized.

The proposal distribution $q(x,y)$ gives the probability density for choosing x as the next point when y is the current point. It is sometimes written as $q(x|y)$.

If the `proppdf` or `logproppdf` satisfies $q(x,y) = q(y,x)$, that is, the proposal distribution is symmetric, `mhsample` implements Random Walk Metropolis-Hastings sampling. If

the `proppdf` or `logproppdf` satisfies $q(x,y) = q(x)$, that is, the proposal distribution is independent of current values, `mhsample` implements Independent Metropolis-Hastings sampling.

`smp1 = mhsample(..., 'symmetric', sym)` draws `nsamples` random samples from a target stationary distribution `pdf` using the Metropolis-Hastings algorithm. `sym` is a logical value that indicates whether the proposal distribution is symmetric. The default value is false, which corresponds to the asymmetric proposal distribution. If `sym` is true, for example, the proposal distribution is symmetric, `proppdf` and `logproppdf` are optional.

`smp1 = mhsample(..., 'burnin', K)` generates a Markov chain with values between the starting point and the k^{th} point omitted in the generated sequence. Values beyond the k^{th} point are kept. `k` is a nonnegative integer with default value of 0.

`smp1 = mhsample(..., 'thin', m)` generates a Markov chain with `m-1` out of `m` values omitted in the generated sequence. `m` is a positive integer with default value of 1.

`smp1 = mhsample(..., 'nchain', n)` generates `n` Markov chains using the Metropolis-Hastings algorithm. `n` is a positive integer with a default value of 1. `smp1` is a matrix containing the samples. The last dimension contains the indices for individual chains.

`[smp1, accept] = mhsample(...)` also returns `accept`, the acceptance rate of the proposed distribution. `accept` is a scalar if a single chain is generated and is a vector if multiple chains are generated.

Examples

Estimate Moments Using Independent Metropolis-Hastings Sampling

Use Independent Metropolis-Hastings sampling to estimate the second order moment of a Gamma distribution.

```
rng default; % For reproducibility
alpha = 2.43;
beta = 1;
pdf = @(x)gampdf(x,alpha,beta); % Target distribution
proppdf = @(x,y)gampdf(x,floor(alpha),floor(alpha)/alpha);
proprnd = @(x)sum(...
    exprnd(floor(alpha)/alpha,floor(alpha),1));
```

```
nsamples = 5000;  
smp1 = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,...  
               'proppdf',proppdf);
```

Plot the results.

```
xxhat = cumsum(smp1.^2)./(1:nsamples)';  
figure;  
plot(1:nsamples,xxhat)
```

Random Walk Metropolis-Hastings Sampling

Use Random Walk Metropolis-Hastings sampling to generate sample data from a standard normal distribution.

```
rng default % For reproducibility
delta = .5;
pdf = @(x) normpdf(x);
proppdf = @(x,y) unifpdf(y-x,-delta,delta);
proprnd = @(x) x + rand*2*delta - delta;
nsamples = 15000;
x = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,'symmetric',1);
```

Plot the sample data.

```
figure;
h = histfit(x,50);
h(1).FaceColor = [.8 .8 1];
```

MinLeafSize property

Class: TreeBagger

Minimum number of observations per tree leaf

Description

The `MinLeafSize` property specifies the minimum number of observations per tree leaf. The default values are 1 for classification and 5 for regression. For `fitctree` or `fitrtree` training, the `'MinParentSize'` value is set to $2 * \text{MinLeafSize}$.

mle

Maximum likelihood estimates

Syntax

```
phat = mle(data)
phat = mle(data, 'distribution', dist)

phat = mle(data, 'pdf', pdf, 'start', start)
phat = mle(data, 'pdf', pdf, 'start', start, 'cdf', cdf)

phat = mle(data, 'logpdf', logpdf, 'start', start)
phat = mle(data, 'logpdf', logpdf, 'start', start, 'logsf', logsf)

phat = mle(data, 'nloglf', nloglf, 'start', start)

phat = mle( ____, Name, Value)
[phat, pci] = mle( ____, Name, Value)
```

Description

`phat = mle(data)` returns maximum likelihood estimates (MLEs) for the parameters of a normal distribution, using the sample data in the vector `data`.

`phat = mle(data, 'distribution', dist)` returns parameter estimates for a distribution specified by `dist`.

`phat = mle(data, 'pdf', pdf, 'start', start)` returns parameter estimates for a custom distribution specified by the probability density function `pdf`. You must also specify the initial parameter values, `start`.

`phat = mle(data, 'pdf', pdf, 'start', start, 'cdf', cdf)` returns parameter estimates for a custom distribution specified by the probability density function `pdf` and custom cumulative distribution function `cdf`.

`phat = mle(data, 'logpdf', logpdf, 'start', start)` returns parameter estimates for a custom distribution specified by the log probability density function `logpdf`. You must also specify the initial parameter values, `start`.

`phat = mle(data, 'logpdf', logpdf, 'start', start, 'logsf', logsf)` returns parameter estimates for a custom distribution specified by the log probability density function `logpdf` and custom log survival function `logsf`.

`phat = mle(data, 'nloglf', nloglf, 'start', start)` returns parameter estimates for the custom distribution specified by the negative loglikelihood function `nloglf`. You must also specify the initial parameter values, `start`.

`phat = mle(____, Name, Value)` also returns the parameter estimates with additional options specified by one or more name-value pair arguments. You can use any of the input arguments in the previous syntaxes.

`[phat, pci] = mle(____)` also returns the 95% confidence intervals for the parameters.

Examples

Estimate Parameters of Burr Distribution

Load the sample data.

```
load carbig
```

The variable `MPG` has the miles per gallon for different models of cars.

Draw a histogram of `MPG` data.

```
histogram(MPG)
```

The distribution is somewhat right skewed. A symmetric distribution, such as normal distribution, might not be a good fit.

Estimate the parameters of the Burr Type XII distribution for the MPG data.

```
phat = mle(MPG, 'distribution', 'burr')
```

```
phat =
```

```
34.6447    3.7898    3.5722
```

The maximum likelihood estimates for the scale parameter α is 34.6447. The estimates for the two shape parameters c and k of the Burr Type XII distribution are 3.7898 and 3.5722, respectively.

Fit Custom Distribution to Censored Data

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom probability density and cumulative distribution function.

```
custpdf = @(data,lambda) lambda*exp(-lambda*data);
custcdf = @(data,lambda) 1-exp(-lambda*data);
```

Estimate the parameter, `lambda`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'pdf',custpdf,...
'cdf',custcdf,'start',0.05,'Censoring',Censored)
phat
```

```
phat =
```

```
0.1096
```

Estimate Parameters of a Noncentral Chi-Square Distribution

Generate sample data of size 1000 from a noncentral chi-square distribution with degrees of freedom 8 and noncentrality parameter 3.

```
rng('default') % for reproducibility
x = ncx2rnd(8,3,1000,1);
```

Estimate the parameters of the noncentral chi-square distribution from the sample data. To do this, custom define the noncentral chi-square pdf using the `pdf` input argument.

```
[phat,pci] = mle(x,'pdf',@(x,v,d)ncx2pdf(x,v,d),'start',[1,1])
phat =
    8.1052    2.6693

pci =
    7.1121    1.6025
    9.0983    3.7362
```

The estimate for the degrees of freedom is 8.1052 and the noncentrality parameter is 2.6693. The 95% confidence interval for the degrees of freedom is (7.0983,9.0983) and the noncentrality parameter is (1.6025,3.7362). The confidence intervals include the true parameter values of 8 and 3, respectively.

Fit Custom Log pdf and Survival Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k)-k*log(lambda)...
             +(k-1)*log(data)-(data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, `lambda` and `k`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'logpdf',custlogpdf,...
           'logsf',custlogsf,'start',[1,0.75],'Censoring',Censored)
phat =
```

```
9.2090    1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

Fit Custom Log Negative Likelihood Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf = @(lambda,data,cens,freq) -length(data)*log(lambda)...
+ nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)
```

```
phat =
```

```
0.1462
```

Estimate Probability of Success

Generate 100 random observations from a binomial distribution with the number of trials, $n = 20$, and the probability of success, $p = 0.75$.

```
data = binornd(20,0.75,100,1);
```

Estimate the probability of success and 95% confidence limits using the simulated sample data.

```
[phat,pci] = mle(data,'distribution','binomial',...
                 'alpha',.05,'ntrials',20)
```

```
phat =
```

```
    0.7370
pci =
    0.7171
    0.7562
```

The estimate of probability of success is 0.737 and the lower and upper limits of the 95% confidence interval are 0.7171 and 0.7562. This interval covers the true value used to simulate the data.

Fit a Distribution with Known Parameter

Generate sample data of size 1000 from a noncentral chi-square distribution with degrees of freedom 10 and noncentrality parameter 5.

```
rng('default') % for reproducibility
x = ncx2rnd(10,5,1000,1);
```

Suppose the noncentrality parameter is fixed at the value 5. Estimate the degrees of freedom of the noncentral chi-square distribution from the sample data. To do this, custom define the noncentral chi-square pdf using the `pdf` input argument.

```
[phat,pci] = mle(x,'pdf',@(x,v,d)ncx2pdf(x,v,5),'start',1)
phat =
    9.9307

pci =
    9.5626
   10.2989
```

The estimate for the noncentrality parameter is 9.9307, with a 95% confidence interval of 9.5626 and 10.2989. The confidence interval includes the true parameter value of 10.

Fit Rician Distribution with Known Scale Parameter

Generate sample data of size 1000 from a Rician distribution with noncentrality parameter of 8 and scale parameter of 5. First create the Rician distribution.

```
r = makedist('Rician','s',8,'sigma',5);
```

Now, generate sample data from the distribution you created above.

```
rng('default');
```

```
x = random(r,1000,1);
```

Suppose the scale parameter is known, and estimate the noncentrality parameter from sample data. To do this using `mle`, you must custom define the Rician probability density function.

```
[phat,pci] = mle(x,'pdf',@(x,s,sigma) pdf('rician',x,s,5),'start',10)
```

```
phat =
```

```
7.8953
```

```
pci =
```

```
7.5405
```

```
8.2501
```

The estimate for the noncentrality parameter is 7.8953, with a 95% confidence interval of 7.5404 and 8.2501. The confidence interval includes the true parameter value of 8.

Fit a Distribution with Additional Parameter

Add a scale parameter to the chi-square distribution for adapting to the scale of data and fit it. First, generate sample data of size 1000 from a chi-square distribution with degrees of freedom 5, and scale it by the factor of 100.

```
rng('default') % for reproducibility
```

```
x = 100*chi2rnd(5,1000,1);
```

Estimate the degrees of freedom and the scaling factor. To do this, custom define the chi-square probability density function using the `pdf` input argument. The density function requires a $1/s$ factor for data scaled by s .

```
[phat,pci] = mle(x,'pdf',@(x,v,s)chi2pdf(x/s,v)/s,'start',[1,200])
```

```
phat =
```

```
5.1079 99.1681
```

```
pci =
```

```
4.6862 90.1215
```

```
5.5297 108.2146
```

The estimate for the degrees of freedom is 5.1079 and the scale is 99.1681. The 95% confidence interval for the degrees of freedom is (4.6862,5.5279) and the scale parameter is (90.1215,108.2146). The confidence intervals include the true parameter values of 5 and 100, respectively.

Input Arguments

data — Sample data

vector

Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

Data Types: `single` | `double`

dist — Distribution type

'normal' (default) | string

Distribution type to estimate parameters for, specified as one of the following.

dist	Description	Parameter 1	Parameter 2	Parameter 3	Parameter 4
'bernoulli'	“Bernoulli Distribution” on page B-2	p: probability of success for each trial	—	—	—
'beta' or 'Beta'	“Beta Distribution” on page B-4	a	b	—	—
'bino' or 'Binomial'	“Binomial Distribution” on page B-9	n: number of trials	p: probability of success for each trial	—	—
'birnbaumsaund'	“Birnbau-Saunders Distribution” on page B-13	β : scale	γ : shape	—	—
'burr' or 'Burr'	“Burr Type XII Distribution” on page B-15	a: scale	c: first shape	k: second shape	—
'Discrete Uniform' or 'unid'	“Uniform Distribution (Discrete)” on page B-187	N: maximum observable value	—	—	—

dist	Description	Parameter 1	Parameter 2	Parameter 3	Parameter 4
'exp' or 'Exponential'	“Exponential Distribution” on page B-34	μ : mean	—	—	—
'ev' or 'Extreme Value'	“Extreme Value Distribution” on page B-38	μ : location	σ : scale	—	—
'gam' or 'Gamma'	“Gamma Distribution” on page B-47	a: shape	b: scale	—	—
'gev' or 'Generalized Extreme Value'	“Generalized Extreme Value Distribution” on page B-53	k: shape	σ : scale	μ : location	—
'gp' or 'Generalized Pareto'	“Generalized Pareto Distribution” on page B-59	k: tail index (shape)	σ : scale	θ : threshold	—
'geo' or 'Geometric'	“Geometric Distribution” on page B-64	p: probability	—	—	—
'hn' or 'Half Normal'	“Half-Normal Distribution” on page B-73	μ : location	σ : scale	—	—
'inversegaussi'	“Inverse Gaussian Distribution” on page B-82	μ : scale	λ : shape	—	—
'logistic'	“Logistic Distribution” on page B-96	μ : location	σ : scale	—	—
'loglogistic'	“Loglogistic Distribution” on page B-98	μ : log location	σ : log scale	—	—
'logn' or 'Lognormal'	“Lognormal Distribution” on page B-100	μ : log location	σ : log scale	—	—
'nakagami'	“Nakagami Distribution” on page B-118	μ : shape	ω : scale	—	—

dist	Description	Parameter 1	Parameter 2	Parameter 3	Parameter 4
'nbin' or 'Negative Binomial'	“Negative Binomial Distribution” on page B-120	r : number of successes	p : probability of success in a single trial	—	—
'norm' or 'Normal'	“Normal Distribution” on page B-135	μ : location (mean)	σ : scale (standard deviation)	—	—
'poiss' or 'Poisson'	“Poisson Distribution” on page B-143	λ : mean	—	—	—
'rayl' or 'Rayleigh'	“Rayleigh Distribution” on page B-146	b : scale	—	—	—
'rician'	“Rician Distribution” on page B-149	s : noncentrality	σ : scale	—	—
'stable'	“Stable Distribution” on page B-151	α : first shape parameter	β : second shape parameter	γ : scale parameter	δ : location parameter
'tlocationscal'	“t Location-Scale Distribution” on page B-172	μ : location	σ : scale	ν : degrees of freedom	—
'unif' or 'Uniform'	“Uniform Distribution (Continuous)” on page B-181	a : lower endpoint (minimum)	b : upper endpoint (maximum)	—	—
'wbl' or 'Weibull'	“Weibull Distribution” on page B-190	a : scale	b : shape	—	—

Example: 'rician'

pdf — Custom probability density function

function handle

Custom probability distribution function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is `newpdf`, then you can specify the function handle in `mle` as follows.

Example: `@newpdf`

Data Types: `function_handle`

cdf — Custom cumulative distribution function

function handle

Custom cumulative distribution function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define `cdf` with `pdf` if data is censored and you use the `'censoring'` name-value pair argument. If `'censoring'` is not present, you do not have to specify `cdf` while using `pdf`.

For example, if the name of the custom cumulative distribution function is `newcdf`, then you can specify the function handle in `mle` as follows.

Example: `@newcdf`

Data Types: `function_handle`

logpdf — Custom log probability density function

function handle

Custom log probability density function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is `customlogpdf`, then you can specify the function handle in `mle` as follows.

Example: `@customlogpdf`

Data Types: `function_handle`

logsf — Custom log survival function

function handle

Custom log survival function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define `logsf` with `logpdf` if data is censored and you use the `'censoring'` name-value pair argument. If `'censoring'` is not present, you do not have to specify `logsf` while using `logpdf`.

For example, if the name of the custom log survival function is `logsurvival`, then you can specify the function handle in `mle` as follows.

Example: `@logsurvival`

Data Types: `function_handle`

nloglf — Custom negative loglikelihood function

`function_handle`

Custom negative loglikelihood function, specified as a function handle created using `@`.

This custom function accepts the following input arguments.

<code>params</code>	Vector of distribution parameter values. <code>mle</code> detects the number of parameters from the number of elements in <code>start</code> .
<code>data</code>	Vector of data.
<code>cens</code>	Boolean vector of censored values.
<code>freq</code>	Vector of integer data frequencies.

`nloglf` must accept all four arguments even if you do not use the `'censoring'` or `'frequency'` name-value pair arguments. You can write `'nloglf'` to ignore `cens` and `freq` arguments in that case.

`nloglf` returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the `'GradObj'` field in `'options'`).

If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mle` as follows.

Example: `@negloglik`

Data Types: `function_handle`

start — Initial parameter values

`scalar` | `vector`

Initial parameter values for the custom functions, specified as a scalar value or a vector of scalar values.

Use `start` when you fit custom distributions, that is, when you use `pdf` and `cdf`, `logpdf` and `logsf`, or `nloglf` input arguments.

Example: 0.05

Example: [100,2]

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `'Censoring', Cens, 'Alpha', 0.01, 'Options', Opt` specifies that `mle` estimates the parameters for the distribution of censored data specified by array `Cens`, computes the 99% confidence limits for the parameter estimates, and uses the algorithm control parameters specified by the structure `Opt`.

'Censoring' — Indicator for censoring

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of `'Censoring'` and a Boolean array of the same size as `data`. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

For example, if the censored data information is in the binary array called `Censored`, then you can specify the censored data as follows.

Example: `'censoring', Censored`

`mle` supports censoring for the following distributions:

Birnbaum-Saunders	Logistic
Burr	Lognormal
Exponential	Nakagami
Extreme Value	Normal

Gamma
Inverse Gaussian
Kernel
Log-Logistic

Rician
t Location-Scale
Weibull

Data Types: `logical`

'Frequency' — Frequency of observations

`array of 1s (default) | vector of nonnegative integer counts`

Frequency of observations, specified as the comma-separated pair consisting of `'frequency'` and an array containing nonnegative integer counts, which is the same size as `data`. The default is one observation per element of `data`.

For example, if the observation frequencies are stored in an array named `Freq`, you can specify the frequencies as follows.

Example: `'frequency', Freq`

Data Types: `single | double`

'Alpha' — Confidence level

`0.05 (default) | scalar value in the range (0,1)`

Confidence level for the confidence interval of parameter estimates, `pci`, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range (0,1). The confidence level of `pci` is `100(1-alpha)%`. The default is 0.05 for 95% confidence.

For example, for 99% confidence limits, you can specify the confidence level as follows.

Example: `'alpha', 0.01`

Data Types: `single | double`

'NTrials' — Number of trials

`scalar value | vector`

Number of trials for the corresponding element of `data`, specified as the comma-separated pair consisting of `'ntrials'` and a scalar or a vector of the same size as `data`.

Applies only to binomial distribution.

Example: `'ntrials', total`

Data Types: `single` | `double`

'Options' — Fitting algorithm control parameters

structure

Fitting algorithm control parameters, specified as the comma-separated pair consisting of 'options' and a structure returned by `statset`.

Not applicable to all distributions.

Use the 'options' name-value pair argument to control details of the maximum likelihood optimization when fitting a custom distribution. For parameter names and default values, type `statset('mlecustom')`. You can set the options under a new name and use that in the name-value pair argument. `mle` interprets the following `statset` parameters for custom distribution fitting.

Parameter	Value
'GradObj'	<p>Default is 'off'.</p> <p>'on' or 'off', indicating whether or not <code>fmincon</code> can expect the custom function provided with the <code>nloglf</code> input argument to return the gradient vector of the negative log-likelihood as a second output.</p> <p><code>mle</code> ignores 'GradObj' when using <code>fminsearch</code>.</p>
'DerivStep'	<p>Default is $\text{eps}^{(1/3)}$.</p> <p>The relative difference, specified as a scalar or a vector the same size as <code>start</code>, used in finite difference derivative approximations when using <code>fmincon</code>, and 'GradObj' is 'off'.</p> <p><code>mle</code> ignores 'DerivStep' when using <code>fminsearch</code>.</p>
'FunValCheck'	<p>Default is 'on'.</p> <p>'on' or 'off', indicating whether or not <code>mle</code> should check the values returned by the custom distribution functions for validity.</p> <p>A poor choice of starting point can sometimes cause these functions to return NaNs, infinite values, or out-of-range values if they are written without suitable error checking.</p>

Parameter	Value
'TolBnd'	<p>Default is 1e-6.</p> <p>An offset for upper and lower bounds when using <code>fmincon</code>.</p> <p><code>mle</code> treats upper and lower bounds as strict inequalities, that is, open bounds. With <code>fmincon</code>, this is approximated by creating closed bounds inset from the specified upper and lower bounds by <code>TolBnd</code>.</p>

Example: `'options',statset('mlecustom')`

Data Types: `struct`

'LowerBound' — Lower bounds for distribution parameters

$-\infty$ (default) | vector

Lower bounds for distribution parameters, specified as the comma-separated pair consisting of `'lowerbound'` and a vector the same size as `start`.

This name-value pair argument is valid only when you use the `pdf` and `cdf`, `logpdf` and `logcdf`, or `nloglf` input arguments.

Example: `'lowerbound',0`

Data Types: `single` | `double`

'UpperBound' — Upper bounds for distribution parameters

∞ (default) | vector

Upper bounds for distribution parameters, specified as the comma-separated pair consisting of `'upperbound'` and a vector the same size as `start`.

This name-value pair argument is valid only when you use the `pdf` and `cdf`, `logpdf` and `logsf`, or `nloglf` input arguments.

Example: `'upperbound',1`

Data Types: `single` | `double`

'OptimFun' — Optimization function

`'fminsearch'` (default) | `'fmincon'`

Optimization function `mle` uses in maximizing the likelihood, specified as the comma-separated pair consisting of `'optimfun'` and either `'fminsearch'` or `'fmincon'`.

Default is `'fminsearch'`.

You can only specify `'fmincon'` if Optimization Toolbox is available.

The `'optimfun'` name-value pair argument is valid only when you fit custom distributions, that is, when you use the `pdf` and `cdf`, `logpdf` and `logsf`, or `nloglf` input arguments.

Example: `'optimfun', 'fmincon'`

Output Arguments

phat — Parameter estimates

scalar value | row vector

Parameter estimates, returned as a scalar value or a row vector.

pci — Confidence intervals for parameter estimates

2-by- k matrix

Confidence intervals for parameter estimates, returned as a column vector or a matrix depending on the number of parameters, hence the size of `phat`.

`pci` is a 2-by- k matrix, where k is the number of parameters `mle` estimates. The first and second rows of the `pci` show the upper and lower confidence limits, respectively.

More About

Survival Function

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function, $F(t)$, is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution, $S(t)$, is the complement of the cumulative distribution function: $S(t) = 1 - F(t)$.

