The software described in this document is furnished under a license agreement. The software may be used or copied only under the terms of the license agreement. No part of this manual may be photocopied or reproduced in any form without prior written consent from The MathWorks, Inc.
FEDERAL ACQUISITION: This provision applies to all acquisitions of the Program and Documentation by, for, or through the federal government of the United States. By accepting delivery of the Program or Documentation, the government hereby agrees that this software or documentation qualifies as commercial computer software or commercial computer software documentation as such terms are used or defined in FAR 12.212, DFARS Part 227.72, and DFARS 252.227-7014. Accordingly, the terms and conditions of this Agreement and only those rights specified in this Agreement, shall pertain to and govern the use, modification, reproduction, release, performance, display, and disclosure of the Program and Documentation by the federal government (or other entity acquiring for or through the federal government) and shall supersede any conflicting contractual terms or conditions. If this License fails to meet the government's needs or is inconsistent in any respect with federal procurement law, the government agrees to return the Program and Documentation, unused, to The MathWorks, Inc.

## Trademarks

MATLAB and Simulink are registered trademarks of The MathWorks, Inc. See www.mathworks.com/trademarks for a list of additional trademarks. Other product or brand names may be trademarks or registered trademarks of their respective holders.

## Patents

MathWorks products are protected by one or more U.S. patents. Please see www.mathworks.com/patents for more information.

## Revision History

| July 2004 | First printing | New for Version 1.0 (Release 14) |
| :--- | :--- | :--- |
| October 2004 | Second printing | Revised for Version 1.0.1 (Release 14SP1) |
| March 2005 | Online only | Revised for Version 1.1 (Release 14SP2) |
| September 2005 | Online only | Revised for Version 1.2 (Release 14SP3) |
| November 2005 | Online only | Revised for Version 2.0 (Release 14SP3+) |
| March 2006 | Online only | Revised for Version 2.1 (Release 2006a) |
| September 2006 | Online only | Revised for Version 2.2 (Release 2006b) |
| March 2007 | Online only | Revised for Version 2.3 (Release 2007a) |
| September 2007 | Online only | Revised for Version 2.4 (Release 2007b) |
| March 2008 | Online only | Revised for Version 2.5 (Release 2008a) |
| October 2008 | Online only | Revised for Version 2.6 (Release 2008b) |
| March 2009 | Online only | Revised for Version 2.7 (Release 2009a) |
| September 2009 | Online only | Revised for Version 2.8 (Release 2009b) |
| March 2010 | Online only | Revised for Version 3.0 (Release 2010a) |
| September 2010 | Online only | Revised for Version 3.1 (Release 2010b) |
| April 2011 | Online only | Revised for Version 4.0 (Release 2011a) |
| September 2011 | Online only | Revised for Version 4.1 (Release 2011b) |
| March 2012 | Online only | Revised for Version 5.0 (Release 2012a) |
| September 2012 | Online only | Online only |
| March 2013 | Revised for Version 5.1 (Release R2012b) |  |
| September 2013 | Online only | Revised for Version 5.2 (Release R2013a) |

## Point Cloud Registration Workflow

## Train a Convolutional Neural Network Using Data in ImageDatastore

Load the sample data as an ImageDatastore object.

```
digitDatasetPath = fullfile(matlabroot,'toolbox','nnet','nndemos',...
    'nndatasets','DigitDataset');
digitData = imageDatastore(digitDatasetPath,...
    'IncludeSubfolders',true,'LabelSource','foldernames');
```

The data store contains 10000 synthetic images of digits $0-9$. The images are generated by applying random transformations to digit images created using different fonts. Each digit image is 28 -by- 28 pixels.

Display some of the images in the datastore.

```
for i = 1:20
    subplot(4,5,i);
    imshow(digitData.Files{i});
end
```

Check the number of images in each digit category.
digitData.countEachLabel

| ans | $=$ |  |
| ---: | :--- | ---: |
| Label |  |  |
|  | Count |  |
|  |  |  |
|  |  | 988 |
| 2 |  | 1026 |
| 3 |  | 993 |

| 4 | 991 |
| ---: | ---: |
| 5 | 1017 |
| 6 | 992 |
| 7 | 999 |
| 8 | 1003 |
| 9 | 988 |

The data contains an unequal number of images per category.
To balance the number of images for each digit in the training set, first find the minimum number of images in a category.

```
minSetCount = min(digitData.countEachLabel{:,2})
minSetCount =
```

    988
    Divide the dataset so that each category in the training set has 494 images and the testing set has the remaining images from each label.

```
trainingNumFiles = round(minSetCount/2);
rng(1) % For reproducibility
[trainDigitData,testDigitData] = splitEachLabel(digitData,...
    trainingNumFiles,'randomize');
```

splitEachLabel splits the image files in digitData into two new datastores, trainDigitData and testDigitData.

Define the convolutional neural network architecture.

```
layers = [imageInputLayer([28 28 1]);
    convolution2dLayer(5,20);
    reluLayer();
    maxPooling2dLayer(2,'Stride',2);
    fullyConnectedLayer(10);
    softmaxLayer();
    classificationLayer()];
```

Set the options to default settings for the stochastic gradient descent with momentum. Set the maximum number of epochs at 20 , and start the training with an initial learning rate of 0.001.

```
options = trainingOptions('sgdm','MaxEpochs',20,...
    InitialLearnRate',0.001);
```

Train the network.
convnet $=$ trainNetwork(trainDigitData,layers,options);

| Epoch | Iteration | Time Elapsed (seconds) | Mini-batch Loss | Mini-batch Accuracy | Base Lear Rate |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2 | 50 | 0.72 | 0.2232 | 92.97\% | 0.001 |
| 3 | 100 | 1.37 | 0.0182 | 99.22\% | 0.001 |
| 4 | 150 | 1.99 | 0.0141 | 100.00\% | 0.001 |
| 6 | 200 | 2.64 | 0.0023 | 100.00\% | 0.001 |
| 7 | 250 | 3.27 | 0.0004 | 100.00\% | 0.001 |
| 8 | 300 | 3.91 | 0.0001 | 100.00\% | 0.001 |
| 10 | 350 | 4.56 | 0.0002 | 100.00\% | 0.001 |
| 11 | 400 | 5.19 | 0.0003 | 100.00\% | 0.001 |
| 12 | 450 | 5.82 | 0.0001 | 100.00\% | 0.001 |
| 14 | 500 | 6.46 | 0.0001 | 100.00\% | 0.001 |
| 15 | 550 | 7.09 | 0.0001 | 100.00\% | 0.001 |
| 16 | 600 | 7.72 | 0.0001 | 100.00\% | 0.001 |
| 18 | 650 | 8.37 | 0.0001 | 100.00\% | 0.001 |
| 19 | 700 | 9.00 | 0.0001 | 100.00\% | 0.001 |
| 20 | 750 | 9.62 | 0.0001 | 100.00\% | 0.001 |

Run the trained network on the test set that was not used to train the network and predict the image labels (digits).

```
YTest = classify(convnet,testDigitData);
TTest = testDigitData.Labels;
```

Calculate the accuracy.

```
accuracy = sum(YTest == TTest)/numel(TTest)
```

accuracy =
0.9984

Accuracy is the ratio of the number of true labels in the test data matching the classifications from classify, to the number of images in the test data. In this case about $99.8 \%$ of the digit estimations match the true digit values in the test set.

## Transfer Learning Using Convolutional Neural Networks

Fine-tune a convolutional neural network pretrained on digit images to learn the features of letter images. Transfer learning is considered as the transfer of knowledge from one learned task to a new task in machine learning [1]. In the context of neural networks, it is transferring learned features of a pretrained network to a new problem. Training a convolutional neural network from the beginning in each case usually is not effective when there is not sufficient amount of training data. The common practice in deep learning for such cases is to use a network that is trained on a large data set for a new problem. While the initial layers of the pretrained network can be fixed, the last few layers must be fine-tuned to learn the specific features of the new data set. Transfer learning usually results in faster training times than training a new convolutional neural network because you do not need to estimate all the parameters in the new network.

NOTE: Training a convolutional neural network requires Parallel Computing Toolbox ${ }^{\mathrm{TM}}$ and a CUDA®-enabled NVIDIA® GPU with compute capability 3.0 or higher.

Load the sample data as an ImageDatastore.

```
digitDatasetPath = fullfile(matlabroot,'toolbox','nnet','nndemos',...
    'nndatasets','DigitDataset');
digitData = imageDatastore(digitDatasetPath,...
    'IncludeSubfolders',true,'LabelSource','foldernames');
```

The data store contains 10000 synthetic images of digits $0-9$. The images are generated by applying random transformations to digit images created using different fonts. Each digit image is 28 -by- 28 pixels.

Display some of the images in the datastore.

```
for i = 1:20
    subplot(4,5,i);
    imshow(digitData.Files{i});
end
```

Check the number of images in each digit category.
digitData.countEachLabel

| ans | $=$ |  |
| ---: | :--- | ---: |
| Label |  |  |
|  |  |  |
|  |  |  |
|  |  | 988 |
| 1 |  | 1026 |
| 2 |  | 1003 |
| 3 |  | 993 |

| 4 | 991 |
| :--- | ---: |
| 5 | 1017 |
| 6 | 992 |
| 7 | 999 |
| 8 | 1003 |
| 9 | 988 |

The data contains an unequal number of images per category.
To balance the number of images for each digit in the training set, first find the minimum number of images in a category.

```
minSetCount = min(digitData.countEachLabel{:,2})
minSetCount =
```

    988
    Divide the dataset so that each category in the training set has 494 images and the testing set has the remaining images from each label.

```
trainingNumFiles = round(minSetCount/2);
rng(1) % For reproducibility
[trainDigitData,testDigitData] = splitEachLabel(digitData,...
    trainingNumFiles,'randomize');
```

splitEachLabel splits the image files in digitData into two new datastores, trainDigitData and testDigitData.

Create the layers for the convolutional neural network.
layers = [imageInputLayer([28 28 1])
convolution2dLayer (5,20)
reluLayer()
maxPooling2dLayer(2,'Stride',2)
fullyConnectedLayer(10)
softmaxLayer()
classificationLayer()];
Create the training options. Set the maximum number of epochs at 20, and start the training with an initial learning rate of 0.001 .

```
options = trainingOptions('sgdm','MaxEpochs',20,...
```

```
'InitialLearnRate',0.001);
```

Train the network using the training set and the options you defined in the previous step.

```
convnet = trainNetwork(trainDigitData,layers,options);
```

| Epoch | Iteration | Time Elapsed (seconds) | Mini-batch Loss | Mini-batch Accuracy | Base Lear Rate |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2 | 50 | 0.71 | 0.2233 | 92.97\% | 0.001 |
| 3 | 100 | 1.37 | 0.0182 | 99.22\% | 0.001 |
| 4 | 150 | 2.02 | 0.0395 | 99.22\% | 0.001 |
| 6 | 200 | 2.70 | 0.0105 | 99.22\% | 0.001 |
| 7 | 250 | 3.35 | 0.0026 | 100.00\% | 0.001 |
| 8 | 300 | 4.00 | 0.0004 | 100.00\% | 0.001 |
| 10 | 350 | 4.67 | 0.0002 | 100.00\% | 0.001 |
| 11 | 400 | 5.32 | 0.0001 | 100.00\% | 0.001 |
| 12 | 450 | 5.95 | 0.0001 | 100.00\% | 0.001 |
| 14 | 500 | 6.60 | 0.0002 | 100.00\% | 0.001 |
| 15 | 550 | 7.23 | 0.0001 | 100.00\% | 0.001 |
| 16 | 600 | 7.87 | 0.0001 | 100.00\% | 0.001 |
| 18 | 650 | 8.52 | 0.0001 | 100.00\% | 0.001 |
| 19 | 700 | 9.15 | 0.0001 | 100.00\% | 0.001 |
| 20 | 750 | 9.79 | 0.0000 | 100.00\% | 0.001 |

Test the network using the testing set and compute the accuracy.

```
YTest = classify(convnet,testDigitData);
TTest = testDigitData.Labels;
accuracy = sum(YTest == TTest)/numel(YTest)
accuracy =
    0.9976
```

Accuracy is the ratio of the number of true labels in the test data matching the classifications from classify, to the number of images in the test data. In this case $99.78 \%$ of the digit estimations match the true digit values in the test set.

Now, suppose you would like to use the trained network net to predict classes on a new set of data. Load the letters training data.

## load lettersTrainSet.mat

XTrain contains 1500 28-by-28 grayscale images of the letters $\mathrm{A}, \mathrm{B}$, and C in a 4-D array. TTrain contains the categorical array of the letter labels.

Display some of the letter images.

```
figure;
for j = 1:20
    subplot(4,5,j);
    selectImage = datasample(XTrain,1,4);
    imshow(selectImage,[]);
end
```

The pixel values in XTrain are in the range [0 1]. The digit data used in training the network net were in [0 255]; scale the letters data between [0 255].

```
XTrain = XTrain*255;
```

The last three layers of the trained network net are tuned for the digit dataset, which has 10 classes. The properties of these layers depend on the classification task. Display the fully connected layer (fullyConnectedLayer).

```
convnet.Layers(end-2)
```

ans =
FullyConnectedLayer with properties:
Name: 'fc'
Hyperparameters
InputSize: 2880
OutputSize: 10
Learnable Parameters
Weights: [10×2880 single]
Bias: [10×1 single]
Use properties method to see a list of all properties.
Display the last layer (classificationLayer).
convnet.Layers(end)
ans $=$
ClassificationOutputLayer with properties:
Name: 'classoutput'
ClassNames: $\{10 \times 1$ cell\}
OutputSize: 10
Hyperparameters
LossFunction: 'crossentropyex'

These three layers must be fine-tuned for the new classification problem. Extract all the layers but the last three from the trained network, net.

```
layersTransfer = convnet.Layers(1:end-3);
```

The letters data set has three classes. Add a new fully connected layer for three classes, and increase the learning rate for this layer.

```
layersTransfer(end+1) = fullyConnectedLayer(3,...
    'WeightLearnRateFactor',10,...
    'BiasLearnRateFactor',20);
```

WeightLearnRateFactor and BiasLearnRateFactor are multipliers of the global learning rate for the fully connected layer.

Add a softmax layer and a classification output layer.

```
layersTransfer(end+1) = softmaxLayer();
layersTransfer(end+1) = classificationLayer();
```

Create the options for transfer learning. You do not have to train for many epochs (MaxEpochs can be lower than before). Set the InitialLearnRate at a lower rate than used for training net to improve convergence by taking smaller steps.

```
optionsTransfer = trainingOptions('sgdm',...
    'MaxEpochs',5,...
    'InitialLearnRate',0.000005,...
    'Verbose',true);
```

Perform transfer learning.

```
convnetTransfer = trainNetwork(XTrain,TTrain,...
```

    layersTransfer,optionsTransfer);
    

Load the letters test data. Similar to the letters training data, scale the testing data between [0 255], because the training data were between that range.

```
load lettersTestSet.mat
```

```
XTest = XTest*255;
```

Test the accuracy.

```
YTest = classify(convnetTransfer,XTest);
accuracy = sum(YTest == TTest)/numel(TTest)
accuracy =
    0.9587
```

## Extract Features from Trained Convolutional Neural Network

NOTE: Training a convolutional neural network requires Parallel Computing Toolbox ${ }^{\text {TM }}$ and a CUDA®-enabled NVIDIA® GPU with compute capability 3.0 or higher.

Load the sample data.

```
[XTrain,TTrain] = digitTrain4DArrayData;
```

digitTrain4DArrayData loads the digit training set as 4-D array data. XTrain is a 28 -by- 28 -by-1-by- 4940 array, where 28 is the height and 28 is the width of the images. 1 is the number of channels and 4940 is the number of synthetic images of handwritten digits. TTrain is a categorical vector containing the labels for each observation.

Construct the convolutional neural network architecture.

```
layers = [imageInputLayer([28 28 1]);
    convolution2dLayer(5,20);
    reluLayer();
    maxPooling2dLayer(2,'Stride',2);
    fullyConnectedLayer(10);
    softmaxLayer();
    classificationLayer()];
```

Set the options to default settings for the stochastic gradient descent with momentum.

```
options = trainingOptions('sgdm');
```

Train the network.

```
rng('default')
net = trainNetwork(XTrain,TTrain,layers,options);
```

| Epoch | Iteration | Time Elapsed (seconds) | Mini-batch Loss | Mini-batch Accuracy | Base Lear Rate |
| :---: | :---: | :---: | :---: | :---: | :---: |

| 28 | 1050 | 9.07 | 0.0260 | 100.00\% | 0.010 |
| 29 | 1100 | 9.49 | 0.0246 | 100.00\% | 0.010 |

Make predictions, but rather than taking the output from the last layer, specify the second ReLU layer (the sixth layer) as the output layer.

```
trainFeatures = activations(net,XTrain,6);
```

These predictions from an inner layer are known as activations or features . activations method, by default, uses a CUDA-enabled GPU with compute ccapability 3.0, when available. You can also choose to run activations on a CPU using the 'ExecutionEnvironment', 'cpu' name-value pair argument.

You can use the returned features to train a support vector machine using the Statistics and Machine Learning Toolbox ${ }^{\mathrm{TM}}$ function fitcecoc.

```
svm = fitcecoc(trainFeatures,TTrain);
```

Load the test data.

```
[XTest,TTest]= digitTest4DArrayData;
```

Extract the features from the same ReLU layer (the sixth layer) for test data and use the returned features to train a support vector machine.

```
testFeatures = activations(net,XTest,6);
testPredictions = predict(svm,testFeatures);
```

Plot the confusion matrix. Convert the data into the format plotconfusion accepts

```
ttest = dummyvar(double(TTest))'; % dummyvar requires Statistics and Machine Learning
```

```
tpredictions = dummyvar(double(testPredictions))';
plotconfusion(ttest,tpredictions);
```

Confusion Matrix

The overall accuracy for the test data using the trained network net is $99.4 \%$.
Manually compute the overall accuracy.

```
accuracy = sum(TTest == testPredictions)/numel(TTest)
```

accuracy =
0.9937

## Read and Play a Video File

Load the video using a video reader object.

```
videoFReader = vision.VideoFileReader('ecolicells.avi');
```

Create a video player object to play the video file.
videoPlayer = vision.VideoPlayer;
Use a while loop to read and play the video frames.

```
while ~isDone(videoFReader)
    videoFrame = videoFReader();
    videoPlayer(videoFrame);
end
```

Release the objects.
release(videoPlayer);
release(videoFReader);

## Find Vertical and Horizontal Edges in Image

Construct Haar-like wavelet filters to find vertical and horizontal edges in an image.
Read the input image and compute the integral image.

```
I = imread('pout.tif');
intImage = integralImage(I);
```

Construct Haar-like wavelet filters. Use the dot notation to find the vertical filter from the horizontal filter.

```
horiH = integralKernel([1 1 4 3; 1 4 4 3],[-1, 1]);
vertH = horiH.
vertH =
    integralKernel with properties:
    BoundingBoxes: [2\times4 double]
            Weights: [-1 1]
        Coefficients: [4×6 double]
            Center: [2 3]
            Size: [4 6]
        Orientation: 'upright
```

Display the horizontal filter.
imtool(horiH.Coefficients, 'InitialMagnification','fit');

Image Tool 1 - (MATLAB Expression) $\square$
83

```
File Tools Window Help

Pixel info: \((X, Y)\) Intensity
Display range: [01]

Compute the filter responses.
```

horiResponse = integralFilter(intImage,horiH);
vertResponse = integralFilter(intImage,vertH);

```

Display the results.
figure;
imshow(horiResponse,[]);
title('Horizontal edge responses'); figure;
imshow(vertResponse,[]);
title('Vertical edge responses');

\section*{Horizontal edge responses}

\section*{Vertical edge responses}

\section*{Blur an Image Using an Average Filter}

Read and display the input image.
I = imread('pout.tif');
imshow(I);

Compute the integral image.
intImage = integralImage(I);
Apply a 7 -by- 7 average filter.
avgH = integralKernel([11 177\(]\), 1/49);
\(J\) = integralFilter(intImage, avgH);
Cast the result back to the same class as the input image.
```

J = uint8(J);
figure
imshow(J);

```

\section*{Define a Filter to Approximate a Gaussian Second Order Partial Derivative in Y Direction}
```

ydH = integralKernel([1,1,5,9;1,4,5,3], [1, -3]);

```

You can also define this filter as integralKernel([1,1,5,3;1,4,5,3;1,7,5,3], [1, \(-2,1]\) ); |. This filter definition is less efficient because it requires three bounding boxes.

Visualize the filter.
ydH.Coefficients
ans =
\begin{tabular}{rrrrr}

\end{tabular}

\section*{Find Corresponding Interest Points Between Pair of Images}

Find corresponding interest points between a pair of images using local neighbhorhoods and the Harris algorithm.

Read the stereo images.
```

I1 = rgb2gray(imread('viprectification_deskLeft.png'));
I2 = rgb2gray(imread('viprectification_deskRight.png'));

```

Find the corners.
```

points1 = detectHarrisFeatures(I1);
points2 = detectHarrisFeatures(I2);

```

Extract the neighborhood features.
```

[features1,valid_points1] = extractFeatures(I1,points1);

```
[features2,valid_points2] = extractFeatures(I2,points2);

Match the features.
```

indexPairs = matchFeatures(features1,features2);

```

Retrieve the locations of the corresponding points for each image.
```

matchedPoints1 = valid_points1(indexPairs(:,1),:);
matchedPoints2 = valid_points2(indexPairs(:,2),:);

```

Visualize the corresponding points. You can see the effect of translation between the two images despite several erroneous matches.
figure; showMatchedFeatures(I1,I2,matchedPoints1,matchedPoints2);

\section*{Find Corresponding Points Using SURF Features}

Use the SURF local feature detector function to find the corresponding points between two images that are rotated and scaled with respect to each other.

Read the two images.
```

I1 = imread('cameraman.tif');
I2 = imresize(imrotate(I1,-20),1.2);

```

Find the SURF features.
```

points1 = detectSURFFeatures(I1);
points2 = detectSURFFeatures(I2);

```

Extract the features.
```

[f1,vpts1] = extractFeatures(I1,points1);
[f2,vpts2] = extractFeatures(I2,points2);

```

Retrieve the locations of matched points.
```

indexPairs = matchFeatures(f1,f2) ;
matchedPoints1 = vpts1(indexPairs(:,1));
matchedPoints2 = vpts2(indexPairs(:,2));

```

Display the matching points. The data still includes several outliers, but you can see the effects of rotation and scaling on the display of matched features.
```

figure; showMatchedFeatures(I1,I2,matchedPoints1,matchedPoints2);
legend('matched points 1','matched points 2');

```

\section*{Detect SURF Interest Points in a Grayscale Image}

Read image and detect interest points.
```

I = imread('cameraman.tif');
points = detectSURFFeatures(I);

```

Display locations of interest in image.
```

imshow(I); hold on;
plot(points.selectStrongest(10));

```

\section*{Using LBP Features to Differentiate Images by Texture}

Read images that contain different textures.
```

brickWall = imread('bricks.jpg');
rotatedBrickWall = imread('bricksRotated.jpg');
carpet = imread('carpet.jpg');

```

Display the images.
figure
imshow(brickWall)
title('Bricks')
figure
imshow(rotatedBrickWall)
title('Rotated Bricks')
figure
imshow(carpet)
title('Carpet')

\section*{Rotated Bricks}

Extract LBP features from the images to encode their texture information.
```

lbpBricks1 = extractLBPFeatures(brickWall,'Upright',false);
lbpBricks2 = extractLBPFeatures(rotatedBrickWall,'Upright',false);
lbpCarpet = extractLBPFeatures(carpet,'Upright',false);

```

Gauge the similarity between the LBP features by computing the squared error between them.
```

brickVsBrick = (lbpBricks1 - lbpBricks2).^2;
brickVsCarpet = (lbpBricks1 - lbpCarpet).^2;

```

Visualize the squared error to compare bricks versus bricks and bricks versus carpet. The squared error is smaller when images have similar texture.
```

figure
bar([brickVsBrick; brickVsCarpet]','grouped')
title('Squared Error of LBP Histograms')
xlabel('LBP Histogram Bins')
legend('Bricks vs Rotated Bricks','Bricks vs Carpet')

```

\section*{Extract and Plot HOG Features}

Read the image of interest.
img \(=\) imread('cameraman.tif');
Extract HOG features.
[featureVector,hogVisualization] = extractHOGFeatures(img);
Plot HOG features over the original image.
```

figure;
imshow(img);
hold on;
plot(hogVisualization);

```

\section*{Find Corresponding Interest Points Between Pair of Images}

Find corresponding interest points between a pair of images using local neighbhorhoods and the Harris algorithm.

Read the stereo images.
```

I1 = rgb2gray(imread('viprectification_deskLeft.png'));
I2 = rgb2gray(imread('viprectification_deskRight.png'));

```

Find the corners.
```

points1 = detectHarrisFeatures(I1);
points2 = detectHarrisFeatures(I2);

```

Extract the neighborhood features
```

[features1,valid_points1] = extractFeatures(I1,points1);
[features2,valid_points2] = extractFeatures(I2,points2);

```

Match the features.
```

indexPairs = matchFeatures(features1,features2);

```

Retrieve the locations of the corresponding points for each image.
```

matchedPoints1 = valid_points1(indexPairs(:,1),:);
matchedPoints2 = valid_points2(indexPairs(:,2),:);

```

Visualize the corresponding points. You can see the effect of translation between the two images despite several erroneous matches.
figure; showMatchedFeatures(I1,I2,matchedPoints1,matchedPoints2);

\section*{Recognize Text Within an Image}
```

    businessCard = imread('businessCard.png');
    ocrResults = ocr(businessCard)
    recognizedText = ocrResults.Text;
    figure;
    imshow(businessCard);
    text(600, 150, recognizedText, 'BackgroundColor', [1 1 1]);
    ocrResults =
ocrText with properties:
Text: '‘ MathWorks®...

figure, imshow(I2);
title('Detected people and detection scores after suppression');

```

Detected people and detection scores before suppression

Detected people and detection scores after suppression

\section*{Train Stop Sign Detector}

Load the positive samples data from a MAT file. The file contains a table specifying bounding boxes for several object categories. The table was exported from the Training Image Labeler app.

Load positive samples.
```

load('stopSignsAndCars.mat');

```

Select the bounding boxes for stop signs from the table.
```

positiveInstances = stopSignsAndCars(:,1:2);

```

Add the image directory to the MATLAB path.
```

imDir = fullfile(matlabroot,'toolbox','vision','visiondata',...
'stopSignImages');
addpath(imDir);

```

Specify the foler for negative images.
```

negativeFolder = fullfile(matlabroot,'toolbox','vision','visiondata',...
'nonStopSigns');

```

Create an imageDatastore object containing negative images.
```

negativeImages = imageDatastore(negativeFolder);

```

Train a cascade object detector called 'stopSignDetector.xml' using HOG features. NOTE: The command can take several minutes to run.
trainCascadeObjectDetector('stopSignDetector.xml',positiveInstances, ...
    negativeFolder, 'FalseAlarmRate', 0.1,'NumCascadeStages',5);
```

Time to train stage 5: 15 seconds
Training complete
Use the newly trained classifier to detect a stop sign in an image.
detector $=$ vision.CascadeObjectDetector('stopSignDetector.xml');
Read the test image.

```
```

img = imread('stopSignTest.jpg');

```
img = imread('stopSignTest.jpg');
Detect a stop sign.
```

```
bbox = step(detector,img);
```

bbox = step(detector,img);
Insert bounding box rectangles and return the marked image.

```
```

detectedImg = insertObjectAnnotation(img,'rectangle',bbox,'stop sign');

```
detectedImg = insertObjectAnnotation(img,'rectangle',bbox,'stop sign');
Display the detected stop sign.
```

```
figure; imshow(detectedImg);
```

```
figure; imshow(detectedImg);
```

Remove the image directory from the path.
rmpath(imDir);

## Track an Occluded Object

Detect and track a ball using Kalman filtering, foreground detection, and blob analysis.
Create System objects to read the video frames, detect foreground physical objects, and display results.

```
videoReader = vision.VideoFileReader('singleball.mp4');
videoPlayer = vision.VideoPlayer('Position',[100,100,500,400]);
foregroundDetector = vision.ForegroundDetector('NumTrainingFrames',10,...
    'InitialVariance',0.05);
blobAnalyzer = vision.BlobAnalysis('AreaOutputPort',false,...
    'MinimumBlobArea',70);
```

Process each video frame to detect and track the ball. After reading the current video frame, the example searches for the ball by using background subtraction and blob analysis. When the ball is first detected, the example creates a Kalman filter. The Kalman filter determines the ball's location, whether it is detected or not. If the ball is detected, the Kalman filter first predicts its state at the current video frame. The filter then uses the newly detected location to correct the state, producing a filtered location. If the ball is missing, the Kalman filter solely relies on its previous state to predict the ball's current location.

```
kalmanFilter = []; isTrackInitialized = false;
    while ~isDone(videoReader)
        colorImage = step(videoReader);
        foregroundMask = step(foregroundDetector, rgb2gray(colorImage));
        detectedLocation = step(blobAnalyzer,foregroundMask);
        isObjectDetected = size(detectedLocation, 1) > 0;
    if ~isTrackInitialized
        if isObjectDetected
            kalmanFilter = configureKalmanFilter('ConstantAcceleration', ...
                    detectedLocation(1,:), [1 1 1]*1e5, [25, 10, 10], 25);
                isTrackInitialized = true;
            end
            label = ''; circle = zeros(0,3);
    else
            if isObjectDetected
                predict(kalmanFilter);
                trackedLocation = correct(kalmanFilter, detectedLocation(1,:));
                label = 'Corrected';
            else
```

```
                trackedLocation = predict(kalmanFilter);
                label = 'Predicted';
            end
            circle = [trackedLocation, 5];
        end
        colorImage = insertObjectAnnotation(colorImage,'circle',...
                        circle,label,'Color','red');
        step(videoPlayer,colorImage);
end
```

Release resources.
release(videoPlayer);
release(videoReader);

## Track a Face

Create System objects for reading and displaying video and for drawing a bounding box of the object.

```
videoFileReader = vision.VideoFileReader('visionface.avi');
videoPlayer = vision.VideoPlayer('Position', [100, 100, 680, 520]);
```

Read the first video frame, which contains the object, define the region.

```
objectFrame = step(videoFileReader);
```

objectRegion = [264, 122, 93, 93];

As an alternative, you can use the following commands to select the object region using a mouse. The object must occupy the majority of the region. figure; imshow(objectFrame); objectRegion=round(getPosition(imrect))

Show initial frame with a red bounding box.
objectImage = insertShape(objectFrame, 'Rectangle', objectRegion,'Color', 'red'); figure; imshow(objectImage); title('Red box shows object region');

Red box shows object region

Detect interest points in the object region.

```
points = detectMinEigenFeatures(rgb2gray(objectFrame), 'ROI', objectRegion);
```

Display the detected points.
pointImage = insertMarker(objectFrame, points.Location, '+', 'Color', 'white'); figure, imshow(pointImage), title('Detected interest points');

Detected interest points

Create a tracker object.
tracker = vision.PointTracker('MaxBidirectionalError', 1);
Initialize the tracker.
initialize(tracker, points.Location, objectFrame);
Read, track, display points, and results in each video frame.

```
while ~isDone(videoFileReader)
    frame = step(videoFileReader);
    [points, validity] = step(tracker, frame);
```

out = insertMarker(frame, points(validity, :), '+'); step(videoPlayer, out);
end

Release the video reader and player.
release(videoPlayer);
release(videoFileReader);

## Assign Detections to Tracks in a Single Video Frame

This example shows you how to assign a detection to a track for a single video frame.
Set the predicted locations of objects in the current frame. Obtain predictions using the Kalman filter System object.

```
predictions = [1,1;2,2];
```

Set the locations of the objects detected in the current frame. For this example, there are 2 tracks and 3 new detections. Thus, at least one of the detections is unmatched, which can indicate a new track.

```
detections = [1.1,1.1;2.1,2.1;1.5,3];
```

Preallocate a cost matrix.

```
cost = zeros(size(predictions,1),size(detections,1));
```

Compute the cost of each prediction matching a detection. The cost here, is defined as the Euclidean distance between the prediction and the detection.

```
for i = 1:size(predictions, 1)
    diff = detections - repmat(predictions(i,:),[size(detections,1),1]);
    cost(i, :) = sqrt(sum(diff .^ 2,2));
end
```

Associate detections with predictions. Detection 1 should match to track 1, and detection 2 should match to track 2 . Detection 3 should be unmatched.

```
[assignment,unassignedTracks,unassignedDetections] = ...
            assignDetectionsToTracks(cost,0.2);
        figure;
        plot(predictions(:,1),predictions(:,2),'*', detections(:,1),...
            detections(:,2),'ro');
        hold on;
        legend('predictions','detections');
        for i = 1:size(assignment,1)
            text(predictions(assignment(i, 1),1)+0.1,\ldots
                        predictions(assignment(i,1),2)-0.1,num2str(i));
            text(detections(assignment(i, 2),1)+0.1,\ldots
                        detections(assignment(i, 2),2)-0.1,num2str(i));
        end
        for i = 1:length(unassignedDetections)
```

```
            text(detections(unassignedDetections(i),1)+0.1,\ldots.
                detections(unassignedDetections(i),2)+0.1,'unassigned');
        end
        xlim([0,4]);
        ylim([0,4]);
```

## Create 3-D Stereo Display

Load parameters for a calibrated stereo pair of cameras.
load('webcamsSceneReconstruction.mat')
Load a stereo pair of images.
I1 = imread('sceneReconstructionLeft.jpg');
I2 $=$ imread('sceneReconstructionRight.jpg');
Rectify the stereo images.
[J1, J2] = rectifyStereoImages(I1, I2, stereoParams);
Create the anaglyph.
A = stereoAnaglyph(J1, J2);
Display the anaglyph. Use red-blue stereo glasses to see the stereo effect.
figure; imshow(A);

## Measure Distance from Stereo Camera to a Face

Load stereo parameters.
load('webcamsSceneReconstruction.mat');
Read in the stereo pair of images.

```
I1 = imread('sceneReconstructionLeft.jpg');
I2 = imread('sceneReconstructionRight.jpg');
```

Undistort the images.

```
I1 = undistortImage(I1,stereoParams.CameraParameters1);
```

I2 = undistortImage(I2,stereoParams.CameraParameters2);

Detect a face in both images.

```
faceDetector = vision.CascadeObjectDetector;
face1 = faceDetector(I1);
face2 = faceDetector(I2);
```

Find the center of the face.

```
center1 = face1(1:2) + face1(3:4)/2;
center2 = face2(1:2) + face2(3:4)/2;
```

Compute the distance from camera 1 to the face.

```
point3d = triangulate(center1, center2, stereoParams);
distanceInMeters = norm(point3d)/1000;
```

Display the detected face and distance.

```
distanceAsString = sprintf('%0.2f meters', distanceInMeters);
I1 = insertObjectAnnotation(I1,'rectangle',face1,distanceAsString,'FontSize',18);
I2 = insertObjectAnnotation(I2,'rectangle',face2, distanceAsString,'FontSize',18);
I1 = insertShape(I1,'FilledRectangle',face1);
I2 = insertShape(I2,'FilledRectangle',face2);
imshowpair(I1, I2, 'montage');
```

## Reconstruct 3-D Scene from Disparity Map

Load the stereo parameters.
load('webcamsSceneReconstruction.mat');
Read in the stereo pair of images.
I1 = imread('sceneReconstructionLeft.jpg');
I2 = imread('sceneReconstructionRight.jpg');
Rectify the images.

```
[J1, J2] = rectifyStereoImages(I1,I2,stereoParams);
```

Display the images after rectification.
figure
imshow(cat(3,J1(:,:,1), J2(:,:,2:3)),'InitialMagnification',50);

Compute the disparity.

```
disparityMap = disparity(rgb2gray(J1), rgb2gray(J2));
figure
imshow(disparityMap,[0,64],'InitialMagnification',50);
```

Reconstruct the 3-D world coordinates of points corresponding to each pixel from the disparity map.

```
xyzPoints = reconstructScene(disparityMap,stereoParams);
```

Segment out a person located between 3.2 and 3.7 meters away from the camera.

```
Z = xyzPoints(:,:,3);
mask = repmat(Z > 3200 & Z < 3700,[1,1,3]);
J1(~mask) = 0;
imshow(J1,'InitialMagnification',50);
```

## Visualize Stereo Pair of Camera Extrinsic Parameters

```
Specify calibration images.
```

```
numImages = 10;
```

numImages = 10;
images1 = cell(1,numImages);
images1 = cell(1,numImages);
images2 = cell(1,numImages);
images2 = cell(1,numImages);
for i = 1:numImages
for i = 1:numImages
images1{i} = fullfile(matlabroot,'toolbox','vision',...
images1{i} = fullfile(matlabroot,'toolbox','vision',...
'visiondata','calibration','stereo',...
'visiondata','calibration','stereo',...
'left',sprintf('left%02d.png',i));
'left',sprintf('left%02d.png',i));
images2{i} = fullfile(matlabroot,'toolbox','vision',...
images2{i} = fullfile(matlabroot,'toolbox','vision',...
'visiondata','calibration','stereo',...
'visiondata','calibration','stereo',...
'right',sprintf('right%02d.png',i));
'right',sprintf('right%02d.png',i));
end

```
end
```

Detect the checkerboards.

```
[imagePoints,boardSize] = detectCheckerboardPoints(images1,images2);
```

Specify world coordinates of checkerboard keypoints, (squares are in mm).

```
squareSize = 108;
worldPoints = generateCheckerboardPoints(boardSize,squareSize);
```

Calibrate the stereo camera system.

```
cameraParams = estimateCameraParameters(imagePoints,worldPoints);
```

Visualize pattern locations.

```
figure;
showExtrinsics(cameraParams);
```

Visualize camera locations.
figure; showExtrinsics(cameraParams,'patternCentric');

## Extrinsic Parameters Visualization

## Read Point Cloud from a PLY File

```
ptCloud = pcread('teapot.ply');
pcshow(ptCloud);
```

## Write 3-D Point Cloud to PLY File

```
ptCloud = pcread('teapot.ply');
pcshow(ptCloud);
pcwrite(ptCloud,'teapotOut','PLYFormat','binary');
```

## Visualize the Difference Between Two Point Clouds

Load two point clouds that were captured using a Kinect device in a home setting.

```
load('livingRoom');
pc1 = livingRoomData{1};
pc2 = livingRoomData{2};
```

Plot and set the viewpoint of point clouds.

```
figure
pcshowpair(pc1,pc2,'VerticalAxis','Y','VerticalAxisDir','Down')
title('Difference Between Two Point Clouds')
xlabel('X(m)')
ylabel('Y(m)')
zlabel('Z(m)')
```

Difference Between Two Point Clouds

## View Rotating 3-D Point Cloud

Load point cloud.

```
ptCloud = pcread('teapot.ply');
```

Define a rotation matrix and 3-D transform.

```
x = pi/180;
R = [ cos(x) sin(x) 0 0
    -sin(x) cos(x) 0 0
        0 0 1 0
        0 0 0 1];
tform = affine3d(R);
```

Compute $x--y_{-}$limits that ensure that the rotated teapot is not clipped.

```
lower = min([ptCloud.XLimits ptCloud.YLimits]);
upper = max([ptCloud.XLimits ptCloud.YLimits]);
xlimits = [lower upper];
ylimits = [lower upper];
zlimits = ptCloud.ZLimits;
```

Create the player and customize player axis labels.

```
player = pcplayer(xlimits,ylimits,zlimits);
xlabel(player.Axes,'X (m)');
ylabel(player.Axes,'Y (m)');
zlabel(player.Axes,'Z (m)');
```

Figure 1: Point Cloud Player $\square$
File Edit View Insert Tools Desktop Window Help

Rotate the teapot around the $z$-axis.

```
for i = 1:360
    ptCloud = pctransform(ptCloud,tform);
    view(player,ptCloud);
end
```

## Hide and Show 3-D Point Cloud Figure

Load point cloud.
ptCloud = pcread('teapot.ply');
Create the player and customize player axis labels.
player = pcplayer(ptCloud.XLimits,ptCloud.YLimits,ptCloud.ZLimits);

Hide figure.
hide(player)
Show figure.
show(player)
view(player, ptCloud) ;

## Align Two Point Clouds

Load point cloud data.

```
ptCloud = pcread('teapot.ply');
figure
pcshow(ptCloud);
title('Teapot');
```

Create a transform object with 30 degree rotation along $z$-axis and translation [5,5,10].

```
A = [cos(pi/6) sin(pi/6) 0 0; ...
    -sin(pi/6)
```

```
    5 5 10 1];
tform1 = affine3d(A);
```

Transform the point cloud.
ptCloudTformed = pctransform(ptCloud,tform1);
figure
pcshow(ptCloudTformed);
title('Transformed Teapot');

Transformed Teapot

Apply the rigid registration.
tform = pcregrigid(ptCloudTformed,ptCloud,'Extrapolate',true);

Compare the result with the true transformation.

```
disp(tform1.T);
tform2 = invert(tform);
disp(tform2.T);
\begin{tabular}{rrrr}
0.8660 & 0.5000 & 0 & 0 \\
-0.5000 & 0.8660 & 0 & 0 \\
0 & 0 & 1.0000 & 0 \\
5.0000 & 5.0000 & 10.0000 & 1.0000 \\
& & & \\
0.8660 & 0.5000 & 0.0000 & 0 \\
-0.5000 & 0.8660 & 0.0000 & 0 \\
0.0000 & -0.0000 & 1.0000 & 0 \\
5.0000 & 5.0000 & 10.0000 & 1.0000
\end{tabular}
```

## Rotate 3-D Point Cloud

Read a point cloud.

```
ptCloud = pcread('teapot.ply');
```

Plot the original data.

```
figure
pcshow(ptCloud);
xlabel('X');
ylabel('Y');
zlabel('Z');
```

Create a transform object with a 45 degrees rotation along the $z$-axis.

```
A = [cos(pi/4) sin(pi/4) 0 0; ...
    -sin(pi/4) cos(pi/4) 0 0; ...
    0 0 1 0; ...
    O O O 1];
tform = affine3d(A);
```

Transform the point cloud.

```
ptCloudOut = pctransform(ptCloud,tform);
```

Plot the transformed point cloud.

```
figure
pcshow(ptCloudOut);
xlabel('X');
ylabel('Y');
zlabel('Z');
```

## Merge Two Identical Point Clouds Using Box Grid Filter

Create two identical point clouds.
ptCloudA $=$ pointCloud(100*rand(1000,3));
ptCloudB $=\operatorname{copy}(p t C l o u d A) ;$
Merge the two point clouds.

```
ptCloud = pcmerge(ptCloudA,ptCloudB,1);
pcshow(ptCloud);
```

## Extract Cylinder from Point Cloud

Load the point cloud.

```
load('object3d.mat');
```

Display the point cloud.

```
figure
pcshow(ptCloud)
xlabel('X(m)')
ylabel('Y(m)')
zlabel('Z(m)')
title('Original Point Cloud')
```

## Original Point Cloud

Set the maximum point-to-cylinder distance ( 5 mm ) for cylinder fitting.

```
maxDistance = 0.005;
```

Set the region of interest to constrain the search.

```
roi = [0.4,0.6,-inf,0.2,0.1,inf];
sampleIndices = findPointsInROI(ptCloud,roi);
```

Set the orientation constraint.
referenceVector $=[0,0,1]$;
Detect the cylinder and extract it from the point cloud by specifying the inlier points.
[model,inlierIndices] = pcfitcylinder(ptCloud,maxDistance,... referenceVector,'SampleIndices', sampleIndices);
pc = select(ptCloud,inlierIndices);
Plot the extracted cylinder.

## figure

pcshow(pc)
title('Cylinder Point Cloud')

## Cylinder Point Cloud

## Detect Multiple Planes from Point Cloud

Load the point cloud.

```
load('object3d.mat')
```

Display and label the point cloud.

```
figure
pcshow(ptCloud)
xlabel('X(m)')
ylabel('Y(m)')
zlabel('Z(m)')
title('Original Point Cloud')
```

## Original Point Cloud

Set the maximum point-to-plane distance $(2 \mathrm{~cm})$ for plane fitting.

```
maxDistance = 0.02;
```

Set the normal vector of the plane.

```
referenceVector = [0,0,1];
```

Set the maximum angular distance to 5 degrees.

```
maxAngularDistance = 5;
```

Detect the first plane, the table, and extract it from the point cloud.

```
[model1,inlierIndices,outlierIndices] = pcfitplane(ptCloud,...
    maxDistance,referenceVector,maxAngularDistance);
plane1 = select(ptCloud,inlierIndices);
remainPtCloud = select(ptCloud,outlierIndices);
```

Set the region of interest to constrain the search for the second plane, left wall.

```
roi = [-inf,inf;0.4,inf;-inf,inf];
sampleIndices = findPointsInROI(remainPtCloud,roi);
```

Detect the left wall and extract it from the remaining point cloud.

```
[model2,inlierIndices,outlierIndices] = pcfitplane(remainPtCloud,...
    maxDistance,'SampleIndices',sampleIndices);
plane2 = select(remainPtCloud,inlierIndices);
remainPtCloud = select(remainPtCloud,outlierIndices);
```

Plot the two planes and the remaining points.

## Remove Outliers from Noisy Point Cloud

Create a plane point cloud.

```
gv = 0:0.01:1;
[X,Y] = meshgrid(gv,gv);
ptCloud = pointCloud([X(:),Y(:),0.5*ones(numel(X),1)]);
figure
pcshow(ptCloud);
title('Original Data');
```

Add uniformly distributed random noise.

```
noise = rand(500, 3);
ptCloudA = pointCloud([ptCloud.Location; noise]);
figure
pcshow(ptCloudA);
title('Noisy Data');
```

Remove outliers.
ptCloudB = pcdenoise(ptCloudA);
figure;
pcshow(ptCloudB);
title('Denoised Data');

Denoised Data

## Downsample Point Cloud Using Box Grid Filter

Read a point cloud.

```
ptCloud = pcread('teapot.ply');
```

Set the 3-D resolution to be ( $0.1 \times 0.1 \times 0.1$ ).

```
gridStep = 0.1;
ptCloudA = pcdownsample(ptCloud,'gridAverage',gridStep);
```

Visualize the downsampled data.

## figure;

pcshow(ptCloudA);

Compare the point cloud to data that is downsampled using a fixed step size.

```
stepSize = floor(ptCloud.Count/ptCloudA.Count);
indices = 1:stepSize:ptCloud.Count;
ptCloudB = select(ptCloud, indices);
figure;
pcshow(ptCloudB);
```

## Measure Distance from Stereo Camera to a Face

Load stereo parameters.
load('webcamsSceneReconstruction.mat');
Read in the stereo pair of images.

```
I1 = imread('sceneReconstructionLeft.jpg');
I2 = imread('sceneReconstructionRight.jpg');
```

Undistort the images.

```
I1 = undistortImage(I1,stereoParams.CameraParameters1);
```

I2 = undistortImage(I2,stereoParams.CameraParameters2);

Detect a face in both images.

```
faceDetector = vision.CascadeObjectDetector;
face1 = faceDetector(I1);
face2 = faceDetector(I2);
```

Find the center of the face.

```
center1 = face1(1:2) + face1(3:4)/2;
center2 = face2(1:2) + face2(3:4)/2;
```

Compute the distance from camera 1 to the face.

```
point3d = triangulate(center1, center2, stereoParams);
distanceInMeters = norm(point3d)/1000;
```

Display the detected face and distance.

```
distanceAsString = sprintf('%0.2f meters', distanceInMeters);
I1 = insertObjectAnnotation(I1,'rectangle',face1,distanceAsString,'FontSize',18);
I2 = insertObjectAnnotation(I2,'rectangle',face2, distanceAsString,'FontSize',18);
I1 = insertShape(I1,'FilledRectangle',face1);
I2 = insertShape(I2,'FilledRectangle',face2);
imshowpair(I1, I2, 'montage');
```

## Remove Motion Artifacts From Image

Create a deinterlacer object.

```
hdinterlacer = vision.Deinterlacer;
```

Read an image with motion artifacts.
I = imread('vipinterlace.png');
Apply the deinterlacer to the image.
clearimage = hdinterlacer(I);
Display the results.

## imshow(I);

title('Original Image');
figure, imshow(clearimage);
title('Image after deinterlacing');

Original Image

Image after deinterlacing

## Find Vertical and Horizontal Edges in Image

Construct Haar-like wavelet filters to find vertical and horizontal edges in an image.
Read the input image and compute the integral image.

```
I = imread('pout.tif');
intImage = integralImage(I);
```

Construct Haar-like wavelet filters. Use the dot notation to find the vertical filter from the horizontal filter.

```
horiH = integralKernel([[1 1 4 3; 1 4 4 3],[-1, 1]);
vertH = horiH.
vertH =
    integralKernel with properties:
    BoundingBoxes: [2\times4 double]
            Weights: [-1 1]
        Coefficients: [4×6 double]
            Center: [2 3]
            Size: [4 6]
        Orientation: 'upright'
```

Display the horizontal filter.

```
imtool(horiH.Coefficients, 'InitialMagnification','fit');
```

Compute the filter responses.

```
horiResponse = integralFilter(intImage,horiH);
vertResponse = integralFilter(intImage,vertH);
```

Display the results.
figure;
imshow(horiResponse,[]);
title('Horizontal edge responses'); figure;
imshow(vertResponse,[]);
title('Vertical edge responses');

## Horizontal edge responses

## Vertical edge responses

## Single Camera Calibration

Create a set of calibration images.

```
images = imageSet(fullfile(toolboxdir('vision'),'visiondata',...
    calibration','fishEye'));
imageFileNames = images.ImageLocation;
```

Detect the calibration pattern.

```
[imagePoints, boardSize] = detectCheckerboardPoints(imageFileNames);
```

Generate the world coordinates of the corners of the squares.

```
squareSizeInMM = 29;
worldPoints = generateCheckerboardPoints(boardSize,squareSizeInMM);
```

Calibrate the camera.

```
params = estimateCameraParameters(imagePoints,worldPoints);
```

Visualize the calibration accuracy.
showReprojectionErrors(params);

Plot detected and reprojected points.

## figure;

imshow(imageFileNames\{1\});
hold on;
plot(imagePoints(:,1,1), imagePoints(:,2,1),'go');
plot(params.ReprojectedPoints(:,1,1), params.ReprojectedPoints(:,2,1),'r+');
legend('Detected Points','ReprojectedPoints');
hold off;

## Remove Distortion From an Image

This example shows you how to use the cameraParameters object in a workflow to remove distortion from an image. The example creates a cameraParameters object manually. In practice, use the estimateCameraParameters or the cameraCalibrator app to derive the object.

Create a cameraParameters object manually.

```
IntrinsicMatrix = [715.2699 0 0;
    0 711.5281 0;
    565.6995 355.3466 1];
radialDistortion = [-0.3361 0.0921];
cameraParams = cameraParameters('IntrinsicMatrix',IntrinsicMatrix,...
    'RadialDistortion',radialDistortion);
```

Remove distortion from the image.

```
I = imread(fullfile(matlabroot,'toolbox','vision','visiondata',...
    'calibration','fishEye','image01.jpg'));
J = undistortImage(I,cameraParams);
```

Display the original and undistorted images.
figure; imshowpair(imresize(I,0.5), imresize(J,0.5), 'montage'); title('Original Image (left) vs. Corrected Image (right)');

## Plot Spherical Point Cloud with Texture Mapping

Generate a sphere consisting of 600-by-600 faces.

```
numFaces = 600;
[x,y,z] = sphere(numFaces);
```

Plot the sphere using the default color map.

```
figure;
pcshow([x(:),y(:),z(:)]);
title('Sphere with Default Color Map');
xlabel('X');
ylabel('Y');
zlabel('Z');
```

Load an image for texture mapping.
I = im2double(imread('visionteam1.jpg'));
imshow(I);

Resize and flip the image for mapping the coordinates.
J = flipud(imresize(I,size(x)));
Plot the sphere with the color texture.

```
pcshow([x(:),y(:),z(:)],reshape(J,[],3));
title('Sphere with Color Texture');
xlabel('X');
ylabel('Y');
zlabel('Z');
```

## Plot Color Point Cloud from Kinect for Windows

This example shows how to plot a color point cloud from Kinect images. This example requires the Image Acquisition Toolbox ${ }^{\mathrm{TM}}$ software and the Kinect camera and a connection to the camera.

Create a System object ${ }^{\text {TM }}$ for the color device.

```
colorDevice = imaq.VideoDevice('kinect',1)
```

Change the returned type of color image from single to unint 8 .

```
colorDevice.ReturnedDataType = 'uint8';
```

Create a System object for the depth device.

```
depthDevice = imaq.VideoDevice('kinect',2)
```

Initialize the camera.

```
step(colorDevice);
step(depthDevice);
```

Load one frame from the device.

```
colorImage = step(colorDevice);
depthImage = step(depthDevice);
```

Extract the point cloud.

```
ptCloud = pcfromkinect(depthDevice,depthImage,colorImage);
```

Initialize a point cloud player to visualize 3-D point cloud data. The axis is set appropriately to visualize the point cloud from Kinect.

```
player = pcplayer(ptCloud.XLimits,ptCloud.YLimits,ptCloud.ZLimits,...
    'VerticalAxis','y','VerticalAxisDir','down');
xlabel(player.Axes,'X (m)');
ylabel(player.Axes,'Y (m)');
zlabel(player.Axes,'Z (m)');
```

Acquire and view 500 frames of live Kinect point cloud data.

```
for i = 1:500
    colorImage = step(colorDevice);
    depthImage = step(depthDevice);
```

```
    ptCloud = pcfromkinect(depthDevice,depthImage,colorImage);
    view(player,ptCloud);
end
```

Figure 1

| $<$ 人 |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |

Release the objects.
release(colorDevice);
release(depthDevice);

## Optical Flow Estimation Using the Farneback Algorithm

Load a video.

```
vidReader = VideoReader('visiontraffic.avi','CurrentTime',11);
```

Set up an optical flow object to do the estimate.

```
opticFlow = opticalFlowFarneback;
```

Read in video frames and estimate optical flow of each frame. Display the video frames with flow vectors.

```
while hasFrame(vidReader)
    frameRGB = readFrame(vidReader);
    frameGray = rgb2gray(frameRGB);
    flow = estimateFlow(opticFlow,frameGray);
    imshow(frameRGB)
    hold on
    plot(flow,'DecimationFactor',[5 5],'ScaleFactor',2)
    hold off
end
```

## Compute Optical Flow Using Lucas-Kanade derivative of Gaussian

Read in a video file.

```
vidReader = VideoReader('viptraffic.avi');
```

Create optical flow object.

```
opticFlow = opticalFlowLKDoG('NumFrames',3);
```

Estimate the optical flow of the objects and display the flow vectors.

```
while hasFrame(vidReader)
    frameRGB = readFrame(vidReader);
    frameGray = rgb2gray(frameRGB);
    flow = estimateFlow(opticFlow,frameGray);
    imshow(frameRGB);
    hold on;
    plot(flow,'DecimationFactor',[5 5],'ScaleFactor',25);
    hold off;
end
```

## Compute Optical Flow Using Horn-Schunck Method

```
Read in a video file.
vidReader = VideoReader('viptraffic.avi');
Create optical flow object.
opticFlow = opticalFlowHS;
Estimate the optical flow of objects in the video.
while hasFrame(vidReader)
    frameRGB = readFrame(vidReader);
    frameGray = rgb2gray(frameRGB);
    flow = estimateFlow(opticFlow,frameGray);
    imshow(frameRGB)
    hold on
    plot(flow,'DecimationFactor',[5 5],'ScaleFactor',25)
    hold off
end
```

## Construct Optical Flow Object and Plot Its Velocity

Construct an optical flow object.
opflow $=$ opticalFlow $(\operatorname{randn}(100,100), \operatorname{randn}(100,100))$;
Plot the velocity of the object as a quiver plot.
plot(opflow,'DecimationFactor',[10 10],'ScaleFactor', 10);

## Point Cloud Processing

## The PLY Format

| In this section... |
| :--- |
| "File Header" on page 2-2 |
| "Data" on page 2-4 |
| "Common Elements and Properties" on page 2-5 |

In this section...
"File Header" on page 2-2
"Data" on page 2-4
"Common Elements and Properties" on page 2-5
The version 1.0 PLY format, also known as the Stanford Triangle Format, defines a flexible and systematic scheme for storing 3D data. The ASCII header specifies what data is in the file by defining "elements" each with a set of "properties." Many PLY files only have vertex and face data, however, it is possible to also include other data such as color information, vertex normals, or application-specific properties.

Note: The Computer Vision System Toolbox ${ }^{\mathrm{TM}}$ point cloud data functions only support the ( $\mathrm{x}, \mathrm{y}, \mathrm{z}$ ) coordinates, normals, and color properties.

## File Header

An example header (italicized text is comment):

```
ply
format binary_big_endian 1.0
element vertex 9200
property float x
property float y
property float z
element face 18000 define "face" element
property list uchar int vertex_indices
end_header
```

file $I D$
specify data format and version
define "vertex" element
define "face" element
data starts after this line

The file begins with "ply," identifying that it is a PLY file. The header must also include a format line with the syntax

```
format <data format> <PLY version>
```

Supported data formats are "ascii" for data stored as text and "binary_little_endian" and "binary_big_endian" for binary data (where little/big endian refers to the byte ordering of multi-byte data). Element definitions begin with an "element" line followed by element property definitions

```
element <element name><number in file>
property <data type><property name 1>
property <data type><property name 2>
property <data type><property name 3>
```

For example, "element vertex 9200" defines an element "vertex" and specifies that 9200 vertices are stored in the file. Each element definition is followed by a list of properties of that element. There are two kinds of properties, scalar and list. A scalar property definition has the syntax

```
property <data type><property name>
```

where <data type> is

| Name | Type |
| :--- | :--- |
| char | (8-bit) character |
| uchar | (8-bit) unsigned character |
| short | (16-bit) short integer |
| ushort | (16-bit) unsigned short integer |
| int | (32-bit) integer |
| uint | (32-bit) unsigned integer |
| float | (32-bit) single-precision float |
| double | (64-bit) double-precision float |

For compatibility between systems, note that the number of bits in each data type must be consistent. A list type is stored with a count followed by a list of scalars. The definition syntax for a list property is

## property list <count data type><data type><property name>

For example,

## property list uchar int vertex_index

defines vertex_index properties are stored starting with a byte count followed by integer values. This is useful for storing polygon connectivity as it has the flexibility to specify a variable number of vertex indices in each face.

The header can also include comments. The syntax for a comment is simply a line beginning with "comment" followed by a one-line comment:

```
comment<comment text>
```

Comments can provide information about the data like the file's author, data description, data source, and other textual data.

## Data

Following the header, the element data is stored as either ASCII or binary data (as specified by the format line in the header). After the header, the data is stored in the order the elements and properties were defined. First, all the data for the first element type is stored. In the example header, the first element type is "vertex" with 9200 vertices in the file, and with float properties " $x$, " " $y$, " and " $z$. "

| float vertex[1].x |
| :--- |
| float vertex[1].y |
| float vertex[1].z |
| float vertex[2].x |
| float vertex[2].y |
| float vertex[2].z |
| .. |
| float vertex[9200].x |
| float vertex[9200].y |
| float vertex[9200].z |

In general, the properties data for each element is stored one element at a time.

```
<property 1><property 2> ... <property N> element[1]
<property 1><property 2> ... <property N> element[2]
```

```
...
```

The list type properties are stored beginning with a count and followed by a list of scalars. For example, the "face" element type has the list property "vertex_indices" with uchar count and int scalar type.

```
uchar count
int face[1].vertex_indices[1]
int face[1].vertex_indices[2]
int face[1].vertex_indices[3]
...
int face[1].vertex_indices[count]
```

```
uchar count
int face[2].vertex_indices[1]
int face[2].vertex_indices[2]
int face[2].vertex_indices[3]
int face[2].vertex_indices[count]
```

$\square$

## Common Elements and Properties

While the PLY format has the flexibility to define many types of elements and properties, a common set of elements are understood between programs to communicate common 3D data types. Turk suggests elements and property names that programs should try to make standard.

| Requirec Elemen <br> Core <br> Property | Property | Data Type | Property Description |  |
| :--- | :--- | :--- | :--- | :--- |
| $\checkmark$ | vertex | x | float | $x, y, z$ coordinates |
| $\checkmark$ |  | y | float |  |

| Require Core Propert | Elemen | Property | Data Type | Property Description |
| :---: | :---: | :---: | :---: | :---: |
| $\checkmark$ |  | z | float |  |
|  |  | nx | float | $x, y, z$ of normal |
|  |  | ny | float |  |
|  |  | nz | float |  |
|  |  | red | uchar | vertex color |
|  |  | green | uchar |  |
|  |  | blue | uchar |  |
|  |  | alpha | uchar | amount of transparency |
|  |  | material_index | int | index to list of materials |
|  | face | vertex_indices | list of int | indices to vertices |
|  |  | back_red | uchar | backside color |
|  |  | back_green | uchar |  |
|  |  | back_blue | uchar |  |
|  | edge | vertex1 | int | index to vertex |
|  |  | vertex2 | int | index to other vertex |
|  |  | crease_tag | uchar | crease in subdivision surface |
|  | materi | red | uchar | material color |
|  |  | green | uchar |  |
|  |  | blue | uchar |  |
|  |  | alpha | uchar | amount of transparency |
|  |  | reflect_coeff | float | amount of light reflected |
|  |  | refract_coeff | float | amount of light refracted |
|  |  | refract_index | float | index of refraction |
|  |  | extinct_coeff | float | extinction coefficent |

# Using the Installer for Computer Vision System Toolbox Product 

- "Install Computer Vision System Toolbox Add-on Support Files" on page 3-2
- "Install OCR Language Data Files" on page 3-3
- "Install and Use Computer Vision System Toolbox OpenCV Interface" on page 3-7

## Install Computer Vision System Toolbox Add-on Support Files

After you install third-party support files, you can use the data with the Computer Vision System Toolbox product. Use one of two ways to install the Add-on support files.

- Select Get Add-ons from the Add-ons drop-down menu from the MATLAB ${ }^{\circledR}$ desktop. The Add-on files are in the "MathWorks Features" section.
- Type visionSupportPackages in a MATLAB Command Window and follow the prompts.

Note: You must have write privileges for the installation folder.

When a new version of MATLAB software is released, repeat this process to check for updates. You can also check for updates between releases.

## Install OCR Language Data Files

| In this section... |
| :--- |
| "Installation" on page 3-3 |
| "Pretrained Language Data and the ocr function" on page 3-3 |

OCR Language Data files contain pretrained language data from the OCR Engine, tesseract-ocr, to use with the ocr function.

## Installation

After you install third-party support files, you can use the data with the Computer Vision System Toolbox product. Use one of two ways to install the Add-on support files.

- Select Get Add-ons from the Add-ons drop-down menu from the MATLAB desktop. The Add-on files are in the "MathWorks Features" section.
- Type visionSupportPackages in a MATLAB Command Window and follow the prompts.

Note: You must have write privileges for the installation folder.

When a new version of MATLAB software is released, repeat this process to check for updates. You can also check for updates between releases.

## Pretrained Language Data and the ocr function

After you install the pretrained language data files, you can specify one or more additional languages using the Language property of the ocr function. Use the appropriate language character vector with the property.

```
txt = ocr(img,'Language','Finnish');
```

## List of OCR language data in support package

## Install and Use Computer Vision System Toolbox OpenCV Interface

Use the OpenCV Interface files to integrate your OpenCV C++ code into MATLAB and build MEX-files that call OpenCV functions. The support package also contains graphics processing unit (GPU) support.

```
In this section...
"Installation" on page 3-7
"Support Package Contents" on page 3-7
"Create MEX-File from OpenCV C++ file" on page 3-8
"Use the OpenCV Interface C++ API" on page 3-9
"Create Your Own OpenCV MEX-files" on page 3-10
"Run OpenCV Examples" on page 3-10
```

## Installation

After you install third-party support files, you can use the data with the Computer Vision System Toolbox product. Use one of two ways to install the Add-on support files.

- Select Get Add-ons from the Add-ons drop-down menu from the MATLAB desktop. The Add-on files are in the "MathWorks Features" section.
- Type visionSupportPackages in a MATLAB Command Window and follow the prompts.

Note: You must have write privileges for the installation folder.

When a new version of MATLAB software is released, repeat this process to check for updates. You can also check for updates between releases.

## Support Package Contents

The OpenCV Interface support files are installed in the visionopencv folder. To find the path to this folder, type the following command:

```
fileparts(which('mexOpenCV'))
```

The visionopencv folder contain these files and folder.

| Files | Contents |
| :--- | :--- |
| example <br> folder | Template Matching, Foreground Detector, and Oriented FAST and <br> Rotated BRIEF (ORB) examples, including a GPU version. Each <br> subfolder in the example folder contains a README.txt file with step- <br> by-step instructions. |
| registry <br> folder | Registration files. |
| mexOpenCV.m <br> file | Function to build MEX-files. |
| README.txt <br> file | Help file. |

The mex function uses prebuilt OpenCV libraries, which ship with the Computer Vision System Toolbox product. Your compiler must be compatible with the one used to build the libraries. The following compilers are used to build the OpenCV libraries for MATLAB host:

| Operating System | Compatible Compiler |
| :--- | :--- |
| Windows $^{\circledR} 32$ bit | Microsoft $^{\circledR}$ Visual Studio ${ }^{\circledR} 2012$ |
| Windows 64 bit | Microsoft Visual Studio 2012 |
| Linux ${ }^{\circledR} 64$ bit | gcc-4.7.2 (g++) |
| Mac 64 bit | Xcode 6.2.0 (Clang++) |

## Create MEX-File from OpenCV C++ file

This example creates a MEX-file from a wrapper C++ file and then tests the newly created file. The example uses the OpenCV template matching algorithm wrapped in a C ++ file, which is located in the example/TemplateMatching folder.

1 Change your current working folder to the example/TemplateMatching folder:

```
cd(fullfile(fileparts(which('mexOpenCV')),'example',filesep,'TemplateMatching'))
```

2 Create the MEX-file from the source file:

```
mexOpenCV matchTemplateOCV.cpp
```

3 Run the test script, which uses the generated MEX-file:
testMatchTemplate

## Use the OpenCV Interface C++ API

The mexOpenCV interface utility functions convert data between OpenCV and MATLAB. These functions support CPP-linkage only. GPU support is available on glnxa64, win64, and Mac platforms. The GPU-specific utility functions support CUDA-enabled NVIDIA GPU with compute capability 2.0 or higher. See the Parallel Computing Toolbox ${ }^{\mathrm{TM}}$ System Requirements, The GPU utility functions require the Parallel Computing Toolbox software.

| Function | Description |
| :--- | :--- |
| ocvCheckFeaturePointsStruct | Check that MATLAB struct represents feature points |
| ocvStructToKeyPoints | Convert MATLAB feature points struct to OpenCV <br> KeyPoint vector |
| ocvKeyPointsToStruct | Convert OpenCV KeyPoint vector to MATLAB <br> struct |
| ocvMxArrayToCvRect | Convert a MATLAB struct representing a rectangle <br> to an OpenCV CvRect |
| ocvCvRectToMxArray | Convert OpenCV CvRect to a MATLAB struct |
| ocvCvBox2DToMxArray | Convert OpenCV CvBox2D to a MATLAB struct |
| ocvCvRectToBoundingBox_\{DataType\} | Convert vector<cv: : Rect> to M-by-4 mxArray of <br> bounding boxes |
| ocvMxArrayToSize | Convert 2-element mxArray to cv: : Size |
| ocvMxArrayToImage_\{DataType\} | Convert column major mxArray to row major <br> cv: :Mat for image |
| ocvMxArrayToMat_\{DataType\} | Convert column major mxArray to row major <br> cv: : Mat for generic matrix |
| ocvMxArrayFromImage_\{DataType\} | Convert row major cv: : Mat to column major <br> mxArray for image |
| ocvMxArrayFromMat_\{DataType\} | Convert row major cv: : Mat to column major <br> mxArray for generic matrix. |
| ocvMxArrayFromVector | Convert numeric vectorT to mxArray |

| Function | Description |
| :--- | :--- |
| ocvMxArrayFromPoints2f | Converts vector<cv: : Point2f> to mxArray |

| GPU Function | Description |
| :--- | :--- |
| ocvMxGpuArrayToGpuMat_\{DataType\} | Create cv: :gpu: :GpuMat from gpuArray |
| ocvMxGpuArrayFromGpuMat_\{DataType\} | Create gpuArray from cv: :gpu: :GpuMat |

## Create Your Own OpenCV MEX-files

Call the mexOpenCV function with your source file.
mexOpencV yourfile.cpp
For help creating MEX files, at the MATLAB command prompt, type:
help mexOpenCV

## Run OpenCV Examples

Each example subfolder in the OpenCV Interface support package contains all the files you need to run the example. To run an example, you must call the mexOpenCV function with one of the supplied source files.

## Run Template Matching Example

1 Change your current working folder to the example/TemplateMatching folder: cd(fullfile(fileparts(which('mexOpenCV')),'example',filesep,'TemplateMatching'))
2 Create the MEX-file from the source file:
mexOpenCV matchTemplateOCV.cpp
3 Run the test script, which uses the generated MEX-file:
testMatchTemplate

## Run Foreground Detector Example

1 Change your current working folder to the example/ForegroundDetector folder: cd(fullfile(fileparts(which('mexOpenCV')), 'example', filesep, 'ForegroundDetector'))
2 Create the MEX-file from the source file:
mexOpenCV backgroundSubtractorOCV.cpp
3 Run the test script that uses the generated MEX-file:
testBackgroundSubtractor.m

## Run Oriented FAST and Rotated BRIEF (ORB) Detector Example

1 Change your current working folder to the example/ORB folder: cd(fullfile(fileparts(which('mexOpenCV')), 'example',filesep,'ORB'))
2 Create the MEX-file for the detector from the source file: mexOpenCV detectORBFeaturesOCV.cpp
3 Create the MEX-file for the extractor from the source file: mexOpenCV extractORBFeaturesOCV.cpp
4 Run the test script, which uses the generated MEX-files:
testORBFeaturesOCV.m

## Run Detect ORB Features (GPU Version) Example

1 Change your current working folder to the example/ORB_GPU folder: cd(fullfile(fileparts(which('mexOpenCV')), 'example',filesep,'ORB_GPU'))
2 Create the MEX-file for the detector from the source file.
PC:
mexOpenCV detectORBFeaturesOCV_GPU.cpp -lgpu -lmwocvgpumex -largeArrayDims Linux/Mac:
mexOpenCV detectORBFeaturesOCV_GPU.cpp -lmwgpu -lmwocvgpumex -largeArrayDims
3 Run the test script, which uses the generated MEX-file:
testORBFeaturesOCV_GPU.m

## Export to Video Files

The Computer Vision System Toolbox blocks enable you to export video data from your Simulink ${ }^{\circledR}$ model. In this example, you use the To Multimedia File block to export a multimedia file from your model. This example also uses Gain blocks from the Math Operations Simulink library.

You can open the example model by typing at the MATLAB command line.
ex_export_to_mmf
1 Run your model.
2 You can view your video in the To Video Display window.

By increasing the red, green, and blue color values, you increase the contrast of the video. The To Multimedia File block exports the video data from the Simulink model to a multimedia file that it creates in your current folder.

This example manipulated the video stream and exported it from a Simulink model to a multimedia file. For more information, see the To Multimedia File block reference page.

## Setting Block Parameters for this Example

The block parameters in this example were modified from default values as follows:

| Block | Parameter |
| :--- | :--- |
| Gain | The Gain blocks are used to increase the red, green, and blue <br> values of the video stream. This increases the contrast of the <br> video: |
|  | Main pane, Gain = 1.2 <br> - <br> Signal Attributes pane, Output data type = Inherit: <br> Same as input |
| To Multimedia File | The To Multimedia File block exports the video to a <br> multimedia file: |
|  | File name = my_output .avi <br> - Write = Video only <br> - Image signal = Separate color signals |

## Configuration Parameters

You can locate the Model Configuration Parameters by selecting Model Configuration Parameters from the Simulation menu. For this example, the parameters on the Solver pane, are set as follows:

- Stop time $=20$
- Type = Fixed-step
- Solver $=$ Discrete (no continuous states)

## Import from Video Files

In this example, you use the From Multimedia File source block to import a video stream into a Simulink model and the To Video Display sink block to view it. This procedure assumes you are working on a Windows platform.

You can open the example model by typing at the MATLABcommand line.
ex_import_mmf
1 Run your model.
2 View your video in the To Video Display window that automatically appears when you start your simulation.

You have now imported and displayed a multimedia file in the Simulink model. In the "Export to Video Files" on page 4-2 example you can manipulate your video stream and export it to a multimedia file.

For more information on the blocks used in this example, see the From Multimedia File and To Video Display block reference pages.

## Setting Block Parameters for this Example

The block parameters in this example were modified from default values as follows:

| Block | Parameter |
| :--- | :--- |
| From Multimedia <br> File | Use the From Multimedia File block to import the multimedia <br> file into the model: |

| Block | Parameter |
| :--- | :--- |
| If you do not have your own multimedia file, use the default <br> vipmen. avi file, for the File name parameter. <br> If the multimedia file is on your MATLAB path, enter the <br> filename for the File name parameter. <br> If the file is not on your MATLAB path, use the Browse <br> button to locate the multimedia file. <br> Set the Image signal parameter to Separate color <br> signals. |  |
| By default, the Number of times to play file parameter |  |
| is set to inf. The model continues to play the file until the |  |
| simulation stops. |  |

## Configuration Parameters

You can locate the Model Configuration Parameters by selecting Model Configuration Parameters from the Simulation menu. For this example, the parameters on the Solver pane, are set as follows:

- Stop time $=20$
- Type = Fixed-step
- Solver $=$ Discrete (no continuous states)

## Batch Process Image Files

A common image processing task is to apply an image processing algorithm to a series of files. In this example, you import a sequence of images from a folder into the MATLAB workspace.

Note: In this example, the image files are a set of 10 microscope images of rat prostate cancer cells. These files are only the first 10 of 100 images acquired.

1 Specify the folder containing the images, and use this information to create a list of the file names, as follows:

```
fileFolder = fullfile(matlabroot,'toolbox','images','imdata');
dirOutput = dir(fullfile(fileFolder,'AT3_1m4_*.tif'));
fileNames = {dirOutput.name}'
```

2 View one of the images, using the following command sequence:

```
I = imread(fileNames{1});
imshow(I);
text(size(I,2),size(I,1)+15, ...
    'Image files courtesy of Alan Partin', ...
    'FontSize',7,'HorizontalAlignment','right');
text(size(I, 2),size(I,1)+25, ....
    'Johns Hopkins University', ...
    'FontSize',7,'HorizontalAlignment','right');
```

3 Use a for loop to create a variable that stores the entire image sequence. You can use this variable to import the sequence into Simulink.

```
for i = 1:length(fileNames)
    my_video(:,:,i) = imread(fileNames{i});
end
```

For additional information about batch processing, see the "Image Sequences and Batch Processing" section for the Image Processing Toolbox ${ }^{\text {TM }}$.

## Configuration Parameters

You can locate the Model Configuration Parameters by selecting Model Configuration Parameters from the Simulation menu. For this example, the parameters on the Solver pane, are set as follows:

- Stop time $=10$
- Type = Fixed-step
- Solver $=$ Discrete (no continuous states)

## Display a Sequence of Images

This example displays a sequence of images, which were saved in a folder, and then stored in a variable in the MATLAB workspace. At load time, this model executes the code from the "Batch Process Image Files" on page 4-6 example, which stores images in a workspace variable.

You can open the example model by typing at the MATLAB command line.
ex_display_sequence_of_images
1 The Video From Workspace block reads the files from the MATLAB workspace. The Signal parameter is set to the name of the variable for the stored images. For this example, it is set to my_video.
2 The Video Viewer block displays the sequence of images.
3 Run your model. You can view the image sequence in the Video Viewer window.

4 Because the Video From Workspace block's Sample time parameter is set to 1 and the Stop time parameter in the configuration parameters, is set to 10, the Video Viewer block displays 10 images before the simulation stops.

## Pre-loading Code

To find or modify the pre-loaded code, select File $>$ Model Properties $>$ Model
Properties. Then select the Callbacks tab. For more details on how to set-up callbacks, see "Callbacks for Customized Model Behavior".

## Configuration Parameters

You can locate the Model Configuration Parameters by selecting Model Configuration Parameters from the Simulation menu. For this example, the parameters on the Solver pane, are set as follows:

- Stop time $=10$
- Type = Fixed-step
- Solver $=$ Discrete (no continuous states)

## Partition Video Frames to Multiple Image Files

In this example, you use the To Multimedia File block, the Enabled Subsystem block, and a trigger signal, to save portions of one AVI file to three separate AVI files.

You can open the example model by typing at the MATLAB command line.

```
ex_vision_partition_video_frames_to_multiple_files
```

1 Run your model.
2 The model saves the three output AVI files in your current folder.
3 View the resulting files by typing the following commands at the MATLAB command prompt:
implay output1.avi
implay output2.avi implay output3.avi
4 Press the Play button.
For more information on the blocks used in this example, see the From Multimedia File, Insert Text, Enabled Subsystem, and To Multimedia File block reference pages.

## Setting Block Parameters for this Example

The block parameters in this example were modified from default values as follows:

| Block | Parameter |
| :--- | :--- |
| From Multimedia File | The From Multimedia File block imports an AVI file into the <br> model. <br> $-\quad$ Cleared Inherit sample time from file checkbox. |
| Insert Text | The example uses the Insert Text block to annotate the video <br> stream with frame numbers. The block writes the frame <br> number in green, in the upper-left corner of the output video <br> stream. <br> - Text: 'Frame \%d' <br> - Color: [0 1 0] <br> - Location: [10 10] |

| Block | Parameter |
| :--- | :--- |
| To Multimedia File | The To Multimedia File blocks send the video stream to three <br> separate AVI files. These block parameters were modified as <br> follows: <br> - <br> File name: output1. avi, output2 . avi, and <br> output3. avi, respectively <br> - Write: Video only |
| Counter | The Counter block counts the number of video frames. The <br> example uses this information to specify which frames are <br> sent to which file. The block parameters are modified as <br> follows: |
| - Number of bits: 8 |  |
| - Sample time: $1 / 30$ |  |$|$| The bias block adds a bias to the input. The block parameters |
| :--- |
| are modified as follows: |
| - Bias: 1 |

| Block | Parameter |
| :--- | :--- |
| Compare To <br> Constant3 | The Compare to Constant3 block send frames 20 to 30 to the <br> third AVI file. The block parameters are modified as follows: <br> - <br> - Operator: >= <br> Constant value: 20 |
| Compare To <br> Constant4 | The Compare to Constant4 block stops the simulation <br> when the video reaches frame 30. The block parameters are <br> modified as follows: |
|  | Operator: $==$ <br> $-\quad$ Constant value: 30 <br> - <br> Output data type: boolean |

## Using the Enabled Subsystem Block

Each To Multimedia File block gets inserted into one Enabled Subsystem block, and connected to it's input. You can do this, by double-clicking the Enabled Subsystem blocks, then click-and-drag a To Multimedia File block into it.

Each enabled subsystem should look similar to the subsystem shown in the following figure.

## Configuration Parameters

You can locate the Model Configuration Parameters by selecting Model Configuration Parameters from the Simulation menu. For this example, the parameters on the Solver pane, are set as follows:

- Type = Fixed-step
- Solver = Discrete (no continuous states)

## Combine Video and Audio Streams

In this example, you use the From Multimedia File blocks to import video and audio streams into a Simulink model. You then write the audio and video to a single file using the To Multimedia File block.

You can open the example model by typing at the MATLAB command line.
ex_combine_video_and_audio_streams
1 Run your model. The model creates a multimedia file called output. avi in your current folder.
2 Play the multimedia file using a media player. The original video file now has an audio component to it.

## Setting Up the Video Input Block

The From Multimedia File block imports a video file into the model. During import, the Inherit sample time from file check box is deselected, which enables the Desired sample time parameter. The other default parameters are accepted.

The From Multimedia File block used for the input video file inherits its sample time from the vipmen. avi file. For video signals, the sample time equals the frame period. The frame period is defined as $1 /($ frame rate). Because the input video frame rate is 30 frames per second (fps), the block sets the frame period to $1 / 30$ or 0.0333 seconds per frame.

## Setting Up the Audio Input Block

The From Multimedia File1 block imports an audio file into the model.
The Samples per audio channel parameter is set to 735 . This output audio frame size is calculated by dividing the frequency of the audio signal ( 22050 samples per second) by the frame rate (approximately 30 frames per second).

You must adjust the audio signal frame period to match the frame period of the video signal. The video frame period is 0.0333 seconds per frame. Because the frame period is also defined as the frame size divided by frequency, you can calculate the frame period of the audio signal by dividing the frame size of the audio signal ( 735 samples per frame) by the frequency ( 22050 samples per second) to get 0.0333 seconds per frame.
frame period $=($ frame size $) /($ frequency $)$
frame period $=(735$ samples per frame $) /(22050$ samples per second $)$
frame period $=0.0333$ seconds per frame
Alternatively, you can verify that the frame period of the audio and video signals is the same using a Simulink Probe block.

## Setting Up the Output Block

The To Multimedia File block is used to output the audio and video signals to a single multimedia file. The Video and audio option is selected for the Write parameter and One multidimensional signal for the Image signal parameter. The other default parameters are accepted.

## Configuration Parameters

You can locate the Configuration Parameters by selecting Model Configuration Parameters from the Simulation menu. The parameters, on the Solver pane, are set as follows:

- Stop time $=10$
- Type = Fixed-step
- Solver $=$ Discrete (no continuous states)

## Import MATLAB Workspace Variables

You can import data from the MATLAB workspace using the Video From Workspace block, which is created specifically for this task.

## Source Block Parameters: Video From Workspace

Video From Workspace (mask) (link)
Outputs video frames from the MATLAB workspace at successive sample times.

If the video signal is a M-by-N-by-T workspace array, the block outputs an intensity video signal, where M and N are the number of rows and columns in a single video frame, and T is the number of frames in the video signal.

If the video signal is a M -by- N -by-C-by-T workspace array, the block outputs a color video signal, where M and N are the number of rows and columns in a single video frame, C is the number of outputs from the block, and T is the number of frames in the video stream.

Parameters
Signal:
rand $(32,32,3,5)$
Sample time:
1

Form output after final value by: Cyclic repetition
Image signal: One multidimensional signal

Use the Signal parameter to specify the MATLAB workspace variable from which to read. For more information about how to use this block, see the Video From Workspace block reference page.

## Transmit Audio and Video Content Over Network

MATLAB and Simulink support network streaming via the Microsoft MMS protocol (which is also known as the ASF, or advanced streaming format, protocol). This ability is supported on Windows operating systems. If you are using other operating systems, you can use UDP to transport your media streams. If you are using Simulink, use the To Multimedia File and From Multimedia File blocks. If you are using MATLAB, use the VideoFileWriter and the VideoFileReader System objects. It is possible to encode and view these streams with other applications.

In order to view an MMS stream generated by MATLAB, you should use Internet Explorer ${ }^{\circledR}$, and provide the URL (e.g. "mms://127.0.0.1:81") to the stream which you wish to read. If you wish to create an MMS stream which can be viewed by MATLAB, download the Windows Media ${ }^{\circledR}$ Encoder or Microsoft Expression Encoder application, and configure it to produce a stream on a particular port (e.g. 81). Then, specify that URL in the Filename field of the From Multimedia File block or VideoFileReader System object.

You cannot send and receive MMS streams from the same process. If you wish to send and receive, the sender or the receiver must be run in rapid accelerator mode or compiled as a separate application using Simulink Coder ${ }^{\mathrm{TM}}$.

If you run the "Transmit Audio and Video Over a Network" on page 4-19 example with sendReceive set to 'send ', you can open up Internet Explorer and view the URL on which you have set up a server. By default, you should go to the following URL: mms://127.0.0.1:80. If you run this example with sendReceive set to 'receive', you will be able to view a MMS stream on the local computer on port 81. This implies that you will need to set up a stream on this port using software such as the Windows Media Encoder (which may be downloaded free of charge from Microsoft).

## Transmit Audio and Video Over a Network

This example shows how to specify parameters to transmit audio and video over a network.

Specify the sendReceive parameter to either 'send' to write the stream to the network or 'receive' to read the stream from the network.

```
sendReceive = 'send';
url = 'mms://127.0.0.1:81';
```

```
filename = 'vipmen.avi';
```

Either send or receive the stream, as specified.

```
if strcmpi(sendReceive, 'send')
    % Create objects
    hSrc = vision.VideoFileReader(filename);
    hSnk = vision.VideoFileWriter;
    % Set parameters
    hSnk.FileFormat = 'WMV';
    hSnk.AudioInputPort = false;
    hSnk.Filename = url;
    % Run loop. Ctrl-C to exit
    while true
        data = step(hSrc);
        step(hSnk, data);
    end
else
    % Create objects
    hSrc = vision.VideoFileReader;
    hSnk = vision.DeployableVideoPlayer;
    % Set parameters
    hSrc.Filename = url;
    % Run loop. Ctrl-C to exit
    while true
        data = step(hSrc);
        step(hSnk, data);
    end
end
```

## Resample Image Chroma

In this example, you use the Chroma Resampling block to downsample the Cb and Cr components of an image. The $\mathrm{Y}^{\prime} \mathrm{CbCr}$ color space separates the luma ( $\mathrm{Y}^{\prime}$ ) component of an image from the chroma ( Cb and Cr ) components. Luma and chroma, which are calculated using gamma corrected R, G, and B ( $\mathrm{R}^{\prime}$, $\mathrm{G}^{\prime}$, $\mathrm{B}^{\prime}$ ) signals, are different quantities than the CIE chrominance and luminance. The human eye is more sensitive to changes in luma than to changes in chroma. Therefore, you can reduce the bandwidth required for transmission or storage of a signal by removing some of the color information. For this reason, this color space is often used for digital encoding and transmission applications.

You can open the example model by typing at the MATLAB command line.
ex_vision_resample_image_chroma

1 Define an RGB image in the MATLAB workspace. To do so, at the MATLAB command prompt, type:

I= imread('autumn.tif');
This command reads in an RGB image from a TIF file. The image I is a 206-by-345-by- 3 array of 8 -bit unsigned integer values. Each plane of this array represents the red, green, or blue color values of the image.
2 To view the image this array represents, at the MATLAB command prompt, type:

```
imshow(I)
```

3 Configure Simulink to display signal dimensions next to each signal line. Select Display > Signals \& Ports > Signal Dimensions.
4 Run your model. The recovered image appears in the Video Viewer window. The Chroma Resampling block has downsampled the Cb and Cr components of an image.
5 Examine the signal dimensions in your model. The Chroma Resampling block downsamples the Cb and Cr components of the image from 206-by- 346 matrices to 206-by-173 matrices. These matrices require less bandwidth for transmission while still communicating the information necessary to recover the image after it is transmitted.

## Setting Block Parameters for This Example

The block parameters in this example are modified from default values as follows:

| Block | Parameter |
| :--- | :--- |
| Image from <br> Workspace | Import your image from the MATLAB workspace. Set the Value <br> parameter to I. |
| Image Pad | Change dimensions of the input I array from 206-by-345-by-3 to <br> 206-by-346-by-3. You are changing these dimensions because the <br> Chroma Resampling block requires that the dimensions of the <br> input be divisible by 2. Set the block parameters as follows: <br> - Method = Symmetric <br> - $\quad$ Add columns to = Right <br> - $\quad$ Number of added columns = 1 <br> $-\quad$ Add row to = No padding |
| The Image Pad block adds one column to the right of each plane of <br> the array by repeating its border values. This padding minimizes <br> the effect of the pixels outside the image on the processing of the <br> image. |  |
| Note When you process video streams, be aware that it is <br> computationally expensive to pad every video frame. You should <br> change the dimensions of the video stream before you process it <br> with Computer Vision System Toolbox blocks. |  |

| Block | Parameter |
| :---: | :---: |
| Selector, Selector1, Slector2 | Separate the individual color planes from the main signal. Such separation simplifies the color space conversion section of the model. Set the Selector block parameters as follows: <br> Selector <br> - Number of input dimensions $=3$ <br> - Index $\mathbf{1}$ = Select all <br> - Index 2 = Select all <br> - Index 3 = Index vector (dialog) and Index $=1$ <br> Selector1 <br> - Number of input dimensions $=3$ <br> - Index $\mathbf{1}$ = Select all <br> - Index 2 = Select all <br> - Index 3 = Index vector (dialog) and Index $=2$ <br> Selector2 <br> - Number of input dimensions $=3$ <br> - Index 1 = Select all <br> - Index 2 = Select all <br> - Index 3 = Index vector (dialog) and Index $=3$ |
| Color Space Conversion | Convert the input values from the $\mathrm{R}^{\prime} \mathrm{G}^{\prime} \mathrm{B}^{\prime}$ color space to the $\mathrm{Y}^{\prime} \mathrm{CbCr}$ color space. The prime symbol indicates a gamma corrected signal. Set the Image signal parameter to Separate color signals. |
| Chroma Resampling | Downsample the chroma components of the image from the 4:4:4 format to the 4:2:2 format. Use the default parameters. The dimensions of the output of the Chroma Resampling block are smaller than the dimensions of the input. Therefore, the output signal requires less bandwidth for transmission. |
| Chroma Resampling1 | Upsample the chroma components of the image from the 4:2:2 format to the 4:4:4 format. Set the Resampling parameter to 4:2:2 to 4:4:4. |

| Block | Parameter |
| :--- | :--- |
| Color Space <br> Conversion1 | Convert the input values from the Y'CbCr color space to the R'G'B' <br> color space. Set the block parameters as follows: <br> $-\quad$ Conversion = Y' CbCr to R ' G ' B' |
|  | - Image signal = Separate color signals |
| Video Viewer | Display the recovered image. Select File>Image signal to set <br> Image signal to Separate color signals. |

## Configuration Parameters

Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. Set the parameters as follows:

- Stop time $=10$
- Type = Fixed-step
- Solver $=$ Discrete (no continuous states)

## Convert Intensity Images to Binary Images

Binary images contain Boolean pixel values that are either 0 or 1. Pixels with the value 0 are displayed as black; pixels with the value 1 are displayed as white. Intensity images contain pixel values that range between the minimum and maximum values supported by their data type. Binary images can contain only 0 s and 1 s , but they are not binary images unless their data type is Boolean.