Tips

When you supply distribution functions, `mle` computes the parameter estimates using an iterative maximization algorithm. With some models and data, a poor choice of starting point can cause `mle` to converge to a local optimum that is not the global maximizer, or to fail to converge entirely. Even in cases for which the log-likelihood is well-behaved near the global maximum, the choice of starting point is often crucial to convergence of the algorithm. In particular, if the initial parameter values are far from the MLEs, underflow in the distribution functions can lead to infinite log-likelihoods.

- “What Is Survival Analysis?” on page 13-2

`fitdist` | `mlecov` | `statset`

Introduced before R2006a

mlecov

Asymptotic covariance of maximum likelihood estimators

Syntax

```
acov = mlecov(params,data,'pdf',pdf)
acov = mlecov(params,data,'pdf',pdf,'cdf',cdf)

acov = mlecov(params,data,'logpdf',logpdf)
acov = mlecov(params,data,'logpdf',logpdf,'logsf',logsf)

acov = mlecov(params,data,'nloglf',nloglf)

acov = mlecov( ____,Name,Value)
```

Description

`acov = mlecov(params,data,'pdf',pdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom probability density function `pdf`.

`mlecov` computes a finite difference approximation to the Hessian of the log-likelihood at the maximum likelihood estimates `params`, given the observed `data`, and returns the negative inverse of that Hessian.

`acov = mlecov(params,data,'pdf',pdf,'cdf',cdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom probability density function `pdf` and cumulative distribution function `cdf`.

`acov = mlecov(params,data,'logpdf',logpdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom log probability density function `logpdf`.

`acov = mlecov(params,data,'logpdf',logpdf,'logsf',logsf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom log probability density function `logpdf` and custom log survival function `logsf`.

`acov = mlecov(params,data,'nloglf',nloglf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom negative loglikelihood function `nloglf`.

`acov = mlecov(____,Name,Value)` also returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters with additional options specified by one or more name-value pair arguments. You can use any of the input arguments in the previous syntaxes.

Examples

Custom Probability Density Function

Load the sample data.

```
load carbig
```

The vector `Weight` shows the weights of 406 cars.

In the MATLAB Editor, create a function that returns the probability density function (pdf) of a lognormal distribution. Save the file in your current working folder as `lognormpdf.m`.

```
function newpdf = lognormpdf(data,mu,sigma)
newpdf = exp(-(log(data)-mu).^2)/(2*sigma^2))./(data*sigma*sqrt(2*pi));
```

Estimate the parameters, `mu` and `sigma`, of the custom-defined distribution.

```
phat = mle(Weight,'pdf',@lognormpdf,'start',[4.5 0.3])
```

```
phat =
```

```
    7.9600    0.2804
```

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,Weight,'pdf',@lognormpdf)
```

```
acov =
```

```
    1.0e-03 *
```

```
    0.1937    -0.0000
```

```
-0.0000    0.0968
```

Estimate the standard errors of estimates.

```
se = sqrt(diag(acov))
```

```
se =
```

```
0.0139
0.0098
```

The standard error of the estimates of mu and sigma are 0.0139 and 0.0098, respectively.

Custom Log Probability Density Function

In the MATLAB Editor, create a function that returns the log probability density function of a beta distribution. Save the file in your current working folder as `betalogpdf.m`.

```
function logpdf = betalogpdf(x,a,b)
logpdf = (a-1)*log(x)+(b-1)*log(1-x)-betaIn(a,b);
```

Generate sample data from a beta distribution with parameters 1.23 and 3.45 and estimate the parameters using the simulated data.

```
rng('default')
x = betarnd(1.23,3.45,25,1);
phat = mle(x,'dist','beta')
```

```
phat =
```

```
1.1213    2.7182
```

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,x,'logpdf',@betalogpdf)
```

```
acov =
```

```
0.0810    0.1646
0.1646    0.6074
```

Custom Log pdf and Survival Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k) - k*log(lambda) ...
             + (k-1)*log(data) - (data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, `lambda` and `k`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime, 'logpdf', custlogpdf, ...
           'logsf', custlogsf, 'start', [1, 0.75], 'Censoring', Censored)
```

```
phat =
```

```
    9.2090    1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat, ReadmissionTime, ...
              'logpdf', custlogpdf, 'logsf', custlogsf, 'Censoring', Censored)
```

```
acov =
```

```
    0.5653    0.0102
    0.0102    0.0163
```

Custom Log Negative Likelihood Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf = @(lambda,data,cens,freq) -length(data)*log(lambda)...
+ nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)
```

```
phat =
```

```
0.1462
```

Compute the variance of the parameter estimate.

```
acov = mlecov(phat,ReadmissionTime,'nloglf',custnloglf)
```

```
acov =
```

```
2.1374e-04
```

Compute the standard error.

```
sqrt(acov)
```

```
ans =
```

```
0.0146
```

Input Arguments

params — Parameter estimates

scalar value | vector

Parameter estimates, specified as a scalar value or vector of scalar values. These parameter estimates must be maximum likelihood estimates. For example, you can specify parameter estimates returned by `mle`.

Data Types: `single` | `double`

data — Sample data

vector

Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

Data Types: `single` | `double`

pdf — Custom probability density function

function handle

Custom probability distribution function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is `newpdf`, then you can specify the function handle in `mlecov` as follows.

Example: `@newpdf`

Data Types: `function_handle`

cdf — Custom cumulative distribution function

function handle

Custom cumulative distribution function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define `cdf` with `pdf` if data is censored and you use the `'censoring'` name-value pair argument. If `'censoring'` is not present, you do not have to specify `cdf` while using `pdf`.

For example, if the name of the custom cumulative distribution function is `newcdf`, then you can specify the function handle in `mlecov` as follows.

Example: `@newcdf`

Data Types: `function_handle`

logpdf — Custom log probability density function

function handle

Custom log probability density function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is `customlogpdf`, then you can specify the function handle in `mlecov` as follows.

Example: `@customlogpdf`

Data Types: `function_handle`

logsf — Custom log survival function

function handle

Custom log survival function, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define `logsf` with `logpdf` if data is censored and you use the `'censoring'` name-value pair argument. If `'censoring'` is not present, you do not have to specify `logsf` while using `logpdf`.

For example, if the name of the custom log survival function is `logsurvival`, then you can specify the function handle in `mlecov` as follows.

Example: `@logsurvival`

Data Types: `function_handle`

nloglf — Custom negative loglikelihood function

function handle

Custom negative loglikelihood function, specified as a function handle created using `@`.

This custom function accepts the following input arguments.

<code>params</code>	Vector of distribution parameter values
---------------------	---

<code>data</code>	Vector of data
<code>cens</code>	Boolean vector of censored values
<code>freq</code>	Vector of integer data frequencies

`nloglf` must accept all four arguments even if you do not use the `'censoring'` or `'frequency'` name-value pair arguments. You can write `'nloglf'` to ignore `cens` and `freq` arguments in that case.

`nloglf` returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the `'GradObj'` field in `'options'`).

If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mlecov` as follows.

Example: `@negloglik`

Data Types: `function_handle`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'censoring', cens, 'options', opt` specifies that `mlecov` reads the censored data information from the vector `cens` and performs according to the new `options` structure `opt`.

'censoring' — Indicator for censoring

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of `'censoring'` and a Boolean array of the same size as `data`. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

For censored data, you must use `cdf` with `pdf`, or `logsf` with `logpdf`, or `nloglf` must be defined to account for censoring.

For example, if the censored data information is in the binary array called `Censored`, then you can specify the censored data as follows.

Example: `'censoring', Censored`

Data Types: `logical`

'frequency' — Frequency of observations

array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of `'frequency'` and an array containing nonnegative integer counts, which is the same size as `data`. The default is one observation per element of `data`.

For example, if the observation frequencies are stored in an array named `Freq`, you can specify the frequencies as follows.

Example: `'frequency', Freq`

Data Types: `single` | `double`

'options' — Numerical options

structure

Numerical options for the finite difference Hessian calculation, specified as the comma-separated pair consisting of `'options'` and a structure returned by `statset`.

You can set the options under a new name and use it in the name-value pair argument. The applicable `statset` parameters are as follows.

Parameter	Value
<code>'GradObj'</code>	Default is <code>'off'</code> . <code>'on'</code> or <code>'off'</code> , indicating whether or not the function provided with the <code>nloglf</code> input argument can return the gradient vector of the negative log-likelihood as a second output.
<code>'DerivStep'</code>	Default is <code>eps^(1/4)</code> . Relative step size used in finite difference for Hessian calculations. It can be a scalar, or the same size as <code>params</code> . A smaller value than the default might be appropriate if <code>'GradObj'</code> is <code>'on'</code> .

Example: `'options', statset('mlecov')`

Data Types: `struct`

Output Arguments

acov — Approximation to asymptotic covariance matrix

p-by-*p* matrix

Approximation to asymptotic covariance matrix, returned as a *p*-by-*p* matrix, where *p* is the number of parameters in `params`.

More About

Survival Function

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function, $F(t)$, is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution, $S(t)$, is the complement of the cumulative distribution function: $S(t) = 1 - F(t)$.

See Also

`mle`

Introduced before R2006a

mnpdf

Multinomial probability density function

Syntax

```
Y = mnpdf(X,PROB)
```

Description

`Y = mnpdf(X,PROB)` returns the pdf for the multinomial distribution with probabilities `PROB`, evaluated at each row of `X`. `X` and `PROB` are m -by- k matrices or 1-by- k vectors, where k is the number of multinomial bins or categories. Each row of `PROB` must sum to one, and the sample sizes for each observation (rows of `X`) are given by the row sums `sum(X,2)`. `Y` is an m -by-1 vector, and `mnpdf` computes each row of `Y` using the corresponding rows of the inputs, or replicates them if needed.

Examples

Compute the Multinomial Distribution pdf

Compute the pdf of a multinomial distribution with a sample size of $n = 10$. The probabilities are $p = 1/2$ for outcome 1, $p = 1/3$ for outcome 2, and $p = 1/6$ for outcome 3.

```
p = [1/2 1/3 1/6];  
n = 10;  
x1 = 0:n;  
x2 = 0:n;  
[X1,X2] = meshgrid(x1,x2);  
X3 = n-(X1+X2);
```

Compute the pdf of the distribution.

```
Y = mnpdf([X1(:),X2(:),X3(:)], repmat(p, (n+1)^2, 1));
```

Plot the pdf on a 3-dimensional figure.

```
Y = reshape(Y,n+1,n+1);  
bar3(Y)  
h = gca;  
h.XTickLabel = [0:n];  
h.YTickLabel = [0:n];  
xlabel('x_1')  
ylabel('x_2')  
zlabel('Probability Mass')  
title('Trinomial Distribution')
```

Note that the visualization does not show x_3 , which is determined by the constraint $x_1 + x_2 + x_3 = n$.

`mnrnd`

Introduced in R2006b

mnrfit

Multinomial logistic regression

Syntax

```
B = mnrfi(X,Y)
B = mnrfi(X,Y,Name,Value)
[B,dev,stats] = mnrfi( ___ )
```

Description

`B = mnrfi(X,Y)` returns a matrix, `B`, of coefficient estimates for a multinomial logistic regression of the nominal responses in `Y` on the predictors in `X`.

`B = mnrfi(X,Y,Name,Value)` returns a matrix, `B`, of coefficient estimates for a multinomial model fit with additional options specified by one or more `Name,Value` pair arguments.

For example, you can fit a nominal, an ordinal, or a hierarchical model, or change the link function.

`[B,dev,stats] = mnrfi(___)` also returns the deviance of the fit, `dev`, and the structure `stats` for any of the previous input arguments. `stats` contains model statistics such as degrees of freedom, standard errors for coefficient estimates, and residuals.

Examples

Multinomial Regression for Nominal Responses

Fit a multinomial regression for nominal outcomes and interpret the results.

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable using a categorical array.

```
sp = categorical(species);
```

Fit a multinomial regression model to predict the species using the measurements.

```
[B,dev,stats] = mnrfit(meas,sp);
```

```
B
```

```
B =
```

```
13.3860    15.4492
 2.4623     1.8196
 5.2948     2.5700
-7.4916    -4.3714
-8.9322    -7.6467
```

This is a nominal model for the response category relative risks, with separate slopes on all four predictors, that is, each category of `meas`. The first row of `B` contains the intercept terms for the relative risk of the first two response categories, `setosa` and `versicolor` versus the reference category, `virginica`. The last four rows contain the slopes for the models for the first two categories. `mnrfit` accepts the third category as the reference category.

The models for the relative risk of an iris flower being a `setosa` versus a `virginica`, and the relative risk of an iris flower being a `versicolor` species versus a `virginica` species are respectively

$$\ln\left(\frac{\pi_{setosa}}{\pi_{virginica}}\right) = 13.38 + 2.46X_1 + 5.29X_2 - 7.49X_3 - 8.93X_4$$

and

$$\ln\left(\frac{\pi_{versicolor}}{\pi_{virginica}}\right) = 15.45 + 1.82X_1 + 2.57X_2 - 4.37X_3 - 7.65X_4$$

The coefficients express the effects of the predictor variables on the relative risk or the log odds of being in one category versus the reference category.

For example, the estimated coefficient 2.46 indicates that the probability of being species 1 (setosa) compared to the probability of being species 3 (virginica) (the relative risk of being a setosa versus a virginica) increases $\exp(2.46)$ times for each unit increase in X_1 , the first measurement, given all else equal.

In terms of log odds, you can say that the relative log odds of being a setosa versus a virginica increases 2.46 times with a one-unit increase in X_1 given all else is equal.

Check the statistical significance of the model coefficients.

```
stats.p
```

```
ans =
```

```
0.2457    0.0031
0.4543    0.1048
0.0773    0.0815
0.0258    0.0007
0.1856    0.0002
```

The P -value of 0.0258 indicates that the third measure is significant on the relative risk of being a setosa versus a virginica (species 1 compared to species 3). The P -values of 0.0007 and 0.0002 indicate that the third and fourth measures are significant on the relative risk of being a versicolor versus a virginica (species 2 compared to species 3).

Request the standard errors of coefficient estimates.

```
stats.se
```

```
ans =
```

```
11.5316    5.2201

-11.7324   -3.5610
```

Multinomial Regression for Ordinal Responses

Fit a multinomial regression model for categorical responses with natural ordering among categories.

Load the sample data and define the predictor variables.

```
load carbig
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and weight of the cars. The response variable is miles per gallon (mpg).

Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg by labeling the response values in the range 9-19 as 1, 20-29 as 2, 30-39 as 3, and 40-48 as 4.

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);
```

Fit an ordinal response model for the response variable miles.

```
[B,dev,stats] = mnrfit(X,miles,'model','ordinal');  
B
```

```
B =
```

```
-16.6895  
-11.7208  
-8.0606  
0.1048  
0.0103  
0.0645  
0.0017
```

The first three elements of **B** are the intercept terms for the models, and the last four elements of **B** are the coefficients of the covariates, assumed common across all categories. This model corresponds to *parallel regression*, which is also called the *proportional odds* model, where there is a different intercept but common slopes among categories. You can specify this using the 'interactions', 'off' name-value pair argument, which is the default for ordinal models.

```
[B(1:3)'; repmat(B(4:end),1,3)]
```

```
ans =
```

```
-16.6895 -11.7208 -8.0606  
0.1048 0.1048 0.1048  
0.0103 0.0103 0.0103  
0.0645 0.0645 0.0645  
0.0017 0.0017 0.0017
```

The link function in the model is `logit('link','logit')`, which is the default for an ordinal model. The coefficients express the relative risk or log odds of the mpg of a car being less than or equal to one value versus greater than that value.

The proportional odds model in this example is

$$\ln \left(\frac{P(\text{mpg} \leq 19)}{P(\text{mpg} > 19)} \right) = -16.6895 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

$$\ln \left(\frac{P(\text{mpg} \leq 29)}{P(\text{mpg} > 29)} \right) = -11.7208 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

$$\ln \left(\frac{P(\text{mpg} \leq 39)}{P(\text{mpg} > 39)} \right) = -8.0606 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

For example, the coefficient estimate of 0.1048 indicates that a unit change in acceleration would impact the odds of the mpg of a car being less than or equal to 19 versus more than 19, or being less than or equal to 29 versus greater than 29, or being less than or equal to 39 versus greater than 39, by a factor of $\exp(0.1048)$ given all else is equal.

Assess the significance of the coefficients.

```
stats.p
```

```
ans =
```

```
0.0000
0.0000
0.0000
0.1899
0.0350
0.0000
0.0118
```

The P -values of 0.035, 0.0000, and 0.0118 for engine displacement, horsepower, and weight of a car, respectively, indicate that these factors are significant on the odds of mpg of a car being less than or equal to a certain value versus being greater than that value.

Hierarchical Multinomial Regression Model

Fit a hierarchical multinomial regression model.

Navigate to the folder containing sample data.

```
cd(matlabroot)
```

```
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load smoking
```

The data set `smoking` contains five variables: sex, age, weight, and systolic and diastolic blood pressure. Sex is a binary variable where 1 indicates female patients, and 0 indicates male patients.

Define the response variable.

```
Y = categorical(smoking.Smoker);
```

The data in `Smoker` has four categories:

- 0: Nonsmoker, 0 cigarettes a day
- 1: Smoker, 1–5 cigarettes a day
- 2: Smoker, 6–10 cigarettes a day
- 3: Smoker, 11 or more cigarettes a day

Define the predictor variables.

```
X = [smoking.Sex smoking.Age smoking.Weight...  
     smoking.SystolicBP smoking.DiastolicBP];
```

Fit a hierarchical multinomial model.

```
[B,dev,stats] = mnrfit(X,Y,'model','hierarchical');  
B
```

```
B =
```

```
43.8148    5.9571   44.0712  
 1.8709   -0.0230    0.0662  
 0.0188    0.0625    0.1335  
 0.0046   -0.0072   -0.0130  
-0.2170    0.0416   -0.0324  
-0.2273   -0.1449   -0.4824
```

The first column of `B` includes the intercept and the coefficient estimates for the model of the relative risk of being a nonsmoker versus a smoker. The second column includes the parameter estimates for modeling the log odds of smoking 1–5 cigarettes a day versus

more than five cigarettes a day given that a person is a smoker. Finally, the third column includes the parameter estimates for modeling the log odds of a person smoking 6–10 cigarettes a day versus more than 10 cigarettes a day given he/she smokes more than 5 cigarettes a day.

The coefficients differ across categories. You can specify this using the 'interactions', 'on' name-value pair argument, which is the default for hierarchical models. So, the model in this example is

$$\ln\left(\frac{P(y=0)}{P(y>0)}\right) = 43.8148 + 1.8709X_S + 0.0188X_A + 0.0046X_W - 0.2170X_{SBP} - 0.2273X_{DBP}$$

$$\ln\left(\frac{P(1 \leq y \leq 5)}{P(y > 5)}\right) = 5.9571 - 0.0230X_S + 0.0625X_A + 0.0072X_W + 0.0416X_{SBP} - 0.1449X_{DBP}$$

$$\ln\left(\frac{P(6 \leq y \leq 10)}{P(y > 10)}\right) = 44.0712 + 0.0662X_S + 0.1335X_A - 0.0130X_W - 0.0324X_{SBP} - 0.4824X_{DBP}$$

For example, the coefficient estimate of 1.8709 indicates that the likelihood of being a smoker versus a nonsmoker increases by $\exp(1.8709) = 6.49$ times as the gender changes from female to male given everything else held constant.

Assess the statistical significance of the terms.

```
stats.p
```

```
ans =
```

0.0000	0.5363	0.2149
0.3549	0.9912	0.9835
0.6850	0.2676	0.2313
0.9032	0.8523	0.8514
0.0009	0.5187	0.8165
0.0004	0.0483	0.0545

Sex, age, or weight don't appear significant on any level. The p -values of 0.0009 and 0.0004 indicate that both types of blood pressure are significant on the relative risk of a person being a smoker versus a nonsmoker. The p -value of 0.0483 shows that only

diastolic blood pressure is significant on the odds of a person smoking 0–5 cigarettes a day versus more than 5 cigarettes a day. Similarly, the p -value of 0.0545 indicates that diastolic blood pressure is significant on the odds of a person smoking 6–10 cigarettes a day versus more than 10 cigarettes a day.

Check if any nonsignificant factors are correlated to each other. Draw a scatterplot of age versus weight grouped by sex.

```
figure()
gscatter(smoking.Age,smoking.Weight,smoking.Sex)
legend('Male','Female')
xlabel('Age')
ylabel('Weight')
```

The range of weight of an individual seems to differ according to gender. Age does not seem to have any obvious correlation with sex or weight. Age is insignificant and weight seems to be correlated with sex, so you can eliminate both and reconstruct the model.

Eliminate age and weight from the model and fit a hierarchical model with sex, systolic blood pressure, and diastolic blood pressure as the predictor variables.

```
X = double([smoking.Sex smoking.SystolicBP...
smoking.DiastolicBP]);
[B,dev,stats] = mnrfits(X,Y,'model','hierarchical');
B
```

B =

44.8456	5.3230	25.0248
1.6045	0.2330	0.4982
-0.2161	0.0497	0.0179
-0.2222	-0.1358	-0.3092

Here, a coefficient estimate of 1.6045 indicates that the likelihood of being a nonsmoker versus a smoker increases by $\exp(1.6045) = 4.97$ times as sex changes from male to female. A unit increase in the systolic blood pressure indicates an $\exp(-.2161) = 0.8056$ decrease in the likelihood of being a nonsmoker versus a smoker. Similarly, a unit increase in the diastolic blood pressure indicates an $\exp(-.2222) = 0.8007$ decrease in the relative rate of being a nonsmoker versus being a smoker.

Assess the statistical significance of the terms.

```
stats.p
```

ans =

0.0000	0.4715	0.2325
0.0210	0.7488	0.6362
0.0010	0.4107	0.8899
0.0003	0.0483	0.0718

The p -values of 0.0210, 0.0010, and 0.0003 indicate that the terms sex and both types of blood pressure are significant on the relative risk of a person being a nonsmoker versus a smoker, given the other terms in the model. Based on the p -value of 0.0483, diastolic blood pressure appears significant on the relative risk of a person smoking 1–5 cigarettes versus more than 5 cigarettes a day, given that this person is a smoker. Because none of the p -values on the third column are less than 0.05, you can say that none of the

variables are statistically significant on the relative risk of a person smoking from 6–10 cigarettes versus more than 10 cigarettes, given that this person smokes more than 5 cigarettes a day.

Input Arguments

X — Observations on predictor variables

n-by-*p* matrix

Observations on predictor variables, specified as an *n*-by-*p* matrix. *X* contains *n* observations for *p* predictors.

Note: `mnrfit` automatically includes a constant term (intercept) in all models. Do not include a column of 1s in *X*.

Data Types: `single` | `double`

Y — Response values

n-by-*k* matrix | *n*-by-1 column vector

Response values, specified as a column vector or a matrix. *Y* can be one of the following:

- An *n*-by-*k* matrix, where $Y(i,j)$ is the number of outcomes of the multinomial category *j* for the predictor combinations given by $X(i,:)$. In this case, the number of observations are made at each predictor combination.
- An *n*-by-1 column vector of scalar integers from 1 to *k* indicating the value of the response for each observation. In this case, all sample sizes are 1.
- An *n*-by-1 categorical array indicating the nominal or ordinal value of the response for each observation. In this case, all sample sizes are 1.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: 'Model', 'ordinal', 'Link', 'probit' specifies an ordinal model with a probit link function.