## Thresholding Intensity Images Using Relational Operators

You can use the Relational Operator block to perform a thresholding operation that converts your intensity image to a binary image. This example shows you how to accomplish this task.

You can open the example model by typing at the MATLAB command line.

```
ex_vision_thresholding_intensity
```

1 You can create a new Simulink model and add the blocks shown in the table.

| Block | Library | Quantity |
| :--- | :--- | :--- |
| Image From File | Computer Vision System Toolbox > <br> Sources | 1 |
| Video Viewer | Computer Vision System Toolbox > <br> Sinks | 2 |
| Relational Operator | Simulink > Logic and Bit Operations | 1 |
| Constant | Simulink > Sources | 1 |

2 Use the Image from File block to import your image. In this example the image file is a 256 -by- 256 matrix of 8 -bit unsigned integer values that range from 0 to 255 . Set the File name parameter to rice.png

3 Use the Video Viewer1 block to view the original intensity image. Accept the default parameters.

4 Use the Constant block to define a threshold value for the Relational Operator block. Since the pixel values range from 0 to 255 , set the Constant value parameter to 128. This value is image dependent.

5 Use the Relational Operator block to perform a thresholding operation that converts your intensity image to a binary image. Set the Relational Operator parameter
to >. If the input to the Relational Operator block is greater than 128, its output is a Boolean 1; otherwise, its output is a Boolean 0.
6 Use the Video Viewer block to view the binary image. Accept the default parameters.
7 Connect the blocks as shown in the following figure.

8 Set the configuration parameters. Open the Configuration dialog box by selecting Simulation > Model Configuration Parameters menu. Set the parameters as follows:

- Solver pane, Stop time $=0$
- Solver pane, Type = Fixed-step
- Solver pane, Solver = discrete (no continuous states)

9 Run your model.
The original intensity image appears in the Video Viewer1 window.

The binary image appears in the Video Viewer window.

Note: A single threshold value was unable to effectively threshold this image due to its uneven lighting. For information on how to address this problem, see "Correct Nonuniform Illumination" on page 11-7.

You have used the Relational Operator block to convert an intensity image to a binary image. For more information about this block, see the Relational Operator block reference page in the Simulink documentation. For additional information, see "Converting Between Image Types" in the Image Processing Toolbox documentation.

## Thresholding Intensity Images Using the Autothreshold Block

In the previous topic, you used the Relational Operator block to convert an intensity image into a binary image. In this topic, you use the Autothreshold block to accomplish the same task. Use the Autothreshold block when lighting conditions vary and the threshold needs to change for each video frame.

Note: Running this example requires a DSP System Toolbox ${ }^{\text {TM }}$ license.
ex_vision_autothreshold
1 If the model you created in "Thresholding Intensity Images Using Relational Operators" on page 4-25 is not open on your desktop, you can open the model by typing
ex_vision_thresholding_intensity
at the MATLAB command prompt.

2 Use the Image from File block to import your image. In this example the image file is a 256 -by- 256 matrix of 8 -bit unsigned integer values that range from 0 to 255 . Set the File name parameter to rice.png
3 Delete the Constant and the Relational Operator blocks in this model.
4 Add an Autothreshold block from the Conversions library of the Computer Vision System Toolbox into your model.
5 Use the Autothreshold block to perform a thresholding operation that converts your intensity image to a binary image. Select the Output threshold check box. This block outputs the calculated threshold value at the Th port.

6 Add a Display block from the Sinks library of the DSP System Toolbox library. Connect the Display block to the Th output port of the Authothreshold block.

Your model should look similar to the following figure:

7 If you have not already done so, set the configuration parameters. Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. Set the parameters as follows:

- Solver pane, Stop time = 0
- Solver pane, Type = Fixed-step
- Solver pane, Solver = discrete (no continuous states)

8 Run the model.
The original intensity image appears in the Video Viewer1 window.

The binary image appears in the Video Viewer window.

In the model window, the Display block shows the threshold value, calculated by the Autothreshold block, that separated the rice grains from the background.

You have used the Autothreshold block to convert an intensity image to a binary image. For more information about this block, see the Autothreshold block reference page in the Computer Vision System Toolbox Reference. To open an example model that uses this block, type vipstaples at the MATLAB command prompt.

## Convert R'G'B' to Intensity Images

The Color Space Conversion block enables you to convert color information from the $\mathrm{R}^{\prime} \mathrm{G}^{\prime} \mathrm{B}$ ' color space to the $\mathrm{Y}^{\prime} \mathrm{CbCr}$ color space and from the $\mathrm{Y}^{\prime} \mathrm{CbCr}$ color space to the $\mathrm{R}^{\prime} \mathrm{G}^{\prime} \mathrm{B}^{\prime}$ color space as specified by Recommendation ITU-R BT.601-5. This block can also be used to convert from the R'G'B' color space to intensity. The prime notation indicates that the signals are gamma corrected.

Some image processing algorithms are customized for intensity images. If you want to use one of these algorithms, you must first convert your image to intensity. In this topic, you learn how to use the Color Space Conversion block to accomplish this task. You can use this procedure to convert any $\mathrm{R}^{\prime} \mathrm{G}^{\prime} \mathrm{B}^{\prime}$ image to an intensity image:
ex_vision_convert_rgb
1 Define an R'G'B' image in the MATLAB workspace. To read in an $R^{\prime} G^{\prime} B^{\prime}$ image from a JPG file, at the MATLAB command prompt, type

I= imread('greens.jpg');
I is a 300 -by- 500 -by- 3 array of 8 -bit unsigned integer values. Each plane of this array represents the red, green, or blue color values of the image.

2 To view the image this matrix represents, at the MATLAB command prompt, type imshow(I)

3 Create a new Simulink model, and add to it the blocks shown in the following table.

| Block | Library | Quantity |
| :--- | :--- | :--- |
| Image From Workspace | Computer Vision System Toolbox > <br> Sources | 1 |
| Color Space Conversion | Computer Vision System Toolbox > <br> Conversions | 1 |
| Video Viewer | Computer Vision System Toolbox > <br> Sinks | 2 |

4 Use the Image from Workspace block to import your image from the MATLAB workspace. Set theValue parameter to I.

5 Use the Color Space Conversion block to convert the input values from the R'G'B' color space to intensity. Set the Conversion parameter to R'G'B' to intensity.
6 View the modified image using the Video Viewer block. View the original image using the Video Viewer1 block. Accept the default parameters.
7 Connect the blocks so that your model is similar to the following figure.

8 Set the configuration parameters. Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. Set the parameters as follows:

- Solver pane, Stop time $=0$
- Solver pane, Type = Fixed-step
- Solver pane, Solver = Discrete (no continuous states)

9 Run your model.
The image displayed in the Video Viewer window is the intensity version of the greens.jpg image.

In this topic, you used the Color Space Conversion block to convert color information from the R'G'B' color space to intensity. For more information on this block, see the Color Space Conversion block reference page.

## Process Multidimensional Color Video Signals

The Computer Vision System Toolbox software enables you to work with color images and video signals as multidimensional arrays. For example, the following model passes a color image from a source block to a sink block using a 384 -by- 512 -by- 3 array.

```
ex_vision_process_multidimensional
```

You can choose to process the image as a multidimensional array by setting the Image signal parameter to One multidimensional signal in the Image From File block dialog box.

The blocks that support multidimensional arrays meet at least one of the following criteria:

- They have the Image signal parameter on their block mask.
- They have a note in their block reference pages that says, "This block supports intensity and color images on its ports."
- Their input and output ports are labeled "Image".

You can also choose to work with the individual color planes of images or video signals. For example, the following model passes a color image from a source block to a sink block using three separate color planes.
ex_vision_process_individual

To process the individual color planes of an image or video signal, set the Image signal parameter to Separate color signals in both the Image From File and Video Viewer block dialog boxes.

Note: The ability to output separate color signals is a legacy option. It is recommend that you use multidimensional signals to represent color data.

If you are working with a block that only outputs multidimensional arrays, you can use the Selector block to separate the color planes. If you are working with a block that only accepts multidimensional arrays, you can use the Matrix Concatenation block to create a multidimensional array. For an example of this process, see Find the Histogram of an Image on page 11-2.

## Video Formats

## Defining Intensity and Color

Video data is a series of images over time. Video in binary or intensity format is a series of single images. Video in RGB format is a series of matrices grouped into sets of three, where each matrix represents an $R$, $G$, or $B$ plane.

The values in a binary, intensity, or RGB image can be different data types. The data type of the image values determines which values correspond to black and white as well as the absence or saturation of color. The following table summarizes the interpretation of the upper and lower bound of each data type. To view the data types of the signals at each port, from the Display menu, point to Signals \& Ports, and select Port Data Types.

| Data Type | Black or Absence of Color | White or Saturation of Color |
| :--- | :--- | :--- |
| Fixed point | Minimum data type value | Maximum data type value |
| Floating point | 0 | 1 |

Note The Computer Vision System Toolbox software considers any data type other than double-precision floating point and single-precision floating point to be fixed point.

For example, for an intensity image whose image values are 8 -bit unsigned integers, 0 is black and 255 is white. For an intensity image whose image values are double-precision floating point, 0 is black and 1 is white. For an intensity image whose image values are 16 -bit signed integers, -32768 is black and 32767 is white.

For an RGB image whose image values are 8 -bit unsigned integers, 000 is black, 255255255 is white, 25500 is red, 02550 is green, and 00255 is blue. For an RGB image whose image values are double-precision floating point, 000 is black, 111 is white, 100 is red, 010 is green, and 001 is blue. For an RGB image whose image values are 16-bit signed integers, -32768-32768-32768 is black, 327673276732767 is white, $32767-32768-32768$ is red, $-3276832767-32768$ is green, and -32768-32768 32767 is blue.

## Video Data Stored in Column-Major Format

The MATLAB technical computing software and Computer Vision System Toolbox blocks use column-major data organization. The blocks' data buffers store data elements from the first column first, then data elements from the second column second, and so on through the last column.

If you have imported an image or a video stream into the MATLAB workspace using a function from the MATLAB environment or the Image Processing Toolbox, the Computer Vision System Toolbox blocks will display this image or video stream correctly. If you have written your own function or code to import images into the MATLAB environment, you must take the column-major convention into account.

## Image Formats

In the Computer Vision System Toolbox software, images are real-valued ordered sets of color or intensity data. The blocks interpret input matrices as images, where each element of the matrix corresponds to a single pixel in the displayed image. Images can be binary, intensity (grayscale), or RGB. This section explains how to represent these types of images.

## Binary Images

Binary images are represented by a Boolean matrix of 0 s and 1 s , which correspond to black and white pixels, respectively.

For more information, see "Binary Images" in the Image Processing Toolbox documentation.

## Intensity Images

Intensity images are represented by a matrix of intensity values. While intensity images are not stored with colormaps, you can use a gray colormap to display them.

For more information, see "Grayscale Images" in the Image Processing Toolbox documentation.

## RGB Images

RGB images are also known as a true-color images. With Computer Vision System Toolbox blocks, these images are represented by an array, where the first plane represents the red pixel intensities, the second plane represents the green pixel intensities, and the third plane represents the blue pixel intensities. In the Computer Vision System Toolbox software, you can pass RGB images between blocks as three separate color planes or as one multidimensional array.

For more information, see "Truecolor Images" in the Image Processing Toolbox documentation.

## View Streaming Video in MATLAB

## Basic Video Streaming

Use the video player vision.VideoPlayer System object when you require a simple video display in MATLAB for streaming video.

## Code Generation Supported Video Streaming Object

Use the deployable video player vision.DeployableVideoPlayer System object as a basic display viewer designed for optimal performance. This object supports code generation on all platforms.

## Preview Video in MATLAB

Use the Image Processing Toolbox implay function to view and represent videos as variables in the MATLAB workspace. It is a full featured video player with toolbar controls. The implay player enables you to view videos directly from files without having to load all the video data into memory at once.

You can open several instances of the implay function simultaneously to view multiple video data sources at once. You can also dock these implay players in the MATLAB desktop. Use the figure arrangement buttons in the upper-right corner of the Sinks window to control the placement of the docked players.

## View Video in Simulink

## Code Generation Supported Video Streaming Block

Use the To Video Display block in your Simulink model as a simple display viewer designed for optimal performance. This block supports code generation for the Windows platform.

## Simulation Control and Video Analysis Block

Use the Video Viewer block when you require a wired-in video display with simulation controls in your Simulink model. The Video Viewer block provides simulation control buttons directly from the player interface. The block integrates play, pause, and step features while running the model and also provides video analysis tools such as pixel region viewer.

## View Video Signals Without Adding Blocks

The implay function enables you to view video signals in Simulink models without adding blocks to your model. You can open several instances of the implay player simultaneously to view multiple video data sources at once. You can also dock these players in the MATLAB desktop. Use the figure arrangement buttons in the upper-right corner of the Sinks window to control the placement of the docked players.

Set Simulink simulation mode to Normal to use implay. implay does not work when you use "Accelerating Simulink Models" on page 13-13.

## Use implay to view a Simulink signal:

1 Open a Simulink model.
2 Open an implay player by typing implay on the MATLAB command line.
3 Run the Simulink model.
4 Select the signal line you want to view.
5 On the implay toolbar, select File > Connect to Simulink Signal or click the咆 icon.

The video appears in the player window.
6 You can use multiple implay players to display different Simulink signals.

Note: During code generation, the Simulink Coder does not generate code for the implay player.

## Annotate Video Files with Frame Numbers

You can use the insertText function in MATLAB, or theInsert Text block in a Simulink model, to overlay text on video streams. In this Simulink model example, you add a running count of the number of video frames to a video using the Insert Text block. The model contains the From Multimedia File block to import the video into the Simulink model, a Frame Counter block to count the number of frames in the input video, and two Video Viewer blocks to view the original and annotated videos.

You can open the example model by typing at the MATLAB command line.
ex_vision_annotate_video_file_with_frame_numbers
1 Run your model.
2 The model displays the original and annotated videos.

## Color Formatting

For this example, the color format for the video was set to Intensity, and therefore the color value for the text was set to a scaled value. If instead, you set the color format to RGB, then the text value must satisfy this format, and requires a 3 -element vector.

## Inserting Text

Use the Insert Text block to annotate the video stream with a running frame count. Set the block parameters as follows:

- Main pane, Text = ['Frame count' sprintf('\n') 'Source frame: \%d']
- Main pane, Color value = 1
- Main pane, Location [x y] = [85 2]
- Font pane, Font face = LucindaTypewriterRegular

By setting the Text parameter to ['Frame count' sprintf('\n') 'Source frame: \%d' ], you are asking the block to print Frame count on one line and the Source frame: on a new line. Because you specified \%d, an ANSI C printf-style format specification, the Variables port appears on the block. The block takes the port input in decimal form and substitutes this input for the \%d in the character vector. You used the Location [xy] parameter to specify where to print the text. In this case, the location is 85 rows down and 2 columns over from the top-left corner of the image.

## Configuration Parameters

Set the configuration parameters. Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. Set the parameters as follows:

- Solver pane, Stop time = inf
- Solver pane, Type = Fixed-step
- Solver pane, Solver = Discrete (no continuous states)

## Draw Shapes and Lines

When you specify the type of shape to draw, you must also specify it's location on the image. The table shows the format for the points input for the different shapes.

## Rectangle

| Shape | PTS input | Drawn Shape |
| :---: | :---: | :---: |
| Single Rectangle | Four-element row vector <br> [x y width height] where <br> - $x$ and $y$ are the one-based coordinates of the upper-left corner of the rectangle. <br> - width and height are the width, in pixels, and height, in pixels, of the rectangle. The values of width and height must be greater than 0 . |  |
| $M$ Rectangles | $M$-by-4 matrix $\left[\begin{array}{cccc} x_{1} & y_{1} & \text { width }_{1} & \text { height }_{1} \\ x_{2} & y_{2} & \text { width }_{2} & \text { height }_{2} \\ \vdots & \vdots & \vdots & \vdots \\ x_{M} & y_{M} & \text { width }_{M} & \text { height }_{M} \end{array}\right]$ <br> where each row of the matrix corresponds to a different rectangle and is of the same form as the vector for a single rectangle. | $M=2$ <br> ( $\mathrm{x}_{1}, \mathrm{y}_{1}$ ) <br> ( $\mathrm{x}_{1}+$ width $_{1-1}, \mathrm{y}_{1}+$ height $_{1-1}$ ) <br> (x,y) <br> ( $\mathrm{x}_{2}+$ width $2-1, \mathrm{y}_{2}+$ height $_{2}-1$ ) |

## Line and Polyline

You can draw one or more lines, and one or more polylines. A polyline contains a series of connected line segments.

| Shape | PTS input | Drawn Shape |
| :---: | :---: | :---: |
| Single Line | Four-element row vector [ $\left.\begin{array}{llll}x_{1} & y_{1} & x_{2} & y_{2}\end{array}\right]$ where <br> - $x_{1}$ and $y_{1}$ are the coordinates of the beginning of the line. <br> - $x_{2}$ and $y_{2}$ are the coordinates of the end of the line. |  |
| $M$ Lines | $M$-by- 4 matrix $\left[\begin{array}{cccc} x_{11} & y_{11} & x_{12} & y_{12} \\ x_{21} & y_{21} & x_{22} & y_{22} \\ \vdots & \vdots & \vdots & \vdots \\ x_{M 1} & y_{M 1} & x_{M 2} & y_{M 2} \end{array}\right]$ <br> where each row of the matrix corresponds to a different line and is of the same form as the vector for a single line. |  |
| Single Polyline with (L-1) Segments | Vector of size $2 L$, where $L$ is the number of vertices, with format, $\left[x_{1}, y_{1}, x_{2}\right.$, $\left.y_{2}, \ldots, x_{L}, y_{L}\right]$. <br> - $x_{1}$ and $y_{1}$ are the coordinates of the beginning of the first line segment. <br> - $\mathrm{x}_{2}$ and $\mathrm{y}_{2}$ are the coordinates of the end of the first line segment and the beginning of the second line segment. <br> - $x_{L}$ and $y_{L}$ are the coordinates of the end of the $(L-1)^{\text {th }}$ line segment. <br> The polyline always contains ( $L-1$ ) number of segments because the first and last vertex points do not connect. The block produces an error message when the number of rows is less than two or not a multiple of two. |  |

| Shape | PTS input | Drawn Shape |
| :---: | :---: | :---: |
| $M$ Polylines with (L-1) Segments | $2 L$-by- $N$ matrix $\left[\begin{array}{ccccccc} x_{11} & y_{11} & x_{12} & y_{12} & \cdots & x_{1 L} & y_{1 L} \\ x_{21} & y_{21} & x_{22} & y_{22} & \cdots & x_{2 L} & y_{2 L} \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ x_{M 1} & y_{M 1} & x_{M 2} & y_{M 2} & \cdots & x_{M L} & y_{M L} \end{array}\right]$ <br> where each row of the matrix corresponds to a different polyline and is of the same form as the vector for a single polyline. When you require one polyline to contain less than ( $L-1$ ) number of segments, fill the matrix by repeating the coordinates of the last vertex. <br> The block produces an error message if the number of rows is less than two or not a multiple of two. | $M=3, L=5$ <br> *Added L=5 matrix entry equal to $L=4$ value, because this polyline contains one segments. |

## Polygon

You can draw one or more polygons.

| Shape | PTS input | Drawn Shape |
| :---: | :---: | :---: |
| Single Polygon with $L$ line segments | Row vector of size $2 L$, where $L$ is the number of vertices, with format, [ $\mathrm{x}_{1} \mathrm{y}_{1} \mathrm{x}_{2}$ $\left.y_{2} \ldots x_{L} y_{L}\right]$ where <br> - $\mathrm{x}_{1}$ and $\mathrm{y}_{1}$ are the coordinates of the beginning of the first line segment. <br> - $x_{2}$ and $y_{2}$ are the coordinates of the end of the first line segment and the beginning of the second line segment. <br> - $x_{L}$ and $y_{L}$ are the coordinates of the end of the $(L-1)^{\text {th }}$ line segment and the beginning of the $L^{\text {th }}$ line segment. |  |

| Shape | PTS input | Drawn Shape |
| :---: | :---: | :---: |
|  | The block connects [ $\mathrm{x}_{1} \mathrm{y}_{1}$ ] to [ $\mathrm{X}_{\mathrm{L}} \mathrm{y}_{\mathrm{L}}$ ] to complete the polygon. The block produces an error if the number of rows is negative or not a multiple of two. |  |
| $M$ Polygons with the largest number of line segments in any line being $L$ | $M$-by- $2 L$ matrix $\left[\begin{array}{ccccccc} x_{11} & y_{11} & x_{12} & y_{12} & \cdots & x_{1 L} & y_{1 L} \\ x_{21} & y_{21} & x_{22} & y_{22} & \cdots & x_{2 L} & y_{2 L} \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ x_{M 1} & y_{M 1} & x_{M 2} & y_{M 2} & \cdots & x_{M L} & y_{M L} \end{array}\right]$ <br> where each row of the matrix corresponds to a different polygon and is of the same form as the vector for a single polygon. If some polygons are shorter than others, repeat the ending coordinates to fill the polygon matrix. <br> The block produces an error message if the number of rows is less than two or is not a multiple of two. |  |

## Circle

You can draw one or more circles.

| Shape | PTS input |
| :--- | :--- |
| Single Circle | Three-element row vector <br> [x y radius $]$ where <br> x and y are coordinates for the center of <br> the circle. <br> radius is the radius of the circle, which <br> must be greater than 0. |
| $M$ Circles | $M-b y-3$ matrix $\left.\begin{array}{ccc}x_{1} & y_{1} & \text { radius } \\ x_{2} & y_{2} & \text { radius } \\ \vdots & \vdots & \vdots \\ x_{M} & y_{M} & \text { radius }\end{array}\right]$ <br> where each row of the matrix corresponds  <br> to a different circle and is of the same form  <br> as the vector for a single circle.  |

## Registration and Stereo Vision

- "Detect Edges in Images" on page 6-2
- "Detect Lines in Images" on page 6-9
- "Single Camera Calibration App" on page 6-13
- "Stereo Calibration App" on page 6-40
- "What Is Camera Calibration?" on page 6-61
- "Structure from Motion" on page 6-69

## Detect Edges in Images

This example shows how to find the edges of rice grains in an intensity image. It finds the pixel locations where the magnitude of the gradient of intensity exceeds a threshold value. These locations typically occur at the boundaries of objects.

Open the Simulink model.
ex_vision_detect_edges_in_image

Set block parameters.

| Block | Parameter setting |
| :--- | :--- |
| Image From File | - File name to rice.png. <br> $-\quad$ Output data type to single. |
| Edge Detection | Use the Edge Detection block to find the <br> edges in the image. <br> Output type = Binary image and <br> gradient components |

| Block | Parameter setting |
| :--- | :--- |
|  | - Select the Edge thinning check box. |
| Video Viewer and Video Viewer1 | View the original and binary images. <br> Accept the default parameters for both <br> viewers. |
| 2-D Minimum and 2-D Minimum1 | Find the minimum value of Gv and Gh <br> matrices. Set the Mode parameters to <br> Value for both of these blocks. |
| Subtract and Subtract1 | Subtract the minimum values from each <br> element of the Gv and Gh matrices. This <br> process ensures that the minimum value <br> of these matrices is 0. Accept the default <br> parameters. |
| 2-D Maximum and 2-D Maximum1 | Find the maximum value of the new Gv <br> and Gh matrices. Set the Mode parameters <br> to Value for both of these blocks. |
| Divide and Divide1 | Divide each element of the Gv and Gh <br> matrices by their maximum value. This <br> normalization process ensures that these <br> matrices range between 0 and 1. Accept the <br> default parameters. |
| Video Viewer2 and Video Viewer3 | View the gradient components of the <br> image. Accept the default parameters. |

Set configuration parameters.
Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. The parameters are set as follows:

- Solver pane, Stop time = 0
- Solver pane, Type = Fixed-step
- Solver pane, Solver = Discrete (no continuous states)
- Diagnostics pane, Automatic solver parameter selection: = none

Run your model and view edge detection results.
The Video Viewer window displays the original image.

The Video Viewer 1 window displays the edges of the rice grains in white and the background in black.

The Video Viewer2 window displays the intensity image of the vertical gradient components of the image. You can see that the vertical edges of the rice grains are darker and more well defined than the horizontal edges.

The Video Viewer3 window displays the intensity image of the horizontal gradient components of the image. In this image, the horizontal edges of the rice grains are more well defined.

The Edge Detection block convolves the input matrix with the Sobel kernel. This calculates the gradient components of the image that correspond to the horizontal and vertical edge responses. The block outputs these components at the Gh and Gv ports, respectively. Then the block performs a thresholding operation on the gradient components to find the binary image. The binary image is a matrix filled with 1 s and 0 s . The nonzero elements of this matrix correspond to the edge pixels and the zero elements correspond to the background pixels. The block outputs the binary image at the Edge port.

The matrix values at the $\mathbf{G v}$ and $\mathbf{G h}$ output ports of the Edge Detection block are doubleprecision floating-point. These matrix values need to be scaled between 0 and 1 in order to display them using the Video Viewer blocks. This is done with the Statistics and Math Operation blocks.

Run the model faster by double-clicking the Edge Detection block and clear the Edge thinning check box.

Your model runs faster because the Edge Detection block is more efficient when you clear the Edge thinning check box. However, the edges of rice grains in the Video Viewer window are wider.

Close the model.

```
bdclose('ex_vision_detect_edges_in_image');
```

## Detect Lines in Images

This example shows you how to find lines within images and enables you to detect, measure, and recognize objects. You use the Hough Transform, Find Local Maxima, Edge Detectionand Hough Lines blocks to find the longest line in an image.

You can open the example model by typing at the MATLAB command line.
ex_vision_detect_lines

The Video Viewer blocks display the original image, the image with all edges found, and the image with the longest line annotated.

The Edge Detection block finds the edges in the intensity image. This process improves the efficiency of the Hough Lines block by reducing the image area over which the block searches for lines. The block also converts the image to a binary image, which is the required input for the Hough Transform block.

For additional examples of the techniques used in this section, see the following list of examples. You can open these examples by typing the title at the MATLAB command prompt:

| Example | MATLAB | Simulink model-based |
| :--- | :--- | :--- |
| Rotation Correction | videorotationcorrection | viphough |

## Setting Block Parameters

| Block | Parameter setting |
| :--- | :--- |
| Hough Transform | The Hough Transform block computes the <br> Hough matrix by transforming the input <br> image into the rho-theta parameter space. <br> The block also outputs the rho and theta <br> values associated with the Hough matrix. <br> The parameters are set as follows: <br> - Theta resolution (radians) = pi/360 <br> - Select the Output theta and rho <br> values check box. |
| Find Local Maxima | The Find Local Maxima block finds the <br> location of the maximum value in the <br> Hough matrix. The block parameters are <br> set as follows: <br> vaximum number of local maxima <br> Ma |
| Selector, Selector1 | Input is Hough matrix spanning <br> full theta range |
| The Selector blocks separate the indices of <br> the rho and theta values, which the Find <br> Local Maxima block outputs at the Idx <br> port. The rho and theta values correspond |  |

| Block | Parameter setting |
| :---: | :---: |
|  | to the maximum value in the Hough matrix. The Selector blocks parameters are set as follows: <br> - Number of input dimensions: 1 <br> - Index mode = One-based <br> - Index Option = Index vector (port) <br> - Input port size $=2$ |
| Selector2, Selector3 | The Selector blocks index into the rho and theta vectors and determine the rho and theta values that correspond to the longest line in the original image. The parameters of the Selector blocks are set as follows: <br> - Number of input dimensions: 2 <br> - Index mode = One-based <br> - Index Option = Index vector (port) |
| Hough Lines | The Hough Lines block determines where the longest line intersects the edges of the original image. <br> - Sine value computation method $=$ Trigonometric function |
| Draw Shapes | The Draw Shapes block draws a white line over the longest line on the original image. The coordinates are set to superimpose a line on the original image. The block parameters are set as follows: <br> - Shape = Lines <br> - Border color = White |

## Configuration Parameters

Set the configuration parameters. Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. Set the parameters as follows:

- Solver pane, Stop time $=0$
- Solver pane, Type = Fixed-step
- Solver pane, Solver = Discrete (no continuous states)
- Solver pane, Fixed-step size (fundamental sample time): $=0.2$

## Single Camera Calibration App

```
In this section...
"Camera Calibrator Overview" on page 6-13
"Open the Camera Calibrator" on page 6-14
"Prepare the Pattern, Camera, and Images" on page 6-15
"Add Images" on page 6-19
"Calibrate" on page 6-28
"Evaluate Calibration Results" on page 6-31
"Improve Calibration" on page 6-35
"Export Camera Parameters" on page 6-38
```

## Camera Calibrator Overview

You can use the camera calibrator to estimate camera intrinsics, extrinsics, and lens distortion parameters. You can use these camera parameters for various computer vision applications. These applications include removing the effects of lens distortion from an image, measuring planar objects, or reconstructing 3-D scenes from multiple cameras.

Note: You can use the Camera Calibrator app with cameras up to a field of view (FOV) of 95 degrees.

## Single Camera Calibration

Follow this workflow to calibrate your camera using the app:
1 Prepare images, camera, and calibration pattern.

2 Load images.
3 Calibrate the camera.
4 Evaluate calibration accuracy.
5 Adjust parameters to improve accuracy (if necessary).
6 Export the parameters object.
In some cases, the default values work well, and you do not need to make any improvements before exporting parameters. If you do need to make improvements, you can use the camera calibration functions in MATLAB. For a list of functions, see "Single Camera Calibration".

## Open the Camera Calibrator

- MATLAB Toolstrip: Open the Apps tab, under Image Processing and Computer Vision, click the app icon.
- MATLAB command prompt: Enter cameraCalibrator

## Prepare the Pattern, Camera, and Images

For best results, use between 10 and 20 images of the calibration pattern. The calibrator requires at least three images. Use uncompressed images or lossless compression formats such as PNG. The calibration pattern and the camera setup must satisfy a set of requirements to work with the calibrator. For greater calibration accuracy, follow these instructions for preparing the pattern, setting up the camera, and capturing the images.

Note: The Camera Calibrator app only supports checkerboard patterns. If you are using a different type of calibration pattern, you can still calibrate your camera using the estimateCameraParameters function. Using a different type of pattern requires that you supply your own code to detect the pattern points in the image.

## Prepare the Checkerboard Pattern

The Camera Calibrator app uses a checkerboard pattern. A checkerboard pattern is a convenient calibration target. If you want to use a different pattern to extract key points, you can use the camera calibration MATLAB functions directly. See "Single Camera Calibration" for the list of functions.

You can print (from MATLAB) and use the checkerboard pattern provided. The checkerboard pattern you use must not be square. One side must contain an even number of squares and the other side must contain an odd number of squares. Therefore, the pattern contains two black corners along one side and two white corners on the opposite side. This criteria enables the app to determine the orientation of the pattern. The calibrator assigns the longer side to be the $x$-direction.

To prepare the checkerboard pattern:
1 Attach the checkerboard printout to a flat surface. Imperfections on the surface can affect the accuracy of the calibration.

2 Measure one side of the checkerboard square. You need this measurement for calibration. The size of the squares can vary depending on printer settings.

3 To improve the detection speed, set up the pattern with as little background clutter as possible.

## Camera Setup

To properly calibrate your camera, follow these rules:

- Keep the pattern in focus, but do not use autofocus.
- Do not change zoom settings between images. Otherwise the focal length changes.

## Capture Images

For best results, use at least 10 to 20 images of the calibration pattern. The calibrator requires at least three images. Use uncompressed images or images in lossless compression formats such as PNG. For greater calibration accuracy:

- Capture the images of the pattern at a distance roughly equal to the distance from your camera to the objects of interest. For example, if you plan to measure objects from 2 meters, keep your pattern approximately 2 meters from the camera.
- Place the checkerboard at an angle less than 45 degrees relative to the camera plane.
- Do not modify the images. For example, do not crop them.
- Do not use autofocus or change the zoom between images.
- Capture the images of a checkerboard pattern at different orientations relative to the camera.
- Capture enough different images of the pattern so that you have covered as much of the image frame as possible. Lens distortion increases radially from the center of the image and sometimes is not uniform across the image frame. To capture this lens distortion, the pattern must appear close to the edges.

The Calibrator works with a range of checkerboard square sizes. As a general rule, your checkerboard should fill at least $20 \%$ of the captured image. For example, the preceding images were taken with a checkerboard square size of 108 mm .

## Add Images

To begin calibration, you must add images. You can add saved images from a folder or add images directly from a camera. The calibrator analyzes the images to ensure they meet the calibrator requirements and then detects the points.

## Add Images from File

Click the Add images button, and select From file. You can add images from multiple folders by clicking Add images for each folder.

## Acquire Live Images

To begin calibration, you must add images. You can acquire images live from a Webcam using the MATLAB Webcam support. You must have the MATLAB Support Package for USB Webcams installed to use this feature. See "Install the MATLAB Support Package for USB Webcams" for information on installing the support package.

1 To add live images, click the Add Images arrow and select From camera.

2 The Camera tab opens. (Formerly called Image Capture tab, as shown in the graphics.) If you have only one Webcam connected to your system, it is selected by default and a live preview window opens. If you have multiple cameras connected and want to use a different one, select the camera in the Camera list.
3 You can set properties for the camera to control the image. Click the Camera Properties field to open a list of your camera's properties. This list varies, depending on your device.

Use the sliders or drop-downs to change any available property settings. The Preview window updates dynamically when you change a setting. When you are done setting properties, click outside of the box to dismiss the properties list.

4 Enter a location for the acquired image files in the Save Location field by typing the path to the folder or using the Browse button. You must have permission to write to the folder you select.

5 Set your capture parameters.

In the Capture Interval field, use the text box or slider to set the number of seconds between image captures. The default is 5 seconds, the minimum is 1 second, and the maximum is 60 seconds.

In the Number of images to capture field, use the text box or slider to set the number of image captures. The default is 20 images, the minimum is 2 images, and the maximum is 100 images.

In the default configuration, a total of 20 images are captured, one every 5 seconds.
6 It is helpful to dock the Preview window in the center of the tool. Move it from the right panel into the middle panel by dragging the banner. It then docks in the middle as shown here.

7 The Preview window shows the live images streamed as RGB data. After you adjust any device properties and capture settings, use the Preview window as a guide to line up the camera to acquire the checkerboard pattern image you wish to capture.

8 Click the Capture button. The number of images you set are captured and the thumbnails of the snapshots appear in the Data Browser panel. They are automatically named incrementally and are captured as . png files.

You can optionally stop the image capture before the designated number of images are captured by clicking Stop Capture.

When you are capturing images of a checkerboard, after the designated number of images are captured, a message displays with the size of the checkerboard square. Click OK.

The Detection Results are then calculated and displayed. For example:

9 Click OK in the Detection Results dialog box.
10 When you have finished acquiring live images, you can click Close Image Capture to close the Camera tab and return to the Calibration tab.

## Analyze Images

After you select the images, in the Checkerboard Square Size dialog box, enter the length of one side of a square from the checkerboard pattern.

The calibrator attempts to detect a checkerboard in each of the added images. An Analyzing Images progress bar window appears, indicating detection progress.

If any of the images are rejected, the Detection Results window appears, which contains diagnostic information. The results indicate how many total images were processed, and how many were accepted, rejected, or skipped The calibrator skips duplicate images.

To view the rejected images, click view images. The calibrator rejects duplicate images. It also rejects images where the entire checkerboard could not be detected. Possible reasons for no detection are a blurry image or an extreme angle of the pattern. Detection takes longer with larger images and with patterns that contain a large number of squares.

## View Images and Detected Points

The Data Browser pane displays a list of images with IDs. These images contain a detected pattern. To view an image, select it from the Data Browser pane.

The Image pane displays the checkerboard image with green circles to indicate detected points. You can verify the corners were detected correctly using the zoom controls. The yellow square indicates the $(0,0)$ origin. The X and Y arrows indicate the checkerboard axes orientation.

## Calibrate

Once you are satisfied with the accepted images, click Calibrate. The default calibration settings assume the minimum set of camera parameters. Start by running the calibration with the default settings. After evaluating the results, you can try to improve calibration
accuracy by adjusting the settings and adding or removing images, and then calibrate again.

## Set Initial Guesses for Camera Intrinsic and Radial Distortion

When there is severe lens distortion, the app can fail to compute the initial values for the camera intrinsics. If you have manufacturer's specifications for your camera and you know the pixel size, focal length, and/or lens characteristics, you can set the initial guesses for camera intrinsics and/or radial distortion manually. To set the initial guesses click the Optimization Options button.

- Select the top checkbox and then enter a 3-by-3 matrix to specify initial intrinsics. If you do not specify an initial guess, the function computes the initial intrinsic matrix using linear least squares.
- Select the bottom checkbox and then enter a 2 - or 3 -element vector to specify the initial radial distortion. If you do not provide a value, the function uses 0 as the initial value for all the coefficients.

## Calibration Algorithm

The calibration algorithm assumes a pinhole camera model:

$$
w\left[\begin{array}{lll}
x & y & 1
\end{array}\right]=\left[\begin{array}{llll}
X & Y & Z & 1
\end{array}\right]\left[\begin{array}{c}
R \\
t
\end{array}\right] K
$$

- $(X, Y, Z)$ : world coordinates of a point
- $(x, y)$ : image coordinates of the corresponding image point in pixels
- $w$ : arbitrary homogeneous coordinates scale factor
- K: camera intrinsic matrix, defined as:

$$
\left[\begin{array}{ccc}
f_{x} & 0 & 0 \\
s & f_{y} & 0 \\
c_{x} & c_{y} & 1
\end{array}\right]
$$

The coordinates $\left[c_{x} c_{y}\right.$ ] represent the optical center (the principal point), in pixels.
When the $x$ and $y$ axis are exactly perpendicular, the skew parameter, $s$, equals 0 .
$f_{x}=F^{*} s_{\mathrm{x}}$
$f_{y}=F^{*} s_{y}$
$F$, is the focal length in world units, typically expressed in millimeters.
[ $s_{\mathrm{x}}, s_{\mathrm{y}}$ ] are the number of pixels per world unit in the $x$ and $y$ direction respectively. $f_{\mathrm{x}}$ and $f_{\mathrm{y}}$ are expressed in pixels.

- $R$ : matrix representing the 3-D rotation of the camera
- $t$ : translation of the camera relative to the world coordinate system

The camera calibration algorithm estimates the values of the intrinsic parameters, the extrinsic parameters, and the distortion coefficients. Camera calibration involves these steps:

1 Solve for the intrinsics and extrinsics in closed form, assuming that lens distortion is zero. [1]
2 Estimate all parameters simultaneously, including the distortion coefficients, using nonlinear least-squares minimization (Levenberg-Marquardt algorithm). Use the closed-form solution from the preceding step as the initial estimate of the intrinsics and extrinsics. Set the initial estimate of the distortion coefficients to zero. [1][2]

## Evaluate Calibration Results

You can evaluate calibration accuracy by examining the reprojection errors and the camera extrinsics, and by viewing the undistorted image. For best calibration results, use all three methods of evaluation.

## Examine Reprojection Errors

The reprojection errors are the distances in pixels between the detected and the reprojected points. The Camera Calibrator app calculates reprojection errors by
projecting the checkerboard points from world coordinates, defined by the checkerboard, into image coordinates. The app then compares the reprojected points to the corresponding detected points. As a general rule, reprojection errors of less than one pixel are acceptable.

The Camera Calibrator app displays, in pixels, the reprojection errors as a bar graph and as a scatter plot. You can toggle between them using the button on the display. You can identify the images that adversely contribute to the calibration from either one of the graphs. You can then select and remove those images from the list in the Data Browser pane.

## Reprojection Errors Bar Graph

The bar graph displays the mean reprojection error per image, along with the overall mean error. The bar labels correspond to the image IDs. The highlighted bar corresponds to the selected image.

Select an image in one of these ways:

- Clicking a corresponding bar in the graph.
- Select an image from the list in the Data Browser pane.
- Slide the red bar to select outlier images.

## Examine Extrinsic Parameter Visualization

The 3-D extrinsic parameters plot provides a camera-centric view of the patterns and a pattern-centric view of the camera. The camera-centric view is helpful if the camera was stationary when the images were captured. The pattern-centric view is helpful if the pattern was stationary. Click the button on the display to toggle between the two visuals. Click and drag a graph to rotate it. Click a checkerboard or a camera to select it. The highlighted data in the visualizations correspond to the selected image in the list. Examine the relative positions of the pattern and the camera to see if they match what you expect. For example, a pattern that appears behind the camera indicates a calibration error.

To view the effects of removing lens distortion, in the Image pane, click the Show Undistorted. If the calibration was accurate, the distorted lines in the image become straight.

It is important to check the undistorted images even if the reprojection errors are low. If the pattern covers only a small percentage of the image, the distortion estimation might be incorrect, even though the calibration resulted in few reprojection errors.

## Improve Calibration

To improve the calibration, you can remove high-error images, add more images, or modify the calibrator settings.

## Add or Remove Images

Consider adding more images if:

- You have less than 10 images.
- The patterns do not cover enough of the image frame.
- The patterns do not have enough variation in orientation with respect to the camera.

Consider removing images if the images:

- Have a high mean reprojection error
- Are blurry
- Contain a checkerboard at an angle greater than 45 degrees relative to the camera plane
- Contain incorrectly detected checkerboard points

## Change the Number of Radial Distortion Coefficients

You can specify 2 or 3 radial distortion coefficients by selecting the corresponding radio button from the Options section. Radial distortion occurs when light rays bend more near the edges of a lens than they do at its optical center. The smaller the lens, the greater the distortion.

Negative radial distortion "pincushion"

No distortion

The radial distortion coefficients model this type of distortion. The distorted points are denoted as $\left(x_{\text {distorted }}, y_{\text {distorted }}\right)$ :
$x_{\text {distorted }}=x\left(1+k_{1}{ }^{*} r^{2}+k_{2}{ }^{*} r^{4}+k_{3}{ }^{*} r^{6}\right)$
$y_{\text {distorted }}=y\left(1+k_{1} * r^{2}+k_{2} * r^{4}+k_{3} * r^{6}\right)$

- $x, y$ - Undistorted pixel locations. $x$ and $y$ are in normalized image coordinates. Normalized image coordinates are calculated from pixel coordinates by translating to the optical center and dividing by the focal length in pixels. Thus, $x$ and $y$ are dimensionless.
- $k_{1}, k_{2}$, and $k_{3}$ - Radial distortion coefficients of the lens.
- $r^{2}: x^{2}+y^{2}$

Typically, two coefficients are sufficient for calibration. For severe distortion, such as in wide-angle lenses, you can select 3 coefficients to include $k_{3}$.

The undistorted pixel locations are in normalized image coordinates, with the origin at the optical center. The coordinates are expressed in world units.

## Compute Skew

When you select the Compute Skew check box, the calibrator estimates the image axes skew. Some camera sensors contain imperfections that cause the $x$ - and $y$-axis of the
image to not be perpendicular. You can model this defect using a skew parameter. If you do not select the check box, the image axes are assumed to be perpendicular, which is the case for most modern cameras.

## Compute Tangential Distortion

Tangential distortion occurs when the lens and the image plane are not parallel. The tangential distortion coefficients model this type of distortion.

Zero Tangential Distortion

Tangential Distortion

The distorted points are denoted as $\left(x_{\text {distorted }}, y_{\text {distorted }}\right)$ :
$x_{\text {distorted }}=x+\left[2 * p_{1} * x * y+p_{2} *\left(r^{2}+2 * x^{2}\right)\right]$
$y_{\text {distorted }}=y+\left[p_{1} *\left(r^{2}+2 * y^{2}\right)+2 * p_{2} * x * y\right]$

- $\quad x, y$ - Undistorted pixel locations. $x$ and $y$ are in normalized image coordinates. Normalized image coordinates are calculated from pixel coordinates by translating to the optical center and dividing by the focal length in pixels. Thus, $x$ and $y$ are dimensionless.
- $p_{1}$ and $p_{2}$ - Tangential distortion coefficients of the lens.
- $r^{2}=x^{2}+y^{2}$

When you select the Compute Tangential Distortion check box, the calibrator estimates the tangential distortion coefficients. Otherwise, the calibrator sets the tangential distortion coefficients to zero.

## Export Camera Parameters

When you are satisfied with calibration accuracy, click Export Camera Parameters. You can save and export the camera parameters to an object or generate the camera parameters as a MATLAB script.

## Export Camera Parameters

Click Export Camera Parameters to create a cameraParameters object in your workspace. The object contains the intrinsic and extrinsic parameters of the camera, and the distortion coefficients. You can use this object for various computer vision tasks, such as image undistortion, measuring planar objects, and 3-D reconstruction. See "Measuring Planar Objects with a Calibrated Camera". You can optionally export the cameraCalibrationErrors object, which contains the standard errors of estimated camera parameters.

## Generate MATLAB Script

Click Generate MATLAB script to save your camera parameters to a MATLAB script, enabling you to reproduce the steps from your calibration session.

## Stereo Calibration App

In this section...<br>"Stereo Camera Calibrator Overview" on page 6-40<br>"Stereo Camera Calibration" on page 6-41<br>"Open the Stereo Camera Calibrator" on page 6-41<br>"Image, Camera, and Pattern Preparation" on page 6-42<br>"Add Image Pairs" on page 6-46<br>"Calibrate" on page 6-49<br>"Evaluate Calibration Results" on page 6-50<br>"Improve Calibration" on page 6-55<br>"Export Camera Parameters" on page 6-58

## Stereo Camera Calibrator Overview

You can use the Stereo Camera Calibrator app to calibrate a stereo camera, which you can then use to recover depth from images. A stereo system consists of two cameras: camera 1 and camera 2. The app estimates the parameters of each of the two cameras. It also calculates the position and orientation of camera 2 relative to camera 1.

The app produces an object containing the stereo camera parameters. You can use this object to rectify stereo images using the rectifyStereoImages function, reconstruct the $3-D$ scene using the reconstructScene function, or compute $3-D$ locations corresponding to matching pairs of image points using the triangulate function.

The suite of calibration functions used by the Stereo Camera Calibrator app provide the workflow for stereo system calibration. You can use them directly in the MATLAB workspace. For a list of functions, see "Single Camera Calibration".

Note: You can use the Camera Calibrator app with cameras up to a field of view (FOV) of 95 degrees.

## Stereo Camera Calibration

Follow this workflow to calibrate your stereo camera using the app:
1 Prepare images, camera, and calibration pattern.
2 Load image pairs.
3 Calibrate the stereo camera.
4 Evaluate calibration accuracy.
5 Adjust parameters to improve accuracy (if necessary).
6 Export the parameters object.
In some cases, the default values work well, and you do not need to make any improvements before exporting parameters. If you do need to make improvements, you can use the camera calibration functions in MATLAB. For a list of functions, see "Single Camera Calibration".

## Open the Stereo Camera Calibrator

- MATLAB Toolstrip: Open the Apps tab, under Image Processing and Computer Vision, click the app icon.
- MATLAB command prompt: Enter stereoCameraCalibrator

## Image, Camera, and Pattern Preparation

For best results, use between 10 and 20 images of the calibration pattern. The calibrator requires at least three images. Use uncompressed images or lossless compression formats such as PNG. The calibration pattern and the camera setup must satisfy a set of requirements to work with the calibrator. For greater calibration accuracy, follow these instructions for preparing the pattern, setting up the camera, and capturing the images.

## Prepare the Checkerboard Pattern

The Camera Calibrator app uses a checkerboard pattern, which is a convenient calibration target. If you want to use a different pattern to extract key points, you can use the camera calibration MATLAB functions directly. See "Single Camera Calibration" for the list of functions.

Note: The Camera Calibrator app only supports checkerboard patterns. If you are using a different type of calibration pattern, you can still calibrate your camera using the estimateCameraParameters function. Using a different type of pattern requires that you supply your own code to detect the pattern points in the image.

You can print (from MATLAB) and use the checkerboard pattern provided. The checkerboard pattern you use must not be square. One side must contain an even number of squares and the other side must contain an odd number of squares. Therefore, the pattern contains two black corners along one side and two white corners on the opposite side. This criteria enables the app to determine the orientation of the pattern. The calibrator assigns the longer side to be the $x$-direction.

To prepare the checkerboard pattern:
1 Attach the checkerboard printout to a flat surface. Imperfections on the surface can affect the accuracy of the calibration.
2 Measure one side of the checkerboard square. You need this measurement for calibration. The size of the squares can vary depending on printer settings.

3 To improve the detection speed, set up the pattern with as little background clutter as possible.

## Camera Setup

To properly calibrate your camera, follow these rules:

- Keep the pattern in focus, but do not use auto-focus.
- Do not change zoom settings between images, otherwise the focal length changes.

## Capture Images

For best results, use at least 10 to 20 images of the calibration pattern. The calibrator requires at least three images. Use uncompressed images or images in lossless compression formats such as PNG. For greater calibration accuracy:

- Capture the images of the pattern at a distance roughly equal to the distance from your camera to the objects of interest. For example, if you plan to measure objects from 2 meters, keep your pattern approximately 2 meters from the camera.
- Place the checkerboard at an angle less than 45 degrees relative to the camera plane.
- Do not modify the images. For example, do not crop them.
- Do not use autofocus or change the zoom between images.
- Capture the images of a checkerboard pattern at different orientations relative to the camera.
- Capture enough different images of the pattern so that you have covered as much of the image frame as possible. Lens distortion increases radially from the center of the image and sometimes is not uniform across the image frame. To capture this lens distortion, the pattern must appear close to the edges.

Specific to stereo camera calibration:

- Make sure the checkerboard pattern is fully visible in both images of each stereo pair.

- Keep the pattern stationary for each image pair. Any motion of the pattern between taking image 1 and image 2 of the pair negatively affects the calibration.
- To create a stereo display, or anaglyph, position the two cameras approximately 55 mm apart. This distance represents the average distance between human eyes.
- For greater reconstruction accuracy at longer distances, position your cameras farther apart.

## Add Image Pairs

To begin calibration, click Add images to add two sets of stereo images of the checkerboard. You can add images from multiple folders by clicking Add images. Select the locations for the images corresponding to camera 1 and camera 2. Enter the length of one side of a square from the checkerboard pattern.

## Analyze Images

The calibrator attempts to detect a checkerboard in each of the added images. An Analyzing Images progress bar window appears, indicating detection progress.

If any of the image pairs are rejected, the Detection Results window appears, which contains diagnostic information. The results indicate how many total image pairs were processed, and how many were accepted, rejected, or skipped The calibrator skips duplicate images.

To view the rejected images, click view images. The calibrator rejects duplicate images. It also rejects images where the entire checkerboard could not be detected. Possible reasons for no detection are a blurry image or an extreme angle of the pattern. Detection takes longer with larger images and with patterns that contain a large number of squares.

## View Images and Detected Points

The Data Browser pane displays a list of image pairs with IDs. These image pairs contain a detected pattern. To view an image, select it from the Data Browser pane.

The Image pane displays the checkerboard image pair with green circles to indicate detected points. You can verify the corners were detected correctly using the zoom controls. The yellow square indicates the $(0,0)$ origin. The X and Y arrows indicate the checkerboard axes orientation.

## Calibrate

Once you are satisfied with the accepted image pairs, click Calibrate. The default calibration settings assume the minimum set of camera parameters. Start by running the calibration with the default settings. After evaluating the results, you can try to improve
calibration accuracy by adjusting the settings and adding or removing images, and then calibrate again.

## Set Initial Guesses for Camera Intrinisics and Radial Distortion

When there is severe lens distortion, the app can fail to compute the initial values for the camera intrinsics. If you have manufacturer's specifications for your camera and you know the pixel size, focal length, and/or lens characteristics, you can set the initial guesses for camera intrinsics and/or radial distortion manually. To set the initial guesses click the Optimization Options button.

- Select the top checkbox and then enter a 3-by-3 matrix to specify initial intrinsics. If you do not specify an initial guess, the function computes the initial intrinsic matrix using linear least squares.
- Select the bottom checkbox and then enter a 2 - or 3 -element vector to specify the initial radial distortion. If you do not provide a value, the function uses 0 as the initial value for all the coefficients.

## Evaluate Calibration Results

You can evaluate calibration accuracy by examining the reprojection errors and the camera extrinsics, and by viewing the undistorted image. For best calibration results, use all three methods of evaluation.

## Examine Reprojection Errors

The reprojection errors are the distances in pixels between the detected and the reprojected points. The Stereo Camera Calibrator app calculates reprojection errors by projecting the checkerboard points from world coordinates, defined by the checkerboard, into image coordinates. The app then compares the reprojected points to the corresponding detected points. As a general rule, reprojection errors of less than one pixel are acceptable.

The Stereo Camera Calibrator app displays, in pixels, the reprojection errors as a bar graph and as a scatter plot. You can toggle between them using the button on the display. You can identify the image pairs that adversely contribute to the calibration from either one of the graphs. You can then select and remove those images from the list in the Data Browser pane.

## Reprojection Errors Bar Graph

The bar graph displays the mean reprojection error per image, along with the overall mean error. The bar labels correspond to the image pair IDs. The highlighted pair of bars corresponds to the selected image pair.

Select an image pair in one of these ways:

- Clicking the corresponding bar in the graph.
- Select the image pair from the list in the Data Browser pane.
- Slide the red bar to select outlier images.

## Examine Extrinsic Parameter Visualization

The 3-D extrinsic parameters plot provides a camera-centric view of the patterns and a pattern-centric view of the camera. The camera-centric view is helpful if the camera was stationary when the images were captured. The pattern-centric view is helpful if the pattern was stationary. Click the button on the display to toggle between the two visuals. Click and drag a graph to rotate it. Click a checkerboard or a camera to select it. The highlighted data in the visualizations correspond to the selected image in the list. Examine the relative positions of the pattern and the camera to see if they match
what you expect. For example, a pattern that appears behind the camera indicates a calibration error.

Show camera-centric view

## Show Rectified Images

To view the effects of stereo rectification, in the Image pane, click Show Rectified. If the calibration was accurate, the images become undistorted and row-aligned.

It is important to check the rectified images even if the reprojection errors are low. Sometimes, if the pattern only covers a small percentage of the image, the calibration achieves low reprojection errors, but the distortion estimation is incorrect. An example of this type of incorrect estimation for single camera calibration is shown below.

## Improve Calibration

To improve the calibration, you can remove high-error image pairs, add more image pairs, or modify the calibrator settings.

## Add and Remove Image Pairs

Consider adding more image pairs if:

- You have less than 10 image pairs.
- The patterns do not cover enough of the image frame.
- The patterns in your image pairs do not have enough variation in orientation with respect to the camera.

Consider removing image pairs if the images:

- Have a high mean reprojection error.
- Are blurry.
- Contain a checkerboard at an angle greater than 45 degrees relative to the camera plane.
- Contain incorrectly detected checkerboard points.

## Change the Number of Radial Distortion Coefficients

You can specify 2 or 3 radial distortion coefficients by selecting the corresponding radio button from the Options section. Radial distortion occurs when light rays bend more near the edges of a lens than they do at its optical center. The smaller the lens, the greater the distortion.

Negative radial distortion "pincushion"

No distortion

Positive radial distortion "barrel"

The radial distortion coefficients model this type of distortion. The distorted points are denoted as $\left(x_{\text {distorted }}, y_{\text {distorted }}\right)$ :
$x_{\text {distorted }}=x\left(1+k_{1}{ }^{*} r^{2}+k_{2}{ }^{*} r^{4}+k_{3}{ }^{*} r^{6}\right)$
$y_{\text {distorted }}=y\left(1+k_{1}{ }^{*} r^{2}+k_{2}{ }^{*} r^{4}+k_{3}{ }^{*} r^{6}\right)$

- $\quad x, y$ - Undistorted pixel locations. $x$ and $y$ are in normalized image coordinates. Normalized image coordinates are calculated from pixel coordinates by translating to the optical center and dividing by the focal length in pixels. Thus, $x$ and $y$ are dimensionless.
- $k_{1}, k_{2}$, and $k_{3}$ - Radial distortion coefficients of the lens.
- $r^{2}: x^{2}+y^{2}$

Typically, two coefficients are sufficient for calibration. For severe distortion, such as in wide-angle lenses, you can select 3 coefficients to include $k_{3}$.

## Compute Skew

When you select the Compute Skew check box, the calibrator estimates the image axes skew. Some camera sensors contain imperfections that cause the $x$ - and $y$-axis of the image to not be perpendicular. You can model this defect using a skew parameter. If you do not select the check box, the image axes are assumed to be perpendicular, which is the case for most modern cameras.

## Compute Tangential Distortion

Tangential distortion occurs when the lens and the image plane are not parallel. The tangential distortion coefficients model this type of distortion.

Zero Tangential Distortion
Lens and sensor are parallel

Tangential Distortion

The distorted points are denoted as ( $x_{\text {distorted }}, y_{\text {distorted }}$ ):
$x_{\text {distorted }}=x+\left[2 * p_{1} * x * y+p_{2} *\left(r^{2}+2 * x^{2}\right)\right]$
$y_{\text {distorted }}=y+\left[p_{1} *\left(r^{2}+2 * y^{2}\right)+2 * p_{2} * x * y\right]$

- $\quad x, y$ - Undistorted pixel locations. $x$ and $y$ are in normalized image coordinates. Normalized image coordinates are calculated from pixel coordinates by translating to the optical center and dividing by the focal length in pixels. Thus, $x$ and $y$ are dimensionless.
- $p_{1}$ and $p_{2}$ - Tangential distortion coefficients of the lens.
- $r^{2}=x^{2}+y^{2}$

When you select the Compute Tangential Distortion check box, the calibrator estimates the tangential distortion coefficients. Otherwise, the calibrator sets the tangential distortion coefficients to zero.

## Export Camera Parameters

When you are satisfied with calibration accuracy, click Export Camera Parameters. You can save and export the camera parameters to an object or generate the camera parameters as a MATLAB script.

## Export Camera Parameters

Click Export Camera Parameters to create a stereoParameters object in your workspace. The object contains the intrinsic and extrinsic parameters of the camera, and the distortion coefficients. You can use this object for various computer vision tasks, such as image undistortion, measuring planar objects, and 3-D reconstruction. You can optionally export the stereoCalibrationErrors object, which contains the standard errors of estimated stereo parameters.

## Generate MATLAB Script

You can also generate a MATLAB script which allows you save and reproduce the steps from your calibration session.

## What Is Camera Calibration?

```
In this section...
"Camera Model" on page 6-62
"Pinhole Camera Model" on page 6-62
"Camera Calibration Parameters" on page 6-64
"Distortion in Camera Calibration" on page 6-66
```

Geometric camera calibration, also referred to as camera resectioning, estimates the parameters of a lens and image sensor of an image or video camera. You can use these parameters to correct for lens distortion, measure the size of an object in world units, or determine the location of the camera in the scene. These tasks are used in applications such as machine vision to detect and measure objects. They are also used in robotics, for navigation systems, and 3-D scene reconstruction.

Examples of what you can do after calibrating your camera:

Remove Lens Distortion

Estimate 3-D Structure from Camera Motion

Estimate Depth Using a Stereo Camera

Measure Planar Objects

Camera parameters include intrinsics, extrinsics, and distortion coefficients. To estimate the camera parameters, you need to have 3-D world points and their corresponding 2-D
image points. You can get these correspondences using multiple images of a calibration pattern, such as a checkerboard. Using the correspondences, you can solve for the camera parameters. After you calibrate a camera, to evaluate the accuracy of the estimated parameters, you can:

- Plot the relative locations of the camera and the calibration pattern
- Calculate the reprojection errors.
- Calculate the parameter estimation errors.

Use the Camera Calibrator to perform camera calibration and evaluate the accuracy of the estimated parameters.

## Camera Model

The Computer Vision System Toolbox calibration algorithm uses the camera model proposed by Jean-Yves Bouguet [3]. The model includes:

- The pinhole camera model [1].
- Lens distortion [2].

The pinhole camera model does not account for lens distortion because an ideal pinhole camera does not have a lens. To accurately represent a real camera, the full camera model used by the algorithm includes the radial and tangential lens distortion.

## Pinhole Camera Model

A pinhole camera is a simple camera without a lens and with a single small aperture. Light rays pass through the aperture and project an inverted image on the opposite side of the camera. Think of the virtual image plane as being in front of the camera and containing the upright image of the scene.

The pinhole camera parameters are represented in a 4-by-3 matrix called the camera matrix. This matrix maps the 3-D world scene into the image plane. The calibration algorithm calculates the camera matrix using the extrinsic and intrinsic parameters. The extrinsic parameters represent the location of the camera in the 3-D scene. The intrinsic parameters represent the optical center and focal length of the camera.

Scale factor Image points World points

Rotation and translation

The world points are transformed to camera coordinates using the extrinsics parameters. The camera coordinates are mapped into the image plane using the intrinsics parameters.

## Camera Calibration Parameters

The calibration algorithm calculates the camera matrix using the extrinsic and intrinsic parameters. The extrinsic parameters represent a rigid transformation from 3-D world coordinate system to the 3-D camera's coordinate system. The intrinsic parameters represent a projective transformation from the 3-D camera's coordinates into the 2-D image coordinates.

## Extrinsic Parameters

The extrinsic parameters consist of a rotation, $R$, and a translation, $t$. The origin of the camera's coordinate system is at its optical center and its $x$ - and $y$-axis define the image plane.

## Intrinsic Parameters

The intrinsic parameters include the focal length, the optical center, also known as the principal point, and the skew coefficient. The camera intrinsic matrix, $K$, is defined as:

$$
\left[\begin{array}{ccc}
f_{x} & 0 & 0 \\
s & f_{y} & 0 \\
c_{x} & c_{y} & 1
\end{array}\right]
$$

The pixel skew is defined as:

$\left[\begin{array}{ll}c_{x} & c_{y}\end{array}\right]$ - Optical center (the principal point), in pixels.
$\left(f_{x}, \quad f_{y}\right)$ - Focal length in pixels.
$f_{x}=F / p_{x}$
$f_{y}=F / p_{y}$
$F$ - Focal length in world units, typically expressed in millimeters.
$\left(p_{x}, \quad p_{y}\right)$ - Size of the pixel in world units.
$s$ - Skew coefficient, which is non-zero if the image axes are not perpendicular.
$s=f_{y} \tan \alpha$

## Distortion in Camera Calibration

The camera matrix does not account for lens distortion because an ideal pinhole camera does not have a lens. To accurately represent a real camera, the camera model includes the radial and tangential lens distortion.

## Radial Distortion

Radial distortion occurs when light rays bend more near the edges of a lens than they do at its optical center. The smaller the lens, the greater the distortion.

Negative radial distortion "pincushion"

No distortion

Positive radial distortion "barrel"

The radial distortion coefficients model this type of distortion. The distorted points are denoted as $\left(x_{\text {distorted }}, y_{\text {distorted }}\right)$ :
$x_{\text {distorted }}=x\left(1+k_{1}{ }^{*} r^{2}+k_{2}{ }^{*} r^{4}+k_{3}{ }^{*} r^{6}\right)$
$y_{\text {distorted }}=y\left(1+k_{1} * r^{2}+k_{2} * r^{4}+k_{3} * r^{6}\right)$

- $\quad x, y$ - Undistorted pixel locations. $x$ and $y$ are in normalized image coordinates. Normalized image coordinates are calculated from pixel coordinates by translating to the optical center and dividing by the focal length in pixels. Thus, $x$ and $y$ are dimensionless.
- $k_{1}, k_{2}$, and $k_{3}$ - Radial distortion coefficients of the lens.
- $r^{2}: x^{2}+y^{2}$

Typically, two coefficients are sufficient for calibration. For severe distortion, such as in wide-angle lenses, you can select 3 coefficients to include $k_{3}$.

## Tangential Distortion

Tangential distortion occurs when the lens and the image plane are not parallel. The tangential distortion coefficients model this type of distortion.

Zero Tangential Distortion

Tangential Distortion

The distorted points are denoted as $\left(x_{\text {distorted }}, y_{\text {distorted }}\right)$ :
$x_{\text {distorted }}=x+\left[2 * p_{1} * x * y+p_{2} *\left(r^{2}+2 * x^{2}\right)\right]$
$y_{\text {distorted }}=y+\left[p_{1} *\left(r^{2}+2 * y^{2}\right)+2 * p_{2} * x * y\right]$

- $x, y$ - Undistorted pixel locations. $x$ and $y$ are in normalized image coordinates. Normalized image coordinates are calculated from pixel coordinates by translating to the optical center and dividing by the focal length in pixels. Thus, $x$ and $y$ are dimensionless.
- $p_{1}$ and $p_{2}$ - Tangential distortion coefficients of the lens.
- $r^{2}=x^{2}+y^{2}$

- "Structure From Motion From Two Views"

## Structure from Motion

```
In this section...
"Structure from Motion from Two Views" on page 6-69
"Structure from Motion from Multiple Views" on page 6-71
```

Structure from motion ( SfM ) is the process of estimating the 3-D structure of a scene from a set of 2-D images. SfM is used in many applications, such as 3 -D scanning and augmented reality.

SfM can be computed in many different ways. The way in which you approach the problem depends on different factors, such as the number and type of cameras used, and whether the images are ordered. If the images are taken with a single calibrated camera, then the 3-D structure and camera motion can only be recovered up to scale. To compute the structure and motion in world units, you need additional information, such as:

- The size of an object in the scene
- Information from another sensor, for example, an odometer.

## Structure from Motion from Two Views

For the simple case of structure from two stationary cameras or one moving camera, one view must be considered camera 1 and the other one camera 2 . In this scenario, the algorithm assumes that camera 1 is at the origin and its optical axis lies along the $z$-axis.

1 SfM requires point correspondences between images. Find corresponding points either by matching features or tracking points from image 1 to image 2. Feature tracking techniques, such as Kanade-Lucas-Tomasi (KLT) algorithm, work well when the cameras are close together. As cameras move further apart, the KLT algorithm breaks down, and feature matching can be used instead.

camera 1

camera 2

| Distance Between Cameras <br> (Baseline) | Method for Finding Point <br> Correspondences | Example |
| :--- | :--- | :--- |
| Wide | Match features using <br> matchFeatures | "Find Image Rotation and <br> Scale Using Automated <br> Feature Matching" |
| Narrow | Track features using <br> vision.PointTracker | "Face Detection and <br> Tracking Using the KLT <br> Algorithm" |

2 To find the pose of the second camera relative to the first camera, you must compute the fundamental matrix. Use the corresponding points found in the previous step for the computation. The fundamental matrix describes the epipolar geometry of the two cameras. It relates a point in one camera to an epipolar line in the other camera. Use the estimateFundamentalMatrix function to estimate the fundamental matrix.

3 Input the fundamental matrix to the cameraPose function. cameraPose returns the orientation and the location of the second camera in the coordinate system of the
first camera. The location can only be computed up to scale, so the distance between two cameras is set to 1 . In other words, the distance between the cameras is defined to be 1 unit.
4 Determine the 3-D locations of the matched points using triangulate. Because the pose is up to scale, when you compute the structure, it has the right shape but not the actual size.

The triangulate function takes two camera matrices, which you can compute using cameraMatrix.
5 Use pcshow to display the reconstruction, and use plotCamera to visualize the camera poses.

To recover the scale of the reconstruction, you need additional information. One method to recover the scale is to detect an object of a known size in the scene. The "Structure From Motion From Two Views" example shows how to recover scale by detecting a sphere of a known size in the point cloud of the scene.

## Structure from Motion from Multiple Views

For most applications, such as robotics and autonomous driving, SfM uses more than two views.

The approach used for SfM from two views can be extended for multiple views. The set of multiple views used for SfM can be ordered or unordered. The approach taken here assumes an ordered sequence of views. SfM from multiple views requires point correspondences across multiple images, called tracks. A typical approach is to compute the tracks from pairwise point correspondences. You can use viewSet to manage the
pairwise correspondences and find the tracks. Each track corresponds to a 3-D point in the scene. To compute 3-D points from the tracks, use triangulateMultiview.

Using the approach in SfM from two views, you can find the pose of camera 2 relative to camera 1 . To extend this approach to the multiple view case, find the pose of camera 3 relative to camera 2, and so on. The relative poses must be transformed into a common coordinate system. Typically, all camera poses are computed relative to camera 1 so that all poses are in the same coordinate system. You can use viewSet to manage camera poses. The viewSet object stores the views and connections between the views.

Every camera pose estimation from one view to the next contains errors. The errors arise from imprecise point localization in images, and from noisy matches and imprecise
calibration. These errors accumulate as the number of views increases, an effect known as drift. One way to reduce the drift, is to refine camera poses and 3-D point locations. The nonlinear optimization algorithm, called bundle adjustment, implemented by the bundleAdjustment function, can be used for the refinement.

The "Structure From Motion From Multiple Views" example shows how to reconstruct a 3 -D scene from a sequence of 2-D views. The example uses the Camera Calibrator app to calibrate the camera that takes the views. It uses a viewSet object to store and manage the data associated with each view.

## Point Feature Types

Image feature detection is a building block of many computer vision tasks, such as image registration, tracking, and object detection. The Computer Vision System Toolbox includes a variety of functions for image feature detection. These functions return points objects that store information specific to particular types of features, including ( $\mathrm{x}, \mathrm{y}$ ) coordinates (in the Location property). You can pass a points object from a detection function to a variety of other functions that require feature points as inputs. The algorithm that a detection function uses determines the type of points object it returns.

## Functions That Return Points Objects

$\left.$| Points Object | Returned By | Type of Feature |

## Local Feature Detection and Extraction

Local features and their descriptors, which are a compact vector representations of a local neighborhood, are the building blocks of many computer vision algorithms. Their applications include image registration, object detection and classification, tracking, and motion estimation. Using local features enables these algorithms to better handle scale changes, rotation, and occlusion. The Computer Vision System Toolbox ${ }^{\text {TM }}$ provides the FAST, Harris, and Shi \& Tomasi methods for detecting corner features, and the SURF and MSER methods for detecting blob features. The toolbox includes the SURF, FREAK, BRISK, and HOG descriptors. You can mix and match the detectors and the descriptors depending on the requirements of your application.

## What Are Local Features?

Local features refer to a pattern or distinct structure found in an image, such as a point, edge, or small image patch. They are usually associated with an image patch that differs from its immediate surroundings by texture, color, or intensity. What the feature actually represents does not matter, just that it is distinct from its surroundings. Examples of local features are blobs, corners, and edge pixels.

Example of Corner Detection

```
I = imread('circuit.tif');
corners = detectFASTFeatures(I,'MinContrast',0.1);
J = insertMarker(I,corners,'circle');
imshow(J);
```

## Benefits and Applications of Local Features

Local features let you find image correspondences regardless of occlusion, changes in viewing conditions, or the presence of clutter. In addition, the properties of local features make them suitable for image classification, such as in "Image Classification with Bag of Visual Words" on page 7-64.

Local features are used in two fundamental ways:

- To localize anchor points for use in image stitching or 3-D reconstruction.
- To represent image contents compactly for detection or classification, without requiring image segmentation.

## What Makes a Good Local Feature?

Detectors that rely on gradient-based and intensity variation approaches detect good local features. These features include edges, blobs, and regions. Good local features exhibit the following properties:

- Repeatable detections:

When given two images of the same scene, most features that the detector finds in both images are the same. The features are robust to changes in viewing conditions and noise.

- Distinctive:

The neighborhood around the feature center varies enough to allow for a reliable comparison between the features.

- Localizable:

The feature has a unique location assigned to it. Changes in viewing conditions do not affect its location.

## Feature Detection and Feature Extraction

Feature detection selects regions of an image that have unique content, such as corners or blobs. Use feature detection to find points of interest that you can use for further processing. These points do not necessarily correspond to physical structures, such as the corners of a table. The key to feature detection is to find features that remain locally invariant so that you can detect them even in the presence of rotation or scale change.

Feature extraction involves computing a descriptor, which is typically done on regions centered around detected features. Descriptors rely on image processing to transform a
local pixel neighborhood into a compact vector representation. This new representation permits comparison between neighborhoods regardless of changes in scale or orientation. Descriptors, such as SIFT or SURF, rely on local gradient computations. Binary descriptors, such as BRISK or FREAK, rely on pairs of local intensity differences, which are then encoded into a binary vector.

## Choose a Feature Detector and Descriptor

Select the best feature detector and descriptor by considering the criteria of your application and the nature of your data. The first table helps you understand the general criteria to drive your selection. The next two tables provide details on the detectors and descriptors available in Computer Vision System Toolbox.

## Considerations for Selecting a Detector and Descriptor

| Criteria | Suggestion |
| :---: | :---: |
| Type of features in your image | Use a detector appropriate for your data. For example, if your image contains an image of bacteria cells, use the blob detector rather than the corner detector. If your image is an aerial view of a city, you can use the corner detector to find man-made structures. |
| Context in which you are using the features: <br> - Matching key points <br> - Classification | The HOG and SURF descriptors are suitable for classification tasks. In contrast, binary descriptors, such as BRISK and FREAK, are typically used for finding point correspondences between images, which are used for registration. |
| Type of distortion present in your image | Choose a detector and descriptor that addresses the distortion in your data. For example, if there is no scale change present, consider a corner detector that does not handle scale. If your data contains a higher level of distortion, such as scale and rotation, then use the more computationally intensive SURF feature detector and descriptor. |
| Performance requirements: <br> - Real-time performance required <br> - Accuracy versus speed | Binary descriptors are generally faster but less accurate than gradient-based descriptors. For greater accuracy, use several detectors and descriptors at the same time. |

## Choose a Detection Function Based on Feature Type

| Detector | Feature Type | Function | Scale Independent |
| :--- | :--- | :--- | :--- |
| FAST [1] | Corner | detectFASTFeatures | No |
| Minimum <br> eigenvalue <br> algorithm[4] | Corner | detectMinEigenFeatures | No |
| Corner detector [3] | Corner | detectHarrisFeatures | No |
| SURF [11] | Blob | detectSURFFeatures | Yes |
| BRISK [6] | Corner | detectBRISKFeatures | Yes |
| MSER [8] | Region with <br> uniform intensity | detectMSERFeatures | Yes |

Note: Detection functions return objects that contain information about the features. The extractHOGFeatures and extractFeatures functions use these objects to create descriptors.

## Choose a Descriptor Method

| Descriptor | Binary | Function and Method | Invariance |  | Typical Use |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  |  | Scale | Rotation | Finding Point <br> Correspondences |  |  |
| HOG | No | extractHOGFeatures(I, ...) | No | No | No | Yes |
| LBP | No | extractLBPFeatures(I, ...) | No | Yes | No | Yes |
| SURF | No | extractFeatures(I, <br> 'Method',''SURF') | Yes | Yes | Yes | Yes |
| FREAK | Yes | extractFeatures(I, <br> 'Method','FREAK') | Yes | Yes | Yes | No |
| BRISK | Yes | extractFeatures(I, <br> 'Method','BRISK') | Yes | Yes | Yes | No |
| • Block <br> Simple pixel <br> neighborhood <br> around a <br> keypoint | No | extractFeatures(I, <br> 'Method','Block') | No | No | Yes | Yes |

## Note:

- The extractFeatures function provides different extraction methods to best match the requirements of your application. When you do not specify the 'Method ' input for the extractFeatures function, the function automatically selects the method based on the type of input point class.
- Binary descriptors are fast but less precise in terms of localization. They are not suitable for classification tasks. The extractFeatures function returns a binaryFeatures object. This object enables the Hamming-distance-based matching metric used in the matchFeatures function.

## Use Local Features

Registering two images is a simple way to understand local features. This example finds a geometric transformation between two images. It uses local features to find welllocalized anchor points.

## Display two images.

The first image is the original image.

```
original = imread('cameraman.tif');
figure;
imshow(original);
```

The second image, is the original image rotated and scaled.

```
scale = 1.3;
J = imresize(original,scale);
theta = 31;
distorted = imrotate(J,theta);
figure
imshow(distorted)
```

Detect matching features between the original and distorted image.
Detecting the matching SURF features is the first step in determining the transform needed to correct the distorted image.

```
ptsOriginal = detectSURFFeatures(original);
```

```
ptsDistorted = detectSURFFeatures(distorted);
```

## Extract features and compare the detected blobs between the two images.

The detection step found several roughly corresponding blob structures in both images. Compare the detected blob features. This process is facilitated by feature extraction, which determines a local patch descriptor.

```
[featuresOriginal,validPtsOriginal] = ...
    extractFeatures(original,ptsOriginal);
[featuresDistorted,validPtsDistorted] = ...
    extractFeatures(distorted,ptsDistorted);
```

It is possible that not all of the original points were used to extract descriptors. Points might have been rejected if they were too close to the image border. Therefore, the valid points are returned in addition to the feature descriptors.

The patch size used to compute the descriptors is determined during the feature extraction step. The patch size corresponds to the scale at which the feature is detected. Regardless of the patch size, the two feature vectors, featuresOriginal and featuresDistorted, are computed in such a way that they are of equal length. The descriptors enable you to compare detected features, regardless of their size and rotation.

## Find candidate matches.

Obtain candidate matches between the features by inputting the descriptors to the matchFeatures function. Candidate matches imply that the results can contain some invalid matches. Two patches that match can indicate like features but might not be a correct match. A table corner can look like a chair corner, but the two features are obviously not a match.

```
indexPairs = matchFeatures(featuresOriginal,featuresDistorted);
```

## Find point locations from both images.

Each row of the returned indexPairs contains two indices of candidate feature matches between the images. Use the indices to collect the actual point locations from both images.

```
matchedOriginal = validPtsOriginal(indexPairs(:,1));
matchedDistorted = validPtsDistorted(indexPairs(:,2));
```

## Display the candidate matches.

figure
showMatchedFeatures(original, distorted, matchedOriginal, matchedDistorted) title('Candidate matched points (including outliers)')

Candidate matched points (including outliers)

## Analyze the feature locations.

If there are a sufficient number of valid matches, remove the false matches. An effective technique for this scenario is the RANSAC algorithm. The estimateGeometricTransform function implements M-estimator sample consensus (MSAC), which is a variant of the RANSAC algorithm. MSAC finds a geometric transform and separates the inliers (correct matches) from the outliers (spurious matches).
[tform, inlierDistorted,inlierOriginal] = ... estimateGeometricTransform(matchedDistorted,... matchedOriginal,'similarity');

## Display the matching points.

```
figure
showMatchedFeatures(original,distorted,inlierOriginal,inlierDistorted)
title('Matching points (inliers only)')
legend('ptsOriginal','ptsDistorted')
```

Matching points (inliers only)

Verify the computed geometric transform.
Apply the computed geometric transform to the distorted image.

```
outputView = imref2d(size(original));
recovered = imwarp(distorted,tform,'OutputView',outputView);
```

Display the recovered image and the original image.
figure
imshowpair(original,recovered,'montage')

## Image Registration Using Multiple Features

This example builds on the results of the "Use Local Features" example. Using more than one detector and descriptor pair enables you to combine and reinforce your results. Multiple pairs are also useful for when you cannot obtain enough good matches (inliers) using a single feature detector.

Load the original image.

```
original = imread('cameraman.tif');
figure;
imshow(original);
text(size(original,2),size(original,1)+15, ...
    Image courtesy of Massachusetts Institute of Technology', ...
    'FontSize',7,'HorizontalAlignment','right');
```

Scale and rotate the original image to create the distorted image.

```
scale = 1.3;
J = imresize(original, scale);
theta = 31;
distorted = imrotate(J,theta);
figure
imshow(distorted)
```

Detect the features in both images. Use the BRISK detectors first, followed by the SURF detectors.
ptsOriginalBRISK = detectBRISKFeatures(original,'MinContrast',0.01); ptsDistortedBRISK = detectBRISKFeatures(distorted, 'MinContrast', 0.01);

```
ptsOriginalSURF = detectSURFFeatures(original);
ptsDistortedSURF = detectSURFFeatures(distorted);
```

Extract descriptors from the original and distorted images. The BRISK features use the FREAK descriptor by default.

```
[featuresOriginalFREAK,validPtsOriginalBRISK] = ...
    extractFeatures(original,ptsOriginalBRISK);
[featuresDistortedFREAK,validPtsDistortedBRISK] = ...
    extractFeatures(distorted,ptsDistortedBRISK);
[featuresOriginalSURF,validPtsOriginalSURF] = ...
    extractFeatures(original,ptsOriginalSURF);
[featuresDistortedSURF,validPtsDistortedSURF] = ...
    extractFeatures(distorted,ptsDistortedSURF);
```

Determine candidate matches by matching FREAK descriptors first, and then SURF descriptors. To obtain as many feature matches as possible, start with detector and matching thresholds that are lower than the default values. Once you get a working solution, you can gradually increase the thresholds to reduce the computational load required to extract and match features.

```
indexPairsBRISK = matchFeatures(featuresOriginalFREAK,...
    featuresDistortedFREAK,'MatchThreshold',40,'MaxRatio',0.8);
indexPairsSURF = matchFeatures(featuresOriginalSURF,featuresDistortedSURF);
```

Obtain candidate matched points for BRISK and SURF.

```
matchedOriginalBRISK = validPtsOriginalBRISK(indexPairsBRISK(:,1));
matchedDistortedBRISK = validPtsDistortedBRISK(indexPairsBRISK(:,2));
matchedOriginalSURF = validPtsOriginalSURF(indexPairsSURF(:,1));
matchedDistortedSURF = validPtsDistortedSURF(indexPairsSURF(:,2));
```

Visualize the BRISK putative matches.
figure
showMatchedFeatures(original, distorted,matchedOriginalBRISK,... matchedDistortedBRISK)
title('Putative matches using BRISK \& FREAK')
legend('ptsOriginalBRISK', 'ptsDistortedBRISK')

Putative matches using BRISK \& FREAK

Combine the candidate matched BRISK and SURF local features. Use the Location property to combine the point locations from BRISK and SURF features.

```
matchedOriginalXY = ...
    [matchedOriginalSURF.Location; matchedOriginalBRISK.Location];
matchedDistortedXY = ...
```

[matchedDistortedSURF.Location; matchedDistortedBRISK.Location];
Determine the inlier points and the geometric transform of the BRISK and SURF features.
[tformTotal, inlierDistortedXY,inlierOriginalXY] = ...
estimateGeometricTransform(matchedDistortedXY, ...
matchedOriginalXY,'similarity');
Display the results. The result provides several more matches than the example that used a single feature detector.
figure
showMatchedFeatures(original, distorted,inlierOriginalXY,inlierDistortedXY) title('Matching points using SURF and BRISK (inliers only)') legend('ptsOriginal', 'ptsDistorted')

## Matching points using SURF and BRISK (inliers only)

Compare the original and recovered image.
outputView = imref2d(size(original));
recovered = imwarp(distorted,tformTotal,'OutputView', outputView);
figure;

```
imshowpair(original,recovered,'montage')
```

## Description

The Training Image Labeler provides an easy way to label objects in images. Using this app, you can:

- Interactively specify rectangular regions of interest (ROIs) for multiple categories of objects.
- Export ROIs for training or evaluating an object detector.
- Train an object detector using the trainCascadeObjectDetector function.

## Open the Training Image Labeler

- MATLAB Toolstrip: Open the Apps tab, under Image Processing and Computer Vision, click the app icon.
- MATLAB command prompt: Enter trainingImageLabeler

## App Controls

You can add an unlimited number of images to the Data Browser. You can then select, remove, and create ROIs, and save your session. When you are done, you can export the ROI information to an XML file.

## Add Images

Use the Add Images icon to select and add images to the Data Browser. You can add more images at any time during your editing session. The source images remain in the folder where they were originally located. The app does not make copies of the original images or move them. If you rotate the images in the Data Browser, the app overwrites the images in their original location with the modified orientation.

The app provides a list of image thumbnails that you loaded for the session. Next to each thumbnail, you see the file name and number of ROIs created in that image.

## Specify Regions of Interest

After you load images, you can delineate ROIs. You can switch between images and continue creating ROIs. The app allows you to create ROI Labels for multiple object categories. Each ROI label has a name and a color. First create the labels and then draw the ROIs in images.

## Create labels:

1 Click the Add ROI label E for each object category.
2 Name each ROI label and select its color.
3 Select the category from the ROI labels list you created.
4 Draw an ROI by dragging the cursor over the object in the image.

- To modify the size of an ROI, click either the corner or side grips. To keep the aspect ratio of the ROI while changing its size, hold Shift.
- To copy and paste an ROI, click within its border to select it. You can select one or more ROIs to move or to copy and paste.
- To delete an ROI, click the red x in its upper-right corner.
- If the object of interest fills the entire image, right-click the image and select Add full image ROI from the menu.

To show or hide the label names in the currently displayed image, select Show ROI Labels.

You can also use the following common shortcuts:

- Ctrl+C to copy
- Ctrl+V to paste
- Ctrl+X to cut

## Remove

Rotate
Sort Remove, Rotate, and Sort Images
You can remove, rotate, or sort the images. Right-click any image to access these options. To select multiple images, press Ctrl+click. To select consecutive images, press Shift+click. To sort images by the number of ROIs, from least amount of ROIs contained in each image, right-click any image and select Sort list by number of ROIs.

## New Session

When you start a new session, you can save the current session before clearing it.

## Open Session

You can open a new session to replace or add to the current session. The app loads the selected MAT session file. To replace your current session, from the Open Session options, select Open an existing session. To combine multiple sessions, select Add session to the current session.

## $\square$ <br> Save Session

You can name and save your session to a .MAT file. The default name is LabelingSession. The saved session file contains all the required information to reload the session in the state that you saved it. It contains the paths to the original images, the coordinates for the ROI bounding boxes for each image, file names, and logical information to record the state of the files.

## Export ROIs

When you click Export ROIs, the app exports the ROI information to the MATLAB workspace as an $M$-by- $N$ table containing the image file names and the ROIs. The image file names are stored in the first column of the table. The subsequent columns contain the ROIs for each category.

| $1$ <br> imageFilename | 2 StopSign | 3 chimney | $\begin{gathered} 4 \\ \text { car } \end{gathered}$ | $\begin{gathered} 5 \\ \text { tree } \end{gathered}$ | $\begin{gathered} 6 \\ \text { person } \end{gathered}$ | 7 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| ,toolbox\vision\visiondata\stopSignImages\image001.jpg ${ }^{\text {' }}$ | [848,281,5... | $]$ | [415,39... | [288,12... | [] |  |  |
| itoolbox\vision\visiondata\stopSignlmages\image002.jpg ${ }^{\text {' }}$ | [385,501,1... | ] | [293,61... | [335,10... | [] |  |  |
| ,toolbox\vision\visiondata\stopSignlmages \image003.jpg ${ }^{\text {' }}$ | [459,368,6... | $]$ | 0 | [636,25... | [853,364... |  |  |
| (toolbox\vision\visiondata\stopSignlmages\image004.jpg | [935,387,6... |  | $3 \times 4$ do... | [1066,1... | [] |  |  |
| (toolbox\vision\visiondata\stopSignlmages\image005.jpg ${ }^{\text {' }}$ | [960,385,8... | [431,83,1... | $3 \times 4$ do... | [1064,7... |  |  |  |
| itoolbox\vision\visiondata\stopSignImages \image006.jpg ${ }^{\text {' }}$ | [1021,337,... | ] | [ | [385,20... | [] |  |  |
| itoolbox\vision\visiondata\stopSignImages\image007.jpg ${ }^{\text {' }}$ | [ | ] |  | [] |  |  |  |

If you only have one ROI label, the app gives you the additional option to export the ROIs as a struct array. The structure contains two fields. One field stores the image file location and the other field stores the corresponding ROI information for each image.