'Model' — Type of model to fit

'nominal' (default) | 'ordinal' | 'hierarchical'

Type of model to fit, specified as the comma-separated pair consisting of 'Model' and one of the following.

'nominal'	Default. There is no ordering among the response categories.
'ordinal'	There is a natural ordering among the response categories.
'hierarchical'	The choice of response category is sequential/nested.

Example: 'Model', 'ordinal'

'Interactions' — Indicator for interaction between multinomial categories and coefficients

'on' | 'off'

Indicator for an interaction between the multinomial categories and coefficients, specified as the comma-separated pair consisting of 'Interactions' and one of the following.

'on'	Default for nominal and hierarchical models. Fit a model with different coefficients across categories.
'off'	Default for ordinal models. Fit a model with a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as <i>parallel regression</i> or the <i>proportional odds model</i> .

In all cases, the model has different intercepts across categories. The choice of 'Interactions' determines the dimensions of the output array B.

Example: 'Interactions', 'off'

Data Types: logical

'Link' — Link function

'logit' (default) | 'probit' | 'comloglog' | 'loglog'

Link function to use for ordinal and hierarchical models, specified as the comma-separated pair consisting of 'Link' and one of the following.

'logit'	Default. $f(\gamma) = \ln(\gamma/(1-\gamma))$
'probit'	$f(\gamma) = \Phi^{-1}(\gamma)$ — error term is normally distributed with variance 1
'comploglog'	Complementary log-log $f(\gamma) = \ln(-\ln(1-\gamma))$
'loglog'	$f(\gamma) = \ln(-\ln(\gamma))$

The link function defines the relationship between response probabilities and the linear combination of predictors, $X\beta$. The link functions might be functions of cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response. For example, for an ordinal model, γ represents the cumulative probability of being in categories 1 to j and the model with a logit link function as follows:

$$\ln\left(\frac{\gamma}{1-\gamma}\right) = \ln\left(\frac{\pi_1 + \pi_2 + \dots + \pi_j}{\pi_{j+1} + \dots + \pi_k}\right) = \beta_{0j} + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_p X_p,$$

where k represents the last category.

You cannot specify the 'Link' parameter for nominal models; these always use a multinomial logit link,

$$\ln\left(\frac{\pi_j}{\pi_r}\right) = \beta_{j0} + \beta_{j1} X_{j1} + \beta_{j2} X_{j2} + \dots + \beta_{jp} X_{jp}, \quad j = 1, \dots, k-1,$$

where π stands for a categorical probability, and r corresponds to the reference category. `mnrfit` uses the last category as the reference category for nominal models.

Example: 'Link', 'loglog'

'EstDisp' — Indicator for estimating dispersion parameter

'off' (default) | 'on'

Indicator for estimating a dispersion parameter, specified as the comma-separated pair consisting of 'EstDisp' and one of the following.

'off'	Default. Use the theoretical dispersion value of 1.
'on'	Estimate a dispersion parameter for the multinomial distribution in computing standard errors.

Example: 'EstDisp', 'on'

Output Arguments

B — Coefficient estimates

vector | matrix

Coefficient estimates for a multinomial logistic regression of the responses in Y , returned as a vector or a matrix.

- If 'Interaction' is 'off', then B is a $k - 1 + p$ vector. The first $k - 1$ rows of B correspond to the intercept terms, one for each $k - 1$ multinomial categories, and the remaining p rows correspond to the predictor coefficients, which are common for all of the first $k - 1$ categories.
- If 'Interaction' is 'on', then B is a $(p + 1)$ -by- $(k - 1)$ matrix. Each column of B corresponds to the estimated intercept term and predictor coefficients, one for each of the first $k - 1$ multinomial categories.

The estimates for the k th category are taken to be zero as `mnrfit` takes the last category as the reference category.

dev — Deviance of the fit

scalar value

Deviance of the fit, returned as a scalar value. It is twice the difference between the maximum achievable log likelihood and that attained under the fitted model. This corresponds to the sum of deviance residuals,

$$dev = 2 * \sum_i^n \sum_j^k y_{ij} * \log \left(\frac{y_{ij}}{\pi_{ij} * m_i} \right) = \sum_i^n rd_i,$$

where rd_i are the deviance residuals. For deviance residuals see `stats`.

stats — Model statistics

structure

Model statistics, returned as a structure that contains the following fields.

beta	The coefficient estimates. These are the same as B .
dfe	Degrees of freedom for error <ul style="list-style-type: none"> • If 'Interactions' is 'off', then degrees of freedom is $n*(k - 1) - (k - 1 + p)$. • If 'Interactions' is 'on', then degrees of freedom is $(n - p + 1)*(k - 1)$.
sfit	Estimated dispersion parameter.
s	Theoretical or estimated dispersion parameter. <ul style="list-style-type: none"> • If 'Estdisp' is 'off', then s is the theoretical dispersion parameter, 1. • If 'Estdisp' is 'on', then s is equal to the estimated dispersion parameter, sfit.
estdisp	Indicator for a theoretical or estimated dispersion parameter.
se	Standard errors of coefficient estimates, B .
coeffcorr	Estimated correlation matrix for B .
covb	Estimated covariance matrix for B .
t	<i>t</i> statistics for B .
p	<i>p</i> -values for B .
resid	Raw residuals. Observed minus fitted values, $r_{ij} = y_{ij} - \hat{\pi}_{ij} * m_i, \quad \begin{cases} i = 1, \dots, n \\ j = 1, \dots, k \end{cases}$ <p>where π_{ij} is the categorical, cumulative or conditional probability, and m_i is the corresponding sample size.</p>
residp	Pearson residuals, which are the raw residuals scaled by the estimated standard deviation:

	$rp_{ij} = \frac{r_{ij}}{\hat{\sigma}_{ij}} = \frac{y_{ij} - \hat{\pi}_{ij} * m_i}{\sqrt{\hat{\pi}_{ij} * (1 - \hat{\pi}_{ij}) * m_i}}, \quad \begin{cases} i = 1, \dots, n \\ j = 1, \dots, k \end{cases}$ <p>where π_{ij} is the categorical, cumulative, or conditional probability, and m_i is the corresponding sample size.</p>
residd	<p>Deviance residuals:</p> $rd_i = 2 * \sum_j^k y_{ij} * \log \left(\frac{y_{ij}}{\pi_{ij} * m_i} \right), \quad i = 1, \dots, n.$ <p>where π_{ij} is the categorical, cumulative, or conditional probability, and m_i is the corresponding sample size.</p>

Introduced in R2006b

mnrnd

Multinomial random numbers

Syntax

```
r = mnrnd(n,p)
R = mnrnd(n,p,m)
R = mnrnd(N,P)
```

Description

`r = mnrnd(n,p)` returns random values `r` from the multinomial distribution with parameters `n` and `p`. `n` is a positive integer specifying the number of trials (sample size) for each multinomial outcome. `p` is a 1-by- k vector of multinomial probabilities, where k is the number of multinomial bins or categories. `p` must sum to one. (If `p` does not sum to one, `r` consists entirely of NaN values.) `r` is a 1-by- k vector, containing counts for each of the k multinomial bins.

`R = mnrnd(n,p,m)` returns `m` random vectors from the multinomial distribution with parameters `n` and `p`. `R` is a m -by- k matrix, where k is the number of multinomial bins or categories. Each row of `R` corresponds to one multinomial outcome.

`R = mnrnd(N,P)` generates outcomes from different multinomial distributions. `P` is a m -by- k matrix, where k is the number of multinomial bins or categories and each of the m rows contains a different set of multinomial probabilities. Each row of `P` must sum to one. (If any row of `P` does not sum to one, the corresponding row of `R` consists entirely of NaN values.) `N` is a m -by-1 vector of positive integers or a single positive integer (replicated by `mnrnd` to a m -by-1 vector). `R` is a m -by- k matrix. Each row of `R` is generated using the corresponding rows of `N` and `P`.

Examples

Generate 2 random vectors with the same probabilities:

```
n = 1e3;
```

```
p = [0.2,0.3,0.5];
R = mnrnd(n,p,2)
R =
    215    282    503
    194    303    503
```

Generate 2 random vectors with different probabilities:

```
n = 1e3;
P = [0.2, 0.3, 0.5; ...
     0.3, 0.4, 0.3];
R = mnrnd(n,P)
R =
    186    290    524
    290    389    321
```

More About

- “Multinomial Distribution” on page B-103

`mnpdf`

Introduced in R2006b

mnrval

Multinomial logistic regression values

Syntax

```
pihat = mnrvl(B,X)
[pihat,dlow,dhi] = mnrvl(B,X,stats)
[pihat,dlow,dhi] = mnrvl(B,X,stats,Name,Value)

yhat = mnrvl(B,X,ssize)
[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats)
[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats,Name,Value)
```

Description

`pihat = mnrvl(B,X)` returns the predicted probabilities for the multinomial logistic regression model with predictors, `X`, and the coefficient estimates, `B`.

`pihat` is an n -by- k matrix of predicted probabilities for each multinomial category. `B` is the vector or matrix that contains the coefficient estimates returned by `mnrfit`. And `X` is an n -by- p matrix which contains n observations for p predictors.

Note: `mnrval` automatically includes a constant term in all models. Do not enter a column of 1s in `X`.

`[pihat,dlow,dhi] = mnrvl(B,X,stats)` also returns 95% error bounds on the predicted probabilities, `pihat`, using the statistics in the structure, `stats`, returned by `mnrfit`.

The lower and upper confidence bounds for `pihat` are `pihat` minus `dlow` and `pihat` plus `dhi`, respectively. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

`[pihat,dlow,dhi] = mnrvl(B,X,stats,Name,Value)` returns the predicted probabilities and 95% error bounds on the predicted probabilities `pihat`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the model type, link function, and the type of probabilities to return.

`yhat = mnrvl(B,X,ssize)` returns the predicted category counts for sample sizes, `ssize`.

`[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats)` also computes 95% error bounds on the predicted counts `yhat`, using the statistics in the structure, `stats`, returned by `mnrfit`.

The lower and upper confidence bounds for `yhat` are `yhat` minus `dlo` and `yhat` plus `dhi`, respectively. Confidence bounds are nonsimultaneous and they apply to the fitted curve, not to new observations.

`[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats,Name,Value)` returns the predicted category counts and 95% error bounds on the predicted counts `yhat`, with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the model type, link function, and the type of predicted counts to return.

Examples

Estimate Category Probabilities for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category probabilities.

Load the sample data.

```
load('fisheriris.mat')
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);  
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species `setosa`, `versicolor`, and `virginica`, respectively.

Fit a nominal model to estimate the species using the flower measurements as the predictor variables.

```
[B,dev,stats] = mnrfits(meas,sp);
```

Estimate the probability of being a certain kind of species for an iris flower having the measurements (6.2, 3.7, 5.8, 0.2).

```
x = [6.2, 3.7, 5.8, 0.2];
pihat = mnrval(B,x);
pihat

pihat =

    0.0017    0.9982    0.0001
```

The probability of an iris flower having the measurements (6.2, 3.7, 5.8, 0.2) being a setosa is 0.0017, a versicolor is 0.9982, and a virginica is 0.0001.

Estimate Upper and Lower Error Bounds for Probability Estimates of Ordinal Responses

Fit a multinomial regression model for categorical responses with natural ordering among categories. Then estimate the upper and lower confidence bounds for the category probability estimates.

Load the sample data and define the predictor variables.

```
load('carbig.mat')
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and the weight of the cars. The response variable is miles per gallon (MPG).

Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg.

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);
miles = double(miles);
```

Now in miles, 1 indicates the cars with miles per gallon from 9 to 19, and 2 indicates the cars with miles per gallon from 20 to 29. Similarly, 3 and 4 indicate the cars with miles per gallon from 30 to 39 and 40 to 48, respectively.

Fit a multinomial regression model for the response variable `miles`. For an ordinal model, the default `'link'` is `logit` and the default `'interactions'` is `'off'`.

```
[B,dev,stats] = mnrfits(X,miles,'model','ordinal');
```

Compute the probability estimates and 95% error bounds for probability confidence intervals for miles per gallon of a car with $x = (12, 113, 110, 2670)$.

```
x = [12,113,110,2670];  
[pihat,dlow,hi] = mnrfits(B,x,stats,'model','ordinal');  
pihat
```

```
pihat =
```

```
0.0615    0.8426    0.0932    0.0027
```

Calculate the confidence bounds for the category probability estimates.

```
LL = pihat - dlow;  
UL = pihat + hi;  
[LL;UL]
```

```
ans =
```

```
0.0073    0.7829    0.0283   -0.0003  
0.1157    0.9022    0.1580    0.0057
```

Estimate Category Counts and Error Bounds for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category counts.

Load the sample data.

```
load('fisheriris.mat')
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);  
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species `setosa`, `versicolor`, and `virginica`, respectively.

Fit a nominal model to estimate the species based on the flower measurements.

```
[B,dev,stats] = mnrfits(meas,sp);
```

Estimate the number in each species category for a sample of 100 iris flowers all with the measurements (6.2, 3.7, 5.8, 0.2).

```
x = [6.2,3.7,5.8,0.2];
yhat = mnrval(B,x,18)
```

```
yhat =
```

```
0.0314    17.9671    0.0016
```

Estimate the error bounds for the counts.

```
[yhat,dlow,hi] = mnrval(B,x,18,stats,'model','nominal');
```

Calculate the confidence bounds for the category probability estimates.

```
LL = yhat - dlow;
UL = yhat + hi;
[LL;UL]
```

```
ans =
```

```
-0.7084    17.2272   -0.0115
 0.7711    18.7069    0.0146
```

Plot the Count Estimates

Create sample data with one predictor variable and a categorical response variable with three categories.

```
x = [-3 -2 -1 0 1 2 3]';
Y = [1 11 13; 2 9 14; 6 14 5; 5 10 10; ...
     5 14 6; 7 13 5; 8 11 6];
[Y x]
```

```
ans =
```

```
1    11    13    -3
2     9    14    -2
6    14     5    -1
5    10    10     0
5    14     6     1
7    13     5     2
```

8 11 6 3

There are observations on seven different values of the predictor variable x . The response variable Y has three categories and the data shows how many of the 25 individuals are in each category of Y for each observation of x . For example, when x is -3, 1 of 25 individuals is observed in category 1, 11 observed in category 2, and 13 observed in category 3. Similarly, when x is 1, 5 of the individuals are observed in category 1, 14 are observed in category 2, and 6 are observed in category 3.

Plot the number in each category versus the x values, on a stacked bar graph.

```
bar(x,Y,'stacked');  
ylim([0 25]);
```

Fit a nominal model for the individual response category probabilities, with separate slopes on the single predictor variable, x , for each category.

```
betaHatNom = mnrfit(x,Y,'model','nominal',...
    'interactions','on')
```

```
betaHatNom =
```

```
-0.6028    0.3832
 0.4068    0.1948
```

The first row of `betaHatOrd` contains the intercept terms for the first two response categories. The second row contains the slopes. `mnrfit` accepts the third category as the reference category and hence assumes the coefficients for the third category are zero.

Compute the predicted probabilities for the three response categories.

```
xx = linspace(-4,4)';
piHatNom = mnrval(betaHatNom,xx,'model','nominal',...
    'interactions','on');
```

The probability of being in the third category is simply $1 - P(Y = 1) - P(Y = 2)$.

Plot the estimated cumulative number in each category on the bar graph.

```
line(xx,cumsum(25*piHatNom,2),'LineWidth',2);
```

The cumulative probability for the third category is always 1.

Now, fit a "parallel" ordinal model for the cumulative response category probabilities, with a common slope on the single predictor variable, x , across all categories:

```
betaHatOrd = mnrfit(x,Y,'model','ordinal',...
    'interactions','off')
```

```
betaHatOrd =
```

```
-1.5001
 0.7266
 0.2642
```

The first two elements of `betaHatOrd` are the intercept terms for the first two response categories. The last element of `betaHatOrd` is the common slope.

Compute the predicted cumulative probabilities for the first two response categories. The cumulative probability for the third category is always 1.

```
piHatOrd = mnrvl(betaHatOrd,xx,'type','cumulative',...  
                'model','ordinal','interactions','off');
```

Plot the estimated cumulative number on the bar graph of the observed cumulative number.

```
figure()  
bar(x,cumsum(Y,2),'grouped');  
ylim([0 25]);  
line(xx,25*piHatOrd,'LineWidth',2);
```

Input Arguments

B — Coefficient estimates

vector or matrix returned by `mnrfit`

Coefficient estimates for the multinomial logistic regression model, specified as a vector or matrix returned by `mnrfit`. It is a vector or matrix depending on the model and interactions.

Example: `B = mnrfit(X,y); pihat = mnrval(B,X)`

Data Types: `single` | `double`

X — Sample data

matrix

Sample data on predictors, specified as an n -by- p . X contains n observations for p predictors.

Note: `mnrval` automatically includes a constant term in all models. Do not enter a column of 1s in X .

Example: `pihat = mnrval(B,X)`

Data Types: `single` | `double`

stats — Model statisticsstructure returned by `mnrfit`

Model statistics, specified as a structure returned by `mnrfit`. You must use the `stats` input argument in `mnrval` to compute the lower and upper error bounds on the category probabilities and counts.

Example: `[B,dev,stats] = mnrfit(X,y);[pihat,dlo,dhi] = mnrval(B,X,stats)`

ssize — Sample sizes

column vector of positive integers

Sample sizes to return the number of items in response categories for each combination of the predictor variables, specified as an n -by-1 column vector of positive integers.

For example, for a response variable having three categories, if an observation of the number of individuals in each category is y_1 , y_2 , and y_3 , respectively, then the sample size, m , for that observation is $m = y_1 + y_2 + y_3$.

If the sample sizes for n observations are in vector `sample`, then you can enter the sample sizes as follows.

Example: `yhat = mnrval(B,X,sample)`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'model', 'ordinal', 'link', 'probit', 'type', 'cumulative'` specifies that `mnrval` returns the estimates for cumulative probabilities for an ordinal model with a probit link function.

'model' — Type of multinomial model

`'nominal'` (default) | `'ordinal'` | `'hierarchical'`

Type of multinomial model fit by `mnrfit`, specified as the comma-separated pair consisting of `'model'` and one of the following.

<code>'nominal'</code>	Default. Specify when there is no ordering among the response categories.
<code>'ordinal'</code>	Specify when there is a natural ordering among the response categories.
<code>'hierarchical'</code>	Specify when the choice of response category is sequential.

Example: `'model', 'ordinal'`

'interactions' — Indicator for interaction between multinomial categories and coefficients

`'on'` | `'off'`

Indicator for an interaction between the multinomial categories and coefficients in the model fit by `mnrfit`, specified as the comma-separated pair consisting of `'interactions'` and one of the following.

<code>'on'</code>	Default for nominal and hierarchical models. Specify to fit a model with different intercepts and coefficients across categories.
<code>'off'</code>	Default for ordinal models. Specify to fit a model with different intercepts, but a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as <i>parallel regression</i> or <i>proportional odds model</i> .

Example: `'interactions', 'off'`

Data Types: logical

'link' – Link function

'logit' (default) | 'probit' | 'comploglog' | 'loglog'

Link function `mnrfit` uses for ordinal and hierarchical models, specified as the comma-separated pair consisting of `'link'` and one of the following.

'logit'	Default. $f(\gamma) = \ln(\gamma/(1 - \gamma))$
'probit'	$f(\gamma) = \Phi^{-1}(\gamma)$ — error term is normally distributed with variance 1
'comploglog'	Complementary log-log $f(\gamma) = \ln(-\ln(1 - \gamma))$
'loglog'	$f(\gamma) = \ln(-\ln(\gamma))$

The link function defines the relationship between response probabilities and the linear combination of predictors, $X\beta$.

γ might be cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response.

You cannot specify the `'link'` parameter for nominal models; these always use a multinomial logit link,

$$\ln\left(\frac{\pi_j}{\pi_r}\right) = \beta_{j0} + \beta_{j1}X_{j1} + \beta_{j2}X_{j2} + \cdots + \beta_{jp}X_{jp}, \quad j = 1, \dots, k-1,$$

where π stands for a categorical probability, and r corresponds to the reference category, k is the total number of response categories, p is the number of predictor variables. `mnrfit` uses the last category as the reference category for nominal models.

Example: `'link', 'loglog'`

'type' – Type of probabilities or counts to estimate

'category' (default) | 'cumulative' | 'conditional'

Type of probabilities or counts to estimate, specified as the comma-separated pair including `'type'` and one of the following.

'category'	Default. Specify to return predictions and error bounds for the probabilities (or counts) of the k multinomial categories.
'cumulative'	Specify to return predictions and confidence bounds for the cumulative probabilities (or counts) of the first $k - 1$ multinomial categories, as an n -by- $(k - 1)$ matrix. The predicted cumulative probability for the k th category is always 1.
'conditional'	Specify to return predictions and error bounds in terms of the first $k - 1$ conditional category probabilities (counts), i.e., the probability (count) for category j , given an outcome in category j or higher. When 'type' is 'conditional', and you supply the sample size argument <code>ssize</code> , the predicted counts at each row of X are conditioned on the corresponding element of <code>ssize</code> , across all categories.

Example: 'type','cumulative'

'confidence' — Confidence level

0.95 (default) | Scalar value in the range (0,1)

Confidence level for the error bounds, specified as the comma-separated pair consisting of 'confidence' and a scalar value in the range (0,1).

For example, for 99% error bounds, you can specify the confidence as follows:

Example: 'confidence',0.99

Data Types: single | double

Output Arguments

pihat — Probability estimates

n -by- $(k - 1)$ matrix

Probability estimates for each multinomial category, returned as an n -by- $(k - 1)$ matrix, where n is the number of observations, and k is the number of response categories.

yhat — Count estimates

n -by- $k - 1$ matrix

Count estimates for the number in each response category, returned as an n -by- k - 1 matrix, where n is the number of observations, and k is the number of response categories.

dlow – Lower error bound

column vector

Lower error bound to compute the lower confidence bound for `pihat` or `yhat`, returned as a column vector.

The lower confidence bound for `pihat` is `pihat` minus `dlow`. Similarly, the lower confidence bound for `yhat` is `yhat` minus `dlow`. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

dhi – Upper error bound

column vector

Upper error bound to compute the upper confidence bound for `pihat` or `yhat`, returned as a column vector.

The upper confidence bound for `pihat` is `pihat` plus `dhi`. Similarly, the upper confidence bound for `yhat` is `yhat` plus `dhi`. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

Introduced in R2006b

moment

Central moments

Syntax

```
m = moment(X,order)
moment(X,order,dim)
```

Description

`m = moment(X,order)` returns the central sample moment of `X` specified by the positive integer `order`. For vectors, `moment(x,order)` returns the central moment of the specified order for the elements of `x`. For matrices, `moment(X,order)` returns central moment of the specified order for each column. For N-dimensional arrays, `moment` operates along the first nonsingleton dimension of `X`.

`moment(X,order,dim)` takes the moment along dimension `dim` of `X`.

Examples

```
X = randn([6 5])
X =
    1.1650    0.0591    1.2460   -1.2704   -0.0562
    0.6268    1.7971   -0.6390    0.9846    0.5135
    0.0751    0.2641    0.5774   -0.0449    0.3967
    0.3516    0.8717   -0.3600   -0.7989    0.7562
   -0.6965   -1.4462   -0.1356   -0.7652    0.4005
    1.6961   -0.7012   -1.3493    0.8617   -1.3414

m = moment(X,3)
m =
   -0.0282    0.0571    0.1253    0.1460   -0.4486
```

More About

Tips

Note that the central first moment is zero, and the second central moment is the variance computed using a divisor of n rather than $n - 1$, where n is the length of the vector x or the number of rows in the matrix X .

The central moment of order k of a distribution is defined as

$$m_k = E(x - \mu)^k$$

where $E(x)$ is the expected value of x .

Class: gmdistribution

Input matrix of means μ

Description

Input matrix of means μ .

multcompare

Multiple comparison test

Syntax

```
c = multcompare(stats)
c = multcompare(stats,Name,Value)
[c,m] = multcompare( ___ )
[c,m,h] = multcompare( ___ )
[c,m,h,gnames] = multcompare( ___ )
```

Description

`c = multcompare(stats)` returns a matrix `c` of the pairwise comparison results from a multiple comparison test using the information contained in the `stats` structure. `multcompare` also displays an interactive graph of the estimates and comparison intervals. Each group mean is represented by a symbol, and the interval is represented by a line extending out from the symbol. Two group means are significantly different if their intervals are disjoint; they are not significantly different if their intervals overlap. If you use your mouse to select any group, then the graph will highlight all other groups that are significantly different, if any.

`c = multcompare(stats,Name,Value)` returns a matrix of pairwise comparison results, `c`, using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence interval, or the type of critical value to use in the multiple comparison.

`[c,m] = multcompare(___)` also returns a matrix, `m`, which contains estimated values of the means (or whatever statistics are being compared) for each group and the corresponding standard errors. You can use any of the previous syntaxes.

`[c,m,h] = multcompare(___)` also returns a handle, `h`, to the comparison graph.

`[c,m,h,gnames] = multcompare(___)` also returns a cell array, `gnames`, which contains the names of the groups.

Examples

Multiple Comparison of Group Means

Load the sample data.

```
load carsmall
```

Perform a one-way analysis of variance (ANOVA) to see if there is any difference between the mileage of the cars by origin.

```
[p,t,stats] = anova1(MPG,Origin,'off');
```

Perform a multiple comparison of the group means.

```
[c,m,h,nms] = multcompare(stats);
```

multcompare displays the estimates with comparison intervals around them. You can click the graphs of each country to compare its mean to those of other countries.

Now display the mean estimates and the standard errors with the corresponding group names.

```
[nms num2cell(m)]
```

```
ans =
```

'USA'	[21.1328]	[0.8814]
'Japan'	[31.8000]	[1.8206]
'Germany'	[28.4444]	[2.3504]

```
'France'      [23.6667]    [4.0711]
'Sweden'      [22.5000]    [4.9860]
'Italy'       [      28]    [7.0513]
```

Multiple Comparisons for Two-Way ANOVA

Load the sample data.

```
load popcorn
popcorn
```

```
popcorn =
```

```
5.5000  4.5000  3.5000
5.5000  4.5000  4.0000
6.0000  4.0000  3.0000
6.5000  5.0000  4.0000
7.0000  5.5000  5.0000
7.0000  5.0000  4.5000
```

The data is from a study of popcorn brands and popper types (Hogg 1987). The columns of the matrix `popcorn` are brands (Gourmet, National, and Generic). The rows are popper types oil and air. In the study, researchers popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Perform a two-way ANOVA. Also compute the statistics that you need to perform a multiple comparison test on the main effects.

```
[~,~,stats] = anova2(popcorn,3,'off')
```

```
stats =
```

```
source: 'anova2'
sigmasq: 0.1389
colmeans: [6.2500 4.7500 4]
coln: 6
rowmeans: [4.5000 5.5000]
rown: 9
inter: 1
pval: 0.7462
```

df: 12

The `stats` structure includes

- The mean squared error (`sigmasq`)
- The estimates of the mean yield for each popcorn brand (`colmeans`)
- The number of observations for each popcorn brand (`coln`)
- The estimate of the mean yield for each popper type (`rowmeans`)
- The number of observations for each popper type (`rown`)
- The number of interactions (`inter`)
- The p -value that shows the significance level of the interaction term (`pval`)
- The error degrees of freedom (`df`).

Perform a multiple comparison test to see if the popcorn yield differs between pairs of popcorn brands (columns).

```
c = multcompare(stats)
```

Note: Your model includes an interaction term. A test of main effects can be difficult to interpret when the model includes interactions.

```
c =
```

1.0000	2.0000	0.9260	1.5000	2.0740	0.0000
1.0000	3.0000	1.6760	2.2500	2.8240	0.0000
2.0000	3.0000	0.1760	0.7500	1.3240	0.0116

The first two columns of **C** show the groups that are compared. The fourth column shows the difference between the estimated group means. The third and fifth columns show the lower and upper limits for 95% confidence intervals for the true mean difference. The sixth column contains the p -value for a hypothesis test that the corresponding mean difference is equal to zero. All p -values (0, 0, and 0.0116) are very small, which indicates that the popcorn yield differs across all three brands.

The figure shows the multiple comparison of the means. By default, the group 1 mean is highlighted and the comparison interval is in blue. Because the comparison intervals for the other two groups do not intersect with the intervals for the group 1 mean, they are highlighted in red. This lack of intersection indicates that both means are different than group 1 mean. Select other group means to confirm that all group means are significantly different from each other.

Perform a multiple comparison test to see the popcorn yield differs between the two popper types (rows).

```
c = multcompare(stats, 'Estimate', 'row')
```

Note: Your model includes an interaction term. A test of main effects can be difficult to interpret when the model includes interactions.

```
c =
```

```
1.0000    2.0000   -1.3828   -1.0000   -0.6172    0.0001
```

The small p -value of 0.0001 indicates that the popcorn yield differs between the two popper types (air and oil). The figure shows the same results. The disjoint comparison intervals indicate that the group means are significantly different from each other.

Multiple Comparisons for Three-Way ANOVA

Load the sample data.

```
y = [52.7 57.5 45.9 44.5 53.0 57.0 45.9 44.0]';  
g1 = [1 2 1 2 1 2 1 2];  
g2 = {'hi'; 'hi'; 'lo'; 'lo'; 'hi'; 'hi'; 'lo'; 'lo'};  
g3 = {'may'; 'may'; 'may'; 'may'; 'june'; 'june'; 'june'; 'june'};
```

y is the response vector and $g1$, $g2$, and $g3$ are the grouping variables (factors). Each factor has two levels, and every observation in y is identified by a combination of factor levels. For example, observation $y(1)$ is associated with level 1 of factor $g1$, level 'hi' of factor $g2$, and level 'may' of factor $g3$. Similarly, observation $y(6)$ is associated with level 2 of factor $g1$, level 'hi' of factor $g2$, and level 'june' of factor $g3$.

Test if the response is the same for all factor levels. Also compute the statistics required for multiple comparison tests.

```
[~,~,stats] = anovan(y,{g1 g2 g3}, 'model', 'interaction', ...  
    'varnames', {'g1', 'g2', 'g3'});
```

Figure 1: N-Way ANOVA

File Edit View Insert Tools Desktop Window Help

Analysis of Variance

Source	Sum Sq.	d. f.	Mean Sq.	F	Prob>F
g1	3.781	1	3.781	336.11	0.0347
g2	199.001	1	199.001	17689	0.0048
g3	0.061	1	0.061	5.44	0.2578
g1*g2	18.301	1	18.301	1626.78	0.0158
g1*g3	0.211	1	0.211	18.78	0.1444
g2*g3	0.011	1	0.011	1	0.5
Error	0.011	1	0.011		
Total	221.379	7			

Constrained (Type III) sums of squares.

The p -value of 0.2578 indicates that the mean responses for levels 'may' and 'june' of factor **g3** are not significantly different. The p -value of 0.0347 indicates that the mean responses for levels 1 and 2 of factor **g1** are significantly different. Similarly, the p -value of 0.0048 indicates that the mean responses for levels 'hi' and 'lo' of factor **g2** are significantly different.

Perform multiple comparison tests to find out which groups of the factors **g1** and **g2** are significantly different.

```
results = multcompare(stats, 'Dimension', [1 2])
```

```
results =
```

1.0000	2.0000	-6.8604	-4.4000	-1.9396	0.0280
1.0000	3.0000	4.4896	6.9500	9.4104	0.0177
1.0000	4.0000	6.1396	8.6000	11.0604	0.0143
2.0000	3.0000	8.8896	11.3500	13.8104	0.0108
2.0000	4.0000	10.5396	13.0000	15.4604	0.0095
3.0000	4.0000	-0.8104	1.6500	4.1104	0.0745

multcompare compares the combinations of groups (levels) of the two grouping variables, `g1` and `g2`. In the `results` matrix, the number 1 corresponds to the combination of level 1 of `g1` and level `hi` of `g2`, the number 2 corresponds to the combination of level 2 of `g1` and level `hi` of `g2`. Similarly, the number 3 corresponds to the combination of level 1 of `g1` and level `lo` of `g2`, and the number 4 corresponds to the combination of level 2 of `g1` and level `lo` of `g2`. The last column of the matrix contains the p -values.

For example, the first row of the matrix shows that the combination of level 1 of `g1` and level `hi` of `g2` has the same mean response values as the combination of level 2 of `g1` and level `hi` of `g2`. The p -value corresponding to this test is 0.0280, which indicates that the mean responses are significantly different. You can also see this result in the figure. The blue bar shows the comparison interval for the mean response for the combination of level 1 of `g1` and level `hi` of `g2`. The red bars are the comparison intervals for the mean response for other group combinations. None of the red bars overlap with the blue bar, which means the mean response for the combination of level 1 of `g1` and level `hi` of `g2` is significantly different from the mean response for other group combinations.

You can test the other groups by clicking on the corresponding comparison interval for the group. The bar you click on turns to blue. The bars for the groups that are significantly different are red. The bars for the groups that are not significantly different are gray. For example, if you click on the comparison interval for the combination of level 1 of `g1` and level `lo` of `g2`, the comparison interval for the combination of level 2 of `g1` and level `lo` of `g2` overlaps, and is therefore gray. Conversely, the other comparison intervals are red, indicating significant difference.

Input Arguments

stats — Test data

structure

Test data, specified as a structure. You can create a structure using one of the following functions:

- `anova1` — One-way analysis of variance.
- `anova2` — Two-way analysis of variance.
- `anovan` — N -way analysis of variance.
- `aocool` — Interactive analysis of covariance tool.
- `friedman` — Friedman's test.

- `kruskalwallis` — Kruskal-Wallis test.

`multcompare` does not support multiple comparisons using `anovan` output for a model that includes random or nested effects. The calculations for a random effects model produce a warning that all effects are treated as fixed. Nested models are not accepted.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Alpha', 0.01, 'CType', 'bonferroni', 'Display', 'off'` computes the Bonferroni critical values, conducts the hypothesis tests at the 1% significance level, and omits the interactive display.

'Alpha' — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the multiple comparison test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). The value specified for `'Alpha'` determines the $100 \times (1 - \alpha)$ confidence levels of the intervals returned in the matrix `c` and in the figure.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

'CType' — Type of critical value

`'tukey-kramer'` (default) | `'hsd'` | `'lsd'` | `'bonferroni'` | `'dunn-sidak'` | `'scheffe'`

Type of critical value to use for the multiple comparison, specified as the comma-separated pair consisting of `'CType'` and one of the following.

Value	Description
<code>'tukey-kramer'</code> or <code>'hsd'</code>	Tukey's honest significant difference criterion
<code>'bonferroni'</code>	Bonferroni method

Value	Description
'dunn-sidak'	Dunn and Sidák's approach
'lsd'	Fisher's least significant difference procedure
'scheffe'	Scheffé's S procedure

Example: 'CType', 'bonferroni'

'Display' — Display toggle

'on' (default) | 'off'

Display toggle, specified as the comma-separated pair consisting of 'Display' and either 'on' or 'off'. If you specify 'on', then `multcompare` displays a graph of the estimates and their comparison intervals. If you specify 'off', then `multcompare` omits the graph.

Example: 'Display', 'off'

'Dimension' — Dimension over which to calculate marginal means

1 (default) | positive integer value | vector of positive integer values

A vector specifying the dimension or dimensions over which to calculate the population marginal means, specified as a positive integer value, or a vector of such values. Use the 'Dimension' name-value pair only if you create the input structure `stats` using the function `anovan`.

For example, if you specify 'Dimension' as 1, then `multcompare` compares the means for each value of the first grouping variable, adjusted by removing effects of the other grouping variables as if the design were balanced. If you specify 'Dimension' as [1,3], then `multcompare` computes the population marginal means for each combination of the first and third grouping variables, removing effects of the second grouping variable. If you fit a singular model, some cell means may not be estimable and any population marginal means that depend on those cell means will have the value NaN.

Population marginal means are described by Milliken and Johnson (1992) and by Searle, Speed, and Milliken (1980). The idea behind population marginal means is to remove any effect of an unbalanced design by fixing the values of the factors specified by 'Dimension', and averaging out the effects of other factors as if each factor combination occurred the same number of times. The definition of population marginal means does not depend on the number of observations at each factor combination. For designed experiments where the number of observations at each factor combination has no meaning, population marginal means can be easier to interpret than simple means

ignoring other factors. For surveys and other studies where the number of observations at each combination does have meaning, population marginal means may be harder to interpret.

Example: `'Dimension', [1,3]`

Data Types: `single` | `double`

'Estimate' — Estimates to be compared

`'column'` (default) | `'row'` | `'slope'` | `'intercept'` | `'pmm'`

Estimates to be compared, specified as the comma-separated pair consisting of `'Estimate'` and an allowable value. The allowable values for `'Estimate'` depend on the function used to generate the input structure `stats`, according to the following table.

Source	Values
<code>anova1</code>	None. This name-value pair is ignored, and <code>multcompare</code> always compares the group means.
<code>anova2</code>	Either <code>'column'</code> to compare column means, or <code>'row'</code> to compare row means.
<code>anovan</code>	None. This name-value pair is ignored, and <code>multcompare</code> always compares the population marginal means as specified by the <code>'Dimension'</code> name-value pair argument.
<code>aoctool</code>	Either <code>'slope'</code> , <code>'intercept'</code> , or <code>'pmm'</code> to compare slopes, intercepts, or population marginal means, respectively. If the analysis of covariance model did not include separate slopes, then <code>'slope'</code> is not allowed. If it did not include separate intercepts, then no comparisons are possible.
<code>friedman</code>	None. This name-value pair is ignored, and <code>multcompare</code> always compares the average column ranks.
<code>kruskalwallis</code>	None. This name-value pair is ignored, and <code>multcompare</code> always compares the average group ranks.

Example: `'Estimate', 'row'`

Output Arguments

c — Matrix of multiple comparison results

matrix of scalar values

Matrix of multiple comparison results, returned as a p -by-6 matrix of scalar values, where p is the number of pairs of groups. Each row of the matrix contains the result of one paired comparison test. Columns 1 and 2 contain the indices of the two samples being compared. Column 3 contains the lower confidence interval, column 4 contains the estimate, and column 5 contains the upper confidence interval. Column 6 contains the p -value for the hypothesis test that the corresponding mean difference is not equal to 0.

For example, suppose one row contains the following entries.

```
2.0000  5.0000  1.9442  8.2206  14.4971  0.0432
```

These numbers indicate that the mean of group 2 minus the mean of group 5 is estimated to be 8.2206, and a 95% confidence interval for the true difference of the means is [1.9442, 14.4971]. The p -value for the corresponding hypothesis test that the difference of the means of groups 2 and 5 is significantly different from zero is 0.0432.

In this example the confidence interval does not contain 0, so the difference is significant at the 5% significance level. If the confidence interval did contain 0, the difference would not be significant. The p -value of 0.0432 also indicates that the difference of the means of groups 2 and 5 is significantly different from 0.

m — Matrix of estimates

matrix of scalar values

Matrix of the estimates, returned as a matrix of scalar values. The first column of **m** contains the estimated values of the means (or whatever statistics are being compared) for each group, and the second column contains their standard errors.

h — Handle to the figure

handle

Handle to the figure containing the interactive graph, returned as a handle. The title of this graph contains instructions for interacting with the graph, and the x -axis label contains information about which means are significantly different from the selected mean. If you plan to use this graph for presentation, you may want to omit the title and the x -axis label. You can remove them using interactive features of the graph window, or you can use the following commands.

```
title('')
xlabel('')
```

gnames — Group names

cell array of strings

Group names, returned as a cell array of strings. Each row of `gnames` contains the name of a group.

More About

Multiple Comparison Tests

Analysis of variance compares the means of several groups to test the hypothesis that they are all equal, against the general alternative that they are not all equal. Sometimes this alternative may be too general. You may need information about which pairs of means are significantly different, and which are not. A *multiple comparison test* can provide this information.

When you perform a simple *t*-test of one group mean against another, you specify a significance level that determines the cutoff value of the *t*-statistic. For example, you can specify the value `alpha = 0.05` to insure that when there is no real difference, you will incorrectly find a significant difference no more than 5% of the time. When there are many group means, there are also many pairs to compare. If you applied an ordinary *t*-test in this situation, the `alpha` value would apply to each comparison, so the chance of incorrectly finding a significant difference would increase with the number of comparisons. Multiple comparison procedures are designed to provide an upper bound on the probability that *any* comparison will be incorrectly found significant.

Introduced before R2006a

multcompare

Class: RepeatedMeasuresModel

Multiple comparison of estimated marginal means

Syntax

```
tbl = multcompare(rm, var)
tbl = multcompare(rm, var, Name, Value)
```

Description

`tbl = multcompare(rm, var)` returns multiple comparisons of the estimated marginal means based on the variable `var` in the repeated measures model `rm`.

`tbl = multcompare(rm, var, Name, Value)` returns multiple comparisons of the estimated marginal means with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the comparison type or which variable to group by.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

var — Variables for which to compute marginal means

string

Variables for which to compute the marginal means, specified as a string representing the name of a between- or within-subjects factor in `rm`. If `var` is a between-subjects factor, it must be categorical.

Data Types: char | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

'Alpha' — Confidence level

0.05 (default) | scalar value in the range of 0 through 1

Confidence level of the confidence intervals for population marginal means, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range of 0 through 1. The confidence level is $100*(1-\alpha)\%$.

Example: 'alpha', 0.01

Data Types: double | single

'By' — Factor to perform comparisons by

string

Factor to do the comparisons by, specified as the comma-separated pair consisting of 'By' and a string. The comparison between levels of `var` occurs separately for each value of the factor you specify.

If you have more than one between-subjects factors, *A*, *B*, and *C*, and if you want to do the comparisons of *A* levels separately for each level of *C*, then specify *A* as the `var` argument and specify *C* using the 'By' argument as follows.

Example: 'By', C

Data Types: char

'ComparisonType' — Type of critical value to use

'tukey-kramer' (default) | 'dunn-sidak' | 'bonferroni' | 'scheffe' | 'lsd'

Type of critical value to use, specified as the comma-separated pair consisting of 'ComparisonType' and one of the following.

Comparison Type	Definition
'tukey-kramer'	Default. Also called Tukey's Honest Significant Difference procedure. It is based on the Studentized range

Comparison Type	Definition
	<p>distribution. According to the unproven Tukey-Kramer conjecture, it is also accurate for problems where the quantities being compared are correlated, as in analysis of covariance with unbalanced covariate values.</p>
'dunn-sidak'	<p>Use critical values from the t distribution, after an adjustment for multiple comparisons that was proposed by Dunn and proved accurate by Sidák. The critical value is</p> $ t = \frac{ \bar{y}_i - \bar{y}_j }{\sqrt{MSE \left(\frac{1}{n_i} + \frac{1}{n_j} \right)}} > t_{1-\eta/2, v},$ <p>where</p> $\eta = 1 - (1 - \alpha)^{\frac{1}{\binom{g}{2}}}$ <p>and ng is the number of groups (marginal means). This procedure is similar to, but less conservative than, the Bonferroni procedure.</p>

Comparison Type	Definition
'bonferroni'	<p>Use critical values from the t distribution, after a Bonferroni adjustment to compensate for multiple comparisons. The critical value is</p> $t_{\alpha/2, \left(\frac{ng}{2}\right)v},$ <p>where ng is the number of groups (marginal means), and v is the error degrees of freedom. This procedure is conservative, but usually less so than the Scheffé procedure.</p>
'scheffe'	<p>Use critical values from Scheffé's S procedure, derived from the F distribution. The critical value is</p> $\sqrt{(ng-1)F_{\alpha, ng-1, v}},$ <p>where ng is the number of groups (marginal means), and v is the error degrees of freedom. This procedure provides a simultaneous confidence level for comparisons of all linear combinations of the means, and it is conservative for comparisons of simple differences of pairs.</p>
'lsd'	<p>Least significant difference. This option uses plain t-tests. The critical value is</p> $t_{\alpha/2, v},$ <p>where v is the error degrees of freedom. It provides no protection against the multiple comparison problem.</p>

Example: 'ComparisonType', 'dunn-sidak'

Output Arguments

tbl — Results of multiple comparison

table

Results of multiple comparisons of estimated marginal means, returned as a table. **tbl** has the following columns.

Column Name	Description
Difference	Estimated difference between the corresponding two marginal means
StdErr	Standard error of the estimated difference between the corresponding two marginal means
pValue	p -value for a test that the difference between the corresponding two marginal means is 0
Lower	Lower limit of simultaneous 95% confidence intervals for the true difference
Upper	Upper limit of simultaneous 95% confidence intervals for the true difference

Examples

Multiple Comparison of Estimated Marginal Means

Load the sample data.

```
load fisheriris
```

The column vector **species** consists of iris flowers of three different species: *setosa*, *versicolor*, and *virginica*. The double matrix **meas** consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas);
```

Perform a multiple comparison of the estimated marginal means of species.

```
tbl = multcompare(rm, 'species')
```

```
tbl =
```

species_1	species_2	Difference	StdErr	pValue	Lower
'setosa'	'versicolor'	-1.0375	0.060539	9.5606e-10	-1.1794
'setosa'	'virginica'	-1.7495	0.060539	9.5606e-10	-1.8914
'versicolor'	'setosa'	1.0375	0.060539	9.5606e-10	0.89562
'versicolor'	'virginica'	-0.712	0.060539	9.5606e-10	-0.85388
'virginica'	'setosa'	1.7495	0.060539	9.5606e-10	1.6076
'virginica'	'versicolor'	0.712	0.060539	9.5606e-10	0.57012

The small p -values (in the `pValue` field) indicate that the estimated marginal means for the three species significantly differ from each other.

Perform Multiple Comparisons with Specified Options

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
R = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Perform a multiple comparison of the estimated marginal means based on the variable `Group`.