## Import ROIs

You can import ROIs created using another labeling method. The ROIs must be stored in a table using the same format as the ROIs exported by the app. The table can be a variable in the MATLAB workspace, or it can be saved as a MAT file.

## Why Train a Detector?

The vision.CascadeObjectDetector System object comes with several pretrained classifiers for detecting frontal faces, profile faces, noses, eyes, and the upper body. However, these classifiers are not always sufficient for a particular application. Computer Vision System Toolbox provides the trainCascadeObjectDetector function to train a custom classifier.

## What Kinds of Objects Can You Detect?

The Computer Vision System Toolbox cascade object detector can detect object categories whose aspect ratio does not vary significantly. Objects whose aspect ratio remains fixed include faces, stop signs, and cars viewed from one side.

The vision.CascadeObjectDetector System object detects objects in images by sliding a window over the image. The detector then uses a cascade classifier to decide whether the window contains the object of interest. The size of the window varies to detect objects at different scales, but its aspect ratio remains fixed. The detector is very sensitive to out-ofplane rotation, because the aspect ratio changes for most 3-D objects. Thus, you need to train a detector for each orientation of the object. Training a single detector to handle all orientations will not work.

## How Does the Cascade Classifier Work?

The cascade classifier consists of stages, where each stage is an ensemble of weak learners. The weak learners are simple classifiers called decision stumps. Each stage is trained using a technique called boosting. Boosting provides the ability to train a highly accurate classifier by taking a weighted average of the decisions made by the weak learners.

Each stage of the classifier labels the region defined by the current location of the sliding window as either positive or negative. Positive indicates that an object was found and negative indicates no objects were found. If the label is negative, the classification of this region is complete, and the detector slides the window to the next location. If the label is positive, the classifier passes the region to the next stage. The detector reports an object found at the current window location when the final stage classifies the region as positive.

The stages are designed to reject negative samples as fast as possible. The assumption is that the vast majority of windows do not contain the object of interest. Conversely, true positives are rare and worth taking the time to verify.

- A true positive occurs when a positive sample is correctly classified.
- A false positive occurs when a negative sample is mistakenly classified as positive.
- A false negative occurs when a positive sample is mistakenly classified as negative.

To work well, each stage in the cascade must have a low false negative rate. If a stage incorrectly labels an object as negative, the classification stops, and you cannot correct the mistake. However, each stage can have a high false positive rate. Even if the detector incorrectly labels a nonobject as positive, you can correct the mistake in subsequent stages.

The overall false positive rate of the cascade classifier is $f^{s}$, where $f$ is the false positive rate per stage in the range ( 01 ), and $s$ is the number of stages. Similarly, the overall
true positive rate is $t^{s}$, where $t$ is the true positive rate per stage in the range ( $\begin{aligned} & 0\end{aligned} 1$ ]. Thus, adding more stages reduces the overall false positive rate, but it also reduces the overall true positive rate.

## Create a Cascade Classifier Using the trainCascadeObjectDetector

Cascade classifier training requires a set of positive samples and a set of negative images. You must provide a set of positive images with regions of interest specified to be used as positive samples. You can use the Training Image Labeler to label objects of interest with bounding boxes. The Training Image Labeler outputs a table to use for positive samples. You also must provide a set of negative images from which the function generates negative samples automatically. To achieve acceptable detector accuracy, set the number of stages, feature type, and other function parameters.

## Considerations when Setting Parameters

Select the function parameters to optimize the number of stages, the false positive rate, the true positive rate, and the type of features to use for training. When you set the parameters, consider these tradeoffs.

| Condition | Consideration |
| :--- | :--- |
| A large training set (in the thousands). | Increase the number of stages and set a <br> higher false positive rate for each stage. |
| A small training set. | Decrease the number of stages and set a <br> lower false positive rate for each stage. |
| To reduce the probability of missing an <br> object. | Increase the true positive rate. However, <br> a high true positive rate can prevent you <br> from achieving the desired false positive <br> rate per stage, making the detector more <br> likely to produce false detections. |
| To reduce the number of false detections. | Increase the number of stages or decrease <br> the false alarm rate per stage. |

## Feature Types Available for Training

Choose the feature that suits the type of object detection you need. The trainCascadeObjectDetector supports three types of features: Haar, local binary patterns (LBP), and histograms of oriented gradients (HOG). Haar and LBP features are often used to detect faces because they work well for representing fine-scale textures. The HOG features are often used to detect objects such as people and cars. They are useful for capturing the overall shape of an object. For example, in the following visualization of the HOG features, you can see the outline of the bicycle.

You might need to run the trainCascadeObjectDetector function multiple times to tune the parameters. To save time, you can use LBP or HOG features on a small subset of your data. Training a detector using Haar features takes much longer. After that, you can run the Haar features to see if the accuracy improves.

## Supply Positive Samples

To create positive samples easily, you can use the Training Image Labeler app. The Training Image Labeler provides an easy way to label positive samples by interactively specifying rectangular regions of interest (ROIs).

You can also specify positive samples manually in one of two ways. One way is to specify rectangular regions in a larger image. The regions contain the objects of interest. The other approach is to crop out the object of interest from the image and save it as a
separate image. Then, you can specify the region to be the entire image. You can also generate more positive samples from existing ones by adding rotation or noise, or by varying brightness or contrast.

## Supply Negative Images

Negative samples are not specified explicitly. Instead, the trainCascadeObjectDetector function automatically generates negative samples from user-supplied negative images that do not contain objects of interest. Before training each new stage, the function runs the detector consisting of the stages already trained on the negative images. Any objects detected from these image are false positives, which are used as negative samples. In this way, each new stage of the cascade is trained to correct mistakes made by previous stages.

As more stages are added, the detector's overall false positive rate decreases, causing generation of negative samples to be more difficult. For this reason, it is helpful to supply as many negative images as possible. To improve training accuracy, supply negative images that contain backgrounds typically associated with the objects of interest. Also, include negative images that contain nonobjects similar in appearance to the objects of interest. For example, if you are training a stop-sign detector, include negative images that contain road signs and shapes similar to a stop sign.

## Choose the Number of Stages

There is a trade-off between fewer stages with a lower false positive rate per stage or more stages with a higher false positive rate per stage. Stages with a lower false positive rate are more complex because they contain a greater number of weak learners. Stages with a higher false positive rate contain fewer weak learners. Generally, it is better to have a greater number of simple stages because at each stage the overall false positive rate decreases exponentially. For example, if the false positive rate at each stage is $50 \%$, then the overall false positive rate of a cascade classifier with two stages is $25 \%$. With
three stages, it becomes $12.5 \%$, and so on. However, the greater the number of stages, the greater the amount of training data the classifier requires. Also, increasing the number of stages increases the false negative rate. This increase results in a greater chance of rejecting a positive sample by mistake. Set the false positive rate (FalseAlarmRate) and the number of stages, (NumCascadeStages) to yield an acceptable overall false positive rate. Then you can tune these two parameters experimentally.

Training can sometimes terminate early. For example, suppose that training stops after seven stages, even though you set the number of stages parameter to 20 . It is possible that the function cannot generate enough negative samples. If you run the function again and set the number of stages to seven, you do not get the same result. The results between stages differ because the number of positive and negative samples to use for each stage is recalculated for the new number of stages.

## Training Time of Detector

Training a good detector requires thousands of training samples. Large amounts of training data can take hours or even days to process. During training, the function displays the time it took to train each stage in the MATLAB Command Window. Training time depends on the type of feature you specify. Using Haar features takes much longer than using LBP or HOG features.

## Troubleshooting

## What if you run out of positive samples?

The trainCascadeObjectDetector function automatically determines the number of positive samples to use to train each stage. The number is based on the total number of positive samples supplied by the user and the values of the TruePositiveRate and NumCascadeStages parameters.

The number of available positive samples used to train each stage depends on the true positive rate. The rate specifies what percentage of positive samples the function can classify as negative. If a sample is classified as a negative by any stage, it never reaches subsequent stages. For example, suppose you set the TruePositiveRate to 0.9, and all of the available samples are used to train the first stage. In this case, $10 \%$ of the positive samples are rejected as negatives, and only $90 \%$ of the total positive samples are available for training the second stage. If training continues, then each stage is trained with fewer and fewer samples. Each subsequent stage must solve an increasingly more difficult classification problem with fewer positive samples. With each stage getting fewer samples, the later stages are likely to overfit the data.

Ideally, use the same number of samples to train each stage. To do so, the number of positive samples used to train each stage must be less than the total number of available positive samples. The only exception is that when the value of TruePositiveRate times the total number of positive samples is less than 1, no positive samples are rejected as negatives.

The function calculates the number of positive samples to use at each stage using the following formula:
number of positive samples $=$ floor(totalPositiveSamples $/(1+$ (NumCascadeStages - 1) * (1-TruePositiveRate)))
This calculation does not guarantee that the same number of positive samples are available for each stage. The reason is that it is impossible to predict with certainty how many positive samples will be rejected as negatives. The training continues as long as the number of positive samples available to train a stage is greater than $10 \%$ of the number of samples the function determined automatically using the preceding formula. If there are not enough positive samples the training stops and the function issues a warning. The function also outputs a classifier consisting of the stages that it had trained up to that point. If the training stops, you can add more positive samples. Alternatively, you can increase TruePositiveRate. Reducing the number of stages can also work, but such reduction can also result in a higher overall false alarm rate.

## What to do if you run out of negative samples?

The function calculates the number of negative samples used at each stage. This calculation is done by multiplying the number of positive samples used at each stage by the value of NegativeSamplesFactor.

Just as with positive samples, there is no guarantee that the calculated number of negative samples are always available for a particular stage. The trainCascadeObjectDetector function generates negative samples from the negative images. However, with each new stage, the overall false alarm rate of the cascade classifier decreases, making it less likely to find the negative samples.

The training continues as long as the number of negative samples available to train a stage is greater than $10 \%$ of the calculated number of negative samples. If there are not enough negative samples, the training stops and the function issues a warning. It outputs a classifier consisting of the stages that it had trained up to that point. When the training stops, the best approach is to add more negative images. Alternatively, you can reduce the number of stages or increase the false positive rate.

## Examples

## Train a Five-Stage Stop-Sign Detector

This example shows you how to set up and train a five-stage, stop-sign detector, using 86 positive samples. The default value for TruePositiveRate is 0.995.

Step 1: Load the positive samples data from a MAT-file. In this example, file names and bounding boxes are contained in the array of structures labeled 'data'.

```
load('stopSigns.mat');
```

Step 2: Add the image directory to the MATLAB path.

```
imDir = fullfile(matlabroot,'toolbox','vision','visiondata','stopSignImages');
addpath(imDir);
```

Step 3: Specify the folder with negative images.
negativeFolder = fullfile(matlabroot,'toolbox','vision','visiondata','nonStopSigns');
Step 4: Train the detector.
trainCascadeObjectDetector('stopSignDetector.xml',data, negativeFolder, 'FalseAlarmRate', 0.2,'NumCascadeStages',5);
Computer Vision System Toolbox software returns the following message:

```
Automatically setting ObjectTrainingSize to [ 33, 32 ]
Using at most 86 of 86 positive samples per stage
Using at most }172\mathrm{ negative samples per stage
Training stage 1 of 5
```

```
Used 86 positive and }172\mathrm{ negative samples
Training stage 2 of 5
```

```
Used 86 positive and }172\mathrm{ negative samples
Training stage 3 of 5
```

```
Used 86 positive and }172\mathrm{ negative samples
Training stage 4 of 5
```

```
Used 86 positive and }172\mathrm{ negative samples
Training stage 5 of 5
```

```
Used 86 positive and }172\mathrm{ negative samples
Training complete
```

All 86 positive samples were used to train each stage. This high rate occurs because the true positive rate is very high relative to the number of positive samples.

## Train a Five-Stage Stop-Sign Detector with a Decreased True Positive Rate

This example shows you how to train a stop-sign detector on the same data set as the first example, (steps $1-3$ ), but with the TruePositiveRate decreased to 0.98 .

Step 4: Train the detector.
trainCascadeObjectDetector('stopSignDetector_tpro_98.xml', data, negativeFolder,... 'FalseAlarmRate', 0.2, 'NumCascadeStages', 5,...

```
    'TruePositiveRate', 0.98);
Automatically setting ObjectTrainingSize to [ 33, 32 ]
Using at most }79\mathrm{ of }86\mathrm{ positive samples per stage
Using at most }158\mathrm{ negative samples per stage
Training stage 1 of 5
```

```
Used }79\mathrm{ positive and }158\mathrm{ negative samples
Training stage 2 of 5
```

```
Used 79 positive and 158 negative samples
Training stage 3 of 5
```

```
Used }79\mathrm{ positive and }158\mathrm{ negative samples
Training stage 4 of 5
```

```
Used }79\mathrm{ positive and }158\mathrm{ negative samples
Training stage 5 of 5
```

```
Used 79 positive and 85 negative samples
Training complete
```

Only 79 of the total 86 positive samples were used to train each stage. This lowered rate occurs because the true positive rate was low enough for the function to start rejecting some of the positive samples as false negatives.

## Train a Ten-Stage Stop-Sign Detector

This example shows you how to train a stop-sign detector on the same data set as the first example, (steps $1-3$ ), but with the number of stages increased to 10 .

Step 4: Train the detector.

```
trainCascadeObjectDetector('stopSignDetector_10stages.xml',data,negativeFolder,...
```

FalseAlarmRate',0.2, 'NumCascadeStages ..... 10)

[. Warning:Unable to generate a sufficient number of negative samples for this stage.Consider reducing the number of stages, reducing the false alarm rateor adding more negative images.Cannot find enough samples for training.
Training will halt and return cascade detector with 6 stagesTraining complete

In this case, NegativeSamplesFactor was set to 2 , therefore the number of negative samples used to train each stage was 172 . Notice that the function generated only 33 negative samples for stage 6 and was not able to train stage 7 at all. This condition occurs because the number of negatives in stage 7 was less than 17, (roughly half of the previous number of negative samples). The function produced a stop-sign detector with 6 stages, instead of the 10 previously specified. The resulting overall false alarm rate is $0.2^{7}=1.28 \mathrm{e}-05$, while the expected false alarm rate is $1.024 \mathrm{e}-07$.

At this point, you can add more negative images, reduce the number of stages, or increase the false positive rate. For example, you can increase the false positive rate, FalseAlarmRate, to 0.5 . The expected overall false-positive rate in this case is 0.0039 .

Step 4: Train the detector.

```
trainCascadeObjectDetector('stopSignDetector_10stages_far0_5.xml',data,negativeFolder,...
'FalseAlarmRate',0.5,'NumCascadeStages',10);

This time the function trains eight stages before the threshold reaches the overall false alarm rate of 0.000587108 and training stops.

## Train Stop Sign Detector

Load the positive samples data from a MAT file. The file contains a table specifying bounding boxes for several object categories. The table was exported from the Training Image Labeler app.

Load positive samples.

```
load('stopSignsAndCars.mat');
```

Select the bounding boxes for stop signs from the table.

```
positiveInstances = stopSignsAndCars(:,1:2);
```

Add the image directory to the MATLAB path.

```
imDir = fullfile(matlabroot,'toolbox','vision','visiondata',...
    'stopSignImages');
addpath(imDir);
```

Specify the foler for negative images.

```
negativeFolder = fullfile(matlabroot,'toolbox','vision','visiondata',...
    'nonStopSigns');
```

Create an imageDatastore object containing negative images.

```
negativeImages = imageDatastore(negativeFolder);
```

Train a cascade object detector called 'stopSignDetector.xml' using HOG features. NOTE: The command can take several minutes to run.

```
trainCascadeObjectDetector('stopSignDetector.xml',positiveInstances, ...
    negativeFolder,'FalseAlarmRate',0.1,'NumCascadeStages',5);
```

\section*{More About}
- "Label Images for Classification Model Training" on page 7-29

\section*{External Websites}
- Cascade Trainer

\section*{Train Optical Character Recognition for Custom Fonts}
```

In this section...
"Open the OCR Trainer App" on page 7-51
"Train OCR" on page 7-51
"App Controls" on page 7-53

```

The optical character recognition (OCR) app trains the ocr function to recognize a custom language or font. You can use this app to label character data interactively for OCR training and to generate an OCR language data file for use with the ocr function.

\section*{Open the OCR Trainer App}
- MATLAB Toolstrip: On the Apps tab, under Image Processing and Computer Vision, click \([\underset{\mathbf{A}}{ }]\), the OCR app icon.
- MATLAB command prompt: Enter ocrTrainer.

\section*{Train OCR}

1 In the OCR Trainer, click New Session to open the OCR Training Session Settings dialog box.

2 Under Output Settings, enter a name for the OCR language data file and choose the output folder location for the file. The location you specify must be writable.
3 Under Labeling Method, either label the data manually or pre-label it using optical character recognition. If you use OCR, you can select either the pre-installed English or Japanese language, or you can download additional language support files.

Note: To download a language support file, type visionSupportPackages in a MATLAB Command Window. Alternatively, on the MATLAB Home tab, in the

Environment section, click Add-Ons \(>\) Get Add-Ons. Then use the search box to find "Computer Vision System Toolbox OCR Language Data."

To limit the OCR to a specific character set, select the Character set check box and add the characters.

4 Add images at any time during the training session. The trainer automatically segments the images for OCR training. Inspect the results to verify expected text segmentation. To improve the segmentation, pre-process your images using the Image Segmenter app. Once the images are added, you can inspect segmentation results from the training image view.

5 Remove any noisy images. To improve segmentation results, you can draw a region of interest to select a portion of an image. The display shows the original image on the left and the edited one on the right. When you are done, click Accept All.

6 Modify the extracted samples from the character view window.
- To correct samples, select a group of samples from the Data Browser pane and change the labels using the Character Label field.
- To exclude a sample from training, right-click the sample and select the option to move that sample to the Unknown category. Unknown samples are listed at the top of the Data Browser pane and are not used for training.
- If the bounding box clipped a character, double-click the character and modify it in the image it was extracted from.

7 After correcting the samples, click Train. When the trainer completes training, the app creates an OCR language data file and saves it to the folder you specified.

\section*{App Controls}

\section*{Sessions}

Starts a new session, opens a saved session, or adds a session to the current one. You can also save and name the session. The sessions are saved as MAT files.

\section*{Add Images}

Adds images. You can add images when you start a new session or after you accept the current collection of images.

\section*{Settings}

Set or change the font display.

\section*{Edit Box}

Selects the image that contains the selected character, along with the bounding boxes. You can create additional regions, merge, modify, or delete existing images. To delete an ROI, use the delete key.

\section*{Train}

Creates an OCR data file from the session. To use the .traineddata file with the ocr function, set the 'Language ' property for the ocr function, and follow the directions for a custom language.

\section*{Generate Function}

Creates an autogenerated evaluation function for verification of training results.

\author{
See Also \\ ocr \| OCR Trainer
}

\section*{Troubleshoot ocr Function Results}

\section*{Performance Options with the ocr Function}

If your ocr results are not what you expect, try one or more of the following options:
- Increase image size 2 -to-4 times larger.
- If the characters in the image are too close together or their edges are touching, use morphology to thin out the characters. Using morphology to thin out the characters separates the characters.
- Use binarization to check for non-uniform lighting issues. Use the graythresh and imbinarize functions to binarize the image. If the characters are not visible in the results of the binarization, it indicates a potential non-uniform lighting issue. Try top hat, using the imtophat function, or other techniques that deal with removing nonuniform illumination.
- Use the region of interest roi option to isolate the text. Specify the roi manually or use text detection.
- If your image looks like a natural scene containing words, like a street scene, rather than a scanned document, try setting the TextLayout property to either 'Block' or 'Word'.

- "Install Computer Vision System Toolbox Add-on Support Files" on page 3-2

\section*{Create a Custom Feature Extractor}

You can use the bag-of-features (BoF) framework with many different types of image features. To use a custom feature extractor instead of the default speeded-up robust features (SURF) feature extractor, use the CustomExtractor property of a bagOfFeatures object.

\section*{Example of a Custom Feature Extractor}

This example shows how to write a custom feature extractor function for bagOfFeatures. You can open this example function file and use it as a template by typing the following command at the MATLAB command prompt:
```

edit('exampleBagOfFeaturesExtractor.m')

```
- Step 1. Define the image sets.
- Step 2. Create a new extractor function file.
- Step 3. Preprocess the image.
- Step 4. Select a point location for feature extraction.
- Step 5. Extract features.
- Step 6. Compute the feature metric.

\section*{Define the set of images and labels}

Read the category images and create image sets.
```

setDir = fullfile(toolboxdir('vision'),'visiondata','imageSets');
imds = imageDatastore(setDir,'IncludeSubfolders',true,'LabelSource',...
'foldernames');

```

\section*{Create a new extractor function file}

The extractor function must be specified as a function handle:
```

extractorFcn = @exampleBagOfFeaturesExtractor;
bag = bagOfFeatures(imgSets,'CustomExtractor',extractorFcn)
exampleBagOfFeaturesExtractor is a MATLAB function. For example:
function [features,featureMetrics] = exampleBagOfFeaturesExtractor(img)
You can also specify the optional location output:

```
```

function [features,featureMetrics,location] = exampleBagOfFeaturesExtractor(img)

```

The function must be on the path or in the current working folder.
\begin{tabular}{|c|c|c|}
\hline Argument & Input/Output & Description \\
\hline img & Input & \begin{tabular}{l}
- Binary, grayscale, or truecolor image. \\
- The input image is from the image set that was originally passed into bagOfFeatures.
\end{tabular} \\
\hline features & Output & \begin{tabular}{l}
- An \(M\)-by- \(N\) numeric matrix of image features, where \(M\) is the number of features and \(N\) is the length of each feature vector. \\
- The feature length, \(N\), must be greater than zero and be the same for all images processed during the bagOfFeatures creation process. \\
- If you cannot extract features from an image, supply an empty feature matrix and an empty feature metrics vector. Use the empty matrix and vector if, for example, you did not find any keypoints for feature extraction. \\
- Numeric, real, and nonsparse.
\end{tabular} \\
\hline featureMetrics & Output & \begin{tabular}{l}
- An \(M\)-by- 1 vector of feature metrics indicating the strength of each feature vector. \\
- Used to apply the 'SelectStrongest ' criteria in bagOfFeatures framework. \\
- Numeric, real, and nonsparse.
\end{tabular} \\
\hline location & Output & \begin{tabular}{l}
- An \(M\)-by- 2 matrix of 1 -based \([x y]\) values. \\
- The \([x y]\) values can be fractional. \\
- Numeric, real, and nonsparse.
\end{tabular} \\
\hline
\end{tabular}

\section*{Preprocess the image}

Input images can require preprocessing before feature extraction. To extract SURF features and to use the detectSURFFeatures or detectMSERFeatures functions, the images must be grayscale. If the images are not grayscale, you can convert them using the rgb2gray function.
[height,width,numChannels] = size(I);
```

if numChannels > 1
grayImage = rgb2gray(I);
else
grayImage = I;
end

```

\section*{Select a point location for feature extraction}

Use a regular spaced grid of point locations. Using the grid over the image allows for dense SURF feature extraction. The grid step is in pixels.
```

gridStep = 8;
gridX = 1:gridStep:width;
gridY = 1:gridStep:height;
[x,y] = meshgrid(gridX,gridY);
gridLocations = [x(:) y(:)];

```

You can manually concatenate multiple SURFPoints objects at different scales to achieve multiscale feature extraction.
```

multiscaleGridPoints = [SURFPoints(gridLocations,'Scale',1.6);
SURFPoints(gridLocations,'Scale',3.2);
SURFPoints(gridLocations,'Scale',4.8);
SURFPoints(gridLocations,'Scale',6.4)];

```

Alternatively, you can use a feature detector, such as detectSURFFeatures or detectMSERFeatures, to select point locations.
```

multiscaleSURFPoints = detectSURFFeatures(I);

```

\section*{Extract features}

Extract features from the selected point locations. By default, bagOfFeatures extracts upright SURF features.
```

features = extractFeatures(grayImage,multiscaleGridPoints,'Upright',true);

```

\section*{Compute the feature metric}

The feature metrics indicate the strength of each feature. Larger metric values are assigned to stronger features. Use feature metrics to identify and remove weak features before using bagOfFeatures to learn the visual vocabulary of an image set. Use the metric that is suitable for your feature vectors.

For example, you can use the variance of the SURF features as the feature metric.
featureMetrics = var(features, [],2);
If you used a feature detector for the point selection, then use the detection metric instead.
featureMetrics = multiscaleSURFPoints.Metric;
You can optionally return the feature location information. The feature location can be used for spatial or geometric verification image search applications. See the "Geometric Verification Using estimateGeometricTransform Function" example. The retrieveImages and indexImages functions are used for content-based image retrieval systems.
if nargout > 2
varargout \(\{1\}=\) multiscaleGridPoints.Location;
end

\section*{Image Retrieval with Bag of Visual Words}

You can use the Computer Vision System Toolbox functions to search by image, also known as a content-based image retrieval (CBIR) system. CBIR systems are used to retrieve images from a collection of images that are similar to a query image. The application of these types of systems can be found in many areas such as a web-based product search, surveillance, and visual place identification. First the system searches a collection of images to find the ones that are visually similar to a query image.

The retrieval system uses a bag of visual words, a collection of image descriptors, to represent your data set of images. Images are indexed to create a mapping of visual words. The index maps each visual word to their occurrences in the image set. A comparison between the query image and the index provides the images most similar to the query image. By using the CBIR system workflow, you can evaluate the accuracy for a known set of image search results.

\section*{Retrieval System Workflow}

1 Create image set that represents image features for retrieval. Use imageDatastore to store the image data. Use a large number of images that represent various viewpoints of the object. A large and diverse number of images helps train the bag of visual words and increases the accuracy of the image search.

2 Type of feature. The indexImages function creates the bag of visual words using the speeded up robust features (SURF). For other types of features, you can use a custom extractor, and then use bagOfFeatures to create the bag of visual words. See the "Create Search Index Using Custom Bag of Features" example.

You can use the original imgSet or a different collection of images for the training set. To use a different collection, create the bag of visual words before creating the image index, using the bagOfFeatures function. The advantage of using the same set of images is that the visual vocabulary is tailored to the search set. The disadvantage of this approach is that the retrieval system must relearn the visual vocabulary to use on a drastically different set of images. With an independent set, the visual vocabulary is better able to handle the additions of new images into the search index.
3 Index the images. The indexImages function creates a search index that maps visual words to their occurrences in the image collection. When you create the bag of visual words using an independent or subset collection, include the bag as an input argument to indexImages. If you do not create an independent bag of visual words, then the function creates the bag based on the entire imgSet input collection. You can add and remove images directly to and from the image index using the addImages and removeImages methods.
4 Search data set for similar images. Use the retrieveImages function to search the image set for images which are similar to the query image. Use the NumResults property to control the number of results. For example, to return the top 10 similar images, set the ROI property to use a smaller region of a query image. A smaller region is useful for isolating a particular object in an image that you want to search for.

\section*{Evaluate Image Retrieval}

Use the evaluateImageRetrieval function to evaluate image retrieval by using a query image with a known set of results. If the results are not what you expect, you can modify or augment image features by the bag of visual words. Examine the type of the features retrieved. The type of feature used for retrieval depends on the type of images within the collection. For example, if you are searching an image collection made up of
scenes, such as beaches, cities, or highways, use a global image feature. A global image feature, such as a color histogram, captures the key elements of the entire scene. To find specific objects within the image collections, use local image features extracted around object keypoints instead.

\section*{Related Examples}
- "Image Retrieval Using Customized Bag of Features"

\section*{Image Classification with Bag of Visual Words}

Use the Computer Vision System Toolbox functions for image category classification by creating a bag of visual words. The process generates a histogram of visual word occurrences that represent an image. These histograms are used to train an image category classifier. The steps below describe how to setup your images, create the bag of visual words, and then train and apply an image category classifier.

\section*{Step 1: Set Up Image Category Sets}

Organize and partition the images into training and test subsets. Use the imageDatastore function to store images to use for training an image classifier. Organizing images into categories makes handling large sets of images much easier. You can use the splitEachLabel function to split the images into training and test data.

Read the category images and create image sets.
```

setDir = fullfile(toolboxdir('vision'),'visiondata','imageSets');
imds = imageDatastore(setDir,'IncludeSubfolders',true,'LabelSource',...
'foldernames');

```

Separate the sets into training and test image subsets. In this example, \(30 \%\) of the images are partitioned for training and the remainder for testing.
```

[trainingSet,testSet] = splitEachLabel(imds,0.3,'randomize');

```

\section*{Step 2: Create Bag of Features}

Create a visual vocabulary, or bag of features, by extracting feature descriptors from representative images of each category.

The bagOfFeatures object defines the features, or visual words, by using the k-means clustering algorithm on the feature descriptors extracted from trainingSets. The algorithm iteratively groups the descriptors into \(k\) mutually exclusive clusters. The resulting clusters are compact and separated by similar characteristics. Each cluster center represents a feature, or visual word.

You can extract features based on a feature detector, or you can define a grid to extract feature descriptors. The grid method may lose fine-grained scale information. Therefore, use the grid for images that do not contain distinct features, such as an image containing scenery, like the beach. Using speeded up robust features (or SURF) detector provides greater scale invariance. By default, the algorithm runs the 'grid' method.

This algorithm workflow analyzes images in their entirety. Images must have appropriate labels describing the class that they represent. For example, a set of car images could be labeled cars. The workflow does not rely on spatial information nor on marking the particular objects in an image. The bag-of-visual-words technique relies on detection without localization.

\section*{Step 3: Train an Image Classifier With Bag of Visual Words}

The trainImageCategoryClassifier function returns an image classifier. The function trains a multiclass classifier using the error-correcting output codes (ECOC) framework with binary support vector machine (SVM) classifiers. The trainImageCategoryClassfier function uses the bag of visual words returned by the bagOfFeatures object to encode images in the image set into the histogram of visual words. The histogram of visual words are then used as the positive and negative samples to train the classifier.

1 Use the bagOfFeatures encode method to encode each image from the training set. This function detects and extracts features from the image and then uses the approximate nearest neighbor algorithm to construct a feature histogram for each image. The function then increments histogram bins based on the proximity of the descriptor to a particular cluster center. The histogram length corresponds to the number of visual words that the bagOfFeatures object constructed. The histogram becomes a feature vector for the image.

2 Repeat step 1 for each image in the training set to create the training data.

3 Evaluate the quality of the classifier. Use the imageCategoryClassifier evaluate method to test the classifier against the validation image set. The output confusion matrix represents the analysis of the prediction. A perfect classification results in a normalized matrix containing 1s on the diagonal. An incorrect classification results fractional values.

\section*{Step 4: Classify an Image or Image Set}

Use the imageCategoryClassifier predict method on a new image to determine its category.

\section*{Multiple Object Tracking}

Tracking is the process of locating a moving object or multiple objects over time in a video stream. Tracking an object is not the same as object detection. Object detection is the process of locating an object of interest in a single frame. Tracking associates detections of an object across multiple frames.

Tracking multiple objects requires detection, prediction, and data association.
- Detection: Detect objects of interest in a video frame.
- Prediction: Predict the object locations in the next frame.
- Data association: Use the predicted locations to associate detections across frames to form tracks.

\section*{Detection}

Selecting the right approach for detecting objects of interest depends on what you want to track and whether the camera is stationary.

\section*{Detect Objects Using a Stationary Camera}

To detect objects in motion with a stationary camera, you can perform background subtraction using the vision.ForegroundDetector System object. The background subtraction approach works efficiently but requires the camera to be stationary.

\section*{Detect Objects Using a Moving Camera}

To detect objects in motion with a moving camera, you can use a sliding-window detection approach. This approach typically works more slowly than the background subtraction approach. To detect and track a specific category of object, use the System objects or functions described in the table.

\section*{Prediction}

To track an object over time means that you must predict its location in the next frame. The simplest method of prediction is to assume that the object will be near its last known location. In other words, the previous detection serves as the next prediction. This method is especially effective for high frame rates. However, using this prediction method can fail when objects move at varying speeds, or when the frame rate is low relative to the speed of the object in motion.

A more sophisticated method of prediction is to use the previously observed motion of the object. The Kalman filter (vision.KalmanFilter) predicts the next location of an object, assuming that it moves according to a motion model, such as constant velocity or constant acceleration. The Kalman filter also takes into account process noise and measurement noise. Process noise is the deviation of the actual motion of the object from the motion model. Measurement noise is the detection error.

To make configuring a Kalman filter easier, use configureKalmanFilter. This function sets up the filter for tracking a physical object moving with constant velocity or constant acceleration within a Cartesian coordinate system. The statistics are the same along all dimensions. If you need to configure a Kalman filter with different assumptions, you need to construct the vision.KalmanFilter object directly.

\section*{Data Association}

Data association is the process of associating detections corresponding to the same physical object across frames. The temporal history of a particular object consists of multiple detections, and is called a track. A track representation can include the entire history of the previous locations of the object. Alternatively, it can consist only of the object's last known location and its current velocity.

\section*{Detection to Track Cost Functions}

To match a detection to a track, you must establish criteria for evaluating the matches. Typically, you establish this criteria by defining a cost function. The higher the cost of matching a detection to a track, the less likely that the detection belongs to the track. A simple cost function can be defined as the degree of overlap between the bounding boxes of the predicted and detected objects. The "Tracking Pedestrians from a Moving Car" example implements this cost function using the bboxOverlapRatio function. You can implement a more sophisticated cost function, one that accounts for the uncertainty of the prediction, using the distance method of the vision.KalmanFilter object. You can also implement a custom cost function than can incorporate information about the object size and appearance.

\section*{Elimination of Unlikely Matches}

Gating is a method of eliminating highly unlikely matches from consideration, such as by imposing a threshold on the cost function. An observation cannot be matched to a track if the cost exceeds a certain threshold value. Using this threshold method effectively results in a circular gating region around each prediction, where a matching detection can be found. An alternative gating technique is to make the gating region large enough to include the \(k\)-nearest neighbors of the prediction.

\section*{Assign Detections to Track}

Data association reduces to a minimum weight bipartite matching problem, which is a well-studied area of graph theory. A bipartite graph represents tracks and detections as vertices. It also represents the cost of matching a detection and a track as a weighted edge between the corresponding vertices.

The assignDetectionsToTracks function implements the Munkres' variant of the Hungarian bipartite matching algorithm. Its input is the cost matrix, where the rows correspond to tracks and the columns correspond to detections. Each entry contains the cost of assigning a particular detection to a particular track. You can implement gating by setting the cost of impossible matches to infinity.

\section*{Track Management}

Data association must take into account the fact that new objects can appear in the field of view, or that an object being tracked can leave the field of view. In other words, in any given frame, some number of new tracks might need to be created, and some number of existing tracks might need to be discarded. The assignDetectionsToTracks function
returns the indices of unassigned tracks and unassigned detections in addition to the matched pairs.

One way of handling unmatched detections is to create a new track from each of them. Alternatively, you can create new tracks from unmatched detections greater than a certain size, or from detections that have certain locations or appearance. For example, if the scene has a single entry point, such as a doorway, then you can specify that only unmatched detections located near the entry point can begin new tracks, and that all other detections are considered noise.

Another way of handling unmatched tracks is to delete any track that remain unmatched for a certain number of frames. Alternatively, you can specify to delete an unmatched track when its last known location is near an exit point.

\section*{Video Mosaicking}

This example shows how to create a mosaic from a video sequence. Video mosaicking is the process of stitching video frames together to form a comprehensive view of the scene. The resulting mosaic image is a compact representation of the video data. The Video Mosaicking block is often used in video compression and surveillance applications.

This example illustrates how to use the Corner Detection block, the Estimate Geometric Transformation block, the Projective Transform block, and the Compositing block to create a mosaic image from a video sequence.

\section*{Example Model}

The following figure shows the Video Mosaicking model:

\section*{Video Mosaicking}

(i)

Copyright 2007-2011 The MathWorks, Inc.

The Input subsystem loads a video sequence from either a file, or generates a synthetic video sequence. The choice is user defined. First, the Corner Detection block finds points that are matched between successive frames by the Corner Matching subsystem. Then the Estimate Geometric Transformation block computes an accurate estimate of the transformation matrix. This block uses the RANSAC algorithm to eliminate outlier input points, reducing error along the seams of the output mosaic image. Finally, the Mosaicking subsystem overlays the current video frame onto the output image to generate a mosaic.

\section*{Input Subsystem}

The Input subsystem can be configured to load a video sequence from a file, or to generate a synthetic video sequence.

If you choose to use a video sequence from a file, you can reduce computation time by processing only some of the video frames. This is done by setting the downsampling rate in the Frame Rate Downsampling subsystem.

If you choose a synthetic video sequence, you can set the speed of translation and rotation, output image size and origin, and the level of noise. The output of the synthetic video sequence generator mimics the images captured by a perspective camera with arbitrary motion over a planar surface.

\section*{Corner Matching Subsystem}

The subsystem finds corner features in the current video frame in one of three methods. The example uses Local intensity comparison (Rosen \& Drummond), which is the fastest method. The other methods available are the Harris corner detection (Harris \& Stephens) and the Minimum Eigenvalue (Shi \& Tomasi).

The Corner Matching Subsystem finds the number of corners, location, and their metric values. The subsystem then calculates the distances between all features in the current frame with those in the previous frame. By searching for the minimum distances, the subsystem finds the best matching features.

\section*{Mosaicking Subsystem}

By accumulating transformation matrices between consecutive video frames, the subsystem calculates the transformation matrix between the current and the first video frame. The subsystem then overlays the current video frame on to the output image. By repeating this process, the subsystem generates a mosaic image.

The subsystem is reset when the video sequence rewinds or when the Estimate Geometric Transformation block does not find enough inliers.

Video Mosaicking Using Synthetic Video
The Corners window shows the corner locations in the current video frame.

The Mosaic window shows the resulting mosaic image.

\section*{Video Mosaicking Using Captured Video}

The Corners window shows the corner locations in the current video frame.

The Mosaic window shows the resulting mosaic image.

\section*{Pattern Matching}

This example shows how to use the 2-D normalized cross-correlation for pattern matching and target tracking. The example uses predefined or user specified target and number of similar targets to be tracked. The normalized cross correlation plot shows that when the value exceeds the set threshold, the target is identified.

\section*{Introduction}

In this example you use normalized cross correlation to track a target pattern in a video. The pattern matching algorithm involves the following steps:
- The input video frame and the template are reduced in size to minimize the amount of computation required by the matching algorithm.
- Normalized cross correlation, in the frequency domain, is used to find a template in the video frame.
- The location of the pattern is determined by finding the maximum cross correlation value.

\section*{Initialization}

Initialize required variables such as the threshold value for the cross correlation and the decomposition level for Gaussian Pyramid decomposition.
```

threshold = single(0.99);
level = 2;
Create System object ${ }^{\text {TM }}$ to read a video file.

```
```

hVideoSrc = vision.VideoFileReader('vipboard.mp4', ...

```
hVideoSrc = vision.VideoFileReader('vipboard.mp4', ...
    'VideoOutputDataType', 'single',...
    'VideoOutputDataType', 'single',...
    'ImageColorSpace', 'Intensity');
```

    'ImageColorSpace', 'Intensity');
    ```

Create three gaussian pyramid System objects for decomposing the target template and decomposing the Image under Test(IUT). The decomposition is done so that the cross correlation can be computed over a small region instead of the entire original size of the image.
```

hGaussPymd1 = vision.Pyramid('PyramidLevel',level);
hGaussPymd2 = vision.Pyramid('PyramidLevel',level);
hGaussPymd3 = vision.Pyramid('PyramidLevel',level);

```

Create two 2-D FFT System objects one for the image under test and the other for the target.
```

hFFT2D1 = vision.FFT;
hFFT2D2 = vision.FFT;

```

Create a System object to perform 2-D inverse FFT after performing correlation (equivalent to multiplication) in the frequency domain.
```

hIFFFT2D = vision.IFFT;

```

Create 2-D convolution System object to average the image energy in tiles of the same dimension of the target.
```

hConv2D = vision.Convolver('OutputSize','Valid');

```

Here you implement the following sequence of operations.
```

% Specify the target image and number of similar targets to be tracked. By
% default, the example uses a predefined target and finds up to 2 similar
% patterns. Set the variable useDefaultTarget to false to specify a new
% target and the number of similar targets to match.
useDefaultTarget = true;
[Img, numberOfTargets, target_image] = ...
videopattern_gettemplate(useDefaultTarget);
% Downsample the target image by a predefined factor using the
% gaussian pyramid System object. You do this to reduce the amount of
% computation for cross correlation.
target_image = single(target_image);
target_dim_nopyramid = size(target_image);
target_image_gp = step(hGaussPymd1, target_image);
target_energy = sqrt(sum(target_image_gp(:).^^2));
% Rotate the target image by 180 degrees, and perform zero padding so that
% the dimensions of both the target and the input image are the same.
target_image_rot = imrotate(target_image_gp, 180);
[rt, ct] = size(target_image_rot);
Img = single(Img);
Img = step(hGaussPymd2, Img);
[ri, ci]= size(Img);
r_mod = 2^nextpow2(rt + ri);
c_mod = 2^nextpow2(ct + ci);
target_image_p = [target_image_rot zeros(rt, c_mod-ct)];
target_image_p = [target_image_p; zeros(r_mod-rt, c_mod)];
% Compute the 2-D FFT of the target image
target_fft = step(hFFT2D1, target_image_p);

```
```

% Initialize constant variables used in the processing loop.
target_size = repmat(target_dim_nopyramid, [numberOfTargets, 1]);
gain = 2^(level);
Im_p = zeros(r_mod, c_mod, 'single'); % Used for zero padding
C_ones = ones(rt, ct, 'single'); % Used to calculate mean using conv

```

Create a System object to calculate the local maximum value for the normalized cross correlation.
```

hFindMax = vision.LocalMaximaFinder( ...
'Threshold', single(-1), ...
'MaximumNumLocalMaxima', numberOfTargets, ...
'NeighborhoodSize', floor(size(target_image_gp)/2)*2 - 1);

```

Create a System object to display the tracking of the pattern.
```

sz = get(0,'ScreenSize');
pos = [20 sz(4)-400 400 300];
hROIPattern = vision.VideoPlayer('Name', 'Overlay the ROI on the target', ...
'Position', pos);

```

Initialize figure window for plotting the normalized cross correlation value
```

hPlot = videopatternplots('setup',numberOfTargets, threshold);

```

\section*{Video Processing Loop}

Create a processing loop to perform pattern matching on the input video. This loop uses the System objects you instantiated above. The loop is stopped when you reach the end of the input file, which is detected by the VideoFileReader System object.
```

while ~isDone(hVideoSrc)
Im = step(hVideoSrc);
Im_gp = step(hGaussPymd3, Im);
% Frequency domain convolution.
Im_p(1:ri, 1:ci) = Im_gp; % Zero-pad
img_fft = step(hFFT2D2, Im_p);
corr_freq = img_fft .* target_fft;
corrOutput_f = step(hIFFFT2D, corr_freq);
corrOutput_f = corrOutput_f(rt:ri, ct:ci);
% Calculate image energies and block run tiles that are size of
% target template.
IUT_energy = (Im_gp).^2;

```
```

    IUT = step(hConv2D, IUT_energy, C_ones);
    IUT = sqrt(IUT);
    % Calculate normalized cross correlation.
    norm_Corr_f = (corrOutput_f) ./ (IUT * target_energy);
    xyLocation = step(hFindMax, norm_Corr_f);
    % Calculate linear indices.
    linear_index = sub2ind([ri-rt, ci-ct]+1, xyLocation(:,2),...
        xyLocation(:,1));
    norm_Corr_f_linear = norm_Corr_f(:);
    norm_Corr_value = norm_Corr_f_linear(linear_index);
    detect = (norm Corr value > threshold);
    target_roi = zeros(length(detect), 4);
    ul_corner = (gain.*(xyLocation(detect, :)-1))+1;
    target_roi(detect, :) = [ul_corner, fliplr(target_size(detect, :))];
    % Draw bounding box.
    Imf = insertShape(Im, 'Rectangle', target_roi, 'Color', 'green');
    % Plot normalized cross correlation.
    videopatternplots('update',hPlot,norm_Corr_value);
    step(hROIPattern, Imf);
    end
release(hVideoSrc);

```

\section*{Summary}

This example shows use of Computer Vision System Toolbox \({ }^{\text {TM }}\) to find a user defined pattern in a video and track it. The algorithm is based on normalized frequency domain cross correlation between the target and the image under test. The video player window displays the input video with the identified target locations. Also a figure displays the normalized correlation between the target and the image which is used as a metric to match the target. As can be seen whenever the correlation value exceeds the threshold (indicated by the blue line), the target is identified in the input video and the location is marked by the green bounding box.