```
T = multcompare(R, 'Group')
```

```
T =
```

Group_1	Group_2	Difference	StdErr	pValue	Lower	Upper
---------	---------	------------	--------	--------	-------	-------

A	B	4.9875	5.6271	0.65436	-9.1482	19.123
A	C	23.094	5.9261	0.0021493	8.2074	37.981
B	A	-4.9875	5.6271	0.65436	-19.123	9.1482
B	C	18.107	5.8223	0.013588	3.4805	32.732
C	A	-23.094	5.9261	0.0021493	-37.981	-8.2074
C	B	-18.107	5.8223	0.013588	-32.732	-3.4805

The small p -value of 0.0021493 indicates that there is significant difference between the marginal means of groups A and C. The p -values of 0.65436 indicates that the difference between the marginal means for groups A and B is not significantly different from 0.

`multcompare` uses the Tukey-Kramer test statistic by default. Change the comparison type to the Scheffe procedure.

```
T = multcompare(R, 'Group', 'ComparisonType', 'Scheffe')
```

```
T =
```

Group_1	Group_2	Difference	StdErr	pValue	Lower	Upper
A	B	4.9875	5.6271	0.67981	-9.7795	19.755
A	C	23.094	5.9261	0.0031072	7.5426	38.646
B	A	-4.9875	5.6271	0.67981	-19.755	9.7795
B	C	18.107	5.8223	0.018169	2.8273	33.386
C	A	-23.094	5.9261	0.0031072	-38.646	-7.5426
C	B	-18.107	5.8223	0.018169	-33.386	-2.8273

The Scheffe test produces larger p -values, but similar conclusions.

Perform multiple comparisons of estimated marginal means based on the variable `Group` for each gender separately.

```
T = multcompare(R, 'Group', 'By', 'Gender')
```

```
T =
```

Gender	Group_1	Group_2	Difference	StdErr	pValue	Lower
Female	A	B	4.1883	8.0177	0.86128	-15.953
Female	A	C	24.565	8.2083	0.017697	3.9449
Female	B	A	-4.1883	8.0177	0.86128	-24.329

Female	B	C	20.376	8.1101	0.049957	0.0033459
Female	C	A	-24.565	8.2083	0.017697	-45.184
Female	C	B	-20.376	8.1101	0.049957	-40.749
Male	A	B	5.7868	7.9498	0.74977	-14.183
Male	A	C	21.624	8.1829	0.038022	1.0676
Male	B	A	-5.7868	7.9498	0.74977	-25.757
Male	B	C	15.837	8.0511	0.14414	-4.3881
Male	C	A	-21.624	8.1829	0.038022	-42.179
Male	C	B	-15.837	8.0511	0.14414	-36.062

The results indicate that the difference between marginal means for groups A and B is not significant from 0 for either gender (corresponding p -values are 0.86128 for females and 0.74977 for males). The difference between marginal means for groups A and C is significant for both genders (corresponding p -values are 0.017697 for females and 0.038022 for males). While the difference between marginal means for groups B and C is significantly different from 0 for females (p -value is 0.049957), it is not significantly different from 0 for males (p -value is 0.14414).

prob.MultinomialDistribution class

Package: prob

Superclasses: prob.ParametricTruncatableDistribution

Multinomial probability distribution object

Description

`prob.MultinomialDistribution` is an object consisting of parameters and a model description for a multinomial probability distribution. Create a probability distribution object with specified parameters using `makedist`.

Construction

`pd = makedist('Multinomial')` creates a multinomial probability distribution object using the default parameter values.

`pd = makedist('Multinomial', 'Probabilities', probabilities)` creates a multinomial distribution object using the specified parameter value.

Input Arguments

probabilities — outcome probabilities

[0.500 0.500] (default) | vector of scalar values in the range [0, 1]

Outcome probabilities, specified as a vector of scalar values in the range [0, 1]. Each vector element is the probability that a multinomial trial has a particular corresponding outcome. The values in `probabilities` must sum to 1.

Data Types: single | double

Properties

probabilities — outcome probabilities

vector of scalar values in the range [0, 1]

Outcome probabilities for the multinomial distribution, stored as a vector of scalar values in the range $[0, 1]$. The values in `probabilities` must sum to 1.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: `char`

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: `single` | `double`**Truncation — Truncation interval**

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: `single` | `double`

Methods

Inherited Methods

<code>cdf</code>	Cumulative distribution function of probability distribution object
<code>icdf</code>	Inverse cumulative distribution function of probability distribution object
<code>iqr</code>	Interquartile range of probability distribution object
<code>median</code>	Median of probability distribution object
<code>pdf</code>	Probability density function of probability distribution object
<code>random</code>	Generate random numbers from probability distribution object
<code>truncate</code>	Truncate probability distribution object
<code>mean</code>	Mean of probability distribution object
<code>std</code>	Standard deviation of probability distribution object
<code>var</code>	Variance of probability distribution object

Definitions

Multinomial Distribution

The multinomial distribution is a generalization of the binomial distribution. While the binomial distribution gives the probability of the number of “successes” in n independent trials of a two-outcome process, the multinomial distribution gives the probability of each combination of outcomes in n independent trials of a k -outcome process. The probability of each outcome in any one trial is given by the fixed probabilities p_1, \dots, p_k .

The multinomial distribution uses the following parameters.

Parameter	Description	Support
probabilities	Outcome probabilities	$0 \leq \text{probabilities}(i) \leq 1$; $\sum_{\text{all}(i)} \text{probabilities}(i) = 1$

The probability density function (pdf) is

$$f(x | n, p) = \frac{n!}{x_1! \dots x_k!} p_1^{x_1} \dots p_k^{x_k} \quad ; \quad \sum_1^k x_i = n, \quad \sum_1^k p_i = 1,$$

where $x = (x_1, \dots, x_k)$ gives the number of each k outcome in n trials of a process with fixed probabilities $p = (p_1, \dots, p_k)$ of individual outcomes in any one trial.

Examples

Create a Multinomial Distribution Object Using Default Parameters

Create a multinomial distribution object using the default parameter values.

```
pd = makedist('Multinomial')
```

```
pd =
```

```
  MultinomialDistribution
```

```
  Probabilities:
```

```
0.5000    0.5000
```

Create a Multinomial Distribution Object Using Specified Parameters

Create a multinomial distribution object for a distribution with three possible outcomes. Outcome 1 has a probability of 1/2, outcome 2 has a probability of 1/3, and outcome 3 has a probability of 1/6.

```
pd = makedist('Multinomial','probabilities',[1/2 1/3 1/6])
```

```
pd =
```

```
    MultinomialDistribution
```

```
    Probabilities:
```

```
    0.5000    0.3333    0.1667
```

Generate a random outcome from the distribution.

```
rng('default'); % for reproducibility
```

```
r = random(pd)
```

```
r =
```

```
    2
```

The result of this trial is outcome 2. By default, the number of trials in each experiment, n , equals 1.

Generate random outcomes from the distribution when the number of trials in each experiment, n , equals 1, and the experiment is repeated ten times.

```
rng('default'); % for reproducibility
```

```
r = random(pd,10,1)
```

```
r =
```

```
    2
```

```
    3
```

```
    1
```

```
    3
```

```
    2
```

```
    1
```

```
    1
```

```
    2
```

```
3
3
```

Each element in the array is the outcome of an individual experiment that contains one trial.

Generate random outcomes from the distribution when the number of trials in each experiment, n , equals 5, and the experiment is repeated ten times.

```
rng('default'); % for reproducibility
r = random(pd,10,5)
```

```
r =
```

```
2     1     2     2     1
3     3     1     1     1
1     3     3     1     2
3     1     3     1     2
2     2     2     1     1
1     1     2     2     1
1     1     2     2     1
2     3     1     1     2
3     2     2     3     2
3     3     1     1     2
```

Each element in the resulting matrix is the outcome of one trial. The columns correspond to the five trials in each experiment, and the rows correspond to the ten experiments. For example, in the first experiment (corresponding to the first row), 2 of the 5 trials resulted in outcome 1, and 3 of the 5 trials resulted in outcome 2.

multivarichart

Multivari chart for grouped data

Syntax

```
multivarichart(y, GROUP)
multivarichart(Y)
multivarichart(..., param1, val1, param2, val2, ...)
[charthandle, AXESH] = multivarichart(...)
```

Description

`multivarichart(y, GROUP)` displays the multivari chart for the vector `y` grouped by entries in the cell array `GROUP`. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or single-column cell array of strings. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of elements as `y`. The number of grouping variables must be 2, 3, or 4.

Each subplot of the plot matrix contains a multivari chart for the first and second grouping variables. The x -axis in each subplot indicates values of the first grouping variable. The legend at the bottom of the figure window indicates values of the second grouping variable. The subplot at position (i,j) is the multivari chart for the subset of `y` at the i th level of the third grouping variable and the j th level of the fourth grouping variable. If the third or fourth grouping variable is absent, it is considered to have only one level.

`multivarichart(Y)` displays the multivari chart for a matrix `Y`. The data in different columns represent changes in one factor. The data in different rows represent changes in another factor.

`multivarichart(..., param1, val1, param2, val2, ...)` specifies one or more of the following name/value pairs:

- `'varnames'` — Grouping variable names in a character matrix or a cell array of strings, one per grouping variable. Default names are `'X1'`, `'X2'`,

- 'plotorder' — A string with the value 'sorted' or a vector containing a permutation of the integers from 1 to the number of grouping variables.

If 'plotorder' is a string with value 'sorted', the grouping variables are rearranged in descending order according to the number of levels in each variable.

If 'plotorder' is a vector, it indicates the order in which each grouping variable should be plotted. For example, [2,3,1,4] indicates that the second grouping variable should be used as the *x*-axis of each subplot, the third grouping variable should be used as the legend, the first grouping variable should be used as the columns of the plot, and the fourth grouping variable should be used as the rows of the plot.

[charthandle,AXESH] = multivarichart(...) returns a handle charthandle to the figure window and a matrix AXESH of handles to the subplot axes.

Examples

Multivari Chart for Grouped Data

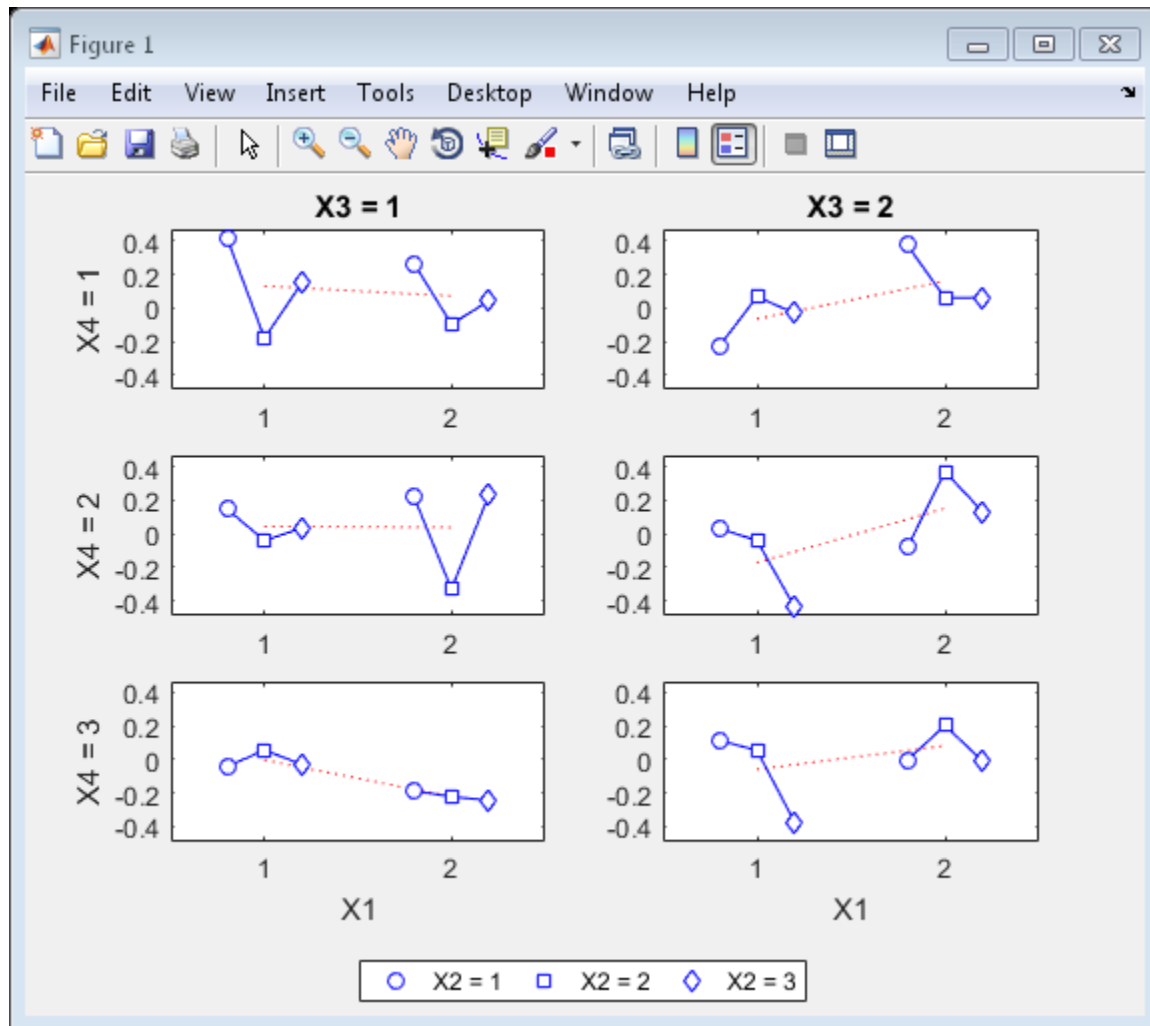

Display a multivari chart for data with two grouping variables.

```
rng default; % For reproducibility
y = randn(100,1); % Randomly generate response
group = [ceil(3*rand(100,1)) ceil(2*rand(100,1))];
multivarichart(y,group)
```

Display a multivari chart for data with four grouping variables.

```
y = randn(1000,1); % Randomly generate response
group = {ceil(2*rand(1000,1)),ceil(3*rand(1000,1)), ...
         ceil(2*rand(1000,1)),ceil(3*rand(1000,1))};
multivarichart(y,group)
```

mvksdensity

Kernel smoothing function estimate for multivariate data

Syntax

```
f = mvksdensity(x,pts,'bandwidth',bw)
f = mvksdensity(x,pts,'bandwidth',bw,Name,Value)
```

Description

`f = mvksdensity(x,pts,'bandwidth',bw)` computes a probability density estimate of the sample data in the n -by- d matrix `x`, evaluated at the points in `pts` using the required name-value pair argument value `bw` for the bandwidth value. The estimation is based on a product Gaussian kernel function.

For univariate or bivariate data, use `ksdensity` instead.

`f = mvksdensity(x,pts,'bandwidth',bw,Name,Value)` returns any of the previous output arguments, using additional options specified by one or more `Name,Value` pair arguments. For example, you can define the function type that `mvksdensity` evaluates, such as probability density, cumulative probability, or survivor function. You can also assign weights to the input values.

Examples

Estimate Multivariate Kernel Density

Load the Hald cement data

```
load hald
```

The data measures the heat of hardening for 13 different cement compositions. The predictor matrix `ingredients` contains the percent composition for each of four cement ingredients. The response matrix `heat` contains the heat of hardening (in cal\g) after 180 days.

Estimate the kernel density for the first three observations in `ingredients`.

```
xi = ingredients(1:3,:);
f = mvksdensity(ingredients,ingredients,...
    'bandwidth',[4.0579 10.7345 4.4185 11.5466])
```

```
f =
    1.0e-05 *
    0.1140
    0.1141
    0.2779
```

Estimate Multivariate Kernel Density Using Grids

Load the Hald cement data.

```
load hald
```

The data measures the heat of hardening for 13 different cement compositions. The predictor matrix `ingredients` contains the percent composition for each of four cement ingredients. The response matrix `heat` contains the heat of hardening (in cal/g) after 180 days.

Create a array of points at which to estimate the density. First, define the range and spacing for each variable, using a similar number of points in each dimension.

```
gridx1 = 0:2:22;
gridx2 = 20:5:80;
gridx3 = 0:2:24;
gridx4 = 5:5:65;
```

Next, use `ndgrid` to generate a full grid of points using the defined range and spacing.

```
[x1,x2,x3,x4] = ndgrid(gridx1,gridx2,gridx3,gridx4);
```

Finally, transform and concatenate to create an array that contains the points at which to estimate the density. This array has one column for each variable.

```
x1 = x1(:, :)';
x2 = x2(:, :)';
x3 = x3(:, :)';
x4 = x4(:, :)';
xi = [x1(:) x2(:) x3(:) x4(:)];
```

Estimate the density.

```
f = mvksdensity(ingredients,xi,...  
  'bandwidth',[4.0579 10.7345 4.4185 11.5466],...  
  'kernel','normpdf');
```

View the size of `xi` and `f` to confirm that `mvksdensity` calculates the density at each point in `xi`.

```
size_xi = size(xi)  
size_f = size(f)
```

```
size_xi =  
  
    26364         4
```

```
size_f =  
  
    26364         1
```

Input Arguments

x — Sample data

numeric matrix

Sample data for which `mvksdensity` returns the probability density estimate, specified as an n -by- d matrix of numeric values. n is the number of data points (rows) in `x`, and d is the number of dimensions (columns).

Data Types: `single` | `double`

pts — Points at which to evaluate `f`

matrix

Points at which to evaluate the probability density estimate `f`, specified as a matrix with the same number of columns as `x`. The returned estimate `f` has the same length as `pts`.

Data Types: `single` | `double`

bw — Value for the bandwidth of the kernel smoothing window

scalar value | d -element vector

Value for the bandwidth of the kernel-smoothing window, specified as a scalar value or d -element vector. d is the number of dimensions (columns) in the sample data x .

If `bw` is a scalar value, it applies to all dimensions.

Silverman's rule of thumb for the bandwidth is

$$b_i = \sigma_i \left\{ \frac{4}{(d+2)n} \right\}^{1/(d+4)}, \quad i = 1, 2, \dots, d,$$

where d is the number of dimensions, n is the number of observations, and σ_i is the standard deviation of the i^{th} variate [2].

Example: 'Bandwidth', 0.8

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: 'Kernel', 'triangle', 'Function', 'cdf' specifies that `mvksdensity` estimates the cdf of the sample data using the triangle kernel function.

'Function' — Function to estimate

'pdf' (default) | 'cdf' | 'survivor'

Function to estimate, specified as the comma-separated pair consisting of 'Function' and one of the following.

Value	Description
'pdf'	Probability density function
'cdf'	Cumulative distribution function
'survivor'	Survivor function

Example: 'Function', 'cdf'

Data Types: char

'Kernel' — Type of kernel smoother

'normal' (default) | 'box' | 'triangle' | 'epanechnikov' | function handle | function name

Type of kernel smoother, specified as the comma-separated pair consisting of 'Kernel' and one of the following.

Value	Description
'normal'	Normal (Gaussian) kernel
'box'	Box kernel
'triangle'	Triangular kernel
'epanechnikov'	Epanechnikov kernel

You can also specify a custom kernel function as a function handle (for example, @normpdf) or a function name in single quotes (for example, 'normpdf'). This calls the specified function using one argument that is an array of distances between data values and locations where the density is evaluated, normalized by the bandwidth in that dimension. The function must return an array of the same size containing the corresponding values of the kernel function.

mvksdensity applies the same kernel to each dimension.

Example: 'Kernel', 'box'

Data Types: char | function_handle

'Support' — Support for the density

'unbounded' (default) | 'positive' | 2-by-*d* matrix

Support for the density, specified as the comma-separated pair consisting of 'support' and one of the following.

Value	Description
'unbounded'	Allow the density to extend over the whole real line

Value	Description
'positive'	Restrict the density to positive values
2-by- d matrix	Specify the finite lower and upper bounds for the support of the density. The first row contains the lower limits and the second row contains the upper limits. Each column contains the limits for one dimension of x .

If 'Support' is 'positive', then `mvksdensity` transforms each dimension of x using a log function, estimates the density of the transformed values, and transforms back to the original scale. If 'Support' is a two-row matrix, then `mvksdensity` uses the transformation $\log((x_i - L_i) / (U_i - x_i))$ in each dimension, where x_i is the elements of x in the i th dimension, and L_i and U_i are the lower and upper limit of the i th dimension, respectively.

'Support' can also be a combination of positive, unbounded, and bounded variables specified as `[0 -Inf L ; Inf Inf U]`.

Example: 'Support', 'positive'

Data Types: single | double | char

'Weights' — Weights for each x value
vector

Weights for each x value, specified as the comma-separated pair consisting of 'Weights' and a vector of the same length as x .

For example, if the weights for the data values are stored in a vector named `xw`, then you can specify the weights as follows.

Example: 'Weights', `xw`

Data Types: single | double

Output Arguments

f — Estimated function values
vector

Estimated function values, returned as a vector of the same length as x .

mvncdf

Multivariate normal cumulative distribution function

Syntax

```
y = mvncdf(X)
y = mvncdf(X,mu,SIGMA)
y = mvncdf(xl,xu,mu,SIGMA)
[y,err] = mvncdf(...)
[...] = mvncdf(...,options)
```

Description

`y = mvncdf(X)` returns the cumulative probability of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of X . Rows of the n -by- d matrix X correspond to observations or points, and columns correspond to variables or coordinates. y is an n -by-1 vector.

`y = mvncdf(X,mu,SIGMA)` returns the cumulative probability of the multivariate normal distribution with mean μ and covariance SIGMA , evaluated at each row of X . μ is a 1-by- d vector, and SIGMA is a d -by- d symmetric, positive definite matrix. μ can also be a scalar value, which `mvncdf` replicates to match the size of X . If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, SIGMA may also be specified as a 1-by- d vector containing just the diagonal. Pass in the empty matrix `[]` for μ to use as its default value when you want to only specify SIGMA .

The multivariate normal cumulative probability at X is defined as the probability that a random vector V , distributed as multivariate normal, will fall within the semi-infinite rectangle with upper limits defined by X , for example, $\Pr\{V(1) \leq X(1), V(2) \leq X(2), \dots, V(d) \leq X(d)\}$.

`y = mvncdf(xl,xu,mu,SIGMA)` returns the multivariate normal cumulative probability evaluated over the rectangle with lower and upper limits defined by xl and xu , respectively.

`[y,err] = mvncdf(...)` returns an estimate of the error in `y`. For bivariate and trivariate distributions, `mvncdf` uses adaptive quadrature on a transformation of the t density, based on methods developed by Drezner and Wesolowsky and by Genz, as described in the references. The default absolute error tolerance for these cases is $1e-8$. For four or more dimensions, `mvncdf` uses a quasi-Monte Carlo integration algorithm based on methods developed by Genz and Bretz, as described in the references. The default absolute error tolerance for these cases is $1e-4$.

`[...] = mvncdf(...,options)` specifies control parameters for the numerical integration used to compute `y`. This argument can be created by a call to `statset`. Choices of `statset` parameters:

- `'TolFun'` — Maximum absolute error tolerance. Default is $1e-8$ when $d < 4$, or $1e-4$ when $d \geq 4$.
- `'MaxFunEvals'` — Maximum number of integrand evaluations allowed when $d \geq 4$. Default is $1e7$. `'MaxFunEvals'` is ignored when $d < 4$.
- `'Display'` — Level of display output. Choices are `'off'` (the default), `'iter'`, and `'final'`. `'Display'` is ignored when $d < 4$.

Examples

Compute the Multivariate Normal cdf

Compute and plot the cdf of a multivariate normal distribution with parameters `MU = [1 -1]` and `SIGMA = [.9 .4; .4 .3]`.

```
mu = [1 -1];
SIGMA = [.9 .4; .4 .3];
figure;
[X1,X2] = meshgrid(linspace(-1,3,25)',linspace(-3,1,25)');
X = [X1(:) X2(:)];
p = mvncdf(X,mu,SIGMA);
surf(X1,X2,reshape(p,25,25));
```

mvnpdf | mvnrnd

Introduced in R2006a

mvnpdf

Multivariate normal probability density function

Syntax

```
y = mvnpdf(X)
y = mvnpdf(X,MU)
y = mvnpdf(X,MU,SIGMA)
```

Description

`y = mvnpdf(X)` returns the n -by-1 vector **y**, containing the probability density of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of the n -by- d matrix **X**. Rows of **X** correspond to observations and columns correspond to variables or coordinates.

`y = mvnpdf(X,MU)` returns the density of the multivariate normal distribution with mean **MU** and identity covariance matrix, evaluated at each row of **X**. **MU** is a 1-by- d vector, or an n -by- d matrix. If **MU** is a matrix, the density is evaluated for each row of **X** with the corresponding row of **MU**. **MU** can also be a scalar value, which `mvnpdf` replicates to match the size of **X**.

`y = mvnpdf(X,MU,SIGMA)` returns the density of the multivariate normal distribution with mean **MU** and covariance **SIGMA**, evaluated at each row of **X**. **SIGMA** is a d -by- d matrix, or a d -by- d -by- n array, in which case the density is evaluated for each row of **X** with the corresponding page of **SIGMA**, i.e., `mvnpdf` computes $y(i)$ using $X(i,:)$ and $SIGMA(:, :, i)$. If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, **SIGMA** may also be specified as a 1-by- d vector or a 1-by- d -by- n array, containing just the diagonal. Specify `[]` for **MU** to use its default value when you want to specify only **SIGMA**.

If **X** is a 1-by- d vector, `mvnpdf` replicates it to match the leading dimension of **MU** or the trailing dimension of **SIGMA**.

Examples

```
mu = [1 -1];
```

```
SIGMA = [.9 .4; .4 .3];  
X = mvnrnd(mu, SIGMA, 10);  
p = mvnpdf(X, mu, SIGMA);
```

mvregress

Multivariate linear regression

Syntax

```
beta = mvregress(X,Y)
beta = mvregress(X,Y,Name,Value)
[beta,Sigma] = mvregress( ___ )
[beta,Sigma,E,CovB,logL] = mvregress( ___ )
```

Description

`beta = mvregress(X,Y)` returns the estimated coefficients for a multivariate normal regression of the d -dimensional responses in Y on the design matrices in X .

`beta = mvregress(X,Y,Name,Value)` returns the estimated coefficients using additional options specified by one or more name-value pair arguments. For example, you can specify the estimation algorithm, initial estimate values, or maximum number of iterations for the regression.

`[beta,Sigma] = mvregress(___)` also returns the estimated d -by- d variance-covariance matrix of Y , using any of the input arguments from the previous syntaxes.

`[beta,Sigma,E,CovB,logL] = mvregress(___)` also returns a matrix of residuals E , estimated variance-covariance matrix of the regression coefficients $CovB$, and the value of the log likelihood objective function after the last iteration $logL$.

Examples

Multivariate Regression Model for Panel Data with Different Intercepts

Fit a multivariate regression model to panel data, assuming different intercepts and common slopes.

Load the sample data.

```
load('flu')
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google query data.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in `Y` are the nine regional flu estimates. Observations exist for every week over a one-year period, so $n = 52$. The dimension of the responses corresponds to the regions, so $d = 9$. The predictors in `x` are the weekly national flu estimates.

Plot the flu data, grouped by region.

```
figure;
regions = flu.Properties.VarNames(2:end-1);
plot(x,Y,'x')
legend(regions,'Location','NorthWest')
```

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta x_{ij} + \varepsilon_{ij}, \quad i = 1, \dots, n; \quad j = 1, \dots, d,$$

with between-region concurrent correlation

$$COV(\varepsilon_{ij}, \varepsilon_{ij'}) = \sigma_{jj'}, \quad j = 1, \dots, d.$$

There are $K = 10$ regression coefficients to estimate: nine intercept terms and a common slope. The input argument X should be an n -element cell array of d -by- K design matrices.

```
X = cell(n,1);
for i=1:n
    X{i} = [eye(d) repmat(x(i),d,1)];
end
[beta,Sigma] = mvregress(X,Y);
```

beta contains estimates of the K -dimensional coefficient vector

$$(\alpha_1, \alpha_2, \dots, \alpha_9, \beta)'$$

Sigma contains estimates of the d -by- d variance-covariance matrix for the between-region concurrent correlations

$$\begin{pmatrix} \sigma_{11} & \cdots & \sigma_{1,9} \\ \vdots & \ddots & \vdots \\ \sigma_{9,1} & \cdots & \sigma_{9,9} \end{pmatrix}.$$

Plot the fitted regression model.

```
B = [beta(1:d)'; repmat(beta(end),1,d)];
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

figure;
h = plot(x,Y,'x',xx,fits,'-');
```

```

for i = 1:d
    set(h(d+i), 'color', get(h(i), 'color'));
end
legend(regions, 'Location', 'NorthWest');

```

The plot shows that each regression line has a different intercept but the same slope. Upon visual inspection, some regression lines appear to fit the data better than others.

Multivariate Regression for Panel Data with Different Slopes

Fit a multivariate regression model to panel data using least squares, assuming different intercepts and slopes.

Load the sample data.

```
load('flu');
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google queries.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in Y are the nine regional flu estimates. Observations exist for every week over a one-year period, so $n = 52$. The dimension of the responses corresponds to the regions, so $d = 9$. The predictors in x are the weekly national flu estimates.

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta_j x_{ij} + \varepsilon_{ij}, \quad i = 1, \dots, n; \quad j = 1, \dots, d,$$

with between-region concurrent correlation

$$COV(\varepsilon_{ij}, \varepsilon_{i'j'}) = \sigma_{jj'}, \quad j = 1, \dots, d.$$

There are $K = 18$ regression coefficients to estimate: nine intercept terms, and nine slope terms. X is an n -element cell array of d -by- K design matrices.

```
X = cell(n,1);
for i=1:n
    X{i} = [eye(d) x(i)*eye(d)];
end
[beta,Sigma] = mvregress(X,Y, 'algorithm', 'cwlsl');
```

`beta` contains estimates of the K -dimensional coefficient vector,

$$(\alpha_1, \alpha_2, \dots, \alpha_9, \beta_1, \beta_2, \dots, \beta_9)'$$

Plot the fitted regression model.

```
B = [beta(1:d)';beta(d+1:end)'];
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

figure;
h = plot(x,Y, 'x',xx,fits, '-');
for i = 1:d
```

```

    set(h(d+i), 'color', get(h(i), 'color'));
end

regions = flu.Properties.VarNames(2:end-1);
legend(regions, 'Location', 'NorthWest');

```

The plot shows that each regression line has a different intercept and slope.

Multivariate Regression With a Single Design Matrix

Fit a multivariate regression model using a single n -by- P design matrix for all response dimensions.

Load the sample data.

```
load('flu');
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google queries.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in Y are the nine regional flu estimates. Observations exist for every week over a one-year period, so $n = 52$. The dimension of the responses corresponds to the regions, so $d = 9$. The predictors in x are the weekly national flu estimates.

Create an n -by- P design matrix X . Add a column of ones to include a constant term in the regression.

```
X = [ones(size(x)),x];
```

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta_j x_{ij} + \varepsilon_{ij}, \quad i = 1, \dots, n; \quad j = 1, \dots, d,$$

with between-region concurrent correlation

$$COV(\varepsilon_{ij}, \varepsilon_{i'j'}) = \sigma_{jj'}, \quad j = 1, \dots, d.$$

There are 18 regression coefficients to estimate: nine intercept terms, and nine slope terms.

```
[beta,Sigma,E,CovB,logL] = mvregress(X,Y);
```

\mathbf{beta} contains estimates of the P -by- d coefficient matrix. \mathbf{Sigma} contains estimates of the d -by- d variance-covariance matrix for the between-region concurrent correlations. \mathbf{E} is a matrix of the residuals. \mathbf{CovB} is the estimated variance-covariance matrix of the regression coefficients. \mathbf{logL} is the value of the log likelihood objective function after the last iteration.

Plot the fitted regression model.

```
B = beta;
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;
figure;
```

```

h = plot(x,Y,'x', xx,fits,'-');
for i = 1:d
    set(h(d+i),'color',get(h(i),'color'));
end

regions = flu.Properties.VarNames(2:end-1);
legend(regions,'Location','NorthWest');

```

The plot shows that each regression line has a different intercept and slope.

Input Arguments

X — Design matrices

matrix | cell array of matrices

Design matrices for the multivariate regression, specified as a matrix or cell array of matrices. n is the number of observations in the data, K is the number of regression coefficients to estimate, p is the number of predictor variables, and d is the number of dimensions in the response variable matrix Y .

- If $d = 1$, then specify X as a single n -by- K design matrix.
- If $d > 1$ and all d dimensions have the same design matrix, then you can specify X as a single n -by- p design matrix (not in a cell array).
- If $d > 1$ and all n observations have the same design matrix, then you can specify X as a cell array containing a single d -by- K design matrix.
- If $d > 1$ and all n observations do not have the same design matrix, then specify X as a cell array of length n containing d -by- K design matrices.

To include a constant term in the regression model, each design matrix should contain a column of ones.

`mvregress` treats NaN values in X as missing values, and ignores rows in X with missing values.

Data Types: single | double | cell

Y — Response variables

matrix

Response variables, specified as an n -by- d matrix. n is the number of observations in the data, and d is the number of dimensions in the response. When $d = 1$, `mvregress` treats the values in Y like n independent response values.

`mvregress` treats NaN values in Y as missing values, and handles them according to the estimation algorithm specified using the name-value pair argument `algorithm`.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'algorithm', 'cwlsl', 'covar0', C` specifies covariance-weighted least squares estimation using the covariance matrix `C`.

'algorithm' — Estimation algorithm

`'mvn' | 'ecm' | 'cwlsl'`

Estimation algorithm, specified as the comma-separated pair consisting of `'algorithm'` and one of the following.

<code>'mvn'</code>	Ordinary multivariate normal maximum likelihood estimation.
<code>'ecm'</code>	Maximum likelihood estimation via the ECM algorithm.
<code>'cwlsl'</code>	Covariance-weighted least squares estimation.

The default algorithm depends on the presence of missing data.

- For complete data, the default is `'mvn'`.
- If there are any missing responses (indicated by `NaN`), the default is `'ecm'`, provided the sample size is sufficient to estimate all parameters. Otherwise, the default algorithm is `'cwlsl'`.

Note: If `algorithm` has the value `'mvn'`, then `mvregress` removes observations with missing response values before estimation.

Example: `'algorithm', 'ecm'`

'beta0' — Initial estimates for regression coefficients

vector

Initial estimates for the regression coefficients, specified as the comma-separated pair consisting of `'beta0'` and a vector with K elements. The default value is a vector of 0s.

The `beta0` argument is not used if the estimation algorithm is `'mvn'`.

'covar0' — Initial estimate for variance-covariance matrix

matrix

Initial estimate for the variance-covariance matrix, `Sigma`, specified as the comma-separated pair consisting of `'covar0'` and a symmetric, positive definite, d -by- d matrix. The default value is the identity matrix.

If the estimation algorithm is `'cwlsl'`, then `mvregress` uses `covar0` as the weighting matrix at each iteration, without changing it.

'covtype' — Type of variance-covariance matrix

'full' (default) | 'diagonal'

Type of variance-covariance matrix to estimate for Y , specified as the comma-separated pair consisting of `'covtype'` and one of the following.

<code>'full'</code>	Estimate all $d(d + 1)/2$ variance-covariance elements.
<code>'diagonal'</code>	Estimate only the d diagonal elements of the variance-covariance matrix.

Example: `'covtype', 'diagonal'`

'maxiter' — Maximum number of iterations

100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as the comma-separated pair consisting of `'maxiter'` and a positive integer.

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

Example: `'maxiter', 50`

'outputfcn' — Function to evaluate each iteration

function handle

Function to evaluate at each iteration, specified as the comma-separated pair consisting of 'outputfcn' and a function handle. The function must return a logical `true` or `false`. At each iteration, `mvregress` evaluates the function. If the result is `true`, iterations stop. Otherwise, iterations continue. For example, you could specify a function that plots or displays current iteration results, and returns `true` if you close the figure.

The function must accept three input arguments, in this order:

- Vector of current coefficient estimates
- Structure containing these three fields:

<code>Covar</code>	Current value of the variance-covariance matrix
<code>iteration</code>	Current iteration number
<code>fval</code>	Current value of the loglikelihood objective function

- Text string that takes these three values:

<code>'init'</code>	When the function is called during initialization
<code>'iter'</code>	When the function is called after an iteration
<code>'done'</code>	When the function is called after completion

'tolbeta' — Convergence tolerance for regression coefficients

`sqrt(eps)` (default) | positive scalar value

Convergence tolerance for regression coefficients, specified as the comma-separated pair consisting of 'tolbeta' and a positive scalar value.

Let \mathbf{b}^t denote the estimate of the coefficient vector at iteration t , and τ_β be the tolerance specified by `tolbeta`. The convergence criterion for regression coefficient estimation is

$$\|\mathbf{b}^t - \mathbf{b}^{t-1}\| < \tau_\beta \sqrt{K} (1 + \|\mathbf{b}^t\|),$$

where K is the length of \mathbf{b}^t and $\|\mathbf{v}\|$ is the norm of a vector \mathbf{v} .

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both

`tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

Example: `'tolbeta', 1e-5`

'tolobj' — Convergence tolerance for loglikelihood objective function

`eps^(3/4)` (default) | positive scalar value

Convergence tolerance for the loglikelihood objective function, specified as the comma-separated pair consisting of `'tolobj'` and a positive scalar value.

Let L^t denote the value of the loglikelihood objective function at iteration t , and τ_ℓ be the tolerance specified by `tolobj`. The convergence criterion for the objective function is

$$\left|L^t - L^{t-1}\right| < \tau_\ell \left(1 + \left|L^t\right|\right).$$

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

Example: `'tolobj', 1e-5`

'varformat' — Format for parameter estimate variance-covariance matrix

`'beta'` (default) | `'full'`

Format for the parameter estimate variance-covariance matrix, `COVB`, specified as the comma-separated pair consisting of `'varformat'` and one of the following.

<code>'beta'</code>	Return the variance-covariance matrix for only the regression coefficient estimates, <code>beta</code> .
<code>'full'</code>	Return the variance-covariance matrix for both the regression coefficient estimates, <code>beta</code> , and the variance-covariance matrix estimate, <code>Sigma</code> .

Example: `'varformat', 'full'`

'vartype' — Type of variance-covariance matrix for parameter estimates

`'hessian'` (default) | `'fisher'`

Type of variance-covariance matrix for parameter estimates, specified as the comma-separated pair consisting of 'vartype' and either 'hessian' or 'fisher'.

- If the value is 'hessian', then `mvregress` uses the Hessian, or observed information, matrix to compute `CovB`.
- If the value is 'fisher', then `mvregress` uses the complete-data Fisher, or expected information, matrix to compute `CovB`.

The 'hessian' method takes into account the increase uncertainties due to missing data, while the 'fisher' method does not.

Example: 'vartype', 'fisher'

Output Arguments

beta — Estimated regression coefficients

column vector | matrix

Estimated regression coefficients, returned as a column vector or matrix.

- If you specify X as a single n -by- K design matrix, then `mvregress` returns **beta** as a column vector of length K . For example, if X is a 20-by-5 design matrix, then **beta** is a 5-by-1 column vector.
- If you specify X as a cell array containing one or more d -by- K design matrices, then `mvregress` returns **beta** as a column vector of length K . For example, if X is a cell array containing 2-by-10 design matrices, then **beta** is a 10-by-1 column vector.
- If you specify X as a single n -by- p design matrix (not in a cell array), and Y has dimension $d > 1$, then `mvregress` returns **beta** as a p -by- d matrix. For example, if X is a 20-by-5 design matrix, and Y has two dimensions such that $d = 2$, then **beta** is a 5-by-2 matrix, and the fitted Y values are $X \times \mathbf{beta}$.

Sigma — Estimated variance-covariance matrix

square matrix

Estimated variance-covariance matrix for the responses in Y , returned as a d -by- d square matrix.

Note: The estimated variance-covariance matrix, **Sigma**, is not the sample covariance matrix of the residual matrix, **E**.

E — Residuals

matrix

Residuals for the fitted regression model, returned as an n -by- d matrix.

If `algorithm` has the value 'ecm' or 'cwlsl', then `mvregress` computes the residual values corresponding to missing values in Y as the difference between the conditionally imputed values and the fitted values.

Note: If `algorithm` has the value 'mvn', then `mvregress` removes observations with missing response values before estimation.

CovB — Parameter estimate variance-covariance matrix

square matrix

Parameter estimate variance-covariance matrix, returned as a square matrix.

- If `varformat` has the value 'beta' (default), then `CovB` is the estimated variance-covariance matrix of the coefficient estimates in `beta`.
- If `varformat` has the value 'full', then `CovB` is the estimated variance-covariance matrix of the combined estimates in `beta` and `Sigma`.

logL — Loglikelihood objective function value

scalar value

Loglikelihood objective function value after the last iteration, returned as a scalar value.

More About

Multivariate Normal Regression

Multivariate normal regression is the regression of a d -dimensional response on a design matrix of predictor variables, with normally distributed errors. The errors can be heteroscedastic and correlated.

The model is

$$\mathbf{y}_i = \mathbf{X}_i\boldsymbol{\beta} + \mathbf{e}_i, \quad i = 1, \dots, n,$$

where

- \mathbf{y}_i is a d -dimensional vector of responses.
- \mathbf{X}_i is a design matrix of predictor variables.
- β is vector or matrix of regression coefficients.
- \mathbf{e}_i is a d -dimensional vector of error terms, with multivariate normal distribution

$$\mathbf{e}_i \sim MVN_d(\mathbf{0}, \Sigma).$$

Conditionally Imputed Values

The expectation/conditional maximization ('ecm') and covariance-weighted least squares ('cwlsl') estimation algorithms include imputation of missing response values.

Let $\tilde{\mathbf{y}}$ denote missing observations. The conditionally imputed values are the expected value of the missing observation given the observed data, $E(\tilde{\mathbf{y}} | \mathbf{y})$.

The joint distribution of the missing and observed responses is a multivariate normal distribution,

$$\begin{pmatrix} \tilde{\mathbf{y}} \\ \mathbf{y} \end{pmatrix} \sim MVN \left\{ \begin{pmatrix} \tilde{\mathbf{X}}\beta \\ \mathbf{X}\beta \end{pmatrix}, \begin{pmatrix} \Sigma_{\tilde{\mathbf{y}}} & \Sigma_{\tilde{\mathbf{y}}\mathbf{y}} \\ \Sigma_{\mathbf{y}\tilde{\mathbf{y}}} & \Sigma_{\mathbf{y}} \end{pmatrix} \right\}.$$

Using properties of the multivariate normal distribution, the imputed conditional expectation is given by

$$E(\tilde{\mathbf{y}} | \mathbf{y}) = \tilde{\mathbf{X}}\beta + \Sigma_{\tilde{\mathbf{y}}\mathbf{y}}\Sigma_{\mathbf{y}}^{-1}(\mathbf{y} - \mathbf{X}\beta).$$

Note: `mvregress` only imputes missing response values. Observations with missing values in the design matrix are removed.

manova1 | mvregresslike

Introduced in R2006b

mvregresslike

Negative log-likelihood for multivariate regression

Syntax

```
nlogL = mvregresslike(X,Y,b,SIGMA,alg)
[nlogL,COVB] = mvregresslike(...)
[nlogL,COVB] = mvregresslike(...,type,format)
```

Description

`nlogL = mvregresslike(X,Y,b,SIGMA,alg)` computes the negative log-likelihood `nlogL` for a multivariate regression of the d -dimensional multivariate observations in the n -by- d matrix `Y` on the predictor variables in the matrix or cell array `X`, evaluated for the p -by-1 column vector `b` of coefficient estimates and the d -by- d matrix `SIGMA` specifying the covariance of a row of `Y`. If $d = 1$, `X` can be an n -by- p design matrix of predictor variables. For any value of d , `X` can also be a cell array of length n , with each cell containing a d -by- p design matrix for one multivariate observation. If all observations have the same d -by- p design matrix, `X` can be a single cell.

NaN values in `X` or `Y` are taken as missing. Observations with missing values in `X` are ignored. Treatment of missing values in `Y` depends on the algorithm specified by `alg`.

`alg` should match the algorithm used by `mvregress` to obtain the coefficient estimates `b`, and must be one of the following:

- 'ecm' — ECM algorithm
- 'cwlsl' — Least squares conditionally weighted by `SIGMA`
- 'mvm' — Multivariate normal estimates computed after omitting rows with any missing values in `Y`

`[nlogL,COVB] = mvregresslike(...)` also returns an estimated covariance matrix `COVB` of the parameter estimates `b`.