\section*{Appendix}

The following helper functions are used in this example.
- videopattern_gettemplate.m
- videopatternplots.m

\section*{Pattern Matching}

This example shows how to use the 2-D normalized cross-correlation for pattern matching and target tracking.

Double-click the Edit Parameters block to select the number of similar targets to detect. You can also change the pyramiding factor. By increasing it, you can match the target template to each video frame more quickly. Changing the pyramiding factor might require you to change the Threshold value.

Additionally, you can double-click the Correlation Method switch to specify the domain in which to perform the cross-correlation. The relative size of the target to the input video frame and the pyramiding factor determine which domain computation is faster.

\section*{Example Model}

The following figure shows the Pattern Matching model:

\section*{Pattern Matching}

Copyright 2003-2008 The MathWorks, Inc.

\section*{Pattern Matching Results}

The Match metric window shows the variation of the target match metrics. The model determines that the target template is present in a video frame when the match metric exceeds a threshold (cyan line).

The Cross-correlation window shows the result of cross-correlating the target template with a video frame. Large values in this window correspond to the locations of the targets in the input image.

The Overlay window shows the locations of the targets by highlighting them with rectangular regions of interest (ROIs). These ROIs are present only when the targets are detected in the video frame.

\section*{Geometric Transformations}
- "Rotate an Image" on page 9-2
- "Resize an Image" on page 9-8
- "Crop an Image" on page 9-12
- "Nearest Neighbor, Bilinear, and Bicubic Interpolation Methods" on page 9-16

\section*{Rotate an Image}

You can use the Rotate block to rotate your image or video stream by a specified angle. In this example, you learn how to use the Rotate block to continuously rotate an image.

Note: Running this example requires a DSP System Toolbox license.
ex_vision_rotate_image
1 Define an RGB image in the MATLAB workspace. At the MATLAB command prompt, type

I = checker_board;
I is a 100-by-100-by- 3 array of double-precision values. Each plane of the array represents the red, green, or blue color values of the image.
2 To view the image this matrix represents, at the MATLAB command prompt, type imshow(I)

3 Create a new Simulink model, and add to it the blocks shown in the following table.
\begin{tabular}{|l|l|l|}
\hline Block & Library & Quantity \\
\hline Image From Workspace & \begin{tabular}{l} 
Computer Vision System Toolbox > \\
Sources
\end{tabular} & 1 \\
\hline Rotate & \begin{tabular}{l} 
Computer Vision System Toolbox > \\
Geometric Transformations
\end{tabular} & 1 \\
\hline Video Viewer & \begin{tabular}{l} 
Computer Vision System Toolbox > \\
Sinks
\end{tabular} & 2 \\
\hline Gain & Simulink > Math Operations & 1 \\
\hline Display & DSP System Toolbox > Sinks & 1 \\
\hline Counter & \begin{tabular}{l} 
DSP System Toolbox > Signal \\
Management > Switches and Counters
\end{tabular} & 1 \\
\hline
\end{tabular}

4 Use the Image From Workspace block to import the RGB image from the MATLAB workspace. On the Main pane, set the Value parameter to I. Each plane of the array represents the red, green, or blue color values of the image.
5 Use the Video Viewer block to display the original image. Accept the default parameters.

The Video Viewer block automatically displays the original image in the Video Viewer window when you run the model. Because the image is represented by double-precision floating-point values, a value of 0 corresponds to black and a value of 1 corresponds to white.

6 Use the Rotate block to rotate the image. Set the block parameters as follows:
- Rotation angle source = Input port
- Sine value computation method = Trigonometric function

The Angle port appears on the block. You use this port to input a steadily increasing angle. Setting the Output size parameter to Expanded to fit rotated input image ensures that the block does not crop the output.
7 Use the Video Viewer1 block to display the rotating image. Accept the default parameters.
8 Use the Counter block to create a steadily increasing angle. Set the block parameters as follows:
- Count event \(=\) Free running
- Counter size \(=16\) bits
- Output = Count
- Clear the Reset input check box.
- Sample time \(=1 / 30\)

The Counter block counts upward until it reaches the maximum value that can be represented by 16 bits. Then, it starts again at zero. You can view its output value on the Display block while the simulation is running. The Counter block's Count data type parameter enables you to specify it's output data type.

9 Use the Gain block to convert the output of the Counter block from degrees to radians. Set the Gain parameter to pi/180.

10 Connect the blocks as shown in the following figure.

11 Set the configuration parameters. Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. Set the parameters as follows:
- Solver pane, Stop time = inf
- Solver pane, Type = Fixed-step
- Solver pane, Solver = Discrete (no continuous states)

12 Run the model.
The original image appears in the Video Viewer window.

The rotating image appears in the Video Viewer1 window.

In this example, you used the Rotate block to continuously rotate your image. For more information about this block, see the Rotate block reference page in the Computer Vision System Toolbox Reference. For more information about other geometric transformation blocks, see the Resize and Shear block reference pages.

Note If you are on a Windows operating system, you can replace the Video Viewer block with the To Video Display block, which supports code generation.

\section*{Resize an Image}

You can use the Resize block to change the size of your image or video stream. In this example, you learn how to use the Resize block to reduce the size of an image:
```

ex_vision_resize_image

```

1 Create a new Simulink model, and add to it the blocks shown in the following table.
\begin{tabular}{|l|l|l|}
\hline Block & Library & Quantity \\
\hline Image From File & \begin{tabular}{l} 
Computer Vision System Toolbox \(>\) \\
Sources
\end{tabular} & 1 \\
\hline Resize & \begin{tabular}{l} 
Computer Vision System Toolbox \(>\) \\
Geometric Transformations
\end{tabular} & 1 \\
\hline Video Viewer & \begin{tabular}{l} 
Computer Vision System Toolbox \(>\) \\
Sinks
\end{tabular} & 2 \\
\hline
\end{tabular}

2 Use the Image From File block to import the intensity image. Set the File name parameter to moon.tif. The tif file is a 537 -by- 358 matrix of 8 -bit unsigned integer values.
3 Use the Video Viewer block to display the original image. Accept the default parameters. This block automatically displays the original image in the Video Viewer window when you run the model.
4 Use the Resize block to shrink the image. Set the Resize factor in \% parameter to 50. This shrinks the image to half its original size.

5 Use the Video Viewer1 block to display the modified image. Accept the default parameters.

6 Connect the blocks as shown in the following figure.

7 Set the configuration parameters. Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. Set the parameters as follows:
- Solver pane, Stop time \(=0\)
- Solver pane, Type = Fixed-step
- Solver pane, Solver = Discrete (no continuous states)

8 Run the model.

The original image appears in the Video Viewer window.

The reduced image appears in the Video Viewer1 window.

In this example, you used the Resize block to shrink an image. For more information about this block, see the Resize block reference page. For more information about other geometric transformation blocks, see the Rotate, Apply Geometric Transformation, Estimate Geometric Transformation, and Translate block reference pages.

\section*{Crop an Image}

You can use the Selector block to crop your image or video stream. In this example, you learn how to use the Selector block to trim an image down to a particular region of interest:
ex_vision_crop_image
1 Create a new Simulink model, and add to it the blocks shown in the following table.
\begin{tabular}{|l|l|l|}
\hline Block & Library & Quantity \\
\hline Image From File & \begin{tabular}{l} 
Computer Vision System Toolbox > \\
Sources
\end{tabular} & 1 \\
\hline Video Viewer & \begin{tabular}{l} 
Computer Vision System Toolbox > \\
Sinks
\end{tabular} & 2 \\
\hline Selector & Simulink > Signal Routing & 1 \\
\hline
\end{tabular}

2 Use the Image From File block to import the intensity image. Set the File name parameter to coins. png. The image is a 246 -by- 300 matrix of 8 -bit unsigned integer values.

3 Use the Video Viewer block to display the original image. Accept the default parameters. This block automatically displays the original image in the Video Viewer window when you run the model.
4 Use the Selector block to crop the image. Set the block parameters as follows:
- Number of input dimensions \(=2\)
- 1
- Index Option = Starting index (dialog)
- Index = 140
- Output Size \(=70\)
- 2
- Index Option = Starting index (dialog)
- Index \(=200\)
- Output Size \(=70\)

The Selector block starts at row 140 and column 200 of the image and outputs the next 70 rows and columns of the image.
5 Use the Video Viewer1 block to display the cropped image. This block automatically displays the modified image in the Video Viewer window when you run the model.
6 Connect the blocks as shown in the following figure.

7 Set the configuration parameters. Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. Set the parameters as follows:
- Solver pane, Stop time = 0
- Solver pane, Type = Fixed-step
- Solver pane, Solver = Discrete (no continuous states)

8 Run the model.
The original image appears in the Video Viewer window.

The cropped image appears in the Video Viewer 1 window. The following image is shown at its true size.

In this example, you used the Selector block to crop an image. For more information about the Selector block, see the Simulink documentation. For information about the imcrop function, see the Image Processing Toolbox documentation.

\section*{Nearest Neighbor, Bilinear, and Bicubic Interpolation Methods}

In this section...
"Nearest Neighbor Interpolation" on page 9-16
"Bilinear Interpolation" on page 9-17
"Bicubic Interpolation" on page 9-18

\section*{Nearest Neighbor Interpolation}

For nearest neighbor interpolation, the block uses the value of nearby translated pixel values for the output pixel values.

For example, suppose this matrix,
123
456
\(\begin{array}{lll}7 & 8 & 9\end{array}\)
represents your input image. You want to translate this image 1.7 pixels in the positive horizontal direction using nearest neighbor interpolation. The Translate block's nearest neighbor interpolation algorithm is illustrated by the following steps:

1 Zero pad the input matrix and translate it by 1.7 pixels to the right.

2 Create the output matrix by replacing each input pixel value with the translated value nearest to it. The result is the following matrix:
\begin{tabular}{lllll}
0 & 0 & 1 & 2 & 3 \\
0 & 0 & 4 & 5 & 6 \\
0 & 0 & 7 & 8 & 9
\end{tabular}

Note: You wanted to translate the image by 1.7 pixels, but this method translated the image by 2 pixels. Nearest neighbor interpolation is computationally efficient but not as accurate as bilinear or bicubic interpolation.

\section*{Bilinear Interpolation}

For bilinear interpolation, the block uses the weighted average of two translated pixel values for each output pixel value.

For example, suppose this matrix,

123
456
\(\begin{array}{lll}7 & 8\end{array}\)
represents your input image. You want to translate this image 0.5 pixel in the positive horizontal direction using bilinear interpolation. The Translate block's bilinear interpolation algorithm is illustrated by the following steps:

1 Zero pad the input matrix and translate it by 0.5 pixel to the right.

2 Create the output matrix by replacing each input pixel value with the weighted average of the translated values on either side. The result is the following matrix where the output matrix has one more column than the input matrix:
\[
\begin{array}{cccc}
0.5 & 1.5 & 2.5 & 1.5 \\
2 & 4.5 & 5.5 & 3 \\
3.5 & 7.5 & 8.5 & 4.5
\end{array}
\]

\section*{Bicubic Interpolation}

For bicubic interpolation, the block uses the weighted average of four translated pixel values for each output pixel value.

For example, suppose this matrix,
123
456
\(\begin{array}{lll}7 & 8 & 9\end{array}\)
represents your input image. You want to translate this image 0.5 pixel in the positive horizontal direction using bicubic interpolation. The Translate block's bicubic interpolation algorithm is illustrated by the following steps:

1 Zero pad the input matrix and translate it by 0.5 pixel to the right.

2 Create the output matrix by replacing each input pixel value with the weighted average of the two translated values on either side. The result is the following matrix where the output matrix has one more column than the input matrix:
\begin{tabular}{cccc}
0.375 & 1.5 & 3 & 1.625 \\
1.875 & 4.875 & 6.375 & 3.125 \\
3.375 & 8.25 & 9.75 & 4.625
\end{tabular}

\title{
Filters, Transforms, and Enhancements
}
- "Adjust the Contrast of Intensity Images" on page 10-2
- "Adjust the Contrast of Color Images" on page 10-6
- "Remove Salt and Pepper Noise from Images" on page 10-11
- "Sharpen an Image" on page 10-16

\section*{Adjust the Contrast of Intensity Images}

This example shows you how to modify the contrast in two intensity images using the Contrast Adjustment and Histogram Equalization blocks.
```

ex_vision_adjust_contrast_intensity

```

1 Create a new Simulink model, and add to it the blocks shown in the following table.
\begin{tabular}{|l|l|l|}
\hline Block & Library & Quantity \\
\hline Image From File & Computer Vision System Toolbox > Sources & 2 \\
\hline Contrast Adjustment & \begin{tabular}{l} 
Computer Vision System Toolbox > Analysis \& \\
Enhancement
\end{tabular} & 1 \\
\hline \begin{tabular}{l} 
Histogram \\
Equalization
\end{tabular} & \begin{tabular}{l} 
Computer Vision System Toolbox > Analysis \& \\
Enhancement
\end{tabular} & 1 \\
\hline Video Viewer & Computer Vision System Toolbox > Sinks & 4 \\
\hline
\end{tabular}

2 Place the blocks listed in the table above into your new model.
3 Use the Image From File block to import the first image into the Simulink model. Set the File name parameter to pout.tif.

4 Use the Image From File1 block to import the second image into the Simulink model. Set the File name parameter to tire.tif.
5 Use the Contrast Adjustment block to modify the contrast in pout.tif. Set the Adjust pixel values from parameter to Range determined by saturating outlier pixels. This block adjusts the contrast of the image by linearly scaling the pixel values between user-specified upper and lower limits.
6 Use the Histogram Equalization block to modify the contrast in tire.tif. Accept the default parameters. This block enhances the contrast of images by transforming the values in an intensity image so that the histogram of the output image approximately matches a specified histogram.
7 Use the Video Viewer blocks to view the original and modified images. Accept the default parameters.

8 Connect the blocks as shown in the following figure.

9 Set the configuration parameters. Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. Set the parameters as follows:
- Solver pane, Stop time = 0
- Solver pane, Type = Fixed-step
- Solver pane, Solver = Discrete (no continuous states)

10 Run the model.
The results appear in the Video Viewer windows.

In this example, you used the Contrast Adjustment block to linearly scale the pixel values in pout.tif between new upper and lower limits. You used the Histogram Equalization block to transform the values in tire.tif so that the histogram of the output image approximately matches a uniform histogram. For more information, see the Contrast Adjustment and Histogram Equalization reference pages.

\section*{Adjust the Contrast of Color Images}

This example shows you how to modify the contrast in color images using the Histogram Equalization block.
```

ex_vision_adjust_contrast_color.mdl

```

1 Use the following code to read in an indexed RGB image, shadow.tif, and convert it to an RGB image. The model provided above already includes this code in file > Model Properties > Model Properties > InitFcn, and executes it prior to simulation.
[X map] = imread('shadow.tif');
shadow = ind2rgb(X,map);
2 Create a new Simulink model, and add to it the blocks shown in the following table.
\begin{tabular}{|l|l|l|}
\hline Block & Library & Quantity \\
\hline \begin{tabular}{l} 
Image From \\
Workspace
\end{tabular} & Computer Vision System Toolbox > Sources & 1 \\
\hline \begin{tabular}{l} 
Color Space \\
Conversion
\end{tabular} & \begin{tabular}{l} 
Computer Vision System Toolbox > \\
Conversions
\end{tabular} & 2 \\
\hline \begin{tabular}{l} 
Histogram \\
Equalization
\end{tabular} & \begin{tabular}{l} 
Computer Vision System Toolbox > Analysis \& \& \\
Enhancement
\end{tabular} & 1 \\
\hline Video Viewer & Computer Vision System Toolbox > Sinks & 2 \\
\hline Constant & Simulink > Sources & 1 \\
\hline Divide & Simulink > Math Operations & 1 \\
\hline Product & Simulink > Math Operations & 1 \\
\hline
\end{tabular}

3 Place the blocks listed in the table above into your new model.
4 Use the Image From Workspace block to import the RGB image from the MATLAB workspace into the Simulink model. Set the block parameters as follows:
- Value = shadow
- Image signal = Separate color signals

5 Use the Color Space Conversion block to separate the luma information from the color information. Set the block parameters as follows:
- Conversion \(=s R^{\prime} G^{\prime} B^{\prime}\) to \(L^{*} a *{ }^{*}\) *
- Image signal \(=\) Separate color signals

Because the range of the \(L^{*}\) values is between 0 and 100, you must normalize them to be between zero and one before you pass them to the Histogram Equalization block, which expects floating point input in this range.

6 Use the Constant block to define a normalization factor. Set the Constant value parameter to 100.

7 Use the Divide block to normalize the L* values to be between 0 and 1. Accept the default parameters.

8 Use the Histogram Equalization block to modify the contrast in the image. This block enhances the contrast of images by transforming the luma values in the color image so that the histogram of the output image approximately matches a specified histogram. Accept the default parameters.
9 Use the Product block to scale the values back to be between the 0 to 100 range. Accept the default parameters.
10 Use the Color Space Conversion1 block to convert the values back to the sR'G'B' color space. Set the block parameters as follows:
- Conversion \(=L^{*} a^{*} b^{*}\) to \(s R^{\prime} G^{\prime} B^{\prime}\)
- Image signal = Separate color signals

11 Use the Video Viewer blocks to view the original and modified images. For each block, set the Image signal parameter to Separate color signals from the file menu.

12 Connect the blocks as shown in the following figure.

13 Set the configuration parameters. Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. Set the parameters as follows:
- Solver pane, Stop time \(=0\)
- Solver pane, Type = Fixed-step
- Solver pane, Solver = Discrete (no continuous states)

14 Run the model.
As shown in the following figure, the model displays the original image in the Video Viewer 1 window.

As the next figure shows, the model displays the enhanced contrast image in the Video Viewer window.

In this example, you used the Histogram Equalization block to transform the values in a color image so that the histogram of the output image approximately matches a uniform histogram. For more information, see the Histogram Equalization reference page.

\section*{Remove Salt and Pepper Noise from Images}

Median filtering is a common image enhancement technique for removing salt and pepper noise. Because this filtering is less sensitive than linear techniques to extreme changes in pixel values, it can remove salt and pepper noise without significantly reducing the sharpness of an image. In this topic, you use the Median Filter block to remove salt and pepper noise from an intensity image:
ex_vision_remove_noise
1 Define an intensity image in the MATLAB workspace and add noise to it by typing the following at the MATLAB command prompt:

I= double(imread('circles.png'));
\(I=\) imnoise(I,'salt \& pepper',0.02);
Iis a 256 -by- 256 matrix of 8 -bit unsigned integer values.
The model provided with this example already includes this code in file \(>\) Model Properties>Model Properties>InitFcn, and executes it prior to simulation.
2 To view the image this matrix represents, at the MATLAB command prompt, type imshow(I)

The intensity image contains noise that you want your model to eliminate.
3 Create a Simulink model, and add the blocks shown in the following table.
\begin{tabular}{|l|l|l|}
\hline Block & Library & Quantity \\
\hline \begin{tabular}{l} 
Image From \\
Workspace
\end{tabular} & Computer Vision System Toolbox > Sources & 1 \\
\hline Median Filter & Computer Vision System Toolbox > Filtering & 1 \\
\hline Video Viewer & Computer Vision System Toolbox > Sinks & 2 \\
\hline
\end{tabular}

4 Use the Image From Workspace block to import the noisy image into your model. Set the Value parameter to I.
5 Use the Median Filter block to eliminate the black and white speckles in the image. Use the default parameters.

The Median Filter block replaces the central value of the 3-by-3 neighborhood with the median value of the neighborhood. This process removes the noise in the image.
6 Use the Video Viewer blocks to display the original noisy image, and the modified image. Images are represented by 8 -bit unsigned integers. Therefore, a value of 0 corresponds to black and a value of 255 corresponds to white. Accept the default parameters.

7 Connect the blocks as shown in the following figure.

8 Set the configuration parameters. Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. Set the parameters as follows:
- Solver pane, Stop time \(=0\)
- Solver pane, Type = Fixed-step
- Solver pane, Solver = Discrete (no continuous states)

9 Run the model.
The original and filtered images are displayed.

You have used the Median Filter block to remove noise from your image. For more information about this block, see the Median Filter block reference page in the Computer Vision System Toolbox Reference.

\section*{Sharpen an Image}

To sharpen a color image, you need to make the luma intensity transitions more acute, while preserving the color information of the image. To do this, you convert an R'G'B' image into the \(\mathrm{Y}^{\prime} \mathrm{CbCr}\) color space and apply a highpass filter to the luma portion of the image only. Then, you transform the image back to the R'G'B' color space to view the results. To blur an image, you apply a lowpass filter to the luma portion of the image. This example shows how to use the 2-D FIR Filter block to sharpen an image. The prime notation indicates that the signals are gamma corrected.
ex_vision_sharpen_image
1 Define an R'G'B' image in the MATLAB workspace. To read in an R'G'B' image from a PNG file and cast it to the double-precision data type, at the MATLAB command prompt, type

I= im2double(imread('peppers.png'));
I is a 384 -by- 512 -by- 3 array of double-precision floating-point values. Each plane of this array represents the red, green, or blue color values of the image.

The model provided with this example already includes this code in file \(>\) Model Properties \(>\) Model Properties \(>\) InitFcn, and executes it prior to simulation.
2 To view the image this array represents, type this command at the MATLAB command prompt:
imshow(I)

Now that you have defined your image, you can create your model.
3 Create a new Simulink model, and add to it the blocks shown in the following table.
\begin{tabular}{|l|l|l|}
\hline Block & Library & Quantity \\
\hline \begin{tabular}{l} 
Image From \\
Workspace
\end{tabular} & Computer Vision System Toolbox > Sources & 1 \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|}
\hline Block & Library & Quantity \\
\hline \begin{tabular}{l} 
Color Space \\
Conversion
\end{tabular} & \begin{tabular}{l} 
Computer Vision System Toolbox > \\
Conversions
\end{tabular} & 2 \\
\hline 2-D FIR Filter & Computer Vision System Toolbox > Filtering & 1 \\
\hline Video Viewer & Computer Vision System Toolbox > Sinks & 1 \\
\hline
\end{tabular}

4 Use the Image From Workspace block to import the R'G'B' image from the MATLAB workspace. Set the parameters as follows:
- Main pane, Value = I
- Main pane, Image signal = Separate color signals

The block outputs the \(\mathrm{R}^{\prime}\), \(\mathrm{G}^{\prime}\), and \(\mathrm{B}^{\prime}\) planes of the I array at the output ports.
5 The first Color Space Conversion block converts color information from the R'G'B' color space to the \(\mathrm{Y}^{\prime} \mathrm{CbCr}\) color space. Set the Image signal parameter to Separate color signals
6 Use the 2-D FIR Filter block to filter the luma portion of the image. Set the block parameters as follows:
- Coefficients = fspecial('unsharp')
- Output size = Same as input port I
- Padding options = Symmetric
- Filtering based on = Correlation

The fspecial('unsharp') command creates two-dimensional highpass filter coefficients suitable for correlation. This highpass filter sharpens the image by removing the low frequency noise in it.
7 The second Color Space Conversion block converts the color information from the \(\mathrm{Y}^{\prime} \mathrm{CbCr}\) color space to the R'G'B' color space. Set the block parameters as follows:
- Conversion = Y'CbCr to R'G'B'
- Image signal \(=\) Separate color signals

8 Use the Video Viewer block to automatically display the new, sharper image in the Video Viewer window when you run the model. Set the Image signal parameter to Separate color signals, by selecting File > Image Signal.
9 Connect the blocks as shown in the following figure.

10 Set the configuration parameters. Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. Set the parameters as follows:
- Solver pane, Stop time \(=0\)
- Solver pane, Type = Fixed-step
- Solver pane, Solver = Discrete (no continuous states)

11 Run the model.
A sharper version of the original image appears in the Video Viewer window.

To blur the image, double-click the 2-D FIR Filter block. Set Coefficients parameter to fspecial('gaussian', [15 15],7) and then click OK. The fspecial('gaussian',[15 15], 7) command creates two-dimensional Gaussian lowpass filter coefficients. This lowpass filter blurs the image by removing the high frequency noise in it.

In this example, you used the Color Space Conversion and 2-D FIR Filter blocks to sharpen an image. For more information, see the Color Space Conversion and 2-D FIR Filter, and fspecial reference pages.

\section*{Statistics and Morphological Operations}
- "Find the Histogram of an Image" on page 11-2
- "Correct Nonuniform Illumination" on page 11-7
- "Count Objects in an Image" on page 11-14

\section*{Find the Histogram of an Image}

The Histogram block computes the frequency distribution of the elements in each input image by sorting the elements into a specified number of discrete bins. You can use the Histogram block to calculate the histogram of the R, G, and/or B values in an image. This example shows you how to accomplish this task:

Note: Running this example requires a DSP System Toolbox license.

You can open the example model by typing
```

ex_vision_find_histogram

```
on the MATLAB command line.
1 Create a new Simulink model, and add to it the blocks shown in the following table.
\begin{tabular}{|l|l|l|}
\hline Block & Library & Quantity \\
\hline Image From File & Computer Vision System Toolbox > Sources & 1 \\
\hline Video Viewer & Computer Vision System Toolbox > Sinks & 1 \\
\hline Matrix Concatenate & Simulink \(>\) Math Operations & 1 \\
\hline Vector Scope & DSP System Toolbox \(>\) Sinks & 1 \\
\hline Histogram & DSP System Toolbox \(>\) Statistics & 3 \\
\hline
\end{tabular}

2 Use the Image From File block to import an RGB image. Set the block parameters as follows:
- Sample time = inf
- Image signal = Separate color signals
- Output port labels: \(=R|G| B\)
- On the Data Types tab, Output data type: = double

3 Use the Video Viewer block to automatically display the original image in the viewer window when you run the model. Set the Image signal parameter to Separate color signals from the File menu.
4 Use the Histogram blocks to calculate the histogram of the R, G, and B values in the image. Set the Main tab block parameters for the three Histogram blocks as follows:
- Lower limit of histogram: 0
- Upper limit of histogram: 1
- Number of bins: \(=256\)
- Find the histogram over: = Entire Input

The \(\mathbf{R}, \mathbf{G}\), and \(\mathbf{B}\) input values to the Histogram block are double-precision floating point and range between 0 and 1. The block creates 256 bins between the maximum and minimum input values and counts the number of \(R, G\), and \(B\) values in each bin.

5 Use the Matrix Concatenate block to concatenate the R, G, and B column vectors into a single matrix so they can be displayed using the Vector Scope block. Set the Number of inputs parameter to 3 .

6 Use the Vector Scope block to display the histograms of the R, G, and B values of the input image. Set the block parameters as follows:
- Scope Properties pane, Input domain = User-defined
- Display Properties pane, clear the Frame number check box
- Display Properties pane, select the Channel legend check box
- Display Properties pane, select the Compact display check box
- Axis Properties pane, clear the Inherit sample increment from input check box.
- Axis Properties pane, Minimum Y-limit \(=0\)
- Axis Properties pane, Maximum Y-limit = 1
- Axis Properties pane, Y-axis label = Count
- Line Properties pane, Line markers \(=.|\mathrm{s}| \mathrm{d}\)
- Line Properties pane, Line colors \(=\left[\begin{array}{lll}1 & 0 & 0\end{array}\right]\left|\left[\begin{array}{lll}0 & 1 & 0\end{array}\right]\right|\left[\begin{array}{lll}0 & 0 & 1\end{array}\right]\)

7 Connect the blocks as shown in the following figure.

8 Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. Set the parameters as follows:
- Solver pane, Stop time \(=0\)
- Solver pane, Type = Fixed-step
- Solver pane, Solver = Discrete (no continuous states)

9 Run the model using either the simulation button, or by selecting Simulation > Start.

The original image appears in the Video Viewer window.

10 Right-click in the Vector Scope window and select Autoscale.
The scaled histogram of the image appears in the Vector Scope window.

You have now used the 2-D Histogram block to calculate the histogram of the R, G, and B values in an RGB image. To open a model that illustrates how to use this block to calculate the histogram of the \(R, G\), and \(B\) values in an RGB video stream, type viphistogram at the MATLAB command prompt.

\section*{Correct Nonuniform Illumination}

Global threshold techniques, which are often the first step in object measurement, cannot be applied to unevenly illuminated images. To correct this problem, you can change the lighting conditions and take another picture, or you can use morphological operators to even out the lighting in the image. Once you have corrected for nonuniform illumination, you can pick a global threshold that delineates every object from the background. In this topic, you use the Opening block to correct for uneven lighting in an intensity image:

You can open the example model by typing
```

ex_vision_correct_uniform

```
on the MATLAB command line.

1 Create a new Simulink model, and add to it the blocks shown in the following table.
\begin{tabular}{|l|l|l|}
\hline Block & Library & Quantity \\
\hline Image From File & \begin{tabular}{l} 
Computer Vision System Toolbox > \\
Sources
\end{tabular} & 1 \\
\hline Opening & \begin{tabular}{l} 
Computer Vision System Toolbox > \\
Morphological Operations
\end{tabular} & 1 \\
\hline Video Viewer & Computer Vision System Toolbox > Sinks & 4 \\
\hline Constant & Simulink > Sources & 1 \\
\hline Sum & Simulink \(>\) Math Operations & 2 \\
\hline Data Type Conversion & Simulink > Signal Attributes & 1 \\
\hline
\end{tabular}

2 Use the Image From File block to import the intensity image. Set the File name parameter to rice. png. This image is a 256 -by- 256 matrix of 8 -bit unsigned integer values.

3 Use the Video Viewer block to view the original image. Accept the default parameters.
4 Use the Opening block to estimate the background of the image. Set the Neighborhood or structuring element parameter to strel('disk', 15).

The strel class creates a circular STREL object with a radius of 15 pixels. When working with the Opening block, pick a STREL object that fits within the objects you want to keep. It often takes experimentation to find the neighborhood or STREL object that best suits your application.

5 Use the Video Viewer1 block to view the background estimated by the Opening block. Accept the default parameters.
6 Use the first Sum block to subtract the estimated background from the original image. Set the block parameters as follows:
- Icon shape = rectangular
- List of signs = - +

7 Use the Video Viewer2 block to view the result of subtracting the background from the original image. Accept the default parameters.
8 Use the Constant block to define an offset value. Set the Constant value parameter to 80.
9 Use the Data Type Conversion block to convert the offset value to an 8-bit unsigned integer. Set the Output data type mode parameter to uint8.
10 Use the second Sum block to lighten the image so that it has the same brightness as the original image. Set the block parameters as follows:
- Icon shape = rectangular
- List of signs = ++

11 Use the Video Viewer3 block to view the corrected image. Accept the default parameters.

12 Connect the blocks as shown in the following figure.

13 Set the configuration parameters. Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. Set the parameters as follows:
- Solver pane, Stop time \(=0\)
- Solver pane, Type = Fixed-step
- Solver pane, Solver = discrete (no continuous states)

14 Run the model.
The original image appears in the Video Viewer window.

The estimated background appears in the Video Viewer1 window.

The image without the estimated background appears in the Video Viewer2 window.

The preceding image is too dark. The Constant block provides an offset value that you used to brighten the image.

The corrected image, which has even lighting, appears in the Video Viewer3 window. The following image is shown at its true size.

In this section, you have used the Opening block to remove irregular illumination from an image. For more information about this block, see the Opening reference page. For related information, see the Top-hat block reference page. For more information about STREL objects, see the strel class in the Image Processing Toolbox documentation.

\section*{Count Objects in an Image}

In this example, you import an intensity image of a wheel from the MATLAB workspace and convert it to binary. Then, using the Opening and Label blocks, you count the number of spokes in the wheel. You can use similar techniques to count objects in other intensity images. However, you might need to use additional morphological operators and different structuring elements.

Note: Running this example requires a DSP System Toolbox license.

You can open the example model by typing
```

ex_vision_count_objects
on the MATLAB command line.

```

1 Create a new Simulink model, and add to it the blocks shown in the following table.
\begin{tabular}{|l|l|l|}
\hline Block & Library & Quantity \\
\hline Image From File & \begin{tabular}{l} 
Computer Vision System Toolbox > \\
Sources
\end{tabular} & 1 \\
\hline Opening & \begin{tabular}{l} 
Computer Vision System Toolbox> \\
Morphological Operations
\end{tabular} & 1 \\
\hline Label & \begin{tabular}{l} 
Computer Vision System Toolbox > \\
Morphological Operations
\end{tabular} & 1 \\
\hline Video Viewer & Computer Vision System Toolbox > Sinks & 2 \\
\hline Constant & Simulink > Sources & 1 \\
\hline Relational Operator & Simulink > Logic and Bit Operations & 1 \\
\hline Display & Simulink > Sinks & 1 \\
\hline
\end{tabular}

2 Use the Image From File block to import your image. Set the File name parameter to testpat1.png. This is a 256 -by- 256 matrix image of 8 -bit unsigned integers.
3 Use the Constant block to define a threshold value for the Relational Operator block. Set the Constant value parameter to 200.
4 Use the Video Viewer block to view the original image. Accept the default parameters.

5 Use the Relational Operator block to perform a thresholding operation that converts your intensity image to a binary image. Set the Relational Operator parameter to <.

If the input to the Relational Operator block is less than 200, its output is 1 ; otherwise, its output is 0 . You must threshold your intensity image because the Label block expects binary input. Also, the objects it counts must be white.
6 Use the Opening block to separate the spokes from the rim and from each other at the center of the wheel. Use the default parameters.

The strel class creates a circular STREL object with a radius of 5 pixels. When working with the Opening block, pick a STREL object that fits within the objects you want to keep. It often takes experimentation to find the neighborhood or STREL object that best suits your application.
7 Use the Video Viewer1 block to view the opened image. Accept the default parameters.

8 Use the Label block to count the number of spokes in the input image. Set the Output parameter to Number of labels.

9 The Display block displays the number of spokes in the input image. Use the default parameters.
10 Connect the block as shown in the following figure.

11 Set the configuration parameters. Open the Configuration dialog box by selecting Model Configuration Parameters from the Simulation menu. Set the parameters as follows:
- Solver pane, Stop time \(=0\)
- Solver pane, Type = Fixed-step
- Solver pane, Solver = discrete (no continuous states)

12 Run the model.
The original image appears in the Video Viewer1 window. To view the image at its true size, right-click the window and select Set Display To True Size.

The opened image appears in the Video Viewer window. The following image is shown at its true size.

As you can see in the preceding figure, the spokes are now separate white objects. In the model, the Display block correctly indicates that there are 24 distinct spokes.

You have used the Opening and Label blocks to count the number of spokes in an image. For more information about these blocks, see the Opening and Label block reference pages in the Computer Vision System Toolbox Reference. If you want to send the number of spokes to the MATLAB workspace, use the To Workspace block in Simulink. For more information about STREL objects, see strel in the Image Processing Toolbox documentation.

\section*{Fixed-Point Signal Processing}
\begin{tabular}{|l}
\hline In this section... \\
"Fixed-Point Features" on page 12-2 \\
"Benefits of Fixed-Point Hardware" on page 12-2 \\
"Benefits of Fixed-Point Design with System Toolboxes Software" on page 12-3
\end{tabular}

Note: To take full advantage of fixed-point support in System Toolbox software, you must install Fixed-Point Designer \({ }^{\text {TM }}\) software.

\section*{Fixed-Point Features}

Many of the blocks in this product have fixed-point support, so you can design signal processing systems that use fixed-point arithmetic. Fixed-point support in DSP System Toolbox software includes
- Signed two's complement and unsigned fixed-point data types
- Word lengths from 2 to 128 bits in simulation
- Word lengths from 2 to the size of a long on the Simulink Coder C code-generation target
- Overflow handling and rounding methods
- C code generation for deployment on a fixed-point embedded processor, with Simulink Coder code generation software. The generated code uses all allowed data types supported by the embedded target, and automatically includes all necessary shift and scaling operations

\section*{Benefits of Fixed-Point Hardware}

There are both benefits and trade-offs to using fixed-point hardware rather than floatingpoint hardware for signal processing development. Many signal processing applications require low-power and cost-effective circuitry, which makes fixed-point hardware a natural choice. Fixed-point hardware tends to be simpler and smaller. As a result, these units require less power and cost less to produce than floating-point circuitry.

Floating-point hardware is usually larger because it demands functionality and ease of development. Floating-point hardware can accurately represent real-world numbers, and
its large dynamic range reduces the risk of overflow, quantization errors, and the need for scaling. In contrast, the smaller dynamic range of fixed-point hardware that allows for low-power, inexpensive units brings the possibility of these problems. Therefore, fixed-point development must minimize the negative effects of these factors, while exploiting the benefits of fixed-point hardware; cost- and size-effective units, less power and memory usage, and fast real-time processing.

\section*{Benefits of Fixed-Point Design with System Toolboxes Software}

Simulating your fixed-point development choices before implementing them in hardware saves time and money. The built-in fixed-point operations provided by the System Toolboxes software save time in simulation and allow you to generate code automatically.

This software allows you to easily run multiple simulations with different word length, scaling, overflow handling, and rounding method choices to see the consequences of various fixed-point designs before committing to hardware. The traditional risks of fixedpoint development, such as quantization errors and overflow, can be simulated and mitigated in software before going to hardware.

Fixed-point C code generation with System Toolbox software and Simulink Coder code generation software produces code ready for execution on a fixed-point processor. All the choices you make in simulation in terms of scaling, overflow handling, and rounding methods are automatically optimized in the generated code, without necessitating timeconsuming and costly hand-optimized code.

\title{
Fixed-Point Concepts and Terminology
}

\author{
In this section... \\ "Fixed-Point Data Types" on page 12-4 \\ "Scaling" on page 12-5 \\ "Precision and Range" on page 12-6
}

Note: The "Glossary" defines much of the vocabulary used in these sections. For more information on these subjects, see the "Fixed-Point Designer" documentation.

\section*{Fixed-Point Data Types}

In digital hardware, numbers are stored in binary words. A binary word is a fixed-length sequence of bits (1's and 0's). How hardware components or software functions interpret this sequence of 1 's and 0 's is defined by the data type.

Binary numbers are represented as either fixed-point or floating-point data types. In this section, we discuss many terms and concepts relating to fixed-point numbers, data types, and mathematics.

A fixed-point data type is characterized by the word length in bits, the position of the binary point, and whether it is signed or unsigned. The position of the binary point is the means by which fixed-point values are scaled and interpreted.

For example, a binary representation of a generalized fixed-point number (either signed or unsigned) is shown below:

where
- \(b_{i}\) is the \(i^{\text {th }}\) binary digit.
- \(w l\) is the word length in bits.
- \(b_{w l-1}\) is the location of the most significant, or highest, bit (MSB).
- \(b_{0}\) is the location of the least significant, or lowest, bit (LSB).
- The binary point is shown four places to the left of the LSB. In this example, therefore, the number is said to have four fractional bits, or a fraction length of four.

Fixed-point data types can be either signed or unsigned. Signed binary fixed-point numbers are typically represented in one of three ways:
- Sign/magnitude
- One's complement
- Two's complement

Two's complement is the most common representation of signed fixed-point numbers and is used by System Toolbox software. See "Two's Complement" on page 12-10 for more information.

\section*{Scaling}

Fixed-point numbers can be encoded according to the scheme
\[
\text { real-world value }=(\text { slope } \times \text { integer })+\text { bias }
\]
where the slope can be expressed as
\[
\text { slope }=\text { slope adjustment } \times 2^{\text {exponent }}
\]

The integer is sometimes called the stored integer. This is the raw binary number, in which the binary point assumed to be at the far right of the word. In System Toolboxes, the negative of the exponent is often referred to as the fraction length.

The slope and bias together represent the scaling of the fixed-point number. In a number with zero bias, only the slope affects the scaling. A fixed-point number that is only scaled by binary point position is equivalent to a number in the Fixed-Point Designer [Slope Bias] representation that has a bias equal to zero and a slope adjustment equal to one. This is referred to as binary point-only scaling or power-of-two scaling:
\[
\text { real-world value }=2^{\text {exponent }} \times \text { integer }
\]
or
\[
\text { real-world value }=2^{- \text {fraction length }} \times \text { integer }
\]

In System Toolbox software, you can define a fixed-point data type and scaling for the output or the parameters of many blocks by specifying the word length and fraction length of the quantity. The word length and fraction length define the whole of the data type and scaling information for binary-point only signals.

All System Toolbox blocks that support fixed-point data types support signals with binary-point only scaling. Many fixed-point blocks that do not perform arithmetic operations but merely rearrange data, such as Delay and Matrix Transpose, also support signals with [Slope Bias] scaling.

\section*{Precision and Range}

You must pay attention to the precision and range of the fixed-point data types and scalings you choose for the blocks in your simulations, in order to know whether rounding methods will be invoked or if overflows will occur.

\section*{Range}

The range is the span of numbers that a fixed-point data type and scaling can represent. The range of representable numbers for a two's complement fixed-point number of word length \(w l\), scaling \(S\), and bias \(B\) is illustrated below:

For both signed and unsigned fixed-point numbers of any data type, the number of different bit patterns is \(2 w l\).

For example, in two's complement, negative numbers must be represented as well as zero, so the maximum value is \(2 w l^{-1}\). Because there is only one representation for zero, there are an unequal number of positive and negative numbers. This means there is a representation for \(-2 w l^{-1}\) but not for \(2 w l^{-1}\) :

For slope \(=1\) and bias \(=0\) :

\section*{Overflow Handling}

Because a fixed-point data type represents numbers within a finite range, overflows can occur if the result of an operation is larger or smaller than the numbers in that range.

System Toolbox software does not allow you to add guard bits to a data type on-the-fly in order to avoid overflows. Any guard bits must be allocated upon model initialization. However, the software does allow you to either saturate or wrap overflows. Saturation represents positive overflows as the largest positive number in the range being used, and negative overflows as the largest negative number in the range being used. Wrapping uses modulo arithmetic to cast an overflow back into the representable range of the data type. See "Modulo Arithmetic" on page 12-9 for more information.

\section*{Precision}

The precision of a fixed-point number is the difference between successive values representable by its data type and scaling, which is equal to the value of its least significant bit. The value of the least significant bit, and therefore the precision of the number, is determined by the number of fractional bits. A fixed-point value can be represented to within half of the precision of its data type and scaling.

For example, a fixed-point representation with four bits to the right of the binary point has a precision of \(2^{-4}\) or 0.0625 , which is the value of its least significant bit. Any number within the range of this data type and scaling can be represented to within \(\left(2^{-4}\right) / 2\) or 0.03125 , which is half the precision. This is an example of representing a number with finite precision.

\section*{Rounding Modes}

When you represent numbers with finite precision, not every number in the available range can be represented exactly. If a number cannot be represented exactly by the specified data type and scaling, it is rounded to a representable number. Although precision is always lost in the rounding operation, the cost of the operation and the
amount of bias that is introduced depends on the rounding mode itself. To provide you with greater flexibility in the trade-off between cost and bias, DSP System Toolbox software currently supports the following rounding modes:
- Ceiling rounds the result of a calculation to the closest representable number in the direction of positive infinity.
- Convergent rounds the result of a calculation to the closest representable number. In the case of a tie, Convergent rounds to the nearest even number. This is the least biased rounding mode provided by the toolbox.
- Floor, which is equivalent to truncation, rounds the result of a calculation to the closest representable number in the direction of negative infinity.
- Nearest rounds the result of a calculation to the closest representable number. In the case of a tie, Nearest rounds to the closest representable number in the direction of positive infinity.
- Round rounds the result of a calculation to the closest representable number. In the case of a tie, Round rounds positive numbers to the closest representable number in the direction of positive infinity, and rounds negative numbers to the closest representable number in the direction of negative infinity.
- Simplest rounds the result of a calculation using the rounding mode (Floor or Zero) that adds the least amount of extra rounding code to your generated code. For more information, see "Rounding Mode: Simplest" in the Fixed-Point Designer documentation.
- Zero rounds the result of a calculation to the closest representable number in the direction of zero.

To learn more about each of these rounding modes, see "Rounding" in the Fixed-Point Designer documentation.

For a direct comparison of the rounding modes, see "Choosing a Rounding Method" in the Fixed-Point Designer documentation.