`[nlogL,COVB] = mvregresslike(...,type,format)` specifies the type and format of `COVB`.

type is either:

- 'hessian' — To use the Hessian or observed information. This method takes into account the increased uncertainties due to missing data. This is the default.
- 'fisher' — To use the Fisher or expected information. This method uses the complete data expected information, and does not include uncertainty due to missing data.

format is either:

- 'beta' — To compute COVB for **b** only. This is the default.
- 'full' — To compute COVB for both **b** and **SIGMA**.

mvregress | manova1

Introduced in R2007a

mvnrnd

Multivariate normal random numbers

Syntax

```
R = mvnrnd(MU, SIGMA)
r = mvnrnd(MU, SIGMA, cases)
```

Description

`R = mvnrnd(MU, SIGMA)` returns an n -by- d matrix `R` of random vectors chosen from the multivariate normal distribution with mean `MU`, and covariance `SIGMA`. `MU` is a vector or n -by- d matrix, and `mvnrnd` generates each row of `R` using the corresponding row of `mu`. `SIGMA` is a d -by- d symmetric positive semi-definite matrix, or a d -by- d -by- n array. If `SIGMA` is an array, `mvnrnd` generates each row of `R` using the corresponding page of `SIGMA`, i.e., `mvnrnd` computes `R(i, :)` using `MU(i, :)` and `SIGMA(:, :, i)`. If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, `SIGMA` may also be specified as a 1-by- d vector or a 1-by- d -by- n array, containing just the diagonal. If `MU` is a 1-by- d vector, `mvnrnd` replicates it to match the trailing dimension of `SIGMA`.

`r = mvnrnd(MU, SIGMA, cases)` returns a `cases`-by- d matrix `R` of random vectors chosen from the multivariate normal distribution with a common 1-by- d mean vector `MU`, and a common d -by- d covariance matrix `SIGMA`.

Examples

Generate Multivariate Normal Random Numbers

Generate random numbers from a multivariate normal distribution with parameters `mu = [2,3]` and `sigma = [1,1.5;1.5,3]`.

```
mu = [2,3];
sigma = [1,1.5;1.5,3];
rng default % For reproducibility
r = mvnrnd(mu, sigma, 100);
```

Plot the random numbers.

```
figure  
plot(r(:,1),r(:,2),'+')
```

mvnpdf | mvncdf | normrnd

Introduced before R2006a

mvtcdf

Multivariate t cumulative distribution function

Syntax

```
y = mvtcdf(X,C,DF)
y = mvtcdf(xl,xu,C,DF)
[y,err] = mvtcdf(...)
[...] = mvntdf(...,options)
```

Description

`y = mvtcdf(X,C,DF)` returns the cumulative probability of the multivariate t distribution with correlation parameters **C** and degrees of freedom **DF**, evaluated at each row of **X**. Rows of the n -by- d matrix **X** correspond to observations or points, and columns correspond to variables or coordinates. **y** is an n -by-1 vector.

C is a symmetric, positive definite, d -by- d matrix, typically a correlation matrix. If its diagonal elements are not 1, `mvtcdf` scales **C** to correlation form. `mvtcdf` does not rescale **X**. **DF** is a scalar, or a vector with n elements.

The multivariate t cumulative probability at **X** is defined as the probability that a random vector **T**, distributed as multivariate t , will fall within the semi-infinite rectangle with upper limits defined by **X**, i.e., $\Pr\{T(1) \leq X(1), T(2) \leq X(2), \dots, T(d) \leq X(d)\}$.

`y = mvtcdf(xl,xu,C,DF)` returns the multivariate t cumulative probability evaluated over the rectangle with lower and upper limits defined by **xl** and **xu**, respectively.

`[y,err] = mvtcdf(...)` returns an estimate of the error in **y**. For bivariate and trivariate distributions, `mvtcdf` uses adaptive quadrature on a transformation of the t density, based on methods developed by Genz, as described in the references. The default absolute error tolerance for these cases is $1e-8$. For four or more dimensions, `mvtcdf` uses a quasi-Monte Carlo integration algorithm based on methods developed by Genz and Bretz, as described in the references. The default absolute error tolerance for these cases is $1e-4$.

`[...] = mvntdf(...,options)` specifies control parameters for the numerical integration used to compute y . This argument can be created by a call to `statset`.

Choices of `statset` parameters are:

- `'TolFun'` — Maximum absolute error tolerance. Default is $1e-8$ when $d < 4$, or $1e-4$ when $d \geq 4$.
- `'MaxFunEvals'` — Maximum number of integrand evaluations allowed when $d \geq 4$. Default is $1e7$. `'MaxFunEvals'` is ignored when $d < 4$.
- `'Display'` — Level of display output. Choices are `'off'` (the default), `'iter'`, and `'final'`. `'Display'` is ignored when $d < 4$.

Examples

Compute the Multivariate t Distribution cdf

Compute the cdf of a multivariate t distribution with correlation parameters $C = [1 \ .4; \ .4 \ 1]$ and 2 degrees of freedom.

```
C = [1 .4; .4 1];
df = 2;
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');
X = [X1(:) X2(:)];
p = mvtcdf(X,C,df);
```

Plot the cdf.

```
figure;
surf(X1,X2,reshape(p,25,25));
```

mvtpdf | mvtrnd

Introduced in R2006a

mvtpdf

Multivariate t probability density function

Syntax

```
y = mvtpdf(X,C,df)
```

Description

`y = mvtpdf(X,C,df)` returns the probability density of the multivariate t distribution with correlation parameters `C` and degrees of freedom `df`, evaluated at each row of `X`. Rows of the n -by- d matrix `X` correspond to observations or points, and columns correspond to variables or coordinates. `C` is a symmetric, positive definite, d -by- d matrix, typically a correlation matrix. If its diagonal elements are not 1, `mvtpdf` scales `C` to correlation form. `mvtcdf` does not rescale `X`. `df` is a scalar, or a vector with n elements. `y` is an n -by-1 vector.

Examples

Compute the Multivariate t Distribution pdf

Compute the pdf of a multivariate t distribution with correlation parameters `C = [1 .4; .4 1]` and 2 degrees of freedom.

```
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');  
X = [X1(:) X2(:)];  
C = [1 .4; .4 1];  
df = 2;  
p = mvtpdf(X,C,df);
```

Plot the pdf.

```
figure;  
surf(X1,X2,reshape(p,25,25))
```

`mvtcdf` | `mvtrnd`

Introduced in R2006b

mvtrnd

Multivariate t random numbers

Syntax

```
R = mvtrnd(C,df,cases)
R = mvtrnd(C,df)
```

Description

`R = mvtrnd(C,df,cases)` returns a matrix of random numbers chosen from the multivariate t distribution, where **C** is a correlation matrix. **df** is the degrees of freedom and is either a scalar or is a vector with **cases** elements. If **p** is the number of columns in **C**, then the output **R** has **cases** rows and **p** columns.

Let **t** represent a row of **R**. Then the distribution of **t** is that of a vector having a multivariate normal distribution with mean 0, variance 1, and covariance matrix **C**, divided by an independent chi-square random value having **df** degrees of freedom. The rows of **R** are independent.

C must be a square, symmetric and positive definite matrix. If its diagonal elements are not all 1 (that is, if **C** is a covariance matrix rather than a correlation matrix), `mvtrnd` rescales **C** to transform it to a correlation matrix before generating the random numbers.

`R = mvtrnd(C,df)` returns a single random number from the multivariate t distribution.

Examples

Generate Multivariate t Distribution Random Numbers

Generate random numbers from a multivariate t distribution with correlation parameters `SIGMA = [1 0.8;0.8 1]` and 3 degrees of freedom.

```
rng default; % For reproducibility
SIGMA = [1 0.8;0.8 1];
R = mvtrnd(SIGMA,3,100);
```

Plot the random numbers.

```
figure;  
plot(R(:,1),R(:,2),'+')
```

Introduced before R2006a

NumObservations property

Class: cvpartition

Number of observations (including observations with missing group values)

Description

Number of observations (including observations with missing group values).

NaiveBayes class

Naive Bayes classifier

Compatibility

`NaiveBayes` will be removed in a future release. Use `fitcnb` to create a `ClassificationNaiveBayes` object instead.

Description

A `NaiveBayes` object defines a Naive Bayes classifier. A Naive Bayes classifier assigns a new observation to the most probable class, assuming the features are conditionally independent given the class value.

Construction

`.NaiveBayes`

Create `NaiveBayes` object

Methods

`disp`

Display `NaiveBayes` classifier object

`display`

Display `NaiveBayes` classifier object

`fit`

Create Naive Bayes classifier object by fitting training data

`posterior`

Compute posterior probability of each class for test data

`predict`

Predict class label for test data

`subsasgn`

Subscripted reference for `NaiveBayes` object

subhref Subscripted reference for `NaiveBayes` object

Properties

<code>CIIsNonEmpty</code>	Flag for non-empty classes
<code>ClassLevels</code>	Class levels
<code>Prior</code>	Class priors
<code>Dist</code>	Distribution names
<code>NClasses</code>	Number of classes
<code>NDims</code>	Number of dimensions
<code>Params</code>	Parameter estimates

Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes](#) in the [MATLAB Object-Oriented Programming](#) documentation.

Examples

Predict the class label using the Naive Bayes classifier:

```
load fisheriris
```

Use the default Gaussian distribution and a confusion matrix:

```
O1 = fitNaiveBayes(meas,species);  
C1 = O1.predict(meas);  
cMat1 = confusionmat(species,C1)
```

This returns:

```
cMat1 =
```

```
    50     0     0  
     0    47     3  
     0     3    47
```

Use the Gaussian distribution for features 1 and 3 and use the kernel density estimation for features 2 and 4:

```
O2 = fitNaiveBayes(meas,species,'dist',...
{'normal','kernel','normal','kernel'});
C2 = O2.predict(meas);
cMat2 = confusionmat(species,C2)
```

This returns:

```
cMat2 =
```

```
    50     0     0
     0    47     3
     0     3    47
```

`fitNaiveBayes`

Introduced in R2009a

prob.NakagamiDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Nakagami probability distribution object

Description

`prob.NakagamiDistribution` is an object consisting of parameters, a model description, and sample data for a Nakagami probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('Nakagami')` creates a Nakagami probability distribution object using the default parameter values.

`pd = makedist('Nakagami', 'mu', mu, 'omega', omega)` creates a Nakagami probability distribution object using the specified parameter values.

Input Arguments

mu — Shape parameter

1 (default) | positive scalar value

Shape parameter for the Nakagami distribution, specified as a positive scalar value.

Data Types: `single` | `double`

omega — Scale parameter

1 (default) | positive scalar value

Scale parameter for the Nakagami distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Properties

mu — Shape parameter

positive scalar value

Shape parameter for the Nakagami distribution, stored as a positive scalar value.

Data Types: `single` | `double`

omega — Scale parameter

positive scalar value

Scale parameter for the Nakagami distribution, stored as a positive scalar value.

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object

std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Nakagami Distribution

The Nakagami distribution is commonly used in communication theory to model scattered signals that reach a receiver using multiple paths.

The Nakagami distribution uses the following parameters.

Parameter	Description	Support
mu	Shape parameter	$\mu > 0$
omega	Scale parameter	$\omega > 0$

The probability density function (pdf) is

$$f(x | \mu, \omega) = 2 \left(\frac{\mu^\mu}{\omega} \right) \frac{1}{\Gamma(\mu)} x^{(2\mu-1)} \exp\left\{ -\frac{\mu}{\omega} x^2 \right\} ; \quad x > 0,$$

where $\Gamma(\cdot)$ is the Gamma function.

Examples

Create a Nakagami Distribution Object Using Default Parameters

Create a Nakagami distribution object using the default parameter values.

```
pd = makedist('Nakagami')  
pd =  
    NakagamiDistribution  
  
    Nakagami distribution  
        mu = 1  
        omega = 1
```

Create a Nakagami Distribution Object Using Specified Parameters

Create a Nakagami distribution object by specifying parameter values.

```
pd = makedist('Nakagami','mu',5,'omega',2)  
pd =  
    NakagamiDistribution  
  
    Nakagami distribution  
        mu = 5  
        omega = 2
```

Compute the mean of the distribution.

```
m = mean(pd)  
m =  
    1.3794
```

nancov

Covariance ignoring NaN values

Syntax

```
Y = nancov(X)
Y = nancov(X1,X2)
Y = nancov(...,1)
Y = nancov(...,'pairwise')
```

Description

$Y = \text{nancov}(X)$ is the covariance `COV` of X , computed after removing observations with NaN values.

For vectors x , $\text{nancov}(x)$ is the sample variance of the remaining elements, once NaN values are removed. For matrices X , $\text{nancov}(X)$ is the sample covariance of the remaining observations, once observations (rows) containing any NaN values are removed.

$Y = \text{nancov}(X1, X2)$, where $X1$ and $X2$ are matrices with the same number of elements, is equivalent to $\text{nancov}(X)$, where $X = [X1(:) \ X2(:)]$.

`nancov` removes the mean from each variable (column for matrix X) before calculating Y . If n is the number of remaining observations after removing observations with NaN values, `nancov` normalizes Y by either $n - 1$ or n , depending on whether $n > 1$ or $n = 1$, respectively. To specify normalization by n , use $Y = \text{nancov}(\dots, 1)$.

$Y = \text{nancov}(\dots, 'pairwise')$ computes $Y(i, j)$ using rows with no NaN values in columns i or j . The result Y may not be a positive definite matrix.

Examples

Generate random data for two variables (columns) with random missing values:

```
X = rand(10,2);
```

```
p = randperm(numel(X));
X(p(1:5)) = NaN
X =
    0.8147    0.1576
      NaN      NaN
    0.1270    0.9572
    0.9134      NaN
    0.6324      NaN
    0.0975    0.1419
    0.2785    0.4218
    0.5469    0.9157
    0.9575    0.7922
    0.9649      NaN
```

Establish a correlation between a third variable and the other two variables:

```
X(:,3) = sum(X,2)
X =
    0.8147    0.1576    0.9723
      NaN      NaN      NaN
    0.1270    0.9572    1.0842
    0.9134      NaN      NaN
    0.6324      NaN      NaN
    0.0975    0.1419    0.2394
    0.2785    0.4218    0.7003
    0.5469    0.9157    1.4626
    0.9575    0.7922    1.7497
    0.9649      NaN      NaN
```

Compute the covariance matrix for the three variables after removing observations (rows) with NaN values:

```
Y = nancov(X)
Y =
    0.1311    0.0096    0.1407
    0.0096    0.1388    0.1483
    0.1407    0.1483    0.2890
```

NaN | cov | var | nanvar

Introduced before R2006a

nanmax

Maximum ignoring NaN values

Syntax

```
y = nanmax(X)
Y = nanmax(X1,X2)
y = nanmax(X,[],dim)
[y,indices] = nanmax(...)
```

Description

`y = nanmax(X)` is the maximum `max` of `X`, computed after removing NaN values.

For vectors `x`, `nanmax(x)` is the maximum of the remaining elements, once NaN values are removed. For matrices `X`, `nanmax(X)` is a row vector of column maxima, once NaN values are removed. For multidimensional arrays `X`, `nanmax` operates along the first nonsingleton dimension.

`Y = nanmax(X1,X2)` returns an array `Y` the same size as `X1` and `X2` with `Y(i,j) = nanmax(X1(i,j),X2(i,j))`. Scalar inputs are expanded to an array of the same size as the other input.

`y = nanmax(X,[],dim)` operates along the dimension `dim` of `X`.

`[y,indices] = nanmax(...)` also returns the row indices of the maximum values for each column in the vector `indices`.

Examples

Find column maxima and their indices for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
```

```
      3      5      NaN
      4      NaN      NaN
[y,indices] = nanmax(X)
y =
      4      5      NaN
indices =
      3      2      1
```

See Also

NaN | max | nanmin

Introduced before R2006a

nanmean

Mean ignoring NaN values

Syntax

```
y = nanmean(X)
y = nanmean(X,dim)
```

Description

$y = \text{nanmean}(X)$ is the mean of X , computed after removing NaN values.

For vectors x , $\text{nanmean}(x)$ is the mean of the remaining elements, once NaN values are removed. For matrices X , $\text{nanmean}(X)$ is a row vector of column means, once NaN values are removed. For multidimensional arrays X , nanmean operates along the first nonsingleton dimension.

$y = \text{nanmean}(X,\text{dim})$ takes the mean along dimension dim of X .

Note: If X contains a vector of all NaN values along some dimension, the vector is empty once the NaN values are removed, so the sum of the remaining elements is 0. Since the mean involves division by 0, its value is NaN. The output NaN is not a mean of NaN values.

Examples

Find column means for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nanmean(X)
y =
```

3.5000 3.0000 NaN

NaN | mean | nanmedian

Introduced before R2006a

nanmedian

Median ignoring NaN values

Syntax

```
y = nanmedian(X)
y = nanmedian(X,dim)
```

Description

`y = nanmedian(X)` is the median of `X`, computed after removing NaN values.

For vectors `x`, `nanmedian(x)` is the median of the remaining elements, once NaN values are removed. For matrices `X`, `nanmedian(X)` is a row vector of column medians, once NaN values are removed. For multidimensional arrays `X`, `nanmedian` operates along the first nonsingleton dimension.

`y = nanmedian(X,dim)` takes the mean along dimension `dim` of `X`.

Examples

Find column medians for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1     NaN
     3     5     NaN
     4    NaN     NaN
y = nanmedian(X)
y =
    3.5000    3.0000    NaN
```

See Also

NaN | median | nanmean

Introduced before R2006a

nanmin

Minimum ignoring NaN values

Syntax

```
y = nanmin(X)
Y = nanmin(X1,X2)
y = nanmin(X,[],dim)
[y,indices] = nanmin(...)
```

Description

`y = nanmin(X)` is the minimum `min` of `X`, computed after removing NaN values.

For vectors `x`, `nanmin(x)` is the minimum of the remaining elements, once NaN values are removed. For matrices `X`, `nanmin(X)` is a row vector of column minima, once NaN values are removed. For multidimensional arrays `X`, `nanmin` operates along the first nonsingleton dimension.

`Y = nanmin(X1,X2)` returns an array `Y` the same size as `X1` and `X2` with `Y(i,j) = nanmin(X1(i,j),X2(i,j))`. Scalar inputs are expanded to an array of the same size as the other input.

`y = nanmin(X,[],dim)` operates along the dimension `dim` of `X`.

`[y,indices] = nanmin(...)` also returns the row indices of the minimum values for each column in the vector `indices`.

Examples

Find column minima and their indices for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
```

```
      3      5      NaN
      4      NaN      NaN
[y,indices] = nanmin(X)
y =
      3      1      NaN
indices =
      2      1      1
```

NaN | min | nanmax

Introduced before R2006a

nanstd

Standard deviation ignoring NaN values

Syntax

```
y = nanstd(X)
y = nanstd(X,1)
y = nanstd(X,flag,dim)
```

Description

`y = nanstd(X)` is the standard deviation `std` of `X`, computed after removing NaN values.

For vectors `x`, `nanstd(x)` is the sample standard deviation of the remaining elements, once NaN values are removed. For matrices `X`, `nanstd(X)` is a row vector of column sample standard deviations, once NaN values are removed. For multidimensional arrays `X`, `nanstd` operates along the first nonsingleton dimension.

If n is the number of remaining observations after removing observations with NaN values, `nanstd` normalizes `y` by $n-1$. To specify normalization by n , use `y = nanstd(X,1)`.

`y = nanstd(X,flag,dim)` takes the standard deviation along the dimension `dim` of `X`. The `flag` is 0 or 1 to specify normalization by $n-1$ or n , respectively, where n is the number of remaining observations after removing observations with NaN values.

Examples

Find column standard deviations for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
```

```
      4   NaN   NaN
y = nanstd(X)
y =
  0.7071  2.8284  NaN
```

Introduced before R2006a

nansum

Sum ignoring NaN values

Syntax

```
y = nansum(X)
y = nansum(X,dim)
```

Description

`y = nansum(X)` is the sum of `X`, computed after removing NaN values.

For vectors `x`, `nansum(x)` is the sum of the remaining elements, once NaN values are removed. For matrices `X`, `nansum(X)` is a row vector of column sums, once NaN values are removed. For multidimensional arrays `X`, `nansum` operates along the first nonsingleton dimension.

`y = nansum(X,dim)` takes the sum along dimension `dim` of `X`.

Note: If `X` contains a vector of all NaN values along some dimension, the vector is empty once the NaN values are removed, so the sum of the remaining elements is 0. The output 0 is not a sum of NaN values.

Examples

Find column sums for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nansum(X)
y =
```

NaN | sum

Introduced before R2006a

nanvar

Variance, ignoring NaN values

Syntax

```
y = nanvar(X)
y = nanvar(X,1)
y = nanvar(X,w)
y = nanvar(X,w,dim)
```

Description

`y = nanvar(X)` is the variance `var` of `X`, computed after removing NaN values.

For vectors `x`, `nanvar(x)` is the sample variance of the remaining elements, once NaN values are removed. For matrices `X`, `nanvar(X)` is a row vector of column sample variances, once NaN values are removed. For multidimensional arrays `X`, `nanvar` operates along the first nonsingleton dimension.

`nancov` removes the mean from each variable (column for matrix `X`) before calculating `Y`. If n is the number of remaining observations after removing observations with NaN values, `nanvar` normalizes `y` by either $n - 1$ or n , depending on whether $n > 1$ or $n = 1$, respectively. To specify normalization by n , use `y = nanvar(X,1)`.

`y = nanvar(X,w)` computes the variance using the weight vector `w`. The length of `w` must equal the length of the dimension over which `nanvar` operates, and its elements must be nonnegative. Elements of `X` corresponding to NaN values of `w` are ignored.

`y = nanvar(X,w,dim)` takes the variance along the dimension `dim` of `X`. Set `w` to `[]` to use the default normalization by $n - 1$.

Examples

Find column standard deviations for data with missing values:

```
X = magic(3);
```

```
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nanvar(X)
y =
    0.5000    8.0000    NaN
```

Introduced before R2006a

nbincdf

Negative binomial cumulative distribution function

Syntax

```
y = nbincdf(x,R,p)
y = nbincdf(x,R,p, 'upper')
```

Description

`y = nbincdf(x,R,p)` computes the negative binomial cdf at each of the values in `x` using the corresponding number of successes, `R` and probability of success in a single trial, `p`. `x`, `R`, and `p` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `y`. A scalar input for `x`, `R`, or `p` is expanded to a constant array with the same dimensions as the other inputs.

`y = nbincdf(x,R,p, 'upper')` returns the complement of the negative binomial cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The negative binomial cdf is

$$y = F(x | r, p) = \sum_{i=0}^x \binom{r+i-1}{i} p^r q^i I_{(0,1,\dots)}(i)$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `p` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbincdf` allows `R` to be any positive value, including nonintegers. When `R` is noninteger, the binomial coefficient in the definition of the cdf is replaced by the equivalent expression

$$\frac{\Gamma(r+i)}{\Gamma(r)\Gamma(i+1)}$$

Examples

Compute Negative Binomial Distribution CDF

```
x = (0:15);  
p = nbincdf(x,3,0.5);  
stairs(x,p)
```

`cdf` | `nbinpdf` | `nbininv` | `nbinstat` | `nbinfit` | `nbinrnd`

Introduced before R2006a

nbinfit

Negative binomial parameter estimates

Syntax

```
parmhat = nbinfit(data)
[parmhat,parmci] = nbinfit(data,alpha)
[...] = nbinfit(data,alpha,options)
```

Description

`parmhat = nbinfit(data)` returns the maximum likelihood estimates (MLEs) of the parameters of the negative binomial distribution given the data in the vector `data`.