\section*{Arithmetic Operations}

\author{
In this section... \\ "Modulo Arithmetic" on page 12-9 \\ "Two's Complement" on page 12-10 \\ "Addition and Subtraction" on page 12-11 \\ "Multiplication" on page 12-12 \\ "Casts" on page 12-14
}

Note: These sections will help you understand what data type and scaling choices result in overflows or a loss of precision.

\section*{Modulo Arithmetic}

Binary math is based on modulo arithmetic. Modulo arithmetic uses only a finite set of numbers, wrapping the results of any calculations that fall outside the given set back into the set.

For example, the common everyday clock uses modulo 12 arithmetic. Numbers in this system can only be 1 through 12 . Therefore, in the "clock" system, 9 plus 9 equals 6 . This can be more easily visualized as a number circle:

... equals 6.
Similarly, binary math can only use the numbers 0 and 1 , and any arithmetic results that fall outside this range are wrapped "around the circle" to either 0 or 1.

\section*{Two's Complement}

Two's complement is a way to interpret a binary number. In two's complement, positive numbers always start with a 0 and negative numbers always start with a 1 . If the leading bit of a two's complement number is 0 , the value is obtained by calculating the standard binary value of the number. If the leading bit of a two's complement number is 1 , the value is obtained by assuming that the leftmost bit is negative, and then calculating the binary value of the number. For example,
\[
\begin{aligned}
& 01=\left(0+2^{0}\right)=1 \\
& 11=\left(\left(-2^{1}\right)+\left(2^{0}\right)\right)=(-2+1)=-1
\end{aligned}
\]

To compute the negative of a binary number using two's complement,
1 Take the one's complement, or "flip the bits."
2 Add a 1 using binary math.

3 Discard any bits carried beyond the original word length.
For example, consider taking the negative of 11010 (-6). First, take the one's complement of the number, or flip the bits:
\[
11010 \rightarrow 00101
\]

Next, add a 1 , wrapping all numbers to 0 or 1 :
\[
\begin{array}{r}
00101 \\
\frac{+1}{00110}
\end{array}
\]

\section*{Addition and Subtraction}

The addition of fixed-point numbers requires that the binary points of the addends be aligned. The addition is then performed using binary arithmetic so that no number other than 0 or 1 is used.

For example, consider the addition of 010010.1 (18.5) with 0110.110 (6.75):
\[
\begin{array}{cc}
010010.1 & (18.5) \\
+0110.110 & (6.75) \\
\hline 011001.010 & (25.25)
\end{array}
\]

Fixed-point subtraction is equivalent to adding while using the two's complement value for any negative values. In subtraction, the addends must be sign extended to match each other's length. For example, consider subtracting 0110.110 (6.75) from 010010.1 (18.5):

Most fixed-point DSP System Toolbox blocks that perform addition cast the adder inputs to an accumulator data type before performing the addition. Therefore, no further
shifting is necessary during the addition to line up the binary points. See "Casts" on page 12-14 for more information.

\section*{Multiplication}

The multiplication of two's complement fixed-point numbers is directly analogous to regular decimal multiplication, with the exception that the intermediate results must be sign extended so that their left sides align before you add them together.

For example, consider the multiplication of 10.11 (-1.25) with 011 (3):

\section*{Multiplication Data Types}

The following diagrams show the data types used for fixed-point multiplication in the System Toolbox software. The diagrams illustrate the differences between the data types used for real-real, complex-real, and complex-complex multiplication. See individual reference pages to determine whether a particular block accepts complex fixed-point inputs.

In most cases, you can set the data types used during multiplication in the block mask. See Accumulator Parameters, Intermediate Product Parameters, Product Output Parameters, and Output Parameters. These data types are defined in "Casts" on page 12-14.

Note: The following diagrams show the use of fixed-point data types in multiplication in System Toolbox software. They do not represent actual subsystems used by the software to perform multiplication.

\section*{Real-Real Multiplication}

The following diagram shows the data types used in the multiplication of two real numbers in System Toolbox software. The software returns the output of this operation in the product output data type, as the next figure shows.

\section*{Real-Complex Multiplication}

The following diagram shows the data types used in the multiplication of a real and a complex fixed-point number in System Toolbox software. Real-complex and complex-real multiplication are equivalent. The software returns the output of this operation in the product output data type, as the next figure shows.

\section*{Complex-Complex Multiplication}

The following diagram shows the multiplication of two complex fixed-point numbers in System Toolbox software. Note that the software returns the output of this operation in the accumulator output data type, as the next figure shows.

System Toolbox blocks cast to the accumulator data type before performing addition or subtraction operations. In the preceding diagram, this is equivalent to the \(\mathbf{C}\) code
```

acc=ac;

```
acc-=bd;
for the subtractor, and
```

acc=ad;
acc+=bc;

```
for the adder, where \(a c c\) is the accumulator.

\section*{Casts}

Many fixed-point System Toolbox blocks that perform arithmetic operations allow you to specify the accumulator, intermediate product, and product output data types, as
applicable, as well as the output data type of the block. This section gives an overview of the casts to these data types, so that you can tell if the data types you select will invoke sign extension, padding with zeros, rounding, and/or overflow.

\section*{Casts to the Accumulator Data Type}

For most fixed-point System Toolbox blocks that perform addition or subtraction, the operands are first cast to an accumulator data type. Most of the time, you can specify the accumulator data type on the block mask. See Accumulator Parameters. Since the addends are both cast to the same accumulator data type before they are added together, no extra shift is necessary to insure that their binary points align. The result of the addition remains in the accumulator data type, with the possibility of overflow.

\section*{Casts to the Intermediate Product or Product Output Data Type}

For System Toolbox blocks that perform multiplication, the output of the multiplier is placed into a product output data type. Blocks that then feed the product output back into the multiplier might first cast it to an intermediate product data type. Most of the time, you can specify these data types on the block mask. See Intermediate Product Parameters and Product Output Parameters.

\section*{Casts to the Output Data Type}

Many fixed-point System Toolbox blocks allow you to specify the data type and scaling of the block output on the mask. Remember that the software does not allow mixed types on the input and output ports of its blocks. Therefore, if you would like to specify a fixedpoint output data type and scaling for a System Toolbox block that supports fixed-point data types, you must feed the input port of that block with a fixed-point signal. The final cast made by a fixed-point System Toolbox block is to the output data type of the block.

Note that although you can not mix fixed-point and floating-point signals on the input and output ports of blocks, you can have fixed-point signals with different word and fraction lengths on the ports of blocks that support fixed-point signals.

\section*{Casting Examples}

It is important to keep in mind the ramifications of each cast when selecting these intermediate data types, as well as any other intermediate fixed-point data types that are allowed by a particular block. Depending upon the data types you select, overflow and/or rounding might occur. The following two examples demonstrate cases where overflow and rounding can occur.

\section*{Cast from a Shorter Data Type to a Longer Data Type}

Consider the cast of a nonzero number, represented by a four-bit data type with two fractional bits, to an eight-bit data type with seven fractional bits:

destination

This bit from the source data type "falls off" the high end with the shift up. Overflow might occur. The result will saturate or wrap.

These bits of the destination data type are padded with 0 's or 1 's.

As the diagram shows, the source bits are shifted up so that the binary point matches the destination binary point position. The highest source bit does not fit, so overflow might occur and the result can saturate or wrap. The empty bits at the low end of the destination data type are padded with either 0's or 1's:
- If overflow does not occur, the empty bits are padded with 0's.
- If wrapping occurs, the empty bits are padded with 0's.
- If saturation occurs,
- The empty bits of a positive number are padded with 1's.
- The empty bits of a negative number are padded with 0's.

You can see that even with a cast from a shorter data type to a longer data type, overflow might still occur. This can happen when the integer length of the source data type (in this case two) is longer than the integer length of the destination data type (in this case
one). Similarly, rounding might be necessary even when casting from a shorter data type to a longer data type, if the destination data type and scaling has fewer fractional bits than the source.

\section*{Cast from a Longer Data Type to a Shorter Data Type}

Consider the cast of a nonzero number, represented by an eight-bit data type with seven fractional bits, to a four-bit data type with two fractional bits:
 from the source, so the result must be sign-extended to fill the destination data type.

As the diagram shows, the source bits are shifted down so that the binary point matches the destination binary point position. There is no value for the highest bit from the source, so the result is sign extended to fill the integer portion of the destination data type. The bottom five bits of the source do not fit into the fraction length of the destination. Therefore, precision can be lost as the result is rounded.

In this case, even though the cast is from a longer data type to a shorter data type, all the integer bits are maintained. Conversely, full precision can be maintained even if you cast to a shorter data type, as long as the fraction length of the destination data type is the same length or longer than the fraction length of the source data type. In that case, however, bits are lost from the high end of the result and overflow might occur.

The worst case occurs when both the integer length and the fraction length of the destination data type are shorter than those of the source data type and scaling. In that case, both overflow and a loss of precision can occur.

\section*{Fixed-Point Support for MATLAB System Objects}
```

In this section...
"Getting Information About Fixed-Point System Objects" on page 12-19

For information on working with Fixed-Point features, refer to the "Fixed-Point"topic.

\section*{Getting Information About Fixed-Point System Objects}

System objects that support fixed-point data processing have fixed-point properties. When you display the properties of a System object, click Show all properties at the end of the property list to display the fixed-point properties for that object. You can also display the fixed-point properties for a particular object by typing vision. <ObjectName>.helpFixedPoint at the command line.

The following Computer Vision System Toolbox objects support fixed-point data processing.
```

Fixed-Point Data Processing Support
vision.AlphaBlender
vision.Autocorrelator
vision.BlobAnalysis
vision.BlockMatcher
vision.Convolver
vision.Crosscorrelator
vision.DCT
vision.Deinterlacer
vision.DemosaicInterpolator
vision.FFT
vision.HoughLines
vision.IDCT
vision.IFFT
vision.MarkerInserter
vision.Maximum
vision.Mean
vision.Median
vision.Minimum

```
```

vision.Pyramid
vision.ShapeInserter
vision.Variance

```

\section*{Setting System Object Fixed-Point Properties}

Several properties affect the fixed-point data processing used by a System object. Objects perform fixed-point processing and use the current fixed-point property settings when they receive fixed-point input.

You change the values of fixed-point properties in the same way as you change any System object property value. You also use the Fixed-Point Designer numerictype object to specify the desired data type as fixed point, the signedness, and the word- and fraction-lengths.

In the same way as for blocks, the data type properties of many System objects can set the appropriate word lengths and scalings automatically by using full precision. System objects assume that the target specified on the Configuration Parameters Hardware Implementation target is ASIC/FPGA.

If you have not set the property that activates a dependent property and you attempt to change that dependent property, a warning message displays. For example, for the vision.EdgeDetector object, before you set CustomProductDataType to numerictype (1,16,15) set ProductDataType to 'Custom'.

Note: System objects do not support fixed-point word lengths greater than 128 bits.
For any System object provided in the Toolbox, the fimath settings for any fimath attached to a fi input or a fi property are ignored. Outputs from a System object never have an attached fimath.

\section*{Specify Fixed-Point Attributes for Blocks}

\author{
In this section... \\ "Fixed-Point Block Parameters" on page 12-21 \\ "Specify System-Level Settings" on page 12-24 \\ "Inherit via Internal Rule" on page 12-25 \\ "Specify Data Types for Fixed-Point Blocks" on page 12-35
}

\section*{Fixed-Point Block Parameters}

System Toolbox blocks that have fixed-point support usually allow you to specify fixedpoint characteristics through block parameters. By specifying data type and scaling information for these fixed-point parameters, you can simulate your target hardware more closely.

Note: Floating-point inheritance takes precedence over the settings discussed in this section. When the block has floating-point input, all block data types match the input.

You can find most fixed-point parameters on the Data Types pane of System Toolbox blocks. The following figure shows a typical Data Types pane.
\begin{tabular}{|c|c|c|}
\hline Main Data Types & & \\
\hline \multicolumn{3}{|l|}{Fixed-point operational parameters} \\
\hline Rounding mode: Floor \(\quad\) - & Overflow mode: Wrap & \\
\hline \multicolumn{3}{|l|}{Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input. When the block input is fixed point, all internal data types are signed fixed point.} \\
\hline Data Type & Assistant Minimum & Maximum \\
\hline Sine table: Inherit: Same word length as input - & >> & \\
\hline Product output: Inherit: Inherit via internal rule & >> & \\
\hline Accumulator: Inherit: Inherit via internal rule - & >> & \\
\hline Output: Inherit: Inherit via internal rule - & >> [] & [] \\
\hline \multicolumn{3}{|l|}{\(\square\) Lock data type settings against changes by the fixed-point tools} \\
\hline
\end{tabular}

All System Toolbox blocks with fixed-point capabilities share a set of common parameters, but each block can have a different subset of these fixed-point parameters. The following table provides an overview of the most common fixed-point block parameters.
\begin{tabular}{|l|l|}
\hline \begin{tabular}{l} 
Fixed-Point Data Type \\
Parameter
\end{tabular} & Description \\
\hline Rounding Mode & \begin{tabular}{l} 
Specifies the rounding mode for the block to use when the \\
specified data type and scaling cannot exactly represent the \\
result of a fixed-point calculation. \\
See "Rounding Modes" on page 12-7 for more information on \\
the available options.
\end{tabular} \\
\hline Overflow Mode & \begin{tabular}{l} 
Specifies the overflow mode to use when the result of a fixed- \\
point calculation does not fit into the representable range of \\
the specified data type.
\end{tabular} \\
\begin{tabular}{l} 
See "Overflow Handling" on page 12-7 for more information on \\
the available options.
\end{tabular} \\
\hline
\end{tabular}
\begin{tabular}{|l|l|}
\hline \begin{tabular}{l} 
Fixed-Point Data Type \\
Parameter
\end{tabular} & Description \\
\hline Intermediate Product & \begin{tabular}{l} 
Specifies the data type and scaling of the intermediate product \\
for fixed-point blocks. Blocks that feed multiplication results \\
back to the input of the multiplier use the intermediate \\
product data type. \\
See the reference page of a specific block to learn about the \\
intermediate product data type for that block.
\end{tabular} \\
\hline Product Output & \begin{tabular}{l} 
Specifies the data type and scaling of the product output for \\
fixed-point blocks that must compute multiplication results.
\end{tabular} \\
\hline \begin{tabular}{l} 
See the reference page of a specific block to learn about the \\
product output data type for that block. For or complex- \\
complex multiplication, the multiplication result is in the \\
accumulator data type. See "Multiplication Data Types" \\
on page 12-12 for more information on complex fixed-point \\
multiplication in System toolbox software.
\end{tabular} \\
\hline Accumulator & \begin{tabular}{l} 
Specifies the data type and scaling of the accumulator (sum) \\
for fixed-point blocks that must hold summation results for \\
further calculation. Most such blocks cast to the accumulator \\
data type before performing the add operations (summation).
\end{tabular} \\
\hline See the reference page of a specific block for details on the

accut \\
\hline Specifies the output data type and scaling for blocks. \\
\hline
\end{tabular}

\section*{Using the Data Type Assistant}

The Data Type Assistant is an interactive graphical tool available on the Data Types pane of some fixed-point System Toolbox blocks.

To learn more about using the Data Type Assistant to help you specify block data type parameters, see the following section of the Simulink documentation:
"Specify Data Types Using Data Type Assistant"

\section*{Checking Signal Ranges}

Some fixed-point System Toolbox blocks have Minimum and Maximum parameters on the Data Types pane. When a fixed-point data type has these parameters, you can use them to specify appropriate minimum and maximum values for range checking purposes.

To learn how to specify signal ranges and enable signal range checking, see "Signal Ranges" in the Simulink documentation.

\section*{Specify System-Level Settings}

You can monitor and control fixed-point settings for System Toolbox blocks at a system or subsystem level with the Fixed-Point Tool. For additional information on these subjects, see
- The fxptdlg reference page - A reference page on the Fixed-Point Tool in the Simulink documentation
- "Fixed-Point Tool" - A tutorial that highlights the use of the Fixed-Point Tool in the Fixed-Point Designer software documentation

\section*{Logging}

The Fixed-Point Tool logs overflows, saturations, and simulation minimums and maximums for fixed-point System Toolbox blocks. The Fixed-Point Tool does not log overflows and saturations when the Data overflow line in the Diagnostics > Data Integrity pane of the Configuration Parameters dialog box is set to None.

\section*{Autoscaling}

You can use the Fixed-Point Tool autoscaling feature to set the scaling for System Toolbox fixed-point data types.

\section*{Data type override}

System Toolbox blocks obey the Use local settings, Double, Single, and Off modes of the Data type override parameter in the Fixed-Point Tool. The Scaled double mode is also supported for System Toolboxes source and byte-shuffling blocks, and for some arithmetic blocks such as Difference and Normalization.

\section*{Inherit via Internal Rule}

Selecting appropriate word lengths and scalings for the fixed-point parameters in your model can be challenging. To aid you, an Inherit via internal rule choice is often available for fixed-point block data type parameters, such as the Accumulator and Product output signals. The following sections describe how the word and fraction lengths are selected for you when you choose Inherit via internal rule for a fixedpoint block data type parameter in System Toolbox software:
- "Internal Rule for Accumulator Data Types" on page 12-25
- "Internal Rule for Product Data Types" on page 12-26
- "Internal Rule for Output Data Types" on page 12-26
- "The Effect of the Hardware Implementation Pane on the Internal Rule" on page 12-26
- "Internal Rule Examples" on page 12-28

Note: In the equations in the following sections, \(W L=\) word length and \(F L=\) fraction length.

\section*{Internal Rule for Accumulator Data Types}

The internal rule for accumulator data types first calculates the ideal, full-precision result. Where \(N\) is the number of addends:
\[
\begin{aligned}
& W L_{\text {ideal accumulator }}=W L_{\text {input to accumulator }}+\text { floor }\left(\log _{2}(N-1)\right)+1 \\
& F L_{i d e a l ~ a c c u m u l a t o r ~}=F L_{\text {input to accumulator }}
\end{aligned}
\]

For example, consider summing all the elements of a vector of length 6 and data type sfix10_En8. The ideal, full-precision result has a word length of 13 and a fraction length of 8 .

The accumulator can be real or complex. The preceding equations are used for both the real and imaginary parts of the accumulator. For any calculation, after the full-precision result is calculated, the final word and fraction lengths set by the internal rule are
affected by your particular hardware. See "The Effect of the Hardware Implementation Pane on the Internal Rule" on page 12-26 for more information.

\section*{Internal Rule for Product Data Types}

The internal rule for product data types first calculates the ideal, full-precision result:
\[
\begin{aligned}
& W L_{\text {ideal product }}=W L_{\text {input } 1}+W L_{\text {input } 2} \\
& F L_{\text {ideal product }}=F L_{\text {input } 1}+F L_{\text {input } 2}
\end{aligned}
\]

For example, multiplying together the elements of a real vector of length 2 and data type sfix10_En8. The ideal, full-precision result has a word length of 20 and a fraction length of 16 .

For real-complex multiplication, the ideal word length and fraction length is used for both the complex and real portion of the result. For complex-complex multiplication, the ideal word length and fraction length is used for the partial products, and the internal rule for accumulator data types described above is used for the final sums. For any calculation, after the full-precision result is calculated, the final word and fraction lengths set by the internal rule are affected by your particular hardware. See "The Effect of the Hardware Implementation Pane on the Internal Rule" on page 12-26 for more information.

\section*{Internal Rule for Output Data Types}

A few System Toolbox blocks have an Inherit via internal rule choice available for the block output. The internal rule used in these cases is block-specific, and the equations are listed in the block reference page.

As with accumulator and product data types, the final output word and fraction lengths set by the internal rule are affected by your particular hardware, as described in "The Effect of the Hardware Implementation Pane on the Internal Rule" on page 12-26.

\section*{The Effect of the Hardware Implementation Pane on the Internal Rule}

The internal rule selects word lengths and fraction lengths that are appropriate for your hardware. To get the best results using the internal rule, you must specify the type of hardware you are using on the Hardware Implementation pane of the Configuration

Parameters dialog box. You can open this dialog box from the Simulation menu in your model.

\section*{ASIC/FPGA}

On an ASIC/FPGA target, the ideal, full-precision word length and fraction length calculated by the internal rule are used. If the calculated ideal word length is larger than the largest allowed word length, you receive an error. The largest word length allowed for Simulink and System Toolbox software is 128 bits.

\section*{Other targets}

For all targets other than ASIC/FPGA, the ideal, full-precision word length calculated by the internal rule is rounded up to the next available word length of the target. The calculated ideal fraction length is used, keeping the least-significant bits.

If the calculated ideal word length for a product data type is larger than the largest word length on the target, you receive an error. If the calculated ideal word length for an accumulator or output data type is larger than the largest word length on the target, the largest target word length is used.

\section*{Internal Rule Examples}

The following sections show examples of how the internal rule interacts with the Hardware Implementation pane to calculate accumulator data types and product data types.

\section*{Accumulator Data Types}

Consider the following model ex_internalRule_accumExp.

In the Difference blocks, the Accumulator parameter is set to Inherit: Inherit via internal rule, and the Output parameter is set to Inherit: Same as accumulator. Therefore, you can see the accumulator data type calculated by the internal rule on the output signal in the model.

In the preceding model, the Device type parameter in the Hardware Implementation pane of the Configuration Parameters dialog box is set to ASIC/FPGA. Therefore, the accumulator data type used by the internal rule is the ideal, full-precision result.

Calculate the full-precision word length for each of the Difference blocks in the model:
\[
\begin{aligned}
& W L_{\text {ideal accumulator }}=W L_{\text {input to accumulator }}+\text { floor }\left(\log _{2}(\text { number of accumulations })\right)+1 \\
& W L_{\text {ideal accumulator }}=9+\text { floor }\left(\log _{2}(1)\right)+1 \\
& W L_{\text {ideal accumulator }}=9+0+1=10 \\
& \\
& W L_{\text {ideal accumulator } 1}=W L_{\text {input to accumulator } 1}+\text { floor }\left(\log _{2}(\text { number of accumulations })\right)+1 \\
& W L_{\text {ideal accumulator } 1}=16+\text { floor }\left(\log _{2}(1)\right)+1 \\
& W L_{\text {ideal accumulator } 1}=16+0+1=17 \\
& \\
& W L_{\text {ideal accumulator } 2}=W L_{\text {input to accumulator } 2}+\text { floor }\left(\log _{2}(\text { number of accumulations })\right)+1 \\
& W L_{\text {ideal accumulator } 2}=127+\text { floor }\left(\log _{2}(1)\right)+1 \\
& W L_{\text {ideal accumulator } 2}=127+0+1=128
\end{aligned}
\]

Calculate the full-precision fraction length, which is the same for each Matrix Sum block in this example:
\[
\begin{aligned}
& F L_{\text {ideal accumulator }}=F L_{\text {input to accumulator }} \\
& F L_{\text {ideal accumulator }}=4
\end{aligned}
\]

Now change the Device type parameter in the Hardware Implementation pane of the Configuration Parameters dialog box to 32-bit Embedded Processor, by changing the parameters as shown in the following figure.

As you can see in the dialog box, this device has 8 -, 16 -, and 32 -bit word lengths available. Therefore, the ideal word lengths of 10,17 , and 128 bits calculated by the internal rule cannot be used. Instead, the internal rule uses the next largest available word length in each case You can see this if you rerun the model, as shown in the following figure.

\section*{Product Data Types}

Consider the following model ex_internalRule_prodExp.

In the Array-Vector Multiply blocks, the Product Output parameter is set to Inherit: Inherit via internal rule, and the Output parameter is set to Inherit: Same as product output. Therefore, you can see the product output data type calculated by the internal rule on the output signal in the model. The setting of the Accumulator parameter does not matter because this example uses real values.

For the preceding model, the Device type parameter in the Hardware
Implementation pane of the Configuration Parameters dialog box is set to ASIC/FPGA. Therefore, the product data type used by the internal rule is the ideal, full-precision result.

Calculate the full-precision word length for each of the Array-Vector Multiply blocks in the model:
\[
\begin{aligned}
& W L_{\text {ideal product }}=W L_{\text {input } a}+W L_{\text {input } b} \\
& W L_{\text {ideal product }}=7+5=12 \\
& W L_{\text {ideal product } 1}=W L_{\text {input } a}+W L_{\text {input } b} \\
& W L_{\text {ideal product } 1}=16+15=31
\end{aligned}
\]

Calculate the full-precision fraction length, which is the same for each Array-Vector Multiply block in this example:
\[
\begin{aligned}
& F L_{\text {ideal accumulator }}=F L_{\text {input to accumula } o r} \\
& F L_{\text {ideal accumulator }}=4
\end{aligned}
\]

Now change the Device type parameter in the Hardware Implementation pane of the Configuration Parameters dialog box to 32-bit Embedded Processor, as shown in the following figure.

As you can see in the dialog box, this device has 8 -, 16 -, and 32 -bit word lengths available. Therefore, the ideal word lengths of 12 and 31 bits calculated by the internal rule cannot be used. Instead, the internal rule uses the next largest available word length in each case. You can see this if you rerun the model, as shown in the following figure.

\section*{Specify Data Types for Fixed-Point Blocks}

The following sections show you how to use the Fixed-Point Tool to select appropriate data types for fixed-point blocks in the ex_fixedpoint_tut model:
- "Prepare the Model" on page 12-35
- "Use Data Type Override to Find a Floating-Point Benchmark" on page 12-40
- "Use the Fixed-Point Tool to Propose Fraction Lengths" on page 12-41
- "Examine the Results and Accept the Proposed Scaling" on page 12-41

\section*{Prepare the Model}

1 Open the model by typing ex_fixedpoint_tut at the MATLAB command line.

This model uses the Cumulative Sum block to sum the input coming from the FixedPoint Sources subsystem. The Fixed-Point Sources subsystem outputs two signals with different data types:
- The Signed source has a word length of 16 bits and a fraction length of 15 bits.
- The Unsigned source has a word length of 16 bits and a fraction length of 16 bits.

2 Run the model to check for overflow. MATLAB displays the following warnings at the command line:

Warning: Overflow occurred. This originated from 'ex_fixedpoint_tut/Signed Cumulative Sum'. Warning: Overflow occurred. This originated from 'ex_fixedpoint_tut/Unsigned Cumulative Sum'.

According to these warnings, overflow occurs in both Cumulative Sum blocks.
3 To investigate the overflows in this model, use the Fixed-Point Tool. You can open the Fixed-Point Tool by selecting Tools > Fixed-Point > Fixed-Point Tool
from the model menu. Turn on logging for all blocks in your model by setting the Fixed-point instrumentation mode parameter to Minimums, maximums and overflows.
4 Now that you have turned on logging, rerun the model by clicking the Simulation button.

5 The results of the simulation appear in a table in the central Contents pane of the Fixed-Point Tool. Review the following columns:
- Name - Provides the name of each signal in the following format: Subsystem Name/Block Name: Signal Name.
- SimDT - The simulation data type of each logged signal.
- SpecifiedDT - The data type specified on the block dialog for each signal.
- SimMin - The smallest representable value achieved during simulation for each logged signal.
- SimMax - The largest representable value achieved during simulation for each logged signal.
- OverflowWraps - The number of overflows that wrap during simulation.

For more information on each of the columns in this table, see the "Contents Pane" section of the Simulink fxptdlg function reference page.

You can also see that the SimMin and SimMax values for the Accumulator data types range from 0 to .9997. The logged results indicate that 8,192 overflows wrapped during simulation in the Accumulator data type of the Signed Cumulative Sum block. Similarly, the Accumulator data type of the Unsigned Cumulative Sum block had 16,383 overflows wrap during simulation.

To get more information about each of these data types, highlight them in the Contents pane, and click the Show details for selected result button (i)
6 Assume a target hardware that supports 32-bit integers, and set the Accumulator word length in both Cumulative Sum blocks to 32. To do so, perform the following steps:

1 Right-click the Signed Cumulative Sum: Accumulator row in the FixedPoint Tool pane, and select Highlight Block In Model.
2 Double-click the block in the model, and select the Data Types pane of the dialog box.
3 Open the Data Type Assistant for Accumulator by clicking the Assistant button ( \(\ggg\) ) in the Accumulator data type row.
4 Set the Mode to Fixed Point. To see the representable range of the current specified data type, click the Fixed-point details link. The tool displays the
representable maximum and representable minimum values for the current data type.

Function Block Parameters: Signed Cumulative Sum
Cumulative Sum
Cumulative sum of input matrix or input vector elements along the specified dimension: rows, columns, or channels.

Fixed-point operational parameters

Floating-point inheritance takes precedence over the settings in the 'Data Type' column below. When the block input is floating point, all block data types match the input.

5 Change the Word length to 32, and click the Refresh details button in the Fixed-point details section to see the updated representable range. When you change the value of the Word length parameter, the Data Type edit box automatically updates.

6 Click OK on the block dialog box to save your changes and close the window.

7 Set the word length of the Accumulator data type of the Unsigned Cumulative Sum block to 32 bits. You can do so in one of two ways:
- Type the data type fixdt ([ ] , 32,0) directly into Data Type edit box for the Accumulator data type parameter.
- Perform the same steps you used to set the word length of the Accumulator data type of the Signed Cumulative Sum block to 32 bits.
7 To verify your changes in word length and check for overflow, rerun your model. To do so, click the Simulate button in the Fixed-Point Tool.

The Contents pane of the Fixed-Point Tool updates, and you can see that no overflows occurred in the most recent simulation. However, you can also see that the SimMin and SimMax values range from 0 to 0 . This underflow happens because the fraction length of the Accumulator data type is too small. The SpecifiedDT cannot represent the precision of the data values. The following sections discuss how to find a floating-point benchmark and use the Fixed-Point Tool to propose fraction lengths.

\section*{Use Data Type Override to Find a Floating-Point Benchmark}

The Data type override feature of the Fixed-Point tool allows you to override the data types specified in your model with floating-point types. Running your model in Double override mode gives you a reference range to help you select appropriate fraction lengths for your fixed-point data types. To do so, perform the following steps:

1 Open the Fixed-Point Tool and set Data type override to Double.
2 Run your model by clicking the Run simulation and store active results button.
3 Examine the results in the Contents pane of the Fixed-Point Tool. Because you ran the model in Double override mode, you get an accurate, idealized representation of the simulation minimums and maximums. These values appear in the SimMin and SimMax parameters.
4 Now that you have an accurate reference representation of the simulation minimum and maximum values, you can more easily choose appropriate fraction lengths. Before making these choices, save your active results to reference so you can use them as your floating-point benchmark. To do so, select Results > Move Active Results To Reference from the Fixed-Point Tool menu. The status displayed in the Run column changes from Active to Reference for all signals in your model.

\section*{Use the Fixed-Point Tool to Propose Fraction Lengths}

Now that you have your Double override results saved as a floating-point reference, you are ready to propose fraction lengths.

1 To propose fraction lengths for your data types, you must have a set of Active results available in the Fixed-Point Tool. To produce an active set of results, simply rerun your model. The tool now displays both the Active results and the Reference results for each signal.
2 Select the Use simulation min/max if design min/max is not available check box. You did not specify any design minimums or maximums for the data types in this model. Thus, the tool uses the logged information to compute and propose fraction lengths. For information on specifying design minimums and maximums, see "Signal Ranges" in the Simulink documentation.
3 Click the Propose fraction lengths button ( \(\stackrel{e^{-F L} \text {. }}{ }\). The tool populates the proposed data types in the ProposedDT column of the Contents pane. The corresponding proposed minimums and maximums are displayed in the ProposedMin and ProposedMax columns.

\section*{Examine the Results and Accept the Proposed Scaling}

Before accepting the fraction lengths proposed by the Fixed-Point Tool, it is important to look at the details of that data type. Doing so allows you to see how much of your data the suggested data type can represent. To examine the suggested data types and accept the proposed scaling, perform the following steps:

1 In the Contents pane of the Fixed-Point Tool, you can see the proposed fraction lengths for the data types in your model.
- The proposed fraction length for the Accumulator data type of both the Signed and Unsigned Cumulative Sum blocks is 17 bits.
- To get more details about the proposed scaling for a particular data type, highlight the data type in the Contents pane of the Fixed-Point Tool.
- Open the Autoscale Information window for the highlighted data type by clicking the Show autoscale information for the selected result button ( i ).
2 When the Autoscale Information window opens, check the Value and Percent Proposed Representable columns for the Simulation Minimum and Simulation Maximum parameters. You can see that the proposed data type can represent \(100 \%\) of the range of simulation data.

3 To accept the proposed data types, select the check box in the Accept column for each data type whose proposed scaling you want to keep. Then, click the Apply accepted fraction lengths button ( \(\AA_{\delta}^{\mathrm{FL}}\) ). The tool updates the specified data types on the block dialog boxes and the SpecifiedDT column in the Contents pane.
4 To verify the newly accepted scaling, set the Data type override parameter back to Use local settings, and run the model. Looking at Contents pane of the FixedPoint Tool, you can see the following details:
- The SimMin and SimMax values of the Active run match the SimMin and SimMax values from the floating-point Reference run.
- There are no longer any overflows.
- The SimDT does not match the SpecifiedDT for the Accumulator data type of either Cumulative Sum block. This difference occurs because the Cumulative Sum block always inherits its Signedness from the input signal and only allows you to specify a Signedness of Auto. Therefore, the SpecifiedDT for both Accumulator data types is fixdt ([],32,17). However, because the Signed Cumulative Sum block has a signed input signal, the SimDT for the Accumulator parameter of that block is also signed (fixdt (1, 32, 17)). Similarly, the SimDT for the Accumulator parameter of the Unsigned Cumulative Sum block inherits its Signedness from its input signal and thus is unsigned (fixdt \((0,32,17)\) ).

\section*{Code Generation}
- "Code Generation in MATLAB" on page 13-2
- "Code Generation Support, Usage Notes, and Limitations" on page 13-3
- "Simulink Shared Library Dependencies" on page 13-12
- "Accelerating Simulink Models" on page 13-13
- "Portable C Code Generation for Functions That Use OpenCV Library" on page 13-14

\section*{Code Generation in MATLAB}

Several Computer Vision System Toolbox functions have been enabled to generate C/C++ code. To use code generation with computer vision functions, follow these steps:
- Write your Computer Vision System Toolbox function or application as you would normally, using functions from the Computer Vision System Toolbox.
- Add the \%\#codegen compiler directive to your MATLAB code.
- Open the MATLAB Coder app, create a project, and add your file to the project. Once in MATLAB Coder, you can check the readiness of your code for code generation. For example, your code may contain functions that are not enabled for code generation. Make any modifications required for code generation.
- Generate code by clicking Generate in the Generate Code dialog box. You can choose to build a MEX file, a C/C++ shared library, a C/C++ dynamic library, or a C/C++ executable.

Even if you addressed all readiness issues identified by MATLAB Coder, you might still encounter build issues. The readiness check only looks at function dependencies. When you try to generate code, MATLAB Coder might discover coding patterns that are not supported for code generation. View the error report and modify your MATLAB code until you get a successful build.

For more information about code generation, see the MATLAB Coder documentation and the "Introduction to Code Generation with Feature Matching and Registration" example.

Note: To generate code from MATLAB code that contains Computer Vision System Toolbox functionality, you must have the MATLAB Coder software.

When working with generated code, note the following:
- For some Computer Vision System Toolbox functions, code generation includes creation of a shared library.
- Refer to the "Code Generation Support, Usage Notes, and Limitations" on page 13-3 for supported functionality, usages, and limitations.

\section*{Code Generation Support, Usage Notes, and Limitations}

Code Generation Support, Usage Notes, and Limitations for Functions, Classes, and System Objects

To generate code from MATLAB code that contains Computer Vision System Toolbox functions, classes, or System objects, you must have the MATLAB Coder software.

\section*{Simulink Shared Library Dependencies}

In general, the code you generate from Computer Vision System Toolbox blocks is portable \(\mathrm{ANSI}^{\circledR} \mathrm{C}\) code. After you generate the code, you can deploy it on another machine. For more information on how to do so, see "Relocate Code to Another Development Environment" in the Simulink Coder documentation.

There are a few Computer Vision System Toolbox blocks that generate code with limited portability. These blocks use precompiled shared libraries, such as DLLs, to support I/ O for specific types of devices and file formats. To find out which blocks use precompiled shared libraries, open the Computer Vision System Toolbox Block Support Table. You can identify blocks that use precompiled shared libraries by checking the footnotes listed in the Code Generation Support column of the table. All blocks that use shared libraries have the following footnote:

Host computer only. Excludes Simulink Desktop Real-Time \({ }^{\text {TM }}\) target.
Simulink Coder provides functions to help you set up and manage the build information for your models. For example, one of the Build Information functions that Simulink Coder provides is getNonBuildFiles. This function allows you to identify the shared libraries required by blocks in your model. If your model contains any blocks that use precompiled shared libraries, you can install those libraries on the target system. The folder that you install the shared libraries in must be on the system path. The target system does not need to have MATLAB installed, but it does need to be supported by MATLAB.

\section*{Accelerating Simulink Models}

The Simulink software offer Accelerator and Rapid Accelerator simulation modes that remove much of the computational overhead required by Simulink models. These modes compile target code of your model. Through this method, the Simulink environment can achieve substantial performance improvements for larger models. The performance gains are tied to the size and complexity of your model. Therefore, large models that contain Computer Vision System Toolbox blocks run faster in Rapid Accelerator or Accelerator mode.

To change between Rapid Accelerator, Accelerator, and Normal mode, use the drop-down list at the top of the model window.

For more information on the accelerator modes in Simulink, see "Choosing a Simulation Mode".

\section*{Portable C Code Generation for Functions That Use OpenCV Library}

The generated binary uses prebuilt OpenCV libraries, which ship with the Computer Vision System Toolbox product. Your compiler must be compatible with the one used to build the libraries. The following compilers are used to build the OpenCV libraries for MATLAB host:
\begin{tabular}{|l|l|}
\hline Operating System & Compatible Compiler \\
\hline Windows 32 bit & Microsoft Visual Studio 2012 \\
\hline Windows 64 bit & Microsoft Visual Studio 2012 \\
\hline Linux 64 bit & gcc-4.7.2 (g++) \\
\hline Mac 64 bit & Xcode 6.2 .0 (Clang++) \\
\hline
\end{tabular}

- validatePropertiesImpl

\section*{Define Basic System Objects}

This example shows how to create a basic System object that increments a number by one. The class definition file used in the example contains the minimum elements required to define a System object.

\section*{Create System Object}

You can create and edit a MAT-file or use the MATLAB Editor to create your System object. This example describes how to use the New menu in the MATLAB Editor.

In MATLAB, on the Editor tab, select New \(>\) System Object \(>\) Basic. A simple System object template opens.

Subclass your object from matlab. System. Replace Untitled with AddOne in the first line of your file.
```

classdef AddOne < matlab.System

```

Save the file and name it AddOne.m.

\section*{Define Algorithm}

The stepImpl method contains the algorithm to execute when you run your object. Define this method so that it contains the actions you want the System object to perform.

1 In the basic System object you created, inspect the stepImpl method template.
```

methods (Access = protected)
function y = stepImpl(obj,u)
% Implement algorithm. Calculate y as a function of input u and
% discrete states.
y = u;
end
end

```

The stepImpl method access is always set to protected because it is an internal method that users do not directly call or run.

All methods, except static methods, expect the System object handle as the first input argument. The default value, inserted by MATLAB Editor, is obj. You can use any name for your System object handle.

By default, the number of inputs and outputs are both 1. Inputs and outputs can be added using Inputs/Outputs. If you use variable number of inputs or outputs, insert the appropriate getNumInputsImpl or getNumOutputsImpl method.

Alternatively, if you create your System object by editing a MAT-file, you can add the stepImpl method using Insert Method > Implement algorithm.

2 Change the computation in the \(y\) function to add 1 to the value of \(u\).
```

methods (Access = protected)
function y = stepImpl(~,u)
y = u + 1;
end

```

Note: Instead of passing in the object handle, you can use the tilde ( \(\sim\) ) to indicate that the object handle is not used in the function. Using the tilde instead of an object handle prevents warnings about unused variables.
3 Remove the additional, unused methods that are included by default in the basic template. Alternatively, you can modify these methods to add more System object actions and properties. You can also make no changes, and the System object still operates as intended.

The class definition file now has all the code necessary for this System object.
```

classdef AddOne < matlab.System
% ADDONE Compute an output value one greater than the input value
% All methods occur inside a methods declaration.
% The stepImpl method has protected access
methods (Access = protected)
function y = stepImpl(~,u)
y = u + 1;
end
end
end

```

\section*{Related Examples}
- "Change Number of Inputs or Outputs" on page 14-8

\section*{More About}
- "System Design and Simulation in MATLAB"

\section*{Change Number of Inputs or Outputs}

This example shows how to specify two inputs and two outputs to a System object.
If you specify the inputs and outputs to the stepImpl method, you do not need to specify the getNumInputsImpl and getNumOutputsImpl methods. If you have a variable number of inputs or outputs (using varargin or varargout), include the getNumInputsImpl or getNumOutputsImpl method, respectively, in your class definition file.

Note: You should only use getNumInputsImpl or getNumOutputs Impl methods to change the number of System object inputs or outputs. Do not use any other handle objects within a System object to change the number of inputs or outputs.

You always set the getNumInputsImpl and getNumOutputsImpl methods access to protected because they are internal methods that users do not directly call or run.

\section*{Update the Algorithm for Multiple Inputs and Outputs}

Update the stepImpl method to specify two inputs and two outputs. You do not need to implement associated getNumInputsImpl or getNumOutputsImpl methods.
```

methods (Access = protected)
function [y1,y2] = stepImpl(~,x1,x2)
y1 = x1 + 1
y2 = x2 + 1;
end
end

```

\section*{Update the Algorithm and Associated Methods}

Update the stepImpl method to use varargin and varargout. In this case, you must implement the associated getNumInputsImpl and getNumOutputs Impl methods to specify two or three inputs and outputs.
```

methods (Access = protected)
function varargout = stepImpl(obj,varargin)
varargout{1} = varargin{1}+1;
varargout{2} = varargin{2}+1;
if (obj.numInputsOutputs == 3)
varargout{3} = varargin{3}+1;
end

```
```

    end
    function validatePropertiesImpl(obj)
        if ~((obj.numInputsOutputs == 2) ||...
            (obj.numInputsOutputs == 3))
                error('Only 2 or 3 input and outputs allowed.');
    end
    end
function numIn = getNumInputsImpl(obj)
numIn = 3;
if (obj.numInputsOutputs == 2)
numIn = 2;
end
end
function numOut = getNumOutputsImpl(obj)
numOut = 3;
if (obj.numInputsOutputs == 2)
numOut = 2;
end
end
end

```

Use this syntax to run the algorithm with two inputs and two outputs.
```

addit = AddOne;
x1 = 3;
x2 = 7;
[y1,y2] = addit(x1,x2);

```

To change the number of inputs or outputs, you must release the object before rerunning it.
```

release(addit)
x1 = 3;
x2 = 7;
x3 = 10
[y1,y2,y3] = addit(x1,x2,x3);

```

\section*{Complete Class Definition File with Multiple Inputs and Outputs}
```

classdef AddOne < matlab.System
% ADDONE Compute output values one greater than the input values

```
```

% This property is nontunable and cannot be changed
% after the setup method has been called or when
% the object is running.
properties (Nontunable)
numInputsOutputs = 3; % Default value
end
% All methods occur inside a methods declaration.
% The stepImpl method has protected access
methods (Access = protected)
function varargout = stepImpl(obj,varargin)
if (obj.numInputsOutputs == 2)
varargout{1} = varargin{1}+1;
varargout {2} = varargin{2}+1;
else
varargout{1} = varargin{1}+1;
varargout{2} = varargin{2}+1;
varargout{3} = varargin{3}+1;
end
end
function validatePropertiesImpl(obj)
if ~((obj.numInputsOutputs == 2) ||...
(obj.numInputsOutputs == 3))
error('Only 2 or 3 input and outputs allowed.');
end
end
function numIn = getNumInputsImpl(obj)
numIn = 3;
if (obj.numInputsOutputs == 2)
numIn = 2;
end
end
function numOut = getNumOutputsImpl(obj)
numOut = 3;
if (obj.numInputsOutputs == 2)
numOut = 2;
end
end
end

```
end

\section*{Specify System Block Input and Output Names}

This example shows how to specify the names of the input and output ports of a System object-based block implemented using a MATLAB System block.

\section*{Define Input and Output Names}

This example shows how to use get InputNamesImpl and getOutputNames Impl to specify the names of the input port as "source data" and the output port as "count."

If you do not specify the getInputNamesImpl and getOutputNames Impl methods, the object uses the stepImpl method input and output variable names for the input and output port names, respectively. If the stepImpl method uses varargin and varargout instead of variable names, the port names default to empty character vectors.
```

methods (Access = protected)
function inputName = getInputNamesImpl(~)
inputName = 'source data';
end
function outputName = getOutputNamesImpl(~)
outputName = 'count';
end
end

```

\section*{Validate Property and Input Values}

This example shows how to verify that the user's inputs and property values are valid.

\section*{Validate Properties}

This example shows how to validate the value of a single property using set.PropertyName syntax. In this case, the PropertyName is Increment.
```

methods
% Validate the properties of the object
function set.Increment(obj,val)
if val >= 10
error('The increment value must be less than 10');
end
obj.Increment = val;
end
end

```

This example shows how to validate the value of two interdependent properties using the validatePropertiesImpl method. In this case, the UseIncrement property value must be true and the WrapValue property value must be less than the Increment property value.
```

methods (Access = protected)
function validatePropertiesImpl(obj)
if obj.UseIncrement \&\& obj.WrapValue > obj.Increment
error('Wrap value must be less than increment value');
end
end
end

```

\section*{Validate Inputs}

This example shows how to validate that the first input is a numeric value.
```

methods (Access = protected)
function validateInputsImpl(~,x)
if ~isnumeric(x)
error('Input must be numeric');
end
end

```
end

- "System Object Input Arguments and ~ in Code Examples" on page 14-94

\section*{Initialize Properties and Setup One-Time Calculations}

This example shows how to write code to initialize and set up a System object.
In this example, you allocate file resources by opening the file so the System object can write to that file. You do these initialization tasks one time during setup, rather than every time you run the object.

\section*{Define Public Properties to Initialize}

In this example, you define the public Filename property and specify the value of that property as the nontunable character vector, default. bin. Users cannot change nontunable properties after the setup method has been called. Refer to the Methods Timing section for more information.
```

properties (Nontunable)
Filename = 'default.bin'
end

```

\section*{Define Private Properties to Initialize}

Users cannot access private properties directly, but only through methods of the System object. In this example, you define the pFileID property as a private property. You also define this property as hidden to indicate it is an internal property that never displays to the user.
```

properties (Hidden,Access = private)
pFileID;
end

```

\section*{Define Setup}

You use the setupImpl method to perform setup and initialization tasks. You should include code in the setupImpl method that you want to execute one time only. The setupImpl method is called once the first time you run the object. In this example, you allocate file resources by opening the file for writing binary data.
```

methods
function setupImpl(obj)
obj.pFileID = fopen(obj.Filename,'wb');
if obj.pFileID < 0
error('Opening the file failed');
end

```
end
end
Although not part of setup, you should close files when your code is done using them. You use the releaseImpl method to release resources.

\section*{Complete Class Definition File with Initialization and Setup}
```

classdef MyFile < matlab.System
% MyFile write numbers to a file
% These properties are nontunable. They cannot be changed
% after the setup method has been called or the object
% is running.
properties (Nontunable)
Filename = 'default.bin' % the name of the file to create
end
% These properties are private. Customers can only access
% these properties through methods on this object
properties (Hidden,Access = private)
pFileID; % The identifier of the file to open
end
methods (Access = protected)
% In setup allocate any resources, which in this case
% means opening the file.
function setupImpl(obj)
obj.pFileID = fopen(obj.Filename,'wb');
if obj.pFileID < 0
error('Opening the file failed');
end
end
% This System object }\mp@subsup{}{}{mM}\mathrm{ writes the input to the file.
function stepImpl(obj,data)
fwrite(obj.pFileID,data);
end
% Use release to close the file to prevent the
% file handle from being left open.
function releaseImpl(obj)
fclose(obj.pFileID);
end
end

```
end

\section*{Set Property Values at Construction Time}

This example shows how to define a System object constructor and allow it to accept name-value property pairs as input.

\section*{Set Properties to Use Name-Value Pair Input}

Define the System object constructor, which is a method that has the same name as the class (MyFile in this example). Within that method, you use the setProperties method to make all public properties available for input when the user constructs the object. nargin is a MATLAB function that determines the number of input arguments. varargin indicates all of the object's public properties.
```

methods
function obj = MyFile(varargin)
setProperties(obj,nargin, varargin{:});
end
end

```

\section*{Complete Class Definition File with Constructor Setup}
```

classdef MyFile < matlab.System
% MyFile write numbers to a file
% These properties are nontunable. They cannot be changed
% after the setup method has been called or while the
% object is running.
properties (Nontunable)
Filename ='default.bin' % the name of the file to create
Access = 'wb' % The file access character vector (write, binary)
end
% These properties are private. Customers can only access
% these properties through methods on this object
properties (Hidden,Access = private)
pFileID; % The identifier of the file to open
end
methods
% You call setProperties in the constructor to let
% a user specify public properties of object as
% name-value pairs.
function obj = MyFile(varargin)
setProperties(obj, nargin, varargin{:});

```
```

        end
    end
    methods (Access = protected)
        % In setup allocate any resources, which in this case is
        % opening the file.
        function setupImpl(obj)
            obj.pFileID = fopen(obj.Filename,obj.Access);
            if obj.pFileID < 0
                error('Opening the file failed');
            end
        end
        % This System objectm writes the input to the file.
        function stepImpl(obj,data)
            fwrite(obj.pFileID,data);
    end
    % Use release to close the file to prevent the
    % file handle from being left open.
    function releaseImpl(obj)
        fclose(obj.pFileID);
    end
    end
end

```

\section*{Reset Algorithm State}

This example shows how to reset an object state.

\section*{Reset Counter to Zero}
pCount is an internal counter property of the System object obj. The user calls the reset method on the locked object, which calls the resetImpl method. In this example, pCount resets to 0 .

Note: When resetting an object's state, make sure you reset the size, complexity, and data type correctly.
```

methods (Access = protected)
function resetImpl(obj)
obj.pCount = 0;
end
end

```

\section*{Complete Class Definition File with State Reset}
```

classdef Counter < matlab.System
% Counter System object'm that increments a counter
properties (Access = private)
pCount
end
methods (Access = protected)
% Increment the counter and return
% its value as an output
function c = stepImpl(obj)
obj.pCount = obj.pCount + 1;
c = obj.pCount;
end
% Reset the counter to zero.
function resetImpl(obj)
obj.pCount = 0;
end
end

```
end

- "Methods Timing" on page 14-91

\section*{Define Property Attributes}

This example shows how to specify property attributes.
Property attributes, which add details to a property, provide a layer of control to your properties. In addition to the MATLAB property attributes, System objects can use these three additional attributes-nontunable, logical, and positiveInteger. To specify multiple attributes, separate them with commas.

\section*{Specify Property as Nontunable}

Use the nontunable attribute for a property when the algorithm depends on the value being constant once data processing starts. Defining a property as nontunable may improve the efficiency of your algorithm by removing the need to check for or react to values that change. For code generation, defining a property as nontunable allows the memory associated with that property to be optimized. You should define all properties that affect the number of input or output ports as nontunable.

System object users cannot change nontunable properties after the setup method has been called or while the object is running. In this example, you define the InitialValue property, and set its value to 0 .
```

properties (Nontunable)
InitialValue = 0;
end

```

\section*{Specify Property as Logical}

Logical properties have the value, true or false. System object users can enter 1 or 0 or any value that can be converted to a logical. The value, however, displays as true or false. You can use sparse logical values, but they must be scalar values. In this example, the Increment property indicates whether to increase the counter. By default, Increment is tunable property. The following restrictions apply to a property with the Logical attribute,
- Cannot also be Dependent or PositiveInteger
- Default value must be true or false. You cannot use 1 or 0 as a default value.
```

properties (Logical)
Increment = true
end

```

\section*{Specify Property as Positive Integer}

In this example, the private property MaxValue is constrained to accept only real, positive integers. You cannot use sparse values. The following restriction applies to a property with the PositiveInteger attribute,
- Cannot also be Dependent or Logical
properties (PositiveInteger)
MaxValue
end

\section*{Specify Property as DiscreteState}

If your algorithm uses properties that hold state, you can assign those properties the DiscreteState attribute. Properties with this attribute display their state values when users call getDiscreteStateImpl via the getDiscreteState method. The following restrictions apply to a property with the DiscreteState attribute,
- Numeric, logical, or fi value, but not a scaled double fi value
- Does not have any of these attributes: Nontunable, Dependent, Abstract, Constant, or Transient.
- No default value
- Not publicly settable
- GetAccess = Public by default
- Value set only using the setupImpl method or when the System object is locked during resetImpl or stepImpl

In this example, you define the Count property.
```

properties (DiscreteState)
Count;
end

```

\section*{Complete Class Definition File with Property Attributes}
```

classdef Counter < matlab.System
% Counter Increment a counter to a maximum value

```
```

% These properties are nontunable. They cannot be changed

```
% These properties are nontunable. They cannot be changed
% after the setup method has been called or while the
% after the setup method has been called or while the
% object is running.
```

% object is running.

```
```

properties (Nontunable)
% The inital value of the counter
InitialValue = 0
end
properties (Nontunable, PositiveInteger)
% The maximum value of the counter
MaxValue = 3
end
properties (Logical)
% Whether to increment the counter
Increment = true
end
properties (DiscreteState)
% Count state variable
Count
end
methods (Access = protected)
% Increment the counter and return its value
% as an output
function c = stepImpl(obj)
if obj.Increment \&\& (obj.Count < obj.MaxValue)
obj.Count = obj.Count + 1;
else
disp(['Max count, ' num2str(obj.MaxValue) ',reached'])
end
c = obj.Count;
end
% Setup the Count state variable
function setupImpl(obj)
obj.Count = 0;
end
% Reset the counter to one.
function resetImpl(obj)
obj.Count = obj.InitialValue;
end
end

```
end

\section*{Hide Inactive Properties}

This example shows how to hide the display of a property that is not active for a particular object configuration.

\section*{Hide an inactive property}

You use the is InactiveProperty Impl method to hide a property from displaying. If the isInactiveProperty method returns true to the property you pass in, then that property does not display.
```

methods (Access = protected)
function flag = isInactivePropertyImpl(obj,propertyName)
if strcmp(propertyName,'InitialValue')
flag = obj.UseRandomInitialValue;
else
flag = false;
end
end
end

```

\section*{Complete Class Definition File with Hidden Inactive Property}
```

classdef Counter < matlab.System
% Counter Increment a counter
% These properties are nontunable. They cannot be changed
% after the setup method has been called or when the
% object is running.
properties (Nontunable)
%Allow the user to set the initial value
UseRandomInitialValue = true
InitialValue = 0
end
% The private count variable, which is tunable by default
properties (Access = private)
pCount
end
methods (Access = protected)
% Increment the counter and return its value
% as an output
function c = stepImpl(obj)

```
```

            obj.pCount = obj.pCount + 1;
            c = obj.pCount;
        end
    % Reset the counter to either a random value or the initial
    % value.
    function resetImpl(obj)
    if obj.UseRandomInitialValue
                obj.pCount = rand();
            else
                obj.pCount = obj.InitialValue;
            end
    end
    % This method controls visibility of the object's properties
    function flag = isInactivePropertyImpl(obj,propertyName)
    if strcmp(propertyName,'InitialValue')
                flag = obj.UseRandomInitialValue;
            else
                flag = false;
            end
        end
    end
    end

```

\section*{Limit Property Values to Finite List}

This example shows how to limit a property to accept only a finite set of character vector values.

\section*{Specify a Set of Valid Character Vector Values}

String sets use two related properties. You first specify the user-visible property name and default character vector value. Then, you specify the associated hidden property by appending "Set" to the property name. You must use a capital "S" in "Set."

In the "Set" property, you specify the valid character vector values as a cell array of the matlab.system.StringSet class. This example uses Color and ColorSet as the associated properties.
```

properties
Color = 'blue'
end
properties (Hidden,Transient)
ColorSet = matlab.system.StringSet({'red','blue','green'});
end

```

Complete Class Definition File with StringSet
```

classdef Whiteboard < matlab.System
% Whiteboard Draw lines on a figure window
%
% This System objectm illustrates the use of StringSets
properties
Color = 'blue'
end
properties (Hidden,Transient)
% Let them choose a color
ColorSet = matlab.system.StringSet({'red','blue','green'});
end
methods (Access = protected)
function stepImpl(obj)
h = Whiteboard.getWhiteboard();
plot(h, ...
randn([2,1]),randn([2,1]), ...

```
```

                    'Color',obj.Color(1));
        end
        function releaseImpl(obj)
            cla(Whiteboard.getWhiteboard());
            hold on
        end
    end
    methods (Static)
        function a = getWhiteboard()
            h = findobj('tag','whiteboard');
            if isempty(h)
                h = figure('tag','whiteboard');
                hold on
            end
            a = gca;
        end
    end
    end

```

\section*{Process Tuned Properties}

This example shows how to specify the action to take when a tunable property value changes during simulation.

The processTunedPropertiesImpl method is useful for managing actions to prevent duplication. In many cases, changing one of multiple interdependent properties causes an action. With the processTunedPropertiesImpl method, you can control when that action is taken so it is not repeated unnecessarily.

\section*{Control When a Lookup Table Is Generated}

This example of processTunedPropertiesImpl causes the pLookupTable to be regenerated when either the NumNotes or MiddleC property changes.
```

methods (Access = protected)
function processTunedPropertiesImpl(obj)
propChange = isChangedProperty(obj,'NumNotes')||...
isChangedProperty(obj,'MiddleC')
if propChange
obj.pLookupTable = obj.MiddleC *...
(1+log(1:obj.NumNotes)/log(12));
end
endend

```

\section*{Complete Class Definition File with Tuned Property Processing}

\section*{Define Finite Source Objects}

This example shows how to define a System object that performs a specific number of steps or specific number of reads from a file.

\section*{Use the FiniteSource Class and Specify End of the Source}

1 Subclass from finite source class.
```

classdef RunTwice < matlab.System \& ...
matlab.system.mixin.FiniteSource

```

2 Specify the end of the source with the isDoneImpl method. In this example, the source has two iterations.
```

methods (Access = protected)
function bDone = isDoneImpl(obj)
bDone = obj.NumSteps==2
end

```

\section*{Complete Class Definition File with Finite Source}
```

classdef RunTwice < matlab.System \& ...
matlab.system.mixin.FiniteSource
% RunTwice System object that runs exactly two times
%
properties (Access = private)
NumSteps
end
methods (Access = protected)
function resetImpl(obj)
obj.NumSteps = 0;
end
function y = stepImpl(obj)
if ~obj.isDone()
obj.NumSteps = obj.NumSteps + 1;
y = obj.NumSteps;
else
y = 0;
end
end
function bDone = isDoneImpl(obj)

```
```

            bDone = obj.NumSteps==2;
        end
    end
    end

```

\section*{Save System Object}

This example shows how to save a System object.

\section*{Save System Object and Child Object}

Define a saveObjectImpl method to specify that more than just public properties should be saved when the user saves a System object. Within this method, use the default saveObjectImpl@matlab. System to save public properties to the struct, s. Use the saveObject method to save child objects. Save protected and dependent properties, and finally, if the object is locked, save the object's state.
```

methods (Access = protected)
function s = saveObjectImpl(obj)
s = saveObjectImpl@matlab.System(obj);
s.child = matlab.System.saveObject(obj.child);
s.protectedprop = obj.protectedprop;
s.pdependentprop = obj.pdependentprop;
if isLocked(obj)
s.state = obj.state;
end
end
end

```

\section*{Complete Class Definition Files with Save and Load}

The Counter class definition file sets up an object with a count property. This counter is used in the MySaveLoader class definition file to count the number of child objects.
```

classdef Counter < matlab.System
properties(DiscreteState)
Count
end
methods (Access=protected)
function setupImpl(obj, ~)
obj. Count = 0;
end
function $y=$ stepImpl(obj, u)
if $u>0$
obj. Count $=$ obj. Count +1 ;
end
$y=o b j$. Count;
end

```
end
end
classdef MySaveLoader < matlab.System
    properties (Access = private)
        child

\section*{Add Header to MATLAB System Block}

This example shows how to add a header panel to a System object-based block implemented using a MATLAB System block.

\section*{Define Header Title and Text}

This example shows how to use getHeader Impl to specify a panel title and text for the MyCounter System object.

If you do not specify the getHeader Impl, the block does not display any title or text for the panel.

You always set the getHeader Impl method access to protected because it is an internal method that end users do not directly call or run.
```

methods (Static, Access = protected)
function header = getHeaderImpl
header = matlab.system.display.Header('MyCounter',...
'Title','My Enhanced Counter');
end
end

```

Complete Class Definition File with Defined Header
```

classdef MyCounter < matlab.System
% MyCounter Count values
properties
Threshold = 1
end
properties (DiscreteState)
Count
end
methods (Static, Access = protected)
function header = getHeaderImpl
header = matlab.system.display.Header('MyCounter',...
'Title','My Enhanced Counter',...
'Text', 'This counter is an enhanced version.');
end
end

```
```

    methods (Access = protected)
        function setupImpl(obj,u)
            obj.Count = 0;
        end
        function y = stepImpl(obj,u)
            if (u > obj.Threshold)
            obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end
        function resetImpl(obj)
        obj.Count = 0;
        end
    end
end

- "What You Cannot Change While Your System Is Running"

\section*{Set Output Size}

This example shows how to specify the size of a System object output using the getOutputSizeImpl method. Use this method when Simulink cannot infer the output size from the inputs during model compilation.

Note: For variable-size inputs, the propagated input size from propagatedInputSizeImpl differs depending on the environment.
- MATLAB - When you first run an object, it uses the actual sizes of the inputs.
- Simulink - The maximum of all the input sizes is set before the model runs and does not change during the run.

Subclass from both the matlab. System base class and the Propagates mixin class.
```

classdef CounterReset < matlab.System \& ...
matlab.system.mixin.Propagates

```

Use the getOutputSizeImpl method to specify the output size.
```

methods (Access = protected)
function sizeout = getOutputSizeImpl(~)
sizeout = [1 1];
end
end

```

View the method in the complete class definition file.
```

classdef CounterReset < matlab.System \& matlab.system.mixin.Propagates
% CounterReset Count values above a threshold
properties
Threshold = 1
end
properties (DiscreteState)
Count
end
methods (Access = protected)
function setupImpl(obj)

```
```

    obj.Count = 0;
    end
function y = stepImpl(obj,u1,u2)
% Add to count if u1 is above threshold
% Reset if u2 is true
if (u2)
obj.Count = 0;
elseif (any(u1 > obj.Threshold))
obj.Count = obj.Count + 1;
end
y = obj.Count;
end
function resetImpl(obj)
obj.Count = 0;
end
function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
if stromp(name,'Count')
sz = [11 1];
dt = 'double';
cp = false;
else
error(['Error: Incorrect State Name: ', name.']);
end
end
function dataout = getOutputDataTypeImpl(~)
dataout = 'double';
end
function sizeout = getOutputSizeImpl(~)
sizeout = [11 1];
end
function cplxout = isOutputComplexImpl(~)
cplxout = false;
end
function fixedout = isOutputFixedSizeImpl(~)
fixedout = true;
end
function inLocked = isInputSizeLockedImpl(~,idx)
if idx == 1
inLocked = false;
else
inLocked = true;

```
```

                end
            end
    end
    end

```

\section*{Set Output Data Type}

This example shows how to specify the data type of a System object output using the getOutputDataTypeImpl method. A second example shows how to specify a gain object with bus output. Use this method when Simulink cannot infer the data type from the inputs during model compilation or when you want bus output. To use bus output, you must define the bus data type in the base work space and you must include the getOutputDataTypeImpl method in your class definition file.

For both examples, subclass from both the matlab. System base class and the matlab.system.mixin. Propagates mixin class.
```

classdef CounterReset < matlab.System \& ...
matlab.system.mixin.Propagates

```

Use the getOutputDataTypeImpl method to specify the output data type as a double.
```

methods (Access = protected)
function dataout = getOutputDataTypeImpl(~)
dataout = 'double';
end
end

```

View the method in the complete class definition file.
```

classdef CounterReset < matlab.System \& matlab.system.mixin.Propagates
% CounterReset Count values above a threshold
properties
Threshold = 1
end
properties (DiscreteState)
Count
end
methods (Access = protected)
function setupImpl(obj)
obj.Count = 0;
end
function resetImpl(obj)
obj.Count = 0;
end

```
```

        function y = stepImpl(obj,u1,u2)
            % Add to count if u1 is above threshold
            % Reset if u2 is true
            if (u2)
            obj.Count = 0;
            elseif (u1 > obj.Threshold)
                obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end
            function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
        if strcmp(name,'Count')
            sz = [1 1];
            dt = 'double';
            cp = false;
            else
                error(['Error: Incorrect State Name: ', name.']);
            end
            end
            function dataout = getOutputDataTypeImpl(~)
        dataout = 'double';
            end
            function sizeout = getOutputSizeImpl(~)
        sizeout = [1 1];
            end
            function cplxout = isOutputComplexImpl(~)
                cplxout = false;
            end
            function fixedout = isOutputFixedSizeImpl(~)
        fixedout = true;
            end
    end
end

```

Use the getOutputDataTypeImpl method to specify the output data type as a bus. Specify the bus name in a property.
```

properties(Nontunable)
OutputBusName = 'bus_name';
end
methods (Access = protected)
function out = getOutputDataTypeImpl(obj)

```
```

        out = obj.OutputBusName;
    end
    end

```

\section*{Specify Whether Output Is Fixed- or Variable-Size}

This example shows how to specify that System object output is fixed- or variable-size.

> This example shows how to specify that a System object output is fixed-size. Fixed-size output is always the same size, while variable-size output can be different size vectors. isOutputSizeLockedImpl accepts the port index and returns true if the input size is locked (variable sized vectors are disallowed) and false if the input size is not locked (variable sized vectors are allowed). Use the isOutputFixedSizeImpl method when Simulink cannot infer the output type from the inputs during model compilation.

Subclass from both the matlab. System base class and the matlab.system.mixin. Propagates mixin class.
```

classdef CounterReset < matlab.System \& ...
matlab.system.mixin.Propagates

```

Use the isOutputFixedSizeImpl method to specify that the output is fixed size.
```

methods (Access = protected)
function fixedout = isOutputFixedSizeImpl(~)
fixedout = true;
end
end

```

View the method in the complete class definition file.
```

classdef CounterReset < matlab.System \& matlab.system.mixin.Propagates
% CounterReset Count values above a threshold
properties
Threshold = 1
end
properties (DiscreteState)
Count
end
methods (Access = protected)
function setupImpl(obj)
obj.Count = 0;
end
function resetImpl(obj)

```
```

        obj.Count = 0;
        end
        function y = stepImpl(obj,u1,u2)
        % Add to count if u1 is above threshold
        % Reset if u2 is true
        if (u2)
            obj.Count = 0;
            elseif (u1 > obj.Threshold)
            obj.Count = obj.Count + 1;
            end
            y = obj.Count;
        end
        function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
        if strcmp(name,'Count')
            sz = [11 1];
            dt = 'double';
            cp = false;
            else
            error(['Error: Incorrect State Name: ', name.']);
            end
            end
            function dataout = getOutputDataTypeImpl(~)
                dataout = 'double';
            end
            function sizeout = getOutputSizeImpl(~)
                sizeout = [11 1];
            end
            function cplxout = isOutputComplexImpl(~)
            cplxout = false;
            end
            function fixedout = isOutputFixedSizeImpl(~)
                fixedout = true;
            end
        end
    end

```

For a System object with variable-size output, you do not need to add any method to the class definition file because variable-size output is the default.

\section*{Specify Discrete State Output Specification}

This example shows how to specify the size, data type, and complexity of a discrete state property using the getDiscreteStateSpecificationImpl method. Use this method when your System object has a property with the DiscreteState attribute and Simulink cannot infer the output specifications during model compilation.

Subclass from both the matlab. System base class and from the Propagates mixin class.
```

classdef CounterReset < matlab.System \& ...
matlab.system.mixin.Propagates

```

Use the getDiscreteStateSpecificationImpl method to specify the size and data type. Also specify the complexity of a discrete state property, which is used in the counter reset example.
```

methods (Access = protected)
function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
sz = [11 1];
dt = 'double';
cp = false;
end
end

```

View the method in the complete class definition file.
```

classdef CounterReset < matlab.System \& matlab.system.mixin.Propagates
% CounterReset Count values above a threshold
properties
Threshold = 1
end
properties (DiscreteState)
Count
end
methods (Access = protected)
function setupImpl(obj)
obj.Count = 0;
end
function resetImpl(obj)

```
```

        obj.Count = 0;
    end
    function y = stepImpl(obj,u1,u2)
        % Add to count if u1 is above threshold
        % Reset if u2 is true
        if (u2)
            obj.Count = 0;
        elseif (u1 > obj.Threshold)
            obj.Count = obj.Count + 1;
        end
        y = obj.Count;
    end
    function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
        sz = [1 1];
        dt = 'double';
        cp = false;
    end
    function dataout = getOutputDataTypeImpl(~)
        dataout = 'double';
    end
    function sizeout = getOutputSizeImpl(~)
        sizeout = [1 1];
    end
    function cplxout = isOutputComplexImpl(~)
        cplxout = false;
    end
    function fixedout = isOutputFixedSizeImpl(~)

\section*{Set Model Reference Discrete Sample Time Inheritance}

This example shows how to disallow model reference discrete sample time inheritance for a System object. The System object defined in this example has one input, so by default, it allows sample time inheritance. To override the default and disallow inheritance, the class definition file for this example includes the allowModelReferenceDiscreteSampleTimeInheritanceImpl method, with its output set to false.
```

methods (Access = protected)
function flag = ...
allowModelReferenceDiscreteSampleTimeInheritanceImpl(obj)
flag = false;
end
end

```

View the method in the complete class definition file.
```

classdef MyCounter < matlab.System
% MyCounter Count values
properties
Threshold = 1;
end
properties (DiscreteState)
Count
end
methods (Static, Access = protected)
function header = getHeaderImpl
header = matlab.system.display.Header('MyCounter',...
'Title','My Enhanced Counter',...
'Text', 'This counter is an enhanced version.');
end
end
methods (Access = protected)
function flag = ...
allowModelReferenceDiscreteSampleTimeInheritanceImpl(obj)
flag = false
end
function setupImpl(obj,u)

```
```

                obj.Count = 0;
    end
    function y = stepImpl(obj,u)
        if (u > obj.Threshold)
            obj.Count = obj.Count + 1;
        end
        y = obj.Count;
    end
    function resetImpl(obj)
        obj.Count = 0;
        end
    end
end

```
```

\section*{Use Update and Output for Nondirect Feedthrough}

This example shows how to implement nondirect feedthrough for a System object using the updateImpl, outputImpl and isInputDirectFeedthroughimpl methods. In nondirect feedthrough, the object's outputs depend only on the internal states and properties of the object, rather than the input at that instant in time. You use these methods to separate the output calculation from the state updates of a System object. Implementing these two methods overrides the stepImpl method. This enables you to use the object in a feedback loop and prevent algebraic loops.

\section*{Subclass from the Nondirect Mixin Class}

To use the updateImpl, outputImpl, and isInputDirectFeedthroughImpl methods, you must subclass from both the matlab. System base class and the Nondirect mixin class.
```

classdef IntegerDelaySysObj < matlab.System \& ...
matlab.system.mixin.Nondirect

```

\section*{Implement Updates to the Object}

Implement an updateImpl method to update the object with previous inputs.
```

methods (Access = protected)
function updateImpl(obj,u)
obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
end
end

```

\section*{Implement Outputs from Object}

Implement an outputImpl method to output the previous, not the current input.
```

methods (Access = protected)
function [y] = outputImpl(obj,~)
y = obj.PreviousInput(end);
end
end

```

Implement Whether Input Is Direct Feedthrough
Implement an isInputDirectFeedthroughImpl method to indicate that the input is nondirect feedthrough.
```

methods (Access = protected)
function flag = isInputDirectFeedthroughImpl(~,~)
flag = false;
end
end

```

\section*{Complete Class Definition File with Update and Output}
```

classdef intDelaySysObj < matlab.System \&...
matlab.system.mixin.Nondirect
% intDelaySysObj Delay input by specified number of samples.
properties
InitialOutput = 0;
end
properties (Nontunable)
NumDelays = 1;
end
properties (DiscreteState)
PreviousInput;
end
methods (Access = protected)
function validatePropertiesImpl(obj)
if ((numel(obj.NumDelays)>1) || (obj.NumDelays <= 0))
error('Number of delays must be positive non-zero scalar value.');
end
if (numel(obj.InitialOutput)>1)
error('Initial Output must be scalar value.');
end
end
function setupImpl(obj)
obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
end
function resetImpl(obj)
obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
end
function [y] = outputImpl(obj,~)
y = obj.PreviousInput(end);
end
function updateImpl(obj, u)
obj.PreviousInput = [u obj.PreviousInput(1:end-1)];

```
```

            end
        function flag = isInputDirectFeedthroughImpl(~,~)
            flag = false;
        end
    end
    end

\section*{Enable For Each Subsystem Support}

This example shows how to enable using a System object in a Simulink For Each subsystem. Include the supportsMultipleInstanceImpl method in your class definition file. This method applies only when the System object is used in Simulink via the MATLAB System block.

Use the supportsMultipleInstanceImpl method and have it return true to indicate that the System object supports multiple calls in a Simulink For Each subsystem.
```

methods (Access = protected)
function flag = supportsMultipleInstanceImpl(obj)
flag = true;
end
end

```

View the method in the complete class definition file.
```

classdef RandSeed < matlab.System
% RANDSEED Random noise with seed for use in For Each subsystem
properties (DiscreteState)
count;
end
properties (Nontunable)
seed = 20;
end
properties (Nontunable,Logical)
useSeed = false;
end
methods (Access = protected)
function y = stepImpl(obj,u1)
% Initial use after reset/setup
% and use the seed
if (obj.useSeed \&\& ~obj.count)
rng(obj.seed);
end
obj.count = obj.count + 1;
[m,n] = size(u1);
% Uses default rng seed
y = rand(m,n) + u1;

```
```

            end
            function setupImpl(obj)
            obj.count = 0;
            end
            function resetImpl(obj)
            obj.count = 0;
            end
            function flag = supportsMultipleInstanceImpl(obj)
                flag = obj.useSeed;
            end
    end
end

```

\section*{System Object Input Arguments and \(\sim\) in Code Examples}

All methods, except static methods, expect the System object handle as the first input argument. You can use any name for your System object handle. In many examples, instead of passing in the object handle, \(\sim\) is used to indicate that the object handle is not used in the function. Using \(\sim\) instead of an object handle prevents warnings about unused variables.

\section*{What Are Mixin Classes?}

Mixin classes are partial classes that you can combine in various combinations to form desired behaviors using multiple inheritance. System objects are composed of a base class, matlab. System and may include one or more mixin classes. You specify the base class and mixin classes on the first line of your class definition file.

The following mixin classes are available for use with System objects.
- matlab.system.mixin.CustomIcon - Defines a block icon for System objects in the MATLAB System block
- matlab. system.mixin.FiniteSource - Adds the isDone method to System objects that are sources
- matlab.system.mixin. Nondirect - Allows the System object, when used in the MATLAB System block, to support nondirect feedthrough by making the runtime callback functions, output and update available
- matlab.system.mixin. Propagates - Enables System objects to operate in the MATLAB System block using the interpreted execution

\section*{Best Practices for Defining System Objects}

A System object is a specialized kind of MATLAB object that is optimized for iterative processing. Use System objects when you need to run an object multiple times or process data in a loop. When defining your own System object, use the following suggestions to help your code run efficiently.
- Define all one-time calculations in the setupImpl method and cache the results in a private property. Use the stepImpl method for repeated calculations.
- If properties are accessed more than once in the stepImpl method, cache those properties as local variables inside the method. A typical example of multiple property access is a loop. Iterative calculations using cached local variables run faster than calculations that must access the properties of an object. When the calculations for the method complete, you can save the local cached results back to the properties of that System object. Copy frequently used tunable properties into private properties. This best practice also applies to the updateImpl and output Impl methods.

In this example, k is accessed multiple times in each loop iteration, but is saved to the object property only once.
```

function y = stepImpl(obj,x)
k = obj.MyProp;
for p=1:100
y = k * x;
k = k + 0.1;
end
obj.MyProp = k;
end

```
- Property default values are shared across all instances of an object. Two instances of a class can access the same default value if that property has not been overwritten by either instance.
- Do not use character vector comparisons or character vector-based switch statements in the stepImpl method. Instead, create a method handle in setupImpl. This handle points to a method in the same class definition file. Use that handle in a loop in stepImpl.

This example shows how to use method handles and cached local variables in a loop to implement an efficient object. In setupImpl, choose myMethod1 or myMethod2 based on a character vector comparison and assign the method handle to the pMethodHandle property. Because there is a loop in stepImpl, assign the
pMethodHandle property to a local method handle, myFun, and then use myFun inside the loop.
```

classdef MyClass < matlab.System
function setupImpl(obj)
if strcmp(obj.Method, 'Method1')
obj.pMethodHandle = @myMethod1;
else
obj.pMethodHandle = @myMethod2;
end
end
function y = stepImpl(obj,x)
myFun = obj.pMethodHandle;
for p=1:1000
y = myFun(obj,x)
end
end
end
function y = myMethod1(x)
y = x+1;
end
function y = myMethod2(x)
y = x-1;
end
end

```
- If the number of System object inputs does not change, do not implement the getNumInputsImpl method. Also do not implement the getNumInputsImpl method when you explicitly list the inputs in the stepImpl method instead of using varargin. The same caveats apply to the getNumOutputsImpl and varargout outputs.
- For the getNumInputsImpl and getNumOutputsImpl methods, if you set the return argument from an object property, that object property must have the Nontunable attribute.
- If the variables in a method do not need to retain their values between calls use local scope for those variables in that method.
- For properties that do not change, define them in as Nontunable properties. Tunable properties have slower access times than Nontunable properties
- Use the protected or private attribute instead of the public attribute for a property, whenever possible. Some public properties have slower access times than protected and private properties.
- Avoid using acustomized stepImpl, get, or set methods, whenever possible.
- Avoid using character vector comparisons within a customized stepImpl, get, or set methods, whenever possible. Use setupImpl for character vector comparisons instead.
- Specify Boolean values using true or false instead of 1 or 0 , respectively.

\section*{Insert System Object Code Using MATLAB Editor}

\author{

}

\section*{Define System Objects with Code Insertion}

You can define System objects from the MATLAB Editor using code insertion options. When you select these options, the MATLAB Editor adds predefined properties, methods, states, inputs, or outputs to your System object. Use these tools to create and modify System objects faster, and to increase accuracy by reducing typing errors.

To access the System object editing options, create a new System object, or open an existing one.

To add predefined code to your System object, select the code from the appropriate menu. For example, when you click Insert Property > Numeric, the MATLAB Editor adds the following code:
```

properties(Nontunable)
Property
end

```

The MATLAB Editor inserts the new property with the default name Property, which you can rename. If you have an existing properties group with the Nontunable
attribute, the MATLAB Editor inserts the new property into that group. If you do not have a property group, the MATLAB Editor creates one with the correct attribute.

\section*{Insert Options}

Properties Properties of the System object: Numeric, Logical, String Set, Positive Integer, Tunable Numeric, Private, Protected, and Custom. When you select String Set or Custom Properties, a separate dialog box opens to guide you in creating these properties.
Methods Methods commonly used in System object definitions. The MATLAB Editor creates only the method structure. You specify the actions of that method.

The Insert Method menu organizes methods by categories, such as Algorithm, Inputs and Outputs, and Properties and States. When you select a method from the menu, the MATLAB Editor inserts the method template in your System object code. In this example, selecting Insert Method > Release resources inserts the following code:
```

function releaseImpl(obj)
% Release resources, such as file handles
end

```

If an method from the Insert Method menu is present in the System object code, that method is shown shaded on the Insert Method menu:

\section*{Create Fahrenheit Temperature String Set}

1 Open a new or existing System object.
2 In the MATLAB Editor, select Insert Property > String Set.
3 In the String Set dialog box, under Name, replace Color with TemperatureUnit.
4 Remove the existing Color property values with the - (minus) button.
5 Add a property value with the + (plus) button. Enter Fahrenheit.
6 Add another property value with +. Enter Celsius.
7 Add another property value with +. Enter Kelvin.
8 Select Fahrenheit as the default value by clicking Default.
The dialog box now looks as shown:

9 To create this string set and associated properties, with the default value selected, click Insert.

Examine the System object definition. The MATLAB Editor has added the following code:
```

properties (Nontunable)

```
```

    TemperatureUnit = 'Fahrenheit';
    end
properties(Constant, Hidden)
TemperatureUnitSet = matlab.system.StringSet({'Fahrenheit','Celsius','Kelvin'});
end

```

For more information on the StringSet class, see matlab.System.StringSet.

\section*{Create Custom Property for Freezing Point}

1 Open a new or existing System object.
2 In the MATLAB Editor, select Insert Property > Custom Property.
3 In the Custom Property dialog box, under System Object Attributes, select Nontunable. Under MATLAB Property Attributes, select Constant. Leave GetAccess as public. SetAccess is grayed out because properties of type constant can not be set using System object methods.

The dialog box now looks as shown:

4 To insert the property into the System object code, click Insert.
```

properties(Nontunable, Constant)
Property
end

```

5 Replace Property with your property.
```

properties(Nontunable, Constant)
FreezingPointFahrenheit = 32;
end

```

\section*{Define Input Size As Locked}

1 Open a new or existing System object.

2 In the MATLAB Editor, select Insert Method > Lock input size.
The MATLAB Editor inserts this code into the System object:
```

function flag = isInputSizeLockedImpl(obj,index)
% Return true if input size is not allowed to change while
% system is running
flag = true;
end

```

\section*{Related Examples}

\section*{Analyze System Object Code}

\author{
In this section... \\ "View and Navigate System object Code" on page 14-106 \\ "Example: Go to StepImpl Method Using Analyzer" on page 14-106
}

\section*{View and Navigate System object Code}

View and navigate System object code using the Analyzer.
The Analyzer displays all elements in your System object code.
- Navigate to a specific input, output, property, state, or method by clicking the name of that element.
- Expand or collapse element sections with the arrow buttons.
- Identify access levels for properties and custom methods with the + (public), \# (protected), and - (private) symbols.

\section*{Example: Go to Steplmpl Method Using Analyzer}

1 Open an existing System object.
2 Select Analyze.
3 Click stepImpl.
```

    Analyzer: PlotRamp
    $\square$

```
- INPUTS
    u
    - OUTPUTS
    \(y\)
    - PROPERTIES
    + RampLimit
- SYSTEM OBJECT METHODS
    getProperty Groups Impl
    getSimulateUsingImpl
    steplmpl
    setuplmpl
    releaselmpl
- CUSTOM METHODS
    + visualize
                                    Help

The cursor in the MATLAB Editor window jumps to the stepImpl method.

\section*{Define System Object for Use in Simulink}

\author{
In this section... \\ "Develop System Object for Use in System Block" on page 14-109 \\ "Define Block Dialog Box for Plot Ramp" on page 14-110
}

\section*{Develop System Object for Use in System Block}

You can develop a System object for use in a System block and interactively preview the block dialog box. This feature requires Simulink.

With the System Block editing options, the MATLAB Editor inserts predefined code into the System object. This coding technique helps you create and modify your System object faster and increases accuracy by reducing typing errors.

Using these options, you can also:
- View and interact with the block dialog design as you define the System object.
- Add dialog customization methods. If the block dialog box is open when you make changes, the block dialog design preview updates the display on saving the file.
- Add icon methods. However, these elements display only on the MATLAB System Block in Simulink, not in the Preview Dialog Box.

\section*{Define Block Dialog Box for Plot Ramp}

1 Create a System object and name it PlotRamp. This name becomes the block dialog box title. Save the System object.
2 Add a comment that contains the block description.
```

% Display a button to launch a plot figure.

```

This comment becomes the block parameters dialog box description, under the block title.

3 Select System Block > Preview Block Dialog. The block dialog box displays as you develop the System object.

4 Add a ramp limit by selecting Insert Property > Numeric. Then change the property name and set the value to 10 .
```

properties (Nontunable)
RampLimit = 10;
end

```

5 Using the System Block menu, insert the getPropertyGrouplsImpl method.
```

methods(Access = protected, Static)
function group = getPropertyGroupsImpl
% Define property section(s) for System block dialog
group = matlab.system.display.Section(mfilename('class'));
end
end

```

6 Add code to create the group for the visualize action..
```

methods(Access = protected, Static)
function group = getPropertyGroupsImpl
% Define property section(s) for System block dialog
group = matlab.system.display.Section(mfilename('class'));
group.Actions = matlab.system.display.Action(@(~,obj)...
visualize(obj),'Label','Visualize');
end
end

```

7 Add a function that adds code to display the Visualize button on the dialog box.
```

methods
function visualize(obj)
figure;

```
```

        d = 1:obj.RampLimit;
        plot(d);
        end
    end

```

8 As you add elements to the System block definition, save your file. Observe the effects of your code additions to the System block definition.

\section*{Block Parameters (preview)}

\section*{PlotRamp}

Display a button to launch a plot figure.
Source code
Parameters
RampLimit: 10
Visualize

Simulate using: Code generation
OK Cancel
Help
Apply

The System Block menu also displays checks next to the methods you have implemented, which can help you track your development.

\section*{INSERT DIALOG METHOD}

Specify dialog header getHeaderImpl

Specify dialog layout getPropertyGroupsImpl

Specify simulation mode
getSimulateUsingImpl

Set simulation mode visibility showSimulateUsingImpl

Set fixed-point settings visibility showFiSettingsImpl

The class definition file now has all the code necessary for the PlotRamp System object.
```

classdef PlotRamp < matlab.System
% Display a button to launch a plot figure.
properties (Nontunable)
RampLimit = 10;
end
methods(Static, Access=protected)
function group = getPropertyGroupsImpl
group = matlab.system.display.Section(mfilename('class'));
group.Actions = matlab.system.display.Action(@(~,obj)...
visualize(obj),'Label','Visualize');
end
end
methods
function visualize(obj)
figure;
d = 1:obj.RampLimit;
plot(d);
end
end
end

```

After you complete your System block definition, save it, and then load it into a MATLAB System block in Simulink.

\section*{Use Enumerations in System Objects}

Enumerated data is data that is restricted to a finite set of values. To use enumerated data in a System object in MATLAB or Simulink, you refer to them in your System objectclass definition and define your enumerated class in a separate class definition file.

For a System object that will be used in MATLAB only, see "Enumerations".
For a System object that will be used in a MATLAB System block in Simulink, see "Enumerated Data"

Enumerations can derive from any integer type smaller than or equal to an int32. For example,
```

classdef Bearing < uint8
enumeration
North (0)
East (90)
South (180)
West (270)
end
end

```

Enumerations can also derive from Simulink. IntEnumType. You use this type of enumeration to add attributes, such as custom headers, to the input or output of the MATLAB System block. See "Use Enumerated Data in Simulink Models".

\section*{Use Global Variables in System Objects}

Global variables are variables that you can access in other MATLAB functions or Simulink blocks.

\section*{System Object Global Variables in MATLAB}

For System objects that are used only in MATLAB, you define global variables in System object class definition files in the same way that you define global variables in other MATLAB code (see "Global Variables").

\section*{System Object Global Variables in Simulink}

For System objects that are used in the MATLAB System block in Simulink, you also define global variables as you do in MATLAB. However, to use global variables in Simulink, you need to declare global variables in the stepImpl, updateImpl, or outputImpl method if you have declared them in methods called by stepImpl, updateImpl, or outputImpl, respectively.

You set up and use global variables for the MATLAB System block in the same way as you do for the MATLAB Function block (see "Data Stores" and "Share Data Globally"). Like the MATLAB Function block, you must also use variable name matching with a Data Store Memory block to use global variables in Simulink.

For example, this class definition file defines a System object that increments the first row of a matrix by 1 at each time step. You must include getGlobalNamesImpl if the class file is P-coded.
```

classdef GlobalSysObjMatrix < matlab.System
methods (Access = protected)
function y = stepImpl(obj)
global B;
B(1,:) = B(1,:)+1;
y = B;
end
% Include getGlobalNamesImpl only if the class file is P-coded.
function globalNames = getGlobalNamesImpl(~)
globalNames = {'B'};
end

```

\section*{end}
end
This model includes the GlobalSysObjMatrix object in a MATLAB System block and the associated Data Store Memory block.

DataStoreMemory
Define a memory region for use by the Data Store Read and Data Store Write blocks. All Read and Write blocks that are in the current (sub)system level or below and have the same data store name will be able to read from or write to this block.