`[parmhat,parmci] = nbinfit(data,alpha)` returns MLEs and $100(1-\alpha)$ percent confidence intervals. By default, `alpha = 0.05`, which corresponds to 95% confidence intervals.

`[...] = nbinfit(data,alpha,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The negative binomial fit function accepts an `options` structure which you can create using the function `statset`. Enter `statset('nbinfit')` to see the names and default values of the parameters that `nbinfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

Note The variance of a negative binomial distribution is greater than its mean. If the sample variance of the data in `data` is less than its sample mean, `nbinfit` cannot compute MLEs. You should use the `poissfit` function instead.

More About

- “Negative Binomial Distribution” on page B-120

`nbincdf` | `nbininv` | `nbinpdf` | `nbinrnd` | `nbinstat` | `mle` | `statset`

Introduced before R2006a

nbiniinv

Negative binomial inverse cumulative distribution function

Syntax

```
X = nbiniinv(Y,R,P)
```

Description

`X = nbiniinv(Y,R,P)` returns the inverse of the negative binomial cdf with corresponding number of successes, `R` and probability of success in a single trial, `P`. Since the binomial distribution is discrete, `nbiniinv` returns the least integer `X` such that the negative binomial cdf evaluated at `X` equals or exceeds `Y`. `Y`, `R`, and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `Y`, `R`, or `P` is expanded to a constant array with the same dimensions as the other inputs.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbiniinv` allows `R` to be any positive value, including nonintegers.

Examples

How many times would you need to flip a fair coin to have a 99% probability of having observed 10 heads?

```
flips = nbiniinv(0.99,10,0.5) + 10  
flips =  
    33
```

Note that you have to flip at least 10 times to get 10 heads. That is why the second term on the right side of the equals sign is a 10.

`icdf` | `nbincdf` | `nbinpdf` | `nbinstat` | `nbinfit` | `nbinrnd`

Introduced before R2006a

nbincpdf

Negative binomial probability density function

Syntax

`Y = nbincpdf(X,R,P)`

Description

`Y = nbincpdf(X,R,P)` returns the negative binomial pdf at each of the values in `X` using the corresponding number of successes, `R` and probability of success in a single trial, `P`. `X`, `R`, and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X`, `R`, or `P` is expanded to a constant array with the same dimensions as the other inputs. Note that the density function is zero unless the values in `X` are integers.

The negative binomial pdf is

$$y = f(x | r, p) = \binom{r+x-1}{x} p^r q^x I_{(0,1,\dots)}(x)$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbincpdf` allows `R` to be any positive value, including nonintegers. When `R` is noninteger, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r+x)}{\Gamma(r)\Gamma(x+1)}$$

Examples

Compute the Negative Binomial Distribution pdf

Compute the pdf of a negative binomial distribution with parameters $R = 3$ and $p = 0.5$.

```
x = (0:10);  
y = nbinpdf(x,3,0.5);
```

Plot the pdf.

```
figure;  
plot(x,y, '+')  
xlim([-0.5,10.5])
```

Introduced before R2006a

nbinrnd

Negative binomial random numbers

Syntax

```
RND = nbinrnd(R,P)
RND = nbinrnd(R,P,m,n,...)
RND = nbinrnd(R,P,[m,n,...])
```

Description

`RND = nbinrnd(R,P)` is a matrix of random numbers chosen from a negative binomial distribution with corresponding number of successes, `R` and probability of success in a single trial, `P`. `R` and `P` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `RND`. A scalar input for `R` or `P` is expanded to a constant array with the same dimensions as the other input.

`RND = nbinrnd(R,P,m,n,...)` or `RND = nbinrnd(R,P,[m,n,...])` generates an `m`-by-`n`-by-... array. The `R`, `P` parameters can each be scalars or arrays of the same size as `R`.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinrnd` allows `R` to be any positive value, including nonintegers.

Examples

Suppose you want to simulate a process that has a defect probability of 0.01. How many units might Quality Assurance inspect before finding three defective items?

```
r = nbinrnd(3,0.01,1,6)+3
r =
    496    142    420    396    851    178
```

random | nbinpdf | nbincdf | nbininv | nbinstat | nbinfit

Introduced before R2006a

nbinstat

Negative binomial mean and variance

Syntax

```
[M,V] = nbinstat(R,P)
```

Description

`[M,V] = nbinstat(R,P)` returns the mean of and variance for the negative binomial distribution with corresponding number of successes, `R` and probability of success in a single trial, `P`. `R` and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `R` or `P` is expanded to a constant array with the same dimensions as the other input.

The mean of the negative binomial distribution with parameters r and p is rq / p , where $q = 1 - p$. The variance is rq / p^2 .

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinstat` allows `R` to be any positive value, including nonintegers.

Examples

```
p = 0.1:0.2:0.9;
r = 1:5;
[R,P] = meshgrid(r,p);
[M,V] = nbinstat(R,P)
M =

Introduced before R2006a

ncfcdf

Noncentral F cumulative distribution function

Syntax

```
p = ncfcdf(x, nu1, nu2, delta)
p = ncfcdf(x, nu1, nu2, delta, 'upper')
```

Description

`p = ncfcdf(x, nu1, nu2, delta)` computes the noncentral F cdf at each value in `x` using the corresponding numerator degrees of freedom in `nu1`, denominator degrees of freedom in `nu2`, and positive noncentrality parameters in `delta`. `nu1`, `nu2`, and `delta` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `p`. A scalar input for `x`, `nu1`, `nu2`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = ncfcdf(x, nu1, nu2, delta, 'upper')` returns the complement of the noncentral F cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The noncentral F cdf is

$$F(x | v_1, v_2, \delta) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) I\left(\frac{v_1 \cdot x}{v_2 + v_1 \cdot x} \middle| \frac{v_1}{2} + j, \frac{v_2}{2}\right)$$

where $I(x | a, b)$ is the incomplete beta function with parameters a and b .

Examples

Compute Noncentral F Distribution cdf

Compare the noncentral F cdf with $\delta = 10$ to the F cdf with the same number of numerator and denominator degrees of freedom (5 and 20 respectively).

```
x = (0.01:0.1:10.01)';  
p1 = ncfcdf(x,5,20,10);  
p = fcdf(x,5,20);  
plot(x,p,'- ',x,p1,'- ')
```

ncfinv

Noncentral F inverse cumulative distribution function

Syntax

```
X = ncfinv(P,NU1,NU2,DELTA)
```

Description

`X = ncfinv(P,NU1,NU2,DELTA)` returns the inverse of the noncentral F cdf with numerator degrees of freedom `NU1`, denominator degrees of freedom `NU2`, and positive noncentrality parameter `DELTA` for the corresponding probabilities in `P`. `P`, `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `P`, `NU1`, `NU2`, or `DELTA` is expanded to a constant array with the same dimensions as the other inputs.

Examples

One hypothesis test for comparing two sample variances is to take their ratio and compare it to an F distribution. If the numerator and denominator degrees of freedom are 5 and 20 respectively, then you reject the hypothesis that the first variance is equal to the second variance if their ratio is less than that computed below.

```
critical = finv(0.95,5,20)
critical =
    2.7109
```

Suppose the truth is that the first variance is twice as big as the second variance. How likely is it that you would detect this difference?

```
prob = 1 - nfcdf(critical,5,20,2)
prob =
    0.1297
```

If the true ratio of variances is 2, what is the typical (median) value you would expect for the F statistic?

```
ncfinv(0.5,5,20,2)
ans =
    1.2786
```

Introduced before R2006a

ncfpdf

Noncentral F probability density function

Syntax

```
Y = ncfpdf(X, NU1, NU2, DELTA)
```

Description

`Y = ncfpdf(X, NU1, NU2, DELTA)` computes the noncentral F pdf at each of the values in X using the corresponding numerator degrees of freedom in $NU1$, denominator degrees of freedom in $NU2$, and positive noncentrality parameters in $DELTA$. X , $NU1$, $NU2$, and $DELTA$ can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of Y . A scalar input for $NU1$, $NU2$, or $DELTA$ is expanded to a constant array with the same dimensions as the other inputs.

The F distribution is a special case of the noncentral F where $\delta = 0$. As δ increases, the distribution flattens like the plot in the example.

Examples

Compute Noncentral F Distribution pdf

Compute the pdf of a noncentral F distribution with degrees of freedom $NU1 = 5$ and $NU2 = 20$, and noncentrality parameter $DELTA = 10$. For comparison, also compute the pdf of an F distribution with the same degrees of freedom.

```
x = (0.01:0.1:10.01)';  
p1 = ncfpdf(x, 5, 20, 10);  
p = fpdf(x, 5, 20);
```

Plot the pdf of the noncentral F distribution and the pdf of the F distribution on the same figure.

```
figure;  
plot(x, p1, 'b-', 'LineWidth', 2)  
hold on
```

```
plot(x,p,'g--','LineWidth',2)  
legend('Noncentral F','F distribution')
```

ncfrnd

Noncentral F random numbers

Syntax

```
R = ncfrnd(NU1, NU2, DELTA)
R = ncfrnd(NU1, NU2, DELTA, m, n, ... )
R = ncfrnd(NU1, NU2, DELTA, [m, n, ... ])
```

Description

`R = ncfrnd(NU1, NU2, DELTA)` returns a matrix of random numbers chosen from the noncentral F distribution with corresponding numerator degrees of freedom in `NU1`, denominator degrees of freedom in `NU2`, and positive noncentrality parameters in `DELTA`. `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `NU1`, `NU2`, or `DELTA` is expanded to a constant matrix with the same dimensions as the other inputs.

`R = ncfrnd(NU1, NU2, DELTA, m, n, ...)` or `R = ncfrnd(NU1, NU2, DELTA, [m, n, ...])` generates an `m`-by-`n`-by-... array. The `NU1`, `NU2`, `DELTA` parameters can each be scalars or arrays of the same size as `R`.

Examples

Compute six random numbers from a noncentral F distribution with 10 numerator degrees of freedom, 100 denominator degrees of freedom and a noncentrality parameter, δ , of 4.0. Compare this to the F distribution with the same degrees of freedom.

```
r = ncfrnd(10,100,4,1,6)
r =
    2.5995    0.8824    0.8220    1.4485    1.4415    1.4864

r1 = frnd(10,100,1,6)
r1 =
    0.9826    0.5911    1.0967    0.9681    2.0096    0.6598
```

random | ncfpdf | ncfcdf | ncfinv | ncfstat

Introduced before R2006a

ncfstat

Noncentral F mean and variance

Syntax

`[M,V] = ncfstat(NU1,NU2,DELTA)`

Description

`[M,V] = ncfstat(NU1,NU2,DELTA)` returns the mean of and variance for the noncentral F pdf with corresponding numerator degrees of freedom in `NU1`, denominator degrees of freedom in `NU2`, and positive noncentrality parameters in `DELTA`. `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `NU1`, `NU2`, or `DELTA` is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral F distribution with parameters ν_1 , ν_2 , and δ is

$$\frac{\nu_2(\delta + \nu_1)}{\nu_1(\nu_2 - 2)}$$

where $\nu_2 > 2$.

The variance is

$$2 \left(\frac{\nu_2}{\nu_1} \right)^2 \left[\frac{(\delta + \nu_1)^2 + (2\delta + \nu_1)(\nu_2 - 2)}{(\nu_2 - 2)^2(\nu_2 - 4)} \right]$$

where $\nu_2 > 4$.

Examples

`[m,v]= ncfstat(10,100,4)`

m =
1.4286
v =
0.4252

NClasses property

Class: NaiveBayes

Number of classes

Description

The `NClasses` property specifies the number of classes in the grouping variable used to create the Naive Bayes classifier.

NumComponents property

Class: gmdistribution

Number k of mixture components

Description

The number k of mixture components.

nctcdf

Noncentral t cumulative distribution function

Syntax

```
p = nctcdf(x,nu,delta)
p = nctcdf(x,nu,delta,'upper')
```

Description

`p = nctcdf(x,nu,delta)` computes the noncentral t cdf at each value in `x` using the corresponding degrees of freedom in `nu` and noncentrality parameters in `delta`. `x`, `nu`, and `delta` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `p`. A scalar input for `x`, `nu`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = nctcdf(x,nu,delta,'upper')` returns the complement of the noncentral t cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Examples

Compute Noncentral t Distribution cdf

Compare the noncentral t cdf with `DELTA = 1` to the t cdf with the same number of degrees of freedom (10).

```
x = (-5:0.1:5)';
p1 = nctcdf(x,10,1);
p = tcdf(x,10);
plot(x,p,'-',x,p1,':')
```

Noncentral t random numbers

Syntax

```
R = nctrnd(V, DELTA)
R = nctrnd(V, DELTA, m, n, ...)
R = nctrnd(V, DELTA, [m, n, ...])
```

Description

`R = nctrnd(V, DELTA)` returns a matrix of random numbers chosen from the noncentral T distribution using the corresponding degrees of freedom in `V` and noncentrality parameters in `DELTA`. `V` and `DELTA` can be vectors, matrices, or multidimensional arrays. A scalar input for `V` or `DELTA` is expanded to a constant array with the same dimensions as the other input.

`R = nctrnd(V, DELTA, m, n, ...)` or `R = nctrnd(V, DELTA, [m, n, ...])` generates an m -by- n -by-... array. The `V`, `DELTA` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
nctrnd(10,1,5,1)
ans =
    1.6576
    1.0617
    1.4491
    0.2930

nctstat

Noncentral t mean and variance

Syntax

`[M,V] = nctstat(NU,DELTA)`

Description

`[M,V] = nctstat(NU,DELTA)` returns the mean of and variance for the noncentral t pdf with NU degrees of freedom and noncentrality parameter $DELTA$. NU and $DELTA$ can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of M and V . A scalar input for NU or $DELTA$ is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral t distribution with parameters ν and δ is

$$\frac{\delta(\nu/2)^{1/2}\Gamma((\nu-1)/2)}{\Gamma(\nu/2)}$$

where $\nu > 1$.

The variance is

$$\frac{\nu}{(\nu-2)}(1+\delta^2) - \frac{\nu}{2}\delta^2 \left[\frac{\Gamma((\nu-1)/2)}{\Gamma(\nu/2)} \right]^2$$

where $\nu > 2$.

Examples

`[m,v] = nctstat(10,1)`

`m =`

1.0837

v =
1.3255

ncx2cdf

Noncentral chi-square cumulative distribution function

Syntax

```
p = ncx2cdf(x,v,delta)
p = ncx2cdf(x,v,delta,'upper')
```

Description

`p = ncx2cdf(x,v,delta)` computes the noncentral chi-square cdf at each value in `x` using the corresponding degrees of freedom in `v` and positive noncentrality parameters in `delta`. `x`, `v`, and `delta` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `p`. A scalar input for `x`, `v`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = ncx2cdf(x,v,delta,'upper')` returns the complement of the noncentral chi-square cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Some texts refer to this distribution as the generalized Rayleigh, Rayleigh-Rice, or Rice distribution.

The noncentral chi-square cdf is

$$F(x | v, \delta) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) \Pr\left[\chi_{v+2j}^2 \leq x\right]$$

Examples

Compute Noncentral Chi-Square cdf

Compare the noncentral chi-square cdf with `DELTA = 2` to the chi-square cdf with the same number of degrees of freedom (4):

```
x = (0:0.1:10)';  
ncx2 = ncx2cdf(x,4,2);  
chi2 = chi2cdf(x,4);  
  
plot(x,ncx2,'b-','LineWidth',2)  
hold on  
plot(x,chi2,'g--','LineWidth',2)  
legend('ncx2','chi2','Location','NW')
```

ncx2stat

Noncentral chi-square mean and variance

Syntax

```
[M,V] = ncx2stat(NU,DELTA)
```

Description

`[M,V] = ncx2stat(NU,DELTA)` returns the mean of and variance for the noncentral chi-square pdf with `NU` degrees of freedom and noncentrality parameter `DELTA`. `NU` and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `NU` or `DELTA` is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral chi-square distribution with parameters v and δ is $v+\delta$, and the variance is $2(v+2\delta)$.

Examples

```
[m,v] = ncx2stat(4,2)
m =
     6
v =
    16
```

`ncx2pdf` | `ncx2cdf` | `ncx2inv` | `ncx2rnd`

Introduced before R2006a

NumVariables property

Class: `gmdistribution`

Dimension d of multivariate Gaussian distributions

Description

The dimension d of the multivariate Gaussian distributions.

ndims

Class: dataset

Number of dimensions of dataset array

Compatibility

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
n = ndims(A)
```

Description

`n = ndims(A)` returns the number of dimensions in the dataset A. The number of dimensions in an array is always 2.

See Also

`size`

ndims

Class: grandset

Number of dimensions in matrix

Syntax

```
n = ndims(p)
```

Description

`n = ndims(p)` returns the number of dimensions in the matrix that is created by the syntax `p(:, :)`. Since this is always a 2-D matrix, `n` is always equal to 2.

See Also

`grandset` | `size`

NDims property

Class: NaiveBayes

Number of dimensions

Description

The `NDims` property specifies the number of dimensions, which is equal to the number of features in the training data used to create the Naive Bayes classifier.

ne

Class: grandstream

Not equal relation for handles

Syntax

`h1 ~= h2`

Description

Handles are equal if they are handles for the same object and are unequal otherwise.

`h1 ~= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `~=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = ne(h1, h2)` stores the result in a logical array of the same dimensions.

See Also

`grandstream` | `ge` | `gt` | `lt` | `eq` | `le`

prob.NegativeBinomialDistribution class

Package: prob

Superclasses: prob.ToolboxFittableParametricDistribution

Negative binomial distribution object

Description

`prob.NegativeBinomialDistribution` is an object consisting of parameters, a model description, and sample data for a negative binomial probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

Construction

`pd = makedist('NegativeBinomial')` creates a negative binomial probability distribution object using the default parameter values.

`pd = makedist('NegativeBinomial', 'R', R, 'p', p)` creates a negative binomial probability distribution object using the specified parameter values.

Input Arguments

R — Number of successes

1 (default) | positive scalar value

Number of successes for the negative binomial distribution, specified as a positive scalar value.

Data Types: `single` | `double`

p — Probability of success

0.5 (default) | positive scalar value in the range (0,1]

Probability of success of any individual trial for the negative binomial distribution, specified as a positive scalar value in the range (0,1].

Data Types: `single` | `double`

Properties

R — Number of successes

positive scalar value

Number of successes for the negative binomial distribution, stored as a positive scalar value.

Data Types: `single` | `double`

p — Probability of success

positive scalar value in the range (0,1]

Probability of success of any individual trial for the negative binomial distribution, specified as a positive scalar value in the range (0,1].

Data Types: `single` | `double`

DistributionName — Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

Data Types: `char`

InputData — Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

This property is read-only.

Data Types: `struct`

IsTruncated — Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

Data Types: `single` | `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a p -by- p matrix, where p is the number of parameters in the distribution. The (i, j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i, i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i, i) elements of the covariance matrix are 0. This property is read-only.

Data Types: `single` | `double`

ParameterDescription — Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

Data Types: `char`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

Data Types: `logical`

ParameterNames — Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

Data Types: char

ParameterValues — Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

Data Types: single | double

Methods

Inherited Methods

<code>cdf</code>	Cumulative distribution function of probability distribution object
<code>icdf</code>	Inverse cumulative distribution function of probability distribution object
<code>iqr</code>	Interquartile range of probability distribution object
<code>median</code>	Median of probability distribution object
<code>pdf</code>	Probability density function of probability distribution object
<code>random</code>	Generate random numbers from probability distribution object
<code>truncate</code>	Truncate probability distribution object

mean	Mean of probability distribution object
negloglik	Negative log likelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

Definitions

Negative Binomial Distribution

The negative binomial distribution models the number of failures x before a specified number of successes is reached in a series of independent, identical trials. This distribution can also model count data, in which case r does not need to be an integer value.

The negative binomial distribution uses the following parameters.

Parameter	Description	Support
R	Number of successes	$r > 0$
p	Probability of success	$0 < p \leq 1$

The probability density function (pdf) when R is an integer is

$$f(x | R, p) = \binom{R+x-1}{x} p^R q^x \quad ; \quad x = 1, 2, \dots, \infty,$$

where $q = 1 - p$ and $\binom{R+x-1}{x}$ is the binomial coefficient.

When R is not an integer, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r+x)}{\Gamma(r)\Gamma(x+1)},$$

where $\Gamma(\cdot)$ is the Gamma function.

Examples

Create a Negative Binomial Distribution Object Using Default Parameters

Create a negative binomial distribution object using the default parameter values.

```
pd = makedist('NegativeBinomial')
```

```
pd =
```

```
NegativeBinomialDistribution
```

```
Negative Binomial distribution
```

```
R = 1
```

```
P = 0.5
```

Create a Negative Binomial Distribution Object Using Specified Parameters

Create a negative binomial distribution object by specifying the parameter values.

```
pd = makedist('NegativeBinomial', 'r', 5, 'p', .1)
```

```
pd =
```

```
NegativeBinomialDistribution
```

```
Negative Binomial distribution
```

```
R = 5
```

```
P = 0.1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

m =

45

More About

- “Negative Binomial Distribution” on page B-120
- Class Attributes
- Property Attributes

negloglik

Negative log likelihood of probability distribution

Syntax

```
nll = negloglik(pd)
```

Description

`nll = negloglik(pd)` returns the value of the negative loglikelihood function for the data used to fit the probability distribution `pd`.

Examples

Negative Log Likelihood for a Fitted Distribution

Load the sample data.

```
load carsmall
```

Create a Weibull distribution object by fitting it to the mile per gallon (MPG) data.

```
pd = fitdist(MPG, 'Weibull')
```

```
pd =
```

```
WeibullDistribution
```

```
Weibull distribution
```

```
A = 26.5079 [24.8333, 28.2954]
```

```
B = 3.27193 [2.79441, 3.83104]
```

Compute the negative log likelihood for the fitted Weibull distribution.

```
wnll = negloglik(pd)
```

```
wnll =  
    327.4942
```

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

Output Arguments

nll — Negative log likelihood

scalar value

Negative log likelihood value for the data used to fit the distribution, returned as a scalar value.

Introduced before R2006a

negloglik

Class: prob.KernelDistribution

Package: prob

Negative loglikelihood

Syntax

```
nll = negloglik(pd)
```

Description

`nll = negloglik(pd)` returns the value of the negative log likelihood function for the data used to fit the probability distribution `pd`.

Input Arguments

pd — **Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object. Fit a probability distribution object to data using `fitdist` or the Distribution Fitting app.

Output Arguments

nll — **Negative log likelihood**

scalar value

Negative log likelihood value for the data used to fit the distribution, returned as a scalar value.

Examples

Negative Loglikelihood for a Kernel Distribution

Load the sample data. Fit a kernel distribution to the miles per gallon (MPG) data.

```
load carsmall;  
pd = fitdist(MPG, 'Kernel')
```

```
pd =  
  
KernelDistribution  
  
Kernel = normal  
Bandwidth = 4.11428  
Support = unbounded
```

Compute the negative loglikelihood.

```
nll = negloglik(pd)  
  
nll =  
  
327.3139
```
